10:00AM U32.00011 Magnetostriiction close to the phase transition in Gd$_5$(Si$_2$Ge$_{1-x}$)$_2$Ge$_x$¹, R. L. HADIMANI, Y. MELIKHOV, J. E. SNYDER, D. C. JILES, Wolfson Centre for Magnetics, Cardiff University, CF24 3AA, U.K. — Gd$_5$(Si$_2$Ge$_{1-x}$)$_2$Ge$_x$ is a potential material for magnetic refrigeration. It has the highest magnetocaloric effect observed for the composition 0.41$\leq x \leq 0.5$ near its first order coupled magnetic-structural phase transition. We have investigated the relationship between the magnetic transition from ferromagnetic to paramagnetic phase and the structural transition from monoclinic to orthorhombic. A series of measurements have been carried out showing magnetostriective strain as a function of temperature at various magnetic field strengths and magnetostriction strain as a function of magnetic field at various temperatures with a magnetic field of up to 7 Tesla. There was fine structure observed in the magnetostriction curve at $H$ near the critical point. The magnetostriction measurements show that close to the critical temperature there is a sudden increase in the magnetostriction of about 100 ppm just before the field induced first order phase transition. This anomaly was observed for both strain vs. magnetic field at various temperatures and for strain vs. temperature at various magnetic field strengths measurements.

10:24AM U32.00013 Kondo-like features in chemically pure magnetic atomic-size contacts, M. REYES-CALVO, JOAQUIN FERNANDEZ-ROSSERT, CARLOS UNTIATED, LT-Nonlab. Depto. de Física Aplicada, Universidad de Alicante — The influence of magnetic frustration in the electronic transport in atomic sized contacts is not yet clear. However, certain features systematically appear in the conductance measurements of magnetic atomic contacts. Specifically, the spectroscopy of atomic size contacts of Ni, Fe or Co reveal the existence of a characteristic significant peak or dip at zero bias that is not present in the case of non-magnetic materials. We have measured the differential conductance as a function of bias at 4K on two hundred monatomic contacts of Ni, Fe and Co fabricated by STM. The zero bias anomaly has been analyzed as using the Kondo- Fano lineshape typical of magnetic adatoms in non-magnetic surfaces. The statistical analysis of the data results in Kondo temperatures around 250 K, 120 K and 80 K for Ni, Co and Fe respectively. A Kondo-like behaviour could arise in chemically pure magnetic contacts if tip atoms behave different due to their smaller coordination.

10:36AM U32.00014 ABSTRACT HAS BEEN MOVED TO SESSION K1
The nitrogen vacancy releases electrons in the system which changes the Mn magnetic interactions in GaN in the presence of nitrogen and gallium vacancies. Previous studies have found the nitrogen vacancy has the lowest formation temperature $T_c$ conductors from first principles.

Thus, both the nitrogen and gallium vacancy are found to impede ferromagnetism. This work is supported by AFOSR-FA 9550-05-1-0462.

3 Supported by NSF-ECCS CAREER and US ONR.

8:36AM U33.00002 Effect of vacancies on ferromagnetism in GaN:Mn dilute magnetic semiconductors from first principles1, PAUL LARSON, SASHI SATPATHY, University of Missouri — In spite of considerable interest in ferromagnetism of the dilute magnetic semiconductor GaN:Mn, the nature of ferromagnetism is still quite controversial. Experimental values for the Curie temperature $T_c$ vary widely depending upon the details of the impurity concentrations. We have performed ab initio density functional studies of the magnetic interactions in GaN in the presence of nitrogen and gallium vacancies. Previous studies have found the nitrogen vacancy has the lowest formation energy. The nitrogen vacancy releases electrons in the system which changes the Mn d$^5$ state to a half-filled Mn d$^4$ state, so that the antiferromagnetic superexchange becomes dominant. The naive picture of Ga vacancies is the release of holes into the system which should increase ferromagnetism. However, we find an antiferromagnetic interaction for the Ga vacancy, as well in agreement with Mahadevan’s work1. This can be attributed to the localized nature of the holes states which do not participate in the transport. This hole localization from the Ga vacancy has been demonstrated using the virtual crystal approximation.

Thus, both the nitrogen and gallium vacancy are found to impede ferromagnetism. This work is supported by AFOSR-FA 9550-05-1-0462.

8:48AM U33.00003 Effect of magnetic short-range order on spin disorder resistivity. ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, Nebraska, USA, MARK VAN SCHILFGAARDE, Department of Chemical and Materials Engineering, Arizona State University, Tempe, Arizona, USA, JULIAN VELEV, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, Nebraska, USA — Spin-disorder resistivity (SDR) of Fe and Ni is studied using the noncollinear density functional theory. The Landauer conductance is averaged over random disorder configurations and fitted to Ohm’s law. In the fully disordered state, SDR for Fe close to $T_c$ is 2 orders of magnitude smaller than the experimental value by a factor of 2.3. This indicates either strong magnetic short-range order (MSRO) or reduced local moment above $T_c$ for Ni. The temperature dependence of SDR for Fe was studied using the mean-field approximation and the Monte Carlo method applied to the classical nearest-neighbor Heisenberg model. Both methods gives the same magnetization dependence of SDR that is in excellent agreement with the results for the isotropic s-d model. Further using the Reverse Monte Carlo method we generated disordered spin structures with strong MSRO. We found the resulting SDR is not significantly different than for Monte Carlo and mean-field methods. This result indicates that for Fe MSRO is not very important for SDR.

9:00AM U33.00004 First-Principle theory of Longitudinal Spin-Fluctuations at high temperatures for itinerant ferromagnets. SERGII KHMELEVSKYI, Center for Computational Material Science, Vienna University of Technology, ANDREI V. VONsovsky, Department of Materials Physics, Royal Institute of Technology, Stockholm, Sweden, PETER MOHN, Center for Computational Material Science, Vienna University of Technology, BJORNE JOHANSSON, Applied Material Physics, Royal Institute of Technology, Stockholm, Sweden — We have developed a framework for calculating parameters of effective magnetic Hamiltonian, which includes transverse as well as longitudinal spin fluctuations (LSF) on equal footing. The method is based on the set of constrained calculations within a Local Spin-Density Approximation and Coherent Potential Approximations. The used effective Hamiltonian is similar to those derived in Moriya-Takahashi theory approximating between local and weak itinerant limits of magnetism. The Curie temperature, magnetic susceptibilities and field induced magnetizations were calculated both for Fe and Ni in good agreement with experiment. The importance of LSF contribution even for qualitatively correct description of magnetism of Ni is demonstrated. The first principles criteria for magnetic moment ‘itineracy’, based on fixed spin moment constrained calculations of a magnetic impurity in the Disordered Local Moment host, is established and applied to various magnetic systems. In particular, the famous Rhodes-Wohlfarth plot has been revisited. It is found that in some cases, like VAu$_2$, the magnetic moments have very local character in contrast to their long-standing interpretation as weak itinerant ferromagnets.
9:12AM U33.00005 Calculation of diamagnetic susceptibility in Cu, graphite and Bi from band-structure1, G. SAMOYLUK, J. SCHMALIAN, B. HARMON, S. BUD’KO, P. CANFIELD, AmesLab/Dept. of Physics, ISU — Since early pioneering work on the orbital diamagnetism of free electrons[1] the problem of calculation of diamagnetic susceptibility has attracted attention in systems such as graphite and bismuth. Recent interest in this problem has been motivated by the unconventional electronic properties of mono- and multilayered graphenes. These materials demonstrate large orbital diamagnetism caused by a specific type of band dispersion: a crossing of two bands, each with linear dispersion near the Fermi level. Significant progress in the theoretical description of orbital diamagnetism of electrons in periodic potentials was achieved by Fukuyama[2], with an exact expression for diamagnetic susceptibility, but with an approximation for band dispersion put in by hand. As an alternate approach, we use band structure obtained from a first-principles calculation (LMTO). The orbital susceptibility was calculated for Cu, as an example of a metal with small orbital diamagnetism, as well as for graphite and Bi, materials with known, large diamagnetic susceptibilities. [1] L. Landau, Z. Physik. 64, (1930) 629. [2] H. Fukuyama, Prog. Theor. Phys. 45, (1971) 704.

9:24AM U33.00006 Magnetic Moment of MnSi1, ROBERT COLLYER, DANA BROWNE, Louisiana State University — MnSi is a metallic helimagnet below 29 K. Density functional theory predicts that it has a moment of 1.0 $\mu_B$/Mn, which is much larger than the measured value of 0.4 $\mu_B$/Mn. By adding a Hubbard-U correction, we have found a ground state with a moment consistent with the experimental value. These solutions possess a novel quadrupolar spin ordering. We discuss their behavior under pressure and in a magnetic field.

9:36AM U33.00007 ABSTRACT WITHDRAWN

9:48AM U33.00008 Piezomagnetic effect in Mn-based antiperovskites, RENAT SABIRIANOV, PAVEL LUKASHCHEV, University of Nebraska, Omaha, KIRILL BËLASHCHENKO, University of Nebraska, Lincoln — We predict large piezomagnetic effect in Mn-based antiperovskites. The magnetic ground state is determined to be the non-collinear $5g$ structure, which can be viewed as a sequence of alternating layers of clockwise and counterclockwise triangular spin currents in (111) plane, resulting in the zero total magnetization of the system. We use PAW method (VASP) within PBE generalized gradient approximation. We find that the system develops non-zero magnetization under biaxial strain due to the lowering of the crystal symmetry from cubic to tetragonal. The system exhibits linear magnetization dependence on the applied strain over the moderate range (up to 1%) of the latter. The magnetization under strain appears as a result of the rotation of local magnetic moments (LMM) on Mn atoms in Mn$_2$N$_2$ plane. Besides, the system exhibits biaxial anisotropy under strain. We propose using the observed piezomagnetic effect to build the magnetoelectric perovskite ferroelectric – antiperovskite piezomagnetic heterostructures. The estimated magnetoelectric coefficient is $\sim 2*10^{-9}$s/m. Because of the piezomagnetic effect, Mn-based antiperovskites can be used in memory cells with electric control of magnetization. It can also be applicable in spintronics, as the system develops a net polarization of up to 30% under external strain.

10:00AM U33.00009 Spin Flip in the Presence of a Complex Absorbing Potential, FRANK MARSIGLIO, FATHI DOGAN, CINDY BLOIS, WONKEE KIM, University of Alberta — We examine the impact of a complex absorbing potential on electron transport, both in the continuum and on a lattice. This requires the use of non-Hermitian Hamiltonians; the required formalism is briefly outlined. The lattice formulation allows us to study the interesting problem of an electron interacting with a stationary spin, and the subsequent time evolution of the electron and spin properties as the electron is absorbed after the initial interaction. Remarkably, the properties of the localized spin are affected ‘at-a-distance’ by the interaction of the (now entangled) electron with a complex potential.

10:12AM U33.00010 Giant Zeeman electric-dipole resonance in antiferromagnetic conductors, REVAZ RAMAZASHVILI, LPTMS, Orsay — Essential dependence of the electron g-factor on the quasiparticle momentum is a fundamental and, so far, largely overlooked property of antiferromagnetic conductors. It leads to a number of remarkable phenomena, such as excitation of spin flip transitions by AC electric field. Absorption intensity of these transitions exceeds that of the Electron Spin Resonance by some four orders of magnitude. I develop a theory of this phenomenon in a weakly doped antiferromagnetic insulator. The predictions may be relevant for a number of antiferromagnetic conductors, ranging from chromium to electron-and hole-doped cuprates, to organic conductors with spin density wave, and to heavy fermion antiferromagnetic metals.

10:24AM U33.00011 Electronic properties and magnetic moments of Mn$_x$Si$_{1-x}$ for $x < 5%$. MICHAEAL SHAUGHNESSY, RYAN SNOW, CHING YAO FONG, University of California Davis Physics Department — Recently, there have been experimental reports about Mn$_x$Si$_{1-x}$ alloys. All show great promise for room temperature spintronic applications. We report on theoretical studies of the electronic properties of Mn$_x$Si$_{1-x}$ for $x < 5\%$, using first principles density functional methods. For the Mn-doped Si, we consider three configurations of the Mn impurities: nearest neighbor (nn), second nearest neighbor (snn), and a three-atom chain configuration. For the nn and snn configurations, the ferromagnetic and antiferromagnetic phases have been compared. The magnetic moment/unit-cell for the nn and ferromagnetic configurations is smaller than for the ferromagnetic snn and chain configurations. The reason will be given. Supported in part by NSF grant: ESC-0725902.

10:36AM U33.00012 Monte Carlo simulation of giant magnetoresistance1, GASTON BARBERIS, IFGW - Unicamp, 13083-970 Campinas, SP, Brazil — Monte Carlo method was used to simulate giant magnetoresistance in solids. A square lattice, composed by Ising spins, was generated by the usual Monte Carlo method, with periodic conditions for the borders. Resistivity was measured considering the number of clusters connected between right and left sides of the lattice, with and without applied magnetic field. The calculation of the number and surface of the connecting clusters was calculated using the Hoshen-Kopelman algorithm [1]. As we developed previously pseudorandom non-periodic numbers [2], which allows that the sizes of the clusters as big as necessary, and the steps near the transition as small as desired. This allowed a detailed study near the percolation region, over and below the magnetic transition. Three dimensional lattices, and models other than Ising for the spin coupling are natural extension of the calculation. [1] J. Hoshen and R. Kopelman, Phys. Rev. B14, 3438 (1976) [2]G.E. Barbaris, Physica B 398, 468 (2007)

10:48AM U33.00013 Propagators for Hamiltonians with Spin-Orbit Coupling, BAILEY HSU, JEAN-FRANCOIS VAN HUELE, Brigham Young University — Quantum mechanical propagators can be used to understand the dynamics of electrons in confined electromagnetic environments. We extend the propagator formalism to include the spin degree of freedom for spin-orbit coupling potentials in two-dimensional geometries. The 2x2 spin propagator allows us to follow the evolution in time and space of the spin-components of localized wave packets. We apply the technique to Rashba and Dresselhaus interactions and present graphical displays of the corresponding spin motions.
8:12AM U35.00002 Determination of best models for adsorption of hydrogen in boron-doped carbon nanoparticles¹, RAINA CEPEL, MATTHEW BECKER, CARLOS WEXLER, PETER PFEIFER, University of Missouri — Nanoporous carbon offers significant hydrogen storage capacities at low pressures in reversible conditions. Storage is achieved by physical adsorption of molecular hydrogen (H₂) on the surface of nanometer-size pores in the carbon matrix. Within the ALL-CRAFT collaboration (http://all-craft.missouri.edu), we conduct a proof-of-concept study of the prediction that boron-doped nanoporous carbon can store as much as 8 weight% at 47 bar and room temperature. By comparing theoretical and experimental H₂ adsorption isotherms for intrinsic and doped carbon, we determine which adsorption models and scenarios (e.g. localized vs. mobile) are consistent with experimental evidence.

8:24AM U35.00003 Metal clustering and catalytic spillover on the nanotubes and graphene for hydrogen storage, FENG DING, PAVEL KRASNOV, YU LIN, BORIS I. YAKOBSON, Rice University — Energies and kinetic barriers associated with transition metal (Sc) clustering on a single-walled carbon nanotube (SWNT) and graphene were studied by all-electron density functional method. The analysis shows that the binding energy of Sc atom on SWNT is highly sensitive to the tube diameter and chirality. The metal atoms do cluster on common SWNT, with diameters ~1-2 nm. Hydrogen binds to the metal cluster chemically and thus opens a way for hydrogen storage via catalytic spillover. However, the hydrogen chemisorption on graphene receptor-substrate is difficult to reconcile with a single H atom binding to carbon being weaker than it is within initial molecular H₂. This paradox is resolved by presenting the process as phase nucleation. Atomistic calculations bridge remarkably with the macroscopic-continuum description, and show a feasible path to 7.7 wt% H-content at nearly ambient conditions. P. O. Krasnov, F. Ding, et al., J. Phys. Chem. C, in press (2007).

8:36AM U35.00004 Hydrogen Storage in Ti Doped Nano Porous Graphene¹, SA LI, PURU JENA, Virginia Commonwealth University, DEPARTMENT OF PHYSICS, VIRGINIA COMMONWEALTH UNIVERSITY TEAM — Clustering of Ti on carbon nanostructures has proved to be an obstacle in their use as hydrogen storage materials. Using density functional theory we show that Ti atoms will not cluster when doped into nanoporous graphene. With each Ti atom binding up to four hydrogen molecules with an average binding energy of 0.54 eV/H₂, this material can be ideal for storing hydrogen. Equally important, nanoporous graphene is magnetic with or without Ti doping, but magnetism disappears when fully saturated with hydrogen. This novel feature suggests that nanoporous graphene can also be used as a hydrogen sensor.

¹This work is supported in part by a grant from the Department of Energy. We would like to thank the PNNL for computer support.

8:48AM U35.00005 Graphenic C₃N₄: A New Template for Metal Decoration and Hydrogen Adsorption¹, YI ZHANG, University of Nevada, Las Vegas, HONG SUN, Shanghai Jiao Tong University, China, CHANGFENG CHEN, University of Nevada, Las Vegas — From density functional theory calculations we identify a graphenic C₃N₄ (g-C₃N₄) structure as an excellent template for stable and well dispersed decoration of alkali and transition metals which, in turn, exhibits a high capacity for hydrogen adsorption with binding energies (a few tenths of eV) suitable for mobile applications. The unique porous micro-structural sites of g-C₃N₄ accommodate the excess N lone-pair electrons and promote strong hybridization between the orbitals of N and metal atoms. It plays a key role in overcoming the tendency of metal-atom clustering that has plagued other proposed hydrogen storage media. These metal decorated g-C₃N₄ may also prove useful in a variety of catalytic and sensing applications.

¹This work was supported by the DOE Coopera-tive Agreement DE-FG36-05GO85028 and DE-FC52-06NA26274 at UNLV and by the NSF grants No.10574089 and No. 50532020 at SJTU.

9:00AM U35.00006 Hydrogen Storage in Titanium-decorated Boron Buckyball, JIA LI, GANG ZHOU, WENHUI DUAN, Department of Physics, Tsinghua University, Beijing 100084, PR China, HOONKYUNG LEE, JISOOK IHH, Department of Physics and Astronomy, Seoul 151-747, Korea — Using first-principles electronic structure calculations, we investigate the potential of Ti-decorated B₈₀ for hydrogen storage medium. The Ti-decorated B₈₀ has the merit of an unexpected large binding energy of a Ti atom to B₈₀ which can overcome the problem of metal clustering. Up to four hydrogen molecules are found to be adsorbed on a single Ti atom coated on B₈₀. At high Ti coverage, we show that the Ti-decorated B₈₀ adsorbs up to 5 wt% hydrogen and the calculated binding energy falls in the desirable range of 0.2-0.6eV/H₂ which is suitable for reversible hydrogen storage at room temperature, near-ambient-pressure conditions.

9:12AM U35.00007 Sequential Dissociative Chemisorption of H₂ on Ti₃H Cluster¹, T.J. DHLIP KUMAR, P. TARAKESHWAR, N. BALAKRISHNAN, Department of Chemistry, University of Nevada Las Vegas, 4505 Maryland Parkway, Las Vegas, NV 89154 USA — Ti nanoparticles have received much attention due to their superior catalytic properties in potential hydrogen storage materials for fuel cell applications. In this study, we show that the energetically stable distorted icosahedral Ti₃H cluster has excellent H₂ adsorption and desorption properties and lead to stable structures upon hydrogen cycling. H₂ adsorption initially leads to a highly stable Ti₃H₂₀ cluster and on further saturation yields the Ti₄H₅ cluster. The chemisorbed H atom in Ti₃H₂₀ occupies above the face of the triangular planes of Ti₁₂ whereas in Ti₁₂H₂₀, H atoms remain dangling above the apex Ti edges. The three coordinated H in Ti₄H₂₀ has higher chemisorption and desorption energies than the fully saturated Ti₁₂H₂₀ cluster. This type of multi-center H-bonds with varied chemisorption energies is structurally significant since adsorption and desorption rate processes could be controlled and deserve attention as potential candidates for hydrogen storage materials.

Cocaine detection using piezoresistive microcantilevers

— A Precursor to Hydrogen Storage

1 Work is supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525).

Department of Physics, University of Tennessee — Sensitive and inexpensive sensors play a significant role in the analysis of drugs and drug metabolites. Specifically, reliable in vivo detection of cocaine and cocaine metabolites serves as a useful tool in research of the body’s reaction to the drug and in the treatment of the drug addiction. We present here a promising cocaine biosensor to be used in the human body. The sensor’s active element consists of piezoresistive microcantilevers coated with an oligonucleotide-based aptamer as the cocaine binder. In vitro cocaine detection was carried out by flowing a cocaine solution over the microcantilevers. Advantages of this device are its low power consumption, its high sensitivity, and its potential for miniaturization. Current studies indicate that silicon carbide nanotubes coated with an oligonucleotide-based aptamer as the cocaine binder. In vivo cocaine detection was carried out by flowing a cocaine solution over the microcantilevers. Advantages of this device are its low power consumption, its high sensitivity, and its potential for miniaturization.

8:00AM U36.00001 Cocaine detection using piezoresistive microcantilevers

1, BERNADETA SRJANTO, Department of Electrical Engineering, University of Tennessee, CHRISTINE F. CHENEY, DAVID L. HEDDEN, ANTHONY GEHL, THOMAS L. 8:00AM U36.00002 Bioinspired optical sensing of picomolar concentrations of lead in solution.

1, ANUSHREE SAHA, VLADISLAV YAKOULEV, University of Wisconsin-Milwaukee, UNIVERSITY OF WISCONSIN-MILWAUKEE TEAM — Lead poisoning is a life threatening medical condition, which can cause irreversible neurological, cardiovascular and reproductive damage. Despite of an extensive research, the minimum amount of lead to be considered hazardous is not yet known. The biophysical interactions of minute quantities of lead with blood are also poorly understood. Albumin being the most important binder and transporter in blood, is known to interact with lead ions in solution. In this report, we present the first experimental evidence that picomolar concentrations of lead strongly affect albumin properties in solution. High precision difference Raman and excitation-emission fluorescence spectroscopies are employed to identify the effect of lead ions on albumin. Both spectroscopies proved to be very effective in detecting lead poisoning at a very early stage, setting a new course for bio-inspired inexpensive platform of lead sensing.

8:24AM U36.00003 Nanofluidic redox-cycling in electrochemical biosensing applications

, BERNARD DE WOLFRUM, MARCEL ZEVENBERGEN, SERGE LEMAY, Kavli Institute of Nanoscience, Delft University of Technology — We have developed a chip-based nanofluidic device which amplifies the sensitivity in electrochemical biosensing applications by orders of magnitude. The amplification is based on rapid redox-cycling between plane parallel electrodes inside a nanochannel. We show that it is possible to monitor the signal of less than one hundred molecules residing in the active area of the nanofluidic sensor. The small number of molecules is reflected in the noise spectrum of the device. In particular, we obtain high sensitivities when detecting catecholamines, which comprise an important group of hormones and neurotransmitters such as serotonin and dopamine. Furthermore, due to the nanochannel design, the sensor is immune to interference by molecules undergoing irreversible redox reactions. We demonstrate the selectivity of the device by detecting target molecules in the presence of ascorbic acid whose oxidized form is only stable on the order of milliseconds. The interference of ascorbic acid is usually a challenge in the detection of catecholamines in biological samples.

8:36AM U36.00004 Detection of Target Biomolecules by Magnetic Reporting Using Rod-Like Nanosensors

, R.P. GUERTIN, E. GOLDBERG, T.P. HARRAH, S. SONKUSALE, K. PARK, Tufts University, S. SUN, Brown University, J. I. OH, M. NAUGHTON, Boston College — We describe the ongoing development of a device to assay a variety of cellular, viral and molecular targets by measuring the increase of the Brownian relaxation time, τ in solution of magnetically-tagged nanoscale detectors. The shift shows as a frequency reduction of the peak of the complex magnetic susceptibility, χ(ω)^−1. Measurements of χ(ω) with 12 nm monodisperse nanoparticles of CoFe2O4 coated with polyethylene glycol reveal spectra with the narrowest lines yet reported. Thin avidin coating of these particles reveals small shifts in χ(ω)^−1. Bacteriophage T4 tail fibers, engineered to specific lengths (30-150 nm), were employed as the platform for magnetic nanoparticle attachment and at the other end for an inserted target peptide epitope. Attachment of the nanoparticles to bacteriophage T4 tail fibers was successful, though no detectable shifts in χ(ω)^−1 were detected due to weak attachment. The advantages associated with non-spherical geometry detectors will be discussed, as well preliminary measurements with rare earth oxide magnetic nanoparticles. Progress on miniaturization and low power requirements of the electronic detection system will be reported. Supported by NERC/BEID (NIAID).

8:48AM U36.00005 A Ringdown Breath Analyzer for Diabetes Monitoring: Breath Acetone in Diabetic Patients

, CHUJII WANG, Dept. of Phys, and the ICET, Mississippi State University, Starkville, MS 39759, cw175@msstate.edu, ARMSTRONG MBI, Dept. of Phys, and the ICET, Mississippi State University, Starkville, MS 39759, MARK SHEPHERD, Endocrinology Consultants Center, 670 Crossover Rd. Tupelo, MS, 38801 — It is highly desirable for millions of diabetic patients to have a non-blood, non-invasive, point-of-care device for monitoring daily blood glucose (BG) levels and the adequacy of diabetic treatment and control. Cavity ringdown spectroscopy, due to its unique capability of high sensitivity, fast-response, and relatively low cost for instrumentation, has the potential for medical application through non-invasive analysis of breath biomarkers. We report the first ringdown acetone breath analyzer for clinic testing with diabetic outpatients. The instrument was set in a clinic center and 34 outpatients (24 T1D and 10 T2D) were tested during a four-day period. 10 T1D subjects and 15 non diabetic persons were tested in our laboratory. Three juvenile-onset T1D subjects were selected for a 24-hr monitoring on the variations of breath acetone and simultaneous BG level. In this talk, we present our research findings including the correlations of breath acetone with BG level and A1C.
9:00AM U36.00006 Integrating Different Types of Nanowire Sensors in a Large Array1, Yaping DAN, University of Pennsylvania, STEPHANE EVOY, University of Alberta, A.T. CHARLIE JOHNSON, University of Pennsylvania — Biological olfactory systems have a key structural feature: different types of sensors in a large array. Humans, for example, possess several hundred distinct types of sensing cells, a level of sensor diversity not yet achieved in artificial olfactory systems. Here, we demonstrate a simple and low-cost electrochemical approach to integrate large numbers of different types of nanowire sensors in an array on the same silicon wafer. In our approach, nanowires are grown inside an on-chip nanochannel template by electrochemistry with each horizontal channel connected to a gold electrode. This design allows for addressable synthesis of a specific type of nanowire in specified channels by providing a voltage to the electrodes connecting to those channels. The process can be further repeated to produce different types of nanowires in other channels using different electroplating solutions. The scale and diversity of this array have a potential to compete with those of biological olfactory systems and the synthesis process is cost-effective enough for commercialization.

9:12AM U36.00007 Compact Femtosecond-Millisecond Transient Absorption Spectrometer, ELIZABETH CARROLL, MELISSA HILL, DORTE MADSEN, KONSTANTIN MALLEY, DELMAR LARSEN, Department of Chemistry, University of California — The measurement of population dynamics in biological, chemical, and solid-state samples occurring over 10−13-10−1 seconds requires a combination of transient absorption techniques, typically involving different laser systems and detection electronics (e.g., femtosecond transient absorption and nanosecond flash photolysis). The difficulty in exactly matching excitation conditions often prohibits connecting ultrafast and longer time measurements, particularly in samples exhibiting nonlinear kinetics. We present a simple solution to bridge the femtosecond and microsecond domains with an inexpensive modification of a kHz amplified Ti:Sapphire laser. By introducing a secondary pulse-picker between the laser oscillator (75 MHz) and amplifier, we can electronically delay unamplified 800-nm probe pulses in 13.3-ns steps. The 5-nJ pulses seed a photonic crystal fiber to produce a supercontinuum (450-1100 nm) for broadband probing. We demonstrate the system capability by resolving formation and decay dynamics, spanning 10 decades (10−14-10−1 s), of photoexcited solvated electrons in sinapic acid, and triplet states and quinonoid intermediates in Vitamin B6.

9:24AM U36.00008 Realization of Confocal and Hyperspectral Microscopy via Compressive Sensing, TING SUN, Rice University, DHARMPAL TAKHAR, JASON LASKA, MARCO DURARTE, VIVEK BANSAL, RICHARD BARANIUK, KEVIN KELLY — Given its important role, factors such as sensitivity, resolution, dwell time, and bandwidth limit are critical parameters for detectors in modern microscopy. A new method known as compressive sensing has emerged, which greatly improves the imaging resolution of these detectors. In our configuration, a digital micromirror device randomly but controllably modulates the light before it is collected at the detector. This process simultaneously compresses the signal because the measurement projects the signal onto a white-noise basis. Subsequently, the data from this incoherent basis is reconstructed into a complete real-space image. Given its compressive nature, far fewer measurements are required than the total number of pixels which greatly decreases the acquisition time of the signal. In addition, the intensity of the compressed signal at the detector is much greater than its raster scan counterpart and therefore results in greater signal sensitivity and improved image quality. These advantages make compressive sensing particularly attractive for use in hyperspectral and confocal microscopy.

9:36AM U36.00009 Fabrication of robust superconducting granular aluminum/palladium bilayer microbolometers with sub-nanosecond response1, THOMAS WILSON, Marshall University — We provide a convenient recipe for fabricating reliable superconducting microbolometers as acoustic phonon detectors with sub-nanosecond response, using image-reversal optical lithography and dc-magnetron sputtering, and our recipe requires no chemical or plasma etching. Our approach solves the traditional problem for granular aluminum bolometers of unreliable (i.e., non-Ohmic) electrical contacts by sequentially sputtering the granular aluminum film and then a palladium capping layer. We use dc calibration data, the method of Danilchenko et al., and direct nanosecond-pulsed photoexcitation to obtain the microbolometer’s characteristic current, thermal conductance, characteristic relaxation time, and heat capacity. We also demonstrate the use of the deconvolution algorithm of Edwards et al., to obtain the phonon flux in a heat pulse experiment with nanosecond resolution.

1Support provided by NSF ECCS 062060.

9:48AM U36.00010 Highly Sensitive Photodetector Based on a Self-assembled Organic Single Submicrometer Ribbon, JIAN WANG, YAN ZHOU, LEI WANG, South China University of Technology, JIAN PEI, Peking University — We demonstrated a highly sensitive air-stable photodetector based on a single submicrometer organic crystalline ribbon self-assembled from a condensed benzo thiophene via solution process. The low cost and simple solution process was employed in the device fabrication process from the submicrometer ribbons preparation to the deposition on the substrate. The photodetector gain is up to 1.3 × 10^3, while the responsivity is about 420 A/W at the field of 2 × 10^5 V/cm. The highest on/off ratio reaches around 1000. The performance is comparable to that of photodetectors based on inorganic nanowires, and even better than those based on carbon nanotube or other bilayer molecular self-assembled nanotubes. In addition, the photo-switching properties to those organic photodetectors were investigated with different metal electrodes. The results show that the surface states created by the thermal evaporation of the heavy gold atoms are responsible for the high photo gain and the slow photocurrent decay. To our best knowledge, this is the first report on photodetectors based on crystalline organic 1D submicrometer ribbons self-assembled via solution process, which combine both advantages of intrinsic properties of the 1D crystalline structure and the simplicity of the solution process.

10:00AM U36.00011 Single carbon nanotube syringe: A model for the study of liquid transport through individual carbon nanotubes, GUANGYU CHAI, Apollo Technologies, Inc. 205 Waymont Court #111, Lake Mary, FL 32746, USA, LEE CHOW, Department of Physics, University of Central Florida, Orlando, FL 32816-2385, USA — The hollow structure of the carbon nanotubes (CNT) and their ability to translocate through plasma membrane of a living cell provide a significant chance to use them as a nano syringe for the delivery of therapeutically active molecules into a live cell. However, the size and the extremely high aspect ratio of the CNTs make the nano syringe device difficult to realize. We successfully prepared a monolithic multwall CNT with a graphitic shield by chemical vapor deposition technique. The graphitic shield provides a handle which allows the manipulation of the supported CNTs. A single CNT syringe device is fabricated with focused ion beam technique. The well-controlled liquid transport through individual CNT is demonstrated.
8:00AM U37.00001 Resistance oscillations in two-dimensional electron systems due to resonant acoustic phonon scattering\(^1\), MICHAEL ZUDOV, ANTHONY HATKE, WENHAO ZHANG, University of Minnesota, LOREN PFEIFFER, KEN WEST, Bell Labs, Alcatel-Lucent — A few years ago a new class of resistance oscillations was discovered in two-dimensional electron systems subject to weak magnetic fields and elevated temperatures [1]. It was proposed that oscillations originate from resonant interaction with acoustic phonons made possible by virtue of a special selection rule which favors electron backscattering. In contrast to other types of magneto-resistance oscillations, such as those appearing under application of microwave or dc electric fields, phonon-induced resistance oscillations (PIRO) have not received much attention and remain poorly understood. Of particular interest are the period and the phase of PIRO, relative contribution and nature of different phonon modes, and the effect of temperature and sample parameters. This talk will briefly review prior and new experimental results and discuss open issues.

\(^1\)This work is supported by NSF DMR-0548014.

8:12AM U37.00002 Effect of dc electric field on resonant acoustic phonon scattering in two-dimensional electron systems\(^1\), WENHAO ZHANG, MICHAEL ZUDOV, University of Minnesota, LOREN PFEIFFER, KEN WEST, Bell Labs, Alcatel-Lucent — We study [1] the effect of dc electric field on transport properties of two-dimensional electron systems in which resonant acoustic phonon scattering dominates linear response resistivity. We observe that dc electric field strongly modifies phonon resonances, transforming resistance maxima into minima and back into maxima. Further, phonon resonances are enhanced dramatically in the non-linear dc response and can be detected even at low temperatures. Most of our observations can be explained by dc-induced (de)tuning of the acoustic phonon resonances and intra-Landau level impurity scattering. We also observe a dc-induced zero-differential resistance state and a resistance maximum which occurs when the electron drift velocity approaches the speed of sound.

\(^1\)This work is supported by NSF DMR-0548014.

8:24AM U37.00003 Effect of electron-phonon scattering on magneto-transport in 2DES, M. G. VAVILOV, University of Wisconsin — We evaluate the contribution of electron-phonon scattering to the non-linear magneto-resistance of two-dimensional electron systems (2DES). Both linear [1] and differential [2] magneto-resistances show oscillatory dependence on the applied magnetic field in high mobility 2DES. These oscillations originate from the relation between the change of electron energy in a scattering event and the cyclotron frequency. In case of electron scattering with phonons in dc electric fields, the change in electron energy is equal to the sum of the energy of an emitted or absorbed phonon and the change of the electrostatic electron energy due to the shift of an electron cyclotron trajectory. We show that the electrostatic contribution in sufficiently strong fields moves the position of maxima and minima of the differential magnetoresistance. We also explain why the phonon-induced magneto-oscillations exist in the linear response regime only at moderately high temperatures, but appear at significantly lower temperatures in stronger electric fields. [1] M.A. Zudov, et al., Phys. Rev. Lett. 86, 3614 (2001). [2] W. Zhang, et al., arXiv:0711.1547v1 (2007).

8:36AM U37.00004 Non-linear dc response in microwave-irradiated two-dimensional electron systems: interplay between ac and dc induced effects\(^1\), ANTHONY HATKE, WENHAO ZHANG, MICHAEL ZUDOV, University of Minnesota, LOREN PFEIFFER, KEN WEST, Bell Labs, Alcatel-Lucent — We study nonlinear dc response of a high-mobility two-dimensional electron system subject to microwave (ac) excitation and weak magnetic fields. Recent experiments [1] studied resistance at different dc excitations as a function of the ratio of the microwave frequency to the cyclotron frequency, \(\epsilon \omega_c\). Here, we examine oscillations in microwave photoconductivity as a function of dc excitation, at different values of \(\epsilon \omega_c\). We find that, for the most part, the oscillation period is the same as in the dark resistivity, and the phase is determined by microwave-induced oscillations at zero dc bias, consistent with the earlier results. However, at some excitation values previously associated with resistance maxima, this approach revealed resistance minima indicating saddle points in the resistivity. We further observed that the oscillation amplitude itself oscillates as a function of \(\epsilon \omega_c\), with the oscillations strongly suppressed near half-integral values. These findings indicate the limitations of the simplified resonant condition proposed in Ref. 1, and might stimulate further theoretical studies.

\(^1\)This work is supported by NSF DMR-0548014.

8:48AM U37.00005 Zero differential resistance state in 2D dimensional electron system in strong magnetic field\(^1\), SERGEY VITKALOV, JING-QIAO ZHANG, The City College of New York, A. A. BYKOV, A. K. KALAGIN, A. K. BAKAROV, Institute of Semiconductor Physics, 630090 Novosibirsk, Russia — We report the observation of a zero differential resistance state (ZDRS) in response to direct current above a threshold value \(I > I_d\), applied to a two-dimensional system of electrons at low temperatures in a strong magnetic field. Entry into the ZDRS, which is not observable above several Kelvins, is accompanied by a sharp dip in the differential resistance. Additional analysis reveals instability of the electrons for \(I > I_d\) and an inhomogeneous, non-stationary pattern of the electric current. We suggest that the dominant mechanism leading to the new electron state is a redistribution of electrons in energy space induced by the direct current.

9:00AM U37.00006 Influence of a Parallel Magnetic Field on the Microwave-Induced Resistance and Photovoltaic Oscillations, CHI ZHANG, KRISTJAN STONE, RUI-RUI DU, Rice University, CHANGLI YANG, Institute of Physics, CAS, China, LOREN PFEIFFER, KEN WEST, Bell Labs, Alcatel-Lucent — Microwave induced photovoltaic (PV) and resistance oscillations (MIRO) were studied in high-mobility (\(\mu > 8 \times 10^{7} \ cm^{2}/V \ s\) 2D electron gas in GaAs/Al\(_{0.33}\)Ga\(_{0.67}\)As Hall bar samples employing a two-axis magnet system (perpendicular field \(B_{\perp}\) and parallel field \(B//\). Consistent with the previous results, strong MIRO were observed and were found to diminish under a \(B//\sim\;1\;T\). We observed two types of PV oscillations: 1) PV oscillations that are periodic in \(1/B_{\perp}\), with a periodicity similar to MIRO, but are anti-symmetric with respect to \(B_{\perp} = 0\); and, 2) PV oscillations due to edge magnetoplasmon modes, which are periodic in \(B_{\perp}\) and are symmetric with respect to \(B_{\perp} = 0\). Characteristically, the \(1/B_{\perp}\) oscillations in PV were completely suppressed by a \(B//\sim\;1\;T\), whereas the \(B_{\perp}\)-periodic oscillations retain their main features even in \(B// \;= \;2\;T\). Experimental data and a brief discussion will be presented. The work at Rice was supported by NSF DMR-0706634.
9:12AM U37.00007 Microwave-Induced Resistance Oscillations in Non-Faraday Configurations, KRISTJAN STONE, ZHUOQUAN YUAN, RUI-RUI DU, Rice University, CHANGLI YANG, Institute of Physics, CAS, China, LOREN PFEIFFER, KEN WEST, Bell Laboratories, Alcatel-Lucent — The microwave-induced resistance oscillations (MIROR) are commonly observed in high-mobility GaAs 2D electron systems (2DES), typically using a Faraday configuration. In a Faraday configuration, the electromagnetic components (E_x and H_y) coincide with the 2DES plane. We explore MIROR in a microstrip line geometry, in which the dominant excitation component in the 2DES plane is H_y. Our samples were 100 or 200 μm wide Hall bars of very-high mobility (εc × 8 × 10^7 cm^2/Vs) GaAs/AlxGa1-xAs heterojunctions or quantum wells with electron density ranging from 2.1 × 10^{11} cm^{-2}. Microwaves from a tunable source (2 GHz - 40 GHz) were fed via a semi-rigid coax cable to the microstrip line over the length of the Hall bar. In a temperature range of 0.3 K – 2.0 K, we observed strong MIROR features. We studied the fractional MIROR using both the microstrip line and dipole antenna geometries. By increasing the power, MIROR features associated with high-mobility 2DES were presented. Experimental data as well as a brief discussion will be presented. The work at Rice was funded by NSF DMR-0706634.

9:24AM U37.00008 Low Temperature Scanning Hall Probe Microscopy of 2D Electron Nanostructures, ZHUOQUAN YUAN, YANHUA DAI, RUI-RUI DU, Rice University, L.N. PFEIFFER, K.W. WEST, Bell Labs, Alcatel-Lucent — Current distribution can provide key information on microscopic properties of 2D electron systems (2DES) in the regime of quantum transport. However, imaging coherent electron flow is proven to be experimentally challenging. We developed a method to image current distribution by using low temperature (0.3K), high spatial resolution (5 μm) scanning Hall probe. We imaged the local magnetic field component perpendicular to the 2DES in GaAs/AlGaAs samples, and then used Fast Fourier Transform (FFT) technique to recover the current distribution from the data of magnetic field. As an example, we will present the data and a brief discussion on imaging geometrical resonance in anti-dot lattices patterned on a very high mobility 2DES. The research at Rice was supported by NSF DMR-0706634.

9:36AM U37.00009 Spin-Orbit Interaction in High-κ Dielectric Gated Rashba-2D Electron Gas and Mesoscopic Rings, YANHUA DAI, ZHUOQUAN YUAN, KRISTJAN STONE, RUI-RUI DU, Physics and Astronomy, Rice University, MIN XU, PEIDE YE, Electrical and Computer Engineering, Purdue University — There is increasing current interest in the quantum interference effect in mesoscopic devices fabricated on a Rashba-2D electron gas (2DEG), where the spin-orbit interaction parameters can be tuned by a potential gate. We explore ring structures that use a gate consisting of thin (5nm-50nm) high-κ dielectric Al2O3 or HFO2 layer and nano-patterned metals. The 2DEG is provided by lattice-matched In0.52Al0.48As/GaAs quantum wells that have a typical electron density n of 1.5 × 10^{12}/cm^2 and mobility μ ≥ 2 × 10^5 cm^2/Vs. The dielectric material was grown by atomic layer deposition. We will present the gate characteristics of Hall bars as well as magnetic transport data from gated mesoscopic rings. The work at Rice is funded by NSF DMR-0706634. Reference: M. Konig et al. Phys. Rev. Lett. 96, 076804 (2006); T. Bergsten et al., Phys. Rev. Lett. 97, 196803 (2006); B. Grbic et al., Phys. Rev. Lett. 99, 176803 (2007).

9:48AM U37.00010 Novel interaction-induced magneto-oscillations in ac conductivity of 2D electron gas, TIGRAN SEDRAKYAN, University of Wisconsin-Madison, MIKHAIL RAIKH, University of Utah — We demonstrate that electron-electron interactions in a high-k dielectric 2D electron gas give rise to the oscillatory correction, δσ_{int}(ω), to the ac magnetoconductivity, σ(ω). Similarly to the conventional single-particle harmonics of the cyclotron resonance, the oscillating correction is periodic in ωc, where ωc is the cyclotron frequency. However, unlike the single-particle oscillations, which are periodic with ω, the interaction correction is periodic with ω^2. Oscillatory behavior of the interaction-induced magnetoconductivity develops at very low magnetic fields, ωc ≪ ω, at such fields the conventional harmonics are suppressed by the disorder. The underlying physical process of the new effect is double backscattering of an electron from the impurity-induced Friedel oscillations. Unlike the case of single-particle oscillations, the electrons travel only a small portion of the Larmor circle during the time ~ω^{-1} between the two backscattering events.

10:00AM U37.00011 Many-body local field corrections to spin Coulomb drag in a quasi-two-dimensional electron system, SAMVEL BADALYAN, Department of Radiophysics, Yerevan State University, 375025 Armenia and Department of Physics, University of Regensburg, 93040 Regensburg, Germany, CHANG SUB KIM, Department of Physics, Chonnam National University, 500-757 Gwangju, Korea, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri - Columbia, Missouri 65211, USA — We investigate the effect of exchange and correlation on spin Coulomb drag in a quasi-two-dimensional electron gas of finite transverse width. We find that the finite transverse width of the electron gas causes a significant reduction of the spin Coulomb drag. This reduction, however, is largely compensated by the enhancement coming from the inclusion of many-body local field corrections beyond the random phase approximation. Our calculations are in very good agreement with and confirm the experimental observations of the spin Coulomb drag by C. P. Weber et al., Nature, 437, 1330 (2005).

10:12AM U37.00012 Evidence of Coulomb Drag between Anderson Insulators, KAREE ELSEYAD, JOHN CARINI, DAVID BAXTER, Indiana University — We report observations of Coulomb drag between 200 Angstrom thick co-sputtered insulating amorphous silicon-niobium alloy films, separated by a thin silicon-oxide barrier. An apparent linear-response regime for the transresistance is found to only exist over a narrow range of layer separations (∼100 Angstroms) and material parameters (niobium concentrations ∼ 7%) at low driving currents (∼1nA) and temperatures below ∼20 Kelvin. The temperature dependence, as well as the magnitude, of the transresistance in this regime is consistent with predictions for that between Anderson insulators with long ranged intra-layer Coulomb interactions, provided that the density of states of the silicon-niobium layers are taken to be that of effectively 3-dimensional systems. This is in contrast with measurements of the temperature dependence of the dc layer-conductivity in such bilayer systems, which suggest that transport should be effectively 2-dimensional at these energies. We will discuss the fabrication and characterization of bilayer samples, as well as possible explanations for the observed magnitude and temperature dependence of the transresistance.

10:24AM U37.00013 Scaling of thermoelectric voltage induced by microwave radiation at the boundary between two-dimensional electron systems, N. ROMERO KALMANOVITZ, I. HOXHA, Y. JIN, S.A. VITKALOV, M.P. SARACHIK, Physics Dept., City College of the City Univ. of New York, I.A. LARKIN, International Center of Condensed Matter Physics, Brasilia, T.M. KLAPWijk, Delft Univ. of Technology, Dept. of Applied Physics — We report measurements of the rectification of microwave radiation (0.7-20 GHz) at the boundary between two-dimensional electron systems created by a narrow gap split gate on a silicon surface for different temperatures, electron densities and microwave power. For frequencies above 4 GHz and different temperatures, the rectified voltage Vdc as a function of microwave power P can be collapsed onto a single universal curve Vdc = f∗(P∗) using two scaling parameters. The scaled voltage, Vdc, is a linear function of power, P∗, for small power and proportional to (P∗)^{1/2} at higher power. A theory is developed which attributes the observed voltage to the thermoelectric response associated with local heating by the microwave radiation of adjacent two-dimensional electron systems with different densities n₁ and n₂. Excellent quantitative agreement is obtained between theory and experiment. *The work at the City College of New York was supported by DOE grant DOE-FG02-84-ER45153. The work at International Center of Condensed Matter Physics, Brasilia, was supported by IBEM fund from Brazilian Ministry of Science and Technology.

8:00AM U38.00001 Thermoelectric response of Lanthanum-doped SrTiO₃ thin-films grown under various oxygen partial pressures , MATTHEW L. SCULLIN, Dept. of Materials Science and Engineering, University of California, Berkeley, CA 94720, JAYAKANTH RAVICHANDRAN, Dept. of Mechanical Engineering, University of California, Berkeley, CA 94720, MARK HUIJGEN, Dept. of Physics, University of California, Berkeley, CA 94720, CHONG-HO YU, Lawrence Berkeley National Labs, Berkeley, CA, 94720, SUBROTO MAJUMDAR, Lawrence Berkeley National Labs, Berkeley, CA, 94720, R. RAMESH, Dept. of Materials Science and Engineering, University of California, Berkeley, CA 94720 — Doped strontium titanate is a strong candidate for the next-generation high-Z bulk thermoelectric material due to both its wide tunability in transport properties and very large carrier effective mass. Thermoelectric thin-films of Sr₁₋ₓLaₓTiO₃₋₈ with various La content were grown via pulsed-laser deposition (PLD) on (001)-oriented LSAT substrates under various oxygen partial pressures. We find that electron transport is dominated by carriers from oxygen vacancies in samples grown at low po₂ < 10⁻⁶ Torr, and that thermopower as high as 1000 µV/K can be achieved even in heavily La-doped samples. Doping combinations that yield resistivities as low as 5 mΩ-cm yield power factors 300 K as high as 0.7 W/m-K, implying ZT

8:12AM U38.00002 “Pudding mold”-type band dispersion as the origin of large thermopower in Na₂CoO₂ , KAZUHIKO KUROKI, Dept. App. Phys.+Chem, Univ. Electro-Commum., RYOTARO ARITA, Cond. Mat. Theory Lab., RIKEN — Na₂CoO₂ is an interesting material in that it has large thermopower, non-trivial magnetic property, and becomes superconducting when water molecules are intercalated. Recently, in Ref. 1 and 2, we proposed that the magnetism and the superconductivity can have the same root. Namely they can originate from the peculiar band dispersion of 11g band. In this study, by using Boltzmann’s equation, we calculated the thermopower of this system. We found that the coexistence of the large thermopower and the low resistivity in this material is not just the density of states, the effective mass, nor the band width, but indeed again the peculiar “pudding mold”-type band dispersion of the 11g band which consists of a dispersive portion below the Fermi level and a dispersionless portion above the Fermi level[3].

8:24AM U38.00003 Thermoelectric properties of Bi₃Sr₂CoO₅ thin films grown by pulsed laser deposition, SHUHANG WANG¹, VENIMADHAV ADAYAM², SHENGMING GUO³, QI LI, XIAOXING XI¹, Department of Physics, The Pennsylvania State University, University Park, USA — Epitaxial and c-axis preferred oriented oxide thermoelectric Bi₃Sr₂CoO₅ thin films have been deposited on LaAlO₃ (100), A₁₂O₃(001) and fused silica substrates using pulsed laser deposition. At room temperature, the Seebeck coefficient and resistivity are of the order of 125 µV/K, 120 µV/K, 110 µV/K, 2 mΩ·cm and 3 mΩ·cm, 2 mΩ·cm, 2 mΩ·cm, 14 mΩ·cm for the films on LaAlO₃ (100), A₁₂O₃(001) and silica substrates respectively. A large negative in-plane magnetoresistance (MR) is observed in the films at low temperatures, with a MR reaching 41% at T=1.8 K in films on LaAlO₃ (100). We also observed a large bias current-dependent resistivity in the films at low temperature, which has been attributed to the suppression of spin-density-wave by electric field.

8:36AM U38.00004 Localization of holes at oxygen sites in a thermoelectric rhodate revealed by photoemission spectroscopy, ISHIDA YUKIARI, BABA TERUHISA, RIKEN SPRing-8 Center, EGUCHI RITSUKO, MATSUNAMI MASA-HARU, ISSP U. Tokyo, TAGUCHI MUNETAKA, CHAINAINI ASHISH, RIKEN SPRing-8 Center, SENBA YASUNORI, OHASHI HARIHIKO, JASRI/SPRING-8, OKAMOTO YOSHIIKO, ISSP U. Tokyo, TAKAGI HIDENORI, RIKEN, SHIN SHIK, RIKEN SPRing-8 Center & ISSP U. Tokyo — We have performed soft-x-ray absorption and photoemission studies on Sr₁₋ₓRh₂O₄⁺[1], a thermoelectric material structurally and electronically analogous to Na₅CoO₂. Metal-insulator transition occurs with hole doping into the Rh 4d t₂g band via introducing Sr vacancies [1]. Valence-band spectra of Sr₁₋ₓRh₂O₄ showed satellite structures ~11 eV below the Fermi level, which cannot be explained by LDA or LDA+U calculations. The O 1s 2p₂p Auger peak in the photoemission spectra appeared from the 11-eV satellite in the vicinity of the O 1s absorption edge, indicating that the satellite is a sign of holes localized at oxygen sites. Concomitantly, doping dependent changes appeared mainly in the O 1s absorption spectra rather than in the Rh 3p₃/2 absorption spectra. We discuss inhomogeneous evolution of the system with hole doping along with Sr-vacancy potential and d-p hybridization. [1] Y. Okamoto, et al., J. Phys. Soc. Jpn. 75, 023704 (2006).
10:12AM U38.00010 A new hybrid exchange-correlation functional for accurate prediction of the electronic and structural properties of ferroelectric oxide bulks and nanostructures , D.I. BILC, Université de Liège, Belgium, R. SHALTAF, Université Catholique de Louvain, Belgium, J. Íñiguez, Institut de Ciencia de Materials de Barcelona, Spain, PH. GHOSEZ, Université de Liège, Belgium — We report a systematic comparison of various DFT and hybrid exchange-correlation functionals for the prediction of the electronic and structural properties of prototypical ferroelectric oxides. We find that some, although not all, usual DFT functionals predict the structure with acceptable accuracy, but always underestimate the electronic band gaps. Conversely, common hybrids yield an improved description of the band gaps, but overestimate the volume and atomic distortions associated to ferroelectricity, giving rise to an unacceptably large c/a ratio for the tetragonal phases of BaTiO$_3$ and PbTiO$_3$. This super-tetragonality is found to be induced mainly by the GGA exchange energy. We thus propose an alternative hybrid functional, B1-WC, that mixes exact exchange following the B1 scheme with the recently improved GGA proposed by Wu and Cohen. This B1-WC renders accurate description of the both structural and electronic properties of typical ferroelectric oxide at the bulk level. The case of Pt/BaTiO$_3$ heterostructures is also considered and a comparison of the of B1-WC and LDA results for atomic relaxation and electronic band alignment at the interface is presented.

1In collaboration with Massimiliano Stengel, Karin M. Rabe and David Vanderbilt.

10:00AM U38.00009 Improper ferroelectricity in perovskite oxide artificial superlattices , MATTHEW DAWBER, NICOLAS STUCKI, CELINE LICHTENSTEIGER, JEAN-MARC TRISCONE, DPMC, University of Geneva, Switzerland, ERIC BOUS-QUET, PATRICK HERMET, PHILIPPE GHOSEZ, Physique Theorique des Materiaux, Université de Liège, Belgium — In paraelectric/ferroelectric heterostructures with thick constituent layers electrostatics is the dominant interaction between layers and we have previously demonstrated that the key ferroelectric parameters, polarization and critical temperature can be tuned over a very large range in PbTiO$_3$/SrTiO$_3$ superlattices by varying the ratio of the layer thicknesses [1]. However, as the layers become thinner, a departure from the electrostatic model is observed, which manifests itself as an unusually high ferroelectric polarization and transition temperature and a high, but temperature independent, dielectric constant. Detailed examination of the phase transitions with temperature reveals that along with these enhanced characteristics there is a fundamental change in the nature of the ferroelectricity. The microscopic origin of this change, a form of improper ferroelectricity, is revealed by first principles calculations to occur through a coupling of oxygen rotations and the polarization mismatch at the interfaces in the material. 10:24AM U38.00011 First principles calculations at fixed dielectric displacement, MASSIMILIANO STENGEL, UCSB; DAVID VANDERBILT, Rutgers University; NICOLA SPALDIN, UCSB — With the experimental advances in growth and characterization of superlattices and thin-film capacitors based on ferroelectric perovskites, it is becoming more and more crucial to achieve a fundamental understanding of these structures by accurate first-principles modeling. Unfortunately, difficulties in the treatment of finite electric fields and macroscopic polarization in periodic systems — in particular when metallic electrodes are present — make the application of ab-initio techniques to such systems particularly challenging. To address these issues, we present here a method to perform first-principles calculations of periodic systems at a fixed value of the macroscopic dielectric displacement. This technique, which complements previously established strategies to fix \( E \) or \( \varepsilon \), provides a simple and natural way to explore the phase diagram of a ferroelectric system as a function of a single electrical order parameter. We demonstrate the power of our approach by computing the electrical equations of state for two symmetrical ferroelectric capacitors which are based on the same combination of materials, Au and BaZrO\(_3\), but are characterized by inequivalent interface geometries and stoichiometries. In particular, we use the information extracted from the centrosymmetric systems to accurately predict the electrical equation of state for an asymmetric capacitor of analogous composition.

10:36AM U38.00012 Broadband Permittivity Measurements of Ruddlesden-Popper \( \text{Sr}_{n+1}\text{Ti}_n\text{O}_{3n+1} \) Thin Films, N. ORLOFF, W. TIAN, D. SCHLOM, J. BOOTH, I. TAKEUCHI — In order to explore the microwave dielectric response of \( \text{Sr}_2\text{TiO}_4\), \( \text{Sr}_3\text{Ti}_2\text{O}_9\), and \( \text{Sr}_4\text{Ti}_3\text{O}_{10} \) thin films, we have performed broadband in-plane quantitative complex permittivity(\( \varepsilon \)) measurements on \( \text{Sr}_{n+1}\text{Ti}_n\text{O}_{3n+1} \) thin films in the frequency range 100Hz-40GHz. The films, of approximately 160 nm thickness, were fabricated by molecular beam epitaxy\(^1\), and standard lithographic techniques were used to define coplanar waveguide transmission lines and interdigitated capacitors using gold. We extracted \( \varepsilon \) from the measured complex S-parameters (0.1-40GHz) and the complex impedance (100Hz-.001GHz), which were measured at 70K, 150K, 200K, and 250K using a cryogenic probe station. We found that below \( \sim 10\text{GHz} \) the \( \varepsilon 's \) of these thin films were approximately constant with frequency: \( \varepsilon \approx 38\), 48, and 100 for \( \text{Sr}_{n+1}\text{Ti}_n\text{O}_{3n+1} \) respectively. In addition, the measured value for \( \varepsilon \) of \( \text{Sr}_2\text{TiO}_4 \) is consistent with recent theoretical calculations\(^2\).

10:48AM U38.00013 Competing structural instabilities in Ti-based layered-perovskite-oxide superlattices\(^3\), SERGE NAKHMANSON, Argonne National Lab — Utilizing first-principles computational techniques, we have mapped out structural instabilities in the Ruddlesden-Popper homologous oxide superlattice families with a general chemical formula \( \text{A}_{n-1}\text{A}_n\text{Ti}_n\text{O}_{3n+1} \), \( \text{A} = \text{Sr}, \text{Ba}, \text{Pb} \) (perovskite-type block) and \( A' = \text{Sr} \) (rocksalt-type block), for \( n = 1-5 \). Our calculations show that each superlattice family has a unique set of “instability footprints” — including the ferroelectric, antiferroelectric and antiferrodistortive types — which may or may not have a strong coupling to epitaxial strain. Furthermore, the existence and strength of structural instabilities within each particular family change dramatically with an increasing number of perovskite-type layers \( n \), granting us wide flexibility to fine-tune the properties of these materials for various device applications or, e.g., for integration into composites with magnetic Ru- or Mn-based layered-perovskite-oxide compounds.

Session U39 GSNP: Focus Session: Structure and Dynamics of Complex Networks
Morial Convention Center 231

8:00AM U39.00001 From network dynamics to human activity and mobility patterns, ALBERT-LÁSZLÓ BARABÁSI, Center for Complex Network Research and Dept. of Physics, Northeastern University; Center for Cancer Systems Biology, Dana Farber Cancer Institute. — The next challenge of network research is to go beyond the structure and quantify the dynamics of interconnected systems. A particular difficult facet of this research requires us to understand the temporal and spatial driving forces that govern social, technological and biological networks. In this talk I will focus on the dynamical mechanism that drive the activity of social networks. While none of us thinks of our daily activity pattern as random, most modeling efforts approximate human activity with fundamentally random spacial and temporal patterns. My purpose is to offer evidence of a series of significant deviations from this random expectation. I will talk about the bursty temporal character of human activity patterns and the travel patterns of individuals. I will show that both human activity and travel patterns are far more regular than the standard Poisson and diffusion models would predict, with implications on agent based models, epidemic modeling as well as the nature of time and space experienced by humans. The work was done in collaboration with Marta Gonzales, Cesar Hidalgo, Kwang-il Goh, Joao Oliveira, and Alexei Vazquez.

8:36AM U39.00002 Finite Size Effects and Symmetry Breaking in the Evolution of Networks of Competing Boolean Nodes\(^1\), KEVIN BASSLER, MIN LIU, University of Houston — The effects of finite network size on the evolutionary dynamics of a Boolean network are analyzed. In the model considered, Boolean networks evolve via a competition between nodes that punishes those in the majority. Finite size networks evolve in a fundamentally different way than infinitely large networks do. The symmetry of the evolutionary dynamics of infinitely large networks that selects for canalizing Boolean functions is broken in finite size networks. In finite size networks there is an additional selection for input inverting Boolean functions. Classes of functions are found empirically to evolve with the same frequency. The classes depend on the symmetry of the evolutionary dynamics and correspond to orbits of the relevant symmetry group. The empirical results match analytic results, determined by utilizing Polya's theorem, for the number of orbits expected in both finite size and infinitely large networks. The reason for the symmetry breaking is due to the need for nodes in finite size networks to behave differently in order to cooperate to collectively perform efficiently. The results suggest that both finite size effects and symmetry are important for understanding the evolution of real-world complex networks, including genetic regulatory networks.

8:48AM U39.00003 Attractors in continuous and Boolean networks\(^1\), JOHANNES NORRELL, JOSHUA SOCOLAR, Physics Department and Center for Nonlinear and Complex Systems, Duke University; BJÖRN SAMUELSSON, Lund University — Random Boolean models of complex regulatory networks are known to exhibit rich dynamical behaviors, including an order/disorder transition. We show that implementation of the nominal Boolean logic of a network using differential equations involving sigmoidal switching functions generically leads to deviations from the Boolean predictions. On simple rings, the “reliable” set of Boolean attractors corresponds to the stable attractors of the analogous continuous system. For networks with more complex logic, however, the set of the continuous attractors is determined by non-Boolean characteristics of the switching events. In large random networks, the nature of the order/disorder transition is altered by collective effects associated with compositions of the sigmoidal switching functions.

\(^1\)Supported by NSF.
9:00AM U39.00004 Scale-Free Overlay Topologies with Hard Cutoffs for Unstructured Peer-to-Peer Networks1, HASAN GUCLU, Los Alamos National Laboratory, MURAT YUKSEL, University of Nevada at Reno — The topology have profound impact on the efficiency of search on unstructured peer-to-peer (P2P) networks as well as other networks. It has been well-known that search on scale-free (power-law) topologies offer outstanding search efficiency as good as $O(\ln \ln N)$ for a range of degree distribution exponents. However, generation and maintenance of such scale-free topologies are hard to realize in a distributed and potentially uncooperative environments as in the P2P networks. A key limitation of scale-free topologies is the high load (i.e. high degree) on very few number of hub nodes. In a typical unstructured P2P network, peers are not willing to maintain high degrees/loads as they may not want to store large number of entries for construction of the overlay topology. So, to achieve fairness and practicality among all peers, hard cutoffs on the number of entries are imposed by the individual peers. Thus, efficiency of the flooding search reduces as the size of the hard cutoff does. Interestingly, we observe that the efficiency of normalized flooding and random walk search algorithms increases as the hard cutoff decreases.

1This work is supported by the U.S. DOE through Grant No. DE-AC52-06NA25396 and by the NSF grant No. 0627039.

9:12AM U39.00005 A Self–organized model for network evolution, GUIDO CALDARELLI, CNR-INFM Centre SMC Dip. Fisica, University “Sapienza” Rome, Italy, ANDREA CAPOCCI, Dip. Fisica Universita’ “Sapienza” Rome, Italy, DIEGO GARLASCHELLI, Dipartimento di Fisica, Università di Siena, Italy — Here we present a self-organized model for the evolution of complex networks. Vertices of the network are characterized by a variable evolving through an extremal dynamics process. The network topology is in turn shaped by the variable itself. More specifically, to each vertex a fitness is assigned; then, in the evolution, the vertex with minimum fitness and its neighbors are updated by extracting new fitesses. For any given realization of fitnesses we can determine the edges in the network through a fitness dependent rule. We show analytically and numerically that this system self-organizes to a nontrivial state. A power–law decay of dynamical and topological quantities above a threshold emerges spontaneously, as well as a feedback between different dynamical regimes and the underlying network’s correlation and percolation properties.

9:24AM U39.00006 Money circulation networks reveal emerging geographical communities, D. BROCKMANN, MPI-DS, Goettingen, Germany & Northwestern University, F. THEIS, CMB, Institute for Bioinformatics, Neuherberg, Germany, V. DAVID, MPI-DS, Goettingen, Germany — Geographical communities and their boundaries are key determinants of various spatially extended dynamical phenomena. Examples are migration dynamics of species, the spread of infectious diseases, bioinvasive processes, and the spatial evolution of language. We address the question to what extend multiscale human transportation networks encode geographical community structures, how they differ from geopolitical classifications, whether they are spatially coherent, and analyse their structure as a function of length scale. Our analysis is based on a proxy network for human transportation obtained from the geographic circulation of more than 10 million dollar bills in the United States recorded at the bill tracking website www.wheresgeorge.com. The data extends that of a previous study (Brockmann et al., Nature 2006) on the discovery of scaling laws of human travel by an order of magnitude and permits an approach to multiscale human transportation from a network perspective.

9:36AM U39.00007 Functional structure through dynamic clustering of neuronal networks1, SARAH FELDT, MICHAL ZOCOWSKI, University of Michigan — We propose a new method for detecting functional structure in neuronal networks based solely upon the information derived from the spike timings of the neurons. Unlike traditional algorithms that depend on knowledge of the topological structure of the network to parse the network into communities, we dynamically cluster the neurons to build communities with similar functional interactions. We define means to derive optimal clustering parameters and investigate what conditions have to be fulfilled to obtain reasonable predictions of functional structures.

1Supported through an NSF Graduate Research Fellowship and NIH Grant EB005583.

9:48AM U39.00008 Citation analysis: Beyond the Journal Impact Factor, MANOLIS ANTONOYIANNAKIS, (1) Physical Review Letters (2) Columbia University — The journal impact factor is a robust measure of the average citation performance of a journal, but the number of citations varies widely from paper to paper within any journal. Therefore, it makes sense to look for additional ways of characterizing journals in terms of their impact. We introduce the “citation density curve” (citations per paper in a given year for papers published in the previous two years, plotted vs. the citation rank of these papers). This curve, which displays a Zipf’s law behavior, contains all the pertinent information about a journal: its size, its impact factor, the maximum number of citations per paper, the relative size of the top-cited portion of the journal, how the citation density varies within the journal, etc. Being the “fingerprint” of a journal, the citation density curve can be used: (a) by editors, for strategic decisions affecting the future of their journal; (b) by citation analysts, for comparing (ranking) journals; and (c) by authors, for assessing the relative impact of their published work. Further, we identify a complementary metric to the impact factor, a single number that characterizes the top-cited portion of a journal. This metric reproduces the ranking of the citation density curves for various journals, and can be readily calculated from the same data used in the impact factor calculations. We propose that this new metric be used as an essential complement to the impact factor in assessing the true impact of journals.

10:00AM U39.00009 Epidemics on adaptive networks with geometric constraints, LEAH SHAW, College of William and Mary, IRA SCHWARTZ, Naval Research Lab — When a population is faced with an epidemic outbreak, individuals may modify their social behavior to avoid exposure to the disease. Recent work has considered models in which the contact network is rewired dynamically so that susceptibles avoid contact with infectives. We consider extensions in which the rewiring is subject to constraints that preserve key properties of the social network structure. Constraining to a fixed degree distribution destroys previously observed bistable behavior. The most effective rewiring strategy is found to depend on the spreading rate.

10:12AM U39.00010 Some aspects on human preference in communication and friendship, DIEGO RYBSKI, HERNAN D. ROZENFELD, Levich Institute and Physics Department, City College of New York, New York, NY 10031, USA, FREDRIK LILJEROS, Department of Sociology, Stockholm University, S-106 91 Stockholm, Sweden, SHLOMO HAVLIN, Minerva Center and Department of Physics, Bar-Ilan University, 52900 Ramat-Gan, Israel, HERNAN A. MAKSE, Levich Institute and Physics Department, City College of New York, New York, NY 10031, USA — The objects of our investigation are social networks consisting of individual actants as nodes and their relations as links. Recently, on-line communities have gained immense popularity as indicated by millions of members participating in these platforms. Fortunately, the information given by member activity provides an ideal environment to study structural preferences of social behavior. In particular, we address the questions of how network topology benefits the spreading rate.

Among others, we find that actants tend to get connected at a distance of 2. Further analysis indicates that the more common neighbors two actants have, the more likely they will be in relation with each other. We attribute this behavior to some kind of social pressure imposed by the neighborhood biasing the actants preferences.
10:24AM U39.00011 Studying Human Dynamics Through Web Analytics, JOSE RAMASCO, I.S.I., Torino, Italy, BRUNO GONCALVES, Emory University, Atlanta Ga, 30322 — When Tim Berners Lee, a physicist at the European Center for Nuclear Research (CERN) first conceived the World Wide Web (WWW) in 1990 as a way to facilitate the sharing of scientific information and results among the centers different researchers and groups, even the most ingenious of science fiction writers could not have imagined the role it would come to play in the following decades. The increasing ubiquitousness of Internet access and the frequency with which people interact with it raise the possibility of using it to better observe, understand, and even monitor several aspects of human social behavior. Websites with large numbers of frequently returning users, such as search engines, company or university websites, are ideal for this task. The properly anonymized logs detailing the access history to Emory University’s website is studied. We find that a small number of users is responsible for a finite fraction of the total activity. A saturation phenomenon is observed where, certain connections age, becoming less attractive to new activity over time. Finally, by measuring the average activity as a function of the day of the week, we find that productivity seems to be higher on Tuesdays and Wednesdays, with Sundays being the least active day.

10:36AM U39.00012 Which Route Will You Choose to Use For Driving Home Tonight in Rush-Hour Traffic?1, BOGDAN DANILA, YUDONG SUN, KEVIN BASSLER, University of Houston — The best answer to the question posed in the title for a city of drivers requires knowing the optimal routes for congested traffic flow on complex networks. This is known to be an NP-hard problem. Despite this fact, we can arrive at optimal answers in integral polynomial time using extensions of a recently introduced heuristic algorithm [Danila, et al., PRe 74, 046106 (2006)] that, at least, scale optimally with network size. Using the optimal routes allows a network to support the maximum traffic load and significantly reduces the average travel time in congested traffic. The results presented apply to vehicular traffic and to traffic on wireless communication networks.

Thursday, March 13, 2008 8:00AM - 11:00AM
Session U40 DBP: Biomolecular Computation Morial Convention Center 232

8:00AM U40.00001 Hydrophobic polymers in nano-sized water droplets, BUDDHI TILAKARATNE, University of Houston, SAMINA MASOOD, University of Houston, CLEAR LAKE, MARGARET CHEUNG, University of Houston — As simulations of biopolymers take place in confined and tight spaces, such as protein folding in the interior of bacteria chaperones or the exit tunnels of ribosomes, quantitative analyses of the confinement effects on both biopolymers and solvent molecules become the center of attention as the solvent-mediated interactions are too profound to solve analytically. We are in the progress to investigate the solvation of hexane molecules in various nano-sized water droplets. Free energy profiles for a single hexane molecule in droplets show that the droplet surfaces are favored. Averaged configurations of hexane molecules at the interior and the surface are computed using the umbrella sampling methods. The implications of our results for protein stability in confined spaces will be discussed.

8:12AM U40.00002 A classical density functional for water, DAVID ROUNDY, DENNIS JACKSON, Oregon State University — We present a classical density functional for water that represents the short-range repulsive interaction using the fundamental-measure-theory hard-sphere functional. The parameters of this functional are chosen to reproduce the experimental liquid density, bulk modulus and surface tension of water, and to ensure coexistence of liquid and vapor phases. This functional inherits from the FMT functional its accurate description of reduced-dimensionality configurations. We will present computations of the hydrophobic hydration energy of hard-sphere solutes, demonstrating an accurate description at both large and small length scales.

8:24AM U40.00003 Hydrophobic interactions at molecular scale, DUBRAVKO SABO, SAMEER VARMA, SUSAN REMPE, MARCUS MARTIN, Sandia National Laboratories — Structural and thermodynamic properties are investigated for one of the simplest hydrophobic solutes, a hydrogen molecule solvated in liquid water. The structural properties are calculated using different representations of the intermolecular interactions within molecular dynamics, Monte Carlo and ab initio molecular dynamics simulation frameworks. Although structural details differ in the radial distribution functions obtained by different force fields all approaches agree that 16 water molecules coordinate hydrogen. The thermodynamic properties are investigated using Monte Carlo molecular simulation and the quasichemical theory of liquids. Results show that the net hydration free energy arises from a balance between chemical association and molecular packing. Additionally, the results suggest the molecular packing is almost equally driven by unfavorable enthalpic and entropic components.

8:36AM U40.00004 Computing absolute binding affinities via non-equilibrium unbinding simulations, F. MARTY YTBREBERG, University of Idaho — We demonstrate that non-equilibrium unbinding simulations can be used to accurately estimate equilibrium absolute binding affinities (ΔG). Utilizing the FKBP protein bound to two different ligands we estimate ΔG within less than 1.0 kcal/mol of experimental values. The methodology is straightforward, requiring no modification to many modern molecular simulation packages. The approach makes use of a physical pathway, eliminating the need for complicated alchemical decoupling schemes. These results suggest that non-equilibrium simulation could provide a viable means to accurately estimate protein-ligand binding affinities.

8:48AM U40.00005 Macromolecular crowding effects on Brownian motion of protein GB1, ANTONIOS SAMIOTAKIS, MARGARET CHEUNG, University of Houston — The effect of macromolecular crowding in the interior of a cell plays an important role in protein folding dynamics and its stability. In the present work the dependence of diffusion coefficients of the macromolecule on various crowding conditions is studied using a coarse-grained representation of protein G B1 domain that includes Go-like interactions. Using Brownian dynamics simulations, diffusion coefficients are computed as a function of the volume fraction of crowders φc and the ratio λ of the sizes of the crowder over that of protein. Deviation from linear Stokes-Einstein relation will be discussed.
9:00AM U40.00006 Core-Shell Model of Folding-Unfolding Transitions (UFT) in Proteins

SVETLANA AROUTIOUNIAN — There are ~10^N conformations for a protein of length N to sort out randomly in search of lowest free energy state. Can protein folding be simple and fast? Core-shell model introduces principles, proposes mechanisms and scores residues of fast, reversible UFT in protein. According to it, during UFT the realm of intra-residual interactions leads the residue motion. The scaffold of hydrophilic residues forms external shell of unstructured, tube-like protein in unfolded state, just as the hydrophobic residues form internal scaffold — core, of the protein in folded state. As UFT proceeds, residue slides into lowest-score position permitted by its structure. Model accounts for experimentally observed features of UFT. It is based on three principles: 1) During UFT protein is virtual - its features or structure are inferred only statistically and with limited precision; 2) Mechanism of UFT memory is not longitudinal, but transverse; 3) Native design overrides specific features of residues - the alphabet of amino acids becomes score-function. Per-residue mechanism of UFT is proposed and score-function is described. Difference graphs of transitional score-function and average genome-wide abundance index show that our score-function is the order parameter of UFT in protein and as virtue of being it, reveals transitional key residues. It echoes the multiple-tier and funnel concepts of FEL perspective. Monte Carlo simulations of UFT in myoglobin illustrate the idea.

9:12AM U40.00007 Potential of mean force of Glycophorin A alpha-helix dimerization

LORANT JANOSI, MANOLIS DOXASTAKIS, University of Houston — Transmembrane proteins recognition and association plays a crucial role in their assembly and function. In spite of the extensive studies, these processes are only partially understood. We investigate the association of the model transmembrane alpha-helices by means of coarse-grained simulations with reference interaction site model theory for simulating proteins in aqueous solution. The reference interaction site model theory based on the liquid theory of statistical mechanics can treat solvent effect with solvent molecular shape and estimate solvation free energy around proteins. We have developed simulation algorithms which combine with generalized-ensemble algorithms and reference interaction site model theory. We showed results of a simulated annealing Monte Carlo simulation, a multicanonical Monte Carlo simulation, and a replica-exchange Monte Carlo simulation with one dimensional reference interaction site model theory for Met-Enkephalin, a penta-peptide [1,2,3]. Recently we have performed a Monte Carlo simulation with three-dimensional reference interaction site model theory for simulating C-peptide in aqueous solution. We will describe these attempts and discuss results of these simulations.

9:24AM U40.00008 Monte Carlo Simulations with reference interaction site model theory for simulating peptide molecules in aqueous solution

AYORI MITSUTAKE, Keio Univ., YUTAKA MARUYAMA, IMS, TAKASHI IMAI, Ritsumei Univ., MASASHI KINOSHITA, Kyoto Univ., YUKO OKAMOTO, Nagoya Univ., FUMIO HIRATA, IMS — We have developed Monte Carlo simulations with reference interaction site model theory for simulating proteins in aqueous solution. The reference interaction site model theory based on the liquid theory of statistical mechanics can treat solvent effect with solvent molecular shape and estimate solvation free energy around proteins. We have developed simulation algorithms which combine with generalized-ensemble algorithms and reference interaction site model theory. We showed results of a simulated annealing Monte Carlo simulation, a multicanonical Monte Carlo simulation, and a replica-exchange Monte Carlo simulation with one dimensional reference interaction site model theory for Met-Enkephalin, a penta-peptide [1,2,3]. Recently we have performed a Monte Carlo simulation with three-dimensional reference interaction site model theory for simulating C-peptide in aqueous solution. We will describe these attempts and discuss results of these simulations.

9:36AM U40.00009 Glassy protein dynamics and gigantic solvent reorganization energy of plastocyanin

DAVID LEBERD, DMITRY MATYUSHOV, Center for Biological Physics, Arizona State University — This work focuses on the results of extensive explicit solvent Molecular Dynamics simulations of plastocyanin, a blue copper electron transfer protein involved in natural photosynthesis. Simulation data indicate that low-frequency non-ergodic fluctuations of the protein matrix tethered to the hydrating water are responsible for a very broad distribution of the vertical energy gaps of one-electron protein reduction/oxidation. The width of the corresponding free energy surfaces yields a reorganization free energy far larger than previously reported for any organic, inorganic, or biological chromophores. However, the Stokes shift is not affected by these slow motions and can be calculated from the polarization response function of the dipolar solvent using microscopic solvation models. The glassy nature of the protein-solvent interface breaks the direct link between the Stokes shift and the reorganization energy from equilibrium (ergodic) electron transfer theories. This suggests a mechanism that accounts for electron transfer in natural proteins, which are characterized by a low reaction free energy combined with a low activation barrier.

9:48AM U40.00010 Modeling low frequency vibrational modes of large biomolecules

OTT0 SANKEY, ERIC DYKEMAN, Arizona State University — Mechanical oscillations of proteins in their native state are relevant to understanding the flexibility of the protein assembly, the binding of substrates, the mechanical action involved in enzymatic activity, and the vibrational response to light scattering. Often, only the low frequency modes are of interest and coarse grained methods or other approximations are used due to the large size of the dynamical matrix. We introduce a computational approach, which exploits the methodology from electronic structure Order N methods, to find the vibrational modes below some high frequency threshold (analogous to a Fermi-level in electronic structure theory). The approach allows systems to be described in atomistic detail. We use a generalized Born force field to model the interactions. Examples of normal modes for icosaheiral viruses (e.g. satellite tobacco necrosis virus), tubular viruses (e.g. M13), and enzymes (e.g. lysozyme, HIV-protease, alpha-lytic protease) will be discussed. This effort is motivated by recent experimental work to produce high amplitude vibrations of viruses from impulsive stimulated Raman scattering.

10:00AM U40.00011 Monte Carlo simulations of Protein Adsorption

SUMIT SHARMA, SANAT K. KUMAR, Columbia University, GEORGES BELFORT, Rensselaer Polytechnic Institute — Amyloidogenic diseases, such as, Alzheimer’s are caused by adsorption and aggregation of partially unfolded proteins. Adsorption of proteins is a concern in design of biomedical devices, such as dialysis membranes. Protein adsorption is often accompanied by conformational rearrangements in protein molecules. Such conformational rearrangements are thought to affect many properties of adsorbed protein molecules such as their adhesion strength to the surface, biological activity, and aggregation tendency. It has been experimentally shown that many naturally occurring proteins, upon adsorption to hydrophobic surfaces, undergo a helix to sheet or random coil secondary structural rearrangement. However, to better understand the equilibrium structural complexities of this phenomenon, we have performed Monte Carlo (MC) simulations of adsorption of a four helix bundle, modeled as a lattice protein, and studied the adsorption behavior and equilibrium protein conformations at different temperatures and degrees of surface hydrophobicity. To study the free energy and entropic effects on adsorption, Canonical ensemble MC simulations have been combined with Weighted Histogram Analysis Method (WHAM). Conformational transitions of proteins on surfaces will be discussed as a function of surface hydrophobicity and compared to analogous bulk transitions.

10:12AM U40.00012 Complexation of Flavonoids with Iron: Structure and Optical Signatures

JUN REN, SHENG MENG, Physics Department and School of Engineering and Applied Sciences, Harvard University, CH. E. LEKKA, Department of Materials Science and Engineering, University of Ioannina, Ioannina 45110, Greece, EFTHIMIOS KAXIRAS, Physics Department and School of Engineering and Applied Studies, Harvard University — Flavonoids exhibit antioxidant behavior believed to be related to their metal ion chelation ability. We investigate the complexation mechanism of several flavonoids, quercetin, luteolin, galangin, kaempferol and chrysin with iron, the most abundant type of metal ions in the body, through first- principles electronic structure calculations based on Density Functional Theory (DFT). We find that the most likely chelation site for Fe is the 3-hydroxyl-4-carbonyl group, followed by 4- carbonyl-5-hydroxyl group and the 3’-4’ hydroxyl (if present) for all the flavonoid molecules studied. Three quercetin molecules are required to saturate the bonds of a single Fe ion by forming six orthogonal Fe-O bonds, though the binding energy per molecule is highest for complexes consisting of two quercetin molecules and one Fe atom, in agreement with experiment. Optical absorption spectra calculated with time-dependent DFT serve as signatures to identify various complexes. For the iron-quercetin complexes, we find a redshift of the first absorbance peak upon complexation in good agreement with experiment; this behavior is explained by the narrowing of the optical gap of quercetin due to Fe(d)–O(p) orbital hybridization.
10:24AM U40.00013 When Cells Collide: A Model for Cell-Assisted Cell Growth based on Direct Contacts. CARL FRANCK, WUI IP, ALBERT BAE, NATHAN FRANCK, ELIJAH BOGART, THANHBINH THI LE, Cornell University — Although intercellular communication is frequently viewed as involving the transport of small molecules through an intracellular fluid medium, biologists have proposed chemical signaling with chemical specificity due to chemical recognition through direct contacts. Considering the collective computation behind the decision of a cell to divide when it senses the presence of a sufficient number of like neighbors, we offer a model for the transition from slow to exponential growth in shaken suspension cell culture of the model eukaryote, Dictyostelium discoideum. Besides exploring an elegantly simple example of multicellular life, this discussion might well prove useful in considering the limits of cell culture on small spatial scales as required for contemporary massively parallel biotechnology.

10:36AM U40.00014 Do Porins Pass CAPs?1, C.B. HANNA, Boise State University, D.A. PINK, St. Francis Xavier University, T.A. GILL, Dalhousie University, T.J. BEVERIDGE, University of Guelph, B.E. QUINN, J.J. DURRANT, Boise State University, M.H. JERICHO, Dalhousie University — The cationic antimicrobial peptide (CAP) protamine is known to inhibit bacterial survival (Pink et al., Langmuir 19, 8852 (2003), and references therein), but the mechanism of attack is as yet undetermined. For Gram-negative bacteria, two pathways have been proposed: (a) self-promoted uptake, and (b) passage through porins. Here, we study the latter possibility, and model part of the outer membrane of a Gram-negative bacterium in an aqueous solution containing multivalent ions and CAPs. The intent is to determine whether CAPs could pass through porins and, if so, what aspects of external (e.g., ionic concentration) and internal (e.g., porin and O-sidechain characteristics) parameters affect their passage. This study is accomplished via Monte Carlo computer simulations of a “minimal model” of the outer membrane of a Gram-negative bacterium with an embedded porin.

Parameterization of Regional and Global Features. CLAYTON BRATTON, Dept.of Physics, Univ. of California, Davis, KAREN REISER, Dept.of Neurological Surgery, Univ. of California, Davis, ANDRE KNOESEN, DIEGO YANKELEVICH, MINGSHI WANG, Dept. of Electrical and Computer Eng., Univ. of California, Davis, ISRAEL ROCHA-MENDOSA, Cardiff School of Biosciences, Univ. of Cardiff, Wales — We have continued development of our novel computational approach for quantifying structural disorder in biomolecular lattices with nonlinear susceptibility based on analysis of polarization-modulated second harmonic signal. Local disorder at the level of molecular organization is identified using a novel signal-processing algorithm sufficiently compact for near real-time analysis. Global and regional disorder within the biostucture is characterized using two-dimensional wavelet transform of the magnitude and phase of the second harmonic signal. Results suggest our signal processing method represents a robust, scaleable tool that allows us to detect both regional and global alterations in signal characteristics of biestructures with a high degree of discrimination.

11:15AM V1.00001 Neutron and X-ray Characterization of Nanostructured Polymeric Materials1. THOMAS RUSSELL, Polymer Science and Engineering Department, University of Massachusetts, Amherst, MA 01003 Amherst — Controlling the orientation and lateral ordering of the block copolymer microdomains is key to their use as templates and scaffolds for the fabrication of nanostructured materials. Processes must be robust, rapid and simple to implement and should not introduce disruptive processing steps that would impede their use. Grazing incidence small angle x-ray scattering (GISAXS) and neutron neutron scattering have proven to be critical for the characterization of the static and real time development of structure in thin films of block copolymers. Here, studies on poly(styrene-b-4-vinylpyridine) (PS-b-P4VP) diblock copolymers prepared from mixed solvents will be discussed that show highly oriented, cylindrical microdomains with a high degree of lateral order on a wide range of substrates, including silicon oxide, polystyrene, germanium, polyimide, and polyl butylene terephthalate). The preferential solvation of the P4VP block with an alcohol was used to induce a reconstruction that left a nanoporous film upon drying. The evaporation of gold onto the reconstructed films produced thermally stable films that are resistant to reactive ion etching. GISAXS was used to quantitatively examine the structure of these composite films and the transfer of the patterns to the underlying substrate. (Research done in collaboration with Soojin Park, Jia-Yu Wang, Bokyung Kim University of Massachusetts, Benjamin Ocko (Brookhaven National Laboratory) and Jin Wang (Argonne National Laboratory).

11:51AM V1.00002 Beyond Wrinkles: Stress and Fold Localization in Thin Elastic Membranes1. LUKA POČIVAVŠEK, University of Chicago — Thin elastic membranes supported on fluid or elastic foundations deviate from their flat geometries upon compression. We demonstrate that the periodic and much studied wrinkled state is but one possible solution for such strained membranes. Folds, sharply localized solutions, appear whenever the membrane is compressed beyond a third of its initial wrinkle wavelength. Eventually the surface transforms into a symmetry broken state with flat regions of membrane coexisting with locally folded points, reminiscent of a crumpled unsupported membrane. We study this transition in many systems including lipid monolayers on liquid subphases of differing viscosity and use neutron and X-ray reflectivity to elucidate the role of the subphase in setting the wrinkle and fold size.

12:27PM V1.00003 Complex Protein Structures by Neutron Scattering1. JENNY GLUSKER, Fox Chase Cancer Center, 333 Cottman Avenue, Philadelphia, PA 19111-2497 — Neutron scattering by an atom, unlike X-ray scattering, does not depend on the atomic number of that atom. Deuterium atoms scatter neutrons to the same extent as carbon or oxygen atoms and give positive peaks in a nuclear density map, while its isotope, hydrogen, gives a negative peak. Therefore neutron diffraction provides two results that are difficult to obtain from macromolecular X-ray diffraction studies: (1) the locations of hydrogen atoms, including the more mobile ones, and (2) the extent to which a hydrogen atom can be replaced by deuterium. For example, one can ascertain whether histidine residues are singly or doubly protonated at the pH of study. Neutron diffraction studies can also be used to determine the absolute configuration of the course of a biochemical reaction by anomalous scattering and enzymatic deuterium of the substrate. Neutron diffraction experiments, however, require large crystals and these are often impossible to obtain for many macromolecules. Examples of reports of the use of neutron diffraction to provide information on enzymatic mechanism will be presented. This includes discriptions of our work on the enzyme D-xylene isomerase for which the orientation of a metal ion-bound water molecule in the active site was found. This water, thought to be involved in the isomerization step, was shown to be water (rather than hydroxyl) at pH 8.0. This analysis also revealed that one lysine has two rather than three attached hydrogen atoms and therefore lacks a positive charge. High-resolution X-ray studies (at 0.94 Å) indicate how some side chains might move during catalysis. This combination of neutron and X-ray diffraction can contribute greatly to the elucidation of enzyme mechanisms. I thank Amy Katz, Xinmin Li, H. L. Carrell, Leighton Coates, Leif Hanson, Joel Haprl, Paul Langan, and Benno Schoenborn who were involved in many of the described studies, and particularly Gerard Bunic. We honor his contributions and regret that he is no longer with us.

1:03PM V1.00004 Observation of a Fragile-to-Strong Dynamic Crossover Phenomenon in Confined Water and Its Relation to the Existence of a Liquid-Liquid Critical Point in Supercooled Water, SOW-HSIN CHEN, Massachusetts Institute of Technology — We have observed a fragile-to-strong dynamic crossover phenomenon of α relaxation time and self-diffusion constant in deeply supercooled 1-d confined water. The α relaxation time is measured by quasi-elastic neutron scattering and the self-diffusion constant by nuclear magnetic resonance. Water is confined in 1-d geometry in cylindrical pores of porous silica material, MCM-41 and in double-wall carbon nanotubes. The crossover phenomenon can also be observed from appearance of a Boson peak in incoherent inelastic neutron scattering. We observe a pronounced violation of the Stokes-Einstein relation at and below the crossover temperature at ambient pressure. Upon applying pressure to the confined water, the crossover temperature is shown to track closely the Widom line emanating from the existence of a liquid-liquid critical point buried in an unattainable deeply supercooled state of bulk water. Relation of the dynamic crossover phenomena to the existence of a density minimum in supercooled confined water will be discussed. The crossover temperature is shown to be sensitively dependent on the degree of hydrophilicity of the confining substrate.

1:39PM V1.00005 Phase Behavior of Block Copolymer/Inorganic Nanoparticle Composites, PAPPANAN THIYAGARAJAN, Argonne National Laboratory — Block copolymers offer as versatile platforms for the fabrication of hybrid nanocomposites with ordered phases useful for various nanotechnology applications. Although the phase behavior of block copolymers is well established the effects of inorganic nanoparticle loading on their phase behavior are not well understood. We carried out a systematic study on the phase behavior of block copolymers with well dispersed nanoparticles. To achieve excellent dispersion of nanoparticles in the polymer phase we used grafted nanoparticles with small polymer chains compatible to a preferred domain of the block copolymer. The nanoparticles sequestered in a preferred domain have profound effects on the thermodynamically induced microphase separation of the block copolymers. To characterize the phase behavior of these systems in a selective solvent we used small angle neutron scattering and that in their bulk and thin film architectures was studied using synchrotron based small angle x-ray scattering and grazing incidence small angle scattering techniques. A number of molecular properties such as the molecular weight of the polymer, segment volume fraction, Flory-Huggins χ parameter and the nanoparticle concentration influence the state of dispersion of nanoparticles and the nanocomposite morphology in bulk and thin film architectures. The addition of homopolymers provides as yet another variable to alter the interfacial tension and to slow the order-disorder transition. We also probed the nanoscale dynamics at the polymer/nanoparticle interfaces in these systems by using x-ray photon correlation spectroscopy. The dynamics of nanoparticles in the composites is strongly dependent on the dimensionality of the morphology of the block copolymer. Furthermore, the interfacial interaction at the polymer/particle interface plays significant role in the stress relaxation in the composites.

Thursday, March 13, 2008 11:15AM - 1:39PM — Session V2 DCMP GIMS: Facilities for Meeting Grand Challenges  
11:15AM V2.00001 A Green Field Fourth Generation Light Source1, GEORGE NEIL, Jefferson Lab — The success of energy recovering linac technology has opened up new opportunities for the development of light sources to satisfy grand challenges in fundamental physics and materials research. A number of laboratories around the world have proposed extensions or upgrades to existing 2nd or 3rd generation light source facilities to take advantage of the higher brightness and short pulse lengths that 4th generation facilities could offer. Ideas range from multiple synchronized coherent sources in the THz to UV range to Compton X-ray sources, synchrotron emission, and on to achievement of multi-particle coherence in amplifiers or even oscillators at short wavelengths. Such proposals are exciting and begin to show the range of performance that such systems can provide. In this talk I will examine the possibilities for light source development unconstrained by existing physical layouts i.e., on a “green field” site. I will then address a set of photonic goals to be achieved and the technological path of development desirable to achieve the full benefits of this next generation of user facilities. In particular, there are specific technical achievements and engineering developments with great leverage on the cost and performance of future machines. I will point toward a development path to set the stage for optimization of technical performance and cost/benefit of this system.

1 Notice: Authored by The Southeastern Universities Research Association, Inc. under U.S. DOE Contract No. DE-AC05-84ER40150. The U.S. Government retains a non-exclusive, paid-up, irrevocable, world-wide license to publish or reproduce this manuscript.

11:51AM V2.00002 Science Driven the Parameters of 4th Generation Light Sources, JEROME HASTINGS, Stanford Linear Accelerator Center — The scientific challenges that can be best addressed with x-rays and the evolution of accelerator based x-ray sources has focused the attention of the x-ray community on new concepts: using the electron beam once rather than storage rings. We will describe this approach and the photon source properties that result with emphasis on peak and average brightness for the study of structure and dynamics in the chemical, materials and biological sciences. Examples from 4th generation sources planned and under construction will be presented.

12:27PM V2.00003 The Science Motivating the UK’s Fourth Generation Light Source Project, WENDY FLAVELL, The University of Manchester — The UK is committed to developing a proposal for a long wavelength (THz - soft X-ray) 4th generation light source that will provide short-pulse synchronised beams to be used in combination. Some of the science motivating the development of this facility is described. The facility will probe ultra-fast dynamics in a wide range of fields. ‘Pump-probe’ experiments will allow the study of chemical reactions and short-lived intermediates on the timescale of bond formation, even for very dilute species. Circularly polarised light sources in a variety of frequency regimes will be used for example to manipulate and monitor carrier charge and spin transport in device structures. The high intensity of the free electron laser (FEL) radiation will allow high resolution in imaging and the opportunity to probe nonlinear regimes and new states of matter. Lower intensity, high repetition rate spontaneous radiation will provide ideal sources for ultra-high energy resolution spectroscopy, especially in the solid state. Around £22 M funding has been obtained for the first stages of the project (construction of a prototype energy recovery linac (ERL) source, science demonstrations and design study work, currently underway at STFC Daresbury Laboratory).
11:15AM V3.00001 Industrial Research at IBM. PAUL HORN, IBM T.J. Watson Research Center — No abstract available.

11:51AM V3.00002 Reflections on Three Corporate Research Labs: Bell Labs, HP Labs, Agilent Labs. JAMES HOLLENHORST, Agilent Technologies — This will be a personal reflection on corporate life and physics-based research in three industrial research labs of the past three decades, Bell Labs during the 1980’s, HP Labs during the 1990’s, and Agilent Labs during the 2000’s. These were times of great change in all three companies. I’ll point out some of the similarities and differences in corporate cultures and how this impacted the research and development activities. Along the way I’ll mention some of the great products that resulted from physics-based R&D.

12:27PM V3.00003 Application Oriented R&D: Aphorisms & Anecdotes (The John Bardeen Lecture). ROBERT FROSCH, John F. Kennedy School of Government, Harvard University — I have learned many lessons from long experience trying to perform, and lead, application oriented R&D. Some of these lessons have been encapsulated in aphorisms. Some aphorisms will be presented, with explication, and illustrated with anecdotes from experience with the NAVY, ARPA, NASA and General Motors.

1:03PM V3.00004 The History of Science and Technology at Bell Labs. DAVID BISHOP, Bell Labs, LGS, Alcatel-Lucent — Over the last 80 years, Bell Labs has been one of the most scientifically and technologically productive research labs in the world. Inventions such as the transistor, laser, cell phone, solar cell, negative feedback amplifier, communications satellite and many others were made there. Scientific breakthroughs such as discovery of the Big Bang, the wave nature of the electron, electron localization and the fractional quantum hall effect were also made there making Bell Labs almost unique in terms of large impacts in both science and technology. In my talk, I will discuss the history of the lab, talk about the present and give some suggestions for how I see it evolving into the future.

1:39PM V3.00005 50 Years of “Scaling” Jack Kilby’s Invention. ROBERT DOERING, Texas Instruments — This year is the 50th anniversary of Jack Kilby’s 1958 invention of the integrated circuit (IC), for which he won the 2000 Nobel Prize in Physics. Since that invention in a little yellow lab at Texas Instruments, IC components have been continuously miniaturized which has resulted in exponential improvement trends in their performance, energy efficiency, and cost per function. These improvements have created a semiconductor industry that has grown to over $250B in annual sales. The process of reducing integrated-circuit component size and associated parameters in a coordinated fashion is traditionally called “feature-size scaling.” Kilby’s original circuit had active (transistor) and passive (resistor, capacitor) components with dimensions of a few millimeters. Today, the minimum feature sizes on integrated circuits are less than 30 nanometers for patterned line widths and down to about one nanometer for film thicknesses. Thus, we have achieved five orders of magnitude in linear-dimension scaling over the past fifty years, which has resulted in about ten orders of magnitude increase in the density of IC components, a representation of “Moore’s Law.” As IC features are approaching atomic dimensions, increasing emphasis is now being given to the parallel effort of further diversifying the types of components in integrated circuits. This is called “functional scaling” and “more then Moore.” Of course, the enablers for both types of scaling have been developed at many laboratories around the world. This talk will review a few of the highlights in scaling and its applications from R&D projects at Texas Instruments.

Thursday, March 13, 2008 11:15AM - 2:15PM –
Session V4 DCMP: Electronic Excitations in Organic Molecular Crystals/Fluctuating Fronts: Beyond a Popular Mean-Field Theory  Morial Convention Center 206

11:15AM V4.00001 Photoemission study on the charge transport mechanism in pentacene thin film. KAZUYUKI SAKAMOTO, Chiba University — Organic molecules are attracting much interest to use for a variety of electronic applications. Pentacene (Pn), which is one of such molecules, has a high application potential due to its high hole mobility. The hole mobility of Pn is almost comparable to that of amorphous silicon. At low temperature, the hole transport in Pn crystal has been reported to have a band-like nature, and the band-like charge transport is expected to play a major part at room temperature as well. One of the origins of the band-like transport is the adequate overlap of the pi-orbitals of adjacent molecules, which produces orbital-derived electronic bands. It is therefore essential to have a proper understanding on the electronic band structures in order to fully comprehend the charge transport mechanism of a Pn crystal. By using angle-resolved photoelectron spectroscopy (ARPES), we have measured the dispersions of the highest occupied molecular orbital (HOMO)-derived bands of single crystal Pn monolayer films grown on substrates. Two HOMO-derived, whose band dispersion widths are larger than the values predicted by theoretical calculations, were clearly observed in the ARPES spectra. Our result indicates that the overlap of the pi-orbitals of adjacent Pn molecules is larger than what was expected from theoretical calculations, and the observed dispersions suggest that the higher binding energy HOMO-derived band mainly contributes to the band-like charge transport mechanism of a Pn crystal. By analyzing the dispersions within a simple tight-binding approximation, the obtained results lead to a hole mobility of \( \mu_{th} > 34.1 \text{ cm}^2/\text{Vs} \) at 140 K.

1This work was financially supported by the 21st-century COE Program at Chiba University and by MEXT of the Japanese Government.
11:51 AM V4.00002 Bandlike transport in organic molecular crystals revealed by subpicosecond transient photoconductivity. FRANK HEGMANN, University of Alberta — The nature of charge carrier photogeneration and transport in organic molecular crystals is not completely understood. In particular, the mechanism responsible for the observed bandlike behavior of charge carriers in these materials, where the carrier mobility increases as the temperature decreases, remains unresolved and is the focus of much research. Using typical device structures to explore intrinsic properties of charge transport in organic semiconductors is complicated by the presence of defects and the necessity to make contacts to the sample. Recently, however, ultrafast techniques that use terahertz (THz) pulses for assessing the electronic properties of materials have been developed. In particular, time-resolved THz spectroscopy allows transient photoconductivity in materials to be probed with subpicosecond time resolution, providing a sensitive non-contact tool for studying the transport of charge carriers before they are trapped at defect sites. This talk will provide an overview of how THz pulses can be used to probe the nature of conductivity and bandlike behavior in organic molecular crystals and thin films.

12:27PM V4.00003 Polarons and Coulomb interactions in organic transistors. SIMONE FRATINI, Instit Neel - CNRS — In organic Field Effet Transistors (FETs), charge carriers accumulate in a two-dimensional layer at the interface between an organic crystal and a gate dielectric. The possibility of tuning several microscopic parameters such as the carrier density, the electron-electron and electron-phonon interactions makes these devices an interesting playground for fundamental physics. Recent experiments have demonstrated that depending on the gate insulator used, the electric mobility in organic FETs can be tuned from metallic-like to insulating-like. This phenomenon can be explained in terms of the formation of small polarons, due to the remote interaction of the charge carriers with the phonons of the gate material [1]. In the devices with the highest polarizabilities, experiments performed at large gate voltages (corresponding to ~ 0.1 carriers/molecule) have revealed a further reduction of the mobility, suggesting the onset of electron-electron interactions [2]. The physics of this novel regime involving both strong electron-phonon and long-range electron-electron interactions will be discussed. If time allows, I shall briefly present how the above picture is modified when the narrow-band organic crystal is replaced by graphene —a two-dimensional sheet of carbon atoms. Although the effect is less striking in that case, the remote scattering with the substrate phonons still constitutes an important limiting factor of the mobility at room temperature, that should be addressed for the design of future graphene devices [3].

1:03PM V4.00004 Particle versus density models in spark formation: X-rays from pulled fronts?. UTE EBERT, CWI Amsterdam and Eindhoven Univ. Techn. — Streamer discharges govern the early stages of sparks and lightning, of spark-like phenomena in water, oil, and semiconductors, in industrial corona reactors, or in gigantic sprite discharges above thunderclouds [1,2]. Thunderstorms recently have been found to emit terrestrial gamma-ray flashes or X-rays towards satellites and towards the ground. These emissions might be explained by particle models of “pulled” streamer ionization fronts. In general, the growing discharge channel has an inner structure with multiple scales [1-3]. While the largest part of this channel can be treated in a density approximation for the electrons and ions, the dynamics of the ionization front is that of a pulled front; it is determined in the leading edge where the density approach eventually breaks down. We therefore investigate a realistic MC particle model for the motion of single electrons in a discharge in pure nitrogen. The particle model not only incorporates particle fluctuations, but also shows that the electron energies are systematically larger in the leading edge of the front than in the corresponding density model, and that the ionization level behind the front is higher as well, while the front velocity hardly changes [3]. These effects increase with increasing applied electric field and might actually cause the recently observed X-ray emission from lightning through rare very energetic runaway electrons in the tail of the distribution. Comparing the leading edge of the particle front with a linear particle avalanche, the avalanche shows the same mean density gradient and energy overshoot in its leading edge as the nonlinear front; hence the pulled front concept in this sense applies to discrete particle models as well [3]. This gives a key to understanding the above effects through analytical approximations and to develop efficient numerical methods coupling particle and density models in space.

1:39PM V4.00005 Fluctuation Effects on Propagating Waves of Self-Assembly in Organosilane Monolayers. JACK DOUGLAS, NIST — Wavefronts associated with reaction–diffusion and self-assembly processes are ubiquitous in the natural world. For example, propagating fronts arise in crystallization and other diverse thermodynamic ordering processes, in polymerization fronts involved in cell movement and division, as well as in the competitive social interactions and population dynamics of animals at much larger scales. Although it is often claimed that self-sustaining or autocatalytic front propagation is well described by mean-field “reaction– diffusion” or “phase field” ordering models, it has recently become appreciated from simulations and theoretical arguments that fluctuation effects in lower spatial dimensions can lead to appreciable deviations from the classical mean-field theory (MFT) of this type of front propagation. The present work explores these fluctuation effects in a real physical system. In particular, we consider a high-resolution near-edge x-ray absorption fine structure spectroscopy (NEXAFS) study of the spontaneous frontal self-assembly of organosilane (OS) molecules into self-assembled monolayer (SAM) surface-energy gradients on oxidized silicon wafers. We find that these layers organize from the wafer edge as propagating wavefronts having well defined velocities. In accordance with two-dimensional simulations of this type of front propagation that take fluctuation effects into account, we find that the interface widths w(t) of these SAM self-assembly fronts exhibit a power-law broadening of in time w(t) ~ t^0.5, rather than the constant width predicted by MFT. Moreover, the observed exponential volumes accord rather well with previous simulation and theoretical estimates. These observations have significant implications for diverse types of ordering fronts that occur under confinement conditions in biological or materials-processing contexts.

Thursday, March 13, 2008 11:15AM - 2:15PM —
Session V5 FPS FGSA: Panel Discussion: Lessons Learned from Katrina: How to Prepare a Department for Catastrophic Events Morial Convention Center R01
stability of the faculty.

The university has asked every department and unit to prepare emergency preparedness plans. Each department has been asked to collect e-mail addresses and begun coordinating with faculty. Xavier created a web page with advice for students, and the chair of the department created a separate blog with contact information for students. The early lack of a clear method of communication made worse the confusion and dismay among the faculty on such issues as when the university would reopen, whether the faculty would be retained, whether they should seek temporary (or permanent) employment elsewhere, etc. With the vision and determination of President Dr. Francis, Xavier was able to reopen the university in January and ran a full academic year from January through August. Since Katrina, the university has asked every department and unit to prepare emergency preparedness plans. Each department has been asked to collect e-mail addresses (non-Xavier), cell phone numbers and out of town contact information. The University also established an emergency website to communicate. All faculty have been asked to prepare to teach classes electronically via Black board or the web. Questions remain about the longer term issues of the size and stability of the faculty.

Katrina, the university has asked every department and unit to prepare emergency preparedness plans. Each department has been asked to collect e-mail addresses (non-Xavier), cell phone numbers and out of town contact information. The University also established an emergency website to communicate. All faculty have been asked to prepare to teach classes electronically via Black board or the web. Questions remain about the longer term issues of the size and stability of the faculty.

11:15AM V5.00001 Lessons Learnt From Hurricane Katrina. , MURTY AKUNDI, Xavier University of Louisiana — Hurricane Katrina devastated New Orleans and its suburbs on Monday August 29th, 2005. The previous Friday morning, August 26, the National Hurricane Center indicated that Katrina was a Category One Hurricane, which was expected to hit Florida. By Friday afternoon, it had changed its course, and neither the city nor Xavier University was prepared for this unexpected turn in the hurricane’s path. The university had 6 to 7 ft of water in every building and Xavier was closed for four months. Students and university personnel that were unable to evacuate were trapped on campus and transportation out of the city became a logistical nightmare. Email and all electronic systems were unavailable for at least a month, and all cell phones with a 504 area code stopped working. For the Department, the most immediate problem was locating faculty and students. Xavier created a list of faculty and their new email addresses and began coordinating with faculty. Xavier created a web page with advice for students, and the chair of the department created a separate blog with contact information for students. The early lack of a clear method of communication made worse the confusion and dismay among the faculty on such issues as when the university would reopen, whether the faculty would be retained, whether they should seek temporary (or permanent) employment elsewhere, etc. With the vision and determination of President Dr. Francis, Xavier was able to reopen the university in January and ran a full academic year from January through August. Since Katrina, the university has asked every department and unit to prepare emergency preparedness plans. Each department has been asked to collect e-mail addresses (non-Xavier), cell phone numbers and out of town contact information. The University also established an emergency website to communicate. All faculty have been asked to prepare to teach classes electronically via Black board or the web. Questions remain about the longer term issues of the size and stability of the faculty.

11:30AM V5.00002 TBD , SHIRLEY LASKA, University of New Orleans — This abstract has not been submitted.

11:45AM V5.00003 Hurricane Katrina at Tulane. , JIM MCCUIRGE, Tulane University — After hurricane Katrina struck New Orleans on August 29, 2005, Tulane University closed for the fall semester. Buildings on campus were closed and armed guards were hired to protect the campus. Faculty members were not allowed access to their offices and laboratories, except for exceptional cases when a Dean went with them. Many faculty members took their research groups to other universities accepting much welcomed invitations from colleagues. Undergraduates went to other colleges and universities, which accepted the without cost and a promise not to recruit them. The university email system went down for months. Collecting information on the welfare of faculty and students was difficult. The university was run from Houston by a small handful of senior administrators. Setting up the schedule of classes for the spring 2006 semester was done without records. Most faculty returned to New Orleans after several weeks. 80% of the city was flooded. Small trailers were provided. Some lived in the FEMA trailers for two years or more. When Tulane reopened, a wide reaching Renewal Plan, worked out by the upper administration, was implemented. A new emergency preparedness plan was also developed and put in place.

12:00PM V5.00004 , G. GREG SEAB, University of New Orleans — No abstract available.

12:15PM V5.00005 Academic environment and dynamics in response to extreme events: Theory and Practice (Katrina Lessons)1, NATALIA SIDOROVSKAIA, Department of Physics, University of Louisiana at Lafayette — The possibility of a catastrophic event requires the department as a unit and the university as an organization to devise a comprehensive emergency response plan to minimize the impact and shorten the recovery stage. Does the academic organizational structure and environment possess key features for the possibility of successful response to extreme events? The post Hurricane Katrina experience of Louisiana universities offers data to address this theoretical question. It also emphasizes that the mitigation plan should include two aspects: preparing/protection a university for/during a catastrophic event and assisting other academic institutions experiencing an extreme event. Short-term and long-term statistics and other data pertain to the interaction of the University of Louisiana at Lafayette (as an assistance unit) with the universities in New Orleans (units in distress), including the dynamics of student population, faculty influx, course adjustments, and response and recovery actions are presented. An attempt is made to categorize the losses and to assess the recovery quality and time. Faculty and institutional administration interviews are summarized to assist in developing future proactive response plans. UL Lafayette and UNO research capabilities and intellectual resources for developing complex models simulating the multi-variable effects of catastrophic events and providing adaptability in the decision-making process are investigated.

1This work was done in collaboration with George E. Ioup and Juliette W. Ioup (Department of Physics, University of New Orleans).

12:30PM V5.00006 Hosting a Katrina Evacuee. , DAVID HOAGLAND, Polymer Sci. and Eng. Dept., Univ. of Massachusetts Amherst — No individual or institution anticipated the impact on the academic research community of hurricane Katrina. When Tulane physicist Wayne Reed asked me to host his research group just a day or two after the disaster, with no authorization or understanding of the commitment, I agreed immediately and then pondered implications. Fortunately, colleagues helped in making the commitment real, only the bureaucracy of my public university posing small hindrances. Industry was remarkably generous in providing Reed with significant “loaner” equipment, and amazingly, a suite of custom Reed experiments was running within weeks. At the end, the most productive collaborations for Reed seemed not to have been with my group, with its similar research, but to other groups at my institution, particularly the synthetic chemists, who gained access to methods previously unique to Tulane while offering samples previously unique to UMass. Quickly designed projects exploiting this match turned out remarkably productive. Although begun with trepidation, hosting of Reed had huge positive benefits to me and UMass, and I believe, also to Reed and Tulane. Some key lessons for the future: (i) industry has capacity and willingness to help academic research during disruption (ii) commitment of a host institution must be immediate, without a wait for formal approvals or arrangement of special funding – delay leads only to discouragement, (iii) continuing academic progress of displaced students must come first, and (iv) intellectual synergy rather than overlap should be the basis for seeking a host. Lastly, NSF or other funding agency should consider a program directly addressing the research needs of unexpectedly disrupted academic scientists, and most particularly, graduate students who face greatly extended studies.

12:45PM V5.00007 Panel Discussion —
**11:15AM V7.00001 Building the Vertebrate Spine**, OLIVIER POURQUÉ, Howard Hughes Medical Institute and Stowers Institute for Medical Research — The vertebrate body can be subdivided along the antero-posterior (AP) axis into repeated structures called segments. This periodic pattern is established during embryogenesis by the somitogenesis process. Somites are generated in a rhythmic fashion from the paraxial mesoderm and subsequently differentiate to give rise to the vertebrae and skeletal muscles of the body. Somite formation involves an oscillator-the segmentation clock-whose periodic signal is converted into the periodic array of somite boundaries. This clock drives the dynamic expression of cyclic genes in the presomitic mesoderm and requires Notch and Wnt signaling. Microarray studies of the mouse presomitic mesoderm transcriptome reveal that the segmentation clock drives the periodic expression of a large network of cyclic genes involved in cell signaling. Mutually exclusive activation of the Notch/FGF and Wnt pathways during each cycle suggests that coordinated regulation of these three pathways underlies the clock oscillator. In humans, mutations in the genes associated to the function of this oscillator such as Dll3 or Lunatic Fringe result in abnormal segmentation of the vertebral column such as those seen in congenital scoliosis. Whereas the segmentation clock is thought to set the pace of vertebrate segmentation, the translation of this pulsation into the reiterated arrangement of segment boundaries along the AP axis involves dynamic gradients of FGF and Wnt signaling. The FGF signaling gradient is established based on an unusual mechanism involving mRNA decay which provides an efficient means to couple the spatio-temporal activation of segmentation to the posterior elongation of the embryo. Another striking aspect of somite production is the strict binary symmetry of the process. Retinoic acid was shown to control aspects of this coordination by buffering destabilizing effects from the embryonic left-right machinery. Defects in this embryonic program controlling vertebral symmetry might lead to scoliosis in humans. Finally, the subsequent regional differentiation of the precursors of the vertebrae is controlled by Hox genes, whose collinear expression controls both gastrulation of somite precursors and their subsequent patterning into region-specific types of structures. Therefore somite development provides an outstanding paradigm to study patterning and differentiation in vertebrate embryos.

**11:51AM V7.00002 Modelling Ultradian Oscillations and Segmentation**, MOGENS JENSEN, Niels Bohr Institute — We model ultradian oscillations in four different eucaryotic systems: Hes1, p53-mdm2, NF-kB and Wnt-Notch. In each of the systems we identify the feed-back loops for the genetic regulations. Oscillations are possible when time delays are present, either by directly introducing a delay, by many steps in the loops or by saturated degradation. The oscillations are important for apoptosis and control of inflammation. The Wnt-Notch system is essential in embryo segmentation and we introduce a model in which the Wnt oscillates by itself but drives the Notch cycle out of phase with the Wnt cycle, in good agreement with experimental observations.

**12:27PM V7.00003 Spatial Patterns of Recurred Sensory Organs in Drosophila**, GEMUNU GUNARATNE, University of Houston — The fruit fly Drosophila is one of the most intensely studied models of development. A subset of nominally identical cells on the anterior wing of Drosophila begins to differentiate at puparium formation, each developing a sensory organ. In wild type flies, every fifth cell becomes such a sensory organ. Recent studies on mutant flies have shown that the transcription factor Senseless and the micro RNA mIR-9a play significant roles in the choice of bristle density and the regularity of their arrangement. We propose that this cell differentiation is due to a Turing-type bifurcation whereby periodic concentration gradients emerge spontaneously from a uniform background. A paradigmatic model with intra-cellular networks and lateral activation and inhibition between neighboring cells (for example, through the Notch signaling pathway) is shown to generate the observed arrangements of sensory organs. The theory makes several experimentally verifiable predictions. For example, we propose methods to create mutant flies with systematically increasing numbers of ectopic bristles. In our theory, post-transcriptional regulatory action of the micro RNA occurs through the choice of stable solutions of the network.

**1:03PM V7.00004 Similarities and differences in the p53-mdm2 and NF-kB feedback loops**, SANDEEP KRISHNA, Niels Bohr Institute, University of Copenhagen — Ultradian oscillations in the p53 and NF-kB signalling systems are produced using similar mechanisms: a negative feedback loop combined with an effective time delay. However, seemingly small differences in the molecular implementation of this mechanism mean that the NF-kB system is in equilibrium in the resting state, while the p53 system is far from equilibrium. I will discuss how this affects the dynamical response of the systems. In particular, I will argue that the nonequilibrium driving makes the p53 system respond much faster to external stimuli than the NF-kB system. The interesting question then is whether this makes sense physiologically, and is consistent with the fact that p53 triggers cell-cycle arrest and apoptosis, while NF-kB triggers the immune response.

**1:39PM V7.00005 Dynamic Changes in microRNAs may Regulate Robustness of Wnt/Notch Signaling**, FREETHI GUNARATNE, University of Houston — The mechanisms by which highly reproducible patterns are formed during embryonic development and organismal evolution despite stochasticity at the single cell level is one of the remaining mysteries in Biology. It has been proposed that a hidden layer of regulation formed through the interaction of microRNAs with protein coding gene networks maybe responsible. Recently developed next generation sequencing technologies afford an unprecedented opportunity to uncover novel aspects of microRNA function and evolution. We find extensive heterogeneity in sequences that correspond to mmu-let-7 (targets Wnt1) and mmu-miR-191 (targets Notch1). Approximately 20% of let-7 and miR-191 have undergone modifications to increase stability and binding to the Wnt1 and Notch1 targets and are likely to be destroyed. In contrast, 80% bind the targets with imperfect complementarity and lower stability and are likely to be sequestered and prevented from forming protein. We propose that these two species together form a highly fluid system that is able to absorb stochastic perturbations in gene expression. A gene that goes on to be translated into functional protein therefore must escape both buffers by significantly high expression.

**Session V8 DFD: Liquid Crystals I: Structure and Defects**

**11:15AM V8.00001 Effect of Concentration Variations on the Interaction of a Sm-A Liquid Crystal and a Nanoparticle**, LUZ J. MARTINEZ-MIRANDA, University of Maryland, College Park, LYNN K. KURIHARA, Navy Research Lab, Washington, DC, RAHINA S. RABIU, University of Maryland and Norfolk State University — We have observed the evolution of the interaction between a Sm-A Liquid Crystal (8CB) and a nanoparticle as the concentration of the nanoparticle is reduced from 30% wt to 0.1%wt. We have observed that a linear structure is observed as the concentration of the particle falls below 15% wt. There is a difference between the functionalization compounds as observed in the study of the 30% wt mixtures. In addition, we have observed that the influence of the nanoparticle in the ordering or disordering of the liquid crystal can be quantified through the integrated intensity of the x-ray signal.

---

11:27 AM V8.00002 Simulating defect structures in nematic liquid crystal shells1,2, LENA LOPATINA, ANDREW KONYA, JONATHAN SELINGER, ROBIN SELINGER, Liquid Crystal Institute, Kent State Univ, ALEX TRAVESSE, Dept of Physics and Astronomy, Iowa State Univ — Recent theoretical and experimental studies have investigated nematic liquid crystals confined to a shell between two spheres. When the shell is very thin, the structure provides an experimental realization of nematic order and defects in a 2D curved geometry. As the shell becomes thicker, the behavior crosses over to a 3D liquid crystal, with different types of defects. To study this dimensional crossover, we perform simulations of nematic order in a shell. For these simulations, we use a disordered lattice, or mesh, constructed through random sequential adsorption on the inner surface, the outer surface, and within the bulk of the shell, with a nematic director on each site of the mesh. By minimizing the energy, we determine the nematic texture as a function of the radii and thickness of the shell, and as a function of the off-center displacement of the inner sphere. The results show a crossover between half-charged vortex line defects for thin shells and boojum pairs for thicker shells, and demonstrate a new equilibrium state with two vortex lines and one boojum pair. They also show a complex evolution of the structures and energy as the inner sphere moves off-center.

11:39 AM V8.00003 String defects in smectic-C monolayers and hybrid nematic films1,2, FANGFU YE, ZHAO LU, LENAPATINA, JONATHAN SELINGER, Liquid Crystal Institute, Kent State Univ, ALEX TRAVESSE, Dept of Physics and Astronomy, Iowa State Univ — Defects are important in determining the structure and statistical mechanics of liquid crystals. In this project, we study the structure of topological defects in smectic-C monolayers and hybrid nematic films. When subjected to boundary conditions requiring a total topological charge of +1, the classical xy model in a flat disk geometry has a ground state of a single vortex of charge +1. By comparison, perfect nematics with directors in the same 2D geometry have two +1/2 vortices repelling each other. We show that slightly tilting directors out of the plane to form a smectic-C monolayer yields two +1/2 vortices bound together by a domain wall, which we call a string defect. We also develop a model easily testable in experiments, in which a thick nematic film is constrained in a cell with weak homeotopic anchoring on one surface and strong planar anchoring on the other surface. For this model, we derive the phase diagram and investigate how the length of string defects changes with the thickness of the cell. We further present numerical simulations of the nematic director in the hybrid film.

11:51 AM V8.00004 Coherent anti-Stokes Raman scattering polarized microscopy of 3D director structures in liquid crystals1,2, IVAN SMALYUKH, University of Colorado at Boulder, ALEXANDER KACHYNSKI, ANDREY KUZMIN, LONAS PRASAD, The State University of New York at Buffalo — We demonstrate labeling-free three-dimensional imaging of director structures in liquid crystals using coherent anti-Stokes Raman scattering (CARS) polarized microscopy [1]. Spatial mapping of the structures is based on the strong sensitivity of a polarized CARS signal to the orientation of selected chemical bonds of anisotropic molecules in liquid crystals. As an example, we study director structures in cholesteric, nematic, and smectic materials. We demonstrate that the CARS images of molecular orientation patterns are consistent with the structure models and with the respective computer-simulated CARS textures.

12:03 PM V8.00005 Light Scattering Study of Biaxiality in Nematic Liquid Crystal Tetrapodes, KRISHNA NEUPANE, SHINWOONG KANG, SUNIL SHARMA, D. CARNEY, T. MEYER, GEORGE H. MEHL, DAVID W. ALLENDER, SATYENDRA KUMAR, SAMUEL SPRUNT, Department of Physics, Kent State University — We have performed dynamic light scattering studies on thermotropic liquid crystalline tetrapodes [1], which reportedly exhibit a uniaxial to biaxial nematic phase transition. Our results [2] support the existence of the biaxial nematic phase in tetrapodes. The uni- to biaxial transition is found to be weakly first-order in a 4-ring tetrapode and second-order in a 3-ring tetrapode, while the isotropic to uniaxial nematic transition is weakly first order in both materials. The temperature dependence of the relaxation rates of the biaxial order parameter modes, and of the intensity associated with biaxial director fluctuations, is explained by a Landau-deGennes model of the free energy.

12:15 PM V8.00006 Effects of dielectric relaxation on the director dynamics of uniaxial nematic liquid crystals1,2, MINGXIA GU, YE YIN, SERGUJ V. SHYANOVSII, OLEG D. LAVENTOVICEH, Chemical Physics Interdisciplinary Program, Liquid Crystal Institute, Kent State University, Kent, Ohio 44242, USA — We derive the reorienting dielectric torque acting on the director, considering the frequency dependence of the dielectric tensor. The model takes account into the effects of multiple relaxations in both parallel and perpendicular components of the dielectric tensor and predicts the “dielectric memory effect” (DME), i.e., dependence of the dielectric torque on both the “present” and “past” values of the electric field and the director. In a sharply rising electric field, the DME slows down director reorientation for the materials whose dielectric anisotropy is positive at low frequencies, but speeds up the response for the dielectrically negative materials. We also demonstrate, both theoretically and experimentally that an induced “memory” polarization leads to a dielectric torque in the switch-off phase which has an opposite sign to that of the LC's dielectric anisotropy, when a thick nematic film is constrained in a cell with weak homeotopic anchoring on one surface and strong planar anchoring on the other surface. For this model, we derive the phase diagram and investigate how the length of string defects changes with the thickness of the cell. We further present numerical simulations of the nematic director in the hybrid film.

12:27 PM V8.00007 Condensation of lyotropic chromonic liquid crystals by additives1,2, LUANA TORTORA, H.-S. PARK, Liquid Crystal Institute, Kent State University, Kent, OH 44242, S.-W. KANG, Department of Physics, Kent State University, Kent, OH 44242, S. KUMAR, Department of Physics, Kent State University, Kent, OH 44242 and DMR NSF, K.V. KAZNATCHEEV, Canadian Light Source, SK S7N 0X4, Canada, O.D. LAVRENTOVICEH, Chemical Physics Interdisciplinary Program, Liquid Crystal Institute, Kent State University, Kent, OH 44242 — Lyotropic chromonic liquid crystals (LCLCs) are formed by molecules with rigid polyaromatic cores and ionic groups at the periphery that aggregate in water. Condensation of LCLCs can be driven by polyanions, organic salt and neutral polymers. At a suitable concentration of additives, a nematic LCLC demixes into a coexisting isotropic phase and a condensed phase with birefringence higher than that in the original N. By employing synchrotron X-ray scattering we demonstrate the formation of a columnar hexagonal (C) phase. Scanning transmission X-ray microscopy, LC PolScope and fluorescent confocal microscopy allow us to map the relative concentration of components in the condensed and isotropic regions. Both electrostatic and entropy effects contribute to the condensation.

1Supported by NSF DMR 0504516, DMR 076290, AFOSR MURI FA9550-06-1-0337, Samsung Electronics Corp.
12:39PM V8.00008 Interactions in the NOBOW and 8CB Mixtures1. DONG CHEN, CHENHUI ZHU, NOEL CLARK, Department of Physics, University of Colorado, Boulder — Mixtures of a bent-core mesogen (NOBOW) and a calamitic mesogen (8CB) are studied using X-ray diffraction (XRD), polarized light microscopy and freeze fracture electron microscopy (FFEM). XRD shows that as the 8CB concentration increases, the transition temperature of Iso-B4 decreases and the correlation length of NOBOW B4 decreases while the correlation length of 8CB SmA increases. Polarized light microscopy reveals that the mixtures have larger chiral domains than pure NOBOW and when the phase of 8CB changes to SmA, they show the same boundary as the chiral domains. FFEM images show more details on the structure of the mixtures. Along with the experiments, we will present theoretical studies on the interactions in the NOBOW and 8CB mixtures.

12:51PM V8.00009 Effect of Solvent Concentration on the Liquid Crystal Phase Transitions of Octylocyanobiphenyl-Hexane Mixtures, KRISHNA SIGDEL, GERMANO IANNACCIONE, WPI — The effect of a non-mesogenic, low-molecular-weight, solvent on the phases of a liquid crystal can be profound. High-resolution ac-calorimetry has been carried out on the isotropic (I-N) and the nematic to smectic-A (N-SmA) phase transitions of the liquid crystal octylocyanobiphenyl (8CB) as a function of hexane concentration. Temperature scans were performed above and below these transition temperatures for all samples. Six 8CB-hexane samples were studied having molar concentrations of 0.017 (0.5% by mass), 0.033 (1%), 0.063 (2%), 0.078 (2.5%), 0.092 (3%) and 0.119 (4%) of hexane. Upon increasing dilution of 8CB by the linear form of hexane, the transition temperatures shift lower while the order of both transitions evolves. These effects may be the consequence of the weakening of the liquid crystal molecular interactions due to the presence of the solvent.

1:03PM V8.00010 Landau potential of polymer stabilized ferroelectric liquid crystals, PAUL ARCHER, INGO DIERKING, The University of Manchester — Polymer stabilized liquid crystals (PSLC) [1] consist of a relatively low concentration of a photo-polymerized monomer (typically less than 10%wt) which is phase separated from the continuous liquid crystal medium. For the case of a polymer stabilized ferroelectric liquid crystal, photo-polymerized in the SmA* phase, the network forms parallel to the smectic layer normal. This results in an elastic coupling between the polymer network and the liquid crystal which alters the characteristics of the SmA* to SmC* phase transition. The generalized model of ferroelectric liquid crystals has been modified to encompass this additional interaction through a polymer coupling coefficient. Analysis of experimental tilt angle and polarization data allows the determination of the polymer coupling coefficient and hence the full Landau potential. Results will be shown and discussed for varying polymer concentration.

1:15PM V8.00011 Varying the optical properties of cholesteric liquid crystals, SABRINA RELAIX, MICHELE MOREIRA, PETER PALFFY-MUHORAY, Liquid Crystal Institute, KSU, MICHEL MITOV, CEMES/CNRS — Cholesteric Liquid Crystals (CLCs) are of particular interest as they form self-assembled photonic band gap (PBG) structures - a macroscopic helical structure, leading to a selective reflection of light - which can be easily tuned by external fields. As PBG materials, CLCs have been used as mirrorless lasers with low lasing thresholds since the density of photon states is suppressed in the reflection band and is enhanced at its edges [1]. The modification of the cholesteric organization – either by the introduction of a pitch gradient across the cell or by the incorporation of nanoparticles in the medium – has direct consequences on the PBG and hence the reflected intensity [2,3]. In this presentation, I will describe the variations in the optical properties of CLC caused by these modifications and will discuss possible applications, such as tuning the CLC laser wavelength or adjusting the laser threshold.

1:27PM V8.00012 Three-dimensional imaging of chemical bond orientation in liquid crystals by coherent anti-Stokes Raman scattering microscopy,1. OLEG D. LAVRETOVICH, HEUNG-SHIK PARK, Liquid Crystal Institute and Chemical Physics Program, Kent State University, Kent, OH 44242, BRIAN G. SAAR, X. SUNNEY XIE, Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA 02138 — Coherent anti-Stokes Raman scattering (CARS) microscopy is used to provide three-dimensional chemical maps of liquid crystalline (LC) samples without the use of external labels. CARS is a polarization-sensitive optical imaging technique that derives contrast from Raman-active molecular vibrations in the sample. Compared to other three-dimensional imaging techniques, CARS offers the most rapid chemical characterization available without the use of external dyes or contrast agents. Examples that illustrate the applicability of CARS microscopy to LCs include textures and defects in nematic and smectic LC, electric Frederiks transition.

1:39PM V8.00013 Low electric field induced phase transition of the B1 bent-core liquid crystal phase to a switching phase, J. KIRCHHOFF, L.S. HIRST, Florida State University — Liquid crystal materials that have ferroelectric and antiferroelectric phases are useful in applications due to their switching properties. The B1 bent-core liquid crystal phase is a columnar phase that does not exhibit switching. A transition from the B1 liquid crystal phase to a switching phase has been seen at an electric field of 10 V/μm, which is much lower than previously seen fields of greater than 25 V/μm [1]. This transition is irreversible upon reduction of the applied field and switching continues almost threshold-less down to an applied field of 40 mV/μm, which has not been previously reported. Any amount of a chiral rod-like dopant increases the field required to transition from the B1 to the switching phase, and the transition becomes reversible with the switching phase relaxing back to the B1 phase after a decrease in the electric field. A small concentration of the rod-like dopant also induces a change from the B1 phase to a new liquid crystal phase. These effects were studied using polarized optical microscopy, calorimetry (DSC), and x-ray measurements.

1:51PM V8.00014 Evidence of Broken Reciprocity in Chiral Liquid Crystals, MICHELE MOREIRA, NITHYA VENKATARAMAN, BAHMAN TAHERI, PETER PALFFY-MUHORAY, Liquid Crystal Institute, KSU — Reciprocity in light scattering is predicated on bounded scattering media with symmetric and linear permittivity, conductivity and permeability. Due to their anisotropy and chirality, cholesteric liquid crystal form periodic dielectric structures. If the periodicity is comparable to the wavelength of light, these phases are self-assembled photonic band gap structures. There appear in the permittivity odd powers of the wave vector resulting from nonlocality and broken inversion symmetry. Evidence of non-reciprocity has been found in optically active crystals by Bennett [1] and in stacks of cholesteric and nematic liquid crystal cells by Takezoe [2]. We present experimental data showing broken reciprocity in transmittance and reflectance in cholesteric cells with different pitches having overlapping but distinct reflection bands. We explain our results in terms of simple analytic descriptions of material properties and propagating modes.

Under the short and violent irradiation exposures used in the accelerated material tests, to the much longer reactor material lifetimes. Retaining uncompromising accuracy. This presents an exciting opportunity to extrapolate, through accurate numerical simulations, the material behavior observed under the short and violent irradiation exposures used in the accelerated material tests, to the much longer reactor material lifetimes. Retaining uncompromising accuracy. This presents an exciting opportunity to extrapolate, through accurate numerical simulations, the material behavior observed.

KATHIE E. NEWMAN, Physics, U. of Notre Dame — A new algorithmic method is discussed, Non-Adiabatic Path Sampling (NAPS), which combines features of transition path sampling (TPS) and molecular dynamics with quantum transitions (MDQT). The goal is to ultimately address problems which involve excited and coupled electronic states, as well as large systems and long timescales (e.g., semiconductor photocatalysis). TPS focuses specifically on trajectories that take the system from reactants to products, which allows the study of chemically producible processes dominated by rare but important events whose timescales are outside the range of direct simulation. In the MDQT algorithm, the nuclear dynamics of the system do not occur on a single Born-Oppenheimer potential energy surface, but rather may involve non-adiabatic transitions between many coupled electronic states. The NAPS algorithm uses the statistical framework of TPS to analyze MDQT trajectories, using the advantages of each method to get results for otherwise inaccessible systems. The algorithm is tested on a simple model of proton transfer. A quantum-mechanical proton in a double-well quartic potential bi-linearly coupled to a thermal bath of classical harmonic oscillators. Results from the model are compared to numerically exact results available in the literature.

ZHANG, KARSTEN REUTER, Fritz-Haber-Institut der Max-Planck Gesellschaft — With respect to oxidation catalysis or oxide formation, surface defects like steps, kinks, or vacancies are widely believed to play a decisive role, e.g., in form of active sites or as nucleation centers. Despite this suggested importance, first-principles investigations qualifying this role for gas-phase conditions that are representative of these applications are scarce. This is mostly due to the limitations of electronic-structure calculations in tackling the large system sizes and huge configuration spaces involved. We overcome these limitations with a first-principles statistical mechanics approach coupling density-functional theory (DFT) calculations with grand-canonical Monte Carlo simulations, and apply it to obtain the phase diagram of on-surface O adsorption at a (111) step on a Pd(100) surface. The link between the electronic and mesoscopic techniques is achieved by a lattice-gas Hamiltonian expansion, in which we parameterize the lateral interactions affected by the step from DFT calculations at a Pd(111) vicinal surface, and all remaining lateral interactions from calculations at Pd(100). For a wide range of O gas-phase conditions we find the (111) step to be decorated by a characteristic zig-zag structure. Intriguingly, this structure prevails even up to the elevated temperatures characteristic for catalytic combustion reactions, where only small amounts of disordered oxygen remain at the Pd(100) surface.

VASILY BULATOV, Lawrence Livermore National Lab — The key challenge in simulations of irradiated materials is that of time scale. Typically, atomistic simulations extend to less than one nanosecond whereas kinetic Monte Carlo (kMC) simulations struggle to reach hours of simulated irradiation. Based on a time-dependent Green’s function formalism, our new kMC algorithm extends the simulated time horizon from minutes to tens and hundreds of years while retaining uncompromising accuracy. This presents an exciting opportunity to extrapolate, through accurate numerical simulations, the material behavior observed under the short and violent irradiation exposures used in the accelerated material tests, to the much longer reactor material lifetimes.

1 This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. (UCRL-ABS-236713).

11:39AM V9.00003 First-passage Monte Carlo for materials under irradiation1, ALEKSANDAR DONEV, VASILY BULATOV, Lawrence Livermore National Lab — The key challenge in simulations of irradiated materials is that of time scale. Typically, atomistic simulations extend to less than one nanosecond whereas kinetic Monte Carlo (kMC) simulations struggle to reach hours of simulated irradiation. Based on a time-dependent Green’s function formalism, our new kMC algorithm extends the simulated time horizon from minutes to tens and hundreds of years while retaining uncompromising accuracy. This presents an exciting opportunity to extrapolate, through accurate numerical simulations, the material behavior observed under the short and violent irradiation exposures used in the accelerated material tests, to the much longer reactor material lifetimes.
12:27PM V9.00007 Solidifying semiconductor nanocrystals from melts: Molecular dynamics simulations. TIANSHU LI, DAVIDE DONADIO, GIULIA GALLI, Department of Chemistry, University of California, Davis — Understanding the nucleation of semiconductor nanocrystals is of fundamental importance in the field of nanoscience. In this study we employ classical molecular dynamics simulations to explore the crystallization of Si nanocrystals from the melt. We focus on the differences between homogeneous and heterogeneous nucleations, where the heterogeneous case is investigated by simulating a liquid slab. In particular, we use the recently developed forward fluxing method [R.J. Allen, D. Frenkel, and P.R. ten Wolde, JCP 124 024102(2006)] to model the evolution of nucleation processes from melts and to compute nucleation rates. We demonstrate that free surfaces act as catalytic nucleation sites by significantly promoting the formation of solid-like small clusters. The presence of solid-like clusters in proximity of the surfaces is found to occur at temperature higher than those at which solid seed nucleation occurs in bulk liquids, highlighting the important role of heterogeneous nucleation under low-under-cooling conditions.

12:39PM V9.00008 Ab-Initio Density Functional Calculation of Interatomic Potentials for Large-scale Atomistic Material Simulations. G.L. ZHAO, Department of Physics and High Performance Computing Laboratory, Southern University and A&M College, Baton Rouge, Louisiana 70813, S. YANG, Department of Physics, Southern University and A&M College — We propose a new method to calculate interatomic potentials, utilizing an ab-initio density functional formalism. The calculated interatomic potentials can be used for large scale atomistic material simulations and predictions. We benchmark the method for the case of copper. We utilized the ab-initio interatomic potential to calculate various properties of transition metal copper, including the lattice constant, the bulk modulus, thermal expansion coefficient, monovacancy formation energy, and phonon frequencies. The calculated results agree very well with experimental values. We further calculated the properties of BCC Cu, utilizing the interatomic potential derived from the electronic structure calculations of FCC Cu, to demonstrate the predictive capabilities of the interatomic potential. The predicted properties of BCC Cu agree very well with experimental and ab-initio density functional results. Part of the work was performed during the stay of G. L. Zhao at Princeton University. The authors gratefully acknowledge the financial support of the National Science Foundation (Award No. 0508245).

12:51PM V9.00009 A New Look at the Evaluation of Embedded Atom Potential Models.1 JAMES N. GLOSII, KYLE J. CAPSERSEN, DAVID F. RICHARDS, ROBERT E. RUDD, FRED H. STREITZ, Lawrence Livermore National Laboratory — The embedded atom method (EAM) potentials have been used extensively since introduced by Daw and Baskes in the mid 1980’s due to their simple incorporation of many-body effects that are missed by simple pair potentials. The computational cost of the inclusion of this additional physics has traditionally been a second pass over the pair data. We will report on an implementation of the EAM model within a molecular dynamics algorithm (MD) that does not require this second pass, substantially reducing the computer time and memory required for evaluation of the potential. The second pass is avoided by using a forward extrapolation in time of the density derivative of the embedding function $dF(\rho(t))/d\rho$. The error in this approximation is controllable and consistent with the error introduced by the finite time step numerical integrators used in the MD.

1:03PM V9.00010 Electronic structure from Maximum Entropy optimization: Applications to band energy and electronic force computation1, HIRO SHIMOMA, PARTHAPRATIM BISWAS, The University of Southern Mississippi — We apply a new entropy optimization scheme to study the electronic density of states for complex disordered materials from a knowledge of spectral moments. We employ the Shannon entropy functional in our work and maximize it subject to the moment constraints to construct the spectral distribution of large Hamiltonian matrix[1]. We illustrate the efficiency and the usefulness of the method by reconstructing a number of exact functions, which are difficult to reproduce by other function reconstruction techniques. The local and global convergence properties of the resulting distribution is studied and the band energy and Fermi level are computed with a high degree of precision. An extension of this method to calculate electronic forces is presented for the purpose of using in large-scale molecular dynamics simulation of materials.

1:15PM V9.00011 Lagrangian Time-Reversible Born-Oppenheimer Molecular Dynamics. ANDERS NIKLASSON, Theoretical Division Los Alamos National Laboratory — A Lagrangian generalization of time-reversible Born-Oppenheimer molecular dynamics [Niklasson et al., Phys. Rev. Lett., vol.97, 123001 (2006)] is proposed. The new formulation enables highly efficient symplectic or geometric integrations of both the nuclear and the electronic degrees of freedom that are stable and energy conserving even under incomplete self-consistency convergence. It is demonstrated how the accuracy is improved by over an order of magnitude compared to previous formulations at the same level of computational cost. The proposed Lagrangian includes extended electronic degrees of freedom as auxiliary dynamical variables in addition to the nuclear coordinates and momenta. While the nuclear degrees of freedom propagate on the Born-Oppenheimer potential energy surface, the extended auxiliary electronic degrees of freedom evolve as a harmonic oscillator centered around the adiabatic propagation of the self-consistent ground state (http://arxiv.org/abs/0711.3466).

1:27PM V9.00012 First-principles calculation combined with multicanonical simulation, YOSHIFUJI YOSHIMOTO, ISSP, University of Tokyo, 5-1-5 Kashiwa-no-ha, Kashiwa, 2778581, Japan — To tackle statistical complexities in condensed matters such as phase transitions of atomic structures with first-principles calculations, Yoshimoto have studied the combination of first-principles calculations and multicanonical methods. By the multicanonical methods, phase space of atomic coordinates can be explored efficiently. Among phase transitions, Yoshimoto focused crystal—liquid transition because it is a basic process for material synthesis and formation of objects (casting). The talk will present his recent results: a direct proof of coexistence between the crystal—liquid transition by a kind of two-component multicanonical ensemble, a multi-order multi-thermal ensemble, with an order parameter defined with structure factors that characterize the transition, and optimization of a model interatomic potential in terms of the ensemble from an accurate one called thermodynamic downfolding of a potential. These provide a principle to project a first-principles approach on a model-based approach containing thermodynamic properties of multiple phases to a maximum of transition. The talk will cover the successful applications of the method to the transition of Si and MgO. Ref: Y. Yoshimoto, J. Chem. Phys. 125, 184103 (2006)

1:39PM V9.00013 Topological Properties of Microstructures in Nanocrystalline Materials. TAO XU, MO LI, Georgia Institute of Technology — Recent experiments show that the topological properties of microstructures in nanocrystalline materials play an important role in the mechanical properties of nanocrystalline materials. However, the fundamental structure-property relationship has not been fully understood due to the difficulties in determining and controlling the microscopic properties of nanocrystalline materials experimentally. In this study, we investigate how different topological properties affect the thermal and mechanical responses of nanocrystalline materials, including grain size distribution, surface area distribution, triple junction length distribution, grain boundary misorientation, etc. Digital microstructures with desired topological properties are generated using Inverse Monte Carlo method and are then relaxed and deformed by large-scale molecular dynamic simulation. In order to characterize the relaxed and deformed digital samples, we use a new grain boundary characterization method to accurately determine the position and thickness of each grain boundary during both relaxation and deformation. Finally, this newly developed algorithm enables us to study the correlation between topological and mechanical properties of nanocrystalline materials.
resonant soft x-ray scattering (RSXS) to answer this question for La holes can be spatially separated in an oxide heterostructure from the disordered doped layers in a way analogous to semiconductor modulation doping. We used measurements have identified a pronounced influence of the dopant atoms on microscopic properties of bulk HTS, therefore raising the question of whether the CNRS UPR5-ESPCI, Paris, France, A. GOZAR, G. LOGVENOV, I. BOZOVIC, Brookhaven National Laboratory, NY 11973, USA — Ability of grow crystalline, S. SMADICI, P. ABBAMONTE, J. LEE, S. WANG, University of Illinois at Urbana-Champaign, IL 61801, USA, C.D. CAVELLIN, Universite Paris 12 and Bi material rendered normal by severe underdoping. It may underlie recent experimental observations of the giant proximity effect between two cuprate superconductors separated by a barrier made of the same effect can undergo an enormous enhancement. We establish this novel proximity effect by a general argument as well as a numerical simulation and argue that it may underlie recent experimental observations of the giant proximity effect between two cuprate superconductors separated by a barrier made of the same material rendered normal by severe underdoping.

11:15AM V10.00001 Superconducting proximity effect and Majorana fermions at the surface1, LIANG FU, CHARLES KANE, University of Pennsylvania — A strong topological insulator is an insulating material in which spin-orbit interaction inverts the band gap at an odd number of time reversed pairs of points in the Brillouin zone. These materials have topologically protected gapless spin-split surface states, whose Fermi arc is characterized by a Berry’s phase of \( \pi \). We study the proximity effect between an s-wave superconductor and the surface states of a strong topological insulator. The resulting two dimensional state resembles a spinless \( p_x + ip_y \) superconductor, but does not break time reversal symmetry. This state supports Majorana bound states at vortices. Such bound states obey non-Abelian statistics and have been studied in the context of topological quantum computing. We show that linear junctions between superconductors mediated by the topological insulator form a non chiral 1 dimensional wire for Majorana fermions, and that circuits formed from these junctions provide a method for creating, manipulating and fusing Majorana bound states.

11:27AM V10.00002 Giant proximity effect in a phase-fluctuating superconductor, DOMINIC MARCHAND, LUCIAN COVACI, MONA BERCIOU, MARCEL FRANZ, Department of Physics and Astronomy, University of British Columbia — When a tunneling barrier between two superconductors is formed by a normal material that would be a superconductor in the absence of phase fluctuations, the resulting Josephson effect can undergo an enormous enhancement. We establish this novel proximity effect by a general argument as well as a numerical simulation and argue that it may underlie recent experimental observations of the giant proximity effect between two cuprate superconductors separated by a barrier made of the same material rendered normal by severe underdoping.

11:39AM V10.00003 Search for Proximity Effect in the Local Pairing Temperature of \( \text{Bi}_2\text{Sr}_2\text{Ca}_x\text{Cu}_4\text{O}_{8+x} \), COLIN PARKER, AAKASH PUSHP, KENJIRO K. GOMES, ABHAY PASUPATHY, Department of Physics, Princeton University, GENDA GU, Brookhaven National Laboratory, SHIMPEI ONO, CRIEPI, Japan, YOICHI ANDO, ISIR, Osaka University, ALI YAZDANI, Department of Physics, Princeton University — The proximity effect is seen when a superconductor is in contact with a metal. The pairing gap in the superconductor is reduced near the interface while superconducting correlations are induced in the metal. Recent results in high-\( T_c \) superconductor \( \text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8 \) indicate that the pairing gap closes homogeneously in space, producing a unique state just above \( T_c \) in these compounds where non-superconducting regions are in contact with regions where the pairing gap can still be measured. We will present detailed scanning tunneling measurements that map the local density of states in the same area of the sample from the low temperature fully gapped regime to the high temperature regime where most gaps have closed. We find that the temperature at which the gap closes locally is sensitive to the gaps in the surrounding region.

3 Work supported by NSF, DOE and PCCM-MRSEC.

11:51AM V10.00004 Superconducting Proximity Effect in Thin Semiconducting Films, MICHAEL VISSERS, SOREN FLEXNER, PAUL WELANDER, KEVIN INDERHEES, TIM MCARDLE, JIM ECKSTEIN, University of Illinois at Urbana Champaign — We report results using a novel 3 terminal device structure that provides two independent resistance measurements that we use to examine the influence of the superconducting proximity effect on both the transport properties of the thin film N layer by quantifying its sheet resistance, \( R_s \), as well as independently measuring the junction conductance across the N-S boundary, \( G_c \). When the N layer is a degenerate semiconductor the changes in these quantities are large. \( G_c \) increases much more than the factor of 2 that Andreev Reflection or BTK theory predicts, and both \( G_c \) and \( R_s \) exhibit reentrance as temperature decreases. We interpret these effects as being due to a transition between a phase fluctuating and phase stiff proximity effect in the N layer. This manifests itself by moving the N-S electrical boundary into the semiconductor, increasing \( G_c \), while simultaneously removing volume available to normal transport forcing the measured conductance to increase at a rate that is much faster than the factor of 2 predicted by the model. We find that the pairing gap closes inhomogeneously in space, producing a unique state just above \( T_c \) in these compounds where non-superconducting regions are in contact with regions where the pairing gap can still be measured. We will present detailed scanning tunneling measurements that map the local density of states in the same area of the sample from the low temperature fully gapped regime to the high temperature regime where most gaps have closed. We find that the temperature at which the gap closes locally is sensitive to the gaps in the surrounding region.

12:03PM V10.00005 Charge leakage in superconducting \( \text{La}_2\text{CuO}_4 \) – \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) superlattices, S. SMADICI, P. ABBAMONTE, J. LEE, S. WANG, University of Illinois at Urbana-Champaign, IL 61801, USA, C.D. CAPELLINI, Universite Paris 12 and CNRS UPS-ESPCI, Paris, France, A. GOZAR, G. LOGVENOV, I. BOZOVIC, Brookhaven National Laboratory, NY 11973, USA — Ability of grow crystalline high-temperature superconductor (HTS) superlattices using molecular beam epitaxy has opened new avenues of research. Scanning tunneling microscopy measurements have identified a pronounced influence of the dopant atoms on microscopic properties of bulk HTS, therefore raising the question of whether the holes can be spatially separated in an oxide heterostructure from the disordered doped layers in a way analogous to semiconductor modulation doping. We used resonant soft x-ray scattering (RSXS) to answer this question for \( \text{La}_2\text{CuO}_4 \) – \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) superlattices. For a 15 x 2 x LCO – 4 x LSCO superlattice with \( x=0.36 \), the measured mode amplitude modulation at the \( O \) edge shows a relatively weak localization of the doped holes to the LSCO layers. By using the interference between “structural” and resonant scattering at the \( Cu L_2 \) edge, the c-axis stress of the LSCO sublattice was also observed.

12:15PM V10.00006 Long range proximity effect in High Tc Josephson NanoJunctions: a quantitative study

JEROME LESUEUR, NICOLAS BERGEAL1, Physique Quantique, LPEM-CNRS-ESPCI, 10 Rue Vauquelin, 75231 Paris, France, MARCO APRILI, LPS-Universite Paris Sud, Bat 510, 91 405 Orsay Cedex, France, TAKIS KONTOS, LPA ENS, 24 rue Lhomond, 75005 Paris, France, MARTIN SIRENA, Physique Quantique, LPEM-CNRS-ESPCI, 10 Rue Vauquelin, 75231 Paris, France, GIANCARLO FAINI, LPN-CNRS, Route de Nozay, 91460 Marcoussis, France, JEAN-PIERRE CONTOUR, UMR-CNRS/THALES, Route N128, 91120 Palaiseau, France — Proximity effect (PE) between a superconductor S and a normal metal N has been a powerful tool to study conventional superconductors. In High Tc (HTc) compounds, low quality interfaces and poor Fermi wave-vector match with most of metals considerably reduce the PE, and make really difficult its study. We have designed Josephson NanoJunctions in which two S reservoirs are coupled through an N layer at a nanoscale, where N is a lightly disordered HTc, whose Tc has been reduced by ion irradiation. In these SNS junctions, Cooper pairs propagate through the N layer by PE. In this situation with no metallic interfaces within the same material, we have shown that a long range PE takes place, which can be quantitatively described by the diffusive Usadel equations. The Josephson coupling temperature can be computed. The role of the order parameter symmetry will be also discussed.

1Present address: Yale University USA

12:27PM V10.00007 The Superconducting State of Pr$_{2-x}$Ce$_x$Cu$_4$: Tunneling study

YORAM DAGAN, Tel Aviv University, ROY BECK, University of California, Santa-Barbara, RICHARD GREENE, University of Maryland — We report a tunneling study between the electron-doped high Tc, cuprate superconductor Pr$_{2-x}$Ce$_x$Cu$_4$, and Lead as a function of doping, x. Our data fits a nonmonotonic d-wave order parameter for the whole doping range studied. From our data we are able to conclude that the electron-doped cuprate Pr$_{2-x}$Ce$_x$Cu$_4$ is a weak coupling, BCS superconductor in the dirty limit. Phys. Rev. Lett. 99, 147004 (2007)

12:39PM V10.00008 Local tunneling spectroscopy and infrared spectroscopy of the electron-doped cuprate Sm$_{2-x}$Ce$_x$O$_{4+y}$

A. ZIMMERS, [1,2,3], Y. NOAT, T. CREN, W. SACKS, D. RODITCHEV, [1] INSF, Paris, France, B. LIANG, R. L. GREENE, [2] CNAM, Univ of Maryland, USA, R. P. S. M. LOBO, N. BONTEMPS, [1] LPEM, ESPCI, Paris, France — We present infrared and local tunneling spectroscopy of the electron-doped cuprate Sm$_{2-x}$Ce$_x$O$_{4+y}$. In STM, at optimal doping x=0.15, a clear signature of the superconducting gap is observed with an amplitude ranging from place to place and from sample to sample (Δ ~ 3.5-6meV). Another spectroscopic feature is simultaneously observed at high energy above ±50meV. Its energy scale and temperature evolution is found to be compatible with previous photoemission and optical experiments. If interpreted as the signature of antiferromagnetic order in the samples, these results could suggest the coexistence on the local scale of antiferromagnetism and superconductivity on the electron-doped side of cuprate superconductors. Using optical spectroscopy, we analyzed the effects of the normal state gap opening (the higher energy gap seen in STM) and phonon structure as a function of temperature and doping from the underdoped to the metallic composition.

12:51PM V10.00009 Spin correlations and magnetic excitation spectrum of electron-doped Nd$_{2-x}$Ce$_x$CuO$_{4}$±δ

EUGENIE MOTOYAMA, GUCHUAN YU, YUAN LI, INNA VISHIK, PATRICK MANG, MARTIN GREVEN, Stanford University, OWEN VAJK, University of Missouri - Columbia, KLAUDIA HRADIL, RICHARD MOLE, Forschungsinstitut für Nanoskopie der Universität Hamburg, Hamburg, Germany — We present the results of local tunneling spectroscopy and infrared spectroscopy for electron-doped Nd$_{2-x}$Ce$_x$CuO$_{4}$±δ, one of the most intriguing issues in the field of high-Tc superconductivity is the electron-hole asymmetry: the hole- or electron-doping of the parent Mott insulators leads to superconductors with differing properties. The phase diagram is asymmetric with respect to electron and hole doping, and for the comparatively less-studied electron-doped materials, the role of electronic correlations and nesting are not as clear as for the hole-doping phase. Inelastic neutron scattering measurements have shown the possibility that in the electron-doped Nd$_{2-x}$Ce$_x$CuO$_{4}$±δ, genuine long-range antiferromagnetism and superconductivity do not co-exist (Motoyama et al., Nature 445, 186 (2007)). However, some uncertainty remains, due to the inhomogeneity of Ce concentration x in the large single crystals. Here we report new results using improved homogeneity. In addition to the implications for the phase diagram using energy-integrated measurements, we discussed the impact of improved crystals on the (energy-resolved) magnetic excitation spectrum in the superconducting state.

1:03PM V10.00010 EXAFS study of the role of apical oxygen on superconductivity in Pr$_{0.88}$La$_{0.12}$Ce$_{0.88}$CuO$_{4}$

S. ROSENKRANZ, D. HASKEL, M. BALASUBRAMANIAN, S. HEALD, Argonne National Laboratory, S. LI, P. DAI, University of Tennessee and ORNL, Y. ANDO, CRIEPI — One of the longstanding puzzles surrounding high-Tc cuprates concerns the apparent asymmetry between electron and hole doping. Whereas hole doping quickly superconductivity, electron doping alone in materials such as Pr$_2$CuO$_y$ is insufficient and superconductivity is only achieved after a high temperature, low-oxygen annealing. While it was believed that this annealing process removes small amounts of oxygen in apical positions assumed to induce localization of the doped electrons, this scenario is incompatible with Raman, infrared- transmission, and ultrasound studies. In contrast, based on synchrotron X-ray and neutron diffraction studies combined with chemical and thermo-gravimetric analysis measurements, we recently showed that the annealing process alleviates minor Cu- deficiencies present in the as-grown sample. Here we present EXAFS studies on powder and single-crystal samples of as-grown and annealed Pr$_{0.88}$La$_{0.12}$Ce$_{0.88}$CuO$_{4}$. Our results are consistent with no change in the occupation of apical oxygen between the superconducting and as-grown samples, providing further evidence that the main effect of the annealing process is to repair defects in the superconducting planes due to Cu- deficiencies present in as grown samples. Work supported by US DOE BES-DM5 DE-AC02-06CH11357

1:15PM V10.00011 High pressure study on Pr$_{1.85}$Ce$_{0.15}$CuO$_{4}$−δ single crystals

COSTEL R. ROTUNDU, Department of Physics, University of Maryland, College Park, MD 20742, USA, VIKTOR V. STRUZHKIN, ALEXANDER GONCHAROV, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, USA, RICHARD L. GREENE, Department of Physics, University of Maryland, College Park, MD 20742, USA — Transport measurements to 2.5 GPa on electron-doped cuprates revealed modest changes in physical properties, if any [1]. Room temperature synchrotron diffraction on powder samples show that the non-superconducting parent Pr$_2$CuO$_4$ exhibits a gradual structural transition from T’ to T phase when subject to pressures greater than 15 GPa [2]. Pr$_{2-x}$Ce$_x$CuO$_4$ (PCCO) is superconducting for a Ce doping range 0.12 – 0.2 (T’ structure). Both pressure and Tc have been reduced by ion irradiation. In these SNS junctions, Cooper pairs propagate through the N layer by PE. In this situation with no metallic interfaces within the same material, we have shown that a long range PE takes place, which can be quantitatively described by the diffusive Usadel equations. The Josephson coupling temperature can be computed. The role of the order parameter symmetry will be also discussed.

1:27PM V10.00012 Recent ARPES results on electron-doped high-Tc superconductors and comparison to their hole-doped counterparts. PIERRE RICHARD, ZHIHUI PAN, MADHAB NEUPANE, YIMING XU, Boston College; PATRICK FOURNIER, Université de Sherbrooke, SHILIANG LI, PENGCHENG DAI, University of Tennessee, Knoxville, ZIQIANG WANG, HONG DING, Boston College — Since the CuO2 planes of cuprates, where high-temperature superconductivity occurs, can be doped either by holes or electrons, it appears important to establish similarities between these two types of doping in order to have an overview of high-temperature superconductors, especially for the electronic structure. Hence, although much less studied by ARPES than their hole-doped counterpart, the electronic structure of the electron-doped cuprates is believed to provide essential hints towards the understanding of high-Tc superconductivity. We present our recent ARPES results on electron-doped cuprates, focusing on various ranges of energy. We compare the results to those obtained on commonly studied hole-doped cuprates.

1:39PM V10.00013 Point contact tunnelling as a probe for the superconducting properties of Niobium RF cavities. T. PROSLIER, J. MOORE, Argonne Nat. Lab., J. ZASADZINSKI, Illinois Inst. Tech., M. PELLIN, J. NOREM, Argonne Nat. Lab., MSD TEAM, HEP TEAM, IIT TEAM — Niobium, with its very high Hc2, has been used in superconducting RF cavities for accelerator systems for 40 years with continuous improvement. The quality of cavities (Q) is governed by the surface impedance RBCS, which depends on the quasiparticle gap, \( \Delta \), and the superfluid density, \( n_s \). Both of these parameters are seriously affected by surface imperfections (metallic phases, dissolved oxygen, magnetic impurities). Surface treatments of Nb cavities improved the Q factor, but are not understood from a fundamental point of view. Point contact tunneling spectroscopy is an ideal, surface sensitive probe as the quasiparticle current measures \( \Delta n \). We present some measurements on SRF cavity-grade Nb using point contact tunneling demonstrating that the nature of the Nb oxide has a significant effect on \( \Delta \). Atomic Layer Deposition was used to grow an alumina oxygen diffusion barrier on Nb providing control of the Nb oxidation layer composition with subsequent annealing. Point contact tunneling on these samples help to unravel the complicated effect of Nb surface oxidation on \( \Delta \).

1:51PM V10.00014 Scanning Tunneling Microscopy of Defect-Induced Superstructure in 2H-NbSe2. HUI WANG, JONGCHEE LEE, MICHAEL DREYER, U of Maryland, College Park, BARRY BARKER, Laboratory of Physical Sciences — Scanning tunneling microscopy and spectroscopy measurements were performed on pure 2H-NbSe2 with defects introduced by tip-sample interaction at 4K. Domains of a new superstructure with a lattice constant equals \( \sqrt{3} a_0 \) instead of \( 3 a_0 \) were observed around the defects. Closer to the defects we also observed the disordered phase of this structure. Both of them are stable under the STM measurements at 4K. Atomically resolved microscopy and spectroscopy studies suggest a 2H to 1T phase transition induced by surface atom sliding.

2:03PM V10.00015 STM Investigation of Bosonic Modes and a Superconducting Gap in the Electron Doped Cuprate Pr1−xLaCe2CuO4. FRANCIS NIESTEMSKI, SHANKAR KUNWAR, SEN ZHOU, Boston College, SHILIANG LI, University of Tennessee, Knoxville, HONG DING, ZIQIANG WANG, Boston College, PENGCHENG DAI, U Tennessee, Knoxville & ORNL, VIDYA MADHAVAN, Boston College — While continual effort in scanning tunneling microscopy (STM) remains focused on the hole-doped cuprates less attention has been given to the equally important electron-doped side of the phase diagram. We use a variable temperature UHV STM to investigate the electron-doped cuprate superconductor Pr1−xLaCe2CuO4. We explore temperatures 2 K and higher and find a superconducting gap that disappears above Tc. We also find satellite features anti-correlated to the gap which we associate with bosonic modes. We relate our findings to neutron scattering results and discuss how this electron doped superconductor differs from more familiar hole-doped cuprates.

11:15AM V11.00001 Evidence of Electron Coupling to High Energy Excitations in a High Temperature Superconductor. XINGJIANG ZHOU, WENTAO ZHANG, GUODONG LIU, LIN ZHAO, HAIYUN LIU, JIANQIAO MENG, XIAOLI DONG, WEI LU, ZHONGXIAN ZHAO, GUILING WANG, HONGBO ZHANG, YONG ZHOU, ZUYAN XU, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, YONG DING, ZIQIANG WANG, Boston College, PENGCHENG DAI, U. of Maryland, College Park, BARRY BARKER, Laboratory of Physical Sciences — Scanning tunneling microscopy and spectroscopy measurements were performed on pure 2H-NbSe2 with defects introduced by tip-sample interaction at 4K. Domains of a new superstructure with a lattice constant equals \( \sqrt{3} a_0 \) instead of \( 3 a_0 \) were observed around the defects. Closer to the defects we also observed the disordered phase of this structure. Both of them are stable under the STM measurements at 4K. Atomically resolved microscopy and spectroscopy studies suggest a 2H to 1T phase transition induced by surface atom sliding.

11:27AM V11.00002 High energy kink in the single particle spectra of the two-dimensional Hubbard model. ALEXANDRU MACRIDDIN, MARK JARRELL, University of Cincinnati, THOMAS MAIER, Oak Ridge National Laboratory, DOUGLAS SCALAPINO, University of California, Santa Barbara — Employing dynamical cluster quantum Monte Carlo calculations we show that the single particle spectral weight \( \omega(k,\omega) \) of the one-band two-dimensional Hubbard model displays a high energy kink in the quasiparticle dispersion followed by a steep dispersion of a broad peak similar to recent ARPES results reported for the cuprates. Based on the agreement between the Monte Carlo results and a simple coupling which calculates the quasiparticle to spin fluctuations, we conclude that the kink and the broad spectral feature in the Hubbard model spectra is due to scattering with damped high energy spin fluctuations.

11:39AM V11.00003 Theory of quasiparticle excitations in cuprates: universal Fermi velocity and high energy anomalies. QIANG-HUA WANG, Nanjing University — Recent measurements of quasiparticles in hole-doped cuprates reveal highly unusual features: 1) the doping-independent Fermi velocity, 2) two energy scales in the quasiparticle spectral function, and 3) a suppression of the low energy spectral weight near the zone center. The underlying mechanism is under hot debate. We addressed these important issues by a new mean field theory and a novel variational Monte Carlo (VMC) study of the \( t-J \) model. We obtained results in both approaches in agreement with the experiments but without invoking extrinsic effects. They reflect the role of strong correlations in the form of local Mottness and antiferromagnetic fluctuations, yielding a strong connection between the low and high energy quasiparticle excitations. Besides, we resolved a long standing issue of the sum rule for quasiparticle spectral weights in traditional VMC studies. The electron doped case was also discussed and we concluded that no high energy anomaly exists in the occupied side, in contrast to the hole doped case.
11:51AM V11.00004 Dispersion and spectral weight analysis of “waterfall” structure in Pb doped Bi2212. QIANG WANG, ZHE SUN, ELI ROTENBERG, HELMUT BERGER, DANIEL DESSAU — Angle resolved photoemission spectroscopy (ARPES) is used to investigate the property of the “waterfall” structure in (Bi, Pb)2Sr2CaCu2O8+δ. The dispersion analysis of the spectrum shows that there is not a “universal high energy scale” in this material. And the spectral weight analysis suggests that the matrix element and the inelastic scattering may have an important role in the formation of the waterfall structure.

12:03PM V11.00005 Magnon Corrections to Cuprate Self Energy1, ROBERT MARKIEWICZ, TANMOY DAS, ARUN BANSIL, Northeastern University — Recently, high energy kinks (‘waterfalls’) have been reported above 200 meV in the ARPES spectra of several cuprates. These kinks are a signal of bosonic coupling and may be responsible for the band renormalizations found at lower energies. We have shown that coupling to collective modes in the spin channel can yield waterfall-like effects in the electronic dispersion in the electron as well as hole doped cuprates. [1] Here we further explore the effects of the magnons in the pseudogap regime, including a discussion of how magnons influence optical properties. [1] R.S. Markiewicz, S. Saharakori, and A. Bansil, cond-mat/0701524, to be published, PRB.

1 Work supported in part by the DOE.

12:15PM V11.00006 Aspects of the electron-phonon interaction in the Cuprates, STEVE JOHNSTON, University of Waterloo, WEI-SHENG LEE, THOMAS DEVEREAUX1, Z.X. SHEN, Stanford University — The ubiquity of the “kink”-structures observed in the band-dispersion of the High-Tc cuprates has made this feature the subject of debate for many years now. At present, the community agrees that the feature is due to electron-boson coupling to a collective mode, however, a consensus has yet to be reached on its identity. In this talk we will review the arguments typically made against the phonon interpretation, which are grounded in knowledge gained from metallic systems. We will then show the complications one encounters in extrapolating from these systems to strongly correlated systems such as the cuprates. We will also discuss some of the common methods for extracting information from photoemission spectra that are cited in the modern literature in order to highlight the strengths and weaknesses of each and their reliability for extracting realistic estimates for parameters such as the electron-boson coupling strength λ.

12:27PM V11.00007 Phonon anomaly in Bi2Sr2CaCu2O8+δ,* JIANDONG GUO, HUAJUN QIN, KEHUI WU, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China, R. G. MOORE, E. W. PLUMMER, University of Tennessee, Knoxville, TN 37996, J. WEN, G. D. GU, Brookhaven National Lab, Upton, NY 11973, JIANDI ZHANG, Florida International University, Miami, FL 33199 — Electron-phonon coupling (EPC) plays in many exotic phenomena displayed by strongly-correlated electron materials, such as the pairing mechanism in high-Tc superconductors and metal-insulator transition in ruthenates. Many studies show a strong renormalization of quasi-particle band structure near Fermi energy associated with the coupling to boson modes ~40-50 meV. However, there is no clear picture of the origin of these modes. With angle-resolved electron energy loss spectroscopy, we have studied the lattice dynamics of Bi2Sr2CaCu2O8+δ surface. The data indicate a phonon anomaly of modes ~50 meV, identified as the in-plane Cu-O stretching modes, where the energy shifts (softens) while the spectral linewidth and weight vary along (0,0)-(π,0) direction. The other feature ~80 meV, attributed to apical oxygen vibrations, exhibits distinct dispersion toward (π,π). Such behaviors are observed both above and below the superconducting Tc. These detailed measurements provide new insights into the nature of EPC in such materials. * Supported by China NSF-10704084, NSF DMR-0346826, NSF and DOE (NSF-DMR-0451163 and DMS&E).

12:39PM V11.00008 Isotope effect on the nodal kink energy in Bi2212, J.F. DOUGLAS, University of Colorado, Boulder, H. IWASAWA, Tokyo University of Science, National Institute of Advanced Industrial Science and Technology, K. SATO, H. EISAKI, Y. YOSHIDA, H. BANDO, — Using low energy angle resolved photoemission spectroscopy (le-ARPES), we have observed an energy shift of the nodal kink upon substitution of 18O for 16O in optimally doped (Tc ~92K) Bi2Sr2CaCu2O8+δ. Studying several samples of each isotope, we find that the kink energy decreases by 3.22 ± 0.72 meV upon 18O substitution, in good agreement with the energy shift one would expect from a phononic mode. This strongly supports the view that the nodal dispersion kink arises from electronic coupling to a phononic mode.

1:03PM V11.00010 Fermi Surface Topology Effects on the Electron-Phonon Coupling in Electron-doped Cuprates, S.R. PARK, D.J. SONG, C.S. LEEM, CHUL KIM, C. KIM1, Institute of Physics and Applied Physics, Yonsei University, Seoul, Korea, B.J. KIM, School of Physics and Center for Strongly Correlated Materials Research, Seoul National University, Seoul, Korea, H. EISAKI2 — We have performed high resolution angle resolved photoemission (ARPES) studies on electron doped cuprate superconductors Sm2−xCexCuO4 (x=0.10, 0.15, 0.18). Imaginary parts of the electron removal self energy for a newly developed method show kink-like features due to electron-bosonic mode coupling. The kink-like feature is seen along both nodal and anti-nodal directions but at different energies of 50 and 70 meV. Such energy scales can be reconciled by taking the Fermi surface topology and phonon dispersions into account, revealing the kink structures are due to the electron-phonon coupling. Estimated electron-phonon coupling constant λ from the self energy is about 0.6 independent of doping and is isotropic. In addition to the low energy feature, we observe a hump structure at 350 meV which is anisotropic and exists only in the anti-nodal spectrum.

1:15PM V11.00011 Theoretical fits of laser-ARPES energy distribution curves of the high Tc superconductor Bi2212. N.C. PLUMB, University of Colorado, P.A. CASEY, Princeton University, J.D. KORALEK, LBNL and UC Berkeley, J.F. DOUGLAS, Z. SUN, University of Colorado, Y. AIURA, K. OKA, H. EISAKI, AIST Tsukuba, P.W. ANDERSON, Princeton University, D.S. DESSAU, University of Colorado — Laser-ARPES has produced spectral lineshapes in photoemission that are much sharper than any previous data, which is due to increased energy and momentum resolution, increased bulk sensitivity, and decreased final state broadening. The lifetimes of these states, extracted from simple Lorentzian fits to the data, are consistent with bulk-sensitive optical data, implying that we are for the first time measuring the intrinsic spectral function. It therefore is appropriate to study the spectral lineshape in detail. We have looked at standard Lorentzian energy distribution curves, as well as extensions based upon Fermi Liquid theory, Marginal Fermi Liquid theory, and of great interest, a non-Fermi Liquid theory based upon Anderson’s treatment of the Gutzwiller projection. The lineshapes based upon the Gutzwiller projection utilize only one free parameter and include no background term, yet they fit the data well over a broad range of temperatures and energies.

1:27PM V11.00012 Properties of high-Tc superconductors from spin-phonon coupling and band models. THOMAS JARLSTORP, DPMC, University of Geneva, CH1211 Geneva 4, Switzerland — An understanding of the rich doping- and \((q, \omega)\)-dependences of spin excitations in high Tc materials is essential since the mechanism of high-Tc superconductivity might be linked to spin fluctuations. Ab-initio band calculations show important spin-phonon coupling (SPC), i.e. antiferromagnetic fluctuations are enhanced when they co-exist with \(q\)-phonons involving O, Cu or La distortions. Parameters for these “1-dimensional” (1D) electron-phonon and spin-wave couplings are obtained from band calculations for long supercells containing phonon distortions and/or staggered fields. The characteristic 2-D q-dependence of the excitations are calculated for a free-electron like band with the use of the ab-initio parameters. The q-dependence depend on the strength of the SPC. The SPC is strongest for in-plane O-modes, weaker for modes involving the heavy atoms, and smallest for apical O, which together with SPC for the phonons at the characteristic frequency lead to a \(q\)-dependent excitation spectrum. These and other properties coming from SPC in the band/free-electron model compare favorably with observations.

1:39PM V11.00013 Universal dispersion anomalies revealed by DQMC simulations of the Hubbard model. B. MORITZ, SLAC, S. JOHNSTON, U. Waterloo, W. MEEVASANA, Stanford U., C. KIM, Yonsei U., T. P. DEVEREAUX, Stanford U. and SLAC, R. T. SCALETTER, UC Davis, Z.-X. SHEN, Stanford U. and SLAC — The recent observation of a “high energy anomaly” (HEA) in hole-doped high-Tc compounds, as well as the half-filled parent insulators, using angle-resolved photoemission spectroscopy (ARPES) has sparked a great deal of interest and intense theoretical and experimental investigations. Using determinant quantum Monte Carlo (DQMC) and maximum entropy analytic continuation (MEM), we investigate the existence of HEA in the single-band Hubbard model. The spectral functions obtained from the simulations reveal a universal HEA across the doping spectrum, similar to that seen in experiment. This signals a cross-over from a quasiparticle-like band at low energy to the incomherent lower Hubbard band at higher energy. A comparison of the self-energy obtained from simulation to that extracted from experiment serves as a further illustration of the similarities. In addition, we perform simulations of the single-band Hubbard model on the electron-doped side of the phase diagram and compare and contrast our results to existing experimental evidence and comment on the possibility that future experiments would find a universal HEA in electron-doped compounds.

1:51PM V11.00014 Local effects of apical oxygen on superconductivity in high-\(T_c\) cuprates. MICHYASU MORI, Tohoku Univ., TAKAMI TOHYAMA, Kyoto Univ., SADAMICHI MAEKAWA, Tohoku Univ. — The superconducting critical temperature \((T_c)\) of high-\(T_c\) cuprates widely distributes among various series of crystal structures, even if the doping rate is optimized in the \(\text{CuO}_2\) planes. In addition, the \(T_c\) is enhanced by applying pressure[1]. These material- and pressure dependences have meaningful correlation with an energy difference of oxygen sites in an apical site and in the \(\text{CuO}_2\) plane \((V_A)\)[2]. On the other hand, Slezak et al. has found that locally modulated gap energy has anti-correlation with a distance between a \(\text{Cu}\) and an apical O-sites, i.e., the larger distance is related to the smaller gap energy[3]. We study such a local effect of apical oxygen on superconductivity by calculating the Madelung potential. In particular, we focus on a local variation of \(V_A\), whose value approximately corresponds to stability of the Zhang- Rice singlet state[2]. It is found that, on neighboring sites of apical sites close to Cu sites, \(V_A\) are locally enhanced compared to other sites. To estimate the gap energy, we propose a toy model like a BCS mean field Hamiltonian with an additional degree of freedom, which describes a role of apical oxygen. These material and pressure variations have meaningful correlation with an energy difference of oxygen sites and gap energy, which approximately corresponds to stability of the Zhang- Rice singlet state[2]. In the future, this effect will be studied on the same system in experiment.

2:03PM V11.00015 Variable Temperature Scanning Tunneling Spectroscopy of Inhomogeneous High Temperature Superconductors. E.W. HUDSON, M. C. BOYER, W.D. WISE, KAMALES CHATTERJEE, YAYU WANG, MIT, TAKESHI KONDO, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, TSUNEHIRO TAKEUCHI, HIROSHI IKUTA, Nagoya University — Scanning Tunneling Microscopy (STM) of the high temperature superconductor \(\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}\) (Bi-2212) long ago revealed large gap variations on nanometer length scales. In this talk I will discuss new results from our temperature dependent STM studies of Bi-2201. In particular, I will focus on the effects of these variations on other observables, such as the states generated around single atom impurities, as well as on other measurement techniques, such as angle resolved photoemission (ARPES).

Thursday, March 13, 2008 11:15AM - 2:03PM – Session V12 DCMP: Metal Insulator Transition I: Vanadium Oxides and Others Morial Convention Center 203

11:15AM V12.00001 Electrical measurements at the metal-insulator phase boundary in \(\text{VO}_2\) nanobeams1. DAVID COBDEN, JIANG WEI ZENGHUI WANG, WEI CHEN, University of Washington — We study the electrical properties of vanadium dioxide nanobeams undergoing the metal-insulator transition (MIT), which occurs at a temperature of \(67^\circ\text{C}\) at ambient pressure. The nature of the MIT in bulk \(\text{VO}_2\), although known to involve electron-electron correlations, has remained elusive since its discovery fifty years ago. In nanobeams clamped at both ends there is a coexistence regime which allows electrical measurements along the phase boundary. Remarkably, the resistivity of the insulating phase turns out to be constant along the phase boundary implying that the transition is driven by electron density, consistent with a Mott-type mechanism. The measurements show that the resistance of a domain wall is negligible, and the resistance of a nanowire gives a direct measure of the length of insulating phase present in the wire, allowing one to study the motion of the domain wall electrically with high precision.

11:27 AM V12.00002 Metal-insulator coexistence in VO$_2$ nanobeams$^1$. JIANG WEI, ZENGHUI WANG, WEI CHEN, DAVID COBDEN, University of Washington — We study the first-order metal-insulator transition (MIT) in vanadium dioxide nanobeams. The MIT occurs sharply at a temperature of $T_c = 67^\circ C$ at ambient pressure. However, in nanobeams clamped at both ends, and hence subjected to a constant length condition, there is a wide coexistence regime between the two phases, which can be visualized in an optical microscope. Above $T_c$, the beam is under axial tension and on warming up follows the phase boundary in the tension/temperature plane. Below $T_c$, the beam buckles under compressive strain. The metallic phase can be supercooled by up to 50°C. Usually there is a single metal-insulator domain wall in each beam, but a mobile bubble-like insulating domain can be induced by applying a nonuniform temperature profile.

11:39 AM V12.00003 Correlation between metal-insulator transition characteristics and electronic structure changes in vanadium oxide thin films, D. RUZMETOV, V. NARAYANAMURTI, S. RAMANATHAN, SEAS, Harvard University, Cambridge, MA, S.D. SENANAYAKE, CSD, Oak Ridge National Lab, Oak Ridge, TN — We correlate electron transport data with energy band structure measurements in vanadium oxide thin films with varying V-O stoichiometry across the VO$_2$ metal-insulator transition (MIT). A set of vanadium oxide thin films were prepared by reactive DC sputtering from a V target at various oxygen partial pressures resulting in films with different MIT strength as determined from the electrical resistance measurements. The results of the near edge X-ray absorption fine structure spectroscopy (NEXAFS) of the O K-edge in identical VO films are presented. Redistribution of the spectral weight from $\sigma^*$ to $\pi^*$ bands is found in the vanadium oxide films exhibiting stronger VO$_2$ MIT. This is taken as evidence of the strengthening of the metal-metal ion interaction with respect to the metal-ligand and indirect V-O-V interaction in vanadium oxide films featuring sharp MIT. We observe also a clear correlation between MIT and the width and the area of the lower $\pi^*$ band which is likely to be due to the emergence of the $d_{1\bar{g}}$ band overlapping with $\pi^*$. The strengthening of this $d_{1\bar{g}}$ band near the Fermi level only in the vanadium oxide compounds displaying the MIT points out the importance of the role of the $d_{1\bar{g}}$ band and electron correlations in the phase transition.

11:51 AM V12.00004 Mott transition in vanadium dioxide (VO$_2$) observed by infrared spectroscopy and nano-imaging$^1$, M.M. QAZILBASH, G.O. ANDREEV, D.N. BASOV, P.C. HO, M.B. MAPLE, Physics Department, University of California - San Diego, M. BREHM, F. KEILMANN, Abt. Molekulare Strukturbiologie, Max-Planck-Institut fur Biochemie and Center for NanoScience, A.V. BALATSKY, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, BONG-JUN KIM, SUN JIN YUN, HYUN-TAK KIM, IT Convergence And Components Lab, ETRI, Daejeon, Korea — The driving mechanism for the temperature-induced insulator-to-metal transition (MIT) in vanadium dioxide (VO$_2$) has been debated for the past five decades. Central to this debate is the relative importance of electron-electron correlations and charge-ordering to the MIT. We report near-field infrared images of VO$_2$ films that directly show the percolative MIT. In combination with far-field infrared spectroscopy, the new data reveal the Mott transition with divergent optical mass in the metallic puddles that emerge at the onset of the MIT.

12:03 PM V12.00005 Avalanches in the Metal-Insulator transition in Vanadium Oxide nanoscaled junctions, AMOS SHARONI, GABRIEL RAMIREZ$^1$, IVAN K. SCHULLER, University of California, San Diego — We present transport measurements on sub-micron devices of VO$_2$. Instead of the usual smooth metal insulator transition, we observe for the first time multiple resistive steps. The temperature driven transition between the two phases occurs through a series of avalanches of different amplitude, ranging over 2 decades of resistance. The data is analyzed assuming a generic normalized probability distribution. Results are similar to those obtained in martensitic transitions or Barkhausen noise in ferromagnets, implying universality of first order phase transition. We will discuss the distribution of resistance avalanches as a function of temperature caused by the percolative nature of resistive transition. In particular we will focus on the effect of the VO$_2$ junction dimensions and the transport measurement conditions (such as applied current and temperature ramp rate) on the results. Work supported by the US –Department of Energy.

$^1$On leave from Universidad del Valle, Cali, Colombia.

12:15 PM V12.00006 Micro X-Ray Diffraction Study of VO$_2$ Films – Separation between Metal-Insulator Transition and Structural Phase Transition, KIM HYUN-TAK, KIM BOUNG-JUN, ETRI in Korea, LEE YONG WOOK, ETRI in Korea, YUN SUN JIN, LIM JUNG-WOOK, ETRI in Korea, SHIN TAE-JU, POSTEC, YOUN HWA-SICK, POSTECH — It has been well-known that VO$_2$ undergoes both a structural phase transition (SPT) from monoclinic (insulator phase) to tetragonal (metal phase) and a discontinuous first-order metal-insulator transition (MIT) (Jump) near 68°C. When the MIT and the SPT occurs simultaneously, the MIT can be regarded as the Peierls transition. When both take place separately, the MIT can be interpreted as the Peierls transition. Peierls transition and Mott transition in VO$_2$ remain controversial. We have investigated a relation of the MIT and the SPT which are simultaneously measured by I-V measurement and synchrotron micro X-ray of the 1B2 line in Pohang accelerator Lab., respectively. A used sample is a VO$_2$-based two terminal device. The result shows that the MIT and the SPT does not occur simultaneously. (References on the MIT: New J. Phys. 6 (1994) 52 (http://www.njp.org), Appl. Phys. Lett. 86 (2005) 242101, Physica B 369 (2005) 76, Phy. Rev. Lett. 97 (2006) 266401, Appl. Phys. Lett. 90 (2007) 023515).

12:27 PM V12.00007 Lateral V/VO$_2$/V Tunnel Junctions Formed by Anodic Oxidation, DAVID KIRKWOOD, KEVIN WEST, JIWEI LU, STUART WOLF, University of Virginia — Anodization has been found to be a simple and cost effective technique to produce oxide films of many transition metals. In this work, we have used anodic oxidation as a means of fabricating lateral V/VO$_2$/V junctions. Vanadium wires grown by ion beam deposition were patterned by lithography and an active working window was defined on the wire. VO$_2$ was then grown under galvanostatic control in a two electrode electrochemical micro-cell. A droplet of oxygen rich saturated Boric acid was used as the electrolyte to electrically connect the Vanadium working electrode to a Platinum wire counter electrode. A constant current of approximately 100 $\mu$A/cm$^2$ was maintained through the cell for various amounts of time. Electrical measurements of the resulting V/VO$_2$/V junctions indicate a metal to insulator transition (MIT) near 340 K that is similar to the structural phase transition and accompanied MIT of VO$_2$ which occurs at this temperature. A 4-fold change in resistance is observed in the junctions. Below this transition temperature a typical junction behavior is observed with a dramatic change in resistance state from high to low with increasing applied current. This non-linear IV characteristic on the junction with a size of 5 $\mu$m by 15 $\mu$m suggests that the anodized VO$_2$ film behaves like a tunneling barrier.
12:39PM V12.00008 The metal to insulator transition in correlated materials – exchange of low and high energy spectral weight, STEFAN G. SINGER, B. SCHULZ, I. MAHNS, M. BASTJAN, G. NEUBER, A. GOOS, P. SAICHU, S. BINDER, A. RUSYDI, K. HORN, S. ELLER, M. RUBHAUSEN, University of Hamburg, G. STRYGANYUK, HASYLAB/DESY, L. COOPER, UIUC, G.A. SAWTZKY, UBC, O. SUSHKOV, University of New South Wales, H. EISAKI, Y. FUJIMAKI, S. UCHIDA, University of Tokyo, K. DÖRR, IFW — The electronic response of correlated system of manganites and cuprates was investigated by a combination of dc conductivity, ellipsometry, and VUV-reflectance covering an energy range from 0 to 22 eV. By performing a stabilized Kramer-Kronig transformation, we obtain the optical conductivity as a function of temperature around the metal to insulator transition. Our main findings are that changes in the kinetic energy exceed energies of more than 22 eV. Within this range we can establish, that high energy spectral weight gets transferred to low energies into the Drude region. We argue that our findings are general phenomena of correlated materials and outline different scenarios to explain our observations.

12:51PM V12.00009 Metal-insulating transition and Zhang-Rice singlets in one-dimensional cuprates: the case of Ca_{2+x}Y_{2-x}Cu_{x}O_{10}²⁺, ALESSIO FILIPPETTI, VINCENZO FIORENTINI, University of Cagliari, Italy — Chain-like Ca_{2+x}Y_{2-x}Cu_{x}O_{10}²⁺ is the ideal prototype of dopable one-dimensional cuprate with zig-zag Cu-O interactions. The observed abundance of Zhang-Rice singlets in the electronic ground state of the system induces peculiar phase transitions in magnetic and conducting properties upon doping. With the use of unconventional first-principles calculations suitors for to the study of strong-correlated materials, we describe the change of electronic and magnetic properties as doping is varied from x=0 to full-doped concentration (i.e. one hole each Cu_{2}O unit). Zhang-Rice singlets are key ingredients to understand the behavior of doped CuO2 units and the rise of high-Tc superconductivity in cuprates. We can visualize ZR singlets in space and energy at varying doping concentration, and their influence on magnetic and dielectric properties. ZR singlets are associated to holes localization on the oxygens, appear for holes concentration above 0.25 per CuO_{2} and persist up to maximum doping (i.e. one hole per CuO_{2}) that is well above the threshold of the metallic regime. Our findings are indicative of the general behavior of low-dimensional doped cuprates and give evidence that first-principles band-energy approaches can be valuably employed to the study of doped cuprates.

1:03PM V12.00010 EXAFS and XANES in Fe_{3−x}M_{x}O_{4}, M = Zn, Ti, Al with 0 ≤ x < 0.065.
J. SABOL, Chemical Consultants, Racine WI, USA, D. OWOC, Z. KAKOL², C. KAPUSTA, A. KOZLOWSKI, AGH-UST, Krakow, Poland, J. HONIG, Purdue Univ., West Lafayette IN, USA — We present an extended EXAFS and XANES study at the Fe K edge of the local structural changes in Fe_{3−x}M_{x}O_{4}, M = Zn, Ti, Al, with x within the first and second order Verwey transition regimes. The aim of this work was to investigate how the local Fe symmetry is altered at the transition, in view of the drastic change of the overall crystal structure. A comparison of the interatomic distances and Debye-Waller factors shows that the local Fe O-structure around either the octahedral or tetrahedral Fe atoms in magnetite remains nearly unaltered crossing the Verwey transition. This is also independent of the level of doping and dopant ion, i.e., independent of lattice parameters, as Zn and Ti increase the unit cell volume and Al decreases the unit cell volume. Therefore, the local distortion of Fe sites is not a parameter sensitive enough to elucidate the mechanism of the Verwey transition and the change of its character. An examination of different factors, other than local order, is needed to explain the apparent charge ordering below the Verwey transition temperature T_{V}.

1:15PM V12.00011 Nonequilibrium Relaxations and Aging Effects near a Metal-Insulator Transition in Two Dimensions.
DRAGANA POPOVIĆ, JAN JAROSZYŃSKI, NHMFL/FSU — The relaxations of conductivity σ(t) have been studied in the glassy regime of a strongly disordered two-dimensional (2D) electron system in Si after a temporary change of carrier density n_{s} during the waiting time t_{w}. Two types of response have been observed: (a) monotonic, where relaxations exhibit aging, i.e. dependence on history, determined by t_{w} and temperature; (b) nonmonotonic, where a memory of the sample history is lost. The conditions that separate the two regimes have been determined. A detailed study of the aging regime [2] reveals an abrupt change in the nature of the glassy phase at the metal-insulator transition (MIT) before it vanishes entirely at a higher density n_{g}. Our results provide further support to theories describing the 2D MIT as the melting of a Coulomb glass, and put constraints on the models of glassy freezing.

1:27PM V12.00012 Photo-induced Metallic States in a Mott Insulator, TAKASHI OKA, University of Tokyo, Department of Tokyo — In the presence of strong AC electric fields, carriers are continuously produced in an insulator and the system may turn metallic. Such photo-induced insulator-to-metal transition was observed in one-dimensional Mott insulators (Iwai et al. P.R.L. (2003)). We have studied the one-dimensional Hubbard model with strong AC electric fields using the time-dependent density matrix renormalization group method. We have changed the strength of the field as well as the frequency. We have observed that metallic states are produced not only when the photon energy, i.e., the frequency of the AC field, is larger than the gap, but also when it is smaller. However, the field must be stronger than a threshold in the latter case. We have also studied the detailed properties of the photo-induced states by calculating the optical and magnetic correlation function.

1:39PM V12.00013 I³⁺-Ir⁴⁺ Charge Disproportionation of Spinel CuIr₂S₄ investigated by Synchrotron Radiaton Photoemission.
HAN-JIN NOH, E.-J. CHO, Dep. of Phys., Chonnam National University, H.-D. KIM, J.-Y. KIM, Pohang Accelerator Laboratory, POSTECH, C.-H. MIN, School of Phys. and Astron., Seoul National University, B.-G. PARK, Dep. of Phys. POSTECH, S.-W. CHEONG, Rutgers Center for Emergent Materials, Rutgers University — We have studied the electronic structure of the spinel CuIr_{2}S_{4} using synchrotron-radiation photoemission spectroscopy. The phase transition from a high temperature paramagnetic metal to a low temperature diamagnetic insulator at ~230 K is clearly observed through the significant line shape change of the Ir 4f photoemission spectra and the ~0.09 eV gap opening of the valence band spectra. The photon energy dependence of the Ir 4f photoemission spectra enable us to characterize the satellite peaks in the metallic phase of CuIr₂S₄, providing compelling experimental evidence for the Ir³⁺-Ir⁴⁺ charge disproportionation in CuIr₂S₄.
11:15AM V13.00001 Dielectric Properties of Ice and Liquid Water from First Principle Calculations 1, DEYOU LIU, FRANCOIS GYGI, GIULIA GALLI, UC Davis — We present a first-principle study of the dielectric properties of ice and liquid water. The eigenmodes of the dielectric matrix, \( \epsilon^{-1} \), are analyzed in terms of maximally localized dielectric functions similar, in their definition, to maximally localized Wannier orbitals obtained from Bloch eigenstates of the electronic Hamiltonian. We show that the lowest eigenmodes of \( \epsilon^{-1} \) are localized in real space and can be separated into groups related to the screening of lone-pairs, intra-, and inter-molecular bonds, respectively. The local properties of the dielectric matrix can be conveniently exploited to build approximate dielectric matrices for efficient, yet accurate calculations of quasiparticle energies.

1This work was supported by DOE SciDAC grant DE-FC02-06ER25794.

11:27AM V13.00002 Strong hybridization of Frenkel excitons in Mott insulators: a novel Wannier function perspective*, CHI-CHENG LEE, Brookhaven National Laboratory, H. C. HSUEH, Tamkang University, WEI KU, Brookhaven National Laboratory — Linear response scheme of the time-dependent density-functional theory (TDDFT) has been quite successful in the study of the excitations of weakly correlated systems. However, its applicability to strongly correlated systems remains unclear, especially due to the poor quality of the exchange-correlation kernel essential for those systems. On the other hand, the local-density approximation + Hubbard U (LDA+U) approximation has been shown to describe quite successfully the ground-state properties and electronic band structures of Mott insulators. Therefore, it is timely to investigate the linear response of the LDA+U functional in the framework of TDDFT in describing excitations of strongly correlated systems. In this talk, a theoretical (diagrammatic) framework of the linear response of LDA+U (TDLDA+U) functional will be presented and applied to the study of Frenkel excitons in NIO within the first-principles Wannier basis. The advantages and disadvantages of LDA+U functional will be discussed, in comparison with more advanced many-body approaches. [1] B. C. Larson, et al. PRL 99, 026401 (2007)*Work supported by U.S. DOE - CSMN

11:39AM V13.00003 Propagation of strongly bound Frenkel excitons in LiF: An effective two-particle kinematic approach of super-atom in ab initio Wannier basis1, CHEN-LIN YEH, HUNG-CHUNG HSUEH, Department of Physics, Tamkang University, Taiwan, WEI KU, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, NY, USA — A general new first-principles Wannier function based method is proposed to better understand the propagation of strongly bound Frenkel excitons. Specifically, long-standing debate of the Frenkel nature of the excitons in LiF is made apparent by the formation of a “super-atom” consisting of Wannier orbitals from both Li and F. On this basis, a new approach is proposed by formulating the kinematic contribution to the propagation of the exciton via an effective two-particle hopping kernel. The same kernel contains both the mass enhancement at strong binding and the decay into continuum at weak binding, and is thus exact in both limits. This kinematic effect is compared with found to overwhelm the conventional interaction-based propagations of exciton in LiF. This general theoretical framework can be directly applied to the study of propagation of local excitations of strongly correlated systems.

11:51AM V13.00004 Ab-initio Total Energy Calculation for Full-potential Multiple Scattering Theory Methods1, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University, AURELIAN RUSANU, MALCOLM STOKES, DON NICHOLSON, MARKUS EISENBACK, Oak Ridge National Laboratory — The ab initio methods (e.g., KKR, KKR-CPA, LSMS) based on multiple scattering theory have the clear advantage of being able to calculate the Green function in a straightforward manner, which has important implications in the application of electronic structure calculations. But these methods have mostly been implemented within muffin-tin approximations. Recent advances in the numerical implementation of full-potential multiple scattering theory and, in particular, the development of an innovative Poisson equation solver have made carrying out the fully self-consistent full-potential calculation possible. In this presentation, we discuss various implementations of the full-potential total energy calculation, and we investigate the convergence of the total energy with respect to the angular momentum expansion cutoff for scattering matrices. Finally, we compare the full-potential total energy with the muffin-tin approximation results.

12:03PM V13.00005 A quantum chemistry roadmap towards highly accurate adsorption energies at ionic surfaces, BO LI, Fritz-Haber-Institut der Max-Planck-Gesellschaft, ANGELOS MICHAELIDES, London Centre for Nanotechnology, University College London and Fritz-Haber-Institut der Max-Planck-Gesellschaft, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft — A roadmap is established to compute adsorption energies of molecules at ionic surfaces with an accuracy approaching chemical accuracy (a precision of 1 kcal/mol or ~43 meV). The approach relies on established quantum chemistry methodologies and involves a separation of the total adsorption energy into contributions from Hartree-Fock and electron correlation, the use of embedded cluster models of the substrate, and extrapolations to the complete basis set limit. Application of the procedure to the example of water on salt, with electron correlation treated at the CCSD(T) level, yields an adsorption energy for a water monomer on NaCl(001) of 480 ± 20 meV.
12:15PM V13.00006 Surface energies of semiconductors by the energy density method. MIN YU, RICHARD M. MARTIN — Energy Density formalism within the first-principles pseudopotential density functional theory has been proposed by Chetty and Martin in 1990s. Although the energy density function is non-unique, nevertheless integrals over surface regions provide unique results for surface energies, and calculations have been carried out by several groups to study the polar surfaces and interfaces of solid state systems such as GaAs (111) and (111) polar surfaces. In our work, we apply this method to wurtzite CdSe to determine the energy of various polar surfaces such as (0001), (0001), and non-polar surfaces such as (1010), (1120), from which we can estimate the equilibrium crystal shape for large nanoclusters. 1. N. Chetty and Richard M. Martin, Phys. Rev. B 45, 6074 (1992). 2. K. Rapcewicz, B. Chen, B. Yakobson, and J. Bernholc, Phys. Rev. B 57, 7281 (1998). 3. N. Moll, A. Kley, E. Pehlke, and M. Scheffler, Phys. Rev. B 54, 8844 (1996).

12:27PM V13.00007 Electron-phonon interaction using Wannier functions: from single-layer graphene to cuprate superconductors. FELICIANO GIUSTINO, Department of Physics, University of California at Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory — The interaction between electrons and phonons is central to many phenomena, including electrical and thermal transport and superconductivity. Recently the electron-phonon (e-ph) interaction has been the focus of intense research efforts in the physics of high-temperature superconductivity and nanoscale transport. Despite the continued interest in the e-ph problem, first-principles calculations remain challenging due to the large computational effort required to describe e-ph scattering processes in the proximity of the Fermi surface. In this talk I will present a method based on Wannier functions which greatly reduces the computational cost of e-ph calculations [1,2]. The underlying idea is to exploit the spatial localization of electrons, and phonons in the maximally localized Wannier representation. After describing the method I will review recent applications to materials of current interest. I will discuss how the e-ph interaction affects the dynamics of Dirac fermions in graphene [3], the origin of superconductivity in boron-doped diamond [4], and the relation between Fermi surface topology and superconductivity in super-hard carbides. I will conclude this presentation by discussing the role of phonons in the angle-resolved photoemission spectra of cuprates [4].

1:03PM V13.00008 Ensemble density functional theory, the atom-in-molecule problem, and reactive charge transfer. SUSAN ATLAS, Department of Physics and Astronomy, University of New Mexico, STEVEN VALONE, Materials Science and Technology Division, Los Alamos National Laboratory — A major challenge in large-scale simulations of complex biomolecular and materials systems is the ability to accurately describe reactive dynamics. We have previously described a new multiscale formalism, based on density functional theory and the embedded-atom method, that enables the rigorous encoding of quantum mechanical excitation effects such as charge polarization and charge transfer within a classical potential. Here we describe a new formulation of a key element of the theory: the deconstruction of molecular densities into subsystem atom-in-molecule components via ensemble constrained-search density functional theory. The method is implemented via the self-consistent solution of coupled sets of Kohn-Sham equations in conjunction with chemical potential equalization across subsystems. This leads to a natural interpretation of dynamical charge transfer and charge polarization in terms of an electronic entropy, thus extending the seminal work of Gross, Oliveira, and Kohn (1988).

1:15PM V13.00009 Correction of Finite Size Errors in Many-body Electronic Structure Calculations. HENDRA KWEE, SHIWEI ZHANG, HENRY KRAKAUER, College of William and Mary — Finite-size (FS) effects are a major source of error in many-body (MB) electronic structure calculations of extended systems. Reducing FS errors is thus a key to broader applications of MB methods in real materials, and the subject has drawn considerable attention. We show that MB FS effects can be effectively included in a modified local density approximation calculation. A parametrization for the FS exchange-correlation functional is obtained. The method is simple and gives post-processing corrections that can be applied to any MB results. Conceptually, it gives a consistent framework for relating FS effects in MB and DFT calculations, which is important if the two methods are to be seamlessly interfaced to bridge length scales. Applications to a model insulator (P₂ in a supercell), to semiconducting Si, and to metallic Na show that the method delivers greatly improved FS corrections.

1 Supported by ONR, NSF, and ARO.

1:27PM V13.00010 Embedding quantum-mechanics in an interatomic potential simulation using local energies. NOAM BERNSTEIN, Naval Research Laboratory, GABOR CSANYI, University of Cambridge — Atomistic simulations that use quantum-mechanical total-energy models provide high accuracy and reliability at the price of computational expense. Classical approximations such as interatomic potentials are much faster, but less transferable. We couple the two approaches concurrently, to describe part of the system quantum-mechanically and part with interatomic potentials, using a weighted sum of atomic energies. This enables us to compute a well defined total energy and part with interatomic potentials, using a weighted sum of atomic energies. The underlying idea is to exploit the spatial localization of electrons, and phonons in the maximally localized Wannier representation. After describing the method I will review recent applications to materials of current interest. I will discuss how the e-ph interaction affects the dynamics of Dirac fermions in graphene [3], the origin of superconductivity in boron-doped diamond [4], and the relation between Fermi surface topology and superconductivity in super-hard carbides. I will conclude this presentation by discussing the role of phonons in the angle-resolved photoemission spectra of cuprates [4].

Using genetic algorithms to find from first-principles the minimum-energy crystal structure starting from random cell vectors and random atomic positions.\(^1\) G. TRIMARCHI, M. D’AVEZAC, ALEX ZUNGER, NREL, Golden CO 80401 — We address the global space-group optimization problem in binary metallic \(A_2B_1\)\(_\text{x} \)\(-\text{y}\)\(_\text{z}\) alloys using an evolutionary algorithm. A set of crystal structures with randomly-chosen lattice vectors and atomic positions is evolved, replacing the highest energy structures with new ones generated through mating or mutation, as well as ab-initio structural relaxation to the nearest local minimum. This was applied to a few compounds whose lattice-type is difficult to guess because the constituent solids \(A\) and \(B\) have different lattice types (e.g., \(A\) is fcc and \(B\) is bcc): (i) compounds with the crystal lattice of either \(A\) or \(B\) constituents, i.e., \(\text{CdPt}_3\), \(\text{AlSc}_3\), \(\text{Al}_5\text{Sc}\); (ii) compounds with a crystal lattice different than that of either constituents, i.e., \(\text{AlSc}\) and \(\text{CuPd}\); (iii) compounds whose crystal lattice is not even of a Bravais type, e.g., \(\text{PdTi}_2\). The optimization scheme retrieved the lowest energy structures within about 100 total-energy evaluations. Not all independent \(GA\) sequences end up giving the same final structure; we select the lowest energy structure from all sequences. Using a model calculation, we will discuss how many independent \(GA\) sequences are needed to find the lowest energy structure with given confidence.

\(^1\) Funded by DOE-SC-BES-DMS

From grand-canonical density functional theory towards rational compound design, ANATOLE VON LILIENFELD, Sandia National Laboratories — The fundamental challenge of rational compound design, i.e., the reverse engineering of chemical compounds with predefined specific properties, originates in the high-dimensional combinatorial nature of chemical space. Chemical space is the hyper-space of a given set of molecular observables that is spanned by the grand-canonical variables (particle densities of electrons and nuclei) which define chemical composition. A brief but rigorous description of chemical space within the molecular grand-canonical ensemble multi-component density functional theory framework will be given \([1]\). Numerical results will be presented for intermolecular energies as a continuous function of alchemical variations within a neutral and isoelectronic 10 proton system, including \(\text{CH}_4\), \(\text{NH}_3\), \(\text{H}_2\text{O}\), and HF, interacting with formic acid \([2]\). Furthermore, engineering the Fermi level through alchemical generation of boron-nitrogen doped mutants of benzene shall be discussed \([3]\).

Session V14 DAMOP: BEC-BCS Crossover Morial Convention Center 205

Properties of a few-body trapped two-component Fermi gas at unitarity\(^1\), JAVIER VON STECHER, Department of Physics and JILA, University of Colorado, Boulder, CO 80309-0440, DOERTE BLUME, Department of Physics and Astronomy, Washington State University, Pullman, Washington 99164-2814, CHRIS H. GREENE, Department of Physics and JILA, University of Colorado, Boulder, CO 80309-0440 — We consider a trapped two-component Fermi system with even and odd number of fermions \(N\). Unlike fermions interact with a short-range two-body potential which does not support a bound state and is characterized by an infinite scattering length. Using two different numerical techniques, i.e., a correlated Gaussians basis expansion method and a fixed-node diffusion Monte Carlo method, we solve the many-body Schrodinger equation and determine the spectrum and structural properties. Analyzing the excitation spectrum and the wavefunctions, we demonstrate that this system exhibits unique universal properties \([1]\), in agreement with analytical predictions \([2]\). Furthermore, we determine the excitation gap up to \(N = 30\) and we compare it with recent predictions. \([1]\) D. Blume, J. von Stecher, and Chris H. Greene, e-print arXiv:cond-mat/0708.2734 \([2]\) F. Werner and Y. Castin, Phys. Rev. A 74, 053604 (2006).

Quantum and thermal fluctuations in the BCS-BEC crossover with unequal mass fermions, ROBERTO DIENER, QI ZHOU, MOHIT RANDERIA, The Ohio State University — A lot of progress has been done in the study of the BCS-BEC crossover for equal-mass fermions in recent years by both theory and experimental groups. An extension of this problem which is starting to receive more attention is the study of mixtures of fermions with different masses, such as a mixture of \(^{40}\)K and \(^{6}\)Li. Using our functional integral method, which we have previously used to study the equal-mass case and which includes the effect of collective excitations \([1]\), we have studied the properties of a fermionic gas with unequal masses across the BCS-BEC crossover. We will present results for different thermodynamical quantities as a function of mass ratio and interaction strength: e.g., the beta parameter at unitarity, the ground state energy as a function of \(1/(k_F \alpha)\), as well as the dimer scattering in the BEC limit as a function of mass ratio which agrees to within 20% with the exact four-body calculation of D. Petrov et al., J. Phys. B At. Mol. Opt. Phys. 38, S645 (2005).

Critical temperature and thermodynamics of the BEC-BCS crossover, EVGENI BUROVSKI, Uni Greifswald, Germany, EVGENY KOZIK,NIKOLAY PROKOF’EV, BORIS SVISTUNOV, UMASS Amherst, MATTHIAS TROYER, ETH Zurich — The strongly-correlated regime of the BCS-BEC crossover can be realized by diluting a system of two-component fermions with a contact attractive interaction and an appropriate ultraviolet regularization. We investigate this system via a novel systematic-error-free continuous-space-time diagrammatic determinant Monte Carlo method. The results allow us to predict the universal curve \(T_c/E_F\) as a function of the parameter \(k_F \alpha\) with the maximum on the BEC side. At unitarity, \(T_c/E_F = 0.152(7)\). We also determine the thermodynamic functions and show how the Monte Carlo results can be used for accurate thermometry.

First- and second-sound-like modes at finite temperature in trapped Fermi gases from BCS to BEC, YAN HE, CHIH-CHUN CHIEN, QIJIN CHEN, KATHRYN LEVIN, University of Chicago — We determine the temperature \((T)\) dependence of first- and second-sound frequency modes for trapped Fermi gases undergoing the BCS to Bose-Einstein condensation (BEC) crossover. Our results are based on numerical solution of the two-fluid equations in conjunction with a microscopic calculation of thermodynamical variables. As in experiment and at unitarity, we show that the lowest radial breathing mode is \(T\) independent. At finite \(T\), higher-order breathing modes strongly mix with second sound. Their complex \(T\) dependence should provide an alternative way of measuring the transition temperature \(T_c\). We will also discuss collective mode frequency for polarized Fermi gas.
12:03PM V14.00005 Transport Properties of a Fermi gas with attractive interactions in the BEC-BCS crossover. CHIH-CHUN CHIEN, YAN HE, QIYUN CHEN, KATHRYN LEVIN, University of Chicago — The transport phenomena of a two-component Fermi gas with attractive interactions are studied at finite temperatures focused on the normal state using a t-matrix formalism in the BEC-BCS crossover. We contrast the behavior of both charged and uncharged systems and address such varied coefficients as DC conductivity and shear viscosity. We show how the behavior above the pairing onset temperature $T^*$ appears to depend rather weakly on the scattering length. At lower temperatures by studying the appropriate Maki–Thompson and Aslamazov-Larkin diagrams, we find more pronounced fluctuation effects the closer the system is to the BCS limit. Interestingly, we observe that these fluctuation effects are more charged than in uncharged systems.

12:15PM V14.00006 Probing two-fluid hydrodynamics in a trapped Fermi superfluid at unitarity1, EDWARD TAYLOR2. ALLAN GRIFFIN, University of Toronto, HUI HU3, XIA-JI LIU, University of Queensland — We develop a variational approach to calculate the density response function at finite temperatures of the lowest-lying two-fluid dipole and breathing modes in a trapped two-component Fermi superfluid close to a Feshbach resonance. The out-of-phase oscillations, which are the analogue in trapped gases of second sound in uniform superfluids, have so far not been observed in cold-atom experiments. At unitarity, we show that these modes are observable at finite temperatures via two-photon Bragg scattering, whose spectrum is related to the imaginary part of density response function. This provides direct evidence for superfluidity and a promising way to test microscopic results for thermodynamics at unitarity. (arXiv:0709.0698, 0711.0561).

12:27PM V14.00007 Shear Viscosity and the Perfectness of Fluid. GAUTAM RUPAK, THOMAS SCHAFFER, North Carolina State University — A recent calculation of the shear viscosity for a unitary gas is presented. Here unitary gas is defined as a non-relativistic Fermi gas with infinite scattering length. The unitary gas is a scale invariant strongly-interacting many-body system, and possesses universal properties that are of interest across subfields in physics. A unitary gas can be realized in cold atomic gas experiments near a Feshbach resonance. Conditions approximating the unitary gas emerge in low energy nuclear physics as well. From general principle, the shear viscosity of a strongly interacting gas should be small, however, quantum mechanics places a lower bound. A strict lower bound indicating how “perfect” a fluid can become has been conjectured from calculations in strongly coupled field theories that have a gravity dual. We test this conjecture with an explicit calculation in a unitary gas, the most strongly interacting non-relativistic system experimentally known.

12:39PM V14.00008 Spectroscopic Signatures of Nonequilibrium Pairing in Atomic Fermi Gases1, MAXIM DZERO, Columbia University, EMIL YUZBASHYAN, Rutgers University, B.L. ALTSHULER, Columbia University, PIERS COLEMAN, Rutgers University — We present the results of a theoretical description of the radio-frequency (RF) spectra for non-stationary states of a fermionic condensate. These states can be produced by a rapid switch of the scattering length. We show that the RF spectrum of the nonequilibrium state with constant BCS order parameter has two features in contrast to equilibrium where there is a single peak. The additional feature reflects the presence of excited pairs in the steady state. In the state characterized by periodically oscillating order parameter RF-absorption spectrum contains two sequences of peaks spaced by the frequency of oscillations. Satellite peaks appear due to a process where an RF photon in addition to breaking a pair emits/absorbs oscillation quanta.

The work of M. D. and P. C. was supported by the DOE Grant No. DOE-DE02-00ER45790. E.Y. was supported by the Alfred P. Sloan Foundation and NSF Grant No. NSF-DMR-0547769.

12:51PM V14.00009 Mean Frequency Shift and Finite Width of RF Spectrum of Paired Fermions, ZHENHUA YU, Department of Physics, University of Illinois, 1110 W. Green Street, Urbana, IL 61801 — Using sum rules we derived the mean frequency shift of the rf spectrum of paired fermions in terms of the derivative of free energy, and explained many features of experiments done at the unitarity point between the lowest hyperfine states of $^6$Li. The calculated mean shifts are however some three times larger than the peak shift observed at the center of the trapped atomic cloud, a discrepancy due to the long tail of the spectrum. Generating the rf spectrum function self-consistently within BCS-Hartree-Fock, we have determined the characteristic frequency where the behavior of the spectrum transits from $\omega^{-3/2}$ to $\omega^{-5/2}$ at large frequency. We discuss how to subtract out the long tail from the spectrum and give an improved estimate for the peak frequency shift from the sum rules.

1:03PM V14.00010 Final-state effects in radio-frequency spectrum of ultracold Fermions, SOURISH BASU, ERICH MUELLER, Cornell University — We model the effects of final-state interaction on the radio-frequency spectrum of a two-component superfluid Fermi gas near resonance. We show how the spectrum evolves as one tunes from weak to strong interactions. Aside from the continuum resulting from the breaking of Cooper pairs, for certain interaction strengths, we predict a sharp peak resulting from converting a pair in one channel to a pair in another channel.

1:15PM V14.00011 Molecular production at a broad Feshbach resonance in Fermi-gas of cooled atoms, DEQIANG SUN, ARTEM ABANOV, VALERY POKROVSKY, Texas A&M University — The problem of molecular production from a degenerate gas of fermions at a broad Feshbach resonance, in a single-mode approximation, is reduced to the linear Landau-Zener problem for operators. The strong interaction leads to significant renormalization of the gap between adiabatic levels. In contrast to the static problem, the close vicinity of the exact resonance does not play a substantial role. The two main physical results are: i) The molecular production is sensitive to the initial magnetic field. ii) In the inverse process of molecule dissociation a large BCS condensate distributed over a broad range of momenta is generated.

1:27PM V14.00012 Bistability in Resonant Fermi Superfluid1, LEI JIANG, HAN PU, Rice University, ANDREW ROBERTSON, HONG LING, Rowan University — The resonant two-channel Fermi superfluid model can be mapped to a quantum optics model that describes a single-mode laser field, subject to Kerr nonlinearity, interacting with an ensemble of inhomogeneously broadened two-level atoms. Using this analogy, we show that under proper conditions bistability will occur in resonant Fermi superfluids, a matter wave analog of a similar phenomenon encountered in nonlinear optical systems.

1This work is supported by NSF, ARO and the Welch Foundation.
1:39PM V14.00013 Collective spin modes in a Fermionic atomic gas , JOHN FELDMANN, HARI DAHAL, Boston College, SERGIO GAUDIO, University of Rome La Sapienza, KEVIN BEDELL, Boston College — We present our theoretical findings on the structure of the spin mode dispersion of a spin-population-imbalanced Fermionic atomic gas in the highly degenerate regime, but above the superfluid critical temperature, near a Feshbach resonance. We employ standard Fermi liquid theory to describe a gas consisting of two species of spin, up and down, existing in an external magnetic field, which models an atom gas of $^6$Li atoms in the two lowest Zeeman states. The spin population imbalance creates a net magnetization, and as a result, the transverse magnetization propagates through the system. We find that a diverging scattering length, as occurs near a Feshbach resonance, affects the phenomenological Landau parameters of the system, whose relation to the scattering length is described by the induced interaction model, and thus in turn affects the structure of the collective spin modes, as well.

11:15AM V15.00001 The structure of preserved information in quantum processes , HUI KHOONG NG, Caltech, ROBIN BLUME-KOHOUT, Perimeter Institute, DAVID POULIN, Caltech, LORENZA VIOLA, Dartmouth College — We present a general operational framework for characterizing the types of information that can be preserved by a quantum process. We demonstrate that information preserving structures (IPS) – encompassing noiseless subsystems, decoherence-free subspaces, pointer bases, and error-correcting codes – are isometric to fixed points of unital quantum processes. This implies that every IPS is a matrix algebra. A structure theorem for fixed points of an arbitrary process further provides a simple and efficient algorithm for finding all noiseless and unitarily noiseless IPS for any quantum process. This framework can be extended to study the structure of approximately preserved information.

11:27AM V15.00002 Decoherence-free subspaces and incoherently generated coherences, RAISA KARASKI, BQIC and Applied Science & Technology, University of California, Berkeley, KARL-PETER MARZLIN, BARRY C. SANDERS, IQIS, University of Calgary, KIRIGITTA WHALEY, BQIC and Dept. of Chemistry, University of California, Berkeley — A decoherence-free subspace (DFS) is a collection of states that is immune to the dominant noise effects created by the environment. DFS is usually studied for states involving two or more particles and is considered a prominent candidate for quantum memory and quantum information processing. We present rigorous criteria for the existence of DFS in finite-dimensional systems coupled to the Markovian reservoirs. This allows us to identify a new special class of decoherence-free states that relies on rather counterintuitive phenomenon, which we call an “incoherent generation of coherences.” We provide examples of physical systems that support such states.

11:39AM V15.00003 Methods for Producing Decoherence-free States and Noiseless Subsystems Using Photonic Qutrits, C. ALLEN BISHOP, MARK BYRD, Physics Department, Southern Illinois University Carbondale — We outline a proposal for a method of preparing a single logically encoded two-stage system (qubit) that is immune to collective noise acting on the Hilbert space of the particles supporting it. The logical qubit is comprised of three photonic 3-state systems (qutrits) and is generated by the process of spontaneous parametric downconversion. The states are constructed using linear optical elements along with three down-conversion sources, and are deemed successful by the simultaneous detection of six events. We also show how to select a maximally entangled state of two qutrits by similar methods. For this maximally entangled state we describe conditions for the state to be decoherence-free which do not correspond to collective errors, but which have a precisely defined relationship between them.

1Supported by the NSF through grant No. 0545798 to MSB.

11:51AM V15.00004 Bounded-strength dynamical control of qubit coherence based on Eulerian cycles, LEA F. SANTOS, Yeshiva University, TAYLOR S. SMITH, WENXIAN ZHANG, LORENZA VIOLA, Dartmouth College — Decoherence and faulty controls are two of the primary obstacles to realize scalable quantum information processing. Here, we investigate dynamical decoupling (DD) techniques for dynamical control and decoherence suppression in the limit of low-power faulty control, using the approach of Eulerian DD introduced in L. Viola and E. Knill, Phys. Rev. Lett. 90, 037901 (2003). By focusing on the illustrative case of single-qubit DD, we identify scenarios where naive transcriptions of bang-bang sequences with finite pulses are outperformed by the Eulerian method – both in terms of DD fidelity and robustness against systematic errors. Results on Eulerian decoherence control in solid-state qubit devices are presented.

1Supported in part by the NSF through grant No. PHY-0555417 and by the DOE through contract No. DE-AC02-07CH11358.

12:03PM V15.00005 Model-independent dynamical decoupling to combat dephasing decoherence, WAYNE WITZEL, BENJAMIN LEE, SANKAR DAS SARMA, University of Maryland, College Park — We present a remarkable finding that a recently [1] discovered series of pulse sequences, designed to optimally restore coherence to a qubit in the spin-boson model of decoherence, is in fact completely model-independent and generically valid for arbitrary dephasing Hamiltonians given sufficiently short delay times between pulses [2]. The series is optimal in that fidelity is maximized for a given number of applied pulses. This is true for sufficiently short delay times because the series, with each pulse, cancels successive orders of a time expansion for the decay of qubit fidelity. Surprisingly, this property is independent of the model of the bath that induces dephasing-type decoherence. For this to be true, a linearly growing set of “unknowns” (the delay times) simultaneously satisfy an exponentially growing set of non-linear equations. This is an unexpected and miraculous property of nature and mathematics. [1] G. S. Uhrig, Phys. Rev. Lett. 98, 100504 (2007). [2] B. Lee, W. M. Witzel, S. Das Sarma, arXiv:0710.1416.

12:15PM V15.00006 Encoding One Logical Qubit Into Six Physical Qubits, BILAL SHAW, MARK WILDE, OGNYAN ORESHKOV, ISAAC KREMSKY, DANIEL LIDAR, University of Southern California — We discuss several methods to protect one qubit against single-qubit errors by encoding it into six physical qubits. We first present a degenerate six-qubit quantum error-correcting code. We explicitly provide the stabilizer generators, encoding circuit, codewords, logical Pauli operators, and logical CNOT operator for this code. We then prove that a six-qubit code cannot simultaneously possess a Calderbank-Shor-Steane stabilizer and correct arbitrary single-qubit errors. We finally construct a six-qubit non-degenerate entanglement-assisted quantum error-correcting code that uses one bit of entanglement shared between the sender and the receiver. We discuss the advantages and disadvantages for each of our six-qubit quantum error-correcting codes.
12:27PM V15.00007 Second-order self-refocusing pulse shapes for arbitrary rotation angles, LEONID P. PRYADKO, University of California, Riverside, PINAKI SENGUPTA, Los Alamos National Laboratory — We construct several families of high-precision 1st- and 2nd-order self-refocusing pulse shapes for rotation angles $\alpha = 0^\circ, 10^\circ, \ldots, 360^\circ$. To characterize their performance, we show that for an arbitrarily-coupled qubit driven by a general one-dimensional symmetric pulse shape, in addition to the net rotation angle, the second-order average Hamiltonian is defined by three parameters. Our 1st- and 2nd-order self-refocusing pulses respectively have one or two of these equal to zero, which makes them useful as a drop-in replacement for hard pulses. We illustrate this by analyzing several commonly-used composite pulses in terms of the average Hamiltonian theory. The results are in an excellent agreement with numerical simulations.

1This research was supported in part by the NSF grant No. 0622242 (LP)

12:39PM V15.00008 Encoded Dynamical Recoupling with Shaped Pulses, YUNFAN LI, University of California, Riverside, DANIEL A. LIDAR, University of Southern California, LEONID P. PRYADKO, University of California, Riverside — Encoded Dynamical Recoupling is a passive error correction technique which can be used to enhance the performance of a quantum error correction code (QECC) against low-frequency component of the thermal bath. The elements of the stabilizer group are used in the decoupling cycle which makes the encoded logic operations fault-tolerant. We studied the effectiveness of this technique both analytically and numerically for several three- and five-qubit codes, with decoupling sequences utilizing either Gaussian or self-refocusing pulse shapes. When logic pulses are intercalated between the decoupling cycles, the technique may be very effective in cancelling constant perturbation terms, but its performance is much weaker against a time-dependent perturbation simulated as a classical correlated noise. The decoupling accuracy can be substantially improved if logic is applied slowly and concurrently with the decoupling, so that a certain adiabaticity condition is satisfied.

12:51PM V15.00009 Generating Novel Spin Echoes Using the Internal Structure of Strong Pi-Pulses, YANQUN DONG, RONA RAMOS, DALE LI, SEAN BARRETT, Yale University — Conventionally, strong pulses used to control coherent evolution are approximated as instantaneous, perfect rotations. However, recent experiments have shown a surprising departure from the conventional theory in standard multipulse NMR experiments using strong pi-pulses. Using our understanding of the role that the finite time duration of any real pulse plays in these effects, we design and experimentally demonstrate new classes of spin echoes.

1:03PM V15.00010 A New Approach to Spin Coherence Control: Extreme Line-narrowing and MRI of Solids, YANQUN DONG, RONA RAMOS, DALE LI, SEAN BARRETT, Yale University — The non-zero duration of strong pulses has been shown to have surprisingly large effects in important NMR experiments. The Hamiltonian terms arising from the internal structure of strong pulses provide us with a new technique of spin coherence control. Using this technique, we design and demonstrate new approaches to line-narrowing and magnetic resonance imaging of solids.

1:15PM V15.00011 Robustness of operator quantum error correction against imperfect initialization, OGVYAN ORESHKOV, University of Southern California — It is known that perfect unitary evolution inside decoherence-free subspaces and line-narrowing and magnetic resonance imaging of solids. Also, we present a scheme for performing state preparation, which is the mapping a fiducial state to an arbitrary target state, and show simulations that drop-in replacement for hard pulses. We illustrate this by analyzing several commonly-used composite pulses in terms of the average Hamiltonian theory. The results are in an excellent agreement with numerical simulations.

1:27PM V15.00012 Quantum Convolutional Coding with Entanglement Assistance, MARK WILDE, TODD BRUN, University of Southern California — We have recently developed quantum convolutional coding techniques for both entanglement distillation and quantum error correction. These techniques assume that the two parties participating in the communication protocols possess prior shared entanglement. Using these methods, we can import arbitrary classical binary or quaternary convolutional codes for use in quantum coding, with no requirement that these codes be self-orthogonal. Moreover, high-performance classical convolutional codes lead to high-performance quantum convolutional codes. We explicitly show how a convolutional entanglement distillation protocol operates, and how to encode and decode a stream of quantum information in an entanglement-assisted quantum convolutional code.

1Support from NSF Grants CCF-0545845 and CCF-0448658.

1:39PM V15.00013 “Slow” and “Fast” Gate Limits In Resilient Quantum Computation, EDUARDO NOVAIS, Duke University, EDUARDO R. MUCCHIOLO, University of Central Florida, HAROLD U. BARANGER, baranger@phy.duke.edu — In the study of resilient quantum computation, there are two common approaches to proving the threshold theorem: one either uses a stochastic error model or uses the operator norm to bound the effects of the noise. In many cases, the underlying microscopic Hamiltonian is hidden due to the rapidly growing complexity of the problem. In particular, the microscopic interacting Hamiltonian in the interaction picture depends on the quantum code and its implementation. Nevertheless, there are two possible ways to keep the discussion code independent. The first situation is to imagine very fast gates acting on the system. The second is to derive an upper bound on the effects of correlations by deriving an effective model. In this talk we discuss these two limits, focusing on how to derive the effective model for “slow gates”.

1This work was supported in part by NSF grants No. CCF 0523509 and No. CCF 0523603. E.R.M. acknowledges partial support from the Interdisciplinary Information Science and Technology Laboratory (12Lab) at UCF.

1:51PM V15.00014 Optimal Control of Large Spin-Atomic Systems with Coherent Electromagnetic Fields, SETH MERKEL, University of New Mexico, SOUMA CHAUDHURY, POUL JESSEN, University of Arizona, IVAN DEUTSCH, University of New Mexico — Cold atomic systems provide an excellent testing ground for quantum control protocols due to the isolation of these systems from their environment and the availability of high precision fields from the “quantum optics toolbox”. In this talk, we look at controlling the sixteen dimensional ground state hyperfine manifold of $^{133}\text{Cs}$ through microwaves and rf-magnetic fields. These controls allow for essentially coherent manipulation of a system that is large enough to exhibit non-trivial dynamics. In particular, we analyze the controllability of this system under different combinations of applied electromagnetic fields. Also, we present a scheme for performing state preparation, which is the mapping a fiducial state to an arbitrary target state, and show simulations that examine the performance of these state preparation protocols.

1This research was supported by NSF Grants No. PHY-0355073 and No. PHY-0355040, ONR Grant No. N00014-05-1-420, and DTO Grant No. DAAD19-13-R-0011.
2:03PM V15.00015 Towards a Quantum Predictive Control Mathematical Formulation, YASSER A. DAVIZON-CASTILLO, Department of Electrical Engineering, Arizona State University — Quantum Feedback Control presents an interdisciplinary research work between Control Theory and Quantum Physics. A novel mathematical formulation is presented for Quantum Predictive Control (QPC) algorithm, based on Receding Horizon Control philosophy at the quantum level. The application of Heisenberg Uncertainty Principle, to quantify the uncertainty in position and momentum, in a real-time control framework is introduced. An estimate of the Sampling Time at quantum level is demonstrated, applying to a case of study for a double well quantum system using the QPC algorithm.

Thursday, March 13, 2008 11:15AM - 2:15PM —
Session V16 DBP: Focus Session: Medical Imaging and Related Technologies Morial Convention Center 208

11:15AM V16.00001 Overview of Medical Imaging, WILLIAM HENDEE, Medical College of Wisconsin — The use of radiation probes to image tissues in the human body has progressed through an extraordinary evolution in the past three decades. Beginning with transmission computed tomography in the 1970s, this evolution has included real-time ultrasound, emission computed tomography, magnetic resonance imaging, and digital radiography. These advances have recently yielded major improvements in imaging such as multi-detector transmission computed tomography, functional magnetic resonance imaging, dual imaging modalities built on a common platform, and image-guided intervention. These improvements and others have accelerated the usefulness of imaging methods in the early detection, definitive diagnosis, and effective intervention of a wide spectrum of diseases and disabilities. They also have led to increases in radiation doses to patients and the population, an issue of major concern to physicists and physicians. At this time there are four major frontiers for research in medical imaging: (1) molecular imaging; (2) functional imaging; (3) multi-modality imaging; and (4) information management. These research frontiers, together with the use of sophisticated imaging technologies in clinical practice, offer rich professional opportunities for physicists.

11:51AM V16.00002 PET Imaging - from Physics to Clinical Molecular Imaging, STAN MAJIEWSKI, Thomas Jefferson National Accelerator Facility — From the beginnings many years ago in a few physics laboratories and first applications as a research brain function imager, PET became lately a leading molecular imaging modality used in diagnosis, staging and therapy monitoring of cancer, as well as has increased use in assessment of brain function (early diagnosis of Alzheimer’s, etc) and in cardiac function. To assist with anatomic structure map and with absorption correction CT is often used with PET in a duo system. Growing interest in the last 5-10 years in dedicated organ specific PET imagers (breast, prostate, brain, etc) presents again an opportunity to the particle physics instrumentation community to contribute to the important field of medical imaging. In addition to the bulky standard ring structures, compact, economical and high performance mobile imagers are being proposed and build. The latest development in standard PET imaging is introduction of the well known TOF concept enabling clearer tomographic pictures of the patient organs. Development and availability of novel photodetectors such as Silicon PMT immune to magnetic fields offers an exciting opportunity to use PET in conjunction with MRI and fMRI. As before with avalanche photodiodes, particle physics community plays a leading role in developing these devices. The presentation will mostly focus on present and future opportunities for better PET designs based on new technologies and methods: new scintillators, photodetectors, readout, software.

12:27PM V16.00003 Room temperature STM imaging in air can damage DNA, even at low tunneling biases and currents1, JOHN BECHHOEFER, PHILIP GRANT, YUEKAN JIAO2, Simon Fraser University — STM images of DNA molecules in air or vacuum at room temperature have been plagued by problems of reproducibility. These difficulties have usually been ascribed to substrate artifacts or tip-related effects. However, the recent discovery that low-energy electron beams cause single-strand breaks in DNA suggests that the tunneling electrons used for STM imaging can damage DNA similarly and could be responsible for many imaging problems. Here, we provide experimental support for such a conclusion. Collecting images from an STM that simultaneously detects light-emission from the tip region, we show that the observed DNA structure changes after the first scan. The organic debris from the DNA quenches the light emission from surface plasmons on the gold substrate. Next, we use an atomic force microscope (AFM) whose stiff tip can be used both for tapping-mode AFM and for STM imaging modes. We assess STM-induced damage by re-imaging the same area in tapping-mode AFM. The bias-dependent change in DNA film thickness correlates with the previously observed rate of DNA strand breaks caused by low-energy electron beams of different energies.

1:03PM V16.00006 Advances in Medical X-Ray Imaging, ROBERT GOULD, University of California San Francisco — No abstract available.

1:22PM V15.00011 Imaging of biological interfaces at the nanoscale, OSCAR MESQUITA, Physics Department, Federal University of Minas Gerais — Transparent objects can render visible in a standard bright-field microscope by slightly defocusing the microscope objective. From contrast fluctuations of images defocused in a controlled way one can measure the fluctuation spectrum of biological membranes and living cells surfaces. We extended our previous defocusing theory, valid for small defocusings, to arbitrarily large defocusings. We discovered that we can measure height fluctuations of transparent interfaces selectively, and obtain elastic properties of layered biological membranes separately. As an example, we measured separately the elastic constants associated with the two opposite surfaces of a red blood cell. The technique is very sensitive and allows us to measure the small increase of surface tension on the surface in contact with the glass-slide, as compared to the one of the free surface. Interface roughness (static and dynamic), down to nanometer amplitudes, can be measured selectively with defocusing microscopy in transparent layered materials.

12:39PM V16.00004 Tomography of biological interfaces using defocusing microscopy, OSCAR MESQUITA, Physics Department, Federal University of Minas Gerais — Transparent objects can render visible in a standard bright-field microscope by slightly defocusing the microscope objective. From contrast fluctuations of images defocused in a controlled way one can measure the fluctuation spectrum of biological membranes and living cells surfaces. We extended our previous defocusing theory, valid for small defocusings, to arbitrarily large defocusings. We discovered that we can measure height fluctuations of transparent interfaces selectively, and obtain elastic properties of layered biological membranes separately. As an example, we measured separately the elastic constants associated with the two opposite surfaces of a red blood cell. The technique is very sensitive and allows us to measure the small increase of surface tension on the surface in contact with the glass-slide, as compared to the one of the free surface. Interface roughness (static and dynamic), down to nanometer amplitudes, can be measured selectively with defocusing microscopy in transparent layered materials.

12:51PM V16.00005 Terahertz spectroscopy of human skin constituents in suspension, CECIL JOSEPH, Submillimeter-Wave Technology Laboratory, University of Massachusetts Lowell, ANNA YAROLOSLAVSKY, MUNIR AL-ARASHI, Harvard Medical School, Massachusetts General Hospital, ANDREW GATESMAN, THOMAS GOYETTE, ROBERT GILES, Submillimeter-Wave Technology Laboratory, University of Massachusetts Lowell — Continuous wave terahertz imaging has the potential to offer a non-invasive medical imaging modality for detecting different types of human cancers. The aim of this study was to identify frequencies of interest for continuous wave terahertz imaging of skin cancer. The absorption characteristics of water, collagen, and elastin were studied in the range between 20 and 100cm⁻¹. In addition, we have recorded and analyzed the terahertz absorption spectra of several substances that are present in human skin (i.e. tryptophan, tyrosine, melanin, urocanic acid, keratin) and their water suspensions with the goal of using them as biomarkers for skin cancer detection.

11:15AM V17.00001 Beyond the second law. , CHRISTIAN VAN DEN BROECK, Hasselt University — According to the second law, the work needed to bring a system from one state to another one, when in contact with a heat bath, is at least equal to the difference in free energies of these states. By a refinement of the work theorem, we derive an exact microscopic expression for the extra dissipation. It is expressed in terms of the relative entropy of the phase space density. Furthermore, lower bounds for the extra dissipation are obtained when only limited information is available. The result is illustrated on various Hamiltonian and stochastic models. The connection to the thermodynamics of computation is briefly discussed. Ref R. Kawai, JMR. Parrondo and C. Van den Broeck, Phys Rev Lett 98, 080602 (2007)

11:51AM V17.00002 Dynamics of Microtubule Growth and Catastrophe1 — SIDNEY REDNER, Boston University, TIBOR ANTAL, Harvard University, PAUL KRAPIVSKY, Boston University, MITCH MAILMAN, BULBUL CHAKRABORTY, Brandeis University — We investigate a simple dynamical model of a microtubule that evolves by attachment of guanosine triphosphate (GTP) tubulin to its end, irreversible conversion of GTP to guanosine diphosphate (GDP) tubulin by hydrolysis, and detachment of GDP at the end of a microtubule. As a function of rates of these processes, the microtubule can grow steadily or its length can fluctuate wildly. In the regime where detachment can be neglected, we find exact expressions for the tubulin and GDP concentrations. The extension of the microtubule is a random walk where the increment is a step-wise. We extract the diffusion constant and the natural frequencies of oscillation (30-200 Hz) from the time-resolved displacement traces. A microindentation apparatus was used to measure the Young’s moduli of the samples for validation and calibration with the MMOCE measurements. This novel real-time non-invasive technique affords the potential for in vivo studies.

12:03PM V17.00003 Work fluctuations in modulated systems: what is and what is not universal in the steady state , MARK DYKMAN, Michigan State University — We study work fluctuations in periodically modulated nonlinear systems. Such systems often have coexisting stable periodic states. Furthermore, lower bounds for the extra dissipation are obtained when only limited information is available. The result is illustrated on various Hamiltonian and stochastic models. The connection to the thermodynamics of computation is briefly discussed. Ref R. Kawai, JMR. Parrondo and C. Van den Broeck, Phys Rev Lett 98, 080602 (2007)

12:15PM V17.00004 Recognizing the role of microscopic reversibility in stochastic systems with optical trapping experiments as an example , ROSS BRODY, University of Maine — With optical tweezer experiments it is possible to confine a particle and observe its Brownian motion in a region of known potential. Recognizing that microscopic reversibility can lead to interesting relationships involving the particle’s motion, for example, the ratio of the conditional probability of making a transition between two points with its spatial reverse is equal to the difference between Boltzmann factors (e−ΔU/kBT), or that the time to make an up-down transition is identical to the time to make a down-up transition. With these relationships in mind, and the Onsager-Machlup action description of a path, we consider a particle in an optical tweezer of varying strength and investigate relationships involving the conditional probabilities, the actions associated with specific paths, and the external work done by varying the strength of the trap.
12:27PM V17.00005 What Do We Measure With Single-Molecule Force Spectroscopy? , CHING-HWA KIANG, NOLAN HARRIS, ERIC BOTELLO, WEI-HUNG CHEN, Rice University — Single-molecule force spectroscopy is a powerful technique for studying detailed intra- and inter-molecular interactions by manipulating single biomolecules at the nanometer scale. Force is measured while one pulls on the molecules. However, relating the measured information to equilibrium thermodynamic properties is challenging. Jarzynski’s equality allows one to reconstruct the free energy surface as a function of molecular end-to-end distance. Using protein folding as an example, we studied the parameters that influence the unfolding process, such as pulling velocity, temperature, and chemical denaturant concentration, in the solution, to demonstrate that valuable equilibrium thermodynamic information can be extracted from this technique. 1. N. C. Harris, V. Song, and C.-H. Kiang, Phys. Rev. Lett., 99 068101 (2007). 2. “Pulling Strings: Stretching Proteins Can Reveal How They Fold,” Science News, 172 22 (2007).

12:39PM V17.00006 Holographic microrheology of biofilms, FOOK CHIONG CHEONG, SIMONE DUARTE, DAVID GRIER, New York University — We present microrheological measurements of polymeric matrices, including the extra-cellular polysaccharide gel synthesized by the dental pathogen S. mutans. As part of this study, we introduce the use of precision three-dimensional particle tracking based on video holographic microscopy. This technique offers nanometer-scale resolution at video rates, thereby providing detailed information on the gels’ complex viscoelastic moduli, including insights into their heterogeneity. The particular application to dental biofilms complements previous studies based on macroscopic rheology, and demonstrates the utility of holographic microrheology for soft-matter physics and biomedical research.

12:51PM V17.00007 Fluctuation relations in a micromechanical oscillator driven far from thermal equilibrium , COREY STAMBAUGH, HÔ BUN CHAN, University of Florida — We explore fluctuation relations in a micromechanical torsional oscillator. In the linear regime when the modulation is weak, we verify that the ratio of the work variance to the mean work is independent of the driving frequency, consistent with standard fluctuation relations for a steady state system near thermal equilibrium. We then apply a strong drive to force the system into nonlinearity. Here the system displays bistability and the relationship between the work and variance is expected to deviate from the linear regime. For a bistable system the total variance has two distinct contributing components. The first results from small fluctuations about a stable state. The work variance is expected to diverge as the system approaches the bifurcation point where the state diagram changes. The other part of the variance results from the system switching between coexisting states. This part of the variance is expected to show a sharp peak near the kinetic phase transition when the populations of the two states are comparable. We compared our experimental results to theoretical predictions that distinguish nonlinear oscillators from equilibrium systems.

1:03PM V17.00008 Effect of charge distribution on the translocation of an inhomogeneously charged polymer through a nanopore , ARUNA MOHAN, ANATOLY KOLOMEISKY, MATTEO PASQUALI, Rice University — We investigate the voltage-driven translocation of an inhomogeneously charged polymer through a nanopore by utilizing discrete and continuous stochastic models. As a simplified illustration of the effect of charge distribution on translocation, we consider the translocation of a polymer with a single charged site in the presence and absence of interactions between the charge and the pore. We find that the position of the charge that minimizes the translocation time in the absence of pore-polymer interactions is determined by the entropic cost of translocation, with the optimum charge position being at the midpoint of the chain for a rodlike polymer and close to the leading chain end for an ideal chain. The presence of attractive or repulsive porecharge interactions yields a shift in the optimum charge position towards the trailing end and the leading end of the chain, respectively. Moreover, our results show that strong attractive or repulsive interactions between the charge and the pore lengthen the translocation time relative to translocation through an inert pore. We generalize our results to accommodate the presence of multiple charged sites on the polymer. Our results provide insight into the effect of charge inhomogeneity on protein translocation through biological membranes.

1:15PM V17.00009 Heat Transport in spin chains, JINSHAN WU, MONA BERCIU, UBC — The Projection operator technique, usually used to study the relaxation toward thermal equilibrium, is extended to investigate non-equilibrium but stationary processes. Particularly, in this work we apply it to study heat transport in short spin chains with Heisenberg, anisotropic Heisenberg and XY couplings plus a large magnetic field. One long-standing question is under what circumstance the relation between heat and energy is expected to deviate from the linear regime.

1:27PM V17.00010 Athermal dynamics of strongly coupled stochastic three-state oscillators, LEV TSIMRING, UCSD, BASTIEN FERNANDEZ, University of Marseille — We study the collective behavior of a globally coupled ensemble of N cyclic stochastic three-state systems with rates of transition from state i − 1 to state i proportional to the number of systems already in state i. While the mean field theory predicts only decaying oscillations in this system, direct numerical simulations indicate that the mean field exhibits stochastic oscillations even in the large N limit. We characterize the regularity of oscillations by the coherence parameter which has a well-defined maximum at the coupling constant of order 1. In contrast, the order parameter characterizing the level of synchrony among oscillators, increases monotonically with the coupling strength. We derive the exact solution of the full master equation for the stationary probability distribution and find the analytical expression for the order parameter.

1:39PM V17.00011 Entropy-driven hysteresis in a model of DNA overstretching, STEPHEN WHITE-LAM, University of Warwick, SANDER PRONK, PHILLIP GEISSLER, UC Berkeley — When pulled along its axis, double-stranded DNA elongates abruptly at a force of about 65 pN. Two physical pictures have been developed to describe this overstretched state. The first proposes that strong forces induce a phase transition to a molten state consisting of unhybridized single strands. The second picture instead introduces an elongated hybridized phase, called S-DNA, structurally and thermodynamically distinct from standard B-DNA. Little thermodynamic evidence exists to discriminate directly between these competing pictures. Here we show that within a microscopic model of DNA we can distinguish between the dynamics associated with each. In experiment, considerable hysteresis in a cycle of stretching and shortening develops as temperature is increased. Since there are few possible causes of hysteresis in a system whose extent is appreciable in only one dimension, such behavior offers a discriminating test of the two pictures of overstretched. Most experiments are performed upon nicked DNA, permitting the detachment (‘unpeeling’) of strands. We show that the long-wavelength motion accompanying strand separation generates hysteresis, the character of which agrees with experiment only if we assume the existence of S-DNA.

1:51PM V17.00012 Replica and extreme-value analysis of the Jarzynski free-energy estimator, MATTEO PALASSINI, FELIX RITORT, Department of Fundamental Physics, University of Barcelona — We analyze the Jarzynski estimator of free-energy differences from nonequilibrium work measurements. By a simple mapping onto Derrida’s Random Energy Model, we obtain a scaling limit for the expectation of the bias of the estimator. We then derive analytical approximations in three different regimes of the scaling parameter x = log(N)/W, where N is the number of measurements and W the mean dissipated work. Our approach is valid for a generic distribution of the dissipated work, and is based on a replica symmetry breaking scheme for x ∝ 1, the asymptotic theory of extreme value statistics for x ≳ 1, and a direct approach for x near one. The combination of the three analytic approximations describes well Monte Carlo data for the expectation value of the estimator, for a wide range of values of N, from N=1 to large N, and for different work distributions. Based on these results, we introduce improved free-energy estimators and discuss the application to the analysis of experimental data.
Ib-PS field effect transistor at various temperatures. We show that the current voltage characteristic at different temperatures follow SCLC type conduction. In this talk we present electronic transport characteristics of poly(3-hexylthiophene) block poly(styrene) copolymer (rr-P3HT). To properly utilize these new types of materials it is necessary to understand the relationship between their molecular structure and electronic transport properties of rr-P3HT. Previous studies have shown that symmetric PSS-PMB block copolymers in the presence of humid air (relative humidity > 50%) are excellent proton conductors at temperatures as high as 90°C. Current work is focused on water uptake and conductivity measurements on asymmetric PSS-PMB block copolymers with PSS as the minor component.

1 The primary author of this paper is Moon Jeong Park. This work was supported by the Office of Basic Energy Sciences of the USDOE.

12:03PM V18.00003 Temperature dependent charge transport properties of poly(3-hexylthiophene) block poly(styrene) copolymer field-effect transistor, Firoze Haque, Paul Stokes, Lei Zhai, Saiful I. Khondaker, Nanoscience Technology Center, Departments of Physics and Chemistry, University of Central Florida Team — Regioregular poly-3-hexylthiophene (r-P3HT) is considered to be one of the most promising and well studied organic semiconductors. Recently attention has been focused on developing di-block copolymers of rr-P3HT by attaching non-conjugated blocks which allows one to tune the electrical properties of rr-P3HT. To properly utilize these new types of materials it is necessary to understand the relationship between their molecular structure and electronic transport properties. In this talk we present electronic transport characteristics of poly(3-hexylthiophene) block poly(styrene) copolymer (r-P3HT-b-PS) field effect transistor at various temperatures. We show that the current voltage characteristic at different temperature follow SCLC type conduction mechanism with $I \propto V^n$, where $n$ varies from 1.5 to 2.2. We also show that the room temperature hole mobility is $\sim 3.5 \times 10^{-5}$ cm$^2$/Vs, and that the mobility decreases with decreasing temperature. The temperature dependent mobility follow activated hopping process. The space charge limited current along with the low mobility of the devices indicates that the charge transport is limited by the insulating poly styrene segment of the di-block polymer.

1 The authors thank Kraton LLC and Dexcel for copolymer samples. Major support for these studies from the National Science Foundation Materials Research Science & Engineering Center (DMR 0213883 - USM) and NSF MRSEC DMR 0213985 (UA) is acknowledged.
12:27PM V18.00005 The Lyotropic Phase Behavior of Diblock Copolymers Swollen with Ionic Liquids. PETER SIMONE, University of Minnesota Department of Chemistry, TIMOTHY LODGE, University of Minnesota Department of Chemistry and Department of Chemical Engineering and Materials Science — The lyotropic phase behavior of poly(1,2-butadiene-co-ethylenoxide) (PB-PEO) has been studied upon addition of two ionic liquids, 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([EMI][TFSI]) and 1-butyl-3-methylimidazolium hexafluorophosphate ([BMI][PF6]). The copolymer/ionic liquid samples ranged from dilute to concentrated, and were characterized via small angle X-ray scattering (SAXS) and cryogenic transmission electron microscopy (cryo-TEM). At moderate to high concentrations, SAXS patterns corresponding to the classical copolymer microstructures of body-centered cubic lattices of spheres, hexagonally packed cylinders, and lamellae were observed. Additionally, at several concentrations, coexisting microstructures and what is thought to be a disordered network microstructure were observed. At low concentration, the morphology of the block copolymer micelles (i.e., spheres, cylinders, and vesicles) was used as a qualitative gauge of the ionic liquid solvent quality, and it was concluded that for PB-PEO, [BMI][PF6] behaves as a more selective solvent than [EMI][TFSI].

12:39PM V18.00006 Structure and Thermodynamics of Block Copolymers Doped with Ionic Liquids. J.M. VIRGILI, N.P. BALSARA, R.A. SEGALMAN, University of California, Berkeley — Incorporation of ionic liquids into block copolymers is of interest for applications such as high temperature fuel cell membranes and polymer processing. These applications take advantage of ionic liquids' attractive physicochemical properties, such as low vapor pressure and high thermal stability. We investigate the structure and thermodynamics of poly(styrene-b-2-vinylpyridine) (PS-PVP) block copolymers doped with an ionic liquid consisting of imidazole and bis(trifluoromethanesulfonyl)amide (HFTSI). Using small angle X-ray scattering (SAXS), we demonstrate that increased ionic liquid doping leads to swelling of lamellar nanodomains in a symmetric PS-PVP block copolymer. At high ionic liquid loadings, we observe break up of the lamellar domains into hexagonally perforated lamellae. We characterize the effect of ionic liquid loading on the order-disorder transition (ODT) temperature of PS-PVP. We observe depression of the PS-PVP ODT temperature with increasing loading of the ionic liquid.

12:51PM V18.00007 Controlling the morphology of liquid crystalline block copolymers: interfacial and liquid crystal content effects. ERIC VERPOELEN, TEJIA ZHANG, PAULA HAMMOND, MIT — By systematically controlling the covalent attachment of side chain liquid crystals to a block copolymer backbone, the morphology of both the liquid crystalline (LC) mesophase and the phase segregated BCP microstructures can be precisely manipulated. A wide range of morphologies can be achieved from a single block copolymer backbone during a one step LC attachment reaction. The anchoring of the smectic LC mesophase to the inter-molecular dividing surface (IMDS) is a key driving force in determining the morphologies for both the bulk and in thin films. In thin films the orientation of the morphology is determined by the minimization of the surface energy with the substrate and air interfaces and the anchoring of the LC mesophase to the substrate. These competing effects can be utilized to manipulate the orientation of as-cast and thermally annealed thin films. Additionally, by controlling the LC content, the mechanical properties of this system can be tailored over a several orders of magnitude. The tune-ability demonstrated in this system will allow for custom design and tailoring of material properties for specific applications such as electromechanical and mechno- optical devices.

1:03PM V18.00008 Self-assembly of side chain liquid crystalline block copolymers. MANAS SHAH, VICTOR PYRAMITSYN, VENKAT GANESAN, University of Texas at Austin — We present a new model based on self-consistent field theory (SCFT) approach to characterize the self assembly behavior in side-chain liquid crystalline block copolymers. Our model considers a micromechanical representation of flexible coil-coil diblock copolymers, with rod-like units grafted to one of the blocks. We present results which elucidate self-assembly arising from the interplay between block copolymer microphase separation and the orientational ordering of the rod segments. Our numerical results are in very good agreement with reported experimental observations. Many of the traditional flexible diblock copolymer microphases are also predicted to occur for side chain liquid crystalline copolymers, with smectic ordering accompanying within the microphases. The equilibrium phase morphologies are observed to depend on the molecular weight of the copolymer, the length of the rod units, the relative volume fractions of each block, and the energetic and orientational interactions between different components. Moreover, for the parameters considered in this article, microphase separation was observed to be a requisite for developing orientational ordering between mesogenic units.

1:15PM V18.00009 Structural Formation Process of Microphase Separated Films with Liquid Crystalline Phase Transition. MOTONORI KOMURA, TOMOKAZU IYODA, Tokyo Institute of Technology — Ordered nanostructures arising from the microphase separation of block copolymers have driven one to fabricate nanofunctional materials as fundamental technology of the coming electronic and photonic materials. Thin films of a series of newly designed amphiphilic block copolymer consisting of hydrophilic polyethylene oxide (PEO) and hydrophobic polymethacrylate with azobenzene-mesogen in side-chain (PMA(Az)) show highly ordered microphase separation with PEO cylinders perpendicularly oriented to the film surface. In the present report, we investigated a structural formation process of the microphase separated films by temperature controlled atomic force microscopy (AFM) and grazing incidence small angle X-ray scattering (GISAXS). These measurements revealed that homeotropic alignments of Az liquid crystalline layers predominated the cylinder orientation, which corresponded to a <110> direction of body centered cubic structure under annealing condition, in disagreement with cylinder orientation of order-order transition of traditional block copolymers.

1:27PM V18.00010 Rod-to-Coil Transition in Polyoligo(9,9-dihexylfluorene-2,7-diyl) diblock copolymers. RAFFAELE MEZZENGA, LAURENT RUBATAT, Fribourg University, Physics Department, Switzerland, XIANGXING KONG, SAMSON JENEKHE, University of Washington, Seattle, USA, JANNE RUOKOLAINEN, Helsinki University of Technology, Finland, MOHAMAD HOJEIJ, EPFL, Switzerland — Self-assembly in the bulk of a series of hybrid triblock copolymers formed by a poly(9,9-dihexylfluorene-2,7-diyl) internal block and two poly(9,9-dihexylfluorene-2,7-diyl) end blocks has been studied. Since the α-helical secondary structure of the PBLG block may be either maintained or suppressed depending on the solvent casting history, the PBLG-PFH-PBLG copolymers exhibit two different conformations: a rod-rod or coil-rod configuration, respectively. To provide insight on the influence of molecular architecture on self-aggregation of these systems, three copolymers with different block ratio were investigated in both conformations using small- and wide-angle scattering techniques and transmission electron microscopy. Time-resolved photoluminescence measurements were performed on the same samples to explore the effect of morphology on photophysical properties. The observed photoluminescence spectra and dominant excited lifetimes of the poly(9,9-dihexylfluorene-2,7-diyl) block were found to differ markedly in rod-rod and coil-rod configurations and were correlated to the morphology of the self-assembled triblock copolymers.

1:39PM V18.00011 The effect of chain stiffness on the morphology of diblock copolymers. G. LEUTY, J. BEDARD, MESFIN TSIGE, Southern Illinois University — One of the most interesting and challenging problems in the science of materials concerns the structure and dynamics of the morphology of block copolymers. These materials generally consist of two or more homopolymer chains or blocks that are covalently bonded to each other to form a single polymer chain. Variation in the stiffness of the different block segments can directly affect the morphology of the system and may thus result in a very rich phase behavior. In the present study, the microphase separation of symmetric diblock copolymers with variable block stiffness and chain length is studied using coarse-grained molecular dynamics simulations. In the lamellar phase, the equilibrium lamellar spacing and orientation of the block segments in the system are found to depend on the relative stiffness between the two block segments. As the chain length of the block segments increases, the morphology changes from the expected lamellar appearance to a cylindrical one.
1:51PM V18.00012 Self-assembled OLEDs from rod-coil block copolymers. Y. TAO, R.A. SEGALMAN, University of California Berkeley and Lawrence Berkeley National Lab — High efficient OLEDs tend to be made of many stacked layers including layers for hole transport, emission, and electron transport, which are produced via a very tedious sequence of high vacuum steps. Since conjugated rod-coil block copolymers form layer structures due to rod-coil repulsions and rod-rod interactions, they are an alternate route towards multi-layer devices which can be solution processed in one single step. A functional conjugated rod-coil block copolymer, poly(alkoxyphenylene vinylene-b-oxadiazole (PPV-b-OX)), incorporates a hole transporting/emissive rod and an electron transporting coil. Grazing Incidence X-ray scattering is used to demonstrate the layered structure of the resulting self-assembled block copolymer film relative to the substrate (electrode). A multi-layer thin film self-assembled from PPV-b-OX shows significant improvement in luminescence and efficiency over pure PPV and PPV/OX blend devices. The correlation between details of thin film structure including lamellar spacing, orientation, and number of layers and device performance will also be discussed.

2:03PM V18.00013 Self-assembly of linear rod-coil block copolymers. LI-JIA AN, JI-ZHONG CHEN, ZHAO-YAN SUN, CHENG-XIANG ZHANG, Changchun Institute of Applied Chemistry, CAS — Rod-coil block copolymer systems have attracted a great deal of attention due to their rich phase behavior. The spontaneous ordering of coil-rod block copolymers is due to the mutual repulsion of the dissimilar blocks and the packing constraints imposed by the connectivity of each block, while the stiff rigidity of the rod segment imparts orientation organization. However, few reports investigate rod-coil block copolymers in three-dimension space. In this work, the self-assembly of linear rod-coil block copolymers is studied by applying self-consistent-field lattice techniques in three-dimension space. The stiffness influences on the self-assembly and the possible orientations of the rods in different structures are focused on for rod-coil diblock copolymers; the interfacial grafting density of the separating rod and coil segments is found exerting important influences on the phase behavior of symmetric coil-rod-coil triblock copolymers; the influences of the intramolecular interactions between the two rods of the symmetric rod-coil-rod triblock copolymer chain on the self-assembly are studied.

11:15AM V19.00001 Mechanochemistry of Molecular Motors. ZEV BRYANT, Stanford University Schools of Medicine and Engineering — Molecular motors lie at the heart of biological processes from DNA replication to vesicle transport. We seek to understand the physical mechanisms by which these nanoscale machines convert chemical energy into mechanical work. I will overview our ongoing use of single molecule tracking and manipulation techniques to observe and perturb substeps in the mechanochemical cycles of individual motors, before concentrating on our recent efforts to dissect the structural basis of a “reverse gear” in myosin VI. The basic actomyosin motor has been embellished, altered, and re-used many times through the evolution of diverse members of the myosin superfamily. Class VI myosins are highly specialized (-) end directed motors involved in a growing list of functions in animal cells, including endocytosis, cell migration, and maintenance of stereociliar membrane tension. How does myosin VI achieve reverse directionality, despite sharing extensive sequence and structural conservation with (+) end directed myosins? We generated a series of truncated myosin VI constructs and characterized the size and direction of the power stroke for each construct using dual-labeled gliding filament assays and optical trapping. Motors truncated near the end of the converter domain generate (+) end directed motion, whereas longer constructs move toward the (-) end, confirming the importance of a class-specific insert that redirects the lever arm. Our quantitative results suggest a surprising model in which the lever arm rotates ~180° during the power stroke. We are currently studying the behavior of engineered myosin VI constructs with artificial lever arms, in order to further challenge and refine our power stroke model.

11:51AM V19.00002 Rare returns on lost effort! Dynamic refolding (after unfolding) of protein domains. EVAN EVANS, Boston University — Dynamic force loading is an established technique for probing the forward kinetics in unfolding of single protein domains. Examined over several orders of magnitude in force rate, the unfolding forces often exhibit a linear dependence on the logarithm of loading rate, revealing the dynamic truncation of a precipitously activation barrier. The slope and force-rate intercept of the linear response characterize the critical molecular length gained in the barrier transition and the force-free rate of barrier passage. On the other hand, if reversed and probed with negative force rates, refolding of a stretched polypeptide chain has been found to yield a linear relation between the squares of the refolding forces and the logarithms of (reverse) force rates. Revealing here the dynamic elevation of a deep harmonic well that confines the unfolded states, the slope and force-rate intercept of the linear response also characterize the effective spring constant of the harmonic well and the unstretched refolding rate. Representing a dynamical corollary to predictions of fluctuation theorems for small systems, the most-frequent amount of mechanical work recovered (from the thermal environment) in refolding increases with each decade reduction in the force-unloading rate and approaches the limit set by near-equilibrium transitions over a logarithmic span related to the free energy of transition.

12:27PM V19.00003 Generalization of distance to higher dimensional objects, and its application to protein folding. STEVEN PLOTKIN, University of British Columbia — After a brief biophysical introduction to motivate the problem, I will show how the notion of calculation of distance between two objects can be generalized to the case where the objects are no longer points, but are one-dimensional. Additional concepts such as nonextensibility, curvature constraints, and noncrossing become central to the notion of distance. I will give some analytical and numerical results for specific examples, and I will discuss applications to biopolymers and protein folding.

1:03PM V19.00004 Getting into shape: the physics of bacterial morphology. KERWYN HUANG, Princeton University — Bacterial cells come in a wide variety of shapes and sizes, with the peptidoglycan cell wall as the primary stress-bearing structure that dictates cell shape. In recent years, cell shape has been shown to play a critical role in regulating many important biological functions including attachment, dispersal, motility, polar differentiation, predation, and cellular differentiation. Though many molecular details of the composition and assembly of the cell wall components are known, how the peptidoglycan network organizes to give the cell shape during normal growth, and how it reorganizes in response to damage or environmental forces have been relatively unexplored. We introduce a quantitative mechanical model of the bacterial cell wall that predicts the response of cell shape to peptidoglycan damage in the rod-shaped Gram-negative bacterium Escherichia coli. To test these predictions, we use time-lapse imaging experiments to show that damage often manifests as a bulge on the sidewall, coupled to large-scale bending of the cylindrical cell wall around the bulge. The direction of the symmetric rod-coil-rod triblock copolymer chain on the self-assembly are studied.

This work was funded by NIH grants 5K25 GM075000 and R01 GM073186.
The ability to sense changes in the environment allows bacteria to respond by altering their phenotype, or behavior, to adapt to new conditions. Alternatively, bacteria have the ability to spontaneously change their phenotype, without sensing. Such behavior is known as stochastic switching. By simply observing dividing bacteria, is it possible to tell whether the cells are sensing their environment? This talk presents a theory that can decouple the action of sensing from the action of natural selection using single-cell observation of bacteria.

11:15AM V20.00001 Inequivalent Down Atom (3x3) structure in Sn/Ge(111) , R. CORTES, Dpto. Fisica Materiales, Univ. Complutense, Spain, A. TEJEDA, MPQ, CNRS, France, J. LOBO-CHECA, Dpt. of Physics, Univ. of Basel, Switzerland, C. DIDIOIT, B. KIERREN, D. MALTERRE, LPM, Univ. Henri Poincare, France, E.G. MICHEL, Dpto. Fisica Mat. Condensada, Univ. Autonoma de Madrid, Spain, A. MASCARAO, Dpto. Fisica Materiales, Univ. Complutense, Spain — The (3x3) phase of Sn/Ge(111) is formed by three Sn atoms in the unit cell, one of them at a higher level than the other two (1-up, 2-down model). Although this model is mostly accepted, it is still controversial because of apparently contradicting experimental results related to the Sn 4d core level line shape. This work reports on high-resolution photoemission spectroscopy (HR-PES) and scanning tunnelling microscopy (STM) experiments on Sn/Ge(111)-(3x3). Our PES data resolve three main components in the Sn 4d core level [1] instead of two found before [2], which are assigned to the three Sn atoms in the unit cell. This indicates that the two down atoms are at slightly different heights, forming an inequivalent-down-atoms (IDA)-(3x3) structure, also confirmed by STM images. These results conclusively solve the long-standing controversy [2] on the interpretation of the Sn 4d core level line shape, and support a model fully consistent with an initial state picture. [1] A. Tejeda et al. Phys. Rev. Lett. In press [2] R.I.G. Uhrberg et al., Phys. Rev. Lett. 85, 1036 (2000) and references there in.

11:27AM V20.00002 Formation of $\sqrt{3}\times\sqrt{3}$ structure by depositing Si on Si(111)-(5x2)/Au1 . F.-K. MEN, A.-L. CHIN, C.-F. JAN, J.-L. GUO, Department of Physics, National Chung Cheng University, Chia-Yi, Taiwan, R.O.C. — By depositing Au on a Si(111) surface at an elevated temperature, 5x2, $\sqrt{3}\times\sqrt{3}$, and 6x6 reconstructions emerge successively as the Au coverage increases. Though great efforts have been made to identify atomic models for each reconstruction, satisfactory result is still lacking. By depositing Si on a 5x2 surface, we have identified the formation of the $\sqrt{3}\times\sqrt{3}$ structure even there was no additional Au being deposited. This observation leads us to speculate (i) the $\sqrt{3}\times\sqrt{3}$ structure has a higher Si density than that of the 5x2 structure, and (ii) the Au density in a single-domain $\sqrt{3}\times\sqrt{3}$ structure, i.e., no domain walls, is roughly equal to that in the 5x2 structure.

11:39AM V20.00003 Temperature-induced Self-pinning and Nano-layering of AuSi Eutectic Droplets , NICOLA FERRALIS, ROYA MABOUDIAN, CARLO CARRARO, University of California at Berkeley — A process for self-pinning of AuSi eutectic alloy droplets to a Si substrate, induced by a controlled temperature annealing in ultra-high vacuum, is presented. Surface pinning of AuSi 3D droplets to the Si substrate is found to be a consequence of the readjustment in the chemical composition of the droplets upon annealing, as required to maintain thermodynamic equilibrium at the solid-liquid interface. Structural and morphological changes leading to the pinning of the droplets to the substrate are analyzed using atomic force microscopy, scanning and transmission electron microscopy. Raman spectroscopy measurements performed on the droplets reveal phase separation upon cooling of the droplets, leading to the formation of amorphous Si-rich channels within the core, and the formation of crystalline Si nanoshells on the outside. The mechanism leading to the pinning and surface layering provide new insight into the role of alloying during growth of silicon nanowires and may be relevant to the engineering of nano-scale Si cavities. We shall also present measurements of the diffusion of Au drops on Si(111) obtained by low-energy electron microscopy.

11:51AM V20.00004 Adsorbate-Induced Faceting of Ir and Re Surfaces , PAYAM KAGHAZCHI, TIMO JACOB, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, 14195 Berlin, Germany, WENHUA CHEN, HAO WANG, THEODORE MADEY, Rutgers University, NJ 08854, USA — Since high-index clean metal surfaces typically have lower surface atom densities and higher surface free energies compared to the close-packed surfaces of the same metal they can be used as the basis for surface reconstruction and facet formation studies. In this context experimentally we found recently that on Ir(210) and Re(111) surfaces strongly interacting adsorbates are able to induce the formation of well defined nanostructures after annealing the system at elevated temperatures. Using density functional theory calculations with the PBE functional and \textit{ab initio} atomistic thermodynamics we studied the adsorption of oxygen and nitrogen on the different surface orientations, which are involved in the nanostructures on Ir(210) and Re(111). Constructing the corresponding (p, T)-surface phase diagrams, we find that at experimental pressure conditions ($P_{O_2} = 5 \times 10^{-10}$ atm) above 1100K for Ir and above 1200K for Re the planar surfaces are stable, while lowering the temperature stabilizes the nanofacets found experimentally. While on Ir(210) most nanoscale pyramids consist of smooth and unreconstructed planes, some (110) facets show a stepped double-missing row superstructure, which is only stable on the faceted surface and at higher temperatures.

12:03PM V20.00005 Oxygen-induced nanoscale pyramidal faceting of Rh(210) surface , GOVIND ., W. CHEN, H. WANG, THEODORE E. MADEY, Department of Physics & Astronomy, Rutgers University, Piscataway, NJ 08854, USA — The adsorption of oxygen and nanometer-scale faceting induced by oxygen have been studied on atomically-rough fcc Rh(210) using LEED and AES. The Rh(210) surface remains planar at room temperature after being exposed to oxygen. Upon annealing at temperatures above 600K, Rh(210) covered by \textasciitilde{}1ML of oxygen undergoes reconstruction to form 3-sided nanoscale pyramids characterized by two (731) facets and a (2x1)-reconstructed (110) facet. The surface remains faceted for T up to 850K. Oxygen can be completely removed from the faceted surface via CO oxidation at 400K or reaction with H$_2$ at room temperature, while preserving the faceted structure. The clean faceted surface remains stable below 600K and irreversibly relaxes to the planar surface at higher temperatures. The clean faceted Rh(210) surface is a potential substrate to study surface reactions whose rates are sensitive to atomic structure and/or nanoscale (facet) size. The results are compared with measurements of oxygen-induced faceting of Ir(210). Work supported by DOE, Office of basic Energy Science
12:15PM V20.00006 Order-disorder phase transition of the Cu(001) surface under equilibrium oxygen pressure. H. IDDAR, D.D. FONG, MSD, Argonne National Laboratory, IL 60439, P. ZAPOL, CSED & MSD, Argonne National Laboratory, IL 60439, P.H. FUOSS, MSD, Argonne National Laboratory, IL 60439, L.A. CURTISS, CSED & MSD, Argonne National Laboratory, IL 60439, G.-W. ZHOU, J.A. EASTMAN, MSD, Argonne National Laboratory, IL 60439 — Understanding atomic processes involved in catalyzed reactions is of great importance and can be achieved by studies of adsorbate-induced surface structures. Copper catalysts are heavily used in methanol and formaldehyde synthesis, two reactions in which oxygen adsorption is an important intermediate step. To better understand catalytic reactions, it is imperative to both identify and characterize the atomic structure of all phases present on metal surfaces at elevated temperatures and pressures relevant to working catalysts. We will report on our discovery of a new high-temperature oxygen-induced surface phase on Cu (001) using a combination of in situ synchrotron x-ray scattering and first-principles theory. This high-temperature phase is characterized by 1/4 ML of randomly-distributed vacancies in the topmost Cu layer with a c(2x2)-O adlayer. Below 473 K a reversible transition to a $\sqrt{2} \times \sqrt{2}$ R45° missing row phase occurs. The results show that this entropy-driven phase transition occurs through the diffusion of Cu vacancies underneath the oxygen superstructure. This work is supported by DOE BES under Contract # DE-AC02-06CH11357.

12:27PM V20.00007 Ab initio phase diagram of oxygen adsorption on W(110)1. MARKUS STÖHR, University of Vienna, Department of Physical Chemistry, STEFFAN MÜLLER, University of Erlangen-Nuremberg, Chair of Solid State Physics, RAIMUND PODLOUCKY, University of Vienna, Department of Physical Chemistry — Oxygen adsorption on the tungsten (110) surface has been studied experimentally as well as by semi-empirical theoretical approaches. Up to now, no ab initio modelling of this adsorption process has been done, for which we present a combined density functional theory (DFT) and cluster expansion (CE) study. For the CE all lateral unit cells with up to 12 atoms were considered. The (2x1) and (2x2) adsorption phases are found to be ground states which is confirmed experimentally [1]. On the basis of effective cluster interactions Monte Carlo (MC) simulations were performed in order to access finite temperature effects. Concerning the atomic structure we find excellent agreement to experimental scanning tunneling microscopy studies [2]. The temperature and coverage dependent short range order parameter is analyzed. From the results of the applied DFT, CE and MC approaches an ab initio surface phase phase diagram can be derived. [1] Wu et al., Physical Review B 39, 7595 (1989). [2] Johnson et al., Phys. Rev. Lett., 71, 1055 (1993).

12:39PM V20.00008 Lattice gas transition of xenon on a fullerite surface1. SILVINA GATICA, Department of Physics, Howard University, MILTON COLE, Department of Physics, Pennsylvania State University — We study a lattice-gas transition of xenon atoms on a honeycomb geometry. It is found from experiments and Monte Carlo simulations that this configuration occurs for xenon adsorbed on a substrate consisting on an array of C60 molecules on Ag(111). At very low coverage the atoms occupy strong-binding 3-fold hollow sites between C60 molecules. In this way, they form a commensurate lattice with nearest neighbor distance 0.58 nm. Using a Lennard Jones model for the Xe-Xe potential, the nearest neighbor interaction strength is $U=96.7$ K. Using the Ising model we estimate the transition critical temperature to be $T_c=30$ K. We compare with our results from Monte Carlo simulations based on more realistic interactions.

12:51PM V20.00009 Stability of the commensurate monolayer solid of xenon/graphite. L.W. BRUCH, Department of Physics, University of Wisconsin-Madison, A.D. NOVACO, Department of Physics, Lafayette College — A stability analysis based on model calculations of the grand potential finds that the transition from hexagonal incommensurate to commensurate monolayer solid of xenon/graphite is continuous with increasing pressure, in agreement with experimental observations. An atomic-scale interaction model gives an internally consistent account of the thermal expansion of the solid at the 2D sublimation curve and of the chemical potential increase for isothermal compression from monolayer condensation to the commensurate solid. An estimate is given for the corrugation energy of xenon/graphite.

1:03PM V20.00010 Molecular dynamics simulations of hexane on graphite at various coverages: the difference explicit hydrogens make1. M.W. ROTH, M.J. CONNOLLY, University of Northern Iowa, Department of Physics, PAUL A. GRAY, University of Northern Iowa, Department of Computer Science, CARLOS WEXLER, University of Missouri Columbia, Department of Physics and Astronomy — Molecular Dynamics simulations of hexane (C6H14) adlayers on graphite are carried out for coverages of 0.5 $\leq \rho \leq$ 1 monolayers. The hexanes have explicit hydrogens and the graphite is modeled as an all - atom, six - layer structure. Above $\rho \cong$ 0.9 the herringbone solid loses orientational order at $T_1=140$ K $\pm$ 3 K. At $\rho = 0.878$ the system presents vacancy patches and $T_1$ decreases to ca. 100 K. As coverage decreases further, the vacancy patches become larger and by $\rho = 0.614$ the solid is a connected network of randomly oriented domains. All cases show a weak nematic mesophase. The melting temperature is $T_2=160$ K $\pm$ 3 K and falls to ca. 145 K by $\rho = 0.614$. The dynamics and energetics observed demonstrate that the explicit-hydrogen model of hexane is substantially more realistic than the UA approximation.

1:15PM V20.00011 Molecular Dynamics study of tetracosane monolayers adsorbed on graphite1. L. FIRLEJ, B. KUCHTA, M.W. ROTH, University of Northern Iowa, Department of Physics, PAUL A. GRAY, University of Northern Iowa, Department of Computer Science, CARLOS WEXLER, University of Missouri Columbia, Department of Physics and Astronomy — We present the results of Molecular Dynamics (MD) simulations of tetracosane (C24H50) monolayers physisorbed on graphite. C24H50 molecules have explicit hydrogens and the graphite is represented by six graphene layers. We focus our analysis on the microscopic mechanism of melting, experimentally observed at T = 340 K. We are looking for the pre-melting transformations with emphasis on the correlation between translational disordering of molecules and their internal degrees of freedom. We analyze several order parameters and their fluctuations along the MD trajectories. We show that the all atom representation of C24H50 is much more sensitive to the model of intramolecular interactions than united atom model. Footprint reduction during melting involves a simultaneous loss of intramolecular and translational order.

1:27PM V20.00012 Test of the universality of the scaling energy in alkanes using melting transition of layer adsorbed on graphite

B. KUCHTA, L. FIRLEJ, M.W. ROTH, University of Northern Iowa, Department of Physics, PAUL A. GRAY, University of Northern Iowa, Department of Computer Science, CARLOS WEXLER, University of Missouri Columbia, Department of Physics and Astronomy — The non-bonded terms together with the torsional energy determine the internal (conformational) degrees of freedom of simulated alkanes. Being able to predict the energy and ordering of conformations correctly is an essential quantity for bringing force field methods into the predictive regime of theoretical methods. To estimate the universality of modern force fields it is helpful to know how different components of classical fields affect the simulated properties. In the case of alkanes, the interplay between torsion potential and the scaling of 1-4 van der Waals and 1-4 charge-charge (QQ) interactions plays a crucial role. It is the purpose of this work to study universality of the scaling factor of 1-4 non-bonded interactions in alkanes. Three alkanes of length from 7 to 30Å (C₇, C₁₂, C₂₄), in an all-atom representation have been analyzed.

1:39PM V20.00013 Heisenberg Spin Systems with Long Ranged Couplings

UTE LÖW, Universität Dortmund, Institut fuer Physik, D44221 Dortmund — Static correlation functions of Heisenberg spin systems with various (non-frustrated) topologies are studied by means of Quantum-Monte Carlo techniques. In particular dimerizations and longer ranged variations of spin couplings and alternations between ferromagnetic and anti-ferromagnetic couplings are considered. The phenomenology of possible ground state phase diagrams is discussed.

1:51PM V20.00014 Hysteresis in the anomalous Hall effect of MnAs thin films

FELIX T. JAECKEL, ANDREAS STINTZ, ABDEL-RAHMAN A. EL-EMAWY, KEVIN J. MALLOY, Center for High Technology Materials, University of New Mexico, 1313 Goddard St. SE, Albuquerque, NM 87106 — We report detailed measurements of the Hall effect in MBE-grown MnAs thin films on (001)-GaAs as a function of temperature. Hysteresis of the Hall resistivity is observed for temperatures between 300 and 355 K. Non-linear behavior of the Hall resistivity persists up to 390 K. The appearance of hysteresis at low temperatures can be explained by the emergence of stable, out-of-plane domains due to the shape anisotropy of the contracting α-phase. However, the persistence of the hysteresis and the anomalous Hall effect at temperatures significantly above 318 K is not consistent with the complete transformation of the α-phase and introduces new questions about the magnetic properties of the β-phase.

Thursday, March 13, 2008 11:15AM - 2:03PM — Session V21 DPOLY: Charged and Ion-Containing Polymers I Morial Convention Center 213

11:15AM V21.00001 Nano-Patterns in Gels of Charged Chains with Self-Attracting Interactions

MONICA OLVERA DE LA CRUZ, Northwestern University, JUAN J. DE PABLO, University of Wisconsin-Madison — Gels of weakly charged chains have large swelling capabilities that depend on pH and/or salt concentration. In the presence of attractions among elastic units, such as poor-solvent conditions, stable nano-patterns are observed. These systems are ideal actuators, since they undergo large volume changes at the nanophase transition. We find that the nanophases are due to the entropy of the counterions, and are stabilized as the monomer density decreases and as the salt concentration increases by hard-core interactions and network heterogeneities. Our model is constructed with results from a non-linear Poisson Boltzmann approach in the limits when it is applicable (low ionic densities) and a grand canonical Monte Carlo method simulation with Donnan partitioning of counterions and co-ions between the gel and reservoir phases. Our theory and simulations are in close agreement with experiments.

11:27AM V21.00002 Interactions in Ion-containing Polymers Probed by ab initio Methods

WENJUAN LIU, RALPH COLBY, Materials Science and Engineering Department, The Pennsylvania State University, MICHAEL JANIK, Department of Chemical Engineering, The Pennsylvania State University, THE PENNSYLVANIA STATE UNIVERSITY TEAM — We use ab initio methods to estimate dipole moments and interaction energetics in ion-containing polymers. Our calculation quantitatively includes electrostatic interactions (using both permanent and induced dipoles) and effectively estimates solvation energetics for ions interacting with various functional groups. Interactions are reported for various small cations with common functional groups on polymers and carboxylate, sulfonate and phosphonate groups that can be present in anionic ionomers. We demonstrate how these interaction energies can be utilized to design polymer membranes with facile ion transport.

11:39AM V21.00003 Conformation transition and counterion distribution of single polyelectrolyte chains in aqueous solution

JIAN ZHAO, SHENQIN WANG, Institute of Chemistry, Chinese Academy of Sciences, Beijing, China — We adopted single fluorescence techniques to study the conformation transition of poly 2-vinylpyridine in its aqueous solution. The first-order conformation transition from extended coil to collapsed globule was observed as the pH value in the solution was raised. The critical pH value was shifted higher largely upon the addition of salt in the solution. The study shows a difference of proton concentration at the chain to that in the solution (a difference of three orders of magnitude), and the addition of salt in the solution increased the local proton concentration at the chain and therefore shift the transition point.

11:51AM V21.00004 Unifying Self-Consistent Field Theory for Weak Polyelectrolytes

KEVIN WITTE, YOU-YEON WON, Purdue University — A self-consistent field (SCF) theory for weak polyelectrolytes has been derived from a grand canonical partition function. The formalism accounts for the location and mixing of the charged and uncharged polymer species, treating the local (spatially dependent) charge fraction as a field variable with which to minimize the total free energy. This method of the derivation gives the resulting equations, especially those governing the local charge fraction, that are identical to the results obtained by Szeifer and coworkers (J. Polym. Sci. B Polym. Phys., 2006) who built upon the mean-field “annealed” free energy expression proposed by Raphael and Joanny (Europhys. Lett., 1990). However, we show that these results are further identical to the “two-state” model of Borukhov, Andelman and Orland (Eur. Phys. J. B, 1998), namely, the potential field due to the polymer charges with which the chains interact and the local charge fraction are shown to be exactly equal. This annealed model is derived by averaging the partition function with regard to the monomer charges. The charged and uncharged states are weighted by their probabilities which is, in our notation, the bulk charge fraction and one minus the bulk charge fraction, respectively. The utility of this theory is demonstrated by comparing its predictions against various experimental results from bulk potentiometric measurements and also from poly electrolyte brush compression studies.

12:03PM V21.00005 Composition and Structure Changes of the Ionic Aggregates with Acid Content and Neutralization Level in Poly (styrene-co-methacrylic acid) Ionomers. WENQIN WANG, TSUNG-TA CHAN, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6272. ANDREW PERKOWSKI, SHULAMITH SCHLICK, Department of Chemistry and Biochemistry, University of Detroit Mercy, Detroit, Michigan 48221, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104 — The morphology of poly(styrene-co-methacrylic acid) (SMAA) copolymers neutralized with copper(II), and the corresponding local structures and compositions of ionic aggregates were investigated as a function of acid content and level of neutralization. Using X-ray scattering and scanning transmission electron microscopy, the sizes of ionic aggregates in Cu(II)-neutralized SMAA were found to be independent of acid content and neutralization level. The number density of ionic aggregates increased with acid content and neutralization level, but the increase is significantly less than expected for a fixed ionic aggregate composition. Electron spin resonance spectroscopy indicates three types of cation sites with corresponding relative population changing with acid content, which further indicates a compositional variation of ionic aggregates with neutralization level. The correlation between morphology and compositional evolution of the ionic aggregates will be discussed.

12:15PM V21.00006 Multiple Nanoscale Morphologies of Poly(Ethylene-co-Acryl Acid) Ionomers. CHRISTOPHER D. CHAN, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, TRAVIS W. RAUGHMAN, Macromolecular and Organic Chemistry, Technical University of Eindhoven, KATHLEEN L. OPPER, KENNETH B. WAGENER, Department of Chemistry, University of Florida, KAREN I. WINEY, Department of Material Science and Engineering, University of Pennsylvania — We have synthesized linear poly(ethylene-co-acrylic acid) (EAA) copolymers with precisely placed acid groups using ADMET (acyclic diene metathesis). In the acid form, the EAA copolymers with precisely placed acid groups exhibit the typical orthorhombic PE crystal structure along with a new layered structure. The layered structures coexist with the PE crystals and have spacings consistent with the separation between acid groups; at 9.5 mol% acid the layer-to-layer spacing is 2.53 nm. When these linear EAA copolymers are neutralized with zinc acetate in solution, high angle annular dark field scanning transmission electron microscopy (HAADF STEM) shows that the Zn-rich ionic aggregates decrease in size as the level of neutralization increases from 25% to 100%. X-ray scattering indicates that the cations decorate the acid-acid layered structure at low neutralization level, but eventually disrupt the layers at higher neutralization levels.

12:27PM V21.00007 Conduction, Ion Association and Dynamics in Polyethylene Oxide-based Polyester Ionomers1. DANIEL FRAGIADAKIS, SHICHEN DOU, RALPH COLBY, JAMES RUNT, Penn State University — A series of single-ion conducting PEO-based polyester copolymers is synthesized, containing different amounts of ionic sulfonate groups covalently attached to the polymer chains. The dynamics of the polymer chains and the mobile lithium cations is investigated using dielectric relaxation spectroscopy. A physical model of electrode polarization is employed to decompose dc conductivity into the contributions of the mobile ion concentration and ion mobility, and the physical meaning of these parameters and relation to literature results on similar systems is discussed. The segmental and local dynamics of the polymer chains is studied. We investigate both the modification of the dynamics due to the presence of the ionic groups, as well as the relation of chain motion to ion transport.

1Supported by the NSF Polymers Program and the Department of Energy

12:39PM V21.00008 Correlation between structure and conductivity in stretched Nafion. ELSHAD ALLAHYAROV, PHILIP TAYLOR, Case Western Reserve University — We have used coarse-grained simulation methods to investigate the effect of stretching-induced structure orientation on the proton conductivity of Nafion-like polyelectrolyte membranes. Recent experimental data on the morphology of ionomers describe Nafion as an aggregation of polymeric backbone chains forming elongated objects embedded in a continuous ionic medium. Uniaxial stretching of a recast Nafion film causes a preferential orientation of these objects in the direction of stretching. Our simulations of humid Nafion show that this has a strong effect on the proton conductivity, which is enhanced along the stretching direction, while the conductivity perpendicular to the stretched polymer backbone is strongly reduced. Stretching also causes the perfluorinated side chains to orient perpendicular to the stretching axis. The sulphonate multiplets shrink in diameter as the stretching is increased and show a spatially periodic ordering in their distribution. This in turn affects the distribution of contained water at low water contents. The water forms a continuous network with narrow bridges between small water clusters absorbed in head-group multiplets. We find the morphological changes in the stretched Nafion to be retained upon removal of the uniaxial stress.

12:51PM V21.00009 Morphology study in block copolymer electrolytes. SCOTT MULLIN, NISITA WANAKULE, NITASH BALSARA, University of California, Berkeley — Poly(styrene-b-ethylene oxide)/lithium bis(trifluoromethane)sulfonimide (SEO/LITFSI) is of interest in battery applications since the doped PEO phase can conduct ions and the glassy PS phase can prevent dendrite growth upon recharging. It is believed that the LITFSI molecules are localized in the PEO microphases. Previous studies have shown that highly conducting electrolytes can be made from symmetric SEO copolymers. The purpose of this study is to explore the conductivity of asymmetric SEO copolymer systems doped with LITFSI. Our studies encompass both neat asymmetric SEO copolymers and SEO copolymers blended with PS homopolymers to separate the effects of architecture of the copolymer molecules and morphology adopted by the system in the melt state. Conductivity is measured by AC impedance, morphology is determined by small angle X-ray scattering, and crystallinity of the PEO chains is determined by differential scanning calorimetry. All samples were prepared in hermetically sealed sample cells in an Argon glovebox.

1:03PM V21.00010 Increased Water Retention in Polymer Electrolyte Membranes Assisted by Capillary Condensation. MOON JEONG PARK, NITASH P. BALSARA, Lawrence Berkeley National Laboratory, University of California, Berkeley — We establish a new systematic methodology for controlling the water retention of polymer electrolyte membranes. We show that block copolymer membranes with well-defined hydrophilic channels in the 2 to 5 nm range remain moist in a relatively dry environment (relative humidity = 50 %) up to temperatures as high as 90 °C. This retention of water leads to an increase in the overall conductivity with increasing temperature. Simple calculations suggest that capillary condensation is important at these length scales. The morphology of the hydrated membranes is determined by a combination of in-situ neutron scattering and cryogenic electron microscopy.

1:15PM V21.00011 Engineering polyelectrolyte multilayer structure at the nanometer length scale by tuning polymer solution conformation. SOHEIL BODDOHI, CHRISTOPHER KILLINGSWORTH, MATT KIPPER, Colorado State University — Chitosan (a weak polycation) and heparin (a strong polyanion) are used to make polyelectrolyte multilayers (PEM). PEM thickness and composition are determined as a function of solution pH (4.6 to 5.8) and ionic strength (0.1 to 0.5 M). Over this range, increasing pH increases the PEM thickness; however, the sensitivity to changes in pH is a strong function of ionic strength. The PEM thickness data are correlated to the polymer conformation in solution. Polyelectrolyte conformation in solution is characterized by gel permeation chromatography (GPC). The highest sensitivity of PEM structure to pH is obtained at intermediate ionic strength. Different interactions govern the conformation and adsorption phenomena at low and high ionic strength, leading to reduced sensitivity to solution pH at extreme ionic strengths. The correspondence between PEM thickness and polymer solution conformation offers opportunities to tune polymer thin film structure at the nanometer length scale by controlling simple, reproducible processing conditions.
complexes. This work is financially supported by the US-DOE grant DE-FG02-02ER46012.

Finally, we use a voltage dependent resonance-tunneling scheme to demonstrate a molecular switch made of F4TCNQ/6T charge transfer complexes. The charge transfer lead to the shift of HOMO and LUMO orbitals of the molecules in complexes with respect to the pure presented. The complexes are formed by self assembly of the electron donor RABE, Humboldt-Universität zu Berlin, Institut f. Physik, Newtonstraße 15, 12489 Berlin, Germany, S.-W. HLA, Ohio University, Physics and Astronomy Department, Athens, OH 45701, N. KOCH, J.P. RABE, Humboldt-Universität zu Berlin, Institut f. Physik, Newtonstraße 15, 12489 Berlin, Germany, S.-W. HLA, Ohio University, Physics and Astronomy Department, Athens, OH 45701 — A low temperature scanning tunneling microscope (STM) and spectroscopy study of organic charge transfer complexes is presented. The complexes are formed by self assembly of the electron donor- α-6T and the electron acceptor tetrafluorotetracyanoquinodimethane (F4TCNQ) on Au (111) surface. The formation of new hybrid molecular orbitals in CTCs is evident by STM imaging at different bias voltages as well as by differential conductance spectra. The charge transfer lead to the shift of HOMO and LUMO orbitals of the molecules in complexes with respect to the pure molecular orbitals. Finally, we use a voltage dependent resonance-tunneling scheme to demonstrate a molecular switch made of F4TCNQ/6T charge transfer complexes. This work is financially supported by the US-DOE grant DE-FG02-02ER46012.

Acknowledgment is made to the donors of Petroleum Research Fund, administered by the ACS, for support of this research.
12:27PM V22.00005 Correlating Structure and Conductivity of Pentathiophene Monolayers, BAS HENDRIKSEN, YABING QI, FLORENT MARTIN, Materials Sciences Division, Lawrence Berkeley National Laboratory, FRANK OGLETREE, The Molecular Foundry, Materials Sciences Division, Lawrence Berkeley National Laboratory, MIQUEL SALMERON, The Molecular Foundry and Materials Sciences Division, Lawrence Berkeley National Laboratory — Understanding the electrical conduction mechanisms in organic materials is important for the development of plastic and molecular electronics. The charge transport properties of conducting molecular layers are expected to strongly depend on the order of the layer and the conformation of the molecules. We used atomic force microscopy (AFM) to study and correlate the structural, mechanical and electrical properties to molecular monolayers of pentathiophene based molecules on solid substrates prepared by the Langmuir-Blodgett technique. The molecular monolayers consist of two phases: one phase of compact micromer size-flowered islands and a phase with less order and a high density of holes. We found that the perpendicular conductivity, i.e. through the monolayer sandwiched between the conductive AFM probe and the conductive substrate, is more than 5 times higher on the well-ordered island phase. This shows that the molecular lattice order has a significant effect on the electronic properties.

12:39PM V22.00006 Direct measurement of photomechanical switching cross-sections of single-molecules on a surface, JONGWON CHO, MATTHEW J. COMSTOCK, NIV LEVY, LUIS BERTIL-BAUTISTA, FRANK LAUTERWASSER, JEAN M. J. FRECHET, MICHAEL F. CROMMIE, University of California at Berkeley — The photomechanical switching of photoactive molecules in solution strongly depends on the wavelength of light. This dependence is crucial to reliably control the photomechanical state of target molecules. Recently, reversible photomechanical switching of individual azobenzene molecular derivatives on the Au(111) surface has been reported for one particular wavelength of UV illumination [1]. To further understand this process and its possible applications in future nanotechnologies, we have investigated photomechanical switching rates and saturation behavior for azobenzene molecular derivatives at a surface under optical stimulation at different wavelengths. Using single-molecule-resolved scanning tunneling microscopy, we have determined both the forward and reverse photomechanical molecular switching cross-sections at different wavelengths. In a dramatic departure from solution-based environments, visible light does not efficiently reverse the photoreaction. [1] Matthew J. Comstock, Niv Levy, Armen Kirakosian, Jongwoon Cho, Frank Lauterwasser, Jessica H. Harvey, David A. Strubbe, Jean M. J. Fréchet, Dirk Trauner, Steven G. Louie, and Michael F. Crommie, Phys. Rev. Lett. 99, 038301 (2007)

12:51PM V22.00007 Many-body treatment of quantum transport through single molecules, JUSTIN BERGFIELD, CHARLES STAFFORD, University of Arizona — We investigate multi-terminal quantum transport through single molecules including intramolecular correlations exactly by using the nonequilibrium Green function approach, but treating the lead-molecule coupling perturbatively via a Dyson expansion [1]. We find many transport features which are not accessible via mean-field approaches such as Coulomb blockade steps and an incipient Hubbard-Mott insulator gap. We also calculated the thermopower exactly and in find, in accordance with recent experimental [2] and theoretical reports, that the transport in this junction is dominated by holes (p-type). This result allowed us to then extract the remaining free parameter, the lead-molecule coupling Γ. The resulting nonlinear I-V curve was found to be in good quantitative agreement with experiment. Finally, we calculated the differential conductance as a function of gating and bias potential to construct a full molecular ‘Coulomb diamond’.

1:03PM V22.00008 Single molecule characterization with well-defined contacts, ALEX NEUHAUSEN, FRANK JAECKEL, JEREMY HIATT, JOSEPH SULPIZIO, DAVID GOLDBADER-GORDON, CHRIS CHIDSEY, W. E. MOERNER, ZHENAN BAO, Stanford University — We demonstrate a novel method to reliably achieve ohmic contact to single molecules in a geometry that allows for simultaneous transport measurements and Raman spectroscopy. We achieve this by lithographically defining gold contacts to a structure composed of a single molecule bridging a pair of gold nanoparticles. The transport measurements indicate negligible resistance from the contacts as compared to the single molecule behavior, and the Raman spectroscopy benefits from strong field enhancement between the two nanoparticles. We prove the presence of single molecules with both stoichiometric and disordered structures. The transport measurements indicate negligible resistance from the contacts as compared to the single molecule behavior, and the Raman spectroscopy benefits from strong field enhancement between the two nanoparticles. We prove the presence of single molecules with both stoichiometric and disordered structures. This work was supported by an NSF NIRT grant.

1:15PM V22.00009 Transport Fluctuations in Metal-Molecule Junctions, JONATHAN MALEN, KANHAY-ALAL BAHETI, PETER DOAK, RACHEL SEGALMAN, ARUN MAJUMDAR, UC Berkeley — Thermopower of metal-molecule junctions is an alternative spectroscopic technique for determining the electronic structure of single-molecules. We have measured the thermopower of such molecular junctions. Temperature bias applied between gold contacts across the bridging molecules generates a thermoelectric voltage. Hitherto, the statistical analysis of the data from both thermopower and conductance measurements has focused on the histogram peaks rather than the spread of the data. We find that the full width half maximums (FWHM) of the voltage histograms are finite at zero temperature bias and increase in proportion to the temperature bias. Johnson Noise is the most likely cause of the zero bias FWHM, and its magnitude is thereby related to the junction conductance. We find that the FWHM of the voltage histograms are finite at zero temperature bias and increase in proportion to the temperature bias. Johnson Noise is the most likely cause of the zero bias FWHM, and its magnitude is thereby related to the junction conductance. We find that the FWHM of the voltage histograms are finite at zero temperature bias and increase in proportion to the temperature bias. Johnson Noise is the most likely cause of the zero bias FWHM, and its magnitude is thereby related to the junction conductance. For 1,4-Benzenedithiol (BDT) the junction conductance associated with the zero bias FWHM is 0.02 eAu, in close agreement with prior conductance measurements of BDT. The dependence of FWHM on temperature bias may provide further insight to the origin of stochastic fluctuations in metal molecule junctions.

1:27PM V22.00010 Electronic transport through single-molecule- and monolayer-based molecular junctions, LUIS AGAPITO, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida, Gainesville, Florida 32611 — We report our development for calculating tunneling electronic transport through molecular junctions, which are composed of two contact leads and the active device in between. The surface Green’s function of the contact leads is obtained following a non-iterative, exact procedure using ab initio data computed with the same level of theory and localized basis set than those used for the active device*. In a 1-dimensional in-wire setting, we describe the electrical switching performance of a single oligo-phenylene-ethynylene molecule connected to graphene-nanoribbons leads. Moreover, in a more realistic 2-dimensional setting, such as the case of self-assembled molecular monolayers, the method is extended to include intermolecular and packing-density effects. * Agapito, L. A.; Cheng, H. P. Journal of Physical Chemistry C 2007, 111, 14266.

1:51PM V22.00012 Substrate-Dependent Electronic Behavior of Polydiacetylene Nanowires
RAJIV GIRIDHARAGOPAL, K. F. KELLY, Rice University — Scanning tunneling microscopy (STM) has been used to study individual polydiacetylene (PDA) nanowires. STM analysis of PDA nanowires on different substrate electrode materials at varying sample bias voltage conditions reveals interesting substrate-dependent effects. PDA nanowires were formed on both graphite and molybdenum disulfide (MoS₂) substrates. Interestingly, the nanowires on graphite appear with different topographic heights depending on the substrate bias voltage, and the height varies substantially with respect to voltage polarity. A similar effect is observed on MoS₂ at negative sample bias voltages, except that the nanowires are almost twice as tall on MoS₂. Even more intriguing is that at positive sample bias voltage conditions, the nanowires on MoS₂ are invisible in all STM images. A comparison of these voltage-dependent effects points to a strong influence of the substrate electrode material on the electronic behavior of these polymer nanostructures. The results reported here have implications for recently-demonstrated technologies such as monolayer PDA transistors and PDA-based organic solar cell devices as well as potential molecular electronic systems.

2:03PM V22.00013 Organic memory devices using the negative differential resistance effect
R. OSTERBACKA, J.K. BARAL, H.S. MAJUMDAR, F. JANSSON, Center for Functional Materials and Department of Physics, Abo Akademi, Finland, A. LAHJO, R.H.A. RAS, J. RUSCHE, O. IKKALA, Department of Engineering Physics and Mathematics and Center for New Materials, Helsinki University of Technology, Finland, H. JIANG, E. KAUPPINEN, VTT Biotechnology, Finland — Of all the organic memory devices reported so far the ones having the negative differential resistance (NDR) is the best in terms of yield, reproducibility and repeatability. We have observed two different kinds of NDR in nanoparticle based organic memory devices. One is the memory-NDR which follows the observation in SiO₂ devices [Simmons et. al. Proc. R Soc. Lond. Ser. A 301 (1967)][7]. Here the I-V characteristics track different paths based on device history. The second type is the tunneling-NDR, where the I-V curves always trace the same path, irrespective of the history. This behavior is similar to the one observed in resonant tunnel diodes and multiple tunneling is the explanation. We have performed a multitude of optical and electrical experiments and clarified the influences of morphology on the complex and interesting device performance observed in this new class of organic electronic devices.

Session V23 DMP GMAG: Focus Session: Charge/Orbital Ordering in Complex Oxides Morial Convention Center 215

11:15AM V23.00001 Evolution of the ‘Orbital Peierls State’ with doping
C. ULRICH, G. KHALIJULLIN, B. KEIMER, Max-Planck-Institute FKF; Stuttgart, Germany, M. REEHUIS, HMI, Berlin, Germany, K. SCHMALZL, A. IVANOV, ILL, Grenoble, France, K. HRADIL, FRM II, Munich, Germany, J. FUJIOKA, Y. TOKURA, University of Tokyo, Japan — Orbital degrees of freedom play an important role in the physics of strongly correlated electron systems. Our extensive investigation of insulating vanadates by neutron scattering has led to the discovery of an unusual magnetic ground state. YVO₃ exhibits two magnetic phases, a C-type phase below 116 K and 77 K and a G-type phase below 77 K. While the magnetic properties of the G-type phase are in accordance with standard theories, the C-type phase shows highly unusual static and dynamic spin correlations. Based on the idea of orbital fluctuations we were able to identify this phase as a theoretically predicted ‘orbital Peierls state’[1]. Neutron scattering experiments on Y₁₋ₓCaₓVO₃ show that the C-type phase, i.e. the ‘orbital Peierls phase’, is stabilized upon doping, while the orbitally ordered G-type phase is quite unstable and disappears at x = 2%. Furthermore, with doping this phase also exhibits a highly unusual spin wave dispersion. These leads us to the conclusions, that the ‘orbital Peierls state’ becomes more robust with Ca-doping, whereas the formerly well defined G-type phase exhibits a more complex behaviour, probably as a consequence of an increase in orbital fluctuations. [1] C. Ulrich et al., PRL 91, 257202 (2003).

11:27AM V23.00002 Magnetic interactions and orbital physics in RVO₃ perovskites
J.-Q. YAN, Ames Laboratory, Ames, IA 50011, S. CHANG, C. BROWN, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, M. HEHLEN, F. TROUW, LANSC, Los Alamos National Laboratory, Los Alamos, NM 87545, R.J. MCQUEENEY, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, IA 50011 — We have performed inelastic neutron scattering study on high quality YVO₃ and LaVO₃ powders. The magnetic interactions determined from the scattering spectra for YVO₃ agree with a previous single crystal study. [1] For LaVO₃, a −Jab > Jc is in sharp contrast to the Jc > Jab in the C-type magnetically (C-AF) ordered state of YVO₃. The mechanism that greatly suppresses Jab in C-AF state of YVO₃ will be discussed together with thermal conductivity [2] and Raman spectroscopy [3] results.

11:39AM V23.00003 Pressure-temperature phase diagram for orbital and spin states in RVO₃ (R=Y,Tb)
DAISUKE BIZEN, KEISUKE NAKATSUKA, TETSUYA MURATA, HIRONORI NAKAO, KAZUAKI IWASA, YOUICHI MU-RAKAMI, Tohoku University, TOYOTAKA OSKABE, JAEA, SHIGEKI MIYASAKA, Osaka University, YOSHINORI TOKURA, University of Tokyo, CERC-AIST — Perovskite-type vanadium oxides RVO₃ (R=Y, La-Lu) show various physical properties coupled with the orbital and spin states. Orbital ordered states of V 3d⁵ in YVO₃ have been systematically investigated by X-ray scattering technique under high-pressure and low-temperature (HP-LT). The pressure-temperature phase diagram for the orbital state was clearly determined from the crystal parameters, i.e. the lattice constants and the reflection conditions. It indicates that the C-type orbital ordering (C-OO) is stabilized as compared to the G-type orbital ordering (G OO) by applying hydrostatic pressure. Based on the result, we succeeded in controlling the ground state of 3d-orbital in TbVO₃ from G-OO to C-OO by applying pressure. The spin state coupled with the orbital was also studied by neutron scattering under HP-LT. It elucidated that the magnetic ground state changed from the C-type spin ordering to the G-type one. This result indicates the strong coupling between orbital and spin states.

11:51AM V23.00004 Stabilization of Charge Ordering by Magnetic Exchange
ROBERT MCQUEENEY, Iowa State University/Ames Laboratory — The magnetic exchange energies in charge ordered La₃Sr₂Fe₃O₈ (LSFO) and its parent compound LaFeO₃ (LFO) have been determined by inelastic neutron scattering. In LSFO, the measured ratio of ferromagnetic exchange between Fe³⁺-Fe³⁺ pairs (J_F) and antiferromagnetic exchange between Fe³⁺-Fe⁵⁺ pairs (J_AF) fulfills the criterion for charge ordering driven by magnetic interactions (J_F/J_AF > 1). The 30% reduction of J_AF as compared to LFO indicates that doped holes are delocalized, and charge ordering occurs without a dominant influence from Coulomb interactions.

The conduction mechanism mediated by the LUMOs of the C$_{60}$ molecule is revealed. Due to the bias effect on the LUMO alignment, negative differential resistance (NDR) is observed in both two- and three-terminal devices at a very low bias. Since the LUMOs can be easily modified by molecular adsorption, the NDR position is tunable and can be used in sensor applications without the need for specific molecular receptors.

1:51PM V23.00012 Incommensurate Magnetic Structure of ZnCr$_2$Se$_4$ and ZnCr$_2$S$_4$. FABIANO YOKAIKIYA, Hahn-Meitner-Institut, Hahn-Meitner-Institut, 100 Glenicker str, Berlin, Germany, HELOISA NUNES BORDALLO, DIMITRI ARGYRIOU, Hahn-Meitner-Institut, 100 Glenicker str, Berlin, Germany, A KRIMMEL, A LOIDL, V TSURKAN, Experimental Physics V, Center for Electronic Correlations and Magnetism, University of Augsburg, D-86135 Augsburg, Germany — Recent studies of chalcogenide chromium spinels have shown a coupling between ferroelectricity and magnetism. The motivation of this work is to determine the magnetic ground state, (including its symmetry properties), to comprehend the coupling of magnetic and ferroelectric order parameters in the spinels ZnCr$_2$Se$_4$ and ZnCr$_2$S$_4$. The incommensurate magnetic structures through the Néel transition in these systems have been studied by high-resolution powder neutron diffraction. Below $T_N$ ($\sim$22K), for both cases, the magnetic structure is described as ferromagnetic layers in the ab-plane stacked in a spiral arrangement along the c-axis with a propagation vector $\mathbf{k} = (0.0, 0.46)$. In ZnCr$_2$Se$_4$ and ZnCr$_2$S$_4$, the magnetic phase transition is of first order. Therefore to use the irreducible co-representation theory, for symmetry analysis, the magnetic phase is described by a linear combination of irreducible representations. In this talk we present results of Rietveld analysis on the magnetic and crystal structure through the magnetic transition.

2:03PM V23.00013 ABSTRACT WITHDRAWN —

Thursday, March 13, 2008 11:15AM - 1:51PM — Session V24 DMP: Focus Session: Transport in Nanostructures VII: Si Interfaces and Carbon

11:15AM V24.00001 Leakage current in deca-nano MOSFET by surface state hopping$. HASSAN RAZA, EDWIN KAN, School of Electrical and Computer Engineering, Cornell University Ithaca NY 14853 — Si surface states have been a topic of recent study [Nature 439, 703 (2006), PRB 76, 045308 (2007)]. In this work, we present transport calculations through these surface states, which result in a two-dimensional system. Among the systems being considered are: (1) $\pi$ and $\pi^*$ states on Si(100)/(2x1) surface with asymmetric dimer reconstruction, and (2) dangling bond wires along and perpendicular to the dimer row direction. Previously, we have reported the electronic structure of these systems in PRB 76, 045308 (2007). Here, we show that these states can give rise to significant current densities and hence may contribute to subthreshold leakage. Furthermore, the transport depends on the location of Fermi level with respect to the band edge and hence on the Fermi level pinning. We use EHT (extended Huckel theory) for the electronic structure and NEGF (non-equilibrium Green's function) formalism for the mean-field quantum transport. EHT has been applied to Si bulk and surfaces and gives quantitative agreement with experiments, e.g. band gap and band dispersions.

11:27AM V24.00002 Tunneling properties of ultra-thin SiO$_2$ barriers: a first-principles study. EUNJUNG KO, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University, Seoul, Korea — We performed first-principles simulations of the electron tunneling through ultra-thin SiO$_2$ barriers in Si(100)/SiO$_2$/Si(100) structures. The atomic structures of the Si/SiO$_2$ interfaces are generated by considering various silicon suboxide states observed in photoemission studies. For comparison, we also consider sharp Si/SiO$_2$ interfaces with dangling bonds. For each atomic structure, the tunneling conductance is calculated by a first-principles scattering-state method based on the ab-initio pseudopotentials and the density functional theory within the local density approximation. As a result we obtained the dependence of the tunneling probabilities on the oxide thickness and on the interfacial structures. Effects of the dangling bonds on the tunneling probabilities will also be discussed. Computational resource for this work is provided by KISTI under the 8th Strategic Supercomputing Support Program.

11:39AM V24.00003 C$_{60}$-based devices: large scale simulations and design. X. H. ZHENG, W. LU, T. A. ABTEW, NC State University, V. MEUNIER, Oak Ridge National Laboratory, J. BERNHOLC, NC State University — C$_{60}$ is one of the most promising building blocks in the design of molecular devices, due to its spherical symmetry and structural reproducibility. In this work, the electron transport properties of two- and three-terminal devices built of C$_{60}$S are investigated. The C$_{60}$S are connected by alkane chains and then sandwiched between aluminum nanowires. The calculations are carried out using a massively parallel real-space multigrid O(N) implementation of density functional theory. The conductance and nonlinear I-V characteristics are evaluated by the LUMOs of the C$_{60}$ molecules is revealed. Due to the bias effect on the LUMO alignment, negative differential resistance (NDR) is observed in both two- and three-terminal devices at a very low bias. Since the LUMOs can be easily modified by molecular adsorption, the NDR position is tunable and can be used in sensor applications without the need for specific molecular receptors.

11:51AM V24.00004 Quasiparticle Gaps of Nanostructures Weakly-Coupled to their Environments: The Case of C60/Metal Interfaces$. JAY SAU, Department of Physics, U C Berkeley, Material Science Division, LBNL, JEFFREY NEATON, Molecular Foundry, LBNL, HYOUNG-JOON CHOI, Department of Physics and IPAP, Yonsei University, Korea, STEVEN G. LOUIE, MARVIN L. COHEN, Department of Physics, U C Berkeley, Material Science Division, LBNL — A new approach based on density functional theory is developed to calculate charging energies and quasiparticle energy gaps of molecular systems weakly-coupled to an external environment. The approach is then applied to the case of a C60 molecule adsorbed on the Au(111) and Ag(100) surfaces. For C60/Au(111), the calculated quasiparticle gap is reduced by 2.34 eV relative to the gas-phase, consistent with recent experiments. For the more strongly-coupled C60/Ag(100) system, the predicted gap is also reduced, but differs from experiment by 0.5 eV. The discrepancy is identified as being due to screening due to charge transferred from the metal to the molecule and is resolved by solving an effective Anderson Hamiltonian within the GW approximation for the carriers in the HOMO and LUMO states, which results in an extra renormalization of the gap for the Ag(100) case.

12:03PM V24.00005 ABSTRACT WITHDRAWN —
12:15PM V24.00006 Electron-phonon scattering effects on transport properties of carbon nanotube devices using time-dependent wave-packet approach. HIROYUKI ISHII, National Institute of Advanced Industrial Science and Technology (AIST), NOBUHIKO KOBAYASHI, University of Tsukuba, KENJI HIROSE, NEC Corporation — Single-walled carbon nanotubes have been expected as nanoscale electronic devices, because the nanotubes are very good conductors exhibiting ballistic transport properties. However, the electronic current is saturated by the electron-phonon coupling. To realize the application of carbon nanotube devices, understanding of the scattering mechanism is required. We investigated the electron-phonon coupling effect on the transport properties of the nanotubes with micron order channel length, using the time-dependent wave-packet approach under a tight-binding approximation [1]. The vibrational atomic displacements in real space are introduced through the time-dependent Schrödinger equation and obtained the diffusion coefficients of the electronic wave packets. From these data, we can extract the mean free path and conductance. We clarified the difference of the phonon scattering effects on the conductance of the metallic nanotube and the semiconducting one. Furthermore we investigate the channel length dependence of resistance from ballistic to diffusive transport characteristics. [1] S. Roche et al., PRL 95 (2005) 076803

12:27PM V24.00007 ABSTRACT WITHDRAWN –

12:51PM V24.00009 Multiple Well Structures of Graphene1,2. HALDUN SEVINCI, Department of Physics, Bilkent University, Ankara 06800, Turkey, MEHMET TOPSAKAL, SALIM CIRACI, UNAM-Institute for Materials Science and Nanotechnology, Bilkent University, Ankara 06800, Turkey. — Based on first-principles calculations we predict that periodically repeated junctions of graphene ribbons of different widths form a multiple-well graphene structure. In such structures, the energy bands of graphene are discretized into unique, size-selected confined states. The width of the well as well as the bad gap, even the magnetic ground state for specific superlattices are modulated in direct space. Orientation of constituent ribbons, their width and length, the symmetry of the junction and their functionalization by adatoms are structural parameters to engineer electronic and magnetic properties of the quantum structure. Not only the size modulation, but also composition modulation such as the heterojunction of BN in honeycomb structure and graphene gives rise to confined states. Devices made from these graphene quantum structures display negative differential resistance. 1Part of the computations has been carried out by using UYBHM at Istanbul Technical University.

1:03PM V24.00010 Direct measurement of electric-field-screening length in thin graphite film. H. MIYAZAKI, RIKEN and JST-CREST, K. TSUKAGOSHI, RIKEN, AIST, and JST-CREST, S. ODADA, Y. AYOAGI, RIKEN, Tokyo TECH, and JST-CREST, T. SATO, S. TANAKA, H. GOTO, A. KANDA, Y. OOTUKA, Univ. of Tsukuba and JST-CREST — Electric-field-screening length in thin graphite film has been clarified by means of dual gated method. Sandwich type device structure which two gate electrodes are situated over and beneath a graphite film was constructed with Al top electrode. The Al electrode naturally generates thin gate insulator at graphite/Al interface, which enables extremely low voltage swing. The two systems are studied to determine how a chemical absorbate and linker influence transport through metallic CNTs. The first system consists of a stand alone metallic CNT with a single oxygen adsorption site, matching a proposed final chemical process for a HNO3 oxidation and reduction process. The second system consists of a CNT-Amide-(CH2)6-Amide-CNT structure in which both CNTs are metallic. Transmission calculations, using our DFT (FIREBALL)-NEGF code show that the amide linker suppresses transmission compared to a direct CNT-polyene linkage studied in [3]. 1. B. R. Goldsmith, et. al., Science, 315, 77 (2007). 2. X. Guo, et. al. Science, 311, 356 (2006). 3. N. Bruque, et. al. Phys. Rev. B, 76, 205322 (2007).

1:15PM V24.00011 Surface Potentials and Layer Charge Distributions in Few-Layer Graphene1. SUJIT DATTA, DOUGLAS STRACHAN, EUGENE MELE, A.T. CHARLIE JOHNSON, Department of Physics and Astronomy, University of Pennsylvania — Elucidating the electronic interaction between an insulating substrate and few-layer graphene (FLG) films is crucial for graphene device applications. We have performed electrostatic force microscopy (EFM) of FLG films. Our measurements reveal that the FLG surface electrostatic potential increases with film thickness, approaching a ‘bulk’ value for samples with five or more graphene layers - contrasting sharply with behavior expected for conventional conducting or semiconductor films. This is in quantitative agreement with the analytic predictions of a nonlinear Thomas-Fermi theory of the interlayer screening by the few-layer graphene's relativistic low energy charge carriers. Furthermore, our measurements are able to resolve previously unseen electronic perturbations extended along crystallographic directions of stressed samples, likely resulting from long-range atomic defects. 1Research supported by Nano/Bio Interface Center through the National Science Foundation NSEC DMR-0425780; the JST DTRA and the Army Research Office Grant # W911NF-06-1-0462; and Department of Energy Grant # DE-FG02-06ER46118.

1:27PM V24.00012 Valley contrasting physics in graphene: magnetic moment and topological transport. QIAN NIU, DI XIAO, WANG YAO, The University of Texas at Austin — We investigate physical properties that can be used to distinguish the valley degree of freedom in graphene systems with broken inversion symmetry. We show that the pseudospin associated with the valley index of carriers has an intrinsic magnetic moment, in close analogy with the Bohr magneton for the electron spin. There is also a valley dependent Berry phase effect that can result in a valley contrasting Hall transport, with carriers in different valleys turning into opposite directions transverse to an in-plane electric field. These effects can be used to generate and detect valley polarization by magnetic and electric means, forming the basis for the so-called valleytronics applications.

1:39PM V24.00013 Quantum transport of 2D Dirac fermions: the 2D symplectic symmetry class of Anderson localization and the Z2 topological term. SHINSEI RYU, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CHRISTOPHER MUDRY, Paul Scherrer Institute, Switzerland, HIDEAKI OBUSE, AKIRA FURUSAKI, RIKEN, Japan — We discuss the quantum transport of the 2D non-interacting Dirac Hamiltonian, which, underlies theoretical descriptions of graphene and surface states of 3D Z2 topological insulators. For a random scalar potential type disorder, a Z2 topological term is derived in the non-linear sigma model encoding the physics of Anderson localization in the symplectic symmetry class. Unlike the Pruisken term (Chern integer) in the IQHE, the Z2 topological term cannot be expressed, in general, as an integral of a local quantity, but as a sign of the Pfaffian of a family of Dirac operators. The Z2 topological term has a significant effect on the renormalization group flow of the conductance.
11:15AM V25.00001 A model for glass transitions in polymer thin films.¹ JANE LIPSON, Dartmouth
College — Polymeric materials formulated as thin films can exhibit glass transition temperatures which are significantly shifted relative to bulk values. Depending on whether the film is supported (on a substrate) or freely-standing the temperature shift can go in different directions relative to the bulk. For all films the magnitude of the shift depends on film thickness. For supported films the shift appears to depend on substrate-polymer interactions, while for free-standing films there is a striking dependence on molecular weight. Experimental data published over the last five years have included some elegant and intriguing results which provide a significant challenge for those wishing to understand these phenomena. In this talk a model that predicts glass transitions in both free-standing and supported films will be presented and tested against extant data. Ideas for future experiments will also be discussed.

¹Work done in collaboration with Scott Milner, ExxonMobil Research and Engineering.

11:51AM V25.00002 Creating defect free structures by directed photochemical reaction in a ternary phase separating system. PRATYUSH DAYAL, OLGA KUKSENOK, ANNA BALAZS, University of Pittsburgh — We present a technique to create long range ordered structure in photosensitive reaction-diffusion systems. Our approach utilizes a reversible photochemical reaction between species A and B in a ternary immiscible ABC blend to yield a defect-free arrangement of phase separated ABC domains. The process essentially consists of two steps. First, the sample is irradiated by virtue of masks creating an illumination pattern which allows the migration of AB components to the covered regions at the expense of the C component. As a result the C component is pinned onto the irradiated regions which in turn leads to pinning of AB domains thereby creating a long range order in the system. Second, the masks are completely removed and whole sample is irradiated uniformly. In this case, the system evolves into a distinctly different ordered structure. The ordering of the system, either before or after removal of the mask, can be locked in by quenching the system at appropriate temperature. Simulation studies reveal that the ordering can be controlled by changing the initial concentration of the blend as well as by varying size and arrangement of the holes in the mask. The defect free morphology has been demonstrated for rectangular, hexagonal and parallel arrangement of the masks.

12:03PM V25.00003 Entropic Effects in the Phase Behavior of Athermal Nanoparticle/Homopolymer Thin Film Mixtures , LUCIANA MELI, ABRAHAM ARCEO, PETER GREEN, University of Michigan — The phase behavior of an athermal nanoparticle/polymer mixture, composed of polystyrene-coated gold nanoparticles embedded in polystyrene thin film hosts, was examined. It is shown that the spatial distribution of nanoparticles is readily tailored through control of: the grafting density of the brush, the length of both grafted and free chains, and the relative size of the nanoparticles in comparison to the size of the polymer melt chains. The distribution of nanoparticles within the polymer host, including a surface-induced phase separation, may be understood as a balance between the conformational entropy of the polymer chains, which is compromised when the chains have to stretch around the nanoparticles and penetrate their brush, and the translational entropy of the nanoparticles, which favors their homogeneous distribution. This is the first report that systematically studies the entropic effects that lead to surface phase transitions in polymer/nanoparticle thin film mixtures. Our results may also prove helpful in understanding nanofiller dispersion in analogous bulk mixtures.

12:15PM V25.00004 Mechanism of Interfacial Instability in Thin Polymer Film in Controlled Solvent Atmosphere , PARMANAMOKARIAN-TABARI, JONATHAN. R. HOWSE, SASHA Y. HERIOT, MARK GEGHEGEGH, RICHARD A.L. JONES, Department of Physics and Astronomy, The University of Sheffield, Sheffield, S3 7RH, UK — Thin films of immiscible polymers made by spin coating have potential for many practical applications like field-effect transistors, LEDs and photovoltaic devices. We have developed a technique based on small angle light scattering and reflectivity to study the process of phase separation in spin cast films in situ during formation. Previous experiments proposed formation of a transient wetting layer which is followed by interfacial instability and leading to lateral phase separation. In our recent work the origin of this instability has been studied. Experiments have been designed to test the Marangoni instability by spin coating the PS/PMMA film in a controlled toluene vapour atmosphere. A fast evaporation rate leads to laterally phase separated structure whereas slow evaporation lowers the solvent gradient inside the film and leads to a self stratiﬁed structure. By comparing the data to a model a better understanding of film evolution has been established.

12:27PM V25.00005 Spanning Trees and the Dynamics of Compact Polymers , ARMIN RAHMANI, ANDREA VELENICH, CLAUDIO CHAMON, Physics Department, Boston University — We introduce a lattice model for a compact loop polymer conﬁned to a two-dimensional box. A mapping to spanning trees on a square lattice we calculate the partition function and the energy of the system as a function of temperature, bending rigidity and elasticity of the polymer. We study the dynamics of the system using a kinetically constrained model whose elementary moves consist of polymer ﬁnger ing or, in the language of the spanning trees, local bond ﬂips taking place at the leaves of the tree. We study, through Monte-Carlo simulations, the time dependence of the energy and the number of leaves in the system when quenched from inﬁnite temperature to various ﬁnite temperatures. We ﬁnd that for temperatures above a critical value, these observables monotonically decay to their equilibrium values whereas, for lower temperatures, a broad non-equilibrium plateau emerges.

12:39PM V25.00006 Upper Limit of Superheating in Polymer Crystals Revealed from Linear Heating Covering Seven Orders of Magnitude in Heating Rate , CHRISTOPH SCHICK, University of Rostock, Germany, ALEXANDER MINAKOV, General Physics Institute, Moscow, Russia, ANDREAS WURM, University of Rostock, Germany — We report about superheating of polymer crystals on linear heating covering the scanning rate range from 0.02 to 1,000,000 K/s. Results obtained by super-fast scanning calorimetry using a thin film sensor [1] are combined with results from DSC. On slow heating semicrystalline polymers tend to recrystallize (reorganize) significantly fast. From previous measurements the onset of melting of isothermally crystallized samples can be attributed to the rising flank of the first melting peak, which is often described by the power law of superheating:

\[ T \sim (T - T_{\alpha})^\alpha \]

with \( \alpha < 0.2 \), which does not correspond to the heat transfer but rather to a nucleation process [2]. At high heating rates superheating saturates. The power law behavior and the saturation of superheating will be discussed. 1. A.A. Minakov, C. Schick, Rev. Sci. Instrum. 78 (2007) 073902. 2. A.A. Minakov, A. Wurm, C. Schick, Europ. Phys. J. E, 23 (2007) 43.
12:51PM V25.00007 Molecular simulation of crystal nucleation of an n-alkane, PENG YI1. GREGORY RUTLEDGE2. Massachusetts Institute of Technology — We report the results of molecular simulations to study crystal nucleation of n-octane from the melt. A realistic united atom force field was employed for n-octane. The melting behavior was first determined by ramping temperature in a set of Monte Carlo simulations. The adiabatic nucleation trajectory was then sampled using the umbrella sampling technique with a set of proposed global and local order parameters, and analyzed for selection of best order parameter. The transition state ensemble has been verified by molecular dynamics simulation. The structure of critical nuclei in the nucleation process is analyzed and the effect of intermediate phases discussed.

1:03PM V25.00008 Entropically Driven Layering Near a Substrate: A Fluids DFT Study, ERIN MCGARRITY, Michigan State University, AMALIE FRISCHKNECHT, Sandia National Laboratory, MICHAEL MACKAY, Michigan State University — We employ a fluids density functional theory to study the phase behavior of athermal polymer/nanoparticle blends near a hard substrate. These blends exhibit two types of first order, entropically driven layering transitions. In the first type of transition, the nanoparticles order to form a layer which is a fixed distance from the surface. The structure and location of this layer depends on nanoparticle radius. In the second type of transition, which occurs at melt-like densities, the nanoparticles and polymers form lamellar structures which resemble colloidal crystals. We examine the effects of packing density, chain length and nanoparticle radius on the system and show that the transitions are first order. In addition we show that the crystalline phase is nucleated by the presence of the surface. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

1:15PM V25.00009 Properties of Ferroelectric Polyvinylidene fluoride-co-trifluoroethylene Nanorods, JODIE LUTKENHAUS, Yale University, THOMAS RUSSELL, University of Massachusetts Amherst — Ferroelectric and piezoelectric nanorods of polyvinylidene fluoride (PVdF) are potential candidates for sensing mechanical stimuli on the nano-scale. Untreated PVdF tends to crystallize in a non-ferroelectric (α) phase. PVdF-co-trifluoroethylene (PVdF-TrFE), on the other hand, readily crystallizes into the ferroelectric (β) phase; however, the structure and properties can be significantly influenced by confinement. Here, the creation of PVdF-TrFE nanorods (dia. = 15 to 200 nm) using anodized aluminum oxide membranes was investigated. The crystallization behavior and the Curie transition (ferro- to paraelectric phase) were studied. Changes in structure and phase were investigated by X-ray diffraction (XRD) and differential scanning calorimetry (DSC). The effects of electrical poling, which increases dipole-orientation within the ferroelectric phase, are discussed.

1:27PM V25.00010 Thermodynamics and Kinetics of Crystallization of Flexible Molecules, BERNHARD WUNDERLICH, Retired — The crystallization of a single atom (as in a metal) is a one-step transfer across the liquid-crystal interface. A flexible chain molecule of n segments needs considerably more steps. A simple description gives it (n - 2) steps. The melting temperature of pentamethylene, i.e., for pentamethylene C5H102 111,000, but only one conformation in the crystal, making the crystallization a multi-step process. At what length are there too many steps to allow the crystallization to be reversible? How can one describe phase separation for flexible molecules containing segments of different chemical nature? How do random segments of different nature and precisely spaced segments of different nature influence the phase separation on crystallization? How is reversible crystallization influenced by chain folding and crystal perfection in the solid state? Some of these old questions can now be answered by temperature-modulated differential scanning calorimetry of precisely made molecules of different length and copolymerized structure.

1:39PM V25.00011 UV-convergent One-loop Theory of Binary Homopolymer Blends, JIAN QIN, FRANK BATES, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota — We analyze the effects of long wavelength composition fluctuations in binary homopolymer blends. We use a generalization of Wang’s theory [1], in which all dependence upon short-wavelength structure is absorbed into a renormalization of an effective χ parameter χ e and of statistical segment lengths. The theory allows us to calculate the collective correlation function S(λ), single chain correlation functions, and the free energy density in homogeneous mixtures. The same formalism can be used to study diblock copolymer melts. The value of χ e N at the critical point of a binary blend exceeds that predicted by Flory-Huggins theory by an amount proportional to 1/√N, though the width of the critical region is proportional to 1/N. For strongly asymmetric blends, however, the binodal value of χ e N is suppressed. The dimensions of individual chains decrease slightly with increasing χ e or with decreasing N, even when χ e = 0. [1] Z.-G. Wang, J. Chem. Phys., 2002, 117:481.

1:51PM V25.00012 Effect of intensity gradient profiles on crystal growth subject to holographic free radical photopolymerization1. THEIN KYU, PANKAJ RATHI, SOOJEOUNG PARK, University of Akron — A theoretical model has been developed to describe a unique phenomenon of photopolymerization-induced crystallization subjected to holographic intensity gradient profiles. A hypothetical phase diagram of a crystalline polymer solution (or blend) is constructed to guide the dynamics of directional crystallization. Calculations of holographic photopolymerization induced crystallization were carried out slightly above the melting temperature of the bends under the conditions of sinusoidal as well as sharp (square) interface. In the case of periodically varying interface, the dynamic calculations revealed that the emerged crystals (spherulites) have out-grown the patterned regions, which is consistent with the crystal growth behavior of the polyethylene oxide/diacrylate system. However, in the case of a sharp holographic the directional growth occurs along the stripes, which is confined within the stratified layers.

Morial Convention Center 218
The vibrational entropic effects stabilize the non-dissociated clusters. This behavior is traced back to the large dynamic effects associated with the formation of nuclei. The free formation energy of the critical cluster plays an essential role in the calculation of nucleation rates. Thus, we have constructed a nucleation rate relation which is easy to calculate and its result is relatively simple to compare with experimental data. The energy formation of a cluster has a few more terms than the traditional classical model. Furthermore, the extra terms in this approach have their roots in the molecular treatment of a cluster formation and they are temperature dependent. We have compared the result of this approach with the original classical theory along with some experimental data. Our initial results seem promising and the temperature correction has a correct trend.

11:15AM V27.00001 Path Integral Approach to Geometrically Frustrated Quantum Antiferromagnets\textsuperscript{1}, MIRACULOUS BHASEEN, University of Cambridge, JOHN CHALKER, University of Oxford — We develop a path integral approach to geometrically frustrated quantum antiferromagnets. Using Hubbard–Stratonovich transformations to decouple the interactions within clusters of spins, we establish a high temperature expansion of the quantum partition function. This semiclassical approach based on conjugate cluster variables allows us to descend below the Curie–Weiss temperature scale, and to describe the emergent spin liquid regime. We make contact with complementary approaches based on spin wave theory.

\textsuperscript{1}We acknowledge support from EPSRC and the Rudolf Peierls Centre for Theoretical Physics.

11:27AM V27.00002 Contractor-Renormalization approach to frustrated magnets in a magnetic field, ANDREAS ABENDSCHEIN, SYLVAIN CAPPONI, Laboratoire de Physique Théorique, Université Paul Sabatier, CNRS - Toulouse, France — We propose to use the Contractor Renormalization (CORE) technique in order to derive effective models for quantum magnets in a magnetic field. CORE is a powerful non-perturbative technique that can reduce the complexity of a given microscopic model by focusing on the low-energy part. We provide a detailed analysis of frustrated spin ladders which have been widely studied in the past. In particular, we discuss how to choose the building block and emphasize the use of their reduced density matrix. With a good choice of basis, CORE is able to reproduce the existence or not of magnetization plateaux in the whole phase diagram contrary to usual perturbation theory. Furthermore, we present recent results for other, potentially more interesting geometries like the Heisenberg bilayer where we also address the issue of plateau formation and point out the analogy between non-frustrated strongly anisotropic models and frustrated SU(2) ones. Finally, we investigate the magnetization curve of the Shastry-Sutherland model and, however in absence of a magnetic field, we consider the square lattice with four-spin ring-exchange.

11:39AM V27.00003 Spin-orbital liquid state on the square lattice with emergent Majorana fermions and $\mathbb{Z}_2$ topological order, ASHVIN VISHWANATH, FA WANG, UC Berkeley — Magnetism from d-electrons often retains orbital degeneracy which can enhance quantum fluctuations and lead to exotic liquid-like ground states with no conventional order. Indeed, experimental systems like LiNiO$_2$, FeSc$_2$S$_4$ etc. with orbital degeneracy show a lack of order down to low temperatures. We introduce a Majorana-fermion slave particle theory to study such states in spin-1/2 models with $e_g$ orbital degeneracy. This is first applied to a square lattice model with enhanced SU(4) symmetry. A mean field treatment predicts a spin-orbital liquid state with nodal Majorana fermion excitations and $\mathbb{Z}_2$ topological order. A variational Monte-Carlo study of the corresponding wavefunction confirms the absence of magnetic order and bond order, which makes it a candidate state for a spin orbital liquid. Comparing against the exact diagonalization studies in [Bosche et al. Eur. Phys. J. B 17, 367 (2006)], our state is found to have significant overlap with the ground state on small lattices. Despite the absence of a variational parameter, our model can also be tested by finite-size effects and applications to $S=3/2$ atoms confined in optical lattices are pointed out.

11:51AM V27.00004 Magnetic monopoles in spin ices and spin excitations in other pyrochlores\textsuperscript{3}, RODERICH MOESSNER, Max-Planck-Institute for the Physics of Complex Systems — Exotic excitations go along with the unusual ground states of frustrated magnets. One of the most striking examples occurs in dipolar spin ice, where the dipole moment of the underlying electronic spin degrees of freedom fractionalise into magnetic monopoles. This constitutes possibly the first instance of fractionalisation in a three-dimensional material. It enables us to account for a mysterious phase transition observed experimentally in spin ice in a magnetic field, which is a liquid-gas transition of the magnetic monopoles. These monopoles can also be detected by magnetic resonances, e.g., in an experiment modelled after the celebrated Stanford magnetic monopole search. We also discuss other instances of unusual pyrochlore excitations.

12:27PM V27.00005 Vortex Berry phases and the magnetization of quantum magnets, AKIHIRO TANAKA, National Institute for Materials Science, KEISUKÉ TOTSUKA, Yokawa Institute of Theoretical Physics, Kyoto University, XIAO HU, National Institute for Materials Science — We revisit the magnetization process of quantum antiferromagnets subject to an external magnetic field, and show how an interpretation in terms of Berry phases emerges. First we develop a continuum variant of the Lieb-Schulz-Mattis- type approach to the 1d problem, and find that the well-known equivalence between solid and liquid behavior is ascribed to the nesting property at the van-Hove singularity preserved under electron correlation. We will also present the results for hyper-Kagome magnets. One of the most striking examples occurs in dipolar spin ice, where the dipole moment of the underlying electronic spin degrees of freedom fractionalises into magnetic monopoles. This constitutes possibly the first instance of fractionalisation in a three-dimensional material. It enables us to account for a mysterious phase transition observed experimentally in spin ice in a magnetic field, which is a liquid-gas transition of the magnetic monopoles. These monopoles can also be detected by magnetic resonances, e.g., in an experiment modelled after the celebrated Stanford magnetic monopole search. We also discuss other instances of unusual pyrochlore excitations.

12:39PM V27.00006 Kinetic ferromagnetism on frustrated lattices, FRANK POLLMANN, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, KIRILL SHTENGEL, Department of Physics, University of California, Riverside, USA, PETER FULDE, Asia Pacific Center for Theoretical Physics, Pohang, Korea — Systems with frustrated interactions are generally characterized by a high density of low–lying excitations which can be responsible for interesting physical effects. Much attention has been paid to the effects of frustration in antiferromagnetic systems. In this talk, however, we present a model of ferromagnetism arising in a frustrated system. We study strongly correlated electrons described by an extended Hubbard Hamiltonian on a kagome lattice at 1/6 and 1/3 filling. In the limit $t/V \ll 1$, we derive an effective low-energy Hamiltonian for this model. The Perron-Frobenius theorem can then be used to show that the ground state of this system is ferromagnetic. We will address the robustness of ferromagnetism to finite temperature effects and other interactions and discuss possible extensions to other lattices.

12:51PM V27.00007 Magnetic fluctuations in the Hubbard Model on Kagome-based frustrated Lattices, MASAFUMI UDAKAWA, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo — We report our results on the interplay between electron correlation and magnetic fluctuations in the geometrically-frustrated Kagome and hyper-Kagome Hubbard models at half filling. These models have two different geometrical units important in the low-energy physics: the frustrated triangle and the non-frustrated loop with even-numbered sites. In order to treat both of them on equal footing, we apply cluster dynamical mean-field theory to large-size clusters up to 12 sites. By calculating the spin susceptibility $\chi(\mathbf{q},\omega)$, we have found in the Kagome system that an anomalous one-dimensional magnetic correlation previously found near the Mott transition [1] is observed even in the non-interacting case at high temperature, and its temperature range gradually suppressed by increasing electron correlation. This behavior is ascribed to the nesting property at the van-Hove singularity preserved under electron correlation. We will also present the results for hyper-Kagome system in relation to the recent experiments on Na$_4$Ir$_2$O$_6$ [2].

1:03PM V27.00008 Study of the $U(1) - Z_4$ cross-over in 2D valence-bond-solids\textsuperscript{1} JIE LOU, ANDERS SANDBVIK, Associate Professor — We consider the 2D Heisenberg model in the overcomplete basis of valence bonds. By tuning matrix elements corresponding closely to the diagonal and off-diagonal terms in Rokhsar-Kivelson quantum dimer model, we show, using a projector quantum Monte Carlo technique, that there is a quantum phase transition into a valence-bond-solid (VBS) state. This system allows us to study the cross-over length-scale \textsuperscript{1}[1] associated with emergent $U(1)$ symmetry of the VBS order parameter \textsuperscript{2}, which has up until now not been possible in other systems \textsuperscript{3}, where the VBS order is weaker and prohibitively large system sizes are needed to observe the stabilization of a manifestly $Z_4$-symmetric VBS. \textsuperscript{[1]} J. Lou, A. W. Sandvik, and L. Balents, Arxiv:0704.1472. \textsuperscript{[2]} T. Senthil, A. Vishwanath, L. Balents, S. Sachdev, and M. P. A. Fisher, Science 303, 1490 (2004). \textsuperscript{[3]} A. 1:15PM V27.00009 Dimerized Bond-Disordered Quantum Spin Models and Harris Criterion JONAS GUSTAFSSON, Goldman Sachs, DAOXIN YAO,ERICA CARLSON, Purdue University, ANDERS W. SANDBVIK, Boston University — We study several different realizations of dimerized bond disorder in the two-dimensional square-lattice $S=1/2$ Heisenberg model, by introducing strong and weak couplings, $J_s, J_w$, randomly, but in such a way that each spin belongs to one strong bond (a dimer). We study the ground-state phase transition occurring at a critical ratio $g_c = J_s/J_w$ for different ways of distributing the dimers: (a) randomly distributed as in the classical dimer model, whence the dimer-dimer correlation function follows a power law, $c(r) \sim r^{-2}$, and (b) the random plaquette (RP) model, where all dimers are first placed horizontally in columns and thereafter any plaquette with dimers is flipped with probability $p = 1/2$ or 1/4. Our calculations show that the Harris criterion for the relevance of disorder is not applicable to these models. In all cases, the disorder does not appear to change the universality class from that obtaining with a regular dimer arrangement.

1:27PM V27.00010 Spontaneous parity breaking of Dirac spin liquid in a magnetic field, YING RAN, University of California, Berkeley, WING-HO KO, PATRICK LEE, XIAO-GANG WEN — The Dirac spin liquid was proposed to be the ground state of the spin-1/2 Kagome antiferromagnets. In a magnetic field, we show that the state with Fermi pocket is unstable to the Landau level (LL) state and the XY ordered state. We mainly focus on the fully gapped LL state, which breaks parity symmetry and thus supports a finite temperature phase transition. We discuss experimental signatures which we can be focus on the fully gapped LL state, which breaks parity symmetry and thus supports a finite temperature phase transition. We discuss experimental signatures which we can be

1:39PM V27.00011 Two-step spin flop transition in quantum spin ladders, TORU SAKAI, Japan Atomic Energy Agency and CREST JST, KYIOMI OKAMOTO, Tokyo Institute of Technology — It is well known that the antiferromagnet with easy-axis anisotropies exhibits a field-induced first-order phase transition, the so-called spin flop. In one-dimensional quantum spin systems, instead of it, a second-order phase transition occurs because of large quantum fluctuations\textsuperscript{1}. Particularly the $S=1$ antiferromagnetic chain with the easy-axis single-ion anisotropy was revealed to exhibit two successive field-induced second-order transitions by our previous numerical analysis\textsuperscript{2}. However, such transitions have not been observed yet. Recently a two-step spin flop transition was observed in the spin ladder system IPA-CuCl$_4$\textsuperscript{3}, which has ferromagnetic rung coupling. In order to clarify the mechanism of the two-step field-induced transition, we investigate the anisotropic spin ladder using the numerical diagonalization and the finite-size scaling analysis. As a result, we revealed that two different field-induced second-order quantum phase transitions possibly occur. Several phase diagrams are also presented. In addition we discuss on a possible two-step spin flop in other materials\textsuperscript{4} and some frustrated systems. \textsuperscript{[1]} C. N. Yang and C. P. Yang, Phys. Rev. 151 (1966) 258. \textsuperscript{[2]} T. Sakai, Phys. Rev. B 58 (1998) 6268. \textsuperscript{[3]} T. Masuda et al, Phys. Rev. Lett. 96 (2006) 047210. \textsuperscript{[4]} H. Miyasaka et al, Inorg. Chem. 42 (2003) 8203.

1:51PM V27.00012 Spin and Singlet Dynamics of the S=1/2 Quantum Kagome Antiferromagnet, ANDREAS LAUCHLI, IRMMA — EPF Lausanne, Switzerland, CLAIRE LHUILLIER, LPTMC, UPMC Paris, France — The Kagome Heisenberg antiferromagnet with spin 1/2 has been the topic of many theoretical investigations. Most of these focused on groundstate properties or were aiming at an explanation of the anomalous high density of singlet excitations. In this contribution we report on exact diagonalization studies concentrating on dynamical correlation functions. First the full dynamical spin structure factor $S(q, \omega)$ on 36 sites has been obtained, showing a broad, rather incoherent spectral response, which furthermore seems to increase significantly at low energies. Then we discuss the time dependent spin autocorrelation function as well as dynamical dimer-dimer correlation functions. All these results combined point towards a highly fluctuating system, both in the singlet and the triplet channel. We conclude by a comparison with recent inelastic neutron scattering measurements on the Herbertsmithite and Volborthite compounds.

2:03PM V27.00013 Pseudo-Dirac Hamiltonians and Flux Phases of SU(N) magnets, F.J. BURNELL, S.L. SONDHI, Princeton University, R. SHANKAR, Yale University — The lattice Dirac Hamiltonian describes a particle hopping on a lattice in a particular background magnetic field. We present a family of hopping Hamiltonians in other background fields that generalize many aspects of the Dirac Hamiltonian to lines and planes of nodes. In our canonical case, hopping on the pyrochlore lattice gives rise to a half filled fermi surface that consists of four intersecting \cite{111} lines. This spectrum is invariant under tetrahedral rotations, rather than all rotations as in the Dirac case, resulting in a more complex matrix anti-commutation structure. This structure arises in a large N treatment of the SU(N) Heisenberg model on the pyrochlore.

11:51 AM V28.00002 Backward-wave optical parametric amplification and mirrorless oscillations in negative-index materials

T. F. George and V. M. Shalaev, Purdue University — Extraordinary properties of mirrorless backward-wave OPO in nanostructured crystal have been recently demonstrated in [1]. Phase matching of backward waves is inherent to negative-index materials (NIMs). Extraordinary, distributed-feedback, properties of OPA and possibility of OPO in NIMs were predicted in [2,3]. Herewith, we show the feasibilities and explore the features of the mirrorless OPO and of the generation of counterpropagating left-handed signal and right-handed idler photons in NIMs. Two different options are investigated. One is OPO based on intrinsic quadratic nonlinearity of the NIM. Another option is four-wave mixing OPO based on separately engineered strong cubic nonlinearity through resonant nonlinear impurities. It is shown that in the latter case the OPO properties can be tailored by quantum control.

12:03PM V28.00003 Tunable photonic crystals with nonlinear composite materials

KIN WAH YU, Chinese University of Hong Kong, Shatin, NT, Hong Kong. J. P. HUANG, G. WANG, Fudan University, Shanghai, China — Photonic crystals (PCs) are periodic dielectric structures that are designed to control the flow of electromagnetic (EM) waves. The main attraction of PCs is the existence of photonic band gaps, for frequencies within which the propagation of EM waves can be forbidden leading to many promising applications in the areas of computing and communication for their advantages over electronics. In this work, we report a novel class of tunable photonic crystals consisting of multilayers of noble-metal nanoparticles in dielectric composites with nonlinear responses [1]. For such PCs, precise tunability of photonic band gaps can be achieved by choosing appropriate pump AC or DC electric fields [2]. Moreover, we study the dynamics of Bloch oscillation in such PCs so as to realize terahertz radiation which is relevant in medical physics.

Supported by RGC Earmarked Grant of Hong Kong SAR Government.

12:15PM V28.00004 Enhanced and Resonant Transmission of Light through Dielectric-filled Subwavelength Waveguides

HUIZHONG XU, PANGSHUN ZHU, HAROLD G. CRAIGHEAD, WATT W. WEBB, School of Applied and Engineering Physics, Cornell University, Ithaca, NY 14853 — We analyze transmission of light through dielectric-filled subwavelength waveguides in a metal using both analytical and numerical methods. Our analysis revealed that a propagating mode can in principle exist in a waveguide of arbitrarily small size when a certain relationship between the dielectric constants of the metallic cladding and filling material is satisfied. Transmission through a subwavelength aperture of finite length can be further enhanced when the length is such that Fabry-Pérot-like resonances are excited. Strong, localized near-field intensity at the exit can be achieved with this mechanism for aperture diameters down to ~\(\lambda/20\). We will describe potential applications of this resonantly enhanced transmission phenomenon in near-field scanning optical microscopy and single-molecule spectroscopy.

This research is supported by NIH grant No. 9-P41-EB001976, NSF grant No. DMR-0520404, and the STC program of the NSF under agreement No. ECS-9876771.

12:27PM V28.00005 Transmission of images with subwavelength resolution to distances of several wavelengths in microwave, terahertz and infrared ranges

PAUL BELOV, Queen Mary University of London, UK, MARIO SILVEIRINHA, University of Coimbra, Portugal, PEKKA IKONEN, CONSTANTIN SIMOVSKI, SERGEI TRETYAKOV, Helsinki University of Technology, FINLAND, YAN ZHAO, YANG HAO, CLIVE PARINI, Queen Mary University of London, UK — The resolution of conventional imaging systems is restricted by the diffraction limit: the details smaller than half-wavelength of radiation cannot be resolved. Using novel engineered media with extreme optical anisotropy and waveguiding properties it is possible to overcome the classical limit and create devices capable of transmitting images with subwavelength resolution over long distances. We report experimental results that demonstrate transmission of a microwave image by means of an array of parallel metallic rods over a distance 3.5 times greater than the wavelength. The resolution of such imaging device is 15 times less than the wavelength. The magnifying, demagnifying and repeating properties of lenses formed by long metallic rods provide a unique solution for subwavelength imaging at microwave and terahertz ranges. At microwave wavelengths, the resolution of such lenses is mainly determined by the characteristic period, which is limited only by the fabrication capability rather than by any physical constraints. At higher frequencies, the resolution is mainly limited by the skin-depth of the rods material.

This research was sponsored through NSF-NIRT grant No. 0304678.

12:39PM V28.00006 All Optical Method for Positioning Single Quantum Dots in Photonic Crystal Nanocavities

SUSSANNA THON, MATTHEW RAKHER, JAN GUDAT, HYOCHUL KIM, WILLIAM IRVINE, DIRK BOUWMEESTER, University of California Santa Barbara, Department of Physics, NICK STOLTZ, PIERRE PETROFF, University of California Santa Barbara, Materials Department — Single self-assembled InAs quantum dots embedded in GaAs photonic crystal (PC) defect cavities are a promising system for cavity quantum electrodynamics experiments. Achieving controllable coupling between the PC cavity mode and quantum dot emission is difficult, however, due to the random nucleation locations and spectral properties of individual quantum dots. We have developed a novel, all optical scheme for locating single dots relative to prefabricated markers on the sample surface with sub-10 nm accuracy which should allow us to custom fabricate PC cavities tuned to the exact position and frequency of the quantum dots. Initial experimental results are presented.

This research was sponsored through NSF-NIRT grant No. 0304678.

12:51PM V28.00007 Effect of Shape Parameters on NanoOptronic Circuit Element Optical Response

TIMOTHY CORRIGAN, University of Maryland, Department of Physics, College Park, MD and University of Maryland, Materials Science, College Park, MD, DOMINIC BRITTI, University of Maryland, Materials Science, College Park, MD, PAUL KOLB, Laboratory for Physical Sciences, College Park, MD, ANDRIE SUSHKOV, DENNIS DREW, University of Maryland, Department of Physics, College Park, MD, SHYHUAH GUO, University of Maryland, Electric Engineering, College Park, MD and Laboratory for Physical Sciences, College Park, MD, RAYMOND PHANEUF, University of Maryland, Materials Science, Physics, and Electric Engineering, College Park, MD, and Lab for Physical Sciences, College Park, MD — We examine the effect on the visible-near IR response of a number geometrical parameters of optical circuit elements with potential applications for guiding light for communications and for use in other metamaterial/optoelectronics applications. Rounding of edges produces a shift in the resonance frequency transmission measurements and in numerical simulations. We also examine the effect of shape parameters on the response of u-shaped and single split-ring Ag structures and discuss the LC circuit model in describing their optical response.

Work supported by the Lab for Physical Sciences.
non-contact method for patterning three-dimensional carbon nanotube microstructures. In this method, a 1 \mu m, WEI-HUSUAN HUNG, RAJAY KUMAR, ADAM BUSHMAKER, MICHAEL J. BRONIKOWSKI, STEPHEN B. CRONIN — We present an optical, measurements of such nanodevices is our future goal.

In particular, it was possible to drill 2.5 nm diameter nanoholes in multiwall carbon nanotubes (MWNT’s). Similarly sized holes were etched through metallic nanowires. We have also fabricated larger nanoholes, as large as 11 nm wide in a 26 nm diameter MWNT, as well as constrictions in MWNT’s. Transport has unusual and potentially useful electrical transport properties. Local control of the parameters of such nano-objects would open even wider possibilities for their applications. We have used the highly focused, high-energy electron beam of a transmission electron microscope to locally modify such nano-objects.

Morial Convention Center 221

THOMAS AREF, UIUC, MIKAS REMEIKA, UCSD, MATTHEW BRENNER, ALEXEY BEZRYADIN, UIUC — Carbon nanotubes and metallic nanowires have unusual and potentially useful electrical transport properties. Local control of the parameters of such nano-objects would open even wider possibilities for their applications. We have used the highly focused, high-energy electron beam of a transmission electron microscope to locally modify such nano-objects. In particular, it was possible to drill 2.5 nm diameter nanoholes in multiwall carbon nanotubes (MWNT’s). Similarly sized holes were etched through metallic nanowires. We have also fabricated larger nanoholes, as large as 11 nm wide in a 26 nm diameter MWNT, as well as constrictions in MWNT’s. Transport measurements of such nanodevices is our future goal.

11:15AM V29.00001 High-Resolution Nanofabrication Using a Highly-Focused Electron Beam, THOMAS AREF, UIUC, MIKAS REMEIKA, UCSD, MATTHEW BRENNER, ALEXEY BEZRYADIN, UIUC — Carbon nanotubes and metallic nanowires have unusual and potentially useful electrical transport properties. Local control of the parameters of such nano-objects would open even wider possibilities for their applications. We have used the highly focused, high-energy electron beam of a transmission electron microscope to locally modify such nano-objects. In particular, it was possible to drill 2.5 nm diameter nanoholes in multiwall carbon nanotubes (MWNT’s). Similarly sized holes were etched through metallic nanowires. We have also fabricated larger nanoholes, as large as 11 nm wide in a 26 nm diameter MWNT, as well as constrictions in MWNT’s. Transport measurements of such nanodevices is our future goal.

11:27PM V28.00010 Wavefront Analysis as a Predictive Tool for Polymer/Liquid Crystal Composites with Nanostructures, JARED COYLE, SAMEET SHRIYAN, ADAM FONTECCHIO, Drexel University — Nano-scale morphology is a key factor in determining the optical performance of holographically-formed polymer dispersed liquid crystal (HPDLC) thin films. The liquid crystal(LC)/polymer interface and droplet structure in these materials effects optical performance. Established microscopy techniques such as SEM and TEM are conventionally used to examine interfacial properties. In this paper, HPDLC reflective and transmissive wavefront analysis are used to examine gratings created using three different polymer formulations: acylate, thiol-ene and a combination of acylate and thiol-ene. Changes in the modulation transfer function, Strehl ratio and wavefront phase of both transmissive and reflective wavefronts are compared to morphological properties shown in SEM images. Wavefront properties were measured using a Shack Hartman wavefront analyzer. Optical performance characteristics were measured using an Ocean Optics spectrometer, halogen light source and oscilloscope.

11:27AM V29.00002 Optical Patterning of Three-Dimensional Carbon Nanotube Microstructures, WEI-HUSUAN HUNG, RAJAY KUMAR, ADAM BUSHMAKER, MICHAEL J. BRONIKOWSKI, STEPHEN B. CRONIN — We present an optical, non-contact method for patterning three-dimensional carbon nanotube microstructures. In this method, a 1 \mu m diameter focused laser spot is used to burn patterns in dense arrays of vertically grown multiwalled carbon nanotubes. The threshold for laser burnout and the depth of burnout are determined by Raman spectroscopy and scanning electron microscopy. Using a high precision translation stage to control the position of the laser spot on the sample, we create several 3D patterns to illustrate this method’s potential use for the rapid prototyping of carbon nanotube microstructures [1]. After laser surface treatment, we observe undercut profiles, changes in nanotube density, and nanoparticle formation, which provide insight into the unique evolution of the nanotube microstructures during the burnout process. This non-lithographic method provides new opportunities for chemically sensitive applications of nanotubes and expands their possible applications into new areas.

11:39AM V29.00003 A Real Time Detection System for Dielectrophoretic Deposition of Carbon Nanotubes, SEBASTIAN SORGENFREI, INANC MERIC, AUSTIN AKYE, SARBAJIT BANERJEE, SAMI ROSENBLATT, IRVING P. HERMAN, KENNETH SHEPARD, Columbia University — Single-walled carbon nanotubes (SWCNTs) have showed considerable potential as building blocks for electronics and sensors but are very difficult to integrate and assemble into larger systems. Dielectrophoretic deposition allows the large-scale positioning and alignment of SWCNT’s but requires precise control to reproducibly generate single-tube devices. We investigate dielectrophoretic deposition of SWCNT’s using an in situ detection system. This apparatus locks into both a small AC signal and the large, mixed-down dielectrophoretic signal, generated by the nonlinearities of the device, making it possible to halt deposition once a nanotube has made electrical contact. This results in a higher yield of single SWCNT’s deposited between two electrodes.

This work was supported in part by the SRC Focus Center Research Program through the C2S2 Center and by the NSF under Grant 0707748.
11:51AM V29.00004 Irradiation-induced phenomena in carbon nanomaterials  ARIKDY KRASHENIN-NIKOV, Accelerator Laboratory, University of Helsinki, and Laboratory of Physics, Helsinki University of Technology, Finland — The irradiation of solids with energetic particles such as electrons or ions is associated with disorder, normally an undesirable phenomenon. However, recent experiments [for an overview, see A.V Krasheninnikov, F. Banhart, Nature Materials, 6 (2007) 723] on bombardment of carbon nanostructures with energetic particles demonstrate that irradiation can have beneficial effects and that electron or ion beams may serve as tools to change the morphology and tailor mechanical, electronic and even magnetic properties of nanostructured carbon systems. We systematically study irradiation effects in carbon nanotubes and other forms of nano-structured carbon experimentally and theoretically by employing various atomistic models ranging from empirical potentials to time-dependent density functional theory. In my presentation, I will briefly review the recent progress in our understanding of ion-irradiation-induced phenomena in nano-structured carbon and present our recent theoretical [A.V Krasheninnikov, et al., Phys. Rev. Lett., 99 (2007) 016104, A. Tolvanen et al., Appl. Phys. Lett. 91 (2007) 173109.] and experimental [O. Lehtinen et al., to be published] results. I dwell on the “beneficial” role of defects and impurities in nanotubes and related systems. Finally, I will present the results of simulations of irradiation-induced pressure build-up inside nanotubes encapsulated with metals [L. Sun, et al., Science 312 (2006) 1199]. Electron irradiation of such composite systems in the transmission electron microscope gives rise to contraction of nanotube shells and thus to high pressure. The irradiation-stimulated pressure can be as high as 40 GPa, which makes it possible to study phase transformations at the nanoscale with high spatial resolution. I will also address the mechanisms of plastic deformation of small metal particles inside carbon shells at high temperatures, which may be important for understanding catalytic growth of carbon nanotubes.

12:27PM V29.00005 Syntheses and characterization of SWCNT assemblies prepared on silicon substrates with different methods of patterning catalyst particles  IRMA KULJANISHVILI, VENKAT CHANDRASEKHAR, Department of Physics and Astronomy, Northwestern University, OWEN LOH, DMITRIY DIKIN, HORACIO ESPINOSA, Department of Mechanical Engineering, Northwestern University, RICHARD PINER, RODNEY S. RUOFF, Department of Mechanical Engineering, University of Texas at Austin — Techniques for controlled way of preparation of single wall carbon nanotubes (SWCNT) on substrates continue to be of interest, including for potential applications in integrated circuits and nanodevices. We report on our work, undertaken to elucidate a number of favorable conditions for controlled patterning and growth of high quality SWCNT. Synthesis is carried out under ambient pressure with methane used as feed gas. A key factor for successful SWCNT growth is known to be the catalytic precursor. We compare several methods of controlled deposition of the catalyst precursors on oxidized silicon substrates using methods such as e-beam lithography, photolithography and screening probe writing methods that allow for maximum flexibility and high efficiency for incorporating SWCNTs into devices or circuit architectures. The advantages and some limitations of these methods of selective patterning will also be addressed. Analysis and characterization of the as-grown SWCNTs was performed by Raman Spectroscopy, AFM and SEM.

12:39PM V29.00006 In-situ calorimetric studies of SWCNT growth  OLEG KUZNETSOV, TOSHIO TOKUNE, ELENA MORA, GUGANG CHEN, AVETIK HARUTYUNYAN, Honda Research Institute USA Inc. — Single-walled carbon nanotubes (SWCNTs) were grown inside of a differential scanning calorimeter (DSC) apparatus with an attached mass spectrometer (MS), using different hydrocarbons (CH₄ and C2H₆) and alumina supported (Fe, Fe/Mo, and Ni) catalysts. This set-up allowed to in situ follow the evolution of calorimetric, thermogravimetric and MS data during the synthesis. A Raman spectrometer (with laser excitations wavelengths 532 and 785 nm) was used for verification of the growth of SWCNTs. DSC studies at temperatures ∼650-900 °C of the interaction between the hydrocarbons and the preliminary reduced alumina supported catalysts showed a release (C2H2) or absorption (CH4) of heat depending on the type of hydrocarbon used. The effect of this energy on the growth of SWCNTs was studied. We found that the incubation time for nanotube nucleation depends on the hydrocarbon type and flow rate, as well as on the synthesis temperature. The origin of the initial endothermic peak observed during nanotube growth with both hydrocarbon sources will be discussed. Furthermore, the kinetics and thermodynamic of hydrocarbon decomposition, carbon atoms diffusion and solid carbon structure formation dependence on the catalyst and synthesis parameters will also be presented.

12:51PM V29.00007 The role of carbon solubility in Fe-C nano-clusters on the growth of small single-walled carbon nanotubes  STEFANO CURTAROLO, NEHA AWASTHY, WAHYU SETYAWAN, Duke University, ELENA MORA, TOSHIO TOKUNE, Honda R.I., KIM BOLTON, Göteborg University, AVETIK HARUTYUNYAN, Honda R.I. — Various diameters of alumina-supported Fe catalysts are used to grow single-walled carbon nanotubes (SWCNTs) with chemical vapor decomposition. We find that the reduction of the catalyst size requires the incubation time for nanotube nucleation on the hydrocarbon type and flow rate, as well as on the synthesis temperature. The origin of the initial endothermic peak observed during nanotube growth with both hydrocarbon sources will be discussed. Furthermore, the kinetics and thermodynamic of hydrocarbon decomposition, carbon atoms diffusion and solid carbon structure formation dependence on the catalyst and synthesis parameters will also be presented.

1:03PM V29.00008 Air assisted growth of long aligned carbon nanotube films  XIANFENG ZHANG, RAKESH SHAH, SAIKAT TALATAPRA, Department of Physics, Southern Illinois University Carbondale — We report on air assisted growth of ultra long aligned bundles of multiwall carbon nanotubes. We found that the growth rate of carbon nanotubes is highly enhanced by introducing a small amount of oxygen during the catalytic decomposition of ferrocene-xylene mixture at 750°C. Millimeter long aligned carbon nanotube films were easily synthesized on silicon dioxide as well as metal substrates by controlling the air flow. Electron microscopy investigations reveal that the films are composed of dense aligned multi-wall CNTs with the diameters ranging from about 30-100 nm. We will also present our preliminary results on the electrical transport measurement performed on these long nanotube bundles.

1:15PM V29.00009 Boron-Doped Carbon Nanotube Films  XIAO MING LIU, H.E. ROMERO, H.R. GUTIERREZ, P.C. EKLUND — Here we report room temperature optical and resistivity studies on transparent thin films of bundled single-walled carbon nanotubes exposed to B₂O₃ at 1000°C. This reaction is proposed to B-dope the films. They are stable in air. At 300K the four-probe sheet resistance and the optical transmission in the NIR-UV range are used to evaluate the effects of this chemical exposure. Our preliminary results show that for films with a visible optical transmittance around 80% (550nm), the sheet resistance in the pristine film is lowered from ~2KΩ to ~300Ω via B₂O₃ exposure, a factor of five decrease. We find that the magnitude of the decrease in the sheet resistance increases in samples with higher transmission. Our results suggest that boron-doped SWNT may provide a better approach to touch-screen technology, as well as for transparent contacts in solar cells.
The atomistic approach combines Monte Carlo methods with total energy electronic structure methods to explore island formation, growth, and lift-off dynamics. This method allows for the simulation of the growth process and provides insights into the energetics of the growth steps. Transient interruptions or changes in hydrocarbon flow are revealed by rapid changes in slope and frequency of the oscillating, exponentially-decaying TRR signal. The associated regions of the nanotube array reveal kinked, band-like patterns along the width of the array as observed in cross-sectional scanning electron microscopy (SEM) images. These bands serve as ‘growth-markers’ to measure length intervals and calibrate growth rates before, during, and after transient perturbations to continuous growth. In addition, extended growth interruptions are explored to understand catalyst poisoning mechanisms. Finally, growth of size-selected, multilayered VANTAs was performed to investigate the interfaces between different growth regions by HRTEM.

1:39PM V29.00011 Chirality-resolved kinetic analysis of single-walled carbon nanotube growth by in-situ Raman spectroscopy, TAKASHI UCHIDA, MASAYA TAZAWA, HIROSHI SAKAI, AKIRA YAMAZAKI, YOSHIHIRO KOBAYASHI, NTT BASIC RESEARCH LABORATORIES TEAM, CREST/JST TEAM, TOKYO UNIVERSITY OF SCIENCE COLLABORATION, MEJII UNIVERSITY COLLABORATION — We investigate the chirality-resolved growth kinetics of single-walled carbon nanotubes (SWCNTs) by in-situ Raman spectroscopy. The SWCNTs are synthesized by ethanol CVD from Co nanoparticle catalysts with pre-defined size before the CVD process. The chirality-sensitive radial breathing mode (RBM) signals in Raman spectra are observed during the CVD process at 80-120 Pa. We have reasonably assigned the chiral indices of the RBM signals observed at higher temperature during the CVD process by taking into account the temperature dependence of the resonance condition of SWCNTs. The growth kinetics analysis from the time evolution of each RBM signal in in-situ spectra reveals that the nanotube nucleation occurs just after the supply of the carbon source gas and does not significantly depend on the growth pressure and chirality. In addition, we have found that the growth duration depends on the growth pressure and chirality and that the graphitic encapsulation of catalyst particles terminates SWCNT growth. These findings make it possible to clarify the chirality-sensitive growth behavior of SWCNTs.

2:03PM V29.00013 Understanding the Growth of Carbon Nanotubes by Catalyst-Assisted Chemical Vapor Deposition, ELIF ERTEKIN, UC Berkeley, JEFFREY GROSSMAN, COMPUTATIONAL NANOSCIENCE GROUP TEAM — In catalyst-assisted chemical vapor deposition, carbon nanotubes are formed when a curved graphene island lifts off the surface of the catalyst particle on which it is growing. While this growth technique offers effective control over patterning and alignment, control over nanotube radius and chirality is ultimately tied to understanding the point at which lift-off occurs. We use atomistic approaches to model the lift-off process via the interplay between the excess energy required to grow a curved (and thus, necessarily defected) graphene island and the interaction energy between the growing island and the underlying catalyst. The monodomain approach combines Monte Carlo and molecular dynamics methods to study the formation, growth, and lift-off of nanotubes on a catalyst surface. Using this approach, we are able to systematically study the effect of incident atomic flux rate, growth temperature, and catalyst curvature. The different defect topologies in the growing graphene cap that result from different growth conditions are a key parameter in determining the chirality of the nanotubes.
Torsion-induced conductance oscillations have been recently observed in multi-wall nanotube \(\delta \phi\) subbands allowed in the nanotube, whereas a change in registry should give rise to a simple inverse dependence. \(\delta \phi\) is the Fermi level shift across subbands vs \(1/d^2\). Hence, the experimental results validate the interpretation of Fermi level shift across subbands related to registry change, as a source of torsion-induced conductance oscillations in carbon nanotubes.

\[\delta \phi \sim \frac{1}{d^2}\]

This dependence is theoretically predicted from the shifting of the corners of the first Brillouin zone of graphene across different subbands allowed in the nanotube, whereas a change in registry should give rise to a simple inverse dependence. \(\delta \phi \sim 1/d^2\). Hence, the experimental results validate the interpretation of Fermi level shift across subbands related to registry change, as a source of torsion-induced conductance oscillations in carbon nanotubes.

\[\delta \phi \sim \frac{1}{d^2}\]

Not only does the precision, low cost, reproducibility and parallelism of our new process create novel opportunities for the implementation and investigation of complex nanosystems, but it also enables us to gain insight into the dynamics of molecular interactions between nanoscale objects of mega-daltons size.

11:51AM V30.00004 Diameter-dependent conductance oscillations in carbon nanotubes upon torsion. NAGAPRIYA K.S., Weizmann Institute of Science, Rehovot, Israel. TZAHI COHEN-KARNI, LIOR SEGEV, ONIT SRUR-LAVI, SIDNEY COHEN, ERNESTO JOSELEVICH, Weizmann Institute of Science, Rehovot, Israel. — Torsion-induced conductance oscillations have been recently observed in multi-wall carbon nanotubes. These oscillations have been interpreted as metallic-semiconductor periodic transitions, while an alternative interpretation attributed the phenomenon to changes in registry between the walls. Here we show that the period of the oscillations is inversely proportional to the squared diameter of the nanotube \(\sim \frac{1}{d^2}\). This dependence is theoretically predicted from the shifting of the corners of the first Brillouin zone of graphene across different subbands allowed in the nanotube, whereas a change in registry should give rise to a simple inverse dependence \(\sim \frac{1}{d^2}\). Hence, the experimental results validate the interpretation of Fermi level shift across subbands related to registry change, as a source of torsion-induced conductance oscillations in carbon nanotubes.

12:03PM V30.00005 Nanomechanical properties of carbon nanotubes determined using a scanning laser vibrometer. LAURA BIEDERMANN, RYAN TUNG, ARVIND RAMAN, RONALD REIFENBERGER, Birck Nanotechnology Center, Purdue University. — To better understand the nanomechanical properties of nanotubes and nanowires, reliable nondestructive techniques that measure their Young’s modulus, \(E\), under ambient conditions are needed. Using a scanning laser vibrometer, the thermally excited eigenfrequencies of plasma-enhanced carbon vapor deposition (PECVD) multiwalled carbon nanotubes (MWNTs) were measured. Due to the small diameters involved, little light is reflected from a bare MWNT. By carefully attaching a small Au-coated glass bead, the intensity of reflected light is sufficiently increased to allow accurate measurements. The length and diameters of the MWNTs are determined using electron microscopy, allowing \(E\) to be inferred from an Euler-Bernoulli analysis of a pinned cantilever beam. A unique aspect of our work is that the attached glass bead exerts a torque on the MWNT. A resonance, attributed to a torsional oscillation, appears for the laden MWNTs, allowing an estimate for the torsional modulus \(G\). Values measured for \(E\) and \(G\), along with a description of the experimental procedure, will be presented at the talk.

12:15PM V30.00006 Mechanical Sensing with Flexible Metallic Nanowires. VLADIMIR DOBROKHOTOV, MEHDI YAZDANPAZH, SANTOSH PABBA, ABDULLAH SAFIR, ROBERT COHN, ElectroOptics Research Institute and Nanotechnology Center University of Louisville. — A calibrated method of force sensing is demonstrated in which the buckled shape of a long flexible metallic nanowire is interpreted to determine the applied force. Using a nanomanipulator the nanowire is buckled in the chamber of a scanning electron microscope (SEM) and the buckled shapes are recorded in SEM images. Force is determined as a function of deflection for an assumed elastic modulus by fitting the shapes using the generalized elastica model. In this calibration the elastic modulus was determined using an auxiliary AFM measurement, with the needle in the same orientation as in the SEM. Following this calibration the needle was used as a sensor in a different orientation than the AFM coordinates to detect a suspended PLLA polymer fiber from which the elastic modulus (2.96 GPa) was determined. In this study the same needle remained rigidly secured to the AFM cantilever beam throughout the entire SEM/AFM calibration procedure and the characterization of the nanofiber.

12:27PM V30.00007 c-axis GaN nanowires for high-quality-factor mechanical oscillators. JASON GRAY, University of Colorado, KRIS BERTNESS, NORMAN SANFORD, National Institute of Standards and Technology, CHARLES ROGERS, University of Colorado. — We report on the electromechanical properties of c-axis GaN nanowires in high-quality-factor mechanical resonators and oscillators. The nanowires are grown by catalyst-free molecular beam epitaxy, are single crystal, hexagonal in cross section, from 50 - 500 nm diameter, and 5 - 15 microns in length depending upon growth time. As-grown nanowires display singly-clamped cantilever mechanical resonances above 1 MHz, with typical resonance full width at half maximum power of less than 100 Hz i.e., a mechanical quality factor, \(Q\), well above 10^4. We are attempting to obtain similar high-\(Q\) for processed nanowires, utilizing dielectrophoresis to position the nanowires within lithographic test structures, and nanowire metallization of two types: First, titanium/aluminum over the ends of the nanowires allows for ohmic contact formation and direct measurement of nanowire resistance versus strain. Second, a layer of aluminum over the entire length of the wires leads to a metallic backbone with a resistance on the order of 50 \(\Omega\). This is useful for simple magnetomotive measurements. We will discuss the processing steps and observed behavior.

With support from GE and the Interdisciplinary Micro/Nano Electromechanical Transducers Center (iMINT) at CU-Boulder.

12:39PM V30.00008 Self-detecting mechanical resonators made from suspended carbon nanotubes. BENITO WITKAMP, MENNO POOT, ANDREAS K. HÜTTTEL, HERRE S.J. VAN DER ZANT, Delft University of Technology. — We study the flexural and torsional mechanical properties of suspended carbon nanotubes. We have used a suspended carbon nanotube as a frequency mixer to detect its own mechanical motion. A single gate-dependent resonance is observed, which we attribute to the fundamental bending mode vibration of the suspended carbon nanotube. Using a continuum model fit to the measurements, we show that the nanotubes in our devices have no slack and that, by applying a gate voltage, the nanotube can be tuned from a regime without strain to a regime where it behaves as a vibrating string under tension. We are currently investigating the low-temperature properties of these devices. We are also investigating the torsional mechanical properties of nanotubes.
12:51PM V30.00009 Characterization and wear resistance of carbon nanotube-based tips for AFM local anodic oxidation nanolithography, LISHAN WENG, Department of Physics, Purdue University, MARK STRUS, ARVIND RAMAN, Department of Mechanical Engineering, Purdue University, LEONID ROKHINSON, Department of Physics, Purdue University — The AFM local anodic oxidation (LAO) lithography is a powerful scanning-probe-based patterning technique for fabrication and post-fabrication tuning of nanoscale structures and devices. The conventional tips suffer from rapid wear which degrades the quality of imaging and LAO lithography. Much research has been devoted to seek for wear-resistant AFM tips, and carbon nanotubes (CNT) are viable candidates. Apart from featuring small diameter, high aspect ratio, and mechanical flexibility, the CNT tips have been shown to last longer during LAO. We investigate the wear of CNT-based tips during LAO lithography by imaging the tips before and after the lithography using scanning electron microscope. CNTs show small contamination on the tip apex while preserve their original length and diameter after more than 200 micron of the lithography. We also analyze tip-surface interaction in order to optimize the quality of lithography and correlate energy dissipation during tapping mode to the line width and line thickness during LAO.

1:15PM V30.00011 Cavity-controlled, electrically-induced infrared emission from a single-wall carbon nanotube, FENGXIAO XIA, MATHIAS STEINER, YU-MING LIN, PHAEDON AVOURIS, IBM Watson Research Center — Single-wall carbon nanotube (SWCNT) is attracting significant attention from the photonics community recently due to its unique optical properties and potential applications in optical communications, optical interconnects, and, in particular, nanophotonics. Tunable and truly nanometer-scale (diameters of 0.5 to 2nm) light emitters can possibly be realized using individual semiconducting nanotubes. However, optical cavities are needed to control the emission wavelength, direction, and emission rate of these broadband, nanoscale emitters. Here, we report the monolithic integration of an electrically-excited light emitter based on a single (SWCNT) with a planar photonic λ/2-cavity. Emission properties were dominated by the cavity characteristics almost regardless of the free-space emission. The broad, free-space emission spectrum of a single SWCNT with a FWHM of 300 to 500nm was transformed to cavity controlled emission with a FWHM of ~40nm. We also modeled the device as a broadband emitter in a planar cavity. Good agreement between the simulated and experimental results was achieved. In our configuration, the maximum enhancement in emission rate is estimated to be 4.4. We consider this result to be an important first step in the development of truly nanometer-scale photonic devices based on SWCNTs.

1:27PM V30.00012 Fluorination and Defluorination of Double-wall Carbon Nanotubes, JUNCHO KANG, MERYL PULIKATHARA, VALERY KHABASHESKU, KEVIN KELLY, RICE University — Due to the unique physical structure double-wall carbon nanotubes (DWNTs), the outer tube can be chemically functionalized while the inner tube is left in pristine condition. Using a fluorinating agent, DWNTs are fluorinated and X-ray photoelectron spectroscopy data indicates that the resulting product composition is equivalent to C3F. The diameter of bare DWNTs is around 2-3 nm as measured by scanning tunneling microscopy, but fluorinated DWNTs possess much larger diameters in a range from 3-10 nm due to a stronger electronic interaction. In addition to imaging the as prepared material, the material was imaged after annealing at temperatures up to 650 K. Due to defluorination, the diameter is decreased down to that of the initial bare DWNTs and atomic resolution of the lattice was recovered. In addition, it was possible to observe that the initial and final structures on the same nanotubes and the evolution of their associated defect structures. Lastly, Raman spectroscopy was employed to confirm the defluorization by revealing the recovery of the RBM peak which disappeared upon fluorination.

1:39PM V30.00013 Magnetic studies of multi-walled carbon nanotube mats: Ultra-high temperature ferromagnetism or superconductivity?, PIETER BEELI, GUO-MENG ZHAO, Department of Physics and Astronomy, California State University, Los Angeles — We report magnetic measurements up to 1200 K on multi-walled carbon nanotube mats using a Quantum Design vibrating sample magnetometer. Extensive magnetic data consistently show two ferromagnetic-like transitions at about 1000 K and 1275 K, respectively. The lower transition at about 1000 K is associated with an Fe impurity and its saturation magnetization is in quantitative agreement with the Fe concentration measured with a vibrating sample magnetometer. Extensive magnetic data consistently show two ferromagnetic-like transitions at about 1000 K and 1275 K, respectively. The lower transition at about 1275 K is consistent with ferromagnetism of any carbon-based phases or magnetic impurities but with the paramagnetic Meissner effect due to the existence of Josephson junctions in a granular superconductor.

3:This research is partly supported by a Cottrell Science Award from Research Corporation.

1:51PM V30.00014 A quadruply twinned core for the growth of nanotetrapods and related structures, S.K. HARK, Z. LIU, The Chinese University of Hong Kong, HARK TEAM — Nanotetrapods and related complex nanoarchitectures, such as multi-armed and tricrystal structures, are key functional elements and interconnections in future “bottom-up” approach to nanotechnology. The growth of these special nanostructures is believed to proceed from a core, several models of have been suggested. However, the occurrence of some tetrapod related nanostuctures, observed by us and also reported by others, can not all be explained by these models. We have obtained aligned ZnCdSe tetrapod related nanostuctures using metalorganic chemical vapor deposition on GaAs substrates. Based on high resolution transmission electron microscopy and crystallographic analyses, we propose a new quadruply-twinned model for their core, from which nanotetrapods, nanowords and related nanoarchitectures can grow. In this model, the core contains four wurtzite structured heptahedrons connected by six (0-113) twins. Different from the other existing models, no polarity of surface is needed to explain the growth of the branching arms of the nanotetrapods.

1The work described in this paper was partially supported by a grant from the Research Grants Council of the Hong Kong Special Administrative Region, China (Project No. 2150521) and CUHK direct grants (Project codes: 2060305).
Ordered layer of Ti for conventional semiconductor interfaces. Density-functional theory calculations including a Hubbard U (LDA+U) have shown that a charge and orbitally that are being incorporated into oxide heterointerfaces offer more degrees of freedom to compensate the charge imbalance at the interface than is the case. 

When oxides meet face to face”. E. Dagotto, Science, 318, 1076 (2007)

Superconducting transitions are consistent with a superconducting sheet as thin as a few nm.

The field effect allows the normal state and superconducting state properties to be spectacularly tuned. The characteristics of the observed superconducting transitions are consistent with a superconducting sheet as thin as a few nm.

Insulating dielectric perovskite oxides. It will be shown that the ground state of this system is superconducting [3]. The superconducting critical temperature is about 200mK. The field effect allows the normal state and superconducting state properties to be spectacularly tuned. The characteristics of the observed superconducting transitions are consistent with a superconducting sheet as thin as a few nm.

1 “When oxides meet face to face”. E. Dagotto, Science, 318, 1076 (2007)

Heterointerfaces$^1$. R. PENTCHEVA, University of Munich, W. PICKETT, University of California Davis — Multivalent transition metal ions that are being incorporated into oxide heterointerfaces offer more degrees of freedom to compensate the charge imbalance at the interface than is the case for conventional semiconductor interfaces. Density-functional theory calculations including a Hubbard U (LDA+U) have shown that a charge and orbitally ordered layer of Ti$^{3+}$ and Ti$^{4+}$ is formed at the interface (IF) between the Mott and the band insulator LaTiO$_3$ (d$^1$) and SrTiO$_3$ (d$^0$) [Phys. Rev. Lett. 99, 016802 (2007)] as well as between the two band insulators LaAlO$_3$ and SrTiO$_3$ [Phys. Rev. B. 74, 035112 (2006)]. Additional complexity relating to charge state and orbital occupation arises at the LaVO$_3$/SrTiO$_3$ interface between these compounds that are d$^2$ and d$^0$ respectively in the bulk: the electron-doped ...-TiO$_2$-LaO... IF may promote a Ti$^{3+}$ charge state, the hole-doped ...-SrO-V-O$_2$-... IF may encourage a V$^{4+}$ ion, or a metallic IF may result. We will present LDA+U predictions of charge states, orbital and spin order, and conducting behavior at these heterointerfaces, and contrast the results with the d$^1$ – d$^0$ and d$^0$ – d$^0$ interfaces mentioned above.

1Supported by a Bavaria California Technology Center grant.

Charge accumulation in nonpolar perovskite quantum well sandwiched by polar Mott-insulating perovskites, CHENG-CHING WANG, University of Texas at Austin, SAHU BHAGAWAN, SWAN, Microelectronics Research Center, HONGKI MIN, WEI-CHENG LEE, MACDONALD ALLAN, H., University of Texas at Austin, CONDENSED MATTER THEORY GROUP AT UT AUSTIN TEAM — We theoretically examine the possibility of having charge accumulation in the (LaTiO$_3$)$_x$/Ba$_2$VO$_4$/LaTiO$_3$$_{1-x}$ layered oxide quantum well system with polar barrier material and non-polar quantum well material using a LDA+U approach. The charge accumulation we find reflects electronic reconstruction which tends to occur near polar/nonpolar heterojunctions. We find enormous orbital reconstruction and both antiferromagnetic and ferromagnetic local in different planes. Lattice relaxation in the structure was allowed as a partial test of the robustness of LDA+U predictions for the properties of this system.

A First Principle Study of the LaAlO$_3$/SrTiO$_3$ Heterointerface, HANGHUI CHEN, Department of Physics, Yale University, SOHRAB ISMAIL-BEIGI, Department of Applied Physics, Yale University — In order to understand the origin of the intriguing high mobility quasi two dimensional electron gas formed at the LaAlO$_3$/SrTiO$_3$$(001)$ heterointerface, we carry out first principle calculations on the electronic structures and properties of complementary interface. The intrinsic polar properties are investigated and the average electronic potential increase by each LaAlO$_3$ layer is calculated, which can account for the recent observed experiment fact that the heterointerface is not metallic until the number of LaAlO$_3$ layers reaches a critical value. We also study the effects of different surface terminations of SrTiO$_3$ which surprisingly turn out to influence the electronic structure of the interface and so far have not been focused on in experiments.

Electrostatic doping in oxide heterostructures, JAEKWANG LEE, ALEXANDER A. DEMKOV, Department of Physics, The University of Texas at Austin — Recent experiments on perovskite heterostructures grown by molecular beam epitaxy or pulsed laser deposition suggest the possibility of creating high mobility two dimensional electron gas at the oxide/oxide interface. However, the origin of charge in these insulating materials is still not clear and deemed controversial. We report a first-principles study of SrTiO$_3$/LaAlO$_3$ heterostructures using density functional theory at the LDA+U level. We consider the energetics and electronic structure of the junction, while focusing on the role of electrostatics. Our results suggest that a complex balance of the crystal filed, Jahn-Teller effect, lattice dynamics and internal electric field result in the robust electrostatic doping for carefully chosen thickness of the oxide layer. We explore the possible uses of this effect in other oxide-based heterostructures.

KAROLINA JANICKA, JULIAN VELEV, EVGENY TSYMBAI, Department of Physics and Astronomy, University of Nebraska-Lincoln, Lincoln, Nebraska, USA — We perform first-principles electronic structure calculations to elucidate the electronic and magnetic properties of LaAlO$_3$/SrTiO$_3$ and LaTiO$_3$/SrTiO$_3$ superlattices. We find that TiO$_2$-terminated interfaces are n-type conducting which is consistent with experimental observations. In both heterostructures we find that charge resides in Ti conduction band and is localized within a few nanometers from the interface. This charge distribution is consistent with metal induced gap states in the gap of SrTiO$_3$ produced by the interfacial charge. In order to understand the magnetism of these oxide heterostructures, we performed spin-polarized calculations which reveal that this interface in a (LaAlO$_3$)$_n$/(SrTiO$_3$)$_n$ superlattice is magnetic with magnetic moment on the Ti atom. For thicker SrTiO$_3$ layers the magnetism decreases and eventually disappears because the electronic structure of the SrTiO$_3$ substrate is non-magnetic.

For magnetism. The inclusion of electron correlations via the LDA+U approximation with U=5eV on Ti atoms makes the two-dimensional electron gas more localized and half-metallic and strengthens the interface magnetization.

Supported by NSF-MRSEC.

Fabrication and characterization of complex oxide RENiO$_3$/LaAlO$_3$ superlattices

M. KAREEV, University of Arkansas, Fayetteville, J.W. FREELAND, Advance Photon Source, Argonne National Lab., J. LIU, University of Arkansas, Fayetteville, B. KIRBY, NIST, Center for Neutron Research, B. KEIMER, Max Planck Institute for Solid State Research, J. CHAKHALIAN, University of Arkansas, Fayetteville — Nowadays has been growing interest to synthesis of atomically thin complex oxide superlattices which can result in novel electronic and magnetic properties at the interface. Here we report on digital synthesis of single unit cell nickel based heterostructures of RENiO$_3$/LaAlO$_3$ (RE = La, Nd and Pr) superlattices on SrTiO$_3$ and LaAlO$_3$ by laser MBE. RHEED analysis, grazing angle XRD and AFM imaging have confirmed the high quality and chemical homogeneity of the epitaxially grown superlattices. The magnetic and electronic properties of the superlattices have been elucidated by polarized X-ray spectroscopies, which show a non-trivial evolution of magnetism and charge of the LNO layer with increasing LNO layer thickness. The work has been supported by U.S. DOD-ARO under Contract No. 402-17291.

1:03PM V31.00008 Band gap engineering in digital manganese-titanate superlattices

XIAOFANG ZHAI, CHANDRA MOHAPATRA, Department of Physics, University of Illinois at Urbana-Champaign, AMISH SHAH, JIANG-MIN ZHUO, Department of Materials Science Engineering, University of Illinois at Urbana-Champaign, ZORAN POPOVIC, SASHI SATPATHY, Department of Physics, University of Missouri, Columbia, ANAND BHATTACHARYA, Argonne National Lab, JAMES ECKSTEIN, Department of Physics, University of Illinois at Urbana-Champaign — The electronic structure of short period digital superlattices of two different phases depends strongly on the superlattice architecture. We have fabricated digital superlattices of super cells consisting of N layers of LaMnO$_3$ and N layers of SrTiO$_3$, N=1, 2, 3, 8, and measured their optical conductivities to probe the way in which the electronic structure depends on N. We found the valence band structure systematically changes, as N decreases, from bulk like band gaps to modified band gaps. The temperature dependence of the derived Mn Jahn-Teller/Mott gap in large period superlattices is completely different from the small period, suggesting different spin ordering states reside in them. The electronic structure of two parent materials are coherently blended at the interface, and the spin ordering is strongly modified. This method of producing meta materials is a promising new way of material engineering.

1:15PM V31.00009 Charge leakage and effective doping of atomically flat (LaMnO$_3$)$_{2n}$/ (SrMnO$_3$)$_{2n}$ superlattice interfaces

J.J. KAVICH, J.W. FREELAND, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439, A. BHATTACHARYA, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, M.P. WARUSAWITHANA, Department of Materials Science and Engineering, Penn State University, J.N. ECKSTEIN, Department of Physics, University of Illinois at Urbana-Champaign, Urbana IL 61801 — Atomically flat molecular beam epitaxy (MBE) grown interfaces in high quality digital superlattices provide a unique investigation of the role of substitutional disorder in complex oxide systems. Circularly polarized x-rays are used to measure the electronic and magnetic properties of the random alloy La$_2$/3Sr$_{1}$/3MnO$_3$ as it is digitally ordered into discrete layers of insulating A-type antiferromagnetic LaMnO$_3$ (LMO) and G-type antiferromagnetic SrMnO$_3$ (SMO) with superlattice configurations of (LMO)$_{2n}$/ (SMO)$_{2n}$. The diffusion of carriers across the interface effectively dopes the interface region. The electronic and magnetic structure of the n=1 digital structure is nearly identical to the solid solution of the same doping that shows that, on average, the charge distributes uniformly over the entire sample. The ferromagnetic insulating nature of the n = 5 superlattice suggests a finite lengthscale of the diffusion of carriers at the interface. Work at Argonne is supported by the U.S. Department of Energy, Office of Science, under Contract No. DE-AC02-06CH11357.

1:27PM V31.00010 Structural Basis of Conduction at LaAlO$_3$-SrTiO$_3$ Interfaces

ROY CLARKE, D. KUMAH, C. CIONCA, University of Michigan, P.R. WILLMOTT, Paul Scherrer Institut, Swiss Light Source, S. A. HERGÉR, C.M. SCHLEPUETZ, S.A. PAULI, D. MARTOCCIA, B.D. PATTERSON, B. DELLEY, Paul Scherrer Institut, Y. YACOBY, Hebrew University, Jerusalem — We present new results on the application of the x-ray phase retrieval method, Coherent Bragg Rod Analysis (COBRA), to heterointerfaces in LaAlO$_3$ thin films grown on SrTiO$_3$ substrates, a system known to form an interfacial quasi-2D electronic gas. We observe a doped, mixed-valence interface which modifies the electronic band structure, lowering the minimum of the conduction band below the Fermi level and thereby rendering the doped interface conducting. In particular the COBRA measurements reveal the formation of an interfacial La,SrTiO$_3$ layer with an accumulation of trivalent Ti at the interface which is responsible for the lattice dilatation and minimizes the electrostatic energy at the TiO$_2$-terminated SrTiO$_3$ substrate surface. The work presented here establishes a structural basis for the formation of the conducting interface.

1:39PM V31.00011 Signatures of Enhanced Ordering Temperatures in Digital Superlattices of (LaMnO$_3$)$_m$/(SrMnO$_3$)$_2m$

A. BHATTACHARYA, CNM & MSM, Argonne National Laboratory, S. J. MAY, MSD, Argonne National Laboratory, L. ROBERTSON, HFIR, Oak Ridge National Laboratory, P. RYAN, APS, Argonne National Laboratory, X. ZHAI, J. N. ECKSTEIN, Department of Physics, UIUC, S. D. BADER, CNM & MSM, Argonne National Laboratory — Digital superlattices of (LaMnO$_3$)$_m$/(SrMnO$_3$)$_2m$ for integers m = 1 - 4 have been synthesized with oxygen assisted oxide MBE. These superlattices are ordered analogues of La$_1$/3Sr$_2$/3MnO$_3$, an antiferromagnetic insulator. Signatures of enhanced ordering temperatures have been observed in transport and magnetic measurements. We interpret this in terms of the effects of enhanced A-site order on d$_{x^2-y^2}$ orbital occupancy. We shall also present evidence in support of our findings with x-ray and neutron scattering.

1Supported: DOE-BES Contract # DE-AC02-06CH11357.
1:51PM V31.00012 Nanoscale Control of an Interfacial Metal-Insulator Transition at Room Temperature
   CHENG CEN, JEREMY LEVY, STEFAN THIEL, GERMAN HAMMERL, CHRISTOF W. SCHNEIDER, JOCHEN MANNHART, KRISTOPHER E. ANDERSON, C. STEPHEN HELLBERG — We report the creation and erasure of nanoscale conducting regions at the interface between two insulating oxides, LaAlO$_3$ and SrTiO$_3$. Using voltages applied by an atomic force microscope (AFM) probe, the buried LaAlO$_3$/SrTiO$_3$ interface is locally and reversibly switched between insulating and conducting states. Persistent field effects are observed using the AFM probe as a gate. Patterning of conducting lines with widths $\sim$3 nm, as well as arrays of conducting islands with densities $>10^{14}$/in$^2$, are demonstrated. The patterned structures are stable for $>24$ hours at room temperature.

   C. STEPHEN HELLBERG, Naval Research Lab, KRISTOPHER ANDERSEN, Northern Arizona University, CHENG CEN, JEREMY LEVY, University of Pittsburgh, STEFAN THIEL, GERMAN HAMMERL, CHRISTOF SCHNEIDER, JOCHEN MANNHART, Augsburg University — Although bulk LaAlO$_3$ and SrTiO$_3$ are both insulating, an electron gas can form at the interface between these compounds. For up to 2 unit cells (uc) of LaAlO$_3$, the interface remains insulating, while for 4 uc and beyond, it is metallic. For 3 uc films, the interface can be reversibly switched from metallic to insulating using voltages applied by an atomic force microscope (AFM). We present first-principles density functional calculations of LaAlO$_3$ films on SrTiO$_3$. We show the AFM induced interfacial metal- insulator transition can be explained by the formation and annihilation of oxygen vacancies on the LaAlO$_3$ surface.

11:15AM V32.00001 Structural and chemical ordering and spin polarization in epitaxial films of Co$_x$Mn$_{1-x}$Ge$_1$ and Co$_x$Mn$_{1-x}$Si$_1$-
   1 B.A. COLLINS, L. HE, F. TSUI. University of North Carolina at Chapel Hill, Y.S. CHU, Y. ZHONG, Argonne National Laboratory — The Heusler alloys of Co$_2$MnGe and Co$_2$MnSi have been predicted to be half-metallic. However, half-metallicity has not been realized owing to its sensitivity to disorders associated with off-stoichiometry and to epitaxial constraints. Combinatorial epitaxial films of Co$_x$Mn$_{1-x}$Ge$_1$ and Co$_x$Mn$_{1-x}$Si$_1$ have been grown on Ge (111) substrates in and around the Heusler stoichiometry using molecular beam epitaxy techniques. The structural and chemical ordering of the films has been examined using x-ray microbeam techniques, including energy dependent anomalous diffraction and diffraction anomalous fine structure. These experiments are shown to be sensitive to various disorders, including stacking faults, and chemical dependent vacancies and site swapping. They reveal that the ordering is very sensitive to the atomic ratio between Co and Mn. Magnetic and spin dependent properties have been examined by magneto-optic effects and in-situ point contact Andreev reflection spectroscopy, and they exhibit strong correlation with the structural and chemical ordering.

11:27AM V32.00002 Control of selforganized magnetic nanocrystals aggregation in (Ga,Fe)N by co-doping with shallow donors and acceptors, A. BONANNI, A. NAVARRO-QUEZADA, T. LI. Johannes Kepler University, Linz - Austria, M. KIECANA, M. SAWICKI, T. DIETL, Institute of Physics, PAS - Warsaw — A number of possible room temperature functionalities has recently been proposed for magnetically doped semiconductors, in which spinodal decomposition leads to the self-organized formation of coherent ferromagnetic nanodots or nanocolumns. It has also been suggested that the decomposition can be controlled in a wide range by growth conditions and co-doping. We have extended our previous structural and magnetic studies of (Ga,Fe)N by examining the effects of Si and Mg co-doping. As before, we have found the magnetic response to consist of a paramagnetic signal from substitutional Fe and of a ferromagnetic component due to Fe$_{1-x}$N nanocrystals. Our results demonstrate that the co-doping reduces the fractional concentration of Fe contributing to the nanocrystals. This shows that tuning of the Fermi energy by co-doping with shallow donors and acceptors

11:39AM V32.00003 Giant anisotropic magnetoresistance in ultra thin (Ga,Mn)As, RASHID RASHEED, MARKUS SCHLAPPS, Institute of Experimental and Applied Physics, University of Regensburg, Universitaetsstrasse 31, 93040 Regensburg, Germany, JANUSZ SADOWSKI, MAX-Lab, Lund University, 22100 Lund, Sweden, WERNER WEGSCHEIDER, DIETER WEISS, Institute of Experimental and Applied Physics, University of Regensburg, Universitaetsstrasse 31, 93040 Regensburg, Germany — We describe the effect of giant anisotropic magnetoresistance (GAMR) for epitaxial ultra thin (Ga,Mn)As as below the metal-insulator transition (MIT). The GAMR is observed for 5 nm-thick Ga$_{0.95}$Mn$_{0.05}$As films after annealing in optimized conditions in planar geometry for patterned Hall bars at T<10K, where longitudinal resistance $R_o$~$\eta$ per/2. The GAMR manifests itself in magnetization-dependent high-resistance (HR) and low-resistance (LR) states along different crystallographic directions. We demonstrate that holes are strongly localized in HR states and localization depends on orientation of magnetization, amplitude of current and magnetic field. The decrease of current amplitude is accompanied by an enhancement of the GAMR for both in-plane and orthogonal-to-plane orientations of magnetic field. Changes of $R_o$ between HR and LR states reach~100% at T=1K. In the Hall geometry the changes of transverse component $R_{xy}$ in magnetic field exceed 1000%. The behaviour of GAMR we ascribe to anisotropic spin-orbit scattering, strong localization below MIT and localization-delocalization effects in magnetic and electric fields.

11:51AM V32.00004 Atom-byatom substitution of Mn in GaAs and visualization of their hole-mediated interactions, DALE KITCHEN, Princeton University — No abstract available.
12:27PM V32.00005 Ferromagnetism in CuO-ZnO multilayers. SUKARAN CHANDRAN. Department of Physics and Astronomy, Wayne State University, Detroit, MI 48201, B.J. KIRBY. NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, K. PADMANABHAN, G. LAWES, R. NAISK. Department of Physics and Astronomy, Wayne State University, MI 48201, SANJIV KUMAR, NCCCM, Bhaga Atomic Research Centre, ECIL Post, Hyderabad 500062, India, V.M. NAISK. Department of National Sciences, University of Michigan-Dearborn, Dearborn, MI 48128 — The magnetic properties of CuO-ZnO heterostructures are examined to elucidate the origin of the ferromagnetic signature in Cu doped ZnO. The CuO and ZnO layer thickness varied from 15 nm to 350 nm, and we observed no significant diffusion of either Cu$^{2+}$ in the ZnO layers or of Zn$^{2+}$ in the CuO layers using Rutherford backscattering spectrometry. Bulk magnetization measurements established that the multilayers exhibit a ferromagnetic moment at room temperature, with a saturation magnetization (∼2.5 emu/cc of CuO) that depends on the CuO size, but not the CuO-ZnO interfacial area. Polarized neutron reflection studies suggest that the ferromagnetism arises from the CuO layers, and not from the interdiffusion of CuO and ZnO. These results indicate that the ferromagnetism in these multicomponent structures arises from the uncompensated surface spins of CuO nanoparticles in the layer rather than from regions of interdiffusing ZnO and CuO.

12:39PM V32.00006 Role of Donor defects in stabilizing room temperature ferromagnetism in Co doped ZnO. LUBNA SHAH, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716, YUAN-QIANG SONG, University of Electronic Science and Technology of China, Chengdu, People’s Republic of China, HUI-LU ZHANG, University of Electronic Science and Technology of China, Chengdu, People’s Republic of China, WEIWANG WANG, ZHU HAO, JOHN XIAO, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716 — Extensive experimental and theoretical work has been done on transition metal doped ZnO diluted magnetic semiconductor, in which defects play a vital role in promoting carrier-mediated ferromagnetism. We explored the influence of interstitial Zinc on physical properties of Co doped ZnO by exposing CuO.5ZnO.5ZO in a Zn vapor. Both X-ray diffraction and X-ray photoelectron spectroscopy indicate the substitution of Co$^{2+}$ in the ZnO lattice. Observed room temperature ferromagnetism in bulk samples shows a decreasing trend with decreasing temperature. This can be explained by taking into the reduction of the carrier density, induced by the interstitial Zinc ions, at low temperature. Carrier density at room temperature is about 8.5 x 10$^{19}$/cm$^3$, which is consistent with predicted value for polaron percolation threshold to induce long range ferromagnetism. The carrier density fell below this threshold at low temperature, results in the disappearance of the ferromagnetism.

12:51PM V32.00007 Ferromagnetism in Rutile Structure Cr doped VO$_2$ Thin Films prepared by Reactive Bias Target Ion Beam Deposition. KEVIN G. WEST, JIWEI LU, LI HE, DAVID M. KIRKWOOD, WEI CHEN, University of Virginia, T. PAUL ADL, Micron Technology, MICHAEL S. OSOFSKY, SYED B. QADRI, US. Naval Research Labs, ROBERT HULL, THOMAS PROFFEN, Manuel WOLF, University of Virginia — First generation spintronics has entered the mainstream of information technology through its utilization of the Magnetic Tunnel Junction (MTJ) in applicable devices such as read head sensors for hard disk drives and Magnetic Random Access Memory (MRAM). The future of spintronics devices requires next generation spintronic materials. Here we report on the novel structural, transport, and magnetic characteristics of V$_1-x$Cr$_x$O$_2$ (0.1 ≤ x ≤ 0.2) thin films deposited on (001) Al$_2$O$_3$ substrates. We show that the metal-insulator transition (MIT) of VO$_2$ is suppressed and the rutile structure is stable down to 100 K. The films are remarkably smooth having a root-mean squared (RMS) surface roughness of 0.3 nm. Films are conductive at room temperature which is consistent with predicted value for polaron percolation threshold to induce long range ferromagnetism. The carrier density fell below this threshold at low temperature, results in the disappearance of the ferromagnetism.

1:03PM V32.00008 Phase transition temperatures and magnetic entropy change in Ni-Mn-In-B based Heusler alloys. ARJUN PATHAK, BHOG AUTAM, IGOR DUBENKO, NAUSHAD ALI, Department of Physics, Southern Illinois University, Carbondale, IL, 62901, MAGNETIC MATERIALS RESEARCH LAB TEAM — One of the aspects of great attention of Heusler alloys is the large value of magnetic entropy change (Δ$S_M$) and their possible application as a working material in magnetocaloric effect based magnetic refrigerators. It was reported earlier that Ni$_{50}$Mn$_{30}$In$_{10}$ has first order martensitic transition temperature $T_M$ ≈ 212K, Curie temperature of austenitic phase $T_C$ ≈ 328K and Δ$S_M$ value associated with $T_M$ and $T_C$ are respectively 15 × 10$^{-3}$ J/kg K$^2$. In the present study, we are reporting the effect of partial substitution of In by B in Ni$_{50}$Mn$_{30}$In$_{10}$ by AC susceptibility, thermal expansion, and magnetization measurements. We observed that substitution of boron sharply increase $T_M$ and significantly enhance the $\Delta S_M$ peak value higher than 30 J/kg K at $T_M$ ≈ 296K; however the $\Delta S_M$ value remains almost same at $T_C$. Therefore, the Ni-Mn-In-B based Heusler alloys will be potential material for room temperature magnetic refrigeration materials. Reference: [1] A. K. Pathak, M. Khan, I. Dubenko, S. Stadler, and N. Ali, Appl. Phys. Lett. 90, 262504 (2007).

1:15PM V32.00009 Magnetic excitations in a quantum spin dimer system Ba$_2$Cr$_2$O$_8$. MAIKO KOFUJ, JUNG-HWA KIM, SEUNG-HUN LEE, Univ. of Virginia, BELLA LAKE, Hahn-Meitner Institute, YIMING QIU, National Institute of Standards and Technology, HIROKI UEDA, YUTAKA UEDA, JISSP, Univ. of Tokyo — We report our neutron scattering measurements on a powder sample of a new quantum spin system Ba$_2$Cr$_2$O$_8$. Spin-lattice coupling and exchange interactions are probed using inelastic neutron scattering measurements probing energy transfers to 50 mK. Instead, bulk susceptibility data exhibit a broad peak around 16K. Our inelastic neutron scattering data at temperatures lower than 30 K show a prominent excitation at hw = 2.2 meV. Q- and temperature dependences of the integrated intensity of the excitation can be well accounted for by a model of weakly coupled quantum dimers. When an external magnetic field is applied, the excitation splits into three energies, which confirms the dimer model. We have investigated how the singlet-to-triplet excitations evolve with increasing the magnetic field up to 14.5 Tesla.

1:27PM V32.00010 Understanding Magnetic Frustration on the Diamond Lattice of Transition Metal Oxide Spinel. BRENT MELOT, KATHARINE PAGE, RAM SESHADRI, Materials Department, University of California, Santa Barbara, CA, 93106–5050 USA, DORON BERGMAN, Physics Department, University of California, Santa Barbara, CA, 93106–9530 USA, THOMAS PROFFEN, Manuel Lujan, Jr. Neutron Scattering Center, Los Alamos National Laboratory, LANSE-12, MS H805, Los Alamos, New Mexico 87545, USA — We present structural and magnetic measurements on the cubic spinel perovskite CuO$_2$Rh$_2$O$_6$(Al$_{1-x}$Ga$_x$O$_{2-x}$) and demonstrate how frustration on the diamond sublattice can be modified through chemical substitution. The effect of substitution is two-fold. Increasing values of $x$ are accompanied by an increase in the lattice parameter resulting in an elongated and consequentially weakened exchange pathway. Our data indicates that the amount of site mixing also increases across the substitution series weakening the A-O-B-O-A superexchange pathway. Monte Carlo simulations were used to compute the exchange coupling constants between nearest and next-nearest neighbor Co atoms. Density functional calculations were also performed to approximate the nearest neighbor coupling constant. For most values of $x$, we find that the frustration parameter, $\Theta_{CW}/T_N$, decreases which we attribute to the weakening competition between nearest and next-nearest-neighbor Co exchange interactions.

1:39PM V32.00011 Half-metallic Silicon Nanowires. EGIN DURGUN, DENIZ CAKIR, NURTEN AKMAN, SALIM CIRACI — This study investigates the atomic structure, mechanical, electronic and magnetic properties of silicon nanowires using first-principles plane wave calculations within density functional theory. We considered bare, hydrogen terminated and transition-metal adsorbed silicon nanowires oriented along [001] direction. Nanowires of different sizes are initially cut from the bulk Si crystal in rod-like forms and subsequently their atomic structures are relaxed. We first present an extensive analysis of the atomic structure, stability, elastic and electronic properties of bare silicon nanowires. The energetics of adsorption and resulting electronic and magnetic properties are examined for different levels of transition metal atom coverage. Adsorption of transition metal atoms resulted in magnetic ground state. The net magnetic moment increases with increasing coverage. While specific Si nanowires acquire half-metallic behavior at low coverage, at high coverage ferromagnetic nanowires become metallic for both spin-direction and some of them have very high spin polarization at the Fermi level. Present results are not only of scientific interest, but can also initiate new research on spintronic applications of silicon nanowires. [1] E.Durgun, D. Cakir, N. Akman and S. Ciraci, Phys. Rev. Lett (2007) (in press).
waves and high frequency electron paramagnetic resonance, STEPHEN HILL, JONATHAN LAWRENCE, Department of Physics, University of Florida, FERRAN MACIA, JOAN MANEL HERNANDEZ, JAVIER TEJADA, Departament de Fisica Fonamental, University of Barcelona, PAULO SANTOS, Paul-Drude-Institut, Berlin, CHRISTOS LAMPROPOULOS, GEORGE CHRISTOU, Department of Chemistry, University of Florida — We report a new experimental technique that integrates high frequency surface acoustic waves (SAWs) with high frequency electron paramagnetic resonance (HFEP) spectroscopy in order to measure spin dynamics on fast time scales in single-molecule magnets. After driving the system out of equilibrium by triggering magnetic avalanches, or simply by heating with short SAW pulses, the evolution of the spin populations within fixed energy levels is measured using HFEP spectroscopy.

Thursday, March 13, 2008 11:15AM - 2:15PM –
Session V33 GMAG FIAP DMP: Focus Session: Theory of Spin Phenomena in Semiconductors
Morial Convention Center 224

11:15AM V33.00001 Design of dilute magnetic semiconductors with room temperature ferromagnetism by controlling spinodal decomposition1. KAZUNORI SATO, ISIR, Osaka University — Owing to the recent development of the first-principles method for calculating magnetic properties of dilute magnetic semiconductors (DMS), it has been recognized that the magnetic percolation effect is disastrous to the high temperature ferromagnetism in DMS in particular for low concentrations [1]. The exchange interactions calculated from first-principles are strong for nearest neighbors, but those interactions are short ranged and can not play an important role for realizing high-\(T_C\) because the solubility of magnetic impurities into DMS is too low to achieve magnetic percolation. To overcome this difficulty and realize room temperature ferromagnetism, we focus on the spinodal decomposition in DMS, and suggest that by controlling the spinodal decomposition high blocking temperature can be realized leading to ferromagnetic behaviour at high temperature [2]. We calculate electronic structure of DMS from first-principles by using the Korringa-Kohn-Rostoker coherent potential approximation (KKR-CPA) method. Then, chemical pair interactions and magnetic exchange interactions between magnetic are calculated. We use the Monte Carlo techniques to simulate spinodal decomposition of DMS and to estimate the magnetic properties of them [3]. The computer simulations for the magnetization process of the decomposition phases indicate that we can control super-paramagnetic blocking temperature by optimizing the size of the clusters by changing the crystal growth condition. This simulation suggests the material design of high blocking temperature DMS by controlling the spinodal decomposition [2]. As another approach for realizing high-\(T_C\) DMS we propose co-doping method to increase solubility limit of transition metal impurities in DMS [4]. This work is based on the collaboration with H. Katayama-Yoshida and T. Fukushima.

11:51AM V33.00002 Defect-induced intrinsic magnetism in wide-gap III-nitrides1. PEIHONG ZHANG, PRATIBHA DEV, YU XUE, University at Buffalo, SUNY — Cation vacancy induced Intrinsic magnetism in GaN and BN is investigated by employing density functional theory based electronic structure methods. The strong localization of defect states favors spontaneous spin polarization and local moment formation. A neutral cation vacancy in Ga\(_2\)N or BN leads to the formation of a net moment of 3\(\mu_B\) with a spin-polarization energy of about 0.5 eV at the low density limit. The extended tails of defect wavefunctions, on the other hand, mediate surprisingly long-range magnetic interactions between the defect-induced moments. This duality of defect states suggests the existence of defect induced or mediated collective magnetism in these otherwise nonmagnetic sp systems.

1 We acknowledge the computational support provided by the Center for Computational.

12:03PM V33.00003 Design of Colossal Solubility of Magnetic Impurities for Semiconductor Spintronics by the Co-doping Method1. TETSUYA FUKUSHIMA, ISIR, Osaka University, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA — Based on first-principles calculations, we propose co-doping method for increasing solubility of magnetic impurities in dilute magnetic semiconductors (DMSs). The concentration dependences of the mixing energy of DMS, such as (Ga,Mn)N, (Ga,Cr)N, (Ga,Mn)As, and (Zn,Cr)Te, show large convexity and these systems have a tendency toward spinodal decomposition. By introducing compensating impurities into these DMS, the mixing energy shows gradual transition from convex to concave concentration dependence resulting in negative mixing energy of magnetic impurities. This observation suggests that the co-doping method dramatically increases the solubility of magnetic impurities in DMS, thus high concentration doping of magnetic impurities into DMS becomes possible.

1 a Grant-in-Aid for Scientific Research on Priority Areas and a Grant-in-Aid for Specially Promoted Research.
12:15PM V33.00004 Suppression of ferromagnetism in Zn$_x$Cr$_{1-x}$Te: A DFT study , JUAREZ L.F. DA SILVA, National Renewable Energy Lab, 1617 Cole Blvd., Golden, CO 80401, USA; GUSTAVO M. DALPIAN, Centro de Ciencias Naturales e Humanas, Universidade Federal do ABC, Santo Andre, SP, Brazil; SU-HUI WANG, National Renewable Energy Lab, 1617 Cole Blvd., Golden, CO 80401, USA — The possibility to control the charge and spin degrees of freedom independently in diluted magnetic semiconductors (DMS) provides an opportunity in the realization of spintronic devices. Therefore, there is a great desire to understand the physical parameters that control $T_C$ in DMS. In this talk, we will report a density functional theory study of Zn$_x$Cr$_{1-x}$Te and Ga$_x$Cr$_{1-x}$As, which show interesting carrier dependence of the $T_C$. We found that the stability of ferromagnetism (FM), which is calculated with respect the anti-ferromagnetic (AFM) phase, can be controlled by $n$- and $p$-type co-doping. For randomly distributed Cr, the maximum FM stability is found to be at $\approx 1.25$ holes per magnetic ion. Furthermore, we studied the formation of magnetic Cr precipitates by analysing the binding energy of two Cr atoms in the host semiconductors. Our results indicate that a simple Coulomb binding picture cannot provide a consistent explanation for the formation of Cr-rich aggregates. Instead, we show the variation of Cr-Cr binding energy can be described quite well using the band coupling model [G. M. Dalpian, S.-H. Wei, A. J. R. da Silva, and A. Fazzio, Solid State Commun. 138, 353 (2006)].

12:27PM V33.00005 Eight-band model of the dilute magnetic semiconductor GaMnAs, A. NILI, University of Cincinnati, M. A. MAJIDI, J. MORENO, University of North Dakota, P. KENT, Oak Ridge National Laboratory, M. JARRELL, University of Cincinnati — The ordered state of GaAs doped with Mn is studied using a self-consistent Dynamical Mean Field treatment parameterized with the LDA band structure of the parent material. The resulting model is an eight-band $k$-$p$ model including the heavy and light valence bands, the split-off valence band and the conduction band. The interaction between randomly distributed magnetic ions and itinerant charge carriers is modeled with a modified double-exchange coupling, which includes the attractive potential between holes and charged magnetic ions. Since our method is not perturbative we can treat both strong and weak coupling regimes. We calculate the transition temperature, the temperature dependence of the local magnetization, the density of states and the spin polarization of the holes. We compare our results with more simplified models.

12:39PM V33.00006 Spin relaxation of two-dimensional excitons in a strong magnetic field, O. OLENDLSKI, T. V. SHAHBAZIAN, Jackson State University — We study spin relaxation of quantum well excitons in a perpendicular magnetic field. We show that in a strong field, the dominant relaxation mechanism for an optically-excited magnetoexciton is phonon-assisted spin-orbit transition of the constituent electron or hole. We calculate relaxation rates for excitons in GaAs quantum wells excited by both left and right-polarized light and find that they are much slower than those in quantum dots due to the dominant contribution of exciton kinetic energy in the final state. We also find that the relaxation rate is very sensitive to the applied in-plane electric field that causes exciton drift in the ground state.

12:51PM V33.00007 Theory of exchange splittings of bands in diluted magnetic semiconductors, TOMASZ DIETL, CEZARY SLIW, Institute of Physics, PAS, Warsaw — A series of recent photoemission and magnetooptical experiments, particularly on magnetically doped nitrides and oxides, but also on (Ga,Mn)As, points to the limiting understanding of the physics governing the sp-d exchange interaction in these systems. We have developed theory of band splittings in diluted magnetic semiconductors taking into consideration a possibility that the magnetic ion can trap a hole. We have found that the exchange coupling between the bound and delocalized carriers has actually a similar magnitude to that characterizing the sp-d exchange. Furthermore, our results demonstrate that the presence of the conduction band state itself renormalizes extended states in a spin-dependent fashion. We show that these two effects can explain the unexpected sign and magnitude of the apparent s- d and p-d exchange integrals determined by magneto optical studies carried out for (Ga,Mn)As [3] as well as for (Zn,Co)O, (Ga,Mn)N, and (Ga,Fe)N [4].

1:03PM V33.00008 Computational materials Design for Spin-Currents Control in Semiconductor Nano-spintronics, HIROSHI KATAYAMA-YOSHIDA, TETSUYA FUKUSHIMA, VAN AN DIENG, KAZUNORI SATO, ISIR, Osaka University — We design the different exchange mechanism like Zener’s double exchange, Zener’s p-d exchange and super-exchange in dilute magnetic semiconductors (DMS) by ab initio calculations. We obtain a universal trend for the exchange interactions [1]. We show that self-organized spinodal nano-decomposition (Dainiaki-Phase) offers the functionality to have high Curie temperatures [2]. We show that spinodal nano-decomposition under layer-by-layer crystal growth condition (2D) leads to quasi-one dimensional nano-structures (Konbu-Phase) with highly anisotropic shape and high $T_C$ [2]. We design a spin-currents-controlled 100 Tera bits/inch$^2$, Tera Hz switching, and non-volatile MRAM based on Konbu-Phase [2]. In addition to the conventional Peltier effect, we propose a colossal thermoelectric cooling power based on the adiabatic spin-entropy expansion in a Konbu-Phase [3]. [1] B. Belhadj et al., J. Phys.-Condens. Matter, 19 (2007) 436227. [2] H. Katayama-Yoshida et al., Phys. stat. sol. (a) 204 (2007) 15. [3] H. Katayama-Yoshida et al., Jpn. J. Appl. Phys. 46 (2007) L777.

1:15PM V33.00009 Effect of Fermi level on Microstructure and Magnetism in (Ga,Mn)N Alloys, JENNIFER CHAN, ZHELIU, STEPHAN LANY, ALEX ZUNGER, National Renewable Energy Lab., Golden, CO 80401 — GaN doped with Mn has been shown experimentally to exhibit either ferro- or antiferro- magnetic behavior, the results varying considerably depending on the microstructure of the sample. Indeed, the electronic structure and magnetic properties appear to be heavily dependent upon growth conditions and ordering of the material. We used ab-initio calculations to investigate the magnetism of various ordered structures of (Ga,Mn)N with respect to Mn composition. The results show that high-spin states with the spins on the Mn aligned in parallel (HS-FM) are stable at low Mn composition ($< 0.5\%$) but not at high Mn composition ($> 5\%$). Instead, for high Mn composition, low-spin states (LS-FM) or states where the spins on the Mn are anti-parallel (FI) are found. Interestingly, upon raising the Fermi level, the HS-FM states are stable for all Mn compositions and their formation enthalpies lower with respect to the neutral Fermi level case indicating that electron doping leads to enhanced Mn solubility and hence charged microstructure. The short and long range ordering, tendency for clustering and magnetic properties will be investigated.

1:27PM V33.00010 First-Principles Study on Electronic Structure of TiO$_2$-Based Dilute Magnetic Semiconductors$^1$, HIDETOSHI KIZAKI, MASAYUKI TOYODA, AZUMUNI SATO, HIROSHI KATAYAMA-YOSHIDA — We investigate the electronic structure in rutile-TiO$_2$-based dilute magnetic semiconductors (DMS) within self-interaction-corrected local density approximation (SIC-LDA). These results are compared with those calculated within standard LDA. Although the calculated band-gap energy and energetic position of Ti 3$d$ bands are different in the LDA and the SIC-LDA, half-metallic density of states is predicted in transition-metal-doped TiO$_2$ for both methods. While the LDA calculations predict high-spin state only for Fe-doped one, in the SIC-LDA calculations high-spin state is realized in V-, Cr- and Mn-doped one and low-spin state is realized in Fe- and Co-doped one. However, the absorption and soft x-ray magnetic circular dichroism measurements in (Ti$_{100-x}$Co$_x$)$_2$O$_2$ indicate the Co$^{2+}$ high-spin state in the $D_{2d}$-symmetry crystal field at the Ti site. These experimental results do not agree with our calculated results. We will discuss the origin of the discrepancy between the theoretical predictions and the experimental observations. In addition, we will discuss the ferromagnetism in TiO$_2$-based DMS.

1:39PM V33.00011 Ferromagnetism in GaN:Gd: A density functional theory study$^1$, LEI LIU, LBNL, UCB, PETER YU, UCB, LBNL, Z.X. MA, LBNL, SAM MAO, LBNL, UCB — First principle calculations of the electronic structure and magnetic interaction of GaN:Gd have been performed within the Generalized Gradient Approximation (GGA) of the density functional theory (DFT) with the on-site Coulomb energy $U$ taken into account (also referred to as GGA+$U$). The magnetic $p-d$ coupling is found to be over two orders of magnitude larger than the $d-d$ exchange coupling. The experimental collosal magnetic moments and room temperature ferromagnetism in GaN:Gd reported recently are explained by the interaction of Gd 4$f$ spins via $p-d$ coupling involving holes introduced by intrinsic defects such as Ga vacancies.

1:51PM V33.00012 Thermodynamics of carrier-mediated magnetism in semiconductors$^1$, A.G. PETUKHOV, South Florida School of Mines and Technology, Rapid City, L. MAKINISTIAN, South Dakota School of Mines and Technology (on leave from CONICET, FI-UNER, Argentina), S.C. ERWIN, Naval Research Laboratory, R. ABOLFATH, University of Texas Southwestern, I. ZUTIC, SUNY Buffalo — We propose a model of carrier-mediated ferromagnetism in semiconductors that accounts for the temperature dependence of the carrier population. The model permits an analysis of the thermodynamic stability of competing magnetic states, opening the door to the construction of magnetic phase diagrams. As an example we analyze the stability of a possible room-temperature ferromagnetic semiconductor, in which temperature leads to an increased carrier density, such that the enhanced exchange coupling between magnetic impurities results in the onset of ferromagnetism as temperature is raised. We apply this approach to studying the thermodynamic fluctuations of magnetization in small systems such as bound magnetic polarons and magnetic nanolands.

$^1$Supported by US ONR, NSF-ECCS and CAREER.

2:03PM V33.00013 Electronic structure and magnetism of Fe$_{1-x}$Mn$_x$N compounds, LI CHEN, Tulane University, TULANE UNIVERSITY TEAM, LINYI NORMAL UNIVERSITY TEAM — The electronic structure and magnetism of Fe$_{1-x}$Mn$_x$N compounds have been studied by a periodic-quantum-mechanical calculation based on density functional theory. The results show that a ferromagnetic ordered phase is stable when Fe is substituted by Mn on cube corner sites, whereas the antiferromagnetic phase is energetically favored when Mn substitutes for Fe on face-centered sites. Mn atom concentration and the substitutional sites have significant influence on the exchange coupling. We predict covalent bonds between face-centered Fe or Mn 3$d$ and N 2$p$ orbitals. In contrast, bonding between the atoms at cube corners and face-centered sites is mainly ionic or metallic.

11:15AM V34.00001 Session Introduction, BEVERLY HARTLLINE, Delaware State University — This abstract not available.

11:25AM V34.00002 The APS 2007 Meeting on Gender Equity in Physics, ARTHUR BIENENSTOCK, Stanford University — This abstract not available.

11:44AM V34.00003 Promoting Positive Images of Women in Physics, BARBARA SANDOW — Why are so few women among the students who study physics? Worldwide statistics show that there have been very few female students in the physics in any country, in the past and in current times. The situation in Germany is outstandingly precarious. The fraction of women to study physics is lower than 15% of all students of the activities in Germany and in other countries. The aims are to bring more girls in to physics, modify the image of scientists and find ways to stop women from dropping out of physics. The experiences and the expectations will be discussed.

12:03PM V34.00004 She’s a Physicist!$^1$, LAURA H. GREENE, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801 USA — Any minority often feels either left out or at the center of attention. The difficulty of blending in creates both challenging obstacles and unique opportunities. Such negative and positive distractions, whether major or minor, can have a profound impact on accomplishing one’s goals. Success requires sustained focus, a constant eye on the “big picture”, and the ever-important sense of humor. In other words, don’t be distracted by the ups and downs, keep your passion focused on the science, and enjoy the ironies. I will discuss some of my personal experiences as a woman and how I have learned to navigate the physics world since before 1970. Through losses and wins, I will share how I have managed to, at least most of the time, keep on keeping on.

$^1$I presently enjoy funding from the U.S. DoE Division of Materials Sciences DE-FG02-07ER46453 through the FSMRL, the NSF DMR 07-06013, and continual support from my sisters and girlfriends
12:22PM V34.00005 Women in Physics in a Rapidly Changing China — LING-AN WU, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China — Despite the upheavals of the 20th century, physics managed to survive quite well in China, where the first woman president of the American Physical Society was born and bred. During the 1950s as a result of policies that emphasized science and engineering, declared equal rights and equal pay for men and women, and assigned jobs to college graduates irrespective of sex, the number of women in physics increased rapidly, many of whom made notable achievements. Since China’s opening up over the last thirty years tremendous changes have taken place, and women now face new opportunities as well as challenges in all aspects of society. Whereas physics used to be regarded as the most elite of the sciences, new fields such as computer science, biotechnology and business are now competing for the best students. Compared with other countries the statistics are not bad; in schools and many physics departments the ratio of women teachers may be 30% or higher, but the numbers drop drastically with rank. Moreover, in some research institutions the ratio of female physicists is actually declining, due to retirement of the older generation and fewer successors. Compulsory retirement for women at an earlier age than for men is also a new factor. Conversely, in recent years the ratio of female graduate students enrolling in physics has increased, even reaching 40% in some universities. However, the reasons for this do not bode well: men are not performing so well as women in entrance exams, while the latter are facing increasing discrimination in employment so they have to seek higher degree qualifications. With the further development of China’s economy there will be abundant demand for qualified personnel including women with a physics background. It is imperative to actively support the upcoming generation of women physicists and not lose them in the leaky pipeline. The Chinese Physical Society has taken certain positive steps, such as the recent establishment of the Xie Xi-De Prize for Women in Physics. However, there is complacency and a general lack of awareness of the special difficulties and discrimination that women in physics face, and this needs to be brought to the attention of all sectors at all levels.

12:41PM V34.00006 Marshak Lectureship Talk: Women in Physics in the Baltic States Region: Problems and Solutions — DALIA SATKOVSKIENE, Vilnius University — In this contribution the gender equality problem in physics will be discussed on the basis of the results obtained implementing the project “Baltic States Network: Women in Sciences and High Technology” (BASNET) initiated by Lithuanian women physicists and financed by European Commission. The main goal of BASNET project was creation of the regional Strategy how to deal with women in sciences problem in the Baltic States. It has some stages and the contribution follows them. The first one was in depth sociological study aiming to find out disincentives and barriers women scientists face in their career and work at science and higher education institutions. Analysis of results revealed wide range of problems concerned with science organization, management and financing common for both counterparts. However it also proved the existence of women discrimination in sciences. As main factors influencing women under-representation in Physics was found: the stereotypes existing in the society where physics is assigned to the masculine area of activity; failings of the science management system, where highest positions are distributed not using the institutionalized objective criteria but by voting, where the correctness of majority solutions is anticipated implicitly. In physics where male scientists are the majority (they also usually compose executive boards, committees etc.) results of such a procedures often are unfavorable for women. The same reasons also influence women “visibility” in physicist’s community and as the consequence possibility to receive needed recourses for their research as well as appropriate presentation of results obtained. The study revealed also the conservatism of scientific community- reluctance to face existing in the scientific society problems and to start solving them. On the basis of the results obtained as well practice of other countries the common strategy of solving women in physics (sciences) in the Baltic States region was formulated. As changing the stereotypes is long lasting process it was decided firstly to concentrate strategy implementation plans on changes in science management policy tackling the problem from the top and allowing receive the most quick results. For this we created the regional Baltic States Network among the corresponding international women working groups, professional organizations (Scientific societies) and corresponding departments of the governmental institutions. BASNET also became a full member of European Platform of Women Scientists (EPWS)-prestige women organization signally influencing the European Community science policy.

Thursday, March 13, 2008 11:15 AM - 2:03 PM —
Session V35 DMP FIAP: Focus Session: Thermoelectric Phenomena in Nanostructured Materials Morial Convention Center 227

11:15AM V35.00001 Thermoelectric Properties of Complex Zintl Phases — G. JEFFREY SNYDER, California Institute of Technology — Complex Zintl phases make ideal thermoelectric materials because they can exhibit the necessary “electron-crystal, phonon-glass” properties required for high thermoelectric efficiency. Complex crystal structures can lead to high thermoelectric figure of merit (zT) by having extraordinarily low lattice thermal conductivity. A recent example is the discovery that Yb$_{11}$MnSb$_{11}$, a complex Zintl compound, has twice the zT as the SiGe based material currently in use at NASA. The high temperature (300K - 1300K) electronic properties of Yb$_{11}$MnSb$_{11}$ can be understood using models for heavily doped semiconductors. The free hole concentration, confirmed by Hall effect measurements, is set by the electron counting rules of Zintl and the valence of the transition metal (Mn$^{1+2}$). Substitution of nonmagnetic Zn$^{1+2}$ for the magnetic Mn$^{1+2}$ reduces the spin-disorder scattering and leads to increased zT (10%). The reduction of spin-disorder scattering is consistent with the picture of Yb$_{11}$MnSb$_{11}$ as an underscreened Kondo lattice as derived from low temperature measurements. The hole concentration can be reduced by the substitution of Al$^{1+2}$ for Mn$^{1+2}$, which leads to an increase in the Seebeck coefficient and electrical resistivity consistent with models for degenerate semiconductors. This leads to further improvements (about 25%) in zT and a reduction in the temperature where the zT peaks. The peak in zT is due to the onset of minority carrier conduction and can be correlated with reduction in Seebeck coefficient, increase in electrical conductivity and increase in thermal conductivity due to bipolar thermal conduction.

11:51AM V35.00002 A theoretical study of thermoelectric metamaterial1 — JIANWEI CAI, GERALD MAHAN, Department of Physics, Penn State University — An artificial crystalline material with nanoparticles connected by conducting linkers is proposed for thermoelectric application. Such materials can be synthesized with chemical approaches. The advantage of such materials for thermoelectric application will be discussed. A simple theoretical model for such materials is proposed. Basic theoretical results about the band and properties of the materials based on perturbation theory will be presented.

1Work funded by NSF DMR-0213623 and the Pennsylvania Ben Franklin Technology Development Fund.

12:03PM V35.00003 High Thermoelectric Performance of Nanostructured Bismuth Telluride Bulk Alloys — B. POUDEL, Q. HAO, Y. MA, A. MINNICH, A. MUTO, Y.C. LAN, B. YU, X. YAN, D.Z. WANG, D. VASHAAE, X.Y. CHEN, M.S. DRESSELHAUS, G. CHEN, Z.F. REN, GMZ ENERGY, INC. TEAM, DEPARTMENT OF PHYSICS, BOSTON COLLEGE TEAM, DEPARTMENT OF MECHANICAL ENGINEERING, DEPARTMENT OF PHYSICS, MIT COLLABORATION — Bismuth Telluride and its alloys are best thermoelectric materials for near room temperature applications like refrigeration and waste heat recovery. We have been pursuing an approach of random nanostructures in bulk to improve ZT of these materials. Here we report that ZT values of these random nanostructured materials were improved significantly over the state-of-the-art values. Experimental data coupled with microstructure studies and modeling shows that the ZT improvement mainly comes from a lower thermal conductivity because of the increased phonon scattering by defects and grain boundaries. Significantly improved power generation and cooling data produced from these samples confirmed the high ZT values.

1Supported partly by DOE and NSF.
The Effect of Bi/Sb ratio on Maximum ZT in Nanostructured p-type Bi$_2$Sb$_2$-Te$_3$ Alloys, YI MA, BO YU, BED POUDEL, YUCHENG LAN, JIAN YANG, ZHIFENG REN, Physics Dept., Boston College, QING HAO, GANG CHEN, Department of Mechanical, Massachusetts Institute of Technology — Alloy nanoparticles Bi-Sb$_2$-Te$_3$ (x = 0.2, 0.3, 0.4, 0.5 and 0.6) were synthesized from bismuth, antimony, and tellurium and compacted into nanostructured bulk samples with full density. The thermoelectric properties were measured in the temperature range of 25 to 250°C. We showed that a maximum dimensionless figure-of-merit (ZT) reached 1.27 at about 100°C for Bi$_{0.4}$Sb$_{1.6}$Te$_3$ (x = 0.4), a significant improvement over the state-of-the-art p-type Bi$_2$Te$_3$ alloys. It is demonstrated that the enhanced ZT mainly comes from a reduced thermal conductivity due to the increased phonon scattering due to the nano size of the grains. Also, the ZT peaks shift from low temperature to high temperature with the decreasing of x, which indicates the less Bi content would benefit the potential power generation application while the more Bi content materials could be used as a potential cooling device. This new route of enhancing ZT value can be applied to other materials.

XAS study of Bi$_2$Te$_3$/Sb$_2$Te$_3$ Superlattices and Sb$_{1.5}$Bi$_{0.5}$Te$_3$ Alloy Film, AZZAM MANSOUR, NSWC, Carderock Division, RAY VENKATASUBRAMANIAN, RTI International — Bi$_2$Te$_3$/Sb$_2$Te$_3$ superlattices are being developed for high performance thermoelectric devices. We have used X-ray absorption spectroscopy (XAS) to investigate the local structure of Sb in 20/40 Å and 10/50 Å Bi$_2$Te$_3$/Sb$_2$Te$_3$ superlattices, a Sb$_2$Bi$_2$Te$_6$ alloy film, and a Sb$_2$Te$_3$ reference film. The films were grown on GaAs using a novel low temperature metal-organic chemical vapor deposition method. Initially, we evaluated the local structure parameters of Sb in the superlattices and the alloy relative to those of the reference Sb$_2$Te$_3$ film. Using temperature dependent Sb K-edge XAS measurements, we were able to separate structural disorder from thermal disorder for the Sb-Te pair. The temperature dependence of thermal disorder was analyzed using the Einstein and Debye models for lattice vibrations. A comparison of the results for the superlattices, the alloy and the reference film will be made. The goal is to identify key structural factors that may contribute to the enhanced value of the figure of merit “ZT” and, hence, the improved conversion efficiency for the superlattices relative to the alloys.

Thermoelectric properties of PbTe/PbSe mesomaterials, FENG CHEN, YAOI WANG, YUNI XUE, C. W. CHU, Dept. of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX 77204-5002, JUN ZHANG, JIE FANG, Dept. of Chemistry, State University of New York at Binghamton, Binghamton, NY 13902-6000, CHUNHUI TAN, ZHIFANG LIN, BOB LUL, Aegis Technology, Inc., 3300A Westminster Ave., Santa Ana, CA 92703 — Ball milled PbTe mixed with PbSe nano-wires (PTSW) or with PbSe nano-crystals (PTSC) are sintered under high pressure. Different sintering conditions are tested to preserve the mesostructures. Thermoelectric properties (resistivity, Seebeck coefficient and thermal conductivity) are measured at various temperatures. Pure ball milled PbTe are also sintered and measured for comparison. In this talk, we will present these data and compare with various PbTe data from the literature. Our results show that this mesostructure approach is promising and the sintering condition is the key factor for further improvement.

Transport Properties of Lead Chalcogenide Nanocomposites, GEORGE NOLAS, JOSHUA MARTIN, STEVE STEFANOSKI, Department of Physics, University of South Florida, Tampa, FL, USA, LI WANG, LIDONG CHEN, Shanghai Institute of Ceramics, Chinese Academy of Sciences, Shanghai 200050, China, UNIVERSITY OF SOUTH FLORIDA TEAM, SHANGHAI INSTITUTE OF CERAMICS TEAM — Lead chalcogenide dimensional nanocomposites were prepared by densifying nanocrystals, synthesized in high purity - high product yield employing an alkaline aqueous solution-phase reaction, by Spark Plasma Sintering. Transport properties were evaluated through temperature dependent resistivity, Hall, thermopower, and thermal conductivity measurements. The physical properties of these materials are strongly sensitive to stoichiometry, doping, and porosity. The transport properties of the nanocomposites were compared to that of bulk polycrystalline materials with similar compositions and carrier concentrations. An enhancement of the room temperature thermoelectric properties of up to 30% over that of the bulk was realized.

Nanostructured thermoelectric skutterudite Co$_{1-x}$Ni$_x$Sb$_3$ alloys, QINYU HE, Boston College, South China Normal University, XIAOWEI WANG, JIAN YANG, YUCHENG LAN, XIAO YAN, BO YU, YI MA, BED POUDEL, GIRI JOSHI, DEZHI WANG, ZHIFENG REN, Boston College, QING HAO, GANG CHEN, MIT, BOSTON COLLEGE, REN’S LAB COLLABORATION, MIT COLLABORATION, SOUTH CHINA NORMAL UNIVERSITY COLLABORATION — Nanostructured Ni-doped skutterudites Co$_{1-x}$Ni$_x$Sb$_3$ (with x ranging from 0.01 to 0.09) have been prepared by ball-milling and direct-current induced hot press. It was found that the thermal conductivity was much reduced due to strong electrons-phonons scattering from Ni-doping and grain boundary phonons scattering from nano-structures in the samples. A maximum dimensionless figure-of-merit of 0.71 has been obtained in Co$_{0.91}$Ni$_{0.09}$Sb$_3$ at 525 °C.

Thermal conductivity reduction by interface roughness in AlN$_x$-GaN$_y$ superlattices, YEE KAN KOH, Univ of Illinois at Urbana-Champaign, YU CAO, Univ of Notre Dame, DAVID CAHILL, Univ of Illinois at Urbana-Champaign, DEBDEEP JENA, Univ of Notre Dame — A reduction of cross-plane thermal conductivity by a factor of two is achieved in AlN$_{12.4}$-GaN$_{25.6}$ superlattices by varying the plasma power during growth. This reduction is attributed to interface roughness, introducing a new parameter to be considered in the design and fabrication of superlattices for thermoelectric applications. Thermal conductivity of AlN$_{12.4}$-GaN$_{25.6}$ superlattices, x ~ 4 nm and 2 < y < 1000 nm, with rough interfaces is then measured by time-domain thermoreflectance. A decreases monotonically as the GaN thickness y decreases, $\Delta = 6.35$ W m$^{-1}$ K$^{-1}$ at y = 2.2 nm. We observe no minimum thermal conductivity as a function of period for these rough superlattices. A continuum model incorporating the effects of interface roughness indicates that diffuse scattering is dominant when y > 20 nm, and significant coherent transmission occurs when y < 20 nm.

High dimensionless figure-of-merit in nanostructured p-type bulk SiGe alloys, GIRI JOSHI, Boston College, HOHYUN LEE, Massachusetts Institute of Technology, XIAOWEI WANG, GOAHAU ZHU, YUCHENG LAN, DEZHI WANG, Boston College, BED POUDEL, GMZ Energy, Inc., MILDRED DRESSELHAUS, GANG CHEN, Massachusetts Institute of Technology, ZHIFENG REN, Boston College — Silicon Germanium (SiGe) alloys have been used for high temperature power generation in thermoelectric generators. Since their performance is related to dimensionless figure-of-merit (ZT), material scientists have focused their attention on possible improvements in ZT of SiGe alloys through an increase in power factor and decrease in thermal conductivity. We have been pursuing an approach of random nanostructures to reduce the thermal conductivity based on the understanding that the reduction of thermal conductivity is primarily responsible for ZT enhancement in superlattices. We have observed 100% improvement in ZT, compared to the state-of-the-art values, in p-type SiGe nanostructured bulk materials, which comes mainly from decrease in thermal conductivity due to the increase in phonon scattering by defects and grain boundaries in nanostructured. These bulk materials also possess superior mechanical properties making them more suitable for fabrication and integration into systems which were made by hot pressing of nanopowders prepared by using high energy ball milling.
1.39PM V35.00011 Nanotubular high thermoelectric figure-of-merit in n-type bulk SiGe alloys. XIAOWEI WANG, Boston College, HOHYUN LEE, Massachusetts Institute of Technology, GAOHUA ZHU, YUCHENG LAN, DEZHI WANG, Boston College, MILDRED DRESSELHAUS, GANG CHEN, Massachusetts Institute of Technology, ZHIFENG REN, Boston College, BOSTON COLLEGE TEAM, MASSACHUSETTS INSTITUTE OF TECHNOLOGY COLLABORATION — Silicon germanium alloys (SiGe) have been the exclusive choice for radiotransfer thermoelectric generators (RTGs) because of its reliability and high operating temperatures. In this paper, by using mechanical alloying method, nano-sized phosphorous-doped (n-type) SiGe alloy powders were produced, followed by direct current induced hot press technique, bulk samples were obtained with ~100% density. The thermoelectric properties, including electrical conductivity, Seebeck coefficient, and thermal conductivity, were measured in the temperature range from 25 to 900 °C. A maximum ZT of around 1.3 at 900 °C was obtained under certain doping concentration and hot press conditions, mainly due to thermal conductivity reduction from nano-structured SiGe grains of 20 nm.

1Department of Mechanical Engineering/Department of Physics and Electrical Engineering

1:51PM V35.00012 Thermoelectric properties of n-type nano bulk Si. GAOHUA ZHU, Boston College, HOHYUN LEE, Massachusetts Institute of Technology, XIAOWEI WANG, GIRI JOSHI, YUCHENG LAN, JIAN YANG, DEZHI WANG, Boston College, MILDRED DRESSELHAUS, GANG CHEN, Massachusetts Institute of Technology, ZHIFENG REN, Boston College, DEPARTMENT OF PHYSICS, BOSTON COLLEGE TEAM, DEPARTMENT OF MECHANICAL ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY TEAM, DEPARTMENT OF PHYSICS AND ELECTRICAL ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY TEAM — Nano Si has been noticed as a promising substitute material for SiGe. We have observed a 150 to 350 % increase in ZT values in the heavily doped n-type nano Si over the single crystal Si, which mainly comes from the significantly lower thermal conductivity due to the nano size of grains achieved by mechanical alloying and hot press. The key to get higher ZT value is to optimize the doping concentration to achieve high power factor and avoid grain growth during hot-pressing to achieve nano particle size in the final bulk form. So far our research on nano bulk Si has shown promising ZT values close to 1, comparable to that of the traditional SiGe alloys. Silicon is lighter, more refractory, and has better thermal stability than Si_{1-x}Ge_{x} and also it is much cheaper than Ge. Pure Si may have advantage over SiGe alloy in mass application of power generation systems.

Thursday, March 13, 2008 11:15AM - 1:51PM -
Session V36 GIMS: Advances in Scanned Probe Microscopy IV: Optical and High Frequency Methods Morial Convention Center 228

11:15AM V36.00001 High-resolution element-selective microscopy using X-ray enhanced Scanning Tunneling Microscopy1, VOLKER ROSE, JOHN FREELAND, KENNETH GRAY, STEPHEN STREIFFER, MATTHIAS BODE, Argonne National Laboratory — Nanoscale structures are at the forefront of fundamental research as well as the keystone for whole new classes of potential applications. Proper understanding of these systems requires tools with both the ability to resolve the nanometer scale as well as provide detailed information about chemical, electronic and magnetic structure. Scanning probe microscopes achieve the requisite high spatial resolution; however, direct elemental determination is not easily accomplished. X-ray microscopes, on the other hand, provide elemental selectivity, but currently have spatial resolution only of tens of nanometers. We present a radically different concept that employs detection of local x-ray interactions utilizing a scanning probe that provides spatial resolution, and x-ray absorption directly yields chemical, electronic, and magnetic sensitivity. The achievement of nanometer spatial resolution with direct elemental selectivity will have a tremendous impact on our ability to probe and understand complex phenomena occurring in nanostuctures.

11:27AM V36.00002 Scanning optical homodyne detection of high-frequency picoscale resonances in cantilever and tuning fork sensors1. J. C. RANDEL, G. ZELTZER, Stanford University, A. K. GUPTA, R. BASHIR, Purdue University, S.-H. SONG, H. C. MANOHARAN, Stanford University — Hybrid high-frequency sensors represent the next generation of scanned probe technology. In this work, higher harmonic modes in nanoscale silicon cantilevers and microscale quartz tuning forks are detected and characterized using a custom scanning optical homodyne interferometer. Capable of both mass and force sensing, these resonators exhibit high-frequency harmonic motion content with picometer-scale amplitudes detected in a 2.5 MHz bandwidth, driven by ambient thermal radiation. Quartz tuning forks additionally display both in-plane and out-of-plane harmonics. The first six electronically detected resonances are matched to optically detected and mapped fork eigenmodes. Mass sensing experiments utilizing higher tuning fork modes indicate greater than six times sensitivity enhancement over fundamental mode operation. (This work supported by NSF and ONR).

11:39AM V36.00003 Radio Frequency Scanning Tunneling Microscopy: Instrumentation and Applications UTKU KEMIKTARAK, Dept. of Physics, Boston University, Boston, MA 02215, TCHEFOR NDUKUM, KEITH C. SCHWAB, Dept. of Physics, Cornell University, Ithaca, NY 14853, KAMIL L. EKINCI, Dept. of Aerospace and Mechanical Eng., Boston University, Boston, MA 02215 — A severe limitation of the scanning tunneling microscope (STM) is its low temporal resolution, originating from the diminished high-frequency response of the tunnel current readout circuitry. In order to overcome this limitation, we have built a radio-frequency STM (RF-STM). Using this instrument, we can attain electronic bandwidths as high as 10 MHz by measuring the reflection from or transmission through the tunnel junction, which is embedded in a resonant inductor-capacitor (LC) circuit. This ~100-fold bandwidth improvement upon the state-of-the-art translates into fast surface topography as well as delicate measurements in mesoscopic electronics and mechanics. Broadband noise measurements across the tunnel junction using this radio-frequency-STM (RF-STM) have allowed us to perform nanoscale thermometry. Furthermore, we have detected high-frequency mechanical motion with a sensitivity approaching 15 fmHz^{-1/2}.
11:51AM V36.00004 Thermomechanical Noise Measurements of Very High Frequency (VHF) Nanomechanical Resonators¹, Carl Hart IV, Kamil Ekinçi, Aerospace and Mechanical Engineering, Boston University, Boston, MA — We have designed and built a near infrared (NIR) optical interferometer for ultra-sensitive displacement measurements on nanomechanical resonators. At moderate optical power levels, we are able to resolve the thermomechanical displacement fluctuations of stiff doubly-clamped beams with fundamental mode frequencies in the 100 MHz range. In a first set of noise measurements, we have determined the quality factors and resonant frequencies of the nanomechanical resonators under ambient atmospheric pressure at room temperature. We will compare these values to those extracted from driven resonance measurements and discuss sources of disagreement. Furthermore, we will discuss extraction of the local temperature of the nanomechanical resonators in order to assess the heating due to the optical probe.

¹This work was sponsored by the Department of the Air Force under Air Force Contract No. FA8721-05-C-0002 and NSF Award ECCS-0643178. The opinions, interpretations and conclusions belong to the authors and are not necessarily endorsed by the US Government.

12:03PM V36.00005 Development of an Evanescent Microwave Probe / Scanning Tunneling Microscope to study Localized Electron Spin Resonance, Christian Long, University of Maryland, Naoyuki Take-Toshi, National Institute of Advanced Industrial Science and Technology, Ichiro Takeuchi, University of Maryland, Haitao Yang, Intematix Corporation, Xiao-Dong Xiang, Intematix Corporation, University of Maryland Team, National Institute of Advanced Industrial Science and Technology Collaboration, Intematix Corporation Collaboration — We have constructed a microwave microscope with an integrated scanning tunneling microscope. In addition to the measurement of complex dielectric constant and conductivity we also perform atomic resolution scanning tunneling microscopy (STM). In this work the probe is operated in a magnetic field, which causes unpaired spins in the sample to precess at the Larmor frequency. When the magnetic field is such that the Larmor frequency of the spins in the sample matches the resonant frequency of the resonator, the transmission coefficient of the resonator (S12) is changed. We measure local ESR by measuring the variation in S12 as a function of magnetic field. In this report, we give an outline of the experimental setup and preliminary spin detection data for various spin radical molecules (one unpaired spin each) on an HPOG substrate (no unpaired spins). Supported by the W. M. Keck Foundation and NSF MRSEC (DMR 0520471).

12:15PM V36.00006 High Frequency Piezoresponse Force Microscopy in the 1-10 MHz Regime, Katayani Seal, Stephen Jesse, Brian Rodriguez, Arthur Baddorf, Sergei Kalinin, Oak Ridge National Laboratory — Imaging mechanisms in Piezoresponse Force Microscopy (PFM) in the high frequency regime above the first contact resonance are analyzed. High operation frequencies are expected to provide several advantages including (a) higher signal to noise ratios due to a larger number of oscillations per pixel time and increased separation from the 1/f noise corner (b) imaging at cantilever resonances with an associated increase in mechanical signal amplification (c) inertial stiffening of the cantilever that minimizes the non-local electrostatic force contribution to the signal and improves tip-surface contact. Furthermore, high frequency operation is an essential component of the PFM-based ferroelectric data storage systems, currently limited by the bandwidth of electromechanical detection (1-10 kHz). At the same time, operation at a high mode number can give rise to several problems, including the (a) response of averaging due to the finite size of the cantilever beam (b) loss of sensitivity if the tip-surface spring constant becomes smaller than the effective spring constant of the cantilever and (c) signal loss due to the bandwidth of the photodetector. Analytical expressions for these limits are considered. We analyze the operation mechanisms in PFM at high frequencies, and demonstrate high quality PFM imaging at 1-10 MHz. Prospects for imaging in the 10-100 MHz range are explored.

12:27PM V36.00007 Contrast sensitive imaging with a cantilever-based near-field microwave probe, Keiji Lai, Worasom Kundhikanjana, Michael Kelly, Zhi-Xun Shen, Geballe Laboratory for Advanced Materials, Stanford University — We have developed a procedure to systematically study the contrast mechanism of our cantilever-based near-field scanning microwave probes with separated excitation and sensing electrodes. Finite-element analysis was employed to model the small impedance change due to the tip-sample interaction. The near-field signal can then be calculated from the S-parameters of the matching network that routes the tip impedance to 50 Ohm feed lines. Using a common-mode cancellation scheme, the microwave electronics is sensitive down to 1aF capacitance change at our working frequencies near 1GHz. Experimental characterization of the microwave probes was performed on ion-implanted Si wafers and patterned semiconductor samples. Pure electrical or topographical signals, in qualitative agreement with simulation, can be obtained using different reflection modes of the probe. Our microscope also shows very high contrast due to conductivity variations of the sample, which can lead to potential applications of the technique.

12:39PM V36.00008 STM and SNOM Type of Scanning Probe Microscopes in the Same Unit: Towards Electrical Modification and Optical Characterization at Nanoscale, Ilya Sychugov, NTB Basic Research Laboratories, Hiroo Omi, Tooru MuraShita, Yoshihiro Kobayashi — Optical and electrical properties of nanostructures can be addressed by radiation or electrical current as a probe. In general, a near-field type of electromagnetic interaction is necessary for an optical probe to enter nanoscale regime. However, a typical scanning near-field microscope utilizes a dielectric fiber tip as an aperture, which makes it unsuitable for electrical measurements. Here, in order to realize both electrical and optical probing at nanoscale, we have combined it with a scanning tunneling microscope (STM). An STM-luminescence (STML) instrument with a conductive and transparent tip, featuring about 40 nm spatial resolution, was reported previously. We have complemented it with a beamsplitter unit in a configuration typical for the fluorescent microscope. The excitation light is guided through a beamsplitter unit to the indium tin oxide (ITO) tip and the signal is collected via the same fiber transmission line in a spectroscopy mode or in a photon mapping regime. The influence of tip geometry on collection efficiency and spatial resolution as well as limitations of such an instrument are discussed. This approach may find its niche not only for combined electrical and optical measurements, but also for electrical modification with subsequent in situ optical probing.

12:51PM V36.00009 A Unique Probe for Tip Enhanced Raman Scattering and Shadow NSOM, Aaron Lewis, Hebrew University of Jerusalem, Hesham Taha, Rimma Dekhter, Galia Zinoviev, Galina Fish, Nanonics Imaging Ltd. — We present a unique atomic force microscope [AFM] probe for tip enhanced Raman scattering [TERS] and a new form of near-field microscopy, "Shadow Near-field Scanning Optical Microscopy". The probe consists of a single gold nanoparticle grown at the tip of a cantilevered nanopipette, exposed to the optical axis of an upright or inverted optical microscope. When these probes are used in combination with a Nanonics MV 2000 AFM/NSOM system, we show that a protocol for independent motion of the probe and the sample can produce enhancement or a shadow effect. Both of these effects are enhanced by the ability to affect different Raman spectra with the tip in & out of contact while independently scanning the sample. We analyzed Raman signals of a thin nanometric strained Si layer deposited on bulk Si and developed an understanding of optical mechanisms of enhancement, scattering and shadowing. Our results show different optical mechanisms occur as a result of tip & sample interactions, including TERS effect obtained by near-field interaction of the probe with the top layer of strained Si. Large enhancements of at least 4 orders of magnitude are seen and analyses of relative intensities of bulk and strained Si Raman peaks show an increase in light scattered by bulk or effective shadowing of the surface.
1:03PM V36.00010 Chemical Imaging of the Surface of Polymeric Nanostructures Using Aper- 
tureless Near-Field IR Microscopy
ZAHRA FAHKRAI, KERSTIN MUELLER, MELISSA PAULITE, XIUJUAN YANG, GILBERT C. 
WALKER, Department of Chemistry, University of Toronto, Toronto, ON, M5S 3H6, Canada — The 
chemical composition of the surfaces of thin films of polystyrene-poly (methyl methacrylate) (PS-PMMA) diblock copolymers is investigated using apertureless near-field IR microscopy. In this technique a tunable IR beam is scattered from an oscillating atomic force microscopy tip. The scattered light is enhanced using a reference signal with the same optical frequency (homodyne) or slightly shifted IR frequency (heterodyne) and detected after demodulation in order to eliminate the background scattering. Using this technique a lateral chemical imaging resolution of <20 nm is achievable. It is demonstrated that this technique can be successfully used to image the surface of PS-PMMA diblock copolymers. Another important result is that an increase in the IR absorption is observed in the PMMA rich domains with a wavenumber dependence that is consistent with the bulk absorption spectrum. The results indicate that even though a topography induced artifact can be observed, when homodyne detection technique is used, the chemical signature of the sample can be detected clearly. This technique can be further used in a variety of different systems to detect the surface structure of polymers or proteins.

1:15PM V36.00011 Scanning thermal microscopy with a fluorescent nanoprobe
BENJAMIN SAMSON, ELIKA SAIDI, LIONEL AIGOY, LPEM / CNRS, PETER LOW, LAAS / CNRS, BEMOJOON KIM, University of Tokyo, Japan, CHRISTIAN BERGAUD, LAAS / CNRS, MICHEL MORTIER, ENSCP / CNRS, LABORATOIRE PHOTONS ET MATIERE TEAM, LABORATOIRE D’ARCHITECTURE ET D’ANALYSE DES SYSTEMES TEAM, INSTITUTE OF INDUSTRIAL SCIENCE, CENTER FOR INTERNATIONAL RESEARCH ON MICROMECHATRONICS TEAM, LABORATOIRE DE CHIMIE DE LA MATIÈRE CONDENSÉE DE PARIS TEAM — We have developed a scanning thermal microscope that uses a fluorescent particle settled at the extremity of an atomic force microscope tip as a nanoscale temperature sensor. When a temperature change occurs, a modification of fluorescence is detectable, enabling to perform thermal images and to determine the local temperature. We will describe the technique in details and present some thermal images on submicron sized nickel nanoheaters heated by an electrical current. We will show that this apparatus works in both DC and AC regimes, in a low frequency range whose upper limit is around the kilohertz. By performing tip approach/retraction curves on a heated wire, we will describe the different thermal transfer mechanisms between the surface and the fluorescent probe.

1:27PM V36.00012 A versatile technique for fabrication of SiC SPM probes
JOEL THERRIEN, DANIEL SCHMIDT, SHEETAL BARROT, BHAVIN PATEL, U. Massachusetts-Lowell — To date SPM probes have largely been fabricated via methods borrowed from the semiconductor industry for fabricating Micro Electro Mechanical Systems. Although these techniques have enabled SPM to see widespread use, the processes put significant limitations on what structures can be made. We report our progress on fabricating SPM cantilevers composed of Silicon Carbide using polymer molding techniques. A pre-ceramic polymer is molded into the desired probe shape and then converted to SiC via pyrolisys. We will also report on progress in using photo-sterolithography for fabrication of even more complex geometries. In addition to opening up a much larger set of probe structures, the use of SiC leads to improved wear resistance of the resulting probes. Among the potential applications, this method enables the fabrication of low spring constant, high resonant frequency cantilevers via cross sectional geometries not accessible to standard fabrication techniques. Such probes are required for high speed tapping and non-contact imaging.

1:39PM V36.00013 In-situ broadband microwave calibrations and measurements using cryo-
genic probe stations
JEFFREY LINDEMUTH, SCOTT YANO, Lake Shore Cryotronics — Until recently, calibration of microwave measurements in cryogenic environments required custom fixtures [1,2]. These fixtures were necessary to accommodate the limited space in typical “down bore” cryostat designs. The typical three measurements (through, short, load, for example) required removing the fixtures from the cryostat three times before loading the sample of interest. We will show that with a 4-probe cryogenic probe station it is possible to simultaneously load a commercially available calibration test strip and the measurement sample. We will demonstrate calibration of the complete S matrix of the microwave network analyzer at each temperature followed by measurement of the sample. In addition, the temperature-dependent effects of the calibration can be determined. We will show short term and long term calibration stability.
[2] Broadband microwave spectroscopy in Corbino geometry for temperatures down to 1.7 K

Thursday, March 13, 2008 11:15AM - 2:03PM –
Session V37 FlAP: QHE and FQHE Morial Convention Center 229

11:15AM V37.00001 Optical Studies of Quantum Phases with Filling Factors 2 ≤ ν ≤3 in 
the Second Landau Level
TREVOR DAVID RHONE, JUN YAN, Columbia University, YANN GALLAIS, Université Paris7, ARON PINCZUK, Columbia University, LOREN PFEIFFER, KEN WEST, Bell labs, Alcatel-Lucent — We report low temperature inelastic light scattering and optical recombination measurements of quantum phases in the second Landau level of 2D electron systems. We focus on states with filling factors 2 ≤ ν < 3. An ultra high mobility, high density GaAs quantum well (240nm) is probed at low temperature (42mK – 1.2K). Low energy spin excitations are studied by resonant inelastic light scattering. We confirm the existence of a ferromagnetic state at ν = 3 by the observation of a well defined long wavelength spin wave mode at the Zeeman energy. Surprisingly, the ferromagnetic spin wave collapses at filling factors slightly away from ν = 3. While this behavior may be a signal of the disappearance of ferromagnetic order in the second Landau level, experiments in progress may offer deeper insights on fundamental interactions and quantum phases in the second Landau level.

1Supported by NSF and DOE

11:27AM V37.00002 Investigations of possible Landau level anticrossings in p-type (110) GaAs 
square wells
NEBILE ISIK, SIF. ROTH, M. BICHLER, A. FONTCUBERTA I MORRAL, G. ABSTREITER, Tech. Univ. Muenchen, M. GRAYSON, Northwestern University — In p-type (110) quantum wells, a single anomalous magnetoresistance peak is observed within the lowest Landau level (ν = 1) of a two-dimensional hole system when the confinement is a triangular potential well [1]. This peak is interpreted as the transport signature of a ± 3/2 spin-reversal level-anticrossing in the lowest Landau level. In recently fabricated 400 Åwide square quantum wells, we observe peaks within several Landau levels, for example, at both ν = 1 and ν = 2. The peak positions in magnetic field B are observed shift with top gate bias and the peak magnitudes are observed to increase with increasing temperature. At a critical top gate bias, however, both original peaks disappear, just as new features appear at higher fields within both the ν = 1 and ν = 2 minima. Dependence of feature position on front and back gate bias will be shown, and temperature dependences will be studied in terms of activated energy gaps. The cause of these peaks will be discussed in terms of possible multiple Landau level anticrossings.

1Supported by DFG Grant GR-2618/1-1
11:39AM V37.00003 Current Instability Induced by Negative Differential Conductivity in the Quantum Hall Regime1, KUAN TING LIN, YULING TSAI, YIPING LIN, J. C. CHEN, Dep. of Physics, National Tsing Hua University, Hsinchu, Taiwan, T.UEDA, S. KOMIYAMA, Dep. of Basic Science, University of Tokyo, Meguro-ku, Tokyo, Japan — We report a new kind of nonlinear effect at \( \nu = 2 \) Hall plateau in a two-dimensional electron gas system formed on a GaAs/AlGaAs heterostructure. Within the temperature \( 16 \, K \leq T \leq 28 \, K \), the current shows discernible zig-zag feature as the applied dc electric field increases beyond a critical value. Such an unstable feature is not only reproducible but also exhibits hysteresis as changing the sweeping direction of the electric field. We identify this current instability as the occurrence of the negative differential conductivity induced by the electric field. Physical origin of the nonlinearities will be presented and discussed.

1Supported by National Science Council (Taiwan)

11:51AM V37.00004 New Observations in the \( N \geq 1 \) Landau Levels of Wide GaAs Quantum Wells, D.R. LUIHMANN, Princeton University, W. PAN, Sandia National Laboratories, D.C. TSUI, Princeton University, L.N. PFIEFFER, K.W. BALDWIN, K.W. WEST, Bell Laboratories — We have studied a series of high-quality wide GaAs/AlGaAs quantum wells at various tilt angles \((\theta)\) with respect to magnetic field. Several interesting observations have been made when the Landau level index is \( N \geq 1 \). The quantum Hall states corresponding to total odd filling factors are seen to be reentrant with increasing \( \theta \), i.e. they disappear and reemerge as \( \theta \) is increased. This observation can be explained by considering oscillations in the tunneling amplitude with increasing \( \theta \). As \( \theta \) is increased further, anisotropy emerges at values of half filling. This is particularly visible in the \( N = 1 \) Landau level at total filling factors \( \nu = 9/2 \) and \( 11/2 \). For even larger values of \( \theta \), anisotropy develops at \( \nu = 5 \) followed by \( \nu = 7 \). We will discuss how each of these observations are effected by quantum well width and also in the context of previous theoretical and experimental results.

12:03PM V37.00005 Edge state tunneling in a point contact at filling fraction \( \nu = 5/2 \), IULIANA P. RADU, MIT, J.B. MILLER, C.R. DILLARD, C.M. MARCUS, Harvard University, M.A. KASTNER, MIT, L.N. PFIEFFER, K.W. WEST, Bell Labs, Alcatel-Lucent — We investigate low temperature transport properties of quantum point contacts (QPCs) fabricated in a GaAs/AlGaAs 2-dimensional electron gas (2-DEG) with mobility \( 2000 \, \text{m}^2/\text{Vs} \) in a perpendicular magnetic field. The 2-DEG exhibits fractional quantum Hall effect, including a well-quantized plateau at \( \nu = 5/2 \). We study the temperature and DC current bias dependence of the transport through the QPC at \( \nu = 5/2 \) while preserving the same filling number in both the QPC and the bulk of the sample. We compare our results to theoretical predictions for quasi-particle tunneling in the weak coupling regime, and extract the quasi-particle charge and the strength of the Coulomb interaction, as reflected by the Luttinger liquid parameter \( g \). This work was partially supported by ARO (W911NF-05-1-0062), by the NSEC program of NSF (PHY-0117795), by NSF (DMR-0353209) at MIT and by Project Q of Microsoft Corporation at Harvard University.

12:15PM V37.00006 Stripes and Bubbles in the \( N=2 \) Landau Level: A DMRG Study, BARRY FRIEDMAN, LAUREN ROD, CANDICE WITHROW, Department of Physics, Sam Houston State University — The phase diagram of the \( N=2 \) Landau level has been reexamined using the density matrix renormalization group (dmrg). Very good agreement at filling factor \( 18/42 \) has been attained with previous dmrg calculations of Shibata and Yoshioka by using 200 states in the blocks. Near \( 1/2 \) filling, we have studied whether the ground state is an anisotropic crystal, suggested by some mean field approaches, or a stripe state, as suggested by other mean field approaches and previous dmrg results. Previous dmrg calculations, i.e. Shibata and Yoshioka, have placed the phase diagram between stripes and bubbles at a filling factor slightly less then \( 4 \) by looking at the projected pair correlation function at the special lines \( x=0 \) and \( y=0 \). We reexamine this boundary by studying the Fourier transform of the projected pair correlation.

12:27PM V37.00007 Interactions and Landau level mixing at large half odd-integer filling, PETER SMITH, MALCOLM KENNETT, Department of Physics, Simon Fraser University — Recent transport experiments on two-dimensional hole systems (2DHs) in a strong perpendicular magnetic field show variations in the anisotropy of resistivity at half odd-integer filling fractions \( \nu = 7/2 \), \( 9/2 \), and \( 11/2 \) that differ from those seen in two-dimensional electron systems. It has been suggested that spin-orbit coupling in 2DHs leads to these unusual transport properties, as it gives rise to Landau level mixing. We consider the general problem of interacting fermions subject to a perpendicular magnetic field with Landau level mixing in the limit of large Landau levels, and discuss the effect of Landau level mixing on charge-density wave formation in comparison to the single Landau level case. We study the case of spin-orbit induced mixing in detail, and discuss implications for experiments.

12:39PM V37.00008 Interaction effects in transport through an electronic Mach-Zehnder interferometer, VITALY GOLOVACH, FLORIAN MARQUARDT, Department of Physics, Arnold-Sommerfeld-Center for Theoretical Physics, and Center for NanoScience, Ludwig-Maximilians-University Munich, Germany — We study theoretically transport through an electronic Mach-Zehnder interferometer in the presence of Coulomb interaction inside the interferometer, using a discrete wave-packet model. We find that the mutual capacitance between the arms of the interferometer leads to a suppression of the visibility of the Aharonov-Bohm oscillations at a large source-drain bias \( \Delta \mu \gg h \nu_{\text{c}} / L \), where \( L \) is the length of the arms and \( \nu_{\text{c}} \) is the electron drift speed. Our numerical simulations indicate that the visibility of the Aharonov-Bohm oscillations is a non-analytic function of the mutual capacitance strength, in the limit \( \Delta \mu \rightarrow \infty \).

12:51PM V37.00009 Universal Periods in Quantum Hall Droplets1, GREGORY A. FIETE, GIL REFAEL, California Institute of Technology, MATTHEW P. A. FISHER, Microsoft Station Q, UCSB — Using the hierarchy picture of the fractional quantum Hall effect, we study the the ground state periodicity of a finite size quantum Hall droplet in a quantum Hall fluid of a different filling factor. The droplet edge charge is periodically modulated with flux through the droplet and will lead to a periodic variation in the conductance of a nearby point contact, such as occurs in some quantum Hall interferometers. Our model is consistent with experiment and predicts that superperiods can be observed in geometries where no interfering trajectories occur. The model may also provide an experimentally feasible method of detecting elusive neutral modes and otherwise obtaining information about the microscopic edge structure in fractional quantum Hall states.

1:03PM V37.00010 Variational Monte Carlo study of the nematic state at half-filled Landau level of the two dimensional electron gas, QUOC DOAN, Florida State University, EFSTRATIOS MANOUSAKIS, Florida State University, Center for Materials Research and Technology — The nematic state of 2DEG at half-filled Landau level (LL) is investigated using the variational Monte Carlo method. The wave function used has Jastrow correlations of the form $\prod_{i<j}(z_i - z_j)^2$ and a Slater determinant having an elliptical Fermi sea. We use the unprojected version of the wave function and apply the Monte Carlo (MC) method to calculate the pair distribution functions and the optimum energies. We compare optimum energies of the nematic state obtained by MC and Fermi hypernetted chain (FHNC/0) approximation with the optimum energies of the stripe ordered state obtained by Hartree-Fock. We find that both FHNC/0 and MC suggest that the nematic state may be energetically favorable as compared to the stripe ordered state at 2nd LL. We have obtained the exact projection of the above mentioned wavefunction of the nematic phase onto the lowest LL. We are in the process of comparing the results obtained with the exact wavefunction on small size systems to those obtained without the projection.

1:15PM V37.00011 Anisotropy in two-dimensional electronic quantum Hall systems at half filling of valence Landau levels, ORION CIFTJA, Department of Physics, Prairie View A&M University, Prairie View, TX 77446, USA, CARLOS WEXLER, Department of Physics and Astronomy, University of Missouri, Columbia, MO 65211, USA — A recent experimental discovery in the quantum Hall regime has been the observation of very strong magneto-transport anisotropies at certain low values of magnetic field below a critical temperature of about 100 mK. While the origin of such anisotropy is yet unknown, we explain the emergence of such anisotropies in terms of electronic liquid crystalline states with broken rotational symmetry. We investigate the stability of liquid crystalline phases with nematic order at half filling of the valence Landau level. Quantum Monte Carlo simulations indicate that while isotropic states are stable in the lowest and first excited Landau level, there are regions of instability towards liquid crystalline states in higher Landau levels. A possible connection of the recently discovered magneto-transport anisotropy in low magnetic fields and these liquid crystalline states is discussed.

1:27PM V37.00012 Quantum Hall hierarchy wave functions from conformal field theory, SUSANNE VIEFERS, University of Oslo, Norway, EMIL BERGHLOTZ, HANS HANSSON, MARIA HERMANNS, ANDERS KARLHEDE, Stockholm University — It has long been known that Laughlin’s wave functions, describing the fractional quantum Hall effect at filling fraction $\nu = 1/(2l+1)$, can be obtained as correlation functions in conformal field theory. We show how to generalize this approach to construct explicit trial wave functions for all states in the quantum Hall hierarchy corresponding to quasi particle (as opposed to quasihole) condensates, including the recently observed state at $\nu = 4/11$. At the filling fractions $\nu = n/(2np+1)$ this construction exactly reproduces Jain’s composite fermion wave functions. An explicit connection is made to Wen’s topological classification of FQH states.

1:39PM V37.00013 FQHE-the soluble limit and beyond, MARIA HERMANNS, EMIL J. BERGHOLTZ, THORS HANS HANSSON, ANDERS KARLHEDE, Stockholm University, JUHA SUORSA, Helsinki University of Technology — We consider the quantum Hall system in the torus geometry. In the limit where the torus becomes thin, the problem is exactly soluble and the hierarchy of quantum Hall states is manifest. Explicit wave functions for a large set of them are constructed with help of conformal field theory. This construction provides a continuation from the exactly soluble limit to the experimental regime. Numerical results on 4/11 supports this picture.

1:51PM V37.00014 The Quantum Hall Effect in Spin Quartets in Graphene, KEISHAV SHRIVASTAVA, University of Malaya — Using the non-relativistic Schroedinger equation, we find that for $(1/2)g=(1/2)\pm 1$ gives zero charge for negative sign and one charge for positive sign. This explains the conductivity at $i=0$ and $1$. For $s=3/2, (1/2)g=2$ for positive sign and hence $g=4$. The substitution in the series, $-(5/2)(g\mu_B H), -(3/2)(g\mu_B H), -(1/2)(g\mu_B H), +(1/2)(g\mu_B H), +(3/2)(g\mu_B H), +(5/2)(g\mu_B H), . . . . , etc., g=4 gives, -10, -6, -2, +2, +6, +10, etc. This series is the same as observed in the experimental data of quantum Hall effect in graphene. When we take $n=2$ in the flux quantization, i.e., $2(hc/e)$, we generate the plateaus at $i=0$ and 1. For $s=3/2$ gives zero charge for negative sign and one charge for positive sign. This explains the conductivity at $i=0$ and $1$. For $s=3/2, (1/2)g=2$ for positive sign and hence $g=4$. The substitution in the series, $-(5/2)(g\mu_B H), -(3/2)(g\mu_B H), -(1/2)(g\mu_B H), +(1/2)(g\mu_B H), +(3/2)(g\mu_B H), +(5/2)(g\mu_B H), . . . . , etc., g=4 gives, -10, -6, -2, +2, +6, +10, etc. This series is the same as obtained in the experimental data of quantum Hall effect in graphene. When we take $n=2$ in the flux quantization, i.e., $2(hc/e)$, we generate the plateaus at $\pm 4$. Thus the plateaus can occur at 0, 1, 4 and at 2, 6, 10, 14, . . . . etc. Thus the quantum Hall effect in graphene is understood by means of non-relativistic theory. The fractions such as $1/3$ or integers such as $0,1,4, . . . . 2,6,10,14, . . .$ multiply the charge and hence describe the “effective charge” of the quasiparticles. This means that there is “spin-charge locking”.

Thursday, March 13, 2008 11:15AM - 2:15PM — Session V38 DCMP: Focus Session: Multiferroics and Multiferroic Composites Morial Convention Center 230

11:15AM V38.00001 In pursuit of strongly coupled multiferroic oxides, CRAIG FENNIE, Argonne National Lab — The rational design of new materials with emergent properties is a riveting challenge today in materials physics. It begins with understanding a mechanism to control the interplay between diverse microscopic degrees of freedom in order to create targeted macroscopic phenomena and ends with the discovery or design of new material realizations. When combined with first-principles density-functional theory, this approach provides an efficient strategy to survey the vast space of possible materials to target for synthesis. In this talk I will discuss our recently proposed strategies to identify new multiferroic oxides in which magnetism not only coexists with but also is strongly coupled to ferroelectricity. In one case the interplay of spins, optical phonons, and strain leads to a competition between different ordered states producing a colossal magnetoelectric effect. In a second case, a ferroelectric distortion can be designed to induce weak-ferromagnetism facilitating the electric-field control of a switchable magnetization. We also present first-principles density-functional calculations for several potential realizations.

11:51AM V38.00002 Growth and characterization of YMnO$_3$ nanocrystalline prisms, E. RAMOS-MOORE, Facultad de Fisica, Pontificia Universidad Catolica de Chile, CAMERON KEENAN, SANDEEP CHANDRIL, Department of Physics, West Virginia University, A. L. CABRERA, Facultad de Fisica, Pontificia Universidad Catolica de Chile, THOMAS H. MYERS, Department of Physics, West Virginia University, DAVID LEDERMAN, Department of Physics, West Virginia University, WEST VIRGINIA UNIVERSITY COLLABORATION, PONTIFICIA UNIVERSIDAD CATOLICA DE CHILE COLLABORATION — YMnO$_3$ epitaxial self-assembled nanoprisms were grown on GaN by molecular beam epitaxy. The prisms formed suddenly after 6 unit cells during Stranski-Krastanow epitaxial growth at 850 °C, with sizes ranging from 20 nm to 60 nm in height and 50 nm to 260 nm in lateral dimensions. They were characterized via energy dispersive analysis of x-rays (EDAX) mapping and x-ray diffraction and reflectivity. EDAX line scans across the prisms showed that the prisms were composed of YMnO$_3$. X-ray diffraction showed a 2.2% strain along the growth direction and a 1.6% compression in the plane when compared to bulk lattice parameters.

This work was funded by ONR (Grant N00014-02-1-0974), the AFOSR (MURI grant F49620-03-1-0330), and NSF (CIAM-DMR grant 0502825) at WVU and by FONDECYT (grant 1060634) at PUC.
12:03PM V38.00003 Properties of YMnO₃ Self-assembled Nanocrystalline Prisms on GaN¹, CAMERON KEENAN, SANDEEP CHANDRIL, THOMAS H. MYERS, DAVID LEDERMAN, Dept of Physics, West Virginia University, ESTEBAN RAMOS-MOORE, ALEJANDRO L. CABRERA, Facultad de Fisica, Pontificia Universidad Catolica de Chile — The high-temperature (850 °C) molecular beam epitaxy deposition of YMnO₃ on HVPE GaN(0001) resulted in the formation of spontaneous ferroelectric domains. Their dimensions ranged from 20 nm to 60 nm in thickness and 50 nm to 500 nm in lateral size. The local dielectric properties of the sample were investigated using scanning surface potential microscopy (SSPM). Raman remanent hysteresis loops were used to compare the switching properties of the samples and underlying film. A larger remanence was observed for the prisms, most probably due to the lack of surrounding film areas that would clamp the ferroelectric response. As a result, the remanent polarization increased roughly linearly with increasing prism surface area.

¹This work was funded by ONR (Grant N00014-02-1-0974), the AFOSR (MURI grant F49620-03-1-0330), and NSF (CIAM-DMR grant 0502825) at WVU and by FONDECYT (grant 1060634) at PUC.

12:15PM V38.00004 Epitaxial growth and electrical properties of perovskite HoMnO₃ thin films, DAISUKE KAN, M. MURAKAMI, Department of Materials Science and Engineering, University of Maryland, W. YU, R.L. GREENE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, S.W. CHEONG, Department of Physics and Astronomy, Rutgers University, I. TAKEUCHI, Department of Materials Science and Engineering, University of Maryland — Recently, it was predicted that orthorhombic HoMnO₃ would exhibit relatively large polarization (of the order of μC/cm²) due to the existence of a ferroelectric order in the E₃ type magnetic structure [1]. We have fabricated perovskite HoMnO₃ thin films on SrTiO₃ (001) substrates by pulsed laser deposition. X-ray 2θ scan shows only indicating that there are no secondary phases. The reciprocal space mapping around the SrTiO₃ (103) Bragg reflection and the φ scan of the HoMnO₃ (103) peak reveals the tetragonal symmetry of the films and the epitaxial relationship, [100]HoMnO₃ // [100]SrTiO₃ and [001]HoMnO₃ // [001]SrTiO₃, confirming that the film has the perovskite structure and not the tetragonal one. The films show good insulating properties at low temperatures. We will present electrical properties of the films including results of FUND measurements in applied magnetic field below the Neel temperature. This work is supported by NSF MRSEC, ARO, and the W. M. Keck Foundation.

12:27PM V38.00005 Magnetic ground state of PbVO₃ and origin of the large tetragonal distortion, KENGO OKA, IKUYA YAMADA, MASAKI AZUMA, MIKIO TAKANO, YUICHI SHIMAKAWA, Inst. Chem. Res., Kyoto Univ., SOSHI TAKESHITA, KOHKI H. SATOH, AKIHITO KODA, RYOSUKE KADONO, Inst. Mater. Sc. & KEK, HIROSHI KOJITANI, MASAKI AOKI, Gakushin Univ. — Magnetic property of PbTiO₃-type perovskite PbVO₃ with a large tetragonal distortion (c/a = 1.23)¹ was investigated. Long-range antiferromagnetic ordering with T_N = 45 K was found by a μSR measurement. Magnetic susceptibility of multi domain crystal showed a broad maximum centered at 180 K indicated the 2-dimensional nature in magnetism. This is consistent with the d_{xy} orbital ordering predicted by the band calculation.² We propose a mechanism that the pyramidal coordination with a short vanadium-apical oxygen bond is stabilized to lift the orbital degeneracy in this d² system. Accordingly, PbMnO₃ (Mn⁴⁺, d⁰) newly stabilized at 15 GPa has a pseudo cubic structure like PbCrO₃. This scenario explains the pressure induced tetragonal to cubic, insulator to metal transition³ of PbVO₃ and similar large tetragonal distortion of BiCoO₃. [1] A. Belik, et al., Chem. Mater. 18 (2006) 798. [2] Y. Uratani, et al., Jpn. J. Appl. Phys., 44 (2005) 7130.

12:39PM V38.00006 A one-cent room-temperature magnetoelectric sensor, CASEY ISRAEL, NEIL MATHUR, Department of Materials Science, University of Cambridge, JAMES SCOTT, Department of Earth Sciences, University of Cambridge — The replacement of silver-palladium with nickel as an electrode material might be adopted as cheap magnetic-field sensors that do not require an electrical power source.

12:51PM V38.00007 Inversion symmetry controlled multiferroic response in an Ising Chain Magnet, YOUNJUNG JO, SEONGSU LEE, HEE TAEK YI, SANGWOOK CHEONG, LUIS BALICAS, NATIONAL HIGH MAGNETIC FIELD LABORATORY TEAM, RUTGERS CENTER FOR EMERGING MATERIALS AND DEPARTMENT OF PHYSICS & ASTRONOMY TEAM — Recently, Choi et al. [1] discovered that ferroelectricity in the Ising chain magnet results from inversion symmetry breaking due to the formation of an alternating ionic order of two different ions leading to an up-up-down-down spin configuration. Here we report the observation of drastic changes in the multiferroic character as a function of temperature variation and through applied magnetic fields. In order to understand the origin of this inter-relationship, we have performed comprehensive characterization experiments on the multiferroic compound, including measurements of dielectric constant, polarization, specific heat, magnetic susceptibility, and resonant x-ray scattering as functions of temperature and applied magnetic field.

1:03PM V38.00008 Inter-relationship among magnetization, polarization and magnetic wave vector in multiferroic spinel CoCr₂O₄, YOUNG JAI CHOI, JUN OKAMOTO, DI-JING HUANG, KUO SHENG CHAO, HONG-JI LIN, CHIEN-TE CHEN, MICHEL VAN VEEENDAAL, THOMAS A. KAPLAN, SANGWOOK CHEONG — It has been known that the spinel CoCr₂O₄ is a multiferroic with conical spiral magnetic order characterized by three physical parameters: magnetization (M), polarization (P) and magnetic modulation vector (Q). We have found that these observables have a close inter-relationship in the multiferroic state and their inter-relationship changes in a methodical manner upon temperature variation and through applied magnetic fields. In order to understand the origin of this inter-relationship, we have performed comprehensive characterization experiments on the multiferroic compound, including measurements of dielectric constant, polarization, specific heat, magnetic susceptibility, and resonant x-ray scattering as functions of temperature and applied magnetic field.

1:15PM V38.00009 Structural and Dielectric Properties of CoFe₂O₄-Ba₀.90La₀.067Ti₀.91Zr₀.09O₃ Composite thin films, EDUARDO DELGADO, Universidad del Valle, CARLOS OSTOS, Universidad Nacional, MARIA MARTINEZ, LOURDES MESTRES, Universidad de Castilla-Leon, DAVID LEDERMAN, West Virginia University, PEDRO PRIETO, Centro de Excelencia en Nuevos Materiales — CoFe₂O₄-Ba₀.90La₀.067Ti₀.91Zr₀.09O₃(CFO-BLZT) composite thin films were grown via RF oxygen magnetron sputtering from a CFO-BLZT mixed target on electrically-conducting single-crystal Nb-doped SrTiO₃ (100) substrates at 1033 K. From scanning electron microscopy coupled with energy dispersive analysis of x-rays we determined that the CFO and BLZT were phase separated. X-ray photoemission spectroscopy showed that the TiO₂ octahedron in the perovskite structure was modified by the lanthanide incorporation. The dielectric characterization showed that the samples were ferroelectric at room temperature. The ferroelectric hysteresis loops measured as a function of magnetic field showed that these samples are multiferroic.
1:27PM V38.00010 Studies of Magnetoelectric properties in (1-x)Pb(Fe$_{2/3}$W$_{1/3}$)$_2$O$_3$-xPbTiO$_3$ solid solutions thin films, ASHOK KUMAR, University of Puerto Rico, RAM KATIYAR, University of Puerto Rico — We have fabricated (1-x)Pb(Fe$_{2/3}$W$_{1/3}$)$_2$O$_3$-xPbTiO$_3$ (PFWT) (x=0.50) thin films on Pt/Si substrates using sol-gel technique. The XRD patterns revealed a single-phase nature of the compound. The microstructure and surface morphology were investigated using SEM and AFM techniques that indicated good homogeneity and had surface roughness of 10-15 nm with particle size of ~ 30-50 nm. The dielectric relaxation studies in these films were carried out measured in the temperature range of 100K-650K and the frequency range of 100Hz-1MHz. Raman and dielectric data indicate that the crystal structure changes from tetragonal to cubic i.e. a ferroelectric phase transition at 575K. The dielectric properties of PFWT thin films were studied in the temperature range 80-600 K over a wide range of frequencies. The slope of the reciprocal of the dielectric constant is 2:1, matched well with the simplest Landau free energy model and it indicates continuous second order displacive ferroelectric phase transition. The polarization hysteresis curve at room temperature illustrated a ferroelectric nature. The detailed of magnetc and magnetoelectric properties with of PFWT will be discussed.

1:39PM V38.00011 Magnetoelectric Effects in hexagonal ferrite-PZT bilayers, V.M. MATHE, G. SRINIVASAN — Materials Science and Engineering, Penn State University — Fe (001) films have been epitaxially grown on ferroelectric Co$_3$Z and Zn$_2$Y are well known hexagonal ferrites with easy plane or uniaxial anisotropies. PZT has high piezoelectric coefficient. This study is on samples with Co$_3$Z or Zn$_2$Y as a magnetostrictive layer and PZT as a piezoelectric layer to form magnetoelectric bilayers. Low frequency (100 Hz) ME coefficient was measured over 0-17 kOe for various orientations of bilayers in a plane parallel to ac and bias magnetic fields. We measured a strong dependence of the ME voltage coefficients on magnitude and orientation of the bias field. The data are compared with theory.

2:03PM V38.00013 Dynamic observation of magnetoelectric coupling effect using magnetic force microscopy and Lorentz TEM, SUNG HWAN LIM, TODD BRINTLINGER, DAIJUKE KAN, YI QI, JOHN CUMINGS, ICHIRO TAKEUCHI, LOURDES SALAMANCA-RIBA — Magnetoelctric Effects in hexagonal ferrite-PZT bilayers, Materials Science and Engineering, Penn State University — Fe (001) films (30 nm) have been epitaxially grown on ferroelectric Co$_3$Z/SrTiO$_3$(001) to study the interaction between the multiferroic components. We report the magnetic properties as a precursor to a full investigation of the multiferroic interactions. Ferromagnetic resonance measurements were carried out at 36 GHz cavity and variable frequency microstrip resonators. Four-fold anisotropy is present in these Fe (001) films with energy density $\sim$1.3x10$^6$ erg/cm$^3$, consistent with bulk Fe values and indicating high quality Fe grown on the ferroelectric. Also present is a small, additional resonance peak, with large out-of-plane uniaxial anisotropy ($\sim$0.75$^2$(20$^2$)) attributed to strained Fe at the interface, although structural data shows the majority of the film is relaxed. This interfacial Fe will likely provide the desired coupling between the ferromagnetic and ferroelectric components in the system. Frequency/fiel in-plane dispersion curves further confirm the high quality of the Fe films in these samples.

11:15AM V39.00001 Anisotropic power-laws in sheared amorphous solids, CRAIG MALONEY, CMU — Dept. of Civil and Environmental Engineering, MARK ROBBINS, Johns Hopkins; Dept. of Physics and Astronomy — The local deformation of two-dimensional Lennard-Jones glasses under imposed shear strain is studied via computer simulations. Spatial correlations in the strain field are highly anisotropic and show apparent power-law behavior with a dramatic angular dependence of the effective scaling exponent. The strongest correlations are for wavevectors roughly perpendicular to the line of maximum resolved shear stress with systematic deviations from this which can be understood in terms of a Mohr-Coulomb effect. These results shed light on the nature of the so-called Jamming transition, supporting the notion that the dense steady flowing state is effectively critical in the slow-driving limit, and provide important, testable predictions for experiments on sheared amorphous materials such as bubble rafts, foams, emulsions, granular packings, etc., which can directly access the particle displacements.

11:27AM V39.00002 Apparent critical scaling for a steady-state sheared glass, THOMAS HAXTON, ANDREA LIU, University of Pennsylvania — We conducted simulations of a two-dimensional model glass at nonzero temperature under steady-state shear, and calculated the shear stress and shear viscosity as a function of temperature, shear rate and density. Over a dynamic range of two to three decades, we find excellent collapse of the data using critical scaling of the shear viscosity as a function of the distance from the jamming surface in the parameter space spanned by temperature, shear stress, and density. The shear viscosity can be rescaled to collapse onto a master function of the rescaled stress, where the scale factors are powers of the displacement in parameter space from the critical jamming surface. The master function separates into two branches, a high-temperature or low-density branch that approaches a finite rescaled viscosity at low stress, and a low-temperature or high-density branch that appears to diverge at a finite value of the rescaled stress. These results are consistent with those of Olsson and Teitel[1], who found scaling collapse near the zero-temperature, zero shear-stress jamming transition. We compare our results to mode-coupling calculations of sheared systems. [1] P. Olsson and S. Teitel, Phys. Rev. Lett. 99, 178001 (2007).

an atomic description of the viscosity of a supercooled liquid capturing the highly non-Arrhenius temperature variation for which no previous calculation has been given. A temperature dependent activation energy for structural relaxation is derived by mapping the potential energy surface and extracting saddle-point configurations and associated atomic coordinates. This essential information is combined with the temperature variation of an effective local energy minimum (inherent structure) to describe shear relaxation by thermal activation. For a binary Lennard-Jones model the calculated viscosity shows a characteristic crossover from strong (Arrhenius) to fragile (highly non-Arrhenius) behavior upon appreciable undercooling; followed by a second crossover from fragile back to strong behavior on approaching the glass transition temperature, both features we believe to be generic. Analysis of atomic displacements associated with barrier crossing in the fragile regime suggests a scenario of correlated motions along a chain of particles as the underlying mechanism for slow viscous relaxation in glassy states.

11:51AM V39.00004 Jamming in systems with attraction1, GREGG LOIS, Yale University — Many materials jam. As density increases or temperature decreases, structural relaxation becomes sluggish and the system approaches mechanical equilibrium without spatial ordering. The concept of a universal jamming transition and the conjecture that the mechanical response at zero temperature is linked to slow dynamics at non-zero temperature has inspired research in a variety of glassy materials such as colloidal suspensions, emulsions, granular media and foams. While most recent theoretical and simulation studies of the jamming transition have focused on systems with purely repulsive interactions, many materials also possess attractive forces. I will present our recent numerical results on the jamming transition in particulate systems with attractive interactions. At zero temperature, instead of the single discontinuous jamming transition observed in purely repulsive systems, attractive systems exhibit two second-order transitions—connectivity and rigidity percolation—which belong to different universality classes than their lattice counterparts. This observation also holds for low temperature before diffusion and activation/bond-breaking become relevant. At higher temperatures, the universality class of the jamming transition can depend on the age of the system. Finally, I will discuss a proposed phase diagram for gelation and rigidification in the temperature-density plane.

12:27PM V39.00005 Is there a connection between structure and heterogeneous dynamics in supercooled liquids?2, WILLIAM KREKELBERG, VENKAT GANESAN, THOMAS TRUSKETT, University of Texas-Austin, Department of Chemical Engineering — Structurally arrested (jammed or glassy) states are prepared from supercooled fluids, though there a number of open questions regarding how that process occurs. One involves explaining why modest increases in structural order accompany the pronounced slowing of liquid-state dynamics near structural arrest. Another involves understanding why self-diffusion in deeply supercooled fluids occurs much faster than would be predicted from knowledge of the viscosity and the Stokes-Einstein relation. Single-particle displacements become heterogeneous near the glass transition, but corresponding structural heterogeneities have been difficult to identify. Collectively, these observations call into question the general prospect of understanding and predicting dynamical behavior of liquids based on structural information. In this talk, we present simulation data on several model systems that show that the dynamics of supercooled liquids can be quantitatively correlated to structure in a simple way. Specifically, we show that the breakdown of the Stokes-Einstein relationship reflects simple and distinct couplings between structure, viscosity, and diffusivity in the supercooled fluid. We also demonstrate how heterogeneous dynamics correlate with dynamically heterogeneous structure.

12:39PM V39.00006 An effective field theory for soft granular matter1, SILKE HENKES, Brandeis University, COREY O’HERN, Yale University, BULBUL CHAKRABORTY, Brandeis University — Work on packings of soft spheres (PRE 68, 011306 (2003)) has demonstrated the existence of a jamming transition and has highlighted the need for a general statistical framework to describe granular packings. We have shown that a statistical ensemble, based on conservation properties of the global stress tensor, is consistent with simulated packings of frictionless disks (PRL 99, 038002 (2007)). We construct an effective field theory based on this ensemble, in the spirit of an earlier attempt (PRL 95, 198002 (2005)). The field theory is constructed by synthesizing results from simulations into one functional form for the effective free energy. We will describe ongoing efforts to derive this form by combining scaling ideas with microscopic properties of the packings.

12:51PM V39.00007 Jamming and correlated percolation on energetically-evolved graphs, SHILIANG XU, JENNIFER SCHWARZ, Physics Department, Syracuse University — Numerical simulations suggest that the zero-temperature jamming transition in repulsive soft spheres has an unusual mixed second-order/first-order character whose exponents appear to be in the same universality class as mean-field k-core percolation. In k-core percolation model, every occupied site must have at least k occupied neighbors. The k-core analogy of jamming is similar to the kinetically constrained analogy of the glass transition where the geometric constraint of k = d + 1 contacts needed for local mechanical stability drives the transition. We now introduce energetics explicitly into the analogy by investigating k-core percolation on a graph where edges are dynamically evolved with the goal of minimizing an xy-model-type interaction between a node and each of its neighbors. The xy-model-type interaction captures the angular arrangements of jammed configurations at the onset of jamming. Moreover, the graph dynamics captures nonequilibrium aspects of jamming that cannot be captured by static approaches such as a version of rigidity percolation with repulsive forces only.

1:03PM V39.00008 A “Hamiltonian” for Jammed Granular Matter, CHAOMING SONG, PING WANG, HERNAN A. MAKSE, Levich Institute and Department of Physics, City College of New York — We introduce a “Hamiltonian”-like function, called the volume function, to describe the microstates of jammed matter such as granular materials and emulsions from a geometrical point of view. We present a theory of volume fluctuations and derive the volume function defined in terms of the available free volume of the particles in the jammed systems. At the microscopic level the volume function provides an accessible “atomistic” formula for the calculation of the Voronoi volume associated with a single particle in terms of field variables. We then coarse-grain the volume function over a scale of a few particle diameters and provide a mesoscopic volume function which is now solely a function of the coordination number. We predict an exponential tail in the distribution of volumes in general agreement with experiments. Our analysis allows the calculation of macroscopic observables using the statistical mechanics of jammed states when it is supplemented by the condition of mechanical equilibrium of jamming.

1:15PM V39.00009 Vacancy localization in the square dimer model, MARK BOWICK, Syracuse University, JEREMIE BOUTTIER, EMMANUEL GUITTER, Saclay, MONWHEA JENG, Syracuse University — We study the classical dimer model on a square lattice with a single vacancy by developing a graph-theoretic classification of the set of all configurations which extends the spanning tree formulation of close-packed dimers. The motion of a vacancy induced by dimer slidings is analyzed including the size distribution of the domain accessible to the vacancy and the probability for a vacancy to be strictly jammed in an infinite system. More generally, the size distribution of the domain accessible to the vacancy is characterized by a power law decay with exponent 9/8. In a finite system, the probability that a vacancy in the bulk can reach the boundary falls off as a power law of the system size with exponent 1/2. The resultant weak localization of vacancies still allows for unbounded diffusion with a diffusion exponent related to that of diffusion on spanning trees.
1:27PM V39.00010 Velocity fluctuations in dense granular flows. JOHN DROZD, COLIN DENNISTON, University of Western Ontario — We use simulations to investigate velocity fluctuations in dry granular flow. Our system is comprised of mono- and poly-disperse sets of spherical grains falling down a vertical chute under the influence of gravity. We find three different classes of velocity distributions depending on factors such as the local density. The class of the velocity distribution depends on whether the grains are in a free-fall, fluid or glassy state. The analytic form of the distributions match those that have been found by other authors in fairly diverse systems. Here, we have all three present in a single system in steady-state. Power-law tails that match recent experiments are also found but in a transition area suggesting they may be an artifact of crossover from one class of velocity distribution to another. By studying both fast and slow flowing systems, we find that the velocity fluctuations are related to collision times by a scaling with the glass transition temperature. We measure collision time distributions along the height of the chute and find that the collision time distributions evolve from exponential tails into power-laws. This suggests that the particles may be forming clusters as they approach the glass state which may correspond to a second order dynamical phase transition.

1:39PM V39.00011 Energy Transport of Jammed Systems1. NING XU, University of Pennsylvania and University of Chicago, VINCENTI VITELLI, University of Pennsylvania, MATTHIEU WYART, Harvard University, ANDREA LIU, University of Pennsylvania, SIDNEY NAGEL, University of Chicago — We perform computer simulations to calculate the thermal conductivity of vibrational modes in jammed sphere packings near the jamming transition (Point J). The diffusivity d(ω) is low for all modes, including those at low frequency ω, and appears to be finite in the zero frequency limit. In ordinary solids, by contrast, d(ω) diverges at low frequencies due to long wavelength plane waves. The low- frequency modes near Point J are very different from plane waves: they are quasi-localized with large anharmonic corrections. Thus, these modes, which can be viewed as harmonic precursors to two-level systems, are poor conductors of energy.

1:51PM V39.00012 Testing ergodicity in dense granular systems. GUO-JIE GAO, JERZY BLAWZDZIEWICZ, COREY O’HERN, Yale University — The Edwards’ entropy formalism provides a statistical mechanical framework for describing dense granular systems. Experiments on vibrated granular columns and numerical simulations of quasi- static shear flow of dense granular systems have provided indirect evidence that the Edwards’ theory may accurately describe certain aspects of these systems. However, a fundamental assumption of the Edwards’ description—that all mechanically stable (MS) granular packings at a given packing fraction and externally imposed stress are equally accessible—has not been explicitly tested. We investigate this assumption by generating all mechanically stable hard disk packings in small bidisperse systems using a protocol where we successively compress or decompress the system and then record the MS packings that occur during the shear flow. We generate a complete library of the allowed MS packings at each value of shear strain and determine the frequency with which each MS packing occurs. We find that the MS packings do not occur with equal probability at any value of shear strain. In fact, in small systems we find that the evolution becomes periodic with a period that grows with system-size. Our studies show that ergodicity can be improved by either adding random fluctuations to the system or increasing the system size.

2:03PM V39.00013 Anomalously Slow Dynamics in the Manhattan Model1. PRASANTA PAL, Department of Applied Physics, Yale University, COREY O’HERN, Department of Mechanical Engineering, Yale University — We study the Brownian dynamics of hard rods in a Manhattan-like traffic grid, in which a series of narrow horizontal and vertical channels intersect at right angles and particles are forbidden from turning at the intersections. We measure the mean-square displacement (msd) as a function of packing fraction φ and determine the δφ at which dynamical arrest occurs as a function of system size, number of intersections, and topology of the grid. We observe that structural relaxation occurs via a complex out-of-equilibrium process in which particles occupy locally dense regions of the grid and then undergo a first passage process. We compare our results for the msd and δφ to that found in model glass-forming liquids in two and three dimensions.

11:15AM V40.00001 Toward multiscale modeling of the chromatin fiber: a coarse grain model for DNA. ALEXEY SAVELYEV, GAREGIN PAPOIAN, Department of Chemistry, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3290 — In eukaryotic cells DNA is compacted a million-fold into a chromatin. Understanding the mechanism of chromatin folding is of great biological importance. All-atom Molecular Dynamics (MD) simulations could provide crucial insights into the electrostatic and structural mechanisms of chromatin folding. However, because of the enormous size of even short chromatin fiber segment and long folding time-scales, atomistic simulations are computationally impractical. Our long-term aim is to build an accurate coarse-grain (CG) model of the chromatin, derived systematically from all-atom simulations of its smaller parts. Here we report the development of the CG model for a linear DNA chain, playing the role of a linker DNA segment in the chromatin. We derived CG inter-DNA electrostatic potential from atomistic simulations with explicit solvent and mobile ions, instead of relying on the standard models of continuum electrostatics, which are inadequate at small intermolecular distances. In addition, we used the ideas of renormalization group theory to construct an optimization scheme to parameterize the CG force field. This novel approach is designed to accurately reproduce correlations among various CG degrees of freedom. The implementation of these correlations was left as an open question in the prior studies of CG polymer models.

11:27AM V40.00002 Sequence and Temperature Dependence of DNA Bending Fluctuations. ROBERT A. FORTIES, RALF BUNDSCHUH, MICHAEL G. POIRIER, Department of Physics, The Ohio State University, 191 West Woodruff Avenue, Columbus, Ohio 43210-1117, USA — Recent DNA cyclization experiments measured J factors indicating that DNA may form sharp bends more easily than predicted by the worm-like chain model. One proposed explanation is that local melting of a few base pairs (bp) introduces flexible hinges [Yan, J. et al., Phys. Rev. E 71, 061905 (2005)]. We incorporate sequence dependence of the local melting into this model and obtain specific predictions for the dependence of J factors on temperature and sequence. We then measure J factors for a 200 bp fragment of lambda DNA and two synthetic 116 bp sequences with different proclivities for melting. The measured temperature and sequence dependence of J factors is found to be in agreement with the sequence dependent model predictions using previously measured free energy costs for melting and reasonable estimates for the flexibility of melted segments of DNA.

11:39AM V40.00003 Mechanically unzipping dsDNA with built-in sequence inhomogeneities and bound proteins. ABHIJIT SARKAR, Virginia State University — We theoretically analyze the force signal from unzipping dsDNA with bound proteins and sequence inhomogeneities. Two different force traces are obtained determined by binding and sequence parameters. Sawtooth force curves, as observed in experiments, are found for short enough designed sequences and binding sites. Longer inhomogeneities lead to force plateaus which correspond to gradual, piece-meal, unzipping of the variant stretch of DNA. We generalize our model to allow comparisons to recent experiments on unzipping decorated DNAs.
The elastic properties of the DNA molecule are important for its function. On a base-pair scale, they modulate protein binding strength, while over hundreds of base-pairs, they govern the statistics of DNA loops. We have used the rigid base–pair (RBP) model to link experiments on DNA elasticity across these scales. In a study of the indirect readout mechanism in protein–DNA binding, we compare calculated DNA elastic free energy differences to experimental affinities. While quantitative predictions are beyond the precision of current parameter sets, qualitative predictions are meaningful; we propose a statistical marker for indirect readout sub-sites in a given co-crystal geometries produced by the CH$_3$ group. More quantitative results from our current investigations using the actual sugar rings and phosphate groups will be presented as in earlier work by our group[1] for hyperfine interactions of trapped muonium atoms in DNA.

In recent work [1] we have studied nucleobases attached to a CH$_3$ group to simulate the influence of their binding to the sugar rings and the phosphate groups in DNA and RNA and the effect of this binding on the nuclear quadrupole interactions of $^{14}$N, $^{17}$O and $^2$H nuclei. Our results from this work have indicated that for $^{17}$O, the binding to the CH$_3$ group moves our results from the free nucleobases closer to the experimentally observed data [2] in the solid nucleobases. We are now investigating the solid nucleobases by the first–principles Hartree-Fock cluster procedure that we have employed earlier for the halogen molecular solids [3]. Our results for the binding energy of an imidazole molecule in the molecular solid system and the $^{14}$N, $^{17}$O and $^2$H quadrupole interaction parameters will be presented.

We have first simulated the influence of the interaction between a nucleobase and a sugar ring using a CH$_3$ group attached to the former. For our electronic structure investigations, we have employed the Hartree-Fock–Roothaan procedure using the Gaussian set of programs. Our preliminary investigations have shown that there are comparable indirect and direct effects on the NQI parameters, the former effect referring to the influence of changes in molecular geometries produced by the CH$_3$ group and the direct effect is due to the electronic interaction between the CH$_3$ group and the nucleobase. More quantitative results from our current investigations using the actual sugar rings and phosphate groups will be presented as in earlier work by our group[1] for hyperfine interactions of trapped muonium atoms in DNA.[1] R.H. Scheicher et al Physica B 374-375 (2006).

2:03PM V40.00015 Simplified Hamiltonians for coarse-grained properties of large single-stranded RNA molecules, PETER PRINSEN, ARON YOFFE, WILLIAM GELBART, Department of Chemistry and Biochemistry, UCLA — Large single-stranded RNA (ssRNA) molecules with a length of a few thousand to a few tens of thousands of nucleotides are quite common in nature. These RNAs generally have a highly branched secondary structure with many short, double-stranded sections. The secondary structure is important for function. However, the prediction of the thermally accessible secondary structures of large ssRNAs is complicated. There are several computer programs available that predict secondary structures of ssRNA. They produce good results for small molecules but are not very reliable for large ones. We are not interested in "high-resolution" structures, however, but in more coarse-grained properties, for example the average three-dimensional size of the molecule. We expect that the available computer programs are useful for determination of these coarse-grained properties but the complicated Hamiltonians they use limit the usefulness of these models for further theoretical investigations. We show that one can simplify these Hamiltonians considerably and still retain important predictive power. The inclusion of stacking energies is crucial but many of the detailed energy rules are not. We define several measures for the size of a secondary structure and we show how these measures are related to each other.

Role of strong correlation and Na dopant order, ZIQIANG WANG, Department of Physics, Boston College, Chestnut Hill, MA 02467 — We argue that the strong Co intra-atomic Coulomb repulsion normalizes the crystal field splitting and the bandwidths of the t2g complex in Na2CoO2, resulting in a single band crossing the Fermi level at all doping levels x explored by ARPES experiments [1]. On this basis, we study the electronic states using a minimal electron-doped, one-band Hubbard model with large U on the triangular lattice. The important role played by the off-plane Na dopants is taken into account by including the ionic electrostatic potential. We find a class of charge and spin density ordered states where the system alleviates antiferromagnetic (AF) frustration via charge inhomogeneity [2]. We show that the √3×2 Na order at x = 0.5 causes weak √3×1 charge order in the Co layer and the emergence of AF order with small electron and hole Fermi surface pockets [2]. This theory of the “0.5 phase” is consistent with neutron scattering, NMR, Shubnikov-de Haas oscillations, and transport experiments. In the sodium rich phases, the high density of off-plane Na dopants (or dilute Na vacancies), in their ordered or disordered form, increases the tendency toward strongly correlated electron behavior as a function of sodium concentration x, ranging from itinerant antiferromagnet (x∼0.84 and 0.5), “Curie-Weiss metal” (x∼0.71) to Fermi liquid (x∼1/3). In this talk, I will discuss our NMR studies of Na2CoO2 for various Na concentration x, with particular emphasis on 59Co evidence for charge ordering in the insulating ground state of NaN5Co2O2 [1-4].

4:18PM W2.00004 Novel electronic states in Na2CoO2: Role of strong correlation and Na dopant order, ZIQIANG WANG, Department of Physics, Boston College, Chestnut Hill, MA 02467 — We argue that the strong Co intra-atomic Coulomb repulsion normalizes the crystal field splitting and the bandwidths of the t2g complex in Na2CoO2, resulting in a single band crossing the Fermi level at all doping levels x explored by ARPES experiments [1]. Session W3 DCMP: Dislocation Patterns and Avalanches Morial Convention Center RO2 - RO3

2:30PM W3.00001 Scale-Free Intermittent Flow in Crystal Plasticity, RICHARD LESAR, Iowa State University — Under stress, crystals irreversibly deform through complex dislocation processes — processes that intermittently change the microscopic material shape through isolated slip events. Using both model computer simulations and ultra-precise nano-scale measurements on nickel micro-crystals we directly determined the size of discrete slip events. The sizes range over nearly three orders of magnitude, and exhibit a shock and aftershock earthquake-like behavior over time. Analysis of the events reveals power-law scaling between the number of events and their magnitude, or scale-free flow. We show that dislocated crystals are a model system for studying scale-free behavior that is observed for many macroscopic systems. By analogy to plate tectonics, smooth macroscopic-scale crystalline glide arises from the spatial and time averages of disruptive earthquake-like events at the nano-scale.
Dislocations with glide only support minimal domain formation. The talk will enumerate various PTV studies of step shear, startup shear and large-amplitude oscillatory shear to show how these crucial experiments have produced step deformation. The transient cohesion provided by chain entanglement due to inter-molecular interactions is found to be higher at a higher applied rate. This take place inhomogeneously in both shear and extension. Most remarkably, an entangled polymer would suffer “delayed” cohesive structural breakdown after a velocimetric observations (PTV, which are available for downloading at http://www3.uakron.edu/rheology/) show that the elastic yielding and subsequent flow than the relaxation rate of entangled chains, a well entangled polymeric liquid yields like a solid before being forced to flow plastically. Recent particle tracking rate that is a sensitive function of molecular weight and its distribution. At high Weissenberg number, i.e., when the rate of external deformation is far greater than the stress relaxation time of entangled chains, a well entangled polymeric liquid relaxes like a solid before being forced to flow plastically.

CR motion was found to be valid for blends and star chains. Even for this case, the tube diameter increases to a level accepted by the CR motion. The partial-DTD picture considering this consistency with the increase of the fully dilated tube diameter over which the CR motion of the probe cannot occur in time, which naturally results in the failure of the full-DTD comparison indicated that the full-DTD picture works satisfactorily for monodisperse linear PI but not for blends of linear PI as well as for monodisperse star PI.

This constant ratio simply results from an implicit coarse-graining procedure that is performed upon measuring different types of quantities in the simulated picture. Even for this case, the tube diameter increases to a level accepted by the CR motion. The partial-DTD picture considering this consistency with the increase of the fully dilated tube diameter over which the CR motion of the probe cannot occur in time, which naturally results in the failure of the full-DTD comparison indicated that the full-DTD picture works satisfactorily for monodisperse linear PI but not for blends of linear PI as well as for monodisperse star PI.

The effective diffusion constant decayed to zero as: $D(t)=D(0)e^{-t/\tau}$, with $\tau=0.8$. Coarsening: Dislocations with glide and climb exhibited profound domain formation, the domains coarsen as $L(t): L(t) \sim t^{1/2}$, with $1/2=0.17$. The formation of domains without shear has been recently observed in GaAs by Rudolph and in dusty plasmas by Quinn and Joree. The domain coarsening was quantitatively captured in di-block copolymers [2], with $1/2=0.19$, in good agreement with our results.

3:42PM W3.00003 Domain Coarsening and Aging in Dislocation Glasses 1, GERGELY ZIMANYI, Physics Department, UC Davis — Dislocation systems were analyzed numerically with 1 and 3 glide axes, at T=0 and T>0, with and without climb. [1] Dislocation free domains formed even without shear, defined by dislocation rich domain walls. The domain formation was most pronounced in the presence of climb, somewhat counter-intuitively. The stability of domains was analyzed. The microscopic processes suppressing the climb-induced decay of domain walls were identified. The dislocation dynamics at low temperatures was markedly glassy. Aging: Dislocations with glide only support minimal domain formation. The autocorrelation function showed aging, scaling with the waiting time as: $C(t,t_0)=C_0(t/t_0^\gamma)$ and $C_0(t) \sim t^{-\beta}$, with $\mu=0.65$ and $\beta=0.54$. Freezing: The effective diffusion constant decayed to zero as: $D(t)e^{\gamma} \sim t^{-\gamma}$, with $\gamma=0.8$. Coarsening: Dislocations with glide and climb exhibited profound domain formation, the domains coarsen as $L(t)$: $L(t) \sim t^{1/2}$, with $1/2=0.17$. The formation of domains without shear has been recently observed in GaAs by Rudolph and in dusty plasmas by Quinn and Joree. The domain coarsening was quantitatively captured in di-block copolymers [2], with $1/2=0.19$, in good agreement with our results.

4:18PM W3.00004 Dislocation Avalanches, Mean Free Path and Patterning 1, L.P. KUBIN, LEM, CNRS-ONERA, 29 Av. de la Division Leclerc, BP72, 92322 Châtillon Cedex, France — Dislocations are the defects that carry plastic flow in crystalline materials. At the defect scale, plastic deformation occurs by dislocation avalanches, which are characterized by scale-free behavior within a bounded domain of amplitudes or energies. The probability distribution functions of these avalanches, their processes of initiation and termination and their contribution to dislocation storage during plastic flow are investigated dislocation dynamics (DD) simulations. The model material is a copper single crystal strained along three high symmetry orientations. The distributions of avalanche amplitudes exhibit, for all orientations, a scaling exponent of 1.6, similar to what is reported in the literature. However, the average value of strain burst amplitudes, taken in the recorded domain of amplitudes, is found to be orientation-dependent. In parallel, a continuum model based on the notion of dislocation mean free path, which predicts the mechanical response of f.c.c. single crystals, was established with the help of DD simulations. It appears that both intermittent and continuum behavior exhibit the same orientation dependencies. Furthermore, for the three tested orientations, the ratio of the continuum mean free path to the average characteristic length traveled by dislocations during avalanches is a constant. This constant ratio simply results from an implicit coarse-graining procedure that is performed upon measuring different types of quantities in the simulated results. As a consequence, it appears that avalanche behavior can effectively be incorporated into continuum models for plasticity. The present results are discussed with respect to the available experimental literature on the deformation of f.c.c. crystals. Finally, the formation of dislocation patterns, that is the self-organization properties of dislocations under strain, is tentatively discussed in terms of the properties of dislocation avalanches.

Thursday, March 13, 2008 2:30PM - 5:30PM — Session W4 DPOLY: Dynamics of Polymers Morial Convention Center 206

2:30PM W4.00001 Dielectric and Viscoelastic Investigation of Entanglement Relaxation, HIROSHI WATANABE, Kyoto University — For a chain (probe) entangled with surrounding chains (matrix), the entanglement is released on large-scale motion of the matrix chains. This constraint release (CR) mechanism plays a central role in the current tube model for entangled chains. Since the distance for the lateral motion of the probe (= tube diameter) increases on CR, the tube model often utilizes the molecular picture of dynamic tube dilation (DTD) to represent the CR effect on the probe dynamics. In the simplest case of full-DTD, the relaxed portion behaves as a solvent giving no constraint and the tube diameter increases to the diameter in the corresponding solution. This talk utilizes cis-polysisoprene (PI) having the type-A dipole to test the validity of the DTD picture with the following strategy. The type-A dipole allows us to dielectrically evaluate the survival fraction f(t) of the diluted tube at time t. The full-DTD picture can be unequivocally tested by comparing the normalized viscoelastic modulus deduced from this picture (2.0-2.3h power of f(t)) with the viscoelastic data. The comparison indicated that the full-DTD picture works satisfactorily for monodisperse linear PI but not for blends of linear PI as well as for monodisperse star PI. The failure of the full-DTD picture for the last two systems is related to the fast relaxation modes in these systems. These modes lead to a significant increase of the fully diluted tube diameter over which the CR motion of the probe cannot occur in time, which naturally results in the failure of the full-DTD picture. Even for this case, the tube diameter increases to a level accepted by the CR motion. The partial-DTD picture considering this consistency with the CR motion was found to be valid for blends and star chains.

3:06PM W4.00002 How does cohesive breakdown occur in entangled polymeric liquids? 1, SHIQING WANG, Department of Polymer Science, University of Akron — Entangled polymers are strongly viscoelastic materials with a characteristic relaxation rate that is a sensitive function of molecular weight and its distribution. At high Weissenberg number, i.e., when the rate of external deformation is far greater than the relaxation rate of entangled chains, a well entangled polymeric liquid yields like a solid before being forced to flow plasticly. Recent particle tracking velocimetric observations (PTV, which are available for downloading at http://www3.uakron.edu/rheology/) show that the elastic yielding and subsequent flow take place inhomogeneously in both shear and extension. Most remarkably, an entangled polymer would suffer “delayed” cohesive structural breakdown after a step deformation. The transient cohesion provided by chain entanglement due to inter-molecular interactions is found to be higher at a higher applied rate. This talk will enumerate various PTV studies of step shear, startup shear and large-amplitude oscillatory shear to show how these crucial experiments have produced a phenomenological level understanding (J. Chem. Phys. 2007, 127, 064903) of various flow phenomena in entangled polymers.

4:18PM W4.00004 Shear Alignment and Realignment of Block Copolymer Microdomains in Thin Films1, RICHARD REGISTER, Princeton University — Bulk block copolymers, like all liquid crystalline structures, are well-known to align under flow. In the past few years, we have shown that analogous flow alignment can be achieved in substrate-supported thin films (<100 nm thick) containing one or a few layers of spherical or cylindrical nanodomains. Alignment can easily be imparted either by pulling a soft rubber pad in contact with the top surface of the film, or by flowing a nonsolvent fluid across the film. The latter geometry opens the possibility to “write” relatively complex patterns on the millimeter or submillimeter scale, where the nanodomain director follows the fluid streamline. Alignment can be achieved via either unidirectional or oscillatory shear, and is conveniently executed in a parallel-plate rheometer, where the substrate-supported film forms one “plate” and the “gap” is filled with the nonsolvent fluid. A threshold stress is required to achieve alignment of the microdomains, a stress which decreases steadily as the temperature is raised towards the polymer’s order-disorder transition temperature. A simple melting-recrystallization model appears to capture the dynamics of overall alignment. Though no grain boundaries remain in well-aligned films, isolated dislocations persist. For sphere-formers, where two or more layers are required for alignment, the isolated dislocations are preferentially oriented in such a way as to facilitate sliding of the two layers of spheres past each other. Once a macroscopic orientation has been imparted to the film (over square-cm area), the microdomains can be reoriented by applying shear in a different direction, but a higher threshold stress is required than was needed for the initial alignment from the polycrystal state. Recently, we have observed a sphere-to-cylinder transition in one particular block copolymer under shear, opening another possible mechanism for shear-induced alignment of the spheres which form when these cylinders relax.

4:54PM W4.00005 Nanoparticle Ionic Liquids, LYNDEN ARCHER, School of Chemical and Biomolecular Engineering — Nanoparticle ionic liquids (NIMS) are a new class of organic-inorganic hybrid materials comprised of a nanoparticle core functionalized with a covalently-attached organic corona. These materials manifest a remarkable transition to a “solvent-free” colloidal liquid state near room temperature. Physical properties of these nanoparticle ionic liquids can be manipulated over an unusually wide range by varying geometric and chemical characteristics of the inorganic core and organic corona. On one end of the spectrum are materials with a high core particle contents, which display properties similar to fragile glasses, stiff waxes, and gels. At the opposite extreme are systems that spontaneously form particle-based ionic fluids characterized by transport properties remarkably similar to simple molecular liquids, but with high dielectric constants, conductivities, and refractive index. This talk will introduce nanoparticle ionic fluids based on charged and uncharged corona species, explore their applications, and will discuss physical and mathematical models for understanding their interactions, complex relaxation dynamics, and rheology.

Thursday, March 13, 2008 2:30PM - 5:30PM – Session W5 FIAP: Sensing Science and Sensors for Industrial Applications Morial Convention Center R01

2:30PM W5.00001 Next-Generation Mid-Infrared Chemical Sensors Challenges and Opportunities, BORIS MIZAIKOFF, Georgia Institute of Technology — No abstract available.

3:06PM W5.00002 Laser Interferometry for Harsh Environment MEMS Sensors, PATRICIA NIEVA, University of Waterloo — Silicon-based MEMS technology has enabled the fabrication of a broad range of sensor and actuator systems that are having a great impact in areas that benefit from miniaturization and increased functionality. The main advantage of Si-based MEMS technologies is their possibility of integration with microelectronics thus allowing the economical production of smart Microsystems. In the automotive industry for example, there is a need for inexpensive smart MEMS sensors for engine control applications. For instance, smart MEMS sensors capable of operating “in cylinder”, where temperatures are around 400 °C, could continuously monitor the combustion quality of the cylinders of automotive engines thus leading to reduced emissions and improved fuel economy. However, when the environment temperature is too high (>180 °C), conventional Si-based microelectronics suffer from severe performance degradation, thus making smart Si-based MEMS impractical. Hence, further development, in terms of new MEMS materials and/or new technologies, is needed especially where high temperature capability is crucial to realizing improved electronic control. Remote sensing through optical signal detection has major advantages for safe signal transmission in harsh environments. It is highly resistant to electromagnetic interference (EMI) and radio frequency interference (RFI) and at the same time, it eliminates the necessity of on-board electronics, which has been one of the main obstacles in the development of smart MEMS sensors for high temperature applications. An economical way to deal with higher temperatures and other aggressive environmental conditions is to build MEMS sensors out of robust materials (e.g. Silicon nitride, SiC) and integrate them with optical signal detection techniques to form MOEMS. In this paper, we review recent trends for the use of laser interferometry for MEMS sensors in the context of using them for high temperature applications. Technological challenges faced in the development of these sensors, including sensitivity to measurement errors, packaging and cost reduction are also outlined. Finally, an overview of Fabry-Perot like MEMS sensors for high temperature applications is presented and issues facing their future progress and economical implementation are discussed.

3:42PM W5.00003 Chemical and Physical Sensing in the Petroleum Industry, MARK DISKO, ExxonMobil Research & Engineering Company — World-scale oil, gas and petrochemical production relies on a myriad of advanced technologies for discovering, producing, transporting, processing and distributing hydrocarbons. Sensing systems provide rapid and targeted information that can be used for expanding resources, improving product quality, and assuring environmentally sound operations. For example, equipment such as reactors and pipelines can be operated with high efficiency and safety with improved chemical and physical sensors for corrosion and hydrocarbon detection. At the interface between chemical engineering and multiphase flow physics, “multi-scale” phenomena such as catalysis and heat flow benefit from new approaches to sensing and data modeling. We are combining chemically selective micro-cantilevers, fiber optic sensing, and acoustic monitoring with statistical data fusion approaches to maximize control information. Miniaturized analyzers represent a special opportunity, including the nanotech-based quantum cascade laser systems for mid-infrared spectroscopy. Specific examples for use of these new micro-systems include rapid monomeric aromatic molecule identification and measurement under ambient conditions at weight ppb levels. We also propose from emerging materials and devices based on nanotechnology, which can one day be available at modest cost for impact in existing operations. Controlled surface energies and emerging chemical probes hold the promise for reduction in greenhouse gas emissions for current fuels and future transportation and energy technologies.
4:18PM W5.00004 Silicon Carbide Micro/Nano Systems for Demanding and Harsh Environment Applications, MEHRAN MEHREGANY, Department of Electrical Engineering and Computer Science, Case Western Reserve University, Cleveland, Ohio 44106 — Micro/nano systems enable the development of smart products and systems by augmenting the computational ability of microelectronics with the perception and control capabilities of sensors and actuators. Micro/nano systems are also known as micro- and nanoelectromechanical systems (MEMS and NEMS), and have been commercialized in a wide range of applications including crash sensing, blood pressure measurement, optical projection, and fluid flow control to name a few. Silicon, in single- and polycrystalline forms, has been the platform semiconductor material underpinning the fabrication of the mechanical and electronic elements of micro/nano systems. However, the materials properties of silicon impose limitations on its use in harsh environment and demanding applications—for example, those involving operation in the presence of high temperatures, corrosive media, high shock loads, erosive flows, and/or high radiation, or involving performance requirements for the mechanical elements that are beyond silicon’s capabilities. Silicon carbide (SiC) is an alternative platform semiconductor material that enables such applications because of its wider bandgap and higher melting/sublimation temperature, elastic modulus, fracture toughness, hardness, chemical inertness, and thermal conductivity. This talk will highlight our most recent SiC material, process, and device advances to enable sensing and actuation in applications such as propulsion instrumentation/control, power generation, resource exploration, nuclear reactor instrumentation, deep space exploration, and communications.

4:54PM W5.00005 SiC Sensors in Extreme Environments: Real-time Hydrogen Monitoring for Energy Plant Applications1, RUBY GHOSH2, Michigan State University — Clean, efficient energy production, such as the gasification of coal (syngas), requires physical and chemical sensors for exhaust gas monitoring as well as real-time control of the combustion process. Wide-bandgap semiconducting materials systems can meet the sensing demands in these extreme environments consisting of chemically corrosive gases at high temperature and pressure. We have developed a SiC-based micro-sensor for detection of hydrogen containing species with millisecond response at 600 °C. The sensor is a Pt-SiO2-SiC device with a dense Pt catalytic sensing film, capable of withstanding months of continuous high temperature operation. The device was characterized in robust sensing module that is compatible with an industrial reactor. We report on the performance of the SiC sensor in a simulated syngas ambient at 370 °C containing the common interferants CO2, CH4 and CO [1], and in addition demonstrate that hours of exposure to ≥1000 ppm H2S and 15% water vapor does not degrade the sensor performance. To elucidate the mechanisms responsible for the hydrogen response of the sensor we have modeled the hydrogen adsorption kinetics at the internal Pt-SiO2 interface, using both the Tempkin and Langmuir isotherms. Under the conditions appropriate for energy plant applications, the response of our sensor is significantly larger than that obtained from ultra-high vacuum electrochemical sensor measurements at high temperatures. We will discuss the role of morphology, at the nano to micro scale, on the enhanced catalytic activity observed for our Pt sensing films in response to a heated hydrogen gas stream at atmospheric pressure.

Thursday, March 13, 2008 2:30PM - 5:30PM –
Session W6 DAMOP: Strong Interacting Fermi Gases with Spin Asymmetry
Morial Convention Center

2:30PM W6.00001 Experiments in spin-polarized Fermi gases—pairing without superfluidity?
CHRISTIAN SCHUNCK, Massachusetts Institute of Technology — Fermionic superfluidity requires pairing of fermions. The nature of fermionic pairing in the strongly interacting regime both in the superfluid and possibly in the normal phase is of interest to condensed matter, nuclear and high energy physics. The experimental realization of high temperature superfluidity in ultracold Fermi gases opens a new approach to explore strongly interacting fermions both in the superfluid and normal phases. One question of relevance for example to superfluidity of quark’s in cold baryonic matter as well as superconductivity has been the stability of the superfluid against an imbalance between the two strongly interacting fermionic components. An imbalance can be caused by different masses of the fermions or an externally applied magnetic field to a superconductor. In our experiments a density imbalance between two fermionic spin components is introduced. We will present the phase diagram of a spin-polarized Fermi gas of 6Li atoms at unitarity, mapping out the superfluid phase versus temperature and density imbalance. The nature of the phase transition changes from first-order to second-order at a tricritical point. At zero temperature, there is a quantum phase transition from a fully-paired superfluid to a partially-polarized normal gas at a critical spin polarization, known the Chandrasekhar-Clogston limit of superfluidity. These observations together with the implementation of an in situ ideal gas thermometer provide quantitative tests of theoretical calculations on the stability of resonant superfluidity. Pairing correlations in the superfluid and normal phases were explored in radio-frequency spectroscopy experiments. We studied how pairing correlations evolve across the superfluid to normal phase transition both as a function of temperature and spin imbalance. Even at spin imbalances above the Chandrasekhar-Clogston limit a gap in the single-particle excitation spectrum is observed. This indicates that the system is in a correlated state and the minority component is paired. The influence of final state interactions on the rf spectra will be discussed. Using a new superfluid 6Li spin mixture we demonstrate that pair dissociation spectra in the BEC-BCS crossover resemble asymmetric molecular dissociation spectra. Work done in collaboration with Y. Shin, A. Schiroztek and W. Ketterle, Department of Physics, MIT-Harvard Center for Ultracold Atoms, and Research Laboratory of Electronics, MIT, Cambridge, MA 02139.

3This work was supported by the NSF, ONR and through a MURI and DARPA program.

3:06PM W6.00002 Theory of RF Spectroscopy in Strongly Interacting Fermi Gases1, ERICH MUELLE, Cornell University — Radio frequency (RF) spectroscopy is an extremely powerful probe of the many-body state of a gas of cold atoms. For example spectra of cold Fermi gases have been used as evidence of superfluidity, and of pairing fluctuations in the normal state. Despite the large amount of information they contain, spectra of trapped gases are not completely trivial to analyze. I will discuss the theory of RF spectroscopy, showing that the link between pairing and the observed spectra is very indirect, and that many of the “pairing” features occur even in a gas with no pairing whatsoever. I will also describe the important role played by final state interactions.

1Work supported in part by NSF Grant PHY-0456261.
3:42PM W6.00003 Phase separation in a spin polarized Fermi gas at the BEC-BCS crossover1, GUTHRIE PARTRIDGE, Rice University — A strongly interacting ultra-cold gas of fermionic \textsuperscript{\textit{6}}Li with unequal numbers of two spin components exhibits two distinct low temperature paired states.\textsuperscript{2} Phase separation, where a uniformly paired core is maintained in the center of the trap by the expulsion of excess unpaired atoms, is observed at the lowest temperatures up to large number imbalance. Sharp boundaries, consistent with a first-order phase transition, are observed between the core and the unpaired atoms. Moreover, the superfluid core deforms markedly, becoming less elongated due to surface tension at the superfluid/normal boundary. At higher temperature, the core remains unpolarized up to a critical polarization, but does not deform. This temperature dependence is consistent with a tri-critical point in the phase diagram. Additionally, we are exploring the possibility that the large critical imbalance for loss of phase separation is a result of relatively small particle number (10\textsuperscript{10}) and high aspect ratio (30) elongated confinement.

To date, no evidence for the long sought Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state has been observed in ultracold atomic gases. It is predicted that in 3D the FFLO phase occupies a very small region of the phase diagram,\textsuperscript{3} whereas in 1D, the stability of the FFLO state is believed to be enhanced. Though the current optical potential is elongated, it is still in the 3D regime, and so a 2D optical lattice potential has been constructed to provide an array of 1D tubes. We will present results of our studies of the polarized Fermi gas in this 1D geometry.

---

4:18PM W6.00004 Few-body physics of trapped unequal mass fermions\textsuperscript{1}, CHRIS H. GREENE, Department of Physics and JILA, University of Colorado, Boulder, CO 80309-0440 — The behavior of a two-component dilute Fermi gas exhibits an interesting dependence on the mass ratio between the two species. Our study tackles this system with 3-20 particles, using two independent techniques. First, an essentially exact diagonalization for 3-6 particles determines both the ground state and also the pattern of excited state energies, and our analysis permits an extraction of the dimer-dimer scattering length and effective range. Secondly, the nature of the system ground state is studied as a function of the mass ratio and the number of particles, up to N=20, using fixed-node diffusion Monte Carlo (DMC) techniques. By using different solution techniques in their overlapping range of applicability from N=3-6, we are able to assess the accuracy of the nodal surface employed in the fixed-node DMC calculation. Physical properties such as the excitation gap will be analyzed over this range of particle number, and the intriguing unitarity limit is also considered.

---

4:54PM W6.00005 Exploring an ultracold Fermi-Fermi mixture: interspecies Feshbach resonances of \textsuperscript{\textit{6}}Li-\textsuperscript{\textit{40}}K, FLORIAN SCHRECK, Oesterreichische Akademie der Wissenschaften — We report on the observation of interspecies Feshbach resonances in an ultracold mixture of two fermionic species, \textsuperscript{\textit{6}}Li and \textsuperscript{\textit{40}}K. Interpretation of the data unambiguously assigns molecular bound states to the various resonances and fully characterizes the ground-state scattering properties in any combination of spin states. Using this knowledge we hope to be able to produce \textsuperscript{\textit{6}}Li-\textsuperscript{\textit{40}}K molecules, cool them to quantum degeneracy, and study their BEC-BCS crossover.

2:30PM W7.00001 Representing Information with Correlated Neural Populations\textsuperscript{1}, MICHAEL BERRY, Princeton University — Using a multi-electrode array, we can record simultaneously from up to 50 ganglion cells, the output neurons of the retina, while stimulating with varied visual images generated on a computer monitor. We find that nearby ganglion cells, the output neurons of the retina, have spatial receptive fields that overlap significantly, leading to correlated firing and redundancy in the visual information that cells encode. Although the strength of correlations among pairs of cells is weak (~10%), the effect in larger populations is dramatic: patterns of spiking and silence in groups of just 10 cells can occur with a probability ~100,000-fold different from that predicted from statistical independence. We show that these strong network correlations can be explained by a model that includes all pairwise interactions, but no higher-order statistics. This model is identical to the Ising model, and predicts that larger populations of neurons may exhibit a form of freezing transition that allows for robust error correction. We have begun to explore these error-correcting properties in simple visual discrimination tasks using large populations of ganglion cells. We find that the correlations among neurons can dramatically reduce the discrimination error.

---

3:06PM W7.00002 Exploring the network structure of concerted activity in the primate retina using maximum entropy methods\textsuperscript{1}, JONATHON SHLENS, Salk Institute for Biological Studies — All visual signals in the brain originate in the electrical activity of retinal ganglion cells (RGCs). Standard models implicitly assume that RGCs signal information independently of one another. However, several studies have demonstrated that significant concerted activity in pairs of RGCs may fundamentally alter visual signals. We recorded the electrical activity of several hundred RGCs in peripheral monkey retina. The regular mosaic organization of RGCs that we recorded from nearly every cell in a region of the visual field. In the presence of constant illumination, pairs of RGCs fired synchronously several-fold more often than expected by chance, indicating significant network interactions. Synchrony was localized and universal amongst cells of the same type indicating that it arises from local and highly stereotyped circuitry. To test whether concerted firing can be explained by known pairwise interactions, we used a maximum entropy approach borrowed from statistical mechanics to predict concerted activity. The model accurately reproduced the data. This suggests that network interactions in the primate retina are well approximated by a nearest neighbor Ising model and concerted activity can be understood based on local interactions within a neural population.

A continuous phase transition in neocortical slice networks1. JOHN BEGGS, Indiana University, Bloomington — Recent experiments demonstrate that activity in neocortical circuits can propagate in the form of avalanches whose sizes follow a power law distribution, suggesting that these circuits operate near a continuous phase transition point. Computational models indicate that this critical point may be optimal for information processing. However, the existence of a power law is not sufficient to establish critical behavior because stochastic processes that do not undergo phase transitions can also produce power laws. We recorded power law distributions of neuronal avalanches from neocortical slices and then pharmacologically perturbed network activity. We then measured deviations from power law behavior. Here we show that these deviations covary systematically with a control parameter, as would be expected for a continuous phase transition. A critical branching model captures this transition, while stochastic models do not. Our findings imply that the physical theory underlying continuous phase transitions can be fruitfully applied to neocortical circuits.

4:18PM W7.00004 Patterns of Neural Activity in Networks with Complex Connectivity, SARA A. SULLA, Northwestern University — An understanding of emergent dynamics on complex networks requires investigating the interplay between the intrinsic dynamics of the node elements and the connectivity of the network in which they are embedded. In order to address some of these questions in a specific scenario of relevance to the dynamical states of neural ensembles, we have studied the collective behavior of excitable model neurons in a network with small-world topology. The small-world network has local lattice order, but includes a number of randomly placed connections that may provide connectivity shortcuts. This topology bears a schematic resemblance to the connectivity of the cerebral cortex, in which neurons are most strongly coupled to nearby cells within fifty to a hundred micrometers, but also make projections to cells millimeters away. We find that the dynamics of this small-world network of excitable neurons depend mostly on both the density of shortcuts and the delay associated with neuronal projections. In the regime of low shortcut density, the system exhibits persistent activity in the form of propagating waves, which annihilate upon collision and are spawned anew via the re-injection of activity through shortcut connections. As the density of shortcuts reaches a critical value, the system undergoes a transition to failure. The critical shortcut density results from matching the time associated with a recurrent path through the network to an intrinsic recovery time of the individual neurons. Furthermore, if the delay associated with neuronal interactions is sufficiently long, activity reemerges above the critical density of shortcuts. The activity in this regime exhibits long, chaotic transients composed of noisy, large-amplitude population bursts.

4:54PM W7.00005 Optimal processing and the statistics of visual input signals, ROB DE RUYTER VAN STEVENINCK, Indiana University Bloomington — Sensory information processing can be seen as a statistical estimation problem, where relevant features are extracted from a raw stream of sensory input containing an imperfect representation of those features. Broadly speaking, the optimal solution to the feature extraction problem depends on the statistical structure of those input signals. Here we study the statistics of natural visual input signals, and the optimal solution to the problem of visual motion detection. Motion detection is a biologically important feature estimation problem, as many animals use vision to estimate their motion through space. Many years ago, Reichardt and Poggio drew attention to two important aspects of this problem. First, computing motion from an array of photoreceptors is an irreducibly nonlinear operation, and second, biological versions of this operation seem mathematically tractable. To paraphrase, the problem is interesting but not hopelessly complicated. In this spirit I will discuss motion estimation in the visual system of the blowfly, with an emphasis on performance under natural conditions. As noted above, the array of photoreceptors in the retina implicitly contains data on self motion, but this relation is noisy, indirect and ambiguous due to photon shot noise and optical blurring, and also as a result of the structure of the natural environment. Further, natural variations in the visual signal to noise ratio are enormous, and nonlinear operations are especially susceptible to noise. One can therefore reasonably hope that animals have evolved interesting optimization strategies to deal with large variations in signal quality. I will present experimental data, both from sampling natural probability distributions, and from motion sensitive neurons in the fly brain, that illustrate some of these solutions and that suggest that the fly indeed approaches optimality. The implications of these findings and their possible generalizations will be discussed.

Thursday, March 13, 2008 2:30PM - 5:18PM –
Session W8 DFD: Liquid Crystals II: Dynamics and Topology Morial Convention Center R06

2:30PM W8.00001 Finite element studies of the soft elastic response in liquid crystal elastomers1, BADEL MBANGA, DEREK ARNOSEL, ROBIN SELINGER, Liquid Crystal Institute, Kent State Univ. — When a liquid crystal elastomer film is stretched in a direction transverse to the nematic director, the resulting stress-strain curve typically displays a plateau region, showing a biaxial fluctuations and the possibility of long range tetrahedratic ordering above the nematic phase. Here we report rheological and optical studies on several elastomers that do not undergo phase transitions can also produce power laws. We recorded power law distributions of neuronal avalanches from neocortical slices and then pharmacologically perturbed network activity. We then measured deviations from power law behavior. Here we show that these deviations covary systematically with a control parameter, as would be expected for a continuous phase transition. A critical branching model captures this transition, while stochastic models do not. Our findings imply that the physical theory underlying continuous phase transitions can be fruitfully applied to neocortical circuits.

2:42PM W8.00002 Fluctuating hydrodynamics of nematics for models of liquid-crystal based biosensors via lattice Boltzmann simulations, ORLANDO GUZMAN, JOSE ANTONIO VELEZ, DAVID CASTANEDA, UAM-Iztapalapa — Experimental biosensors based on liquid crystals (LC) use nematics to detect the presence of specific analytes, via the optical textures exhibited by the LC at long times. Efforts to model the time evolution of these textures have relied on relaxation models, ignoring transport phenomena. In this work we include hydrodynamics into a model for these LC biosensors, using lattice Boltzmann (LB) methods and assess the effect on the lifetime of multidomain structures, characteristic of high concentrations of analyte. We apply Yeoman’s et al. LB algorithm, which reproduces the hydrodynamic equations developed by Beris and Edwards for LCs. We also take into account thermal fluctuations, by adding random perturbations to the hydrodynamic modes. Following Adhikari et al., their amplitude is determined by the Fluctuation-Dissipation theorem and we excite both hydrodynamic and the sub-hydrodynamic modes (also called ghost modes). As a result, we analyze the influence of the fluctuations and hydrodynamics on the movement of topological defects.

2:54PM W8.00003 Viscous properties of bent core nematic liquid crystals measured using a nanoliter viscometer1, CHRISTOPHER BAILEY, JOHN HARDEN, ANTAL JAKLI. Kent State University — Since the development of bent core liquid crystal mesogens showing the nematic phase, much work has been done to study the physical properties of these materials in the form of dielectric spectroscopy, dynamic light scattering, and magnetic field induced phase transitions. Some results of these studies showed interesting behaviors such as slow biaxial fluctuations and the possibility of long range tetrahedratic ordering above the nematic phase. Here we report rheological and optical studies on several bent core mesogens showing the nematic and nematic phases. For the rheological studies, we built a viscometer capable of measuring viscoselastic properties with two centipoise resolution with only using 10NL of fluid. Results show abnormal viscosity and optical behavior near the isotropic to nematic phase transition.

from an ordered state to states with a fixed order parameter (variety of correlated systems. In this talk, we present the results of numerical studies of 2- and 3-dimensional Ising spin systems subjected to thermal cycling.

4:00PM W8.00011 Topology and Geometry of 1D Translational Order on Curved Surface, XIANGJUN XING, SACUCA, State University — It is shown that one dimensional translational order on two dimensional curved substrate is naturally described by differential forms. A new type of global dislocation defects is identified and its relation with the topological properties of the embedding (compact) manifold is explored using algebraic topological methods. The associated topological charge classifies all ground states with no local defects. The energetics of smectic order on curved substrate is also discussed. Coupling between nematic director field and extrinsic curvature is shown to be important. As a simple application, the phase diagram of smectic order on a torus is analyzed. Two phases are identified: a small/thin phase where the nematic director is locked by curvature and a large/fat phase where the director varies continuously with system parameters.

4:18PM W8.00010 Local photo-reorientation of a liquid crystal using a laser focused on an azo-dye-based monolayer, YUE SHI, NOEL CLARK, Department of Physics and Liquid Crystal Material Research Center, University of Colorado at Boulder — The orientation adopted by molecules in an azobenzene-based self-assembled monolayer (azo-SAM) is perpendicular to the polarization of incident green light due to isomerization, aligning liquid crystal (LC) correspondingly. To study the local photo reorientation of the LC, the exciting laser is focused into a small spot on the azo-SAM, of a hybrid cell made with nematic LC sandwiched between the azo-SAM and a homeotropic surface. Under irradiation with changing polarization, a variety of interesting phenomena are observed, including winding of rings of reorientation and orientational slipping. Results vs. exciting light intensities and different rotating frequencies will be reported.

4:30PM W8.00011 Topology and Geometry of 1D Translational Order on Curved Surface, XIANGJUN XING, SACUCA, State University — It is shown that one dimensional translational order on two dimensional curved substrate is naturally described by differential forms. A new type of global dislocation defects is identified and its relation with the topological properties of the embedding (compact) manifold is explored using algebraic topological methods. The associated topological charge classifies all ground states with no local defects. The energetics of smectic order on curved substrate is also discussed. Coupling between nematic director field and extrinsic curvature is shown to be important. As a simple application, the phase diagram of smectic order on a torus is analyzed. Two phases are identified: a small/thin phase where the nematic director is locked by curvature and a large/fat phase where the director varies continuously with system parameters.

4:42PM W8.00012 Coarsening of two-dimensional islands in freely suspended smectic A films, DUONG NGUYEN, CHEOL PARK, JOSEPH MACLENAN, MATTHEW GLASER, NOEL CLARK, University of Colorado, Boulder — We have observed coalescence driven coarsening of islands (edge dilation loops) in freely suspended Smectic A liquid crystal films. This is a good realization of a two-dimensional system, with films as thin as one molecular length (3-4 nm). The film is drawn by spreading material across a circular hole of about 4 mm in diameter, after which the film is suspended by the meniscus in contact with the edge of the hole. Islands are generated by blowing air parallel to the film surface, which produces a shearing force that breaks a thick region of the film into circular islands. Depending on the Smectic A material, we observe either strong or weak short-range repulsion between dilation loops, leading to slow or fast coalescence, respectively. Over time, the average size of islands increases as the number of islands drops. The observed coarsening dynamics is compared with theoretical predictions.

4:54PM W8.00013 The Ground States of Nematic Order on a Sphere and Topological Defects, HOMIN SHIN, MARK BOVICK, XIANGJUN XING, SACUCA, State University — We study the ground states of a spherical nematic order and the resulting configuration of topological defects. To emulate the ground state, we use hard rods confined on the surface of a sphere and very gradually compress the system up to the maximum packing density with Monte Carlo simulations. The nematic phases with four +1/2 disclination defects are clearly observed. Although the tetrahedral structure of four +1/2 defects is expected, we find all the defects most likely sitting on a great circle. The theoretical reasoning is provided with the calculation of defect energies in terms of the elastic anisotropy. Finally, we present that the allowance of some softness to the rods gives rise to qualitative changes in the director field surrounding the defect core.

5:06PM W8.00014 Thermal-Cycle Memory Functions and Ising Dynamics, BRAD JOHNSON, DAVID PATRICK, Advanced Materials Science and Engineering Center, Western Washington University — The Ising model provides a rich system for the study of a variety of correlated systems. In this talk, we present the results of numerical studies of 2- and 3-dimensional Ising spin systems subjected to thermal cycling from an ordered state to states with a fixed order parameter (<1), with differing overall morphologies, and back to a quenched state. We find that for systems with initial states generated by thermal disordering above Tc, the initial state of a given order parameter has larger ‘islands’ of like-spin (than the case for random disorder with the same overall order parameter) and consequent quenches of the state to T<Tc result in a strong correlation to a particular final average order parameter. The function we find is given by (S) ≈ tanh(B + Sinit), where Sinit is the order parameter of the initial state, <S> is the average quenched order parameter, and B is a constant that depends upon the morphology of the initial state. The reason for the strong correlation stems from the energies associated with spins at the borders of large clusters. This ‘memory effect’ does not occur in 3D (due to the larger number of near-neighbors). Finally, we discuss the ‘memory function’ in the context of interfacial states of liquid crystals.

Thursday, March 13, 2008 2:30PM - 5:30PM — Session W9 DCMP: Theoretical Methods and Applications Morial Convention Center R07

2:30PM W9.00001 Polarization model revisited, MICHAEL GALPERIN, Los Alamos National Laboratory, ABRAHAM NITZAN, Tel Aviv University, MARK A. RATNER, Northwestern University — We revisit a polaron model proposed by us as a possible mechanism for nonlinear conductance, and discuss difference in polaron formation within isolated system vs. molecular junction situation. Within one-level model we present approximate expression for electronic Green function corresponding to inelastic transport case, which in appropriate limits reduces to expressions presented previously for isolated molecule and for molecular junction coupled to slow vibration (static limit). Relevance of the isolated molecule-type consideration to describe properties of molecular junctions is discussed.

2:42PM W9.00002 A theoretical investigation of the porphyrin-gold junction: applications to molecular wires, MATT MCKENZIE, ZORABEL LEJEUNE, JAYNE GARNO, BING CHEN, Louisiana State University — An important step in the miniaturization of electronic devices involves molecular wires and junctions at the nanoscale level. Porphyrins are a promising material for such objects because of their unique electronic, chemical, and optical properties. The model porphyrin used in this study is a free based tetra-substituted with two phenyl rings and two pyridyl rings as peripheral groups which could provide a mechanism for enhanced electron transfer. The goal of this study is to elucidate the electron transfer processes between the model porphyrins and Au(111). The orbital structures and properties are determined using Car-Parrinello molecular dynamics. The geometry of the porphyrin on the gold surface is explored; from a complete reorientation of the molecule with respect to the surface to different orientations of the pyridyl groups. The calculated electronic conductivity, using the Kubo-Greenwood formula, will be compared to experimental findings using conductive probe Atomic Force Microscopy.
2:54PM W9.00003 Ion-Ion Interactions in Simple Metallic Systems: Beyond Linear Response

JAMES PORTER, Dept. of Physics and Astronomy, Colby College, NEIL ASHCROFT, GEOFFRÉY CHESTER, Laboratory of Atomic and Solid State Physics, Cornell University — We extend the formalism of electronic response theory to second order in perturbing pseudopotentials and examine the physical consequences on effective ionic pair potentials for certain simple metals, under standard conditions. The pseudopotentials, assumed to be transferable, are of the Ashcroft empty-core form. Our results show that inclusion of second-order response terms in the pair potentials leads to the deepest potential minima having locations that are within 8% of the experimental nearest neighbor distances for crystalline sodium, magnesium, aluminum, and metallic silicon, all in their standard one-atom atmospheres. Second-order response effects are found to be becoming increasingly important as the valence increases. We briefly discuss two natural extensions of this research, namely to three-body potentials and to changes expected in pair potentials at higher densities.

3:06PM W9.00004 Algorithm for extraction of quantum oscillation orbits from band structure data

PATRICK ROURKE, STEPHEN JULIAN, University of Toronto — In determining the Fermi surface of a material, quantum oscillation measurements are often compared to band structure calculations. Each oscillation frequency corresponds to an electron (or hole) orbit on the Fermi surface, perpendicular to the applied magnetic field; only orbits enclosing areas that are locally extremal are detected. To facilitate comparisons between theory and experiment, we have developed an algorithm, "SKGAEF," which finds extremal orbits in band structure calculations and determines quantum oscillation frequencies, effective masses and band specific heat contributions. Our code uses a k-space supercell approach, and can successfully locate geometrically-complicated orbits. Example results will be presented for the heavy fermion material UPt3.

3:18PM W9.00005 Development of the relativistic tight-binding model for Platinum

ALEXANDER TCHERNATINSKY, J. WOODS HALLEY, University of Minnesota — As a first step in a program to understand the mechanism of oxygen reduction on a platinum surface in an aqueous environment, we developed a relativistic self consistent tight- binding model for platinum. We applied a scheme that we successfully previously used for the description of titanium (S. Erdin, et al., PRB, 72, 035405 (2005)) in which the electronic structure problem is described by an energy functional containing onsite terms depending self consistently on the local charge and interatomic terms. Due to the high atomic number of platinum, relativistic effects are known to be significant in the electronic structure. We include relativistic effects in the onsite functions of the tight binding model by making them self consistently dependent on the local Mulliken charge (as before) and also on the expectation values of the total atomic angular momentum number $J$ of the atom and the occupation numbers of the $5d_{3/2}$ and $5d_{5/2}$ atomic orbitals in the tight binding basis. We find that this set of variables can uniquely describe the low energy states of the isolated platinum atom including relativistic effects. Their values are calculated self consistently in the tight binding model for the metal. The model was used to calculate the electronic structure of relaxed, low index platinum surfaces. Results will be compared with DFT results and with experiment. This work was supported in part by Minnesota Supercomputing Institute and U.S.DOE.

3:30PM W9.00006 Equivalence of dipole correction and Coulomb cutoff techniques in supercell calculations

LIPING YU, V. RANJAN, NC State U, Raleigh, W. LU, J. BERNHOLC, M. BUONGIORNO NARDELLI, NC State U, Raleigh and ORNL, TN — In ab initio calculations for surfaces or non-periodic systems one often relies on the supercell approximation, where periodic replicas are separated by enough empty space to avoid spurious interactions between successive images. However, a vacuum separation is not sufficient to screen dipolar interactions that appear in asymmetrically charged or polar systems. Two solutions have been proposed in the literature: (i) the dipole correction, and (ii) Coulomb cutoff formalism that eliminates interactions between periodic replicas. We compare these methods under the same conditions in the framework of plane wave DFT calculations. It is found that the two methods produce equivalent results for the total energy, force, charge density and self-consistent potential. In band structure calculations, the results coincide for occupied states but differ for delocalized unoccupied ones in small supercells. This discrepancy can be used as a criterion to identify supercell sizes that are sufficiently large to obtain converged results.

3:42PM W9.00007 Issues related to Convergence Properties of First Principles Full Potential Multiple Scattering Electronic Structure Calculations

AURELIAN RUSANU, G. MALCOLM STOCKS, MARKUS EISENBACK, DON M. NICHOLSON, Oak Ridge National Laboratory, YANG WANG, Pittsburgh Supercomputer Center — Despite some clear advantages for specific problems, the implementation of full potential electronic structure methods based on the use of multiple scattering theory (MST) (KKR derived approaches) has received much less investment than alternate electronic structure methods. Here we describe some new techniques that facilitate an easy and accurate implementation of first principles full potential MST methods. The method consists of solving: (1) the full-potential single site scattering problem, where we avoid the usage of the shape function by surface integrals methods to determine the scattering matrices, and (2) the Poisson problem, where the site centered full-potential is constructed from a sphere bounded non-overlapping charge density and a smooth space-filling charge density. Specifically, we discuss issues related to accuracy and convergence properties of these techniques within the context of the order-N Locally Self-consistent Multiple Scattering (LSMS) method.

3:54PM W9.00008 First-principles investigation of electronic band gap in multiwalled carbon nanotube: Role of mechanical deformations

PAVAN K. VALAVALA, Department of Physics and Mechanical Engineering-Engineering Mechanics, Michigan Technological University, GREGORY M. ODEGARD, Department of Mechanical Engineering-Engineering Mechanics, Michigan Technological University, RANJIT PATI, Department of Physics, Michigan Technological University, Houghton, MI 49931 — The carbon nanotube (CNT) structures have been the subject of intense research in recent years. Some studies have shown that the electronic band gap in single walled CNT can be modulated through mechanical deformations such as flattening. It has been shown that single walled CNTs undergo a semiconductor-metallic and semiconductor-metallic-semiconducting transition when subjected to deformations. However, the modulation of electronic band gap of multiwalled CNT under mechanical deformations has not been studied. We have used first- principles gradient density functional approach to explore the role of flattening on the electronic properties of MWCNT structures. The influence and the effect of flattening on the electronic properties of the constituent single walled CNTs are also explored.

4:06PM W9.00009 Atomic-scale Analysis of the Interactions Between Atomic Hydrogen and Multi-walled Carbon Nanotubes

ANDRE R. MUNIZ, TEJINDER SINGH, DIMITRIOS MAROUDAS, University of Massachusetts at Amherst — We present a detailed atomic-scale analysis of the interactions of atomic hydrogen with the internal layers of multi-walled carbon nanotubes (MWCNTs). The analysis is based on a synergistic combination of classical molecular dynamics (MD) with first-principles density functional theory (DFT). The Adaptive Interatomic Reactive Empirical Bond Order (AIREBO) potential is employed in the MD simulations of H-MWCNT interactions and the resulting structural relaxations. Parameters that have been varied in our analysis include nanotube diameters, number of nanotube walls, inter-wall spacing, and temperature. The MD simulations reveal that, under certain conditions, H chemisorption onto internal MWCNT walls and H diffusion in the space between walls can induce the formation of inter-shell sp3 C-C bonds. The MD mechanisms are in good agreement with our DFT calculations of optimal pathways of C-C bond formation and provide interpretations for the formation of nanocrystalline carbon, which has been observed experimentally upon H2 plasma exposure of MWCNTs.
4:18PM W9.00010 Electronic Property Control of Single-Walled Carbon Nanotubes by Functionalization. CHIAYUN WU, YOUNG-KYUN KWON, Univ of Mass - Lowell — Single-walled carbon nanotubes exhibit remarkable electronic properties. It is well known that there are two types of single-walled carbon nanotubes: metallic and semiconducting. However, separating semiconducting carbon nanotubes from metallic ones is a “holy grail” problem in nanoelectronics fields. Using ab initio density functional theory, we will present the effects of various functional groups, such as 4-bromobenzene diazonium tetrafluoroborate, on SWNTs. Modifications in electronic and transport properties due to such functionalization will be discussed. Possible mechanism converting metallic tubes to semiconducting ones will be addressed.

4:30PM W9.00011 Design of Janus Nanoparticles with Atomic Precision. QIANG SUN, Peking University, QIAN WANG, PURU JENA, Virginia Commonwealth University, YOSHI KAWAZOE, Tohoku University — Janus nanoparticles, characterized by their anisotropic structure and interactions have added a new dimension to nanoscience because of their potential applications in biomedicine, sensors, catalysis and assembled materials. The technological applications of these nanoparticles, however, have been limited as the current chemical, physical, and biosynthetic methods lack sufficient size and shape selectivity. We report a technique where gold clusters doped with tungsten can serve as a seed that facilitates the natural growth of anisotropic nanostructures whose size and shape can be controlled with atomic precision. Using ab initio simulated annealing and molecular dynamics calculations on Au\_nW (n>12) clusters, we discovered that the W\_n@Au\_12 cage cluster forms a very stable core with the remaining Au atoms forming patchy structures on its surface. The anisotropic geometry gives rise to anisotropies in vibrational spectra, charge distributions, electronic structures, and reactivity, thus making it useful to have dual functionalities. In particular, the core-patch structure is shown to possess a hydrophilic head and a hydrophobic tail. The W\_n@Au\_12 clusters can also be used as building blocks of a nano-ring with novel properties.

4:42PM W9.00012 Uniaxial compression of group-IV nanoparticles from ab-initio molecular dynamics simulations. PRASANJIT SAMAL, MATTEO COCCIONI, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 - 0132, U.S.A. — Uniaxial compressions of isolated systems from ab-initio molecular dynamics are made possible through the extension of the electronic enthalphy method [Phys. Rev. Lett. 94, 145501 (2005)] previously introduced for finite systems under hydrostatic pressure. Through this novel approach experimental settings with nanoparticles indented between parallel plates can be reproduced and simulated more realistically, thus allowing for more reliable comparisons between experimental data and simulation results. Molecular dynamics simulations for some group-IV nanoparticles under uniaxial compression have been performed using this extended scheme. Comparison with the deformation of the same systems under hydrostatic loads will elucidate the differences and similarities in the nucleation events of structural transformations and in their kinetic pathways.

4:54PM W9.00013 Explaining the electroluminescence of single molecules. JOHN BUKER, GEORGE KIRCZENOW, Simon Fraser University — Experimental studies of electroluminescence from molecules on complex substrates have yielded intriguing relationships between the current-voltage characteristics and optical emission from such systems. In this talk we propose a theoretical model that is able to account for many observed properties of these systems. We obtain distinct photon emission spectra and corresponding I-V curves for different couplings of the electrodes to the molecule, that are consistent with experimental data. We find emission to be highly dependent on the details of the tip/molecule and molecule/substrate coupling, and make further photon emission predictions for systems not yet achieved experimentally.

5:06PM W9.00014 Toward quantitative acoustic molecular gas sensing. ANDI PETCULESCU, University of Louisiana at Lafayette — Laser spectroscopy techniques provide unrivaled tools for detailed molecular sensing studies. Critical applications such as gas monitoring in life-support systems often require sensors that are not only fast and sufficiently accurate but also rugged and not needing extensive maintenance and calibration. Acoustic sensors are widely used to this end, based on measuring sound speed changes. These, however, can only constrain the overall molecular mass. For reasons unknown, researchers have habitually disregarded acoustic attenuation. Beside the classical sound loss mechanisms due to viscosity, heat conduction, and diffusion, the non-classical contribution to attenuation arises from the inability of internal molecular degrees of freedom to follow the acoustic temperature fluctuations. This connects acoustic attenuation to the molecular relaxation times. In the laboratory, acoustic studies of molecular relaxation in fluids require that the ambient pressure be varied over a wide range at a given frequency in order to cover the relaxation processes. In a fast-sensing device, this would be highly impractical. A novel algorithm is presented here relying on measuring sound speed and attenuation at one pressure and two frequencies to reconstruct the full frequency dependence of the effective specific heat for the main relaxation processes. This would enable a smart sensor to infer the concentration and nature of contaminant molecules in a base gas.

5:18PM W9.00015 A delta-function model for three-dimensional axisymmetric crystals. PING DU, HARRIS WONG, Louisiana State University — A surface energy polar plot contains two possible singularities: the cusps that give facets on an equilibrium crystal, and the circular arcs connecting the cusps that can lead to missing orientations. The common approach of specifying the surface energy usually cannot handle both singularities simultaneously. We model the surface stiffness to avoid missing orientations. Furthermore, a facet is represented by the Dirac delta function with the weight of the delta function equal to the width of the facet. Thus, both singularities are treated precisely. This approach has been shown to work for two-dimensional symmetric [1] and axially symmetric [2] crystals. Here, we apply the delta function to model three-dimensional axisymmetric crystals and obtain analytic solutions to the nonlinear differential equation governing the crystal shape. We find that at every point on the crystal surface the chemical potential is equipartitioned between the axial and the azimuthal component.

Thursday, March 13, 2008 2:30PM - 5:18PM
Session W10 DMP: Focus Session: Hybrid Magnetic-Superconducting Systems III Morial Convention Center RO8
through transport measurements, both for bulk and mesoscopic samples. 3:30PM W10.00004 Vortex lattice matching effects in superconducting Mo₃Si films with magnetic pinning centers. , DAVID PEREZ DE LARA, Dept. Fisica de Materiales, Universidad Complutense, 28040 Madrid (Spain), ALEJANDRO ALIJA, ALEJANDRO JUNQUERA, Dept. Fisica, Universidad Oviedo, 33007 Oviedo (Spain), JOSE M. COLINO, Dept. de Fisica, Universidad de Castilla la Mancha, Ciudad Real, Spain, JESUS MARTIN, Dept. Fisica de Materiales, Universidad Complutense, 28040 Madrid (Spain), MARIA VELEZ, Dept. Fisica, Universidad Oviedo, 33007 Oviedo (Spain), JOSE V. ANGUITA, Instituto Microelectronica, CSIC, Tres Cantos, 28760, JOSE L. VICENT, Dept. Fisica de Materiales, Universidad Complutense, 28040 Madrid (Spain) — Electron Beam Lithography and sputtering techniques have been used to fabricate arrays of Ni nanodots on Si (100) substrate. Nb films and amorphous Mo₃Si films were grown on top of the magnetic array by magnetron sputtering. The same arrays were used in both superconducting systems; therefore the same periodic pinning potential is induced in both systems. Magnetotransport and (I, V) curves were measured close to the films critical temperatures. Matching effects are observed between the periodic array of pinning potentials and the driving vortex lattice. The different vortex dynamics will be discussed in both systems. We want to thank Spanish Ministerio de Educacion y Ciencia grants NAN2004-09087, FIS2005-07392.

3:42PM W10.00005 Confined vortex phase in superconductor-ferromagnet nanocomposites. , MILORAD MILOSEVIC, Departement Fysica, Universiteit Antwerpen, Belgium, MAURO DORIA, Instituto de Fisica, Universidade Federal do Rio de Janeiro, Brazil, FRANCISCO PEEGERS, Departement Fysica, Universiteit Antwerpen, Belgium — In the fifties, Abrikosov found the coexistence of superconductivity with magnetic vortices in the superconducting density of states in the coexistence region is followed as function of temperature and external magnetic field. Similar to exotic superconductors, internal complexes of vortex loops may also arise around embedded nanomagnets in artificial superconducting hybrids, where high density of magnetic particles can be controlled by tuning the strength of the field emanating from the dots and compensating the applied field. Static vortex patterns and dynamic effects, such as guided vortex motion and vortex ratchet effects, were studied in the superconductor/ferromagnet hybrids consisting of the superconducting film covered by magnetic dots, bars, loops with the in-plane magnetization. In-plane magnetic dipoles create asymmetric pinning sites responsible for the appearance of the magnetic dipole vortex ratchets theoretically predicted by Carneiro and now found experimentally. Switchable flux pinning landscape has been created by tuning the magnetic states of the in-plane magnetized loops. (Phys.Rev.Lett. 98, 117005 (2007), Appl. Phys. Lett. 90, 182501 (2007), Phys. Rev. B (R) 76, 60503 (2007))

4:30PM W10.00006 Interplay of Superconducting with Magnetic Vortices, A. HOFFMANN, J.E. PEARSON, G. MIHAJLOVIČ, MGD and CNM, Argonne National Laboratory, V. METLUSHKO, L. FUMAGALLI, J.C. SAUTNER, N. JAHEDI, ECE, University of Illinois at Chicago, — Periodic arrays of magnetic structures are well known to give rise to commensurate pinning of superconducting vortices in adjacent superconducting films. We compared the pinning effects due to magnetic dots with either single domain or vortex magnetization configuration. There is a clear correlation between the magnetoresistance in the superconductor and the magnetization configuration of the magnetic dots, indicating that the pinning of the superconducting vortices is strongly enhanced for the magnetic vortex state. The origin of this enhanced pinning is due to the locally larger magnetic stray fields produced by the magnetic vortex cores. The absence of an symmetry for parallel and anti-parallel orientation between the superconducting vortex flux and the magnetic vortex cores suggests that the enhanced pinning is not due to magnetostatic interactions but is rather due to the local suppression of superconductivity by highly localized, large perpendicular stray magnetic fields generated by the magnetic vortex cores.
4:06PM W10.00007 Enhancement of superconductivity by parallel magnetic field in ultrathin α-Pb films. ASHWANI KUMAR, H. JEFFREY GARDNER, PENG XIONG, Department of Physics and MARTECH, Florida State University — A modified dilution refrigerator equipped with in situ film growth and a rotating sample stage is used to study the effect of magnetic field on ultrathin homogeneous Pb films. An insulating layer of Sb (~ 1 nm) is first deposited to ensure electrical and possibly structural uniformity down to a single atomic layer for the subsequently deposited Pb. Through incremental deposition of Pb, a film with increasing thickness (thus decreasing R and increasing Tc) is obtained and transport measurements in perpendicular and parallel magnetic field are performed in situ at different film thicknesses. Any perpendicular field is found to suppress superconductivity, and at sufficient strength induces an electrically inhomogeneous insulating state. In contrast, the same film is at least two orders of magnitude less sensitive to a parallel field. More strikingly, a moderate parallel magnetic field actually increases the Tc of the film, resulting in large negative magnetoresistance in the transition region in parallel fields as large as 3T. The dependence of this effect on the film thickness, impurities and temperature will be presented and discussed. 1J.S. Parker et al., Europhys. Lett. 75, 950 (2006).

4:18PM W10.00008 An Effective Action approach to inhomogeneous superconductors: Application to F/S/F spin valves. ADNAN REBEI, Seagate Technology — The interplay between magnetism and superconductivity can be studied in simple systems such as ferromagnetic-superconductor-ferromagnetic tri-layers. Many recent experiments [1] measured a critical temperature dependence of the superconductor as a function of the relative orientations of the surrounding ferromagnetic layers. This layered system gives rise to an in-homogenous gap equation for the superconductor due to the polarization at the ferromagnetic-superconductor interfaces irrespective of the orientation of the magnetization in-plane or out-of-plane. Real space formulations are therefore better suited to study this kind of systems. We show that an Effective Action formulation similar to the one proposed by Weinberg [2] is very advantageous in this respect as was shown in normal-ferromagnetic-normal systems in [3].

4:30PM W10.00009 Multilayered ferromagnet/superconductor nanostructures: proximity effect, decoupled superconductivity, and hierarchy of critical temperatures. Y. N. PROSHIN, Kazan State University, Russia, N. G. FAZLEEVA, University of Texas at Arlington, USA, M. G. KHUSAINOV, Vostok branch, Kazan State Technical University, Russia — The four-layered F'/S'/F''/S'' nanostructure consisting of rather dirty superconducting (S) and ferromagnetic (F) metals is studied within the theory of the proximity effect taking detailed account of the boundary conditions. The new pi phase superconducting states are obtained for the F'/S'/F''/S'' nanostructure in addition to the known “superlattice” states. The dependence of the critical temperature versus the F layers thicknesses is investigated. It is shown that the F'/S'/F''/S'' nanostructure can experience decoupled superconductivity. The latter manifests itself through a hierarchy of the critical temperature Tc, which can be different for different S' and S'' layers. An optimal set of parameters is determined, for which the difference between the critical temperatures for different S' and S'' layers becomes significant. The corresponding phase diagrams are constructed and discussed.

4:42PM W10.00010 Paramagnetic Intrinsic Meissner Effect in Layered Superconductors\(^1\). ANDREI LEBED, Dept. of Physics, University of Arizona — Free energy of a quasi-two-dimensional superconductor with a coherence length perpendicular to the conducting layers being less than an inter-layer distance is calculated. The free energy is shown to differ from that in the textbook Lawrence-Doniach model at high fields, where the Meissner currents are found to create an unexpected positive magnetic moment due to shrinking of the Cooper pairs “sizes” by a magnetic field. This unique phenomenon - paramagnetic intrinsic Meissner effect (PIME) in a bulk [1] - is suggested to detect by measuring in-plane magnetization and torque in layered organic and high-Tc superconductors as well as in superconducting superlattices.

5:06PM W10.00012 Synchronization by internal cavity mode and resonant electromagnetic emission from intrinsic Josephson junction stacks\(^1\). ALEXEI KOSHELEV\(^2\), Argonne National Laboratory — Intrinsic Josephson-junction stacks realized in mesas fabricated out of high-Tc superconductors may be used as sources of coherent electromagnetic radiation. The major challenge is to synchronize Josephson oscillations in all junctions to get significant radiation. A simple way to solve this problem is to excite the in-phase Fiske mode when the Josephson frequency matches the Fiske-resonance frequency set by the stack lateral size[1]. A finite direct coupling to such mode exists in mesas with lateral modulation of the Josephson critical current identical in all junctions [2]. The powerful almost standing electromagnetic wave is excited inside the crystal in the resonance promoting full synchronization. We evaluate behavior of the I-V characteristics and radiated power near the resonance. We will discuss several relevant issues including (i) stability of the coherent state, (ii) mechanism of damping including external radiation and leaking of radiation into the bulk crystal, and (iii) angular dependence of external radiation. Thursday, March 13, 2008 2:30PM - 5:18PM –
Session W11 DCMP: Theory of Superconductivity in Cuprates II Morial Convention Center R09
2:30PM W11.00001 Theory of Strongly Correlated Superconductivity[^1]. WILLIAM PUTIKKA, Ohio State University — Superfluid behavior is relatively common in strongly correlated fermion systems. This suggests there is a common reason for this behavior rooted in the strong correlations. I propose such a mechanism, developed in the context of the 2D $t$-$J$ model, where $d_{x^2-y^2}$ superconducting fluctuations have recently been observed[^1]. The $d_{x^2-y^2}$ fluctuations are not due to antiferromagnetic spin fluctuations; the AF fluctuations compete with superconducting fluctuations. Pairing fluctuations have their own origin based on strong correlations. The key to understanding how this comes about is the high temperature entropy. Strong correlations not only create order at low temperatures, they also reduce the entropy at high temperatures. The response of the system is to rearrange the degrees of freedom into separate spin and charge excitations. These excitations have very different energy scales, allowing the charges to develop pairing correlations before the spin degrees of freedom become coherent. At lower temperatures where the spins become coherent they determine the symmetry of the electronic pairing wavefunction in a manner to best avoid the magnetic fluctuations in the system.

[^1]: Supported by NSF ECS-0523918.

2:42PM W11.00002 Magnetism and superconductivity in the $t$-$t'$-$J$ model. FEDERICO BECCA, LEONARDO SPANU, MASSIMO LUGAS, SANDRO SORELLA, CNR-INFM Democritos and SISSI (Trieste) — We present a systematic study of the phase diagram of the $t$-$t'$-$J$ model by using the Green's function Monte Carlo (GFMC) technique, implemented within the fixed-node (FN) approximation and a wave function that contains both antiferromagnetism and d-wave pairing. This enables us to study the interplay between these two kinds of order and compare the GFMC results with the ones obtained by the simple variational approach. By using a generalization of the forward-walking technique, we are able to calculate true FN ground-state expectation values of the pair-pair correlation functions. In the case of $t' = 0$, there is a large region with a coexistence of superconductivity and antiferromagnetism, that survives up to $\delta_c \sim 0.10$ for $J/t = 0.2$ and $\delta_c \sim 0.13$ for $J/t = 0.4$. The presence of a finite $t'/t < 0$ induces a strong suppression of both magnetic (with $\delta_c < 0.03$, for $J/t = 0.2$ and $t'/t = -0.2$) and pairing correlations. In particular, the latter ones are depressed both in the low-doping regime and around $\delta \sim 0.25$, where strong size effects are present.

2:54PM W11.00003 Phase Fluctuations in high-Tc Superconductors. YUCEL YILDIRIM, WEIGUO YIN, WEI KU, Brookhaven National Laboratory — Thermal fluctuation induced destruction of phase coherence of superconductivity in High-Tc superconductors is investigated via numerical quantum Monte Carlo solution of a new theoretical model at finite-temperature. Our simple effective boson Hamiltonian, derived from the pairing sector of the $t$-$t'$-$J$ model, can be considered as a natural extension of the hard-core boson with additional information about the internal structure of the local fermion pairs. The local solution is found to consist of d-wave pairing, hybridizing with neighboring p-wave pairs. The possible connection with the pseudo-gap phase will also be addressed.

3:06PM W11.00004 Suppression of Superfluid Density in Underdoped Cuprates. WEI-CHENG LEE, Department of Physics, the University of Texas at Austin, Austin TX 78712, JAIRAINO SINNOVA, Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA, ANTON O. BURKOV, Department of Physics and Astronomy, University of Waterloo, Waterloo, Ontario, Canada N2L 3G1, YOGESH JOGLEKAR, Department of Physics, Indiana University-Purdue University Indianapolis, Indianapolis, Indiana 46202, USA, ALLAN H. MACDONALD, Department of Physics, the University of Texas at Austin, Austin TX 78712 — A key challenge for theories of high-$T_c$ cuprates is to explain why the superfluid density vanishes as the antiferromagnetic insulator state is approached. Viewing a cuprate as a doped Mott insulator gives a natural explanation for this property, but one that is not obviously compatible with the fact that superconductivity always vanishes at finite doping. We propose another possible explanation, starting from weak-coupling conventional d-wave BCS theory and calculating the correlation contribution to the superfluid density. We show that triplet fluctuations of the d-wave superconducting order parameter are canonically conjugate to antiferromagnetic fluctuations, and that this causes the correlation energy to increase in magnitude when superconductivity is weakened by a phase gradient. In our theory the inelastic neutron scattering resonance has the character of a magnetic plasmon rather than the character of an exciton.

3:18PM W11.00005 Stability of inhomogeneous superconducting states in the doped t-J model. MANUELA CAPELLO, DIDIER POILBLANC, Laboratoire de Physique Theorique, CNRS, and Universite Paul Sabatier, Toulouse, France — Using quantum Monte Carlo techniques, we have investigated the stability of inhomogeneous RVB superconducting states in the $t$-$J$ model by using the Green's function Monte Carlo (GFMC) technique, implemented within the fixed-node (FN) approximation and a wave function that contains both antiferromagnetism and d-wave pairing. This enables us to study the interplay between these two kinds of order and compare the GFMC results with the ones obtained by the simple variational approach. By using a generalization of the forward-walking technique, we are able to calculate true FN ground-state expectation values of the pair-pair correlation functions. In the case of $t' = 0$, there is a large region with a coexistence of superconductivity and antiferromagnetism, that survives up to $\delta_c \sim 0.10$ for $J/t = 0.2$ and $\delta_c \sim 0.13$ for $J/t = 0.4$. The presence of a finite $t'/t < 0$ induces a strong suppression of both magnetic (with $\delta_c < 0.03$, for $J/t = 0.2$ and $t'/t = -0.2$) and pairing correlations. In particular, the latter ones are depressed both in the low-doping regime and around $\delta \sim 0.25$, where strong size effects are present.

3:30PM W11.00006 “Glue” approximation for the pairing interaction in the Hubbard model with next nearest neighbor hopping. EHSAN KHATAMI, ALEXANDRU MACRIDIN, MARK JARRELL, University of Cincinnati — Recently, several authors have employed the “glue” approximation for the Cuprates in which the full pairing vertex is approximated by the spin susceptibility. We study this approximation using Quantum Monte Carlo Dynamical Cluster Approximation methods on a 2D Hubbard model. By considering a reasonable finite value for the next nearest neighbor hopping, we find that this “glue” approximation, in the current form, does not capture the correct pairing symmetry. Here, d-wave is not the leading pairing symmetry while it is the dominant symmetry using the “exact” QMC results. We argue that the sensitivity of this approximation to the band structure changes leads to this inconsistency and that this form of interaction may not be the appropriate description of the pairing mechanism in Cuprates. We suggest improvements to this approximation which help to capture the the essential features of the QMC data.

3:42PM W11.00007 Pairing glue in the Hubbard and t-J models: Insights from a dynamic cluster approximation study. THOMAS MAIER, Oak Ridge National Laboratory, DOUGLAS SCALAPINO, University of California, Santa Barbara, MARK JARRELL, University of Cincinnati — We will discuss dynamic cluster non-crossing approximation studies of the superconducting gap function $\Phi(k,\omega)$ in the 2D Hubbard and t-J models. The momentum and frequency dependence of the gap reflect the spatial structure and dynamics of the pairing interaction responsible for d-wave pairing. For both models we find that two mechanisms are simultaneously active. An instantaneous contribution to the gap arises from states whose energies reflect the Mott scale and which give rise to the exchange coupling $J$. The dominant contribution, however, is retarded and comes from energies that correspond to the spin fluctuation spectrum. It is therefore reasonable to speak of a dynamic “pairing glue” which gives rise to d-wave superconductivity in the Hubbard and t-J models.
Arizona — The superconducting $\kappa$ explained within an anisotropic triangular lattice\[1\] under ambient pressure, and the appearance of superconductivity under pressure has led several investigators to suggest that the superconductivity can be , HONGTAO LI, University of Arizona, R. TORSTEN CLAY, Mississippi State University, S. MAZUMDAR, University of A triangular lattice observed in transport measurements at the special structure of La $\text{Ba}_2\text{Cu}_3\text{O}_6$.\[1\] $\text{CuO}_2$.

We speculate that this effect could lead to a region of globally phase coherent portion of the superconducting order must have s-wave symmetry. We find that the Josephson coupling between the s-wave components of the order parameter on two droplets separated by a distance $r$ falls off as a slower power law than does the d-wave component. Thus, for dilute enough droplets, even if the local gap structure within each droplet is dominantly d-wave-like, we do not find any hint of long range superconducting correlations. Neither is there any region of the Hubbard $d$ limit, when antiferromagnetism gives way to d-wave superconductivity. We have performed exact diagonalizations on a 16-site periodic anisotropic triangular electronic system, under a set of special circumstances, the superconducting condensate, like the magnetic order, can occur at a nonzero wave vector corresponding to a spatial period double that of the charge order. In this case, the Josephson coupling between near neighbor planes, especially in a crystal with the special structure of $\text{La}_2\text{Ba}_2\text{Cu}_3\text{O}_6$, vanishes identically. We propose that this is the underlying cause of the dynamical decoupling of the layers recently observed in transport measurements at $x = 1/8$.

Many experimental implications of various types of assumed order are discussed in the context of the cuprate superconductors.

Disorder

Some experimental implications of various types of assumed order are discussed in the context of the cuprate superconductors.

Disorder

4:06PM W11.00009 Dynamical Layer Decoupling in a Stripe-Ordered High-$T_c$ Superconductor, EDUARDO FRADKIN, UIUC, EREZ BERG, EUN-AH KIM, STEVE KIVELSON, Stanford University, VADIM OGANESEYAN, Yale University, JOHN TRANQUADA, Brookhaven National Laboratory, SHOUCHENG ZHANG, Stanford University — In the stripe-ordered state of a strongly correlated two-dimensional electronic system, under a set of special circumstances, the superconducting condensate, like the magnetic order, can occur at a nonzero wave vector corresponding to a spatial period double that of the charge order. In this case, the Josephson coupling between near neighbor planes, especially in a crystal with the special structure of $\text{La}_2\text{Ba}_2\text{Cu}_3\text{O}_6$, vanishes identically. We propose that this is the underlying cause of the dynamical decoupling of the layers recently observed in transport measurements at $x = 1/8$.

4:18PM W11.00010 Exact diagonalization study of electronic nematic and d-wave states, HYEONJIN DOH, THOMAS GRZESIAK, HAE-YOUNG KEE, University of Toronto — It was proposed that the d-density wave (ddw) and the electronic nematic states are relevant phases in the phase diagram of high $T_c$ cuprates. The two phases break different symmetries, and their order parameters have been used to describe the characteristic broken symmetries. Here we show that the two order parameters transform into each other under a local gauge transformation, which implies that the order parameters cannot represent different broken symmetric states, if a Hamiltonian is invariant under such a transformation. The two order parameters describe distinctly different states, when the nearest neighbor hopping integral is finite, but the states are nearly degenerate at a strong coupling limit. We also present a phase diagram of a Hamiltonian with correlated hopping, and nearest neighbor repulsive interactions using Lanczos exact diagonalization where we find an interesting interplay between the ddw and nematic states. We compare our results with the previous mean field calculation, and discuss a possible relevance to a d-wave superconducting state.

4:30PM W11.00011 Competition between superconductivity and antiferromagnetism as a boson-fermion mixture problem, GERARDO ORTIZ, LEONID ISAEV, Indiana University - Dep. of Physics, CRISTIAN D. BATISTA, Los Alamos National Laboratory — It is widely believed that the key to understanding the mechanism of superconductivity in cuprate materials and heavy fermion compounds lays in the competition between two quantum orders: superconductivity and antiferromagnetism, which complicates the choice of relevant effective degrees of freedom. Here we present a new isomorphic mapping, preserving the dimension of the on-site Hilbert space, where holons are represented by fermionic and spinons — by bosonic degrees of freedom, which, we claim, are the relevant ones in a certain regime (low density). Starting from t-J-like models we show that the original Hamiltonian can be exactly mapped onto a mixture of interacting fermion and boson gases. It is then demonstrated that this system may be considered as dilute under certain experimentally reasonable conditions. In this limit we show that the fermion gas exhibits a pairing instability, caused by a two boson exchange, which implies superconductivity of holons in the original repulsive model. Although the long-range Coulomb interaction is, in principle, capable of suppressing this state, we argue about a physical mechanism for its compensation, which is relevant for real materials. Our results also lead to a mechanism for superfluidity in ultracold boson — fermion gas mixtures.

4:42PM W11.00012 Stability of nodal quasi-particles in superconductors with coexisting orders, EREZ BERG, CHENG-CHIEN CHEN, STEVEN A. KIVELSON, Stanford University — The possible existence of nodal quasi-particles is one of the most distinctive properties of unconventional superconductors. Nodal quasi-particles have many unique experimental fingerprints, such as a linear temperature dependence of the superfluid density. It is therefore interesting to ask under what conditions can they exist generically. Here, we establish a condition for the perturbative stability of zero energy nodal points in the quasi-particle spectrum of superconductors in the presence of a general coexisting commensurate order. The nodes are found to be stable if the Hamiltonian commutes with the Fermi surface and is quasiperiodic under a specific lattice translation. The principle is demonstrated with a few examples. Some experimental implications of various types of assumed order are discussed in the context of the cuprate superconductors.

4:54PM W11.00013 S-wave superconductivity from predominantly d-wave pairing, PAUL ORETO, Department of Physics, Stanford University, BORIS SPIVAK, Department of Physics, University of Washington, Seattle, STEVEN KIVELSON, Department of Physics, Stanford University — We have studied the zero temperature properties of a system consisting of dilute superconducting droplets embedded in a weakly disordered Fermi liquid metal. Even under the assumption that the pairing interaction occurs exclusively in the d-wave channel, irregularities in the shape of the droplets, or impurities within the droplet generically induce local mixing of s-wave and d-wave components of the superconducting order. Moreover, we find that the Josephson coupling between the s-wave components of the order parameter on two droplets separated by a distance $r$ falls off as a slower power law than does the d-wave component. Thus, for dilute enough droplets, even if the local gap structure within each droplet is dominantly d-wave-like, the globally phase coherent portion of the superconducting order must have s-wave symmetry. We speculate that this effect could lead to a region of globally s-wave superconductivity in highly overdoped cuprates.

5:06PM W11.00014 Absence of superconductivity in the $\frac{1}{2}$-filled band Hubbard model on a triangular lattice, HONGTAO LI, University of Arizona, R. TORSTEN CLAY, Mississippi State University, S. MAZUMDAR, University of Arizona — The superconducting $\kappa$-(BEDT-TTF)$_2$X salts are strongly dimerized, with one hole per dimer unit cell. The occurrence of antiferromagnetism under ambient pressure, and the appearance of superconductivity under pressure has led several investigators to suggest that the superconductivity can be explained within an anisotropic triangular lattice $\frac{1}{2}$-filled band Hubbard Hamiltonian. Within this picture, pressure takes the system closer to the isotropic limit, when antiferromagnetism gives way to d-wave superconductivity. We have performed exact diagonalizations on a 16-site periodic anisotropic triangular lattice as a function of the Coulomb interaction (Hubbard U) and the anisotropy to investigate this claim. We calculate bond orders, double occupancies, spin-spin correlations, spin structure factors and $d_{\pi_x\sigma}$ Superconducting pair-pair correlations. We are able to confirm the Mott metal-insulator transition and antiferromagnetism, but we do not find any hint of long range superconducting correlations. Neither is there any region of the Hubbard U where these correlations are enhanced by the interaction strength.

---

Thursday, March 13, 2008 2:30PM - 5:30PM – Session W12 DCMP: Metal Insulator Transition II: Theory Morial Convention Center 203

1 Supported by DE-FG02-06ER46315
2:30PM W12.00001 Effect of frustration on charge dynamics for a doped two-dimensional triangular Hubbard lattice. TAKAMI TOHYAMA, Yukawa Institute for Theoretical Physics, Kyoto University — We examine the optical conductivity $\sigma(\omega)$ and the chemical potential $\mu$, together with the spin correlation, in the strong-coupling limit of a hole-doped two-dimensional triangular Hubbard model near half filling by using an exact diagonalization technique [1]. In contrast to the case of a square lattice without frustration, the doping dependences of $\mu$ and the Drude weight indicate that the charge degree of freedom is weakly coupled to the spin degree of freedom. However, we find that $\sigma(\omega)$ shows strong incoherent excitations extended to a higher energy region. This implies that geometrical frustration in strongly correlated electron systems influences incoherent charge dynamics. Momentum-dependent charge dynamics is also compared with that of the square lattice.

2:42PM W12.00002 Exact diagonalization analysis of the Anderson-Hubbard model and comparison to real-space self-consistent Hartree-Fock solutions. XI CHEN, Dept. of Physics, Queens University, PAKWON Leung, Dept. of Physics, Hong Kong University of Science and Technology, ROBERT GOODING, Dept. of Physics, Queens University — We have obtained the exact ground state wave functions of the Anderson-Hubbard model for different electron fillings on a 4x4 lattice with periodic boundary conditions. When compared to the uncorrelated ground states (Hubbard interaction set to zero) we have found evidence of very effective screening, producing smaller charge inhomogeneities due to the Hubbard interaction, particularly at 1/2 filling, and have successfully modelled these local charge densities with non-interacting electrons that experience a static screening of the impurity potentials. Further, we have compared such wave functions to self-consistent real-space unrestricted Hartree-Fock solutions and have found that these approximate ground state wave functions are very successful at reproducing the local charge densities, and may indicate the role of dipolar backflow in producing a novel metallic state in two dimensions.

2:54PM W12.00003 Electronic Griffiths phase near a disordered Mott transition in $D = 2$. ERIC ANDRADE, Florida State University and Univ. of Campinas, EDUARDO MIRANDA, Univ. of Campinas, VLAD DOBROSAVLJEVIC, Florida State University — We investigate the effects of weak and moderate disorder on the $T = 0$ Mott Metal-Insulator Transition (MIT) in two dimensions, by solving the disordered Hubbard Model within the so-called Statistical Dynamical Mean Field Theory (statDMFT) [1]. In the weak disorder regime, we recover the results of the standard DMFT limit [2], including strong disorder screened close to the MIT. For moderate disorder, the screening of the disorder remains strong, but is reduced by fluctuation effects absent in high dimensions. For disorder strength $W$ smaller then the on-site interaction $U$, the transition remains the Mott character, where the local quasiparticles weights $Z_i$ vanish on all sites at the transition, indicating the transmutation of all electron into local magnetic moments. In contrast to the behavior in high dimensions [2], the corresponding distribution function $P(Z)$ is found to assume a singular form as the transition is approached, indicating the emergence of an electronic Griffiths phase [3] preceding the MIT.

2:54PM W12.00004 An Exactly Solvable Model with a Tunable Mott Gap without Broken Symmetry. DANIEL HANSEN, B. SRIRAM SHAstry, UCSC Physics — The 1d Hubbard model at half filling provides the only known example of a Mott Hubbard insulating state, with a Mott charge gap without any concomitant broken symmetry. Such a state has inspired much current work in correlated matter in low dimensions. We present a model, where the Mott gap can be manipulated and in fact made to vanish with some parameter. Using the higher conserved currents found by Shastry in 1986 for the 1d Hubbard model, we construct a new model which does show a tunable Mott gap. The model is given by the hamiltonian

$$H = H_{\text{Hubbard}}(U) + \lambda I_3(U),$$

where $H_{\text{Hubbard}}$ is the Hubbard hamiltonian and $I_3$ is its third conserved current. The new model has exactly the same space time symmetries as the Hubbard model, but possesses two parameters, $U$, $\lambda$. The phase diagram in $\lambda - U$ is explored using numerical methods and the Bethe Ansatz. It displays several interesting features including a “superconducting" type state. A significant role is played by a band transition at $U = 0$ (similar to the Lifshitz transition), wherein the two fermi points of the Hubbard model break up into 6 Fermi points. We also find a variety of second order transitions.

3:30PM W12.00006 Insulator-Insulator Transitions in an Ionic Hubbard Model. ARA GO, GUN SANG JEON, Seoul National University — We study the ionic Hubbard model in one and two dimensions at zero temperature. As the Hubbard interaction is increased, the system is known to transform from a band insulator to a Mott insulator. The former phase is induced by the alternating on-site potential energy while the strong local Hubbard interaction drives the system towards correlated Mott insulator. In order to examine the transition nature, we perform the cellular dynamical mean-field calculation on a finite-size system, an exact diagonalization technique. From the computed local density of states we estimate the spectral gap as the interaction strength is varied. We also calculate the momentum-dependent density of states which exhibits characteristic features for different phases.

3:42PM W12.00007 The Anderson-Mott transition for a correlated 2D system. MARIA ELISABETTA PEZZOLI, FEDERICO BECCA, GIUSEPPE SANTORO, INFN-CNR Democritos and SISSA (Trieste), MICHELE FABRIZIO, INFN-CNR Democritos, SISSA, and ICTP (Trieste) — The interplay of disorder and electron-electron interaction can lead a bidimensional system to different phase transitions. We show that the Gutzwiller wave function generalized for an inhomogeneous system and with a long-term Jastrow factor provides a proper variational description of the Mott Hubbard insulating state, with a Mott charge gap without any concomittant broken symmetry. Such a state has inspired much current work in correlated systems. We construct a new model which does show a tunable Mott gap. The model is given by the hamiltonian

$$H = H_{\text{Hubbard}}(U) + \lambda I_3(U),$$

where $H_{\text{Hubbard}}$ is the Hubbard hamiltonian and $I_3$ is its third conserved current. The new model has exactly the same space time symmetries as the Hubbard model, but possesses two parameters, $U$, $\lambda$. The phase diagram in $\lambda - U$ is explored using numerical methods and the Bethe Ansatz. It displays several interesting features including a “superconducting" type state. A significant role is played by a band transition at $U = 0$ (similar to the Lifshitz transition), wherein the two fermi points of the Hubbard model break up into 6 Fermi points. We also find a variety of second order transitions.

3:54PM W12.00008 The 2D Metal-Insulator Transition: A percolative Monte Carlo study. DONALD PRIOUR JR., University of Missouri, Kansas City, SANKAR DAS SARMA, University of Maryland, College Park — We examine the metal-insulator transition (MIT) in two dimensional electronic systems (e.g. n doped GaAs heterostructures) in the presence of a long-range Coulombic random potential set up by a nearby layer of charged impurities. An iterative scheme taking into account nonlinear screening is used to obtain the inhomogeneous “landscape" of electron-rich and electron-depleted regions. The percolation (or not) of electron rich areas (in the regime of electronic densities $n$ where linear screening breaks down) is determined by a variant of the Hoshen Kopelman algorithm. Identifying the percolation transition as the metal-insulator transition, we calculate the critical electron density $n_c$ as a function of the concentration of charged impurities, the separation $d$ of the impurity layer from the electronic layer, and the thickness of the impurity rich region; the effect of correlated impurity positions is also examined. Using finite size scaling analysis, we calculate the critical exponent $\delta$ for the asymptotic scaling $\sigma \propto (n - n_c)^\delta$ in the vicinity of the MIT. We acknowledge support from US-ONR and NRI-NSF.
4:06PM W12.00009 Quantum and thermal fluctuation effects on solid-light systems . MARTIN HOHENADLER, University of Cambridge, MARKUS AICHHORN, University of Wuerzburg, CHARLES TAHAN, PETER LITTEWOOD, University of Cambridge — Several theoretical proposals of strongly correlated polariton systems which exhibit a quantum phase transition from a Mott insulator to a superfluid phase have recently been made. Here we study Mott phases of polaritons in a model of optical microcavities in a photonic crystal with nearest-neighbor photon hopping. The variational cluster approach takes into account quantum fluctuations exactly on the lengthscale of finite clusters, and yields phase diagrams and single-particle spectra at zero and finite temperature in one and two dimensions. The relation of the model to the well-known Bose-Hubbard model is explored, and implications of our findings concerning the stability of the Mott state at finite temperatures for technological applications are discussed.

4:18PM W12.00010 Effects of electron correlations on delocalization and percolation of electronic states . KENDALL MALLORY, Point Loma Nazarene University — A simulation of the effects of electron correlations on the formation of delocalized states and percolating clusters is presented. The model includes disorder in site locations and energy and uses a semi-classical approach to finding matrix elements and diagonalizing the Hamiltonian. We are also looking for scale invariant properties in the system.

4:30PM W12.00011 Dynamic mean-field theory of the ionic Hubbard model , JI-WOO LEE, Myongji University, Yong-In, South Korea, GUN SANG JEON, Seoul National University, Seoul, South Korea — We study the ionic Hubbard model in the infinite dimensions in the framework of dynamical mean-field theory. Exact diagonalization is used to obtain the impurity Green’s function to satisfy the self-consistent equation. We obtain a phase diagram in the parameter space of local ionic potential strength, $\Delta$ and local repulsive energy, $U$ exhibiting three phases: Mott insulator, metal, band insulator. Analyzing the spectral density, we compare our results with those of iterative perturbation theory and quantum Monte Carlo study in two dimensions.

4:42PM W12.00012 Evolution of the Mott-Hubbard insulator transition in bulk nonequilibrium; dynamical mean field theory . RYAN HEARY, JONG HAN, State University of New York at Buffalo — The equilibrium dynamical mean-field theory (DMFT) is extended to the steady-state nonequilibrium in which the Hubbard lattice is populated by left and right movers. The nonequilibrium boundary condition is imposed in the non-interacting limit by applying a chemical potential shift between the left and right movers of the homogeneous bulk system. The success of this theory lies in the fact that the local Green function can be calculated nonperturbatively using the imaginary-time formulation of the steady-state nonequilibrium [1]. We study the evolution of metallic quasi-particle excitations near the Mott-Hubbard insulator transition as a function of the chemical potential bias. The nonequilibrium DMFT algorithm will be presented along with the nonlinear nonequilibrium destruction of the Kondo resonance. [1] J. E. Han, R. J. Heary, Imaginary-time formulation of steady-state nonequilibrium: application to strongly correlated transport, accepted to Phys. Rev. Lett. arXiv:0704.3198.

4:54PM W12.00013 Non-local Coulomb correlations in metals close to a charge order insulator transition . JAIME MERINO, Universidad Autonoma de Madrid — Recent extensions of dynamical mean-field theory (DMFT) to clusters either in its real space (CDMFT) or momentum space versions (DCA) have become important tools for the description of electronic properties of low dimensional strongly correlated systems. In contrast to single site DMFT, short range correlation effects on electronic properties of systems close to the Mott transition can be analyzed. We have investigated the charge ordering transition induced by the nearest-neighbor Coulomb repulsion $V$ in the 1/4-filled extended Hubbard model using CDMFT. We find a transition to a strongly renormalized charge ordered Fermi liquid at $V_{CO}$ and a metal-to-insulator transition at $V_{MI}$. Short range antiferromagnetism occurs concomitantly with the CO transition. Approaching the charge ordered insulator, $V$<$V_{MI}$, the Fermi surface deforms and the scattering rate of electrons develops momentum dependence on the Fermi surface.

5:06PM W12.00014 Exact steady state non-equilibrium DOS of the Hubbard model . ALEXANDER JOURA, JIM FREERICKS, Georgetown University, USA; THOMAS PRUSCHKE, University of Goettingen, Germany — Using a non-equilibrium Kadanoff-Baym-Keldysh formalism, we derive exact equations relating the retarded Green’s function to the retarded self-energy for lattice electrons in presence of a constant and uniform electric field $E$. Such an approach allows us to go beyond linear response theory and study the behavior of systems for arbitrarily large electric fields. We find that the conventional dynamical mean-field theory (DMFT) algorithm is the same as in equilibrium except for a significantly modified lattice Dyson equation which couples together frequencies separated by the Bloch frequency. We apply the method to the Hubbard model and solve the model within the DMFT framework. As an impurity solver, we employ the numerical renormalization group (NRG). We discuss how the density of states (DOS) evolves as the electric field strength $E$ and interaction strength $U$ change. In particular, when both $E \ll 1$ and $U \ll 1$ the DOS is a set of equally spaced peaks (the so-called Wannier-Stark ladder). Increasing $U$ leads to a broadening of the peaks, which finally merge and then evolve into a DOS that is quite similar to the equilibrium DOS. Increasing $E$ while keeping $U \ll 1$ splits the peaks, resulting in novel behavior for the DOS, which is reminiscent of a metal-insulator transition (but the system carries current).

5:18PM W12.00015 Mott transition and Universality at finite temperatures . STEFANOS PAPANIKOLAOU, University of Illinois, Urbana-Champaign, RAFAEL M. FERNANDES, Instituto de Fisica “Gleb Wataghin”, Universidade Estadual de Campinas and Laboratorio Nacional de Luz Sincrotron, Campinas, SP, Brazil, EDUARDO FRADKIN, PHILIP W. PHILLIPS, University of Illinois, Urbana-Champaign, JOERG SCHMALIAN, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, RASTKO SKNEPNEK, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — We consider the finite temperature Mott critical point which has been the subject of recent experimental investigation. We demonstrate that this critical point is in the Ising universality class, consistent with all available experimental data. We show that, even though the thermodynamic behavior of the system near such a critical point is described by an Ising order parameter, the global conductivity depends on other singular observables and, in particular, the energy density, leading to the emergence of multiple crossover regimes. Finally, we show that in the presence of weak disorder the dimensionality of the system has crucial effects on the size of the critical region that is probed experimentally. ArXiv:0710.1627 and in press at Physical Review Letters.

**Thursday, March 13, 2008 2:30PM - 5:18PM – Session W13 DCOMP: Quantum Monte Carlo** Morial Convention Center 204
2:30PM W13.00001 The Continuous Time Quantum Monte Carlo method as a cluster solver in the Dynamical Cluster Approximation, KARLIS MIKELSONS, ALEXANDRU MACRIDIN, MARK JARRELL, University of Cincinnati, EMANUEL GULL, MATTHIAS TROYER, ETH Zuerich, Switzerland, SEBASTIAN FUCHS, THOMAS PRUSCHKE, University of Goettingen, Germany — We have investigated the application of the Continuous Time Quantum Monte Carlo (CTQMC) method, based on interaction expansion, to solve the Hubbard model within the Dynamical Cluster Approximation (DCA). We show that CTQMC reproduces results obtained with the well known Hirsch - Fye method (HFQMC), including non-perturbative phenomena. We discuss the advantages and limitations of CTQMC as a cluster solver in the DCA. Since any QMC method suffers from fermion sign problem at low temperatures and large system sizes, we present the results of a detailed study of the sign problem within CTQMC, and compare it to HFQMC. We also discuss potential extensions of (CTQMC+DCA) for treating the phases with broken symmetry.

2:42PM W13.00002 Continuous-time method for quantum impurity models, EMANUEL GULL, ETH Zurich, PHILIPP WERNER, Columbia University, OLIVIER PARCOLLET, Service de Physique Theorique, CEA/DSM/SPHT-CNRS/SPM/URA, MATTHIAS TROYER, ETH Zuerich — We present a new continuous-time quantum Monte Carlo algorithm for quantum impurity problems. The method allows an efficient simulation of large cluster impurity models with density density coupling. We compare the computational effort and average sign to alternative quantum Monte Carlo approaches, such as the discrete-time Hirsch-Fye algorithm [J. E. Hirsch and R. M. Fye, Phys. Rev. Lett. 56, 2521 (1986)] and the weak coupling solver by Rubtsov, Savkin and Lichtenstein [Phys. Rev. B 72 035122 (2005)].

2:54PM W13.00003 Progress in the study of Molecular Hydrogen-Benzene binding†, TODD D. BEAUDET, MICHELE CASULA, JEONGNIM KIM, RICHARD M. MARTIN, University of Illinois at Urbana-Champaign — In this work we present a quantum Monte Carlo study of the hydrogen-benzene system where binding is very weak. We demonstrate that the binding is well described at both the VMC and DMC levels by a single determinant correlated geminal wave function1 with an optimized compact basis set that includes diffuse functions. Agreement between VMC and fixed node DMC binding energies is found to be within 0.16 mHa, suggesting the calculations are well-converged with respect to the basis. This relative insensitivity to basis set and superposition error is an advantage of the QMC methods we employ. Comparison is made with a Slater-Jastrow wave function at the DMC level using a trial function comprised of PBE single-body orbitals, empirical models and previous work2. The physical underpinnings of the interaction will be discussed including the role of diffuse basis functions in this system. Progress on systems where binding is expected to be more favorable for practical hydrogen storage will also be presented.

3:06PM W13.00004 Geometry optimization with a noisy potential energy surface, JEFFREY GROSS-MAN, LUCAS WAGNER, University of California, Berkeley — Molecular and solid systems in the excited state and in the weak-binding regime (for example) are often not described well by current density functional(DFT) methods, often leading to inaccurate minimum energy structures. Quantum Monte Carlo(QMC) is a tempting method to improve on these deficiencies, since it offers a highly accurate fully correlated first principles description. However, QMC suffers from two major deficiencies: 1) forces are not easily calculated and 2) the energy is obtained with stochastic uncertainty, which makes optimization a challenging task. We examine several ways of compensating for this uncertainty while only using the reliable total energies obtained in QMC.

3:18PM W13.00005 Quantum Monte Carlo calculations of NiO, RYO MAEZONO, Japan Advanced Institute of Science and Technology, Japan., MIKE D. TOWLER, RICHARD. J. NEEDS, TCM, Cavendish Laboratory, University of Cambridge, U.K. — We describe variational and diffusion quantum Monte Carlo (VMC and DMC) calculations [1] of NiO using a 1024-electron simulation cell. We have used a smooth, norm-conserving, Dirac-Fock pseudopotential [2] in our work. Our trial wave functions were of Slater-Jastrow form, containing orbitals generated in Gaussian-basis LHY periodic calculations. Jastrow factor is optimized using variance minimization with optimized cutoff lengths using the same scheme as our previous work. [4] We apply the lattice regulated scheme [5] to evaluate non-local pseudopotentials in DMC and find the scheme improves the smoothness of the energy-volume curve.

3:30PM W13.00006 Efficient orbital storage and evaluation for quantum Monte Carlo simulations of solids, KENNETH ESSLER, Carnegie Institution of Washington — Researchers have applied continuum quantum Monte Carlo methods to solids with great success, but thus far applications have been largely limited to crystals with simple geometry. In these simulations, three-dimensional cubic B-splines have proven to be a fast and accurate means of storing and evaluating electron orbitals. While B-splines require less memory than other spline interpolation schemes, modern cluster nodes often have insufficient memory to store the orbitals for more complex systems. We introduce three techniques, appropriate in different circumstances, to dramatically reduce the memory required for orbital storage, while retaining high accuracy: the generalized tiling of primitive-cell orbitals into a supercell of arbitrary shape, the use of nonuniform grids for localized orbitals, and the periodic replication of localized orbitals. We give examples for cubic boron nitride and wüstite (FeO), and show that these methods can reduce the memory used for orbital storage by more than two orders of magnitude. Finally, we introduce an open-source B-spline library to facilitate the incorporation of these methods into QMC simulation codes.

3:42PM W13.00007 Triplet pairings and fermion wave functions nodal topologies, LUBOS MITAS, MICHAL BAJDICH, SHUMING HU, North Carolina State University — Fixed-node quantum Monte Carlo methods rely on accurate fermion nodes of trial wave functions. Recently, we have shown that BCS wave functions possess for generic singlet ground states possess the correct minimal number of two nodal cells. This contrasts with the Hartree-Fock wave functions which exhibit higher counts of four or more nodal domains resulting in incorrect nodal topologies. We prove that for fully spin-polarized systems one can show the same effect. As a simple example, we consider the HF wave function for the lowest quartet of S symmetry and even parity for three electrons in a Coulomb potential. The wave function of this state $1S(1s2s\bar{3}s)$ has six nodal cells corresponding to $3!$ reordering of the radii. We show that paffian with triplet pairings is the simplest wave function which has the correct topology with two nodal cells. We further expand the study to some exactly solvable models to study the exact nodal structures dependence on potentials.
3:54PM W13.00008 Compact and accurate quantum Monte Carlo wave functions for first-row atoms\textsuperscript{1}. F. R. PETRZIELO, LASSP, Cornell University, JULIEN TOULOUSE, Universite Pierre et Marie Curie, Paris, France, W. A. AL-SAIDI, C. J. UMRIGAR, LASSP, Cornell University, R. G. HENNIG, Materials Science and Engineering, Cornell University — Many-body wave functions for the first row atoms (Li to Ne) are represented as expansions in eigenstates of $L^2, L_z, S^2, S_z$ multiplied by a Jastrow factor. This configuration state function (CSF) expansion provides a systematic means for improving a wave function by including CSFs corresponding to higher excitations. Optimization of all wave function parameters including Jastrow, CSF and orbital coefficients as well as basis exponents, starting from a simple initial guess, results in compact and accurate wave functions (low energy and variance of local energy). Further improvements by use of backflow transformations are explored. This work aims to develop insight into selecting the relevant CSFs particularly for large systems, where it is difficult to include all CSFs to a given order.

4:06PM W13.00009 A DQMC study of cohesion energy of small Li clusters based on an RVB nodal structure\textsuperscript{1}. DANIEL NISSENBAUM, Northeastern University, LEONARDO SPANU, UC Davis and SISSA, Italy, CLAUDIO ATTACALITE, SISSA, Italy, BERNARDO BARBIELLINI, ARUN BANSIL, Northeastern University — We have carried out a diffusion Quantum Monte Carlo study (DQMC) of the cohesion energy of small (2, 4, and 8 atom) Li clusters based on Resonating Valence Bond (RVB) wavefunctions, and compared the results to the corresponding values obtained via wavefunctions utilizing a typical Hartree-Fock (HF) nodal structure (Jastrow-Slater wavefunctions). The RVB wavefunction allows more flexibility in the nodal structure than the HF wavefunction, and yields some improvement in the cohesion energy of Li$_2$, with comparable gain for the larger clusters. Interestingly, the variance of the local energy for the variationally optimized (VQMC) RVB wavefunction is found to be significantly smaller than for the VQMC-optimized Jastrow-Slater wavefunction, resulting in faster convergence of the DQMC calculations. This would make the RVB wavefunction a promising candidate for investigating larger and more complicated clusters.

4:18PM W13.00010 An Improved Pressure Estimator for quantum Monte Carlo\textsuperscript{1}. JEREMY MCMINIS, JEONGNIM KIM, DAVID CEPERLEY, Department of Physics, University of Illinois, CARLO PIERLEONI, Department of Physics, University of L’Aquila — Assaraf and Caffarel have developed a systematic method for deriving reduced variance estimators for observables for quantum Monte Carlo calculations and have applied to forces[1], the one body density and the spherical and system averaged pair density. It has yet to be applied to a thermodynamic observable. In this work we derive an expression for an improved pressure estimator for use in variational Monte Carlo and diffusion Monte Carlo calculations. We show that because the dependence of the trial wave function on the density is known, for the homogeneous electron gas this new estimator is accurate and efficient to implement. We discuss its application to many-body Hydrogen at high pressure. [1] Roland Assaraf and Michel Caffarel, J. Chem. Phys. 113, 4028 (2000)

\textsuperscript{1}The work performed at the Materials Computation Center was supported by the National Science Foundation under grant no. DMR-03 25939 ITR, and through the Frederick Seitz Materials Research Laboratory (U.S. Dept. of Energy grant no. DEFG02-91ER45439).

4:30PM W13.00011 The Model Periodic Coulomb interaction in k-space: modelling the spherically averaged structure factor. RENE GAUDOIN. Donostia International Physics Center (DIPC), Manuel de Lardizabal Pasealeku, E-20018 Donostia, Basque Country, Spain, IDOIA GURTUBAY, Materia Kondentsatuaren Fisika Saila, Zientzia eta Teknologia Fakultatea, Euskal Herririo Unibertsitatea, PO 644, E-48080 Bilbo, Basque Country, Spain, TXEMA PITARKE, CIIC nanGUNE Consolider, Mikeltegi Pasealeku 56, E-2009 Donostia, Basque Country, Spain — Within Quantum Monte Carlo (QMC) calculations the Model Periodic Coulomb (MPC) interaction is a well known method to reduce finite size effects related to the long range nature of the Coulomb interaction. Recently we presented a method based on modelling the continuous-k spherically averaged structure factor (SF) to understand and reduce Coulomb finite size effects. Here we show that our SF based method can be viewed as k-resolved MPC. This allows us to analyse the implicit assumptions that underlie MPC and what to do when these assumptions are not justified, i.e. in non-interaction Hartree-Fock systems or even surfaces. While we present data for the homogeneous electron gas the method itself is general.

4:42PM W13.00012 Backflow transformation improves QMC calculations of silicon self-interstitial defects\textsuperscript{1}. WILLIAM D. PARKER, KEVIN P. DRIVER, JOHN W. WILKINS, Ohio State University, RICHARD G. HENNIG, Cornell University — Recent advances in quantum Monte Carlo (QMC) reduce error introduced by approximations. Direct improvement of the trial wave function through backflow transformation of the electron coordinates\textsuperscript{1} produces a wave function closer to the ground state by moving electrons out of the way of a given electron. Adding plane waves of particle position to the Jastrow factor\textsuperscript{2} augments the accounting for interparticle correlation in QMC calculations by capturing the “corners” of the simulation cell neglected when the Jastrow is only a function of pair separation. Hybrid density functionals have produced better starting trial wave functions for molecules by incorporating some exact exchange to more accurately describe electron-electron interactions. We apply backflow transformation, plane-wave-expanded Jastrow factors and hybrid functional trial wave functions to QMC calculations of silicon self-interstitial defects. [1] Lopez-Rios et al., Phys. Rev. E 74, 066701 (2006). [2] Drummond et al., Phys. Rev. B 70, 235119 (2004).

4:54PM W13.00013 Density Dependence of Fixed-Node Errors. KEVIN RASCH, LUBOS MITAS, Center for High Performance Simulation, Dept of Physics, North Carolina State University — With both variational and diffusion Monte Carlo (VMC and DMC) methods, we calculate the ground state energy of isoelectronic free ions in the first row of the periodic table for both Hartree-Fock and Configuration Interaction based trial wave functions. As it is well-known, the fixed-node DMC is exact in the limit that the fermion nodes of the trial wave function are also exact. This study is focused on understanding the density dependence of the fixed-node error since one expects that with increasing density of electrons the errors would be more pronounced due to higher frequency of sampling of the nodal regions and/or areas with low potential energy. For this purpose we construct Hartree-Fock and multi-reference wave functions and quantify the fixed-node biases. We compare strongly bonded highly localized cations, neutral atoms and weakly bonded anions. We compare the absolute and relative sizes of fixed-node errors and their relationships to multi-reference wave functions.

5:06PM W13.00014 Slater determinant and pfaffian expansions for wave functions in electronic structure quantum Monte Carlo. MICHAL BAJDICH, LUBOS MITAS, CHIPS, Department of Physics, North Carolina State University — We investigate several types of expansions in Slater determinants and pfaffians for trial wave functions in fixed-node quantum Monte Carlo. The long expansions in determinants are analyzed in order to identify the terms with the largest contributions towards decreasing the fixed-node errors. We further investigate the efficient mapping of these terms onto pfaffian expansions. We apply this technique to test the cases of molecular and atomic systems and we discuss the amounts of recovered correlation energy relative to the expansion size. Finally, following upon our previous study [1], we explore how multiple Slater determinants and pfaffians for the accurate description of the wave functions of simple solids. [1] M. Bajdich et al. Phys. Rev. Lett. 96, 130201 (2006).
Quantum analysis of nonlinear beam splitter with second order nonlinearity.

W-system fields leads to the formation of a new type of EIT system: a Bose-Einstein condensate (BEC) trapped in a double well potential. A weak probe propagates through one of the wells and interacts with atoms in a three-level coherent superposition of its center–of–mass motion, if the wavelength is comparable to the well separation and if the external state of the atom is post-selected.

Simultaneously used for slowing down and generating higher vibrational states, but beyond the Lamb-Dicke regime concerning the tunneling split groundstate. The first case leads to an extended Jaynes-Cummings model which can be solved exactly. We show that the coupling between internal and external degrees of freedom of the atom induced by the cavity mode can provide a coherent coupling between identical electronic states in the two wells that leads to the formation of inter-well dressed states.

The inter-well coupling results in the formation of two ultra-narrow absorption resonances for the probe field that are inside of the ordinary EIT transparency window, which can be interpreted in terms of the inter-well dressed states and the formation of a novel type of dark state involving the coupling laser and the inter-well tunneling. To either side of these ultra-narrow resonances there is normal dispersion with ultra-large slope controlled by $g$. For realistic values of $g$, the large slope of this dispersion yields group velocities for the probe field that are two orders of magnitude slower than standard EIT systems. Additionally, we discuss the effects of the inter-well coupling on the nonlinear susceptibility, $\chi^{(3)}$.

Electromagnetically-induced transparency (EIT) in a four-level atom system

By turning off one of the two probe fields, a standard EIT behavior can be recognized in two independent V-systems. Our novel EIT technique is applied to ultra-cold Mg atoms in low-lying states. The density matrix formalism is employed for finding coherences between Zeeman levels of the upper $\text{^1P}_1$ state in our W-system. Solving the master equation for a population-trapped four-level atom system and assuming a zero population density on the Zeeman levels of the $\text{^1P}_1$ state give atomic susceptibilities for the dark states associated to the two probe fields. The analysis of the EIT behavior in our W-system is done by varying (1) the Rabi frequencies for the triplet state and (2) the detuning of the two probe lasers. The dependence of the EIT features with the B-field is also discussed.

Coherent optical spectroscopy of a strongly coupled semiconductor microcavity quantum-dot system

We describe recent experiments in which a fiber taper waveguide is used to perform steady-state coherent linear and nonlinear optical spectroscopy of a strongly coupled microcavity–QD system, probing the system on its photonic channel (rather than its matter channel, as in PL). Under weak driving, vacuum Rabi splitting is observed, while increasing the drive strength reveals saturation for an average intracavity photon number of less than one. (1) K. Srinivasan and O. Painter (2007), to appear in Nature, Dec. 6, 2007 (preprint: physics/0707.3311).

Monitoring electron spin decoherence in a quantum dot by weak measurement

This work was supported by Hong Kong RGC Project 2160322

Spontaneous emission from a tunneling atom

We study the tunneling of a two-level atom in a double well potential in which the atom couples either to a single electromagnetic field mode of a cavity to the full continuum of electromagnetic modes in three dimensions. Both studies are within the Lamb-Dicke regime concerning transitions to higher vibrational states, but beyond the Lamb-Dicke regime concerning the tunneling split groundstate. The first case leads to an extended Jaynes-Cummings model which can be solved exactly. We show that the coupling between internal and external degrees of freedom of the atom induced by the cavity mode can dramatically change the tunneling behavior. In general the tunneling process becomes quasiperiodic. If the cavity is fed with a coherent state, a collapse and revival of the tunneling can occur. Accessing the internal degrees of freedom of the atom with a laser allows to coherently manipulate the atom position, and in particular to prepare the atom in one of the two wells. In the second case, the tunneling process may decohere, depending on the wavelength corresponding to the internal transition and on the spontaneous emission rate. Interference fringes appear in the emitted light from a tunneling atom, or an atom in a stationary coherent superposition of its center–of–mass motion, if the wavelength is compatible to the well separation and if the external state of the atom is post-selected.

Session W14 DAMOP: Quantum Optics Morial Convention Center 205
3:42PM W14.00007 Single photon nonlinearities using arrays of cold polar molecules, T. BRAGDON, R. M. RAJAPAKSE, University of Connecticut, A. M. REY, ITAMP, S. F. YELIN, University of Connecticut, ITAMP — We model single photon nonlinearity via dipole-dipole interaction in cold polar molecules using the protected Dicke-like symmetric manifold for potential optical quantum computation processing. We report on potential decoherences described by phonon dispersion, spontaneous, and stimulated decays. We compare to individually addressed molecules from previous work, and discuss briefly the feasibility in optical quantum computation processing as an element of a controlled-Z gate.

3:54PM W14.00008 Fermionization of strongly interacting photons in one-dimensional nonlinear medium, DARRICK CHANG, VLADIMIR GRITSEV, Harvard University, GIOVANNA MORIGI, University of Barcelona, VLADAN VULETIC, MIT, MIKHAIL LUKIN, EUGENE DEMLER, Harvard University — Understanding strongly correlated quantum systems is a central problem in many areas of physics. The collective behavior of interacting particles gives rise to a variety of phenomena such as condensation in quantum chromodynamics, spontaneous symmetry breaking and phase transitions, and electron fractionalization in one dimensional systems and in the quantum Hall regime. While such systems typically involve strongly interacting massive particles, optical photons can also interact with each other in a nonlinear medium. In practice, however, such interactions are typically very weak. We describe a novel technique that allows the creation of a strongly correlated quantum gas of photons, which is made possible by the tight field confinement that can be achieved in a number of novel, one-dimensional optical systems. This confinement enables the generation of large optical nonlinearities via the interaction of photons with a nearby cold atomic gas, which can be further amplified by an optical Bragg grating that traps these photons within the medium. In its extreme, we show that a quantum light field can undergo fermionization in such one-dimensional media, which can be probed via standard photon correlation measurements. Realization of such systems can open a route for quantum simulators of matter Hamiltonians using light fields and novel applications in metrology and quantum information.

4:06PM W14.00009 Entangled-photon absorption in semiconductor nanostructures, FELIPE VALLEJO, LUIS QUIROGA, Universidad de los Andes — We present a comparative study of two-photon absorption by semiconductor nanostructures for two kind of light: (i) Light with wave-like classical properties (laser light) and (ii) A new type of quantum entangled light. First, we report on results concerning entangled-photon absorption processes due to a novel class of collisional processes in coreshell quantum dots. Second, we use the framework of the effective-mass approximation both the classical as well as the entangled two-photon absorption in quantum wells (QWs) and quantum wires (QWRs) have been addressed. Results for non-entangled light with polarization both parallel and perpendicular to the directions of confinement are in perfect agreement with the ones already known. We proceed to extend those results to the less explored case of entangled light absorption in semiconductor nanostructures. The absorption spectra for entangled light is richer in structure and complexity as compared with the classical light class. We find that the absorption rate (cross-section) for entangled light depends additionally on a new important parameter, the entanglement time $T_e$, which gives rise to quantum interference effects. As a result, entangled photons produce entangled-induced transparencies.

4:18PM W14.00010 Photon Tunneling Through Dielectric Bandgaps and Evanescent Gaps, NATALIA RUTTER, SERGEY POLYAKOV, PAUL LETT, ALAN MIGDALL, NIST, Gaithersburg, MD — We implement an optical tunneling testbed using the precise simultaneity of creation of twin photons produced by parametric down conversion and a Hong-Ou-Mandel interferometer. With this setup, we can measure photon traversal times of a sample with fs precision. We use this setup to compare the time for a photon to traverse dielectric stacks of odd versus even numbers of layers of alternating indexes of refraction. Preliminary data shows that subtle changes in the stack structure result in dramatic variations in photon traversal times ($\sim 10$ fs) that can range from sub- to super-luminal. Our ultimate goal is to use this setup to investigate photon tunneling times in regions of true evanescent propagation and compare them to the traversal times in our dielectric stack bandgap samples where the propagation is oscillatory. This allows us to test the suitability of certain optical models of tunneling and highlight the pitfalls that occur when relying on conditional measurements.

4:30PM W14.00011 Nonlinear wave scattering by small barrier potentials, WENJIE WAN, JASON W. FLEISCHER, Princeton University — Scattering by a barrier potential is a fundamental problem in wave physics, involving issues of boundary conditions, resonances, radiation, etc. While scattering in the linear case is well-known, the nonlinear case has received far less attention. In the nonlinear regime, self-interaction affects tunneling and re-radiation dynamics, often leading to new topological structures (e.g. dark solitons and vortices). Examples include molecules of both quantum and classical systems, plasmons, and nonlinear optics. Here, we focus on the optical case by considering plane-wave scattering from an optically-induced barrier potential (step index) inside a photorefractive crystal. We experimentally demonstrate shock wave formation (dark soliton trains) in 1D and vortex generation in 2D, as a function of barrier height and input wave angle. We show numerically that these results arise from a combination of tunneling, scattering, and Optical superflow around the boundary. Applications both within and beyond optics will be discussed.

4:42PM W14.00012 Photon localization and Dicke superradiance in atomic gases: crossover to a “small world” network, ERIC AKKERMANS, Technion and Yale University, AHARON GEROS, Technion, ROBIN KAISER, Nice University — We study photon propagation in a gas of $N$ atoms, using an effective Hamiltonian that accounts for photon mediated atomic dipolar interactions. The configuration average density $P(\Gamma)$ of photon escape rates is obtained from the spectrum of the $N \times N$ random matrix $\Gamma_{ij} = \sin(x_{ij})/x_{ij}$, where $x_{ij}$ is the dimensionless random distance between the $i$th and $j$th atoms. A scaling function is defined to study photons escape rates as a function of disorder and system size. We show that for a strong enough disorder, photons do not escape the gas. This localization is described using a mapping of this problem onto statistical properties of random networks. We show that there is no localization phase transition as expected in disordered systems typically involving strongly interacting massive particles, optical photons can also interact with each other in a nonlinear medium. In practice, however, such interactions are typically very weak. We describe a novel technique that allows the creation of a strongly correlated quantum gas of photons, which is made possible by the tight field confinement that can be achieved in a number of novel, one-dimensional optical systems. This confinement enables the generation of large optical nonlinearities via the interaction of photons with a nearby cold atomic gas, which can be further amplified by an optical Bragg grating that traps these photons within the medium. In its extreme, we show that a quantum light field can undergo fermionization in such one-dimensional media, which can be probed via standard photon correlation measurements. Realization of such systems can open a route for quantum simulators of matter Hamiltonians using light fields and novel applications in metrology and quantum information.

4:54PM W14.00013 Fermi two atom problem in extended Fredrichs-Lee Model, KAVAN MODI, JAMES ZABEL, GEORGE SUDARSHAN, The University of Texas at Austin — In 1932 Fermi calculated the time required for excitation transition between two atoms. He found the minimum time to be the distance between the atoms divided by the speed of light. Recently, Hegerfeldt, using a very basic argument of analyticity of the wavefunction, showed that the excitation amplitude of the second atom must be finite for all times or zero for all times. We are studying this problem in detail using a modified Fredrichs-Lee model where two discrete states are connected by a continuum. We can solve for the transition amplitude exactly in our model, without assuming that a photon is the mediator between the two discrete modes. Our model should shed some light on the conceptual difficulties that have bothered the community for long.

Thursday, March 13, 2008 2:30PM - 5:18PM — Session W15 GQI: Quantum Entanglement II, Morial Convention Center 207
2:30PM W15.00001 Experimental demonstration of anyonic statistics with multichain entanglement.  
HARALD WEINFURTER, WITLEF WIECZOREK, CHRISTIAN SCHMID, NIKOLAI KIESEL, REINHOLD Pohlner,  
University of Munich, Max-Planck-Institute for Quantum Optics, Germany, JIANNIS PACHOS, University of Leeds, UK — Particles in nature are usually distinguished  
according to their statistics in two categories: bosons and fermions. However, if one considers only two spatial dimensions statistical behaviour ranging from  
bosonic to fermionic is found. Particles exhibiting such a behaviour are called anyons. Our experimental demonstration of anyonic statistics is based on a  
particular two-dimensional model: the toric code proposed by Kitaev [1]. There, anyons arise as excitations that are generated by local operations. We show  
that for this model anyonic behaviour is revealed for as little as four qubits [2]. This enabled us to experimentally demonstrate anyonic statistics in a quantum  
simulation with four-phonon entanglement.

2:42PM W15.00002 Entanglement entropy and other observables of topological phases with  
finite correlation length. STEFANOS PAPANIKOLAOU, University of Illinois, Urbana-Champaign, KUMAR S. RAMAN, University of California,  
Riverside, EDUARDO FRADKIN, University of Illinois, Urbana-Champaign — We elucidate the topological features of the entanglement entropy of a region in  
two dimensional quantum systems with a finite correlation length. Firstly, we suggest that simpler reduced quantities, related to the von Neumann entropy, could be  
deﬁned to compute the topological entropy. We use our methods to compute the entanglement entropy for the ground state wave function of a quantum  
eight-vertex model in its topological phase, and show that a finite correlation length adds corrections of the same order as the topological entropy which come  
from sharp features of the boundary of the region under study. We also calculate the topological entropy for the ground state of the quantum dimer model on a  
triangular lattice by using a mapping to a loop model. The topological entropy of the state is determined by loop conﬁgurations with a non-trivial winding  
umber around the region under study. Finally, we consider extensions of the Kitaev wave function, which incorporate the effects of electric and magnetic charge  
ﬂuctuations, and use it to investigate the stability of the topological phase by calculating the topological entropy. arXiv: 0709.0729

2:54PM W15.00003 Valence-Bond Monte Carlo for Chains of Non-Abelian Quasiparticles. HUAN  
TRAN, NICK BONESTEEL, Department of Physics and NHMFL, Florida State University — In non-Abelian FQH states, quasiparticles carry quantum numbers  
(topological charge) which characterize a degenerate Hilbert space. When these quasiparticles are close enough together, the degeneracy of this Hilbert space is  
lifted and the quasiparticles are said to interact. Here we show that the valence-bond Monte Carlo method introduced by Sandvik for spin-1/2 systems can be  
generalized to simulate 1D chains of such interacting non-Abelian quasiparticles. For uniform chains, our Monte Carlo results for the ground state energy agree  
with known exact values. For random chains we conﬁrm numerically that, as expected, the ground state freezes into a random singlet phase. By suitably  
generalizing the notion of valence-bond entanglement entropy to the non-Abelian case we also conﬁrm the predicted result that in this phase the entropy of a  
block of length L scales as $S_L \sim \frac{d}{\ln L}$, where $d$ is the quantum dimension of the quasiparticles. Work supported by US DOE.

3:06PM W15.00004 Geometry of metal-insulator transitions in one-dimension. NOAH BRAY-ALI,  
University of Southern California, LORENZO CAMPOS VENUTI, Quantum Information Group, Institute for Scientific Interchange (ISI), Viale Settimio Severo  
65, I-10133 Torino, Italy, MARCO COZZINI, Dipartimento di Fisica, Politecnico di Torino, Corso Duca degli Abruzzi 24, I-10129 Torino, Italy, Quantum  
Information Group, Institute for Scientific, PAOLO ZANARDI, Quantum Information Group, Institute for Scientific Interchange (ISI), Viale Settimio Severo 65,  
I-10133 Torino, Italy, Univ. of Southern Califor. — We use the geometric approach to quantum critical points to study the metal-insulator transitions driven by  
chemical potential, or repulsion, $U$, in the one-dimensional Hubbard model. The transition to the band-insulator, as $U \rightarrow U_c$, exhibits conventional scaling  
of the ground-state fidelity metric tensor $G_{\mu,\nu} \equiv \text{Re} \left[ \langle \partial_\mu \psi \partial_\nu \psi \rangle - \langle \partial_\mu \psi \rangle \langle \partial_\nu \psi \rangle \right]$. For example, the metric diverges as $G_{U/V} \sim 1/n$, where, $n \sim \sqrt{U-U_c}$,  
is the band filling. At the Mott transition, the metric behavior depends on the path of approach to the critical point.

3:18PM W15.00005 Topological order at finite temperature: protected or not protected?  
CLAUDIO CASTELNOVO, University of Oxford, CLAUDIO CHAMON, Boston University — We investigate the behavior of the entanglement and topological  
order in the two- and three-dimensional toric code at finite temperature. From our results, we infer that quantum topological order is fragile with respect to  
thermal fluctuations in spite of the presence of a finite energy gap at zero temperature. In two dimensions, all topological order evaporates at any non-vanishing  
temperature in the thermodynamic limit. On the contrary, in three dimensions not all topological information is lost, although the topologically protected  
quantum information (qubit) stored in the ground state of the system is immediately degraded to topologically protected classical probabilistic information (pbit)  
at any infinitesimal temperature, in the thermodynamic limit. All information is eventually lost beyond a finite temperature phase transition. We comment on  
the implications of our results with respect to braiding operations and topological quantum computing.

3:30PM W15.00006 Long distance entanglement mediated by gapped spin chains. AIORES FERREIRA,  
JOAO LOPES DOS SANTOS, CFP and Dept Fisica, Faculdade de Ciencias da Universidade do Porto — This talk will describe an analytical approach for the  
computation of Long Distance Entanglement (LDE) mediated through one-dimensional quantum spin chains recently found in numerical studies [1]. I review  
the formalism that allows the computation of LDE for weakly interacting probes with gapped many-body systems and show that, at zero temperature, a DC  
response function determines the ability of the physical system to develop genuine quantum correlations between the probes. In the second part of the talk, I  
show that the biquadratic Heisenberg spin-1 chain is able to produce LDE in the thermodynamical limit and that the finite antiferromagnetic Heisenberg chain  
maximally entangles two spin-1/2 probes very far apart. This is of crucial importance since feasible mechanisms of entanglement extraction from real solid state  
systems and their ability to transfer entanglement between distant parties are essential ingredients for the implementation of Quantum Information protocols,  
such as teleportation or superdense coding.

3:42PM W15.00007 Entanglement of Impurities in Spin Chains1, ERIK SORENSEN, McMaster, NICOLAS LAFORENCIE, UP-sud, MING-SHYANG CHANG, IAN AFFLECK, UBC — Entanglement in $J_1 - J_2$, $S = 1/2$ quantum spin chains with an impurity is studied using analytic methods as well as large scale numerical density matrix renormalization group methods. The impurity contribution to the uniform part of the entanglement entropy, $S_{imp}$, is defined and analyzed in detail both in the gapless, $J_2 \leq J_1$, as well as the dimerized phase, $J_2 > J_1$, of the model. This quantum impurity model is in the universality class of the single channel Kondo model and we show that in a quite universal way the presence of the impurity in the gapless phase, $J_2 \leq J_1$, gives rise to a large length scale, $\xi_K$, associated with the screening of the impurity, the size of the Kondo screening cloud. The universality of the Kondo screening imprints scale of the form $S_{imp}(L)/S_{Kondo}(L)$ for a system of size $L$. At the critical point, $J_2^c$, an analytic approach based on a Fermi liquid picture, valid at distances $r \gg \xi_K$ and energy scales $T < T_K$, is developed and analytic results at $T = 0$ and $T \neq 0$ are obtained. In the dimerized phase an appealing picture of the entanglement is developed in terms of a thin soliton (TS) ansatz permitting variational calculations and the notions of impurity valence bonds (IVB) and single particle entanglement (SPE) are introduced.

1We acknowledge support from NSERC, CIAR, CFI and SHARCNET.

3:54PM W15.00008 Entanglement Entropy of States with Long-Range Magnetic Order, WENXIN DING, NICHOLAS BONESTEEL, KUN YANG, FSU & NHMFL — We study the bipartite entanglement entropy of spin models whose ground states have perfect ferromagnetic (FM) or antiferromagnetic (AFM) long-range order. For the FM case the entanglement entropy is taken to be one-half the quantum mutual information so as to properly take into account the ground state degeneracy. The calculation of the entropy for this case is then straightforward and agrees with previous work using a different approach. For the AFM case the problem is reduced to that of four coupled spins. This simplification allows us to determine the asymptotic behavior of the entropy analytically with results which agree well with exact numerical calculations. In both the FM and AFM cases we find the entropy grows logarithmically with block size, $N_1$. For example, if we take $N_1 = N/2$, where $N$ is the total number of spins, then in the FM case the entropy, $E$, scales as $E \approx \frac{1}{2} \ln N_1$, and in the AFM case, $E \approx \ln N_1$. In both cases the area law is clearly violated. Implications of these results for more general states with long range order are also discussed.

4:06PM W15.00009 Entanglement Entropy in the Two-Dimensional Random Transverse Field Ising Model1, STEPHAN HAAS, Department of Physics and Astronomy, University of Southern California, RONG YU, Department of Physics and Astronomy, University of Southern California and Department of Physics, University of Tennessee, HUBERT SALEUR, Service de Physique Theorique, CEN Saclay, Gif Sur Yvette, F-91191, France — We have applied the numerical strong disordered renormalization group method to the two-dimensional random transverse field Ising model, and studied the scaling behavior of the entanglement entropy. The leading term of the entanglement entropy scales linearly with the block size, following the so-called area law. However, besides this area law contribution, a subleading logarithmic correction at the quantum critical point is resolved. This correction is understood from the point of view of an underlying percolation transition, both at finite and at zero temperature.

4:18PM W15.00010 Entanglement Entropy and Complexity in Random Systems1, RODRIGUEZ-LAGUINA JAVIER, Mathematics Dept, Universidad Carlos III, Madrid (Spain) — Entanglement is considered to be the hallmark of quantum physics, and entanglement entropy (EE) is one of its most natural measurements. Its utility as a marker for quantum criticality for random systems is well established. Recently, it has been shown that the scaling of the running-time in some quantum annealing methods is also related to it. In this work we show how the behaviour of this magnitude in some random systems can provide insight about the complexity of the structure of their quantum critical points. Moreover, we provide some hints that point towards a relation between the behaviour of the EE and the complexity class of classical problems. References: J. Rodriguez-Laguna, J. Phys. A: Math. Theor. 40, 12043 (2007), and JSTAT P05008 (2007).

4:30PM W15.00011 Entanglement Entropy Scaling in the Disordered Golden Chain, LUKASZ FIDKOWSKI, GIL REFAI, Caltech, NICK BONESTEEL, KUN YANG, FSU, JOEL MOORE, Berkeley — For pure critical spin chains, the scaling of the entanglement entropy of a region of size $L$ with its complement is proportional to $\log L$ with the constant of proportionality being the central charge of the associated conformal field theory. Certain strongly disordered spin chains exhibit critical points with similar $\log L$ scaling. Here we study the disordered golden chain (modeled by fibonacci anyons), and show that the usual random singlet critical point achieved with random antiferromagnetic (AFM) couplings is unstable to ferromagnetic (FM) perturbations. We identify the new mixed FM-AFM fixed point and compute its entanglement entropy scaling.

4:42PM W15.00012 Quantum Ergodicity and the Dynamical Generation of Entanglement in Kicked Coupled Tops, COLLIN TRAIL, VAIBHAV MADHOK, IVAN DEUTSCH, SHOHINI GHOSE, LEIGH NORRIS, ARJENDU PATTANAYAK — We explain how the long-time average dynamically generated entanglement in a Hamiltonian bipartite system is related to the corresponding classical dynamics in the semiclassical limit. Where classical dynamics is chaotic, ergodic mixing leads to the generation of “random quantum states.” These states possess the typical entanglement of a state randomly sampled from the appropriate Hilbert space under the unitarily invariant Haar measure. We exemplify these results using a system of coupled kicked-tops in which entanglement and chaos arise from the same physical effect in contrast to previous studies. We present quantitative predictions of the dynamically generated entanglement, which is influenced by the time symmetries of the system and the structure of the Hilbert space, under a variety of different conditions, and show a close fit to numerical simulations.

5:06PM W15.00014 Few-electron anisotropic quantum dots in low magnetic fields: exact-diagonalization results for excitations, spin configurations, and entanglement

CONSTANTINE YANNOULEAS, UZI LANDMAN, School of Physics, Georgia Institute of Technology — Following earlier studies for $N = 2 - 6$ electrons in anisotropic quantum dots, covering a broad range of confinement anisotropies and strength of inter-electron repulsion, will be presented for zero and low magnetic fields. The excitation spectra are analyzed as a function of the magnetic field and of quantum-dot anisotropy. Analysis of the many-body wave functions through spin-resolved two-point correlations reveals that the electrons tend to localize forming Wigner molecules (WMs). For strong anisotropy, the WMs acquire a linear geometry, and the wave functions with a total spin projection $S_z = (N - 2)/2$ are similar to the strongly entangled $W$ states. For intermediate anisotropy, the WMs exhibit a more complex structure. The degree of entanglement can be quantified through the use of the von Neumann entropy.

Session W16 DBP: Focus Session: Novel Biomedical Techniques

Morial Convention Center 208

2:30PM W16.00001 Novel Radiation Sources Based on Ultra-High-Power Lasers: New Capabilities for Radiology and Radiotherapy

DONALD UMSTADTER, University of Nebraska, Lincoln — As the maximum power level of compact lasers steadily increases, new opportunities are enabled for their use in bio-medicine and medicine. For instance, the Diocles laser at the University of Nebraska, Lincoln, now produces a peak power of 150-terawatts ($1.5 \times 10^{14}$ W) from a table-top-size system. When light at this power level is focused, it can accelerate electrons, and produce quasi-monoeenergetic beams of x-rays, similar to those produced by much larger synchrotron light sources. Such MeV-energy beams create new opportunities in biomedicine, radiology and radiography. Examples to be discussed include structural analysis of bio-molecules, diffraction-enhanced imaging for computed tomography, and radio-sensitization-enhanced radiotherapy. This talk will describe the current status of laser-based x-ray technology, as well as the potential advantages and prospects for their use in medicine.

1 Supported by AFOSR, DARPA, DHS, DOE and NSF.

3:06PM W16.00002 New techniques required to understand the by-stander effect in situ.

RICHARD BRITTEN, Eastern Virginia Medical School — The bystander effect has been known for nearly a century under various names, of which the abscopal effect is probably the most well known. More recently the by-stander effect has received a lot of attention, and various models have been developed to assess the relative importance of the bystander effect in radiation treatment. It is clear that irradiated cells release factors that lead to alterations in the physiology of adjacent irradiated cells, both via inter-cellular junctions and through systemic factors. Most studies that have sought to identify the systemic factors and the cellular mechanisms that are responsible for the bystander effect have by necessity used in vitro systems. The purpose of this presentation is to alert the audience to the various techniques that are available to study the proteomic changes related to the bystander effect in situ. We shall pay attention to the use of MALDI-imaging to track spatial proteomic changes in tissue that have been exposed to microbeams.

3:42PM W16.00003 The Physics of Up-Conversion Nanophosphors for Cancer Treatment

SHUANG-FANG LIM, WILLIAM RYU, Princeton University, ROBERT RIEHN, North Carolina State University, ROBERT AUSTIN, Princeton University — Upconversion phosphors are rare-earth containing crystalline materials which can convert infrared light to visible light (hence the name up-conversion), via excitation of real levels of rare earths. They overcome limitations of current organic fluorophors and quantum dots and have unique properties that enable advanced imaging, drug delivery applications and light-based chemotherapy. The process by which near-IR photons (980 nm) are summed in a rare-earth excitation of real levels of rare earths. They overcome limitations of current organic fluorophors and quantum dots and have unique properties that enable advanced imaging, drug delivery applications and light-based chemotherapy. The purpose of this presentation is to alert the audience to the various techniques that are available to study the proteomic changes related to the bystander effect in situ. We shall pay attention to the use of MALDI-imaging to track spatial proteomic changes in tissue that have been exposed to microbeams.

3:54PM W16.00004 Disposal of Energy by UV-B Sunscreens

THOMAS NORDLUND, Dept. of Physics, Univ. of Alabama/Birmingham, RAJAGOPAL KRISHNAN, Dept. of Dermatol., Univ. of California/SF — Ideal sunscreens absorb dangerous UV light and dispose of the energy safely. “Safe disposal” usually means conversion to heat. However, efficient absorption entails a high radiative rate, which implies high energy-transfer capabilities for Radiology and Radiotherapy. When light at a power level is focused, it can accelerate electrons, and produce quasi-monoeenergetic beams of x-rays, similar to those produced by much larger synchrotron light sources. Such MeV-energy beams create new opportunities in biomedicine, radiology and radiography. Examples to be discussed include structural analysis of bio-molecules, diffraction-enhanced imaging for computed tomography, and radio-sensitization-enhanced radiotherapy. This talk will describe the current status of laser-based x-ray technology, as well as the potential advantages and prospects for their use in medicine.

4:06PM W16.00005 Microdosimetry of onidividual cells with microbeam facilities

PAUL GUEYE, Hampton University — This abstract has not been submitted.

4:42PM W16.00006 Dynamical Systems, Cytokine Storms, and Blood Filtration

GLENN FOSTER, ALFRED HUBLER, Center for Complex Systems Research, University of Illinois at Urbana-Champaign, Department of Physics — Various infections and non-infectious diseases can trigger immune cells and the proteins (cytokines) the cells use to communicate with each other to be caught in a positive feedback loop; this “cytokine storm” is frequently fatal. By examining the network of cytokine-immune cell interactions we will illustrate why anti-mediator drugs have been generally ineffective in stopping this feedback. A more effective approach may be to try and reduce interactions by dampening many signals at once by filtering the cytokines out of the blood directly (think dialysis). We will argue that feedback on an out of control nonlinear dynamical system is easier to understand than its normal healthy state and apply filtration to a toy model of immune response.
4:54PM W16.00007 Differentiation of benign epithelia, prostatic intraepithelial neoplasia and, stromal region of prostate biopsies using Raman spectroscopy, HOUBEI DAI, JAGDISH THAKUR, RATNA NAIK, Wayne State University, FAZLUL SARKAR, WAEL SAKR, Karmanos Cancer Research Institute, GREG AINER, ALEX CAO, ABHILASH PANDYA, Wayne State University, VAMAN NAIK, University of Michigan-Dearborn — A pilot study was performed to differentiate the benign epithelium (BE), prostatic intraepithelial neoplasia (PIN) and, stromal regions from deparaffinized prostate needle biopsies using Raman spectroscopy. Raman spectra were collected from six deparaffinized prostate tissues and all the three regions showed different Raman spectral features that may represent unique Raman signatures of these regions. One of the unique features observed in these spectra is that the ratio of the two peak heights at 1449 cm$^{-1}$ and 1338 cm$^{-1}$ is constant with different values for BE and PIN. While the peak at 1338 cm$^{-1}$ is quite weak in the stromal regions. Multivariate statistical methods clearly separated the spectra from three different regions of the tissues into three distinct groups. This study demonstrates the feasibility of using deparaffinized tissue biopsy samples for the diagnostic purpose.

5:06PM W16.00008 Medical Application of the Geant4 Simulation Toolkit, JOSEPH PERL, Stanford Linear Accelerator Center — Geant4 is a toolkit for the simulation of the passage of particles through matter. While Geant4 was originally developed for High Energy Physics (HEP), applications now include Nuclear, Space and Medical Physics. Medical applications of Geant4 in North America and throughout the world have been increasing rapidly due to the overall growth of Monte Carlo use in Medical Physics and the unique qualities of Geant4 as an all-particle code able to handle complex geometry, motion and fields with the flexibility of modern programming and an open and free source code. Work has included characterizing beams and brachytherapy sources, treatment planning, retrospective studies, imaging and validation. This talk will provide an overview of these applications, with a focus on therapy, and will discuss how Geant4 has responded to the specific challenges of moving from HEP to Medical applications.

Thursday, March 13, 2008 2:30PM - 5:06PM — Session W17 DBP: General Biological Physics Morial Convention Center 209

2:30PM W17.00001 Actin-mediated bacterial propagation as dissipative dynamics of F-actin concentration: onset of motion, comet profile, velocity fluctuations, VINCENZO BENZA, Universita’ dell’insubria — Bacterial motion under the action of an actin gel network is described in terms of the F-actin concentration dynamics driven by polymerization, elasticity, and coupling with the bacterium. An explicit formula for the velocity clarifies the role of the different factors contributing to propagation. As regards the onset of motion, we find that smaller ratios of the branching/nucleation rates give rise to an increasingly long buildup time before startup. In the cruise regime the linear growth of the comet length versus velocity is analytically shown and numerically verified; as the length increases the concentration maximum decreases. Both features have been observed in kinematics experiments [1]. By expanding our previous work [2], we show that a larger elasticity modulus makes a larger velocity but with a smaller contribution from the interface polymerization. At steady state we find two regimes: constant velocity when the branching rate dominates over the nucleation rate, intermittent velocity when the two rates are comparable. In this case the concentration profile does not display macroscopic fluctuations, but the distance of its maximum from the bacterium surface oscillates: this behavior has its counterpart in the intermittency of the cruise velocity.

2:42PM W17.00002 The contraction of Vorticella in different Ca concentration solutions, DEEPENDRA KANTHA, DAVID VAN WINKLE, Department of Physics, Florida State University and Center for Materials Research and Technology (MARTECH) — The contraction of the stalk of *Vorticella Convallaria* was studied in media with different concentrations of calcium ion solution. Seven solutions were prepared by adding different amounts of CaCl$_2$ in the range of 0.001M to 0.004M EGTA, 0.1M KCl and 0.02M MOPS. The pH values of the solutions were maintained between 6.7 and 6.9. The contractions were recorded as images (image sequences) by a Phantom V5 camera (Vision Research) on a bright field microscope with 20X objective, with the image resolution of 256 $\times$ 128 pixels at 7000 pictures per second. The change in length of stalk as a function of time was analyzed to compute velocity, acceleration, force and force coefficient. The apparent force coefficient increases linearly with time until the whole stalk is maintained between 6.7 and 6.9. The contractions were recorded as cines (image sequences) by a Phantom V5 camera (Vision Research) on a bright field microscope with 20X objective, with the image resolution of 256 $\times$ 128 pixels at 7000 pictures per second. The change in length of stalk as a function of time was analyzed to compute velocity, acceleration, force and force coefficient. The apparent force coefficient increases linearly with time until the whole stalk is contracting. Considering time dependence of force coefficient, the contracting length is modeled as:

$$L(t) = \frac{L_0}{2} \left[ \left(1 + \frac{C_1}{A} \right) \exp \left( -\frac{C + A t}{2m} \right) + \left(1 - \frac{C_1}{A} \right) \exp \left( -\frac{C - A t}{2m} \right) \right]$$

Where $L_0$ is initial contractile length, $C = 6\eta r$, $A = \sqrt{C^2 - 4m K(t)}$, $\eta$ is coefficient of viscosity, $m$ is mass and $r$ is radius of zooid.

2:54PM W17.00003 Kinetics of Multideterminate Ligand Binding, IGOR GONCHARENKO, MIKE COLVIN, AJAY GOPINATHAN, University of California, Merced — The binding of multivalent ligands to cell surface receptors is an inherent feature of many biological processes and is technologically important in designing drug delivery systems. We analyze the binding and unbinding kinetics of a multi-armed ligand to normal and cancerous cells in terms of the residence time. By mapping the problem to a first passage time solution of the dynamics described by a multi-dimensional Fokker-Plank equation we are able to derive the residence times of the ligands on the cell surface as a function of the number of arms, binding affinity, polymer statistics of the linker arms as well as density, distribution and types of receptor binding sites. Our results point towards ways of optimizing these parameters so as to selectively target diseased cells with specially designed ligands that are capable of drug delivery. Our results also shed light on the recognition and response kinetics of a variety of cell types with specific functions that are triggered by the binding of surface receptors to exogenous ligands.

3:06PM W17.00004 Single cell visualization of DNA repair in vivo, AZADEH SAMADANI, BrandeisUniversity, AMY ROWAT, SEAS, Harvard University, JENNIFER MAKRIDAKIS, JAMES HABER, Brandeis University — The creation of a DNA double-strand-break constitutes the most dangerous type of DNA damage. Efficient response to DNA damage may lead to hypersensitivity to cellular stressors, susceptibility to genomic defects and resistance to apoptosis, which can lead to cancer. Current research on DNA repair has enabled numerous breakthroughs in our understanding of the DNA repair mechanisms at the population level. However, similar understanding at the level of single cells has been lacking mainly because of two reasons: 1) population level measurements do not visualize the repair process and therefore the exact mechanism by which the donor and recipient sequences are brought together is not well understood. 2) they are only sensitive to the mean of a distribution and usually hide the cell-to-cell variability of the repair processes. In my lab we utilize a multidisciplinary approach to address specific aspects of the DNA repair at the single cell level. By tagging several locations on DNA, its dynamic is visualized. Furthermore the exact timing of the repair process is measured. In our experiments, individual cells are followed over long periods of time and many cellular generations in a microfluidic device, in which a precise control of the microenvironment of the cells is possible.
3:18PM W17.00005 Current reversal in collective rocking ratchets induces by ground state instability

We thanks Spanish Ministerio Educacion y Ciencia grants NAN04-09087, FIS05-07392.

3:30PM W17.00006 A Mathematical Exploration of MAP Kinase Behavior

3:42PM W17.00007 Electric field control of the cell orientation

1. JOSE L. VICENT, LUIS DINIS, ELVIRA M. GONZALEZ, Universidad Complutense, 28040 Madrid, Spain, JOSE V. ANGUIITA, Instituto Microelectronica, CSIC, 28760 Madrid, Spain, JUAN M.R. PARRONDO, Universidad Complutense, 28040 Madrid, Spain — A collective mechanism for current reversal in rocking ratchets is proposed. The mechanism is based on a two-dimensional instability of the ground state of the system. We illustrate our results with numerical simulations and experiments using the dynamics properties of superconducting vortex lattice in Nb superconducting films fabricated on top of Si substrates with array of asymmetric nanodefects.

4:42 PM W17.00012 AC electrokinetics of dense inhomogeneous biological cells suspensions under nonuniform applied fields, K.L. CHAN, The Chinese University of Hong Kong, J.P. HUANG, Fudan University, K.W. YU, The Chinese University of Hong Kong — When a biological cell is placed in a nonuniform AC (or DC) electric field, force would be induced because of the interaction between the induced electric dipole moment of the particle and the external electric field. This phenomenon is called dielectrophoresis (DEP). [1] In this study a new method is proposed to handle biological cells with arbitrary permittivity and conductivity profiles, and determine the importance of multiple effect as compared with the approximate point dipole calculation [2], which is valid if the external field is homogeneous. In real situations, cells often possess arbitrary graded profiles and the study of higher multipole effects can lead to a better understanding. We also extend the calculation to dense cells suspensions by the effective medium theories [3]. The study reveals significant effects on the DEP due to higher concentration.

4:54 PM W17.00013 Folding of Pollen Grains, ELENI KATIFORI, Department of Physics, Harvard University, Cambridge MA, SILAS ALBEN, School of Mathematics, Georgia Institute of Technology, Atlanta, GA, ENRIQUE CERDA, Departamento de Física, Universidad de Santiago, Chile, DAVID NELSON, Department of Physics, Harvard University, JACQUES DUMAIS, Department of Organismic and Evolutionary Biology, Harvard University — At dehiscence, which occurs when the anther reaches maturity and opens, pollen grains dehydrate and their volume is reduced. The pollen wall deforms to accommodate the volume loss, and the deformation pathway depends on the initial turgid pollen grain geometry and the mechanical properties of the pollen wall. We demonstrate, using both experimental and theoretical approaches, that the design of the apertures (areas on the pollen wall where the stretching and the bending modulus are reduced) is critical for controlling the folding pattern, and ensures the pollen grain viability. An excellent fit to the experiments is obtained using a discretized version of the theory of thin elastic shells.

Session W18 DPOLY DBP: Focus Session: Dynamics of Nucleic Acid-Protein Interactions
Morial Convention Center 210

2:30PM W18.00001 Single-Molecule Dynamics of a DNA Aptamer Targeting VEGF Protein, CHRISTY LANDES, University of Houston — Single-molecule fluorescence resonance energy transfer (SMFRET) and SMFRET autocorrelation analysis were used to examine structural fluctuations in a DNA aptamer that binds and exhibits inhibition activity towards the vascular endothelial growth factor (VEGF) protein, a protein that is involved in macular degeneration. The aptamer’s most stable conformation contains 4 Watson-Crick base pairs, resulting in only a shallow negative potential relative to the unfolded state. The weakly stable folded state and the manifold of unfolded structures quickly interconvert. In contrast, in the presence of the VEGF target, the aptamer folding rate constant decreases and the fluctuations in both the unfolded and folded states decrease in frequency, but are not eliminated. A possible relationship between activity and aptamer flexibility is discussed.

3:06PM W18.00002 Thermal Disorder Effect on the DNA Electronic Structure, ALEXANDER BALEFF, Duke University, ELIZABETH HATCHER, University of Maryland, Baltimore, SHAHAR KEINAN, RAVINDRA VENKATRAMANI, DAVID BERATAN, Duke University — We address the effect of the thermal dynamics of DNA structure on the energy and localization of the DNA electronic orbitals. Structural ensembles are generated for several DNA sequences by molecular dynamics simulations employing CHARMM and AMBER force fields. In the shortest sequences studied (CATG, GAAG, CAGT, GACG), the highest occupied molecular orbitals (HOMOs) expectedly reside on the guanines (Gs), yet in a significant number of the structures the orbitals are observed to be delocalized between the Gs and the bridging adenines (As). Adding more Gs to the ends of the sequence expectedly shifts the orbitals toward the G clusters, yet the amount of orbital delocalization to the bridge is still significant. These observations suggest that a) contrary to the predominant view in the field, G-to-A thermal hopping may contribute significantly to the charge transfer in DNA even in the short-distance range, and b) the contribution of DNA structural fluctuations to triggering the charge transfer is as significant as that resulting from the ion gating mechanism.

3:18PM W18.00003 Thermodynamic Restriction on Evolutionary Optimization of Transcription Factor Proteins, ALEXANDER GROSBERG, LONGHUA HU, University of Minnesota, ROBIJN BRUINISMA, University of California Los Angeles — Conformational fluctuations are believed to play an important role in the process by which transcription factor proteins locate and bind their target site on the genome of a bacterium. Using a simple model, we show that the binding time can be minimized, under selective pressure, by adjusting the spectrum of conformational states so that the fraction of time spent in more mobile conformations is matched with the target recognition rate. The associated optimal binding time is then within an order of magnitude of the limiting binding time imposed by thermodynamics, corresponding to an idealized protein with instant target recognition. Thus, we claim that it is possible for the overall binding rate of a transcription factor to approach the theoretical limiting value but only by a suitable choice of energy spectrum of conformational sub-states, and only if the dimensionless binding rate is of the order of one, or larger than one, where dimensionless binding rate is determined as the product of binding rate and the average time spent by the protein on one DNA base pair in one turn of 1D sliding along DNA. Numerical estimates suggest that typical bacteria operate in this regime of optimized conformational fluctuations.

3:30PM W18.00004 Electron affinities of nucleobases, glycine and their complexes1, ED S. CHEN, Baylor College of Medicine, EDWARD C. CHEN, The Wentworth Foundation — The electron affinities of adenine, guanine, and the amino acids except for glycine have not been measured in the gas phase. New valence state electron affinities of the subject molecules are reported from reduction potentials and literature anion photoelectron spectra. These are supported by quantum mechanical calculations. Multiple negative ion potential energy curves are calculated to consolidate reduction potentials, electron impact spectra in helium nanodroplets, negative ion mass spectra, electron transmission spectra, electron spin resonance data for DNA, A method of measuring negative valence state electron affinities using ESR data is proposed. The adiabatic electron affinities are: in eV Adenine, 1.08(5), Guanine, 1.65(10), Cytosine, 1.04(5), Thymine, 0.98(5), Uracil, 0.99(5), Glycine, 0.50(5). Adenine: thymine 1.40(5) eV. Excited dipole resonance data for DNA, A method of measuring negative valence state electron affinities using ESR data is proposed. 3:42PM W18.00005 Chemical physics of DNA packaging in a nucleosome core particle, ANDREW SPAKOWITZ, BARIZ SUDHANSHU, Stanford University — The fundamental unit of packaged DNA, the nucleosome core particle, contains 146 base pairs of DNA wrapped 1.7 times around a cationic protein complex called the histone octamer. A string of nucleosomes is organized into higher-order structures at the sites of gene expression. The nucleosome’s most stable conformation contains 4 Watson-Crick base pairs, resulting in only a shallow negative potential relative to the unfolded state. We proceed to construct a free energy surface to predict the dynamic response in tension. We employ the wormlike chain model to describe the DNA strand as a thermally fluctuating polymer chain. The chain adsorbs on a spool that accommodates the volume loss, and the deformation pathway depends on the initial turgid pollen grain geometry and the mechanical properties of the pollen wall. We demonstrate, using both experimental and theoretical approaches, that the design of the apertures (areas on the pollen wall where the stretching and the bending modulus are reduced) is critical for controlling the folding pattern, and ensures the pollen grain viability. An excellent fit to the experiments is obtained using a discretized version of the theory of thin elastic shells.
we discuss how different patterns of nucleosome positions, periodic or random, could either facilitate or suppress heterochromatin stability and formation. The role nucleosome positioning might play in the formation of heterochromatin, a compact form of DNA generically responsible for gene silencing. In particular, the octamer experience a sequence dependent energy landscape due to the variation in DNA bend stiffness with sequence composition. In this talk, we consider the physics and astronomy of heterochromatin.

The role of nitrogen vacancies and hydrogen in conductivity of InN.

Anderson Janotti, Chris G. Van de Walle, Materials Department, University of California, Santa Barbara, CA 93106 — Using first-principles methods we investigate the electronic properties and stability of the nitrogen vacancy and monatomic hydrogen in InN. We find that nitrogen vacancies act as shallow donors, but they have high formation energies in n-type InN. Therefore, N vacancies are unlikely to cause the observed unintentional n-type conductivity in as-grown InN. Hydrogen can occupy interstitial as well as substitutional sites in InN. Interstitial hydrogen has low formation energy, is stable in the bond-center configuration, and acts exclusively as a shallow donor (H⁺). The calculated frequency of the H-N stretching mode is 3050 cm⁻¹. Hydrogen can also substitute for nitrogen in InN, bonding equally to the four In nearest neighbors in a multicenter-bond configuration [1]. Substitutional hydrogen also has low formation energy and, counterintuitively, forms a double-donor center. Our results suggest that hydrogenic hydrogen is a plausible cause of the unintentional n-type conductivity that is almost universally observed in as-grown InN.

3:42PM W19.00007 Electrical activation studies of Al\textsubscript{0.4}Ga\textsubscript{0.6}N and Al\textsubscript{0.5}Ga\textsubscript{0.5}N implanted with silicon for n-type doping. ELIZABETH MOORE, YUNG KEE YEO, Air Force Institute of Technology, MEE-YI RYU, Kangwon National University, ROBERT HENGELOTH, Air Force Institute of Technology — A systematic electrical study of Si-implanted Al\textsubscript{0.4}Ga\textsubscript{0.6}N with Al concentrations of 40 and 50\% grown on sapphire substrates by MEMOCVD has been made as a function of ion dose and anneal temperature. The silicon ions were implanted at 200 keV with doses from 1x10\textsuperscript{14} to 1x10\textsuperscript{16} cm\textsuperscript{-2} at room temperature. The samples were proximity cap annealed from 1150 to 1350 °C for 20 minutes in a nitrogen environment. Hall-effect measurements were made from 10 to 700 K and cathodoluminescence measurements were taken at 7 K. Electrical activations of nearly 100\% were obtained for the Al\textsubscript{0.4}Ga\textsubscript{0.6}N:Si after annealing at 1350 °C for 20 minutes for doses of 1x10\textsuperscript{15} and 5x10\textsuperscript{15} cm\textsuperscript{-2} and after annealing at 1200 °C for 20 minutes for the dose of 1x10\textsuperscript{15} cm\textsuperscript{-2}. The Al\textsubscript{0.5}Ga\textsubscript{0.5}N:Si also had high activations of nearly 100\% for the two lower doses after annealing at 1300 °C for 20 minutes, while for a dose of 1x10\textsuperscript{15} cm\textsuperscript{-2}, an activation of 66\% was obtained after the same annealing treatment. The highest room temperature mobility for the Al\textsubscript{0.4}Ga\textsubscript{0.6}N and Al\textsubscript{0.5}Ga\textsubscript{0.5}N samples is 61 and 55 cm\textsuperscript{2}/V·s, respectively for the samples annealed at 1350 °C for 20 minutes. CL spectra support the electrical results in determining the optimal annealing conditions.

3:54PM W19.00008 Effects of Dopants and Annealing on the Structure and Electronic properties of GaAsN\textsuperscript{1}. YU JIN, MATTHEW REASON, HAILING CHEN, CAGLIYAN KURDACK, RACHEL GOLDMAN, University of Michigan — In this work, we investigate the effects of different n-type dopants and rapid thermal annealing (RTA) on the structure and electronic properties of GaAsN bulk-like films grown by molecular beam epitaxy. For as-grown GaAs:N:Si and GaAsTe films, similar free carrier densities (n) and electron mobilities (μ) are observed. However, after post-growth RTA, a substantial increase in both n and μ is observed in the GaAsTe films, with negligible change in those of the GaAs:N:Si films. Apparently, RTA reduces the concentration of N-related trapping and scattering centers in GaAsTe. On the other hand, the annealing process enhances the diffusion of Si, presumably leading to the formation of additional N\textsubscript{As}–Si\textsubscript{Si} defect complexes. For both GaAsTe and GaAsSi films, x-ray rocking curves reveal reduced lattice parameters following annealing, suggesting a decrease in the interstitial [N], which leads to the improvement in electronic properties for the GaAsTe films. In the case of GaAsSi, the reduction in interstitial [N] is presumably balanced by an increase in the density of N\textsubscript{As}–Si\textsubscript{Si} defect complexes. The effect of dopants and annealing on the structure and electronic properties of InGaAsN will also be discussed.

1Supported by NSF-FRG, grant # DMR-0660406, monitored by L. Hess.

4:06PM W19.00009 Bismuth related transitions in the electronic properties of high quality dilute GaAs\textsubscript{1−xBi\textsubscript{x}}. LEKHNATH BHUSAL, DENIS KARAIASKAJ, RYAN FRANCE, AARON PTAK, ANGELO MASCARENHAS, National Renewable Energy Laboratory, 1617 Cole Blvd, Golden CO-80401, TOM TIEDJE, AMPLE, Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, Canada, V6T 1Z4 — In this work we will present the electronic and optical properties of dilute GaAs\textsubscript{1−xBi\textsubscript{x}} epilayers for the range of samples with concentration up to ~3\%. Variation of fundamental band gap (E\textsubscript{G}) and the transition from the spin-orbit split off valance band (E\textsubscript{V} + Δ) using the contactless modulated electroreflectance will be presented as a function of temperature (77-300K) and Bi concentrations. We will also discuss the isoelectronic codoping of Bi and nitrogen, as the excellent quality of GaAsBi samples presented in the work opens the path for the codoping of Bi with N to improve the electronic properties of dilute nitride III-V alloys.

We acknowledge the financial support of the Department of Energy, Office of Sciences, Basic Energy Sciences, and Division of Material Sciences.

4:18PM W19.00010 A defect relaxation model for the carbon vacancy in SiC. JAMIYANAA DASHDORJ, MARY ELLEN ZVANUT, Physics Department, University of Alabama at Birmingham — Deep level intrinsic defects in high purity semi-insulating SiC play an important role in electrical compensation necessary to achieve high resistivity. We use a constant light intensity approach to steady-state photo-electron paramagnetic resonance (EPR) and time-dependent photo-EPR to study the ionization cross sections and relaxation energies of the well-studied defect, the positively charged carbon vacancy, V\textsuperscript{+}C. As-grown 4H-SiC samples with room temperature resistivity of 10\textsuperscript{10} Ohm-cm were studied at 4 K and 80 K. The shape of the absorption curve for V\textsuperscript{+}C, as revealed by the steady state measurements, has a peak at 2.3 eV and photo-threshold at 1.8 eV. We interpret the difference between these two values as a structural relaxation upon release of an electron from the defect to conduction band. Consistently, preliminary time-dependent measurements reveal a Franck-Condon transition at 2.3 eV for release of an electron from the defect to the conduction band, and a second Franck-Condon transition at an energy greater than 1.3 eV for capture of electron at the defect from the valence band. The difference of no more than 1 eV may be interpreted as a relaxation energy, consistent with the interpretation of steady-state data. The details of the experimental approach and the formulation of the relaxation model will be presented.

4:30PM W19.00011 Direct Imaging of Point Defect Configurations for Au Atoms Inside Si Nanowires\textsuperscript{1}. K. VAN BENTHEM, S.H. OH, A.Y. BORISEVICH, W. LUO, Oak Ridge National Laboratory, P. WERNER, N.D. ZAKHAROV, MPI for Microstructure Physics, S.T. PANTELIDES, Vanderbilt University, S.J. PENNYCOOK, Oak Ridge National Laboratory — Aberration-corrected scanning transmission electron microscopy (STEM) was used to directly image individual Au atom configurations inside Si nanowires grown by Au-catalyzed vapor-liquid-solid molecular beam epitaxy. A three-dimensional analysis of the nanowire microstructure revealed Au atom concentrations five orders of magnitude higher than equilibrium values in bulk silicon. Three distinct interstitial Au atom configurations were identified in addition to the substitutional configuration. The stability of the observed point defect configurations was further investigated by density-functional theory. The observed configurations are in excellent agreement with theory. However, comparison of the number densities of the various configurations with the calculated formation energies indicates an effective temperature of approximately 1000 degrees centigrade suggesting significant beam-induced atomic diffusion.

This work was supported by the Office of Basic Energy Sciences, DMSE (AYB, SJP) and DSUF (AYB, KvB), an NSF-NIRT project (SHO), and the European Union (NDZ).

4:42PM W19.00012 Ni doping of semiconducting boron carbide\textsuperscript{1}. S. ADENWALLA, JING LIU, NINA HONG, Physics and Astronomy, Univ. of Nebraska-Lincoln — Semiconducting boron carbide (BC) is intrinsically p-type. The addition of Ni has been shown to dope it n-type. I-V measurements on Ni doped BC on both p- and n-type Si (1x10\textsuperscript{15} cm\textsuperscript{-3} and 4.5x10\textsuperscript{15} cm\textsuperscript{-3}) indicate changes in the doping level with increasing Ni concentration. At the highest dopant level, Ni doped BC on n-type Si showed n-n+ diode characteristics. The change of doping concentration was confirmed by the built-in potential increase from 0.1 V in the low Ni doped p-n diode to 1.2 V in the high Ni-doped p-n diode as well as by measurements of the reverse saturation current. The addition of Ni does not lead to significant structural changes in the BC as measured by x-ray diffraction. X-ray fluorescence data indicate an upper bound of 2 ppm for the Ni concentration. Using these results homojunction p-n diodes were fabricated from layers of undoped p-type BC and Ni doped n-type BC and characterized by I-V and capacitance-voltage (C-V) measurement. Homojunction devices are shown to be especially promising for thermal neutron detection.

\textsuperscript{1}Funded by NSF-0725881 and NASA NNG05GM89G.
4:54PM W19.00013 First principles investigations into alkali intercalation of hexagonal boron nitride. BAHADIR ALTINTAS, Abant Izzet Baysal University, Department of Chemistry, CIHAN PARLAK, RESUL ERYIGIT, Abant Izzet Baysal University, Department of Chemistry — Although hexagonal boron nitride (hBN) is quite similar to graphite structurally, it has been very difficult to obtain any intercalation compound of hBN while there are hundreds of graphite intercalation compounds. We have investigated the possible intercalation of hBN by alkali atoms in the density functional theory framework by using pseudopotentials and plane-wave basis. The structural, electronic and lattice dynamical properties of hypothetical hBN analogues of LiC$_3$, LiC$_6$, K$_5$C$_6$, Cs$_5$C$_6$, Ca$_5$C$_6$ are calculated. We have found that although the electronic structure, band structure and free surface of alkali intercalated hBN is very similar to that of alkali intercalated graphite, the lattice dynamics show a set of negative frequency modes which indicate that alkali-intercalated hBN is not stable.

5:06PM W19.00014 Effects of point defects on the electrical properties of aluminum antimonide: a first principles investigation. VINCENZO LORDI, DANIEL ÅBERG, PAUL ERHART, Lawrence Livermore Lab — A first principles study is conducted on the effects of point defects on the electrical properties of bulk AI$_3$Sb, a material of interest for room temperature gamma radiation detection. Detailed calculations were performed for all native defects, including vacancies, antisites, interstitials, and split interstitials, and also for a variety of impurities (H, C, Si, Ge, Sn, P, O, S, Se, Te). Formation energies of each defect in different charge states were calculated to determine the equilibrium defect density and net carrier density. Carrier scattering rates for each defect were calculated using perturbation theory to determine the effects on electron and hole transport. The most detrimental, as well as innocuous, defects were identified. Relative solubilities of the impurities were examined along with their scattering rates to find efficient dopants that minimize mobility degradation. Finally, carrier trapping cross sections and energy levels were calculated to study the role of each defect in deep level trapping.

2:30PM W20.00001 Electronic structure of epitaxial CrO$_2$(100) and CrO$_2$(110) films. C. A. VENTRICE JR, H. GEISLER, Texas State Univ., D. R. BORST, Univ. of New Orleans, G. X. MIAO, A. GUPTA, Univ. of Alabama — Half-metallic ferromagnets are conducting solids whose conduction electrons undergo magnetic ordering with a spin polarization of 100% at 0 K. Although CrO$_2$ is predicted to be a half-metallic ferromagnet, previous attempts to make devices using CrO$_2$ have resulted in a degradation of performance instead of an enhancement. Using ultra-violet photoluminescence spectroscopy at the CAMD synchrotron, we have measured the electronic properties of epitaxial CrO$_2$(110)/TiO$_2$(110) and CrO$_2$(100)/TiO$_2$(100) surfaces grown using a CrO$_2$ precursor. Clean, stoichiometric CrO$_2$ surfaces have been prepared either by exposure to white light, which desorbs OH groups from the surface, or by sputtering and annealing in O$_2$. The measurements of the CrO$_2$ surfaces show no emission at E$_F$, after sputtering and annealing the surfaces in oxygen. However, the white light prepared surfaces show a small density of states at E$_F$. Photon energy dependent photoemission experiments show no increase in the density of states at E$_F$ as the photon energy is lowered from 50 eV to 15 eV, which increases the bulk sensitivity of these measurements. These results indicate that CrO$_2$ behaves more like a semi-metal than a half-metal and that surface disorder can induce a semi-metal to semiconductor transition at its surfaces.

2:42PM W20.00002 Variation of Growth Mode with Orientation for Epitaxial CrO$_2$ Films. KRISHNA CHETRY, HUNTER SIMS, WILLIAM BUTLER, ARUN GUPTA, University of Alabama — Thin films of CrO$_2$ have been grown epitaxially on (110) and (100) oriented TiO$_2$ substrates. CrO$_2$(100) films grow in a layer by layer mode, while an island growth mode is observed for CrO$_2$(110) films as confirmed from atomic force microscopy (AFM) studies. To better understand the differences in the growth mode, we have performed first principles-based calculations using density functional theory implemented within the VASP code to study the surface and interface energies of CrO$_2$(100), (110), TiO$_2$(100) and (110) systems. For these calculations a periodic repeating slab geometry is used with a sufficient vacuum width and thickness to converge the surface energy within 0.01 meV/Å$^2$. From our calculations we find that $\sigma_{\text{CrO}_2}/\sigma_{\text{TiO}_2} > \chi_{\text{CrO}_2} + \gamma_{\text{CrO}_2}$, where $\sigma$ is the surface energy and $\gamma$ is the interfacial energy between CrO$_2$ and TiO$_2$ system. This result is consistent with the island growth mode observed experimentally for (110) orientation. For the case of (110) orientation also we find that $\sigma_{\text{CrO}_2} < \chi_{\text{CrO}_2} + \gamma$, which does not match with our experimental results. We speculate that formation of some oxygen deficient phase of chromium oxide in the very first monolayer, which then gets converted to CrO$_2$ by accepting oxygen from the second layer, favors the layer-by-layer growth mode in CrO$_2$(100).

2:54PM W20.00003 Self-Assembled Epitaxial Multiferroic Nanocomposite Films Prepared by Polymer-Assisted Deposition. HONGMEI LUO, HAO YANG, EVE BAUER, T. MARK MCCLESKEY, ANTHONY K. BURRELL, QUANXI JIA, Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos, NM 87545 — Multiferroic materials, which show simultaneous electric and magnetic ordering, have attracted considerable interest recently due to their unusual physical properties and potential device applications. Here we demonstrate that a cost-effective chemical solution approach of polymer-assisted deposition (PAD) is a very promising technique to grow self-assembled epitaxial multiferroic nanocomposite thin films: such as BaTiO$_3$-NiFe$_2$O$_4$ films grown on (001)-oriented LaAlO$_3$ substrate. X-ray diffraction (XRD), atomic force microscopy (AFM) and high resolution transmission electron microscopy (HRTEM) analyses show clear epitaxial relationship between the two phases and the substrate. The ferroelectric BaTiO$_3$ grains are embedded in the ferrimagnetic spinel NiFe$_2$O$_4$ matrix. The composite films exhibit both ferroelectric and ferrimagnetic properties. The structure and properties will be discussed and compared with the nanocomposite films prepared by pulsed-laser deposition (PLD) method.

1This work was supported by LDRD Project at LANL.

3:06PM W20.00004 Structural and electrical properties of self-assembled (BiFeO$_3$)$_{0.5}$(Sm$_2$O$_3$)$_{0.5}$ nanocomposite films. HAO YANG, Superconductivity Technology Center, Los Alamos National Laboratory, H. WANG, Department of Electrical and Computer Engineering, Texas A&M University, J.L. MACMANUS-DRISCOLL, Department of Materials Science and Metallurgy, University of Cambridge, Q.X, JIA, Superconductivity Technology Center, Los Alamos National Laboratory — Self-assembled (BiFeO$_3$)$_{0.5}$(Sm$_2$O$_3$)$_{0.5}$ nanocomposite films were deposited on (001) SrTiO$_3$ and Nb-doped SrTiO$_3$ substrates by pulsed laser deposition using a single uniformly mixed target. Analysis from both high-resolution X-ray diffraction and transmission electron microscopy revealed self-assembled epitaxial two-phase BiFeO$_3$ (BFO) and Sm$_2$O$_3$ (SmO) composites in nanoscale. The BFO and SmO domains have grown alternately and vertically aligned with average column size of 10 nm. The dielectric properties of BFO:SmO nanocomposite films were investigated and compared with those of pure BFO and SmO thin films. The dielectric constant of the nanocomposites can be well described by a parallel connection of two individual dielectrics of BFO and SmO. On the other hand, the dielectric loss of nanocomposite films is lower than the theoretical value from such a parallel connection model. This might originate from the reduction of leakage current density of BFO phase in nanocomposite film due to the much larger interfacial area and the strong out-of-plane strain of BFO column.
3:18PM W20.00005 Checkerboard pattern formation in spinel oxide films. TOSHIHITO ASADA, NISSAN ARC, LTD., Rutgers Univ., YOICHI HOBIE, SOONYONG PARK, NARA LEE, Rutgers Univ. — A few-nanometer-size columnar superlattice with a checkerboard (CB) structure has been fabricated by harnessing Jahn-Teller structural distortions. In this talk, we will discuss the growth mechanism of the CB structures in thin films, obtained from the results of our transmission electron microscopy. Ionic diffusion for the phase separation occurs along the direction parallel to the twin boundaries in the high-temperature tetragonal phase. This anisotropic phase separation suggests the importance of the strain associated with the twin structure in the high-temperature tetragonal phase. 1. S. Yeo et al., Appl. Phys. Lett. 89, 233120 (2006). 2. C. L. Zhang et al., Appl. Phys. Lett. 90, 133123 (2007).

3:30PM W20.00006 Thermal Stability of Epitaxial SrTiO$_3$ Thin Films on Si (001). C. YONG, RAJESWARI KOLAGANI, S. ADHIKARI, Towson U, W. VANDERLINDE, Lab for Physical Sciences, L. SALAMANCA-RIBA, U of Maryland, Y. LIANG, Motorola Labs, S. FRIEDRICH, Lawrence Livermore National Lab — Epitaxial SrTiO$_3$ on Si(001) is important for application as a high $\kappa$ (Kappa) gate oxide and is also suitable as a buffer layer for the subsequent growth of other perovskite oxide thin films to enable integration of perovskite oxide functionality with Si. For the latter application, the thermal stability of the interface structure in epitaxial SrTiO$_3$ thin films grown by molecular-beam epitaxy on Si (001) becomes a key issue since most of the perovskite layers are grown at relatively high temperatures (750-850 °C). SrTiO$_3$ and Si are intrinsically thermodynamically unstable in proximity to each other, with some reduction of the $\text{TiO}_2$ and oxidation of the Si to be expected. We have used x-ray diffraction and micro-analytical techniques including optical microscopy, atomic force microscopy (AFM), scanning electron microscopy (SEM) and transmission electron microscopy (TEM) to study the thermal stability of epitaxial SrTiO$_3$ thin films grown by molecular beam epitaxy (MBE) on Si (001). Elemental composition of the amorphous interface layer (AIL) and of the epitaxial SrTiO$_3$ film will change during various thermal treatments and gas environments encountered in the subsequent growth of other oxide layers.

3:42PM W20.00007 Design and characterization of Pb(Zr,Ti)O$_3$ /CoFe$_2$O$_4$ Multilayer epitaxial thin films. NORA ORTEGA, ASHOK KUMAR, RAM KATIYAR, University of Puerto Rico — Multiferroics are a novel class of next generation multifunctional materials. Intensive research is being pursued towards the development of materials with high magnetoelectric (ME) coupling. We have fabricated epitaxial Pb(Zr,Ti)$_x$CoFe$_2$O$_4$ (PZT-CFO) multilayer (ML) thin films using pulsed laser deposition on (001) oriented lattice matched SrRuO$_3$/SrTiO$_3$ (SRO/STO) substrates. X-ray diffraction and Raman analysis revealed that PZT and CFO were in the perovskite and spinel phases respectively, in the multilayer thin films having high crystalline quality. The TEM and STEM line scan of the multilayer thin films showed that the layered structure was maintained. Magnetic hysteresis loop showed the ferromagnetic behavior of ML structure, which is independent of the ML configuration. Ferroelectric properties and temperature dependence magnetization will be discussed.

3:54PM W20.00008 Epitaxial oxide heterostructures on silicon. AGHAM POсадAS, J.W. REINER, F.J. WALKER, C.H. AHN. Yale University — Silicon-based MOSFETs will soon be limited by the large off-state leakage current due to tunneling through the 1 nm thick silicon oxynitride gate dielectric layer. One solution is to replace the silicon oxynitride with a high dielectric constant material, such as LaAlO$_3$, which has a relatively large dielectric constant of 24 and band gap of 5.6 eV. We have recently grown LaAlO$_3$ epitaxially on silicon via a transition layer consisting of SrTiO$_3$. The thickness of this SrTiO$_3$ layer is kept between 2 and 5 unit cells because of considerations of epitaxial strain and the atomic-scale interactions between the perovskite structure and the silicon substrate. The oxide heterostructures show atomically abrupt interfaces and dielectric constants close to the bulk value of LaAlO$_3$. Frequency and voltage dependent measurements of the complex impedance of the as-grown oxide heterostructures show a pinned Fermi level and a high density of interface states. Annealing at temperatures in wet oxygen shows that the Fermi level can be unpinned, with a greatly reduced density of interface states.

4:06PM W20.00009 Pulsed Laser Deposition of SrTiO$_3$ Thin Films: Time-Resolved X-ray Studies$^1$. JOEL BROCK, GOKHAN ARIKAN, JOHN FERGUSON, ARTHUR WOLL, Cornell University — X-ray scattering and reflectivity have been used to measure the static atomic structure of surfaces and interfaces for several decades. Modern synchrotron x-ray facilities now deliver sufficient flux to make time-resolved measurements on a wide variety of evolving surface and interface systems feasible. Here, we use time-resolved x-ray diffuse scattering studies of Pulsed Laser Deposition (PLD) of SrTiO$_3$ films on the (001) surface of SrTiO$_3$ to obtain detailed insight into the fundamental, atomic-scale growth mechanism. The data demonstrate that during-layer-by-layer growth, islands are nucleated during the 1$^{st}$ pulse. The size of the pulse determines the nucleation density. During and in between subsequent pulses, the islands coarsen and coalesce. Line shape analysis of the diffuse scattering reveals that adatom capture occurs at the same time as coarsening. The time-resolved x-ray data obtained as a function of miscut further demonstrate that kinetic growth models based on adatom diffusion on singular surfaces are missing essential physical mechanisms which are step-edge density dependent.

4:18PM W20.00010 Nucleation of MB$_2$ thin films on Si by low temperature CVD: island statistics and growth kinetics. A. YANGUAS-GIL, N. KUMAR, J.R. ABELSON, Materials Science and Engineering Dep., U. of Illinois at Urbana-Champaign — HfB$_2$ thin films are deposited onto H-terminated Si by CVD using the single source precursor Hf(BH$_4$)$_2$, which affords extremely conformal and smooth film growth. HfB$_2$ films are technologically important as hard coatings and as impurity diffusion barriers. We analyze the nucleation process by in-situ spectroscopic ellipsometry (SE) and ex-situ AFM. The objective is to derive mechanistic information on the growth kinetics from a statistical analysis of the early stages of growth. The experimental results reveal that HfB$_2$ nucleates on Si(001) forming 3D islands and that there is an agreement between the SE data and the AFM measurements. Quantitative information on island statistics is extracted from AFM data taken after various growth times. The island height distribution functions are consistent with the presence of a physisorbed state of the precursor molecule. This situation is similar to that of the capture zone 2D island growth models in the literature and is in agreement with previous results on the steady state growth of HfB$_2$. The island spatial distribution and the correlation between island height and capture zone area indicate that nucleation is random and keeps on taking place until coalescence is reached. We show that the nucleation rate can be enhanced by surface activation, leading to a reduction in the grain size and lateral correlation length of the films.

4:30PM W20.00011 STM study of MOCVD-grown a-plane ZnO thin films: film thickness, growth temperature, and substrate miscut effects. O. DULUB, U. DIEBOLD, Department of Physics, Tulane University, New Orleans, Louisiana 70118, G. SARAF, Y. LU, Department of Electrical and Computer Engineering, Rutgers University, New Jersey 08854 — ZnO films with a-plane orientation were grown on r-plane (011bar2) sapphire substrates using metal-organic chemical vapor deposition (MOCVD). The surface morphology of ZnO films with various thicknesses (20 – 2000 nm), growth temperatures (300 - 580°C), and substrate miscut orientations and angles (0.2 - 2°) was characterized by low energy electron diffraction (LEED) and scanning tunneling microscopy (STM). Our results show strong dependence of surface morphology on growth parameters and the substrate miscut. STM images reveal uniform surfaces with small, rectangular terraces during the initial growth stage (20 nm-thick film). Films with thicknesses between 100 and 450 nm have a characteristic wave-like surface morphology with needle-shaped domains running predominantly along the crystallographic c-direction. Films with a thickness of 2000 nm exhibit more flat surfaces, but with c-oriented facets. We observed an increasing surface quality of the films with increasing growth temperature. Films grown at 580°C exhibit the flattest surface morphology. Film morphologies show strong dependence on the substrate miscut angle as well as on the miscut direction at all growth conditions.
region have weak net polar-orientations with H pointing towards the liquid. At high pH (pH ∼ 11), water species contributing to the different parts of the spectrum. The result shows that at low pH (pH < ∼ 2), water molecules in both ice-like and liquid-like composition of the oxides forming the scale, and in the residual stress levels are found.

**Wednesday, March 13, 2008 2:30PM - 5:18PM - Session W21 DCMP: Surfaces and Interfaces II** Morial Convention Center 213

2:30PM W21.00001 Nano-confined water on surfaces of metal oxide nanoparticles, ANDREY LEVCHENKO, JULIANA BOERIO-GOATES, BRIAN WOODFIELD, ALEXANDER KOLESNIKOV, NANCY ROSS, DAVID WESOLOWSKI, DAVID COLE, ALEXANDER KOLESNIKOV, UNIVERSITY OF CALIFORNIA — DAVIS TEAM, DEPARTMENT OF CHEMISTRY AND BIOCHEMISTRY, BRIGHAM YOUNG UNIVERSITY COLLABORATION, INTENSE PULSED NEUTRON SOURCE, ALEXANDRA NAVROTSKY, PETER A ROCK THERMOCHEMISTRY LABORATORY AND NEAT ORU, UNIVERSITY OF CALIFORNIA - DAVIS TEAM, YOICHIRO MATSUMOTO, The University of Tokyo — The thermal decomposition of ultrathin oxide layers on silicon surface was investigated with TPD technique. Oxide layers were formed on Si(100) at 400°C by exposure to O2 molecular beam. The desorption spectrum of SiO for the initial coverages between 1.7 and 2.6 monolayers exhibits a relatively low peak at the lower temperature and a high peak at the higher temperature. The former peak corresponds to the unstable binding state, where O atoms are presumably trapped at the dangling bonds. The latter corresponds to the more stable binding states of O atoms at the dimer bridge sites and the dimer backbone sites. The most of O atoms are at the stable binding states, from which the desorption rate is well described by Avrami kinetics. This result is consistent with the reaction model which takes account of the void formation and growth as observed in STM studies. The rate-determining step is the reaction at void perimeter even if the overlap between voids becomes quite large. The Avrami exponents determined from our experiment suggest that the increase in the initial coverage makes the oxide adlayer more stable and suppresses the rate of void nucleation at the potential nucleation sites.

2:42PM W21.00002 X-ray Reflectivity Study of Thermal Capillary Waves and the Interfacial Profiles of Water-Alcohol Mixtures, YOONNAM JEON, JAEGO SUNG, DOSEOK KIM, Department of Physics and Program of Integrated Biotechnology, Sogang University, Seoul, Korea, WEI BU, DAVID VAKNIN, Ames laboratory and Department of Physics and Astronomy, Iowa State University, USA — The liquid/vapor interfaces of water-alcohol (methanol, ethanol, and propanol) mixtures were investigated by X-ray reflectivity. Analysis of X-ray reflectivity data shows that the interfacial widths (surface roughnesses) of all mixtures at a fixed temperature depend solely on the surface tension of the mixture, and the intrinsic surface roughness is on the order of inter-atomic distances, and within error, independent of solution constituents. The implications of our results in the regard to the origin of the intrinsic roughness and the capillary wave-vector cutoffs applicable to X-ray scattering will be discussed.

2:54PM W21.00003 Viscoelasticity of Water in Sub-nanometer Gaps1, TAI-DE LI, ELISA RIEGO, School of Physics, Georgia Tech, SCHOOL OF PHYSICS, GEORGIA TECH TEAM — Direct and simultaneous measurements of the normal and lateral forces encountered by a nanosize spherical silicon tip approaching a solid surface in purified water were reported. For tip-surface distances, 0.03nm < d < 2nm, experiments and grand canonical molecular-dynamics simulations find oscillatory solvation forces for hydrophilic surfaces, mica and glass, and less pronounced oscillations for a hydrophobic surface, graphite. The simulations reveal layering of the confined water density and the development of hexagonal order in layers proximal to a quartz surfase. For subnanometer hydrophilic confinement, the lateral force measurements show orders of magnitude increase of the viscosity with respect to bulk water, agreeing with a simulated sharp decrease in the diffusion constant. No significant viscosity increase is observed for hydrophobic surfaces.

3:06PM W21.00004 ABSTRACT WITHDRAWN —

3:18PM W21.00005 Study of Hydrophobic Water Interfaces with Phase-sensitive Sum-frequency Vibrational Spectroscopy1, CHUANSHAN TIAN, Y. RON SHEN, UC Berkeley — Self-assembled monolayer of octade-cytrichlorosilane (OTS) on fused silica has been used extensively as a representative hydrophobic surface in study of water/hydrophobic interfaces. However, the interfacial water structure and how it changes upon solvated ions are not clear. We have carried out a study on OTS/water interface using the newly developed phase-sensitive sum-frequency vibrational spectroscopy (PS-SFVS). It allows measurement of both real and imaginary parts of the surface spectral response with the latter playing a role equivalent to absorption and emission coefficients and provides information on net polar-orientations of various interfacial water species contributing to the different parts of the spectrum. The result shows that at low pH (pH< ∼ 2), water molecules in both ice-like and liquid-like region have weak net polar-orientations with H pointing towards the liquid. At high pH (pH> ∼ 11), they are well aligned with H pointing to the solid substrate. It is due to that OTS/silica is negatively charged at high pH because of the adsorption of OH⁻ ions on methyl groups of OTS, so that the surface field will reorient part of the interfacial water molecules.

3:30PM W21.00006 Electronic Structure and adsorption of Pentacene on Cu and Ag (110). ABDELKADER KARA, Department of Physics, University of Central Florida, Orlando FL32816 — The adsorption of pentacene (C_{22}H_{14}) at coverages of one and 0.8 monolayer on Ag(110) and Cu(110) is studied using density functional theory. The unit cells for these systems are 6x2 and 7x2 for Ag(110) and Cu(110), respectively. The pentacene molecule adsorbs nearly flat (with a structural corrugation of about 0.6 Å) at a position 2.5 above the surface. On Ag(110), the adsorbed pentacene is even flatter (0.45 corrugation) and sits higher (about 2.8 Å) than the case of Cu. On Cu(110), most of the carbon atoms adsorb on top of Cu atoms, which is not the case on Ag(110). The resulting changes in the electronic states and the nature of the bonding will be discussed and comparison between the two systems will be presented.

3:42PM W21.00007 Plasmonic Coupling of a Gold Colloid and a Gold Film, ALBERT CHANG, FEI LE, FELICIA TAM, NAOMI HALAS, PETER NORDLANDER, KEVIN KELLY, Rice University — Engineering of plasmon resonances is important for a variety of applications, including but not limited to surface enhanced Raman spectroscopy (SERS) and near field scanning optical microscopy (NSOM). Of special interest are systems where the plasmons of a nanoparticle and a thin gold film are coupled. This coupling allows for a greater degree of control of the plasmon resonance of the system, as well as a strong, localized, enhancement of the incident electric field. We demonstrate that this coupling, and the resulting enhancement, can be used for SERS applications, and explore its impact on potential NSOM applications.

3:54PM W21.00008 Dipole interactions between dielectric spheres in AC electric fields, MANISH MITTAL, ERIC FURST, University of Delaware — Rheological properties of Electrorheological (ER) suspensions change dramatically on application of electric field. One of the key issues in the study of ER fluids is the nature and strength of the forces between suspended particles. Micron-sized dielectric spheres aggregate to form linear chains on the application of an AC electric field. The dipole-dipole attraction is the dominant force in this process. The dipole moment has contributions from Maxwell-Wagner charge distribution and the double layer polarization. Using optical tweezers the force between a pair of polystyrene spheres has been measured by observing the displacement of particle held in a static optical trap, of known trap stiffness, from its equilibrium position. At a fixed salt concentration, frequency and electric field strength the radial and tangential force have been measured as a function of the center-to-center separation (r) and angle (θ) with the electric field to create a 2-dimensional force map. Such a complete 2-dimensional interaction profile of micron-sized particles has never been measured before. Subsequently the effect of field, frequency and background salt concentration was studied. It was found that adding salt and increasing field frequency suppressed dipolar interactions. This effect can be explained qualitatively by the double layer polarization theory. Finally the effect of particle geometry was studied by measuring interactions between particles of different size and shape.

4:06PM W21.00009 Gap-mode enhanced Raman scattering of organic monolayers on flat Au(111) surface, KATSUYOSHI IKEDA, NORIHIRO FUJIMOTO, KOHEI OUSAKI, HOKKAIDO UNIVERSITY TEAM — A metal-molecule junction is recognized as a fundamental issue of molecular-based nano-devices. Charge transport through organic layers is strongly affected by chemical and physical properties of metal-molecular interfaces. In order to investigate molecular structures adsorbed on metal surfaces, surface-enhanced Raman scattering (SERS) is widely utilized as a powerful spectroscopic tool. Because of the electromagnetic origin of SERS, however, conventional SERS spectroscopy is applicable only for "rough" metal surfaces. Since various adsorption sites are exposed on rough metal surfaces, it is difficult to obtain intrinsic information of metal-molecular junctions. Here, we provide a simple method of enhanced Raman spectroscopy for organic monolayers on "flat" metal surfaces based on gap-mode plasmon excitation. The gap-mode enhanced Raman spectra measured on "flat" Au(111) single crystal facets were compared with conventional SERS spectra, and adsorption site dependence of molecular structures was discussed.

4:18PM W21.00010 Cooperative plasmon-mediated fluorescence of molecules near a metal nanoparticle, V. N. PUSTOVIT, T. V. SHAHBAZYAN, Jackson State University — We study radiative and nonradiative decays of an ensemble of molecules attached to a metal nanoparticle. We show that when the system size is smaller than the radiation wavelength, the excited molecular dipoles are hybridized with each other via the nanoparticle surface plasmon, leading to cooperative plasmon-mediated emission similar to Dicke superradiance. In particular, an ensemble of N molecules located at random positions but at the same distance from nanoparticle surface has only 3 bright (superradiant) eigenstates each characterized by the single-molecule plasmon-enhanced radiative decay rate multiplied by approximately N/3, while the remaining N-3 states are optically dark (subradiant). The fluorescence quenching by the nanoparticle exhibits a similar behavior, with bright states having single-molecule nonradiative decay rate multiplied by the same factor and dark states having much longer still finite non-radiative lifetime due to contribution of higher angular momenta. As a result, the radiation power of an ensemble is thrice that of a single molecule near a nanoparticle irrespective to total number of molecules. Calculations were performed for both perpendicular and parallel dipole orientations with respect to the nanoparticle surface.

4:30PM W21.00011 Anisotropic mass enhancement factors of Γ state on Be(0001) surface, TJEY CHIEN, University of Tennessee, KNOXVILLE, ÉMILE RIENKS, MARIA JENSEN, Institute for Storage Ring Facilities and Interdisciplinary Nanoscience Center (INANO), University of Aarhus, Denmark, ASIER EIGUREN, EUGENE CHULKOV, Donostia International Physics Center (DIPC), 20018 San Sebastian/Donostia, Spain, PHILIP HOFMANN, Institute for Storage Ring Facilities and Interdisciplinary Nanoscience Center (INANO), University of Aarhus, Denmark, WARD PLUMMER, University of Tennessee, Knoxville — It is controversial on the values of mass enhancement factors, λ, of Be(0001) Γ state. Three possible explanations are: (1) λ is anisotropic along the Fermi circle; (2) method-based difference for extracting λ; (3) failure of theoretical model for capturing EPC features. We demonstrate a systematically survey of λ along the Fermi circle of Be(0001) Γ state. By adopting different methods to extract λ, the possibility of method-based inconsistency was ruled out. The trend of the anisotropic λ is clear and is confirmed by theoretical calculations, though the values are inconsistent with experiment. With model data simulation, we are confident about the extracted λ while we have noisy data. The possible explanation is that the DFT-LDA calculation can not catch the features of EPC on Be(0001) Γ state correctly. This work is financially supported by National Science Foundation (grants NSF-DMR-0451163).
4:42PM W21.00012 Electron-phonon induced complex quasiparticles in the 1x1 H/W(110) surface.¹, ASIER EIGUREN, Donostia International Physics Center (DIPC). CLAUDIA AMBROSCH-DRAKL, Montan University Leoben — We show that the solution of the complex Dyson equation for the electron-phonon problem induces several quasiparticle states for a given wave vector. The Dyson equation is considered in the full complex plane and it is solved without considering the imaginary part of the self-energy as a small parameter. By a first principle application of the formalism to the 1x1 H covered W(110) surface, we show that some aspects of the surface band splitting [Rotenberg et. al., Phys. Rev. Lett. 84, 2925 (2000)] can be traced back to electron-phonon coupling, where we present the energy and lifetimes of each quasiparticle. Despite this breakdown of the single quasi-particle picture, it is remarkable that the spectral functions are very well Represented by the predicted multiple quasi-particles. From these results, we can deduce that some of the features that previously where prescribed in ARPES spectra as incoherent structure could eventually be re-interpreted as contributions from additional quasi-particle states. Our method could also help to understand similar phenomena observed in high Tc cuprates and various other surfaces.

4:54PM W21.00013 Light-enhanced diffusion at the solid-liquid interface, SUNG CHUL BAE, JANET WONG, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois — Positively-charged rhodamine 6G molecules were allowed to adsorb onto quartz and mica surfaces and their translational and rotational diffusion was studied simultaneously by combined fluorescence correlation spectroscopy and time-correlated single photon counting. Surprisingly, the surface translational diffusion coefficient increased in direct proportion to the laser power used to excite these dye molecules. To elucidate the diffusion mechanism, we have investigated the excitation wavelength dependence, the spatial position dependence of diffusion coefficients, and the correlations between rotation and translation motion.

5:06PM W21.00014 Epitaxial Growth of Quinacridone Derivative on Ag(110), XIAOBO HE, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China & University of Tennessee, Knoxville, TN 37936, JINMING CAI, DONDXIA SHI, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China, WERNER A. HOFER, Department of Chemistry, The University of Liverpool, Liverpool L69 2BX, UK, E. WARD PLUUMER, Oak Ridge National Lab, Oak Ridge, TN 37831 and Univ of Tennessee, Knoxville, TN 37936, HONGJUN GAO, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China. — The growth behavior of quinacridone-derivative (QAC10C) molecules on Ag(110) surface is studied using low-energy scanning tunneling microscopy and low energy electron diffraction. At low coverage two distinct molecular orientations can be observed on silver terraces. At higher coverage up to 1 monolayer, depending on the growth temperature we observe two different structures on Ag(110) surface. At 100K the molecules organize in a complete monolayer on the surface, with a network-like structure. At 300K, the molecular orientation on the surface gives rise to row-like ordering, with a substantially higher molecular density. A theoretical analysis reveals that the structure of the molecular layer is controlled by the competition between molecular deposition rates and molecular diffusion along the surface.

Thursday, March 13, 2008 2:30PM - 5:18PM — Session W22 DMP DPOLY: Focus Session: Organic Photovoltaics and LEDs — Center 214

2:30PM W22.00001 Probing Photoconductivity in Phthalocyanines by Terahertz Spectroscopy, CHEN XIA, BRIAN KUBERA, VOLODIMYR DÜZHKO, HEFEI SHI, KENNETH SINGER, JIE SHAN, Department of Physics, Case Western Reserve University — Liquid crystals (LCs) are a relatively new class of photoconductors. Surprisingly high carrier mobilities have lately been reported in LCs. Although the high photogeneration order in these systems has been recognized to play an essential role in the high carrier mobilities, the mechanism of charge transport and carrier photogeneration are still not well understood. In this work, we investigate phthalocyanine (Pc) derivatives belonging to a family of discotic LCs as a model system. Optical pump/terahertz probe spectroscopy was employed to measure frequency dependence of the photocconductivity in Pc from 0.2 to 2.5THz. Photoconductivity appears within ~1ps (limited by time resolution of setup) after photoexcitation. It is followed by a fast decay of a few ps and a slow decay of 10's ps. Distinct frequency dependences were observed in the polycrystalline and liquid crystalline phases. The mechanism of charge transport and free carrier generation and recombination in the material will be discussed.

2:42PM W22.00002 Solution Processed Carbon Nanotube /PMMA Nano Composite Infrared Photodetectors, YI LIU, LIWEI LIU, PAUL STOKES, QUN HUO, SAIFULI KHONDAKER, University of Central Florida, NANOSCIENCE TECHNOLOGY CENTER, DEPARTMENTS OF PHYSICS & CHEMISTRY, UNIVERSITY OF CENTRAL FLORIDA TEAM — Solution processable nanostructured materials are of great interest for electronic and optical devices because of their enhance functionality, easy processibility, flexibility, and low cost of fabrication. We tested multi walled carbon nanotube networks dispersed in poly (methyl methacrylate) (PMMA) matrix for use as the infrared (IR) photodetectors at room temperature in ambient condition. Our study reveals both negative and positive infrared response depending upon the dark conduction of the composite. The temperature dependence of resistance, photo intensities and bias voltages dependence of IR response will be presented. This work shows promising novel route for the fabrication of infrared bolometric photo detector based on solution-processed carbon nanotube/PMMA composites.

2:54PM W22.00003 Triplet excitons in a ladder-type conjugated polymer: application in organic optoelectronics¹, K. YANG, M. ARIF, S. GUHA, University of Missouri-Columbia — Trace concentrations of metallic impurities present at the ppm level in conjugated polymers allow photophysical studies of triplet states at room temperature. We present temperature- dependent photoinduced absorption (PIA) and photoluminescence studies of diaryl (diphenyl)-substituted ladder-type poly (paraphenylene) (PhLPPP) containing a trace concentration of covalently bound Pd atoms. The T₁-T₂ peak (~1.3 eV) observed in the PIA blue shifts with increasing temperatures at a rate higher compared to the blue shift of singlet excitons in the sample with increasing temperatures. The temperature shift of the PIA signal arises both due to the temperature dependence of the triplet mobility as well as its mean free path. Our observations suggest that with increasing temperatures the triplet excitons remain localized on smaller chain segments. A triplet lifetime of ~12 ms was determined at room temperature. Furthermore, we will discuss the application of triplet state enhanced polymers in photovoltaic applications.

¹We thank Prof. U. Scherf for the donation of the material. This work was supported by NSF-ECCS # 0523656.
3:06PM W22.00004 Photovoltaic Effect in a Composite involving the Nonconjugated Conductive Polymer, Poly(β-pinene) and C_{60}, ADITYA KUMAR PALTII, ANANTHAKRISHNAN NARAYANAN, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL — Photovoltaic effect in a composite involving a nonconjugated conductive polymer, poly(β-pinene) and C_{60}, will be reported. The photovoltaic cell was fabricated using indium tin oxide coated glass as one electrode and aluminum as the other, with a poly(β-pinene)-C_{60} composite film sandwiched between the electrodes. Nitrogen laser (emission at 325 nm) and illuminant white light bulbs (emission at 300-700nm) were used as the light sources and the photo-voltage produced was recorded for different light intensities. The photo-voltage produced had a linear dependence on the light intensity. About 100 mV was generated for an intensity of ~4 mW/cm^2. Pristine poly(β-pinene) has a photoluminescence peak at 360 nm for excitation at 280 nm. As we have observed, this photoluminescence is quenched when C_{60} is added to poly(β-pinene) to form the composite. Therefore, the observed photovoltaic effect appears to be a result of excited-state electron transfer from poly(β-pinene) to C_{60}.

3:18PM W22.00005 Femtosecond and CW transient studies of photoinduced charge transfer in donor/acceptor blends for organic solar cells1, JOSH HOLT, SANJEEV SINGH, TOMER DRORI, ALEXANDRE NDOBE, Z. VALY VARDENY, University of Utah — Current developments in organic solar cells (~6% power conversion efficiency) require understanding and control of photoinduced charge transfer donor-acceptor pairs. In this work we provide and compare evidence that poly(2-methoxy-5(2′-ethyl)hexoxy-phenylenediyline) (MEH-PPV, donor) blended with 2,4,7-trinitrofluorenone (TNF, strong acceptor) form a below-gap charge transfer complex (CTC) state that extends absorption into the near infrared (NIR). Transient PA measurements show direct photoexcitation into the CTC state where significant charge species are initially photogenerated, the majority of which geminately recombine within ~10 ps, but the few that escape geminate recombination are subsequently captured in long-lived traps. Polaron could also be photoexcited with high efficiency at NIR excitation, with similar fate. This shows that a CTC state exists below the MEH-PPV optical gap, but with low dissociation efficiency, which leads to poor photovoltaic effect. We compare our results to those in blends of MEH-PPV/C_{60}, where apparently the obtained CTC state has a much higher dissociation efficiency.

3:30PM W22.00006 Quantum efficiency in organic phototransistors, WILLIAM HAMMOND, JIANGENG XUE, University of Florida — Organic optoelectronic devices hold a prominent role in current applied physics research. Although these devices inherently suffer from lower carrier mobility than inorganic devices, their mechanically flexible nature and low material costs enable new and interesting applications. Organic phototransistors, for example, may enable simplified circuits for large area and flexible sensors. Here we report the spectral dependence of the external quantum efficiency of organic phototransistors (OFETs) based on pentacene and C_{60}. Furthermore, we explore the gain mechanism in these devices and the effect of transistor structure on internal photomultiplication.

3:42PM W22.00007 Ultrafast dynamics in blends of π-conjugated polymers/fullerenes1, SANJEEV SINGH, MINGHONG TONG, CHUANXIANG SHENG, ZEEV VARDENY, University of Utah — We have studied the ultrafast dynamics of photogenerated charges and excitons in a variety of π-conjugated polymer/fullerene blends using the transient pump-probe photomodulation (PM) spectroscopy with ~100 fs resolution. These composites serve as active layers in organic photovoltaic devices with high power conversion quantum yield, due to the existence of a photoinduced charge transfer (PCT) reaction between the polymer and the fullerene molecules. Our transient PM spectrum spans a broad energy range from 0.1-2.4 eV, and this allows us to monitor the transient behavior of the various photoinduced absorption (PA) bands of polaron and excitons in the PM spectrum; as well as the transient excitation stimulated emission, and photoelectrochemical (PB) of the ground state. The PB dynamics reflect the ground state recovery; hence, it can be used to determine the long-lived polaron photogeneration quantum efficiency in these systems.

1Supported in part by the DOE grant 04-ER 46109 at the University of Utah.

3:54PM W22.00008 Spin Response in Organic Light Emitting Diodes1, FUJIAN WANG, CUNGENG YANG, TOMER DRORI, Z. VALY VARDENY, Department of Physics, University of Utah — To understand the origin of the magnetic field effect in OLEDs, we studied the large magnetoresistance (MR) and magneto-electroeluminescence (MEL) of OLEDs based on pristine MEH-PPV polymer, as well as MEH-PPV doped with various concentrations of radical impurities and C_{60} molecules. In contrast to OLED based on pristine MEH-PPV that show MR and MEL up to 12% at room temperature, we found in MEH-PPV:C_{60} based OLED the MR and MEL decrease substantially with increasing C_{60} molecule concentration. For MEH-PPV:C_{60} devices with C_{60}, concentration of 50%, the MR effect is less than 0.3% at room temperature. In MEH-PPV:radical devices the MR and MEL effects again differ substantially from those found in pristine and C_{60} doped MEH-PPV devices. At 50% radical concentration the MR and MEL effects are about 1% and 3.5%, respectively. The results are discussed with existing models for the magnetic field effects in OLEDs.

4:06PM W22.00009 Organic Semiconductors: devices, growth and ordered assembly1, FABIO CICOIRA, Cornell University — Organic semiconductors are employed in devices such as field-effect transistors (FETs), light-emitting diodes and photovoltaic cells. Besides their technological interest, these devices are model systems to study physical processes in organic semiconductors [1]. Light-emitting field effect transistors (OLEFETs) based on organic semiconducting films are a novel class of devices integrating the transistor function with the light emission [2]. I will discuss LEFETs based on oligothiophenes [3] and oligoacenes [4][5], in particular their optoelectronic properties and the films growth physics. A unique property of organic semiconductors is the ability to form ordered assemblies at surfaces that can be studied by scanning tunneling microscopy (STM). I will discuss the growth and architectural motifs of copper of two organic semiconductors: the linear and planar quinqueithiophene [6] and the branched non-planar rubrene [7]. These studies show the ability of organic semiconductors to form fascinating self-assembled motifs and are of paramount importance to understand the early stages of growth of organic films. Organic electrochemical transistors (OECTs) are expected to play a key role in future organic electronics. OECTs are ideal candidates for biosensing applications thanks to their low driving voltage and their ability to operate in aqueous environment. A great deal of work is needed to understand the device physics of OECTs and optimize their performance. I will discuss advances in the field drawing examples from studies on devices based on the conducting polymer PEDOT:PSS.

Spin injection effects on exciton distributions in conjugated organic semiconductors, Mohammad Yunus, Paul Paul, Darryl Smith, and Lee Alamos National Laboratory — Conjugated organic semiconductors are under rapid development as the active material in organic light emitting diodes (OLEDs). Experiments and holes injected into the organic semiconductor form bound singlet or triplet excitons. Singlet excitons may recombine radiatively giving rise to light emission whereas triplet excitons do not recombine radiatively. Thus the quantum efficiency of OLEDs is limited by the fraction of singlet excitons, χS. In this work, we explore theoretically an approach to control χS through spin-polarized electron and hole injection from ferromagnetic contacts. Conventional ferromagnetic transition metals and half-metallic materials, such as LSMO, are considered as candidate electrode materials. The electron and hole transport in the organic semiconductor is treated through the conventional device equations with the formation of excitons described by a Landegev process. Once formed, the excitons may recombine or diffuse. Triplet excitons have a lower recombination probability and hence a longer diffusion length. The model calculations yield steady state spatial profiles for singlet and triplet exciton densities in the organic semiconductor.

Electrically detected coherent spin manipulation of polaron pairs in an MEH-PPV OLED, Heather Seipel, Dane Mccamey, Seoyoung Paik, Manfred Walter, Nick Borys, John Lupton, Christoph Boehme, Department of Physics, University of Utah — Understanding of spin relaxation in organic light emitting diodes (OLEDs) is important for determining the maximum device efficiencies, due to the spin dependence of electronic transitions in organic materials. Here, we present an experiment demonstrating that coherent spin motion of polaron spin pairs can influence the current through an OLED fabricated using the prototypical conjugated polymer poly[2-methoxy-5-(2-ethyl-hexyloxy)-1,4-phenylene vinylene] (MEH-PPV). We observe a change in the zero-bias photocurrent transient through an OLED device following a short, coherent microwave pulse resonant with polaron pair spin transitions. The shape of the current transient provides information about the recombination rates of polaron pairs in both the singlet and triplet configurations. By varying the length of this pulse, coherent Rabi oscillations are detected, which reveal that the polaron pairs sensitive for the signal remain coherent for >0.5 µs. Due to these extremely long coherence times, we conclude that spin mixing processes are unable to significantly influence the spin state of the polaron pairs.

Tunable and White Light Emitting Diodes of Single Component Fluorinated Benzoxazole Graft Copolymers, Shih Jung Bai, Chienu-Chang Wu, Institute of Materials Science and Engineering, National Sun Yat-sen University — Coil-like graft copolymers of poly(Am-co-B-(1-x)) containing identical heterocyclic aromatic benzoxazole with trifluoromethyl-ethyl as the backbone and pendant of monohydroxyl (Am) and/or di-acyloxy (B-(1-x)) on their phenylene ring were studied for luminescence properties. The copolymers were synthesized with molar fraction m ranging from 0.25, 0.5, 0.75 to 1, and then dissolved and spun onto Spectrosol® quartz slide or indium-tin-oxide (ITO) substrate. The fluorescence and PL emissions of copolymers were investigated by ultraviolet-visible absorption covering 185 nm to 800 nm and photoluminescence (PL) emission excited at 363 nm. The PL results exhibited an excellent chromatic tuning range from green to white emission as m decreased. Aluminum electron injectors were evaporated onto the copolymer/ITO unit making it into mono-layer light emitting diodes for current-voltage and electroluminescence (EL) responses. An emission threshold voltage of 6 V was achieved for all the mono-layer copolymer devices. The Commission Internationale de l’Eclairage chromaticities of the EL emission were from (0.25, 0.53) to (0.24, 0.31) covering a wide visible range including white light emission.

Parameters controlling magnetic transitions in manganites, B. Dabrowski, S. Kolessnik, O. Chmaissem, J. Mais, Department of Physics, Northern Illinois University, DeKalb, IL 60115, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439 — Using description of structural and physical properties of perovskites in terms of the tolerance factor t(x,T,d), which is dependent on composition, temperature, and oxygen-content, we have established synthetic methods and studied composition-structure-properties for new manganites La1−xSrxBaMnO3+δ. These are stable solid solutions limits normally achieved during the synthesis in air. Parameters controlling magnetic transitions have been identified through examples of single-valent compounds of RmO3 (the Mn-O-Mn bond angles that can be equivalently described in terms of the tolerance factor) and Sr1−xCa2MnO3 (the tolerance factor and the variance of A-site ion sizes), and the mixed-valent La0.5Sr0.5BaMnO3 (the tolerance factor, variance of sizes, and the local strains described in terms of the elongated Mn-O bonds). By using an example of kinetically stable, atomically-ordered layered-perovskites RSm2MnO6 we show that the increase of Curie temperature Tc and enhancement of colossal magneto-resistive effect at room temperature, can be achieved through reduction of variance of sizes and local strains. Work at NIU was supported by the NSF-DMR-0302617 and at ANL by the U.S. DOE under contract No. DE-AC02-06CH11357.

Parameters controlling magnetic transitions in manganites, B. Dabrowski, S. Kolessnik, O. Chmaissem, J. Mais, Department of Physics, Northern Illinois University, DeKalb, IL 60115, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439 — Using description of structural and physical properties of perovskites in terms of the tolerance factor t(x,T,d), which is dependent on composition, temperature, and oxygen-content, we have established synthetic methods and studied composition-structure-properties for new manganites La1−xSrxBaMnO3+δ. These are stable solid solutions limits normally achieved during the synthesis in air. Parameters controlling magnetic transitions have been identified through examples of single-valent compounds of RmO3 (the Mn-O-Mn bond angles that can be equivalently described in terms of the tolerance factor) and Sr1−xCa2MnO3 (the tolerance factor and the variance of A-site ion sizes), and the mixed-valent La0.5Sr0.5BaMnO3 (the tolerance factor, variance of sizes, and the local strains described in terms of the elongated Mn-O bonds). By using an example of kinetically stable, atomically-ordered layered-perovskites RSm2MnO6 we show that the increase of Curie temperature Tc and enhancement of colossal magneto-resistive effect at room temperature, can be achieved through reduction of variance of sizes and local strains. Work at NIU was supported by the NSF-DMR-0302617 and at ANL by the U.S. DOE under contract No. DE-AC02-06CH11357.

Phase separation in (001) and (110) La2/3Ca1/3MnO3 epitaxial films, J. Fontcuberta, I.C. Infante, F. Sanchez, Institut de Ciencia de Materials de Barcelona-CSIC, Campus UAB, 08193 Bellaterra, Spain, M. Wojcik, E. Jedryka, Institute of Physics, Polish Acad. of Sci., Al. Lotnikow 32/46, 02668 Warszawa, Poland, S. Estrade, J. Arbiol, F. Peiro, EME/CerMAE/IN2UB, Universitat de Barcelona, 08028 Barcelona, Spain — Recent reports on the formation of a highly conducting layer at the interface between two insulators have driven a strong interest to interface physics. To explore strain and polarity effects on electronic phase separation (PS), we have grown epitaxial films of La2/3Ca1/3MnO3 (LCMO) on (001) and (110) SrTiO3 (STO) substrates. (001) LCMO/STO and (110) LCMO/STO interfaces differ on the polarity sequence. Measurements of the LCMO layers show that the (110) LCMO films display always “better” magnetic properties that their (001) LCMO counter-partners and do not show any traces of PS. Moreover, we have analyzed the properties of (001) and (110) thin LCMO films capped with a thin STO barrier and compared with those of bare LCMO films. It turns out that STO capping induces PS in (001) LCMO films but not in (110) films. Reasons for this asymmetrical behaviour will be discussed.

Crystal Properties of Oxygen Composition Controlled La1−xSrMnO3+δ Single Crystals, Yuji Yokota, Jun-Ichi Shimoyama, Tetsuro Ogata, Atsushi Nakamura, Hiraku Ogino, Shigeru Horii, Kohji Kishino, Department of Applied Chemistry, University of Tokyo Team — The La1−xSrMnO3+δ is known to have various magnetic and crystal structures as functions of x. Although this system has relatively large oxygen nonstoichiometry, the effects of excess oxygen on the crystal structure and physical properties have not been well understood. In the present study, the crystal structure and physical properties of excess oxygen controlled La1−xSrMnO3+δ single crystals were systematically studied. Single crystals with nominal compositions of La1−xSrMnO3+δ (0.05 ≤ x ≤ 0.2) were grown by the floating zone method. Thin plate-like crystals were obtained from the grown boules and controlled the oxygen content by post-annealing in various atmospheres. With increasing δ, the orthorhombic of the as-grown La0.95Sr0.05MnO3+δ crystal changed to the rhombohedral through pseudo-cubic orthorhombic. In addition, ferromagnetic behaviors appeared accompanying the CMR effect and Tc increased as a function of δ. These are attributable to an increase of valence of Mn by excess oxygen. Relationships among the Sr substitution level, excess oxygen content, crystal structure and magnetic behaviors of La1−xSrMnO3+δ will be discussed.
3:06PM W23.00004 Improved CMR properties of RE-doped (La,Sr)MnO$_3$ single crystals  JUN-ICHI SHIMOYAMA, Department of Applied Chemistry, University of Tokyo, TETSURO OGATA, YUUI YOKOTA, HIRAKU OGINO, SHIGERU HORII, KOHJI KISHIO — The relationships among crystal structure, $T_C$ and CMR effect have been eagerly studied for (La,Sr)MnO$_3$ system mainly as a functions of the Sr composition, x thus far. In the present study, we have attempted to improve the CMR properties near room temperature of the present system by optimizations of $T_C$ and $T_C$ phase transition temperature between orthorhombic and rhombohedral through RE mixing and elimination of excess oxygen, i.e. cation vacancies, for (La$_{1-x}$Sr$_x$)$_3$MnO$_7$ single crystals with $x = 0.2$ and 0.25, which have higher $T_C$ than room temperature and essentially high electronic conductivity. Crystal boules with nominal compositions of La$_{0.75-x}$Pr$_x$Sr$_{0.25}$MnO$_7$ ($x = 0.0, 0.05, 0.15$) were grown by the floating zone method. Crystal structure of La$_{0.75-x}$Pr$_x$Sr$_{0.25}$MnO$_7$ at $\sim 300$ K changed from orthorhombic ($z = 0, 0.15, 0.25$) to orthorhombic ($z = 0.3$) due to a decrease in mean ionic radius of A site. In addition, Pr-doping systematically decreased the coexistence at different length scales of ferromagnetic, charge/orbital order has been recently recognized as an intrinsic feature of several strongly correlated electron systems. Using inelastic neutron scattering, we have studied the spin dynamics of the archetypical material (La,Pr)$_3$Ca$_{3-x}$MnO$_7$, where competing ground states coexist at low temperature. The low-$T$ spin wave excitations at $H = 0$ and $2T$ are drastically different. We discuss this difference in terms of magnetic excitations from ferromagnetic clusters of different length scales.

3:18PM W23.00005 Unconventional spin-dynamics in a phase separate, weakly disordered perovskite manganite$^1$, FENG YE, JAIME FERNANDEZ-BACA, PENGCHENG DAI, HYE-JUNG KANG, JEFFREY LYNN, CHENGLIN ZHANG, S.-W. CHEONG — The intense investigation of perovskite manganites has revealed a variety of fascinating properties. The phenomena known as phase separation, the coexistence at different length scales of ferromagnetic, charge/orbital order has been recently recognized as an intrinsic feature of several strongly correlated systems. With a new analytic model and inelastic neutron scattering, we have studied the spin dynamics of the archetypical material (La,Pr)$_3$Ca$_{3-x}$MnO$_7$, where competing ground states coexist at low temperature. The low-$T$ spin wave excitations at $H = 0$ and $2T$ are drastically different. We discuss this difference in terms of magnetic excitations from ferromagnetic clusters of different length scales.

3:30PM W23.00006 Phase separation in Pr$_{0.55}$Ca$_{1.45}$MnO$_{3.1+}$ evidenced by magnetic excitations$^1$, SONGXUE CHI, The University of Tennessee, Knoxville, FENG YE, JAYMIE LAMOUR, University of Tennessee, Knoxville, FENG YE, JAIME FERNANDEZ-BACA, Oak Ridge National Laboratory, HYE JUNG KANG, JEFFREY W. LYNN, YING CHEN, NIST Center for Neutron Scattering, YOSHIO KANEKO, YOSHINORI TOKURA, University of Tokyo — At doping levels $x \approx 0.5$, a coexistence of commensurate (CM) and incommensurate (ICM) magnetic peaks are observed in single-layered manganites Pr$_{1-x}$Ca$_{1+x}$MnO$_3$ with elastic neutron scattering. Temperature dependence measurements of the magnetic intensities with different energy resolutions indicate a glassy nature of the magnetic moments. The magnetic excitation measurements using inelastic neutron scattering on the $x=0.45$ system reveal both symmetric and asymmetric behaviors about the CM peak positions. This strongly suggests two types of magnetic excitations originated from separated phases: the CE-type magnetic phase and an additional electronic phase caused by extra electrons introduced into the CE template.

3:42PM W23.00007 Signature of Magnetic Phase Separation in Pr$_{1-x}$Ca$_{x}$MnO$_3$,$^1$ DALGIS MESA, HAO SHA, JIANDI ZHANG, Florida International University, Miami, FL 33199, F. YE, Oak Ridge National Laboratory, Oak Ridge, TN 37831, P.C. DAI, J. A. FERNANDEZ-BACA, Oak Ridge National Laboratory, HYE JUNG KANG, JEFFREY W. LYNN, YING CHEN, NIST Center for Neutron Scattering, YOSHIO KANEKO, YOSHINORI TOKURA, University of Tokyo — At doping levels $x \approx 0.5$, a coexistence of commensurate (CM) and incommensurate (ICM) magnetic peaks are observed in single-layered manganites Pr$_{1-x}$Ca$_{1+x}$MnO$_3$ with elastic neutron scattering. Temperature dependence measurements of the magnetic intensities with different energy resolutions indicate a glassy nature of the magnetic moments. The magnetic excitation measurements using inelastic neutron scattering on the $x=0.45$ system reveal both symmetric and asymmetric behaviors about the CM peak positions. This strongly suggests two types of magnetic excitations originated from separated phases: the CE-type magnetic phase and an additional electronic phase caused by extra electrons introduced into the CE template.

3:54PM W23.00008 Anomalous Short Range Charge Ordering in La$_{1-x}$Ca$_x$MnO$_3$ , JING TAO, Brookhaven National Lab, S.J. PENNYCOOK, Oak Ridge National Lab, Y. ZHU, Brookhaven National Lab — Long range charge ordered (CO) phases have been observed at low temperatures in manganites in certain doping ranges. Structural characterization of the long-range CO phase showed that the CO superlattice is always along the $a$ axis in bulk samples [1]. Here we report the observations of a short range CO phase in La$_{1-x}$Ca$_x$MnO$_3$ samples as a function of cation concentration $x$, temperature and magnetic field using in-situ electron microscopy. We find short range CO nanoclusters with the CO superlattice in both perpendicular directions (a and c axes) in single crystal samples. The a and c axis nanoclusters have different densities, and show different dependences on temperature and magnetic field. Time evolution of the CO nanoclusters with the CO superstructure along the anomalous direction (c axis) is also recorded, which implies that the energy barrier between the two types of the CO structure is very small [2] [1]. P. G. Radaelli et al., PRB 59, 14440 (1999) [2]. Research sponsored by the Office of Basic Energy Sciences, Division of Materials Sciences and Engineering and by appointment to the ORNL Postdoctoral Research Program administered jointly by ORNL and ORISE. Work at BNL was supported by the U.S. DOE/BES under Contract No. DE-AC02-98CH10886.

4:06PM W23.00009 Spatially-Resolved X-Ray Microstructural Studies of Bulk Phase Separation in Manganites$^1$, J.D. BUDAI, Oak Ridge National Lab, D.D. SARMA, Ind. Inst. of Sci., W. LIU, ANL, J.Z. TISCHLER, B.C. LARSON, ORNL, G. SHENOY, ANL, D. TOPWAL, Ind. Inst. of Sci., S.-W. CHEONG, Rutgers Univ. — We have used spatially-resolved, 3D x-ray microdiffraction to study phase separation in two directionally-solidified, transition-metal oxide systems: (Y,Eu)MnO and (Lu,La)SbMnO. Both systems exhibit micron-scale coexistence of separate single-crystal lamellar domains (hex/ortho and hex/thomb respectively) when grown by a floating zone method. Micron-resolution 3D x-ray microscopy reveals the domain morphologies, lattice orientations, and local strain fields within the phase-separated eutectic systems. The orientations of the lamellae are consistent with energetic predictions and the formation of low-energy, semi-coherent interfaces. In addition, we observe a bias for larger strain fluctuations in one phase. More generally, the microstructural features observed experimentally in these well-defined, micron-scale eutectic domains provide clues to the domain interactions believed to exist in similar, more homogeneous, nanoscale manganite systems. Structural studies at the nanoscale will be enabled in the future by advances in x-ray focusing optics.

4:30PM W23.00011 Domain Mapping of a Ca-doped Manganese, JOSHUA TURNER, University of Oregon, K. JESSICA THOMAS, MARY UPTON, JOHN HILL, Brookhaven National Laboratory, JEAN JORDAN-SWEET, National Synchrotron Light Source, YOSHINORI TOKURA, YASUHIDE TOMIOKA, Correlated Electron Research Center, STEPHEN KEVAN, University of Oregon — In the last few years, disorder has emerged as a key without which the colossal magnetoresistance (CMR) effect would not exist. Single crystals represent the simplest arenas to observe and study the peculiarities central to the manganites. This is in contrast to polycrystalline compositions for instance, where rampant strain fields can veil fundamental physics. By micro-focusing x-rays through a glass capillary, we have performed a microtopography technique to map the crystallographic domain structure of the Ca-doped manganese crystal, PCMO. This technique serves as a domain-mapping alternative tool to TEM that does not require challenging sample preparation procedures. Surprisingly, we find micron size domain structure. We suggest that the separation of crystallographic domains by twin boundaries is more relevant than previously believed. These boundaries could affect the large-scale, submicron size disorder that has been observed recently, and also may play a role in the heterogeneous nature of the CMR effect.

4:42PM W23.00012 Temperature-Dependent Electronic Structure of the Colossal Magnetoresistive Manganese La$_{0.7}$Sr$_{0.3}$MnO$_3$ via Hard X-Ray Photoemission, FRANCESCO OFFI, CNISM and Dip. di Fisica, Università Roma Tre, Rome, NORMAN MANNELLA, Physics, U. Tennessee Knoxville, GIANCARLO PANACCIONE, TASC-INFN-CNR, Trieste, Italy, TOMMASO PARDINI, Physics UC Davis, ANDREA FONDACARO, ESRF, Grenoble, PIERO TORELLI, CNR-INFN-S3, Modena, SIMO HUOTARI, ESRF, Grenoble, MARK WEST, Mat. Sci. Div., LBNL, JOHN MANN, Department of Physics and Astronomy, California State University, Los Angeles — We report magnetic susceptibility $\chi(T)$ measurements on oxygen-isotope exchanged La$_{1-x}$Ca$_x$MnO$_3$ up to 700 K. The $1/\chi(T)$ data show that the ferromagnetic exchange-energy $J$ depends strongly on the oxygen-isotope mass. The isotope effect on $J$ decreases with temperature up to 400 K and then increases again with temperature above 400 K. This unusual temperature dependence cannot be explained by existing theories of the colossal magnetoresistance effect for doped manganites. We suggest that a correct model for description of the physics of manganites should be based on double-exchange and the formation of localized bipolarons in the paramagnetic state.

5:06PM W23.00014 Origin of the Non-Linear Pressure Effects in Perovskite Manganites, ZHIQIANG CHEN, TREVOR TYSON, KEN AHN, New Jersey Institute of Technology, ZHONG ZHONG, Brookhaven National Laboratory, JINZHU HU, University of Chicago — High pressure resistivity and x-ray diffraction measurements were conducted on La$_{0.5}$Pr$_{0.5}$MnO$_3$ to $\sim$6 GPa and $\sim$7 GPa, respectively. At low pressures the metal-insulator transition temperature ($T_{MI}$) increases linearly up to a critical pressure, P* $\sim$ 3.4 GPa, followed by reduction of $T_{MI}$ at higher pressure. Analysis of the bond distances and bond angles reveal that a bandwidth increase drives the increase of $T_{MI}$ below P*. The reduction of $T_{MI}$ at higher pressures is found to result from Jahn-Teller distortions of the MnO$_6$octahedra. The role of anharmonic interatomic potentials is discussed.

5:18PM W23.00015 Phonon-induced magnetic deflagration and detection of very fast CMR in manganites, FERRAN MACIA, JOAN MANEL HERNANDEZ, GUILLER ABRIL, ALBERTO HERNANDEZ-MINGUEZ, Universitat de Barcelona, FRANCISCO PARISI, Comision Nacional de Energia Atomica, PAULO V. SANTOS, Paul-Drude Institut fur Korperelektronik, JAVIER TEJADA, Universitat de Barcelona — In this work we describe experiments in which we have used surface acoustic waves to induce controlled magnetic avalanches in (La, Pr)-based manganites. The avalanches propagate inside the sample following the law of the magnetic deflagration, and occur at well determined values of the temperature and the applied magnetic field, that depend on the phase separation fraction. Another important point is that the magnetic avalanche is accompanied by colossal variation of the electrical resistance in about 0.1 ms. F. Macia et al., Phys. Rev. B 76, 174424 (2007). F. Macia et al., Phys. Rev. B, submitted.

Surprisingly, thermally enhanced. For 260–302 K the onset time for photo-crystallization decreases with increasing temperature, but the crystallization rate is T-independent.

K. TANIOKA, NHK Laboratories, Tokyo — Photo-crystallization of amorphous (a-) Se is investigated as a function of temperature (T = 250–340 K) and exposure to 435 nm light. Raman scattering and modulated DSC on bulk As\(_2\)Se\(_3\) glasses result in the following observations: (1) the glass transition temperature (T\(_g\)) is 324 ± 2°C. (2) The rate of crystallization is 

Evidence for Quasi Tetrahedral S=As(S\(_1\)/\(_2\))\(_3\) local structures in As\(_x\)S\(_{1-x}\) glasses, PING CHEN, P. BOOLCHAND, C. HOLBROOK, Univ. Cincinnati, K. JACKSON, Central Mich., D. GEORGIEV, Univ. of Toledo, M. MICOLAULT, Univ. Paris — Raman scattering and modulated DSC on bulk As\(_x\)S\(_{1-x}\) glasses in the 0.08 < x < 0.41 range is studied\(^1\). We have examined a set of 4 samples (1181°C, 203°C, 324.7°C, 4254°C) with different T\(_g\)s indicated in parenthesis, in m-DSC, Raman and IR experiments to elucidate the role of bonded water. Our results show that the glass transition endotherm of sample 4 (dry) is characteristic of a stressed-rigid glass, while that of sample 1 (wet) of a flexible glass. Although Raman scattering of samples 1 and 4 look superficially similar, they are different in details; the Boson peak in sample 4 has a stronger intensity than in sample 1. IR reflectance function strength in the mid-IR range is weaker for sample 4 than for sample 1, and furthermore differs in details. These results show that presence of water disrupts the P-O-P chain network by replacing bridging O with terminal OH\(^-\) ends. And once water is bonded, it is difficult to remove it completely. These results will be compared to previous reports in the field. \(^1\) D.I. Novita and P. Boolchand Phys. Rev. B (in press) Supported by NSF grant DMR 04-56472.

Evidence of Intermediate Phase in (Na\(_2\)O)\(_x\) (GeSe\(_2\))\(_{1-x}\) glasses, V. ROMICHEVARLA, PING CHEN, D. NOVITA, P. BOOLCHAND, Univ. Cincinnati, M. MICOLAULT, Univ. of Paris, W. HUFF, Univ. Cincinnati — Intermediate phases have been observed in covalent glasses, but ionically bonded network systems have received much less attention in this respect. We have now examined titled glasses in m-DSC, Raman scattering, IR reflectance and Birefringence experiments over wide range of soda concentration, 3 < x < 30%. Thermal experiments reveal a sharp reversibility window (RW) in the 14% < x < 19% soda range, which correlates well with a broad global maximum in molar densities (germanate anomaly). Raman and IR reflectance TO and LO mode frequencies exhibit anomalies between x\(_1\) (1) = 14% (stress transition) and x\(_2\) (2) = 19% (rigidity transition), with optical elasticity power-laws confirming the nature of the transitions. Birefringence measurements dramatize the macroscopically stress-free nature of the Intermediate Phase (IP) in the RW. These data also suggest that the germanate anomaly can be understood as a direct consequence of the multiscale structural self-organization of glasses in the IP. \(^1\) Supported by NSF grant DMR 04-56472.

Competing effects in the photo-crystallization of a-Se HARP films, R.E. TALLMAN, B.A. WEINSTEIN, Physics Dept., SUNY at Buffalo, A. REZNIK, J.A. ROWLANDS, Sunnybrook Health Sciences Centre, Toronto. M. KUBOTA, K. TANIOKA, NHK Laboratories, Tokyo — Photo-crystallization of amorphous (a-) Se is investigated as a function of temperature (T = 250–340 K) and exposure time by Raman scattering in photo-active films used in high-gain avalanche rushing photoconductor (HARP) cameras. We observe different temperature regimes that reflect the competition of viscosity-driven and strain-driven processes. No photo-crystallization is seen below 260K, and above 318K the crystallization rate is thermally enhanced. For 260–302 K the onset time for photo-crystallization decreases with increasing temperature, but the crystallization rate is T-independent. Surprisingly, photo-crystallization is strongly suppressed in a 15 degree range around the glass transition at \(T_g\) ~ 310K. Our results are in qualitative accord with a theory by Stephens\(^1\) that treats the effects of local strain on the growth of crystalline-Se domains within an a-Se matrix – the strain arising from the density difference between the crystalline and amorphous phases. \(^1\) R.B. Stephens, J. Appl. Phys. 51, 6197 (1981).
2:30PM W25.00001 Design of Responsive Peptide-based Hydrogels as Therapeutics. JOEL SCHNEIDER, University of Delaware — Hydrogels composed of self-assembled peptides have been designed to allow minimally invasive delivery of cells in vivo. These peptides undergo sol-gel phase transitions in response to biological media enabling the three-dimensional encapsulation of cells. Peptides are designed such that when dissolved in aqueous solution, exist in an ensemble of random coil conformations rendering them fully soluble. The addition of an exogenous stimulus results in peptide folding into beta-hairpin conformation. This folded structure undergoes rapid self-assembly into a highly crosslinked hydrogel network whose nanostructure is defined and controllable. This mechanism, which links intramolecular peptide folding to self-assembly, allows temporally resolved material formation. In general, peptides can be designed to fold and assemble affording hydrogel in response to changes in pH or ionic strength, the addition of heat or even light. In addition to these stimuli, DMEM cell culture media is able to initiate folding and consequent self-assembly. DMEM-induced gels are cytocompatible towards NIH 3T3 murine fibroblasts, mesenchymal stem cells, hepatocytes, osteoblasts and chondrocytes. As an added bonus, many of these hydrogels possess broad spectrum antibacterial activity suggesting that adventitious bacterial infections that may occur during surgical manipulations and after implantation can be greatly reduced. Lastly, when hydrogelation is triggered in the presence of cells, gels become impregnated and can serve as a delivery vehicle. A unique characteristic of these gels is that when an appropriate shear stress is applied, the gel will shear-thin, becoming an injectable low viscosity gel. However, after the application of shear has stopped, the material quickly self-heals producing a gel with mechanical rigidity nearly identical to the original hydrogel. This attribute allows cell-impregnated gels to be delivered to target tissues via syringe where they quickly recover complementing the shape of the tissue defect. This shear-thin delivery method is a convenient way to introduce cells to wound sites.

3:06PM W25.00002 Synchrotron x-ray diffraction study on the size distribution and mechanical stability of microtubules by microtubule-associated-protein (MAP) tau, M.C. CHOI, U. RAVIV, H. MILLER, M. GAYLORD, E. KIRIS, D. VENTIMIGLIA, L. WILSON, M.W. KIM, S. FEINSTEIN, C.R. FAFNYA, UNIV. OF CALIFORNIA AT SANTA BARBARA TEAM, KOREA ADVANCED INSTITUTE OF SCIENCE AND TECHNOLOGY TEAM, HEBREW UNIV OF JERUSALEM TEAM — In neurons, microtubules (Mts), 25nm protein nanotubes, are used extensively as tracks for transporting nutrients and cellular components between the cell body and axons. MAP tau regulates microtubule assembly and, in a poorly understood manner, inter-MT interactions. Altered tau-MT interactions leads to MT depolymerization and tau tangles, which is implicated in a large number of neurodegenerative diseases. We will show that the size distribution and the enhanced mechanical stability of Mts by tau bindings are dependent on tau isoforms. Supported by DOE DE-FG02-06ER46314, NSF DMR-053347, and NIH GM-59288, NIH RO1-NS35010.

3:18PM W25.00003 Effect of Mg Ions on Microrheological Properties of F-actin Solution across Isotropic-Nematic Phase Transition1, JUN HE, MICHAEL MAK, YIFENG LIU, JAY TANG, Brown University — We studied microrheological properties of F-actin across the isotropic-nematic phase transition region by video particle tracking and laser deflection particle tracking methods. The two methods give consistent results. As the nematic order parameter increases with the actin concentration, G’ (along the alignment) and G’’ grow apart, with G’’ larger than G’. The moduli scale with actin concentration as G’_c \propto \epsilon^{-0.542+0.13} and G’’_c \propto \epsilon^{1.38+0.15}. Furthermore, G’ and G’’ dependence on [Mg^{2+}] were measured and compared for 1 mg/ml isotropic and 4 mg/ml nematic F-actin solutions. For isotropic phase, G’ increase with [Mg^{2+}] up to 6 mM and then plateaus; for nematic phase, G’_c is larger and both G’ and G’’ increase with [Mg^{2+}] monotonically all the way up to 16 mM, above which F-actin bundle formation occurs. In both isotropic and nematic phases, G’’ only weakly depends on [Mg^{2+}]. In conclusion, particle tracking microrheology reveals rich rheological features of F-actin affected by I-N phase transition and by tuning weak electrostatic interactions among the filaments.

3:30PM W25.00004 The stability of cellulose, TONGYE SHEN, S. GNANAKARAN, T-Division, LANL — Stabilities and dynamics of cellulose, which is a common structural component of plants and microorganisms, are critical to understanding the biocompatibility and applications of cellulose-based materials. We studied the self-assembly of cellulose molecules by developing a computational model that accurately predicts the equilibrium properties of cellulose nanofibril assemblies. Our model reveals that hydrogen bonding (HB) stabilizes the nanofibril structure through a combination of intramolecular and intermolecular interactions. This understanding can guide the design of novel cellulose-based materials with improved properties for applications such as textiles and drug delivery.

3:42PM W25.00005 ABSTRACT WITHDRAWN —

3:54PM W25.00006 Transient Binding and Viscous Dissipation in Semi-flexible Polymer Networks, OLIVER LIELEG, TU Muenchen, Germany, MIREILLES CLAESSENS, Universiteit Twente, The Netherlands, ANDREAS BAUSCH, TU Muenchen, Germany — Nature specifically chooses from a myriad of actin binding proteins (ABPs) to tailor the cytoskeletal microstructure. Herein, cells rely on the dynamics of the cytoskeleton as its structural and mechanical adaptability is crucial to allow for dynamic processes. A molecular understanding of such biological complexity calls for an in vitro system with well-defined structural rearrangements and cross-linker dynamics to elucidate the physical origin of the unique viscoelastic properties of cells. As we present here, the frequency-dependent viscoelastic response of cross-linked in vitro actin networks is determined by the binding kinetics of cross-linking molecules. Independent from the particular network structure, the viscous dissipation (loss modulus) exhibits a pronounced minimum in an intermediate frequency which is dominated by elasticity. We show that in this frequency regime the molecular origin of the viscoelastic response is given by the non-static nature of actin/ABP bonds as they are subjugated to chemical on/off kinetics. The time scale of the resulting stress release is set by the lifetime distribution of the cross-linking molecule and therefore can be tuned independently from other relaxation mechanisms. We speculate that unbinding of distinct cross-links might be the molecular mechanism employed by cells for mechanosensing.

4:06PM W25.00007: Microtubule Self-Assembly, YONGSEOK JHO, M.C. CHOI, UCSB/KAIST, O. FARAGO, BGU, MAHNWON KIM, P.A. PINKUS, UCSB/KAIST — Microtubules are important structural elements for neurons. Microtubules are cylindrical pipes that self-assemble from tubulin dimers. We investigate the nature of the interactions which are essential to stabilize such the cylindrical assembly of protofilaments. We use Monte Carlo simulations to suggest the pathways for assembly and disassembly of the microtubules.

1Supported by NSF (DMR0405156) and PRF (42835-AC7).
5:06PM W25.00012 Dimensional percolation of sheared nano-rod dispersions and consequences for highly anisotropic property tensors1. M. GREGORY FOREST, University of North Carolina at Chapel Hill, XIAOYU ZHENG, Kent State University, RUHAI ZHOU, Old Dominion University, RICHARD VAIA, Nanostructured and Biological Materials Branch, AFRL/MLBP — The Doi-Hess theory for flowing nano-rod dispersion yields orientational probability distribution functions for the nano-particle phase in flow-processed thin films. These numerical databases for variable shear rate, particle aspect ratio and volume fraction are then combined with a Monte Carlo algorithm to populate sheared dispersions. Nano-rod cluster statistics are then computed to determine percolation thresholds, which yield transitions from zero to one, two and three dimensional percolating paths. Finally, effective property enhancements are computed which include standard volume-averaged homogenization and percolation cluster statistics.

1Research support from AFOSR FA9550-06-1-0063, NSF DMS-0604891

5:18PM W25.00013 Polymer Crystallization-Driven Gelation of an Ionic Liquid. DAVID HOAGLAND, JOHN HARNER, Univ. of Massachusetts Amherst — Polyelectrolyte gels and gels derived from polyelectrolyte solutions are a broad class of materials with diverse applications ranging from gelling agents in foods and pharmaceuticals to hydrogels in tissue engineering involving biomimetic self-assembly. We consider a class of ionic liquids that forms stable gel networks under the influence of physicochemical processing. 1-Ethyl-3-methylimidazolium ethyl sulfate [EMIM][EtSO4] is hygroscopic, and with water uptake, the modulus drops.

5:30PM W25.00014 Avalanches, hardening and softening in dense cross-linked actin networks. JAN ASTROM, CSC – Finnish IT Center for Science, Esbo, Finland, SUNIL KUMAR, Indian Institute of Technology Madras, India, ILPO VATTULAINEN, Tampere University of Technology, Finland, MIKKO KARTTUNEN, The University of Western Ontario, Canada — Actin filament networks enable cell motility, cell division and cell differentiation, and provide the framework for mechanical tension in animal cells. Actin filament networks can be thought of as flows of biopolymers through a random network of obstacles.

4:42PM W25.00010 Equilibrium Size Distribution of Twisted Biopolymer Bundles. GREGORY GRASON, University of Massachusetts, Amherst, ROBJIN BRUINSMA, University of California at Los Angeles — Using a continuum elastic model of hexagonal filament packing, we demonstrate that molecular-scale chirality strongly affects the equilibrium properties of aggregates, or bundles, of biopolymers, such as DNA and F-actin. We show that biopolymers tend to form bundles with long-range, chiral stress patterns, twisting or braiding helically around the central bundle axis. Due to the build-up of elastic stress on the outer surface, the cohesive energy of chiral filament bundles has a non-monotonic dependence on filament number. As a consequence, we demonstrate for two cases—bundles with 1) columnar-hexagonal order and 2) columnar-solid order—that a stable phase of dispersed bundles is thermodynamically stable below the point of bulk condensation and below a critical surface energy for the bundle exterior. This work suggests that the large characteristic radius biopolymer bundles observed in in vitro studies of is not a product of some mysterious long-range force or kinetic limitations of bundle growth, but rather in-plane elastic stresses which result from the local preference for the chiral packing of filaments.

4:54PM W25.00011 The Dependence of Actin Filament Assembly on Linking Agent Concentration. LAM NGUYEN, QI WANG, WEI YANG, LINDA HIRST, Florida State University — This experimental and computational study focused on the properties of actin filament bundles and networks induced by the actin filament cross-linker, α-actinin. Structural properties of actin filament networks linked by the α-actinin protein were studied experimentally by using confocal microscopy. We varied the concentrations of actin and linking agents to study their effects on the properties of the bundles and networks. The study showed that the molar ratio of α-actinin to actin played an important role in the properties of the network structure, determining the branching frequency of the bundles. An experimentally guided simulation based on the α-actinin/actin filament system was carried out using CHARMM to attempt to replicate the features of the real system and therefore to study the physics behind the actin filament assembly process in different regimes.

4:30PM W25.00009 Loop Closure Dynamics of Flexible and Semi-flexible Polymer. JEN-FANG CHANG, YENG-LONG CHEN, Academia Sinica, INST. OF PHYS., ACADEMIA SINICA TEAM, RCAS, ACADEMIA SINICA TEAM — It is widely believed that DNA looping due to multi-site DNA-binding proteins is important for DNA transcription, replication, and recombination. The chain closure problem has been studied in several Monte Carlo simulations to determine the chain closure probabilities and the chain conformation to infer dynamic properties. In this work, we investigate how the loop closure dynamics of flexible and semi-flexible polymers depend on the polymer length and the reactive site position using Brownian dynamics simulation, accounting for hydrodynamic interactions. Our study examines the probability of closing for two reactive sites along the chain and the shape of the loop formed by closing. In addition, intrachain hydrodynamic interactions are found to affect the diffusivity of circular chains compared to linear chains, in accord with experimental observations. We also consider the dynamics of chain closing under strong slt-like confinement as a function of slt height.

4:18PM W25.00008 Direct Observation of Early-Time Hydrogelation in β-Hairpin Peptide Self-Assembly. TUNA YUCEL, Materials Science and Engineering, University of Delaware, Newark, DE 19716, JOEL SCHNEIDER, Chemistry and Biochemistry, University of Delaware, Newark, DE 19716, DARRIN POCHAN, Materials Science and Engineering, University of Delaware, Newark, DE 19716 — Triggered hydrogelation of MAX 1 peptide (NH2-(VK)17-PPT-(KV)17-CONH2) proceeds through peptide intramolecular folding into β-hairpins and immediate self-assembly into branched clusters of well defined (uniform, 3 nm cross section), semi-flexible, β-sheet-rich nanofibers. Cryogenic transmission electron microscopy indicates that dangling fibrils extend from one growing cluster to another and lead to early, intercluster communication in solution. At the apparent percolation threshold, the dynamic shear modulus measured by oscillatory rheology ($G'\omega$, $G''\omega$) and the field-intensity autocorrelation function measured by dynamic light scattering ($g_1(\tau) \times \tau^{-1}$) show power-law behavior with comparable critical dynamic exponents ($\nu \approx 0.47$ and $\beta \approx 0.45$). Finite interpenetration of percolating cluster with smaller clusters, along with permanent intercluster entanglements, increase the network rigidity. The self-assembly of MAX 1 peptide was contrasted and compared with the assembly of other biopolymeric networks in literature.
5:42PM W25.00015 Crystal aggregation in kidney stones; a polymer aggregation problem. J. WESSON, A. BESHENSKY, P. VISWANATHAN, W. ZACHOWICZ, J. KLEINMAN, Medical College of Wisconsin — Kidney stones most frequently form as aggregates of calcium oxalate monohydrate (COM) crystals with organic layers between them, and the organic layers contain principally proteins. The pathway leading to the formation of these crystal aggregates in affected people has not been identified, but stone forming patients are thought to have a defect in the structure or distribution of urinary proteins, which normally protect against stone formation. We have developed two polyelectrolyte models that will induce COM crystal aggregation in vitro, and both are consistent with possible urinary protein compositions. The first model was based on mixing polyanionic and polycationic proteins, in portions such that the combined protein charge is near zero. The second model was based on reducing the charge density on partially charged polyanionic proteins, specifically Tamm-Horsfall protein, the second most abundant protein in urine. Both models demonstrated polymer phase separation at solution conditions where COM crystal aggregation was observed. Correlation with data from other bulk crystallization measurements suggest that the anionic side chains form critical binding interactions with COM surfaces that are necessary along with the phase separation process to induce COM crystal aggregation.

Thursday, March 13, 2008 2:30PM - 5:18PM – Session W26 DCP: Focus Session: Advances in Atmospheric Aerosol Science IV Morial Convention Center 218

2:30PM W26.00001 "The optics of atmospheric aerosol particles". CHRISTOPHER SORENSEN, Kansas State University — No abstract available.

3:06PM W26.00002 The Molecular Picture Behind Resonance Phenomena in Aerosol Spectra. RUTH SIGNORELL, University of British Columbia, Chemistry Department — The study of icy aerosol particles with sizes in the submicron range is a highly interdisciplinary subject at the juncture of nanosciences, atmospheric physics, and astrophysics. The microphysics of aerosol clouds in the atmospheres of planets and their moons, such as ammonia clouds on Jupiter and Saturn or methane aerosols on Titan, is currently very much in the focus of the scientific community. Particularly broad interest has been sparked by the recent Cassini-Huygens mission to Saturn’s moon Titan, which has illuminated the importance of methane clouds for Titan’s weather and their analogy to the role of water ice clouds in Earth’s atmosphere. The present contribution focuses on the influence of intrinsic particle properties, such as shape, size or architecture, on infrared optical properties of icy aerosol particles. Intrinsic particle properties manifest themselves in mid-infrared extinction spectra by modifying the structure of vibrational bands. We ultimately aim at unravelling the microscopic origin of the characteristic patterns found in the spectra of these weakly bound molecular aggregates. To this end we compare our experimental results with different model calculations combining molecular dynamics simulations with vibrational quantum dynamics.

3:42PM W26.00003 Investigations of Hygroscopic Growth and Phase Transitions of Atmospheric Particles by Noncontact Atomic Force Microscopy (AFM). BENJAMIN OCKO, Brookhaven National Laboratory, SUSAN OATIS, University of New York, Stony Brook, MATTHEW STRASBERG, STEPHEN SCHWARTZ, ANTONIO CHECCO, Brookhaven National Laboratory — Aerosol particles (nanometer to micrometer sized particles suspended in air) affect atmospheric radiation and cloud microphysics. A correct description of their behavior in the atmosphere is essential to accurate climate modeling. The processes by which initially hydrophobic particles become hygroscopic, accrete water from the vapor, undergo phase transition from solid particles to solution droplets are important but not well understood at a fundamental level. We have carried out AFM studies to measure changes in particle size and morphology as a function of the relative humidity for particles of sodium chloride (a substance whose bulk hygroscopic properties are well characterized) deposited on substrates with differing surface energies (Silicon Oxide, Carboxy- and Methyl-terminated organic thin-films). For particles with height > 50 nm, deliquescence was observed with a relative humidity near 75% (±2%), is consistent with measurements of suspended aerosols. These preliminary results demonstrate that environmental AFM is a viable probe for studying the hygroscopic behavior of salt nanoparticles on solid supports. Supported by the U.S. Department of Energy, DE-AC02-98CH.

3:54PM W26.00004 Extinction by Single and Multiple Particles1. MATTHEW BERG, CHRISTOPHER SORENSEN, AMIT CHAKRABARTI, Kansas State University — The combined effect of scattering and absorption is referred to as extinction and is responsible for the redistribution of radiant energy by a particle. This presentation will show that extinction is due to wave interference. Simulations of the energy flow caused by the interference graphically demonstrate how extinction redistributes the energy of incident light. Both single and multi-particle systems are considered. A conceptual, phase-based explanation is given that builds on previous work and illustrates the physical meaning of the optical theorem. Implications regarding the measurement of extinction are discussed.

1Funded by the NASA Graduate Student Researchers Program

4:06PM W26.00005 Scattering Patterns for Spherical and Non-spherical Particles. CHRISTOPHER SORENSEN, Kansas State University — Aerosols affect our climate directly by scattering and absorbing light. These optical properties depend on the size, shape, and composition. We have recently described patterns that appear in the phase function for spherical particles. Mie scattering, when the scattered intensity is plotted versus the scattering wave vector q = 2ksin(theta/2) [1, 2]. These patterns involve three different power law regimes and a quasi-universality on the phase-shift parameter rho: 2kR(m-1), where R is the radius and m the refractive index. Similar patterns appear for non-spherical particles. These patterns give us an empirical description of scattering by particles of arbitrary shape and refractive index. In other work we have explored the consequences of symmetry or its lack on polarization and backscattering. These results can be useful for predicting the scattering of atmospheric aerosol particles. [1] C.M. Sorenson and D.F. Fischbach, Opt. Commun. 173,145 (2000). [2] M.J. Berg, C.M. Sorenson, and A. Chakrabarti, Applied Optics 44, 7487-7493 (2005). I acknowledge very useful collaborations with M. Berg and A. Chakrabarti.

4:18PM W26.00006 Understanding aerosol-cloud interactions. ATHANASIOS NENES, Schools of Earth & Atmospheric Sciences and Chemical & Biomolecular Engineering, Georgia Institute of Technology — The effects of aerosols on clouds (known as the “aerosol indirect climatic effect”) are thought to have a net climatic cooling effect which partially offsets greenhouse gas warming. Regional impacts of aerosols on precipitation and cloudiness can be even stronger. Despite its importance, the complex and multi-scale nature of aerosol-cloud interactions makes quantitative assessments of the indirect effect one of the most uncertain components of anthropogenic climate change. This talk will present the approaches used to observationally study them and represent them in models. We will provide an assessment of what has been learned and point out key research challenges for the future.
4:54PM W26.00007 Alkyl Polyoxyethylene Surfactant Residue Distribution after Sessile Droplet Evaporation. H. YUNJI MI, Albany State University, HEPING ZHU, USDA Agricultural Research Service, KWAICHOW CHAN COLLABORATION, HE Ping ZHU COLLABORATION — Post-evaporation residues of an Alkyl Polyoxyethylene surfactant on a slightly hydrophilic surface are studied. An edge-detecting contrast recognition algorithm is used to measure the areas of small (7-30µm diameter) surfactant “islands” which form during the evaporation process as a result of flows within the droplet and surface tension gathering. “Island” distributions broaden with increased concentration, accompanied by higher mean interior island size. Fitting the histogram of island sizes beginning with the principle peak reveals a general form: \( y = (6 \times 10^{-6}) C x^{-1.5} \) where \( y \) is frequency, \( C \) the concentration and \( x \) is a constant having value between 2.55 and 3.00. Log-log plots evidence a linear behaviour over two orders of magnitude. Total area covered does not increase in a linear fashion with concentration, as one may expect. Rather, a “critical” concentration is achieved at approximately 0.15%, above which area increase is less pronounced.

5:06PM W26.00008 ABSTRACT WITHDRAWN

Thursday, March 13, 2008 2:30PM - 5:18PM
Session W27 GMAG: Focus Session: Spin Glasses and SrCu\(_2\)(BO\(_3\))\(_2\)

5:20PM W27.00001 Unconstrained Chern-Simons theory for the geometrically frustrated spin compound SrCu\(_2\)(BO\(_3\))\(_2\) . CRISTIAN BATISTA, PINAKI SENGUPTA, LANL, SUCHITRA SEBASTIAN, Univ. of Cambridge, NEIL HARRISON, LANL — We show that an unconstrained Chern-Simons theory – where the local densities are determined in a self-consistent manner – correctly reproduces the sequence of magnetization plateaus recently observed in the geometrically frustrated spin compound SrCu\(_2\)(BO\(_3\))\(_2\) in an external magnetic field. The theory predicts that at the plateaus, the triplets are arranged in stripe patterns which is consistent with NMR experiments at and close to the 1/8 plateau.

5:42PM W27.00002 Fractalisation drives crystalline states in the frustrated spin system SrCu\(_2\)(BO\(_3\))\(_2\) . SUCHITRA SEBASTIAN, Cambridge University, N. HARRISON, P. SENGUPTA, C.D. BATISTA, S. FRANCOUAL, NHMFL, Los Alamos National Laboratory, E. PALM, T. MURPHY, NHMFL, Tallahassee, H.A. DABKOWSKA, B.D. GAULIN, McMaster University — Geometrical frustration in the spin dimer material SrCu\(_2\)(BO\(_3\))\(_2\) leads to a singlet Shashty-Sutherland groundstate at low magnetic fields, but complex spin superstructures at higher fields. Our magnetisation measurements reveal a fine substructure of quantum Hall-like plateaux at all 1/q ratios 2 < q < 9 and p/q = 2/9 in magnetic fields up to 85 T and temperatures down to 29 mK, within the sequence of previously identified plateaux at 1/8, 1/4, and 1/3 of the saturated magnetisation. We identify this hierarchy of plateaux as a consequence of confined bosons in SrCu\(_2\)(BO\(_3\))\(_2\) mimicking the high magnetic field fractalisation predicted by the Hofstadter butterfly for fermionic systems. Such an experimental realisation of the Hofstadter butterfly has not been previously achieved in real interacting materials, given the unachievably high magnetic fluid flux densities or large lattice periods required. By a theoretical treatment that includes short-range repulsion in the Hofstadter treatment, stripe-like spin density-modulated phases are revealed in SrCu\(_2\)(BO\(_3\))\(_2\) as emergent from a fluidic fractal spectrum.

6:00PM W27.00003 Doped Valence Bond Solid and Superconductivity on the Shastry-Sutherland Lattice . BOHM-JUNG YANG, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, YONG BAEK KIM, Department of Physics, University of Toronto, Toronto, Ontario, Canada, JAEJUN YU, Department of Physics and Astronomy, Seoul National University, Seoul, Korea, KWON PARK, School of Physics, Korea Institute for Advanced Study, Seoul, Korea — Motivated by recent experiments on SrCu\(_2\)(BO\(_3\))\(_2\), we present a theoretical framework for understanding the ground states of the doped Mott insulator on the Shastry-Sutherland lattice. To provide a unified theoretical framework for both the valence bond solid state found in undoped SrCu\(_2\)(BO\(_3\))\(_2\) and the doped counterpart in on-going experimental pursuit, we analyzed the \( t-J-V \) model via the bond operator formalism. The interplay between strong dimerization and the nearest-neighbor repulsive interaction leads to different behaviors of the doped holes determining the overall phase diagram. Specifically, if the nearest-neighbor repulsive interaction, \( V \), is smaller than a critical value, \( V_c \), the hole-pairing within dimers is preferred, resulting in the \( S \)-wave superconductivity at any non-zero \( x \). On the other hand, if \( V \) is larger than \( V_c \), the density of paired-holes within the same dimers vanishes at finite \( x \) and the plaquette \( D \)-wave superconductivity with a peculiar spatial pattern emerges. Implications to future experiments are discussed.

6:20PM W27.00004 Critical Properties of the Unconventional Spin-Peierls System TiOBr . J.P. CLANCY, B.D. GAULIN, Department of Physics and Astronomy, McMaster University, F.C. CHOU, Center for Condensed Matter Sciences, National Taiwan University — TiOBr is one of only three inorganic compounds which have been shown to undergo a spin-Peierls (SP) transition, developing a dimerized singlet sequence of magnetization plateaus recently observed in the geometrically frustrated spin compound SrCu\(_2\)(BO\(_3\))\(_2\) as emergent from a fluidic fractal spectrum.

3:18PM W27.00005 Thermal properties and Ehrenfest relation in an “ideal” spin glass. S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory/Iowa State University, G.M. SCHMIEDESHOFF, Department of Physics, Occidental College — In order to test whether the Ehrenfest relation is applicable to the spin glass “transition,” we report temperature-dependent heat capacity and thermal expansion measurements on an “ideal” spin glass material: single grain isocohedral Gd-Mg-Zn quasicrystal and its non-magnetic counterpart, Y-Mg-Zn. Spin-glass state related signatures are clearly seen in the Gd-Mg-Zn data sets. Directly measured pressure dependence of the freezing temperature in Gd-Mg-Zn is compared to its evaluation through the Ehrenfest relation.

1 Supported by US DOE BES DE-AC02-07CH11358 and NSF DMR-0704406.
3:30PM W27.00006 Anomalous field-sweep rate dependence of magnetization process of a spin-glass system Fe$_{1-x}$Mn$_x$TiO$_3$. N. MIURA, H. ARUGA KATORI, A. ITO, RIKEN, M. SCHOENHART, R. GROESSINGER, Tech. Univ. Vienna, N. V. KOZLOVA, K. DOERR, IFW, Dresden, RIKEN TEAM, VIENNA TEAM, IFW TEAM — A mixed compound Fe$_{60-x}$Mn$_x$TiO$_3$ is a typical ising spin-glass. When a magnetic field is applied to the spin-glass state with a rather fast sweep rate 0.2 < dB/dt < 1 T/s by a steady field magnet, the sample shows step-like jumps in the magnetization, whereas in a pulse magnet with an even faster sweep rate above 700 T/s, it shows a smooth metamagnetic transition. The field of the step-like jump is decreased as the sweep rate is increased, which is contrary to any relaxation phenomena with a slow response time. In the case of smooth metamagnetic transition at faster sweep rates, the transition field is increased as the sweep rate is increased. In this study, we investigated the magnetization process in the intermediate range of field sweep rate between 1.0 and 124 T/s using an ultra-long-pulse magnet. It was found that as the sweep rate is increased, the jump behavior changes over to the metamagnetic behavior at around 2.5 T/s, where the transition field takes the minimum. The observed results are suggestive of some locally grown non-equilibrium spin alignment. The jump behavior is discussed in connection with similar phenomena in perovskite manganites.

3:42PM W27.00007 The Free Energy Landscape of a Two-Dimensional Spin Glass from a Hard- Spin Mean-Field Treatment, MICHAEL MIHALCO, SUSAN MCKAY, University of Maine — The two-dimensional Ising antiferromagnet on a triangular lattice shows no ordered phase at finite temperatures until frustration is relieved, often accomplished through dilution (Grest and Gabl PRL 43, Netz and Berker PRL 66) or by the addition of randomly placed ferromagnetic bonds. Using the second approach, we have created a two-dimensional spin-glass phase with tunable frustration and explored its free energy landscape using a hard-spin mean-field approach (Netz and Berker PRL 66). The Monte Carlo implementation of this method quickly provides a self-consistent solution of site magnetizations, and we have used the overlaps and internal energies of various solutions to explore the energy landscape as a function of temperature and the number of frustrated plaquettes. Results indicate a multiplicity of solutions and a rich structure of overlaps, which are sensitive to the temperature and level of frustration. This method shows clearly the distinctions between the spin-glass phase and the bordering ferromagnetic ordering that occurs once the ferromagnetic interactions dominate.

3:54PM W27.00008 Field-Driven Hysteresis of the d=3 Ising Spin Glass: Hard-Spin Mean-Field Theory, BURCU YÜCESOY, Istanbul Technical University and University of Massachusetts, Amherst, A. NIHAT BERKER, Koç University — Hysteresis loops are obtained in the Ising spin-glass phase in d = 3, using frustration-conserving hard-spin mean-field theory.[1] The system is driven by a time-dependent random magnetic field $H(t)$ that is conjugate to the spin-glass order $Q$, yielding a field-driven first-order phase transition through the spin-glass phase. The hysteresis loop area $A - A_0$ scales with respect to the sweep rate $h$ of magnetic field as $A - A_0 \sim h^\beta$. In the spin-glass and random-bond ferromagnetic phases, the sweep-rate scaling exponent $\beta$ changes with temperature $T$, but appears not to change with antiferromagnetic bond concentration $\rho$. By contrast, in the pure ferromagnetic phase, $\beta$ does not depend on $T$ and has a sharply different value than in the two other phases.

4:06PM W27.00009 Quantum Induced Asymmetric Phase Diagrams of Spin-Glass Systems, C. NADIR KAPLAN, A. NIHAT BERKER, Koç University — The spin-1/2 quantum Heisenberg spin-glass system is studied in all spatial dimensions $d$ by renormalization-group theory.[1] Strongly asymmetric phase diagrams in temperature and antiferromagnetic bond probability $p$ are obtained in dimensions $d \geq 3$. The asymmetry at high temperatures approaching the pure ferromagnetic and antiferromagnetic systems disappears as $d$ is increased. However, the asymmetry at low but finite temperatures remains in all dimensions, with the antiferromagnetic phase receding to the ferromagnetic phase. A finite-temperature second-order phase transition is obtained in the antiferromagnetic and spin-glass phases occur in $d \geq 6$, resulting in a new multicritical point at its meeting with the boundaries to the paramagnetic phase. In $d = 3, 4, 5$, a paramagnetic phase reaching zero temperature intervenes asymmetrically between the ferromagnetic and antiferromagnetic phases. There is no spin-glass phase in any dimension.

4:18PM W27.00010 Spin phonon induced colinear order and magnetization plateaus in triangular and kagome antiferromagnets. Applications to CuFeO$_2$, FA WANG, ASHVIN VISHWANATH, Department of Physics, University of California at Berkeley; Material Sciences Division, Lawrence Berkeley National Laboratory — Coupling between spin and lattice degrees of freedom is important in geometrically frustrated magnets where they can lead to degeneracy lifting and novel orders. We show that moderate spin-lattice couplings in triangular and Kagome antiferromagnets can induce complex colinear magnetic orders. When classical Heisenberg spins on the triangular lattice are coupled to Einstein phonons, a rich variety of phases emerge, including the experimentally observed four sublattice state and the five sublattice 1/5th magnetization plateau state seen in the magneto-electric material CuFeO$_2$. In addition we predict magnetization plateaus at 1/3, 3/7, 1/2, 3/5 and 5/7 at these couplings. Strong spin-lattice couplings induce a striped colinear state, seen in α-NaFeO$_2$ and MnBr$_2$. On the Kagome lattice, moderate spin-lattice couplings induce colinear order, but an extensive degeneracy remains.

4:30PM W27.00011 Jahn-Teller coupling and magnetic ground state in vanadium spinels, GIA-WEI CHERN, OLEG TCHERNYSHYOV, Johns Hopkins University — The interplay of orbital, lattice, and spin degrees of freedom in vanadium spinels has attracted much interest among researchers. The V$^{4+}$ ion has two electrons occupying three degenerate $t_{2g}$ orbitals and is thus Jahn-Teller active. It also has a total spin $S = 1$ in accordance with Hund’s rules. Moreover, the V$^{4+}$ ions sitting on the B-site of spinel form a pyrochlore lattice, the interactions between these localized spin and orbital degrees of freedom are thus geometrically frustrated.[1] Here we present a theoretical model for the ground states of vanadium spinels. We view all of the vanadates (Cd, Zn, Mg on the one hand and Mn on the other) within the same model in which the influence of Mn is simulated by magnetic field as $A - A_0 \sim h^\beta$. In the spin-glass and antiferromagnetic phases occur in $d \geq 6$, resulting in a new multicritical point at its meeting with the boundaries to the paramagnetic phase. In $d = 3, 4, 5$, a paramagnetic phase reaching zero temperature intervenes asymmetrically between the ferromagnetic and antiferromagnetic phases. There is no spin-glass phase in any dimension.

4:42PM W27.00012 AC Susceptibility and Heat Capacity Studies of Geometrically Frustrated Pyrochlores, DANIEL ANTONIO, ANDREW CORNELIUS, UNLV, JASON GARDNER, Brookhaven National Lab, NIST — Materials with a geometrically frustrated pyrochlore lattice have been of interest due to their unusual ground states. Tb$_2$Ti$_2$O$_7$ is known for going to a spin liquid ground state and does not transition to a long-range ordered state down to at least 50 mK [1]. Ho$_2$Ti$_2$O$_7$ has a macroscopically degenerate spin ice ground state which resembles that of the proton ordering in water ice [2]. Heat Capacity measurements of Tb$_2$Ti$_2$O$_7$ were done from 300 K to 0.36 K and AC magnetic susceptibility measurements of Ho$_2$Y$_2$Ti$_2$O$_7$ and Zr$_2$La$_2$Ti$_2$O$_7$ were done for frequencies from 10 Hz to 10 kHz down to 1.8 K, both in magnetic fields up to 9 T. These experiments were performed to further understand the factors leading to their unusual behavior and the effects of introducing disorder through doping with nonmagnetic elements. Determination of the effect of an external field on the hyperfine crystal field at the Tb sites was done. In addition, unusual behavior in the ac susceptibility of the Ho samples at lower temperatures was observed.[1] J.S. Gardner et al., Phys. Rev. Lett. 82, 1012 (1999)[2] S.T. Bramwell and M.J.P. Gingras, Science 294, 1495 (2001)
4:54PM W27.00013 Local studies of AC demagnetization in a model frustrated magnet. JIE LI, XIAOLIN KE, CRISTIANO NISOLI, PAUL LAMMERT, VINCENT CRESPI, PETER SCHIFFER, The Penn State Univ. — We have studied the process of ac demagnetization using a model system consisting of single-domain ferromagnetic islands arranged on perpendicular square lattices such that the interaction between the islands is frustrated by the geometry of the arrays. The sample is first subjected to an oscillating magnetic field whose magnitude is stepped down by different step sizes and the sample is rotating at the same time. We find that the net moment of the arrays can be readily brought to near zero with the magnetic field step size below a certain threshold value. However the interaction energy of the demagnetized array state continues to decrease linearly with decreasing step size even as the step size approaches zero. We characterize the result in terms of developing local correlations between the island moments, with strong analogies to other athermal magnetic systems. This research has been supported by the Army Research Office.

5:06PM W27.00014 Dimensional Crossover in ZnMn$_2$O$_4$. WILLIAM RATCLIFF, National Institute of Standards and Technology (NCNR), YING CHEN, GORAN GARASPOVIC, YIMING QIU, National Institute of Standards and Technology (NCNR), U. Maryland (Materials Science and Engineering), QING HUANG, JEFFREY LYNN, National Institute of Standards and Technology (NCNR), SUNMOG YEO, Rutgers University (Department of Physics), SANG CHEONG, Rutgers University (Department of Physics), PAULA PICCOLI, ARTHUR SCHULTZ, Argonne National Lab (IPNS) — ZnMn$_2$O$_4$ crystallizes at high temperatures as a cubic spinel. At lower temperatures, it undergoes a Jahn Teller distortion which lowers its symmetry to tetragonal. At lower temperatures (TN~60 K), the system orders magnetically. Fits to the order parameter, line shape of powder diffraction peaks, and the direct observation of rods of scattering in single crystal diffraction experiments show the system to be two dimensional. This is likely due to the interplay between orbital ordering and frustration. In this talk I discuss the magnetic structure and spin waves of this system. I will also discuss an interesting crossover in the dimensionality of the magnetism in this compound.

Session W28 DCMP: Superlattices and Nanostructures: Electronic Properties II Morial Convention Center 220

2:30PM W28.00001 Tunnel spectroscopy in an ac-driven triple dot quantum shuttle. J. VILLAVICENCIO, Universidad Autónoma de Baja California, México, I. MALDONADO, Centro de Investigación Científica y de Educación Superior de Ensenada, México, R. SÁNCHEZ, Instituto de Ciencia de Materiales de Madrid-CSIC, Spain, E. COTA, Universidad Nacional Autónoma de México, México, G. PLATERO, Instituto de Ciencia de Materiales de Madrid-CSIC, Spain — Within the framework of a fully quantum mechanical approach we use the density matrix master equation formalism to study the electronic transport in a triple dot quantum shuttle in the presence of an ac-field. We show that the ac-field induces photos-assisted tunneling which manifests itself as sidebands in the electronic current. We also show that these new tunneling sidebands can be explained in terms of simple sum rules involving the number of absorbed and emitted photons and the oscillator states participating in the process. Finally, we demonstrate that the tunneling channels can be controlled by manipulating the frequency and intensity of the ac-field, giving rise in particular to coherent destruction of tunneling (CDT).

2:42PM W28.00002 Fabrication and Characterization of a CMOS-Based Quantum Dot Device. MING XIAO, E. YABLONOVITCH, H.W. JIANG, UCLA — Silicon-based single electron devices are particularly attractive for implementing quantum information processing due to the extremely long electron spin lifetimes. We report here the demonstration of a stack-gated CMOS structure that can define a quantum dot in the few-electron regime with a sensitive, high bandwidth field effect transistor. Multiple lower layer side gates, as small as 50nm, on an ion-implanted Si/SiO2 wafer electrostatically define the quantum dot. A top gate that controls the electron population in the quantum dot is then fabricated on top of an isolating AlO3 layer made by atomic layer deposition (ALD). The low-temperature ALD process provides excellent device stability and preserving the integrity of the side gates. We found that the devices can be operated effectively both in the accumulation mode and in the depletion mode. Transport through the quantum dots in the few-electron regime for currents less than 100fA can be reliably studied with a good reproducibility. We will detail our fabrication and characterization processes in this presentation.

2:54PM W28.00003 Transport through a triple quantum-dot ring in high-spin state. YUNORI NISIKAWA, Osaka City University, TAKAHIDE NUMATA, AKIRA OGURI, Osaka City University — Using the numerical renormalization group (NRG), we study transport through a triple quantum-dot ring in high-spin state, connected to two noninteracting leads symmetrically. The transport is determined by two phase shifts for quasi-particles with even and odd parities. An isolated triple quantum-dot ring has a high spin ground state of S = 1 caused by a Nagaoka ferromagnetism, when it has one extra electron introduced into a half-filling. The results show that the conduction electrons screen the local moment within two separate stages with different energy scales. The half of the S = 1 is screened first by one of the channel degrees, and then at very low temperature the remaining half is fully screened to form a Kondo singlet. A two-terminal conductance in the series configuration is suppressed similar or equal to 0, while plateau of a four-terminal parallel conductance reaches a unitary limit value similar or equal to 4e^2/h of two conducting modes. We also present the relation between electronic states and thermodynamic quantities calculated using NRG eigen energies.

3:06PM W28.00004 Valley Splitting in Different Landau Levels of a Si/SiGe Quantum Point Contact. LISA McGUIRE, University of Wisconsin-Madison, K.A. SLINKER, MARK FRIESEN, University of Wisconsin-Madison, SRIJIT GOSWAMI, J.O. CHU, IBM Research Division-T.J. Watson Research Center, ROBERT JOYNT, S.N. COPPERSMITH, MARK A. ERIKSSON, University of Wisconsin-Madison — Si/SiGe is an interesting platform for spin physics and quantum information due to the weak spin-orbit coupling in Si and the presence of nuclear spin zero isotopes. However, silicon has a near degeneracy of orbital states in the conduction band arising from multiple valley minima, which could enhance decoherence rates and complicate qubit operation. Recent measurements in a quantum point contact have shown that the valley splitting is large, of order 0.5 ~ 2 meV. Here, we investigate fundamental mechanisms of valley splitting by taking into account the valley couplings between Landau levels. We also account for the dependence of valley splitting on materials parameters such as miscut angle and device orientation. From our data, we are able to extract distinct valley splittings from the lowest two Landau levels, which vary similarly as a function of gate voltage (i.e., channel width). We are further able to place bounds on local variations of the tilt angle of the quantum well interface. Work supported by ARQ, NSA, and NSF. 1 S. Goswami et al., Nature Physics 3 (1): 41-45 JAN 2007.
3:18PM W28.00005 Counting statistics and conditional evolution in a quantum electromechanical system, STEVEN BENNETT, AASHISH CLERK, McGill University — We present a theoretical study of full counting statistics (FCS) and conditional evolution of a quantum point contact (QPC) coupled to a mechanical oscillator. Such a system has recently been studied in several experiments. Starting from a microscopic model, we derive a master equation for the reduced density matrix that contains several important differences from the usual equation used to describe conditional position evolution (i.e., the dynamics of the oscillator inferred from a particular measurement outcome of current through the QPC). The master equation may then be solved analytically to obtain the FCS and conditional evolution. We find that the oscillator can significantly affect the FCS, leading to a highly non-Gaussian distribution characterized by an enhanced third moment even for very weak coupling. In the conditional evolution we find clear evidence that the back-action of the QPC on the oscillator cannot simply be described as coupling to an effective thermal bath.

3:30PM W28.00006 Thermo-electric effects in nanostructures out of equilibrium, YONATAN DUBI, ROBERTO D’AGOSTA, MASSIMILIANO DI VENTRA, University of California-San Diego — As technology advances into the nanoscale regime, probing the electronic properties of nanoscale circuits has become a major challenge. Specifically, it has been suggested that thermo-electric effects may serve as a tool to study electronic properties of nanoscale systems, and experiments on thermo-power in quantum point contacts (QPCs) and molecular circuits have been performed. On the theoretical side, however, linear-response theory is inadequate to determine the dynamical formation of the thermo-electric effect. Here, we propose a novel scheme to calculate dynamical thermo-electric effects in nanostructures arbitrarily far from equilibrium using a local generalization of the Lindblad master equation. We demonstrate the method by calculating the charge imbalance of a QPC in the presence of Coulomb interactions and a temperature gradient, and obtain the long-time energy distribution in the QPC out of equilibrium. Our suggested scheme can be implemented into stochastic time-dependent current-density functional theory [PRL, 98, 226403 (2007)], thus providing a valuable tool in studying the interplay of charge and energy currents for arbitrary many-body systems.

3:42PM W28.00007 Universality and the thermal dependence of the conductance of nanodevices, LUIZ N. OLIVEIRA, Univ. Sao Paulo, ANTONIO C. SERIDONIO, Univ. Brasilia, MAKOTO YOSHIDA, Univ. Estadual Paulista — The conductance of a quantum wire side-coupled to a quantum dot will be discussed. In this device, plots of the conductance $G$ vs. the gate voltage $V_g$ applied to the dot display Fano antiresonances due to the interference between the current traversing the wire and the flux of electrons that hop to the dot to bypass the adjacent section of the wire; at fixed $V_g$'s, the interference accounts for a variety of thermal dependences $G(T)$. Analytical renormalization-group arguments will be presented that map $G(T)$ to the universal curve $g(T/T_K)$ for the conductance of the spin-degenerate Anderson impurity Hamiltonian, with temperatures normalized by the Kondo temperature $T_K$. This linear, universal mapping will be shown to (i) generate curves in excellent agreement with the measurements of Sato et al. [Phys. Rev. Lett. 95, 066801 (2005)] and justify those authors' phenomenological description of their data; (ii) fit novel numerical renormalization-group data for the conductance of the side-coupled device; and (iii) link $G(T)$ to the conductance of the single-electron transistor.

3:54PM W28.00008 Electronic Properties of Quantum Point Contacts in a Quantum Ring, A. DEVRIM GUCLU, Duke University, CYRUS J. UMIRGAR, Cornell University, HAROLD U. BARANGER, Duke University — We investigate the electronic properties of a narrow constriction (quantum point contact) in a quantum ring using variational and diffusion Monte Carlo methods. Quantum point contacts are basic building blocks of nanoscale devices. The experimental control over their width allowed the observation of conductance quantization in integer steps of $G_0 = 2e^2/h$. However, a puzzling additional structure is also observed around $0.7G_0$ in some devices. One possible explanation is the formation of a local quasi-bound state. Here, we present a first quantum Monte Carlo calculation showing that electrons can be strongly localized in the constriction, with a well quantized electron number $N$ that varies abruptly as the width of the point contact decreases. We also study the low-lying excited states and investigate the possibility of a spin texture as a function of applied gate voltage.

4:06PM W28.00009 Piezoelectric models for semiconductor quantum dots, MORTEN WILLATZEN, BENNY LASSEN, DANIELLE BARETTIN, University of Southern Denmark, LOK LEW YAN VOON, Wright State University, UNIVERSITY OF SOUTHERN DENMARK COLLABORATION, WRIGHT STATE UNIVERSITY COLLABORATION — The importance of fully-coupled and semi-coupled piezoelectric models for quantum dots will be presented and compared to corresponding results for one-dimensional heterostructures. Electron energies differences of up to around 30 meV were found possible for GaN/AlN quantum dots.

4:18PM W28.00010 High sensitivity cantilevers for measuring persistent currents in normal metal rings, ANIA BLESZYNJSKI JAYICH, WILL SHANKS, Yale University, ROB ILIC, Cornell University, JACK HARRIS, Yale University — We propose a new approach to measuring persistent currents in normal metal rings. By integrating micron-scale metal rings into sensitive micromechanical cantilevers and using the cantilevers as torque magnetometers, it should be possible to measure the rings' persistent currents with greater sensitivity than the SQUID-based and microwave resonator-based detectors used in the past. In addition, cantilever-based detectors may allow for measurements in a cleaner electromagnetic environment. We have fabricated ultra sensitive cantilevers with integrated rings and measured their mechanical properties. We present an estimate of the persistent current sensitivity of these cantilever-based detectors, focusing on the limits set by the cantilever's Brownian motion and the shot noise in the laser interferometer that monitors the cantilever.

4:30PM W28.00011 Electron Pair Resonance in the Coulomb Blockade, MIKHAIL RAIKH, University of Utah, ERAN SELA, University of British Columbia, HEUNG-SUN SIM, Korea Advanced Institute of Science and Technology, YUVAL OREG, Weizmann Institute of Science, FELIX VON OPPEN, Free University of Berlin — Transport through a nanostructure in the regime of Coulomb blockade is dominated by elastic single-electron cotunneling. We study many-body corrections to the cotunneling current via a localized state with energy $e_0$ at large bias voltages $V$. We show that the transfer of electron pairs, enabled by the Coulomb repulsion in the localized level, results in ionization resonance peaks in the third derivative of the current with respect to $V$, centered at $eV = \pm 2e_0/3$. Our results predict the existence of previously unnoticed structure within Coulomb-blockade diamonds. Remarkably, this new structure emerges within the standard Anderson Hamiltonian conventionally used for description of transport through nanostructures.
4:42PM W28.00012 Quantum Dot Array for Simulating the Hubbard Model, CHING-TZU CHEN, DENNIS M. NEWNS, CHANG C. TSUET, IBM Thomas J Watson Research Center, JEFFREY J. URBAN, The Molecular Foundry, Lawrence Berkeley National Lab — As the simplest theory that incorporates strong onsite Coulomb repulsion, the Hubbard model is fundamental to the understanding of phenomena in strongly correlated systems, e.g. the metal-insulator transition in transition-metal oxides. It is widely believed that the 2D square-lattice Hubbard model captures the puzzling physics of high-temperature superconductivity. Since an analytical solution of the model is not viable, we propose to study its properties through a “quantum simulator” made from quantum dot arrays (QDAs). In this talk, we first demonstrate the correspondence between the Hubbard Hamiltonian and the simplified model for the QDA. We then address the scaling of the crucial parameters for designing a practical simulator. Two systems for implementing the QDA are proposed — the self-assembled nanocrystal arrays, and the lithographically defined 2D-electron-gas QDA. Preliminary experimental results derived from these systems will be presented.

4:54PM W28.00013 Correlation effects with low electron density along a potential barrier in quantum point contacts. KARAN ARYANPOUR, JONG HAN, Department of Physics, SUNY at Buffalo — We study correlated electrons effect in the conductance through Quantum Point Contacts (QPC). Conductance of a QPC is quantized in steps of $G_0 = \frac{2e^2}{h}$ (e the charge of an electron and h Planck's constant). Experiments also reveal an additional neutral shoulder near $0.7G_0$ referred to as the 0.7 anomaly. Evidence supporting spin 1/2 magnetic moment formation in the conductance channel has motivated scenarios such as the Kondo effect. We intend to address whether or not the 0.7 anomaly is a many-body effect associated with the formation of a spin 1/2 magnetic moment in the conductance channel. We employ the Quantum Monte Carlo (QMC) technique for electrons on a 1-D QPC lattice with an adiabatic potential barrier. The QPC lattice includes the Hubbard lattice in the QPC region and two leads modeled by semi-infinite chains and we calculate the conductance along the chain using the Kubo formula. The physics is determined by the competition between the many-body interaction and the small kinetic energy at the top of the potential barrier. Due to the singular nature of the density of states at low electron density along with the spatial inhomogeneity, the many-body effects are expected to differ from conventional wide-band limit physics.

Thursday, March 13, 2008 2:30PM - 5:30PM — Session W29 DMP: Focus Session: Carbon Nanotubes and Related Materials XIV: Theory and Sensing Morial Convention Center 221

2:30PM W29.00001 Electron-phonon interaction and excited states relaxation in carbon nanotubes. VASILI PEREBEINOS, IBM - Watson — We will discuss the role of electron-phonon interaction on excited states relaxation and phonon spectra in carbon nanotubes (CNTs). The electron-phonon interaction leads to the polaronic effects of the charge carriers, but it also renormalizes the energy and the lifetime of phonons. We present a theoretical model that predicts the changes induced in the phonon modes of CNTs as a function of the charge carrier doping, i.e. position of the Fermi level. In agreement with the predictions, our experiments show sharpening and blue shifts of the G-phonons of metallic CNTs, but only blue shifts for semiconducting CNTs, making the Raman scattering a useful probe of local doping of CNTs. In the reverse process of photoconductivity, light is absorbed creating excited states. We will discuss electronic relaxation of high energy excited states leading to the strong impact excitation and light emission, which intensity is determined by electric field, phonon scattering, and impact excitation cross section.

3:06PM W29.00012 Study of Butane adsorption on Purified HiPco Carbon Nanotubes. TOYO FURUHASHI, DINESH RAWAT, ALDO MIGONE, Southern Illinois University, Carbondale, IL-62901 — We investigated the adsorption characteristics of butane on purified HiPco single-walled carbon nanotubes for coverages in the first layer. We measured 9 full isotherms between 180 and 260K. The results for butane are compared with those obtained in a previous study of ethane adsorption on the same substrate. Comparable values for the specific surface area of the substrate were found when this quantity was measured using either ethane or butane. This strongly suggests that both of these species have access to essentially the same adsorption sites. We also determined that the strength of binding of the hydrocarbon chains to the SWNT bundles correlates, roughly linearly, with molecular length. An increase in chain length provides a greater number of contacts between sites on the substrate and the adsorbate species, thus, resulting in an increase in the values of the binding energies.

3:06PM W29.00002 Study of Butane adsorption on Purified HiPco Carbon Nanotubes. TOYO FURUHASHI, DINESH RAWAT, ALDO MIGONE, Southern Illinois University, Carbondale, IL-62901 — We investigated the adsorption characteristics of butane on purified HiPco single-walled carbon nanotubes for coverages in the first layer. We measured 9 full isotherms between 180 and 260K. The results for butane are compared with those obtained in a previous study of ethane adsorption on the same substrate. Comparable values for the specific surface area of the substrate were found when this quantity was measured using either ethane or butane. This strongly suggests that both of these species have access to essentially the same adsorption sites. We also determined that the strength of binding of the hydrocarbon chains to the SWNT bundles correlates, roughly linearly, with molecular length. An increase in chain length provides a greater number of contacts between sites on the substrate and the adsorbate species, thus, resulting in an increase in the values of the binding energies.

3:18PM W29.00003 Adsorption Kinetics of CH4 on Purified HiPco Single-Walled Carbon Nanotubes. MURAT BULUT, DINESH S. RAWAT, ALDO D. MIGONE, Southern Illinois University Carbondale — We present the results of an adsorption kinetics study of CH4 on two sets of purified HiPco SWNTs. We monitor the time evolution of the pressure from the instant at which gas is added to the cell containing the nanotubes to the moment at which equilibrium is reached. The two sets of samples were baked, under vacuum, at different temperatures (300 and 400°C). The difference in baking temperatures resulted in a difference in the specific surface areas; the sample treated at 400°C has a 15% larger surface area than the sample treated at 300°C. It also caused a difference in the kinetic behavior of the samples; the equilibration times for the two samples differ by a factor of 3. Moreover, the sample heated at 400°C exhibits two distinct equilibration times, while the one heated at 300°C exhibits only one. These changes are probably the result of partially opening the purified SWNTs by baking them at 400°C, which does not occur when we heat them only to 300°C.

This work was supported by NSF through grant # DMR-0705077.
3:30PM W29.00004 Adsorption kinetics of diatomic molecules on carbon nanotube bundles. JARED BURDE, MERCEDES CALIBI, Dep. of Physics, Southern Illinois Univ. Carbondale — A Kinetic Monte Carlo algorithm is used to explore the kinetics of adsorption of diatomic adsorbates on one-dimensional chains of sites. In particular, we monitor the evolution of the orientational configuration of the adsorbate as equilibrium is being reached at different values of temperature and chemical potential. We also analyze the dependence of the orientational evolution of the phases on the interactions between the molecules and on the presence of adsorption sites with different energies.

3:42PM W29.00005 Equilibration times of adsorption on external surfaces of carbon nanotube bundles. NAYELI ZUNIGA, Dep. of Physics, Southern Illinois Univ. Carbondale, JARED BURDE, MERCEDES CALIBI, ep. of Physics, Southern Illinois Univ. Carbondale — We investigate the adsorption kinetics of gases on the exterior of a carbon nanotube bundle by monitoring the uptake and exchange of particles in regions of the surface characterized by different binding energies. By using a Kinetic Monte Carlo scheme, we follow the time evolution of the gas uptake for different values of external pressure and temperature. The presence of adsorption sites with different energies gives rise to distinctive features on the equilibration time as function of the coverage. We show that preliminary experimental results for CF4, Ar, and CH4 on nanotube bundles with closed ends are consistent with our results.

3:54PM W29.00006 Adsorption kinetics of binary mixtures on carbon nanotube bundles. SEYOUNG TSIGE, JARED BURDE, MERCEDES CALIBI, Dep. of Physics, Southern Illinois Univ. Carbondale — We examine kinetic selectivity effects that take place during the adsorption of a binary mixture on one-dimensional chains. After reaching equilibrium at the same chemical potential, the species with the higher binding energy will enjoy the greatest coverage. However, the weaker-binding species has faster adsorption kinetics and is able to reach a coverage higher than its equilibrium value before the stronger species can adsorb significantly. The result of this process is an ‘overshoot’ in the fractional coverage of the weaker species that is reached at a time long before the system equilibrates. We analyze the appearance of this overshoot as a function of the temperature, chemical potentials, and energy parameters of the system.

4:06PM W29.00007 Hydrogen sensing properties of palladium-decorated carbon nanotube circuits. VAIKUNTH KHALAP, TATYANA SHEPS, ALEXANDER KANE, PHILIP COLLINS — Sensitive hydrogen gas sensors can be fabricated from carbon nanotube circuits decorated with palladium metal, and we have investigated the responsible physical mechanisms using isolated, single-walled carbon nanotubes (SWCNTs). Hydrogen sensitivity arises from two active mechanisms, neither of which is the mere adsorption of Pd onto pristine SWCNTs. The first mechanism relies on the chemical sensitivity of Schottky barriers present when semiconducting SWCNTs are contacted by metals. Pd decoration of the barrier region, or the use of pure Pd as the contact metal, produces a modest H2 sensitivity, if any. A more sensitive mechanism involves Pd-decorated defect sites, which in both metallic and semiconducting SWNTs results in reversible conductance swings of 100%. This presentation will review the temporal dynamics and pressure dependence of both mechanisms.

4:18PM W29.00008 Electrical Measurement of Single Molecule Catalysis using Carbon Nanotubes. BRETT R. GOLDSMITH, ALEXANDER A. KANE, VAIKUNTH KHALAP, Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697, JOHN CORONEUS, Department of Molecular Biology and Biochemistry, University of California Irvine, Irvine, CA 92697, GREGORY A. WEISS, Departments of Chemistry, Molecular Biology and Biochemistry, University of California Irvine, Irvine, CA 92697, PHILIP G. COLLINS, Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697 — We demonstrate single molecule chemical sensors based on single-walled carbon nanotubes (SWNT). The architecture uses a SWNT conductor having a single, reactive species covalently bonded to the sidewall [1]. Dynamics of the molecule are electrically transduced as it interacts with its surrounding environment. As a test case, we investigate the catalytic modification of EDC by a carboxylate. After creating a carboxylic terminus on the SWNT, the circuit is monitored for several hours and through hundreds of individual EDC reactions. Statistical analysis determines the lifetime of the carbonyl-EDC complex, as well as the catalytic turnover rate, from discrete events. Because the carboxylate site can be readily derivatized with proteins, peptides, or other functional molecules, the technique shows promise as a tool for single molecule research independent of optics and scanning probe microscopy. 1. B. R. Goldsmith, et al. Science 315, 77 (2007).

4:30PM W29.00009 Artificial introduction of defects in carbon nanotubes through Argon and Hydrogen ion irradiation, and application to chemical sensors. PRABHAKAR BANDARU, JEFFREY NICHOLS, MARK HOFER, Materials Science, UC, San Diego — The goal of this study is to quantify the effect of defect density on the electrochemical properties of multi-walled CNTs. Consequently, ion irradiation, with argon (Ar) and hydrogen (H), individually, has been performed to systematically incorporate defects into vertically aligned MWCNTs. Raman spectroscopy was used to characterize the amount of disorder within the nanotube samples. The electrochemical behavior of the irradiated MWCNT samples was then characterized through cyclic voltammetry (CV) measurements. Raman spectroscopy revealed an increase in the disorder in MWCNTs with the argon and hydrogen irradiation, as evidenced by an increase in the ID/IG peak intensity ratio. However, Ar is intercalated into the CNTs, and charges the nanotubes (forming dangling bonds), while H treatment terminates residual CNT dangling bonds. In CV, we have seen that only the Ar treated samples exhibit perfect reversible Nernstian behavior characteristic of ideal electrodes. Hydrogen treated CNT electrode ensembles seem to exhibit quicker response, as glucose sensors, with exquisite (~ 1 µM) sensitivity.

4:42PM W29.00010 Structure and thermodynamics of a Neon monolayer adsorbed on carbon nanotube bundles. OSCAR VILCHES, MICHEL BIENFAIT, Universite de la Mediterranee. MARK JOHNSTON, STEPHANE ROLS, ILI, Grenoble, SUBRAMANIAN RAMACHANDRAN, University of Washington — We report results from neutron diffraction measurements of five monolayer coverages of Ne adsorbed on single-wall, closed-end carbon nanotube bundles (SWCNB). Our recent thermodynamic study of Ne adsorbed on SWCNB, Phys. Rev. B, 76, 075404 (2007), showed one-dimensional (1d) solid behavior below 4K at doses less than 0.08 monolayer, which crossed over to 3d-like behavior above 16K without signature of a phase transition. Above 0.18 monolayer there is a 2d-like solid behavior below 8K, with Debye temperatures in the 45 to 53K range, consistent with our results. We also analyze the adsorption of a binary mixture on one-dimensional chains. After reaching equilibrium at the same chemical potential, the species with the higher binding energy will enjoy the greatest coverage. However, the weaker-binding species has faster adsorption kinetics and is able to reach a coverage higher than its equilibrium value before the stronger species can adsorb significantly. The result of this process is an ‘overshoot’ in the fractional coverage of the weaker species that is reached at a time long before the system equilibrates. We analyze the appearance of this overshoot as a function of the temperature, chemical potentials, and energy parameters of the system.

4:54PM W29.00011 Structure of a DNA-carbon nanotube hybrid using replica exchange molecular dynamics. ROBERT JOHNSON, A.T. CHARLIE JOHNSON, MICHAEL KLEIN, University of Pennsylvania — DNA-carbon nanotube hybrids (DNA-CN) are novel nanoscale materials that consist of single-wall carbon nanotubes coated with a self-assembled monolayer of single stranded DNA (ssDNA). Many recent experiments have demonstrated that this nanomaterial is an ideal candidate for a variety of nanotechnological applications. Despite the importance of this material, a complete understanding of its structural and physical properties is lacking. Recent molecular dynamics (MD) simulations of this nanomaterial have provided information about the self-assembly mechanisms and possible ssDNA conformations that characterize DNA-CN. However, MD simulations of biopolymers at low temperatures (T ~ 300 K) result in kinetic trapping and limits sampling of ssDNA configurational space. Here, we present the results of large scale replica exchange molecular dynamics simulations that provide robust sampling of the multitude of ssDNA conformations about SWCN.

5:06PM W29.00012 Photon sensing with carbon nanotubes: low-temperature photothermal effect on carbon nanotube transistors, LIHONG HERMAN, ADAM TSEEN, JIWOONG PARK, Cornell University — While thermal effects on the electrical properties of carbon nanotubes (CNTs) are an area of great interest, the effect of single photons on the low temperature conductance of CNTs has not been carefully studied. We recently developed a low-temperature fiber-based laser confocal microscope with simultaneous electrical measurement capability and diffraction-limited laser illumination and detection. In our experiment, CNT devices functionalized with gold nanoparticles were illuminated with a focused laser beam while their conductance was measured at temperatures as low as 300 mK. Photon absorption by either CNTs or gold nanoparticles results in local heating and provides spatially-resolved information about the thermal effects on transport in the CNT as the laser is scanned across the device. Our technique can be easily extended to the study of single-photon effects in other nanostructures including nanowires and graphene in the near future.

5:18PM W29.00013 Transport and Charge Sensing in $^{12}$C and $^{13}$C Carbon Nanotube Double Quantum Dots¹, HUGH CHURCHILL, Harvard University, DAVID MARCOS, Harvard University/Consejo Superior de Investigaciones Cientificas, ANDREW BESTWICK, JENNIFER HARLOW, Harvard University, CAROLYN SWERTZCHA, SUSAN WATSON, Harvard University/Middlebury College, CHARLES MARCUS, Harvard University — We report measurements of gate-defined carbon nanotube double quantum dot devices with a charge sensor fabricated on the same nanotube. The methane used during growth controls the $^{13}$C content of the nanotubes. $^{12}$C nuclei have zero nuclear spin, and $^{13}$C nuclei have spin 1/2. We compare samples with natural abundance (1%) and enriched (99%) $^{13}$C content. A strong isotope effect is observed in the magnetic field dependence of transport at finite bias. Fast control of these devices is demonstrated using a pulsed-gate technique.

Thursday, March 13, 2008 2:30PM - 5:30PM — Session W30 DMP: Nanotubes and Nanowires III: Other Properties II Morial Convention Center 222

2:30PM W30.00001 Nanotube Radio, KENNETH JENSEN, JEFF WELDON, HENRY GARCIA, ALEX ZETTL, University of California at Berkeley — We have constructed a fully functional, fully integrated radio receiver from a single carbon nanotube. The nanotube serves simultaneously as all essential components of a radio: antenna, tunable band-pass filter, amplifier, and demodulator. A direct current voltage source, as supplied by a battery, powers the radio. Using carrier waves in the commercially relevant 40-400 MHz range and both frequency and amplitude modulation techniques, we demonstrate successful music and voice reception.

2:42PM W30.00002 Template-Based Electroless deposition and TEM Analysis of TiO$_2$ nanotubes¹, ISABEL SCHULTZ, HAIDONG LIU, ZUXIN YE, WENHAO WU, Texas A & M University — We report on the fabrication of TiO$_2$ nanotubes using a template-based electroless deposition method. We used anodic aluminum oxide membranes of pore diameter $\sim$ 200 nm as the templates. The TiO$_2$ nanotubes were fabricated by first dipping the membranes into a titanium tetrafluoride solution at 60 °C for 30 minutes, and then annealing at 225 °C for 2 hours. The composition of the nanotubes verified using the energy dispersive spectroscopy. We used scanning electron microscopy (SEM) and transmission electron microscopy (TEM) to study the surface morphology of the nanotubes extracted after the membranes were dissolved. The nanotubes were found to be uniform along the length of the nanotube. For TEM analysis, an ion-milling technique was also used to produce a thin sample region so that the cross-section of the nanotubes remaining in their original pore channels could be directly imaged. The thickness of the TiO$_2$ nanotubes is about 50 nanometers, and could be controlled by varying the deposition time. Potential applications of these semiconducting TiO$_2$ nanotubes for forming nanostructured semiconducting interfaces will be discussed.

¹Supported by NSF under Grant Nos. DMR-0551813 and DMR-0606529 and DOE under Grant No. DE-FG02-07ER46450

2:54PM W30.00003 Electron Microscopy Analyses of Nanowires Electrochemically Deposited into Porous Membranes¹, HAIDONG LIU, ZHIPING LUO, ZUXIN YE, WENHAO WU, Texas A & M University — We fabricated single crystal nanowires of Zn, Sn and Pb by electrochemically depositing materials into the pores of porous anodic aluminum oxide membranes and polycarbonate membranes. We applied an in situ self-contacting technique to electrically contact single nanowires with macroscopic electrodes of Au, Sn, and Pb pre-fabricated on the membrane surfaces. We observed an anomalous long-range proximity effect in this nanowire/electrode system. In this talk, we describe electron microscopy methods we used to analyze the structure and the composition of the nanowires/electrode system. These included analyses of extracted nanowires using the scanning electron microscope (SEM) and transmission electron microscope (TEM). Nanowires remaining in their original pore channels were also analyzed with TEM using samples prepared by ion-milling and ultramicrotomy. These analyses revealed that the nanowires were single crystalline. Furthermore, the interface between the nanowires and the electrodes were directly imaged. The chemical compositions of the nanowires were also confirmed by the energy dispersive spectroscopy (EDS) analyses and mappings.

3:06PM W30.00004 Characterization of individual SnO$_2$ nanowires with surface science techniques, KAHIBULAKH KATSIEV, ULRIKE DIBOLD, Tulane University, ANDREI KOLMAKOV, Southern Illinois University — Tin oxide is widely used as a solid-state gas sensor for detection of combustible and toxic gases. Recently, the use of nanobelts and nanoribbons has been suggested as novel materials for gas sensing applications. Large-surface-to-volume ratio of the semiconducting metal oxide nanobelts and the congruence of the carrier screening length with their lateral dimensions make them highly sensitive and efficient transducers of surface chemical processes into electrical signal. The surface morphology of an individual nanobelt (NB) was studied with STM. Atomically resolved STM images of NBs reveal an 1X1 (101) SnO$_2$ structure on the top surface of the NB. The thermal stability of the NBs was studied with SEM. The critical temperatures were determined, where structural changes occur in UHV, O$_2$, and air. XPS was used to characterize chemical composition and monitor the cleanliness of the NB material. Ca and C contamination was detected on as-grown SnO$_2$ nanobelts. O plasma, ozone treatment, and annealing in oxygen were used to remove the contaminants.

3:18PM W30.00005 Structure and Stability of Metal Oxide Nanowires, DE NYAGO TAFEN, JAMES LEWIS, West Virginia University, Morgantown, WV — We present a comprehensive theoretical study — within the framework of ab initio density functional theory method — of the structural and stability properties of metal oxide nanowires. We consider nanowires with (100) growth direction with several diameters and surface facet configurations. A stability analysis of the results obtained for these nanowires is used to determine the most stable geometries. We show that the perimeter of the nanowires is a meaningful dimensional parameter, and that the surface facets play a central role on the energetics of the nanowires. The results are compared to available experimental data.
3:30PM W30.00006 First principles investigation of InN non-polar surfaces and nanowires\textsuperscript{1}, ALEKSANDRS TERENCEJEVS, Politecnico of Torino, Torino, Italy, ALESSANDRA CATELLANI, CNR-IMEM, Parma, Italy, GIANGAROLO CICERO, Politecnico of Torino, Torino, Italy — In the last years InN nanostructures have been proposed for application in solar cells, because of the outstanding electronic properties of this nitride compound. An increase of solar energy conversion in these kinds of cells requires a deep knowledge of surfaces properties, and on the effect of confinement on the electronic properties of the material. Here we present an investigation of the structural and electronic properties of InN nanowires as obtained by means of ab initio Density Functional calculations. First we discuss the results for the clean (1-100) and (11-20) faces, which are usually exposed in nanostructures, then we show how InN electronic properties change in nanowires due to confinement effects. We will finally present a possible InN functionalization pathway based on the use of molecules containing thiol groups. Our results show that thiol groups may attach to the surface following an exothermic process (dissociation energy is about 2.5 eV/mol for the (11-20) surface), thus they represent an effective anchoring group for the realization of hybrid InN based devices.

3:42PM W30.00007 Van Der Waals Interaction between Two Parallel Radially Deformed Single Wall Carbon Nanotubes\textsuperscript{1}, ADRIAN POPESCU, LILIA WOODS, University of South Florida, IGOR BONDAREV, North Carolina Central University — The van der Waals potential energy is calculated between two parallel infinitely long radially deformed single walled carbon nanotubes within the pairwise Lennard-Jones approximation for extended systems. The nanotubes will undergo different geometrical radial shape transitions if an external hydrostatic pressure with an increasing strength is applied. We describe these shapes with analytically in order to facilitate the calculations. The most preferred mutual orientations are determined in all considered cases in terms of their potential well depths, equilibrium distances, and geometrical parameters. We find that the interaction evolves in such a way as to keep the distance between the interacting surfaces comparable to the graphene-graphene distance in graphite. In addition, the universal graphical potential concept is extended to radially deformed carbon nanotubes. These results can be used as a guide for future experiments to investigate interactions between deformed carbon nanotubes.

3:54PM W30.00008 Atomic Structure of the Si(111)-4x1-In System\textsuperscript{1}, BARRY HAYCOCK, West Virginia University & Dublin Institute of Technology, J.D. O’MAHONY, Dublin Institute of Technology — The indium-induced 4 x 1 reconstruction on silicon (111) has been extensively studied due to its unique physical and structural properties, which indicate so-called “Quantum Wire Behaviour”. The likely crystallographic structure of this system has been hotly debated since 1999. The structure was mathematically modeled by Tsay using a planewave calculation method in 2005, which yielded results of atomic positions that matched closely to the Bunk model. In this study we model the th this system using the molecular dynamics (MD) package Fireball, taking as a starting point the atomic positions of the Bunk model. This ab-initio tight-binding MD method has the advantage of being able to operate with a very large number of atoms per cell in a single calculation, thus allowing for a very large superslab in the calculation model. This allows for greater surface area and thus is expected to produce a more accurate surface characteristic calculation result. The results of this calculation are compared to the recent results of Tsay.

4:06PM W30.00009 Vapor-solid-solid growth mechanism driven by epitaxial match between solid AuZn alloy catalyst particle and ZnO nanowire at low temperature, RODRIGO LACERDA, LEONARDO CAMPOS, MATTEO TONEZZER, ANDRE FERLAUTO, ROGERIO PANIAGO, SERGIO OLIVEIRA, LUIZ ORLANDO LADEIRA, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, VINCENTZO GRILLO, TASC-INFM-CNR National Laboratory, Trieste, Italy — The present paper provides a comprehensive picture of the precise mechanism of ZnO vapor-solid-solid nanowire growth at low temperatures and gives the fundamental reasons responsible [1]. We demonstrate by using a combination of synchrotron XRD and high resolution TEM that the growth dynamics at low temperatures is not governed by the well-known VLS mechanisms. Based on the Au-Zn phase diagram, temperature measurement and temperature size effects, we show that growth occurs via VSS. The precise composition of the Au-Zn catalyst nanoparticle has been determined to be γ-AuZn. Furthermore, we experimentally observe that there is an indication of a epitaxial relationship between the ZnO nanowires and the γ-AuZn seed particle. A critical new insight on the driving factor of VSS growth is proposed in which the VSS process occurs by a solid diffusion mechanism that is driven by a preferential oxidation process of the Zn inside the alloy catalyst induced by an epitaxial match between the ZnO(10-10) plane and the γ-AuZn(222) plane. [1] L. C. Campos et al, Adv. Materials (accepted for publication).

4:18PM W30.00010 Temperature effects in the stability of pure and doped gold nanowires, ANTONIO J.R. DA SILVA, Instituto de Fisica - USP Brazil, EDWIN HOBIR JR., ADALBERTO FAZZIO, Instituto de Fisica - USP Brazil — Gold nanowires have attracted a great deal of attention, one of the reasons being the ability to form linear gold chains that are one atom wide and that have just a few atoms in length. One of the amazing characteristics of these wires is their stability, even at ambient temperatures. Therefore, it is very important to understand why they are stable and why they break. Moreover, inserted impurities, such as H and C, can dramatically affect their stability. In the present work we use state-of-the-art ab initio molecular dynamics to perform simulations of pure and doped Au nanowires. We propose a general mechanism that helps to explain the stability of these wires and the rupture process. We show that triplets of Au atoms in the neck of atomically thin nanowires have an instability towards rupture at a length of around 6.0-6.1 angstroms. At this length, the potential energy surface (PES) describing the motion of the central atom changes from a single minimum at the middle of the triplet, to a double minimum profile. This provides a consistent picture of the mechanism of rupture of metallic nanowires. Impurities such as C and H also have this behavior. However, as they have stiffer bonds, these PES instabilities always happen in pure Au bonds.

4:30PM W30.00011 Surface Effects on the Electronic, Magnetic and Structural Properties of Free-standing InP nanowires, TOME SCHMIDT, Universidade Federal de Uberlândia — Nanowires due to their large surface-to-volume ratio of particular interest is the understanding of the surface structure and the electronic effects due to surface states. In this work we investigate the structural and electronic properties of InP nanowires aligned along the [111] direction, in which the surface have been studied by passivating with hydrogens or OH radicals and also oxidized. The magnetic properties of Mn doped InP nanowires with different surface termination have been also investigated. Our ab initio density functional calculations show that hydrogen passivation removes the surface states, opening up the band gap. Our results for oxygen adsorbed on the hydrogen passivated InP nanowires, show that there are many configurations where the oxygenes are chemisorbed processes. For Mn doped InP nanowires our results reveal that the surface of the nanocrystals play a fundamental role on the impurity stability and on the magnetic properties of InP nanowires. The formation energy of pairs of Mn impurities in unpasivated nanowires are lower that than of the bulk InP. Most of the Mn pair configurations present FM coupling and their prefer to be inside the nanowire and not on the surface.
4:42PM W30.00012 Shift- and injection-current optical response of BN nanotubes1. NORBERTO ARZATE, Centro de Investigaciones en Optica, Mexico, FRED NASTOS, Department of Physics, University of Toronto, RAUL A. VAZQUEZ-NAVA, Centro de Investigaciones en Optica, Mexico, MIGUEL GONZALEZ, Centro Universitario de los Lagos, Mexico, BERNARDO MENDOZA, Centro de Investigaciones en Optica, Mexico, JOHN SIPE, Department of Physics, University of Toronto — We present the frequency dependence of the electrical shift and injection currents optically generated on BN nanotubes. The shift and injection currents are a second order effect that is associated to a divergence of the nonlinear susceptibility at zero frequency. The shift current is generated with linearly polarized light and the injection current can be generated with circularly polarized light. We make use of density functional theory and pseudopotentials to calculate the nanotube structures and their electronic states. The current-coefficient calculations are done in optical rectification, within the independent particle approximation and within a full band structure scheme. We also obtain the frequency dependence for the shift distance that the center of electron charge moves in the shift-current process and for the swarm velocity or maximum velocity acquired by the electrons in the injection process.

4:54PM W30.00013 An ab initio study of the interaction of transition metal atoms with single-wall armchair SiC nanotubes1. KAZI ALAM, ASOK RAY — A systematic study of Fe atom encapsulated and adsorbed in armchair SiC nanotubes has been performed using hybrid density functional theory calculations within finite cluster approximation. A detailed comparison of the binding energies, equilibrium positions, Mulliken charges and spin magnetic moments of Fe atoms has been performed for three types of nanotubes. The electronic states, HOMO-LUMO gaps, and changes in gaps with respect to the bare nanotube gaps have been investigated as well. Binding energies of the encapsulated and adsorbed Fe atoms indicate that these structures are stable and show site dependence. For both cases significant band gap decrease is observed for type 1 nanotubes enabling band gap tailoring. This decrease is not observed for the other two types in both cases of interactions. All the structures are found to have magnetic ground states with very high magnetic moments indicating the possibility of them being used as nanomagnets.

5:06PM W30.00014 Energetics of Cu Nanowires1. MINE KONUK, Department of Physics, Istanbul Technical University, Maslak, 34469 Istanbul, Turkey, BERK ONAT, Informatics Institute, Istanbul Technical University, Maslak, 34469 Istanbul, Turkey, SONDAN DURUKANOGLU, Department of Physics, Istanbul Technical University, Maslak, 34469 Istanbul, Turkey — We have calculated activation energies for several single atom and vacancy diffusion mechanisms on the <100> and <110> axially oriented, rectangular Cu nanowires with a particular interest in determining the effect of varying cross-sectional area on the activation barriers for the investigated processes. The calculations are performed using the nudged elastic band technique based on the interaction potential obtained from the embedded atom method. Our results on activation barriers for adatom diffusion mechanisms indicate a clear dependence on the cross-sectional area of the nanowires. We, furthermore, find that the energy barrier for single vacancy diffusion is decreasing drastically near the outer wall compared to barriers for single vacancy diffusions taking place in the interior region of the nanowire.

5:18PM W30.00015 Ab Initio Computational Studies of the Electronic and Optical Properties of SiC Nanotubes. GUANG-YU GUO, I-JEN WU, Department of Physics, National Taiwan University, Taipei 106, Taiwan — Since the discovery of carbon nanotubes (CNTs) in 1991 by Iijima, carbon and other nanotubes have attracted considerable interest worldwide because of their unusual properties and also great potentials for technological applications. Though CNTs continue to attract great interest, other nanotubes such as BN nanotubes (BN-NTs) may offer different opportunities that CNTs cannot provide. We have carried out systematic computational studies of various physical properties of SiC nanotubes. In this talk, we will present ab initio calculations of electronic, linear and nonlinear optical properties of SiC nanotubes [1].

Thursday, March 13, 2008 2:30PM - 5:30PM —

2:30PM W31.00001 Magnetic and Structural Properties of Sr-Doped Ba$_2$-$x$Sr$_x$CoO$_4$. HAO SHA, JIANDI ZHANG, Department of Physics, Florida International University, Miami, FL 33199, Q. HUANG, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, Y.O. GARLEA, B.C. SALES, D. MANDRUS, R. JIN, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — We have studied the structural and magnetic properties of a newly synthesized compound Ba$_2$-$x$Sr$_x$CoO$_4$ with different doping ($x$) levels. Monoclinic Ba$_2$CoO$_4$ is an antiferromagnetic (AFM) insulator with Neel temperature $T_N = 25$ K and a two-dimensional character with spins aligned in the ac plane. The isovalent Sr doping causes changes in both crystal structure and magnetic properties. With increasing $x$, $T_N$ initially increases then decreases after reaching the maximum at $x=0.5$. Correspondingly, its crystal structure changes from monoclinic ($x < 0.5$) to orthorhombic ($x \geq 0.5$) at room temperature. The correlation between crystal structure and physical properties will be discussed.

1Supported by NSF-DMR0346826, and DOE DE-FG02-04ER46125

2:42PM W31.00002 Electronic structure changes in novel $J_{eff}$=1/2 system: Ruddlesden-Popper series Sr$_{n+1}$Ir$_n$O$_{3n+1}$ (n=1, 2, and $\infty$). S.J. MOON, J.S. LEE, W.S. CHOI, T.W. NOH, ReCOE & FPRD, Department of Physics and Astronomy, Seoul National University, Korea, H. JIN, J. YU, CSCMR & FPRD, Department of Physics and Astronomy, Seoul National University, Korea, Y.S. LEE, Department of Physics, Soongsil University, Seoul, Korea, V. DURAIARAJ, G. CAO, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA, A. SUMI, H. FUNAKUBO, Department of Innovative and Engineered Materials, Interdisciplinary Graduate School of Science and Engineering, Tokyo Institute of Technology, Japan — We investigated the electronic structures of Ruddlesden-Popper series Sr$_{n+1}$Ir$_n$O$_{3n+1}$ (n=1, 2, and $\infty$) compounds with optical spectroscopy and first-principles calculation. Among Sr$_{n+1}$Ir$_n$O$_{3n+1}$, while SrIrO$_3$ is a metal, Sr$_2$IrO$_4$ and Sr$_3$Ir$_2$O$_7$ are insulators. In optical conductivity spectra $\sigma(\omega)$, we found unique bandwidth-driven changes of the electronic structures which were quite different from those of 3$d^5$ 4$d^1$ $S=1/2$ systems. From the comparison between $\sigma(\omega)$ and the results of first-principles calculation, we found that the intriguing changes of the electronic structures can be realized by the cooperative interaction between the $S=1/2$ and the electron correlation. These results clearly demonstrate that Sr$_{n+1}$Ir$_n$O$_{3n+1}$ should be considered as a $J_{eff}=1/2$ single band system.

1Supported by NSF-DMR0346826, and DOE DE-FG02-04ER46125
2:54PM W31.00003 Electrical Resistance of Quasi-1D Li$_{0.9}$Mo$_6$O$_{17}$ at Very High Magnetic Field$^1$, CARLOS A.M. DOS SANTOS, Escola de Engenharia de Lorena – USP, J. MORENO, NAMS, The Richard Stockton College of New Jersey, B.D. WHITE, J.J. NEUMEIER, Montana State University, L. BALICAS, NHMFL-Tallahassee — Recently, photoemission experiments, band structure calculations, tunneling, and the description of the electrical resistivity by two power-law terms suggest that Li$_{0.9}$Mo$_6$O$_{17}$ is an excellent example of a metallic Luttinger-liquid (LL) [a,b]. The crossover from metallic to insulating-like behavior near $T_M = 28$ K was addressed by thermal expansion experiments which suggest that a dimensional crossover sets the stage for superconductivity [b]. To obtain more information about the crossover at $T_M$, magnetoresistance measurements were performed under very high magnetic field ($0 < H < 23$ tesla). The results show that the minimum at $T_M$ increases with increasing $H$. The power-law temperature dependence of the electrical resistance at $T_M(H)$ is also evaluated. [a] C. A. M. dos Santos, M. S. da Luz, Yi-Kuo Yu, J. J. Neumeier, J. Moreno, and B. D. White. Submitted to Phys. Rev. Lett. (2007). [b] C. A. M. dos Santos, B. D. White, Yi-Kuo Yu, J. J. Neumeier, and J. A. Souza, Phys. Rev. Lett. 98, 266405 (2007).

3:06PM W31.00004 Unconventional magneto-transport in novel layered cobalt oxides, ICHIRO TERASAKI, Waseda University — Among strongly correlated transition-metal oxides, cobalt oxides are known to have unique features arising from the spin-state degree of freedom tightly coupled with Co valence. The Co$^{4+}$ ion in the low-spin state is responsible for anomalous metallic states such as large thermopower in Na$_2$CoO$_3$ and unconventional superconductivity in hydrated Na$_2$CoO$_2$. The Co$^{2+}$ ion favors the high-spin state, which makes magnetic insulators. The Co$^{3+}$ ion is most interesting in the sense that the low-, intermediate- and high-spin states are nearly degenerate, where a spin-state crossover/transition occurs with temperature or pressure. Recently we have discovered two complex layered cobalt oxides, which exhibit unprecedented transport originated from interplay between charge, orbital and spin-states. The first one is Sr$_2$CoO$_{2+}$, in which the Co-O Kagome lattice and two-types of Co-O pillars are stacked along the c axis [1]. The conduction electrons in the Kagome lattice interact with Ising spins in the pillars, and shows two-step plateau in the magnetoresistance along the c axis. The second one is Sr$_2$YCo$_{10}$O$_{25}$, which exhibits a ferromagnetic insulating state below 340 K. Various substitutions of Sr, Y and Co sites dramatically suppress this ferromagnetic state, and concomitantly modify the magneto- and thermoelectric transport. We will discuss the structure-property relationship based on structure analyses. The main part of this work was done in collaboration with S. Ishiwata, W. Kobayashi, and M. Takano.

3:42PM W31.00005 Search for Half-Metallic Antiferromagnetism in Double Perovskites, V. PARDO, University of California Davis, W. E. PICKETT, University of California Davis — The wide class of double perovskite oxides was proposed earlier (PRB 57, 10613 [1998]) as promising for producing a half-metallic antiferromagnet [HMAFM] (more correctly, a spin-compensated half metal). Here we present examples of the affects of structural distortions on the electronic and magnetic properties in selected members. For La$_2$CrNiO$_6$, the idealized perovskite structure had led to a spin-antiparallel state with net moment of 0.6 $\mu_B$, but a ferromagnetic half-metallic state (4 $\mu_B$) was 150 meV per metal atom lower in energy (within local density approximation). Starting with experimental information on LaCoO$_3$ and LaNiO$_3$ and their alloys, we have relaxed the volume and the (seven) internal coordinates within the orthorhombic Pnma space group. The charge states can be characterized by Cr$^{4+}$ and Ni$^{2+}$. The ferromagnetic state is lower by 50 meV within the generalized gradient approximation. Using LDA+U ($U=3$ eV on each transition metal ion) opens a gap of 0.6 eV (FM insulator) and is favored by 120 meV over the antialigned state. Although no HMAFM state is obtained, these results show that structural relaxation must be suppressed this ferromagnetic state, and concomitantly modify the magneto- and thermoelectric transport. We will discuss the structure-property relationship based on structure analyses. The main part of this work was done in collaboration with S. Ishiwata, W. Kobayashi, and M. Takano.

3:54PM W31.00006 Electrical transport and thermodynamic properties of SrNbO$_{3.41}$, ARIANA DE CAMPOS, Montana State University, ANN DEML, University of Wisconsin-River Falls, B.D. WHITE, Montana State University, C.A.M. DOS SANTOS, Escola de Engenharia de Lorena-USP, M.S. DA LUZ, J.J. NEUMEIER, Montana State University — In 1991, Lichtenberg et al.$^1$ reported the electric conductivity of SrNbO$_{3.41}$ revealing quasi-1D behavior. This system offers many possibilities to vary the compositional, structural, chemical, and physical properties.$^1$ Depending upon the temperature range and crystallographic direction, it exhibits metallic behavior or a metal-semiconductor transition. In this work, the properties of SrNbO$_{3.41}$: single crystals are revisited. The single crystals were grown by the floating zone method and characterized by x-ray diffraction. Electrical resistivity as a function of temperature was measured with four-probe and Montgomery methods. We will also report results of heat capacity and thermal expansion measurements.$^2$ F. Lichtenberg et al., Z. Phys. B 84, 369 (1991); F. Lichtenberg et al., Prog. Solid State Chem 29, 1-70 (2001).

$^1$This material is based upon work supported by the Brazilian Agency CNPq (Grant No. 201439/2007-7), the NSF (Grant No. DMR-0504769) and U.S. DOE Office of Basic Energy Sciences (Grant No. DE-FG-06ER46269).

4:06PM W31.00007 Extreme electron-phonon coupling in magnetic rubidium sesquioxide, ROBERT DE GROOT, Rijksuniversiteit Groningen, JISK ATTEMA, Radboud University, S. RIYADI, GREÃŒME BLAKE, Rijksuniversiteit Groningen, GILLES DE WIJS, Radboud University, THOMAS PALSTRA, Rijksuniversiteit Groningen — Rb$_2$O$_3$ is a black, opaque oxide. Early work suggests that the stability range of the sesquioxide phase in the rubidium-oxygen phase diagram is rather broad. Rb$_2$O$_3$ remains cubic down to the lowest temperature measured (5 K). The open oxygen form dumbbells with interatomic distances in between those of peroxide and superoxide anions, and strong athermal motion persists down to low temperatures. [1] Electronic-structure calculations show that the dynamics at low temperature is caused by 6 phonon modes of zero frequency, which induce a very strong electron-phonon interaction. The softness of half of these modes is suppressed by the application of pressure. Calculated using the average oxygen positions, rubidium sesquioxide is a half-metallic ferromagnet. [2]

4:18PM W31.00008 Gigantic optical magneto-electric effect in CuB$_2$O$_4$, MITSURU SAITO, KOUJI TANIGUCHI, TAKAHISA ARIMA, Tohoku University — It has been recognized since 1960s that magneto-electric (ME) materials may also show an optical magneto-electric (OME) effect showing up as a change in optical absorption with reversal of the propagating direction of light. The OME effect is an interesting object of scientific research and provides possibilities for applications. However, the changes in absorption coefficient ever discovered were very small (less than 0.2%). We present a gigantic OME effect in a noncentrosymmetrical weak ferromagnet CuB$_2$O$_4$, in which the absorption coefficient changes by a factor of three with reversal of a very weak magnetic field of 300 eC. This magnitude of OME effect enables us to observe it by a CCD camera with linearly polarized near-infrared and visible light. Spectroscopic study and comparison of OME effect with magnetization indicate an important role of canted antiferromagnetic spin ordering and local symmetry of a square Cu$^{2+}$ site. The gigantic OME effect can be applicable to optical devices like magnetic switching of color in the future.
4:30PM W31.00009 Resonant inelastic X-ray scattering study of quasi-zero-dimensional copper metaborate. JASON HANCEOK, GUILLAUME CHABOT-COUTURE, MARTIN GREVEN, Stanford University, GUERMAN PETRAKOVSKI, Kirenskii Institute, Siberia, KENJI ISHII, JUN'ICHIRO MIZUKI, Japan Atomic Energy Agency — Cu$_2$O$_6$ consists of many CuO$_6$ plaquettes separated by B ions. We report a study of the electronic excitation spectra of this system in order to explore the relationship between excitation symmetry and the resonant inelastic X-ray scattering (RIXS) technique. We find a small number of well separated features in the experimentally accessible range of 0.5-15 eV energy transfer, and weak dispersion is suggestive of the quasi-zero-dimensional nature of this system. Systematic trends in the data are suggestive of a composite nature to one of the observed features. Using a cluster model, we describe these unexpected trends and clarify how the choice of experimental geometry selectively influences the sensitivity to particular excitation symmetries in the RIXS experimental technique.

4:42PM W31.00010 Powder neutron diffraction study of quasi-one-dimensional Li$_0.9$Mo$_6$O$_{17}$

MARIO S. DA LUZ, Montana State University, C.A.M. DOS SANTOS, Escola de Engenharia de Lorena, B.D. WHITE, J.J. NEUMEIER, Montana State University, Q. HUANG, J.B. LEAO, J.W. LYNN, NIST Center for Neutron Research — The crystallographic structure of quasi-one-dimensional Li$_0$$_9$Mo$_6$O$_{17}$ was investigated by Rietveld refinement of powder neutron diffraction data at temperatures in the range 5 K < T < 295 K. Structural parameters, atomic positions, occupation numbers, and isotropic thermal parameter B$_{iso}$ will be reported. The occupancy was refined revealing a Li occupancy greater than 0.9. Bond valences sums will also be reported for various Li and Mo sites. At room temperature, the crystal was found to exhibit monoclinic symmetry with space group P21/c and lattice parameters $a = 12.7506(1)$, $b = 5.5242(1)$, $c = 9.4913(2)$ and $\beta = 90.593(1)^\circ$. Good agreement between the temperature dependence of lattice parameters and high resolution thermal expansion results was obtained. *C. A. M. dos Santos, B. D. White, Yi-Kuo Yu, J. J. Neumeier, and J.A. Souza, Phys. Rev. Lett. 98, 266405 (2007).*

5:06PM W31.00012 X-ray absorption and x-ray magnetic dichroism study on Ca$_3$CoRhO$_6$ and Ca$_2$FeRh$_2$O$_6$. TOBIAS BURNUS, ZHIWEI HU, University of Cologne, Germany, JULIO C. CEZAR, European Synchrotron Radiation Facility, Grenoble, France, SEIJI NITAKA, KENJI ISHII, JUN'ICHIRO MIZUKI, Japan Atomic Energy Agency — We have investigated the structural and physical properties of Ca$_3$CoRhO$_6$ single crystals using x-ray absorption and x-ray magnetic dichroism. The magnetic susceptibility data indicate that there are several magnetic transitions above room temperature. The possible correlation between charge, spin, and lattice will be explored.

5:18PM W31.00013 Anisotropy in magnetic properties of single crystal LiFePO$_4$. GAN LIANG, Sam Houston State University, KEESONG PARK, JOHN MARKERT, University of Texas at Austin, JIYING LIAO, DAVID VANKIN, Ames Lab and Iowa State University — We report the experimental and theoretical results on the anisotropies in the magnetic properties and x-ray absorption spectra of single crystal LiFePO$_4$. A mean-field theory is developed to explain the observed strong anisotropies in Lande g-factor, paramagnetic Curie temperature, and effective moment for LiFePO$_4$ single crystals. The values of the in-plane nearest- and next-nearest-neighbor spin-exchange ($J_1$ and $J_2$), inter-plane spin-exchange ($J_3$), and single-ion anisotropy ($D$), obtained recently from neutron scattering measurements, are used for calculating the Curie temperatures with the formulas derived from the mean-field Hamiltonian. It is found that the calculated Curie temperatures match well with that obtained by fitting the magnetic susceptibility curves to the modified Curie-Weiss law.

Thursday, March 13, 2008 2:30PM - 5:30PM —

Session W32 GMAG DMP FIAP: Focus Session: Domain Wall Motion and Itinerant Magnetism

2:30PM W32.00001 Domain wall motion under the non-uniform transverse magnetic field with rigid domain structure. CHUN-YEOL YO, Dept. of Phys. Inha University — Another method for the domain wall movement in a nanowire geometry with rigid domain structure will be proposed. We find that a transverse domain wall move to the energy minimum position under a non-uniform transverse magnetic field in order to minimize the Zeeman energy. By the collective coordinate approach, the domain wall dynamics under non-uniform transverse magnetic field in nanowire geometry is investigated. The validity of concept of the present method and the domain wall equation of motion are confirmed by micromagnetic simulations. It is found that the domain wall velocity of a few 100 m/s can be obtained for the moderate conditions based on the analytic and numerical studies. The direction of the domain wall movement depends only on the magnetization direction inside of the domain wall itself, not on the one of the domain. Therefore, it is possible to achieve field driven domain wall motion with rigid domain structures. The non-uniform transverse magnetic field driven domain wall motion has a superior nature of the rigidity of the domain structure during the domain walls movement in addition to the all advantages of conventional field driven domain wall movement.
2:42PM W32.00002 Crossed Ratchet Effects for Magnetic Domain Wall Motion1, JOSE I. MARTIN, A. PEREZ-JUNQUER, Dpto. Fisica, U. Oviedo, Spain, V.I. MARCONI, A.B. KOLTON, Dpto. Fisica Atomica Molecular y Nuclear and GISC, U. Complutense, Madrid, Spain, L.M. ALVAREZ-PRADO, Dpto. Fisica, U. Oviedo, Spain, Y. SOUCHE, Inst. Neel, CNRS and U. Joseph Fourier, Grenoble, France, A. ALIJJA, M. VELEZ, Dpto. Fisica, U. Oviedo, Spain, J.V. ANGIUTA, IMMM, CNM, CSIC, Tres Cantos, Spain, J.M. ALAMEDA, Dpto. Fisica, U. Oviedo, Spain, J.M.R. PARRONDO, Dpto. Fisica Atomica Molecular y Nuclear and GISC, U. Complutense, Madrid, Spain — The driven motion of domain walls in extended amorphous magnetic films patterned with a periodic array of asymmetric holes has been studied experimentally and theoretically. We find two crossed ratchet effects of opposite sign that change the preferred sense for domain wall propagation, depending on whether a flat or a kinked wall is moving. These crossed effects have an interesting consequence with potential applications: the system keeps memory of the sign of the last saturating state even in a zero magnetization configuration. By solving numerically a simple $\phi^4$-model we show that the essential physical ingredients for this effect, the competition between drive, elasticity and asymmetric pinning, are quite generic and could be realized in other experimental systems involving elastic interfaces moving in multidimensional ratchet potentials.

2:54PM W32.00003 In Situ TEM Observation of Current-Induced Domain Wall Motion in Patterned Permalloy Wires1, TODD BRINTLINGER2, JOHN CUMINGS3, University of Maryland — Using a transmission electron microscope (TEM) operating in Lorentz mode, we observe the movement of a domain-wall due to the flow of current in a permalloy wire. The wire is formed on electron-transparent silicon nitride membranes using standard electron beam lithography and thermal vacuum deposition. The resulting wire geometry is 30 nm thick, ~100nm wide, and microns long. A custom-built electrical measurement stage and palladium leads deposited on top of the permalloy wires allow in situ measurements on the wire in the TEM. Lorentz mode imaging (Fresnel contrast) allows the determination of the domain wall location. We observe the domain wall to move in the direction of electron flow, with a current density of around $1 \times 10^{11}$ A/m$^2$ being required to move the wall. We will present the nanofabrication process, results, and interpretation of these experiments.

1This work was supported by NSF MRSEC DMR 0520471 and conducted at the Maryland Nanocenter. We acknowledge the use of the NISP laboratory, a MRSEC shared equipment facility.

3:06PM W32.00004 Stochastic Current-Driven Domain-Wall Motion Observed by X-Ray Microscopy, GUIDO MEIER, University of Hamburg, Germany — Transmission x-ray microscopy can directly visualize the influence of a spin-polarized current on the magnetization of micro- and nanostructures. We investigate the stochastic motion of domain walls in curved wires [1] and the motion of vortices in squares [2]. To observe domain-wall motion pulses of nanosecond duration and high current density are send through permalloy wires and either move or deform the domain wall. The current pulses have nanosecond duration and a high current density of up to $1.0 \times 10^{12}$ A/m$^2$ and drive the wall either undisturbed, i.e. as a composite particle through the wire or causes structural changes of the magnetization. Repetitive pulse measurements reveal the stochastic nature of current induced domain-wall motion. From the experiments we estimate the ratio between the degree of nonadiabatic and the Gilbert damping parameter indicating the importance of the nonadiabatic contribution to current driven domain-wall motion. To compare experimental results with theory the spin-torque transfer model of Zhang and Li [3] is implemented in the micromagnetic framework OOMMF [4]. The code is applied to determine the current-induced domain wall velocity using the material parameters of permalloy. The simulations support the interpretation of the experimental results. Sinusoidal high-density currents are applied to micrometer-sized permalloy squares containing ferromagnetic vortices. Spin-torque induced vortex gyration on the nanosecond timescale is observed. The phase of the gyration in structures with different chirality are compared to an anamorphic model and micromagnetic simulations, considering both alternating spin-polarized currents and the current’s Oersted fields. This analysis reveals that spin-torque is the main source of motion. Supported by the DFG via SFB 668 and GK 1286 as well as by the U.S. DOE Contract No. DE-AC02-05-CH11231. References:

3:42PM W32.00005 The dynamics of field and current-driven magnetic domain wall depinning1, GEOFFREY BEACH, UT Austin, CARL KNUTSON, MAXIM TSOI, JAMES ERSKINE — The depinning of a magnetic domain wall from a well-defined potential well was studied experimentally on timescales ranging from minutes down to tens of nanoseconds. At longer timescales, the behavior follows the classical Neel-Brown model of thermal activation, one of the few observations of this process for the ideal case of a single energy barrier. Below one microsecond, however, the depinning rate becomes independent of the activation volume and assumes a more universal behavior. This transition is due to a vanishing of the energy barrier at a critical field, beyond which the rate of de pinning depends primarily on the torque supplied by the field and spin current. A dc spin-polarized current flowing across the domain wall has the effect of lowering the energy barrier by an amount that is predominantly quadratic in current, independent of its direction. This is seen to arise from a shift of the wall in the energy potential due to the adiabatic component of spin-transfer torque.

1Supported by NSF-DMR-0404252 and the R. A. Welch Foundation

4:06PM W32.00007 Domain wall motion by subcritical harmonic current, YURY ADAMOV, ARTEM ABANOV, JAIRO SINOVA, Texas A&M University — We consider the behavior of the domain wall in the bianisotropic magnetic wire. We show that while the domain wall cannot be moved by the constant current below the certain threshold value (critical current), if we add an alternating component to the current the domain wall starts to move with nonzero velocity. We obtain the analytic expression for this velocity and make suggestions of possible experiments.
4:18PM W32.00008 Theory of Electromotive Force Induced by Domain Wall Motion, SHENGYUAN YANG, DI XIAO, QIAN NIU, Department of Physics, The University of Texas at Austin — We formulate a theory on the dynamics of conduction electrons in the presence of moving magnetic textures in ferromagnetic materials. We show that the variation of local magnetization in both space and time gives rise to topological fields, which induce electromotive forces on the electrons. Universal results are obtained for the emf induced by both transverse and vortex domain walls traveling in a magnetic film strip, and their measurement may provide clear characterization on the motion of such walls.

4:30PM W32.00009 Oscillatory domain wall motion in a single-crystal ultrathin Au/Co/Au system, KEOKI A. SEU, Physics Department, University of Oregon and Advanced Light Source, Lawrence Berkeley National Laboratory, SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, SUNGYUN PARK, Busan Center, Korea Basic Science Institute, Busan 609-735 Korea, CHARLES M. FALCO, College of Optical Sciences, University of Arizona, STEPHEN D. KEVAN, Physics Department, University of Oregon — We have used x-ray photon correlation spectroscopy together with resonance soft x-ray scattering to measure domain dynamics in a Au/Co/Au system that exhibits a spin reorientation phase transition (SRT) in the temperature range of 200-300 K. The incoming photon energy was tuned at the Co L3 edge and the coherence is established with a ~10 nm pinhole. The resultant speckle pattern is measured with a CCD camera in time as a function of temperature 200 K to 300 K. The correlation coefficient, which is an indicator of domain wall dynamics, shows damped oscillatory behavior in time. The period of the oscillations is approximately 120 sec. The frequency and damping constant were found to depend on the length-scale and temperature changes through the phase transition. Our results show that the SRT dynamics on a mesoscopic length scale and slow time scale can be surprisingly complex.

4:42PM W32.00010 Thermodynamics of Itinerant Magnets: A Simple Classical Model with Longitudinal Spin Fluctuations, JAMES GLASBRENNER, ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, University of Nebraska - Lincoln — The effects of longitudinal spin fluctuations (LSF) on the thermodynamics of magnetic metals are studied using a model Hamiltonian with only one “ityperance parameter.” We performed Monte Carlo simulations and compared the results with the mean-field theory. A non-trivial complication is the choice of phase space measure. We explored two options: the “classical” measure and the “flat” measure. Our central result is that magnetic short-range order is always weak, and the mean-field theory is in a very good agreement with Monte Carlo results. Additionally, the results are very sensitive to the choice of the phase space measure, which is a limitation of our model. Nevertheless LSF are essential for the correct description of magnetic thermodynamics and their absence in the adiabatic approximation leads to unphysical results for itinerant systems. Deviations from the Curie-Weiss law due to LSF are also observed and discussed.

4:54PM W32.00011 High Pressure Study of Magnetic Order in an Itinerant Electron System: Investigating Weak vs. Strong Coupling, RAFAEL JARAMILLO, The University of Chicago, Y. FENG, J. C. LANG, Z. ISLAM, APS, Argonne National Laboratory, T. F. ROSENBAUM, The University of Chicago — We measure directly the spin- and charge-density-wave order parameters of the itinerant antiferromagnet Cr via x-ray diffraction as the system is driven towards its quantum critical point with pressure using diamond anvil cell techniques. The exponential decrease of the spin and charge diffraction intensities with pressure confirms the harmonic scaling of spin and charge in this incommensurate system, while the evolution of the incommensurate ordering vector provides important insight into the difference between tuning with pressure and chemical doping. Measurement of the charge density wave over several orders of magnitude of diffraction intensity provides the clearest demonstration to date of a weakly coupled BCS-like ground state. Evidence for coexistence of this weak coupling ground state with incipient magnetic fluctuations at high temperatures in chromium and other more strongly coupled systems raises intriguing questions about the meaning of weak vs. strong coupling and suggests a new category of quantum phase transitions.

5:06PM W32.00012 Dynamic susceptibility of itinerant ferromagnets in the ordered state1, MATTHEW VANNETTE, SERGEY BUD’KO, PAUL CANFIELD, RUSLAN PROZOROV, Iowa State University, Dept of Physics & Astronomy and Ames Laboratory — Measurements of radio-frequency dynamic susceptibility of ferromagnets exhibit striking differences between local moment and itinerant systems. Whereas local moment systems show a sharp peak at the Curie temperature ($T_c$) which evolves to higher temperatures and lower amplitudes with applied dc magnetic field, itinerant systems show a broad maximum at temperatures well below $T_c$. The itinerant system’s maximum is suppressed in amplitude and shifts to lower temperatures with applied dc magnetic field. Existing Stoner or spin fluctuations theories derive strictly zero-field susceptibility and we propose a generalization of these models to incorporate the effect of applied dc field. A good agreement between our semi-phenomenological approach and experimental results obtained on several generally accepted itinerant materials with various $T_c$’s is presented.

5:18PM W32.00013 Elementary excitations in antiferromagnetic Heisenberg spin segments, MARCO AFFRONTE, CNR-INFM-S3 and University of Modena, ALBERTO GHIRRI, MARCO EVANGELISTI, ANDREA CANDINI, CNR-INFM-S3, STEFANO CARRETTA, PAOLO SANTINI, GIUSEPPE AMORETTI, University of Parma, Dpt of Physics, RACHEL DAVIES, GRIGORE TIMOC, RICHARD WINPENNY, University of Manchester, CNR-INFM-S3 TEAM, UNIVERSITY OF PARMA TEAM, UNIVERSITY OF MANCHESTER TEAM — We report on ac-susceptibility, low temperature magnetization and specific heat measurements on molecular compounds, shortly named (Cr$_2$)$_2$, (Cr$_2$)$_2$, Cr$_3$, (NCCr)$_2$Nz, that comprise different variants of spin arrays. These systems constitute real examples of collections of identical antiferromagnetic Heisenberg spin segments. We indeed show that this picture, with dominant exchange term in the spin Hamiltonian ($J/k_B$ ranging from 13 to 16 K in all compounds) and weak anisotropy term, fits well the measured physical properties. The character of energy spectra of these variants with those of similar cyclic spin systems evidences effects associated to: i) the breaking the cyclic boundary conditions and ii) odd and even nuclearity of spin segments.

Thursday, March 13, 2008 2:30PM - 5:30PM –
Session W33 GMAG FIAP DMP: Focus Session: Spins in Narrow Gap Semiconductors Morial Convention Center 224

2:30PM W33.00001 Spin Injection, Manipulation, and Detection, in InAs Nanodevices1, C.M. JONES, B.T. JONKER, B.R. BENNETT, J.R. MEYER, M.E. TWIGG, T.L. REINECKE, D. PARK, S.V. PEREVERZEV, C.S. BADESCU, C.H. LI, A.T. HANBICKI, O. VAN TERVE, I. VUGRAFTMAN, Naval Research Laboratory — In this talk the authors will discuss their progress using InAs heterostructures to produce spin-polarized injection and detection, as well as manipulation of coherent spin-polarized electrons for a spin-based FET (SpinFET). High-quality n-type InAs heterostructures demonstrate many favorable characteristics necessary to the study of spin dynamics, including 2DEG’s with small effective mass ($m^* = 0.023$) and large g-factor (g = -15). Previously, high-mobility InAs heterostructures have been demonstrated in which electrons pass ballistically over hundreds of nanometers up to room temperature. Our devices seek to exploit the strong Spin-Orbit effect present in InAs to manipulate coherent spin-polarized electrons during transport, by producing perpendicular electric field using isolated top-gates fabricated over the electron transport region.

1This work was supported by ONR.
2:42PM W33.00002 Electrical Spin Injection into InAs Wetting Layer – CONNIE H. LI, GEORGE KIOSEOGLOU, AUBREY T. HANBICKI, RAMASI GOSWAMI, STEVE HELLBERG, BERRY T. JONKER, Naval Research Lab, MESUT Yasar, ATHOS PETROU, SUNY Buffalo — InAs is an attractive material for optoelectronic and high-speed transistor devices due to its large bandgap and high electron mobility. Owing to its large Rashba spin-orbit coupling, the 2DEG formed in InAs-based heterostructures has also been proposed for spin transport within a spin FET. Here we demonstrate efficient spin injection from Fe into a thin (~3ML) InAs wetting layer (WL) that forms on GaAs before the formation of QDs. Cross sectional TEM shows that the WL is continuous laterally over many microns, and transport measurements reveal 2DEG-like behavior. The WL electron magnetic focusing effect is observable up to 150 K, while the multiplet structure in the maxima shows a more pronounced temperature dependence and fades at higher temperature. Our observation is important to understand zero-field spin splitting mechanisms in a system with strong-spin orbit interaction.

Supported by: NSF-DMR-0507866 and AFOSR Young Investigator Program 06NE231.

3:06PM W33.00004 Spin coherence times in n-type InSb thin films – R.L. KALLAHER, J.J. HEREMANS, Department of Physics, Virginia Tech, Blacksburg, VA — In order to investigate the spin coherence times in the narrow gap semiconductor InSb, low temperature magnetoresistance measurements were performed on Te-doped thin films of InSb in weak perpendicularly applied magnetic fields. The measured changes in the resistance, as a function of applied field, in these n-type films show anti-localization phenomena that occur as a consequence of the strong spin-orbit interaction present in InSb. Hence, the magnitude of both the spin and the coherence times of the electrons in InSb can be determined by fitting the measured magnetoresistance curves to a localization theory that includes the effects of spin-orbit scattering. Such fits reveal that for the Te-doping levels investigated, the spin coherence times vary from approximately 20 ps to 200 ps at low temperatures, with very weak or no temperature dependence below 10 K. Furthermore, by analyzing the spin coherence times in films with different Te-doping densities, it is shown that the Elliot-Yafet mechanism is responsible for the spin decoherence in doped InSb at low temperatures.

Supported by: NSF-DMR-0507866 and NSF-DMR-0520550.

3:30PM W33.00006 Temperature dependence of spin-resolved transverse magnetic focusing in InSb- and InAs heterostructures – J.J. HEREMANS, R.L. KALLAHER, R.B. LILLIANFELD, Virginia Tech, HONG CHEN, University of North Florida, N. GOEL, S.J. CHUNG, M.B. SANTOS, University of Oklahoma, W. VAN ROY, G. BORCHARS, IMEC (Belgium) — Spin-orbit interaction in InSb/InAlSb and InSb/AlGaSb heterostructures leads to spin-split orbital motion. The spatial separation of semiclassical cyclotron orbits is experimentally detected by measuring the magnetoresistance of lithographically patterned mesoscopic ballistic transverse magnetic focusing geometries. The 1st and 2nd focusing maxima show multiplet structure, consistent with spin-split ballistic orbits and spin-dependent reflection off the focusing barrier. In InSb, the transverse magnetic focusing effect is observable up to 150 K, while the multiplet structure in the maxima shows a more pronounced temperature dependence and fades by 80 K. In InAs, the transverse magnetic focusing effect persists to 60 K, and the multiplet structure is visible up to 20 K. The difference in temperature dependence between maxima and multiplet structure indicates that a length scale separate from the mean-free-path governs the observation of splitting, pointing to the use of transverse magnetic focusing for quantifying the temperature dependence of spin coherence. (NSF DMR-0618235, DMR-0080054, DMR-0209371)

3:42PM W33.00007 External electric field effects on AAS oscillations in narrow gap semiconductors – R. B. LILLIANFELD, R. L. KALLAHER, D. E. DAVIS, J. J. HEREMANS, Virginia Tech, HONG CHEN, University of North Florida, N. GOEL, S. J. CHUNG, M. B. SANTOS, University of Oklahoma, W. VAN ROY, G. BORCHARS, IMEC (Belgium) — We present experiments on quantum interference phenomena in semiconductors with strong spin-orbit interaction, using mesoscopic parallel ring arrays fabricated on InSb/InAlSb and InAs/AlGaSb heterostructures. From gate modulation, the WL is continuous laterally over many microns, and transport measurements reveal 2DEG-like behavior. The WL low temperature resistance of the ring arrays as a function of weak perpendicularly applied magnetic fields as well as applied gate voltage. The low field magnetoresistance in the arrays has the h/2e periodicity characteristic of Altschuler-Aronov-Spivak (AAS) oscillations. Despite reduced gate action typical of narrow-gap heterostructures (characterized by Hall measurements), we note an effect on the oscillatory magnetoresistance. The AAS oscillation magnitudes acquire a quasi-periodic modulation as function of gate voltage, and the localization background broadens at higher electron densities. The nature of these influences is examined. (NSF DMR-0618235, DMR-0080054, DMR-0209371)

3:54PM W33.00008 Measurements of spin polarization and spin relaxation in 2D electron gases – S.M. FROLOV, University of British Columbia, A. VENKATESAN, W. YU, J.A. FOLK, UBC, W. WEGSHEIDER, University of Regensburg — Pure spin currents are generated and detected using quantum point contacts in narrow channels of a GaAs/AlGaAs 2D electron gas. A spin relaxation length of 50 microns is achieved due to a cancellation of Rashba and Dresselhaus spin-orbit interactions along 110 crystal direction. Spin currents observed at zero magnetic field are correlated with the 0.7 conductance feature of quantum point contacts, suggesting static spontaneous spin polarization.
The spin interference effect was investigated for square and rectangular loop arrays that were nanostructured in InGaAs/InAlAs quantum wells. The Rashba and Dresselhaus terms quantitatively. Koga et al., PRB 70, 161302(R) (2004); ibid. 74, 041302(R) (2006). [2] Koga et al., phys. stat. sol. (C) 3, 4220 (2006).

4:18PM W33.00010 Aharonov-Casher effect in hole ring with spin-orbit interaction, MARIO BORUNDA, ALEXEY KOVALEV, Physics Department, Texas A&M University, TOMAS JUNGWIRTH, Institute of Physics, Academy of Sciences of the Czech Republic, LAURENS MOLKEN, Physikalisches Institut (EP3), Universität Würzburg, JAIRO SINOVA, Physics Department, Texas A&M University — We study the quantum interference effects induced by the Aharonov-Casher phase in a ring structure two-dimensional heavy-hole (HH) system with spin-orbit interaction. The influence of the spin-orbit interaction on the transport causes interference effects which are a signature of the topological Aharonov-Casher phase. We present numerical calculations of the magnetocconductance and spin dependent transport in realistic semiconductor ring structures.

4:30PM W33.00011 Plasmons of a two-dimensional electron gas with Rashba and Dresselhaus spin-orbit coupling, JESUS A MAYTORENA, CATALINA LOPEZ-BASTIDAS, Centro de Ciencias de la Materia Condensada, UNAM Ensenada, Mexico, ELMER CRUZ, CICESE, CCMC UNAM, Ensenada, Mexico — We calculate the dielectric response of a two-dimensional electron gas with both Rashba and Dresselhaus spin-orbit (SO) coupling within the self-consistent-field approach. We obtain the dispersion relations of the collective modes and the regions of single-particle excitations, related with intra- and inter-spin transitions. The interplay of both types of SO couplings give rise to an angular anisotropy of the spin-splitting energy. As consequence, the plasmon spectrum and the Landau damping regions show a dependence on the direction of the wave vector transfer. This response is in contrast to that of vanishing Rashba or Dresselhaus case. We also discuss the dependence of this spectral characteristics on the electron density and SO coupling strengths, and derive expressions for the intra- and inter- SO plasmons in the long-wavelength limit.

4:42PM W33.00012 Magnetoplasmon excitations in Rashba spintronic quantum wires: Maxons, rotons, and negative-B dispersion, MANVIR KUSHWAHA, University of Puebla, Puebla, Mexico — We report on the theoretical investigation of plasmon excitations in a quasi-two-dimensional electron gas in the presence of a harmonic potential, a perpendicular magnetic field, and the spin-orbit interaction (SO) induced by the Rashba effect. The result system is a Q1D quantum wire with free propagation in the y direction and magnetoelectric quantization along the x. The problem involves three length scales: \( l_0 = \sqrt{\hbar/m^*\omega_c} \), \( l_r = \sqrt{\hbar/m^*\omega_r} \), and \( l_d = h^2/(2m^*\alpha) \), which characterize the relative strengths in the interplay of confinement, the magnetic field, and the Rashba SOI. The resulting Schrödinger-like equations are two coupled equations, which cannot be solved in an explicit form. However, invoking the limits of a strong magnetic field, \( l_r \ll l_0 \) and \( l_d \ll 1 \) allow us to solve this set of coupled equations exactly. We then derive and discuss the dispersion relations for collective excitations within the framework of Bohm-Pines’ RPA. The intrasubband and intersubband magnetoplasmons in a Q1DEG are characterized, respectively, by the negative-B dispersion and the magnetoroton excitation. Here we scrutinize the effect of the Rashba SOI on these characteristics in depth. We observe that the SOI modifies drastically the behavior of both magnetoplasmons in the long wavelength limit and may render them relatively more susceptible to the Landau damping in the short wavelength limit.

4:54PM W33.00013 Resonant spin polarization and Hall conductances in a two-dimensional electron gas, DEGANG ZHANG, Texas Center for Superconductivity and Department of Physics, University of Houston, TX 77204, YAO-MING MU, Center for Advanced Materials, University of Houston, TX 77204, CHIN-SEN TING, Texas Center for Superconductivity and Department of Physics, University of Houston, TX 77204 — We have studied transport properties in a two-dimensional electron gas with equal Rashba and Dresselhaus spin-orbit interactions under a perpendicular magnetic field. By employing the exact solution for this system, we found resonant charge and spin Hall conductances at a certain magnetic field, where all the nearest-neighboring Landau levels cross. Near the magnetic field, there exists a resonant spin polarization, which can also induce resonant charge and spin Hall effects.

5:06PM W33.00014 Spin signal recovery in a two-dimensional electron gas with a quantum point contact, JAE-SEUNG JEONG, HYUN-WOO LEE, Department of Physics, Pohang University of Science and Technology — We study transport properties of the spin-polarized current in a two-dimensional electron gas (2DEG) including a quantum point contact (QPC) in the presence of Rashba spin-orbit (RSO) coupling. Spin-resolved conductance is investigated numerically using a recursive Green function method, with special attention to the quantum effects of spin-charge transport channels. It is found that when the conductance is examined as a function of the RSO coupling strength, the conductance modulation ratio, defined as the ratio between the maximum and minimum conductances, can be enhanced by the QPC in the ballistic and weakly diffusive regime as well. Decaying rate of the spin-polarization can be also reduced.

5:18PM W33.00015 Semiclassical Equations of Motion for Bloch Electrons in External Fields, Including Spin-Orbit Interaction, W.C. KERR, Wake Forest U. — This talk considers an electron moving in a periodic potential with spin-orbit interaction and perturbed by external slowly varying electric field and uniform magnetic field. Superposition of the time-independent Bloch spinor states of the unperturbed Hamiltonian gives a wave packet state with both wavevector space and spin-orientation amplitude factors. The time-dependent variational principle produces equations of motion for the wave packet in both configuration and wavevector space and for the spin-orbit orientation factors. For spinless electrons this procedure yields the familiar semiclassical equations of motion augmented by an orbital magnetic moment contribution to the Bloch band energy and an “anomalous velocity” proportional to a Berry curvature. The inclusion of spin-orbit interaction gives additional contributions to the velocity involving different Berry curvatures. One is a spin-dependent contribution to the magnetic moment, and another is an electric dipole-like contribution that is also proportional to the spin operator.

Thursday, March 13, 2008 2:30PM - 5:30PM — Session W35 FIAP: Focus Session: Nanotechnology II Morial Convention Center 227
2:30PM W35.00001 TEBAL: Nanosculpting devices with electrons in a transmission electron microscope1. MARIJA DRNDIC, University of Pennsylvania — Manipulation of matter on the scale of atoms and molecules is an essential part of realizing the potential that nanotechnology has to offer. In this talk I will describe transmission electron beam ablation lithography (TEBAL), a method for fabricating nanostructures and fully integrated devices on silicon nitride membranes by nanosculpting evaporated metal films with electron beams. TEBAL works by controllably exposing materials to an intense and highly focused beam of 200 keV electrons inside the transmission electron microscope (TEM). The effect of electron irradiation can be used to controllably displace or ablate regions of the metal with resolution on the scale of tens of atoms per period. In situ TEM imaging of the ablation action with atomic resolution allows for real-time feedback control during fabrication. Specific examples presented here include the fabrication and characterization of nanogaps, nanorings, nanowires with tailored shapes and curvatures, and multi-terminal devices with nanoscale gaps between the terminals. These nanostructures are fabricated at precise locations on a chip and seamlessly integrated into large-scale circuitry. I will discuss how the combination of high resolution, geometrical control and yield make TEBAL attractive for many applications including nanoelectronics, superconductivity, nanofluidics and molecular (DNA) translocation studies through nanopore-based transistors. Drndic, "Nanopacks by direct high-resolution imaging and electronic characterization of nanostructures", Applied Physics Letters, 88 (6), 063116, 2006.

3:06PM W35.00002 Atomic Precision in Nano-Electronics, DOUGLAS STRACHAN, DANVERS JOHNSTON, BETH GUITON, YE LU, SUJIT DATTA, PETER DAVIES, DAWN BONNELL, CHARLIE JOHNSON, University of Pennsylvania — One of the greatest challenges in developing molecular-scale devices is to fabricate and monitor their formation with atomic precision. Recently, we have developed an electromigration technique that employs feedback for controllably electromigrating a nano-scale electrode with atomic precision at room temperature [1]. We will discuss our recent progress advancing this technique towards atomically precise nano-electronics. This will include in-situ transmission electron microscopy which shows evidence for highly crystalline electrode formation and the parallel fabrication of nanoscale devices, and scaling-up to very large-scale integrated-circuits. Our results have implications on the development of a wide range of novel molecular-scale devices. Funding provided by: NSF-NSEC/NBIC DMR-0425780, NSF-NIRT Grant No. 0304531, and MRSEC award No. DMR05-20020. [1] D. R. Strachan, et al., Appl. Phys. Lett. 86, 043109 (2005).

3:18PM W35.00003 Quantifying the properties of nano-composites. MURRAY DAW, BO ZHANG, JIAN HE, TERRY TRITT, Clemson University — With the proliferation of nano-composites produced for possible thermoelectric application, we ask the question: To what extent is a given nano-composite like other composites? Or, in other words, when do we know that we have something new? To address this we apply the classical theory of composites to specific nano-composites grown and characterized at Clemson. The theory is very simple and assumes essentially very simple properties of the materials, the most important being Fourier's Law/Ohm's Law. Given this assumption, the theory of composites can be applied to the nano-composites based on what is known of the microstructure. This "classical" result then forms the basis by which the properties can be compared to determine if non-classical effects are being observed. One simple theory is the application of rigorous bounds, such as the Hashin-Strikman Bounds which are based only on very simple microstructural descriptors. Another simple theory is the application of FEM, which can be constructed directly from SEM images of the samples using the NIST code "OOF". The FEM produces specific predictions for the composite properties. We find that the Hashin-Strikman Bounds are very useful for analyzing the thermal conductivities of composites composed of metals and insulators, while the SEM technique can be applied successfully.

3:30PM W35.00004 ‘Focused Assembly’ of V$_2$O$_5$ Nanowires for Fabrication of Metallic Nanowire Sensors, TAE HYUN KIM, SUNG MYUNG, KWANG HEO, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University, HND TEAM — We present a method named ‘focused assembly’ for high-precision assembly of pristine V$_2$O$_5$ nanowires (NWs) on solid substrates. In this method, ‘microscale’ self-assembled monolayer patterns with ‘gradient’ surface molecular density ‘focused’ the assembly of V$_2$O$_5$ NWs onto the ‘nanoscale’ regions on a metallic thin film just like a lens focuses the light. The assembled NWs could be utilized as a shadow mask during the ion-milling process to generate metallic NW-based devices. As a proof of concepts, we successfully demonstrated the fabrication of metallic NW-based sensors to detect thiols molecules or hydrogen gas under ambient conditions. This focused assembly phenomenon gives us new insights about the directed assembly process of nanostructures. Furthermore, this approach provides us an easy, but efficient, means to mass-produce NW-based devices for various practical applications such as field effect transistors, chemical sensors and nanoscale interconnectors.

3:42PM W35.00005 Nanomechanical Spectroscopy: A novel route to label-free chemical sensing, PETER GREANEY, JEFFREY GROSSMAN, Center of Integrated Nanomechanical Systems, U. C. Berkeley — We propose a novel spectroscopic technique in which the vibrational modes of an analyte molecule are probed directly using a nanoscale mechanical resonator. It is anticipated that such “nanomechanical spectroscopy” can provide a method for label free chemical sensing. We elucidate the concept of the nanomechanical spectroscopy with the example of using an array of carbon nanotubes to detect a series of simple test molecules. In these examples, energy is transferred between the molecular vibrations of the analyte and specific phonon modes of the carbon nanotubes. Molecular dynamics simulations are used to explore the feasibility of this energy exchange for chemical sensing, and limits of both sensitivity and selectivity.

3:54PM W35.00006 ‘Lens’ Effect in Directed Assembly of Nanowires on Gradient Molecular Patterns, MOON GYU SUNG, SUNG MYUNG, JIWOO IM, SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University, HND TEAM — We report a new phenomenon, named here as the ‘lens’ effect, in the directed-assembly process of nanowires (NWs) on self-assembled monolayer (SAM) patterns. In this process, the adsorption of NWs is focused in the nanoscale regions at the center of microscale SAM patterns with gradient surface molecular density just like an optical lens focuses light. As a proof of concepts, we successfully demonstrated the massive assembly of V$_2$O$_5$ NWs with single-walled carbon nanotubes (swCNTs) with a nanoscale resolution using only microscale molecular patterning methods. This work provides us with important insights about the directed-assembly process, and from a practical point of view, it allows us to generate nanoscale patterns of NWs over a large area for mass fabrication of NW-based devices.

4:06PM W35.00007 In$_2$O$_3$ Nanoparticles for Gas Sensors, ZENXCING ZHANG, DANIELA CARUNTU, CHARLES J. O’CONNOR, WEILIE ZHOU, Advanced Materials Research Institute, University of New Orleans, New Orleans, LA 70148 — In the last decades, sensors based on nanostructured materials have attracted much attention. Generally, nanosensors often demonstrate excellent sensitivities because of their high specific surface area and comparable size to the detected targets (chemicals or biomolecules). So far, lots of efforts have been put on the fabrication of nanowires based nanosensors. In this talk, we reported our recent work on employing wet-chemically synthesized indium oxide (In$_2$O$_3$) nanoparticles for gas sensing. The nanoparticles were self-assembled between the gold electrodes patterned on silicon substrates covered with thermal oxide film using e-beam nanolithography. Several gases, such as ammonia (NH$_3$), hydrogen sulfide (H$_2$S), etc., were used for the testing. The results exhibit that the sensitivity can be reached down to PPM order. In addition, the sensitivity in terms of nanoparticle size, temperature, etc., were also investigated.
4:18PM W35.00008 Environment of TiO\textsubscript{2} nanoparticles as an important factor to achieve highly efficient on dye sensitized solar cells\textsuperscript{1}, TEREZA PARONYAN, M.C. LIN, DEPT. OF APPLIED CHEMISTRY, NATIONAL CHIAO TUNG UNIV. TEAM, INST. FOR PHYSICAL RESEARCH, NAAS, ASHTAFAR, ARMENIA COLLABORATION, DEPT. OF CHEMISTRY, EMORY UNIV. COLLABORATION — Amorphous TiO\textsubscript{2} nanoparticles were synthesized through sol gel technique. Environment of nanoparticles was neutralized by ammonia, and pH 5.8 of TiO\textsubscript{2} gel was achieved in result, which is close to the point of zero charge (PZC) of anatase TiO\textsubscript{2}. Highly interconnected, mesoporous, transparent films were fabricated from the TiO\textsubscript{2} colloid with pH 5.8. AFM, SEM XRD analyses were carried out for the investigation the size of nanoparticles, the surface morphology and the crystal structure of films. Volt-ampic characteristics showed an improvement in the cell efficiency along with the increasing of pH TiO\textsubscript{2} colloid. The cells parameters (Voc, FF, Jsc, η) were studied depending on the pH of TiO\textsubscript{2} colloid. Increasing pH of the colloid from 2.1 to 5.8 enhanced the overall conversion efficiency of the dye-sensitized solar cells by approximately 30\%, and 9.2 \% of efficiency was achieved with N719 dye under illumination by simulated AM1.5 solar light (100 mW/cm\textsuperscript{-2}).

\textsuperscript{1}This work was financially supported by 952001INER027 and 962001INER0029 Solar Energy Projects of Taiwan. The authors thank to Prof. A.M. Kichhtian for discussions.

4:30PM W35.00009 Electron Thermal Microscopy of Multiwalled Carbon Nanotubes , KAMAL BALOCH, TODD BRINTLINGER, JOHN CUMINGS, University of Maryland — A thorough electrical and thermal characterization of carbon nanotubes (CNTs) is essential for their application as electrical and thermal devices. We demonstrate high-resolution thermal imaging of multiwalled CNT using electron thermal microscopy. This is achieved by observing the solid to liquid phase transition of low melting point indium islands in a transmission electron microscope. High resolution thermal maps thus obtained provide a qualitative analysis of transfer of heat along a CNT suggesting a trend of CNT acting as a heat spreader. Also, important parameters like thermal conductivity of the CNT can be extracted by finite element modeling. The temperatures involved are \sim 200C and the samples can be operated over several voltage cycles. Experimental technique, high resolution maps, real time videos, and simulation results will be presented.

4:42PM W35.00010 The Nuclear Environment for Electron Spins in a Double Quantum Dot\textsuperscript{1}, DAVID REILLY, Harvard University, JACOB TAYLOR, MIT, JASON PETTA, Princeton, CHARLES MARCUS, Harvard, MICAH HANSON, ART GOSSARD, UCSD, HARVARD COLLABORATION, UCSD COLLABORATION — We report measurements examining the nuclear spin environment for electrons in a GaAs double quantum dot. The hyperfine field, which drives transitions of a two-electron spin state, is detected via spin-to-charge transfer and rf-QPC readout. Fluctuations of the hyperfine field are measured to be broadband, with spectral content ranging from millisecond to the decoherence time of \sim 10 seconds. In addition, we demonstrate dynamic nuclear polarization (DNP) using a cyclic gate-pulse sequence. Relaxation of the DNP is studied using time-resolved measurements and found to be sensitive to the spin-state of electrons. The presence of a small DNP is found to suppress hyperfine fluctuations by a factor of \sim 100, leading to a time-ensemble dephasing time, T\textsubscript{2} \sim 1 microsecond for electron spins.

\textsuperscript{1}This work was supported by DARPA, DTO, NSF-NIRT (EIA-0210736) and Harvard Center for Nanoscale Systems. Research at UCSB supported in part by QuEST, an NSF Center.

4:54PM W35.00011 Nanoscale probing of material properties across antiparallel domain wall in ferroelectrics , VASUDEVA RAO ARAVIND, LILI TIAN, NOZOMI ODAKAWA, SAMRAT CHOUDHURY, PAVEL CAPEK, VOLKMAR DIEROLF, ANNA N. MOROZOVSKA, EUGENE A. ELISEEV, LONG-QING CHEN, YASUO CHO, SERGEI KALININ, VENKATRAMAN GOPALAN, Department of Materials Science and Engineering, Pennsylvania State University, University Park, PA 16802, USA — Although the intrinsic width of an ideal antiparallel ferroelectric domain wall is expected to be step-like on a unit cell level (\sim 0.5nm), we have recently shown that actual widths of these walls can extend to \sim 200nm in lithium niobate and lithium tantalate (L.Tian et al., Physical Review Letters (in review)). In this work we study the variation of material properties coercive field and switchable ferroelectric polarization as a function of the distance from the domain wall in lithium niobate. Until recently, the study of these material properties on the nanoscale were limited by the lack of theoretical modeling of the instrument resolution limits. Using experimental results and theoretical modeling we demonstrate the relation between intrinsic width of the domain wall and its effect on material properties.

5:06PM W35.00012 Electrostatic and Nanotechnology Multidisciplinary Approach - for Space Radiation Shielding , RAM TRIPATHI, JOHN WILSON, NASA Langley Research Center, Hampton, VA 23681, ROBERT YOUNQUIST, NASA, The John F. Kennedy Space Center, FL 32899 — For the success of NASA's new vision for space exploration to Moon, Mars and beyond, exposures from the hazards of severe space radiation in deep space long duration missions is a "must solve" problem. The exploration beyond low Earth orbit to enable routine access of space will require protection from the hazards of the accumulated exposures of space radiation. There is a need to look to new horizons for newer technologies. The present multidisciplinary investigation explores the feasibility of using the active electrostatic shielding in concert with the state-of-the-art materials shielding and protection technologies. The full space radiation environment has been used, for the first time, to explore the feasibility of multidisciplinary shielding. The goal is to repel enough positive charge ions so that they miss the spacecraft without attracting thermal electrons and further attenuate the exposure using nano-materials. Conclusions are drawn for the future directions of space radiation protection.

5:18PM W35.00013 Probing Local Structures in ZrO\textsubscript{2} Nanocrystals Using EXAFS\textsuperscript{1}, Y.L. SOO, P.J. CHEN, S.H. HUANG, T.J. SHIU, T.Y. TSAI, Y.H. CHOW, Y.C. LIN, S.C. WENG, S.L. CHANG, National Tsing Hua University, J.F. LEE, NSRRC, Taiwan, C.L. CHEUNG, R.F. SABIRIANOV, F.N. NAMAVAR, F.W. MEI, University of Nebraska — Extended x-ray absorption fine structure (EXAFS) has been employed to investigate the local structures surrounding Zr in cubic zirconia thin films prepared by an ion beam assisted deposition technique. These materials have demonstrated promising mechanical properties such as improved hardness and lubricant wettability compared to yttria-stabilized zirconia. To verify the cubic structure of zirconia in films prepared under different growth conditions and to fully understand the mechanism leading to their unique physical properties, the structural information is a required prerequisite. Since zirconia is in the form of nanosized crystallites, conventional x-ray diffraction method is not useful for this purpose. Our x-ray results reveal cubic-like structure with O vacancies around Zr in several nanocrystal samples. Powders of cubic zirconia prepared using chemical methods were also measured for comparison.

\textsuperscript{1}This research is supported by NSC under project number 95-2112-M-007-014.

Thursday, March 13, 2008 2:30PM - 5:42PM — Session W36 DMP: Focus Session: Materials for Photovoltaics and Photocatalysis III

2:30PM W36.00001 TBD, DARIN LAIRD, Plextronics — This abstract not available.
3:06PM W36.00002 Hole Mobility Studies on Thiophene-Based Conjugated Polymers Developed for Use in Organic Electronic Devices , N.C. HESTON, Univ of Florida, Dept of Phys, J. MEI, Univ of Florida, Dept of Chem, D.B. TANNER, Univ of Florida, Dept of Phys, J.R. REYNOLDS, Univ of Florida, Dept of Chem — In optimizing organic electronic devices, such as solar cells and field effect transistors, the mobility plays a crucial role affecting many aspects of performance, including: charge separation efficiencies, carrier densities, and drain currents. By fabricating hole-dominated devices and fitting the measured current-voltage characteristics to the field-dependent space-charge-limited mobility model we were able to measure hole mobilities in a set of conjugated polymers including p-Pt-BTD-Th, p-Pt-BTD-EDOT, and both regio-regular and regio-random P3HT. These materials have been shown to exhibit promise as active layers in organic solar cells, light-emitting diodes, and field effect transistors. We present the results of these measurements and the effects induced by thermal annealing.

3:18PM W36.00003 Molecular and electronic structure at C_{60}/pentacene interfaces , S.W. ROBEY, D.B. DOUGHERTY, NIST-Gaithersburg, W. JIN, W.G. CULLEN, G.J. DUTTON, J.E. REUTT-ROBEY, University of Maryland — Successful utilization of organic donor-acceptor systems for photovoltaic applications requires understanding factors controlling molecular and electronic structure at interfaces. We have used STM, STS, and photoemission to study the donor-acceptor system C_{60}/pentacene. At low coverage, C_{60} is deposited on a well-ordered pentacene bilayer structure on Ag (111) adsorbs in between two adjacent pentacene rows. Isolated C_{60} molecules are easily observed at room temperature indicating that the mobility of C_{60} on pentacene is significantly smaller than on metal surfaces. Some images of C_{60} reveal structure that may indicate a preferred C_{60} orientation. Electrostatic contributions to intermolecular interactions are discussed to help explain C_{60} adsorption between pentacene molecules. With increasing coverage, C_{60} forms linear chains, still locked to underlying pentacene rows. A further increase in coverage results in domains of disordered C_{60} that we propose result from competing C_{60}− C_{60} and C_{60}/pentacene interactions. Information on nanoscale transport gaps and band alignment was obtained using constant-current distance-voltage spectroscopy. A gap of 4.5 eV is found over the linear C_{60} chains compared with a gap of 3.6 eV for the surrounding pentacene bilayer.

3:30PM W36.00004 Porous nanocrystalline TiO_2 thin films for dye-sensitized solar cells , XI-AOJUAN FAN, Marshall University, CLAUDIA SWANSON, DAVID ROGOW, University of California, AKHILESH TRIPATHI, Rigaku Corporation, SCOTT OLIVER, University of California — We report a rapid and low cost method to fabricate porous TiO_2 thin films used as anode electrodes for solid state dye-sensitized solar cells. Polymethylmethacrylate (PMMA) gel was used as template to define a network co-structure with alkali titanium oxide, then spin cast on substrates. After removing polymer, smooth and crack-free large area TiO_2 thin films with fine pores were generated. Thin film structures were detected by powder & grazing incident X-ray diffraction. Thickness can be controlled over a range of tens of nanometers to several microns by precursor viscosity, spin coating speed and coating times. The SEM image shows the highest quality porous TiO_2 film derived from a certain concentration of precursor. The above TiO_2 thin films were then used to fabricate solid state dye sensitized solar cells. Porphyrine dye and poly(ethylene glycol) electrolyte with I^-/I_3^- redox couple were used in the cells. Current−voltage curves were recorded. The open circuit voltage boosts to more than 1.0 V. The reasons for the high open circuit voltage probably will be discussed. Overall photo-electricity conversion efficiency reaches 2.05% under an illumination of one solar unit (AM1.5, 100 mW/cm^2).

3:42PM W36.00005 TiO2 nanowire sensitized by natural dyes for solar cell applications , SHENG MENG, JUN REN, EFTHIMIOS KAXIRAS, Harvard University — We investigate the electronic coupling between a semiconductor TiO_2 nanowire and a natural dye sensitizer based on time-dependent first-principles calculations. The model dye molecule, cyanidin is found to dissociate into the quinonoidal form upon adsorption, rendering its highest occupied molecular orbitals (HOMO) located in the middle of TiO_2 bandgap and its lowest-unoccupied molecular orbital (LUMO) at the bottom of TiO_2 conduction band. The visible light absorption is greatly enhanced with two prominent peaks at 460 nm and 650 nm. The excited electrons are injected into the TiO_2 conduction band within a ultrafast timescale of <50 fs, with negligible non-radiative energy dissipation and recombination.

3:54PM W36.00006 Electronic structure of N3 DYE molecules on the TiO_2(110) surface and on anatase nanoparticle films , ERIC, BERSCH, Rutgers University, SYLVIE RANGAN, University of Texas at Dallas, JEAN-PATRICK THEISEN, ROBERT A. BARTYNSKI, JUDITH D. SORGE, DUNBAR P. BIRNIE, Rutgers University — We have used direct and inverse photoemission to measure the occupied and unoccupied electronic states, and their alignment with the band edges of the substrate, of N3 dye adsorbed on the rutile TiO_2(110) surface and on anatase TiO_2 nanoparticle thin films. In dye-sensitized solar cell applications, the HOMO-LUMO gap determines the useful portion of the solar spectrum, and charge transfer of photoexcited electrons to the substrate depends on the alignment of the LUMO to the TiO_2 conduction band edge. Samples were prepared and passivated with a pivalate layer in UHV, then sensitized in air in a solution of N3 dye in acetonitrile. STM measurements show that the pivalic acid forms an ordered overlayer on the TiO_2(110) surface and that the N3 dye molecules can be imaged after sensitization. Our spectroscopic measurements show that contamination (presumably from water in the ambient) is significantly reduced and that the N3 HOMO occurs at 1.1 eV above the TiO_2 valence band edge. The LUMO of the TiO_2 is found at 0.3 eV above the conduction band edge. Comparison with experimental and theoretical values from the literature will be discussed.

4:06PM W36.00007 Electronic structure of N3 DYE molecules on the ZnO single crystal and epitaxial film surfaces , JEAN-PATRICK THEISEN, ERIC BERSCH, SYLVIE RANGAN, YICHENG LU, ROBERT BARTYNSKI — Most dye-sensitized solar cells use TiO_2 nanoparticle films as the electrode, but ZnO offers an interesting alternative. We have used direct and inverse photoemission to measure the occupied and unoccupied electronic states, and their alignment with the band edges of the substrate, of N3 dye adsorbed on ZnO(0001), ZnO(11-2), epitaxial ZnO a-plane film surfaces, and ZnO nanopillars. As the unoccupied states of ZnO are of sp-character and of relatively low cross section, the LUMO of the dye is easily observed. Samples were prepared and passivated with a pivalate layer in UHV, then sensitized in air in a solution of N3 dye in acetonitrile. As opposed to the case of the TiO_2(110) surface, STM measurements indicate that the pivalic acid does. From UPS, the N3 HOMO is found at ~0.8 eV above the ZnO valence band edge, and the LUMO is found ~1.5 eV above the conduction band edge for the epifilm. Differences in dye adsorption and orbital alignment for these different ZnO surfaces will be discussed.

4:18PM W36.00008 Towards visible light activity of wide band gap photocatalysts: Surface functionalization of ZnO with ZnS , JAYEETA LAHIRI, MATTHIAS BATZILL, Department of Physics, University of South Florida, Tampa, FL 33620 — We show that at the ZnO/ZnS interface the band alignment is favorable for reducing the photo excitation threshold energy; signifying that the combination of two wide band gap photocatalysts can yield a material with visible light activity. Modification of ZnO with a sub monolayer ZnS is investigated by scanning tunneling microscopy (STM) and photoemission spectroscopy. STM studies indicate that the ZnS grows by nucleation and spreading of 2D clusters of monolayer height (~ 2.5 Å). Photoemission spectroscopy is used to measure the band alignment between ZnO and ZnS, as well as measure the changes in the surface charge region and work function. An increase in work function by 1.1 eV is observed and a staggered band alignment is found with ZnS states effectively narrowing the band gap for photo excitation from 3.4 to 2.7 eV. We propose that the combination of these structural and electronic properties of the modified ZnO surface result in an improved, visible light active photocatalyst.
4:30PM W36.00009 Energy bands and point defects in CuInSe₂ and CuGaSe₂ calculated by Quasiparticle Self-Consistent GW. 
MARK VAN SCHILFGAARDE, TAKAOK KOTANI, Arizona State University — CuIn_xGa_1−xSe_2, or CIGS, is emerging as a leading candidate for second-generation solar cell applications. Here we present the bulk energy band properties and dielectric response of CuInSe₂ and CuGaSe₂, computed within the Self-Consistent GW (QSGW) approximation. QSGW has been proven to be a reliable, true ab initio predictor of QP levels in a wide variety of materials systems; it is expected to be similarly reliable for chalcoprite semiconductors. The fundamental gap agrees well with experiment. Also, the electron and hole effective masses are evaluated. Various kinds of point defects were considered using certain approximations to QSGW. Of particular interest are low-energy cation defects (antisites and vacancies). Rather unusual properties of these levels are found, owing to the unique role that shallow Cu d states play in CIGS.

4:42PM W36.00010 Synthesis of type II core/shell nanowires for photovoltaic application, WEILIE ZHOU, KAI WANG, JIAJUN CHEN, Advanced Materials Research Institute, University of New Orleans, YONG ZHANG, JOHN PERN, YANFA YAN, ANGELO MASCARENHAS, National Energy Renewable Laboratory, NATIONAL ENERGY RENEWABLE LABORATORY COLLABORATION — The core/shell semiconducting nanowires based on II-VI semiconductors, involving with type II band energy alignments, are predicted to be a new kind of nanostructured materials for efficient charge separation for stable and efficient photovoltaic devices. In this talk, we report a successful synthesis of II-VI semiconducting core/shell nanowires by a relatively simple and low-cost approach. The structures and optical properties were characterized by applying a set of comprehensive techniques. A sharp interface and the epitelial relationship between the core and shell were observed. Two excitonic absorption peaks were clearly found at respective excitonic bandgaps, indicating a good crystallinity of both the core and shell. Compared to the single component nanowires, the PL spectrum of the core/shell nanowires shows a reduction in intensity and a slight blue shift at the band edge emission of the core nanowires, which may partially arise from spatially charge separation between the core and shell. The direct growth of core/shell nanowires represents a major step toward fabricating a low-cost, high efficiency and stable solar cell.

5:45PM W36.00011 Nanocoax Solar Cells, M.I. NAUGHTON, K. KEMPA, Z.F. REN, J. RYBCZYNSKI, T. PAUDEL, Y. GAO, Y. XU, Boston College — A novel architecture for high efficiency solar energy conversion, employing separated photo– and –voltaic pathways and vertically-aligned, nanoscale, metallic coaxial wires (nanocoax) which are indeed simultaneously thick (tall) and thin (narrow). Photons captured by nanoscale antennas are channeled axially as TEM-mode radiation in the nanocoax annulus, which is filled with a PV medium. This annulus is unprecedentedly thin radially (~100 nm), such that exciton lifetimes and subsequent electron and hole diffusion lengths of virtually any PV material are sufficiently long to enable highly efficient solar energy conversion. We discuss results with radial p – i – n junctions using α-Si PV and carbon nanofiber coax center conductors, where nanocoax solar cell efficiencies exceed those of comparable planar junctions. Moreover, this nanoscale architecture can be considered a feasible portal to 3rd generation solar power.

5:06PM W36.00012 Low temperature pulsed electrically detected magnetic resonance on a-Si:H p-i-n solar cells, THOMAS HERRING, HEATHER SEIPEL, DANE MCCAMEY, CHRISTOPH BOEHME, University of Utah, CRAIG TAYLOR, Colorado School of Mines, JIAN HU, FENG ZHU, ARUN MADAN, MV Systems, Golden, CO — Hydrogenated amorphous silicon (α-Si:H) has become one of the most important semiconductor materials, with applications including solar cells and thin film transistors. In spite of this, and more than 30 years of intensive studies of this material, the microscopic nature of various recombination mechanisms in this material are still not well understood. Recently, pulsed electrically and optically detected magnetic resonance (p-EDMR, p-ODMR, respectively) spectroscopy has provided a method for directly and quantitatively observing some of these microscopic processes. Here, we present p-EDMR measurements on a-Si:H p-i-n solar cells at temperatures T ≤ 40K, with a comparatively low light intensity. After a short, coherent microwave excitation, we record transients for a range of externally applied magnetic fields. The results show the presence of a number of resonances, which we discuss with regard to previous continuous wave (cw-) ESR and cw-EDMR studies, as well as cw- and p-ODMR measurements.

5:18PM W36.00013 Carrier Multiplication in Semiconductor Nanocrystals: Theoretical Screening of Candidate Materials, JUN-WEI LUO, ALBERTO FRANCESCHETTI, ALEX ZUNGER, National Renewable Energy Lab — The process of Direct Carrier Multiplication (DCM) involves the creation of two electron-hole pairs as a result of exciting a nanostructure by one photon with energy two times larger than the band gap 

5:30PM W36.00014 Exploring the Use of Self-Assembled InGaAs/GaAsP Quantum Dots as Intermediate Band Solar Cells (IBSC) , VOICIU POPECU, GABRIEL BETSTER, ALEX ZUNGER, National Renewable Energy Laboratory, Golden, CO — It has been recently proposed that the efficiency of photovoltaic solar cells based on wide-gap III-V absorbing materials can be enhanced if quantum dots are embedded in such structures, leading to confined electron and hole states that can be excited to the band edges of the wider-gap matrix material, thereby capturing the lower energy (IR) solar photons. Such proposals, however, were not scrutinized so far by modern quantum-dot calculations. We apply our pseudopotential Linear-Combination-of Bloch-Bands (LCBB) approach to this problem. Lens-shaped dots of InGaAs were vertically stacked with varying dot-dot separation. The effects of spin-orbit, multi-band, and multi-valley coupling are included by a direct diagonalization of the atomistic problem. Lens-shaped dots of InGaAs were vertically stacked with varying dot-dot separation. The ratio 

The effects of spin-orbit, multi-band, and multi-valley coupling are included by a direct diagonalization of the atomistic problem. A matrix of GaAsP was chosen so as to strain-balance the system epitaxially on a GaAs(x) substrate. We will discuss the energies of the band edges of the matrix material, and those of the confined dot levels relative to the expected values for ideal IBSC operation, as well as their variation with respect to either the vertical dot-dot separation, or the band gap of the matrix material.

Thursday, March 13, 2008 2:30PM - 5:30PM — Session W37 DCMP: Focus Session: Multiferrocity in BiFeO₃-based films — Morial Convention Center
2:30PM W37.00001 First-principle calculations of electronic structure of bismuth ferrate and manganate with the mullite structure. JEN-CHANG CHEN, CHING-MING WEI, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, 10617, Taiwan — We applied ab initio total-energy calculation to study the electronic structure of Bi$_2$Fe$_2$O$_5$ and Bi$_2$Mn$_2$O$_6$ single crystals. Both crystals are orthorhombic with the centro-symmetric structure and belong to the mullite-type material. Most of bismuth-based oxides exhibit good ferroelectricity, pyroelectricity and piezoelectricity. However, little researches of electronic structure and properties have been done on the bismuth ferrate and bismuth manganate. In this study, we band structure, density of state, partial density of state and magnetic moment of both bismuth ferrate and bismuth manganate at zero Kelvin were calculated. The effect of Fe and Mn atom within the structure were discussed. The phase stability of these two crystals was also examined.

2:42PM W37.00002 The structural, magnetic, and electric properties of Sr and Ca-doped BiFeO$_3$ films. CHAN-HO YANG, M. HUIJBEREN, Y.-H. CHU, L.W. MARTIN, M. HOLCOMB, R. RAMESH, Department of Material Science Engineering and Department of Physics, University of California, Berkeley, M. CHI, N. BROWNING, Department of Materials Science and Engineering, University of California, Davis — Many perovskite oxides, as holes are doped, exhibit unusual physical phenomena such as superconductivity, colossal magnetoresistance, metal-insulator transition, and charge ordering. We are exploring the consequences of hole doping into a well known multiferroic, the antiferromagnetic ferroelectric, BiFeO$_3$. In this presentation, the systematic investigation on structural, electronic, and magnetic properties will be presented for nominally hole-doped BiFeO$_3$ obtained by partially substituting Ca for Sr and Sr for Ca. The ordering of ferroelectricity and magnetic ordering at room temperature, has polarization along [111] direction and is a G-type antiferromagnet. The divalent ion doping weakens the ferroelectric properties but improves magnetization owing to cluster-glass-like magnetism. We will discuss the magnetic properties based on superexchange mechanism. The structural characterization by X-ray diffraction, scanning microscopy and TEM will be presented. The SQUID and the dielectric constant measurements as a function of magnetic field and temperature will be also reported.

2:54PM W37.00003 Phase diagram for Bi$_{1-x}$Ca$_x$MnO$_3$ (x < 0.4). YUHAI QIN, TREVOR TYSON, New Jersey Institute of Technology, SANG-WOOK CHEONG, Rutgers University, XIAO-NONG XU, Nanjing University — The multiferroic BiMnO$_3$ system, in which ferroelectric and ferromagnetic orders can coexist, has attracted much research work in the past years for its potential technological applications. For the more general system Bi$_1-x$Ca$_x$MnO$_3$, the phase diagram for the Ca rich region (x < 0.4) has been established[1]. In order to understand the multiferroic behavior near the x=0 system, the hole-doped region (0<x<0.4) was investigated. We have completed the magnetic, transport, and structural phase diagram of Bi$_1-x$Ca$_x$MnO$_3$, by performing detailed structural (XRD and XAFS) and electrical measurements on Bi$_1-x$Ca$_x$MnO$_3$ (0<x<0.4), showing the transition form the highly distorted monoclinic phase to the orthorhombic phase. This work is supported by NSF DMR-0512196 and DOE Grant DE-FG02-07ER46402. [1] H. Woo, et al, Phys. Rev. B: Condensed Matter and Materials Physics 63, 134412/1 (2001).

3:06PM W37.00004 Combinatorial discovery of morphotropic phase boundary in a lead-free high $T_c$ piezoelectric perovskite Bi$_{1-x}$(RE)$_x$FeO$_3$. F. FUJINO, D. KAN, A. VARATHARAJAN, C.J. CHENG, V. NAGARAJAN, M. MURAKAMI, S.-H. LIM, D. HUNTER, C.J. FENNIE, L. SALAMANCA-RIBA, M. WUTTIG, I. TAKEUCHI — We have recently discovered a morphotropic phase boundary (MPB) in Bi$_{1-x}$Sm$_x$FeO$_3$ which has a simple perovskite structure. We have systematically investigated compositionally varied Sm doped BiFeO$_3$ thin films using the combinatorial approach and found that ferroelectric properties and piezoelectric properties show pronounced enhancement at the MPB. The samples were fabricated by combinatorial pulsed laser deposition on SrTiO$_3$ (001) substrates with a SrRuO$_3$ buffer layer. The boundary is a rhombohedral to pseudo-orthorhombic structural transition which exhibits a ferroelectric to antiferroelectric transition at approximately $T_{mp}$=120 K, intrinsic $d_33$ comparable to those of PbZr$_{0.52}$Ti$_{0.48}$O$_3$ thin films. Transmission electron microscopy (TEM) reveals presence of nanodomains at the MPB. TEM also reveals onset and formation of antiferroelectric domains as the composition is swept near the MPB, where electron diffraction patterns show systematic structural tilt transitions of the system as a function of Sm doping. Finally, we report on structural transitions and ferroelectric properties in other Bi$_{1-x}$(RE)$_x$FeO$_3$ systems systematically studied by the composition spread technique. This work is supported by NSF MRSEC, AR0, and the W. M. Keck Foundation. Research at UNSW is supported by DEST Australia, Australian Research Council Grant DP 0666231 and ARNAM Travel Grant.

3:18PM W37.00005 The effect of structural and chemical perturbations in multiferroic BiFeO$_3$ epitaxial films. DAE HO KIM, H.N. LEE, M. VARELA, H.M. CHRISTEN, Mat. Sci. and Tech. Div., Oak Ridge Nat. Lab., Oak Ridge, TN, M.D. BIEGALSKI, Center for Nanophase Mat. Sci., Oak Ridge Nat. Lab., Oak Ridge, TN, C.J. CALLENDE, D.P. NORTON, Dept. of Mat. Sci. & Engr., Univ. of Florida, Gainesville, FL — The compatibility between the lone-pair driven ferroelectric distortion and antiferromagnetic order in BiFeO$_3$ attracts a lot of attention. A detailed understanding of ferroelectric properties in BiFeO$_3$ is gained by investigating the effect of structural/chemical perturbations in strained epitaxial films with chemical modifications. Our work shows that the ferroelectric polarization along [111] exhibits weak dependency on epitaxial strain on a (001) substrate. A detailed examination of role induced by magnetic ions, we have grown BiFe$_{1-x}$Cr$_x$O$_3$ epitaxial films and observed a ferroelectric to antiferroelectric transition with increasing the Cr content. Furthermore, epitaxial films of Bi$_{1-x}$Ba$_x$FeO$_3$ were grown to investigate the effect of structural variation in connection with change in the valence of Fe ion. The results reveal a high stability of the ferroelectric distortion in epitaxial BiFeO$_3$ films.

3:30PM W37.00006 Structural, electrical and magnetic properties of Bi(Fe$_{1-x}$Ti$_{1-x}$)O$_3$ thin films. N.M. MURARI, R. MELGAREJO, R. THOMAS, R.S. KATIYAR, Department of Physics and Institute for Functional Nanomaterials, University of Puerto Rico, San Juan, P.O. Box 23343, PR 00931 — Multiferroic materials have recently seen a surge of research activities due to its applications in the memory, spintronics, sensors devices and micro mechanical systems (MEMS). BiFeO$_3$ is a naturally occurring multiferroics. However, the large leakage current is a concern for practical applications and substitution at Bi and Fe is commonly employed to circumvent this problem. Here, Fe substitution by Ti is considered for this purpose. Thin films on Pt/Ti/SiO$_2$/Si were grown by chemical solution deposition (CSD) and characterized for structure and symmetry by XRD and Raman scattering, surface morphology by AFM, dielectric properties by impedance analyzer, and the leakage current by I-V measurements. Magnetic (M-H) and electric (P-V) hysteresis loops were also studied. Variation of dielectric constant (e') and loss tangent (tanδ) with temperature, frequency and temperature were systematically studied. Further, the effect of Ti substitution on the electrical properties will be presented.

3:42PM W37.00007 Piezoelectricity and structure of epitaxial ferroic thin films at high electric fields. ALEXEI GRIGORIEV, RIBECCA SICHIEL, University of Wisconsin-Madison, HO NYUUNG LEE, Oak Ridge National Lab, CHANG-BEOM EOM, University of Wisconsin-Madison, ZHONGHOU CAI, ERIC C. LANDAHL, BERNHARD ADAMS, ERIC M. DUFRESNE, Argonne National Lab, PAUL G. EVANS, University of Wisconsin-Madison — With mastering the techniques to grow nearly perfect epitaxial thin oxide films, there are emerging opportunities to control the structure and properties of oxide materials using extremely high electric fields. To unveil the piezoelectric and structural properties of Pb(Zr,Ti)O$_3$ and BiFeO$_3$ epitaxial thin films at electric fields which are a few times stronger than the low-frequency dielectric breakdown field, we employed time-resolved structural measurements synchronized with electric field pulses of a nanosecond duration. At these extreme fields we measured record-high piezoelectric strains and explored nonlinearities in piezoelectric responses predicted to occur due to the changes in interatomic interactions.
3:54PM W37.00008 Giant Polarization Rotation in BiFeO$_3$/SrTiO$_3$ Thin Films,

M.C. LANGNER, Y.H. CHU, L.M. MARTIN, M. GAJEK, R. RAMESHI, J. ORENSTEIN, UC Berkeley, LBNL — We use optical second harmonic generation to probe dynamics of the ferroelectric polarization in (111) oriented BiFeO$_3$ thin films grown on SrTiO$_3$ substrates. The second harmonic response indicates 3m point group symmetry and is consistent with a spontaneous polarization normal to the surface of the film. We measure large changes in amplitude and lowering of symmetry, consistent with polarization rotation, when modest electric fields are applied in the plane of the film. At room temperature the rotation is an order of magnitude larger than expected from reported values of the dielectric constant and increases further (as 1/T) as temperature is lowered. We propose a substrate interaction model to explain these results.

4:18PM W37.00010 Exchange biasing with multiferroic: electric field effects on magnetic and magnetotransport properties.

J. FONTCUBERTA, Institut de Ciencia de Materials de Barcelona-CSIC, Campus UAB, Bellaterra 08193, Catalonia, Spain — Room-temperature multiferroic materials are scarce and display a weak magnetoelectric coupling and thus huge difficulties exist for controlling the magnetic state by using an electric field or viceversa. A possible alternative to circumvent this limitation is to exploit the clamping of ferroelectric and antiferromagnetic domains in biferroic materials and use a suitable exchange-bias existing with ferromagnetic materials to tune the magnetic response of the ferromagnet. In this presentation we shall overview recent experiments on exchange-biasing using hexagonal YMN$_2$ biferroics and Permalloy as a soft-ferromagnet. Exchange-bias on ferromagnetic materials is most commonly evidenced by their magnetic response, although magnetotransport measurements are also very adequate to monitor the exchange bias. We will present and discuss first how exchange-bias is manifested and monitored. Next, we will describe the effects of an electric field, biasing the ferroelectric (and antiferromagnetic) epitaxial layer, on the exchange bias. We will show that under appropriate conditions, magnetization can be switched by application of a suitable electric field. We will discuss the significance of the results with particular attention to role of current leakages across the ferroelectric.

4:54PM W37.00011 Investigation of the electrical switching of magnetization through exchange interactions with a magnetoelectric multiferroic.

A. LEE, ALEX DE LOZANNE, University of Texas at Austin, YING-HAO CHU, LANE W. MARTIN, MIKÉL BARRY, QIAN ZHAN, KILHO LEE, Z. Q. QIU, R. RAMESHI, University of California, Berkeley — The coupling between antiferromagnetic (AF) and ferromagnetic (FM) ordering at an interface between the two types of materials has been well established and provides the basis for modern day hard drives. BiFeO$_3$ is a magnetoelectric multiferroic material which shows coupling between ferroelectric (FE) and AF phases. The Curie and Neél temperatures are $\sim$820 and 370 °C, respectively, permitting room temperature operation. Manipulation of the FE ordering via external electric fields affects the AF ordering which in turn permits control over the magnetization of an adjacent FM material. We present the results of our investigation into the control of magnetic domains using electric fields. The object of investigation is a multilayer film of Co$_{30}$Fe$_{30}$Fe$_{30}$/BiFeO$_3$/SrRuO$_3$/SrTiO$_3$(001) patterned into islands. A magnetic force microscope is used both to image the magnetic domains and to apply the potential across the film.

5:06PM W37.00012 Anisotropic photo-control of spontaneous polarization in BiFeO$_3$ thin films: Indications of photo-assisted magnetoelectric effect.

D.S. RANA, I. KAWAYAMA, H. MURAKAMI, M. TONOUCHI, Institute of Laser Engineering, Osaka University, JAPAN TEAM — The terahertz (THz) emission from multiferroic BiFeO$_3$(BFO) due to ultra-fast depolarization of electric order helps in evaluating its ferroelectric behavior [1]. In this work, we investigate THz-emission in BFO films on (LaAlO$_3$)$_{0.7}$(Sr$_3$Al$_2$O$_6$)$_{0.3}$ (LSAT) substrates along (100), (110) and (111) directions. THz emission amplitude ($E_{THz}$) and its electric field dependence are similar in BFO (100) and BFO (110): $E_{THz}$ as function of electric field translates to ferroelectric-like hysteresis loop, and sign and amplitude of THz-emission are commensurate with the applied electric field. On the contrary, in BFO (111) the hysteretic loop is absent, $E_{THz}$ varies linearly with electric field and the polarity of THz-emission is opposite to that of the electric field. These results suggest that THz-emission is mainly a result of ultrafast depolarization but with a superimposed character of ultrafast reorientation or demagnetization of antiferromagnetic (AFM) order. Though AFM order in BFO makes the determination of magnetoelectric (ME) coupling rather difficult, the photo-assisted electric field control of AFM order shown in the present work is suggestive of photo-assisted ME effect. 1. K. Takahashi et al., Phys. Rev. Lett. 96, 117402 (2006).

5:18PM W37.00013 Measurements of Bandgap of Epitaxial BiFeO$_3$ Films by UV-VIS Absorption and Cathodoluminescence Spectroscopies.

A.J. HAUSER, Department of Physics, The Ohio State University, Z. JHANG, Department of Electrical Engineering, The Ohio State University, L. MIER, R. RICCIARDO, P.M. WOODWARD, T.L. GUSTAFSON, Department of Chemistry, The Ohio State University, L.J. BRILLSON, Department of Electrical Engineering, The Ohio State University, F.Y. YANG, Department of Physics, The Ohio State University — We report measurements of the bandgap of pure-phase epitaxial BiFeO$_3$ thin films on (001)-oriented SrTiO$_3$ substrates, via UV-VIS absorption and cathodoluminescence (CL) spectroscopies. 70 nm thick BiFeO$_3$ films were grown using ultrahigh vacuum RF magnetron sputtering at substrate temperatures between 500 °C and 600 °C. X-ray diffractometry shows that samples grown in this temperature range are epitaxial and pure-phase. UV-VIS absorption spectra show a consistent bandgap of 2.5 ± 0.03 eV for all growth temperatures. A small tail in the UV-VIS absorption spectra just below the bandgap extends down to 2.2 eV, indicating some electronic states within the bandgap. The bandgap was confirmed via CL measurements, where a bandgap of 2.46 ± 0.01 eV was obtained for samples at growth temperatures of 550 °C and 600 °C. To our knowledge, this report is the first measured value of electronic band and defect structure for epitaxial BiFeO$_3$ films and confirms theoretical predictions.

Session W39 GSNP: Focus Session: Jamming II: Packing and Force Networks

Morial Convention Center 231
2:30PM W39.00001 A phase diagram for jammed matter reveals the nature of the random loose and random close packing of spheres . PING WANG, CHAOMING SONG, HERMAN A. MAKSE, Levich Institute and Department of Physics, City College of New York — We employ statistical mechanics of jammed matter to demonstrate the phase diagram of all possible jammed configurations of frictional and frictionless granular packings. This provides a statistical definition of RLP and RCP, predicts their density values in close agreement with simulations, and establishes the concomitant equations of state relating observables such as the coordination number, z, entropy, S, and volume fraction, φ. We show that the RCP state is not a unique point in the phase space but extends along a line of zero compactivity, a temperature-like variable, predicted to be at a constant \( \eta_{RCP} = 0.634 \), but with different z. The lowest density of RLP appears as a line of infinite compactivity parameterized by z, ending at the minimum possible density theoretically predicted to be \( \Phi_{RLP} = 0.543 \). The nature of the disorder of the packings is statistically characterized by the entropy which is shown to be larger in the random loose case than in the random close case.

2:42PM W39.00002 Random loose packing of rough spheres1 . GREG FARRELL, MICHAEL MARTINI, NARAYAN MENON, Dept of Physics, UMass Amherst — We report experiments in which random loose packings of spheres are created by sequential deposition of monodisperse (3.18 ± 0.05mm) PMMA beads of high sphericity in a fluid. The deposition speed is controlled by varying the relative densities of the spheres and the fluid, as well as by varying fluid viscosity. As in the work of Onoda and Liniger, we find that the volume fraction of the sediment asymptotically approaches a lower limit as we approach neutral buoyancy. However, we find that deposition in increasingly viscous fluids has the same effect. We also study the effect on the packing of controlled chemical roughening of the surface of the spheres. The volume fractions attained can be significantly lower than the often-quoted volume fraction of 0.555 for random loose packing. Thus there is no unique volume fraction for the random loose packing of spheres; the measured volume fraction, even in the limit of slow deposition dynamics is determined by particle surface properties.

3:06PM W39.00004 Analysis of Configurational Entropy in Jammed Granular Matter . CHRISTOPHER BRISCOE, CCNY - Levich Institute, PING WANG, CHAOMING SONG, HERMAN MAKSE — Energy fluctuations in jammed granular matter are negligible and cannot control the statistical mechanics. It is of interest to explore volume fluctuations in an effort to describe the statistical mechanics of jammed matter, originally proposed by Edwards. Current studies have introduced the concept of a theoretical phase diagram for jammed matter, providing plausible statistical explanations for the RCP and RLP states, along with intermediate jammed states, as a function of coordination number, z, friction coefficient \( \mu \), and volume fraction, \( \phi \). Entropy can be derived from this theoretical framework by means of a Hamiltonian, with energy and temperature replaced by volume, W, and compactivity, X, where X is an analogue of temperature. Our present efforts are to calculate the Shannon entropy of jammed granular packings along various paths of the phase diagram, resulting in an extensive entropy density, and X, as a function of \( \phi \), providing a new equation of state for jammed granular matter.

3:18PM W39.00005 Jamming of Frictional Spheres . ABDULLAH CAKIR, LEONARDO SILBERT, Southern Illinois University — Packings of monodisperse, frictional spheres are studied for a wide range in particle friction coefficient on approach to the jamming transition — the point where the packing loses mechanical stability. In particular, we focus on dynamical properties through the study of the vibrational normal modes. The dynamical matrix includes terms that take into account the rotational degrees of freedom due to non-central forces in the presence of friction. The influence of friction on the normal mode frequencies and particle polarization vectors are examined. Distinct from frictionless systems, for finite friction, the normal modes now allow for particle rotations.

3:30PM W39.00006 Hard Discs on the Hyperbolic Plane . CARL MODES, RANDALL KAMIEN, University of Pennsylvania — We examine a simple hard disc fluid with no long range interactions on the two dimensional space of constant negative Gaussian curvature, the hyperbolic plane. This geometry provides a natural mechanism by which global crystalline order is prohibited, allowing us to construct a tractable model of disordered monodisperse hard discs. We extend free area theory and the virial expansion to this regime, deriving the equation of state for the system, and compare its predictions with simulation near an isostatic packing in the curved space.

3:42PM W39.00007 Random subcubes as a toy model for constraint satisfaction problems . THIERRY MORA, Princeton Univ, LENKA ZDEBOROVA, LPTMS, Univ. Paris-Sud — abstract-Many hard combinatorial problems, such as Random Satisfiability, have been shown to reproduce some nontrivial properties of glassy materials. In particular, it has been proved that the configurational landscapes of the hardest problems are made of many disconnected ergodic components, leading to rich phase diagrams. Here we present an exactly solvable random-subcube model inspired by the structure of hard constraint satisfaction and optimization problems. Our model reproduces the structure of the solution space of the satisfiability and coloring problems, and undergoes the same phase transitions. Distance properties, and their relation to ergodicity, are studied. The model can also be generalized to define a continuous energy landscape useful for studying several aspects of glassy dynamics.

3:54PM W39.00008 Random Packing of Platonic Solids . TABER HERSUM, MARTIN-D. LACASSE, HUBERT KING, ExxonMobil Research & Engineering Company — While a large amount of literature has been devoted to the packing of spheres, very little is known about the packing of regular polyhedra, such as platonic solids. This presentation will describe numerical work on the packing of model systems in which mono-disperse tetrahedra, cubes, dodecahedra, and icosahedra are randomly packed. Energy fluctuations in jammed granular matter are mapped to random satisfiability and coloring problems, and undergoes the same phase transitions. Distance properties, and their relation to ergodicity, are studied. The point where the packing loses mechanical stability. In particular, we focus on dynamical properties through the study of the vibrational normal modes. The dynamical matrix includes terms that take into account the rotational degrees of freedom due to non-central forces in the presence of friction. The influence of friction on the normal mode frequencies and particle polarization vectors are examined. Distinct from frictionless systems, for finite friction, the normal modes now allow for particle rotations.

4:08PM W39.00009 Experiments on Random Packings of Tetrahedrons1 . ALEXANDER JAOSHLIVI, PAUL CHAISKIN, New York University — We have performed experiments related to the random packing of tetrahedral. The main experiments are MRI scans of tetrahedral molecule from which we determine their positions and orientations. We have done a direct analysis of the dice packing. The dice differ from mathematical tetrahedral in having slightly rounded vertices and edges. We have performed a best fit to each die to a perfect tetrahedral and then relaxed the packing to reduce the resulting overlaps. Analyzed data for the dice, the relaxed tetrahedra and simulations include the packing density, the orientational and spatial correlation functions, the average coordination number as well as the distribution of point to face, edge to edge and edge to face contacts. We also study the boundary effects from the walls and the distribution of constraints per particle. Our measurements indicate that random packed tetrahedral have a very small spatial or orientational correlation length. They are more random, that is with smaller and shorter range correlations than what has been found for spheres, or ellipsoids.

1 NSF, DMR0604295.
Local pressure distributions in the force network ensemble for granular media, BRIAN TIGHE, Universiteit Leiden — We present an analytic calculation of the probability distribution of pressure on individual grains in a static granular packing. We maximize entropy within an ensemble of all possible force networks on a fixed contact network, which incorporates force balance on each grain. Similar to energy in the microcanonical ensemble, the average pressure in each configuration is fixed. Subject to this global constraint alone, entropy maximization would yield a pressure distribution with an exponential tail. We demonstrate that, as a direct consequence of local force balance, there exists an additional global conserved quantity. Maximizing entropy while also respecting this new conserved quantity, we find a pressure distribution that, in frictionless packings, grows as a power law for small pressures and decays with a Gaussian tail. The form of the distribution is confirmed by numerics. As we increase the coefficient of friction, the tail approaches an exponential.

Using MR Elastography to Image Force Chains in a Quasi-Static Granular Assembly, L. SANFRATELLO, S.A. ALTOBELLI, NMR, R.P. BEHRINGER, Duke University, E. FUKUSHIMA, ABQMR — Questions about the internal structure of dense granular assemblies remain unanswered for lack of 3D experimental data. It is known from 2D observations and from the boundaries of 3D systems that non-uniform stresses are present on container boundaries as well as at the bottom of granular piles. These forces are seen in 2D to be distributed by force chains, where most of the stress is transmitted through a small number of chains with much of the assembly transmitting little or none of the force. However, force chains have yet to be fully visualized in 3D. We propose a variation of magnetic resonance elastography (MRE) to image 3D force chains within a densely packed granular assembly. MRE is an MRI technique whereby small periodic displacements within an elastic material can be measured. Multiple bipolar motion encoding gradients incorporated into a typical pulse sequence, and applied at the frequency of mechanical oscillations, are used to detect the displacements. We have verified our MRE technique using a gel (Perma-Gel). We now extend this method to image force chains within a 3D granular assembly of particles under stress, on top of which is superimposed a small-amplitude vibration. It is our hypothesis that significant coherent displacements will be found only along force chains while most particles will move randomly. Experimental results will be presented.

Abstract Contact Percolation in Dense Granular Flow, FUPING ZHOU, ExxonMobil Research and Engineering Company, DENIZ ERTAS, ExxonMobil Research and Engineering — Steady-state rheology of spheres are studied in the dense flow regime with three-dimensional molecular dynamics simulations in two different geometries: Simple shear flow and gravity-driven chute flow. The same set of constitutive equations, which are only a function of the local dimensionless strain rate, I, are found to characterize bulk macroscopic observables such as density, internal Coulomb coefficient and scaled velocity fluctuations in both cases. A transition has been identified at a finite (non-universal) value of I = Ic, corresponding to the percolation transition of the instantaneous contact network. For I < Ic, an infinite contact network spans the system. The flow dilutes and the internal Coulomb coefficient increases with increasing I. For I > Ic, the instantaneous contact network is broken into finite clusters. The system dilutes further with increasing I while the internal Coulomb coefficient becomes independent of I, reaching a maximum tilt angle for steady chute flow. Scaled velocity fluctuations exhibit power-law dependence on I on both sides of Ic, with a minimum at the transition. The transition is distinct from the “jamming” transition at I = 0 associated with the rigidity percolation of the contact network.

Dynamics of the Granular Jamming Transition, MAHESH BANDI, Los Alamos National Laboratory, ANDRIAS LIBAL, Johns Hopkins University, MICHAEL RIVERA, ROBERT ECKE, Los Alamos National Laboratory — We experimentally study the force fluctuations felt by a probe disk as it is dragged through a two-dimensional bi-disperse system of randomly packed photo-elastic disks. The fluctuations are studied as a function of packing fraction where the system goes from an unjammed to a jammed state with increasing packing fraction. As the system approaches the Jamming Point, the fluctuations are expected to diverge and become increasingly intermittent. We will present preliminary results of the force fluctuations felt by the probe disk as measured by a force transducer and compare them with visual data as obtained from the force-chains formed by the photo-elastic disks.

Stick-Slip and Granular Force Networks, ROBERT BEHRINGER, PEIDONG YU, Duke University — We describe friction/failure experiments for a granular system consisting of photoelastic particles. The goal of the experiments is to provide a microscopic understanding of stick-slip friction for an object that is pulled across a granular material. The granular material consists of a photoelastic disks (biphasic distribution) that are confined to a vertically oriented channel. A slider that is rough at the grain scale is pulled across the upper surface of the material. The pulling is accomplished by a screw-driven platform that is connected to the slider by a spring. Photoelastic image data are acquired by a camera and light source that move with the platform. Non-periodic stick-slip occurs for the regime of parameters studied here. During a stick event, force builds up in a strong network of force chains in the granular material. When one or more of the chains break, a slip event occurs. Energy changes from these events are power-law distributed. Analysis of failure points and slip events yields the effective friction coefficients, which are broadly scattered. An alternative description involves modeling the force chain network as a collection of springs. Failure of one spring can lead to a cascade and hence the broad distribution of energy losses.

Session W40 DBP GSNP: Focus Session: Networks, Regulation, and Pathways in Cell Biology

2:30PM W40.00001 Metabolism and evolution: A comparative study of reconstructed genome-level metabolic networks, EIVIND ALMAAS, Lawrence Livermore Natl Lab — The availability of high-quality annotations of sequenced genomes has made it possible to generate organism-specific comprehensive maps of cellular metabolism. Currently, more than twenty such metabolic reconstructions are publicly available, with the majority focused on bacteria. A typical metabolic reconstruction for a bacterium results in a complex network containing hundreds of metabolites (nodes) and reactions (links), while some even contain more than a thousand. The constrain-based optimization approach of flux-balance analysis (FBA) is used to investigate the functional characteristics of such large-scale metabolic networks, making it possible to estimate an organism’s growth behavior in a wide variety of nutrient environments, as well as its robustness to gene loss. We have recently completed the genome-level metabolic reconstruction of Yersinia pseudotuberculosis, as well as the three Yersinia pestis biovars, Antiqua, Mediaevalis, and Orientalis. While Y. pseudotuberculosis typically only causes fever and abdominal pain that can mimic appendicitis, the evolutionary closely related Y. pestis strains are the aetiological agents of the bubonic plague. In this presentation, I will discuss our results and conclusions from a comparative study on the evolution of metabolic function in the four Yersiniae networks using FBA and related techniques, and I will give particular focus to the interplay between metabolic network topology and evolutionary flexibility.

Work was performed under the auspices of the DoE by LLNL under Contract DE-AC52-07NA27344, and supported by LDRD grant 06-ERD-061.
3:06PM W40.00002 Level architecture in genetic regulatory networks and the role of microR-NAs, J. M. SCHWARZ, Physics Department, Syracuse University — It is well known that genes that code for proteins regulate the expression of each other through protein-mediated interactions. With the discovery of microRNAs (miRNAs), it has been conjectured that there are many such regulatory miRNAs in the cell that are never transcribed into proteins but are important for regulation and, hence, could explain the nature of the non-coding (or junk) DNA. Furthermore, miRNAs are highly conserved molecules. So, just as genes that code for proteins form regulatory networks, we conjecture that miRNAs form a higher-level regulatory network amongst themselves as mediated by the genes-coding-for-proteins regulatory network to form a complex organism. We investigate this conjecture within the framework of random Boolean networks where the two-level architecture is modelled via two coupled random Boolean networks with one network taking precedence over the other for various input/output values. Aspects of the evolution of the lower-level network will also be addressed.

3:18PM W40.00003 Tailoring the metabolism against mutations, NATALI GULBAHCE, Northeastern University, ADILSON E. MOTTER, Northwestern University, EIVIND ALMAAS, Lawrence Livermore National Laboratory, ALBERT LASZLO BARABASI, Northeastern University — In the post-genomic era, organisms can be modelled at the whole-cell level in silico via steady state methods to describe their metabolic capabilities. We use two such methods, Flux Balance Analysis and Minimization of Metabolic Adjustment to explore the behavior of cells (of E. coli and S. cerevisiae) after severe mutations. We propose experimentally feasible ways of modifying the underlying biochemical reaction network of a mutant cell such that cell functionality, in particular growth rate, is significantly improved.

3:30PM W40.00004 Form, Function, and Evolvability in Biological Networks, ANDREW MUGLER, Physics Dept, Columbia University, EYTZ ZIV, College of Physicians and Surgeons, Columbia University, ILYA NEMENMAN, CCS-3/CNLS, Los Alamos National Laboratory, CHRIS H. WIGGINS, Dept of Applied Physics & Applied Math/C2B2, Columbia University — A driving problem in systems biology for several years has been exploring the extent to which the topology of a small biological network constrains or guides its function. The absence of such constraint would allow a given network to evolve without rewiring its underlying form. We introduce a quantitative measure of this evolvability that does not rely on pre-defining the preferred function of a given topology. We then study the stochastic description of the experimental setup of Guet [1], treating chemical inducers as functional inputs and the expression of a reporter gene as the functional output. We take an information-theoretic approach, allowing the system to set parameters that optimize signal processing ability, thus enumerating the highest-fidelity functions. We find that, while all networks studied are highly evolvable by our measure—meaning that the function has little dependence on location in parameter space—the evolvability is correlated with individual topological features. Certain topological attributes, then, are shown (with statistical significance) to convey evolvability to biological networks. [1] C. C. Guet et al., Science 296, 1466 (2002).

3:42PM W40.00005 Noisy out of necessity: Probabilistic behavior during cellular differentiation, GUROL SUEL, UT Southwestern — Diverse organisms ranging from bacteria to mammalian stem cells undergo pluripotent differentiation where a single cell can commit to one out of several cell fates. How do underlying genetic circuits comprised of interactions between genes and proteins allow cells to "choose" a specific cell fate and execute the appropriate differentiation program? To address this question we investigate a simple bacterial differentiation system utilizing mathematical modeling and quantitative single cell measurements. In particular we are interested in elucidating the role of circuit dynamics and stochastic behavior in cellular differentiation.

4:18PM W40.00006 Analysis of temperature-dependent changes in the metabolism of Yersinia pestis,1 ALI NAVID, EIVIND ALMAAS, Lawrence Livermore National Laboratory — The gram-negative bacterium Yersinia pestis is the aetiological agent of bubonic plague, a zoonotic infection that occurs through the bite of a flea. It has long been known that Y. pestis has different metabolic needs upon transition from the flea gut environment (26 °C) to that of a mammalian host (37 °C). To study this and other outstanding questions about metabolic function of Y. pestis, we used the available genomic, biochemical and physiological data to develop a constraint-based flux balance model of metabolism in the avirulent 91001 strain (biovar Mediaevalis) of this organism. Utilizing two sets of whole-genome DNA microarray expression data, we examined the system level changes that occur when Y. pestis acclimates to temperature shifts. Our results point to fundamental changes in its oxidative metabolism of sugars and use of amino acids, in particular that of arginine. This behavior is indicative of an inefficient metabolism that could be caused by adaptation to life in a nutrient rich environment.

4:28PM W40.00007 Information processing in the E. coli Chemotaxis Network, LIN WANG, SIMA SETAVESHGAR, Department of Physics, Indiana University, Bloomington, IN — Biochemical signal transduction, broadly defined as the conversion of the concentration of an input signal to an output response, is the most basic level of biological information processing. The chemosensory pathway in bacterial chemotaxis is the best-characterized signal transduction network, and as such it provides an ideal system for probing the physical principles governing complex cellular signaling and response. Using an experimentally realistic stochastic implementation of the E. coli chemotaxis network and motor response, we investigate optimality of the chemotactic response in terms of input/output information transmission.

4:42PM W40.00008 Correlated Phenotypic Transitions to Competence in Bacterial Colonies, INBAL HECHT, Center for Theoretical Biological Physics, University of California, San Diego, ESHEL BEN-JACOB, School of Physics and Astronomy, Tel Aviv University, Israel, HERBERT LEVINE, Center for Theoretical Biological Physics, University of California, San Diego — Genetic competence is a phenotypic state of a bacterial cell in which it is capable of importing DNA, presumably to hasten its exploration of alternate genes in its quest for survival under stress. Recently, it was proposed that this transition is uncorrelated among different cells in the colony. Motivated by several discovered signaling mechanisms which create colony-level responses, we present a model for the influence of quorum-sensing signals on a colony of B. Subtilis cells during the transition to genetic competence. Coupling to the external signal creates an effective inhibitory mechanism, which results in anti-correlation between the cycles of adjacent cells. We show that this scenario is consistent with the specific experimental measurements, which fails to detect some underlying collective signaling mechanisms. Rather, we suggest other parameters that should be used to verify the role of a quorum-sensing signal. We also study the conditions under which phenotypic spatial patterns may emerge.

4:54PM W40.00009 On the Selection of Bistability in Genetic Regulatory Circuits, CHEOL-MIN GHIM, EIVIND ALMAAS, Lawrence Livermore National Laboratory, MICROBIAL SYSTEMS BIOLOGY TEAM — Bistability is a defining character of switching and memory devices. Many regulatory circuits observed in cellular reaction networks contain "bistability motifs" that endow a cell with efficient and reliable switching between different physiological modes of operation. One of the best characterized system, the lac operon in E. coli, has been shown to display a saddle-node bifurcation when induced by nonmetabolizable lactose analogue inducers, such as isopropylthio-β-D-galactoside (IPTG) and thio-methyl-galactoside (TMG). Motivated by the absence of bifurcation in the same system with its natural inducer, lactose, we studied the conditions for bistability and rationalized its fitness effects in the light of evolution. Stochastic simulations as well as mean-field approach confirm that history-dependent behavior as well as nongenetic inheritance, being realized by bistability motifs, may be beneficial in fluctuating environments.

5:06PM W40.00010 Mutual information in random Boolean models of regulatory networks

JOSHUA SOCOLAR, Physics Dept. and Center for Systems Biology, Duke University. ANDRE RIBEIRO, Tampere University of Technology. BJORN SAMUELSSON, Lund University. JASON LLOYD-PRICE, STUART KAUFFMAN, University of Calgary — In a large, complex network of interacting elements, such as a genetic regulatory network within a cell, the average of the mutual information over all pairs of elements is a global measure of how well the system can coordinate its internal dynamics. We study the average pairwise mutual information I in random Boolean networks (RBNs) as a function of the distribution of Boolean rules implemented at each element, assuming that the links in the network are randomly placed. As the number N of network nodes approaches infinity, NI exhibits a discontinuity at parameter values corresponding to critical RBNs. For finite systems, NI peaks near the critical value, but slightly in the disordered regime for typical parameter variations. The source of high values of NI is the indirect correlations between pairs of elements from different long chains with a common starting point. The contribution from pairs that are directly linked approaches zero for critical networks and peaks deep in the disordered regime.

5:18PM W40.00011 Dynamical properties of structured Boolean networks

ANDREW POMERANCE, WOLFGANG LOSERT, MICHELLE GRIVAN, EDWARD OTT, University of Maryland, College Park — Boolean networks have been used since the 60s as a model for genetic control networks. In this model, each node takes on the value 0 or 1, modeling whether a gene is expressed or not, and updates at each time step according to a function of the value of its inputs. Random boolean networks (RBNs), where each node is randomly connected to other nodes and the function governing the dynamics is initially randomly generated, have been particularly well-studied. In particular, since these are deterministic, finite systems, the system must eventually settle into a periodic or fixed point attractor. A key question has been the scaling of the number of attractors with system size. In this talk we present results on how network structure effects the behavior of Boolean networks with randomly assigned dynamical rules. For example, we show that the number of attractors is dramatically increased by the addition of community structure to the network from the baseline RBN count with the same number of nodes. Furthermore, imposing bipartite structure on the network has little effect on the number of attractors.

Session X3 DCMP: Interface Phenomena in Oxides – Morial Convention Center RO2 - RO3

8:00AM X3.00001 2D Superconductivity at the LaAlO3/SrTiO3 interface

NICOLAS REYREN, University of Geneva — In 2004 Ohtomo and Hwang [1] discovered that the interface between two insulating oxides, LaAlO3 and SrTiO3 (both band insulators), is metallic with a high mobility. This publication triggered a lot of work around the world (see for instance [2, 3]). We have studied the ground state of this system and discovered superconductivity [4]. The studied LaAlO3 samples are grown epitaxially by pulsed laser deposition on TiO2-terminated SrTiO3 substrates and are annealed in situ in oxygen. The superconducting properties in the LaAlO3/SrTiO3 heterostructures display signatures of 2D superconductivity and agree with the Beresinskii-Kosterlitz-Thouless (BKT) predictions. However, for low currents, IV curves show some deviation from the expected behavior of a perfect infinite 2D system. These deviations are attributed to the finite lateral size of the measured path. Experiments to probe this size effect have been done to check this interpretation.

8:36AM X3.00002 Magnetic effects at the interface between nonmagnetic oxides

ALEXANDER BRINKMAN, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, The Netherlands — The electronic reconstruction at the interface between two insulating oxides can give rise to a highly conductive interface. In analogy to this remarkable interface-induced conductivity we show how, additionally, magnetic effects can be induced at the interface between the otherwise nonmagnetic insulating perovskites SrTiO3 and LaAlO3 [1]. A large negative magnetoresistance, up to 50% at 50 mK, of the interface is found together with a logarithmic temperature dependence of the sheet resistance. These magnetic effects only appear in samples that have been grown under conditions that minimize the incorporation of oxygen vacancies. It is suggested that the interface electronic reconstruction induces localized magnetic moments in the SrTiO3 that interact with the conduction electrons. At low temperatures, the sheet resistance reveals magnetic hysteresis with a long relaxation time scale. The conducting oxide interface now provides a versatile system to induce and manipulate magnetic moments in otherwise nonmagnetic materials.

9:12AM X3.00003 Transport properties observed at hetero-interfaces of LaAlO3 on SrTiO3; intrinsic or extrinsic interface effect?

GERTJAN KOSTER1, GLAM, Stanford University — We have made very thin films of LaAlO3 on TiO2 terminated SrTiO3 and have measured the properties of the resulting interface in various ways. Transport measurements show a sheet carrier density of 10^{16} cm^{-2} and a mobility around 10^{3} cm^{2} V^{-1} s^{-1}. In situ UPS results indicate that oxygen vacancies play an important role in the creation of the charge carriers and that these vacancies are introduced by the pulsed laser deposition process used to make the hetero-interfaces [1]. Our results explain for the first time the origin of the large sheet carrier densities and high mobility observed previously [2]. XAS and spectroscopic ellipsometry [3] measurements confirm the existence of (oxygen) defects in the SrTiO3. Simple model calculations confirm the plausibility of having defects at the origin of charge carriers while still maintaining a high mobility. By means of annealing experiments in atomic oxygen we try to answer the question whether an intrinsically doped interface does indeed exist at lower carrier concentrations [2]. Due to its reactive nature (i.e., binding energy in an oxygen molecule is about 5 eV), atomic oxygen will have much more power to eliminate any oxygen vacancies compared to conventional annealing methods.

Work presented was done at Stanford University.

Friday, March 14, 2008 8:00AM - 11:00AM –
Session X4 DCMP GQI: Approaching Quantum Limits in Optomechanical Systems – Morial Convention Center 206
Sensing nanomechanical motion with a microwave cavity interferometer.

CINDY REGAL, JILA: NIST and the University of Colorado, Boulder — Optomechanical and electromechanical systems utilizing micro and nanomechanical oscillators offer a promising route towards manipulation of macroscopic objects at the quantum level. In this talk I present experiments that use principles of popular optomechanical systems yet employ light at microwave frequencies. Operating at microwave frequencies allows us to also harness technology associated with electromechanical systems, such as very light nanoscale mechanical objects and on-chip circuit elements compatible with a dilution refrigerator environment. Specifically, in our work we embed a nanomechanical flexural resonator inside a superconducting transmission-line microwave cavity, where the mechanical resonator’s position couples to the cavity capacitance and thus to the resonant frequency of the cavity. With our device we realize near state-of-the-art force sensitivity ($3 \times 10^{-19} \text{N}$/Hz) and thus add to only a handful of techniques able to measure thermomechanical motion at 10’s of miliKelvin temperatures. Our current measurements achieve a promising total displacement uncertainty at 140 times the quantum limit and a measurement imprecision as low as 30 times the quantum limit, as well as elucidate the important steps that will be required to progress towards the full quantum limit of displacement detection with this new system.

Strong dispersive coupling between a micromechanical oscillator and a high finesse optical cavity.

JACK HARRIS, Departments of Physics and Applied Physics, Yale University, New Haven, CT — Very sensitive mechanical detectors spanning roughly seventeen orders of magnitude in size are rapidly approaching a regime in which either the mechanical device itself or its readout should demonstrate quantum behavior. One of the main technical barriers to actually reaching this regime has been the difficulty of integrating ultrasensitive micromechanical devices with high-finesse optical cavities. Recently we have developed a robust means for addressing this issue, and have integrated a 50 nm-thick membrane (with a quality factor $>1,000,000$) into an optical cavity with a finesse $\sim 20,000$. Although the membrane is nearly transparent, it couples to the optical cavity dispersive. This coupling is strong enough to enable coherent control of the mechanical resonance of the membrane. We will describe our experimental results, as well as our progress towards observing quantum effects in this system.

Cavity Assisted Sideband Cooling of Mechanical Motion.

FLORIAN MARQUARDT, Arnold Sommerfeld Center for Theoretical Physics, Center for NanoScience, and Ludwig-Maximilians University Munich, Germany — This talk will provide a pedagogical introduction to the theoretical ideas that form the basis for cooling a mechanical cantilever using light-induced forces. During recent years, these concepts have been realized in a series of experiments by various groups, that have demonstrated impressive progress in cooling. Several of them will be discussed in the following talks of this session. Ultimately, this line of research may lead to the quantum-mechanical ground state of the center-of-mass motion of objects composed of many billions of atoms. A common ingredient is the use of an optical cavity to resonantly enhance the radiation pressure force affecting the motion of the cantilever. I will start by reviewing the classical description of how a time-retarded force leads to enhanced friction and thus cooling. Then I will present a fully quantum-mechanical description, that takes into account the opposing effect of the photon shot noise [F. Marquardt, J. P. Chen, A. A. Clerk and S. M. Girvin, Phys. Rev. Lett. 99, 093902 (2007); see also I. Wilson-Rae, N. Nooshi, W. Zwerger and T. J. Kippenberg, Phys. Rev. Lett. 99, 093901 (2007)]. This theory yields a quantum-limit for the reachable photon number that can be made arbitrarily small, provided a high-finesse cavity is combined with a high-frequency mirror (the “resolved sideband limit,” analogous to ion cooling). Various different ways of experimentally measuring the photon number will be mentioned. Finally, I will briefly give an outlook regarding the possibilities for quantum-coherent experiments that will open up once the ground state has been reached. This talk primarily reports joint work with A. Clerk, J. P. Chen, and S. Girvin.

Laser Cooling of Gram Scale Objects.

THOMAS CORBITT, Massachusetts Institute of Technology — Laser cooling of macroscopic mechanical oscillators is a rapidly growing field with applications in high precision measurements, gravitational wave detectors, and exploration of the classical-quantum transition. Here I will describe a series of cooling experiments, which are inspired by gravitational wave detectors, to trap and cool gram scale mirror oscillators. To approach quantum limits of oscillators with such a high mass requires the use of a variety of cooling techniques. The techniques employ non-mechanical forces both to trap the mirror by increasing its effective mechanical resonant frequency, and to cool the mirror by damping its motion within the trap. The non-mechanical forces are created from either radiation pressure in a detuned optical resonator, or from electronic feedback forces in an active servo. As the experiments approach the quantum regime, an assortment of non-classical behavior and effects should become evident, such as quantum radiation pressure noise, and squeezing and entanglement of the light and mirror states. I will discuss the prospects for observation of these effects, in light of current performance and expected upgrades.

Towards experimental optomechanical entanglement between a movable mirror and a cavity field.

MARKUS ASPELMEYER, Austrian Academy of Sciences — The quantum regime of mechanical systems offers fascinating new possibilities for both applied and fundamental physics. Quantum optics provides a well-developed tool box to help entering and controlling this regime as is evidenced by the recent successes in laser-cooling of micromirrors that promise cooling capabilities to the mechanical quantum ground state. I will start by reviewing the classical description of how a time-retarded force leads to enhanced friction and thus cooling. Then I will describe a series of cooling experiments, which are inspired by gravitational wave detectors, to trap and cool gram scale mirror oscillators. To approach quantum limits of oscillators with such a high mass requires the use of a variety of cooling techniques. The techniques employ non-mechanical forces both to trap the mirror by increasing its effective mechanical resonant frequency, and to cool the mirror by damping its motion within the trap. The non-mechanical forces are created from either radiation pressure in a detuned optical resonator, or from electronic feedback forces in an active servo. As the experiments approach the quantum regime, an assortment of non-classical behavior and effects should become evident, such as quantum radiation pressure noise, and squeezing and entanglement of the light and mirror states. I will discuss the prospects for observation of these effects, in light of current performance and expected upgrades.

THURSDAY, MARCH 13, 2008 8:00AM - 11:00AM —
Session X4 DCMP: Superconducting Sources of THz-Radiation

8:00AM X4.00001 Sensing nanomechanical motion with a microwave cavity interferometer.

CINDY REGAL, JILA: NIST and the University of Colorado, Boulder — Optomechanical and electromechanical systems utilizing micro and nanomechanical oscillators offer a promising route towards manipulation of macroscopic objects at the quantum level. In this talk I present experiments that use principles of popular optomechanical systems yet employ light at microwave frequencies. Operating at microwave frequencies allows us to also harness technology associated with electromechanical systems, such as very light nanoscale mechanical objects and on-chip circuit elements compatible with a dilution refrigerator environment. Specifically, in our work we embed a nanomechanical flexural resonator inside a superconducting transmission-line microwave cavity, where the mechanical resonator’s position couples to the cavity capacitance and thus to the resonant frequency of the cavity. With our device we realize near state-of-the-art force sensitivity ($3 \times 10^{-19} \text{N}$/Hz) and thus add to only a handful of techniques able to measure thermomechanical motion at 10’s of miliKelvin temperatures. Various different ways of experimentally measuring the photon number will be mentioned. Finally, I will briefly give an outlook regarding the possibilities for quantum-coherent experiments that will open up once the ground state has been reached. This talk primarily reports joint work with A. Clerk, J. P. Chen, and S. Girvin.

9:48AM X4.00004 Laser Cooling of Gram Scale Objects.

THOMAS CORBITT, Massachusetts Institute of Technology — Laser cooling of macroscopic mechanical oscillators is a rapidly growing field with applications in high precision measurements, gravitational wave detectors, and exploration of the classical-quantum transition. Here I will describe a series of cooling experiments, which are inspired by gravitational wave detectors, to trap and cool gram scale mirror oscillators. To approach quantum limits of oscillators with such a high mass requires the use of a variety of cooling techniques. The techniques employ non-mechanical forces both to trap the mirror by increasing its effective mechanical resonant frequency, and to cool the mirror by damping its motion within the trap. The non-mechanical forces are created from either radiation pressure in a detuned optical resonator, or from electronic feedback forces in an active servo. As the experiments approach the quantum regime, an assortment of non-classical behavior and effects should become evident, such as quantum radiation pressure noise, and squeezing and entanglement of the light and mirror states. I will discuss the prospects for observation of these effects, in light of current performance and expected upgrades.

10:24AM X4.00005 Towards experimental optomechanical entanglement between a movable mirror and a cavity field.

MARKUS ASPELMEYER, Austrian Academy of Sciences — The quantum regime of mechanical systems offers fascinating new possibilities for both applied and fundamental physics. Quantum optics provides a well-developed tool box to help entering and controlling this regime as is evidenced by the recent successes in laser-cooling of micromirrors that promise cooling capabilities to the mechanical quantum ground state. I will discuss the prospects and challenges to generate (opto-mechanical) quantum entanglement, which is an important resource for quantum information processing and is also at the heart of Schrödinger’s “cat paradox.”
8:36 AM X5.00002 Emission of Coherent THz-Radiation from Superconductors. ULRICH WELP, Argonne National Laboratory — Josephson junctions naturally convert dc-voltages into high-frequency electromagnetic radiation, with 1 mV corresponding to 0.483 THz, and many such junctions emitting in phase at the same frequency can produce useful emission power. Stacks of junctions with unsurpassed packing density occur naturally in the layered high temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_8$, in which the superconducting CuO$_2$-layers are coupled through the intrinsic Josephson effect. However, achieving synchronization of the high-frequency oscillations of all the junctions in the stack has so far been a major challenge. We demonstrate that coherent continuous-wave THz-radiation of sizable power can be extracted from intrinsic Josephson junctions in the layered high-temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_8$. In analogy to a laser cavity, the excitation of an electromagnetic cavity resonance inside the sample generates a macroscopic coherent state in which a large number of junctions are synchronized to oscillate in phase. The emission power is found to increase as the square of the number of junctions reaching values of 0.5 μW at frequencies up to 0.85 THz. The available power is potentially much larger, as there is evidence that 20 μW of power are pumped into the observed THz cavity resonance. The emission persists up to temperatures of ~50 K. Emission does not require the application of a magnetic field, significantly simplifying the design of superconducting THz-sources. In fact, a single applied D.C. current leads to the efficient excitation of continuous coherent THz-radiation. This work was supported by the U.S. Department of Energy under Contract No. DE-AC02-06CH11357 – Basic Energy Sciences, the Japanese Ministry of Education, Culture, Sports, Science and Technology, and the Turkish TUBITAK under Project No. 106T053. In collaboration with L. Ozuyer, A. E. Koshelev, C. Kunter, N. Gopalasmi, Q. Li, M. Tachiki, K. Kadowaki, T. Yamamoto, H. Minami, H. Yamaguchi, T. Tachiki, K. E. Gray, W.-K. Kwok.

9:12 AM X5.00003 Radiation Due to Josephson Oscillations in Layered Superconductors. LEV BULAEVSKII, Los Alamos National Laboratory — The power of direct tunable radiation into free space induced by Josephson oscillations in intrinsic Josephson junctions of highly anisotropic layered superconductors is derived. The super-radiation regime in a current biased crystal is considered when no dc magnetic field is applied. It is assumed that crystal is cut in the form of thin plate parallel to the ac-plane with the thickness of several microns along the a-axis and length of several hundreds microns along the c-axis. At large number of intrinsic junctions oscillations in such BSCCO crystal are synchronized providing high radiation power proportional to squared number of junctions and high efficiency up to 1/3 in the THz frequency range. The radiation correction to the current-voltage characteristic in this regime depends only on crystal shape. When the ac-edge of such a crystal is irradiated by external electromagnetic wave, radiation from both ac-edges of the crystal is enhanced (stimulated radiation) at higher-current part of the Shapiro step. The main part of external radiation is in the direction opposite to incident wave. This effect of stimulated radiation may be used for amplification of electromagnetic waves. BSCCO crystal with modulated critical current and length several tens microns along the b-axis also provides high THz-radiation power from the ac-edges at discrete Josephson frequencies corresponding to the crystal thickness along the b-axis. In this case the effective power of radiation power in this case is due to Fiske resonances and super-radiation regime. The powerful almost standing electromagnetc wave is excited inside the crystal in the resonance. This wave is homogeneous across the layers meaning that the oscillations are synchronized in all junctions in the stack. In this situation the synchronization of radiation in different junctions is enforced by both super-radiation regime and similar critical current profile in all junctions of the crystal.

9:48 AM X5.00004 THz emission from a slice of high-Tc superconducting single crystal. HUABING WANG, National Institute for Materials Science, Tsukuba 3050047, Japan — Copper oxide superconductors possess intrinsically a layered crystalline structure in which the superconducting and non-superconducting layers interlace each other. Therefore the crystal itself consists of a number of superconducting junctions sequentially stacked along the c axis of the crystal, and these junctions are often referred to as intrinsic Josephson junctions (IJJs). In the case of Bi$_2$Sr$_2$CaCu$_2$O$_8$+δ (BSCCO), each IJJ measures approximately 1.5 nm thick. Many groups have been exploring the possibilities to develop terahertz (THz) detectors and oscillators based on IJJs, due to their high collective plasma frequencies (up to THz region), the uniformity in junction properties, the easiness to make a large junction array, and the low loss at high frequencies. Some years ago, IJJs single out from inside a slice of BSCCO single crystal with a double-sided process, THz response was successfully observed as sharp Shapiro steps at frequencies up to 2.5 THz, and harmonic mixings were carried out with harmonic numbers as large as 90. Recently observed have been THz oscillations in various structures of BSCCO IJJs, which can be excited by dc bias, in-plane magnetic fields, or microwave irradiations at several gigahertz. Needless to say, for practical applications, it is necessary to synchroize the emissions from IJJs, couple the THz oscillations into a finite channels, guide them in a controllable way, monitor the frequencies and power levels, and preferably do the jobs using an integrated system. We have been making extensive efforts to explore these ideas, and will report our latest results at the meeting.

10:24 AM X5.00005 Mechanism of the terahertz wave emission from intrinsic Josephson junctions of Bi$_2$Sr$_2$CaCu$_2$O$_8$, MASASHI TACHIKI, The University of Tokyo — We propose a mechanism for the strong emission of terahertz wave recently observed in current-biased mesa-shaped Bi$_2$Sr$_2$CaCu$_2$O$_8$ single crystals at Argonne National Laboratory. When the mesa width is approximately equal to or larger than the phase coherence length (c-axis), an external current is applied along the c-axis of the crystal. The modulating current is designed to result in a resonance excitation of cavity-mode of the transverse Josephson plasma in the voltage state. When the oscillating electric and magnetic fields of the excited plasma wave propagate in the direction opposite to incident wave, this effect of stimulated radiation may be used for amplification of electromagnetic waves. BSCCO crystal with modulated critical current and length several tens microns along the b-axis also provides high THz-radiation power from the ac-edges at discrete Josephson frequencies corresponding to the crystal thickness along the b-axis. The available power is potentially much larger, as there is evidence of stimulated radiation in this case is due to Fiske resonances and super-radiation regime. The powerful almost standing electromagnetic wave is excited inside the crystal in the resonance. This wave is homogeneous across the layers meaning that the oscillations are synchronized in all junctions in the stack. In this situation the synchronization of radiation in different junctions is enforced by both super-radiation regime and similar critical current profile in all junctions of the crystal.
9:12AM X6.00003 Electron tunneling in epitaxial magnetic tunnel junctions

XIAOQUANG ZHANG, Oak Ridge National Laboratory — The remarkable progress in the performance of tunneling magnetoresistance (TMR) junctions using MgO as the barrier layer, has confirmed the theoretical prediction of a very high TMR ratio from first-principles calculations [1,2]. The theoretical prediction was based on the understanding of the band filtering effect by a class of barrier materials, including ZnSe, and even vacuum, in addition to MgO, along particular crystalline orientations. The combination of the preferential filtering for the electrons with the $\Delta_3$ symmetry by the barrier layer, and the presence of the $\Delta_3$ band only in the majority spin channel of Fe, FeCo and Co electrodes, results in the high TMR ratio previously believed only achievable with half-metallic electrodes. Here we show that the agreement between the experiment and the first-principles theory goes beyond the TMR. The effects of barrier thickness, interface resonance states, and quantum confinement calculated from the first-principles for MgO based magnetic tunnel junctions are compared with experimental data. In addition to excellent agreement for each case, additional insights are obtained from the first-principles calculations that are otherwise not directly available from the experiments. We also discuss other candidate materials for high TMR junctions.

3 This research was conducted at the Center for Nanophase Materials Sciences, which is sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. Department of Energy.

9:48AM X6.00004 TMR-related effects in structures involving semiconductors

JEAN-MARIE GEORGE, Unité Mixte de Physique CNRS-Thales — The growth of semiconductor heterostructures incorporating ferromagnetic material is a challenge for today’s spintronics. We will report on GaMnAs/III-V and MnAs/III-V tunnel junctions that fulfill this condition. In the case of GaMnAs related junctions, the complexity of the transport mechanisms associated with spin-orbit coupled states make this material a powerful means for finding novel effects and provides new challenges for theoretical understandings. This includes tunnel magnetoresistance (TMR) across single and double barriers [1] and tunnel anisotropic magnetoresistance (TAMR). As an illustration, the resonant TAMR on a GaAs quantum well can be used as a probe of the GaMnAs valence band anisotropy [2]. In the case of MnAs, the necessary low temperature growth mode to avoid intermixing at the interfaces favors the insertion of As anti-site in the III-V spacer layer. We will show how the tunneling magnetoresistance is then modified and how the major role of the defects in the conduction can be taken into account. For this we have proposed an analytical model of spin-dependent resonant tunneling through a 3D assembly of localized states (spread out in energy and in space) in a barrier [3]. An inhomogeneous distribution of localized states leads to resonant tunneling magnetoresistance inversion and asymmetric bias dependence as evidenced with a set of experiments with MnAs/GaAs(7–10 nm)/MnAs tunnel junctions. By extension, we show the possibility of using such spectroscopic measurements to show the spin asymmetry of ferromagnetic electrodes sandwiching an inhomogeneous tunnel barrier.

10:24AM X6.00005 Influence of spin polarized current on superconductivity and spin transport in organic semiconductors

JAGADEESH MOODERA, MIT — Spin conserved tunneling from a ferromagnetic (FM) electrode through an insulating barrier with a superconductor as the spin detector, was discovered by Meservey and Teword three decades ago. This phenomenon of spin polarized tunneling has been successfully utilized to understand many aspects of magnetism and superconductivity. In recent years enormous success is seen in magnetic tunnel junctions both from the fundamental viewpoint as well as due to their application in information technology. In general, BCS superconductivity with Cooper pairs formed at the Fermi level with electrons of opposite spins is not compatible with ferromagnetism which have parallel spin configuration. The superconducting state can be influenced by injecting spin polarized current in a controlled manner by properly tailoring the interfacial transmissivity between a ferromagnet (F) and a superconductor (S), resulting in a large magnetoresistance (MR) of over 1100% for a F/I/S/F multilayer system (I - insulator) or even infinite MR can be achieved in epitaxial metallic systems. Due to the competition between ferromagnetism and superconductivity, the superconducting transition temperature ($T_C$) in the spin parallel configuration is shifted below that of the spin anti-parallel configuration. This $T_C$ shift can much larger than that predicted by theories. Oscillation in $T_C$ is also observed. The field is the spin transport properties in organic semiconductors (OSs), a least explored area. Because OSs are composed of mostly light elements (i.e. C, H, N, O) and thus have a weaker spin-orbit interaction, low hyperfine interactions, spin coherence lengths can be long in these materials. Large spin decay length was observed in amorphous Rubrene. Recent developments in electron spin polarized tunneling through ultrathin layers of the molecular organic semiconductors such as Alq3 and Rubrene will be discussed.

8:00AM X7.00001 Mott Transition, Antiferromagnetism, and d-wave Superconductivity in Two-Dimensional Organic Conductors and in Cuprates Using Cluster Dynamical Mean Field Theory

A.-M.S. TREMBLAY, Universite de Sherbrooke — The main features of the phase diagram of high-temperature superconducting cuprates are a Mott insulator at half-filling, a pseudogap at finite doping and, in the ground state, the competition between antiferromagnetism, d-wave superconductivity and possibly other inhomogeneous phases. In the layered organics of the $\kappa$-BEDT-T family, it is pressure instead of doping that is varied but the competing phases and the Mott insulating behavior are similar to the cuprates. Approaches that claim to explain d-wave superconductivity in the cuprates must also explain this phenomenon in all other related classes of compounds described by the Hubbard model. Using Cluster Dynamical Mean-Field theory, we show that the main features of both phase diagrams, cuprates and organics, can be understood from the one-band model with hopping parameters taken from band structure and interaction of the order of the bandwidth. We emphasize the case of the organics, studying the Mott transition, antiferromagnetism and superconductivity on the anisotropic triangular lattice. The Mott transition in the normal phase can be continuous or first order depending on the value of the frustrating hopping $t'/t$. A d-wave superconducting phase appears between an antiferromagnetic insulator and a metal for $t'/t = 0.3 - 0.7$, or between a nonmagnetic Mott insulator (spin liquid) and a metal for $t'/t \geq 0.8$, in agreement with experiments on layered organic conductors including $\kappa$-(ET)$_2$Cu$_2$(CN)$_3$. These phases are separated by a strong first order transition. The phase diagram gives much insight into the mechanism for d-wave superconductivity and on the question of the glue.

9:12AM X7.00003 Nodal/Antinodal Dichotomy and the Two Gaps of a Superconducting Doped Mott Insulator . MARCELLO CIVELLI, Institut Laue Langevin — Using Cellular Dynamical Mean Field Theory, implemented with exact diagonalization as impurity solver, we study the superconducting state of the hole-doped two-dimensional Hubbard model. We mainly focus on qualitative aspects which characterize the approach to the Mott transition. We will show that our formalism leads to a natural decomposition of the photoemission energy-gap into two components. A first gap, stemming from the anomalous self-energy, dominates near the nodes and decreases with decreasing doping. The second gap has an additional contribution from the normal self-energy, inherited from the normal-state pseudo-gap. It is dominant near the antinodes and increases as the Mott insulating phase is approached. This behavior of the one-particle gap is relevant in the light of recent experimental studies reporting the presence of two different energy scales in the nodal and antinodal regions of high-temperature superconductors.

9:48AM X7.00004 DCA study of magnetic mediated superconductivity in the Hubbard model1, MARK JARRELL2, University of Cincinnati — The Dynamical Cluster Approximation (DCA) with quantum Monte Carlo as a cluster solver is used to study pairing in the two dimensional Hubbard model. The DCA adds non-local corrections to dynamical mean field theory by mapping the lattice onto a self-consistently embedded periodic cluster. The qualitative features of the cuprate phase diagram are captured by the DCA with a 2x2 cluster, which provides a mean field solution of the model. With increasing cluster size, the results are found to converge and display a finite d-wave transition temperature, establishing the presence of superconductivity in the model. A decomposition of the pairing interaction into its cross channels reveals that pairing is mediated by S=1 spin fluctuations. A simple renormalized spin fluctuation model is found to capture many of the properties of pairing and the spectra, including the high-energy kink waterfall structure and the structure of the leading order parameter. However, it fails to capture realistic features including long-ranged hopping, phonons and the pseudogap. Phonons, in particular, are found to enhance the pairing interaction by enhancing antiferromagnetism. Despite this, superconductivity is suppressed by local (Holstein, Breathing and Buckling) phonon modes through the formation of polaron which dramatically reduce the particle mobility.

10:24AM X7.00005 DMFT calculations of materials properties using the continuous time QMC method1, CHRIS MARIANELLI, Lawrence Livermore National Laboratory — The combination of DFT with DMFT has proven to be an instrumental method for describing realistic strongly correlated electron systems. In essence, DMFT treats the strongly correlated electrons near the Fermi surface while DFT treats the electrons which are less correlated. DMFT effectively maps the intractable lattice many-body problem onto a tractable impurity many-body problem. The DMFT impurity problem must be solved using numerical methods or approximate analytical methods, and this is the bottleneck of the entire procedure. Continuous time QMC has recently emerged as a dominant method to solve the DMFT impurity problem. We present applications of DFT+DMFT(QTMC-atomic-limit) to the cobaltates and Pu. In Pu, a variety of physical properties are calculated such as the Photoemission spectra, magnetic susceptibility, and the heat capacity. These physical properties are probed as a function of temperature and volume, and compared with experimental measurements. Additionally, we demonstrate the effect of the full on-site exchange interaction on the physical observables. In the cobaltates, the Fermi surface and heat capacity are calculated for Na0.3CoO2. We demonstrate that the topology of the Fermi surface depends sensitively upon the bare Hamiltonian. It is shown that consistent agreement with heat capacity measurements and ARPES experiments can only be achieved if the ω0 satellite pockets are not present at the Fermi surface.

Session X8 DFD: Focus Session: Wormlike Micellar Fluids and Vesicles Morial Convention Center R06

8:00AM X8.00001 Rheo-NMR of shear banded flow in wormlike micelles , PAUL CALLAGHAN, Victoria University of Wellington — Rheo-NMR gives access to detailed information about the flow field generated by the device used to induce deformational flow. It also provides information about colloidal or molecular organisation and dynamics, under conditions of flow. In particular, NMR offers the possibility of measuring nuclear spin relaxation times and molecular self-diffusion coefficients, sensitive respectively to molecular brownian motions and their restrictions due to local structure. Furthermore, through the use of orientation-dependent terms in the spin interactions, such as the quadrupole or dipolar interactions, NMR permits the measurement of molecular order parameters. When combined with imaging methods, NMR in principle allows such measurements to be spatially localized, often with resolution down to a few 10s of microns In the study of shear banding phenomena in wormlike micelles, Rheo-NMR has proven of especial value, not only indicating the clear existence of shear bands, but also that they are associated with fluctuations, and sometimes, with molecular alignment. The subtlety of the correspondence (or lack of correspondence) between birefringence effects and shear banded flow has also been revealed. Recent measurements of shear-banded flow under Couette flow of the micellar system 10% w/v cetylpyridinium chloride and sodium salicylate (CPyCl/NaSal) molar ratio 2:1 in 0.5 M NaCl in 1H2O, indicate that shear banding fluctuations are consistent with the shear stress fluctuations observed in rheological measurements. Furthermore we find a coupling between flow fluctuations in the gradient and vorticity directions. Using 2H NMR spectroscopy on a deuterated probe molecule (n-decane) in the wormlike micellar interior, direct measurement of the shear-induced nematic phase transition is reported. More recently we have used Rheo-NMR to investigate the flow and alignment properties of worm-like micelles formed by a 5% w/v solution of the BASF difunctional block copolymer non-ionic surfactant, Pluronic P105 in water along with 4.3% w/v 1-phenylethanol-d5. A variety of shear-banding and alignment behaviours are observed, along with both stable and fluctuating flows.
we observe a tracer depletion in the high-shear phase, which may be to high normal forces.

Newtonian fluid. The dynamic microstructure of the fluid gives rise to a rich diversity of hydrodynamic phenomena. Generally, these fluids are studied in a low concentration regime (0-20 mM of surfactant). In this talk, we will discuss recent rheological and acoustic measurements of highly concentrated wormlike micellar fluids with concentrations of 50 - 400 mM cetyltrimethylammonium bromide (CTAB) and 30 - 240 mM (respectively) sodium salicylate (NaSAL) in the temperature range of 22 - 45 Celsius. In 200 mM CTAB fluids, the activation energy, derived from stress relaxation time measurements, exhibit a discontinuous shift from about 60 kT below 33 Celsius to about 40 kT above. Speed of sound and acoustic attenuation measurements were obtained by a broadband Fourier spectroscopic method using ultrasonic waves between 2 and 8 MHz. Each of the concentrations measured exhibits an peak in the acoustic attenuation between 33 and 38 Celsius. The speed of sound increases monotonically over 22 - 40 Celsius, very similar to pure water in both magnitude and temperature dependence. Measurement attenuations as a function of acoustic power using high intensity focused ultrasound will also be discussed.

For TEA fractions greater than 30 mM. For TEA fractions greater than 55 mM, threadlike micelle structures are present. From the SANS data we

In contrast to ‘inert’ polymeric networks, wormlike micelles continuously break and reform leading to an additional relaxation mechanism and the name ‘living polymers’. Observations in both classes of entangled fluids have shown that steady and transient shearing flows of these solutions exhibit spatial inhomogeneities such as ‘shear-bands’ at sufficiently large applied strains. In the present work, we investigate the dynamical response of a class of two-species elastic network models which can capture, in a self-consistent manner, the creation and destruction of elastically-active network segments, as well as diffusive coupling between the microstructural conformations and the local state of stress in regions with large spatial gradients of local deformation. These models incorporate a discrete version of the micellar breakage and reforming dynamics originally proposed by Cates and capture, at least qualitatively, non-affine tube deformation and chain disentanglement. The ‘flow curves’ of stress and apparent shear rate resulting from an assumption of homogeneous deformation is non-monotonic and linear stability analysis shows that the region of non-monotonic response is unstable. Calculation of the full inhomogeneous flow field results in localized shear bands that grow linearly in extent across the gap as the apparent shear rate increases. Time-dependent calculations in step strain, large amplitude oscillatory shear (LAOS) and in start up of steady shear flow show that the velocity profile in the gap and the total stress measured at the bounding surfaces are coupled and evolve in a complex non-monotonic manner as the shear bands develop and propagate.

9:48AM X8.00006 Investigating the structures and phase behavior of anionic perfluorinated surfactant using SANS, GARFIELD WARREN, DOBRIN BOSSEV, Indiana University — We have examined the structures formed by mixtures of tetraethylammonium perfluorooctylsulfonate (TEAFOS) and lithium perfluorooctylsulfonate (LiFOS) in water using small angle neutron scattering (SANS). SANS is an ideal method to characterize the morphology of such soft materials because the characteristic length scale of the surfactant structures and the possibility to apply the contrast variation technique. Results were obtained for mixtures at a constant surfactant concentration of 100 mM and different TEA/Li ratios at a temperature of 30 °C. SANS curves were obtained either from the fluorinated micellar core or from the hydrogenated counterion atmosphere surrounding the micelles applying contrast matching. A transitional change in shape from spherical to prolate micelles was observed for TEA fractions greater than 30 mM. For TEA fractions greater than 55 mM, threadlike micelle structures are present. From the SANS data we are able to correlate the counterion binding of the two different species to the shape and size of the micellar structure and confirm the role that the counterion environment plays in macroscopic rheological properties.

10:00AM X8.00007 Fabrication of phospholipid vesicles from double emulsions in microfluidics, INSUN YOON, Mount Holyoke College, ANDERSON H. SHUM, DAEYON LEE, DAVID A. WEITZ, School of Engineering and Applied Sciences, Harvard University — Phospholipids self-assemble into lipid vesicles also known as liposomes. The formation of liposomes via conventional techniques such as electroformation has been studied extensively. However, the liposomes formed through electroformation are polydisperse and have low encapsulation efficiency. We present a new method to fabricate monodisperse phospholipid vesicles with high encapsulation efficiency from water-in-oil-in-water double emulsions. We generate phospholipid stabilized monodisperse double emulsions using a glass microcapillary device. This process allows efficient encapsulation within the inner aqueous drop. The middle oil phase is a volatile organic solvent in which phospholipids are dissolved. As the organic solvent evaporates, phospholipids self-organize into vesicles. This technique is versatile in the choice of phospholipids and we have generated vesicles from different types of phospholipids.
We find that although these dynamics are difficult to observe in traps, it is possible to observe them in optical lattices; particularly they can survive in $F=2$ optical lattices. These dynamics have unique dependence on quadratic Zeeman fields and potential depth in optical lattices. Quantum fluctuation-controlled spin dynamics are sensible to the variation of fluctuations and the potential induced by quantum fluctuations can be tuned by a biaxial spin nematic. Recently we also study coherent spin dynamics mainly driven by quantum fluctuations. Unlike the usual mean-field driven dynamics, hyperfine spin $F=2$ dynamics of hyperfine spin $F=2$ Cold Atoms.

10:12AM X8.00008 Concentration dependence of dynamics of a droplet microemulsion, MICHIHIRO NAGAO, Indiana University, HIDEKI SETO, Kyoto University, Japan — We will present a concentration dependence of dynamics of a spherical droplet microemulsion, consisting of aerosol-OT (AOT), as a surfactant, water, and decane. This mixture forms spherical microemulsion in a wide range of concentration. With keeping water to surfactant ratio constant, concentration of water plus surfactant was changed. The static structure of this system has been determined by small-angle neutron scattering (SANS) using the relative form factor method in the droplet concentration range from 5 to 75 % [1].

Dynamics of droplet microemulsions have been determined using neutron spin echo technique, which is suitable to measure dynamics of systems in nanometer and nanosecond scales. We measured dynamics of the system at 5, 30, and 60 % of droplet concentration. Using analogous data reduction procedure to SANS, contribution of shape fluctuations is decoupled from structure fluctuations. Concentration dependence of shape fluctuations and structure fluctuations will be discussed. [1] M. Nagao et al., Phys. Rev. E 75, 061401 (2007).

10:24AM X8.00009 Dielectrophoresis of Functional Phospholipid Vesicles, VICTORIA FROUDE, YINGXI ELAINE ZHU, University of Notre Dame — Recently, there has been an emerging interest in using AC-dielectrophoresis (DEP) to transport and assemble phospholipid vesicles (liposomes) and nanoparticles to form functional bio-assembly where the underlying charge polarization mechanism of colloids in AC fields strongly depends on nano-scaled surface charge. In this work, we study liposomes segregation and aggregation in the presence of nanocolloids and salts in which the biological functionality of liposomes is augmented by the physical functionality of inorganic coating and particles. Liposomes, synthesized by sonication with L,2-Dioleoyl-sn-Glycero-3-Phosphate (DOPA), are manipulated at varied AC-field frequencies across fabricated micro-electrodes in a quadrupole configuration on glass. We observe the co-assembly of liposome and opposite-charged nanocolloids by confocal microscopy and SEM, where the smaller nanocolloids are captured in between liposome junctions to form stabilized composite vesicles at several distinct frequencies. We observe a strong dependence of the liposome DEP mobility on the number of nanoparticles present in suspension and propose a new mechanism based on charge segregation and charged nanocolloid entainment in the double layer.

10:36AM X8.00010 High-throughput Microsphere Encapsulation in Emulsion Droplets by Electrospray, WUEN-SHIU CHEN, KENG-HUI LIN, Institute of Physics, Academia Sinica, Taipei, Taiwan — Colloidal clusters generated through emulsion encapsulation and evaporation open up the possibilities for assembly of complex crystal structures. Encapsulation in monodisperse emulsion droplets facilitates higher yield of identical clusters as building blocks. We utilize electrospray in an oil-in-water co-flow fluidic device to generate uniform emulsion droplets in micron size and at the rate of ten thousand droplets per second. We investigate the effect of applied voltage, flow rate and the conductivity of liquid on the droplet formation. We further show that incorporation of microspheres into the inner oil fluid enables the encapsulation and formation of clusters.

8:00AM X9.00001 Amplification of quantum fluctuations across a quantum phase transition in a spinor BEC, SABRINA LESLIE, JENNIE GUZMAN, MUKUND VENGALATTORE, DAN STAMPER-KURN, Department of Physics, UC Berkeley — We study the amplification of quantum fluctuations in a $^{87}$Rb spinor BEC that is rapidly quenched from its paramagnetic phase to its ferromagnetic phase. By characterizing the onset of spontaneous ferromagnetism and the amplification properties of the spinor condensate, we probe the initial quantum fluctuations from which the resulting structures evolve. To characterize the spinor condensate as an amplifier, we temporally and spatially resolve the evolution of the vector magnetization profile as a function of the end point of the quench. In particular, we describe the formation of transversely magnetized domains and vortices as a function of the end point.

8:12AM X9.00002 Equilibrium phases of a dipolar spinor Bose gas, MUKUND VENGALATTORE, S. R. LESLIE, J. GUZMAN, C. SMALLWOOD, D. M. STAMPER-KURN, University of California, Berkeley — We investigate the effect of magnetic dipole interactions in determining the properties of $F = 1$ spinor Bose gases of $^{87}$Rb. Due to the competition between the local ferromagnetic interaction and the long-range, anisotropic dipole interaction, we observe the spontaneous formation of modulated spin domains that exhibit crystalline order. The formation of this modulated spin texture is accompanied by the creation of spin vortices in this dipolar superfluid. We observe this modulated phase both as an equilibrium phenomenon by cooling an incoherent thermal spinor gas, and as a result of a dynamical instability in a pure transversely magnetized spinor condensate. We clarify the crucial role played by dipolar interactions in the creation of the crystalline phase in the spinor condensate and study the finite temperature phase diagram of this dipolar quantum fluid.

8:24AM X9.00003 Dynamical instability of the XY spiral state of ferromagnetic condensates, ROBERT CHERNG, VLADIMIR GRITSEV, Harvard University, DAN STAMPER-KURN, University of California, Berkeley, EUGENE DEMLER, Harvard University — We calculate the spectrum of collective excitations of the XY spiral state prepared adiabatically or suddenly from a uniform ferromagnetic $F = 1$ condensate. For spiral wavevectors past a critical value, spin wave excitation energies become imaginary indicating a dynamical instability. We construct phase diagrams as functions of spiral wavevector and quadratic Zeeman energy.

8:36AM X9.00004 Spin Nematics and Quantum Fluctuation-Controlled Coherent Spin Dynamics of Hyperfine Spin $F=2$ Cold Atoms, JUN LIANG SONG, GORDON SEMENOFF, FEI ZHOU, The University of British Columbia — We show that quantum fluctuations lift the accidental continuous degeneracy that was found in the mean field analysis of spin nematic states of hyperfine spin $F=2$ $^{87}$Rb. Two distinct spin nematic states with higher symmetries are selected out depending on scattering lengths: a uniaxial spin nematic and a biaxial spin nematic. Recently we also study coherent spin dynamics mainly driven by quantum fluctuations. Unlike the usual mean-field driven dynamics, quantum fluctuation-controlled spin dynamics are sensible to the variation of fluctuations and the potential induced by quantum fluctuations can be tuned by four or five orders of magnitude in optical lattices. These dynamics have unique dependence on quadratic Zeeman fields and potential depth in optical lattices. We find that although these dynamics are difficult to observe in traps, it is possible to observe them in optical lattices; particularly they can survive in $F=2$ $^{87}$Rb condensates with a relatively short life time.

This work is supported by the office of the Dean of Science, University of British Columbia, NSERC(Canada), Canadian Institute for Advanced Research, and the Alfred P. Sloan foundation.
8:48AM X9.00005 Nematic order by disorder in spin-2 BECs. RYAN BARNETT, Caltech, ARI TURNER, EUGENE DEMLER, Harvard, ASHVIN VISHWANATH, Berkeley — The effect of quantum and thermal fluctuations on the phase diagram of spin-2 BECs is examined. They are found to play an important role in the nematic part of the phase diagram, where a mean-field treatment of two-body interactions is unable to lift the accidental degeneracy between nematic states. Quantum and thermal fluctuations resolve this degeneracy, selecting the uniaxial nematic state, for scattering lengths a₁ greater than a₂, and the square biaxial nematic state for a₂ less than a₁. Paradoxically, the fluctuation induced order is stronger at higher temperatures, for a range of temperatures below T_c. For the experimentally relevant cases of spin-2 ⁸⁷Rb and ⁴⁰K, we argue that such fluctuations could successfully compete against other effects like the quadratic Zeeman field, and stabilize the uniaxial phase for experimentally realistic conditions. A continuous transition of the Ising type from uniaxial to square biaxial order is predicted on raising the magnetic field. These systems present a promising experimental opportunity to realize the ‘order by disorder’ phenomenon.

9:00AM X9.00006 ABSTRACT WITHDRAWN —

9:12AM X9.00007 Ultracold dipolar gases — challenge for Experiments and Theory. MIKHAIL BARANOV, Universiteit van Amsterdam — Recent experimental progress in trapping and cooling of molecular gases boosts an interest to the interdisciplinary field of quantum gases with dominant dipole-dipole interactions. An unprecedented level of experimental control together with specific physical properties of the dipole-dipole interaction provides a unique possibility to find new physical phenomena and practical applications. In this talk, recent achievements in studies of ultracold dipolar gases, both fermionic and bosonic, are presented. We focus our attention on many-body properties of such systems and discuss how the characteristic features of the dipole-dipole interaction: long range and anisotropy, affect their collective behavior and result in novel macroscopic quantum phenomena.

9:48AM X9.00008 Spin-orbit interaction effects in cold atomic systems. TUDOR STANESCU, VICTOR GALITSKI, University of Maryland — We propose a scheme for the realization of spin-orbit interaction in cold atomic systems. We show that, in a system of trapped multi-level atoms moving in the presence of spatially modulated laser fields, the atom-laser interaction generates an emergent pseudo-spin-1/2 degree of freedom that couples to the momentum, leading to an effective spin-orbit interaction. The parameters of the spin-orbit coupling can be modified by controlling the laser fields. Atomic spin-orbit interacting systems open the possibility of studying new effects that are not usually considered, or not accessible in solid state systems. We consider explicitly the problem of strongly non-equilibrium spin dynamics by studying the evolution of an initially spin-polarized Fermi gas in a two-dimensional harmonic trap. We derive the non-equilibrium behavior of the polarization and show that it is characterized by periodic echoes with a frequency equal to the trapping frequency. We also consider a system of multi-level Bose atoms. In the presence of spin-orbit coupling, the single-particle band structure is generally anisotropic and contains two minima at finite momenta. At low temperatures, the bosons condense into these states, leading to a new type of Bose-Einstein condensate.

10:00AM X9.00009 Dipolar bosons in an array of one-dimensional tubes¹. JULIA S. MEYER, The Ohio State University, CORINNA KOLLATH, Centre de Physique Theorique, Ecole Polytechnique, THIERRY GIAMARCHI, University of Geneva, DPMC-MaNEP — Ultra-cold atomic and molecular gases offer a unique possibility to realize a range of novel interacting many-body systems. While in solid state systems electrons interact via the long-range Coulomb interactions, the interactions in cold gases are essentially local. However, the use of dipolar atoms or molecules allows one to surmount this limitation. We investigate bosonic atoms or molecules interacting via dipolar interactions in a planar array of one-dimensional tubes. In the situation where the dipoles are oriented perpendicular to the tubes by an external field, various quantum phases can be realized by varying the strength of the interactions and the orientation of the dipoles with respect to the plane of the array. We find a ‘sliding Luttinger liquid’ phase in which the tubes remain Luttinger liquids and two-dimensional charge density wave ordered phases with different kinds of order. In particular, a stripe phase in which the bosons in different tubes are aligned as well as a checkerboard phase occur.

10:12AM X9.00010 Phase space deformation of dipolar Fermi gas². HAN PU, Rice University, TAKAHIKO MIYAKAWA, Tokyo University of Science, TAKAARI SOGO, Kyoto University, HONG LU, Rice University — We consider a system of quantum degenerate spin polarized fermions in a harmonic trap at zero temperature, interacting via dipole-dipole forces. Under the semi-classical framework, we introduce a variational Wigner distribution function to characterize the deformation and compression of the Fermi gas in phase space and use it to examine the stability of the system. We emphasize the important roles played by the Fock exchange term of the dipolar interaction which results in a non-spherical Fermi surface.

10:24AM X9.00011 ABSTRACT WITHDRAWN —

10:36AM X9.00012 Towards Microwave Trapping of Cold Polar Molecules¹. Y.-C. CHEN, C.-C. HSIEH, T.-S. KU, P. DWIVEDI, R. HO, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, Taiwan — We describe our progress on production and trapping of cold SrF molecules. Specifically, we generate the SrF molecules by laser ablation of its solid precursor. We use helium buffer gas cooling as the first cooling stage to cool molecules down to a few Kelvin. To guide the generated cold molecules to ultrahigh vacuum region for further spectroscopic studies and trapping, we are also developing the electrostatic guiding of molecules. The experimental results will be presented. For a second-stage cooling in order to cool molecules down to ultracold regime, we plan to perform the sympathetic cooling of molecules with ultracold cesium atoms in a microwave trap. We have succeeded to build a microwave trap based on a high-power microwave Fabry-Perot resonator. We can couple 1.4 kW power into the cavity with a coupling efficiency more than 80% under locked conditions. The trap depth for the absolute ground state of SrF molecules is 300mK. The design and performance as well as future improvements will be discussed in details.

Friday, March 14, 2008 8:00AM - 11:00AM —
Session X10 DCMP: Superconducting Devices and Applications  Morial Convention Center RO8
8:00AM X10.00001 A tunable parametric amplifier based on a SQUID array resonator with nearly quantum-limited sensitivity, MANUEL CASTELLanos-BELTRAN, KONRAD LEHNERT, JILA, NIST and the University of Colorado, and the Department of Physics, University of Colorado, Boulder, Colorado 0309-0440, USA. — Recently, there has been an increasing number of compelling applications for quantum-limited amplifiers at microwave frequencies. These include the readout of superconducting qubits and ultrasensitive measurements of the motion of nanomechanical beams. Although quantum-limited microwave amplifiers have already been demonstrated, they have suffered from both limited bandwidth and dynamic range. We create a Josephson parametric amplifier from a transmission line resonator whose inner conductor is made from a series SQUID array. By changing the magnetic flux through the SQUID loops, we are able to adjust the circuit’s resonance frequency and, consequently, the center of the amplified band over an octave (4-8 GHz). This tunability circumvents some of the problems related to a limited bandwidth. We will discuss recent results that include demonstration of large gain (30 dB), nearly quantum-limited sensitivity and noise squeezing.

8:12AM X10.00002 Parametric amplification in a DC SQUID amplifier at 1.7 GHz, JOSE AUGMENTADO, LAFE SPIETZ, K.D. IRWIN, NIST — At NIST we have recently developed a DC SQUID-based microwave amplifier employing a resonant input circuit. In conventional operation this amplifier can be operated in a linear, phase-preserving mode. However, it can also be operated as a degenerate parametric amplifier with the SQUID functioning as a first stage amplifier. We will discuss the performance of this hybrid operation and the possibility of generating squeezed states in this system.

8:24AM X10.00003 Progress at NIST on DC SQUID Microwave Amplifiers, LAFE SPIETZ, K. D. IRWIN, J. AUGMENTADO, NIST — We report on the development at NIST of microwave amplifiers using DC SQUIDs. Our design approach is to use small SQUIDs which can be modeled as lumped element circuits, thus separating the design process for the SQUID from that of the microwave impedance transformers. We present our model of the impedance, gain and noise of such a SQUID and measurements of the characteristics of our amplifiers.

8:36AM X10.00004 Input Impedance of the Microstrip SQUID Amplifier, DARIN KINION, Lawrence Livermore National Laboratory, JOHN CLARKE, Physics Department, University of California Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — We present measurements of the complex scattering parameters of microstrip SQUID amplifiers (MSA) cooled to 4.2 K. The input of the MSA is a microstrip transmission line in the shape of a square spiral coil surrounding the hole in the SQUID washer that serves as the ground plane. The input impedance is found by reversing the scattering parameter (S11) and is described well by a low-loss transmission line model. We map the low-loss transmission line model into an equivalent parallel RLC circuit in which a resistance R, inductance L, and capacitance C are calculated from the resonant frequency, characteristic impedance and attenuation factor. Using this equivalent RLC circuit, we model the MSA and input network with a lumped circuit model that accurately predicts the observed gain given by the forward scattering parameter (S21). We will summarize results for different coil geometries and terminations as well as SQUID bias conditions. A portion of this work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory in part under Contract W-7405-Eng-48 and in part under Contract DE-AC52-07NA27344 and by Lawrence Berkeley National Laboratory under Contract No. DE-AC02-05CH11231.

8:48AM X10.00005 In vivo T1 maps at fields from 0.001 to 150 mT with SQUID based MRI, M. HATRIDGE, S. BUSCH, T. WONG, M. MOESSLE, A. PINES, J. CLARKE, UC Berkeley/LBNL — High field magnetic resonance imaging (MRI) uses differences in the longitudinal relaxation times (T1) of protons to differentiate tissue types. Using phantoms and ex vivo human tissue, we have demonstrated that T1 contrast at low fields can be much greater than that at high fields, suggesting that one can, for example, distinguish tumors from healthy tissue without the use of contrast agents. Our MRI system polarizes protons at fields up to 150 mT using a water-cooled electromagnet. Subsequently, we ramp down the polarizing field and measure the proton nuclear magnetic resonance at typically 0.132 mT in the presence of three-dimensional field gradients using a SQUID coupled to an untuned, second-derivative gradiometer. Our system is capable of imaging the human arm in vivo with a resolution of 2x2x10 mm3. By switching the field to an intermediate field value for a variable time, we can obtain T1 maps at fields between 0.001 and 150 mT. We present in vivo T1 dispersion curves in the same range of magnetic fields for several types of tissue in the human arm. Work supported by USDOE.

9:00AM X10.00006 Fast, single-photon detection with a superconducting Nb nanowire, ANTHONY ANNUNZIATA, ANDREW MACK, JOEL CHUDOW, DANIEL SANTAVICCA, Yale University, AVIAD FRYDMAN, Bar Ilan University, MICHAEL ROOKS, IBM - Watson Research Center, LUIGI FRUNZIO, DANIEL PROBER, Yale University — We investigate the performance of a superconducting nanowire detector made from an ultra-thin, pure Nb film. Single photon counting performance is shown with good quantum efficiency at 470 nm. We report the reset time, jitter, and dark count rate for single photon detection. We compare these results to reports for NbN detectors. The Nb detector has a faster reset time for the same size active area, with similar quantum efficiency. These detectors have a variety of potential applications ranging from VLSI circuit diagnostics to quantum communication and single molecule spectroscopy. This work is supported by NSF – EPDT and IBM research.

9:12AM X10.00007 Local superfluid densities probed via current-induced superconducting phase gradients, ALEXEY BEZRYADIN, University of Illinois at Urbana-Champaign, DAVID HOPKINS, LAM research, DAVID PEKKER, Harvard University, TZU-CHIEH WEI, University of Waterloo, PAUL GOLDBART, University of Illinois at Urbana-Champaign — We have developed a superconducting phase gradiometer consisting of two parallel DNA-templated nanowires connecting two thin-film leads [1,2,3]. We have ramped the cross current flowing perpendicular to the nanowires, and observed oscillations in the lead-to-lead resistance due to cross-current-induced phase differences. By using this gradiometer we have measured the temperature- and magnetic-field dependence of the superfluid density, and observed an amplification of phase gradients caused by elastic vortex displacements. We examine our data in light of Miller-Bardeen theory of dirty superconductors and a microscale version of Campbell’s model of field penetration.

This work supported by DOE Grants No.DEFG02-07ER46453 and No. DEFG02-91ER45439 and by NSF DMR Grant No. 0134770.

9:24AM X10.00008 Entanglement of Two Josephson Vortex Quantum Bits in Resonant Cavity, ISAAC O’BRYANT, RAMESH P. DHUNGANÀ, JU H. KIM, University of North Dakota — We investigate the entanglement between two Josephson vortex qubits (JQV’s) in a resonant cavity. A JQV may be fabricated using two closely spaced microresistor sites in an insulator layer of a long Josephson junction. The phase dynamics of a Josephson vortex (or fluxon) may be described using the perturbed sine-Gordon equation. In a uniform electromagnetic field, it is found that the resonant cavity interacts with fluxons only when they are trapped on a microresistor. The effect of a resonant cavity on the two JQV’s may be represented as a deformation of the two-qubit potential function. We examine the effects of resonant cavity and magnetic induction on the potential for two non-interacting JQV’s. The deformation of the potential due to the resonant cavity yields a significant increase in the two-fluxon tunneling compared to the single-fluxon tunneling, indicating that entanglement between the two JQV’s is significantly increased. We compute the concurrence to estimate how the entanglement is affected by the magnetic induction effect and the coupling between the fluxons and the resonant cavity.
9:36AM X10.00009 Death of entanglement of two Josephson vortex qubit due to the dissipation effect, RAMESH DHUNGANA, ISAAC O'BRYANT, JU KIM, University of North Dakota — We investigate the effects of the dissipation on the two entangled Josephson vortex qubits (i.e. JVQ) using spin-boson model. It has been suggested that the decoherence time for a JVQ can be longer than the time for which it can be measured because it couples only weakly to the sources of decoherence. The entanglement of two JVQs due to the magnetic induction effect between two long Josephson junctions and their coupling to a single mode resonant cavity may be destroyed due to the same source of decoherence, which are present in the environment. We consider the decoherence effect on the JVQ system by using a dissipative thermal bath. We estimate its effect on entanglement, which can be measured in terms of concurrence, to show that the entanglement may die down quickly due to the decoherence once. We compare the entanglement survival of two JVQs in the dissipative environment with the decoherence time for a single JVQ qubit and discuss its effect on the two qubit operation.

9:48AM X10.00010 Probing Temperature Dependent Noise in Flux Qubits via Macroscopic Resonant Tunneling, A.J. BERKLEY, R. HARRIS, M.W. JOHNSON, J. JOHANSSON, P. BUNYK, S. GOVOROV, M.C. THOM, S. UCHAarkin, C.J.S. TRUINcK, M.H.S. AMIN, D-Wave Systems Inc. — 100-4401 still Creek Dr., Burnaby, BC V5C 6G9, Canada, S. HAN, Department of Physics and Astronomy, University of Kansas, Lawrence KS, USA, B. BUMBLE, A. FUNG, A. KAUL, A. KLEINsasser. Jet Propulsion Laboratory, California Institute of Technology, Pasadena CA, USA, D.V. AVERIN, Department of Physics and Astronomy, SUNY Stony Brook, Stony Brook NY, USA — Macroscopic resonant tunneling between the two lowest lying states of a bistable RF-SQUID is used to characterize flux noise in a potential qubit. Detailed measurements of incoherent decay rates as a function of flux bias revealed that the Gaussian shaped tunneling rate is not peaked at the resonance point, but is shifted to a flux bias at which the internal well is higher than the target well. This observation indicates that the dominant low frequency (1/f) flux noise in this device is quantum mechanical in nature. The r.m.s. amplitude of the noise, which is proportional to decoherence rate 1/T_2, was observed to be weakly dependent on temperature below 70 mK.

10:00AM X10.00011 Simulation of a YBCO Superconducting Quantum Interference Filter, STEPHEN M. WU, SHANE A. CYBART, JOHN CLARKE, R.C. DYNES, Physics Department, University of California, Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory — A Superconducting Quantum Interference Filter (SQUIF) consists of a serial or parallel combination of SQUIDS of varying area that at constant current bias produces a sharp voltage peak at zero magnetic field. We simulated a series array of 300 SQUIDS to calculate the voltage response versus applied magnetic field. We chose representative values of the junction critical current I_c and resistance R_N for YBCO Josephson junctions. We varied the areas to maximize the sharpness and height of the voltage peak. We used the results of the simulation to design a SQUIF that we fabricated and tested. The measured voltage response of the device was smaller than the predictions of the model. The agreement was significantly improved by including the effects of the geometric inductances of the SQUID loops and the Fraunhofer diffraction pattern of the individual junctions, both of which reduced the predicted amplitude of the SIF response. It is likely that the remaining discrepancies are due partly to random variations in I_c and R_N in the experimental device, which we shall include in future simulations, and partly to the effects of thermal noise. This work was supported by AFSOR.

10:12AM X10.00012 Measurements of a YBCO superconducting quantum interference filter with planar ion-damaged Josephson junctions, SHANE A. CYBART, S. WU, J. SIDDIOI, JOHN CLARKE, R.C. DYNES, Department of Physics, University of California Berkeley and Material Science Division, Lawrence Berkeley National Laboratory — We have fabricated a superconducting quantum interference filter (SQUIF) containing 300 SQUIDS connected in series. Loops in a YBCO film were patterned using photolithography and argon ion milling. The Josephson junctions were formed with ion bombardment through 30 nm wide slits that were patterned with electron beam lithography and reactive ion etching of a 25 nm germanium / 800 nm photoresist mask. The ion damage lowered the Tc of the 30 nm unmasked region resulting in SS's junctions, where supercondconductor S has a Tc of 85 K, and S' of 75 K. The IcRn product for individual junctions was determined to be 0.02 mV from current-voltage characteristics measured at 73K. Voltage versus magnetic field curves were measured for different static bias currents. They show a dip at zero field which increases with increasing bias up to a saturation value of 2 mV. The maximum transfer coefficient was 17 mV/mT. Noise properties and linearity measurements will be presented. This work was supported by AFOSR, and by DOE through the LBLN Molecular Foundry.

10:24AM X10.00013 Fabrication and evaluation of the superconducting d-dot device manufactured with the Y_{0.9}La_{0.1}Ba_{1.9}Cu_{3}O_{y} thin film by a DC Sputtering method, MASAHIDE NISHIYAMA, Osaka Pref. Univ. & JST-CREST, HIROAKI SATO, Osaka Pref. Univ., MASUO YAMAMOTO, Osaka Pref. Univ. & JST-CREST, SEIJI ADACHI, HIRONORI WAKANA, KEICHII TANABE, SRL-ISTEC, TAKAKAZU ISHIDA, Osaka Pref. Univ. & JST-CREST — The d-dot device is composed of a square shaped d-wave superconductor buried into a s-wave superconductor thin film. The internal phase difference at neighboring square side junction causes a half-quantum-flux at each corner of square of d-wave superconductor. We have developed the method for preparing the d-dot with YBCO thin film by PLD method previously. In the present work, we employed a DC sputtered Y_{0.9}La_{0.1}Ba_{1.9}Cu_{3}O_{y} thin film with ramp edge, which is a well-established standard process for fabricating high-T_{c} single flux quantum (SFQ) device of SRL-ISTEC. Evaluations of this d-dot device are performed by I-V and R-T measurements. The magnetic flux structure has been investigated by a scanning SQUID microscope.

10:36AM X10.00014 High frequency flux sampling SQUID microscope, CONSTANTINE VLHACOS, C.NAM, Department of Electrical and Computer Engineering, University of Maryland College Park and the Laboratory for Physical Sciences, JOHN MATTHEWS, Physics Department, University of North Carolina — We have fabricated a high frequency flux sampling SQUID microscope. This device is based on a high-T_{c} superconducting thin film Y_{0.9}La_{0.1}Ba_{1.9}Cu_{3}O_{y}, which is grown on a sapphire substrate. The SQUID is a single flux quantum device which is fabricated using a standard process for high-T_{c} thin film technology. The SQUID is a single flux quantum device which is fabricated using a standard process for high-T_{c} thin film technology. The SQUID is a single flux quantum device which is fabricated using a standard process for high-T_{c} thin film technology.

10:48AM X10.00015 Scanning Tunneling Microscopy Studies of AlN Tunnel Barriers, Y. LI, Cornell, J. READ, H. TSENG, R. BUHRMAN — Typical Josephson junctions (JJs) utilize alumina (AlO_{x}) tunnel barriers due primarily to the reliable thermal oxidation procedure that yield high quality Nb-Al-AlO_{x}-Nb JJs in the low and moderate (≤ 10^{2} A/cm²) critical current density (J_{c}) regime[1]. However, AlN provides the possibility of forming ultra-thin barriers with fewer defects, and hence lower sub-gap leakage currents, and thus could improve device performance in the high J_{c} regime [2-4]. We present results from an X-ray photoelectron spectroscopy (XPS) and scanning tunneling spectroscopy (STS) study of thin AlN layers on Nb formed by reactive radio frequency (rf) sputtering from an AlN target in a mixture of Ar and N gases. The XPS spectra indicates that O is generally incorporated into the nitride layer during growth in high and near-ultra-high vacuum, thus forming AlO_{x}N_{y}. The STS measurements reveal that these AlO_{x}N_{y} layers exhibit an increase in bandgap with increased N content in the process gas. Decreased band-tails and improved surface stability suggest the barrier deposition can be modified through moderate post-growth annealing. We will provide suggestions for optimization of rf sputtered AlO_{x}N_{y} layers for use in high J_{c} Nb and AlN based JJs. [1] Miller, APL 63, 1423 (1993) [2] Wang, APL 64, 2034 (1994) [3] Kleinsasser, IEEE TES 5, 2318 (1995) [4] Kaul, JMRs 20, 3047 (2005)
Symmetry properties and residual transport in superconducting PrOs$_4$Sb$_{12}$. TAYSEER ABU ALRUB, STEPHANIE CURNOE, Memorial University — We identify a three-component order parameter in the triplet channel as the most probable candidate for superconductivity in PrOs$_4$Sb$_{12}$. Two different superconducting phases have been observed in PrOs$_4$Sb$_{12}$; the lower temperature ‘B phase’ occupies the bulk of the phase diagram and breaks time reversal symmetry while the higher temperature ‘A phase’ found in a narrow region below H$_c$, and possibly does not exist at all. The gap function in the A phase is unitary and has two nodes in the [001] direction. In the B phase, the gap function is nonunitary and the lower branch has four cusp nodes in the $\{\pm x, \pm y, 0\}$ directions. The conductivity tensor, due to isotropic impurity scattering, has inequivalent diagonal components due to the off-axis nodal positions of the B phase.

This work was supported by NSERC of Canada.

Scanning SQUID imaging of Sr$_2$RuO$_4$ and PrOs$_4$Sb$_{12}$, CLIFFORD HICKS, JOHN KIRTLER, Department of Applied Physics, Stanford University, MARTIN HUBER, University of Colorado Denver, KATHRYN MOLER, Department of Applied Physics, Stanford University — We present scanning SQUID magnetometer data on the superconducting materials strontium ruthenate (Sr$_2$RuO$_4$) and praseodymium-osmium-antimonide (PrOs$_4$Sb$_{12}$), both of which are believed to have spin-triplet pairing and to generate spontaneous time-reversal-symmetry-breaking fields below their superconducting transition temperatures. Our images, taken with a SQUID with a resolution of 3μm and approximately 100μG, do not show evidence for spontaneous TRSB fields, in contrast with muon spin rotation data which indicates gauss-scale fields in both materials. The fields indicated by μSR data must therefore have a short length scale and/or a short time scale. Supposing that the TRSB fields are static with the magnitudes indicated by μSR data we place upper limits on their length scales in both Sr$_2$RuO$_4$ and PrOs$_4$Sb$_{12}$. We also place upper limits on the strength of any distributed fields that might exist at sample edges and order parameter domain walls.

This work was supported by the Department of Energy (DE-AC02-76SF00015).

Gauge-invariant electromagnetic response of a chiral $p_x+ip_y$ superconductor, ROMAN LUTCHYN, PAVEL NAGORNYKH, VICTOR YAKOVENKO, University of Maryland — We study electromagnetic properties of spin-triplet superconductors with chiral $p_x+ip_y$ symmetry of the pairing order parameter. As a result of spontaneously broken time-reversal symmetry, the electromagnetic response of $p_x+ip_y$ superconductor contains additional (anomalous) terms that are not present in conventional superconductors. Using effective action approach, we show that in $p_x+ip_y$ superconductors an external electric field may generate transverse Hall-like currents which depend explicitly on the chirality of the pairing order parameter. We also find an analog of the London equation in the anomalous electromagnetic response which implies complete screening of Cooper-pair intrinsic orbital momentum. The implications of our results to the experiments on Sr$_2$RuO$_4$ are discussed.

8:36 AM X11.00004 Stability of Half-Quantum Vortices in px-ipy Superconductors, SUK BUM CHUNG, University of Illinois at Urbana-Champaign, HENDRIK BLÜHM, EUN-AH KIM, Stanford University — We have analyzed the possibility of finding half-quantum magnetic vortices in a quasi-two-dimensional CHUNG, University of Illinois at Urbana-Champaign, HENDRIK BLUHM, EUN-AH KIM, Stanford University — We have analyzed the possibility of finding half-quantum magnetic vortices in a quasi-two-dimensional Sr$_2$RuO$_4$. Two different superconducting phases have been observed in PrOs$_4$Sb$_{12}$; the lower temperature ‘B phase’ occupies the bulk of the phase diagram and breaks time reversal symmetry while the higher temperature ‘A phase’ is found in a narrow region below H$_c$, and possibly does not exist at all. The gap function in the A phase is unitary and has two nodes in the [001] direction. In the B phase, the gap function is nonunitary and the lower branch has four cusp nodes in the $\{\pm x, \pm y, 0\}$ directions. The conductivity tensor, due to isotropic impurity scattering, has inequivalent diagonal components due to the off-axis nodal positions of the B phase.

This work was supported by Joint Quantum Institute Postdoctoral Fellowship(RL) and Graduate Assistantship (PN).

Angle-resolved Photoemission Study of Ca$_{1.8}$Sr$_{0.2}$RuO$_4$, MADHAB NEPANE, P. RICHARD, Z.-H. PAN, Y. XU, Department of Physics, Boston College, Chestnut Hill, MA 02467 USA, R. JIN, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831 USA, X. DAI, Institute of Physics and National Laboratory for Condensed Matter Physics, Beijing, China, Z. WANG, H. DING, Department of Physics, Boston College, Chestnut Hill, MA 02467, USA — We report angle-resolved photoemission spectroscopy results of the Fermi surface of Ca$_{1.8}$Sr$_{0.2}$RuO$_4$ which is at the boundary between a magnetic metal and an antiferromagnetic insulator in the phase diagram of the Ca-substituted strontium ruthenates. We did observe an orbital-selective Mott transition, which is, however, different with what has been predicted theoretically [1] for this material. Our ARPES results are consistent with both magnetic and transport properties observed in this material.

Superconducting pairing symmetries in the 3-K and bulk phases of Sr$_2$RuO$_4$, ZHENYI LONG, BENJAMIN CLouser, RONALD MEYER, SONGRUI ZHAO, KELLY MCCARTHY, YING LIU, Pennsylvania State University, HIROSHI YAGUCHI, YOSHITERU MAENO, Kyoto University, Japan, TIJIANG LIU, ZHIQIANG MAO, Tulane University — We report recent progress on our single-particle tunneling and phase-sensitive measurements on 3-K and bulk phases of Sr$_2$RuO$_4$. The latter refers to an electronic phase of Sr$_2$RuO$_4$ that features Ru microdomains embedded in a single crystal of Sr$_2$RuO$_4$. These Ru microdomains are of a mesoscopic size and varying shape. Therefore their pairing symmetries are not subject to the same set of constraints as those in the bulk. We have performed tunneling measurements on the 3-K phase to identify all possible pairing states in this unique superconducting system. The junctions used earlier were prepared by pressing In wire onto a cleaved ab face of a Ru-containing Sr$_2$RuO$_4$ single crystal containing multiple Ru microdomains. More recently we focused on tunnel junctions prepared on pre-selected single Ru microdomains. Possible existence of an intrinsic mixed pairing state in the interior of a Ru microdomain featuring simultaneous presence of both the $s$- and $p$-wave superconducting condensates. We will also discuss briefly our current effort in the phase-sensitive measurements on bulk Sr$_2$RuO$_4$, focusing on detecting possible $/k_F$ dependence of the order parameter and the existence of domains.
9:12AM X11.00007 Hall Conductivity in a Spin-Triplet Superconductor, WONKEE KIM, Texas Center for Superconductivity, F. MARSIGLIO, University of Alberta, C. S. TING, Texas Center for Superconductivity — We calculate the Hall conductivity for a spin-triplet superconductor, using a generalized pair ordering dependent on an arbitrary phase, \( \phi \). A promising candidate for such an order parameter is \( \text{Sr}_2\text{RuO}_4 \), whose superconducting order parameter symmetry is still subject to investigation. The value of this phase can be determined through Kerr rotation and DC Hall conductivity measurements. Our calculations impose significant constraints on \( \phi \).

9:24AM X11.00008 Upper Critical Field and SdH Quantum Oscillation Studies in Organic Superconductor \( \beta \)-(BEDT-TTF)\(_2\)SF\(_5\)CH\(_3\)CF\(_2\)SO\(_3\) \(-\text{(ET)}\)\(_2\)Cu[N(CN)\(_2\)]Br\(_2\) \(-\text{(BEDT-TTF)} \)\(_2\)SF\(_5\)CH\(_3\)CF\(_2\)SO\(_3\), KYUIL CHO\(^1\), BRAUNEN E. SMITH, WILLIAM A. CONIGLIO, LAUREL WINTER, CHARLES C. AGOSTA, Clark University, JOHN A. SCHLUETER, Argonne National Laboratory — Upper critical fields and SdH quantum oscillations in the organic superconductor \( \beta \)-(BEDT-TTF)\(_2\)SF\(_5\)CH\(_3\)CF\(_2\)SO\(_3\) have been studied by measuring the in-plane rf penetration depth with a tunnel diode oscillator technique. Previous measurements from other groups, with the applied field parallel to the conducting layers, were inconsistent. We report here that for the applied field parallel to the conducting layers the low temperature upper critical fields exceed the Pauli paramagnetic limit calculated by using a semi-empirical method. We will also discuss SdH quantum oscillation with the applied field perpendicular to the conducting layers, which has been found to have a frequency of 181 T and an effective mass of 1.84 m\(_e\). The effective mass is consistent with those of other groups, but the oscillation frequency smaller than theirs (~196 T).

\(^1\)We thank the DOE BES grant #ER46214 for support.

9:36AM X11.00009 Absolute penetration depth measurements in deuterated organic superconductor \( \kappa \)-(ET)\(_2\)Cu[N(CN)\(_2\)]Br\(_2\), TYSON OLHEISER, N. SALOVICH, R.W. GIANNETTA, University of Illinois at Champaign-Urbana, J. SCHLUETER, Chemistry and Materials Science Divisions, Argonne National Laboratory — Penetration depth measurements were performed on fully deuterated \( \kappa \)-(ET)\(_2\)Cu[N(CN)\(_2\)]Br, an organic superconductor. A novel aluminum plating technique was used to determine the absolute penetration depth \( \lambda(T) \). As the cooling rate is varied from 30 mK/min to 180 K/min we observe systematic changes in \( T_C \), superconducting fraction and \( \lambda(T) \). The data is analyzed using a model of superconducting domains embedded in an antiferromagnetic background.

\(^3\)Work at UIUC supported by NSF DMR 05-03882.

9:48AM X11.00010 Determination of the Pauli Paramagnetic Limit in Quasi 2D Superconductors\(^1\), BRAUNEN E. SMITH, KYUIL CHO, WILLIAM A. CONIGLIO, CHARLES C. AGOSTA, Clark University — We have calculated the Pauli paramagnetic limit (\( H_p \)) for different quasi 2D superconductors using a semi-empirical method. We then compared the calculated Pauli paramagnetic limits to penetration depth data obtained using a tunnel diode oscillator technique at low temperatures in a swept applied magnetic field. The organic superconductors examined are layered such that their behavior is dependent on their orientation to the applied magnetic field. In order to eliminate the effect of vortex dynamics, we examined data taken with the conducting layers oriented parallel to the applied magnetic field. For one of these materials, \( \kappa \)-(BEDT-TTF)\(_2\)Cu[N(CN)\(_2\)]Br, we find that eliminating vortex effects leaves us with one remaining feature in the data that may correspond to \( H_p \). We also find that the material \( \beta \)-(BEDT-TTF)\(_2\)SF\(_5\)CH\(_3\)CF\(_2\)SO\(_3\) exhibits a change in slope for temperature versus upper critical field when the upper critical field exceeds the calculated \( H_p \). In addition, many of the examined quasi 2D superconductors, including the above organic superconductors and CeColn\(_5\), exhibit upper critical fields that exceed their calculated \( H_p \), suggesting some type of non-conventional superconductivity.

\(^1\)We thank the DOE BES grant #ER46214 for support.

10:00AM X11.00011 Second harmonic magnetic field oscillations in LCSCO in magnetic fields, ALBERT MIGLIO, Los Alamos National Lab, JON BETTS, YOKO SUZUKI, LANL, IZABELA STROE, NHMFL TEAM — We describe a second harmonic technique to probe the thermal conductivity of LCSCO with superconductivity suppressed by high magnetic fields. The technique is suitable for the high noise environment of pulsed magnets. By subtracting the thermal conductivity in field and at zero field, we obtain information about the temperature dependence of the order parameter. Work performed under the auspices of the National High Magnetic Field Laboratory.

10:12AM X11.00012 Disorder induced weak and strong localization and their influence on superconductivity in underdoped Bi\(_2+\)xSr\(_2-x\)CuO\(_6\). HUIQIAN LUO, PENG CHENG, HAI-HU WEN, National Laboratory for Superconductivity, Institute of Physics, CAS — in-plane resistivity and magnetoresistance(MR) measurements were carried out on high-quality underdoped Bi\(_2+\)xSr\(_2-x\)CuO\(_6\), \( 0.1 \leq x \leq 0.4 \) single crystals. The results show that the superconductivity and the normal state MR behaviors strongly rely on the doping level of samples. In the slightly doping level of Bi, a metallic normal state and a finite superconducting transition temperature are observed, and there is always a positive MR in the normal state which is explained by the fluctuating superconductivity mixed with the transport of quasiparticles. With further doping, the low temperature resistivity shows an up turn together with a negative MR. Detailed analysis on the negative MR in this region may suggest that weak localization effect is dominant. As the superconductivity is depressed by more doping and thus more disorders, the delocalization gets much harder and the spin-order contribution may be involved in MR. Moreover, in the heavily underdoped doping, the superconductivity is suppressed completely and resistivity evolves into a strong localization behavior with a Coulomb gap opening at the Fermi energy. After summarizing the doping dependence of MR, we construct a new phase diagram to illustrate how does the disorder give the influence both on the superconductivity and magnetoresistance.

10:24AM X11.00013 Unusual diamagnetic response in p-wave superconductors \( \text{Sr}_2\text{RuO}_4 \), LU LI, JOSEPH CHECKELSKY, W. F. BRINKMAN, Department of Physics, Princeton University, M. KRIENER, Y. MAENO, Department of Physics, Kyoto University, Kyoto 606-8502, Japan, NAI PHUAN ONG, Department of Physics, Princeton University — The magnetization \( M \) of the p-wave superconductor \( \text{Sr}_2\text{RuO}_4 \) has not been measured previously in the geometry with magnetic field \( H || c \) because of the small upper critical field \( (H_{c2} \approx 660 \text{ Oe}) \) and low \( T_c \) \((1.4 \text{ K})\). We have used high-resolution torque magnetometry to study in detail the magnetization curves in this geometry. We find that, in the superconducting state, the \( M-H \) curves display highly unusual hysteretic behavior. In the critical state, whenever \( H \) crosses zero, we observe a break in the slope \( \partial M/\partial H \). In a broad field interval \([ -H_c, H_0 ] \) bracketing zero field, \( M \) is reversible (to our resolution) under reversal of sweep direction. This anomalous behavior is not encountered in conventional type-II superconductors, where the critical-state behavior is always non-reversible. A possible interpretation of these unusual features is the existence of reversible edge currents. We also discuss the magnetization curves with \( H \parallel ab \), where \( M \) jumps sharply at \( H = H_{c2} \). Research supported by NSF grant DMR 0213706.
10:36AM X11.00014 Emergence of dissipative structures in current-carrying stabilized superconducting wires. GEORGE LEVIN, PAUL BARNES, Air Force Research Laboratory, JOSE RODRIGUEZ, Department of Physics and Astronomy, California State University, Los Angeles, JOHN BULMER, Air Force Research Laboratory, JAKE CONNORS, Ohio State University — We discuss the emergence of a dissipative structure in current-carrying superconducting wire. This is a phenomenon similar to the emergence of thermal convection cells, oscillatory chemical reactions, etc. In response to the initial localized temperature perturbation that leads to current exchange between the superconductor and the stabilizer the temperature and critical current density of the wire acquire spontaneous spatial modulation that forces the transport current to crosscross the interface between the superconducting film and metal stabilizer. This generates additional heat that makes such a structure self-sustainable. The central role in this phenomenon is played by the interfacial resistance between the stabilizer and superconducting film. The spatial scale of the modulation is of the order of the thermal diffusion length. This resistance also determines the speed of propagation of the conventional normal zone. We will present the results of numerical and analytical analysis of a model which describes current sharing between the superconducting and normal metal layers - a configuration typical of the state of the art YBCO-coated conductors.

10:48AM X11.00015 Thermoelectric effects and band-dependent scattering of normal-state quasiparticles in spin-triplet superconductor Sr$_2$RuO$_4$. ZHUAN XU, XIANGFAN GU, Zhejiang University, China, TIJIAN LIU, DAVID FOBES, ZHIQIANG MAO, Tulane University, YING LIU, Pennsylvania State University — We present the first measurement on Nernst effects in the normal state of odd-parity, spin-triplet superconductor Sr$_2$RuO$_4$. Below 100 K, the negative Nernst signal was found to be large and nonlinear as a function of magnetic field with its absolute value increasing rapidly as the temperature was lowered. After reaching a maximum around $T^* = 20 - 25$ K, however, the Nernst signal drops linearly with the decreasing temperature. No corresponding feature was found around this temperature in the specific heat. We argue that the large value of the Nernst signal is related to the presence of multibands and the nonlinearity to band-dependent magnetic fluctuation in Sr$_2$RuO$_4$. Furthermore, the quasiparticle scattering from the magnetic fluctuation is suppressed below $T^*$ due to the emergence of coherence among quasiparticles in the $\gamma$-band, an active band for superconductivity in Sr$_2$RuO$_4$. Results on temperature dependence of the thermopower, which was seen to exhibit a sharp kink around $T^*$, provided further support to this picture of band-dependent normal-state properties. Our thermoelectric measurements appear to suggest that the suppression of the magnetic fluctuation makes it possible for the spin-triplet superconductivity to emerge in Sr$_2$RuO$_4$. 

Friday, March 14, 2008 8:00AM - 10:36AM — Session X12 DCMP: Charge Density Wave and Charge Order Morial Convention Center 203

8:00AM X12.00001 Fermi Surface Evolution Across Multiple CDW Transitions in RTe$_3$. R.G. MOORE, Stanford Synchrotron Radiation Laboratory, Stanford Linear Accelerator Center, Menlo Park, CA 94025, V. BROUET, Laboratoire de Physique des Solides, Universite Paris-Sud, Bat 510, UMR 8505, 91405 Orsay, France. J. LAVEROCK, S. DUGDALE, H. H. Wills Physics Laboratory, University of Bristol, Bristol BS8 1TL, United Kingdom, R. HE, N. RUI, I.R. FISHER, Z.-X. SHEN, Geballe Laboratory for Advanced Materials and Department of Applied Physics, Stanford University, Stanford, CA 94305 — The Fermi surface (FS) evolution across multiple charge density wave (CDW) transitions is investigated using angle-resolved photoemission spectroscopy. Low temperature measurements reveal two incommensurate CDW gaps created by perpendicular FS nesting vectors. A larger gap (≈250 meV) arising from a CDW with q$_{CDW} \sim 0.7c*$ is in good agreement with the expected trend determined from light rare earth members of the bi-layer family of rare earth trilivate compounds (RTe$_3$). A second, smaller gap (≈50 meV) is due to a second CDW with q$_{CDW} \sim 0.7a*$ never before seen in other RTe$_3$ compounds. The temperature dependence of the FS and the two CDW gaps is characterized.

1Work supported by DOE Office of Science, Division of Materials Science, with contract DE-FG03-01ER45929-A001 and NSF grant DMR-0604701.

8:12AM X12.00002 Momentum and time dependent electronic dynamics in the CDW compound TbTe$_3$. FELIX SCHMITT, Department of Applied Physics, Stanford University, Stanford, CA 94305, PATRIC KIRCHMANN, LAURENZ RETTIG, MARCEL KRENZ, Department of Physics, Freie Universitaet Berlin, Germany, NANCY RU, JUN-HAW CHU, Department of Applied Physics, Stanford University, Stanford, CA 94305, ROB MOORE, Stanford Synchrotron Radiation Laboratory, Stanford University, Stanford, CA 94305, UWE BOVENSIEPEN, MARTIN WOLF, Department of Physics, Freie Universitaet Berlin, Germany, IAN FISHER, Department of Applied Physics, Stanford University, Stanford, CA 94305, ZHI-XUN SHEN, Department of Applied Physics and Stanford Synchrotron Radiation Laboratory, Stanford University, Stanford, CA 94305 — The rare earth tritellurides RTe$_3$ are charge-density-wave (CDW) systems in which the coupling strength can be tuned by substituting different rare earths. By using ultrashort IR pump and UV probe laser pulses, we have performed time resolved angular resolved electron photoemission spectroscopy (trARPES) on TbTe$_3$ and have observed the time-resolved closing of the CDW gap in the electronic band structure. To our knowledge, this is the first time-resolved study showing momentum dependent charge dynamics. We will also talk about other results on RTe$_3$ compounds.

8:36AM X12.00004 Quantum and classical mode softening near the charge-density-wave/superconductor transition of Cu$_3$TiSe$_2$: Raman spectroscopic studies. MINJUNG KIM, HARINI BARATH, S.L. COOPER, P. ABBAMONTE, E. FRADKIN, Dept. of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at U, E. MOROSAN, R.J. CAVA, Department of Chemistry, Princeton University, Princeton, NJ 08544, USA — We report temperature- and x-dependent Raman studies of the charge density wave (CDW) amplitude modes in Cu$_3$TiSe$_2$, which allow us to study the temperature- and x-dependence of the soft mode in this system. Among the key results: we find that the A$_{2g}$ amplitude mode exhibits identical power law scaling with the reduced temperature, p(T/TCDW), and the reduced Cu content, p=x/\kappa, i.e., \omega_0 \sim (1-p)^{0.15}, suggesting that mode softening is independent of the control parameter used to approach the CDW transition; we provide evidence that x-dependent mode softening originates from the expansion of the lattice, which leads to a x-dependent reduction of the electron-phonon coupling constant; and we infer from our x-dependent mode softening results the presence of a quantum critical point, x_c(T=0)=0.07, within the superconducting phase of Cu$_3$TiSe$_2$.

8:48AM X12.00005 Insulating charge density wave for a half-filled SU(N) Hubbard model with an attractive on-site interaction in one dimension. JIZE ZHAO, KAZUO UEDA, XIAOQUN WANG, The Institute for Solid State Physics, University of Tokyo — We study a one-dimensional SU(N) Hubbard model with an attractive on-site interaction and $N > 2$ at half-filling on the bipartite lattice using density-matrix renormalization-group method and a perturbation theory. We find that the ground state of the SU(N) Hubbard model is a charge density wave state with two-fold degeneracy. All the excitations are found to be gapful, resulting in an insulating ground state, in contrast to that in the SU(2) case. Moreover, the charge gap is equal to the Cooperon gap, which behaves as $-2N U^2/(N - 1)U$ in the strong coupling regime. However, the spin gap $\Delta_s$ and the quasiparticle gap $\Delta_1$ grow as well open exponentially in the weak coupling region, while in the strong coupling region, they linearly depend on $U$ such that $\Delta_s \sim -U(N - 1)$ and $\Delta_1 \sim -U(N - 1)/2$.

9:00AM X12.00006 Spin-soliton excitations from the Bond-Charge-Density Wave spin-Peierls state in the $1/2$-filled band. R.T. CLAY, R.P. HARDIKAR, Mississippi State University, S. MAZUMDAR, University of Arizona — The spin-Peierls (SP) transition is commonly discussed in the context of the $1/2$-filled band where the SP state is bond-dimerized. Spin excitations from the SP state generate spin solitons in pairs with opposite-phased bond alternation in between the solitons. As thermal excitations generate additional solitons, oppositely-phased regions overlap and ultimately give way to the uniform phase. Throughout the process, the charges on the sites remain uniform. This simple description has to break down in $1/2$-filled band systems where the SP state is a Bond-Charge-Density Wave (BCDW) state with coexisting bond and charge-tetramerization. At $1/2$-filled spin excitations are necessarily accompanied by changes in site charges. We prove the highly interesting result that site charges here can change locally in two different ways, leading to two different kinds of spin solitons. Which kind of soliton dominates is parameter-dependent. The two kinds of solitons promote two different high temperature states, which are either bond-dimerized or charge-dimerized. We discuss experimental consequences of our work.

9:12AM X12.00007 Measurements of the effect of charge density wave fluctuations on the $^{87}$Rb spin echo decay rate in Rb$_{0.30}$MoO$_3$. W.G. CLARK, GUOQING WU, S.E. BROWN, UCLA — Measurements and interpretation of the spin echo decay rate ($1/T_2$) for the $^{87}$Rb quadrupolar split satellite lines in the charge density wave (CDW) system Rb$_{0.30}$MoO$_3$ (blue bronze) are reported over the temperature ($T$) range 80 K to 250 K at several alignments of the magnetic field ($B = 9.00$ T). In contrast to the central transition, where the contribution of CDW fluctuations to $1/T_2$ is very small, they provide a large contribution to $1/T_2$ for the satellite lines below the CDW transition at $T_{CDW} \approx 180$ K. This sensitivity to CDW fluctuations shows that $1/T_2$ of the satellite lines should be a much more sensitive probe of both electric field driven and thermal motions of the CDW than the effects of density wave motion on the central transition, which has been used for prior work on this topic. A major goal of our future work is to exploit this property to obtain detailed measurements of electric field driven and thermal motion of the CDW in this material over a wide temperature range. This work has been supported by NSF Grants DMR-0334869 (WGC) and 0520552 (SEB).

9:24AM X12.00008 Electro-Optic Search for Critical Divergence of the Charge-Density-Wave Diffusion Constant at the Onset of Depinning in Blue Bronze. J.W. BRILL, L. LADINO, E.G. BITTLE, M. UDDIN, University of Kentucky — We have used electro-reflectance measurements to study charge-density-wave (CDW) polarization dynamics at voltages near the CDW depinning onset ($V_{on}$) in the quasi-one-dimensional conductor blue bronze. For low voltages, where the phase-slip rate is low, it is expected that the polarization relaxation time should be inversely proportional to the CDW diffusion constant, which is expected to diverge at $V_{on}$. At $T = 78$ K, we observe saturation of the relaxation time at low voltages, suggesting that we are in this low phase-slip, “elastic” limit and allowing us to estimate the non-critical value of the CDW diffusion constant $D(\infty) \sim 0.02$cm$^2$/s, consistent with the measured phonon velocity. At other temperatures, the relaxation time increases with decreasing voltage even at the lowest voltages we measure, indicating we are still dominated by phase-slip. In no case, however, do we observe the expected “critical speeding up”, setting an upper limit on the critical region of $V_1/V_{on} < 0.06$.

1Research supported by NSF grant DMR-0400938.

9:36AM X12.00009 Position and Current Dependence of Charge-Density-Wave Polarization Dynamics. L. LADINO, J.W. BRILL, University of Kentucky — We have studied the frequency and position dependence of charge-density-wave (CDW) polarization by simulating the response to square-waves of variable amplitude and frequency using parameters appropriate for niobium triselenide at $T = 90$ K, in its upper CDW state. For these simulations, we have numerically solved the phase-slip augmented diffusion model introduced by Adelman et al (Phys. Rev. B 54, 1833 (1996)) for time domain studies. At each position in the sample, the frequency dependence was fit to a modified harmonic oscillator expression and the position and current dependence of the fitting parameters determined. In particular, both the delay time ($1/\text{resonant frequency}$) and relaxation time decrease with increasing current (and phase-slip rate) and increase with distance from the contact, with the delay time vanishing adjacent to the contact, as experimentally observed with electro-optic measurements in blue bronze. No decay of the polarization at long times is observed however, in contrast to electro-optic results.

1Research supported by NSF grant DMR-0400938.

9:48AM X12.00010 Thermolectric studies of charge density wave dynamics. ROSS MCDONALD, NHMFL-Los Alamos, NEIL HARRISON, JOHN SINGLETON, NHMFL-LANL, TEAM CDW COLLABORATION — The conventional pyroelectric effect is intimately connected to the symmetry, or rather lack of center of symmetry, of the material. Although the experiments we discuss involve studies of low symmetry materials, the pyroelectric currents observed are of an entirely new origin. Systems with broken-translational-symmetry phases that incorporate orbital quantization can exhibit significant departures from thermodynamic equilibrium due to a change in magnetic induction. For charge density wave systems, this metastable state consists of a balance between the density-wave pinning force and the Lorentz force on the extended currents due to the drift of cyclotron orbits. In this way the density wave pinning potential plays a similar role to the edge potential in a two-dimensional electron gas, leading to a large Hall angle and quantization of the Hall resistance. A thermal perturbation that reduces the pinning potential returns the system towards thermal equilibrium, via a phason avalanche orthogonal to the sample surface. The observation of this new form of pyroelectric effect in the high magnetic field phase ($B > 30$ T) of the organic charge transfer salt $\alpha$-(BEDT-TTF)$_2$KHg(SCN)$_4$, thus provides a measure of the phason thermopower.
10:00AM X12.00011 Super-Crystalline CDW Phase in Organic Conductor (Per)$_2$Pt(mnt)$_2$\(^{1,2}\), SI WU, ANDREI LEBED, Dept. of Physics, Univ. of Arizona — We suggest a model \([1,2]\), where phase transitions between the Peierls and Super-Crystalline [or soliton wall superlattice (SWS)] charge-density-wave (CDW) phases occur in a magnetic field. The model accounts for peculiarities of an electron spectrum in a quasi-one-dimensional (Q1D) conductor (Per)$_2$Pt (mnt)$_2$. In particular, we show that the Pauli spin-splitting effects improve the nesting properties of a realistic Q1D electron spectrum, and, therefore, a high resistance Peierls CDW phase is stabilized in high magnetic fields. In low and very high magnetic fields, a periodic SWS (or Super-Crystalline) phase is found to be a ground state. We discuss \([3]\) possible experimental investigations of the theoretically predicted phase transitions in (Per)$_2$Pt(mnt)$_2$ to discover a unique SWS phase.

10:12AM X12.00012 Temperature dependence of charge-ordering in (TMTCF)$_2$X, C = S, Se\(^{1}\), SUMIT MAZUMDAR, University of Arizona, RAHUL HARDIKAR, R. TORSTEN CLAY, Mississippi State University — Quasi one-dimensional 1/4-filled band charge transfer solids (CTS) undergo two distinct phase transitions as temperature decreases. At high temperature (\(\approx 100K\)) these materials undergo a 4K\(_X\) (period-two) charge or bond ordering transition. At low temperature, these CTS undergo a magnetic transition to either a spin-Peierls (SP) or anti-ferromagnetic (AFM) ground state, both of which coexist with charge-order (CO). Understanding the relationship between the high and low temperature CO states is a key problem here. We show that (i) the critical nearest neighbor Coulomb interaction V that drives the high temperature Wigner crystal CO is spin-dependent; (ii) as a consequence, for intermediate values of V, there occurs a transition from the Wigner crystal CO to a Bond-Charge-Density wave (BCDW) can occur as temperature decreases. This transition is consistent with recent NMR observations of a charge redistribution occurring simultaneously with the SP state. Our theory is able to explain the competition between the Wigner crystal and SP phases, as well as the occurrence of two difference AFM phases.

10:24AM X12.00013 Infrared investigation of the charge ordering pattern in the organic spin ladder candidate (DTTTF)$_2$Cu(mnt)$_2$\(^{1}\), J.L. MUSFELDT, S. BROWN, University of Tennesse, S. MAZUMDAR, University of Arizona, R.T. CLAY, Mississippi State University, M. MAS-TORRENTE, C. ROVIRA, Institut de Ciencia de Materials de Barcelona, J.C. DIAS, R.T. HENRIQUES, M. ALMEIDA, Universidade de Lisboa — We measured the variable temperature infrared response of the spin ladder candidate (DTTTF)$_2$Cu(mnt)$_2$ in order to distinguish between two competing ladder models, rectangular versus zigzag, proposed for this family of materials. The distortion along the stack direction below 235 K is consistent with a doubling along \(b\) through the metal-insulator transition. While this would agree with either of the ladder models, the concomitant transverse distortion rules out the rectangular ladder model and supports the zigzag scenario. A mode analysis provides the microscopic basis for this distortion and an estimate for the degree of charge ordering. Intramolecular distortions within the DTTTF building block molecule also give rise to on-site charge asymmetry.

Friday, March 14, 2008 8:00AM - 10:00AM — Session X13 DCOMP: Quantum Monte Carlo Methods and Strongly Correlated Systems

Morial Convention Center 204

8:00AM X13.00001 Variational approach for 1D antiferromagnetic Heisenberg chain with matrix-product states, YING-JER KAO, National Taiwan University, LING WANG, ANDERS SANDVIK, Boston University — In order to explore the practical applicability of variational Monte Carlo simulations based on matrix-product states (MPS) \([1]\), we present two implementations for the one-dimensional antiferromagnetic Heisenberg model with periodic boundary conditions \([2]\). We compare the convergence properties of two different schemes, which use either two sets of matrices corresponding to the two sublattices, or a 2-spin block representation. It is found that the use of symmetries considerably speeds up the convergence with the matrix size \(D\). We also present an efficient “cooling” schedule for the stochastic method used to optimize the matrices, which significantly reduces the computational effort. Finally, we will discuss application of the scheme to \(n\)-leg ladders with periodic boundary condition.

8:12AM X13.00002 Excited states from variational Monte Carlo simulations with matrix-product states\(^{1}\), LING WANG, Boston University, YING-JER KAO, National Taiwan University, ANDERS SANDVIK, Boston University — We report a further development \([1]\) of a recently proposed variational Monte Carlo method for matrix-product states (MPS) \([2]\). Using the frustrated \(J_1 - J_2\) Heisenberg chain as a test case, we show how the matrices can be optimized not just for the ground state, but also, simultaneously, for the lowest states in several different lattice and spin symmetry sectors. This is useful in, e.g., studies of quantum phase transitions associated with crossings of excited-state energies.

Supported by NSF Grant No. DMR-0513930.

8:24AM X13.00003 Scale-renormalized matrix-product states for correlated quantum systems\(^{1}\), ANDERS SANDVIK, Boston University — A generalization of matrix product states (MPS) is introduced which is suitable for describing interacting quantum systems in two and three dimensions. These \(\text{scale-renormalized matrix-product states (SR-MPS)}\) are based on a course-graining of the lattice in which the blocks at each level are associated with matrix products that are further transformed (scale renormalized) with other matrices before they are assembled to form blocks at the next level. Using variational Monte Carlo simulations of the two-dimensional transverse-field Ising model as a test, it is shown that the SR-MPS converge much more rapidly with the matrix size than a standard MPS. It is also shown that the use of lattice-symmetries speeds up the convergence very significantly.

Supported by NSF Grant No. DMR-0513930.

The phonon spectral function is given in both the metallic Luttinger liquid and the insulating charge density wave phase, for a wide range of phonon properties of the systems via momentum dependent phonon spectral functions and electron Greens functions. In case of the standard Holstein model, we present as well as Holstein type models, with momentum dependent couplings (e.g. breathing phonons) and arbitrary phonon dispersions. We access the dynamical EVERTZ, PETER PIPPAN, Techn. Univ. Graz — Using a QMC method based on exact phonon integration in Fourier space and on loop updates in particle state. For higher representation, we have not observed any VBS state, although the disappearance of the Neel order parameter has been detected as we increase N. from the Neel state to the VBS state around N=5 for the fundamental representation, we also find that there is an apparent U(1) symmetry in the VBS split-spin representation is used for high-dimensional representations. While we have confirmed our previous result[3] that the ground state switches University of Tokyo — The SU(N) generalization of the Heisenberg model is studied with a new loop algorithms with non-binary loop variables.[1] The[3] K. Harada, N. Kawashima and M. Troyer, Phys. Rev. Lett. 90...[24AM X13.00008 Spin waves and local magnetizations on the Penrose tiling . ATTILA SZALLAS, ANURADHA JAGANNATHAN, Laboratoire de Physique des Solides, CNRS-UMR 8502, Universite Paris-Sud, 91405 Orsay, France — The Penrose tiling is a perfectly ordered two dimensional structure with fivefold symmetry and scale invariance under site decimation. Quantum spin models on such a system can be expected to differ significantly from more conventional structures as a result of its special symmetries. We consider a Heisenberg antiferromagnet on the Penrose tiling, a quasiperiodic system having an inhomogeneous Neel-ordered ground state. Spin wave energies and wavefunctions are studied in the linear spin wave approximation. A linear dispersion law is found at low energies, as in other bipartite antiferromagnets, with an effective spin wave velocity lower than in the square lattice. Spatial properties of eigenmodes are characterized in several different ways. At low energies, eigenstates are relatively extended, and show multifractal scaling. At higher energies, states are more localized, and, depending on the energy, confined to sites of a specified coordination number. The ground state energy of this antiferromagnet, and local staggered magnetizations are calculated. Perpendicular space projections are shown, showing the underlying simplicity of this “complex” ground state. A simple analytical model, the two-tier Heisenberg star, is presented to explain the staggered magnetization distribution in this antiferromagnetic system.

8:36AM X13.00004 DMRG applied to quantum impurity models . ANDREAS WEICHSELBAUM, JAN VON DELFT, Ludwig Maximilian University — Quantum impurity models are analyzed routinely and reliably at very low energies using the Numerical Renormalization Group (NRG). Its great benefit of energy scale separation, however, comes at the cost of limited resolution at finite energy. By realizing that the NRG shares the same algebraic structure as the density matrix renormalization group (DMRG) given in terms of matrix product states, several strict NRG constraints such as its rigid discretization scheme in energy space can be relaxed due to the variational principle of DMRG. Our recent work in that respect will be discussed. 8:48AM X13.00005 Ameliorating the sign problem for frustrated magnets using plaquette grouping , KEVIN BEACH, University of Alberta — Frustrated quantum magnets are not amenable to simulation using conventional quantum Monte Carlo because of the infamous sign problem. In the overcomplete basis of singlet product states, updates have a many-to-one property that allows for grouping of updates around plaquettes in such a way that the negative sampling weights are almost entirely eliminated. Results for the J1-J2 quantum Heisenberg model on the square lattice are discussed.

9:00AM X13.00006 Bold Diagrammatic Monte Carlo: Generic Technique for Polaron Problems (and More?) , BORIS SVISTUNOV, NIKOLOY PROKOF’EV, University of Massachusetts, Amherst — We introduce a Monte Carlo scheme for sampling bold-line diagrammatic series specifying an unknown function in terms of itself. The range of convergence of this bold(-line) diagrammatic Monte Carlo (BMC) is significantly broader than that of a simple iterative scheme for solving integral equations. With BMC technique, a moderate “sign problem” turns out to be an advantage in terms of the convergence of the process. As an illustrative application, we solve the problem of fermipolaron (one spin-down particle interacting with the spin-up fermionic sea). The problem solved is prototypical for all polaron problems, and, probably, for many-particle systems as well.

9:12AM X13.00007 Interfacing Determinant Quantum Monte Carlo and Density Functional Theory1, NIKOLAI ZARKEVICH, University of California, Davis, CA 95616, ZHAOJUN BAI, Computer Science Department, University of California, Davis, CA 95616, SERGEY SAVRASOV, RICHARD SCALETTER, Physics Department, University of California, Davis, CA 95616, MARK JARRELL, Physics Department, University of Cincinnati, OH 45221 — Over the last decade many body theory and electronic structure calculations have come together within the “LDA+DMFT” approach in which dynamical mean field theory (DMFT) provides a frequency dependent self-energy \( \Sigma(\omega) \) for electronic structure calculation within the local density approximation (LDA). Here we describe initial results with a new approach which uses the determinant Quantum Monte Carlo method to supply the self energy. This technique has the advantage of providing a momentum dependent \( \Sigma(k,\omega) \). However, the fermion sign problem can limit the ability to access the ground state value of the self energy. We present tests of the approach on a model of cuprate superconductors.

9:24AM X13.00008 Spin waves and local magnetizations on the Penrose tiling . ATTILA SZALLAS, ANURADHA JAGANNATHAN, Laboratoire de Physique des Solides, CNRS-UMR 8502, Universite Paris-Sud, 91405 Orsay, France — The Penrose tiling is a perfectly ordered two dimensional structure with fivefold symmetry and scale invariance under site decimation. Quantum spin models on such a system can be expected to differ significantly from more conventional structures as a result of its special symmetries. We consider a Heisenberg antiferromagnet on the Penrose tiling, a quasiperiodic system having an inhomogeneous Neel-ordered ground state. Spin wave energies and wavefunctions are studied in the linear spin wave approximation. A linear dispersion law is found at low energies, as in other bipartite antiferromagnets, with an effective spin wave velocity lower than in the square lattice. Spatial properties of eigenmodes are characterized in several different ways. At low energies, eigenstates are relatively extended, and show multifractal scaling. At higher energies, states are more localized, and, depending on the energy, confined to sites of a specified coordination number. The ground state energy of this antiferromagnet, and local staggered magnetizations are calculated. Perpendicular space projections are shown, showing the underlying simplicity of this “complex” ground state. A simple analytical model, the two-tier Heisenberg star, is presented to explain the staggered magnetization distribution in this antiferromagnetic system.

9:36AM X13.00009 Loop Algorithm for the SU(N) Heisenberg Model . NAOKI KAWASHIMA, ISSP, University of Tokyo — The SU(N) generalization of the Heisenberg model is studied with a new loop algorithms with non-binary loop variables.[1] The split-spin representation is used for high-dimensional representations. While we have confirmed our previous result[3] that the ground state switches from the Neel state to the VBS state around N=5 for the fundamental representation, we also find that there is an apparent U(1) symmetry in the VBS state. For higher representation, we have not observed any VBS state, although the disappearance of the Neel order parameter has been detected as we increase N. [1] N. Kawashima and K. Harada, J. Phys. Soc. Jpn. 73 1397 (2004).

9:48AM X13.00010 Dynamical properties of SSH and breathing type Hamiltonians . HANS GERD EVERTZ, PETER PIPPAN, Techn. Univ. Graz — Using a QMC method based on exact phonon integration in Fourier space and on loop updates in particle space, we study fermionic systems coupled to dynamical phonons in one dimension. Within this method it is possible to investigate Su-Schrieffer-Heeger (SSH) as well as Holstein type models, with momentum dependent couplings (e.g. breathing phonons) and arbitrary phonon dispersions. We access the dynamical properties of the systems via momentum dependent phonon spectral functions and electron Greens functions. In case of the standard Holstein model, we present precise data for the phonon spectral function in both the metallic Luttinger liquid and the insulating charge density wave phase, for a wide range of phonon frequencies.

Friday, March 14, 2008 8:00AM - 11:00AM — Session X15 DBP FIAP: Emerging Nano-based Diagnostics and Therapeutics: Approaches to Cancer Treatment Morial Convention Center 207
8:00AM X15.00001 Intracellular Mechanics-Based Drug Screening for Cancer Metastasis, YILDER TSENG, University of Florida — In 2007 alone, close to 1.5 million new cancer cases and over half of a million deaths from cancer are projected to occur in US. In general, cancer is much easier to be successfully treated before metastasis; the five-year survival rates for most of the cancers in the metastatic stage are lower than 10%. The origin of cancer is due to genomic instability; however, the genomics or proteomics studies focus on this phenomenon cannot thoroughly elucidate how cancer metastasis proceeds. During this process, cancer cells protrude and conquer their physical barriers, resist shear stress, establish anchorage and finally settle in a new environment. Each development in this process involves mechanical forces. Thus, whether force generation and cancer cells' mechanical properties can be integrated into the current mainstream of cancer research and offer new insight is worthy of being investigated. To measure the change of cell mechanics, specifically intracellular mechanics, a tool that least disrupts the probed cell’s behavior and, simultaneously, can obtain real time quantitative measurement is necessary. To satisfy these criteria, we have developed a technique, ballistic intracellular nanorheology (BIN), in which we trace and analyze the trajectories of nanoparticles that have been ballistically bombarded into the cytoplasm of individual cells. This technique allows us to probe the effects of chemical or mechanical stimuli on intracellular mechanics in various types of cells, on culture dishes or in a three-dimensional matrix. BIN is currently, the first and only method available that can be applied to perform such tasks. Using this technique, we have gained detailed information about how the cytoskeletal remodeling pathways control the intracellular mechanics. We have also obtained information on the tempo-correlation between agonists and intracellular mechanics and how cells utilize their intracellular mechanics to react extracellular shear stress. These studies have set the framework for us to understand the mechanical mechanism of cancer cell metastasis on a molecular level. In this talk, I will describe the working principal using this technique to screen cancer drugs that prevent cancer metastasis.

8:36AM X15.00002 Targeted Multifunctional Nanoparticles cure and image Brain Tumors: Selective MRI Contrast Enhancement and Photodynamic Therapy, RAOUl KOPELMAN, University of Michigan — Aimed at targeted therapy and imaging of brain tumors, our approach uses targeted, multi-functional nano-particles (NP). A typical nano-particle contains a biologically inert, non-toxic matrix, biodegradable and bio-eliminable over a long period time. It also contains active components, such as fluorescent chemical indicators, photo-sensitizers, MRI contrast enhancement agents and optical imaging dyes. In addition, its surface contains molecular targeting units, e.g. peptides or antibodies, as well as a clamping agent, to prevent uptake by the immune system, i.e. enabling control of the plasma residence time. These dynamic nano-platforms (DNP) contain contrast enhancement agents for the imaging (MRI, optical, photo-acoustic) of targeted locations, i.e. tumors. Added to this are targeted therapy agents, such as photosensitizers for photodynamic therapy (PDT). A simple protocol, for rats implanted with human brain cancer, consists of tail injection with DNPs, followed by 5 min red light illumination of the tumor region. It resulted in excellent cure statistics for 9L glioblastoma. 3Thank you to the National Cancer Institute and the National Science Foundation, Division of Materials Research

9:12AM X15.00003 Microcantilever Biosensors, THOMAS THUNDAT, Oak Ridge National Laboratory — Micromachined cantilever beams respond to molecular adsorption by with mechanical bending. For small concentrations, the bending signal is directly proportional the surface concentration of adsorbed molecules. Selectivity in detection is accomplished by immobilizing specific receptors on one of the surfaces of the cantilever. We have developed microcantilever arrays for multiplexed, label-free detection of biomolecules. Photo-sensitive readout of cantilever bending offers a simple and rapid signal transduction that is compatible with microfabrication. Although the microcantilever-based biosensing appears to high sensitivity and selectivity, reproducibility of the technique appears to be a challenge. We have developed a novel method of immobilizing receptors that increases the reproducibility. We have demonstrated simultaneous detection of cancer and cardiac markers using cantilever arrays with immobilized receptors. We will also discuss a receptor-free mode of achieving selectivity.

9:48AM X15.00004 Magnetic sifters and biochips for early diagnosis and therapy monitoring of cancer, CHRIS EARHART, Stanford University — Magnetic nanoparticles conjugated with biomolecules or recognition moieties are finding wide applications in medicine. In this context, we are developing a micromachined magnetic sifter and magnetic nanoparticles aimed for sample preparation applications in early diagnosis of cancer. The microfabricated sifter consisting of arrays of micron sized slits etched through a silicon wafer. A magnetic film is deposited on the wafer, producing high magnetic field gradients, comparable in magnitude to gradients in planar flow devices. As the solution flows through the die, magnetic particles are captured by the magnetic material surrounding the slits. The large number of slits allows for processing of large volumes of liquid, much greater than that of planar microfluidic devices. The sifters can be simply attached to a syringe or tube, resulting in a portable and user-friendly tool for molecular biology. The separation efficiencies of ~ 50% for one pass through the sifter have been achieved. We have also designed and fabricated several types of magnetic biochips consisting of arrays of giant magnetoresistive (GMR) spin valve detectors with appropriate dimensions, surface chemistry, and microfluidics. An advanced electronic test station has been set up as a demonstration vehicle for the integrated evaluation of our magnetic biochips with commercial and custom magnetic nanoparticle labels for DNA or protein biomarkers. The magnetic biochip is capable of detecting down to 1-30 nanotags. Real-time detection of DNA signatures and protein targets in buffer and serum samples has been successfully performed in our laboratories, suggesting that magnetic biochips hold great promises for molecular diagnostics of cancer and other diseases. In collaboration with Chris M. Earhart, Wei Hu, Robert J. Wilson, Sebastian J. Osterfeld, Robert L. White, Nader Pourmand, and Shan X. Wang @ Stanford University. This work was supported by grants from NIH (1U54CA119367-01) and DARPA/Navy (N00014-02-1-0807).

10:24AM X15.00005 Microdevices for biomolecular detection and single cell analysis, SCOTT MANALIS, MIT — Recent advances towards developing biomolecular and single cell applications for a mass-based biosensor known as the suspended microchannel resonator (SMR) will be presented. In SMR detection, target molecules or cells flow through a vibrating suspended microchannel and are captured by receptor molecules attached to the interior channel walls. What separates the SMR from the existing resonant mass sensors is that the receptors, targets, and their aqueous environment are confined inside the resonator, while the resonator itself can oscillate at high Q in an external vacuum environment, thus yielding extraordinarily high sensitivity. This approach solves the problem of viscous damping that degrades the sensitivity of cantilever resonators in solution. We have achieved a resolution of approximately 1 femtogram (1 Hz bandwidth) which is represents an improvement of six order of magnitude improvement over a high-end commercial quartz crystal microbalance. This gives access to intriguing applications such as mass based flow cytometry, real-time monitoring of single cell growth, and the direct detection of protein biomarkers.

8:48AM X18.00003 Theory of the effect of deformation on the relaxation and mechanical properties of polymer glasses . KANG CHEN, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — Recently Saltzman and Schweizer have developed a statistical dynamical theory of segmental relaxation in deeply supercooled polymer melts by combining and extending methods of mode coupling, dynamic density functional and activated barrier hopping theories. The approach is built on the concept of a nanometer scale nonequilibrium free energy which quantifies dynamic localization due to interchain forces. We have now generalized this approach to treat quiescent relaxation, physical aging, and nonlinear mechanical properties in the nonequilibrium glass state. Applied stress weakens dynamical constraints in the effective free energy which accelerates alpha relaxation and softens the elastic modulus. A constitutive equation has been constructed which allows the prediction of dynamic yielding and mechanical response under constant strain rate, constant stress (creep), and other modes of deformation. Multiple predictions that fundamentally differ from the phenomenological Eyring model are made for the temperature and strain rate dependence of the dynamic yield stress and the deformation modified segmental relaxation time. Comparison of the theoretical results with experiments on PMMA reveals good agreement. The coupling of stress and aging, the strain softening effect, and large deformation strain hardening, can also be treated within our approach.

9:00AM X18.00004 Why Temperature Variation of the Chain Relaxation is Universal for Many Polymers? . ALEXEI SOKOLOV, The University of Akron, UNIVERSITY OF AKRON TEAM — Temperature variations of chain and segmental modes are traditionally described through corresponding friction coefficients. It is usually assumed that the same friction mechanism controls dynamics of both processes. As a result, their temperature dependence is expected to be the same. It is known, however, that segmental relaxation in many polymers varies faster than the chain one when temperature approaches Tg. We present an analysis of temperature variations of segmental and chain modes for different polymers. We demonstrate [1] that the chain relaxation shows universal temperature dependence for many polymers when it is presented vs Tg/T. Even polymers with strongly different temperature behavior of segmental dynamics (fragility) exhibit the same behavior for the chain relaxation. These results indicate complete decoupling in behavior of chain and segmental modes and emphasize our deficiency in understanding the microscopic mechanism of the chain friction coefficient. Possible mechanisms that lead to so universal behavior of chain relaxation are discussed at the end.

8:00AM X18.00001 Elastomeric Photopolymers: Shaping Polymer Gels with Light . JULIA KORNFIELD, California Institute of Technology, Division of Chemistry and Chemical Engineering — Polymer gels that possess a latent ability to change shape, which can be triggered in a spatially resolved manner using light—“elastomeric photopolymers”—have been developed to meet the need for materials that can be reshaped without direct contact, e.g., to non-invasively adjust an implanted lens in the human eye. The physics of diffusion and swelling in elastomers are applied to create a transparent silicone suitable for making a foldable intraocular lens that can be reshaped using near ultraviolet light. A crosslinked silicone network dynamics. The approach is built on the concept of a nanometer scale nonequilibrium free energy which quantifies dynamic localization due to interchain forces. We have now generalized this approach to treat quiescent relaxation, physical aging, and nonlinear mechanical properties in the nonequilibrium glass state. Applied stress weakens dynamical constraints in the effective free energy which accelerates alpha relaxation and softens the elastic modulus. A constitutive equation has been constructed which allows the prediction of dynamic yielding and mechanical response under constant strain rate, constant stress (creep), and other modes of deformation. Multiple predictions that fundamentally differ from the phenomenological Eyring model are made for the temperature and strain rate dependence of the dynamic yield stress and the deformation modified segmental relaxation time. Comparison of the theoretical results with experiments on PMMA reveals good agreement. The coupling of stress and aging, the strain softening effect, and large deformation strain hardening, can also be treated within our approach.

8:36AM X18.00002 Dynamics of Swollen Gel Layers Anchored to Solid Surfaces . GEORGE FYTAS, FORTH, University of Crete, Greece, MARIA GIANNELI, University of Crete, Greece, ROBERT ROSKAMP, ULRICH JONAS, KALOIAN KOYNOV, WOLFGANG KNOLL, MIPIP Mainz, Germany, BENOIT LOPPINET, FORTH, Greece — Thin responsive hydrogel films are currently under development for biosensor applications. Photocrosslinkable poly(N-isopropylacrylamide) (PNIPAAm) based chains are spin coated as thin films (about 1 micron) and UV irradiated with variable doses to control the crosslink density. The obtained anchored gel layers can swell in ethanol or water up to about 10 microns for low crosslinking densities. Dynamics of the swollen layers and diffusion of different tracers (as analyte mimics) are studied by dynamic light scattering (PCS) and fluorescence correlation spectroscopy (FCS). PCS resolved fast and slow diffusions, attributed to cooperative diffusion and long range concentration heterogeneities. Higher crosslink densities give rise to faster cooperative diffusion, i.e. short dynamic mesh sizes. FCS revealed the importance of electrostatic interactions between probe and negatively charged network. While a negatively charged dye senses local dynamics with a moderate slow down, a positively charged dye exhibited substantially retarded diffusion. Larger tracers are used to assess the size dependent gel penetrability, whereas large particles, trapped into the network, expectedly follow the network dynamics.

12:00PM X18.00005 Molecular dynamics simulations of layers of linear and branched alkanes under shear . P. SOZA, P.U. Catolica Chile, F.Y. HANSEN, Tech. Univ. of Denmark, H. TAUB, U. Mo.-Columbia, U.G. VOLKMANN, P.U. Catolica Chile — We have previously studied the equilibrium structure and dynamical excitations in films of the linear alkane tetracosane (n-C24H50) and the branched alkane squalane (C30H62) in great detail. Here we report the results of nonequilibrium molecular dynamics simulations of these systems in order to compare the rheological properties of alkanes of the same length but with different architecture. The simulations were done in the NVT ensemble using the reverse nonequilibrium algorithm proposed by F. Müller-Plathe et al. The viscosity was calculated for different shear rates and compared with experimental values. Different structural parameters such as the mean end-to-end distance, the radius of gyration, and the angle of alignment of the molecules with the flow were studied as a function of the shear rate. A.D. Enevoldsen et al., J. Chem. Phys. 126, 104703-10 (2007); 126, 104704-17 (2007). [3] F. Müller-Plathe et al., Phys. Rev. E, 59, 4894 (1998)

8:24AM X18.00006 On the influence of excluded volume in polymer melts . HENDRIK MEYER, J.P. WITTMER, J. FARAGO, A. JOHNER, J. BASCHNAGEL, ULP Institut Charles Sadron, CNRS UPR22, Strasbourg, France — Flory’s ideality hypothesis states that polymer chains in the melt have random walk like conformations as if there would be no excluded volume. However, it was shown recently that the excluded volume interaction induces corrections to scaling which are long range and which give rise to a power law decay of bond-bond correlation function [1] as well as to corrections to the Kratky plateau of the form factor [2]. In this presentation, we focus on the Rouse mode analysis by switching on the excluded volume potential gradually to study the crossover from phantom chains (representing perfect random walks described by the Rouse model) to real polymer melts [3]. In the melt, significant corrections have to be made to the static Rouse mode spectrum and consequences for the dynamics are briefly discussed. This gives also evidence that subdiffusive behaviour found in contradiction to the Rouse model is also caused by the excluded volume interaction. [1] J. Wittmer, H. Meyer, J. Baschnagel et. al. Phys. Rev. Lett. 93 (2004) 147801. Phys. Rev. E 76 (2007) 011803. [2] J. Wittmer et. al. EPL 77 (2007) 56003. [3] H. Meyer et. al. accepted at Eur. Phys. J. E (2007)
9:36AM X18.00007 Observation of Anomalous Viscosity in Entangled Polymer Films near the Glass Transition  . ZHANG JIANG, Dept. of Physics, University of California at San Diego & Advanced Photon Source, ANL, M. K. MUKHOPADHYAY, SUNIL K. SINHA, Dept. of Physics, University of California at San Diego, SURESH NARAYANAN, Advanced Photon Source, ANL, LAURENCE B. LURIO, Dept. of Physics, Northern Illinois University, SANGHOON SONG, HYUNJUNG KIM, Dept. of Physics & Interdisciplinary Program of Intergrated Biotechnology, Sogang University, Korea — We have studied the viscous relaxation of surface waves on molten polystyrene films of various molecular weights ($M_w$) using x-ray photon correlation spectroscopy. The relaxation time has been measured as a function of wave vector from high temperatures down to near the bulk glass transition temperature ($T_g$). We find a transition from a single exponential regime through a stretched exponential to another single exponential regime with increasing temperature. The transport dynamics of polymer films at $T_g$ where the effective viscosity saturates at that of chains with critical molecular weight for entanglement. These results are interpreted in terms of the freezing-out of relaxation modes involving full chains and large segments until only fluctuations of chain segments of critical entanglement length survive. We also find no evidence for a low viscosity surface layer near $T_g$.

9:48AM X18.00008 Kohrausch Parameter Determination for Simple Chain Models  . JOHN MCCOY, TAYLOR DOTSON, JULIENNE HEFFERNAN, KEENAN DOTSON, Materials Department, New Mexico Tech, Socorro, NM 87801, JOANNE BUDZIEN, DOUGLAS ADOLF, Sandia National Laboratories, Albuquerque, NM 87185 — The second Legendre polynomials of the end-to-end vector of freely jointed and freely rotating chains were extracted from molecular dynamics simulations and analyzed in terms of the Kohrausch-Williams-Watts (KWW) function. Of particular interest is the variation of the stretching exponent, $\beta$, as a function of state point and, consequently, of the detailed compliance with time-temperature superposition. A new analysis methodology is introduced that permits the determination of $\beta$ at the needed level of precision. Detailed time-temperature superposition does not hold for freely-jointed or freely-rotating chain liquids. Indications of a breakdown in time-temperature superposition are also found in violations of Stokes-Einstein and Debye-Stokes-Einstein behavior.

10:00AM X18.00009 Understanding Fragility in Polymers  . KUMAR KUNAL, The University of Akron, CHRISTOPHER ROBERTSON, Bridgestone Americas Center for Research and Technology, ALEXEI SOKOLOV, The University of Akron, THE UNIVERSITY OF AKRON TEAM, BRIDGESTONE AMERICAS CENTER FOR RESEARCH AND TECHNOLOGY COLLABORATION — Glass transition in polymeric liquids is an important phenomenon that still remains poorly understood. It is accompanied by strongly non-Arrhenius temperature variations of segmental relaxation time $\tau_\alpha$. The deviations of $\tau_\alpha$ from Arrhenius behavior is described by the fragility parameter, $m$: $m = \beta \log (\tau_\alpha/(T-T_g))/\tau_\alpha T_g$, where $T_g$ is the glass transition temperature. It appears that polymers are very fragile compared to small molecular weight liquids. However, there are some polymers that have intermediate fragility too. The reason for high fragility of polymers remains a topic of active discussion. We have studied various polymer systems using dielectric spectroscopy and dynamic mechanical analysis, and present an analysis of the results in the framework of chain flexibility, symmetry of the monomer and the packing efficiency of the polymer melt.

10:12AM X18.00010 Dye Reorientation as a Probe of Stress-induced Mobility in PMMA Glasses  . HAU-NAN LEE, University of Wisconsin-Madison, KEEWOOK PAENG, STEPHEN SWALLEN, MARK EDIGER — To understand the response of molecular glasses to deformation, we perform optical measurements of dye reorientation in PMMA glasses under stress. The reorientation of probes can be used to monitor the segmental dynamics of a polymer melt. We utilize this method to quantitatively determine the stress-induced mobility in PMMA glass during tensile creep deformation. At 377 K ($T_g$-18 K), a stress of 20 MPa accelerates the mobility by a factor of 100, while 11 MPa has almost no effect. After removing the stress, we observe that the enhanced mobility slowly disappears, even though the overall strain is still very large.

10:24AM X18.00011 On the effect of Molecular weight and Frequency dependence of $T_g$ on the interpretation of Dynamic viscosity data  . J.P. IBAR, Un. de Pau URM256, Pau 64013, A. ALLAL UNIV. DE PAU 64013 COLLABORATION — In this work, we re-plot dynamic data for a series of monodispersed Polystyrene melts, and their blends, obtained at constant temperature and variable frequency $\omega$, to enable a new analysis at constant ($T-T_g$) instead, where $T_g$ is made a function of $M_n$ and $\omega$. $T_g$ ($\omega$) is determined by DMA, from the shift of the max of $E''$ with $\omega$. $T_g$ increases rapidly with $\omega$ and levels off at higher $\omega$. The $M_n$ dependence of $T_g$ varies in a similar way, quickly plateaus off at approximately $M_n$=2 Me, consistent with a free volume interpretation. It is shown that correction for the $T_g$ dependence on $M_n$ and $\omega$ does play an important role in the determination of the scaling parameters exponents, such as the molecular weight dependence exponent for $M_n$=2 Me data, or the low frequency tail representative of the terminal behavior for blends of monodispersed samples. The paper concludes that a true separation of the variables to determine the independent effect of structural (local) and molecular weight (scaling) factors, can only be done at constant ($T-T_g$). The incidence of $T_g$($\omega$, $M_n$) on the superposition at low $\omega$, is also reviewed.

10:36AM X18.00012 Influence of pressure (density) on fast dynamics in polymers  . LIANG HONG, BURAK BEGEN, ALEXANDER KISLIUK, ALEXEI SOKOLOV, University of Akron, DR SOKOLOV'S GROUP TEAM — Understanding the microscopic nature of the fast dynamics in disordered materials is still a challenge. In particular, the origin of the collective vibrations, the so-called Boson peak, remains a subject of active discussion. It’s known that Boson peak spectra change significantly under pressure. Analysing the role of density in the Boson peak might help to unravel its microscopic nature. In this work, we use light scattering to study influence of pressure (up to 1.5 GPa) on fast dynamics in different polymers. In all cases, the observed shift of the Boson peak frequency with pressure is significantly stronger than change of sound velocities. This result clearly indicates that elastic continuum approximation cannot describe the pressure-induced variations. We demonstrate that the main variation of the Boson peak amplitude is due to changes of the Debye level, although detailed quantitative analysis is not possible due to the light-to-vibration coupling coefficient, which also varies with pressure. Analysis also shows there is a correlation between pressure-induced changes in the Boson peak frequency and amplitude.

10:48AM X18.00013 Visualization and Analysis of the Dynamics of Methanol Transport in Poly(Methyl Methacrylate)  . ADAM EKENSEAIR, RICHARD KETCHAM, NICHOLAS PEPPAS, The University of Texas at Austin — The relative rates of the diffusional and relaxational processes during the absorption of penetrating molecules in glassy polymers determine the nature of the transport process and lead to a myriad of transport phenomena, such as Fickian, Case II, and anomalous absorption behavior. Many proposed models account for the majority of anomalous behavior that has been observed. However, there is still a disconnect between theory and experiment, as data must be fit to the model and adjustable parameters determined. We propose that a better understanding of the dynamics of penetrant transport in glassy polymers can be achieved by careful and detailed investigations into the role the polymeric network structure plays in influencing the transport mechanism. We introduce a novel technique to visualize and quantify transport dynamics and mechanisms in situ. High-resolution X-ray computed tomography, a completely nondestructive technique that can be used to visualize features in the interior of opaque solids, has been successfully adapted to examine the transport dynamics of methanol into glassy poly (methyl methacrylate) discs synthesized by an infusion-mediated free radical polymerization. In addition to tracking methanol absorption and dimensional swelling, the time-dependent concentration profiles within the polymer disc were determined.
8:00AM X22.00001 Ab initio simulations of the transport properties of Mn$_{12}$ based spin-devices . CHAITANYA DAS PEMMARAJU, IVAN RUNGGER, STEFANO SANVITO, Trinity College Dublin, Ireland, COMPUTATIONAL SPINTRONICS GROUP, TCD TEAM . Single-molecule magnets (SMMs) represent a unique playground for fundamental quantum physics and exhibit exotic phenomena such as magnetic hysteresis as well as magnetization reversal through quantum tunneling . Recently, transport measurements on Mn$_{12}$ based molecular magnets in single-molecule-transistor devices have been realized . In this work we present ab initio transport[1] calculations of Mn$_{12}$ molecules functionalized by thioether groups and sandwiched between gold contacts . We find the transport properties of these SMMs to be dominated by tunneling type behaviour across the organic functional groups and asymmetric coupling to the leads . We observe asymmetric I-V curves under positive and negative bias . In addition we demonstrate that the I-V characteristic changes upon changing the magnetic state of the molecule, suggesting that electrical single-spin detection can be indeed obtained from a detailed knowledge of the I-V .

8:12AM X22.00002 Modeling the organic magnet Fe[TCNE]$_2$ . J. MORENO, M.A. MAJIDI, University of North Dakota, K.I. POKHODNYA, North Dakota State University — Recent experiments have revealed the crystal structure of Fe[TCNE]$_2$ , (TCNE = tetracyano-ethyleno), an organic-based magnet with a transition temperature around 100 K and a saturation magnetization corresponding to an effective spin of 3/2 per formula unit . Its structure consists of undulating layers of TCNE anion-radicals bound to four Fe(II) ions, where Fe ions between adjacent layers coupled via diamagnetic σ-dimerized TCNE . Since the angular momentum of Fe(II) is almost quenched due to the asymmetric crystal field, we model the system using a Heisenberg Hamiltonian with antiferromagnetic in-plane coupling between the Fe(II) S=2 spins and the near-neighbor (TCNE) S = 1/2 spins and also antiferromagnetic superexchange coupling between the Fe(II) spins at adjacent planes . By comparing our results with magnetization measurements as function of temperature and field, we extract the values of the inter- and intra-plane antiferromagnetic couplings . We discuss how to extend our approach to other TCNE-based magnets, such as the amorphous semiconducting V[TCNE]$_2$ , a room temperature ferrimagnet and promising candidate for multifunctional spintronic applications .

8:24AM X22.00003 Reversible Photoinduced Magnetism in V-Cr Prussian blue analogues . K. DENIZ DUMAN, JUNG-WOO YOO, N.P. RAJU, Physics, The Ohio State University, AMBER C. MCCONNELL, WILLIAM W. SHUM, KENDRIC J. NELSON, JOEL S. MILLER, Chemistry, University of Utah, A.J. EPSTEIN, Physics and Chemistry, The Ohio State University — The cyan-o-bridged bi-metallic compounds, so called “Prussian blue magnets,” display a broad range of interesting photoinduced magnetic phenomena . A notable example is Fe-Co Prussian blue magnet, which exhibits light-induced changes in between magnetic states together with glassy behavior[1,2] . Here, we report reversible photoinduced magnetic phenomena in V-Cr Prussian blue analogue (K$_{1.54}$V$_{0.65}$Cr(CN)$_{6}$)(SO$_{4}$)$_{0.13}$3.1H$_2$O, one of the few room temperature molecule-based magnets . Illumination with UV light suppresses magnetization, whereas subsequent illumination with green light increases magnetization . This recovery effect of green light is observed only when the sample is previously UV-irradiated . This suggests a hidden metastable magnetic state with a long lifetime at low T (<100 K) . Results of detailed magnetic studies and the likely microscopic mechanisms will be discussed . [1] Hashimoto et al. science 272, 5262 (1996); [2] Pejakovic, et al. PRL 85 1994 (2000)

8:36AM X22.00004 Magnetic properties of organic-based Ni[TCNE](MeCN)$_2$[BF$_4$] magnet . KONSTANT IN POKHODNYA, CNSE NDSU, Ohio State University; University of Utah, VICTOR DOKUKIN, JOEL S. MILLER, University of Utah — A new organic-based magnet Ni[TCNE](MeCN)$_2$[BF$_4$] (1 composite-hyphenylene) was synthesized via reaction of NiBr$_2$(TCNE) and Ni(NCMe)$_2$(BF$_4$)$_3$ in CH$_2$Cl$_2$ . Zero field cooled and field cooled magnetizations, M(T)$_{ZFC}$ and M(T)$_{FC}$, at 0.5 mT rise sharply below 70 K indicative of an onset of a magnetic transition . M(T)$_{ZFC}$ reaches maximum at 25 K followed by a rapid decrease suggesting antiferromagnetic (AF) interaction . In contrast, M(T)$_{FC}$ rises upon further cooling signifying a strong irreversibility in accord with sharp increase of a remanant magnetization below 30 K and hysteretic behavior of M(H) . The M(H) at 2 K increases rapidly with field and approaches saturation above ~ 0.5 T . At 9 T M(H) reaches 2.24 $\mu_B$/molecule that is significantly higher than 1.30 $\mu_B$ expected for AF coupled Ni(II) S = 1 and [TCNE]$^-$ (S = 1/2) suggesting a ferromagnetic (FM) interaction . The unpaired Ni$^{2+}$ spins and those on the [TCNE]$^-$ reside in orthogonal orbitals resulting in FM coupling . Assuming that similarly to Fe[TCNE][FeCl$_2$(MeCN)$_2$] 1 consists of Ni$^{2+}$ - μ$_{Fe}$-[TCNE]$^-$ layers we believe that the decrease of M(T)$_{ZFC}$ below 25 K is due to AF coupling between the layers while the interaction within the layer is FM in contrast to the AF one reported for Fe, V, and Mn analogues .

Supported in part by DOE (DE-FG03-93ER45504, DE FG 02-86BR45271 and DE-FG02-01ER45831) and AFOSR (F49620-03-10175) and NSF ND EPSCoR EPS-0447679 grants.

8:48AM X22.00005 Magnetoresistance in bulk heterojunction solar cells . RONALD OESTERBACKA, Abo Akademi University, SAYANI MAJUMDAR, University of Turku, HIMALDRI MAJUMDAR, HARRI AARNIO, Abo Akademi University, REINO LAIHO, University of Turku — The magnetoresistance (MR) response of the poly(3-hexyl thiophene) and poly(3-hexyl thiophene):1-(3-methoxy carbonyl) propyl-1-phenyl-[6,6]-methanofullerene (PHT:PCBM) based bulk heterojunction solar cells have been studied . Positive MR was always observed at room temperature in both the devices . In both cases the magnitude of the MR signal decreases at lower temperature and shows positive to negative sign inversion at 100K for the solar cells and at 200K for P3HT . The detailed voltage and temperature dependence of MR will be presented which will give important insight of the magnetic field effect on the bulk carrier mobility in the organic solar cells . We have observed tendency of retaining magnetic history in both the devices and it has been studied .

9:00AM X22.00006 Extending transfer-matrix studies of charge transport in dsDNA: diagonal ladder model . STEPHEN WELLS, RUDOPH ROEMER, University of Warwick — The π-stacking of aromatic bases along the axis of the DNA double helix suggests that DNA should be capable of supporting electron transport . This possibility has been investigated by a variety of experimental methods, including charge-transfer between intercalated dye molecules and direct measurement of conductivity in DNA molecules bridging two electrodes . In order to explore either the biological or nanotechnological significance of charge transport in DNA, we need theoretical models capable of predicting the influence of DNA sequence and structure on its charge transport properties . Transfer matrix methods have been used in conjunction with a ladder model of dsDNA (incorporating charge transfer between adjacent bases along a strand, and between hydrogen-bonded base pairs) to predict different transport properties for random, repetitive, or coding DNA sequences . It has been suggested that DNA charge transport may be involved in cellular mechanisms to detect and repair damage to DNA strands . We present extensions to the ladder model to allow for, firstly, charge transfer “diagonally” (from a base on a 5’ strand to an adjacent base on a 3’ strand, for example), and secondly, variations in hopping amplitudes due to bending of the helix (for example, in wrapping round a histone complex) . Hence we take into account the extent of the electronic states and the geometry of the DNA strand in our modeling .
9:12AM X22.00007 Sequence Dependent Charge Transport on Double Stranded DNA1, EFTA YUDIARSAH, SERGIO E. ULLOIA, Ohio University — The transport properties of different double-stranded DNA sequences are studied by transfer and scattering matrix methods. The DNA is described by a tight-binding model with realistic sequence-specific hopping integrals. Our results show that, in qualitative agreement with experimental results [1], even a single base mismatch on the sequence can dramatically change the conductance of short DNA sequences. The change in conductance is larger if the mismatch is on the energetically favorable path of transmission: the path with the most bases with energy close to the Fermi energy of the contacts. This trend is independent on which strand is being connected to the electrodes, although similar sequences have drastically different conductance values. We also study the effect of structural “nicks” on the DNA conductance. In accordance with experimental results [2], the conductance is changed by several orders of magnitude in the presence of the nicks, depending on the position of the defect on the strand. As the conductance of a strand is found to be dependent on the sequence of bases, this suggests an electronic approach to sequencing [1]. [1] J. Hihath et al., Proc. Natl. Acad. Sci. U. S. A. 102, 16979 (2005). [2] B. Hartzel et al., Appl. Phys. Lett. 82, 4800 (2003).

9:24AM X22.00008 Theory of electron conductance across a DNA basepair, MYEONG LEE, OTTO SANKEY, Arizona State University — In recent years, research on electron tunneling through DNA basepairs has become more important due to its potential application in DNA sequencing technology. The goal is to recognize and identify a specific DNA base by measuring the hydrogen bond mediated tunneling current across a DNA base pair junction. In this talk, we discuss the results of density functional theory in the intrinsic conductance through DNA basepairs (Watson-Crick base pairs, Wobble base pairs, etc), and in particular the role of the hydrogen bond on the tunneling current.

9:36AM X22.00009 Charge transport in guanine crystals, FRANK ORTMANN, KARSTEN HANNEWALD, FRIEDHELM BECHSTEDT, ETSF and IFTO, Friedrich Schiller University Jena, Germany — Charge-transport processes in organic molecular crystals exhibit similarities and differences to those in r-conjugated polymers. For both types of condensed matter the polaronic effects are of high importance. These effects can cause a transition from bandlike transport to thermally activated hopping. While the hopping regime is prevalent for DNA polymers, it is not clear if the same holds also for crystalline guanine or if band transport dominates. Also the influence of the temperature is rarely discussed in literature. In our approach to the problem of charge-carrier transport in these systems [1], we discuss the temperature dependence of the polaron bandwidth and the mobility in guanine crystals [2].

Friday, March 14, 2008 8:00AM - 10:48AM —
Session X23 DMP MAG: Focus Session: Multiferroics III: Other —
Morial Convention Center 215

8:00AM X23.00001 Pyroxenes: A novel class of multiferroics1, 2, D.J. KHOWSKII, Koeln University, S. JODLAU, P. BECKER, J. MYDOSH, TH. LORENZ, S.V. STREITSLSOV, D.C. HEZEL, L. BOHATY — Pyroxenes with the general formula AMSi2O6 (M = mono- or divalent metal) are shown to be a new class of multiferroic materials. In particular, we have found so far that NaFeSi2O6 becomes ferroelectric in a magnetically ordered state below 6 K. Similarly, magnetically driven ferroelectricity is also detected in the Li homologues, LiFeSi2O6 (Tc = 18 K) and LiCs2Si2O6 (Tc = 11 K). In all these monoclinic systems the electric polarization can be strongly modified by magnetic fields. Measurements of magnetic susceptibility, polarization current and dielectric constants (and their dependence on magnetic field) are performed using a natural crystal of aegirine (NaFeSi2O6) and synthetic crystals of LiFeSi2O6 and LiCs2Si2O6 grown from melt solution. For NaFeSi2O6 a temperature versus magnetic field phase diagram is proposed. Exchange constants are computed on the basis of ab initio band structure calculations. The possibility of a spiral magnetic structure caused by frustration as origin of the multiferroic behaviour is discussed. We propose that other pyroxenes may also be multiferroic, and that the versatility of this family offers an exceptional opportunity to study general conditions for and mechanisms of magnetically driven ferroelectricity.

8:12AM X23.00002 Magnetic field induced ferroelectricity in Mn11.9Fe0.1WO4, RAJIT CHAUDHURY, BERND LORENZ, YAQI WANG, YANYI SUN, CHING-WU CHU, TCSUH and Department of Physics, University of Houston, Houston, Texas 77204-5002, USA — We discovered the external magnetic field induce ferroelectric phase in Mn11.9Fe0.1WO4, which is paraelectric at zero magnetic field. The ferroelectric phase appears in fields above 4 Tesla applied along the easy axis of magnetization and the spontaneous polarization along the b-axis was measured by the pyroelectric method as a function of temperature and magnetic field. The temperature and magnetic field dependence of spontaneous polarization shows strong coupling between magnetic and ferroelectric orders. We interpret that the improper ferroelectricity in this compound is driven by non collinear spin structure which breaks the inversion symmetry. We propose high-field neutron scattering experiments to characterize the magnetic structure in the ferroelectric phase.

8:24AM X23.00003 Quantum theory of multiferroics in quasi-one-dimensional spin-1/2 frustrated magnets1, SHIGEKI ONODA, MASASHIRO SATO, RIKEN (Institute of Physical and Chemical Research), Wako 351-0198, Japan, YASUHIRO SAIGA, Department of Physics, Nagoya University, Nagoya 464-8602, Japan, SHUNSUKU FURUKAWA, RIKEN (Institute of Physical and Chemical Research), Wako 351-0198, Japan — A theory is developed to understand recent experimental findings on quasi-one-dimensional spin-1/2 multiferroics LiCuVO3 and LiCu2O2. For this purpose, weakly coupled frustrated quantum spin chains with and without the zigzag structure are studied by means of an effective field theory based on the bosonization in one dimension. A chiral ground state with gapless incommensurate spin excitations can be stabilized in the presence of an easy-plane anisotropy. This state is driven by a three-dimensional coupling to the incommensurate helimagnetic state, in accordance with the experimental observations. We also reveal the quantum dynamics of the spin, the chirality and the electromagnon as well as the finite-temperature phase diagram, which reflect the one-dimensional nature of the quantum fluctuations.

1The work is partly supported by the Grant-in-Aids from the Japan Society for the Promotion of Science.

8:36AM X23.00004 Correlation between spin helicity and electric polarization vector in quantum chain magnet LiCu2O2, SHINICHIRO SEKI, YUICHI YAMASAKI, YOSHINORI TOKURA2, Department of Applied Physics, University of Tokyo, MINORU SODA, MASATO MATSUURA, KAZUMA HIROMA, The Institute for Solid State Physics, University of Tokyo — Measurements of polarized neutron scattering were performed on the multiferroic quantum chain magnet LiCu2O2. In the ferroelectric ground phase, the existence of transverse spiral spin component in the bc-plane was confirmed. When the direction of electric polarization is reversed, the vector spin chirality as defined as Cij = S1 × S2 is also reversed. This directly proves that the spin-current model Pij ∝ eij × Cij is applicable even to this eij-electron quantum S=1/2 system. Differential scattering intensity of polarized neutrons shows a large discrepancy from that expected for the classical bc-cycloidal spin structure, implying either the complexity of magnetic structure or the effect of quantum fluctuation.

8:48AM X23.00005 Multiferroics versus Quantum Fluctuations in Spin-1/2 Frustrated Chains
 SHUNSUKÉ FURUKAWA, MASAHIRO SATO, SHIGEKI ONODA, RIKEN — We study interplay of the chiral spin ordering and quantum fluctuations in a spin-1/2 frustrated chain, which is the simplest model for one-dimensional multiferroic cuprates like LiCuVO$_4$ and LiCu$_2$O$_2$. In a Heisenberg chain, it is known that the classical helical magnetic order is suppressed by strong quantum fluctuations and valence-bond solid phases emerge. In fact, weak easy-plane spin anisotropies exist in the above materials, because of the XXZ-type anisotropy and a phonon-induced biquadratic Dzyaloshinskii-Moriya interaction. In particular, when the nearest-neighbor exchange coupling is much weaker than the antiferromagnetic second-neighbor one, our exact-diagonalization calculations combined with the bosonization analyses show that such anisotropies bring about the vector-chiral spin ordering and the associated multiferroic behavior. This chiral state is accompanied by slightly incommensurate algebraic spin correlations, which, with a three-dimensional coupling, explains the magnetic order experimentally observed in LiCuVO$_4$.

9:00AM X23.00006 Optical spectroscopic study on magnetoelectric MnWO$_4$. WOO SEOK CHOI, Seoul National University, KOUJI TANIGUCHI, Tohoku University, SOON JAE MOON, SUN JUNG KIM, SUNG SEOK A. SEO, Seoul National University, YOON SANG LEE, Soongsil University, TAKA-HISA ARIMA, Tohoku University, TAE WON NOH, Seoul National University — We report optical spectroscopic investigation on a multiferroic oxide compound, MnWO$_4$. This compound is known to exhibit ferroelectricity induced by the incommensurate spiral magnetic ordering in a temperature range of 7.6 K and 12.7 K [1]. We grew single crystals of MnWO$_4$ by using the floating zone method. To examine the optical anisotropy originating from the monoclinic crystal structure, we measured reflectivity spectra of MnWO$_4$ with light polarizations along three crystallographic axes, and calculated the optical conductivity spectra through the Kramers-Kronig transformation for each axis. We discuss the anisotropic phonon structures and electronic structures with temperature and magnetic field dependence in relation to its multiferroic properties.

9:00AM X23.00007 Ferroelectric domain topology of the multiferroic spin spiral system MnWO$_4$. D. MEIER, TH. LOTTERMOSER, G. YUAN, M. FIEBIG, HISK P - Univ. Bonn, Germany, P. BECKER, L. BOHATY, Institute of Crystallography, Univ. Cologne, Germany — The strong interest in magnetoelectric multiferroics is due to their potential concerning the design of novel multifunctional devices, as well as to their unusual physical properties. Among these, Tb$_2$Mn$_2$O$_7$, Ni$_2$V$_2$O$_8$, and MnWO$_4$ form a particularly challenging group: The key factor for ferroelectricity lies in the long-wavelength magnetic order. Many aspects of the precise nature of the ferroelectric state in such a spiral magnet, and in particular their coupling to the magnetic order, are still largely unclear. Here we report about the three-dimensional spatial distribution of ferroelectric domains in MnWO$_4$, revealed by optical second harmonic generation (SHG). Although ferroelectricity is induced by cycloidal spiral magnetic order, 180° domains as in a conventional ferroelectric are observed. Their coupling to the coexisting magnetic order and modifications of this coupling by external parameters such as temperature variation are discussed using spatially resolved SHG for probing both the magnetic and the ferroelectric order in one experimental run.

9:00AM X23.00008 Magnetic field control of the ferroelectric polarization in multiferroic MnWO$_4$. KOUJI TANIGUCHI, NOBUYUKI ABE, TAKAHIWA ARIMA, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, TAISHI TAKENOBU, YOSHIHIRO IWASA, Institute for Materials Research, Tohoku University — The relationship between magnetic order and ferroelectric properties has been investigated for MnWO$_4$. Spontaneous electric polarization is observed in a cycloidal spiral spin phase. The magnetic-field dependence of electric polarization indicates that the noncollinear spin structure plays a key role for the appearance of ferroelectric phase. Destabilization of the ferroelectric phase and an electric polarization flop from the b direction to the a direction have been observed when a magnetic field is applied along the b axis. On the other hand, the ferroelectric phase is stabilized when a magnetic field is applied along the a, c- and the spin easy axes. We have also found that the magnetic field induced ferroelectric polarization disappears in a high magnetic field above $12T$ along the spin easy axis. These phenomena provide us useful information for giant magnetoelectric effects because MnWO$_4$ is a simple system without rare-earth f-moments.

9:36AM X23.00009 Ferroelectricity in Mn$_{0.9}$Fe$_{0.1}$WO$_4$ induced by magnetic fields: A simple model calculation. B. LORENZ, R. P. CHAUDHURY, C. W. CHU, TCSUH and Department of Physics, University of Houston — Replacing Mn$^{2+}$ by Fe$^{3+}$ in multiferroic MnWO$_4$ results in the complete loss of ferroelectricity at zero magnetic field. However, it was shown that in Mn$_{0.9}$Fe$_{0.1}$WO$_4$ an external magnetic field restores the ferroelectric state. We present a simple mean field calculation of the Heisenberg model with ferromagnetic nearest and antiferromagnetic next nearest neighbor interactions and uniaxial anisotropy in an external magnetic field. The various commensurate and incommensurate magnetic phases in Mn$_{0.9}$Fe$_{0.1}$WO$_4$ with increasing Fe substitution is explained by the enhancement of the anisotropy. We show that the external field does indeed restore the helical spin structure in Mn$_{0.9}$Fe$_{0.1}$WO$_4$ and that the observed field-induced ferroelectricity can be explained.

9:48AM X23.00010 Correlation between magnetic, dielectric phase and strain in a Mn$_3$O$_4$ single crystal. T. SUZUKI, KATSUFUJI, Dept. of Physics, Waseda University — Mn$_3$O$_4$ has a tetragonal distorted spinel structure below 1443 K and exhibits a ferrimagnetic ordering at $T_N = 43$ K. This compound exhibits further magnetic phase transitions at 39 K and 33 K, where Mn$^{2+}$ and Mn$^{3+}$ spins are cantled from the collinear spin structure. We measured the dielectric constant and strain of a Mn$_3$O$_4$ single crystal. We found that both dielectric constant and strain have clear anomalies at the magnetic transition temperatures. We also found that dielectric constant is suppressed (enhanced) by 2% when magnetic field is applied parallel (perpendicular) to the direction of electric field within the $ab$ plane below $T_N$. In addition, strain along the $ab$ plane also has anisotropic magnetic field dependence. These results can be explained as follows: (1) There is an orthorhombic distortion below $T_N$, presumably induced by the orbital ordering of Mn$^{3+}$; (2) anisotropy of dielectric constant and strain within the $ab$ plane appears due to the orthorhombic distortion, and (3) the alignment of crystalline domains with applied magnetic field occurs, resulting in the large magnetic field dependence of dielectric constant and strain.

10:00AM X23.00011 Polar Behavior in a Magnetic Oxide Via A-Site Size Disorder. DAVID J. SINGH, ORNL, CHUL HONG PARK, Pusan National University — Density functional calculations are used to test a new mechanism for ferroelectricity in magnetic perovskites based on A-site size disorder. Calculations of the structure and magnetic ordering of (La,Lu)MnO$_3$ show that this mechanism is effective for this material, which is predicted to be both polar (ferroelectric or relaxor) and ferromagnetic, depending on the Lu concentration.

1 This work supported by DOE, DMS&E.
10:12AM X23.00012 Electric field control of magnetic phase transitions in Ni$_3$V$_2$O$_8$. P. KHAREL, C. SUDAKAR, Wayne State University, A.B. HARRIS, University of Pennsylvania, R. NAHK, G. LAWES, Wayne State University — In certain multiferroics, including Ni$_3$V$_2$O$_8$, the ferroelectric order is induced by the magnetic structure, leading to the simultaneous onset of spin and charge ordering. We have prepared thin films of Ni$_3$V$_2$O$_8$ by sputter deposition. Films annealed at 1000°C crystallize with closely packed rod-like grains. XRD confirms that the films are single phase Ni$_3$V$_2$O$_8$ and highly oriented along the b-axis. We observe a hysteretic magnetic anomaly at 3.6 K, which is consistent with a first order phase transition from a canted magnetic state to incommensurate magnetic order. This transition temperature is suppressed by $\Delta T$=0.2 K in an electric field of 30MV/m. An anomaly in the dielectric constant is observed at 6.3K, corresponding to a transition between two incommensurate magnetic states. Because the electric field acts as a field conjugate to the order parameter, it causes a rounding of the phase transition and an apparent increase in the transition temperature by $\Delta T$=0.2 K when the sample is biased at 25 MV/m. The E-T phase boundary for the 3.6 K phase transition is linear, while the 6.3 K phase boundary shifts roughly like E vs.$T^2$, consistent with estimates from critical scaling. We will discuss the electric field control of magnetic order parameter in these films and some important implications of this result for the multiferroic material thin film research.

10:24AM X23.00013 Direct Evidence of Magnetoelastic Coupling in Ni$_3$V$_2$O$_8$.1, LUCIANA I. VERGARA, J. CAO, J. L. MUSFELDT, University of Tennessee, N. ROGADO, R. CAVA, Princeton University, F. YEN, R. P. CHAUDHURY, B. LORENZ, University of Houston — We investigate the infrared active phonons of the Kagome staircase compound Ni$_3$V$_2$O$_8$ as a function of temperature to elucidate changes in magnetoelastic coupling through the cascade of low-temperature magnetic transitions. A detailed analysis of the a- and c-polarized vibrational mode trends demonstrates that: i) the approach to the cascade of magnetic transitions is driven by the high frequency stretching modes and the highest frequency bending mode along a; ii) the paramagnetic to high-temperature incommensurate phase transition is driven by low frequency c-polarized modes; and iii) the high-temperature to low-temperature incommensurate phase transition is driven by all a-polarized modes plus the NiO$_6$ stretching mode along c. Work is in progress to elucidate the trends along b. Overall, we find that the phonons are sensitive to the magnetic state, indicating that the lattice is flexible, coupling strongly to the spin system in this multiferroic material.

This work is supported by the U.S. Department of Energy.

10:36AM X23.00014 Magnetic field effect on the magnetic structure of Ba$_3$CoGe$_2$O$_7$. C.R. DELA CRUZ, S. LEE, Dept. of Physics and Astronomy, Univ. of Tennessee, Knoxville, S.-W. CHEONG, RCEM and Rutgers University, Picataway, N.J. Y. CHEN, J. LYNN, NIST-NCNR Gaithersberg, MD. H. MOOK, Neutron Scattering Science Division, ORNL, Oak Ridge, TN. P. DAI1, Dept. of Physics, Univ. of Tennessee — Multiferroic materials have recently attracted much interest fueled by the discovery of the coexistence and mutual interference of long range magnetic and ferroelectric order in them. Further attention to these compounds is gained due to their potential for device applications made possible by the controllability of the spontaneous polarizations by magnetic fields or the bulk magnetization by an electric field via the sizable magneto-dielectric coupling in them. The fundamental microscopic mechanism for the phenomena is yet to be fully understood but an essential component has been suggested to be the non-linear coupling of the ferroelectric and magnetic order parameters with a spatially varying magnetization. It is thus the focus of this work to study the static magnetic structure of the compound Ba$_3$CoGe$_2$O$_7$ below its magnetic and ferroelectric ordering temperature of 7K. Neutron diffraction measurements were done on the compound under applied magnetic fields up to 7 T along the crystal’s c-axis.

Session X24 DCMP: Nanotubes: Transport, Synthesis and Growth Morial Convention Center 216

8:00AM X24.00001 Quantum electron transport in toroidal carbon nanotubes. MARK JACK, MARIO ENCINOSA, Florida A&M University, Physics Department, Tallahassee, FL 32307. — Electron transport under bias is treated in tight-binding approximation using a non-equilibrium Green’s function approach. Density-of-states D(E), transmissivity T(E), and current I$_{CD}$ are calculated through a (3,3) armchair nanotorus with laterally attached metallic leads and a magnetic field penetrating the toroidal plane. Plateaus in T(E) through the torus are observed as a function of both the relative angle between leads and magnetic flux. Initial computational studies performed with 1800 atoms and attached leads show substantial computational slowdown when increasing the system size by a factor of two. Results are generated by inverting the device Hamiltonian with a standard recursion method extended to account for unit cell toroidal closure. Significant computational speed-up is expected for a parallelized code on a multiprocessor computer cluster. The dependence of electronic features on torus size and torus curvature is tested for three tori with 900, 1800 and 3600 carbon atoms, respectively. References: 1. M. Jack and M. Encinosa, Quantum electron transport in toroidal carbon nanotubes with metallic leads. ArXiv: quant-ph/0709.0760. 2. M. Encinosa and M. Jack, Dipole and solenoidal magnetic moments of electronic surface currents on toroidal nanostructures. J. Comp.-Aided Mat. Design (Springer), 14 (1) (2007) 65 – 71.

8:12AM X24.00002 Ab initio study of solvent effects on electrical transport of molecular bridge between electrodes. ARHIRO TAWARA, TOMOFUMI TADA, SATOSHI WATANABE, Department of Materials Engineering, Graduate School of Engineering, The University of Tokyo and Creast, Japan Science and Technology Agency — The electrical conductance of benzene dithiolate (BDT) between gold electrodes has been actively investigated to realize single molecular devices. However, almost all of previous theoretical studies for the electrical conductance of BDT were done assuming 0K and vacuum in spite that many measurements have been performed at room temperature in solution [1,2]. In this study, we have investigated the electrical transport of BDT molecules in water solution using ab initio nonequilibrium Green’s function method and Car-Parrinello molecular dynamics at room temperature. The calculated time-averaged conductance of the BDT in water solution, 0.190 G$_0$, is clearly different from the value calculated without water, 0.201 G$_0$. Detailed analysis shows that this difference can be attributed to the effect of dipole moments of water molecules on the potential profile of the BDT molecule. [1] X. Xiao et al., Nano Lett. 4, 267 (2004). [2] M. Kiguchi et al., Appl. Phys. Lett. 89, 213104 (2006).

8:24AM X24.00003 Low-temperature electronic transport in Pt-nanocluster decorated alumina template grown carbon nanotubes. SWASTIK KAR, CATERINA SOLDANO, LI CHEN, Rensselaer Polytechnic Institute, SAIKAT TALAPATRA, University of Southern Illinois at Carbondale, ROBERT VAJTAI, SAROJ NAYAK, PULICKEL AJAYAN, Rensselaer Polytechnic Institute — Alumina template grown nanotubes are known to be highly disordered tube when compared to arc-discharge grown tubes. This is due to the particular type of growth process involved. Temperature dependence study reveals a slow power law dependence of the conductance as a function of the temperature. Large value of power law exponents found in pristine tubes, suggest that the transport mechanism takes place through tunneling between adjacent graphene flakes. When platinum-decorated, those devices show a Luttinger liquid behavior in the high-T regime and a large suppression of the conductance at low-T due to the interplay of disorder and e-e interactions. Transport properties are studied in light of a recently proposed model for disordered multi-channel quantum wires. Magneto-transport measurements (|B|<5T) show the presence of weak localization and a small but distinct Rashba spin-orbit scattering effect in the low-field regime (|B|<5T), the latter attributed to the surface decoration. Coherent transport is found to be recovered with increasing applied electric field.

8:36AM X24.00004 Electronic properties of doped semiconductor nanowires. MAMADOU DIARRA, CHRISTOPHE DELERUE, IEMN-ISEN, YANN-MICHEL NIQUET, CEA/DRFMC/SP2M/LSim, GUY ALLAN, IEMN-ISEN — Semiconductor nanowires have shown very promising properties, which opens new opportunities for the design of nanoscale devices. The physics of these nanowires is not yet fully understood. In this context, theory and numerical simulation give valuable insights. We present self-consistent tight binding calculations of donor and acceptor impurities in semiconductor nanowires, either in a free standing configuration or surrounded by a metallic gate and an oxide. We show that the dielectric mismatch between the nanowires and their surroundings increases the binding energies of dopant impurities up to a few hundreds of meV [1]. This decreases the doping efficiency and affects the behavior of nanowire devices. The effect of the environment will be discussed. When the nanowires are surrounded by an oxide, polaronic effects largely contribute to the binding energy of the dopants [2].

8:48AM X24.00005 The effect of the sodium and iodine doping on the electronic band structure of the polyicosahedral Si nanowire: A first principles study. KENGO NISHIO, Research Institute for Computational Sciences (RICS), National Institute of Advanced Industrial Science & Technology (AIST), TAIŞŬKE OZAKI, TETSUYA MORISHITA, WATARU SHINODA, MASUHIRO MIKAMI, JAIST — In a previous molecular dynamics study, we predicted a polyicosahedral Si nanowire which has a Si20 fullerene cage per icosahedral Si100 nanodot [1]. The unique cage structure is distinct from the crystalline diamond Si nanowire. Encapsulating a guest atom into the Si20 cage allows us to tune the physical properties of the nanowire. Here, we report on a first-principles study of the effect of the sodium and iodine doping on the electronic band structure of the hydrogen-terminated polyicosahedral Si nanowire [2]. Our calculations reveal that the guest-free polyicosahedral Si nanowire is a semiconductor with a 1.20 eV band gap. We also find that the semiconducting nanowire becomes metallic by the sodium and iodine doping, suggesting that the electronic band structure of polyicosahedral Si nanowires can be tuned by doping appropriate guest atoms. [1] J. Chem. Phys. 125, 074712 (2006). [2] submitted to PRB

9:00AM X24.00006 Electronic structures and electron-phonon interactions of boron-doped carbon nanotube. TAKASHI KORETSUNE, SUSUMU SAITO, Tokyo Institute of Technology — We study the boron-doped single-walled carbon nanotubes using first-principles method based on the density functional theory. The total energy, band structure and density of states are calculated. From the formation energy of boron-doped nanotubes with different diameter, it is found that the narrower tube needs lower energy to substitute a carbon atom with a boron atom. Using the result of different doping rate in the (10,0) tube, we extrapolate the result to low boron density limit and find that the ionization energy of the acceptor impurity level is approximately 0.2 eV. Furthermore, we discuss the doping rate dependence of the density of states at the Fermi level and the electron-phonon interactions which are important for superconductivity.

9:12AM X24.00007 Edge states and magnetism in carbon nanotubes with line defects. HELIO CHACHAM, MARIO S. C. MAZZONI, SIMONE S. ALEXANDRE, Universidade Federal de Minas Gerais — Under certain conditions, magnetic ordering has been predicted to occur in carbon nanostructures even in the absence of transition metal impurities. These conditions involve situations in which electronic localization takes place, such as at zig-zag edges or defects in graphene sheets and ribbons or in topological defects in carbon nanostructures. In the present work, we apply first-principles calculations to investigate the interplay between electronic and magnetic properties of carbon nanotubes with line defects. We consider three types of defects: lines of C-O-C epoxy groups, and defects resulting from the substitution of the oxygen atoms by CH2 or C2H4 divalent radicals. We find that the line defects behave as pairs of coupled graphene edge states, and a variety of electronic and magnetic ground states is predicted as a function of defect type, nanotube diameter, and a possibly applied transverse electric field.

9:24AM X24.00008 Effects of intrinsic spin-orbit coupling in carbon nanotubes1. CARLOS A. BÜSSE, MAHDI ZAREA, NANCY Sandler, Department of Physics and Astronomy, Ohio University, Athens OH 45701 USA. — The electronic structure and transport properties of carbon nanotubes (NTs) are the subject of intense theoretical and experimental studies. Tight-binding model predict these quasi-1D systems to be metallic or insulating depending on their chiral wrapping. Furthermore, external magnetic fields applied along the NT’s axis, are expected to change these behaviors by opening (metallic) or closing (insulating) gaps. In this work we present preliminary numerical results obtained solving a tight-binding Hamiltonian [1] for band structures of armchair and zigzag NTs in the presence of the intrinsic spin-orbit (I-SO) interaction and magnetic fields. The I-SO interaction has dramatic effects, opening gaps for metallic NTs that are proportional the I-SO coupling constant. When considering an external field, the I-SO generated gaps show a quadratic dependence on the field strength in contrast with the linear dependence predicted in the absence of this interaction. Insulating tubes show increased gaps that do not close even in the presence of external fields.

9:36AM X24.00009 Transport properties of single vacancies in nanotubes. ALEXANDRE R. ROCHA, J.E. PADILHA, ADALBERTO FAZZIO, ANTONIO J.R. DA SILVA, Instituto de Física - USP Brazil — We present transport, density of states and electronic transport calculations of single vacancies in carbon nanotubes. We confirm that the defect reconstructs into a pentagon and a nonagon following the removal of a single carbon atom. This leads to the formation of a dangling bond. Finally we demonstrate that care must be taken when calculating the density of states of impurities in one dimensional systems in general. We show that obtaining information about the transport properties of such systems with defects solely from the density of states of a periodic DFT calculation can be misleading. The appearance of mini-gaps and oscillations, even in the limit of large unit cells, can be erroneously associated with changes induced by the defect itself instead of a figment of the procedure. In fact, we demonstrate that those mini-gaps vanish if the appropriate approach is taken, namely a Green’s function method where the effects of semi-infinite electrodes are considered and a true open system is calculated.

9:48AM X24.00010 The structural and electronic properties of vacancy clusters in carbon nanotubes. ALEX TAEKYUNG LEE, YONG-JU KANG, KEE JOO CHANG, Korea Advanced Institute of Science and Technology — Carbon vacancies, which can be generated by electron or ion irradiation, significantly modify the structural and electronic properties of carbon nanotubes. Recent experiments showed that vacancy-type defects induce structural changes such as junction, shrinkage, and bending. In this work we study the atomic and electronic structure of vacancy clusters up to six missing atoms in carbon nanotubes through both first-principles and tight-binding calculations. We find that vacancy defects are generally stable when they are aligned along the tube axis, forming a vacancy-chain. Due to the curvature effect, this feature is different from that found for graphene, where vacancies tend to aggregate into a lump. For the even-numbered vacancies in the (5,5) and (9,0) nanotubes, we find that clustering of vacancies leads to the local shrinkage, with a smaller diameter tube sandwiched between two semi-infinite tubes. In this case, the defect levels near the Fermi level are mostly associated with 7- or 8-membered rings, whereas those for odd-numbered vacancies result from the remnant dangling bonds.
10:00AM X24.00011 Synthesis of Triangle Tungsten Oxide Nanosheets with Potassium Doped - RONG HU, KUNQUAN HONG, HUASHENG WU — We report that large quantity of tungsten oxide nanosheets are synthesized by oxidizing tungsten plate directly. Using potassium hydrate as the catalyst and tungsten plate as the substrate, those triangle tungsten oxide nanosheets with thickness of 50-300 nm and wide up to tens of micrometers are obtained on a large scale. The angles of the triangle nanosheets are around 35° and 50° statistically. We discussed the potential reason of this peculiar phenomenon, besides the several characterizations results of the grown nanosheets. The probable growth mechanism is also investigated.

10:12AM X24.00012 CVD synthesis of graphene — TAO JIANG, JOEL THERRIEN, U. Massachusetts-Lowell — We will report on the use of Chemical Vapor Deposition (CVD) to grow sheets of graphene on substrates suitable for the semiconductor industry. Growth starts with the deposition of seed crystals of graphene on the substrate. CVD growth is found to result in growth at the edges of the seeds, rather than on the surfaces. The result is increases in the size of the seed crystal without additional layers of graphene forming on top of the crystal. This technique holds promise for forming large areas of high quality single layer graphene on inexpensive substrates.

10:24AM X24.00013 New opportunities from controlled growth of carbon nanotubes — SEOKWOO JEON, ROBERT CALDWELL, YUYAO SHAN, HANFEI WANG, JINYAO TANG, SAMI ROSENBLATT, COLIN NUCKOLLS, JAMES HONE, Columbia University — Aligned growth of carbon nanotubes (CNT) has been an important issue to researchers involved in CNT, and recent work has proved the possibility of alignment by using special substrates (i.e. quartz, sapphire, etc.) where CNT can grow along crystallographic axes. We present here two applications of aligned tubes produced from quartz substrates. The first is the realization of an integrated platform for using CNTs as electrodes for single molecules toward sensing applications; numerous sensing units can be generated by photolithography without long, tedious e-beam writing steps due to the precise control of location and direction of CNTs over a large area (~1X1 cm). The second is measurement of the high frequency properties of CNTs, which is difficult due to the high impedance of single-tube devices. By a slight modification of growth parameters, we have achieved growth of ‘serpentine’ CNTs on quartz substrates that permit the fabrication of low-impedance devices using multiple identical CNT sections.

10:36AM X24.00014 Diffusion-limited and pressure-driven electrodeposition in a microfluidic channel — GEOFF STEEVES, University of Victoria, ALEX WLASENKO, DENNIS ZAKOPCAN, DAVID SINTON, University of Victoria — Self-terminating electrochemical fabrication has previously been devised to create quantum point contacts with single-atom contacts, but the structure of the growth has been poorly controlled. We have introduced a microfluidic channel with which to apply pressure-driven flow during the formation of the junction between two Au electrodes. Without applied flow, dendritic growth and dense branching morphologies were typically observed at the cathode. The addition of applied pressure-driven flow resulted in a densely packed gold structure that filled the channel. Our computer simulation yielded insight into the regimes where the diffusion, flow and electric field between the electrodes individually dominated growth. Proposals for further sophistication in both experiment and simulation will also be presented.

10:48AM X24.00015 Continuous and Scalable Fabrication of Transparent Conducting Thin Films of Single Walled Carbon Nanotubes — BUDHAPADA DAN, MAINAK MAJUMDAR, MATTEO PASQUALI, Rice University — We report the fabrication of optically transparent and electrically conducting thin films of single-walled carbon nanotubes (SWNT) using the industrially scalable, fast and simple process of Rod-Coating. Rheology was used to study four different surfactants, their capacity to disperse SWNT in water and the viscoelastic properties of the resulting dispersion. A combination of two different surfactants was found ideal to make a uniform dispersion with high concentration of SWNT and the specific viscoelastic properties desired for coating. Rod coating with this coating fluid produced highly uniform, transparent and conducting SWNT thin films. The films were also treated with various strong acids which lead to further significant improvement in properties. Our results show that the choice of surfactant for making the coating dispersion has a strong effect on the electro-optical properties of the SWNT films. Films with sheet resistance of 100 Ohm/sq and 300 Ohm/sq for respective transparency of 70% and 90%, in the visible region, were obtained with this process. The development of this continuous and scalable fabrication process will thus bring the SWNT films closer to commercial application.

Friday, March 14, 2008 8:00AM - 11:00AM — Session X25 DPOLY: Block Copolymer Phase Behavior Morial Convention Center 217

8:00AM X25.00001 Molecular Simulation of Bicontinuous Phases in Diblock Copolymer Melts — FRANCISCO MARTINEZ-VERACOECHEA, FERNANDO ESCOBEDO, Cornell University — Molecular simulations are used to study the stabilization of different bicontinuous phases in diblock copolymer (DBC) melts. The stabilization approach entails attempting to reduce the packing frustration inside the bicontinuous phases nodes by the addition of a ‘filler’ with affinity for the A component. Two different strategies are considered: 1) addition of selective- solvent particles, and 2) addition of homopolymer. Approximate phase boundaries were found via free-energy calculations. A very dissimilar phase behavior is observed upon increasing the amount of the “additive” in the two different strategies. While with the first strategy (i.e., addition of selective solvent) we observed the progression Gyroid (G) → Perforated Lamellae (P) → Lamella → Reversed-Gyroid. With the second strategy (i.e., addition of homopolymer) we observed the progression of morphologies G → Cylinder → Double Diamond (DD) → Plumber’s Nightmare (P). In both the DD and the P phases, the homopolymer concentrates preferentially in the nodes, suggesting the reduction of the nodes’ packing frustration. In addition, a novel morphology was observed, wherein cylinders of two different diameters alternate in a tetragonal packing. The contrasting difference in the phase behavior observed for the two strategies is understood as a consequence of the difference in mixing entropy exhibited by the two additives.

8:12AM X25.00002 Orthonormhic Fddd Network in Diblock Copolymer Melts — MIKIHITO TAKE-NAKA, MYUNG IM KIM, SATOSHI AKASAKA, TSUTOMU WAKADA, SHOTARO NISHITSUJI, HIROKAZU HASEGAWA, Kyoto University — Poly(styrene-block-polyisoprene) (S-I) diblock copolymer melts with asymmetric volume fraction are shown to form an orthonormhic Fddd network structure, which Tyler et al. predicted with self-consistent field theory for diblock copolymer melts. The studies with small-angle X-ray scattering and transmission electron microscopy revealed that the microphase-separated structure of the S-I diblock copolymer melts with asymmetric volume fraction shows the sequence of transition of disorder-ordered phase with decreasing temperature. Fddd phase appears within the narrow composition and temperature range where gyroid, lamella, and hexagonally perforated layer (HPL) phases appear. The ratio of unit cell parameters (a:b:c) estimated from the peak positions of the scattering function is 1:2:00:3.51, which agrees with the result of the theoretical calculation by Tyler et al. In this orthonormhic structure with the observed unit cell parameters, the higher order reflections 022, and 004 overlaps with the reflection 111 at the first order peak.

8:24AM X25.00003 Fluctuation effects in block copolymers, ERIN M. LENNON, RICHARD ELLIOTT, GLENN H. FREDRICKSON, University of California, Santa Barbara — Using recently developed techniques for locating phase transitions, we study the effects of fluctuations in a field theoretic model on block copolymer behavior. Specifically, we couple the use of complex Langevin dynamics within a field theoretic framework and thermodynamic integration techniques for the calculation of free energies of fluctuating systems to show a revised prediction of the diblock copolymer phase diagram. Further, these methods are extended into blend systems to investigate unbinding transitions and critical micelle concentrations in cylindrical phases.

8:36AM X25.00004 Scaling of Diblock Copolymer Lamella near the Order Disorder Transition, ANDREW B. CROLL, AN-CHANG SHI, KARI DALNOKI-VERESS, McMaster University — Our accumulated knowledge of the physics of diblock copolymer phase transitions is extensive after decades of intense interest. There are, however, several inconsistencies between experiment and current theoretical understanding. Nanosamples are prepared from block copolymer solutions using high aspect ratio nanohole template holders. By significantly out of agreement with theory near the order disorder transition (ODT), this length scales as $(\chi N)^m$ where $\chi$ is the Flory–Huggins interaction parameter and $N$ is the number of monomers. Experiments yield $m = 0.8$ while theory predicts $m = 1$. We use optical microscopy to make real space measurements of the thickness of symmetric polystyrene - block - poly (2 vinyl pyridine), which we find to scale linearly - as predicted by theory. Our experiment suggests two simple optical methods for the measurement of $\chi$.

8:48AM X25.00005 Self-assembly of Asymmetric Architectures: Study of the Phase Behavior of an ABAC Block Copolymer, MICHAEL BLUEMLE, GUILLAUME FLEURY, TIMOTHY LODGE, FRANK BATES, University of Minnesota, Department of Chemical Engineering and Materials Science — We have investigated the bulk phase behavior of the asymmetric tetra-block poly(cyclohexylethylene-b-ethylene-b-cyclohexyethylene-b-dimethylsiloxane) (CECD) in order to elucidate the effects of asymmetry created by introducing a third chemically distinct block to the well-studied CEC triblock. These tetra-block polymers are especially attractive due to the potential of degrading the D block, leaving a mechanically robust polyoldefin nanoprotransport material. Starting with CEC triblocks that self-assemble into different morphologies (hexagonally packed cylinders and lamellae), varying amounts of D have been added, creating two series of polymers along distinct isothetics. A combination of small-angle x-ray scattering, transmission electron microscopy and dynamic mechanical spectroscopy have revealed the complex phase behavior of these asymmetric polymers. Addition of as little as nine percent D by volume drastically changes the tetra-block morphological behavior as compared to their precursor CEC triblocks. These promising results exhibit the influence of asymmetry on the self-assembly of complex architectures in block copolymers.

9:00AM X25.00006 Soft and Strong Thermoplastic Elastomers Through Molecular Design, FOLUSHO OYEROKUN, GLENN FREDRICKSON, UCSB, DALE HANDLIN, Kraton Polymers — Thermoplastic elastomers (TPE) that have a low linear modulus and yet are strong at large extension are of great importance in a variety of technological applications. Current TPE designs based on ABA triblock copolymers are limited in that the maximum volume fraction of the hard A blocks, which correlates with the material strength, is restricted by the constraint that the A domains be discrete while the soft B domains are continuous. In this study, we have investigated new designs of TPEs that utilize polydispersity of the hard blocks in tandem with novel block architectures to control morphology in microphase separated AB block copolymers. Self-consistent field theory calculations confirm that these designs stabilize spherical and cylindrical phases at higher volume fractions of the hard blocks, with the maximum volume fraction of the hard block in some cases approaching twice that of a conventional ABA thermoplastic elastomer.

9:12AM X25.00007 Influence of Soft Segment Composition on Phase Separated Microstructure of PDMS-Based Multiblock Polyurethane Copolymers, TAEYI CHOI, Penn State University, JADWIGA WEKSLER, AJAY PADALGIKAR, AorTech Biomaterials, JAMES RUNT, Penn State University — Multiblock polyurethane (PU) copolymers with polydimethylsiloxane (PDMS) based soft segments possess intriguing microphase separation behavior and excellent biocompatibility. In this study we investigate the microphase-separated structure of PDMS-PUs with various well-defined soft segment compositions, which is closely connected to the structural and surface properties of these copolymers. The PDMS-PUs are shown to exhibit a three phase, core-shell like morphology. Intra- and intercomponent hydrogen bonding was explored using FTIR spectroscopy and quantitative analysis of hard/soft segment mixing was determined by small-angle X-ray scattering. The presentation will focus on the latest findings, particularly the role of PDMS in controlling the details of the microphase-separated texture.

9:24AM X25.00008 Nanoparticle-Regulated Phase Behavior and Morphological Development in an Ordered Block Copolymer, MICHELLE BOWMAN, North Carolina State University, STEVEN SMITH, Procter & Gamble Co., JON SAMSETH, SINTEF Materials & Chemistry, MICHAEL BOCKSTALLER, Carnegie Mellon University, RUSSELL THOMPSON, University of Waterloo, KIM RASMUSSEN, Los Alamos National Laboratory, RICHARD SPONTAK, North Carolina State University — Although microphase-ordered block copolymer motifs are employed to template inorganic nanoparticles, only recently has the effect of nanoparticles on copolymer self-assembly been explored. In this work, we examine the influence of nanoparticles on the copolymer order-disorder transition (ODT) temperature. Theoretical results from a hybrid self-consistent field/density functional theory — supported by experimental observations of a model copolymer/nanoparticle system — confirm that judicious selection of nanoparticle size and selectivity can be used to increase the ODT temperature at constant concentration. For a given nanoparticle size and selectivity, we show that there likewise exists a critical nanoparticle concentration beyond which the ODT temperature decreases. The ability of nanoparticles to increase the ODT temperature is a unique consequence of their size and is not expected for small-molecule additives. At high concentrations, the nanoparticles form percolated colloidal networks that represent highly confined environments for the copolymer molecules.

9:36AM X25.00009 Effects of Lithium Salts on the Domain Size of Polyethylene Oxide Containing Block Copolymers, NISITA WANAKULE, SCOTT MULLIN, NITASH BALSARA, UC Berkeley — The morphology of block copolymers with and without lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) salts are measured with small-angle x-ray scattering (SAXS). The block copolymers comprise of polyethylene oxide (PEO), a polymer with a higher dielectric constant that dissolves LiTFSI, and polystyrene (PS), a polymer with a lower dielectric constant that does not dissolve LiTFSI. Due to the hygroscopic nature of the salts, blend preparation is performed completely in a glovebox and the SAXS samples are sealed off in airtight sample holders. To ensure that moisture contamination does not affect morphology, Karl-Fischer titrations are performed after SAXS measurements. Our data will be compared with literature results that indicate a 300% increase in the domain spacing of PEO-containing block copolymers spacing due to the addition of LiTFSI.

9:48AM X25.00010 Weak Segregation Theory of Microphase Separation in Block Copolymers: New Results and Perspectives, IGOR ERUKHIMOVICH, Moscow State University — The weak segregation theory (WST) of microphase separation in block copolymers (BC) is based on the vision by Landau (1937) and seminal breakthrough by Leibler (1980) into microscopic theory of as well as the Brazovskii-Fredrickson-Helfand (1975, 1987) understanding of the corresponding fluctuation effects. The WST is especially helpful in the situation when the ODT temperature decreases. The ability of nanoparticles to increase the ODT temperature is a unique consequence of their size and is not expected for small-molecule additives. At high concentrations, the nanoparticles form percolated colloidal networks that represent highly confined environments for the copolymer molecules.
10:00AM X25.00011 Tunable Microphase Segregation of Gradient Copolymers: Ordering in Materials with Sinusoidal Composition Profiles, MICHELLE MOK, WESLEY BURGHARDT, JOHN TORKELSON, Northwestern University — Gradient copolymers are a class of polymers that exhibit a gradual change in composition along the entire chain from mostly A-monomer to mostly B-monomer. Theoretical work has predicted that gradient copolymers organize into sinusoidal composition profiles rather than the step-like profiles seen for block copolymers. Here, small-angle x-ray scattering and rheological studies were performed to investigate the impact of gradient design and comonomer choice on this unique ordering. Samples showed a variety of non-terminal behaviors consistent with their chain architecture relative to block copolymers, indicating highly tunable microphase segregation. Scattering results also demonstrated that a range of ordering is attained, with higher order peaks visible in more microphase-segregated samples. In addition, it was demonstrated for the first time that application of high amplitude oscillatory shear induced domain shear alignment in a manner similar to block copolymers, even though gradient copolymers do not possess distinct domain boundaries.

10:12AM X25.00012 Polydispersity effects in block copolymer melts1, MARK MATSEN, Department of Mathematics, University of Reading — We examine the effects of polydispersity on the phase behavior of diblock copolymer melts using self-consistent field theory (SCFT). The calculations are performed with an efficient spectral-based algorithm that can handle high degrees of polydispersity with only a modest increase (i.e., a factor of 2 or 3) in computational cost over that of monodisperse melts [Matson, EPJE, 21, 199 (2006)]. We find that even small degrees of polydispersity can have a significant effect on the domain sizes and the position of the phase boundaries. For large polydispersities, fractionation also becomes important and the phase diagram develops large two-phase coexistence regions [Matson, PRL, 99, 148304 (2007)]. As a consequence, the complex gyroid phase becomes unstable with respect to the coexistence of lamellae and cylinders.

10:24AM X25.00013 Polydispersity-Driven Morphological Transitions in ABC Triblock Terpolymers, ADAM J. MEULER, CHRISTOPHER J. ELLISON, CHRISTOPHER M. EVANS, University of Minnesota Department of Chemical Engineering and Materials Science, MARC A. HILLYER, University of Minnesota Department of Chemistry, FRANK S. BATES, University of Minnesota Department of Chemical Engineering and Materials Science — The use of synthetic polymerization techniques (e.g., controlled radical polymerizations) that often yield polydispersity indices greater than 1.1 is becoming more widespread. Advances in these methodologies have increased the number of monomers amenable to incorporation in block copolymers and will potentially drive commercial costs down. Since many block copolymer properties are governed by the underlying mesostructure, understanding the influence of polydispersity on morphological behavior should prove vital to the success of block copolymer commercialization efforts. This presentation will focus on polydispersity-driven morphological transitions in poly(isoprene-b-styrene-b-ethylene oxide) (ISO) triblock terpolymers. ISO triblocks with polydisperse polystyrene blocks were prepared by anionic polymerization and their morphological behavior was characterized using small-angle x-ray scattering and dynamic mechanical spectroscopy. Only lamellar microstructures were identified along the f1 = f2 isopleth for polydisperse ISO triblocks, while an orthorhombic network (O(3)) was previously identified in monodisperse ISO triblocks.

10:36AM X25.00014 Scaling of the ODT of Block Copolymers in Compressed CO2, CURRAN CHANDLER, TIMOTHY FRANCIS, JAMES WATKINS, University of Massachusetts, Amherst; Department of Polymer Science & Engineering — It is well-known that diblock copolymers with sufficient χN form periodic microphase-separated domains upon cooling through an order-disorder transition (ODT). We have investigated the scaling behavior of the ODT as a function of polymer volume fraction, ϕ, of several nearly symmetric poly(styrene-2-vinylpyridine) and poly(styrene-isopropene) diblock copolymer/diluent systems in relation to the well-known dilution approximation. Using compressed CO2 in the place of conventional liquid diluents allowed the determination of the scaling parameter, α, for highly concentrated systems where ϕ ranges from 0.85 to 1.0 at high temperatures. The scaling was determined by combining optical birefringence measurements of the ODT (λODT) with the ellipsometric swelling measurements (α) of the constituent homopolymers at increasing CO2 pressures. We show that sorption of small volume fractions of CO2 results in significant reductions in the observed ODTs. Yet, α was clearly shown not to be universal even for a specific diblock copolymer. For styrene-isopropene copolymers, it appears that α is an increasing function of copolymer molecular weight, with α taking on both positive and negative values.

10:48AM X25.00015 Pressure Effect on Phase Behavior of Weakly Interacting Block Copolymers by using FTIR spectroscopy, HYE JEONG KIM, SEUNG BIN KIM, JIN KON KIM, Pohang Univ. of Sci. Tech., YOUNG MEE JUNG, Kangwon National University, YOUNG MEE JEONG COLLABORATION — Hydrostatic pressure effect on the phase transition of polystyrene-block-poly(n-pentyl methacrylate) [PS-b-PnPMA] copolymer was investigated by FTIR spectroscopy. The size of closed-loop consisting of both the lower disordered-to-ordered transition and the upper ordered-to-disordered transition became smaller with increasing pressure. The functional groups belonging to the PS block are much more sensitive to pressure compared with those belonging to the PS block. The sensitivity of the functional groups change with pressure is different from that with temperature.

Friday, March 14, 2008 8:00AM - 11:00AM –
Session X27 GMAG: Focus Session: Exchange Bias and Magnetic Interactions Morial Convention Center 219

8:00AM X27.00001 Uncompensated moments in antiferromagnets: Origin and role in exchange bias, IGOR V. ROSCHCHIN, Physics Department, University of California, San Diego and Texas A&M University, ZHI-PAN LI, Physics Department, University of California, San Diego and University of South Florida, MARIA VARELA, STEPHEN J. PENNYCOOK, Oak Ridge National Laboratory, IVAN K. SCHULLER, Physics Department, University of California, San Diego — Exchange bias (EB) is a ferromagnet (FM) – antiferromagnet (AF) proximity effect. The depth profile of the magnetization across the interface between a FM (Co) and an AF (FeF2) in an EB system has been measured. [1] It was found that both uncompensated and compensated magnetic moments are present in FeF2. The origin of these moments remains an open question. Our high-resolution STEM study confirms that FeF2 grows epitaxially on MgF2, and its structural quality is very high. It also reveals that the substrate surface imperfections do not necessarily affect the quality of the FeF2 layer. In magnetization measurements of just a thin film of FeF2, without a FM, we find an uncompensated magnetization. This magnetization demonstrates temperature dependence and horizontal hysteresis loop shift, typical for EB. Dependence of this magnetization on the substrate, film parameters and cooling conditions will be discussed. Work supported by US DOE.

8:12AM X27.00002 Strong anisotropy suppression at the CoO Neél temperature in perpendicularly exchange-biased CoO/CoPt multilayers. ERIK SHIPTON, KEITH CHAN, UC San Diego, OLAV HELLWIG, Hitachi GST, ERIC E. FULLERTON, UC San Diego — We have performed high-field torque magnetometry measurements on perpendicularly exchange-biased CoO/CoPt multilayers. From magnetometry measurements we observe perpendicular exchange bias that goes to zero at a blocking temperature of 200 K. Torque measurements were performed from 2 to 400 K in fields up to 9 T. There is significant hysteresis even at 9 T fields suggesting instabilities in the AF layer. This hysteresis persists up to the blocking temperature. Surprisingly, there is a large reduction in the uniaxial anisotropy with increasing temperature with a minimum at 250 K, the estimated Neél temperature of the CoO layers, followed by an increase in the anisotropy with increasing temperature. The anisotropy of Co/Pt multilayers without the CoO layers monotonically decreases with increasing temperature. This suggests that there is an additional planar anisotropy arising from the CoO that counters the anisotropy of the Co/Pt layers, and that the contribution from the CoO is maximized at the Neél temperature as observed by Grimsditch et al. [1]. These results show that the addition of antiferromagnetic layers may be used to tune the temperature dependence anisotropy response of magnetic systems. [1] M. Grimsditch et al., Phys. Rev. Lett. 90, 257201 (2003).

8:24AM X27.00003 Pinned magnetization in the exchange bias system Permalloy/CoO. SUJOY ROY, Advanced Light Source, Lawrence Berkeley National Laboratory, ELIZABETH BLACKBURN, University of California, San Diego, CECILIA SANCHEZ-HANKE, Brookhaven National Laboratory, SUNIL SINHA, AMI BÉKOWITZ, University of California, San Diego — Interfacial effects are understood to be crucial in the development of exchange bias. In particular, the role of uncompensated spins is important, although because the interface is buried these uncompensated spins can be difficult to measure. Penetrating radiation such as neutrons or x-rays are one of the few tools available to do this. The problem of exchange bias is further complicated by the myriad differences observed from system to system, indicating that the local environment of the magnetic ions has a strong effect on the type of coupling that dominates across the interface. In turn, understanding this coupling is vital in understanding the microscopic origin of exchange bias in a given system. In this paper, we present soft x-ray reflectivity data that show that in the exchange biased state (i.e. below the Neél temperature 289 K for CoO) there is an interfacial layer between the Py and CoO that possesses a net magnetization at room temperature. In the exchange biased state, this contains the uncompensated spins from the CoO layer, and a significant fraction of the spins in this layer are pinned.

8:36AM X27.00004 Ultrafast frustration in the magnetization in exchange biased Ni/FeF$_2$. AMIT PORAT, School of Physics and Astronomy, Tel-Aviv University, Tel Aviv 69978, Israel, IVAN K. SCHULLER, Physics Department, University of California - San Diego, La Jolla, CA 92093-0319, SHIMSHON BAR-AD, School of Physics and Astronomy, Tel-Aviv University, Tel Aviv 69978, Israel — We used the magneto optical Kerr effect to study fast optically-induced magnetization dynamics in a Ni/FeF$_2$ exchange bias bilayer. We find that sub-picosecond laser pulses trigger an unexpected out of plane precession of the Ni magnetization, surprisingly in external magnetic fields that overcome the exchange bias (unlike previously reported precessions in bilayers). Even more surprisingly the precession persists for excitation intensities that completely decouple the Ni from the FeF$_2$. The experimental results suggest that the FeF$_2$ layer even at the thermally-excited interface is frustrated by the opposing antiferromagnetic fields created by the external field, the Ni layer, and the underlying thermally unexcited FeF$_2$ layer. The frustrated FeF$_2$ layer reorients, which in turn triggers the precession of the Ni. This implies that the decoupling at high excitation intensities does not only involve the Ni, but also the interfacial FeF$_2$ layer, which decouples from the cold underlying bulk FeF$_2$. The decoupling thus leads to a reversal of the exchange bias, as we found experimentally.

8:48AM X27.00005 Antiferromagnetic Domain Size Measurement in Fe$_{0.70}$Zn$_{0.30}$F$_2$/Co Bilayers. DAVID LEDERMAN, HONGTAO SHI, Dept of Physics, West Virginia University, MICHAEL FITZSIMMONS, Los Alamos National Laboratory — The size of the antiferromagnetic domains of an epitaxial (110) Fe$_{0.70}$Zn$_{0.30}$F$_2$ doped layer is measured by ferromagnetic resonance. The antiferromagnetic Fe$_{0.70}$Zn$_{0.30}$F$_2$ layer is significantly narrower at the switching temperature than at either 25 or 30 K. This result is consistent with models that predict an inverse relationship between the antiferromagnetic domain size and exchange bias.

9:00AM X27.00006 Scaling behavior of the exchange-bias training effect. SRINIVAS POLISETTY, SARBESWAR SAHOO, CHRISTIAN BINEK, University of Nebraska-Lincoln — The dependence of the exchange-bias training effect on temperature and ferromagnetic film thickness is studied in detail and scaling behavior of the data is presented. Thickness-dependent exchange bias and its training are measured using the magneto-optical Kerr effect. A focused laser beam is scanned across a Co wedge probing local hysteresis loops of the Co film which is pinned by an antiferromagnetic CoO layer of uniform thickness. A phenomenological theory is best fitted to the exchange-bias training data resembling the evolution of the exchange-bias field on subsequently cycled hysteresis loops. Best fits are done for various temperatures and Co thicknesses. Data collapse on respective master curves is achieved for the thickness and temperature-dependent fitting parameters as well as the exchange bias and coercive fields of the initial hysteresis loops. The scaling behavior is strong evidence for the validity and the universality of the underlying theoretical approach based on triggered relaxation of the pinning layer towards quasi-equilibrium. [1] Srinivas Polisetty, Sarbeswar Sahoo, Christian Binek, Phys. Rev. B 76, 184423 (2007).

9:12AM X27.00007 Interlayer coupling in Co/NiO/Fe trilayers studied by element-specific XMCD and XMCD effects. J. WU, J. CHOI, Dept. of Physics, Univ. of California at Berkeley, Berkeley, CA 94720, C. WON, Dept. of Physics, Kyung Hee Univ., Seoul 130-701, Korea, A. SCHOLL, A. DORAN, E. ARENHOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, Y.Z. WU, X.F. JIN, Dept. of Physics, Fudan Univ., Shanghai 200433, P. R. China, Z.Q. QIU, Dept. of Physics, Univ. of California at Berkeley, Berkeley, CA 94720 — Co/NiO/Fe layers are grown on Ag(001) substrate using Molecular Beam Epitaxy (MBE). Element-specific magnetic domain images on both ferromagnetic (FM) Co and Fe layers and antiferromagnetic NiO layer are obtained using X-ray Magnetic Circular Dichroism (XMCD) and X-ray Linear Dichroism (XMLD), respectively. By comparing these magnetic domain images, we find that the Co-Fe interlayer coupling across the NiO spacer layer exhibits a transition from a 90°-coupling to a collinear coupling as the NiO film thickness increases. This observation is shown to be directly related to the NiO magnetic structure and its interaction at the Co/NiO and NiO/Fe interfaces.
9:24AM X27.00008 Thermodynamics of Co/Cr superlattices1, T. MUKHERJEE, S. SAHOO, R. SKOMSKI, D.J. SELLMYER, CH. BINEK, University of Nebraska-Lincoln — Progress in ultra thin film growth has resulted in many novel surface and interface induced properties of artificial heterostructures. Here, we study magnetic superlattices of ultrathin Co and Cr films grown by Molecular Beam Epitaxy methodology at a base pressure below 1×10^{-10} mbar. Our approach is based on controlling two distinct magnetic degrees of freedom. First, the critical temperature, T_c, of individual Co films is tailored via geometrical confinement of the correlation length perpendicular to the film. Various thickness dependent values, T_c, between zero and the bulk Curie temperature of 1388 K are realized. Second, the T_c-tailored Co films are antiferromagnetically coupled through Cr interlayer films. The oscillating coupling strength is tailored via the Cr interlayer thickness. The resulting thermodynamic properties of such Co/Cr superlattices are studied with the help of SQUID magnetometry. Particular emphasis is laid on tailoring magnetic entropy changes in the vicinity of room temperature. X-ray diffraction and X-ray reflectivity are used to correlate structural data with the magnetic properties.

9:36AM X27.00009 Cooling Field Dependence of Magnetization Depth Profiles in Exchange-coupled Superlattices1, MICHAEL FITZSIMMONS, Los Alamos National Laboratory, KARINE DUMESNIL, CATHERINE DUFOUR, Laboratoire de Physique des Matériaux, Université Henri Poincare Nancy, France — In DyFe2/YFe2 superlattices, competition between ferromagnetic exchange coupling of adjacent Fe spins and antiferromagnetic coupling of Fe spins with rare earth spins leads to an antiparallel arrangement (confirmed with XMCD and neutron scattering) of magnetization across the DyFe2/YFe2 interfaces in low fields at 300 K. After cooling this simple structure to 12 K, the DyFe2 magnetization becomes pinned and the sample exhibits very large exchange bias (~2 T) and a large (35%) negative shift of the sample magnetization along the magnetization axis. However, when a large magnetic field is applied at room temperature, the magnetization adopts a spin-flop configuration across the DyFe2/YFe2 interfaces (confirmed with XMCD and neutron scattering). When cooled in a large field, the sample yields neither exchange bias nor a shift of the sample magnetization along the magnetization axis.

9:48AM X27.00010 In-plane anisotropy of NiCo multilayers, P. PANAYJIRAWUT, M.S. RZCHOWSKI, University of Wisconsin-Madison — We have grown NiCo magnetic multilayers on Si substrates by sputter deposition. The Ni$_{0.6}$Co$_{0.4}$ bilayer that repeats to form the multilayer ranges from 2 nm to 12 nm in thickness. The total multilayer thickness ranges from 50 nm to 75 nm. Room temperature vibrating sample magnetometer (VSM) measurements show that the multilayers have in-plane uniaxial magnetic anisotropy with K_u \sim 1.2x10^5 erg/cc. This is apparently induced during growth by the sputtering geometry, as we also see uniaxial in-plane anisotropy in individual 30 nm thick Ni (K_u \sim 0.3x10^5 erg/cc) and Co (K_u \sim 2.9x10^5 erg/cc) sputtered films. However the multilayer anisotropy is more complex as it arises from an interaction between the Ni and Co layers, with the Ni and Co layer magnetizations to first approximation rotating together.

10:00AM X27.00011 Determination of inhomogeneous magnetic profiles in an asymmetric Fe/Gd multilayer, EUGENY KRAVTSOV, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, SUZANNE G.E. TE VELTHUIS, YONGSEONG CHOI, J. SAMUEL JIANG, Materials Science Division, Argonne National Laboratory — We have studied the dependence of the detailed magnetization depth profile in a [Fe(35 A)/Gd(50 A)]$_n$ multilayer on the applied magnetic field and temperature. Utilizing the complementarity of x-ray resonant magnetic reflectivity (element-specificity and high spatial resolution) and polarized neutron reflectivity (large magnetic scattering cross sections), we applied a unified approach by simultaneous refinement and resolved the complex magnetization profiles. It was found that the small number of periods together with the asymmetric termination (Fe-top, Gd-bottom) lead to unique inhomogeneous magnetic phases, which are characterized by significant twisting of Fe and Gd magnetic moments and non-uniform distribution of magnetization density within the Gd layers.

1Work at Argonne is supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

10:12AM X27.00012 Magnetic Compensation in Ferrimagnetic Bimetallic Oxalates1, PETER REIS, University of North Dakota and Oak Ridge National Laboratory, RANDY FISHMAN, FERNANDO REBOREDO, Oak Ridge National Laboratory, CUANNA MORENO, University of North Dakota — Bimetallic oxalates are layered organic magnets with the chemical formula A[M(II)M'(III)(ox)]$_n$, where M(II) and M'(III) are transition metal ions, A is an organic cation, and ox = C$_2$O$_4$. For some ferrimagnetic bimetallic oxalates, the magnetization changes sign at a compensation temperature below the ferrimagnetic transition temperature. We have initiated a systematic study of these compounds by examining the possibility of magnetic compensation for any possible combination of transition metal ions. Our model includes spin-orbit coupling for both M(II) and M(III) ions, the antiferromagnetic exchange between neighboring metal ions mediated by the oxalate bridges, and the effects of the ligand fields. Using mean-field theory, we predict candidates that may exhibit magnetic compensation for certain choices of the intercalated cation A.

10:24AM X27.00013 Giant Negative Magnetization in a Class of Layered Molecular-Based Magnets1, RANDY FISHMAN, FERNANDO REBOREDO, Oak Ridge National Lab — Bimetallic oxalates are a class of layered molecular-based magnets with transition metals M(II) and M(III) coupled by oxalate molecules in an open honeycomb structure. Energy, structure, and symmetry considerations are used to construct a reduced Hamiltonian, including exchange and spin-orbit interactions, that explains the magnetic compensation and giant negative magnetization in some of the ferrimagnetic Fe(II)Fe(III) compounds. By shifting the Fe(II) ions with respect to the oxalate molecules, the organic cation between the magnetic layers alters the C$_2$-symmetric crystal field and the orbital angular momentum of the ground-state doublet at the Fe(II) sites. We provide new predictions for the spin-wave gap, the effects of uni-axial strain, and the optical flipping of the negative magnetization in Fe(II)Fe(III) bimetallic oxalates [1]. [1] R.S. Fishman and F.A. Reboredo, Physical Review Letters 99, 217203 (2007).

10:36AM X27.00014 Effect of thermal fluctuation on the recoil loops of exchange-coupled nanocomposite magnets. CHUANBING RONG, YUZI LIU, J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019 — Exchange-coupled hard/soft nanocomposite magnets have attracted great attention due to the very high potential energy product. One of the most effective ways to characterize the exchange-coupling strength in the nanocrystalline magnets is the measurement of recoil loops. It is often noted that the recoil curves are widely open for the hard/soft nanocomposite magnets but are narrow and even close for the single-phase magnets. In this work, we studied recoil loops of the FePt/Fe3Pt nanocomposite magnets. It was interesting to find that the parameter that describes the openness of the loops, $\Delta m_{rc}$, is significantly dependant on the sweep rate of applied field, especially for the nanocomposite magnets with high soft-phase content, where $\Delta m_{rc}$ is maximum difference between upper and lower magnetization curves of the recoil loops. The quantitative analysis shows a reciprocally linear relation between $\Delta m_{rc}$ and the activation volume, which means that the recoil loops are intimately related to the thermal fluctuation. The large open area of the nanocomposite magnets compared to that of single phase magnets is attributed to the more unstable magnetization process in the exchange-hardened soft phase.

10:48AM X27.00015 Effects of additives on hydrogen absorption and desorption characteristics of Nd(Fe,Mo)12 alloys. JINGZHI HAN, CHANGSHENG WANG, HONGLIN DU, HAIYING CHEN, YINGCHANG YANG, School of Physics, Peking University, 100871 — Effects of additives such as Co, Zr, Nb and Ga on hydrogen absorption and desorption characteristics of Nd(Fe,Mo)12 alloys are investigated. The results show that Zr or Nb addition increases the temperature of the disproportionation reaction and, Co or Ga addition reduces the temperature of the disproportionation. The corresponding D-H-HRD phenomena are discussed, and whether leading to anisotropic powders or not is suggested to be related to crystal growth direction of the Nd-Fe-B and Nd(Fe,Mo)12 system. However, according to the XRD measurement of the magnetic oriented samples, the anisotropic HDDR powders are not found. In order to analyze the reason leading to the anisotropic Nd(Fe,Mo)12 and anisotropic NdFe5B powders, the similarities and differences of the Nd(Fe,Mo)12 and NdFe5B systems and their corresponding HDDR phenomena are discussed, and whether leading to anisotropic powders or not is suggested to be related to crystal growth direction of the Nd-Fe-B and Nd(Fe,Mo)12 system. At the same time, it is also found that the Nb addition is helpful for improving the magnetic properties of the HDDR Nd(Fe,Mo)12 and NdFe5B magnetic materials, and the HDDR NdFe10.3Nb1.2Mo1.5X powders have a Br of 54 emu/g, a iHc of 3950 Oe. Moreover, the Mr/Ms ratio of the above powders reaches 0.60.

Friday, March 14, 2008 8:00AM - 10:48AM — Session X28 DMP: Focus Session: Optical Properties of Nanostructures VII: Surface Plasmons and Periodic Arrays — Morial Convention Center 220

8:00AM X28.00001 Plasmonic propagation along Metal/Semiconductor/Metal nanowires. LAETITIA BERNARD, MARLEEN H. VAN DER Veen, DANIEL TURNER-EvANS, ERIC R. DUFRESNE, MARK A. REED, Faculty of Engineering, Yale University, Kwan SKINNER, SEAN WASHBURN, Department of Physics and Astronomy, University of North Carolina — Recent advances demonstrated metallic nanowires as structures allowing selective coupling of photons to fluctuations in the surface density of electrons, and the propagation of these plasmon modes along the wire. We report here the observation of such propagating plasmons in heterogeneous metal/semiconductor/metal nanowires. Specifically, we excite one end of a Au/CdSe/Au nanowire with focused laser light and demonstrate the coupling of photons into the plasmon modes of the wire. These modes propagate along the wire, being emitted as elastically scattered photons, exclusively at the metal/semiconductor interfaces and the distal end. Through control of the excitation wavelength and wire composition, we gain insights about the nature of the plasmon propagation through CdSe, allowing direct comparison with standard metal studies. This contributes to the growing interest in plasmonics within nanoscale devices by extending it to semiconductor materials, and goes towards the integration of optics with nanotechnology.

8:12AM X28.00002 Plasmonic Interfaces for Electro-Optic Characterization of Molecular Junctions. MARLEEN H. VAN DER Veen, LAETITIA BERNARD, JASON MERRILL, ERIC R. DUFRESNE, MARK A. REED, Yale University — Metallic nanowires have interesting optical applications that make them promising platforms for sensing applications. The optical properties originate from the excitation of surface plasmon polaritons with light. We use this phenomenon to develop new spectroscopic tools to characterize the nature and details of the molecular structures with nanometer-scale devices. To achieve optical excitation at the nanometer-scale, we use a far field plasmon launching and emission technique based on nanowires coupled to molecular junctions. It is shown that plasmons can couple efficiently across small interfaces and can propagate along crossed nanowires. Furthermore, the light emitted as elastic scattered photons can be used to selectively couple light into the region of molecules for optical excitation. The possibility of doing local optical excitation of molecules simultaneously with their current-voltage measurements could lead to a new sensing platform for molecules based on plasmonic interfaces.

8:24AM X28.00003 Study of the absorption spectra of periodic hole arrays. DIMITRIOS KOUKIS, DANIEL ARENAS, SINAN SELCUK, A.F. HEBARD, D.B. TANNER, S.V. SHABANOV — The absorption of light by periodic hole arrays was studied for various open area fractions and wavelengths. We determined the absorption by measurements of the transmittance (T) and reflectance (R) at normal incidence and calculating the absorption as A = 1-R-T. The reflectance and transmittance were both measured, using a microphotometer in the near infrared region and Bruker IFS 113v in the mid-infrared region. Periodic hole arrays are characterized by "extraordinary" transmittance (larger than the predictions of geometrical optics) at frequencies just below the onset of first order diffraction by the periodic array. The absorption minimum occurs at frequencies slightly larger than the transmittance maximum. The absorption results for the various open area fractions were compared to theoretical predictions.
9:00AM X28.00006 Optical mapping of surface plasmon near-field spatial distribution in triangular silver nanostructures, ANDREW JONES, MATTHIAS RANG, University of Washington, BENJAMIN WILEY, Washington University, ZHI-YUAN LI, Institute of Physics, Chinese Academy of Science, YOUNAN XIA, Washington University, MARKUS RASCHKE, University of Washington — Plasmonic metal nanostructures have attracted interest in diverse fields including biomolecular sensing and nano-phononics. To understand the correlation of the optical response with the shape and size of the structure, we optically stimulate localized surface plasmons on chemically prepared Ag triangular nanostructures and utilize scattering-type Scanning Near-field Optical Microscopy (aSNOM) to map the optical near-field distribution with a spatial resolution down to 10nm. Using homodyne amplification allows for phase selective probing and identification of specific plasmon eigenmodes. For large triangles the superposition of several modes results in a complex distribution of the electric field whereas for smaller particles the distribution takes on a dipolar pattern.

9:12AM X28.00007 Photonic delocalization and optical propagation in one-dimensional random n-mer dielectric systems, RUWEN PENG, ZENG ZHAO, FENG GAO, LUSHUAI CAO, DE LI, ZHAN WANG, XIPING HAO, MU WANG, National Laboratory of Solid State Microstructures, NATIONAL LABORATORY OF SOLID STATE MICROSTRUCTURES TEAM — We have both theoretically and experimentally investigated the propagation of electromagnetic waves in a one-dimensional random n-mer (RN) dielectric system. Due to the positional correlation in the RN structure, the localization - delocalization transitions of photons happen at expected frequencies of photons. Multiple resonant transmissions are found in the photonic band gap. At each resonant mode, zero- Lyapunov exponent and undecayed field distribution of electromagnetic waves have been found through the whole system. Furthermore, the channel is opened for photonic transport at the resonant frequency, and the density of states of photons increases step by step as frequency increases. The theoretical results are experimentally demonstrated in RN dielectric multi-layer films of SiO2/TiO2 for visible and near infrared light.

9:24AM X28.00008 Quasiparticle dynamics and optical propagation in an optically-pumped microcavity far from equilibrium, PAUL EASTHAM, Imperial College London, RICHARD PHILLIPS, University of Cambridge — We propose and analyze a model for creating highly non-equilibrium quantum condensates from excitons and photons in a semiconductor microcavity on timescales shorter than any thermalization times. In a theoretical study of microcavity dynamics we show that a tailored optical pulse can directly create a supercooled exciton population by an analogue of adiabatic rapid passage. This state involves no macroscopic occupations and is thus not a condensate. At later times, however, it spontaneously develops into a quantum condensate far from equilibrium. This class of condensates encompasses phenomena similar to superradiance and lasing, but also includes states which give access to non-equilibrium Bose condensation in a solid-state system.

9:36AM X28.00009 Random Laser Emission from ZnO Nanocomposite Hybrids, A. STASSINOPoulos, S. H., ANASTASIADIS, D. G. PAPAZOGLOU, D. ANGLOS, Foundation for Research and Technology-Hellas, Greece, D. TSAGARAKIS, R. N. DAS, E. P. GIANNELIS, Cornell University — Highly scattering hybrid structures are produced either by incorporating ZnO nanoparticles in inert polymeric or inorganic sol-gel matrices or by depositing them on flexible substrates. All structures exhibit intense laser-like emission upon optical pumping. The ZnO particles provide both the gain and the strong scattering power, leading to photon localization due to multiple scattering. The polymer matrix offers ease of material fabrication and processability while the elastic substrate offers flexibility in view of potential applications. Excitation of the hybrids by laser pulses shows threshold behavior demonstrated by a dramatic increase in the emitted light intensity and significant spectral and temporal narrowing. We study the influence of pump pulse duration and sample temperature on the random laser efficiency whereas we measure the coherence length of the emission. Nanocomposite fabrication issues and pumping conditions are varied aiming at performance optimization and, thus, potential use of such materials in future light emission devices. Sponsored by the Greek GSRT, by NATO's Scientific Affairs Division and by the EU.

This work was supported by the EC Network of Excellence SANDIE, Contract No. NMP4-CT-2004-500101.
10:12AM X28.00012 Probing Bright and Dark Surface Plasmon Modes in Au Nanoparticles Using a Fast Electron Beam, MING-WEN CHU, Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan, VIKTOR MYROSHNYCHENKO, F. JAVIER GARCÍA DE ABAJO, Instituto de Optica, CSIC Madrid, Spain, CHENG HSUAN CHEN, Center for Condensed Matter Sciences, National Taiwan University, Taipei, Taiwan, CENTER FOR CONDENSED MATTER SCIENCES, NATIONAL TAIWAN UNIVERSITY, TAIPEI, TAIWAN TEAM, INSTITUTO DE OPTICA, CSIC MADRID, SPAIN TEAM — We have studied the surface plasmons (SPs) of individual and coupled Au nanoparticles (NPs) with various sizes and shapes by electron energy-loss spectroscopy (EELS) using a 2-nm monochromatized fast electron beam in a scanning transmission electron microscope (STEM). EELS spectra were investigated with the beam in grazing incidence, the optical near-field setup, and bright SP modes (visible by light) were identified in both individual, coupled NPs ranging from near-IR to visible regimes. In an individual long rod with an aspect ratio of ~6, a dark SP mode invisible by light was surprisingly characterized, supported by calculations of the macroscopic dielectric responses. With the NPs coupling, rich bright, dark SP modes emerge and the suppression of one mode over the other is dictated by the beam position when approaching a geometrically centered site. The electron scattering geometry thus plays the role the SP-mode selection, never documented before.

10:24AM X28.00013 Quantum confined Stark effect in organic fluorophores, XIHONG PENG, Rensselaer Polytechnic Institute (RPI), JOHN ANDERSON, US Army Corps of Engineers, GARY TEPPER, SUPRIYO BANDOPADHYAY, Virginia Commonwealth Univ, SAROJ NAYAK, RPI — Fluorescent molecules have widely been used to detect and visualize structure and processes in biological samples due to its extraordinary sensitivity. However, the emission spectra of fluorophores are usually broad and the accurate identification is difficult. Recently, experiments show that energy shifts by Stark effect can be used to aid the identification of organic molecules [1]. Stark effect originates from the shifting/splitting of energy levels when a molecule is under an external electric field, which shows a shift/splitting of a peak in absorption/emission spectra. The size of the shift depends on the magnitude of the external field and the molecular structure. In this talk we will show our theoretical study of the peak shifts on emission spectra for a series of organic fluorophores such as tyrosine, tryptophan, rhodamine123 and coumarin314 using density functional theory. We find that a particular peak shift is determined by the local dipole moments of molecular orbitals rather than the global dipole moment of the molecule. These molecular-specific shifts in emission spectra may enable to improve molecular identification in biosensors. Our results will be compared with experimental data. [1]Unpublished, S. Sarkar, B. Kanchibotla, S. Bandopadhyay, G. Tepper, J. Edwards, Anderson, and R. Kessick.

10:36AM X28.00014 Effects of electron heating on femtosecond laser-induced coherent acoustic phonons, JINCHENG WANG, CHUNLEI GUO, University of Rochester — In this work, we employ a surface plasmon technique to resolve the dynamics of femtosecond laser-induced coherent acoustic phonons in noble metals. Clear acoustic oscillations are observed in our experiments. We further find that the initial phase decreases linearly with pump fluence. Our model calculations show that the hot electrons instantaneously excited by femtosecond pulses contributes to the generation of coherent acoustic phonons in metals.

Friday, March 14, 2008 8:00AM - 11:00AM – Session X29 DMP: Focus Session: Carbon Nanotubes and Related Materials XV: Electronic Structure and Optical Properties Morial Convention Center 221

8:00AM X29.00001 Saturation of Photoluminescence from Carbon Nanotubes at High Laser Intensities: Exciton-Exciton Annihilation near the Mott Density, YOICHI MURAKAMI, Rice University, The University of Tokyo, JUNICHIRO KONO, Rice University — We have carried out a nonlinear photoluminescence excitation (PLE) spectroscopy study of carbon nanotube ensembles using intense, femtosecond, and wavelength-tunable optical pulses. For all PL features we examined, their intensities were seen to saturate at high laser fluence, irrespective of whether the excitation was resonant or non-resonant with the E_22 transition. As the fluence was increased from the linear regime to the saturation regime, excitation resonances at E_22 energies gradually broadened and eventually became completely flat at the highest fluence, indicating that the PL intensity became independent of the excitation wavelength. However, the energies and lineshape of PL emission peaks did not show any changes throughout the entire range of fluence used. Through absorption spectroscopy at high laser intensities, we also demonstrated that E_22 absorption peaks do not show any shift or broadening even at high laser fluence, indicating that state-filling or scattering is not the cause of the observed “flattening” of the excitation spectra. We developed a model to explain these observations by carefully taking into account the spatial overlap of excitons when the average inter-exciton distance approaches the Bohr radius in the exciton-exciton annihilation process.

8:12AM X29.00002 Curvature Effects on the E_{23} and E_{44} Exciton Transitions in Semiconducting Single-Walled Carbon Nanotubes, STEPHEN DOORN, ERIK HARDOZ, Los Alamos National Laboratory, SERGEI BACHILO, BRUCE WEISMAN, Rice University — We discuss recent measurements of the E_{33} and E_{44} transitions of small diameter (0.7 to 1.2 nm) single-walled carbon nanotubes using deep blue (415 to 465 nm) resonance Raman spectroscopy and photoluminescence excitation spectroscopy in the UV and blue regions (280 to 480 nm). Individual radial breathing mode features, as well as Raman and photoluminescence excitation maxima, are assigned to specific nanotube chiralities. Transition-dependent trends in RBM intensities are discussed. We present a scaling law analysis of transition energies and show that energies for nanotubes with diameter less than 0.9 nm are not explained by previous scaling law descriptions for larger diameter nanotubes. This new behavior at small diameters is interpreted in terms of both a crossing-over of the E_{33} and E_{44} trend lines for a given 2n-m branch, and a chirality dependence in the many-body exciton effects that becomes significant at high curvatures.

8:24AM X29.00003 Exciton binding energies in metallic single-walled carbon nanotubes are comparable to those in semiconducting ones, ZHENDONG WANG, SUMIT MAZUMDAR, University of Arizona — Excitons in metallic single-walled carbon nanotubes (M-SWCNTs) have attracted both theoretical and experimental attention recently. It has been claimed that exciton binding energies in M-SWCNTs are of an order of magnitude smaller than those in semiconducting single-walled carbon nanotubes (S-SWCNTs). We have investigated M-SWCNTs within a two-electron Hamiltonian that has previously reproduced quantitatively the absolute energies as well as the binding energies of both longitudinal and transverse excitons in S-SWCNTs. We are able once again to reproduce quantitatively the available absolute exciton energies and the optical absorption spectra of M-SWCNTs with diameters 0.9 - 1.4 nm. While we need a dielectric constant larger than in the S-SWCNTs, our calculated exciton binding energies in this diameter range are 0.2 - 0.3 eV, only slightly smaller than those in S-SWCNTs with similar diameters.

1. Fagan et al. 2. Shaver et al. Our observations exchange-split bright and dark exciton bands with Aharonov-Bohm-phase-dependent energies, masses, and oscillator strengths, which successfully reproduces states, making the triplet state optically active. Supported by ONR (No. N00014-06-1-0228) and NSF.

 observable Zeeman splitting, or for the dark exciton to be observed. We instead suggest that the EuS provides spin orbit coupling to mix the singlet and triplet its position shifts by approximately 7 meV. From this we estimate that the EuS layer produces an effective magnetic field of 7 T. This is too small to produce so that the spin-up level lies 0.36 eV below the spin-down level. We monitor the nanotube photocurrent at 4.2K for magnetic fields between 0 and 50 mT.

 for carbon nanotubes are not observable under normal conditions, including the so-called dark excitonic states and the spin triplet states. Here, we develop a theoretical model of one-dimensional magneto-excitons, based on recently-proposed of the form of the diffusion coefficient assuming exciton-phonon coupling as the underlying mechanism will be discussed.

 This work was supported by grants from the National Institutes of Health P41-RR05969, and NSF CCR 02-10843.

 1. O. N. TORRENS, J. M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, M. ZHENG, DuPont CR&D — Phonon sideband optical spectroscopy determines the energy of the dark \( K \)-momentum exciton for (6,5) carbon nanotubes (CNTs). One-phonon sidebands appear in absorption and emission, split by two zone-boundary (\( K \)-point) phonons. Their average energy locates the \( E_{11} \) \( K \)-momentum exciton 36 meV above the \( E_{11} \) bright level, higher than available theoretical estimates. A model for exciton-phonon coupling shows the absorption sideband depends sensitively on the \( K \)-momentum exciton effective mass and has minimal contributions from zone-center phonons, which dominate the Raman spectra of CNTs.

Supported by NSF MRSEC DMR-0520020.

 10:00AM X29.00009 Dark excitons in single-walled carbon nanotubes investigated by electroabsorption spectroscopy, HIDEO KISHIDA, Y. NAGASAWA, S. IMAMURA, A. NAKAMURA, Department of Applied Physics, Nagoya University, Japan — We report electroabsorption (EA) spectra in micelle-wrapped single walled carbon nanotubes (SWNT). By applying the high electric field (up to 85kV/cm), the absorption spectra of semiconducting SWNTs show field-induced change in the region of \( E_{11} \) and \( E_{22} \) transitions. The EA spectra are essentially reproduced by the second derivative curves of the absorption spectra. Such spectral features indicate that the bright (one-phonon allowed) exciton and dark (two-phonon allowed) exciton for each chiral index are nearly degenerate. The closer scrutiny of the EA spectra reveals that the dark excitons for several chiral indices are located on the higher energy side of the bright states.

 10:12AM X29.00007 \( K \)-momentum dark exciton energy in carbon nanotubes, O. N. TORRENS, J. M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA, 19104 — We observe room temperature, sub-Tesla magnetic field effects on the photoluminescence of aqueous suspensions of single-walled carbon nanotubes and on the electrical transport of carbon nanotube composites. The nearly identical field scale found in both cases suggests a common origin for the phenomena. In aqueous suspensions, weak magnetic fields decrease the nanotube photoluminescence intensity by \( \sim 0.1\% - 1\% \), an effect which saturates by \( \sim 1 \) Tesla. We explore this magnetic darkening as a function of surfactant, magnetic field and direction, temperature, and nanotube chirality. For carbon nanotube epoxy composites and aerogels, low magnetic fields produce a similar decrease in the device resistivity, which is found to be temperature dependent. We discuss these new magnetic field effects in the context of excitonic magneto physics and magnetic field effects observed in other organic semiconductor systems.

Supported by NSF MRSEC DMR-0520020.

 1. O. N. TORRENS, J. M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA — We have investigated excitons in semiconducting single-walled carbon nanotubes (SWNTs) through low-temperature magneto-photoluminescence (PL) of highly-aligned SWNT films in magnetic fields (B) up to 55 T. The magnetic field was generated using the 60 T long pulse magnet powered by a 1.4 GVA motor-generator at the National High Magnetic Field Lab in Los Alamos, NM. Polyacrylic acid films containing DNA suspended CoMoCAT SWNTs were stretch-aligned, and the alignment factor was analyzed by polarized Raman spectroscopy. Utilizing two well-defined measurement geometries, SWNT || B and SWNTs \( \perp \) B, we provide unambiguous evidence that the PL from excitons in SWNTs is sensitive only to the B-component parallel to the tube axis. We developed a theoretical model of one-dimensional magneto-excitions, based on recently-proposed exchange-split bright and dark exciton bands with Aharonov-Bohm-phase-dependent energies, masses, and oscillator strengths, which successfully reproduces our observations.

10:36AM X29.00012 Free Carrier Auger Relaxation of Excitons in Carbon Nanotubes, JESSE KINDER, EUGENE MELE, University of Pennsylvania — We study a relaxation pathway in doped carbon nanotubes in which optically pumped excitonic states interact with free electrons or holes through an Auger process. The exciton recombines nonradiatively, transferring its energy and momentum to a free carrier. The calculated decay rate depends on temperature, exciton density, and the amount of doping. For optically excited bright excitons, conservation of energy and momentum forbid this decay below a critical doping density. For the heavier dark excitons, recombination is allowed for any nonzero doping density. By studying the phase space for this Auger process and exciton-exciton annihilation, we find that the free carrier interaction can dominate the relaxation rate at low exciton densities.

10:48AM X29.00013 Magnetic Brightening of Dark Excitons in Individual Single-Walled Carbon Nanotubes1, A JIIT SRIVASTAVA, JUNICHIRO KONO, Rice University, HAN HTOON, VICTOR I. KLIMOV, Los Alamos National Laboratory — We have performed micro-photoluminescence (PL) studies on individual single-walled carbon nanotubes (SWNTs) at varying temperatures (T = 4 K – 100 K) in magnetic fields (B) up to 5 T, which provide direct evidence for the existence of dark excitons in SWNTs. Only when the B was parallel to the tube axis, we observed the appearance of a secondary peak at a lower energy with respect to the main emission peak. The secondary peak increased in intensity with increasing B at the expense of the main peak. At the lowest T, a complete reversal of emission intensity from the main peak to the side peak was seen as the B was increased. However, the main peak was recovered as the T was increased at a fixed B. These behaviors can be explained by assigning the main and secondary peaks to the lowest-energy bright and dark singlet exciton states, respectively. The absence of these behaviors in B perpendicular to the tube axis convincingly suggests that brightening is induced by the Aharonov-Bohm phase. The zero-field dark-bright splitting is found to be ~1.2 meV, which is lower than most theoretical predictions.

8:00AM X30.00001 Modeling of multiscale porous media, B. BISWAL, ICP, University of Stuttgart, Germany, P.-E. OREN, Numerical Rocks AS, Norway, R.J. HELD, StatoilHydro ASA, Norway, S. BAKKE, Numerical Rocks AS, Norway, R. HILFER, ICP, University of Stuttgart, Germany — A continuum geometrical model for reconstructing three dimensional pore scale microstructure of multiscale porous media is presented. Pore scale geometries of different carbonate textures are successfully reconstructed with informations from thin sections. The reconstructed models incorporate correlations with the primordial depositional textures, scale dependent intergranular porosity over many decades, vuggy porosity, a percolating pore space, a fully connected matrix space, strong resolution dependence and wide variability in the permeabilities and other properties. A method to generate synthetic micro-CT images at arbitrary resolution is also developed. The model can be extended to a wide class of multiscale porous media.

1This research was funded by StatoilHydro ASA.

8:12AM X30.00002 Direct observation of pore blocking and advanced adsorption in nanoporous alumina: cooperative effects at the origin of hysteresis1, FELIX CASANOVA, CASEY E. CHIANG, University of California San Diego, CHANG-PENG LI, University of Michigan, IVAN K. SCHULLER, University of California San Diego — We tailor anodized alumina with independent pores with well-defined, simple geometries (inkbottle, funnel), in order to study the effects of pore morphology in hysteretical capillary condensation, independently from other cooperative processes such as network effects. We confirm, by direct observation using optical interferometry, the occurrence of two cooperative phenomena: the classical pore blocking effect in nearly ideal 'inkbottle' pores (which has usually been employed to describe hysteresis loops in disordered interconnected porous materials) and the advanced adsorption in pores with a change in the cross section. Both effects have been predicted in theoretical and simulation works, but not directly observed experimentally before. They are relevant for the development of a theory of the poorly understood hysteresis in complex porous materials.

1Supported by AFOSR and Spanish MEC-Fullbright.

8:24AM X30.00003 Acoustic Band Pass, Band Gap and Dispersion in Discrete Media at Micro and Nano Scales, HASSON TAVOSSI, Valdosta State University — Acoustic properties of models of crystals, when measured at macroscopic scale, are found experimentally to have remarkable similarities with the same wave properties observed at atomic and nano-scales. It can be shown that, elastic moduli and other wave properties such as; band-pass, forbidden band, wave tunneling, attenuation, cutoff-frequency, and dispersion, depend on the similar structural factors as for phonons in crystals. Acoustic properties of the macroscopic models of discrete media, in the length scale range; 1.5 mm to 30 micrometers, and the frequency range; audible to ultrasonic are studied. The Band-pass, band-gap, attenuation, and dispersion expressed in wave-number (ka), show similar characteristics as the phonons in solids. These findings can lead to a better understanding of the wave properties of solids at nanoscales. The readily analyzable wave models at large scale are convenient tools to verify experimentally the models for complex binary composites. Experimental findings and numerical results for wave properties of discrete structures at large scale are compared with atomic scale wave behavior of solids, for a wide range of frequencies, from audible to ultrasound, to show the common characteristics with the phonons behavior in solids.
8:36AM X30.00004 Conducting-tip AFM Studies of Multi-Walled Carbon Nanotube/Polymide Nanocomposites, A. TRIONFI, D. SCRYMGEOUR, J.W.P. HSU, Sandia National Laboratories, M.J. ARLEN, D. WANG, L.-S. TAN, R.A. VAIA, Air Force Research Laboratory — Electrical transport studies of multi-walled carbon nanotube (c-MWNT)/polymer nanocomposites have shown metallic behavior with conductivity $\sigma = \sigma_0 (\phi^2 - \phi)^3$ above the percolation threshold. The conductivity depends on three aspects of the conducting network (CN): the conductivity of the constituent c-MWNT, the number of c-MWNT making up the CN, and the detailed interconnectivity of the CN. Conducting-tip atomic force microscopy (C-AFM), we have studied the density and conductivity of the c-MWNT CN as a function of c-MWNT loading between 0.5 - 5.0 wt % in a polymide matrix. Using the Principle of Delese, the volume fraction of the c-MWNT CN can be calculated from the conducting areal density measured in the C-AFM scans. The results of the C-AFM tests have shown localized areas of electrical transport associated with c-MWNT as well a clear dependence of conducting areal density and conductivity on the c-MWNT loading. This work was performed in part at the US Department of Energy, Center for Integrated Nanotechnologies, at Los Alamos and Sandia National Laboratories. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

8:48AM X30.00005 Systematic Study of Microwave Absorption, Heating, and Microstructure Evolution of Porous Carbon Powder Metal Compacts, DARIN ZIMMERMAN, JOHN DIEHL, EARNIE JOHNSON, KELLY MARTIN, NICHOLAS MISKOVSKY, CHARLES SMITH, GARY WEISEL, BROCK WEISS, The Pennsylvania State University, Altoona College, JUNKUN MA, Southeastern Louisiana University — We present a systematic study of the absorption, heating behavior, and microstructure evolution of porous copper powder metal compacts subjected to 2.45 GHz microwave radiation and explain our observations using known physical mechanisms. Using a single mode microwave system, we place the compacts in pure electric (E) or magnetic (H) fields and compare the heating trends. The observed trends in the E- and H-field heating reflect the dramatic changes in the conductivity, permittivity, and permeability of the samples caused by the microstructure evolution during heating in the two types of fields. The observed dependence of the initial microwave heating of the samples suggests that the microwave absorption in the sample is dominated by the properties of the individual metal particles composing the sample.

9:00AM X30.00006 Do pores strengthen materials? – A pore size effect analysis, CATALIN PICU, MOHAN NUGGehally, MARK SHEPHERD, Rensselaer Polytechnic Institute — Pores with radius larger than several microns are known to reduce the yield and flow stress of ductile materials and to increase their toughness. In this work we discuss a new mechanism leading to an increase in the strength of a material by nanosized pores. We show that voids grow by the emission of dislocations. As the void radius is reduced, while their volume fraction is kept constant, the mean spacing between voids decreases and their number increases. This makes the concurrent dislocation nucleation from neighboring voids more difficult. The situation is equivalent to increasing the density of dislocation sources in the material. Furthermore, we show that the critical stress for dislocation nucleation form an isolated void also increases as the pore size is reduced. The analysis is performed using a computationally efficient adaptive atomistic-continuum method.

9:12AM X30.00007 First-Principles Calculations for the Dislocations in Titanium Nitride, RAMKUMAR GUDIPATI, University of Tulsa, Y.G. SHEN, City University of Hong Kong, WENTAO XU, University of Kentucky, A.S. RAO, H.L. DANG, SANWU WANG, University of Tulsa — Nanostructured superhard materials have been successfully synthesized in recent years. The hardness of nanosuperlatticess and nanocomposites significantly exceeds that of the component materials. While it is believed that the nanodimensions are needed to impede dislocation activity and grain-boundary sliding, relevant calculations are rare. We report first-principles density-functional calculations for the core structures and energetics of various dislocations including the [110], [110], [111], [110][100], [100][100] and [100][110] edge dislocations in bulk TiN. We found that the formation energies of the core dislocations were continuously increased when their sizes decreased. We also found that the most common types of dislocations in TiN are the [110][110] and [110][111] edge dislocations. The obtained results are helpful for elucidating the atomic-scale mechanism for the superhardness of nanocomposites.

9:24AM X30.00008 Interaction of RDX Explosive Molecules with Metal-Organic, KHORGOLKHUU ODBADRakh, JAMES LEWIS, West Virginia University — We have studied interactions of cyclotrimethylene trinitramine (RDX), a highly energetic explosive molecule, with metal-organic framework of composition Zn$_2$ O$_2$ (1,4-benzene dicarboxylate)$_3$ (MOF-5), within ab initio density functional theory method. The structures were optimized with the Fireball atomic orbital basis sets to a good agreement with experimental values. Optimal surface geometries have been obtained for MOF-5-RDX system and first principles estimates of the binding energies, charge transfer, and activation barriers are given.

9:36AM X30.00009 Control of Microcellular Structure in Polymeric Foams via Nanofiller Size and Surface Chemistry, KEREM GOREN, LINDA SCHADLER, RAHMI OZISIK, Rensselaer Polytechnic Institute — Polymeric foams are used in many applications, where thermal insulation, selective sound inhibition or low density materials are needed. They are generally produced by blending polymer with a chemical blowing agent, which releases inert gas at processing temperatures. There are two major drawbacks to this process: chemical residues that form during the decomposition of blowing agent and formation of large (macroporous) pores that weaken the material. To overcome these drawbacks, supercritical carbon dioxide (scCO2) is used. Use of scCO2 along with nanofillers provide heterogeneous nucleation, and present the opportunity to control pore size and pore distribution. In the current study, the effect of silica size and silica-scCO2 interaction on microcellular structure was investigated. Two different silica fillers were synthesized: 15 and 150 nm. These silica nanofillers were surface modified with tridecafluoro-1,1,2,2-tetrahydrooctyl triethoxysilanes. Dynamic Light Scattering, FT-IR, TGA, and SEM were used to characterize the samples. Results indicate that there is a strong correlation between surface chemistry, and hence scCO2 and filler interaction on pore size and size distribution.

9:48AM X30.00010 Diffusion in an array of cavities in two and three dimensions . MYKYTA V. CHUBYNSKY, FRANCIS TORRES, GARY W. SLATER, Department of Physics, University of Ottawa, Canada — We consider diffusion of point-like particles in arrays of cavities separated by infinitely thin walls with holes. We show that in the small-hole limit, the effective diffusion coefficient $D$ is related to the electrical capacitance of a plate of the same shape as the hole. Applying this result to elongated holes in 3D, we find an interesting logarithmic dependence of $D$ on the hole width. A logarithmic dependence is also obtained in 2D. As a consequence, the diffusion rate reaches 10% of the free diffusion rate when the hole widths are only about $10^{-6}$ of the cavity size. The theoretical predictions are validated using a numerically exact computational method. In the opposite limit, where holes span the cavity boundaries nearly completely and only small pieces of walls remain, analytical calculations are also possible. The result in this case is interesting, since a finite reduction in the diffusion coefficient is obtained even for infinitely thin walls, contrary to predictions of various effective-medium theories that this reduction should be proportional to the excluded volume fraction.

10:00AM X30.00011 First principles modeling of structure and properties of multi-component amorphous steels , VIATCHESLAV KAZIMIROV, DESPINA LOUCA, University of Virginia, MICHAEL WIDOM, Carnegie Mellon University, MICHAEL WIDOM COLLABORATION — Amorphous steels (iron based metallic glasses) exhibit unique physical properties that have opened the venue to new commercial applications as well as renewed the interest in this field. To provide a realistic description of the three dimensional structures and associate the coordinated environment of atoms to physical properties, first principles quantum mechanical molecular dynamics (MD) simulations along with the pair density function (PDF) analysis of neutron and X-ray diffraction data were used by way of considering chemical effects, ionic size ratio and concentration. Direct comparison of the simulated atomic structures obtained from MD with the local atomic structures determined experimentally show a very good agreement between the two, indicating that this theoretical approach can be applied towards simulating multi-component alloys. The atomic coordinates were used to develop the building blocks of cluster-like structures that give rise to the short-range order. The diffusion rates of different atom species were modeled at several temperatures that allowed us to describe the quenching process. In addition, the bulk moduli as a function of chemical composition were simulated and showed a very good agreement with the ones obtained experimentally.

10:12AM X30.00012 Structural, dynamic and electronic properties of amorphous Al$_2$O$_3$: ab-initio molecular dynamics calculations$^1$. GONZALO GUTIERREZ, University of Chile, Chile, SERGIO DAVIS, Royal Institute of Technology, Sweden — First principles molecular dynamics (MD) calculations of amorphous Al$_2$O$_3$ in a system consisting of a supercell of 80 atoms is reported. A detailed analysis of the interatomic correlations allows us to conclude that the short range order is mainly composed by AlO$_4$ tetrahedra, but in contrast to classical MD results, also an important number of AlO$_2$ units are present. The vibrational density of state, calculated by means of the velocity autocorrelation function, present two main bands, a low frequency one related to the inter-tetrahedron vibration and a high frequency band related to the intra-tetrahedron vibration. By means of a geometry relaxation we obtain a fully relaxed system, and calculated its elastic properties. The reported bulk modulus is 193.4 GPa, the smallest among the several phases of alumina. The electronic properties were characterized by means of both the total and partial electronic density of states as well as by means of the electron localization function. The system present a rather small gap of 2.4 eV. The consequences of these results will be discussed.

$^1$Grant Anillo ACT/24-Chile.

10:24AM X30.00013 Disorder Induced Transition into a One-Dimensional Wigner Glass. SHIMUL AKHANJEE, JOSEPH RUDNICK, UCLA — The destruction of quasi-long range crystalline order as a consequence of strong disorder effects is shown to accompany the strict localization of all classical plasma modes of one-dimensional Wigner crystals at $T = 0$. We construct a phase diagram that relates the structural phase properties of Wigner crystals to a plasmon delocalization transition recently reported. Deep inside the strictly localized phase of the strong disorder regime, we observe “glass-like” behavior. However, well into the critical phase with a plasmon mobility edge, the system retains its crystalline composition. We predict that a transition between the two phases occurs at a critical value of the relative disorder strength. This transition has an experimental signature in the AC conductivity as a local maximum of the largest spectral amplitude as function of the relative disorder strength.

10:36AM X30.00014 Structural and electronic properties of amorphous silicon carbide: A first principles and experimentally constrained molecular relaxation approach$^1$. PARTHAPRATIM BISWAS, The University of Southern Mississippi, RAYMOND ATTA-FYNN, University of Texas at Arlington — We present first-principles modeling of amorphous silicon carbide within a localized basis density functional formalism to study the electronic, vibrational and structural properties for system containing 10000 atoms. Our work for Si$_{50}$-C$_{50}$ system shows that the short range chemical order is dominated by heteronuclear Si-C bonds with coordination defect with a degree of chemical disorder. We calculate the electronic density of states that shows a presence of clean optical gap in the spectrum and study the localization nature of the electronic band tail states and vibrational eigenstates. We compare our results with existing models and experimental data available in the literature. Finally, we presents some preliminary results for models obtained by experimentally constrained molecular relaxation technique [1,2] that directly uses experimental data in conjunction with a classical force-field.

8:00AM X31.00001 Metallic Spin Liquid Behavior and Unconventional Anomalous Hall Transport of the Geometrically Frustrated Kondo Lattice Pr$_2$Ir$_2$O$_7$ — SATORU NAKATSUI, Institute for Solid State Physics, University of Tokyo — Among metallic magnets on geometrical frustrated lattices, the pyrochlore oxide Pr$_2$Ir$_2$O$_7$ is unique for its metallic spin liquid behavior and unconventional Hall transport phenomena. Despite the Weiss temperature $T^\ast = 20$ K due to the RKKY interaction, Pr$_2$Ir$_2$O$_7$ exhibits no magnetic long range order, but spin freezing at a very low temperature $\sim 120$ mK. Instead, the Kondo effect, including In$^T$ dependence in the resistivity, emerges and leads to partial screening of the $J_1$-moments below $T^\ast$. Moreover, the underscreened 4f-moments show spin-polarization behavior below a renormalized energy scale of $\theta_{\text{K}} \sim 1.7$ K. Interestingly, in this spin-fluid-like paramagnetic regime, the Hall resistivity $\rho_{xy}$ becomes largely enhanced, and shows behavior far different from anomalous Hall effects (AHE) due to the spin-orbit coupling observed in ordinary magnetic conductors. We discuss the origin of the metallic spin liquid behavior and unconventional AHE in terms of the spin chirality due to the non-coplanar texture of the $<111>$ Ising-like Pr moments. This work is based on the collaboration with Y. Machida, T. Tayama, T. Sakakibara (ISSP, Univ.of Tokyo), Y. Maeno (Kyoto Univ.), S. Onoda (RIKEN, Tokyo), C. Broholm (Johns Hopkins Univ.), C. Stock and J. van Duijn (ISIS), L. Balicas (NHMFL), Jung Young Cho, and Julia Y. Chan (Louisiana State Univ.).

This work is partly supported by Grant-in-Aid for Scientific Research on Priority Areas (190520019052003).

8:36AM X31.00002 Magnetic phase diagram of (Sr$_{1-x}$Ca$_x$)$_3$Ru$_2$O$_7$ (0 $\leq$ x $\leq$ 1.0) — Z.Q. MAO, Tulane University (TU), Z. QU, TU, L. SPINU, University of New Orleans, J. PENG, T.J. LIU, D. FOBES, TU, V. DOBROSAVLJEVIC, NHMFL and Florida State University, H.Q. YUAN, W. BAO, Los Alamos National Laboratory, J.W. LYNN, National Institute of Standards and Technology — The layered ruthenates (Sr$_{1-x}$Ca$_x$)$_3$Ru$_2$O$_7$ have received widespread attention in recent years since they display a remarkable range of unique superconducting and magnetic properties, such as spin triplet superconductivity and metamagnetic quantum criticality. We have recently studied properties of the double layered (Sr$_{1-x}$Ca$_x$)$_3$Ru$_2$O$_7$ solid solution series and established the magnetic phase diagram of this system using the high-quality single crystals grown by floating-zone method. We have observed rich magnetic ground states in this system: (I) itinerant metamagnetic state (0.08 $\leq$ x $\leq$ 0.4); (II) enhanced PM state accompanied by non-Fermi liquid behaviors near x $\sim$ 0.08; (III) ferromagnetic cluster glass (CG) phase featuring an extremely large Wilson ratio (~120) and enhanced electron correlation (0.40 $\geq$ x $\geq$ 0.08); (IV) long-range AFM state (1 $\geq$ x $\geq$ 0.40). Furthermore, we found a new phase which shows an unconventional anomalous Hall effect in a low temperature range immediately above the CG phase. The magnetization of this phase is found to follow a new scaling expression derived by phenomenologically extending the quantum Griffiths phase model.

8:48AM X31.00003 ARPES Investigations of the Electronic Structure Evolution of the Doped Ruthenate (Sr$_{1-x}$Ca$_x$)$_3$Ru$_2$O$_7$ — WILLIAM DUNKEL, Stanford University, FELIX BAUMBERGER, MILAN ALLAN, University of St. Andrews, WORAWAT MEEVASANA, Stanford University, ZHIQIANG MAO, Tulane University, ZHI-XUN SHEN, Stanford University — The bilayer ruthenate system (Sr$_{1-x}$Ca$_x$)$_3$Ru$_2$O$_7$ can be grown in the full range of dopings with the end members being an antiferromagnetic “bad metal” (x=1) and a paramagnetic Fermi liquid displaying a metamagnetic transition under applied field (x=0). Recent transport and magnetization measurements have shown that the system displays disorder-induced unconventional quantum critical behavior near the doping level x~0.3. We present ARPES data for a range of dopings to investigate the associated electronic structure evolution.

9:00AM X31.00004 Study of the Layered Perovskite Sr$_3$Ru$_2$O$_7$ by STS and ARPES — MILAN ALLAN, J. LEE, University of St. Andrews, UK, Cornell University, M. WANG, A. SCHMIDT, Cornell University, F. BAUMBERGER, A. TAMAI, J. FARRELL, University of St. Andrews, UK, C. Stock and J. van Duijn (ISIS), L. Balicas (NHMFL), Jung Young Cho, and Julia Y. Chan (Louisiana State Univ.) — The Ruddlesden-Popper series, Sr$_{n+1}$Ru$_n$O$_{3n+1}$ exhibits a variety of electronic phases, including triplet superconductivity (n=1) or metamagnetism (n=2). Here we report studies of the electronic structure of the bilayered perovskite Sr$_3$Ru$_2$O$_7$ (n=2) by means of scanning tunneling spectroscopy. Special attention is given to the influence of titanium impurity atoms on the local electronic structure. A comparison with angle resolved photoemission experiments on the same set of samples is drawn.

9:12AM X31.00005 Quasi-3D ordered lattice modulations in a bilayer ruthenate with no long-range order — ZAHRIRUL ISLAM, Argonne National Laboratory (ANL), ZHE QU, Tulane University (TU), YEJUN FENG, JONATHAN LANG, ANL, JIN PENG, ZHIQIANG MAO, TU — Bulk measurements reveal disorder-induced unconventional quantum critical behaviors in (Sr$_{1-x}$Ca$_x$)$_3$Ru$_2$O$_7$ (SCRO) compounds, in particular, near x $\sim$ 0.3. Here we report X-ray scattering studies on SCRO with x = 0.3, as well as those for the end members. We find that at x = 0.3 robust 2-unit-cell periodic lattice modulations exist that are characterized by ($\frac{1}{2}$, 0, 0) and ($\frac{1}{2}$, $\frac{1}{2}$, 0), respectively, even at room temperature. These modulations are transversely polarized and quasi-3D ordered in that they are fully coherent in the basal plane with c axis correlations at least one unit cell in extent. These modulations are due to correlated displacements of the O atoms. The displacement pattern is consistent with 2q modes of distortion of RuO$_6$ octahedra, signifying the presence of lattice and orbital correlations, although no long-range magnetic or orbital order is present. These modulations are absent in the end members.

9:24AM X31.00006 Doping-Induced Structural and Physical Properties Changes in Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$ Single Crystals — BIAO HU, Univ. of Tennessee, Knoxville, TN 37996, MANUEL ANGST, Materials Science and Technology Division, ORNL, Oak Ridge, TN 37831, OVIDIU GARLEA, Neutron Scattering Science Division, ORNL, Oak Ridge, TN 37831, V.B. NASCIMENTO, Univ. of Tennessee, Knoxville, TN 37996, DAVID MANDRUS, Materials Science and Technology Division, ORNL, Oak Ridge, TN 37831, E.W. PLUMMER, Univ. of Tennessee, Knoxville, TN 37996 and Materials Science and Technology Division, ORNL, Oak Ridge, TN 37831, R. JIN, Materials Science and Technology Division, ORNL, Oak Ridge, TN 37831 and Univ. of Tennessee, Knoxville, TN 37996 — In the homologous strontium ruthenate systems Sr$_{n+1}$Ru$_n$O$_{3n+1}$, double-layered Sr$_3$Ru$_2$O$_7$ exhibits unique physical properties. However, the partial substitution of Ru by the smaller Mn was found to change its ground state from a paramagnetic metal to an antiferromagnetic insulator with less distorted crystal structure. Interestingly, our Hall effect measurements show no change in the carrier concentration (x $\leq$ 0.2), suggesting that Mn is isovalent with Ru in Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$. This is further supported by the magnetization data, which yield effective spin S = 3/2 for Mn corresponding to Mn$^{+\frac{3}{2}}$. In addition to bulk physical properties, the doping dependence of the surface structure and lattice dynamics of Sr$_3$(Ru$_{1-x}$Mn$_x$)$_2$O$_7$ single crystals will be discussed.
9:36AM X31.00007 Relation between structure and magnetic properties in (Sr$_{1-x}$Ca$_{x}$)$_3$Ru$_2$O$_7$\textsuperscript{1} , J. PENG, Tulane University (TU). Z. QU, TU, L. SPINU, University of New Orleans, T.J. LIU, D. FOBES, Z.Q. MAO, TU — The (Sr$_{1-x}$Ca$_{x}$)$_3$Ru$_2$O$_7$ solid solution series exhibits rich magnetic ground states, ranging from itinerant metamagnetism, ferromagnetic instability, ferromagnetic cluster glass, to antiferromagnet.\textsuperscript{[1]} In this talk, we report a study on the relation between structure and magnetic properties in (Sr$_{1-x}$Ca$_{x}$)$_3$Ru$_2$O$_7$. Our Rietveld refinement of x-ray scattering data shows that the rotation angle of RuO$_6$ octahedra increases with increasing $x$, and approaches saturation for $x > 0.2$. The orthorhombicity, which is caused by the tilting of RuO$_6$ octahedra, occurs for $x > 0.4$ and enhances significantly for $x > 0.7$. By comparing these structural characteristics with the magnetic properties, we conclude that the ferromagnetic instability originates from the RuO$_6$ octahedra rotation, and the tilting of RuO$_6$ octahedra causes a significant magnetic anisotropy.\textsuperscript{[1]} Z. Qu et al. arXiv:0708.1291 (2007).

\textsuperscript{1}Work at Tulane is supported by NSF, DOE and the Research Corporation. Work at UNO is supported by DARPA.

9:48AM X31.00008 QPI in Sr$_3$Ru$_2$O$_7$ , JINHO LEE, University of St. Andrews, Cornell University, M. WANG, Cornell University, M. ALLAN, University of St. Andrews, A. SCHMITZ, Cornell University, F. BAUMBERGER, A. TAMAI, J. FARRELL, University of St. Andrews, J. C. DAVIS, Cornell University, Brookhaven National Laboratory, A. MACKENZIE, University of St. Andrews — Sr$_{n+1}$Ru$_n$O$_{3n+1}$ family drew substantial attention recently due to its plethora of electronic phases like triplet superconductivity or metamagnetism. Sr$_3$Ru$_2$O$_7$ (n = 2) is very similar to the triplet superconductor Sr$_3$Ru$_2$O$_4$ in 2D conductivity as well as in structure, but shows no superconductivity. Understanding of the underlying band structure is the first step to fathom this strongly correlated oxide. STM has proven to be a high precision tool to measure band dispersions in momentum space along with the atomically resolved real space spectroscopic properties. Here we report the first atomically resolved 2D spectroscopic maps in Sr$_3$Ru$_2$O$_7$ where QPI patterns are observed and discuss the band landscape responsible for the QPI in this energy range.

10:00AM X31.00009 Orbital Hierarchy Inversion and Magnetic Transition in Mn Doped Sr$_4$Ru$_3$O$_7$\textsuperscript{1} , MUHAMMED HOSSAIN, University of British Columbia, M.W. HAVERKORT, Z.H. HU, T. BURNUS, C.F. CHANG, S. KLEIN, J.D. DENLINGER, H.-J. LIN, C.T. CHEN, R. MATHIEU, Y. KANEKO, Y. TOKURA, S. SATOW, Y. YOSHIDA, H. TAKAGI, A. TANAKA, I.S. ELFIMOV, G.A. SAWATZKY, L.H. TJENG, A. DAMASCHELLI — Oxidine ruthenates are very important class of compounds that are extremely sensitive to impurities. Here we present a study of the Mn doped Sr$_4$Ru$_3$O$_7$ by X-ray Absorption Spectroscopy (XAS) and a combination of density functional theory (LSDA) and cluster calculations. We find that delocalized RuO matrix forces the Mn impurities to behave as a negative charge transfer system and donate a hole. As a result Mn impurities behave as Mn$^{3+}$ acceptors. Our XAS data clearly shows that the occupied $e_g$ orbitals have an in-plane alignment: a very surprising result in a tetragonally distorted system elongated along the c-axis. LSDA calculations reveal very strong anisotropy in oxygen bandwidth leading to a reversal of the $e_g$ crystal field hierarchy. This work further establishes that the Mn atoms are sitting in a bath of a uniaxial exchange field that gradually goes out-of-plane to in-plane as the Mn doping level is increased. Overall, the behavior has some similarities with Mn doped GaAs and may be relevant to the physics of dilute magnetic semiconductors.

\textsuperscript{1}ALS Doctoral Fellowship, Advanced Light Source, LBNL.

10:12AM X31.00010 Temperature dependence of a zero bias anomaly in scanning tunnelling spectra of Sr(4)Ru(3)O(10)\textsuperscript{1} , BERNHARD NANSSEU, TATJANA NOVGORODOV, MICHAEL WAELSCHE, JÜRGEN HAGER, University of Kassel, JIANDI ZHANG, Florida International University, Miami, R. MOORE, WARD PLUMMER, Oak Ridge National Laboratory, ZHIQIANG MAO, Tulane University, RENE MATZDORF, University of Kassel — We have studied a zero bias anomaly in scanning tunnelling spectra of layered ruthenate Sr(4)Ru(3)O(10). This material shows a dip-like feature in the dI/dV spectra, which has previously observed in the single-layer Sr(2)RuO(4) and double-layer Sr(3)Ru(2)O(7) ruthenates. We have studied in particular the temperature dependence of the zero bias anomaly, which is in all three materials different. The triple-layer material shows intergrowth of single and double layers, which have been identified by their spectroscopic fingerprint. Finally, we discuss different effects as possible explanations for the zero bias anomaly.

\textsuperscript{1}The work was supported by NSF-DMR0346826 and the Deutsche Forschungsgemeinschaft.

10:24AM X31.00011 Anisotropy of magneto resistivity in trilayered ruthenate Sr$_4$Ru$_3$O$_{10}$\textsuperscript{1} , Evidence for orbital dependent metamagnetism , D. FOBES, M. ZHOU, T.J. LIU, Z. QU, Tulane University, USA, H.Q. YUAN, M. SALAMON, University of Illinois, Urbana-Champaign, USA, Z.Q. MAO, Tulane University, USA — Trilayered ruthenate Sr$_4$Ru$_3$O$_{10}$ is ferromagnetic with $T_c \approx 100K$ and moderate in-plane magnetic field ($B_c \approx 2T$) induces an itinerant metamagnetic transition [1,2]. Such metamagnetism within a FM ground state cannot be understood with a single band model of a field-tuned Stoner transition. We have measured azimuthal angular dependence of in-plane and out-of-plane magneto resistivity ($\rho_{ab}(\phi)$ and $\rho_c(\phi,B)$). We found that for B$<$B$_{c}$, at fixed field $\rho_{ab}(\phi)$ exhibits a two-fold anisotropy attributable to anisotropic behavior of an Ising ferromagnet, while $\rho_c(\phi)$ does not show such a behavior. For B$>$B$_{c}$, both $\rho_{ab}(\phi)$ and $\rho_c(\phi)$ exhibit a four-fold symmetry anisotropy, but the minimum value in $\rho_{ab}(\phi)$ and $\rho_c(\phi)$ occurs along different directions, i.e., [100] and [010] for $\rho_{ab}$, and [110] and [110] for $\rho_c$. Such a difference in anisotropic behavior between $\rho_{ab}(\phi)$ and $\rho_c(\phi)$ provides strong support that metamagnetism in Sr$_4$Ru$_3$O$_{10}$ is orbital dependent, i.e., ferromagnetic and metamagnetic bands coexist.

Work at Tulane is supported by NSF, DOE and the Research Corporation.

10:36AM X31.00012 Fermi Surface mapping of Sr$_4$Ru$_3$O$_{10}$ using Angle Resolved Photoemission , R.S. SINGH, F. WANG, J.W. ALLEN, University of Michigan, J.D. DENLINGER, Lawrence Berkeley National Lab, X.N. LIN, GANG CAO, University of Kentucky — Layered strontium ruthenates in the Ruddlesden-Popper series (Sr$_{n+1}$Ru$_n$O$_{3n+1}$) are scientifically interesting and technologically promising materials exhibiting various novel electronic and magnetic properties. We will show the effect of dimensionality on the electronic structure as one goes from two dimensional to three dimensional crystal structures by increasing n. In particular, we will present new results and analysis of photon energy dependent angle resolved photoemission spectroscopy measurements on Sr$_4$Ru$_3$O$_{10}$ and make detailed comparison of Fermi surface maps with recently measured Shubnikov-de Haas frequencies and available LDA band structure calculations corresponding to various layered strontium ruthenates.

Studies of MTJ crystal structure have implications for the development of high-performance MTJs, making them viable for MRAM and sensor applications. Careful engineering of the MgO tunnel barriers, CoFeB electrodes, and their interfaces is essential for high levels of tunneling magnetoresistance (TMR), particularly the CoFeB/MgO/CoFeB system, which exhibits large TMR. Unfortunately, these magnetoresistance devices suffer from considerable noise.

Incorporating a very desirable trait for magnetic random access memory and hard drive read heads, theory predicts high levels of tunneling magnetoresistance (TMR) which are achievable with magnetic tunnel junctions (MTJs) featuring the necessary elements for picoTesla MTJ sensors. However, challenges such as high noise levels and the need for greater precision in the performance of such MTJs exist in the integration of the necessary components of the sensor and illustrate the trade-offs that must be considered. For example, values of the TMR above 100% contribute very little, while lowering the saturation field of the free layer below 10 Oe is essential. These and other insights identify the critical issues than need attention and can guide research into productive directions.

We investigated MTJs with rf-sputtered or electron-beam evaporated MgO barrier layers, and we used TaN, Ta/Ru, and Ta/CuN as alternative seed layers for the MTJ growth. We report on changes in both tunnel barrier and electrode crystallization as a function of anneal temperature, which we find to be dependent on both the MgO deposition method and the seed layer composition. Our complete MTJ structures using rf-sputtered MgO barriers achieve TMR in excess of 200%, and correlation with these XRD results sheds light on the complex dependence of MTJ performance on growth and processing conditions.

We have studied the complex longitudinal ($\sigma_{xx}$) and transverse ($\sigma_{xy}$) conductivities in a series of Ca$_x$Sr$_{1-x}$Ru$_2$O$_3$ films by using the Landau-Lifshitz-Gilbert equation in non-linear regime. The results also suggest that this new experimental technique to detect FMR is very useful for characterizing the LA-FMR. Using the same structure, we electrically detected the LA-FMR of the Py by measuring the tunneling resistance in a sweeping external dc magnetic field. We will report on changes in both tunnel barrier and electrode crystallization as a function of anneal temperature, which we find to be dependent on both the MgO deposition method and the seed layer composition. Our complete MTJ structures using rf-sputtered MgO barriers achieve TMR in excess of 200%, and correlation with these XRD results sheds light on the complex dependence of MTJ performance on growth and processing conditions.

8:36AM X32.00004 FMR spectroscopy with very large precession cone angle in magnetic tunnel junctions

TAKAHIRO MORIYAMA, XIN FAN, JOHN Q. XIAO, Department of Physics and Astronomy, University of Delaware — Unlike the small angle precession with low power microwave excitation, which has been extensively studied using conventional ferromagnetic resonance (FMR) techniques, the large angle precession involves nonlinear response of the magnetizations. Large angle ferromagnetic resonance (LA-FMR) measurements can help to understand the magnetization dynamics with high power excitation generally found in current induced spin switching and microwave assisted switching, etc. Recently we have performed magnetoresistance measurements in IrMn/FeCo/AIOx/Permalloy (Py) magnetic tunnel junctions excited by a large power microwave [1]. Using the same structure, we electrically detected the LA-FMR of the Py by measuring the tunneling resistance in a sweeping external dc magnetic field. We found that the resonance frequency depends on the microwave power, i.e. precession cone angle, as well as the dc magnetic field, which can be well explained by using the Landau-Lifshitz-Gilbert equation in non-linear regime. The results also show that this new experimental technique to detect FMR is very useful for characterizing the LA-FMR.

8:48AM X32.00005 Technique for Minimizing the Effect of 1/f Noise in Magnetic Sensors

ALAN EDELSTEIN, GREG FISCHER, JAMES BURNETTE, U.S. Army Research Laboratory, SHU-FAN CHENG, Naval Research Laboratory, EDMUND NOWAK, Dept. of Physics and Astronomy, Univ. of Delaware, Newark, DE, WILLIAM EDELHOFF, NIST, Gaithersburg MD, CATHY NORDMAN, NVE, Eden Prairie MN — Sensors such as magnetic tunnel junctions with MgO barriers offer the possibility of increased sensitivity. The magnetoresistance of these junctions can be as large a 400%. Unfortunately, these magnetoresistance devices suffer from having considerable 1/f noise. We have a device, the MEMS flux concentrator, that modulates the field at the position of the sensor and thus increase the frequency of the field to be detected to kHz frequencies where the 1/f noise is much smaller. It does this by having flux concentrators on MEMS flaps that are driven to move electrostatic comb drives. The flaps on each side of the sensor are connected by springs so that the desired motion is a normal mode. The signal appears as sidebands that can be demodulated using a lock-in amplifier. The device will increase the sensitivity at 1 Hz of many sensors by a factor of 100. Tests indicate that the device does not increase the noise and that it will function at frequencies lower than 1 Hz. Results of initial tests will be reported.
This approach is demonstrated using super-paramagnetic particles of 2 \( \mu \)m. An optical tweezers was used to trap and position a single super-paramagnetic particle over a Spin Valve sensor, with the particle then detected by the sensor.

Using Spin Valve Sensors

The exchange bias increased at low temperatures from 50Oe to 350Oe when FeMn layers are on both surfaces of Co terminated [FeMn10nm/Co4nm/FeMn10nm] multilayer, compared to single FeMn layer. However for the Gd terminated [FeMn10nm/Co4nm/FeMn10nm] multilayer the Gd/FeMn interface does not induce exchange bias. Moreover exchange spring behavior is observed around compensation temperature due to the uncompensated moment in FeMn layers.

The work at UTA was supported by a grant No(Y-1215) from The Welch Foundation.

9:24AM X32.00008 Exchange bias in a ferrimagnetic/antiferromagnetic system\(^1\). M.R. HOSSU, The University of Texas at Arlington, Arlington, TX 76019, S. DEMIRTAS, M.B. SALAMON, University of Texas at Dallas, Richardson, TX 75083, A.R. KOYMEM, The University of Texas at Arlington, Arlington, TX 76019 — The effect of antiferromagnetic FeMn on ferrimagnetic (Co4nm/Gd4nm)\(_1\) multilayer was investigated by measuring the exchange bias and coercivity fields. It was observed that magnetic properties depend on whether the multilayers are Co or Gd terminated. The exchange bias increased at low temperatures from 500e to 3500e when FeMn layers are on both surfaces of Co terminated [FeMn10nm/Co4nm/FeMn10nm] multilayer, compared to single FeMn layer. However for the Gd terminated [FeMn10nm/Co4nm/FeMn10nm] multilayer the Gd/FeMn interface does not induce exchange bias. Moreover exchange spring behavior is observed around compensation temperature due to the uncompensated moment in FeMn layers.

10:36AM X32.00014 Interplay of Magnetic and Structural Anisotropy in CoNi Multilayer Thin Films . JOSEPH DVORAK, NSLS, BNL, KATHRYN KRYCKA, NCNR, NIST, JEAN-MARC BEAUJOUR, WENYU CHEN, ANDREW KENT, New York University, CHI-CHANG KAO, NSLS, BNL — Interfacial perpendicular magnetic anisotropy (PMA) is important for spin transfer devices and has been predicted to overcome dipolar shape anisotropy for [t Co|2t Ni] multilayers with thicknesses, t , of 4 Å or less [1]. Layered between Cu, however, thickness dependent PMA (t=1, 2, 3, 4 and 6 Å) is not sufficiently strong to produce perpendicular magnetization. Anomalous diffraction reveals that the Co and Ni are exponentially strained by the Cu within the sample plane. As calculated in reference 2 this trilgonal strain would be sufficient to overcome the PMA. Ferromagnetic resonance measurements [3] indicate that the net Lande g-factors are enhanced above bulk for all thicknesses, and increase further with decreasing layer thickness. By applying element-specific x-ray magnetic circular dichroism (XMCD) we have been able to study the Co and Ni individually. Both elements show increasing spin to orbit ratios with decreasing thickness magnetized either in-plane or along sample normal. In all cases the spin to orbit ratio is enhanced along the sample normal compared with the in-plane direction. [1] Phys. Rev. Lett. 68, 682 (1992) [2] Phys. Rev. B 69, 104424 (2004) [3] Eur. Phys. J. B 59, 475 (2007)

10:48AM X32.00015 Classical and Quantum Routes to Linear Magnetoresistance . JINGSHI HU, University of Chicago & Massachusetts Institute of Technology, T.F. ROSENBAUM, University of Chicago — We show that either adding a few parts per million of the proper chemical impurities to indium antimonide, a well-known semiconductor, or redesigning the material’s structure on the micrometer scale, can transform its response to an applied magnetic field. The former approach is a spectacular manifestation of magnetotransport in the extreme quantum limit, when only one Landau band is partially filled; the latter a classical outgrowth of disorder, turned to advantage. In both cases the magnetoresistive response at the heart of magnetic sensor technology can be converted to a simple, large and linear function of field that does not saturate. Harnessing the effects of disorder has the further advantage of extending the useful applications range of such a magnetic sensor to very high temperatures by circumventing the usual limitations imposed by phonon scattering.

8:12AM X33.00002 Spin Resolved Cyclotron Resonance and Magneto-absorption in InSb Multiple Quantum Wells1 . XINGYUAN PAN, G.D. SANDERS, C.J. STANTON, University of Florida, T. KASTURIARACHCHI, W. GEMPEL, X.H. ZHANG, R.C. MEYER, N. GOEL, M. EDIRISORIYA, T.D. MISHIMA, R.E. DOEZEMA, M.B. SANTOS, University of Oklahoma, Y.J. WANG, National Institute for Quantum and Complex Dynamics, University of California Santa Barbara — The nitrogen-vacancy (N-V) impurity center is a promising solid- state spin system for solid-state quantum information processing. Many desirable quantum properties have been found at room temperature, including long spin-coherence times, demonstration of single N-V spin quantum gate operation, discovery of rapid spin polarization and achievement of readout of single N-V spins. There have been many EPR experiments to investigate electronic structures and dynamics of impurities in diamond. Most of the studies were however performed by low-field EPR. High-frequency EPR generally has a great advantage for spectral and time resolution and absolute sensitivity due to very high spin-polarizations in high magnetic fields. High-frequency EPR for the diamond system therefore enables the investigation of ensembles of low-concentration impurities. In this presentation, we will discuss high-field properties of spin relaxations of impurities on diamond studied with 240 GHz cw and pulsed EPR.

8:36AM X33.00004 Electron-nuclear interactions in lightly-doped GaAs, studied through optically-detected magnetic resonance (ODMR)\(^1\). JOHN COLTON, Brigham Young University, LEE WIENKES, University of Minnesota-Twin Cities, ANDREW GIERKE, University of Wisconsin-Madison, SUSAN ALLEMANN, University of Wisconsin-La Crosse, ALLAN BRACKER, Naval Research Laboratory — Electron-nuclear interactions have been studied in lightly-doped GaAs via optically-detected magnetic resonance (ODMR). Thermally-polarized electrons were resonated with ~10 GHz microwaves; the spin states were detected with cw optical Kerr rotation. The electron-nuclear interaction was manifested through an effective magnetic field produced by the hyperfine interaction between nuclei and donor electrons, which caused a shift in the electron ODMR peak position. The effective nuclear field could be eliminated by simultaneous magnetic resonance of the three nuclear species. A measurement of the nuclear spin relaxation time was obtained (5.6 minutes) by tracking the amount of effective nuclear field, in the absence of nuclear magnetic resonance. Finally, optically-detected electron-nuclear double resonance (ODENDOR) was also performed, by monitoring changes in the electron Kerr rotation signal while sweeping through nuclear resonant frequencies one at a time.

8:48AM X33.00005 Pseudospin Resonance in Semiconductor Bilayers, SAEED H. ABEDINPOUR, MARCO POLINI, MARIO P. TOSI, NEST-CNR-INFN and Scuola Normale Superiore, I-56126 Pisa, Italy, BILAL TANATAR, Department of Physics, Bilkent University, Bilkent, 06800 Ankara, Turkey, ALLAN H. MACDONALD, Department of Physics, The University of Texas at Austin, Austin, Texas 78712, USA, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri-Columbia, Columbia, Missouri 65211, USA — The pseudospin degree of freedom in a semiconductor bilayer gives rise to a collective mode analogous to the ferromagnetic resonance mode of a ferromagnet. We present a theory of the dependence of the energy and the damping of this mode on layer separation \(d\). Based on these results, we discuss the possibility of realizing transport-current driven pseudospin-transfer oscillators in semiconductors.

9:00AM X33.00006 Location and Magnetic Hyperfine Properties of Mn\(^{2+}\) in Silicon, R.H. PINK, SUNY Albany, ARCHANA DUBEY, UCF Orlando, S.R. BADU, SUNY Albany, R.H. SCHEICHER, Upsalla University, Sweden, M.B. HUANG, SUNY Albany, LEE CHOW, UCF Orlando, T.P. DAS, SUNY Albany, UCF Orlando — Crystalline Silicon doped with the transition metal ion Mn\(^{2+}\) is ferromagnetic at room temperature and thus potentially a useful material for spintronic applications. In attempting to understand from first principles the location of Mn\(^{2+}\) and the electronic structure of the ferromagnetic system we have started work first on the dilute system. We have used the Hartree-Fock cluster procedure to determine the binding energies of the three likely locations for Mn\(^{2+}\), substitutional (S), tetrahedral interstitial (\(T_i\)) and hexagonal interstitial (\(H_i\)) locations allowing for relaxation of the silicon neighbors. Our calculations show that the H\(_i\) location is unstable and the S and \(T_i\) are stable. Our nuclear magnetic hyperfine interactions results for \(^{57}\)Mn nucleus and \(^{29}\)Si neighbor will be presented and compared with electron spin resonance \([1]\) experimental data.

9:12AM X33.00007 The Nuclear Spin Relaxation in the Semiconductor Double Quantum Dots: Study of Spin Diffusion, EDDY YUSUF, XUEDONG HU, Physics Department, University at Buffalo, SUNY, Buffalo 14260 — We study the relaxation of the nuclear spins in a semiconductor double quantum dot. We focus on spin diffusion as an important channel for nuclear spin relaxation. The diffusion of the nuclear spin polarization arises from the Fermi contact hyperfine interaction between electrons in the quantum dots and the nuclear spins, as well as the magnetic dipolar interaction between nuclear spins. We calculate the nuclear spin polarization relaxation time and the nuclear diffusion constant within the density matrix framework. We explore the behavior of the relaxation time and diffusion constant for a wide range of conditions, including variations in temperature, the initial degree of nuclear polarization, dot sizes, and the strength of the applied magnetic field. We compare our results to the available experimental data and discuss various experimental schemes to further test the outcome of our calculation. \([1]\) A. Greilich, et al., Science 317, 1896 (2007) \([2]\) S. Das Sarma, et. al., Solid State Commun. 133, 737 (2005)

9:24AM X33.00008 Microscopic theory of electron spin relaxation in N@C\(_{60}\), Z.G. YU, SRI International — Endohedral N@C\(_{60}\) exhibits an extremely long electron spin relaxation time and offers a great potential in storing and processing quantum information. Here we present a microscopic theory of electron spin relaxation in N@C\(_{60}\). The theory combines (1) the spin-orbit interaction of N 2p electrons, which mixes the ground state \(^4\)S with excited \(^2\)P and \(^2\)D states, and (2) the coupling between the N 2p electrons and C\(_{60}\) H\(_v\) vibrations, which facilitates transitions between \(^2\)P and \(^2\)D states. The spin relaxation occurs via a two-phonon (Raman) process by absorbing a H\(_v\) phonon and emitting another at the (approximately) same frequency. The theory consistently explains measured spin relaxation time \(T_1\) and its temperature dependence, and predicts two distinct spin decoherence \(T_2\) constants. In addition, the excellent agreement between theory and experiment suggests a universal importance of the two-phonon Raman process in determining spin relaxation in nanosstructures such as quantum dots, where a one-phonon process is ineffectual in flipping electron spins because of the lack of low-energy phonons in nanostuctures.

9:36AM X33.00009 Electronic and transport properties of a lateral triple quantum dot molecule in a magnetic field, F. DELGADO\(^1\), Y.-P. SHIM, M. KORKUSINSKI, P. HAWRYLAK, Quantum Theory Group, Institute for Microstructural Sciences, NRC, Ottawa, ON, Canada K1A 0R6 — We present a theory of spin, electronic and transport properties of a few-electron lateral triangular triple quantum dot molecule in a magnetic field. Our theory is based on a Hubbard model and the Linear Combination of Harmonic Orbitals combined with Configuration Interaction method to arbitrary magnetic fields. The one-particle spectra obtained as a function of the magnetic field exhibit Aharonov-Bohm oscillations. As a result, by changing the magnetic field it is possible to engineer the degeneracies of single-particle levels, and thus control the total spin of the many-electron system. For the triple dot with two and four electrons we find oscillations of total spin due to the singlet-triplet transitions occurring periodically in the magnetic field. In the three-electron system we find a transition from a magnetically frustrated to the spin-polarized state. The impact of these phase transitions on the addition spectrum are analyzed and the qualitative behaviour of the current through the quantum molecule under spin blockade conditions is studied as a function of the applied magnetic field.

\(^1\)Department of Physics, University of Ottawa, MacDonald Hall, 150 Louis Pasteur, Ottawa, ON, Canada KIN 6N5
to previous Si(100) studies, we observe three resonant peaks, which we attribute to a) the two well known hyperfine spilt phosphorus resonances, and b) the of phosphorus donor electrons in silicon. These studies have been undertaken on the Si (100) interface, due to its wide utilization in the semiconductor industry.

CHRISTOPH BOEHME, Department of Physics, University of Utah — Recently, there has been a large effort towards the electrically detection of spin coherence manipulation in high fields, and these results will also be discussed.

microscopic processes leading to the signals discussed. Finally, pulsed EDMR (Rabi oscillations, Hahn echos) was performed to investigate spin coherence and defects near the Si-SiO₂ interface, were observed. The temperature dependence of the observed signals in the range T = 3K - 10K will be presented, and the microscopic processes leading to the signals discussed. Finally, pulsed EDMR (Rabi oscillations, Hahn echos) was performed to investigate spin coherence and manipulation in high fields, and these results will also be discussed.

10:12AM X33.00012 Electrically-detected magnetic resonance in accumulation-layer MOSFETs, LAURENS WILLEM VAN BEVEREN, University of New South Wales, DANE MCCAMEY, University of Utah, HANS HUEBL, Technische Universität München, ANDREW FERGUSON, University of Cambridge, TIM DUTY, ROBERT CLARK, University of New South Wales — Spin-dependent transport, originating from neutral-impurity scattering, in silicon accumulation-layer MOSFETs was reported more than a decade ago in an electron-spin resonance (ESR) cavity setup [1]. There, current measurements on the MOSFET showed ESR features with a hyperfine (HF) splitting of 42 G, indicative of electrons whose wavefunctions overlap with phosphorous nuclei in the silicon crystal. Here, we report the observation of electrically-detected magnetic resonance (EDMR) in phosphorus-doped silicon MOSFETs without the constraint of a cavity and down to the mK-regime in a dilution refrigerator with a superconducting magnet.

Instead, the ESR-field is generated by an on-chip shorted coplanar stripline (CPS), allowing broadband operation. Continuous-wave EDMR was achieved up to 30 GHz. The EDMR spectra show (i) the two hyperfine-split (42 G) ESR lines and (ii) an EDMR signal that is centered between the hyperfine lines, associated with the ‘free electron’ ESR response. [1] R. Ghosh and W. Silsbee, Phys. Lett. 85, 439 (1992).

10:24AM X33.00013 Electrically detected magnetic resonance in Si:P at high magnetic fields (B = 8.5 T), DANE MCCAMEY, Department of Physics, University of Utah, GAVIN MORLEY, London Centre for Nanotechnology, LOUIS CLAUDE BRUNEL, JOHAN VAN TOL, National High Magnetic Field Laboratory, Florida State University, HEATHER SEIPEL, CHRISTOPH BOEHME, Department of Physics, University of Utah — Phosphorus doped silicon (Si:P) is a technologically important material with possible uses in spintronic and quantum information processing devices. A useful way to understand the properties of this material is by investigation of the spin dependence of its transport processes. Whilst numerous studies of this type have been performed on Si:P at low magnetic fields, no systematic investigation has been undertaken at high magnetic fields. We will present an electrically detected magnetic resonance (EDMR) study of Si:P, with a native oxide surface, at B = 8.5 T (f_{resonance} ~ 240 GHz). The change in the sample photocurrent, ΔI/I, was measured as a function of B using a microwave chopping method. Resonant signals from the P donors, as well as P₁ defects near the Si-SiO₂ interface, were observed. The temperature dependence of the observed signals in the range T = 3 K - 10 K will be presented, and the microscopic processes leading to the signals discussed. Finally, pulsed EDMR (Rabi oscillations, Hahn echos) was performed to investigate spin coherence and manipulation in high fields, and these results will also be discussed.

10:36AM X33.00014 Pulsed electrically detected magnetic resonance of phosphorus donors near the Si(111)-SiO₂ interface, SEOYOUNG PAIK, HEATHER SEIPEL, SANG-YUN LEE, THOMAS HERRING, DANE MCCAMEY, CHRISTOPH BOEHME, Department of Physics, University of Utah — Recently, there has been a large effort towards the electrically detection of spin coherence of phosphorus donor electrons in silicon. These studies have been undertaken on the Si (100) interface, due to its wide utilization in the semiconductor industry. Here, we present a pulsed electrically detected magnetic resonance study on P donors near the Si(111) interface. We observe the transient current after a short, coherent microwave pulse as a function of both the magnitude and relative orientation (with respect to the [111] direction) of the applied magnetic field. Similar to previous Si(100) studies, we observe three resonant peaks, which we attribute to a) the two well known hyperfine split phosphorus resonances, and b) the P₁f defect resonance. The P₁f resonance exhibited an anisotropy with field direction, in agreement with conventional ESR studies. In addition, we observe a fourth isotropic resonance, with a g-factor of g = 2.0051±0.0004. We conclude that, aside from the anticipated and well known P-P₁ transition, at least one additional spin dependent recombination pathway exists at the Si(111)-SiO₂ interface.
8:12AM X35.00002 “Ultimate” SOI MOSFETs

THOMAS J. WALLS, KONSTANTIN K. LIKHAREV, Stony Brook University

— Silicon-On-Insulator (SOI) field-effect transistors (MOSFETs) are being aggressively scaled toward the 10-nm frontier - see, e.g., Ref. [2]. In our earlier work [1], we have carried out a detailed analysis of the performance and parameter variation sensitivity of double-gate sub-10-nm MOSFETs using a self-consistent numerical solution of the 2D Poisson equation and 1D Schrodinger equation. However, for very small devices the 1D approximation misses some important details of the device physics. In this work, we have used the momentum-space formalism, developed in 1989 by A. Szafer and A. D. Stone [3] to fully account for 2D quantum effects.

At the meeting, we will present a comparison of our new results with our previous 1D approximation, as well as calculations of the gate capacitance of the transistors. This work has been supported in part by the ONR.

8:24AM X35.00003 Novel Ferroelectric CMOS Nonvolatile Logic

M. TAKAHASHI, T. HORIUCHI, Q.-H. LI, S. WANG, K. Y. YUN, S. SAKAI, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan — We propose a novel and promising nonvolatile-logic circuit constructed by p channel type (Pch) and n channel type (Nch) ferroelectric gate field effect transistors (FeFETs), which we named a ferroelectric CMOS (FeCMOS) circuit. The circuit works as both logic and memory. We fabricated a NOT logic FeCMOS device which have Pt metal gates and gate oxides of ferroelectric SrBi2Ta2O9 (SBT) and high-k HfAlO on Si. Key technology was adjusting threshold voltages of the FeFETs as well as preparing those of high quality. We demonstrate basic operations of the NOT-logic response, memory writing, holding and non-destructive reading. The memory writing is done by amplifying the input node voltage to a higher level when the node was logically high and to a lower one when it was logically low just before the writing operation. The data retention was also measured. The retained high and low voltages were almost unchanged for 1.2 days. The idea of this FeCMOS will enhance flexibility of circuit designing by merging logic and memory functions. This work was partially supported by NEDO.

8:36AM X35.00004 Study on threshold voltages of Pt/SrBi2Ta2O9/Hf-Al-O/Si FeFETs

Q.-H. LI, M. TAKAHASHI, S. WANG, T. HORIUCHI, C.C. WANG, K.Y. YUN, Y. FUHIHATA, S. SAKAI, National Institute of Advanced Industrial Science and Technology, Tsukuba, Japan — Complementary ferroelectric-gate field-effect transistors (FeFETs) are attractive for nonvolatile-logic circuit applications after the achievement of long data retention for both n- and p-channel FeFETs [1, 2]. To demonstrate nonvolatile logic circuits, the threshold voltage should be well controlled. Due to ferroelectricity two threshold voltages $V_{t,\text{left}}$ and $V_{t,\text{right}}$ can be defined from $I_d = V_{ds}$ curves as gate voltages at $I_d = 10^{-6}$ A. More than 90 n- or p-channel Pt/SrBi2Ta2O9/Hf-Al-O/Si FeFETs on a Si chip are studied. The average $V_{t,\text{left}}$ and $V_{t,\text{right}}$ are 1.19 and 2.38 V for n-channel FeFETs, and -0.76 and 0.40 V for p-channel FeFETs, respectively. The standard deviations of $V_t$ are 3-5% and 7-8% of the memory window for the n- and p-channel FeFETs, respectively. $V_t$ positions are adjusted by varying the well doping concentrations. Our results indicate possible circuit demonstration. This work was partially supported by NEDO.

8:48AM X35.00005 The Nanowire iJFET

BART SOORE, WIM MAGNUS, IMEC, Kapeldreef 75, B-3001 Leuven, Belgium — The cylindrical geometry of nanowire surrounding gate MOSFETs gives rise to outstanding electrostatic control in comparison to planar devices. On the other hand, we expect that for ultrasmall nanowire diameters, the interaction of electrons with the surface (e.g. surface roughness and high-k) will be detrimental for device performance due to mobility degradation. In order to avoid these surface interactions we consider a surrounding nanowire operated not in MOSFET mode, but in “JFET mode.” We thus consider a nanowire with silicon body radius $R$ and surrounding oxide of thickness $t_{ox}$ with a surrounding metal gate where both source, drain and silicon body are doped uniformly with a donor density $N_D$. Applying a negative gate voltage pushes the electrons away from the interface between the insulator and metal gate, and as a result a depletion region is induced. For sufficient negative gate voltage the depletion region reaches the center of the silicon body, and pinch-off occurs. For large radii, we construct a compact model, and we show that reasonable pinch-off voltages are realized when the wire radius or the donor density is sufficiently small. Using the gradual channel approximation we are able to obtain current-voltage characteristics that constitute a “proof of concept” for this device. In the case of ultrasmall radii, we perform a quantum mechanical analysis of the electronic structure.

9:00AM X35.00006 Extraordinary Electroconductance in Ti-GaAs hybrid thin film structures

YUN WANG, A.K.M. NEWAZ, JIAN WU, S.A. SOLIN, Washington University in St. Louis, V.R. KAVASSERI, NIU JIN, I.S. AHMAD, I. ADESIDA, University of Illinois at Urbana-Champaign — Device performance due to mobility degradation. In order to avoid these surface interactions we consider a surrounding nanowire operated not in MOSFET mode, but in “JFET mode.” We thus consider a nanowire with silicon body radius $R$ and surrounding oxide of thickness $t_{ox}$ with a surrounding metal gate where both source, drain and silicon body are doped uniformly with a donor density $N_D$. Applying a negative gate voltage pushes the electrons away from the interface between the insulator and metal gate, and as a result a depletion region is induced. For sufficient negative gate voltage the depletion region reaches the center of the silicon body, and pinch-off occurs. For large radii, we construct a compact model, and we show that reasonable pinch-off voltages are realized when the wire radius or the donor density is sufficiently small. Using the gradual channel approximation we are able to obtain current-voltage characteristics that constitute a “proof of concept” for this device. In the case of ultrasmall radii, we perform a quantum mechanical analysis of the electronic structure.

9:12AM X35.00007 Optimizing Transport Properties of a Potential Molecular Electronic Device

JULIO L. PALMA, CHAO CAO, HAI-PING CHENG, JEFFREY L. KRAUSE, University of Florida — Future generations of electronic devices will have the dimensions of molecular size. The ability to control the transport properties of single molecules will have a major impact on this promising technology. The azobenzene molecule has been proposed recently as a component of a light-driven molecular switch. This molecule has two stable conformations in its ground state: cis and trans. The molecule can be converted from one configuration to the other by photo-excitation. Previous calculations showed that the trans configuration has a considerably higher conductance than the cis configuration. In this work, we study the effects of chemical substituents on the electron transport properties of azobenzene. The effects of such substituents are crucial in predicting structures that may have optimized properties with slightly different chemical structures. For the azobenzene studies, we include electron donating groups (-NH2) and electron withdrawing groups (-NO2) in meta- and otho positions with respect the azo group. The transport properties are calculated using first principles methods that combine non-equilibrium Green’s function (NEGF) technique with density functional theory (DFT).

1DOE contract DE-FG02-02ER45995 to HP and JLK
9:24AM X35.00008 Ion Sources for Deep and Shallow Ion Implantation1 — ADY HERSHCOWITCH, BNL, V. BATALIN, I. TEP, A. BUGAEV, HCEI, V. GUSHENETS, B. JOHNSON, A. KOLOMIETS, G. KROPACHEV, R. KIBEBA, T. KULEVOY, I. LITOVKO, E. MASUNOV, E. OKS, V. PERSHIN, S. PETRENKO, S. POLOZOV, H. POOLE, PVI, OXARD CA, I. RUDSKOY, D. SELEZNEV, P. STOROZHENKO, A. SVAROVSKI, G. YUSHKOV — Various ions, but mostly B, P, Sb, & As, are implanted, over a wide range of energies into materials used in the construction of semiconductors. These energies range from as low as 100 eV for shallow surface implantations, to as high as multi-MeV for deep implantation into the substrate.

State of the art ion sources meet industry needs for the energy range of 10 eV to 300 keV. But at the two extremes (100’s of eV and at multi-MeV), there is room for improvement due to space charge limitations at the low energy range and due to inefficiency in acceleration at the higher energy range. A joint R&D effort focusing on meeting industry needs has been in progress for the past four years. This endeavor has resulted in record steady state output currents of higher charge state Antimony and Phosphorous ions as well as Decaborane molecular ions. This talk is a synopsis of an extensive ion source R&D program designed to address industry needs.

1Supported by DOE Contract No. DE-AC02-98CH1-886.

9:36AM X35.00009 Infrared Near-field Microscopy of Semiconductor Devices — FRITZ KEILMANN, ANDY J. HUBER, RAINER HILLEBRAND, Max-Planck-Institut für Biochemie — We report optical imaging at ultrahigh resolution < 30 nm of cross-sectional preparations of state-of-the-art transistors. Our technique employs a scanning optical near-field microscope of scattering type (s-SNOM). It is based on a tapping-mode AFM with a standard, metallized tip, and an interferometric receiver. This detects a pseudo-heterodyne signal detection that is filtered at a low harmonic of the tapping frequency. The illumination wavelength of 10.7 µm allows to record specific contrasts—which are obtained in amplitude as well as in phase—distinguishing not only all material components in the transistors, but furthermore highlighting the charge carriers. Prospects of quantitative carrier density mapping will be discussed. A.J. Huber et al., Adv. Mat. 19, 2209 (2007)

9:48AM X35.00010 Resistance Switching Behavior in Epitaxially Grown NiO — S.R. LEE, J.H. BAK, Y.D. PARK, K. CHAR, Seoul National University, D.C. KIM, R. JUNG, S. SEO, X.S. LI, G.S. PARK, I.K. YOO, Samsung Advanced Institute of Technology — Reproducible resistance switching behavior has been found in NiO films prepared by a pulsed laser deposition system. The I-V measurements of epitaxially grown NiO on SrRuO₃ electrode show a bipolar resistive memory switching behavior, in contrast with a unipolar switching behavior of polycrystalline NiO on Pt electrode. In order to understand the resistive memory switching mechanism in NiO, the I-V characteristics and memory switching property of epitaxial NiO prepared under various synthesis conditions and electrodes has been investigated. The IV measurements at room temperature suggest that the interface between NiO and the electrode plays an important role on the resistive switching phenomena. To analyze the role of the interface, our efforts to control the interfaces and to measure the I-V characteristics at low temperature will be presented.

10:00AM X35.00011 Temperature-Dependence of the Resonant Pump Wavelength in Optical Pumping Injection Cavity Lasers — L.J. OLAFSEN, Baylor University, K.G. YOUNG, University of Houston, T.C. MCALPINE, College of Wooster, W.W. BEWLEY, I. VURGAFTMAN, J.R. MEYER, U.S. Naval Research Laboratory, H. LEE, R.U. MARTINELLI, Sarnoff Corporation — An optical pumping injection cavity (OPIC) laser contains a type-II W active region enclosed between two GaSb/AlAsSb distributed Bragg reflector mirrors, where the thickness of the etalon cavity surrounded by the mirrors is tuned to the desired pump wavelength. Multiple reflections of the pump photons result in more efficient absorption of the pump beam and consequently higher efficiencies and lower lasing thresholds. An optical parametric oscillator is used to pump the OPIC lasers at resonance, where the threshold pump intensities are minimized and output efficiencies are maximized. The resonant pump wavelength varies linearly with temperature. In addition to presenting light-light results, including efficiencies and thresholds as a function of temperature, the temperature-dependence of the resonant pump wavelength will be discussed, including the relative variations and contributions of lattice constant and refractive index with temperature.

10:12AM X35.00012 Mid-IR Photonic-Crystal Interband Cascade Lasers — MUJIN KIM, CHUL SOO KIM, WILLIAM BEWLEY, CHADWICK CANEDY, JAMES LINDLE, JILL NOLDE, DIANE LARRABEE, IGOR VURGAFTMAN, JERRY MEYER, Code 5613, Naval Research Laboratory, Washington DC 20375, CODE 5613 NRL TEAM — Photonic-crystal distributed-feedback (PCDFB) semiconductor lasers have the potential to maintain optical coherence over very large areas. We report an electrically pumped PCDFB laser operating in a true single mode in the mid-infrared. A two-dimensional grating aperture was formed on top of an interband cascade laser emitting at 3.3 µm by patterning a high-index Ge layer. The grating and the 400-µm-wide gain stripe were tilted by 20° with respect to the facet. Current spreading was prevented by ion bombarding the region outside the gain stripe rather than etching of a ridge. The gain region at the edge of the cavity was terminated by ion bombardment, since feedback from the back facet is undesirable. A single mode was emitted with maximum cw output power > 60 mW, resolution-limited spectral linewidth (side-mode suppression ratio 27 dB), and single-lobe spatial far-field with angular full width at half maximum of 0.5°. Comparison of the near and far field patterns indicated effective $M^2 \approx 3$. The observation of low efficiency is thought to be due primarily to inadequate grating coupling, which can be remedied by thickening the Ge layer.

10:24AM X35.00013 ABSTRACT WITHDRAWN —

10:36AM X35.00014 Electrical Characterization of Critical Phase Change Conditions in Nanoscale Ge$_2$Sb$_2$Te$_5$ Pillars — OZKAN OZATAY, BARRY STIPE, JORDAN KATINE, BRUCE TERRIS, Hitachi Global Storage Technologies, San Jose Research Center, San Jose, CA 95135 — Following the original work of Ovshinsky on disordered semiconductors that exhibit ovonic threshold switching (OTS) there has been substantial interest in the electronic reversible switching properties of chalcogenides. The current induced phase transitions between amorphous and crystalline phases in these materials of magnitude changes in the electrical conductance which makes them an ideal candidate for non-volatile data storage applications. In this work we investigate the scaling of critical programming conditions required to observe such transitions between highly resistive (disordered) and highly conductive (ordered) states by constructing a resistance map with various pulse widths and amplitudes under different non-volatile data storage applications. In this work we investigate the scaling of critical programming conditions required to observe such transitions between highly resistive (disordered) and highly conductive (ordered) states by constructing a resistance map with various pulse widths and amplitudes under different non-volatile data storage applications. In this work we investigate the scaling of critical programming conditions required to observe such transitions between highly resistive (disordered) and highly conductive (ordered) states by constructing a resistance map with various pulse widths and amplitudes under different non-volatile data storage applications. In this work we investigate the scaling of critical programming conditions required to observe such transitions between highly resistive (disordered) and highly conductive (ordered) states by constructing a resistance map with various pulse widths and amplitudes under different non-volatile data storage applications.

10:48AM X35.00015 Charge Transport Phenomena in Detectors of the Cryogenic Dark Matter Search — KYLE SUNDQUIST, University of California, Berkeley, CDMS COLLABORATION — The Cryogenic Dark Matter Search (CDMS) seeks to detect putative weakly-interacting massive particles (WIMPS), which could explain the dark matter problem in cosmology and particle physics. By simultaneously measuring the number of charge carriers and the energy in athermal phonons created by particle interactions in intrinsic Ge and Si crystals at a temperature of 40 mK, a signature response for each event is produced. This response, combined with phonon pulse-shape information, allows CDMS to actively discriminate candidate WIMP interactions with nuclei apart from electromagnetic radioactive background which interacts with electrons. The challenges associated with these techniques are unique. Carrier drift-field are maintained at only a few V/cm, else drift-emitted Luke-Neganov phonons would dominate the phonons of the original interaction. Under such conditions, carrier scattering is dominated by zero-point fluctuations of the lattice ions. It has been an open question how well the 8 Kelvin data prominent in the literature depicts this case. We compare the simulated transport properties of electrons and holes in $< 100$ $\text{Ge}$ at 40 mK and at 8 K, and apply this understanding to our detectors.
Newton, Abbe, and the relation between refractive index and dispersion.

WILLIAM KARSTENS, Saint Michael’s College, DAVID Y. SMITH, University of Vermont and Argonne National Laboratory — Chromatic aberration in lenses is corrected by combining glasses with different index/dispersion characteristics. The correction is based on an empirical linear relation between index and dispersion, a rule known qualitatively for many years that was given definitive form by Abbe and Schott in 1886. Despite a long history, its physical basis has remained obscure. Here we show it is a consequence of the spectral shape of the glasses’ UV absorption by expanding the Kramers-Kronig relation for the index in a series of absorption-spectrum moments. To first order, the index is determined by the inverse-first moment, the dispersion by the inverse-third moment. For a complex glass, these moments may be rewritten as sums of UV-absorption moments for the glass-former and the glass-modifiers. The total index is then a series of absorption-spectrum moments. To first order, the index is determined by the inverse-first moment, the dispersion by the inverse-third moment. Newton’s erroneous conclusion that achromatic lenses could not be made was based on the limited range of glasses available to him, all of which fell on a single index-dispersion line.

8:12AM X36.00002 A Non-Perturbative Series Solution for Diffraction Gratings with Arbitrary Profiles

DANIEL NKEMZI, University of Buea, Cameroon, PRABASAJ PAUL, Denison University — In this work, we use a boundary continuation technique to obtain an iterative series expansion for the scattering of a plane wave by a diffraction grating with an arbitrary profile function. The method is efficient and is simple to apply. The results of numerical experiments show excellent agreement with the C-method and the coupled-wave approach.

8:24AM X36.00003 Surface-enhanced Raman scattering by silver clusters at planar dielectric interface above the critical angle.

DENIS PRISTINSKI, NIST, SILIYU TAN, HENRY DU, Stevens Inst of Tech — Light refraction at the planar interface of dielectric media prevents light propagation in the optically denser medium at angles above the critical value. This limitation is broken when the evanescent wave is excited at the opposite side of the interface. The polarization and angle dependence of the light emitted above the critical angle has been previously studied for both luminescence and elastic scattering. In this work we demonstrate the possibility to quantitatively characterize the effect using surface-enhanced Raman signal from thiocyanate molecules adsorbed on clustered silver nanoparticles at the water-glass interface. Evanescently excited silver nanoparticles demonstrate strong polarization dependence for both absorption and emission, and wider range of emission angles, as compared with the model of a radiating dipole at a similar interface.

8:36AM X36.00004 A novel time resolved resonance Raman technique - applications in correlated systems.

B. SCHULZ, I. MAHNS, A. GOOS, P. SAICHU, S. BINDER, S.G. SINGER, A. RUSYDI, M. RUEBHAUSEN, Institute of Applied Physics, University of Hamburg, D-20355 Hamburg, Germany, S.-W. CHEONG, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, P. GUPTASARMA, Department of Physics, University of Wisconsin, Milwaukee, Wisconsin 53211, USA — In many modern materials the functionality of a system can be observed by studying the order parameters in the time domain. Here, we present a time resolved pump probe resonance Raman system that allows to study order parameters in an energy range from 5 meV to several eV and in a time domain from 1 ps to several ns. Due to our fully achromat, all reflective Raman spectrometer, [1] we are able to combine pump and probe beams ranging in energy from the near infrared to the deep ultraviolet. We show exemplary measurements on the melting process in charge order Manganites (La₀.₆Ca₀.₄MnO₃) as well as studies on the temporal evolution of the superconducting parameter in high-Tc cuprates.

8:48AM X36.00005 The Physics of Coherent Anti-Stokes Raman Spectroscopy.

LASZLO UJJ, Department of Physics, University of West Florida, Pensacola, FL 32514 — Coherent anti-Stokes Raman Spectroscopy (CARS) has been shown to be one of the most powerful experimental methodologies for obtaining vibrational information from both stable and transient molecular species. The general theoretical and experimental principles associated with CARS, together with specific examples of its applications to important molecular systems, are presented. A concise theoretical formalism of CARS, and its electronically resonant variant, is presented with an emphasis on points relevant to the interpretation of experimental spectra. The instrumental components required for obtaining typical CARS data are illustrated in a brief description of a picoseconds and a nanosecond experimental system used to record CARS spectra. The details of the design and operation of an all solid-state broadband nanosecond CARS system will be presented. Specific examples of picosecond CARS data are taken from measurements of stable and transient intermediates comprising the photoresponses of photoactive proteins.

Polarization sensitive CARS spectra taken with the nanosecond system are also presented. Finally, an overview of developments in this field to be anticipated is discussed. Reference: Laszlo Ujj and George H. Atkinson, Coherent Anti-Stokes Raman Spectroscopy, in Handbook of Vibrational Spectroscopy, John Wiley and Sons, Ltd., 2002.

9:00AM X36.00006 High quality optical and mechanical properties of a dispersive optomechanical device.

ANDREW JAYICH, BENJAMIN ZWICKL, CHENG YANG, JACK HARRIS, Yale University — We have characterized the optical and mechanical properties of a high finesse Fabry Perot cavity (F=17,000) dispersively coupled to a micromechanical SiN₄ membrane. The membrane’s fundamental and higher-order vibrational modes show quality factors above 10⁶ and a spectrum corresponding to a simple drumhead model. The optical cavity’s transverse and longitudinal spectrum is also in agreement with theory. We find that the cavity’s full transmission and reflection properties can be modeled quantitatively once the membrane’s small optical loss is accounted for. We will discuss the role of avoided crossings between higher-order optical modes in this system, particularly within the context of potential QND measurements of micromechanical devices.

9:12AM X36.00007 Using Multiple FROG Traces to Generate a Single High Dynamic Range Trace.

SEBASTIAN W. WINKLER, WILLIAM M. DENNIS, University of Georgia, Department Physics and Astronomy — Frequency resolved optical gating (FROG) is a powerful technique that has been used to characterize the complex electromagnetic field of ultrafast pulses for more than a decade. However, FROG relies on detector with a high dynamic range; at least 10⁶. If the detector’s dynamic range is insufficient, the FROG phase retrieval code will not work properly. We describe a method to generate a single FROG trace with high dynamic range from multiple FROG traces of the same pulse but using different integration times. We present successfully retrieved fields from data captured using a spectrometer that would otherwise have insufficient dynamic range for FROG trace acquisition.
9:24AM X36.00008 Theoretical Considerations for Surface Thermal Lensing Studies Using Polarized Light. MARSHALL THOMSEN, Eastern Michigan University — Surface Thermal Lensing (STL) is a well-established photothermal technique for locally probing the optical, thermal, and mechanical properties of a surface. A periodically chopped laser beam, the pump beam, irradicates a sample. A portion of the pump beam is absorbed by the sample and converted into thermal energy, resulting in a periodic local thermal expansion of the surface. A second, weaker and broader laser beam, the probe beam, is directed off-normal at the surface, covering the entire heated area. The result is a modulated diffraction pattern embedded in the reflected portion of the probe beam. The addition of polarizers both between the probe laser and the sample and between the sample and the detector opens up the possibility of gaining further information about the surface. In particular, the repeated flexing of the surface of a polymer sample may give rise to local rearrangement of polymer chains. The resulting asymmetry may be visible through a polarization analysis of STL signals.

9:36AM X36.00009 Intra-valence transitions for uncooled short wave infrared detection1. A.G. UNIL PERERA, S.G. MATSIKS, P.V.V. JAYAWEERA, Georgia State University, H.C. LIU, M. BUCHANAN, National Research Council Canada, GEORGIA STATE UNIVERSITY USA TEAM, NATIONAL RESEARCH COUNCIL CANADA TEAM — An infrared detector based on p-GaAs/AlGaAs heterojunction exhibiting response in the 2-5 µm range at room temperature is demonstrated. The basic principle of the detector utilizes inter-valence (heavy hole, light hole, and split-off hole) absorption of a highly p-doped GaAs layer (emitter). The dark current is limited by the work function at the interface between the highly doped emitter and the undoped AlxGa1-xAs barrier. The barrier height can be tailored by varying the Al fraction to obtained the desired operating temperature. The split-off energy of the material determines the split-off threshold and the band offset determines the free carrier threshold for the photo excited carriers. Detector performance can be controlled by varying these two thresholds. A device consisting of 30 periods of 3×1016 cm-3 p-doped GaAs emitter and Al0.57Ga0.43As barrier regions between two contact layers shows infrared detection up to 330 K with a peak responsivity of 1.4 A/W and D* of 2.6×109 Jones at 2.5 µm. Different materials should give rise to different wavelength threshold infrared detectors operating at high temperatures.

1Work supported by US NSF grant # ECS 05-53051.

9:48AM X36.00010 Room Temperature Terahertz Detection based on Electron Plasma Resonance in an Antenna-Coupled Gallium Arsenide MESFET. SANGWOO KIM, Phys. Dept., UCSB, JERAMY ZIMMERMAN, Materials Dept., UCSB, PAOLO FOCARDI, Jet Propulsion Lab, Pasadena, CA, DONG HO WU, Naval Research Lab, Washington, D.C., ARTHUR C. GOSSARD, Materials Dept., UCSB, MARK S. SHERWIN, Phys. Dept., UCSB — Terahertz detectors utilizing quantum transitions require cryogens since the thermal energy (kT) needs to be smaller than the transition energy (1 THz ~ 4 meV). A bulk 3-D plasma is a classical excitation, and hence does not saturate with temperature. Plasma absorptions occur at a density-dependent frequency 1/2π√(n_DAD2/me). For 1 THz radiation, the corresponding 3-D free electron density is n_D ~ 1015 cm-3 in GaAs, a density that can be easily achieved. The density of electrons can be made tunable if a device such as a Field Effect Transistor is employed. We utilize these facts in order to realize a room temperature Terahertz detector. Our device consists of twin-slot antennas, coplanar waveguides, and a GaAs Metal-Semiconductor-Field-Effect-Transistor (MESFET). While the sensitivity of the first set of devices is not competitive, we were able to observe the resonance behavior by sweeping bias voltages. This talk will present design, fabrication, recent measurement, and possible future improvement of our detector. Work supported by NSF-DMR 0703925 and Naval Research Lab.

10:00AM X36.00011 Signal Restoration from Atmospheric Degradation in Terahertz Spectroscopy. DONG HO WU, Naval Research Laboratory, SEONG KONG, Temple University — We present a method of restoring signals in Terahertz (THz) spectroscopy by removing the distortion from the observed THz signals. The distortion is generated by the absorption and scattering of gas molecules and water vapor in the atmosphere, during the transmission of THz beams through the air from the source to the spectrometer. Such atmospheric degradation causes spurious spectral dips and peaks in the THz spectrum, which often obscure the spectral peaks specific to the material of interest. This fact makes it challenging to measure the THz spectroscopic signatures of objects at a distance in a humid air environment. A THz signal restoration filter based on an artificial neural network model can be very effective in removing noisy absorption peaks caused by atmospheric degradation in THz spectra.

10:12AM X36.00012 Compressed Sensing and its Applications in Imaging. DHARMPAL TAKHAR, TING SUN, JASON LASKA, MARCO DUARTE, RICHARD BARANIUK, KEVIN KELLY, Department of Electrical and Computer Engineering, Rice University, Houston, Texas — Compressed sensing is a new sampling theory which allows reconstructing signals using sub-Nyquist measurements/sampling. This can significantly reduce the computation required for image/video acquisition/encoding, at least at the sensor end. Compressed sensing works on the concept of sparsity of the signal in some known domain, which is incoherent with the measurement domain. We exploit this technique to build a single pixel camera based on an optical modulator and a single photosensor. Random projections of the signal (image) are taken by optical modulator, which has random matrix displayed on it, corresponding to the measurement domain (random noise). This randomly projected signal is collected on the photosensor and later used for reconstructing the signal. In this scheme we are making a tradeoff between the spatial extent of sampling array and a sequential sampling over time with a single detector. In addition to this method, we will also demonstrate a new design which overcomes this shortcoming by parallel collection of many random projections simultaneously. Applications of this technique in hyperspectral and infrared imaging will be discussed.

10:24AM X36.00013 Test of search methods to extract quasi-periodical signals in noise from gravitational wave detectors. GIOVANNI SANTOSTASI, McNeese State University — We have tested several techniques to extract quasi-periodical signals in a simulated advanced gravitational wave detector noise. These methods include chi-square, Zn-square, H-test and Bayesian methods. The efficiency and usefulness, in different contexts, of these methods is discussed.

10:36AM X36.00014 High temperature resonant ultrasonic spectroscopy methods. GUANGYAN LI, University of Mississippi, GARY LAMBERTON, General Electric Corporation, JOSH GLADDEN, University of Mississippi — Resonant ultrasonic spectroscopy (RUS) is a technique to obtain the full elastic tensor of single crystal materials by measuring the mechanical resonances of a polished sample. Any direct resonance measurement at high temperatures is limited by the fact that most ultrasonic transducers have an upper operational limit of 200-300°C. High temperature RUS measurements are made possible by separating the sample, placed in a tube furnace, and the transducers with buffer rods made of low acoustic attenuation materials with good thermal stability such as ceramic alumina or fused quartz. Tests on stainless steel demonstrated that the system has the ability of acquiring resonance signals at temperatures up to 800°C. Experimental issues such as additional resonance peaks introduced by the buffer rods and sample loading will be addressed. The apparatus has been used to study high temperature elastic properties of p-zint, piezoelectrics, single crystal quartz, a novel piezoelectric material kepertite, and the glass transition around 400°C in bulk metallic glass compounds. Good results from these studies and high temperature test runs of aluminum and stainless steel demonstrate the potential for RUS measurements at elevated temperatures.
10:48AM X36.00015 Development of a low cost, low temperature cryocooler using the Gifford McMahon cycle. A. RAMANAYAKA, R. MANI, Georgia State University — Although Helium is the second most abundant element, its concentration in the earth’s atmosphere is fairly low and constant, as the portion that escapes from the atmosphere is replace by new emission. Historically, Helium was extracted as a byproduct of natural gas production, and stored in gas fields in a National Helium Reserve, in an attempt to conserve this interesting element. National policy has changed and the cost of liquid Helium has increased rapidly in the recent past. These new circumstances have created new interest in alternative eco-friendly methods to realizing and maintaining low temperatures in the laboratory. There have been number of successful attempts at making low temperature closed cycle Helium refrigerators by modifying an existing closed cycle system, and usually the regenerator has been replaced in order to achieve the desired results. Here, we discuss our attempt to fabricate a low cost, low temperature closed cycle Helium refrigerator starting from a 15K Gifford McMahon system. We reexamine the barriers to realizing lower temperature here and our attempts at overcoming them.

Friday, March 14, 2008 8:00AM - 10:48AM
Session X37 FIAP: Semiconductors IV: Electronic and Optical Properties II Morial Convention Center

8:00AM X37.00001 Electronic Structure of Silicon Phases Resulting from Decompression from $\beta$-Sn1, BRAD MALONE, JAY SAU, MARVIN COHEN, UC Berkeley, Lawrence Berkeley National Laboratory — We present an ab initio study of the electronic structure of the silicon phases that result from decompression from the metallic $\beta$-Sn phase, namely the BC8 (Si III), the hexagonal diamond (Si IV), the R8 (Si XII), and the yet unobserved ST12 phases. To correct for the inadequacies in the DFT-LDA quasiparticle energy spectra we employ quasiparticle corrections with the framework of the GW approximation. In doing so we find that the R8 phase should be semiconducting at lower pressures We also analyze the effect of strain and doping on these materials in an attempt to find novel applications for these phases, from high-mobility semiconductors to superconductivity.

8:12AM X37.00002 First principles calculations of optical and x-ray spectra from atomic coordinates alone1, J.J. KAS, M. PRANGE, F.D. VILA, Y. TAKIMOTO, J.J. REHR, University of Washington — Theoretical calculations of various x-ray and optical spectroscopies often rely on semi-empirical or phenomenological models to account for many-body effects and thermal vibrations. Typically such models include a number of parameters which complicate fitting schemes that extract physical quantities from experimental spectra. Here we present an approach for ab initio calculations of these spectra starting from structure alone. A many-pole model of the dielectric function is introduced to calculate the self-energy and spectral function[2] while a density functional theory calculation of the dynamical matrix is used to calculate effects of thermal vibrations. [2] In addition, core-hole effects are incorporated with RPA screening. [2] This approach has been incorporated into FEFF9, a new version of the real-space multiple-scattering FEFF code for broad spectrum calculations of various optical and x-ray spectra.

8:24AM X37.00003 Surface states of the Topological Insulator Bi$_{1-x}$Sb$_x$. JEFFREY TEO, LIANG FU, CHARLES KANE, University of Pennsylvania — The alloy Bi$_{1-x}$Sb$_x$ is a narrow gap semiconductor for .07 < x < .22. Based on the bulk bandstructures of Bi and Sb this material was recently predicted to be a three dimensional strong topological insulator (STI). The STI is distinguished from ordinary insulators by a $Z_2$ topological invariant characterizing the bulk and by the presence of topologically protected surface states, whose Fermi arc encloses an odd number of Dirac point. Here we study the surface states of the 111 face of Bi$_{1-x}$Sb$_x$ using a semi infinite tight binding model. This calculation demonstrates explicitly the topological character of the surface states. In addition, we examine other robust, model independent features of the surface states which arise due to (1) charge neutrality at the surface, (2) the presence in the bulk bandstructure of a 3 dimensional Dirac point with a small mass and (3) the presence of mirror symmetry, which leads to an additional topological characterization of the band structure in terms of a mirror Chern integer. Implications for photoemission experiments will be discussed.

8:36AM X37.00004 Optical, Electronic and Structural Properties of Y$_x$Sc$_{1-x}$N. ROBERT BRUCE VANDOVER, JOHN GREGOIRE, STEVE KIRBY, Cornell University — Semiconducting Y$_x$Sc$_{1-x}$N thin films are reactively sputtered onto a variety of surfaces, resulting in films varying from nanocrystalline to epitaxial (single crystalline). As a function of composition, we investigate the variations in the crystalline lattice, Hall mobility, absorptivity and direct and indirect band gaps. We find this material to be a solid solution semiconductor across the entire composition range. The tunable band gap and high absorptivity of this semiconductor make it an interesting photovoltaic material. Details on this application will be presented as well as prospects of this material’s use as the host for ferromagnetic transition metals.

8:48AM X37.00005 Free-electron induced mode mixing and surface-polariton enhanced reflected THz-field. DANHONG HUANG, USAF Research Lab, GODFREY GUMBS, Hunter College of CUNY, PLAU ALSING, DAVE CARDIMONA, USAF Research Lab — The main result of this talk is the prediction of large enhancements at the band edges of a coupled Bloch-surface-plasmon-polariton band in the spectrum of the reflected far electromagnetic field due to anti-crossing gaps induced by the strong coupling between the continuous surface-plasmon-polariton mode and the discrete Bloch-like modes. The existence of these Bloch-like modes is a direct consequence of the nonlocal mixing of specular and diffraction modes of the reflected electromagnetic field by free-electron induced optical polarization and the interference of a pair of surface optical-polarization waves with opposite Bragg order numbers in the presence of a grating. The interference of these two counter-propagating surface waves leads to the formation of a Wannier-like state with associated electromagnetic fields localized within the grating-gap regions. The effects of the sheet density, grating period and absorption loss on the optical enhancements of both transmitted and reflected electromagnetic fields are investigated.
9:00AM X37.00006 Absorption and Photoluminescence Analysis of InAs/GaSb Superlattices Exhibiting Lateral Composition Modulation. JULIA WICKETT, University of Houston, JIANHUA LI, Rigaku Americas Corp., DONNA STOKES, University of Houston — The effects of lateral composition modulation (LCM) in (InAs)$_{1/2}$/(GaSb)$_{1/2}$ superlattices on the structure and optical response of the material have been investigated by double crystal x-ray diffraction (XRD). infrared absorption and photoluminescence (PL). Superlattices (SL) grown by molecular beam epitaxy (MBE) on GaSb (001) substrates with InSb interfacial bonds. Various buffer/substrate combinations were employed to determine if strain manipulation could be used to improve the optical response of the system. Modeling of XRD data has been used to determine the strain state of the SL layers with respect to the growth template. Absorption and PL measurements indicate that strain significantly affects the optical responses of the samples and manipulation and control over the strain state of the system will be key in employing LCM superlattices for optical applications.

9:12AM X37.00007 Probing ErAs nanoparticle density of states using capacitance-voltage$^1$, KASEY RUSSELL, VENKATESH NARAYANAMURTI, Harvard University, JOSHUA ZIDE, ARTHUR GOSSARD. UC Santa Barbara — Two asymmetric In$_{0.53}$Ga$_{0.47}$As/In$_{0.53}$Al$_{0.47}$As double-barrier samples are fabricated and compared using low-temperature capacitance-voltage measurements. The two samples are identical except for a layer of ErAs nanoparticles embedded within the quantum well layer of one of the samples. A clear difference in the capacitance-voltage profile is observed between the two samples, and the difference is attributed to additional available states associated with the ErAs nanoparticles. These results are compared with a charge-step simulation of the low-frequency capacitance of the device in order to estimate the density of states contributed by the ErAs nanoparticles.

9:24AM X37.00008 Photon-like plasmon polariton in a nanocoaxial waveguide$^1$, YUN PENG, XIWEN WANG, KRZYSZTOF KEMPFA, Boston College — We study propagation of electromagnetic waves in a nano-coaxial waveguide for frequencies below the surface plasmon frequency. We show, that for sufficiently low frequencies, the waveguide supports a photon plasmon mode that resembles, and indeed reduces to the conventional TEM mode of the conventional coaxial, known in the radiotechnology. We consider also coupling of the mode to the external radiation, and show that it can be made very efficient with appropriate antenna-like arrangements.

1Supported in part by grants from MITTc and Solasta Inc.

9:36AM X37.00009 X-ray Absorption Study of Amorphous Metal Semiconductor Alloys $M_xS_i_{1-x}$ (M: Gd, Y) Near the Metal Insulator Transition. ERIK HELGREN, F. HELLMAN, UC Berkeley, LI ZENG, UCSD, J.W. FREELAND, P. RYAN, D. HASKEI, R. WINARSKI, Argonne National Lab, M. VAN VEENENDAAL, N. Illinois University, R. WU, UC Irvine — X-ray absorption structure (XAS) at both Si K edges and Gd M edges were measured at compositions close to the metal insulator transition (MIT) for amorphous $Gd_xS_i_{1-x}$ ($x = 0.11 - 0.21$) and $Y_xS_i_{1-x}$ ($x=0.13$) from 10-300K. Spectral lineshape is unchanged as a function of composition, despite the presence of the MIT at $x = 0.14$. Comparison with calculations indicates that Gd is in the $3+$ state for all compositions and temperatures measured. An anomalous temperature dependence of the MIT is observed, and we provide a theoretical explanation for this behavior. Based on this result we offer an alternative explanation for the MIT, which is related to charge transfer or $4f$ charge transfer or $4f$-edge resonant inelastic x-ray scattering (RIXS) experiment, we found that resonant enhancements occur both near and above the Eu L$_3$ absorption peak. In both resonance experiments, we identify a number of narrow energy loss features and compare those features with the optical spectroscopy spectrum. Interestingly, we observed a drastic dependence on measurement geometry in a resonant enhancement above the Eu L$_3$ absorption peak. We discuss the excitation symmetry based on the geometry dependence. This study demonstrates the utility of the rare-earth L$_3$-edge RIXS as a probe of excited states in rare-earth systems.

1Supported in part by NIST Grant 70 NAMB 2H003 (APS) and DOE Grant DE-FG03-97ER45623 (JJR).

10:00AM X37.00011 Effect of Dielectric Response on the Magic Angle Mystery in EELS$^1$. ADAM SORINI, JOHN REHR, University of Washington, ZACHARY LEVINE, National Institute of Standards and Technology — The “magic” collection angle in electron energy-loss spectroscopy (EELS) is that angle at which the collection angle in an anisotropic sample “magically” becomes orientation independent. The “mystery” is that non-relativistic theory predicts a magic angle typically a factor of two too large in modern EELS experiments. Recently it has been shown that a relativistic treatment largely explains the discrepancy [1]. Here, we suggest that the dielectric response of the sample can lead to still larger angle corrections for low-energy-loss spectra [2]. These dielectric effects are included in a relativistic, independent particle theory using the generalized Lorentz gauge. The effect is illustrated by a calculation of the magic angle including both relativistic and first principles dielectric corrections for graphite and for boron nitride.

1Supported in part by NIST Grant 70 NAMB 2H003 (APS) and DOE Grant DE-FG03-97ER45623 (JJR).

10:12AM X37.00012 Wave-front engineering by Huygens-Fresnel principle for nonlinear optical interactions in domain engineered structures. ZHU YONGYUAN, Nanjing University — The wave-front engineering for nonlinear optical interactions was discussed. Using Huygens-Fresnel principle we developed a general theory and technique for domain engineering with conventional quasi-phase-matching (QPM) structures being the special cases. We put forward the concept of local QPM, which suggests that the QPM is fulfilled only locally not globally. Experiments agreed well with the theoretical prediction. The proposed scheme integrates three optical functions: generating, focusing and beam splitting of second-harmonic wave, thus making the device more compact. This work was supported by the State Key Program for Basic Research of China (Grant No. 2004CB619003) and also by the NNSF of China (Grant Nos.10523001, 10504013 and 10674065).
10:24AM X37.00013 Influence of Phonon dimensionality on Electron Energy Relaxation1, ILARI MAASILTA, JENNI KARVONEN, University of Jyväskylä — We studied experimentally the role of phonon dimensionality on electron-phonon (e-p) interaction in thin copper wires evaporated either on suspended silicon nitride membranes or on bulk substrates, at sub-Kelvin temperatures. The power emitted from electrons to phonons was measured using sensitive normal metal-insulator-superconductor (NIS) tunnel junction thermometers. Membrane thicknesses ranging from 30 nm to 750 nm were used to clearly see the onset of the effects of two-dimensional (2D) phonon system. We observed for the first time that a 2D phonon spectrum clearly changes the temperature dependence and strength of the e-p scattering rate, with the interaction becoming stronger at the lowest temperatures below ∼ 0.5 K for the 30 nm membrane.1

10:36AM X37.00014 Hartree-Fock-Cluster Investigation of Nuclear Quadrapole Interactions in Solid Chalcogens, Selenium and Tellurium.1, M.M. ARYAL, Tribhuvan University, Nepal, N.B. MAHARJAN, Tribhuvan University Nepal, SUNY Albany, D.D. PAUDYAL, D.R. MISHRA, S.R. BYAHUT, Tribhuvan University, Nepal, R.H. SCHEICHER, Upsala University, Sweden, S.R. BADU, SUNY Albany, J. JEOG, Univ. Ulsan South Korea, LEE CHOW, UCF Orlando, T.P. DAS, SUNY Albany, UCF Orlando — Using the first-principles Hartree-Fock-Cluster Procedure, we have studied the electronic structures of pure chain like Selenium and Tellurium, pure ring structured Selenium, Tellurium impurity in chain and ring-structured Selenium and Tellurium impurity in chain-structured Tellurium chain. For our investigations in all the systems we have carried out convergence studies with respect to variational basis set sizes, sizes of clusters and electron correlation effects using many-body perturbation theory. Using our calculated electronic field-gradient parameters q in the pure chain systems and employing the experimental quadrupole coupling constants (e2Q), the values Q(77Se)=(0.50±0.04) × 10−28 m2 and Q(125Te)=(0.2 ±0.2) × 10−28 m2. Results will also be presented for the asymmetry parameters η for the pure chain systems and the e2Q and η for 77Se in selenium ring. Our calculated values for e2Q and η for the impurity systems will also be presented and compared with available experimental data and earlier theoretical results.

Friday, March 14, 2008 8:00AM - 10:24AM —
Session X39 GSNP: Miscellaneous Topics in Statistical Physics Mortional Convention Center 231

8:00AM X39.00001 Enhancement of epidemic extinction by random vaccination1, IRA SCHWARTZ, Naval Research Laboratory, MARK DYKMAN, Michigan State University — We study the probability of epidemic extinction in large populations. We use the susceptible-infected-susceptible (SIS) model since it forms the foundation of many epidemic processes. Fluctuations in the SIS system have two sources. The major source is the randomness of the “reactions” in which the number of susceptibles and/or infected changes. In addition, we assume that vaccination is done at random, leading to the decrease of the number of susceptibles. The vaccination is modeled by a Poisson process. The probability distribution is found from the master equation, which is solved in the eikonal approximation. It is shown that, even in the absence of vaccination, the logarithm of the extinction rate displays scaling dependence on the parameters. It scales as the square of the distance to the parameter value where the average number of infected vanishes. This is very different from the familiar 3/2 scaling law for saddle-node bifurcations. Finally, we show that even weak vaccination can dramatically increase the extinction probability. The correction to the logarithm of the probability becomes exponential in the vaccination rate when this rate is not too small.

8:12AM X39.00002 Inhomogeneous Coupling in 2-Channel Asymmetric Simple Exclusion Processes, KONSTANTINOS TSEKOURAS, ANATOLY KOLOMEISKY, Rice University — Asymmetric exclusion processes for particles moving on parallel channels with inhomogeneous coupling are investigated theoretically. Particles interact with hard-core exclusion and move in the same direction on both lattices, while transitions between the channels is allowed at one specific location in the bulk of the system. An approximate theoretical approach describing the dynamics in the vertical link and horizontal lattice segments exactly but neglecting the correlation between horizontal and vertical transport is developed. It allows us to calculate stationary phase diagrams, particle currents and densities for symmetric and asymmetric transitions between the channels. It is shown that in the case of the symmetric coupling there are three stationary phases, similarly to the case of single-channel totally asymmetric exclusion processes with local inhomogeneity. However, the asymmetric coupling between the lattices lead to a very complex phase diagram with ten stationary-state regimes. Extensive Monte Carlo computer simulations generally support theoretical predictions, although simulated stationary-state properties slightly deviate from calculated in the mean-field approximation, suggesting the importance of correlations in the system. Dynamic properties and phase diagrams are discussed by analyzing constraints on the particle currents across the channels.

8:24AM X39.00003 Brownian Gas: a field theory with a Poissonian ground state1, ANDREA VELENICH, CLAUDIO CHAMON, Physics Department, Boston University, DIRK KREIMER, Institut des Hautes Etudes Scientifiques and Department of Mathematics and Statistics, Boston University — As a first step towards a satisfying field theory of Brownian particles in interaction, we study exactly the non-interacting case, its combinatorics and its non-linear time-reversal symmetry. The field theory is nevertheless interacting; the vertex is the hallmark of the original particle nature of the gas and enforces the constraint of a strictly positive density field as opposed to a Gaussian free field. We compute exactly all the non-interacting case, its combinatorics and its non-linear time-reversal symmetry. The field theory is nevertheless interacting: the vertex is the hallmark of the

8:36AM X39.00004 Wave electrophoretic trapping and chaos1, BOYD EDWARDS, LLOYD CARROLL, AARON TIMPERMAN, JARROD SCHIFFBAUER, JON MEASE, West Virginia University — Synchronized oscillating electric potentials are applied to a periodic array of stationary cylindrical electrodes in a stationary conducting viscous fluid. These potentials produce a longitudinal traveling wave that traps high-mobility ions that reveal the formation of intrinsic localized modes (ILMs) in a nonlinear electrical lattice. The lattice studied is a discrete transmission line consisting of two inductors and a diode (with voltage-dependent capacitance) per unit cell, and it forms a ring. We show that when this ring circuit is driven uniformly at large amplitudes, an instability of the uniform mode leads to the appearance of sharply localized features. Under certain driving conditions, these ILMs can become locked to the driver.

8:48AM X39.00005 Experimental Study of Energy Localization in a Nonlinear Electrical Lattice, LARS ENGLISH, RITOBAN BASU THAKUR, RYAN STEARRETT, DICKINSON COLLEGE, PHYSICS TEAM — Experimental results are presented that reveal the formation of intrinsic localized modes (ILMs) in a nonlinear electrical lattice. The lattice studied is a discrete transmission line consisting of two inductors and a diode (with voltage-dependent capacitance) per unit cell, and it forms a ring. We show that when this ring circuit is driven uniformly at large amplitudes, an instability of the uniform mode leads to the appearance of sharply localized features. Under certain driving conditions, these ILMs can become locked to the driver.
9:00AM X39.00006 Multiple traveling solitons in one-dimensional monatomic quartic lattices, SANGHAMITRA NEOGI, GERALD MAHAN. Department of Physics, The Pennsylvania State University — We discuss the generation of traveling soliton waves in a one-dimensional monatomic quartic lattice using numerical techniques. We apply an external forcing function or a pulse to the end atom of a free chain of monatomic atoms to generate traveling solitons. When the strength of the forcing function is above a threshold value, multiple traveling solitons are observed to flow down the chain. The number of traveling solitons in the chain increases rapidly with the increase in pulse strength beyond this critical value. The amplitudes and velocities of these multiple solitons increase with the increase in pulse strength for small pulse strengths. For larger values of pulse strengths, the amplitudes and velocities of all the multiple solitons saturate. The frequencies and wave vectors of all the traveling solitons on the quartic lattice are within a very narrow range of values. These values are independent of the pulse strength.

9:12AM X39.00007 Statistical mechanics rooted in maximum entropy method shows absence of the Gibbs paradox, CHIH-YUAN TSENG, National Central University — Studying the Gibbs paradox problem indicates Gibbs's statistical mechanics may not be a general theory for thermodynamics. We found that most of conventional resolutions only provide explanations for “supplementary” introduction of the Gibbs correction rather than re-develop statistical theory to comprehend corresponding aspects. In this talk, we will show a general theory of statistical mechanics based on generalized maximum entropy method, which is designed for inductive inference. The general theory integrates prior knowledge of the system and measurements of macroscopic properties into a general ensemble. Based on the general theory, the 1/N! is simply a prior distribution that denotes our prior knowledge for indistinguishability of N microstates instead of the correction for the canonical ensemble. There is no Gibbs paradox. It is simply a consequence of incomplete statistical description for classical thermodynamic systems.

9:24AM X39.00008 High-Precision Thermodynamic and Critical Properties from Tensor Renormalization-Group Flows, MICHAEL HINCZEWSKI, TUBITAK - Bosphorus Univ., Feza Gursel Institute, A. NIHAT BERKER, Koç Univ., and M.I.T. — The recently developed tensor renormalization-group (TRG) method [1] provides a highly precise technique for deriving thermodynamic and critical properties of lattice Hamiltonians. The TRG is a local coarse-graining transformation, with the elements of the tensor at each lattice site playing the part of the interactions that undergo the renormalization-group flows. These tensor flows are directly related [2] to the phase diagram structure of the infinite system, with each phase flowing to a distinct surface of fixed points. Fixed-point analysis and summation along the flows give the critical exponents, as well as thermodynamic functions along the entire temperature range. Thus, for the ferromagnetic triangular lattice Ising model, the free energy is calculated to better than 10^{-5} along the entire temperature range. Unlike previous position-space renormalization-group methods, the truncation (of the tensor index range D) in this general method converges under straightforward and systematic improvements. Our best results are easily obtained with D = 24, corresponding to 4624-dimensional renormalization-group flows. [1] M. Levin and C.P. Nave, Phys. Rev. Lett. 99, 120601 (2007). [2] M. Hinczewski and A.N. Berker, arXiv:0709.2803v1 [cond-mat.stat-mech], Phys. Rev. E, in press.

9:36AM X39.00009 Nucleation in a long-range repulsive model, KIPTON BARROS, WILLIAM KLEIN, Boston University. — We employ a model with long-range repulsive interactions to study nucleation from a fluid to a crystalline phase. The long-range interactions make the metastable fluid phase long lived. From our simulations we find a divergence of the susceptibility at the spinodal, as predicted by mean-field theory. We also observe nucleation events and verify that the nucleating droplets, when they occur, match the numerical saddle point solutions of the free energy functional. In one dimension, where Alexander-McTague type symmetry arguments cannot be satisfied, we find that nucleation does not occur and that the fluid-solid transition is continuous. In two and three dimensions the transition is first order, with nucleating droplets of hexagonal and bcc symmetries.

1Supported in part by the NSF Grant No. DGE-0221680.

9:48AM X39.00010 Phase transitions in the long-range antiferromagnetic Ising model, RACHELE DOMINGUEZ, KIPTON BARROS, WILLIAM KLEIN, Boston University — We study the long-range antiferromagnetic Ising model to understand microphase separation in block-copolymer systems and dipolar Ising models. When quenched to low temperatures, the system initially obeys a Cahn-Hilliard-Cook-like linear theory and then orders into a "striped" or "clumpy" phase. The system also exhibits order-to-order transitions between the stable stripe and clump phases. From the free energy density obtained from coarse graining the Ising model, we use Langevin dynamics to investigate these transitions. I will discuss the nature of the transitions into the ordered phases as well as computational and theoretical methods for obtaining the phase diagram of the system.

10:00AM X39.00011 Emergent Structures in Dissipative Wave-Particle Systems, DAVIT SIVIL, ALFRED HUBLER, Center for Complex Systems Research, Department of Physics, University of Illinois at Urbana-Champaign — We study the motion of a particle with mass m on a vibrated string of length L. We assume that there is a friction force between the particle and the string. The string is sinusoidally forced at both ends. We find that the particle has attractors located at x=L/2 +/- nωc/2ω, where ω is the frequency of the waves on the string, and n ∈ Z. We also study the attractors of the same system with multiple driving frequencies. We also compared our results with numerical simulations.

10:12AM X39.00012 Absence of structural glass transition in a monoatomic model liquid predicted to undergo an ideal glass transition, MATTHIAS TROYER, CHARLOTTE GILS, HELMUT KATZGRABER, ETH Zurich — We study numerically a monodisperse model of interacting classical particles predicted to exhibit a static liquid-glass transition. Using a dynamical Monte Carlo method we show that the model does not freeze into a glassy phase at low temperatures. Instead, depending on the choice of the hard-core radius ends. We find that the particle has attractors located at x=L/2 - nπc/ω, where ω is the frequency of the waves on the string, and n ∈ Z. We also study the attractors of the same system with multiple driving frequencies. We also compared our results with numerical simulations.

Friday, March 14, 2008 8:00AM - 11:00AM — Session X40 DBP: Self Assembled Protein Cages Morial Convention Center 232

8:00AM X40.00001 A minimal model for protein coat dynamics in intracellular vesicular transport, RANJAN MUKHOPADHYAY, Clark University, HUI WANG, Lehigh University, GREG HUBER, University of Connecticut Health Center — Within eukaryotic cells, proteins are transported by vesicles formed from coated regions of membranes. The assembly of coat proteins deforms the membrane patch and drives vesicle formation. Once the vesicle has pinched off, the protein coat rapidly disassembles. Motivated by recent experimental results, we propose a minimal model for the dynamics of coat assembly and disassembly and study the spatio-temporal behavior of the system. We will show that for a range of parameters, our model can robustly generate a steady state distribution of protein clusters with characteristic sizes and will obtain the scaling behavior of average cluster size with the parameters of the model. We will also discuss the coupling of coat dynamics to sorting of cargo proteins.
8:12AM X40.00002 The study of viral assembly with fluorescence fluctuation spectroscopy . JOACHIM MUELLER, BIN WU, YAN CHEN, University of Minnesota — Enveloped viruses contain an encapsulating membrane that the virus acquires from the host cell during the budding process. The presence of the enveloping lipid membrane complicates the physical characterization of the proteins assembled within the virus considerably. Here we present a method based on fluorescence fluctuations that quantifies the copy number of proteins within an enveloped viral particle. We choose the viral protein Gag of the human immunodeficiency virus (HIV) type 1 as a model system, because Gag expressed in cells is sufficient to produce viral-like particles (VLPs) of the same size as authentic virions. VLPs harvested from cells that express fluorescently labeled Gag were investigated by two-photon fluorescence fluctuation spectroscopy. The autocorrelation functions of the fluctuations revealed a hydrodynamic size of the fluorescent VLPs consistent with previous results based on electron microscopy. Further analysis of the fluctuations revealed a copy number of Gag per virion that is inconsistent with the prevailing model of HIV assembly. We will discuss the implications of our experimental results for the assembly process of VLPs.

8:24AM X40.00003 Spherical Proteins and Viral Capsids Studied by Theory of Elasticity . ZHENGYANG YANG, Department of Physics & Astronomy, University of Pittsburgh, IVET BAHAR, Department of Computational Biology, University of Pittsburgh, MICHAEL WIDOM, Department of Physics, Carnegie Mellon University — Coarse-grained elastic network models have been successful in elucidating the fluctuation dynamics of proteins around their native conformations. It is well established that the low-frequency collective modes derived by simplified normal mode analysis depend on the overall 3-dimensional shape of the biomolecule. Given that the large scale collective motions are usually involved in biological function, our objective in this work is to gain more insights into large scale collective motions of spherical proteins and virus capsids by considering a continuous model with perfect spherical symmetry. To this end, we compare the global dynamics of proteins and the analytical solutions from an elastic wave equation with spherical boundary conditions. In addition, an icosahedral discrete model is generated and analyzed for validating our continuous model. Applications to lumazine synthase, satellite tobacco mosaic virus and other viruses shows that the spherical elastic model can efficiently provide insights on collective motions that are otherwise obtained by detailed elastic network models.

8:36AM X40.00004 Low frequency mechanical modes of viruses with atomic detail . ERIC DYKEMAN, OTTO SANKEY, Arizona State University — The low frequency mechanical modes of viruses can provide important insights into the large global motions that a virus may exhibit. Recently it has been proposed that these large global motions may be excited using impulsive stimulated Raman scattering producing permanent damage to the virus. In order to understand the coupling of external probes to the capsid, vibrational modes with atomic detail are essential. The standard approach to find the atomic modes of a molecule with \( N \) atoms requires the formation and diagonalization of a \( \sqrt{3N \times N} \) matrix. As viruses have \( 10^3 \) or more atoms, the standard approach is difficult. Using ideas from electronic structure theory, we have developed a method to construct the mechanical modes of large molecules such as viruses with atomic detail. Application to viruses such as the cowpea chlorotic mottle virus, satellite tobacco necrosis virus, and M13 bacteriophage show a fairly complicated picture of the mechanical modes.

8:48AM X40.00005 Diversity of in-vivo assembled HIV-1 capsids . SE IL LEE, TOAN NGUYEN, Physics, Georgia Institute of Technology — Understanding the capsid assembly process of Human Immunodeficiency Virus (HIV), the causative agent of Acute Immuno Deficiency Syndrome (AIDS), is very important because of recent intense interest in capsid-oriented viral therapy. The unique conical shapes of mature HIV-1 capsid have drawn significant interests in the biological community and started to attract attention from the physics community. Previous studies showed that in a free assembly process, the HIV-1 conical shape is not thermodynamically stable. However, if the volume of the capsid is constrained during assembly and the capsid protein shell has high spontaneous curvature, the conical shape is stable. In this work, we focus on in-vivo HIV-1 capsid assembly. For this case, the viral envelope membrane present during assembly imposes constraint on the length of the capsid. We use an elastic continuum shell theory to approximate the energies of various HIV-1 capsid shapes (spherical, cylindrical and conical). We show that for certain range of viral membrane diameter, the conical and cylindrical shapes are both thermodynamically stable. This result is supported by experimental observation that in-vivo assembled HIV-1 capsids are very heterogeneous in shapes and sizes. Numerical calculation is also performed to improve theoretical approximation.

9:00AM X40.00006 An elastic model of partial budding of retroviruses . RUI ZHANG, TOAN NGUYEN, School of Physics, Georgia Institute of Technology — Retroviruses are characterized by their unique infection strategy of reverse transcription, in which the genetic information flows from RNA back to DNA. The best known representative is the human immunodeficiency virus (HIV). Unlike budding of traditional enveloped viruses, retrovirus budding happens together with the formation of spherical virus capsids at the cell membrane. Led by this unique budding mechanism, we proposed an elastic model of retrovirus budding in this work. We found that if the lipid molecules of the membrane are supplied fast enough from the cell interior, the budding always proceeds to completion. In the opposite limit, there is an optimal size of partially budded virions. The zenith angle of these partially spherical capsids, \( \alpha \), is given by \( \alpha \sim (\tau^2/\kappa \sigma)^{1/4} \), where \( \kappa \) is the bending modulus of the membrane, \( \sigma \) is the surface tension of the membrane, and \( \tau \) characterizes the strength of capsid protein interaction. If \( \tau \) is large enough such that \( \alpha \approx \pi/2 \), the budding is complete. Our model explained many features of retrovirus partial budding observed in experiments.

9:12AM X40.00007 Calibrating elastic parameters from molecular dynamics simulations of capsid proteins . STEPHEN HICKS, CHRISTOPHER HENLEY, Cornell University — Virus capsids are modeled with elastic network models in which a handful of parameters determine transitions in assembly [1] and morphology [2]. We introduce an approach to compute these parameters from the microscopic structure of the proteins involved. We consider each protein as one or a few rigid bodies with very general interactions, which we parameterize by fitting the simulated equilibrium fluctuations (relative translations and rotations) of a pair of proteins (or fragments) to a 6-dimensional Gaussian. We can then compose these generalized springs into the global capsid structure to determine the continuum elastic parameters. We demonstrate our approach on HIV capsid protein and compare our results with the observed lattice structure (from cryo-EM [3] and AFM indentation studies).

9:24AM X40.00008 Coarse-grained mechanics of viral shells . WILLIAM S. KLUG, MELISSA M. GIBBONS, University of California, Los Angeles — We present an approach for creating three-dimensional finite element models of viral capsids from atomic-level structural data (X-ray or cryo-EM). The models capture heterogeneous geometric features and are used in conjunction with three-dimensional nonlinear continuum elasticity to simulate nanoindentation experiments as performed using atomic force microscopy. The method is extremely flexible; able to capture varying levels of detail in the three-dimensional structure. Nanoindentation simulations are presented for several viruses: Hepatitis B, CCMV, HK97, and \( \phi 29 \). In addition to purely continuum elastic models a multiscale technique is developed that combines finite-element kinematics with MD energetics such that large-scale deformations are facilitated by a reduction in degrees of freedom. Simulations of these capsid deformation experiments provide a testing ground for the techniques, as well as insight into the strength-determining mechanisms of capsid deformation. These methods can be extended as a framework for modeling other proteins and macromolecular structures in cell biology.

9:36AM X40.00009 ABSTRACT HAS BEEN MOVED TO SESSION C1 —
10:00AM X40.00011 Poisson pulsed control of particle escape\textsuperscript{1}, MARIE MCCRARY, LORA BILLINGS, Montclair State University, IRA SCHWARTZ, Naval Research Laboratory, Washington, DC, MARK DYKMAN, Michigan State University — We consider the problem of escape in a double well potential. With a weak background Gaussian noise, the escape rate is well known and follows an exponential scaling with the noise intensity $D$. Here, we consider adding a small Poisson noise to the Gaussian noise. We compute the change in escape time as we add Poisson distributed pulses of a given duration and amplitude. The escape rate acquires an extra factor which is determined by the system dynamics and is inversely proportional to $D$. As a result, for small $D$ even weak Poisson pulses can lead to a significant change of the escape rate. The Poisson noise induced factor depends sensitively on the interrelation between the noise correlation time and the relaxation time of the system. We compare analytical results with extensive numerical simulations. The numerical computation of escape rates for multiple interacting particles in a well will also be shown.

10:12AM X40.00012 Quorum sensing and biofilm formation investigated using laser-trapped bacterial arrays, VERNITA GORDON, JOHN BUTLER, IVAN SMALYUKH, MATTHEW PARSEK, GERARD WONG, University of Illinois, Urbana-Champaign — Studies of individual, free-swimming (planktonic) bacteria have yielded much information about their genetic and phenotypic characteristics and about “quorum sensing,” the autoinducing process by which bacteria detect high concentrations of other bacteria. However, in most environments the majority of bacteria are not in the planktonic form but are rather in biofilms, which are highly structured, dynamic communities of multiple bacteria that adhere to a surface and to each other using an extracellular polysaccharide matrix. Bacteria in biofilms are phenotypically very different from their genetically-identical planktonic counterparts. Among other characteristics, they are much more antibiotic-resistant and virulent. Such biofilms form persistent infections on medical implants and in the lungs of cystic fibrosis patients, where Pseudomonas aeruginosa biofilms are the leading cause of lung damage and, ultimately, death. To understand the importance of different extracellular materials, motility mechanisms, and quorum sensing for biofilm formation and stability, we use single-gene knockout mutants and an infrared laser trap to create a bacterial aggregate that serves as a model biofilm and allows us to measure the importance of these factors as a function of trapping time, surface, and nutritional environment.

10:24AM X40.00013 Self-Polarization of Cells in Elastic Gels, ASSAF ZEMEL, SAMUEL SAFRAN, Department of Materials and Interfaces, The Weizmann Institute of Science, Rehovot, 76100, Israel — The shape of a cell as well as the rigidity and geometry of its surroundings play an important role in vital cellular processes. The contractile activity of cells provides a generic means by which cells may sense and respond to mechanical features. The matrix stresses, that depend on the elasticity and geometry of cells, feedback on the cells and influence their activity. This suggests a mechanical mechanism by which cells control their shape and forces. We present a quantitative, mechanical model that predicts that cells in an elastic medium can self-polarize to form well ordered stress fibers. We focus on both single cells in a gel, as well as on an ensemble of cells that is confined to some region within the gel. While the magnitude of the cellular forces is found to increase monotonically with the matrix rigidity the anisotropy of the forces, and thus the ability of the cells to polarize, is predicted to depend non-monotonically on the medium’s rigidity. We discuss these results with experimental findings and with the observation of an optimal medium elasticity for cell function and differentiation.

10:36AM X40.00014 Active suspensions in shear flow\textsuperscript{1}, A. AHMADI, M.C. MARCHETTI, Physics Department, Syracuse University, Syracuse NY 13244, T.B. LIVERPOOL, Department of Mathematics, University of Bristol, Bristol BS8 1TW, UK — We report on the structure and rheology of an active suspension of cytoskeletal filaments and motor proteins in shear flow. Hydrodynamics equations for an active suspension were derived earlier by us [arXiv:q-bio.CB/0703029v1] by coarse-graining the Smoluchowski equation for a model of filaments and motors. The model incorporates the coupling of orientational order to flow and accounts for the exchange of momentum between filaments and solvent. In the present study we investigate the role of active crosslinkers on the formation and stability of ordered states (polar and nematic) under external shear flow. We also study the effect of motor activity on the rheological behavior of the ordered states away from boundaries. This work may also be relevant for the understanding of the flow-driven reorientation of endothelial cells under the shear stress imposed by blood flow.

10:48AM X40.00015 Selective advantage for sexual replication with random haploid fusion\textsuperscript{1}, EMMANUEL TANNENBAUM, Ben-Gurion University of the Negev — This talk develops a simplified set of models describing asexual and sexual replication in unicellular diploid organisms. The models assume organisms whose genomes consist of two chromosomes, where each chromosome is assumed to be functional if and only if it is equal to some master sequence. The fitness of an organism is determined by the number of functional chromosomes in its genome. For a population replicating sexually, a cell replicates both of its chromosomes and then divides and splits its genetic material evenly between the two cells. For a population replicating sexually, a given cell first divides into two haploids, which enter a haploid pool. Within the haploid pool, haploids fuse into diploids, which then divide via the normal mitotic process. When the cost for sex is small, as measured by the ratio of the characteristic haploid fusion time to the characteristic growth time, we find that sexual replication with random haploid fusion leads to a greater mean fitness for the population than a purely asexual strategy. The results of this talk are consistent with previous studies suggesting that sex is favored at intermediate mutation rates, for slowly replicating organisms, and at high population densities.

11:15AM Y3.00001 Theoretical studies of quantum interference effects in graphene. EDWARD MCCANN, Lancaster University — We review the recently-developed theory of weak localization in monolayer and bilayer graphene [Phys. Rev. Lett. 97, 146805 (2006); Phys. Rev. Lett. 98, 176806 (2007)]. Owing to the chiral nature of electrons in a monolayer of graphite (graphene) one can expect weak antilocalization and a positive weak-field magnetoresistance in it. For high-density monolayer graphene and for any-density bilayers, the dominant factor affecting weak localization properties is trigonal warping of graphene bands, which reflects asymmetry of the carrier dispersion with respect to the center of the corresponding valley. The suppression of weak antilocalization by trigonal warping is accompanied by a similar effect caused by random-bond disorder (due to bending of a graphene sheet) and by dislocation/antidislocation pairs. As a result, weak localization in graphene can be observed only in samples with sufficiently strong inter-valley scattering due to atomically sharp scatterers or by edges in a narrow wire, reflected by a characteristic form of conventional negative magnetoresistance. We show this by evaluating the dependence of the magnetoresistance of graphene on relaxation rates associated with various possible ways of breaking a “hidden” valley symmetry of the system.

1 In collaboration with K. Kechedzhi, V.I. Falko, H. Suzuura, T. Ando, and B.L. Altshuler. Supported by EPSRC First Grant EP/E063519/1, the Royal Society, and the Daiwa Anglo-Japanese Foundation.

11:51AM Y3.00002 Quantum interference in Epitaxial Graphene: Evidence for Chiral Electrons. XIAOSONG WU, School of Physics, Georgia Tech — The extraordinary transport properties of graphene originate from its unique band structure. Electrons in the band have chirality, which correlates the directions of the momentum and the pseudospin. This chirality prevents electrons from being back-scattered, hence causing a particular quantum phase coherent phenomenon, called weak-antilocalization. Recent theoretical work suggested that multilayer epitaxial graphene (EG) grown on SiC possesses essentially same band structure as single layer graphene because of the rotational stacking order between layers. We have investigated the magnetoresistance of EG. We found that weak anti-localization manifests itself as a broad cusp-like depression in the longitudinal resistance for magnetic fields 10 mT < B < 5 T. An extremely sharp weak-localization resistance peak at B = 0 is also observed. These features quantitatively agree with graphene weak-(anti)localization theory implying the chiral electronic character of the samples. Scattering contributions from the trapped char ges in the substrate and from trigonal warping due to the graphite layer on top are tentatively identified. The phase coherence length was found about 1 μm at 4.2 K and the main phase-breaking mechanism was e−e scattering.

Supported by NSF-NIRT Grant No. 0404084, NSF-MRI Grant No. 0521041, a grant from Intel, and a USA-France travel grant from CNRS.

12:27PM Y3.00003 Quantum Interference in Single and Bilayer Graphene. ALEXANDER SAVCHENKO, School of Physics, University of Exeter, Exeter EX4 4QL, U.K. — It is known that interference of charge carriers scattered by impurities results in a quantum correction to the conductivity of the two-dimensional (2D) system. This phenomenon of weak localization (WL) is usually seen as a distinct conductance fluctuation, as magnetic field changes the phase of interfering waves. Here we show that quantum interference in graphene – a single layer of carbon atoms [1] – is very different from that in conventional 2D systems. Due to the chiral nature of carriers, it becomes sensitive to different elastic scattering mechanisms. By changing the geometry and quality of samples we show that quantum interference in graphene can take a variety of forms, and that WL is a sensitive tool to detect defects in graphene crystals [2]. We perform a comparative study of WL in single-layers and bilayers. Although the two systems are different in their spectrum (massless and massive fermions, respectively), the carriers in both are chiral. As a result WL in a bilayer is also affected by elastic scattering [3]. Analysis of the magnetoresistance using theories [4] allows us to determine the phase-breaking time as well as times of inter- and intra-valley scattering, which together control WL. They are found at different carrier densities, including the electro-neutral point where the nominal carrier density is zero. We show that in all cases WL is not suppressed, and that the reason for this is strong inter-valley scattering. The study of WL is complemented by AFM imaging of the surface which provides information about the nature of the defects responsible for the different manifestations of WL in graphene systems. In addition to the studies of WL, we perform analysis of universal conductance fluctuations (UCF) in both systems. They have the same physical origin as WL – quantum interference – and are controlled by the same characteristic times. We compare the times found from analysis of WL and UCF.

1:03PM Y3.00004 Experimental studies of conductance fluctuation and tunneling spectroscopy of weakly disordered graphene devices. YING LIU, Department of Physics, The Pennsylvania State University, University Park, PA, 16802 — We measured the conductance fluctuation and tunneling spectra of single-, bi- and trilayer graphene prepared by mechanical exfoliation. Reproducible fluctuations in conductance as a function of applied gate voltage or magnetic field were found in the electric transport measurements. As the Fermi energy was tuned to near the charge neutral point, the amplitude of the conductance fluctuation was suppressed quickly from a value consistent with universal conductance fluctuations, even though the devices were still well within the weakly disordered regime. The physical origin of the observed suppression may be related to the presence of edge states, or puddles of electrons or holes in graphene devices. The tunneling spectra of planar tunnel junctions of micron size were found to exhibit interesting features that evolve with the backgate voltage, temperature, and applied magnetic field. The implications of these observations will be discussed. This work is done in collaboration with Neal Staley, Conor Puls, and Haohua Wang.

1:39PM Y3.00005 Excitations from Filled Landau Levels in Graphene. ANDREW IYENAGAR — Recent experimental progress has allowed the fabrication of graphene, a two-dimensional honeycomb lattice of carbon atoms that forms the basic planar structure in graphite. Graphene exhibits a host of interesting properties that can be understood in terms of a non-interacting system whose single-particle excitations are described by the Dirac equation. What, then, is the role of the Coulomb interactions between electrons in graphene? In this talk, I will present a study of the collective excitations of graphene in the quantum Hall regime. These excitations open a window into the nature of Coulomb interaction effects and may be observable by optical spectroscopy. Such excitations are well-understood in the case of the standard two-dimensional electron gas (2DEG), in which the low-lying collective mode spectrum may be interpreted in terms of a single particle-hole pair bound into a stable exciton by Coulomb forces. Using a similar analysis for graphene, we find that, in spite of the linear electronic dispersion near the Dirac points, the exciton spectrum is qualitatively quite similar to that of the 2DEG. On the other hand, the additional pseudospin degree of freedom strongly changes many-body corrections relative to the 2DEG case. We also find that the presence or absence of certain branches of the exciton spectrum is sensitive to the number of filled spin and pseudospin sublevels. Finally, I will discuss these results in relation to infrared spectroscopy measurements and comment on the screening of the Coulomb interaction in graphene.

Friday, March 14, 2008 11:15AM - 2:15PM –
Session Y4 DCMP: New Symmetries and Excitations in Multiferroics
Morial Convention Center 206
11:15AM Y4.00001 Observation of ferrotoroidic order in LiCoPO₄₁, MANFRED FIEBIG, HISKP, University of Bonn, Nussallee 14-16, 53115 Bonn, Germany — Domains are an essential property of any ferroic material. Three forms of ferroic order (ferromagnetism, ferroelectricity, ferroelasticity) are widely known. It is currently debated whether to include an ordered arrangement of magnetic vortices as fourth form of ferroic order termed ferrotoroidicity [1]. Although there are reasons to do this from the point of view of thermodynamics a crucial hallmark of the ferroic state, i.e., a ferrotoroidic domain structure, has not been observed before. Here ferrotoroidic domains are spatially resolved by optical second harmonic generation in LiCoPO₄ where they coexist with independent antiferromagnetic domains [2]. The origin of ferrotoroidicity in LiCoPO₄ is discussed and the general relation between ferrotoroidicity and antiferromagnetism or spin-spiral magnetism will be highlighted. Their space- and time asymmetric nature relates ferrotoroidics to multiferroics with magnetoelectric phase control and other systems in which space and time asymmetry leads to exciting possibilities for future application.

11:51AM Y4.00002 Symmetry in Multiferroics, SANG-WOOK CHEONG, Rutgers University — Symmetries govern Nature ubiquitously from the beauty of human faces to the local gauge invariance of quantum field theory. Magnetic order in frustrated magnets can occur without space inversion symmetry. When it relaxes to the magnetically-ordered configuration through exchange-striction, lattice can also loose inversion symmetry, leading to the presence of ferroelectric polarization. In these magnetically-driven ferroelectrics, dielectric properties turn out to be highly susceptible to applied magnetic fields. Both symmetric and antisymmetric exchange coupling can be involved in the exchange-striction. One form of symmetry often broken in Nature is the symmetry between left- and right-handedness. For example, the manner in which light propagates naturally selects one handedness, and is customarily described by a right-handed rule, depicting the relationship among the oscillating electric field, magnetic field and propagation vector of light. Chiral molecules also have a definite handedness, and given the preponderance of chiral molecules, it is not surprising that most complex proteins as well as their constituent amino acids are chiral. What is remarkable however, is that most of naturally occurring amino acids share the same chirality; only left-handedness. Such handedness, or chirality, appears to be a characteristic signature of life. In the multiferroic spinel Co₂FeO₄, conical magnetic order accompanies ferroelectric polarization as well as ferromagnetic moment. The relevant handedness and chirality in the multiferroic state will be also discussed.

12:27PM Y4.00003 Towards a microscopic theory of toroidal moments in periodic crystals¹. NICOLA SPALDIN, Materials Department, UC Santa Barbara — The recent resurgence of interest in magnetoelectric multiferroics has prompted discussion of the relevance of the concept of magnetic toroidal moments in such systems. In particular, the toroidal moment has the same symmetry as the antisymmetric part of the linear magnetoelectric tensor, suggesting a role in mediating coupling between magnetic and electric polarization in multiferroics. In addition, materials in which the toroidal moments are aligned cooperatively – so-called ferrotoroidics – have been proposed to complete the group of primary ferroics. Here we review the basic microscopic and macroscopic definitions of toroidal moments and illustrate the difficulties in evaluating the toroidal moment of an infinite periodic system. We show that periodic boundary conditions give rise to a multivaluedness of the toroidal moment per unit cell, in close analogy to the case of the electric polarization in bulk periodic crystals. We then evaluate the toroidal moments of several multiferroic and magnetoelectric materials (BaNiFe₄O₁₂, LiCoPO₄, GaFeO₃ and BiFeO₃) in the “localized dipole limit”, where the toroidal moment is caused by a time- and space-reversal symmetry-breaking arrangement of localized magnetic moment.

1:03PM Y4.00004 Role of Spin current in multiferroic behavior, NAOTO NAGAOSA, Dept. Applied Physics, The University of Tokyo — No abstract available.

1:39PM Y4.00005 Electromagnons in multiferroics¹. ANDREI SUSHKOV, Department of Physics, University of Maryland — Multiferroic materials with simultaneous magnetic and ferroelectric order exhibit strong cross coupling between electric and magnetic phenomena. One important new effect is the strong coupling between the low lying magnetic and lattice excitations to produce spin waves that interact strongly with light by acquiring electric dipole activity from the phonons. As a result, these excitations, which are called electromagnons, produce contributions to the static dielectric constant which appear in the ordered phases and that can be manipulated with an applied magnetic field. This appears to be the origin of the giant magneto-capacitance effect observed in these multiferroics. Predicted more than three decades ago, electromagnons were reliably observed only recently. In my talk, I will discuss electromagnons in two classes of multiferroic materials: RmO₃ and RmN₂O₅ (R = Y, Rare Earth) in which the multiferrocicity derives from different mechanisms. Correspondingly the electromagnons in these two materials systems have characteristically different spectra and selection rules. The electromagnon H-T phase diagrams for Eu₀.75Y₀.25MnO₃, TbMnO₃, TbMn₂O₅ will be presented. I will also discuss the outstanding problems in understanding these novel excitations and the prospects for electromagnons in other materials.

In present and future high performance CMOS devices, the dedicated introduction is Raman spectroscopy, enabling strain and composition determination in silicon structures on the µ-scale with high accuracy. It will be shown for various strained silicon and silicon-germanium film structures, that optical near-field information can be obtained on a scale promising for CMOS device characterization. Local strain measurements are achieved utilizing TERS with metal coated AFM tips positioned in the region of interest. Experimental results of µRaman and of TERS scans for the strain distribution in island and line structures of thin films are discussed as well as possibilities and limitations for further improvement of the spatial Raman resolution.

---

12:27PM Y5.00003 Temporal and Spatial Distributions of Water in Ion-Containing Perfluorosulfonic Polymers

EVANGELOS MANIAS, Penn State University — The spatial distribution and the molecular dynamics of water in perfluorinated ionomer polymeric membranes (Nafion 11x in the acid form) were quantified at several hydration levels by Atomic Force Microscopy and Dielectric Relaxation Spectroscopy, respectively. A variety of concurrent AFM modes, including interleave and intermittent contact methods, is necessary to map the water-containing domains on the polymer surfaces, whereas at least two different dielectric relaxation setups are needed to record the range of water dynamics that develop in these systems as the hydration level changes. The competition between sulfonic-group/water attraction and water/water hydrogen-bonding, in addition to confinement effects, give rise to at least three “states” of water, manifested through distinct dynamical behaviors: The fastest process observed was identified as the cooperative picosecond relaxation of free/isotropic, bulk-like water, whereas the slowest process —with microsecond relaxation times— corresponds to water molecules strongly bound to the charged sulfonic groups. An intermediate relaxation, in the picosecond range and about three times slower than those of bulk water, is shown to contain substantial dynamical heterogeneities and most probably corresponds to a variety of local environments that are cumulatively defined as “loosely bound” water. AFM studies, probing the same surfaces at various hydration levels, provides insights on the location and geometry of the water domains that contribute to the various dynamical “states”. Both the spatial and temporal distributions of water are sensitive to the sample preparation conditions, especially with respect to the geometry and dynamics of the “loosely bound” water domains.

---

11:51AM Y5.00002 Using Folding Pathways to Predict Protein Structure

KARL FREED, University of Chicago — Since the demonstration that the amino acid sequence of a protein encodes its structure, the prediction of structure from sequence remains an outstanding problem that impacts numerous scientific disciplines. By iteratively fixing secondary structure assignments of residues during Monte Carlo simulations of folding, a coarse grained model without homology information or explicit side chains outperforms current homology-based secondary structure prediction methods. The computationally rapid algorithm also generates tertiary structures with backbone conformations of comparable accuracy to existing all-atom methods for many small proteins, particularly for low homology sequences. Given appropriate search strategies and scoring functions, reduced representations can accurately predict secondary structure as well as three-dimensional structures, thereby increasing the size of proteins approachable by ab initio methods and the accuracy of template-based methods, in particular for sequences with low homology. In addition, we will discuss recent advances in understanding non-linear electrostatic contributions to transfer free energies in continuum electrostatic models.

---

11:15AM Y5.00005 Ion- and pH-dependent volume transitions in biopolymer gels

FERENCE HORKAY, Laboratory of Integrative and Medical Biophysics, National Institutes of Health — Swelling and collapse of polyelectrolyte gels are the result of a balance of different interactions that control the osmotic pressure and network elasticity. In biopolymer systems ions often play a central role in determining the phase behavior. For example, DNA condensation induced by multivalent cations is crucial for its packaging. It is known that biological processes, such as nerve excitation and muscle contraction, are mediated by divalent cations. In general, relatively little is known about the interaction between multivalent ions and charged biopolymers due to the lack of an appropriate theory and the absence of a sufficiently broad base of experimental data. Recent experimental observations made by anomalous small-angle X-ray scattering indicate that the spatial extent of the counterion cloud is significantly reduced in the case of divalent ions relative to the monovalent ions. An understanding of ion induced swelling/collapse transition in polyelectrolyte gels may shed light on the mechanism of important physiological processes. We compare the effects of pH, ion strength and counterion valence on the structure and osmotic properties of biopolymer gels. Systematic studies made on DNA gels indicate that monovalent salts gradually reduce gel swelling but do not cause discontinuous volume transition. In dilute suspensions of these particles, we studied the swelling response for different AAc fractions as a function of pH. In the concentrated suspensions, pH-induced particle expansion can cause transitions between fluid, glassy and crystalline phases. Data will be presented on the dynamics of the observed phase behavior.

---

1:03PM Y5.00004 Microrheological studies of solvent-response dynamics of polyelectrolytes

VICTOR BREDVIELD, Georgia Institute of Technology — We have developed a dialysis cell for microrheology, which provides unique capabilities for studying microstructural dynamics of macromolecular solutions due to sudden changes in solvent composition (e.g., ionic strength, pH, solvent/cosolvent ratio). The device was used to determine the response of sodium sulphonated polystyrene (NaPSS) solutions of different molecular weights to changes in counterion concentration. In general, polyelectrolyte chains collapse upon addition of counter-ions, but recent numerical simulations by Hsiao and Luijten (PRL 97, 2006) predicted reexpansion at high concentrations of multivalent counterions. We tested and confirmed these predictions for trivalent chloride salts (Al, In, Ti), although the effect is subtle and strongly varies between the cations investigated. Another study employed the dialysis cell to characterize pH-induced swelling and deswelling of colloidal microparticle mixtures of a polyelectrolyte (NaPSS) and a pH-responsive coil (NIPAM-co-PAA) copolymer. The acid copolymer caueses pH-responsiveness, swelling the particles at high pH due to deprotonation. In dilute suspensions of these particles, we studied the swelling response for different AAc fractions as a function of pH. In the concentrated suspensions, pH-induced particle expansion can cause transitions between fluid, glassy and crystalline phases. Data will be presented on the dynamics of the observed phase behavior.

11:15AM Y6.00001 Local strain analysis for CMOS technology by Raman and Nano-Raman spectroscopy

MICHAEL HECKER, AMD Saxony LLC & Co. KG — In present and future high performance CMOS devices, the dedicated introduction of mechanical strain into active silicon regions is an important challenge to progress technology. For both basic understanding of the structure-strain relationship and for developing improved device structures, local measurement of the strain state has become essential. A promising technique that meets these requirements is Raman spectroscopy, enabling strain and composition determination in silicon structures on the µm-scale with high accuracy. Locally enhanced Raman intensities due to tip enhanced Raman spectroscopy (TERS) can be utilized to downscale the spatial resolution of Raman spectroscopy significantly below the optical diffraction limit. It will be shown for various strained silicon and silicon-germanium film structures, that optical near-field information can be obtained on a scale promising for CMOS device characterization. Local strain measurements are achieved utilizing TERS with metal coated AFM tips positioned in the region of interest. Experimental results of µRaman and of TERS scans for the strain distribution in island and line structures of thin films are discussed as well as possibilities and limitations for further improvement of the spatial Raman resolution.

3 NSF-DMR-0602877 and ONR-00014-05-1-0614
11:51AM Y6.00002 Hydrogen storage by physisorption on Metal Organic Frameworks, ANNE DAILLY, General Motors, R&D center, CES Laboratory — Cryo-adsorption systems based on materials with high surface area properties have the main advantage that they can store and release hydrogen with fast kinetics and high reversibility over multiples cycles. Recently Metal Organic Frameworks (MOFs) have been proposed as promising adsorbents for hydrogen. These crystallographically well organized hybrid solids resulting from the three dimensional connection of inorganic clusters using organic linkers show the largest specific surface areas of all known crystalline solids. The determination of the relationships between physical properties (chemistry, structure, surface area . . .) of the MOFs and their hydrogen storage behavior is a key step in the characterization of these materials, if they are to be designed for hydrogen storage applications. Excess hydrogen sorption measurements for different MOFs will be presented. We show that maximum hydrogen uptake at high pressure and 77K does not always scale with the specific surface area. A linear correlation trend only apply within a class of specific materials and breaks down when the surface area measurement does not represent the surface sites that are available to H2. The influence of pore size and shape will also be discussed by comparing several MOFs with different structure types. The hydrogen adsorption and binding energy at low pressure are strongly dependent on the metal ions and the pore size.

12:27PM Y6.00003 Characterization of the pore geometry of porous media and the saturating fluids using 2-dimensional diffusion - NMR relaxation measurements, MARTIN DOMINIK HRLIMANN, Schlumberger - Doll Research — No abstract available.

1:03PM Y6.00004 Non-linear Optical Spectroscopy of Interfaces, MOHSEN YEGANEH, ExxonMobil Research and Engineering Co., Corporate Strategic Research — The critical role played by interfaces can be extended to areas such as nanometer size sensors, electronic devices, fuel cells, composite materials, corrosion, lubrication, oil recovery, catalysis, biology, and aqueous environments. The development of superior technologies in these areas can be driven by rapid advances in interfacial science. Second-order nonlinear optical spectroscopy, particularly sum-frequency generation (SFG) spectroscopy, is well suited for advanced characterization of interfaces. It possesses long penetration depths and intrinsic interface specificity. This talk discusses the general principle of SFG spectroscopy as applied in a petrochemical industry with brief examples related to polymer surfaces, aqueous/oxide interfaces and adsorption of molecular additives from liquid onto solid surfaces.

1:39PM Y6.00005 Development of Silicide Contacts for CMOS devices: Advantages of using Synchrotron Radiation, CHRISTIAN LAVOIE, IBM T.J. Watson Research Center — Silicide films have been used for close to two decades as the contact to the source, drain and gate of state-of-the-art complementary-metal-oxide-semiconductor (CMOS) devices. The desired properties for this contact layer have limited the choice of applicable silicides to low resistivity TiSi2, CoSi2 and NiSi. The stringent and evolving requirements in material properties imposed by continuous scaling have forced modifications to current materials or implementation of the following best candidate. The recent conversion from CoSi2 for the 90 nm technology to NiSi in 65 nm technology and beyond represent a good example of the complexity associated with the integration of a new material. The requirements necessary to achieve performance in current devices are so stringent that even a material such as NiSi studied for more than 3 decades exhibited unexpected characteristics in very thin films and in small devices. The use of intense x-ray beams allows for the characterization of such materials in reduced dimensions and has brought to light multiple unknown behaviors. For example, the morphological stability of NiSi is much lower than originally expected, a result of the complexity in the phase sequence, of the strong anisotropy in properties related to the non-cubic crystal structure and of the very peculiar texture of these films. This early thermal degradation of the contacts has been controlled through process optimization and recently through the use of Ni alloys. In this presentation the impact of using intense x-ray sources for materials optimization will be discussed. The access to these powerful setups has allowed the rapid characterization and optimization of large parameter spaces necessary to develop the knowledge for implementation of new materials in state-of-the-art devices.

Friday, March 14, 2008 11:15AM - 2:51PM — Session Y7 DBP DCP: Control of Light with Bacteriorhodopsin

11:15AM Y7.00001 Earle K. Plyler Prize Talk: Stark Realities, STEVEN BOXER, Stanford University — Stark spectroscopy is the effect of an electric field on a spectrum. Measurements of the Stark effect give information on the change in dipole moment and polarizability for a spectroscopic transition. The great majority of Stark effect measurements have been and still are made in the gas phase where spectroscopic transitions are very narrow and a Stark splitting can be readily measured. There are many fewer examples of Stark spectroscopy measurements in condensed phases, largely because of the perceived difficulty of applying a large electric field. While this is the case for liquid samples, where molecular alignment and low breakdown voltages complicate the measurement, it is simple to immobilize the molecule of interest, either by embedding it in a thin polymer film or by freezing the solvent. The latter is completely general and any sample that forms a high quality optical glass, including protein samples, can be studied. In this talk I will present an overview of applications of Stark effects to diverse systems. We divide the phenomenon into two broad classes: classical Stark effects, where the applied field acts as a perturbation shifting a transition; and non-classical Stark effects, where the applied field affects the intrinsic absorption lineshape and/or populations of states. Classical Stark effects provide quantitative information on the dipolar nature of excited states for electronic or vibrational transitions. Once calibrated, the spectroscopic transition can be used to probe electric fields in organized complex systems such as proteins and changes in those fields accompanying mutations, catalysis, ligand binding and folding. Vibrational Stark effects are particularly useful in this context, and this has led to diverse strategies for introducing unique and sensitive probes for electrostatic fields in proteins. Non-classical Stark effects embrace the many effects that electric fields can have on reaction dynamics, particularly involving electron transfer, either photoinduced or in mixed valence systems. For such systems, the electric field can alter the absorption or emission lineshape substantially because the potential surface depends upon the field and the spectrum depends on the shape of the potential. Examples of each type will be presented.
other natural photoreceptors such as pharaonis phoborhodopsin, proteorhodopsin, photoactive yellow protein and the blue light plant photoreceptor phototropin.

During this talk, switching pump intensity, switched probe profile and phase, and relative phase-shift. Optimized conditions for all-optical switching that include optimized time, switching pump intensity, switched probe profile and phase, and relative phase-shift. Optimized conditions for all-optical switching that include optimized

To this end we have studied the integration of a suitably engineered protein, bacteriorhodopsin (BR), with semiconductor optoelectronic devices and circuits. Successful integration will potentially lead to ultrasensitive sensors with polarization selectivity and built-in preprocessing capabilities that will be useful for high speed tracking, motion and edge detection, biological detection, and artificial vision systems. In this presentation we will summarize our progresses in this area, which include fundamental studies on the transient dynamics of photo-induced charge shift in BR and the coupling mechanism at protein-semiconductor interface for effective immobilizing and selectively integrating light sensitive proteins with microelectronic devices and circuits, and the device engineering of BR-transistor-integrated optical sensors as well as their applications in phototransceiver circuits.

Work done in collaboration with Pallab Bhattacharya, Jonghyun Shin, Department of Electrical Engineering and Computer Science, University of Michigan, Ann Arbor, MI; Robert R. Birge, Department of Chemistry, University of Connecticut, Storrs, CT 06269; and György Váró, Institute of Biophysics, Biological Research Center of the Hungarian Academy of Science, H-6701 Szeged, Hungary.

2:15PM Y7.00006 All-Optical Switching in Bacteriorhodopsin Based on Excited-State Absorption

SUKHDEV ROY, Dayalbagh Educational Institute — Switching light with light is of tremendous importance for both fundamental and applied science. The advent of nano-bio-photonics has led to the design, synthesis and characterization of novel biomolecules that exhibit an efficient nonlinear optical response, which can be utilized for designing all-optical biomolecular switches. bacteriorhodopsin (BR) protein found in the purple membrane of Halobacterium halobium has been the focus of intense research due to its unique properties that can also be tailored by physical, chemical and genetic engineering techniques to suit desired applications. The talk would focus on our recent results on all-optical switching in BR and its mutants, based on excited-state absorption, using the pump-probe technique. We would discuss the all-optical control of various features of the switching characteristics such as switching contrast, switching time, switching pump intensity, switched probe profile and phase, and relative phase-shift. Optimized conditions for all-optical switching that include optimized values of the small-signal absorption coefficient (for cw case), the pump pulse width and concentration for maximum switching contrast (for pulsed case), would be presented. We would discuss the desired optimal spectral and kinetic properties for device applications. We would also discuss the application of all-optical switching to low power all-optical computing devices, such as, spatial light modulators, logic gates and multiplexers and compare their performance with other natural photo receptors such as pharaothis phorhodopsin, proteorhodopsin, photoactive yellow protein and the blue light plant photoreceptor photocarepin.

Friday, March 14, 2008 11:15AM - 1:39PM

Session Y8 DFD: Hydrodynamics of Surfaces and Films Morial Convention Center R06
11:27AM Y8.00002 Rheology and Micro rheology of Actin-Lipid Composites at the Air-Water Interface1, 2, ROBERT WALDER, University of California, Irvine, ALEX LEVINE, University of California, Los Angeles, CHRISTOPH SCHMIDT, Third Physical Institute: Biophysics Georg-August-Universität, Goettingen, Germany, MICHAEL DENNIN, University of California, Irvine — We report on the mechanical properties of a composite material that is a combination of a Langmuir monolayer chemically linked to an actin filament network. This composite system is a 2 dimensional analogue of a cellular membrane and is also expected to have interesting nonlinear mechanical properties. To measure these mechanical properties, we employ traditional rheology and have developed unique microrheological capabilities based on an optical tweezer setup combined with a Couette surface rheometer. This combination of techniques will allow the study of both bulk and local mechanical responses of the composite material to external forces. Studying such materials allows us to simultaneously study a biomimetic material that should provide useful insights into the mechanical properties of biological cells, while also providing a 2 dimensional soft matter system to study the properties of semi-flexible polymer networks.

11:39AM Y8.00003 ABSTRACT WITHDRAWN —

11:51AM Y8.00004 Elasticity and capillarity: wet hairs and origami, JOSÉ BICO, LINGGUO DU, BENOIT ROMAN, PMMH-ESPCI, JEROME GUILLET, ENS, Paris — Capillary forces are responsible for a large range of everyday observations: the shape of rain droplets, the imbibition of a sponge, the clumping of wet hair into bundles. Although they are often negligible on macroscopic structures, surface capillary forces may overcome volume forces at small scales and deform compliant micro-structures. Capillary-induced sticking can prevent the actuation of mobile elements in MEMS, or even cause their collapse. Capillary forces also have important consequences in biology such as the buckling of the airway lumen induced by surface tension, which can eventually cause the lethal closure of lung airways. We will review a few experimental situations where capillary forces are able to deform two types of objects: rods, and thin sheets. For instance, the nanotubes of a “carbon nanotube carpet” self-assemble into conical “teepee” structures after the evaporation of a solvent and can produce intriguing cellular patterns. Similarly macroscopic wet hairs tend to assemble into bundles through a cascade of successive pairings. The comparison of the physical ingredients involved in these phenomena, attracting capillary forces acting against bending elasticity, leads to a characteristic length: a slender structure longer than this “elasto-capillary” length is considerably bent by capillary forces. The case of thin sheets is trickier because of geometrical constrains, which generally leads to singularities.

12:03PM Y8.00005 Flow fields in soap films: effects of surface viscosity and film thickness, VIKRAM PRASAD, ERIC R. WEEKS, Emory University — A soap film is a thin fluid layer (10 nm to 1 microns thick) separated from bulk air phases above and below it by two surfactant monolayers. We measure the flow field in these films by two-particle microrheology, which looks at the correlated Brownian motion of pairs of embedded tracer particles separated by a distance R. In thin soap films with the thickness comparable to the particle size, and with mobile surfactant interfacial layers, this flow field is long ranged. On the other hand, the flow field in a 3D fluid is known to decay as 1/R. We vary the thickness of the soap film, the mobility (surface viscosity) of the interface and the size of the polystyrene probe particles to quantify the transition of the hydrodynamics of the film from quasi-2D to 3D-like behavior.

12:15PM Y8.00006 Effective Viscosity of a Dilute Suspension of Membrane-bound Inclusions, MARK L. HENLE, ALEX J. LEVINE, Department of Chemistry and Biochemistry, University of California, Los Angeles — In 1906, Einstein famously calculated the effective viscosity of a dilute solution of spheres suspended in a viscous solvent [Annalen der Physik 19, 289 (1906)]. In this talk, we consider the two-dimensional analogue of this problem: that is, we calculate the effective viscosity of a dilute suspension of disks embedded in a two-dimensional fluid membrane. The rheological properties of particle-decorated membranes and fluid-fluid interfaces are important in a variety of soft matter systems. For example, the cell membrane contains a suspension of membrane-bound inclusions (e.g. transmembrane proteins, lipid rafts), which modifies the transport kinetics of the membrane. Also, the interfacial viscosity of liquid-liquid interfaces in colloid-stabilized emulsions plays a key role in preventing droplet coalescence. We include the dissipation caused by flows both within the membrane and in the surrounding bulk fluids. When the flows within the membrane dominate the dissipation, the particle suspension effectively shifts the membrane viscosity. Conversely, when flows induced in the bulk fluids dominate the dissipation, the suspension in the membrane shifts the bulk viscosity. In both limits, we obtain simple analytic expressions for the appropriate effective viscosity.

12:27PM Y8.00007 Contact line motions of drying solutions, FRANCOIS LEQUEUX, CECILE MONTEUX, ASTRID TAY, PMMH-ESPCI, EMMANUELLE RIO, LPS/ORSAY, LAURENT LIMAT, GUILLAUME BERTLOOT, ADRIEN DAERR, MSC/PARIS, PMMD/ESPCI/PARIS TEAM, LPS/ORSAY/FRANCE TEAM, MSC/PARIS/FRANCE TEAM — If most the studies on wetting deal with pure liquids in the absence of evaporation, in practical situations, the liquid is often a solution with an evaporating solvent. This is encountered both in coating and in surface cleaning. In that case, the contact line of a solution is the location of many divergent phenomena. The hydrodynamics dissipation diverges at the contact line: 1) the drying rate diverges at the contact line 2) the concentration diverges at the contact line. The coupling of these phenomena leads to complex effect for the contact line motion. We have observed that an advancing contact line of a colloidal suspension exhibit a stick-slip motion. Moreover, for similar reasons in the case of an advancing contact line of a polymer solution, the contact angle exhibit a minimum as a function of velocity – at which the polymer accumulates on a length of typically 5 nm in the vicinity of the contact line. All these phenomena can explained quantitatively using simple scaling arguments that we will present.

12:39PM Y8.00008 Obtaining Reproducible Slip Measurements on Smooth Hydrophobic Surfaces, SEAN P. MCBRIDE, B.M. LAW, Kansas State University — Over the past decade, the world market for microfluidic technologies and applications of such devices has soared. The slip length parameter at the liquid-surface interface of these devices describes how easily a fluid flows over the surface. As microfluidic devices decrease in size, slip becomes very important. Despite the undeniable success of these devices in recent years, the literature illustrates that numerous discrepancies exist for the slip magnitude measured using different experimental methods. As the need for smaller microfluidic devices approaches, the need for the most efficient drop transport. This capillary ratchet mechanism may also find applications in micro scale fluid transport, such as valveless pumping of fluid drops.

1Center for Bits and Atoms, MIT.
12:51PM Y8.00009 Fabrication of non-aging superhydrophobic surfaces by packing flower-like hematite particles, ANMIN CAO, LIANGLIANG CAO, DI GAO, University of Pittsburgh — We demonstrate the fabrication of non-aging superhydrophobic surfaces by packing flower-like micrometer-sized hematite particles. Although hematite is intrinsically hydrophilic, the nanometer-sized protrusions on the particles form textures with overhanging structures that prevent water from entering into the textures and induce a macroscopic superhydrophobic phenomenon. These superhydrophobic surfaces do not age even in extremely oxidative environments—they retain the superhydrophobicity after being stored in ambient laboratory air for 4 months, heated to 800 degree C in air for 10 hours, and exposed to ultraviolet ozone for 10 hours.

1:03PM Y8.00010 Liquid slip probed by second harmonic generation1, DAN LIS, Laboratoire Lasers & Spectroscopies, University of Namur, STEVE GRANICK, BAE SUNG CHUL, Departments of Materials Science and Engineering, Chemistry, and Physics, University of Illinois, SCIENTIFIC EXCHANGE COLLABORATION — Second harmonic generation has been used to probe how a solid surface responds to flow past it. The surface is quartz, the measurements are made in total internal reflection configuration, and comparison of responses to light with s and p incident polarisation allows us to determine the orientation of dye molecules physisorbed before the onset of the shear flow. By monitoring the orientation of the dye at different fluid viscosity and different shear rate, we deduce the surprising relation between shear rate and surface stress.

1:15PM Y8.00011 Determination of Inter-Phase Line Tension in Langmuir Films3, ELIZABETH K. MANN, LU ZOU, Kent State University, JACOB R. WINTERSMITH, ANDREW J. BERNOFF, Harvey Mudd College, JAMES C. ALEXANDER, J. ADIN MANN, JR., Case Western Reserve University, PREM BANSET, EDGAR E. KOOIJMAN, Kent State University — The hydrodynamic response of a thin fluid film, whether a Langmuir monolayer at the air/water interface or a cell membrane, is difficult to model, since it involves the coupling of both bulk and surfaces phases. However, such hydrodynamic response is not only intrinsically critical for transport within the layer, it also provides the major available means to evaluate an important parameter for phase-separated layers, the line tension. We have developed a line-integral formulation of the hydrodynamic response of phase-separated layers with short-ranged forces, and tested it by comparisons between numerical simulations based on this model and experiment. These experiments both validate the model and demonstrate that the line tension can be determined with unprecedented accuracy and precision. Two systems have been studied to date: a simple smectic liquid crystal multilayer and coexistence between phases in binary lipid/cholesterol mixed layers. For the latter case, long-range dipole-dipole interactions are introduced into the model.

1:27PM Y8.00012 ABSTRACT WITHDRAWN –

Friday, March 14, 2008 11:15AM - 2:15PM –
Session Y9 DAMOP: BEC/Matter Optics/Atom Interferometry Morial Convention Center RO7

11:15AM Y9.00001 Phase diagram of a Bose gas near a wide Feshbach resonance, LAN YIN, Peking University — The phase diagram of a homogeneous Bose gas with a repulsive interaction near a wide Feshbach resonance is studied at zero temperature. The Bose-Einstein-condensation (BEC) state of atoms is a metastable state. When the scattering length $a$ exceeds a critical value depending on the atom density $n$, the molecular BEC state becomes a unstable coherent mixture of atoms and molecules. (http://arxiv.org/abs/0710.5318)(cond-mat/0710.5318)

11:27AM Y9.00002 Initial States of BEC mixtures Produced by Cooling in the Presence of a Feshbach Resonance, LAURA HALMO, Georgia Southern University, MARK EDWARDS, Georgia Southern University and NIST — We have studied the types of Bose–Einstein condensate (BEC) mixtures produced as a result of different cooling paths. These results are relevant to a recent experiment in which a mixture of $^{85}$Rb and $^{87}$Rb BECs was cooled in three stages: (1) optical pre–cooling, (2) evaporative cooling in a magnetic trap, and (3) evaporatively cooled in an optical trap. We used that, upon transfer to the optical trap, the state of the mixture of thermal gases can be represented by the superposition of a small number of low–lying trap eigenstates each with high occupation. In this case, the field operator can be approximated as a c–number and its evolution will be governed by the nonlinear Schrödinger equation. We investigated the density profiles that resulted from different initial thermal distributions as well as non–thermal initial distributions. We also performed studies of the effect of varying the $^{85}$Rb/$^{87}$Rb scattering length via a Feshbach Resonance. We found condensate states that differ markedly from the standard Thomas–Fermi ground states of the Gross–Pitaevskii equation.

11:39AM Y9.00003 Interference between atomic Bardeen-Cooper-Schrieffer gases, TUN WANG, Austrian Academy of Science, SUSANNE YELIN, Univ. of Connecticut — We study the interference between two atomic Bardeen-Cooper-Schrieffer (BCS) gases using noise correlations. Fringes as seen in the interference between two Bose-Einstein Condensates (BECs) do not to exist due to the requirement that two BCS gases have to initially overlap to interfere. This requirement results from the fact that the spin up and spin down fermions in a Cooper pair have opposite momenta. Nevertheless, BCS gases still interfere with each other, and their interference patterns share many aspects with those of BECs.

11:51AM Y9.00004 Single and double reflection Michelson atom interferometers in a weakly-confining magnetic trap, RUDRA KAFLE, JAMES STICKNEY, WPI, DANA ANDERSON, JILA, University of Colorado and NIST, ALEX ZOZULYA, WPI — We analyze the operation of a BEC based atom interferometer, where the atoms are held in a weakly-confining magnetic trap and manipulated with diffraction gratings produced by counter-propagating laser beams. A simple analytic model is developed to describe the dynamics of the interferometer. It is used to find the region of parameters corresponding to high values of the interference fringe contrast for both single and double reflection geometries. We demonstrate that for a double reflection interferometer the coherence time can be increased by shifting the recombination time. Finally, we compare the theory with recent experimental realizations of these interferometers and estimate when phase diffusion and finite temperature phase fluctuations become important.

1:15PM Y8.00011 Determination of Inter-Phase Line Tension in Langmuir Films1, ELIZABETH K. MANN, LU ZOU, Kent State University, JACOB R. WINTERSMITH, ANDREW J. BERNOFF, Harvey Mudd College, JAMES C. ALEXANDER, J. ADIN MANN, JR., Case Western Reserve University, PREM BANSET, EDGAR E. KOOIJMAN, Kent State University — The hydrodynamic response of a thin fluid film, whether a Langmuir monolayer at the air/water interface or a cell membrane, is difficult to model, since it involves the coupling of both bulk and surfaces phases. However, such hydrodynamic response is not only intrinsically critical for transport within the layer, it also provides the major available means to evaluate an important parameter for phase-separated layers, the line tension. We have developed a line-integral formulation of the hydrodynamic response of phase-separated layers with short-ranged forces, and tested it by comparisons between numerical simulations based on this model and experiment. 11:15AM Y9.00001 Phase diagram of a Bose gas near a wide Feshbach resonance, LAN YIN, Peking University — The phase diagram of a homogeneous Bose gas with a repulsive interaction near a wide Feshbach resonance is studied at zero temperature. The Bose-Einstein-condensation (BEC) state of atoms is a metastable state. When the scattering length $a$ exceeds a critical value depending on the atom density $n$, the molecular excitation energy is imaginary and the atomic BEC state is dynamically unstable against molecule formation. The BEC state of diatomic molecules has lower energy, where the atomic excitation is gapped and the molecular excitation is gapless. However when the scattering length is above another critical value, $n a^3 > 0.0164$, the molecular BEC state becomes a unstable coherent mixture of atoms and molecules. (http://arxiv.org/abs/0710.5318)(cond-mat/0710.5318)

11:27AM Y9.00002 Initial States of BEC mixtures Produced by Cooling in the Presence of a Feshbach Resonance, LAURA HALMO, Georgia Southern University, MARK EDWARDS, Georgia Southern University and NIST — We have studied the types of Bose–Einstein condensate (BEC) mixtures produced as a result of different cooling paths. These results are relevant to a recent experiment in which a mixture of $^{85}$Rb and $^{87}$Rb BECs was cooled in three stages: (1) optical pre–cooling, (2) evaporative cooling in a magnetic trap, and (3) evaporatively cooled in an optical trap. 11:51AM Y9.00004 Single and double reflection Michelson atom interferometers in a weakly-confining magnetic trap, RUDRA KAFLE, JAMES STICKNEY, WPI, DANA ANDERSON, JILA, University of Colorado and NIST, ALEX ZOZULYA, WPI — We analyze the operation of a BEC based atom interferometer, where the atoms are held in a weakly-confining magnetic trap and manipulated with diffraction gratings produced by counter-propagating laser beams. A simple analytic model is developed to describe the dynamics of the interferometer. It is used to find the region of parameters corresponding to high values of the interference fringe contrast for both single and double reflection geometries. We demonstrate that for a double reflection interferometer the coherence time can be increased by shifting the recombination time. Finally, we compare the theory with recent experimental realizations of these interferometers and estimate when phase diffusion and finite temperature phase fluctuations become important.
12:03PM Y9.00005 Prospects for a Gradient Magnetometer Atom Interferometer1, FRANK A. NARDUCCI, JON P. DAVIS, Naval Air Systems Command — Atom interferometers form the basis for state-of-the-art sensors, including gravimeters, gravity gradiometers, gyroscopes and atomic clocks. Notably absent from this list are magnetometers, which can have a wide range of applications ranging from military to medical applications. We propose a scheme to realize an atom interferometer gradient magnetometer. We begin by demonstrating a light-pulse magnetic beam-splitter. The analysis is based on a full multi-level 2-laser field Maxwell-Bloch model including state selection rules, polarization selectivity, laser detuning, and Doppler averaging. We then consider an ensemble of atoms subject to a $\pi/2 - \pi - \pi/2$ pulse sequence. The phase of the interference pattern depends on the phase of the action along the classical path and on the phase of the combined laser fields imprinted on the atoms during the pulse sequence. From this analysis, we conclude that, to first order, the phase of the interferometer output is insensitive to the field across the interferometer, but is sensitive to the gradient of the field. Using realizable numbers from existing interferometers, we show that a gradient magnetometer of this type has can have a greater gradient sensitivity than many current magnetic sensors. We discuss the status of our current experiments using ultra-cold atoms.

3Supported by ILIR and IAR grants from the Office of Naval Research

12:15PM Y9.00006 Bose–Josephson Junction with Binary Mixture of Bosonic Atoms, MARK EDWARDS, Georgia Southern University and NIST, JEFFREY HEWARD, Georgia Southern University, INDUBALA SATIJA, George Mason University and NIST, RADHA BALAKRISHNAN, Institute of Mathematical Sciences, PHILLIP NAUDUS, George Mason University — We consider a Bose–Josephson junction consisting of a binary mixture of two weakly coupled Bose–Einstein condensates confined in a symmetric double–well external potential. In a single condensate confined in a double–well potential, when the condensate wavefunction is approximated as a linear combination of the lowest two eigenmodes of the potential, the result is a dynamical system analogous to those that describe the current and phase across a Josephson junction. Josephson oscillations and nonlinear self–trapping are among the effects predicted by this dynamical system. Using the same two–mode approximation, the condensate mixture can be mapped to two coupled, non–rigid pendula. Although the system is found to exhibit periodic dynamics, the tunneling dynamics of the individual components can be periodic, quasiperiodic, as well as chaotic. We also investigate the experimental signatures of these effects and the goodness of the two–mode approximation by solving the coupled Gross–Pitaevskii equations that govern the behavior of the system.

12:27PM Y9.00007 Dynamics of phase separation in cold-atom boson-fermion mixtures1, DMITRY SOLENOV, Department of Physics, Clarkson University, Potsdam, New York 13699-5820, DMITRY MOZYRSKY, Theoretical Division (T-4), Los Alamos National Laboratory, Los Alamos, NM 87545 — We study the kinetics of the first order phase separation transition in boson-fermion cold atom mixtures. At low enough temperatures such a transition is driven by quantum fluctuations responsible for the formation of critical nuclei of a stable phase. Based on a microscopic description of interacting boson-fermion mixtures we derive an effective action for the critical droplet and obtain asymptotic expression for the nucleation rate in the vicinity of the phase transition and near the spinodal instability of the mixed phase. We show that in the former case the transition rate is significantly modified by dissipation due to interaction with fermion excitations. The regimes where quantum nucleation can be experimentally observed in cold atom systems are identified.

12:39PM Y9.00008 Quantum phases of mixtures of atoms and molecules on optical lattices1, VALY ROUSSEAU, PETER DENTENEER, Institut-Lorentz — We investigate the phase diagram of a two-species Bose-Hubbard model with an additional conversion term, where two particles from the first species can be converted into one particle of the second species, and vice-versa. The model can be related to ultra-cold atoms experiments where Feshbach resonance, used to tune the scattering length, produces long-lived bound states viewed as diatomic molecules. The model is solved exactly by means of Quantum Monte Carlo simulations. We find that the model exhibits an exotic incompressible “Super-Mott” phase where the particles from both species can flow with signs of superfluidity, but with anti-correlations such that there is no global supercurrent.

1This work is part of the research program of the ‘Stichting voor Fundamenteel Onderzoek der materie (FOM)’, which is financially supported by the ‘Nederlandse Organisatie voor Wetenschappelijk Onderzoek (NWO)’.

12:51PM Y9.00009 First order behaviour of Bose Fermi mixtures across a Feshbach resonance, CHARLES MATHY, Department of Physics, Princeton University, FRANCESLA MARCHETTI, Rudolf Peierls Center for Theoretical Physics, University of Oxford, MEERA PARISH, DAVID HUSE, Department of Physics, Princeton University — We analyze the phase diagram of a mixture of bosonic and fermionic atoms, whose interaction is tuned by varying a magnetic field across a Feshbach resonance. To this end, we introduce a two-channel model and study it with a mean field approach. The phase diagram is found to contain both second order and first order phase transitions, which lead to a regime of densities where phase separation is predicted. We explain why our model is consistent with the experimental observation of collapse, which is usually captured by a single-channel model, and discuss in which systems one is most likely to encounter the physics we are describing.

1:03PM Y9.00010 Boson-Fermion mixture and superconducting phases on the honeycomb lattice, DORON BERGMAN, PETER ORTH, KARYN LE HUR, Yale University — We explore theoretically the different phases of a Boson-Fermion mixture in a honeycomb lattice model. With realistic band structure and interactions, we find that much like phonons in a solid, the bosonic atoms induce effective attractive interactions between the fermions. The attractive interactions can then lead to a number of superconducting phases, which we explore. Using a Bogoliubov and mean-field approach, as well as a full RG treatment, we derive the phase diagram. Possible phases of the system include s-wave as well as $p+ip$ superconducting states. We also analyze the nature of the vortices in the different superconducting states, as these are of great interest as a possible realization of emergent non-Abelian statistics. We explain how tuning between different superconducting phases can be achieved in a cold atomic gas realization of this system.

1:15PM Y9.00011 Supersymmetry and Goldstino-like Mode in Bose-Fermi Mixtures, YUE YU, ITP, Beijing, KUN YANG, National High Magnetic Field Laboratory and Florida State University — Supersymmetry is assumed to be a basic symmetry of the world in many high energy theories, but none of the super partners of any known elementary particle has been observed yet. We argue that supersymmetry can also be realized and studied in ultracold atomic systems with a mixture of bosons and fermions, with properly tuned interactions and single particle dispersion. We further show that in such non-relativistic systems supersymmetry is either spontaneously broken, or explicitly broken by a chemical potential difference between the bosons and fermions. In both cases the system supports a sharp fermionic collective mode similar to the Goldstino mode in high-energy physics, due to supersymmetry. We also discuss possible ways to detect this mode experimentally.
1:27PM Y9.00012 Preemptive phase-transitions in multicomponent BECs\footnote{Work supported by Research Council of Norway.}, STEINAR KRAKSET\footnote{Work supported by Norwegian Research Council}
Norw. Univ. of Sci & Tech, ESKIL KULSET DAHL, Norw. Univ. of Sci & Tech, EGOR BABAEEV, University of Massachusetts Amherst, ASLE SUDBO, Norw. Univ. of Sci & Tech — We use analytical arguments and large-scale Monte-Carlo simulations to investigate phase transitions between various complex superfluid phases in a two-component Bose-Einstein condensate with varying non-dissipative drag between the two components. We focus on establishing the phase diagram and in detail the individual and composite superfluid densities that the system features, using a representation in terms of the phases of the superfluid ordering fields. In particular, we describe a novel preemptive scenario, whereby drag induces a first-order transition from the interplay between two phase-transitions that individually would have been in the $3DXY$-universality class. Our results may shed light on similar phenomena occurring in certain multicomponent superconductors and in scenarios of deconfined quantum criticality in certain quantum antiferromagnetic systems.

1:39PM Y9.00013 Chaos Threshold in Bose-Hubbard Model, AMY CASSIDY, University of Southern California,
VANJA DUNJKO, MAXIM OLSHANII, University of Massachusetts Boston — The goal of this work is to determine the criterion for chaos in the one-dimensional mean-field Bose-Hubbard model. We investigate the time evolution of this system with a few low-energy momentum modes excited initially. A threshold for chaos is defined from calculations of the largest Lyapunov exponent, which is compared with the predictions of the Chirikov criterion of overlapping resonances. Additionally, the results are compared with a closely related fully integrable model.

1:51PM Y9.00014 Quantum quench dynamics in analytically solvable one-dimensional models, ANIBAL Iucci, University of Geneva, MIGUEL A. CAZALILLA, Centro de Fisica de Materiales, San Sebastian, Spain, THIERRY Giamarchi, University of Geneva — In connection with experiments in cold atomic systems, we consider the non-equilibrium dynamics of some analytically solvable one-dimensional systems which undergo a quantum quench. In this quench one or several of the parameters of the Hamiltonian of an interacting quantum system are changed over a very short time scale. In particular, we concentrate on the Luttinger model and the sine-Gordon model in the Luther-Emery point. For the latter, we show that the order parameter and the two-point correlation function relax in the long time limit to the values determined by a generalized Gibbs ensemble first discussed by J. T. Jaynes [Phys. Rev. 106, 620 (1957); 108, 171 (1957)], and recently conjectured by M. Rigol et al. [Phys. Rev. Lett. 98, 050405 (2007)] to apply to the non-equilibrium dynamics of integrable systems.

2:03PM Y9.00015 Superconducting-vortex WCP describes the dragging anisotropy quantitatively. This picture is further supported by the observation that vortex motion is more erratic along the $O_3$-chains than across them. The decay and oscillations of the current are analytically derived, and studied numerically along with the momentum distribution after the quench. In the case of small supercurrent boosts $\nu^3$, we find that the current surviving at long times is proportional to $\nu^3$.

Friday, March 14, 2008 11:15AM - 2:15PM
Session Y10 DCMP: Superconducting Nanostructures II Morial Convention Center R08

11:15AM Y10.00001 Studying pinning on the nanoscale by vortex dragging in a YBa$_2$Cu$_{3-\delta}$O$_{9-\delta}$ single crystal, O. M. AUSLAENDER, LAN LUAN, Stanford University, E. ZELDOV, Weizmann Institute of Science, K. A. MOLER, Stanford University, D. A. BONN, RUIXING LIANG, W. N. HARDY, University of British Columbia — We have used a magnetic force microscope to drag individual, well isolated vortices in a detwinned YBa$_2$Cu$_{3-\delta}$O$_{9-\delta}$ single crystal. At this slight degree of overdoping, a vortex can be described as a one-dimensional elastic string. We find an angle dependent dragging distance, implying that it is easier to drag a vortex along the Cu-O chains than across them. We understand this as a manifestation of single vortex weak collective pinning (WCP) by oxygen vacancies across the Cu-O chains, the dominant source of pinning in our sample. Single vortex WCP arises when individual pinning sites are too weak individually, but able to compete with elasticity by cumulative effect. Using the usual single vortex WCP assumption of isotropic point pinning sites at uncorrelated positions we find that the anisotropy of superconductivity in YBa$_2$Cu$_{3-\delta}$O$_{9-\delta}$ only partially accounts for the angle dependence. Relaxing that assumption to account for the known vacuum of the vacancies to cluster along the Cu-O chains, we find that single vortex WCP describes the dragging anisotropy quantitatively. This picture is further supported by the observation that vortex motion is more erratic along the chains than across them.

11:27AM Y10.00002 Fabrication and characterization of YBa$_2$Cu$_{3-\delta}$O$_{7-\delta}$ Aharonov-Bohm rings and ultra-long nanowires, PAICHIA KUO, JESSIE SHUEN, Institute of Physics, Academia Sinica, Taiwan, PATRICK MORALES, J.Y.T. WEI, Dept. of Physics, University of Toronto, Canada — We report a novel technique to fabricate YBa$_2$Cu$_{3-\delta}$O$_{7-\delta}$ (YBCO) nanowires with characteristic length scale smaller than the YBCO penetration depth. The nanowires presented here are Aharonov-Bohm rings $\sim 15 \mu m$ in diameter, and 200 nm nanowires $\sim 300 \mu m$ in length. These devices have TC behaviors similar to that of unpatterned YBCO thin films. Fabrication of nanostructured complex oxide is a challenge even with advanced thin film growth techniques since either chemical or physical etching tends to compromise the film properties. The effective method is to epitaxially deposit thin film onto nano-patterned oxide substrate without any post-deposition treatment. Our novel technique takes advantage of the 3Dmicromachining capability of focused-ion-beam to nano-pattern the oxide substrate without the inherent surface damage and edge rounding problems caused by the energetic ion beam. This method is a reliable way to fabricate nanostructures of complex oxides and hence enables the studies of their properties.

11:39AM Y10.00003 Electrical Transport Properties of Nanostructured YBa$_2$Cu$_{3-\delta}$O$_{7-\delta}$ Rings and Wires\footnote{Work supported by: NSERC, CFI/OIT, Canadian Institute for Advanced Research and Core Facilities for Nanoscience and Nanotechnology (NanoCore) at Academia Sinica Taiwan.}, P. MORALES, J.Y.T. WEI, Dept. of Physics, University of Toronto, P.C. KUO, J. SHUEN, M.K. WU, Institute of Physics, Academia Sinica Taiwan — The resistance and current-voltage characteristics of nanostructured high-$T_c$ superconducting YBa$_2$Cu$_{3-\delta}$O$_{7-\delta}$ rings and wires were studied as a function of temperature and applied magnetic field. The rings and wires were fabricated by pulsed laser deposition of YBa$_2$Cu$_{3-\delta}$O$_{7-\delta}$ on patterned SrTiO$_3$ substrates. The substrates were patterned using two different techniques. The first technique is based on selective epitaxial growth, and the second, using a method based on focused ion beam. Nanostructured superconducting rings were fabricated with a diameter of $1.5\mu m$ with the width of the arms of the rings being 150nm. The low field magnetoresistance of the rings exhibit characteristics indicative of quantum interference effects. Nanostructured superconducting wires were fabricated with lengths up to 300$\mu m$ and widths as small as 200nm. The current-voltage characteristics of the wires exhibit discontinuities under current biasing and $s$-shaped non-linearities under voltage biasing characteristic of the formation of phase slip lines, the 2D analog of phase-slip centers.
11:51AM Y10.00004 Flux and bias driven superconducting to normal transition in an SNS proximity dc SQUID1, JIAN WEI, PAUL CADDEN-ZIMANSKY, VENKAT CHANDRASEKHAR, Northwestern University — We measure the magnetoresistance of a dc SNS SQUID in the form of a mesoscopic normal-metal loop in contact with two superconducting electrodes. Below the transition temperature of the superconducting leads, large $h/2e$ periodic magnetoresistance oscillations can be observed when the normal sections of the SNS junctions enter a proximity regime induced by the superconducting electrodes. As the temperature is lowered, the entire device becomes superconducting. In this regime, sharp switching from the zero-resistance state to a finite-resistance state is seen at half-integer flux quanta. With the application of a dc bias current at even lower temperatures, periodic switching from the superconducting state to the fully normal state can be produced with the external field. The observation of periodic flux-driven transitions in this device suggests that beyond the current SQUID theory for SNS junctions that incorporates the kinetic energy of the coherent electrons in the junctions is needed.

12:03PM Y10.00005 Charge and mass of Cooper pairs in small superconducting rings, VICTOR VAKARYUK, University of Illinois at Urbana-Champaign — It is well known that response of a neutral fermionic superfluid to rotation or a superconductor to magnetic field and/or rotation involves such characteristics of a Cooper pair as, stretching terms a little, its mass $2m$ and charge $2e$. Here $m$ and $e$ are essentially bare mass and charge of particles constituting the Cooper pair e.g. electrons in case of superconductors. On a phenomenological level this is a consequence of the fact that expressions for currents are written for pairs of particles. We analyze this situation in BCS framework and show that for superfluids mesoscopically constrained in (at least) one spatial dimension the pair’s mass and charge become smaller than their values in bulk case (i.e. $m$ and $2e$). One of the implications of this result is the absence of $h/2e$ harmonic in the response of small superconducting rings or tubes to external magnetic field.

1ignoring tiny relativistic corrections

12:15PM Y10.00006 Emergence of $h/e$-period oscillations in the critical temperature of small superconducting rings enclosing magnetic flux, T2U-CHIEH WEI, Institute for Quantum Computing and Department of Physics and Astronomy, University of Waterloo, 200 University Ave. W., Waterloo, ON N2L 3G1, Canada, PAUL M. GOLDBART, Department of Physics, University of Illinois at Urbana-Champaign, 1110 West Green Street, Urbana, Illinois 61801-3080, USA — The Little-Parks critical-temperature oscillations, with magnetic flux, of a large-radius hollow cylindrical superconductor have a period $h/2e$. This oscillation period reflects the binding of electrons into Cooper pairs. On the other hand, the single-electron Aharonov-Bohm oscillations in the resistance or persistent current in a clean metallic ring have period $h/e$. By using the Gor'kov approach to BCS theory, we investigate oscillations in the critical temperature of a superconducting ring, for radii that are comparable to the superconducting coherence length. In this regime, oscillations in the critical temperature of period $h/e$ emerge, in addition to the usual Little-Parks-period oscillations. We argue that in the clean limit there is a superconductor-normal phase transition at nonzero flux, as the ring radius becomes sufficiently small, and that this transition can be either second- or first-order, depending on the ring radius and the external flux. In the dirty limit, we argue the transition is rendered second-order, which results in continuous quantum phase transitions tuned by flux and radius.

12:27PM Y10.00007 Current fluctuations in rough Josephson tunnel junctions1, FRANK WILHELM, GEORG HEINRICH, University of Waterloo — The barrier material of superconducting tunnel junction has become the focus of interest as there is evidence that it limits the intrinsic quantum coherence of superconducting qubits. It is also potentially responsible for $1/f$ noise in SQUIDs. We study the model of a “sieve” junction of many opaque transport channels plus few pinholes, modeling a rough tunnel barrier. Even if the pinholes have a small effect on the subgap current, they completely dominate the shot noise at low voltages. Remarkably, even a fully open pinhole contributes shot noise because the size of the charge quantum it carries is uncertain. The full-counting statistics of charge transfer leads to a multimodal distribution. It is discussed, to what extent this distribution can be interpreted as the onset of telegraph or $1/f$ noise. This theoretical work is based on an extensive full counting statistics calculation using Keldysh Green’s function.

12:39PM Y10.00008 Josephson effect through a resonant level coupled to a single oscillator model1, MIKAEL FOGELSTROM, JONAS SKOLDBERG, TOMAS LOFWANDER, Dept. of Microtechnology and Nanoscience (MC2), Chalmers University of Technology — Motivated by very recent experiments on superconducting transport through single-walled carbon nanotubes, we investigate the supercurrent through a one-level quantum dot connected to a single phonon mode. Calculations are done using non-equilibrium Green’s function methods within a self-consistent Born approximation, i.e. assuming that the tunneling rate is much larger that the effective electron-phonon coupling. We calculate both the modified Andreev-bound state spectrum and the renormalization of the phonon density-of-states in situations when the phonon-mode is either in or out-off thermal equilibrium with the electron system. Based on our calculations we discuss possible Andreev-state spectroscopy.

12:51PM Y10.00009 Quantum Phase Slips in 1D Josephson Junction arrays, JACK LIDMAR, KTH Stockholm — One-dimensional arrays of Josephson junctions can undergo a zero temperature superconductor-insulator quantum phase transition by tuning the Josephson coupling. Quantum phase slips (QPS) play the key role in this transition. In the superconducting regime they are very rare, while in the insulating Coulomb blockade regime, they proliferate and destroy the phase coherence. We derive an expression for the QPS rate that is amenable to quantum Monte Carlo simulations and perform calculations in a realistic model of an array over a wide range of parameters including the transition region. In particular we can determine the scaling properties of the QPS rate at the transition.

1:03PM Y10.00010 Macroscopic Resonant Tunneling through Andreev Interferometers, JEFF WEISS, University of Arizona, MARLIES GOORDEN, University of Geneva, PHILIPPE JACQUOD, University of Arizona — We investigate the conductance through and the spectrum of ballistic Andreev interferometers, chaotic quantum dots attached to two $s$-wave superconductors, as a function of the phase difference $\phi$ between the two order parameters. A combination of analytical techniques – random matrix theory, Nazarov’s circuit theory and the trajectory-based semiclassical theory – allows us to explore the quantum-to-classical crossover in detail. When the superconductors are not phase-biased, $\phi = 0$, we recover known results that the spectrum of the quantum dot exhibits an excitation gap, while the conductance across two normal leads carrying $N_N$ channels and connected to the dot via tunnel contacts of transparency $T_N$ is $\propto T_N^{\frac{1}{2}} N_N$. In contrast, when $\phi = \pi$, the excitation gap closes and the conductance becomes $G \propto N_N N_N$ in the universal regime. In the tunneling regime, $T_N \ll 1$, resonant contributions induce an order-of-magnitude enhancement of the conductance towards $G \propto N_N^2$ in the short-wavelength limit. We relate this to the emergence of a giant peak in the density of states at the Fermi level. Our predictions are corroborated by numerical simulations.
of the two-component wave form. As their relative phase is undetermined. We report on the use of the phase sensitivity of the transient grating experiment to separate the individual components.

Conventional pump-probe methods have revealed at least two components in the change in transmission. Resolving these components is inherently ambiguous.

Evolution of the amplitude changes in the transmission of $YBa_2Cu_3O_{7-x}$ thin films have been measured using the charge-grating technique. In this technique two non-collinear pulses are interfered to create a sinusoidal spatial variation in superfluid density, which leads to a grating in the transmission coefficient. Evolution of the amplitude and phase of this grating in the time-domain can be monitored by the coherent detection of a time-delayed diffracted probe pulse. Previous experiments using conventional pump-probe methods have revealed at least two components in the change in transmission. Resolving these components is inherently ambiguous as their relative phase is undetermined. We report on the use of the phase sensitivity of the transient grating experiment to separate the individual components of the two-component wave form.

11:27AM Y11.00002 Visible-pump, THz-probe measurement of the photocarrier mobility in an undoped cuprate. J. STEVEN DODGE, Simon Fraser University, RUIXING LIANG, University of British Columbia — We present new experimental results on the mobility of photoexcited carriers in Sr$_2$CuCl$_3$O$_4$, an undoped cuprate. We use ultrafast laser pulses to excite photocarriers in the antiferromagnetic insulating lattice. We then probe the low-frequency dynamical conductivity of the resulting nonequilibrium state with time-domain terahertz spectroscopy. We observe the prompt onset of photoconductivity followed by a non-exponential decay on ps timescales. Assuming all photoexcited carriers are free we observe a peak mobility of ~0.1 cm$^2$/Vs, much lower than the Hall mobility in chemically doped systems with similar carrier concentrations. Such a low mobility suggests the formation of polarons or excitons after photoexcitation. We will also discuss the temperature dependence of the nonequilibrium state.

11:39AM Y11.00003 Time-resolved spectroscopy of the charge-transfer gap in Sr$_2$CuO$_2$Cl$_2$. J. STEVEN DODGE, Simon Fraser University, ANDREAS SCHUMACHER, Lawrence Berkeley National Laboratory, LANCE MILLER, Ames Laboratory, DANIEL CHEMLA, Lawrence Berkeley National Laboratory — We present energy- and time-resolved pump-probe spectroscopy near the charge-transfer gap in the undoped cuprate compound Sr$_2$CuO$_2$Cl$_2$. Upon photoexcitation, an increase in absorption is observed for energies below 1.95 eV, whereas a decrease occurs above 1.95 eV. Overall, the spectral weight is not conserved over the probe range of 1.6-2.3 eV. No hole-burning is observable at the pump energy $E_{pump}=2.1$ eV. The transient spectral changes appear as one spectral unit instantaneously after the excitation, and they decay, again as one spectral unit, on a picosecond time scale. The photoinduced response relates simply to the thermal response, indicating a common boson-mediated origin. These results support a theoretical model that places the gap energy near 1.5 eV, well below the peak in the charge-transfer absorption spectrum. In this model, the photoexcited state decays rapidly to the gap energy via phonon emission, and the presence of the additional phonons then has the same effect on the charge-transfer absorption as an increase in the equilibrium lattice temperature.

11:51AM Y11.00004 Unusual Spectral Signatures in Na-doped Oxychloride High Temperature Superconductors. M. BRUNNER, University of California, Santa Cruz, K.-H. KIM, H.-G. LEE, S.-I. LEE, Pohang University of Science and Technology, M.R. PETERSON, B.S. SHASTRY, G.-H. GWEON, University of California, Santa Cruz — Electron spectroscopy studies on Na-doped oxychloride samples (Na-COC, (NaCa)$_2$Cu$_2$O$_2$Cl$_2$) have received much attention recently, due to the facts that Na-COC samples are easy to cleave, the crystal structure is relatively simple among the cuprates, and the spectroscopy reveals enhanced signatures of putative “competing order.” Here, we report the electronic structure of Na-COC investigated by angle resolved photoelectrode spectroscopy (ARPES) as a function of momentum, energy, and doping, with an emphasis on unusual nature of some signatures clearly observed in this family of the cuprates. We discuss those signatures in relation to the recently discovered high energy dispersion anomaly and the suggested charge order.

12:03PM Y11.00005 Competition scenario in Raman and ARPES experiments in electron-doped cuprates. BELEN VALENZUELA, ELENA BASCONES, Instituto de Ciencias Materiales de Madrid (CSIC) — Raman and ARPES experiments in the superconducting state of electron doped cuprates have shown deviations from the predictions of a monotonic d-wave superconducting gap. Two scenarios have been proposed to explain these experiments: a non-monotonic BCS gap on a large Fermi surface and a two band model due to the truncation of the Fermi surface by antiferromagnetic correlations. We calculate angle resolved photoemission spectrum and Raman signal in the superconducting phase using a two-band model where superconductivity and antiferromagnetism competes and compare our results with others theoretical scenarios. We also discuss the effect of the non-monotonicity of the gap on the tunneling experiments.

12:15PM Y11.00006 Appearance of Universal Metallic Dispersion in a Doped Mott Insulator. HSIN LIN, S. SAHRAKORPI, R.S. MARKIEWICZ, Northeastern U., M. LINDROOS, Northeastern U. and TUT Finland, X.J. ZHOU, Stanford U. and LBNL, T. YOSHIDA, U. of Tokyo, W.L. YANG, Stanford U. and LBNL, T. KAKESHI, U. of Tokyo, H. EISAKI, Stanford U. and U. of Tokyo, S. UCHIDA, U. of Tokyo, SEIKI KOMIYA, CRIEPI Japan, YOICHI ANDO, Osaka U., F. ZHOU, Z.X. ZHAO, Chinese Acad. of Sci., T. SASAGAWA, Stanford U. and TIT Japan, A. FUJIMORI, U. of Tokyo, Z. HUSSAIN, LBNL, Z.-X. SHEN, Stanford U. and LBNL, A. BANSIL, Northeastern U. — Under strong electronic correlations the parent compounds of all cuprate high-temperature superconductors assume the so-called Mott-Hubbard insulating state. By what routes these insulators rapidly to the gap energy via phonon emission, and the presence of the additional phonons then has the same effect on the charge-transfer absorption as an increase in the equilibrium lattice temperature. We present new experimental results on the mobility of photoexcited carriers in Sr$_2$CuCl$_3$O$_4$, a undoped cuprate. We use ultrafast laser pulses to excite photocarriers in the antiferromagnetic insulating lattice. We then probe the low-frequency dynamical conductivity of the resulting nonequilibrium state with time-domain terahertz spectroscopy. We observe the prompt onset of photoconductivity followed by a non-exponential decay on ps timescales. Assuming all photoexcited carriers are free we observe a peak mobility of ~0.1 cm$^2$/Vs, much lower than the Hall mobility in chemically doped systems with similar carrier concentrations. Such a low mobility suggests the formation of polarons or excitons after photoexcitation. We will also discuss the temperature dependence of the nonequilibrium state.

12:27PM Y11.00007 Systematic ARPES study of Ln$_2$Bi$_2$Sr$_{2-x}$CuO$_{6+y}$, ZHIIHUI PAN, MADHAB NEUPANE, YIMING XU, ZIQIANG WANG, Boston College, HUIQIAN LUO, LEI FANG, HAIHU WEN, Institute of Physics and National Lab for Condensed Matter Physics China, HONG DING, Boston College — Ln$_2$Bi$_2$Sr$_{2-x}$CuO$_{6+y}$ is a good candidate to investigate the effects of charge doping and potential disorder to the properties of the high-Tc cuprates. The samples with different Ln elements exhibits very different property, and can used as a probe to study the superconductivity with different Ln substitutions. High-quality single crystals of Ln$_2$Bi$_2$Sr$_{2-x}$CuO$_{6+y}$ have been synthesized over a wide substitution range. We will report our high-resolution ARPES results on of Ln$_2$Bi$_2$Sr$_{2-x}$CuO$_{6+y}$.

12:39PM Y11.00008 Strong correlation effects in the electron momentum density distribution of La$_{2-x}$Sr$_x$CuO$_4$. B. BARBIELLINI, Northeastern U. — NU, P.E. MUNARENS, NU and Delft University of Technology, S. KAPRZYK, NU and AGH, Poland, R.S. MARKIEWICZ, NU, M. ITOU, Y. SAKURAJI, JASRI/Pring-8, Japan, K. YAMADA, Tohoku Univ., Japan, A. BANSIL, NU — Compton scattering offers unique capabilities for measuring absolute spectral weights, which are not obtainable by other spectroscopies. Moreover, this technique is genuinely a bulk-sensitive probe. In this connection, we have carried out a series of high resolution Compton scattering measurements on oriented single crystals of La$_{2-x}$Sr$_x$CuO$_4$ at three different dopings x=0, 0.15 and 0.30, together with corresponding computations based on the LDA and on models for treating strong correlation effects. Theoretical predictions are compared and contrasted with the experimentally reconstructed two-dimensional electron momentum densities to identify strong correlation effects in the spectra, and to delineate how these effects evolve as the system undergoes the transition from the Mott insulator to the superconductor. Work supported in part by the USDOE.
12:51PM Y11.00009 New analysis of the electronic excitations in the Mott insulator Nd$_2$CuO$_4$ using momentum-dependent intensity maps. GUILLAUME CHABOT-COUTURE, Stanford University, JASON N. HANCOCK, Stanford University/SSRL, DIEGO M. CASA, Advanced Photon Source, ANL, PATRICK K. MANG, THOMAS GOG, Advanced Photon Source, ANL, MARTIN GREVEN, Stanford University/SSRL — Resonant inelastic X-ray scattering (RIXS) is a rapidly advancing technique that allows the measurement of electronic excitations in correlated-electron systems. In order to extend this technique, we developed a new circle to perform azimuthal rotations of the crystal. This allowed us to perform precise measurements of the electronic excitations as a function of the momentum transfer in the copper-oxygen planes and the incident photon polarization. As a result, we discovered that Cu K edge RIXS is at most weakly polarization dependent when the polarization is kept in the copper-oxygen planes. We used this new circle to determine the intensity variations of different energy-loss excitations across many Brillouin zones. These intensity maps as well as inelastic spectra measured at high-symmetry points in the Brillouin zone allow an improved analysis of the electronic-excitation spectral weight in this material. We discuss our findings in the context of past measurements on other cuprate systems.

1:03PM Y11.00010 Valence Electronic Structure of YBCO Probed by X-ray Standing Waves. JORG ZEGENHAGEN, SEBASTIAN THIESS, TIEN-LIN LEE, ESRF, CARMELA ARUTA, INFN, Rome, CHENG-TIEN LIN, MPI-FKF, Stuttgart, FEDERICA VENTURINI, NICHOLAS BROOKES, BRUCE C.C. COWIE, ESRF — The photoelectron emission spectrum of the valence band of the high-temperature superconductor YBa$_2$Cu$_3$O$_{6.5}$ (YBCO) in the X-ray regime is dominated by contributions from the copper sites (d states) because of the comparably large cross section. With the help of the x-ray standing wave (XSW) technique in combination with photoelectron spectroscopy, it is possible to separate the contributions to the valence band originating from different lattice sites, even if they are populated by the same element. In this work, by applying the XSW method with photoelectron spectroscopy, we discriminated the contributions to the YBCO valence band coming from the nonequivalent in-plane and chain copper sites. Within the resolution of our measurements, the contributions of Cu-I and Cu-II to the valence band were found to be identical.

1:15PM Y11.00011 Doping Dependence of New Electronic Excitations in La$_{2−x}$Sr$_x$CuO$_4$ Observed by K-edge RIXS. D.S. ELLIS, JUNGO HI, Univ. Toronto, J.P. HILL, Brookhaven National Lab, S. WAKIMOTO, Japan Atomic Energy Research Institute, R.J. BIRGENEAU, Univ. California Berkely, T. GOG, D. CASA, Argonne National Lab, Y.-J. KIM, Univ. Tokyo — Resonant inelastic xray scattering (RIXS) spectra of the cuprate La$_{2−x}$Sr$_x$CuO$_4$ are measured for single crystal samples with progressively larger value of x, ranging from undoped to the overdoped regime. As x is increased in the underdoped region, the lowest energy excitation above the charge transfer gap is sharply suppressed, but many of the general spectral features and overall spectral weight distribution above the gap do not appreciably change, and the broad intensity around the same energy of the exciton remains constant. As the sample becomes overdoped, a much more pronounced change of the spectral weight above the charge transfer gap occurs. An in-gap state at ~1.8 eV in the undoped case, which shows no dispersion with momentum, broadens and shifts down in energy as the doping is increased. The amount of the observed shift is to within an order of magnitude of the change calculated from simple crystal field model.

1:27PM Y11.00012 Charge superstructures in Zn-doped La$_{2-x}$Sr$_x$CuO$_4$. J. C. LEE, University of Illinois, A. RUSYDI, University of Hamburg, S. SMADICI, S. WANG, P. ABBAMONTE, University of Illinois, M. ENOKI, M. FUJITA, Tohoku University, M. RUEBHAUSEN, University of Hamburg, K. YAMADA, Tohoku University. We have observed valence band charge order in both twinned and untwinned samples of La$_{1.95}$Sr$_{0.05}$Cu$_{1.95}$Zn$_{0.05}$O$_4$ with resonant soft x-ray scattering. In the untwinned sample the order was observed to be mainly electronic and centered at the (0,0.084,2) position in reciprocal space, indicating diagonal charge order with period 12a$_o$, where a$_o$ is the orthorhombic lattice parameter. This order has approximately half the wavelength of the magnetic order previously observed with neutron scattering in this system, suggesting a stripe interpretation. Preliminary measurements on a twinned sample revealed four satellites at (0,K,2), where K takes on integer multiples of the value 0.011. Relationships between these effects and the crystal structure of La$_{1.95}$Sr$_{0.05}$Cu$_{1.95}$Zn$_{0.05}$O$_4$ will be discussed. *M. Matsuda, et. al., Phys. Rev. B 73, 140503(R) (2006)

1:39PM Y11.00013 The model high-Tc superconductor HgBa$_2$CuO$_{4+δ}$: a quantitative annealing, transport and magnetic susceptibility study. NEVEN BARISIC, YUAN LI, GUILLAUME CHABOT-COUTURE, YU GUICHUAN, Stanford University, YONGCHAN CHO, Pusan National University, XUDONG ZHAO, Jinlin University, MARTIN GREVEN, Stanford University, GREVEN TEAM — The investigation of the physical properties of high-Tc superconductors (HTSCs) is complicated by several materials-related obstacles. In order to obtain reliable experimental results, homogeneous single crystals are needed, which are difficult to obtain due to chemical and/or electronic disorder. HgBa$_2$CuO$_{4+δ}$ (Hg1201) is a particularly interesting HTSC, since it possesses the highest superconducting transition temperature (Tc=97 K) among single Cu-O layers. Recently, we reported a new recipe for the growth of unprecedentedly large, gram-sized monocrystals of Hg1201 [1]. Here, we demonstrate that it is possible to select samples of the highest quality, with very few vortex pinning centers, and to dope them uniformly over a wide range of hole concentration. Furthermore, we show that those crystals can be cleaved and contacted with high-quality electrical contacts. These results make Hg1201 a particularly interesting model system for extensive experimental investigation. [1] X. Zhao et al., Adv. Mater. 18, 3243 (2006)

1:51PM Y11.00014 ABSTRACT WITHDRAWN —
The relativistic infinite plane, PRESTON JONES, University of Louisiana Monroe — In general relativity there have been several proposals as to what constitutes a uniform field. We give the gravitational field due to an infinite plane with finite mass per unit area, and show that this is the closest general relativistic analog to the Newtonian uniform field. Although we work in 4D we show that the 5D generalization of this solution is the starting point for many current research papers in particle physics and cosmology dealing with infinite extra dimension theories known as brane world models. This physical picture of the brane world models as higher dimensional versions of the general relativistic plane allows one to understand many of the features of these models in simple terms.

Einstein’s 1918 Position on the Role of Ether in Relativity Theory, TOM MORTON, Northrop Grumman Corp — In his 1918 “Dialog about Objections to the Theory of Relativity”, Einstein emphasized the potential applicability of the Ether concept in General Relativity. He noted that “Lorentz brought a rigid substance embodying coordinate systems into play, but SRT denied the existence of all ether concepts. However, GRT is different, and empty space has physical qualities characterized as the components of gravitational potential. This situation can very well be interpreted by speaking of an ether whose state varies from point to point. However, one has to be careful not to attribute to this ether any matter-like properties such as a distinct velocity at each point.” This presentation seeks to identify the qualities required of an ether. Concepts might include ether as a cause of gravity, and as the source medium for the production of electric charge. The ether might conceivably take the form of a diffuse mixture of positive and negative electric charge.

Absolute Planck Values: Moving Beyond the Arbitrary Assignment of Unity, JOHN LAUBENSTEIN, IWPD Research Center — Planck Values provide a valuable tool in efforts to understand basic universal relationships; however, they fall short of having any truly intrinsic value. Planck Values come with the assumption that unity can be assigned to up to five of the fundamental universal constants. While constraining these values to unity may be convenient, it by no means ensures that intelligent life anywhere in the universe would make the same assumptions. Further, the peculiar value of the inverse fine structure constant of 137 suggests that it is naíve to assume that any of the physical constants are equal to unity or any other simplistic number. Through an analysis of gravitation and electrostatic force, the IWPD Research Center has derived a logical argument for a revised set of Planck Values that represent absolute values with true universal significance. Of greatest importance, is a recounted Planck Mass that serves as a truly fundamental unit of mass at the quantum scale. This finding contrasts with the significantly large value associated with the current Planck Mass and provides new information that may be critical in the search to unify General Relativity with Quantum Mechanics.

A Zero free Parameter and Zero Counter Term Requirement Found By Replacing the Gauge Derivative General Covariance with Metric Nontrivial General Covariance in The Dirac Equation, DAVID MAKER, none — We replace the general covariance in the gauge derivatives in the Standard Model (SM) with a metric general covariance. The result is a new Dirac equation pde ($i \gamma^{\mu} \partial_{\mu} \psi + \lambda \omega \psi = 0$) for the electron, where here $i$ is just the spatial component. To illustrate the power of this technique we note here that equivalence principle considerations allow only one type of charge $e$. Therefore, $\lambda = 0$ at $r = 0$ with stability the result. Note also that near $r = 2/\lambda$ for this new Dirac equation gives a azimuthal trifolium, 3 charge shapes; so this ONE charge $e$ (so don’t need color to guarantee this) spends 1/3 of its time in each lobe (fractionally charged lobes), the lobe structure is locked into the center of mass (asymptotic freedom), there are six 2P states (corresponding to the 6 flavors) which are the main properties of quarks! without invoking free parameters. The $S$ matrix of this new pde gives the W and Z as resonances and does not require renormalization counterterms or free parameters thereby restoring sanity to theoretical physics. It is vital that the physics community adopt this method if it is to break out of the 30 years of stagnation created by the confusion caused by these free parameters and counterterms.

The Atomic Model, EVAN RAGLAND, Retired Engineer, Eholo Circle, Diamond Head, MS 39255 — An atomic model atomic model positons concentric electron and nucleus fields spinning together about an empty center. It is alternative to the generally accepted planetary system in which electron point particles orbit about a center clump of nucleon point particles. Introduced in 1922 as an alternative to the standard model of the nucleus it applies scientific space-time knowledge unknown when the standard model was conceived. Originally advanced in the spirit of alternative equivalent it evolved to model the entire atomic structure plus many features of space-time. Structural definitions assume space-time properties of: unification expansion, special relativity, electrical field, magnetic field, spin field, gravity field, and space-time surface effect. Field effects are associated with Faraday lines of force field. Model properties feature symmetry and complementarily. Mass structures of the electron, proton, and neutron atom plus the atomic and nuclear constituents of all elements are developed. In addition the nuclear strong force is defined, the magnetic anomaly explained, etc. Model logic constructs the electron as the complement of the hydrogen (proton) atom.

Proof of the Wave Nature of Plants, ORVIN WAGNER, Wagner Research Laboratory — I assume plants operate with a set of frequencies. These frequencies and the means of these frequencies are equal in all directions. We can then write (w=avh/2 or the the distance between adjacent branches, leaves, etc. The ratios, $v_{v}/v_{h}$, are ratios of small integers for sufficient samplings. For example, for Ponderosa pine the ratio is 3/1 or for delicious apple 4/3. Note that these ratios represent the shape of the tree or other plant and their interactions with gravity. These ratios are derivable by other means such as use the ratio of $\#$ of horizontal needles per unit length from a horizontal sample to the $\#$ of needles per unit length from a vertical sample from p-pine. Or measure the vertical and horizontal velocities. My literature provides many other proofs of the wave nature of plants. I suggest that the waves in relative wave outside of plants (outside 4.9 m/s) are a dark matter related since they travel at such low velocities. See my present web site at home.budget.net/~oeodph.

Post modern physics (a revolution in modern physics), SHAHRAM MALEKZADEH, Assistant Professor — When you make a deep study in Classic and modern physics you will find great and numerous weak points. On the other hand when you want to dismiss a wrong theory you should accept the other maybe incorrect theory so I think that we should write the physics from very beginning. Here I mentioned new theories on each field that can be a start for other scientists. Theories like “cyclone theory” which is about light travel or “matrix theory” which denotes that the materials are not made only atoms but an external capsule named matrix.
Disk systems, and hard sphere system for Hard Sphere Equation of State and First Order Phase Transition. Also to be discussed briefly, is the outlook for the development of the quantum version of RMCS for quantum systems. Suggesting that RMCS may provide a highly efficient computational scheme in contrast to traditional Monte Carlo methods which normally require "large" behavior of the solid phase equation of state. Early results show that RMCS provides accurate results in the fluid phase employing "small" n values, thus discussing the power of RMCS as a materials investigative tool will be tested within the region of first order phase transition as well as for correct asymptotic configurations. RMCS results for the equation of state of the hard sphere system from low densities to densities in the neighborhood of closest packing will be range, with arbitrary inter-particle interactions. RMCS employs a new ensemble, the "nearest neighbor ensemble" involving the PDF for "n" nearest neighbor configurations. The formalism provides a unified description which has metadynamics and canonical sampling as limiting cases. Convergence and errors can be rigorously and easily controlled. The parameters of the simulation can be tuned so as to focus the computational effort only on the physically relevant regions of the order parameter space. The algorithm is tested on the reconstruction of alanine dipeptide free energy landscape. [1] A. Barducci, G. Bussi and M. Parrinello, Phys. Rev. Lett., accepted (2007).

Well-tempered metadynamics: a smoothly-converging and tunable free-energy method, ALESSANDRO BARDUCCHI, GIOVANNI BUSSI, MICHELE PARRINELLO, ETH Zurich — We present [1] a new molecular dynamics algorithm for sampling the canonical distribution. In this approach the velocities of all the particles are rescaled by a properly chosen random factor. The algorithm is formally justified and it is shown that, in spite of its stochastic nature, a quantity can still be defined that remains constant during the evolution. In numerical applications this quantity can be used to measure the accuracy of the sampling. We illustrate the properties of this new method on Lennard-Jones and TIP4P water models in the solid and liquid phases. Its performance is excellent and largely independent on the thermostat parameter also with regard to the dynamic properties. [1] G. Bussi, D. Donadio and M. Parrinello, J. Chem. Phys. 126, 014101 (2007).

Hard-sphere variational CPMD approach, GERALD FAUSSURIER, CHRISTOPHE BLANCARD, CEA, PIER LUIGI SILVESTRELLI, Padova University, CEA COLLABORATION, PADOVA UNIVERSITY COLLABORATION — We present a variational method to determine the free total energy of the electron and ion system using the Gibbs-Bogolyubov inequality and a hard-sphere reference system applied to the quantum molecular dynamics code CPMD. Numerical results and comparisons with quantum molecular dynamics simulations and experiments are presented and discussed for dense and expanded aluminum.

Classical Simulation versus Perturbation Theory of Anharmonicity in 2D Lennard-Jones Triangular Lattice, XIAO SHEN, TAO SUN, JULIE STERN, PHILIP B. ALLEN, SUNY at Stony Brook — Classical molecular dynamics simulation and perturbation theory are two methods that can treat the anharmonicity in solids. Classical molecular dynamics simulation can treat anharmonic effects to high order. Perturbation theory beyond lowest order is difficult, and has convergence issues. However, perturbation theory easily treats the thermodynamic limit, while simulation is necessarily done on a finite system. This raises interesting questions such as whether molecular dynamic simulation will give the correct decay rate when the phonon mean free path is larger than the simulation cell. We try to answer such questions, and explore the limits of both methods, by comparing their results. The system we studied is a two dimensional triangular lattice model with a Lennard-Jones potential.

Dissipation in an electric field-driven synthetic rotary caltrop-based molecular motor, CORINA BARBU, VINCENT CRESPI, The Pennsylvania State University — A molecular caltrop has a three-legged base for attachment to a substrate and a vertical molecular shaft functionalyzed with a dipole-carrying molecular rotor at the upper end. The desired rotational motion of the rotor can generate dissipation when the motor is driven at frequencies which are close to the natural frequencies of soft vibrational modes in the structure or librational of the rotator about field direction. Classical molecular dynamics simulations elucidate the role of these resonances and investigate motor performance under external drive.

Convergence Rates of a Dynamic Monte Carlo Reaction-Free Method for Interacting particles, MARTA GUERRA, MARK NOVOTNY, Physics and HPC2 Center for Computational Sciences, Mississippi State University, HIROSHI WATANABE, NOBUYASU ITO, Department of Applied Physics, University of Tokyo — We calculated the efficiency of a Reaction-Free Monte Carlo method in the limit of low temperatures and/or high densities for d-dimensional particles interacting through a repulsive power-law r^{-d} as well as Lennard-Jones Interactions. Theoretically we find the algorithmic efficiency is proportional to \( \rho^{p/2} T^{-d/2} \) where \( \rho \) is the particle density and T the temperature. For different powers (p) in 1, 2 and 3 dimensions as a function of T and \( \rho \) we report results in agreement with our theoretical predictions

Introducing the Reduced Monte Carlo Scheme (RMCS) with Application for High Substitution of the State and First Order Phase Transition, UDUEZI EDGAL, Old Dominion University, DAVID HUBER, University of Wisconsin-Madison — This is the first demonstration of a novel approach, the “Reduced Monte Carlo Scheme” (RMCS), developed for the investigation of the statistical thermodynamic properties of multi-scale material systems (classical and quantum) over the entire temperature and density range with arbitrary inter-particle interactions. RMCS employs a new ensemble, the “nearest neighbor ensemble” involving the PDF for “n” nearest neighbor configurations. RMCS results for the equation of state of the hard sphere system from low densities to densities in the neighborhood of closest packing will be discussed. The power of RMCS as a materials investigative tool will be tested within the region of first order phase transition as well as for correct asymptotic behavior of the solid phase equation of state. Early results show that RMCS provides accurate results in the fluid phase employing “small” n values, thus suggesting that RMCS may provide a highly efficient computational scheme in contrast to traditional Monte Carlo methods which normally require “large” systems for computation. Also to be discussed briefly, is the outlook for the development of the quantum version of RMCS for quantum systems.
12:39PM Y13.00008 ABSTRACT WITHDRAWN –

12:51PM Y13.00009 Angular momentum form of Verlet algorithm for rigid molecules , MIYABI HIYAMA, CREST, Toyota Central R&D Labs., Inc., TOMOYUKI KINJO, SHIAMI HYODO, Toyota Central R&D Labs., Inc. — We seek to make an algorithm based on the Verlet method which could be applied to non-Hamiltonian and explicit time dependent Hamiltonian systems for rigid molecules. For the first step of this aim, we will propose an algorithm based on the Verlet method for rigid molecules and investigate the characteristics of this algorithm for simple system. In our algorithm, the equations of motion for rigid molecules are integrated by Verlet framework in the angular momentum form. This simple algorithm is named 'the angular momentum Verlet algorithm'. We will show the results of MD simulations for 125 carbon tetrachloride molecules using the angular momentum Verlet algorithm. The relative total energy fluctuations are compared with those using the standard leap-frog and the Gear predictor-corrector algorithms. The energy drift using the angular momentum Verlet algorithm is smaller than that using the leap-frog or the Gear predictor-corrector algorithms, especially in the case of MD simulation with the large time interval.

1:03PM Y13.00010 Absorbing boundary conditions for molecular dynamics and multiscale modeling . S. NAMILAE, D.M. NICHOLSON, P.K.V. NUKALA, Computer Science and Mathematics Division, Oak Ridge National Laboratory, C.Y. GAO, Department of Chemical Engineering, University of Tennessee, Y.N. OSESKY, Computer Science and Mathematics Division, Oak Ridge National Laboratory, D.J. KEFFER, Department of Chemical Engineering, University of Tennessee — We present an application of differential equation based local absorbing boundary conditions to molecular dynamics. The absorbing boundary conditions result in the absorption of the majority of waves incident perpendicular to the bounding surface. We demonstrate that boundary conditions developed for the wave equation can be applied to molecular dynamics. Comparisons with damping material boundary conditions are discussed. The concept is extended to the formulation of an atomistic-continuum multiscale scheme with handshaking between the regions based on absorbing boundary conditions. The multiscale model is effective in minimizing spurious reflections at the interface.

1:15PM Y13.00011 Coupling atomistic molecular dynamics and fluctuating hydrodynamics: shear and sound1. RAFAEL DELGADO-BUSCALIONI, Universidad Autonoma de Madrid, GIANNI DE FABRITIIS, Universidad Pompeu Fabra, Barcelona — Bridging spatio-temporal scales is the main objective of multiscale modeling and one of the hot-topics in the simulation community. However, compared to gas and solid phase, hybrid schemes based on molecular-continuum domain decomposition of the liquid phase are relatively less developed. The present hybrid model (see PRL 97, 134501 and PRE 76, 036709) is the first to include several decisive features: the molecular domain is described with atomistic accuracy (chemical specificity), and it is embedded within a continuum fluid description based on the Landau-Lifshitz fluctuating hydrodynamics equations. The hybrid scheme is thermodynamically consistent (e.g. the MD domain is an open subsystem in agreement with the grand canonical ensemble) and fluctuations of mass, momentum and stress are seamlessly connected across the molecular-continuum interface. As the scheme is based on mass and momentum conservation, it enables to solve shear and sound waves traveling across both domains. Due to its relevance we consider water as working solvent. As a test case, we have studied the reflection of sound waves by a lipid monolayer (DMPC) immersed in aqueous solvent.

1:27PM Y13.00012 Concurrent triple-scale simulation of molecular liquids , MATEJ PRAPROTNIK, Max Planck Institute for Polymer Research, Ackermannweg 10, Mainz, Germany & National Institute of Chemistry, Hjaurihova 19, Ljubljana, Slovenia, KURT KREMER, Max Planck Institute for Polymer Research, Ackermannweg 10, Mainz, Germany, RAFAEL DELGADO-BUSCALIONI, Depto. Fisica Teorica de la Materia Condensada, Universidad Autonoma de Madrid, Campus de Cantoblanco, Madrid, Spain — We present a triple-scale simulation of a molecular liquid, in which the atomistic, coarse-grained and continuum descriptions of the liquid are concurrently coupled. The presented approach successfully sorts out the problem of large molecules insertion in the hybrid particle-continuum simulations and thus opens up the possibility to perform efficient grand-canonical molecular dynamics simulations of open molecular liquid systems.

1:39PM Y13.00013 Averaged Equations for Species Interactions in Binary Particulate Systems , DUAN ZHANG, JIN LIU, Los Alamos National Laboratory — Averaged equations for disperse two-phase flows are relatively well-studied compared to averaged equations for binary particulate systems. Disperse two-phase flows can be viewed as a limit of binary particulate system, in which the continuous phase consists of large amount of small particles, such as molecules, and the disperse phase consists of smaller number of large particles. Therefore averaged equations for disperse two-phase flows provide a guide for the derivation of averaged equations for binary particulate systems. A correct system of averaged equations for binary particulate systems has to recover the averaged equations for disperse two-phase flows in this limit. In this talk it is shown that this can only be done by introducing an interspecies stress in a binary particulate system. Although the framework of deriving the averaged equations is applicable to general particulate systems, numerical simulations are performed for a granular system to study the behaviors of the species exchange force, interspecies stresses and interspecies stress.

2:03PM Y13.00015 A numerical method for miscible two-fluid flow at a large density ratio . SIINA HAAPANEN, Stanford University — A computational algorithm for direct numerical simulation of a binary system of miscible fluids at a large density ratio is described. The method is three-dimensional, with two of the three spatial dimensions periodic. A pseudo-spectral discretization is used in the periodic directions, and an eighth order compact finite difference scheme is utilized in the non-periodic direction. The Mach number of the flow is small, and the equations of motion are integrated forward in time using a fractional step method. A constant coefficient elliptic equation (Poisson equation) is solved to determine the pressure. The method is applied to test problems including the Rayleigh-Taylor instability and a miscible two-fluid shear flow. The accuracy of the method, and its stability at a large density ratio of the fluids are discussed.

Friday, March 14, 2008 11:15AM - 2:15PM

Session Y15 GQI: Focus Session: Quantum Metrology and Control: Fundamental Limits and Applications Morial Convention Center 207

11:15AM Y15.00001 Quantum Enhanced Sensing, Measurement, and Control , SETH LLOYD, MIT — This talk investigates how quantum-mechanical effects such as squeezing and entanglement can be used to enhance the precision and sensitivity of imaging, measurement, and control. Entanglement can give a substantial enhancement to sensitivity even in the presence of high levels of noise and loss.
11:51AM Y15.00002 Environmental Constraints in Practical Photonic Quantum Sensing.¹, YAAKOV WEINSTEIN, GERALD GILBERT, MICHAEL HAMRICK, MITRE Quantum Information Science Group — We report on research directed to problems associated with the propagation of photonic signal states in quantum sensing. Attention is devoted to constraints associated to realistic propagation environments for practical applications of quantum sensing.

¹Research supported by DARPA under MITRE Project 0707D070-QA and by the MITRE Technology Program under grant #07MSR205.

12:03PM Y15.00003 Quantum efficiency of binary-outcome solid-state detectors¹, ALEXANDER N. KOROTKOV, University of California, Riverside — We discuss the definitions of the quantum efficiency for binary-outcome detectors of solid-state qubits, focusing on the subclass of quantum non-demolition detectors. Similar to the previously considered case of linear detectors, the definitions of the quantum efficiency are based on the relation between the ensemble decoherence and the information acquired from the measurement (this information determines the lower bound for the ensemble decoherence). Quantum efficiency is analyzed for several models of binary-outcome detectors, including indirect projective measurement, linear detector in a binary-output regime, detector for a phase qubit, and detector based on tunneling into continuum.

¹supported by the DTO/ARO grant

12:15PM Y15.00004 Quantum Metrology with Product States¹, ANIMESH DATTA, SERGIO BOIXO, University of New Mexico, STEVEN FLAMMIA, Perimeter Institute, Waterloo, ANIL SHAJI, CARLTON CAVES, University of New Mexico, EMILIO BAGAN, Universitat Autònoma de Barcelona — We study the performance of initial product states of $n$ of New Mexico, STEVEN FLAMMIA, Perimeter Institute, Waterloo, ANIL SHAJI, CARLTON CAVES, University of New Mexico, EMILIO BAGAN, Universitat Autònoma de Barcelona — We study the performance of initial product states of $n$-body systems in generalized quantum metrology protocols that involve estimating an unknown coupling constant in a nonlinear $k$-body ($k \ll n$) Hamiltonian. We obtain the theoretical lower bound on the uncertainty in the estimate of the parameter. For arbitrary initial states, the lower bound scales as $1/n^2$, and for initial product states, it scales as $1/n^{n-1/2}$. We show that the latter scaling can be achieved using simple, separable measurements. We formulate a simple model, based on the evolution of angular-momentum coherent states, which explains the $O(n^{-3/2})$ scaling for $k = 2$, implementable with short-time measurements. The model shows that the perturbative expansion generated by the quadratic Hamiltonian does not play a role in the enhanced sensitivity scaling. We show that phase decoherence does not affect the $O(n^{-3/2})$ sensitivity scaling for initial product states.

¹Office of Naval Research No. N00014-07-1-0304

12:27PM Y15.00005 Efficient feedback controllers for continuous-time quantum error correction. ANDREW LANDAHL, BRAD CHASE, J.M. GEREMIA, University of New Mexico — We present an efficient approach to continuous-time quantum error correction that extends the low-dimensional quantum filtering methodology developed by van Handel and Mabuchi [quant-ph/0511221 (2005)] to include error recovery operations in the form of real-time quantum feedback. We expect this paradigm to be useful for systems in which error recovery operations cannot be applied instantaneously. While we could not find an exact low-dimensional filter that combined both continuous syndrome measurement and a feedback Hamiltonian appropriate for error recovery, we developed an approximate reduced-dimensional model to do so. Simulations of the five-qubit code subjected to the symmetric depolarizing channel suggests that error correction based on our approximate filter performs essentially identically to correction based on an exact quantum dynamical model.

12:39PM Y15.00006 Passive Cooling of a Micromechanical Oscillator with a Resonant Electric Circuit. K.R. BROWN, J. BRITTON, R.J. EPSTEIN, J. CHIAVERINI, D. LEIBFRIED, D.J. WINELAND, NIST Boulder — Currently there is considerable interest in the cooling of macroscopic mechanical oscillators, as strong cooling may allow one to reach the quantum regime of such oscillators. Recent advances in fabrication and cooling techniques have brought this regime much closer. Here we present theoretical and experimental results for cooling of the fundamental mode of a miniature cantilever by capacitively coupling it to a driven rf resonator circuit. Cooling results from the rf capacitive force, which is phase shifted relative to the cantilever motion due to the finite decay time of the resonant circuit. If this force varies with an appropriate phase shift relative to the motion of the cantilever, it can oppose the velocity of the cantilever, leading to cooling. We demonstrate this technique by cooling a 7 kHz cantilever from room temperature to 45 K, obtaining reasonable agreement with a model for the cooling, damping, and frequency shift. Extending the method to higher frequencies in a cryogenic system could enable ground state cooling and may prove simpler than related optical experiments in a low temperature apparatus.

12:51PM Y15.00007 Sensitive orthogonal optical monitoring of a micromechanical oscillator. AKO CHIJIOKE, JOHN LAWALL, National Institute of Standards and Technology, Gaithersburg, MD — Optical sensing of oscillations of a mechanical microresonator is of crucial interest for a number of purposes including observation of quantum behavior of macroscopic objects and force microscopy. The majority of optical sensing schemes use light aligned with the axis of mechanical oscillation. We present sensitive monitoring of the oscillations of a micromechanical resonator orthogonal to the field in an optical cavity, and its particular advantages.

1:03PM Y15.00008 Sideband Resolved Cooling of a Nanomechanical Resonator Parametrically Coupled to a Microwave Resonator. JARED HERTZBERG, Department of Physics, University of Maryland, TRISTAN ROCHELEAU, TCHEFOR NDUKUM, KEITH SCHWAB, Department of Physics, Cornell University — We have created a nanostructure formed by a radio-frequency nanomechanical (NEMS) resonator capacitively coupled to a 5 GHz superconducting, co-planar waveguide (CPW) resonator. Recently, we have shown that it is possible to passively cool a NEMS resonator to within a few tens of quanta of its ground state, $N = 25$ [1]. By driving this coupled system at a frequency $\omega_{pump} = \omega_{CPW} - \omega_{NEMS}$, we expect to produce an active cooling process in the sideband resolved limit which in principle [2] should be capable of preparing the ground state of motion, with occupation factors $N_{\parallel} 1$. In future work, we expect to be able to demonstrate backaction evading position detection and ultimately squeezed quantum states of the mechanical device by using more advanced pumping schemes, such as double sideband pumping. [1] A. Naik et al, Nature 443, 193 - 196 (2006) [2] F. Marquardt et al, Phys. Rev. Lett. 99, 093902 (2007)

1:15PM Y15.00009 Parametric Amplification of Quantum Signals with a Josephson Ring Modulator. NICOLAS BERGEAL, FLAVIUS SCHAKERT, MICHAEL METCALFE, VLADIMIR MANUCHARYAN, RAJAMANI VIJAYARGHAVAN, MARKUS BRINK, MICHEL DEVORET, Yale University Applied Physics — Quantum Mechanics puts a limit on how small the degradation of information passing through a phase preserving amplifier can be. It is known theoretically that the minimum noise added by the amplifier to the signal amounts at least to half a photon at the signal frequency. Is it possible to construct a practical amplifier working at microwave frequencies that would reach this quantum limit? We have developed a new device aiming at answering this question, which is of practical importance for the readout of solid state qubits, and more generally, for the measurement of very weak signals in various areas of science. The device is based on a ring of four Josephson junctions which connects two microwave resonators corresponding to the signal and idler modes. It can be operated both as an amplifier and a frequency converter. Theoretical aspects and experimental results will be presented.
1:30PM Y18.00011 Impact of Atomic Gap Size on Sensitivity and Backaction of APC Displacement Detectors, N.E. FLOWERS-JACOBS, K.W. LEHNERT, JILA, NIST and the University of Colorado, and the Department of Physics, University of Colorado, Boulder, Colorado 80309-0440, USA — Recently our group created a mesoscopic displacement detector formed by coupling an atomic point contact (APC) to a nanomechanical beam and demonstrated a displacement imprecision limited by the fundamental shot-noise in the number of electrons that tunnel across the APC [1]. We continue this work by using a cryogenic apparatus that flexes the device substrate to mechanically adjust the size of the APC atomic gap 	extit{situ}. The resulting changes in the APC displacement detector’s intrinsic noise properties are measured by observing the 1 K random thermal motion of the nanomechanical beam at resonance frequencies up to 200 MHz. The goal of this work is to explore the effect of atomic gap size and shape on displacement sensitivity, understand the origin of the observed measurement backaction, and measure the recoil force of tunneling electrons. [1] N. E. Flowers-Jacobs, D. R. Schmidt, and K. W. Lehnert, \textit{Phys. Rev. Lett.} \textbf{98}, 096804 (2007)

1:51PM Y18.00012 Quantum Zeno Effect in Detection of Itinerant Microwave Photons, FERDINAND HELMER, Arnold Sommerfeld Center for Theoretical Physics, Physics Department, Center for NanoScience, Ludwig-Maximilians University Munich, Germany, MATTEO MARIANTONI, Walther Meissner Institut, Bayerische Akademie der Wissenschaften, Garching, Germany, ENRIQUE SOLANO, FLORIAN MARQUARDT, Arnold Sommerfeld Center for Theoretical Physics, Physics Department, Center for NanoScience, Ludwig-Maximilians University Munich, Germany — We analyze detection of itinerant photons using a QND measurement. We show that the backaction due to the continuous measurement poses a fundamental limit for the fidelity of detection in such a scheme. We illustrate this using a setup where signal photons have to enter a cavity in order to be detected dispersively. The measurement signal in this approach is the phase shift imparted to an intense beam passing through a second cavity mode. The restrictions on the fidelity are a consequence of the Quantum Zeno effect, and we discuss both analytical results and quantum trajectory simulations of the measurement process. Finally, we briefly mention a possible experimental realization in the context of superconducting circuit QED.

2:03PM Y18.00013 Rapid Purification protocols for Optical Homodyning, ARAVIND CHIRUVELLI, Louisiana State University, KURT JACOBS TEAM — Recently Jacobs (PRA 67 030301 (2003)) and Wiseman and Ralph (New J. Phys 8, 90(2006)) have discovered rapid purification protocols for a qubit using quantum feedback. We present these protocols in optical setting. These could also be very useful in quantum state preparation for various uses in metrology and control.

Friday, March 14, 2008 11:15AM - 2:03PM

11:15AM Y18.00001 The effect of confinement on the structure of polystyrene melt films, MRINMAY K. MUKHOPADHYAY, SUNIL K. SINHA, University of California, San Diego, CA 92093, LAURENCE B. LURIO, CURT DECARO, Northern Illinois University, DeKalb, IL 60115, ZHANG JIANG, MICHAEL SPRUNG, Advanced Photon Source, Argonne, IL 60439 — The structure factor of thin, Si supported, polystyrene films has been measured using grazing incidence wide angle diffuse x-ray scattering. Measurements were made as function of thickness and molecular weight from bulk-like films down to films of thickness of the polymer radius of gyration. A standing wave technique was employed to isolate the scattering component from the film interior. We observe a diffuse background and a liquid scattering ring whose intensity, for thick films, depends only on the magnitude of the scattering vector. In thinner films the intensity in the scattering ring is strongly concentrated along the surface normal direction. We interpret this peak as due to the chain-chain correlations and the concentration of scattering along the surface normal is indicating preferential stacking of the polymer chains parallel to the surface.

11:27AM Y18.00002 Tuning the Glass Transition Temperature over 100 K using Polymer-Polymer Interfaces, CONNIE B. ROTH, Dept. of Physics, Emory University, RODNEY D. PRIESTLEY, SOYOUNG KIM, Dept. of Chemical and Biological Eng., Northwestern University, JOHN M. TORKELSON, Dept. of Chemical and Biological Eng. and Materials Sci. and Eng., Northwestern University — During the past decade considerable research has focused on the impact of the free surface and substrate interactions on the glass transition temperature (Tg) in nanoconfined geometries. For example, the large (up to 80 K) Tg reductions that have been observed in free-standing films indicate that we still have much to learn about the nature of the glass transition. Here we focus on an entirely different kind of interface, a polymer-polymer interface, which we show can have an even stronger impact on the Tg dynamics than a free surface. We demonstrate that the interactions across a narrow polymer-polymer interface are sufficient to tune the Tg of a single polymer material by over a 100 K simply by changing the type of polymer in the adjoining layer. The cooperative segmental dynamics of the two immiscible polymers are strongly coupled over length scales of several tens of nanometers. These results have significant impact on our understanding of the glass transition in multilayer films and nanostructured polymer blends with large amounts of polymer-polymer interface. These findings also suggest new methods for controlling polymer properties in nanoconfined geometries.

11:39AM Y18.00003 The viscoelastic properties of ultrathin polymer films as measured with a novel nanobubble inflation technique, PAUL O'CONNELL, GREGORY MCKENNA, Texas Tech University — Using a nanobubble inflation technique developed within our laboratory, we have measured the absolute biaxial compliance of polymer films as thin as 11.3 nm. Previous results have shown that the degree of reduction in Tg with film thickness is not universal viz., PVAc shows no reduction even for the thinnest films while the PS shows a significant reduction at a thickness below approximately 80nm. In addition the rubbery plateau region for both materials shows dramatic stiffening as the thickness is reduced (<300 times) and scales as approximately the square of film thickness. We have extended the analysis of the data to directly determine the creep compliance function from the measured data rather than the minimization routine used previously. Creep compliance master curves constructed from data at varying thicknesses show that time-temperature superposition is valid even at the thinnest film thickness. The temperature-time shift factors are consistent with a WLF-type dependence and indicate a reduction in Tg for PS at 11.3nm of 53K while no significant reduction (< 3K) is seen for PVAc.
11:51AM Y18.00004 Fabricating Nanoscale Gratings with Gradient Pattern Height by Annealing Imprinted Polymer Patterns

YIFU DING, HYUNWOOK RO, JIRUN SUN, JING ZHOU, SHENG LIN-GIBSON, CHRISTOPHER SOLES, Polymer Division, National Institute of Standards and Technology — The evolution of nanoimprinted polymer patterns during isothermal annealing is driven by the interplay of the pattern features, material properties of the polymer, and the polymer/substrate interactions. With proper control of these factors, a range of hierarchical nanostructures can be fabricated through thermal annealing of the imprinted polymer patterns. Here we demonstrate an example of creating polystyrene (PS) gratings with gradient pattern height. This is achieved by annealing the imprinted PS gratings under a temperature gradient. In the simplest case, the pattern decay rate is determined by the viscosity and surface tension of the PS. Consequently, the degree of the gradient pattern height can be well controlled through the “fragility” of the PS, i.e., its temperature dependence of the viscosity. Such a gradient grating is extremely useful in the combinatorial studies of the effect of the surface topology on the cell behaviors and controlled wettability.

12:03PM Y18.00005 Substrate and chain size dependence of near surface dynamics of glassy polymers

DONGPING QI, University of Waterloo, ZAHRA FAKHRAAI, JAMES FORREST, University of Waterloo — We report on the application of nanohole relaxation technique to study the surface relaxation of i-PMMA thin films. This allows us to obtain the time dependent relaxation function at a number of different sample temperatures for the first 2-3 nm of the free surface. By studying the film thickness dependence of the near-free surface relaxation for films on different substrates we are able to determine the range over which the substrate directly affects the free surface relaxation. This also allows us to determine a limiting thickness where the free surface relaxation is not affected by the substrate. For such films we determine the Mw dependence of the near free surface relaxation time and find a surprising linear Mw dependence. The Mw dependence is discussed in terms of possible motions as well as polymer configurations near the free surface.

12:15PM Y18.00006 Molecular Simulation of Confined Polymer Films: Structure, Dynamics and the Glass Transition

VIKRAM KUPPA, GREGORY RUTLEDGE, Massachusetts Institute of Technology — Molecular Dynamics simulations are used to probe the structure and dynamics of polymers in extreme confinements. The simulations mimic intercalated nanocomposites in which polymer chains are trapped in nanometer sized slit pores between layered inorganic surfaces: our system consists of thin films of bead-spring chains spatially restricted in one dimension by surfaces comprised of monomer beads arranged in an FCC configuration. The responses of the system are studied as a function of slit spacing, polymer-wall interaction strength and temperature. The glass transition temperatures, as well as the fragility of the confined films are seen to increase with increasing confinement and with increasing attraction of the polymer with the confining wall.

12:27PM Y18.00007 Probing Relaxation in Glassy Freestanding Diblock Copolymer Films

ADAM N. RAEGEN, ANDREW B. CROLL, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — We employ an axi-symmetric deformation and modulus test (ADAM) to measure the response of a thin freestanding diblock copolymer film to an external load. The method measures the deformation of a spin cast film when an axi-symmetric load is applied by a flat circular punch. The flat punch minimizes uncertainties in the experiment, while the use of spin cast films provides a very smooth contact surface. The use of diblock copolymers allows us to change the internal structure of the film from disordered to ordered (lamellar) and surface topography (flat if there are an integer number of lamellae, and islands, bicontinuous or holes for non-integer) by changing the annealing history and thickness of the sample. We discuss our results in terms of the elastic modulus and creep compliance of the films.

12:39PM Y18.00008 Ellipsometric Investigation of the Surface Dynamics of a Polymer Film near the Glass Transition Temperature

ASHIS MUKHOPADHYAY, CHRISTOPHER GRABOWSKI, Wayne State University — We have investigated the surface dynamics of poly (butyl methacrylate) films by using a phase-modulated ellipsometer, which can measure thickness at angstrom-level resolutions. Experiments were performed for a range of temperatures, both above and below the glass transition temperature (Tg) of this system. Thickness-thickness correlation functions were calculated at each temperature using ellipsometry data collected at 200 Hz frequency. Our results indicate that, above Tg, the relaxation time stays relatively constant (∼1 sec) and the correlation functions obey a simple exponential decay. As Tg is approached, a dramatic increase in the relaxation time is observed and the correlation functions are best fitted with a stretched exponential Kohlraush-Williams-Watts (KWW) relation.

1:03PM Y18.00010 Suppression of the Tg-Confinement Effect in Thin Polymer Films by the Presence of an Anti-Plasticizer

SOYOUNG KIM, MANISH MUNDRA, CONNIE ROTH, JOHN TORKELSON, Northwestern University — The effect of film thickness on the glass transition temperature (Tg) of poly(vinyl acetate) supported on silica was studied via ellipsometry for films that were in the bone-dry state and also with several weight percent water sorbed into the film. The presence of water resulted in a decrease of the Tg of bulk poly(vinyl acetate) films but an increase in the density of the films. This combination of effects indicates that water acts as an anti-plasticizer in poly(vinyl acetate). We demonstrate that the bone-dry poly(vinyl acetate) films exhibit a significant reduction in Tg with decreasing film thickness below about 50 nm. In contrast, the poly(vinyl acetate films) containing several weight percent water exhibited no reduction in Tg relative to bulk Tg with decreasing film thickness down to a thickness of about 10 nm. These results are in accord with recent theoretical analysis (Riggelman et al., PRL 97, 045502 (2006)) indicating that the presence of anti-plasticizers leads to a suppression of confinement effects on the behavior of polymer films and indicate that caution should be employed when studying confinement effects in polymer systems that may sorb significant levels of water from the atmosphere.

1:21PM Y18.00011 Polymer Wall Interactions and Dynamics in Confinements

BOOA RAM CHANDRA, SUDHAMAS MITRA, VIKRAM KUPPA, GREGORY RUTLEDGE, Massachusetts Institute of Technology — Molecular Dynamics simulations are used to probe the structure and dynamics of polymers in extreme confinements. The simulations mimic intercalated nanocomposites in which polymer chains are trapped in nanometer sized slit pores between layered inorganic surfaces: our system consists of thin films of bead-spring chains spatially restricted in one dimension by surfaces comprised of monomer beads arranged in an FCC configuration. The responses of the system are studied as a function of slit spacing, polymer-wall interaction strength and temperature. The glass transition temperatures, as well as the fragility of the confined films are seen to increase with increasing confinement and with increasing attraction of the polymer with the confining wall.

1:45PM Y18.00012 Dynamic response of polymers near glass transition

JING, CHRISTIAN FRETIGNY, CNRS, PPMD TEAM — Dewetting experiments of thin polystyrene films on a liquid substrate are performed in the vicinity of the glass transition. It is shown that this technique reveals the extensional creep compliance function of the polymer. The viscosity in the flow regime is very much reduced when the film thickness becomes comparable to the gyration radius of the polymer. This long time behaviour may be associated with the large length scales involved in the viscous flow which should be modified by confinement. On the contrary, the rubbery plateau remains unaffected by the confinement up to a fraction of the coil size. This can be related to the short length scales involved in the rubber elasticity. In the viscoelastic region, physical aging of the sample is clearly evidenced: Structural recovery complicates the short times dewetting response. Preliminary results are presented of the confinement effects on aging properties of ultra thin films as revealed in this original way.
1:15PM Y18.00011 New Measurements of the Effects of Confinement on the Glass Transition Temperature of Freely Standing Polymer Films  
JOHN TORKELSON, SOYOU NG KIM, CONNIE ROTH, Northwestern University — Pioneering work by the Dutcher group (PRL 77, 2002 (1996)) a dozen years ago led to the first measurement of the T<Tg effect in freely standing polymer films. Their studies were especially intriguing because of the observations of very large Tg reductions relative to bulk Tg and a strong molecular weight dependence of the Tg-confinement effect. Such a molecular weight dependence is absent in the Tg-confinement effect of supported polymer films. Because of experimental difficulties associated with freely standing films, especially when the films are less than 100 nm thick, only a few related experiments have been reported by other research groups. Here we describe new results involving the measurement of Tg via the temperature dependence of fluorescence intensity of dyes labeled at trace levels to the polymer chains. Present measurements on freely standing films of poly(methyl methacrylate) (PMMA) have demonstrated reductions in Tg relative to bulk values of 20 to 25 K in films of 25-40 nm thickness. Tg reductions of at least 5 K are observed when PMMA films are 80 nm thick. Studies are also underway with polyurethane films and with polymers of different molecular weight.

1:27PM Y18.00012 Glass transition in ultra thin polymeric films measured by differential AC-Chip calorimetry  
H. HUTH, A. MINAKOV, C. SCHICK, University of Rostock, Institute of Physics, Uniplate 3, 18051 Rostock, Germany — The film thickness dependence of glass transition in polymer films is still controversially discussed. For different experimental probes different dependencies are observed and a generally accepted link to molecular mobility is not yet established. Calorimetry has proven to provide useful information about glass transition, because it establishes a direct link to energetic characterization. In several cases a direct comparison with results from other dynamic methods like dielectric spectroscopy is possible giving further insights. For thin films in the μm...nm range standard calorimetric methods are mostly not applicable. In the recent years there are new developments in the field of calorimetry which overcome these limitations. We set up a differential AC-chip calorimeter capable to measure the glass transition in nanometer thin films with pJ/K sensitivity. Changes in heat capacity can be measured for sample masses below one nanogram even above room temperature as needed for the study of the glass transition in nanometer thin polymeric films. The glass transition in thin films was determined at well defined experimental time scales. No thickness dependency of the glass transition temperature was observed within the error limits - neither at constant frequency nor for the traces in the activation diagrams.

1:39PM Y18.00013 Relaxation Kinetics of Nanostructures on Polymer Surface: Effect of Orientation, Spacial Confinement, and Chain Mobility  
H.G. PENG, Y.P. KONG, A.F. YEE, Depart. of Chemical Engineering and Materials Science, Univ. of California, Irvine — Nanostructures provide an opportunity for studying relaxation and chain dynamics of polymers when the radius of gyration is not small compared with the dimension of the structure. PS (PDI=1.03-1.05, Mw=6.4 to 1571 kg/mol) gratings of varying line-widths (600 nm, 270 nm, and 30 nm) were fabricated by nanoimprint lithography. When annealed at T ~ bulk Tg, the grating height monitored with an AFM relaxes as surface tension and other driving forces overcome the polymer viscosity. The temperature for rapid relaxation decreases as the feature size diminishes for all molecular weights (MWs), but a simple explanation based on surface enhanced mobility fails to explain the results. The residual molecular orientation effect is identified as the main relaxation driving force for gratings of MWs much larger than the entanglement MW. Comparison between the various nanostructure sizes allows to observe the spatial confinement effect and to determine whether a thin mobile surface layer exists.

Friday, March 14, 2008 11:15AM - 2:03PM  
Session Y22 DPOLY: Interfaces and Adhesion II  
Morial Convention Center 214

11:15AM Y22.00001 Polymer monolayer - substrate adhesion strength  
MOSHE GOTTLIEB, HAIM DVIR, Ben-Gurion University — Polymer monolayers have been deposited on several chemically different solid substrates. The substrates ranged from hydrophobic to hydrophilic and from chemically inert to highly reactive. In addition few of the surfaces were also exposed to ionizing irradiation. The extent of surface coverage and surface topology were experimentally determined for the different surfaces and polymers. The adsorbed layer thickness was determined optically. The strength of polymer interaction with the substrate was investigated using contact-mode Atomic Force Microscopy. Typically, for each polymer a characteristic layer thickness was measured irrespective of the nature of the surface or strength of the polymer-surface adhesion. Adhesion strength was attributed mainly to van der Waals interactions with no indications of large scale covalent bonding between the polymer and the substrate. Hydrophobic interactions, surface topology, and initial conditions existing during film deposition seem to dominate the interaction between the polymer and the substrate.

11:27AM Y22.00002 Role of Interfacially Active Diblock Copolymers toward Controlling the Glass Transition of Thin Polymer Films  
HYUNJOON OH, PETER GREEN, University of Michigan, Ann Arbor — We show that small concentrations of polystyrene-b-poly(methylmethacrylate) (PS-b-PMMA) diblock copolymers significantly alter the thickness, h, dependence of the glass transition temperature as needed for the study of the glass transition in nanometer thin polymeric films. The glass transition in thin films was determined at well defined experimental time scales. No thickness dependency of the glass transition temperature was observed within the error limits - neither at constant frequency nor for the traces in the activation diagrams.

11:39AM Y22.00003 Weak interfaces for UV cure nanoimprint lithography  
FRANCES HOULE, ANN FORNO, IBM Almaden Research Center, EVA SIMONYI, IBM T.J. Watson Research Center, DOLORES MILLER, HOA TRUONG, IBM Almaden Research Center — Nanoimprint lithography using a photocurable organic resist provides a means of patterning substrates with a spatial resolution in the few nm range. The usefulness of the technique is limited by defect generation during template removal, which involves fracture at the interface between the template and the newly cured polymer. Although it is critical to have the lowest possible interfacial fracture toughness (Gc less than 0.1 Jm-2) to avoid cohesive failure in the polymer, there is little understanding on how to achieve this using reacting low viscosity resist fluids. Studies of debonding of a series of free-radical cured polyhedral silesquioxane crosslinker formulations containing selected reactive diluents from fluorosilane-coated quartz template materials will be described. At constant diluent fraction the storage modulus of cured resists follows trends in initial reaction rate, not diluent Tg. Adhesion is uncorrelated with both Tg and storage modulus. XPS studies of near-interface compositions indicate that component segregation within the resist fluid on contact with the template, prior to cure, plays a significant role in controlling the fracture process.
11:51AM Y22.00004 Spincoating of ultrathin chitosan films . CHRIS MURRAY, JOHN DUTCHER, University of Guelph — We have studied the spincoating of ultrathin chitosan films onto silicon wafer substrates from dilute solutions of chitosan dissolved in acetic acid solutions. This particular example of spincoating presents unique difficulties due to the non-volatility of the solvent, but also provides unique information since the spincoating process is slow enough to allow detailed measurements of the drying of the film. The resulting film thickness, as measured using ellipsometry, is a strong function of the relative humidity (RH) in the surrounding atmosphere, which can be easily controlled. By using a simple model for the dependence of film thickness on spin speed and RH, we obtain a measure of water uptake in chitosan films that can be compared with that estimated from sorption isotherms measured using ellipsometry.

12:03PM Y22.00005 Protein Diffusion at the Interface of Responsive Polymer Thin Films . SHENGQIN WANG, YINGXI ELAINE ZHU, Dept. of Chemical and Biomolecular Engineering, Univ. of Notre Dame, IN — Protein adhesion at polymer interfaces has been much explored, yet the interfacial friction is not. We employ fluorescence correlation spectroscopy (FCS) and single-molecule imaging to examine the translational dynamic processes of proteins at the responsive polymer interfaces, whose surface hydrophobicity and interfacial viscoelasticity are tunable experimentally. We focus on the dynamics of human serum albumin (HSA) and lubricin, a nutritious protein in synovial fluids, at the interface of responsive poly(N-isopropylacrylamide) (PNIPAM) brush layers. The effects of PNIPAM brush thickness, grafting density, and surface hydrophobicity on protein interfacial diffusivity are investigated. We observe the coupling of the local protein dynamics at the protein-PNIPAM interfaces with the interfacial viscoelasticity of PNIPAM brush thin films.

12:15PM Y22.00006 Structure and dynamics of molecules undergoing lubricated sliding . VIVEK PRABHU, SHUHUI KANG, KRISTOPHER LAVERY, NIST, KWANG-WOO CHOI, NIST, Intel Corp., WEN-LI WU, ERIC K. LIN, NIST — Polymer thin films are used as imaging layers for photolithography to define high spatial resolution features for the semiconductor industry. These chemically amplified photoresist materials, however, may be reaching their intrinsic limits as desired feature sizes approach macromolecular dimensions. A photocatalyzed reaction defines a chemical image which is subsequently resolved by dissolution in an aqueous base solution. A method to characterize the reaction-diffusion process was developed using infrared spectroscopy and tested by neutron reflectivity. We determine the thin film reaction kinetics, photocatalysis trapping behavior, and photoacid diffusivity by measuring the reaction kinetics. The temperature-dependent reaction rate and mechanism for observed pinning of the reaction-diffusion front will be discussed. These results predict the increase of the latent image formation which is a crucial step in photolithography resolution and fidelity.

12:27PM Y22.00007 Measurement advances to follow polymer thin film reaction-diffusion processes . LILIN HE, Clemson University — THUSITHA, ETAMPAWALA DVORA, PERAHIA Department of Chemistry, Clemson University, Clemson, SC 29634 JAROSLAW MAJEWSKI, Lujan Neutron Scattering Center, Los Alamos National Laboratory, Los Alamos, NM 87545 CHRISTOPHER J. CORNELIUS Sandia National Laboratories, MS 0886, Albuquerque, New Mexico 87185-0886 The penetration of solvent into a polymer that consists of incompatible groups is determined by the specific interactions with the guest molecule, where interfacial structure and dynamics of the polymer affect the onset of the process. The current work presents a neutron reflectometry study of the penetration of methanol into sulfonated polyphenylene thin films. The imonomer films were exposed to saturated deuterated methanol vapor and reflectometry patterns were recorded until equilibrium was reached. The process incorporates two stages where the vapors first wet the surface and then penetrate into the film. Significant swelling takes place as soon as the film is exposed to the vapors. Similar to previous studied in water, the onset diffusion is Fickian followed by an anomalous diffusion process. The entire process is faster than that observed for water.

12:39PM Y22.00008 Methanol Diffusion into Thin Ionomer Films: An in situ Study Using Neutron Reflectometry . LILIN HE, Clemson University — THUSITHA, ETAMPAWALA DVORA, PERAHIA Department of Chemistry, Clemson University, Clemson, SC 29634 JAROSLAW MAJEWSKI, Lujan Neutron Scattering Center, Los Alamos National Laboratory, Los Alamos, NM 87545 As the temperature increases, the polymer and its solvent will diffuse into each other, and the polymer film will expand and contract. The penetration of solvent into a polymer that consists of incompatible groups is determined by the specific interactions with the guest molecule, where interfacial structure and dynamics of the polymer affect the onset of the process. The current work presents a neutron reflectometry study of the penetration of methanol into sulfonated polyphenylene thin films. The imonomer films were exposed to saturated deuterated methanol vapor and reflectometry patterns were recorded until equilibrium was reached. The process incorporates two stages where the vapors first wet the surface and then penetrate into the film. Significant swelling takes place as soon as the film is exposed to the vapors. Similar to previous studied in water, the onset diffusion is Fickian followed by an anomalous diffusion process. The entire process however is faster than that observed for water.

12:51PM Y22.00009 Pattern formation in dewetting Nanoparticle/Polymer Bilayers . ALAN ESKER, RITUPARNA PAUL, UFUK KARABIYIK, MICHAEL SWIFT, JOHN HOTTLE, Virginia Tech — Comprised of inorganic cores and flexible organic coronae with 1 – 2 nm diameter monodisperse sizes, polyhedral oligomeric silsesquioxanes (POSS) are ideal model nanofillers. Our discovery that one POSS derivative, triisopropanol-POSS (TPP), can form Langmuir-Blodgett (LB) films on hydrophobic substrates, allows us to create thin film bilayers of precisely controlled thickness and architecture. Work with poly(t-butylacrylate) (PtBA)/TPP bilayers reveals a two-step dewetting mechanism in which the upper TPP layer dewets first, followed by the formation of isolated holes with intricate, fractal, nanofiller aggregates. Like the PtBA/TPP bilayers, poly(styrene) (PS)/TPP bilayers also undergo a two-step dewetting mechanism. However, the upper TPP layer initially forms cracks that may arise from mismatches in thermal expansion coefficients. These cracks then serve as nucleation sites for complete dewetting of the entire bilayer. Understanding the rich diversity of surface patterns that can be formed from relatively simple processes is a key feature of this work.

1:03PM Y22.00010 Case II diffusion and solvent-polymer films drying: a meso-scale model . DIDIER LONG, CNRS/Université de Paris Sud, MIREILLE SOUCHE, Université de Paris sud — This model is based on the fact that dynamics in liquids close to the glass transition is spatially heterogeneous [Ediger2000,Souche2007], with characteristic size 3 to 4nm in van der Waals liquids. Before considering large scale diffusion experiments, we consider first the evolution of the dynamics of a layer of thickness 3 to 4nm, submitted to an arbitrary time varying activity $a(t)$. This procedure allows in principle to calculate a constitutive relation for the dynamics of solvent-polymer mixtures, that can then be used for calculating the evolution of macroscopic samples in contact with a reservoir of solvent. We show how these constitutive relations allow for explaining case-II diffusion in glassy polymers and provide a physical interpretation for the parameters of the Thomas-Windle model. Regarding the process of film drying, we show that films up to 1 micrometer thick can be almost completely dried in an accessible experimental time, even at temperatures well below the polymer glass transition temperature. This is a consequence: 1- of the presence of the fast path 2- of the film being out equilibrium, and in a dynamical state which is much faster than the one it would have at equilibrium. When drying a thicker film, we show that a glassy crust may appear on the free surface, as has been shown experimentally. Ediger M.D., Annu. Rev. Chem., 51 (2000) 99; Souche M. and Long D., Europhys. Lett., 77 (2007) 48002.
1:15PM Y22.00011 Non solvent-induced dewetting of thin polymer films1. TONG-FEI SHI, LIN XU, LI-JIA AN — The dewetting of thin liquid films is important to various technological processes. Most of the studies on dewetting are through thermal dewetting, whereas solvent-induced dewetting has received very little attention. Generally the main difference between thermal dewetting and solvent-induced dewetting is that the cause of instability is the long-range force of van der Waals interactions in the thermal dewetting whereas it is the short-range force of polar interactions in the solvent-induced dewetting. In these reports on solvent-induced dewetting, nearly all solvents, which are chosen, can dissolve the polymers. However, few reports focus on the dewetting induced by non solvent, which cannot dissolve polymer. In this work, the process of non solvent-induced dewetting of thin polystyrene (PS) films on hydrophilic surfaces at room temperature has been studied by using water as a non solvent. It is observed that the process of non solvent-induced dewetting is greatly different from other previous dewetting processes. The PS film is in non-viscous state. A mechanism of non solvent-induced dewetting, different from other previous dewetting mechanisms, is deduced: penetration, replacement and coalescent.

---

1:27PM Y22.00012 Mechanical Properties of Thin Polymer Films Studied by Atomic Force Microscopy, BLANDINE JEROME, LPMCN Lyon (F) & LBNL Berkeley, CHRISTIAN VIALLETON, LPMCN & MATEIS-INS Lyon (F), LAURENT CHAZEAU, MATEIS-INS Lyon (F), ELISABETH CHARLAIX, LPMCN Lyon (F) — Introducing inorganic nanoparticles into a polymer is known to modify the macroscopic mechanical properties of the material. This is often interpreted by assuming the presence of a polymer layer with different properties at the interface with the particles. There is however little direct information available on the mechanical properties of such an interfacial layer. We have used an Atomic Force Microscope (AFM) as a nano-indentor to probe the mechanical response of thin poly(styrene butadiene) random copolymers deposited on oxidized silicon wafers (model silica surface). Indentations were performed at different approach and retraction speeds at room temperature (polymer in the rubbery state) on films with thicknesses ranging from 40nm to 500nm. Approach and retraction curves obtained at high speeds are characteristic of the indentation of an elastic material with an adhesive tip/polymer contact. At low speeds, the adhesion forces dominate for low applied forces, while the elasticity of the polymer dominates the behaviour at high applied load. This allows us to separate the mechanical response of the polymer film from the tip-polymer adhesion that involves some dissipation taking place close to the contact line between the polymer free surface and the tip.

---

1:39PM Y22.00013 Molecular Dynamics Simulations of Adhesion at Epoxy Interfaces, SARAH-JANE FRANKLAND, THOMAS CLANCY, National Institute of Aerospace, THOMAS GATES, NASA-LaRC — With composite materials becoming more prevalent as metal parts are being replaced on aircraft, adhesives are being developed for composite bonds which are suitable for the various thermal, mechanical and environmental changes that take place over the lifetime of the aircraft. The key molecular structure-property relationships that enable the chemical compatibility of the adhesive with the adherend can be identified with molecular dynamics simulation (MD). MD can assess the role of different chemical moieties in the adhesive, and their behavior in the presence or absence of solvents under different thermo-mechanical conditions. In the present work, MD simulations are used to calculate factors that affect the work of adhesion with and without solvent present. MD simulations are carried out at the interface between components of epoxy-based adhesives and composite adherends. The simulations utilize molecular models of networks which are representative of specific chemistries of the epoxy system. The simulations include both bulk and interface models of the components. The paper will present the simulation methodology, and the results for the work of adhesion.

---

1:51PM Y22.00014 Interfacial Properties of Polydimethylsiloxane-Water Systems1, AHMED E. ISMAIL, GARY S. GREST, MARK J. STEVENS, Sandia National Labs, MESFIN TSIGE, Southern Illinois University at Carbondale, DAVID R. HEINE, Coming — Polydimethylsiloxane (PDMS) is a main constituent of silicone adhesives, which have a wide use as adhesives. Often these adhesives are used as sealants. The interaction between water and PDMS is of fundamental importance. To improve our understanding at the molecular level, we have performed molecular dynamics (MD) simulations of PDMS in the presence of water, with the long-term goal of studying how water molecules affect the mechanical behavior of PDMS at the surface. Knowledge of the basic interfacial properties of a multicomponent system, such as the surface tension, contact angle, and diffusion constant, are essential to obtain the proper dynamic behavior in a molecular simulation of adhesion and wetting processes. Explicit-atom simulations of 101 or more atoms were used to determine liquid-vapor surface tension and the contact angle for water on the surface of PDMS. We present results for the dependence of the surface tension on chain length and end-group functionality.

Friday, March 14, 2008 11:15AM - 1:15PM – Session Y23 DMP GMAG: Focus Session: Electronic Structure of Complex Oxides Morial Convention Center 215

11:15AM Y23.00001 Magnetic Moment Collapse-Driven Mott Transition in MnO1, JAN KUNES, University of Augsburg — Metal-insulator transition in strongly correlated electron systems has been one of the central themes of condensed matter physics for a few decades. In the simplest model system, the single band Hubbard model, the transition, which is still not completely understood, is driven by the ratio of the on-site repulsion to the bare bandwidth. Real materials with multiple bands offer possibility of alternative scenarios of the metal-insulator transition. In this talk we will present a numerical study of MnO under high pressure using combination of the standard bandstructure theory and modern many-body methods (dynamical mean-field theory). Our results reveal a close relationship between the high-spin to low-spin transition and metallization, which can be interpreted as the moment collapse driving the metallization. We find an inosstructural volume collapse of about 13% accompanying the transition. While the moment collapse, which is essentially an atomic effect, is obtained by most electronic structure methods, the metal-insulator transition can be described reliably only when dynamical correlations are taken into account. We find our results to compare very well to the available experimental data. In order to demonstrate the capability of the computational method PES and ARPES spectra obtained on the related NiO with and without hole doping will also be presented.

11:51AM Y23.00002 Origin of magnetism in the Fe$_2$O$_3$–FeTiO$_3$ system from correlated band theory$^1$. ROSSITZA PENTCHEVA, HASAN SATAD NABI, University of Munich — The high remanent magnetization measured in ex-solutions of the canted antiferromagnet hematite (Fe$_2$O$_3$) and room-temperature paramagnet ilmenite (FeTiO$_3$) has recently received considerable attention not only in the geoscience community [1] but also for possible spintronics applications. To resolve the microscopic origin of magnetism in this system, we have performed density functional theory calculations, varying systematically the concentration, distribution, and charge state of Ti (Fe) in a hematite (ilmenite) host. We find that including electronic correlation within the LDA+U approach is decisive to obtain the correct ground state of the end members, α-Fe$_3^+$O$_2$ and Fe$^{2+}$Ti$^{4+}$O$_3$. In a single Ti layer in the hematite host, Ti is not inert as commonly assumed but plays an active role in compensating the charge mismatch at the interface and the emergence of magnetism and the preferred charge state is Ti$^{3+}$, Fe$^{4+}$. As soon as a thicker ilmenite-like block forms, the most favorable compensation mechanism is through Ti$^{2+}$ and a disproportionation in the Fe contact layer in Fe$^{2+}$, Fe$^{3+}$ giving theoretical evidence for the lanellar magnetism hypothesis [1]. The substitution of Ti (or Fe) in Fe$_2$O$_3$ (FeTiO$_3$) leads to impurity levels in the band gap and in some cases to half-metallic behavior.

12:03PM Y23.00003 Electronic structure of Mn and Fe oxides, WALTER HARRISON, Stanford University — We present a clear, simple tight-binding representation of the electronic structure and cohesive energy (energy of atomization) of MnO, Mn$_2$O$_3$, and MnO$_2$, in which the formal charge states Mn$^{2+}$, Mn$^{3+}$, and Mn$^{4+}$, respectively, occur. It is based upon localized cluster orbitals for each Mn and its six oxygen neighbors. This approach is fundamentally different from local-density theory (or LDA+U), and perhaps diametrically opposite to Dynamical Mean Field Theory. Electronic states were calculated self-consistently using existing parameters [1], but it is found that the charge density is quite insensitive to charge state, so that the starting parameters are adequate. The cohesive energy per Mn is dominated by the transfer of two s electrons to oxygen p states, the same for all three compounds. The differing transfer of majority d electrons to oxygen p states, and the coupling between them, accounts for the observed variation in cohesion in the series. The same description applies to the perovskites, such as La$_2$Sr$_{1-x}$MnO$_3$, and can be used for FeO, Fe$_2$O$_3$ (and FeO$_2$); Because the formulation is local, it is equally applicable to impurities, defects and surfaces.

12:15PM Y23.00004 Configurational Electronic Entropy and the Phase Diagram of Mixed-Valence Oxides: The Cases of Li$_2$FePO$_4$ and Fe$_2$O$_3$$^4$. FEI ZHOU, Materials Science and Engineering, MIT, THOMAX MAXISCH, GERBRAND CEDER — We demonstrate that configurational electronic entropy, previously neglected, is a new factor controlling the final-temperature phase stability of mixed-valence oxides, in our case Li$_2$FePO$_4$. First-principles LDA+U calculations were performed on 245 Li$_2$FePO$_4$ structures with different lithium/vacancy and electron/hole distributions, and Monte Carlo simulations were used to determine the phase diagram based on a coupled cluster-expansion model. While transformations from low-T ordered or immiscible states are almost always driven by configurational disorder (i.e. random occupation of lattice sites by multiple species), in FePO$_4$–LiFePO$_4$ the formation of a solid solution is almost entirely driven by electronic, rather than ionic configurational entropy. We argue that such an electronic entropic mechanism, rather than an ionic one, may be relevant to most other mixed-valence systems. Details in Phys. Rev. Lett. 97, 155704 (2006). Recently we have studied the Verwey transition in magnetite Fe$_3$O$_4$. The configurational entropy of the $t_{2g}$ electrons on the iron B sub-lattice is found to lead to a first-order phase transition, although the mechanism is substantially more complicated than that Verwey originally proposed.

12:27PM Y23.00005 Can pristine semiconducting oxides be ferromagnetic? HAO HONG NGUYEN, Laboratoire LEMA, UMR 6157 CNRS, Université F. Rabelais, Tours, France, A. BARLA, CELLS-ALBA, Barcelona, Spain, J. SAKAI, Lab. LEMA, QUE HUONG NGUYEN, Marshall University, Huntington, WV 25701 — The recent finding of FM in HfO$_2$ thin films of Coey's group has urged us to re-judge the role of TM doping in introducing FM into semiconducting oxides. Our observation of FM in undoped TiO$_2$, HfO$_2$, In$_2$O$_3$, ZnO, and SnO$_2$ confirmed that magnetism is possible in pristine oxide thin films, and FM is likely due to oxygen vacancies. This assumption is confirmed by our XMCD measurement on TiO$_2$ films: The FM in TiO$_2$ films is indeed intrinsic, and stems from both O-2p and Ti-3d electrons. In semiconducting oxides, the origin of magnetism is not due to the doping, but oxygen vacancies/defects. A big issue is how to find a more appropriate model to explain the behavior of the mechanism. We propose a model based on an electronic structure calculation using the tight binding method in the confinement configuration. Vacancy sites in TiO$_2$, HfO$_2$, In$_2$O$_3$ films could create spin splitting and high spin state, so that the exchange interaction between the electrons surrounding the oxygen vacancy with the local field of symmetry could lead to a FM ground state. Calculations give the results of 3.18 $\mu_B$/vac for TiO$_2$, 3.05 $\mu_B$/vac for HfO$_2$ and 0.16 $\mu_B$/vac for In$_2$O$_3$. This model suggests that confinement effects play an important role in shaping up magnetic properties of low dimension systems.

12:39PM Y23.00006 Charge regulation via a negative feedback: transition metal atoms in semiconductors and insulators$^1$. HANNES RAEBIGER, STEPHAN LANY, ALEX ZUNGER, NREL, Golden, CO 80401 — Transition metal (TM) atoms in semiconductors and insulators produce energy levels in the band gap, whose occupation can be altered by shifting the Fermi level e.g. via doping. Changes in level occupation correspond to changes in the formal oxidation state. Such changes are associated with inward/outward lattice relaxations recorded as "ionic radii," different magnetic moments, and a core shift in x-ray photoemission. We show, via density-functional calculations within the plane-wave supercell method for TM atoms including Cr, Mn, Fe, and Co in the semiconductor hosts GaAs and Cu$_2$O, as well as in the ionic insulator host MgO, that changes in gap-level occupation result in only very small changes of charge on the TM atom itself. We show that this is due to an inherent negative feedback that regulates the TM charge via a TM–ligand rehybridization. Further, the inward/outward lattice relaxations and XPS core shifts, often associated with a change of the TM charge, in fact follow from the TM–ligand rehybridization, as the TM charge is kept unchanged via the inherent negative feedback.

12:51PM Y23.00007 Electronic Structure of Cubic Copper Monoxide, P.M. GRANT, W. SIEMONS, G. KOSTER, R.H. HAMMOND, T.H. GEBALLE, Stanford University — We report the calculation of the band structure and optical properties of the rocksalt form of copper monoxide. Although this particular crystal structure does not exist in bulk form for CuO, at least two groups, including ourselves, have succeeded in growing by "forced epitaxy," several atomic layers of cubic CuO on rocksalt proxy substrates such as MgO and STO. For our computation, we employed the DFT/LDA+U method known to give valid results for rocksalt NiO and FeO. Our results show cubic CuO, like these two materials, to be an antiferromagnetic Mott-Hubbard insulator whose band gap is primarily determined by charge transfer between filled O 2p bands and empty Cu 4s states, with localization of the Cu 3d hole by on-site coulomb repulsion frustrating what otherwise would be metallic behavior. We compare our results with NiO, FeO and the natural form of CuO found in the monoclinic mineral tenorite.
The spin-ladder compound Sr$_2$Cu$_2$O$_2$Cl$_2$ has a complex phase diagram including charge-density-wave order as well as unconventional superconductivity under high pressure. Due to its quasi-one-dimensional nature, fundamental questions about the high-$T_c$ cuprates might be more easily addressed in this context. However, due to the spatial proximity of neighboring ladders inter-ladder Coulomb repulsion as well as hopping between ladders might still be important. Using the functional renormalization group, we study a model of coupled Cu$_2$O$_2$ ladders. We investigate instabilities towards charge, spin, and pairing order as a function of hole doping, inter-ladder hopping, and interaction strength starting from experimentally relevant hopping parameter.\[1\]

Session Y24 DCMP: Nanotube Devices and Applications

Friday, March 14, 2008 11:15AM - 2:15PM –

11:15AM Y24.00001 Self-Assembled, Self-Aligned Carbon Nanotube Thin Film Transistors

MICHAEL ENGEL, JOSHUA SMALL, YU-MING LIN, IBM T. J. Watson Research Center, ALEX GREEN, MARK HERSAM, Northwestern University, PHAEDON AVOURIS, IBM T. J. Watson Research Center — Carbon nanotube field-effect transistors (FETs) were fabricated and studied, and transistors (FETs) were fabricated and studied, and transistors in which there are no detectable secondary phases and the Curie temperature ($T_c$) is higher than 400 K. Single Mn$_x$Ge$_{1-x}$ nanowires could be the promising building blocks for both electrical and fundamental questions about the high-$T_c$ superconductors.

Carbon nanotubes used in this study have been purified and separated by their electronic structure, where the semiconducting tube percentage is as high as 99%, confirmed by both transport measurements on individual nanotubes and by optical absorption spectra. Through a simple self-assembly technique, we have produced aligned nanotube arrays. Thin film transistors based on these aligned nanotube arrays are fabricated with both back- and top-gate layouts, showing good switching performance and a high drive current. It is found that top-gated and back-gated devices exhibit distinct switching behaviors due to screening effects. Results on device channel length dependence will also be presented.

HOOTAN FARHAT, HYUNGBIN SON, YING FENG, MILDRED DRESSELHAUS, JING KONG, MIT — Heat dissipation is an important concern for nanoscale electronic devices. Freely suspended carbon nanotubes experience self heating during electron transport due to a lack dissipation channels for acoustic phonon\[1\]. Nanotubes lying on a SiO$_2$ substrate, however, are often assumed to be in good thermal contact with the underlying substrate \[2\]. In this work we show that there is substantial self-heating in nanotubes lying on a SiO$_2$ substrate. We use Raman spectroscopy to monitor the temperature of carbon nanotube field-effect transistors (FETs) as a function of the applied bias voltage. The temperature is determined from the shift in frequency and the broadening of the high energy Raman modes. Our results suggest that nanotubes FETs on a substrate can reach temperatures upwards of 700K before saturation. \[1\] Pop et al., PRL 95, 155505 (2005) \[2\] Lazzeri et al., PRB 73, 165419 (2006)

11:39AM Y24.00003 Gate-all-around carbon nanotube field-effect transistor

ZHIHONG CHEN, DAMON FARMER, IBM T.J. Watson Research Center, SHENG LIU, ROY GORDON, Department of Chemistry and Chemical Biology, Harvard University, PHAEDON AVOURIS, IBM T.J. Watson Research Center, JOERG APPIENZELLER, School of Electrical and Computer Engineering, Purdue University — The ultra-thin body of carbon nanotubes allows for aggressive channel length scaling while maintaining excellent gate control. In general, a gate-all-around (GAA) structure is expected to be the ideal geometry that maximizes electric field control in FETs. Combining the ultra-thin body of a carbon nanotube with a GAA device geometry is a natural choice for ultimate device design. In this talk, we demonstrate a gate-all-around single wall carbon nanotube field-effect transistor. This is the first successful experimental implementation of an off-chip gate and gate-dielectric assembly with subsequent deposition on a suitable substrate.

11:51AM Y24.00004 MnxGe1-x nanowires field-effect transistor for spintronics applications\[1\].

XINHAN HAN, MASAAKI OGAWA, MINSHEUNG WANG, KANG L. WANG, JUSTIN D. HOLMES, University of California, Los Angeles — Group IV Dilute Magnetic Semiconductors (DMS) materials attract much attention not only because of the potential for integration of DMSs with current COMS technology, but also the enhanced spin lifetime and coherent length due to small spin-orbit coupling and lattice inversion symmetry. On the other hand, nanowires are the versatile building blocks for the assembly of functional devices to do fundamental studies in nanoscale. Here we presents Mn$_x$Ge$_{1-x}$ (Mn ~ 0.5-1%) nanowires in which there are no detectable secondary phases and the Curie temperature ($T_c$) is higher than 400 K. Single Mn$_x$Ge$_{1-x}$ nanowire back gated field effect transistors (FETs) were fabricated and studied, and p-type depletion mode was observed with an on/off ratio of 10$^4$, threshold voltage of ~ 0.53 V, maximum transconductance of 0.2 $\mu$S, and subthreshold swing (SS) of 210 mV/decade. The mobility was estimated to be around 340 cm$^2$/Vs. These results show the high performance of our Mn$_x$Ge$_{1-x}$ nanowire FET, which indicates the Mn$_x$Ge$_{1-x}$ nanowires could be the promising building blocks for both electrical and spintronics devices.

12:03PM Y24.00005 Transient Random Telegraph Signal in carbon nanotube field effect transistors\[1\], TSZ-WAH CHAN, BRIAN BURKE, KENNY EVANS, KEITH WILLIAMS, Department of Physics, University of Virginia — We have studied transient Random Telegraph Signal (RTS) induced in carbon nanotube-channel field effect transistors (FETs) by operating them at high bias. RTS arises from the population and depopulation of charge traps at specific energies that are scanned by sweeping the gate in a FET. At high bias, surface adsorbates/dopants interact with the SWNT and produce transient charge traps, which are manifest in the RTS signature. Transient RTS has been seen at temperatures from 200K up to room temperature. We speculate that RTS spectra could provide a characteristic signature of specific adsorbates or adducts on the nanotube channel. This capability is of interest not only for potential sensing technology but also provides a way to introduce controllable quantum interference resonances in the channel transport.

12:15PM Y24.00006 Large oscillating non-local voltage in multi-terminal single wall carbon nanotube devices\textsuperscript{1}, GUNNAR GUNNARSSON, University of Basel, JELENA TRBOVIC, University of Basel, CHRISTIAN SCHOENENBERGER, University of Basel, UNIVERSITY OF BASEL TEAM — Spin field-effect transistor has been recently realized in single wall carbon nanotube (SWCNT) devices contacted with NiPd alloy \cite{1}. In order to separate charge related effects from that of pure spin transport we measure a non-local voltage in SWCNTs by using a four-terminal structure. The four contacts divide the tube into three quantum dots (QD) which we control by the back-gate voltage $V_g$. We inject the current through the first QD by using excitation voltage of 200 $\mu$V and measure the non-local signal $V_{nl}$ across the third QD. We measure large oscillating non-local voltage as a function of $V_g$ with amplitude of $V_{nl} \sim 2\mu$V \cite{2}. While the classical resistor model can account for the negative sign of the non-local voltage its large amplitude means need deeper understanding. We discuss the origin of this large non-local signal and its effect on the non-local spin transport measurements in this type of devices. \cite{1} S. Sahoo, et al. Nature Phys. 1 99 (2005). \cite{2} G. Gunnarsson et al., arXiv:0710.0365v1.

12:27PM Y24.00007 Probing the electrostatics of a metal-carbon nanotube Schottky diode using capacitive measurements, YU-CHIH TSENG, JEFFREY BOKOR, UC Berkeley — Capacitance-voltage measurement is a technique widely used to characterize metal-semiconductor contacts. We apply this technique to measure the capacitance-voltage across a p-type Schottky contact formed by titanium and a semiconducting carbon nanotube. Ohmic and Schottky contacts are made on the nanotube using palladium and titanium, respectively. The results agree qualitatively with simulations done using a Poisson-Schroedinger solver, considering only the electrostatics. We found additional frequency-dependent effects in the capacitance measurement that indicate the presence of electronic states arising from adsorbates or defects on the length of the nanotube.

12:39PM Y24.00008 Hypergolic fuel detection using Single Walled Nanotube Networks, SHARVIL DESAI, Dept. of Physics and Electrical and Computer Engg., University of Louisville, Louisville, KY, KAPILA HEWAPARAKRAMA, Dept. of Physics, University of Louisville, Louisville, KY, GAMINI SUMANASEKERA, Dept. of Physics and Electrical and Computer Engg., University of Louisville, Louisville, KY — Reliable and accurate detection of hypergolic fuels is vital to U. S. Missile Defense Agency. In this research a simple and highly sensitive SWNT network sensor was developed for real time monitoring of hydrazine leaks to ppm level concentrations. Upon exposure to hydrazine vapor, the resistance of n-type (after degassing) nanotubes is observed to decrease rapidly. The response time exhibits a linear dependence on the concentrations of the vapor. It was also found that the resistance of the sample can be recovered by pumping on the sample and exposing to UV light. The experimental results support chemical adsorption of hydrazine on SWNTs. Theoretical results of hydrazine-SWNT interaction \cite{1} are compared with the experimental observations. Results of similar study on ammonia, dimethyl hydrazine, and naphthalene will also be presented. \cite{1} Min Yu, C. S. Jayanthi, Shi-Yu Wu, APS 2008

12:51PM Y24.00009 Electrically Tunable Spin Polarization in a Carbon-Nanotube Spin Diode, CHRIS MERCHANT, NINA MARKOVIC, Johns Hopkins University — We have studied the current through a carbon nanotube quantum dot with one ferromagnetic and one normal-metal lead. For the values of gate voltage at which the normal lead is resonant with the single available non-degenerate energy level on the dot, we observe a pronounced decrease in the current for one bias direction. We show that this rectification is spin-dependent, and that it stems from the interplay between the spin accumulation and the Coulomb blockade on the quantum dot. Our results imply that the current is spin-polarized for one direction of the bias, and that the degree of spin polarization is fully and precisely tunable using the gate and bias voltages. As the operation of this spin diode does not require high magnetic fields or optics, it could be used as a building block for electrically controlled spintronic devices.

1:03PM Y24.00010 Detection of adsorbed gas atoms on suspended single-walled carbon nanotube micro-balances, ZENGHUI WANG, University of Washington, JIANG WEI, OSCAR VILCHES, DAVID COBDEN — Monolayers of gas atoms or molecules adsorbed on suspended single-walled carbon nanotubes offer the opportunity to study the phases and phase transitions of a unique low dimensional system. They are expected to resemble the well studied 2D monolayers on planar graphite, but with tight cylindrical boundary conditions imposed. The adsorbed density can be measured by using the nanotube itself as a vibrating microbalance, whose vibration amplitude is detected through the induced modulation of the conductance. We are initially studying the noble gases Ne, Kr and Xe, which are attractive for their simplicity and which show discontinuous phase transitions on 2D graphite that from basic considerations should be altered or suppressed as the dimensionality is reduced. We will also study oxygen monolayers, because oxygen has more complex 2D ordering on graphite, being magnetic and nonspherical, and because of the surprisingly large doping effect reported for oxygen on nanotubes which remains to be fully understood. We will survey the resonant behavior of a number of nanotube microbalances we have made, including examples with quality factor greater than 1000, and the damping effect of a gaseous environment. We will then report on our progress in detecting adsorbed layers and phase transitions in them.

1:15PM Y24.00011 Ab initio design of realistic nanotube sensors, ADALBERTO FAZZIO, ALEXANDRE ROCHA, MARIANA ROSSI, ANTONIO J.R. DA SILVA, Instituto de Física - USP Brazil — The understanding of the electronic transport properties of nanoscopic devices present tantalizing possibilities. It has been demonstrated that carbon nanotubes can be used as sensors for hazardous gases. Large scale computer simulations have an important role to play in predicting the transport properties of such systems. In order to do so one must take into account devices which are a few hundred nanometers in length and present defects randomly distributed along the structure. These defects act as binding sites for the molecules one wishes to detect. In this work we initially use density functional theory (DFT) to determine the most likely defects in highly nitrogen-doped carbon nanotubes, and to calculate the dissociation path of ammonia and hydrogen sulphide molecules onto these defects. Finally we use a combination of DFT and recursive Green’s functions techniques to first assemble and then calculate the electronic transport properties of nanotubes up to 200 nm in length and with defects randomly distributed along the structure. We demonstrate that these nanotubes present relatively large resistance changes even at low coverages which leads to highly sensitive devices. The result is a new paradigm in computer-aided sensor design, where one can simulate realistic sensors.

1:27PM Y24.00012 Utilizing Carbon Nanotubes for 1-D Mass Transport, GAVI BEGTRUP, A. ZETTL, University of California, Berkeley — Precision control of the size and placement of materials on the nanoscale creates many opportunities for customizable materials. Recent reports have shown that carbon nanotubes act as efficient one-dimensional mass transport platforms. We have designed nanotube devices on custom fabricated electron transparent substrates compatible with transmission electron microscopy in order to study mass transport mechanisms and applications in situ. Here we report the results of these studies.

1:39PM Y24.00013 Measurement of metal/carbon nanotube contact resistance by shortening contact length, CHUN LAN, DMITRI ZAKHAROV, RONALD REIFENBERGER, Birck Nanotechnology Center, Purdue University — Estimating the contact resistance to a minimum contact length of a nanotube interconnect to a nanoscale electronic device is a major challenge. In this study, we describe a novel experiment using a focused ion beam to sequentially shorten the contact length between a nanotube and an evaporated metallic film. We develop a theoretical model that relates the measured resistance change as a function of contact length to the intrinsic linear resistivity of the nanotube as well as the specific contact resistivity between the nanotube and the deposited metallic film. In this way, we arrive at an estimate for the optimal contact length of the metal film to the carbon nanotube. The results for Au and Ag contacts to multi-wall carbon nanotubes will be summarized. Our method is quite general and can be used to accurately determine the contact resistance of any metallic film to a wide variety of nanotubes and nanowires.
1:51PM Y24.00014 Bolometric Response of a Single-Wall Carbon Nanotube\textsuperscript{1}, DANIEL SANTAVICCA, JOEL CHUDOW, YAN YIN, MARKUS BRINK, ANTHONY ANNUNZIATA, LUIGI FRUNZIO, DANIEL PROBER, Dept. of Applied Physics, Yale Univ., ALAN TRUE, CHARLES SCHMUTTENMAER, Dept. of Chemistry, Yale Univ., MENINDER PUREWAL, YURI ZUEV, PHILIP KIM, Deps. of Physics and Applied Physics, Columbia Univ. — We report on the low temperature bolometric (thermal) rf response of individual metallic single-wall carbon nanotubes. This response is used to determine the thermal conductance of the nanotube. Previous work has demonstrated heterodyne mixing in individual carbon nanotubes using either an ac-driven I-V nonlinearity or a gate-modulated conductance. We distinguish between bolometric mixing and the response due to non-thermal electrical nonlinearities. These experiments are a precursor to proposed terahertz measurements of the frequency-dependent bolometric response of an individual single-wall nanotube.

\textsuperscript{1}This work is supported by NSF-CHE, NSF-DMR, and Yale University.

2:03PM Y24.00015 I-V transport measurements of a single unsupported MWCNT under various bending deformations\textsuperscript{1}, SUENNE KIM, Texas Materials Institute. University of Texas at Austin, JEEHOON KIM, MORGANN BERG, ALEX DE LOZANN\`{E}, Department of Physics, University of Texas at Austin — Using a home-made low-temperature high-vacuum probe setup we have obtained more details about the transport characteristics of multiwall carbon nanotubes (MWCNTs). We report our experimental studies on the improvement of the nanowelding between the CNTs and a metallic (W) probe tip in our SEM, which gives a clean and firm contact that satisfies for both electrical and mechanical requirements. We observe hysteresis of the I-V curves between bending and un-bending cycles, effective and efficient fabrication of junctions in the MWCNTs and their respective I-V characteristics, and the deformation-dependent saturation behaviors in the I-V curves of the MWCNTs. All these observations may be qualitatively understood using a simple phenomenological model for localizaion effects in the deformed hexagonal lattice of graphene.

\textsuperscript{1}Supported by Ilun foundation (SK) and NSF-DMR-0308575.

Friday, March 14, 2008 11:15AM - 2:03PM – Session Y25 DPOLY: Theory and Simulations III Morial Convention Center 217

11:15AM Y25.00001 Early Stage Crystallization in Isotactic Polypropylene: Influence of Nanofillers, RAHMI OZISIK, XIAOFENG CHEN, Rensselaer Polytechnic Institute, SANAT KUMAR, Columbia University, PHILLIP CHOI, University of Alberta — Formation of helices in isotactic polypropylene was studied using on-lattice, coarse-grained, Metropolis Monte Carlo simulations. Influence of polymer-particle interaction and particle size on polymer crystallization was studied by inserting isotropic particles into neat IPP melt. Results indicated that attractive interaction between polymer and particle plays a dominant role in the formation of helical structures. Repulsive interaction excludes polymer chains from the neighborhood of the surface and triggers crystallization transition earlier (at higher temperatures). Irrespective of the energy potential used, flat surface always influences the orientation of the helices to be parallel to the surface. Confinement effect was also investigated by changing the gallery spacing between two flat surfaces. Confinement significantly prohibits the growth of long helical structures but has no effect on the overall helicity as well as the ordering of helices.

11:27AM Y25.00002 Early Stage Crystallization in Isotactic Polypropylene: Influence of Substrate-Polymer Interaction and Confinement, XIAOFENG CHEN, RAHMI OZISIK, Rensselaer Polytechnic Institute, SANAT KUMAR, Columbia University, PHILLIP CHOI, University of Alberta — Formation of helices in isotactic polypropylene was studied using on-lattice, coarse-grained, Metropolis Monte Carlo simulations. Influence of polymer-substrate interaction on polymer crystallization was studied by placing IPP chains on a flat surface. Results indicated that attractive interaction between polymer and particle plays a dominant role in the formation of helical structures. Repulsive interaction excludes polymer chains from the neighborhood of the surface and triggers crystallization transition earlier (at higher temperatures). Irrespective of the energy potential used, flat surface always influences the orientation of the helices to be parallel to the surface. Confinement effect was also investigated by changing the gallery spacing between two flat surfaces. Confinement significantly prohibits the growth of long helical structures but has no effect on the overall helicity as well as the ordering of helices.

11:39AM Y25.00003 Growth, non-coalescence and assembly of water drops that form ordered arrays over evaporating polymer solutions, VIVEK SHARMA, School of Polymer, Textile and Fiber Engineering, MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta GA 30332 — Breath figures are patterns formed, when cold solid or liquid substrates contact humid air. Typically, the condensed water drops exhibit a range of sizes, and their self-similar growth is marked by coalescence in late stages. But in the breath figures formed on evaporating polymer solutions exposed to the blast of humid air, non-coalescent drops grow and self-assemble into close packed arrays of nearly monodisperse drops. These drops evaporate away leaving an ordered array of air bubbles in polymer film. In this study, we elucidate the physics that drives nucleation, growth, non-coalescence and assembly of drops. We compute the growth kinetics of a droplet population under the mass and heat transport of water vapor that are intimately coupled with the corresponding fluxes of the evaporating solvent. We elucidate the role of solvent, polymer and air flow conditions and determine why the drops are non-sticky and why drops and pores are monodisperse.

11:51AM Y25.00004 Theory of competitive counterion adsorption on flexible polyelectrolytes: Divalent salts\textsuperscript{1}, ARINDAM KUNDAGRAMI, M. MUTHUKUMAR, Polymer Science and Engineering, University of Massachusetts Amherst — Counterion distribution around an isolated flexible polyelectrolyte in the presence of a divalent salt is evaluated using the adsorption model [M. Muthukumar, J. Chem. Phys. 120, 9343 (2004)] that considers temperature, salt concentration, and local dielectric heterogeneity as physical variables in the system. Self-consistent calculations of effective charge and size of polymer show that divalent counterions replace condensed monovalent counterions in competitive adsorption. The theory further predicts that at modest physical conditions, polymer charge is compensated and reversed with increasing divalent salt. Consequently, the polyelectrolyte collapses and reswells, respectively. Lower temperatures and higher degrees of dielectric heterogeneity enhance condensation of all species of ions. Complete diagram of states for the effective charge is calculated as functions of temperature and salt concentration. A simple theory of ion-bridging is also presented which predicts a first-order collapse of polyelectrolytes. The theoretical predictions are in agreement with generic results from experiments and simulations.

\textsuperscript{1}NSF, NIH, and MRSEC

12:03PM Y25.00005 Confinement free energy of flexible polyelectrolytes in spherical cavities, RAJEEV KUMAR, M. MUTHUKUMAR, UMASS, Amherst — A single flexible polyelectrolyte chain in a spherical cavity is analyzed using self-consistent field theory (SCFT) in the presence of solvent molecules and salt ions. It is found that the confinement of the chain leads to creation of a charge density wave along with the development of a potential difference across the centre of cavity and the surface. We have computed different energetic and entropic contributions to the free energy of the system. In particular, the role of wall-segment repulsive interactions and concentration fluctuations (at one loop level) in free energy has been explored. Results for the finite size corrections to free energy and osmotic pressure will be presented. Predictions about the effects of salt concentration, chain length, radius of the cavity, electrostatic interaction strength, degree of ionization and solvent quality will also be presented.
12:15PM Y25.00006 Simulation study of proton transport in ionomers\textsuperscript{1}. PHILIP TAYLOR, ELSHAD ALAHAYAROV, Case Western Reserve University — Coarse-grained molecular-dynamics simulations were used to study the morphological changes induced in a Naﬁon-like ionomer by the imposition of a strong electric ﬁeld. We observe that proton transport through this polymer electrolyte membrane is accompanied by morphological changes that include the formation of structures aligned along the direction of the applied ﬁeld. The polar head groups of the ionomer side chains assemble into clusters, which then form rod-like formations, and these cylindrical structures then assemble into a hexagonally ordered array aligned with the direction of current ﬂow. For dry ionomers, at current densities in excess of 1 A/cm\textsuperscript{2} these rod-like clusters undergo an inner micro-phase separation, in which distinct wire-like lines of sulfonate head groups are accompanied by similar wire-like alignments of bound protons. The clusters appear to be of two types. If there are two, four, or ﬁve lines of sulfonates then there is an equal number of lines of protons, but if there are three lines of sulfonates then they are accompanied by four lines of protons. Occasionally these lines of sulfonates and protons form a helical structure. Upon removal of the electric ﬁeld, the hexagonal array of rod-like structures remains, but the microphase separation disappears below the threshold current of 1 A/cm\textsuperscript{2}.

\textsuperscript{1}Work supported by DOE Grant DE-FG02-05ER46244.

12:27PM Y25.00007 Polymer capture by electro-osmotic ﬂow of oppositely charged nanofluids. CHU TAI ANDREW WONG, M. MUTHUKUMAR, Department of Polymer Science and Engineering, University of Massachusetts Amherst — We have addressed theoretically the hydrodynamic effect on the translocation of DNA through nanopores. We consider the cases of nanopore surface charge being opposite to the charge of the translocating polymer. We show that, because of the high electric ﬁeld across the nanopore in DNA translocation experiments, electro-osmotic ﬂow is able to create an adsorbing region comparable to the size of the polymer around the nanopore. Within this capturing region, the velocity gradient of the ﬂuid ﬂow is high enough for the polymer to undergo coil-stretch transition. The stretched conformation reduces the entropic barrier of translocation. The diffusion limited translocation rate is found to be proportional to the applied voltage. In our theory, many experimental variables (electric ﬁeld, surface potential, pore radius, dielectric constant, temperature, and salt concentration) appear through a single universal parameter. We have made quantitative predictions on the size of the adsorption region near the pore for the polymer and on the rate of translocation.

12:39PM Y25.00008 Depletion interaction and effect of polydispersity in non-adsorbing polymer solutions\textsuperscript{1}. DADONG YAN, SHUANG YANG, C.C. HAN, State Key Laboratory of Polymer Physics and Chemistry, Institute of Chemistry, Chinese Academy of Sciences, Beijing 100080, China, AN-CHANG SHI, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario L8S 4M1, Canada — The depletion effect between two spherical colloidal particles in non-adsorbing polymer solutions is investigated using the self-consistent ﬁeld theory. The density distributions of polymer segments, the depleted amount and depletion potential are calculated numerically in bi-spherical coordinates. The effects of chain length, bulk concentration, and solvency are also investigated for the dilute regime, semidilute regime and high concentration. Also, the effect of polymer polydispersity on the depletion interaction between two plates immersed in a non-adsorbing polymer solution with Schulz molecular weight distribution is studied within self-consistent-ﬁeld theory. For the case of two large spheres the Derjaguin approximation is used to study the effect of polydispersity.

\textsuperscript{1}NSFC Major Project No.20490220.

12:51PM Y25.00009 Unimolecular spreading of a molecular brush on adsorbing surface. EKATERINA ZHULINA, Institute of Macromolecular Compounds 199004 St. Petersburg Russia, SERGEY PANYUKOV, Lebedev Physics Institute 117924 Moscow Russia, MICHAEL RUBINSTEIN, University of North Carolina Chapel Hill NC 27599 USA — Using scaling concepts and the analytical self-consistent-ﬁeld theory we explore different conformations of a molecular brush on a planar substrate in nonsolvent environment (air-solid interface). The relationship between architecture and stress in adsorbed macromolecule is determined in terms of spreading parameter, grafting density and degree of polymerization of the side chains. A novel tentlike shape of molecular cross-section as well as rectangular and combined (tentlike + rectangular) conformations are predicted and examined. We demonstrate that strong adsorption of densely branched macromolecules on a planar substrate can lead to stress in molecular backbone sufficient to break covalent bonds.

1:03PM Y25.00010 Effect of chain stiffness on structural and thermodynamic properties of polymer melts. JUTTA LUETTMER-STRATHMANN, University of Akron — Static and dynamic properties of polymers are affected by the stiffness of the chains. In this work, we investigate structural and thermodynamic properties of a lattice model for semiflexible polymer chains. The model is an extension of Shaffer's bond-ﬂuctuation model\textsuperscript{1} and includes attractive interactions between monomers and an adjustable bending penalty that determines the Kuhn segment length. For isolated chains, a competition between monomer-monomer interactions and bending penalties determines the chain conformations at low temperatures. For dense melts, packing effects play an important role in the structure and thermodynamics of the polymeric liquid. In order to investigate static properties as a function of temperature and chain stiffness, we perform Wang-Landau type simulations and construct densities of states over the two-dimensional state space of monomer-monomer and bending contributions to the internal energy. In addition, we present ﬁrst results from an algorithm for equation-of-state effects in lattice models.

1:15PM Y25.00011 Ameba-like diffusion in two-dimensional polymer melts: how critical exponents determine the structural relaxation. TORSTEN KREER, HENDRIK MEYER, JOERG BASCHNAGEL, Institut Charles Sadron, 6 rue Boussingault, 67083 Strasbourg, France — By means of numerical investigations we demonstrate that the structural relaxation of linear polymers in two dimensional (space-filling) melts is characterized by ameba-like diffusion, where the chains relax via frictional dissipation at their interfacial contact lines. The characteristic diffusion exponents determine the length scale, which does not exist in three dimensions. We show how this length scale follows from the critical exponents, which hence characterize not only the static but also the dynamic properties of the melt. Our data is in agreement with recent theoretical predictions, concerning the time-dependence of single-monomer mean-square displacements and the scaling of concomitant relaxation times with the degree of polymerization. For the latter we demonstrate a density crossover-scaling as an additional test for ameba-like relaxation. We compare our results to the conceptually different Rouse model, which predicts numerically close exponents. Our data can clearly rule out the classical picture as the relevant relaxation mechanism in two-dimensional polymer melts.

1:27PM Y25.00012 Connections between static and dynamic properties of atheral polymer melts: a Monte Carlo simulation study. NENAD STOJILJOVIC, Physics Department, John Carroll University, JUTTA LUETTMER-STRATHMANN, Departments of Physics and Chemistry, The University of Akron — The motion of individual chains in polymer melts and blends is governed by local friction and entanglement effects. In simulations and experiments it can be difﬁcult to separate these effects since both local friction coefﬁcients and entanglement lengths depend on the thermodynamic state and the chain structure and since many systems display neither ideal Rouse nor fully entangled dynamics. In this work, we investigate local and chain dynamics of atheral polymer melts with Monte Carlo simulations of two versions of Shaffer's bond-ﬂuctuation model\textsuperscript{1}. S. Shaffer, J. Chem. Phys. 101, 4005 (1994). In the ﬁrst version, bonds are allowed to cross each other with the result that the chains do not entangle; in the second, bond crossings are prohibited and entanglement effects become apparent. Since both versions of the model have very similar static properties, local friction and entanglement effects can be separated. With simulations for a range of densities and chain lengths, we investigate connections between static and dynamic properties, in particular, scaling with the packing length and the size of the moving segment responsible for local friction.
1:39PM Y25.00013 Thermodynamic modeling of melt deformation.1,  J.P. IBAR, Universite de Pau, Pau 64013 France — In current tube models, the chain is the focus of interest; it is the statistical system. For entangled chains, part of the chain (of molecular weight M) becomes the system. In the statistical model of this paper, systems are sets of conformers coherently interactive, where interactive coupling is defined with respect to 2 types of interaction between conformers, covalent or intermolecular. The duality is explained by a new statistics, a crossed-statistics, which calculates the conformational state of all conformers, not just whether they are cis, gauche or trans, but also whether they are either covalently or inter-molecularly bonded. Entanglements manifestation result from a disturbance of the crossed-statistics by the increase of the number of covalently bonded conformers resulting in thermodynamically stable dual phases. The deformation of a statistical system results from a change of the conformation population between the flexed and trans conformations in the direction of the imposed macroscopic field vector. Shear or elongational flow mechanisms differ for the amount played by diffusion in feeding the deformed systems with undeformed (or relaxed) conformers to minimize the total energy required to accommodate the macroscopic deformation. Strain, strain rate and temperature determine how many systems are deformed and to what extent.

1:51PM Y25.00014 Can a material clock based model describe highly non-linear creep?1, GRIGORI MEDVEDEV, JAMES CARUTHERS, Purdue University — Most constitutive models developed to date assume that the non-linear behavior observed in glassy polymers is due to a deformation dependent material clock, where the challenge is to find the correct functional form of how the rate of relaxation depends upon structural variables. A two order-of-magnitude change in mobility upon deformation has been observed experimentally [1], confirming that a material clock is a necessary component of any constitutive description. A non-linear viscoelastic constitutive theory [2], where the clock is configurational energy based, captures with a single parameter a wide variety of phenomena, including yield, stress/ volume/ enthalpy relaxation, and physical aging. The model is also successful in describing linear creep and recovery; however, it fails dramatically in case of highly non-linear creep in the glass transition region. No change in the functional form of the material clock can significantly improve the prediction of the model for non-linear creep. We postulate that spatial dynamic heterogeneity of glassy materials, which is well established experimentally, must be incorporated into the constitutive model in order to describe non-linear creep. Friday, March 14, 2008 11:15AM - 2:15PM –
Session Y27 GMAG: Focus Session: Kagome Magnets Morial Convention Center 219

11:15AM Y27.00001 Magnetic Diffuse Scattering in the Frustrated Kagome Antiferromagnet YBaCoO$_3$ — PASCAL MANUEL, LAURENT CHAPON, PAOLO RADAELLI, ISIS Facility, Rutherford Appleton Laboratory, JOHN MITCHELL, HONG ZHENG, Materials Science Division, Argonne National Laboratory, 9700 S. Cass Ave, Argonne IL 60439 — Cobalt oxides of composition RBaCo$_2$O$_7$ (R=Y, Tb-Lu) crystallize with a lattice structure topologically related to that of the pyrochlore. Considering only the magnetic transition metal sublattice, R-114 appears as Kagome sheets linked by triangular layers and is therefore expected to provide a new materials class for exploring geometric magnetic frustration. We have recently shown that stoichiometric R-114 compound orders antiferromagnetically into a long-range ordered (LRO) structure with features common to the $\sqrt{3} \times \sqrt{3}$ negative chirality spin arrangements often found in Kagome net systems. In contrast, small excesses of O added to the system, as little as 0.1, destroys this LRO state. To explore the nature of the frustrated magnetism in this novel system, we have measured magnetic diffuse scattering on YBaCo$_3$O$_7$ and YBaCo$_2$O$_7$-$\delta$ single crystals at the ISIS facility. Large maps of reciprocal space in several planes have been recorded showing a very structured diffuse scattering. The data compared to models obtained by the Monte-Carlo method using the metropolis algorithm, reveal the exact nature of the disordered ground state in this new class of frustrated magnets.

11:27AM Y27.00002 $^{65}$Cu, $^{35}$Cl, and $^1H$ NMR in the S=1/2 Kagomé Lattice ZnCu$_7$(OH)$_6$Cl$_2$ — TAKASHI IMAI, Dept. of Physics, McMaster University, Canada, E.A. NYTKOC, B.M. BARTLETT, M.P. SHORES, D.G. NOCERA, Dept. of Chemistry, M.I.T. — ZnCu$_7$(OH)$_6$Cl$_2$ (S=1/2) is a promising new candidate for an ideal Kagomé Heisenberg antiferromagnet, because there is no magnetic phase transition down to ~50 mK. We investigated its local magnetic and lattice environments with NMR techniques (ArXiv:cond-mat/0703141). From $^{35}$Cl Knight shift data, we demonstrate that the intrinsic spin susceptibility follows a Curie-Weiss law down to ~0.2T, then decreases toward T = 0. Comparison of $^1H$ and $^{35}Cl$ spin-lattice relaxation rate 1/T$_{1}$ evidences for slow freezing of the lattice near ~50 K, presumably associated with OH bonds. Spin dynamics near T = 0 obey a power-law behavior in the presence of high magnetic fields.

11:39AM Y27.00003 Theory of Collinear ordering on the Kagome Lattice of Zn-parataramite$^3$ — LARS FRITZ, Harvard University, MICHAEL LAWLER, YONG-BAEK KIM, University of Toronto, SUBIR SACHDEV, Harvard University — We present a theory of the collinearly ordered phase discovered in a recent neutron scattering experiment [1] on Zn-paratacamite, Zn$_3$Cu$_4$(OH)$_6$Cl$_2$, at small x. Zn-parataramite has been considered as an excellent model system for the kagome lattice of spin-1/2 moments with antiferromagnetic exchange interactions. We studied both the classical and quantum Heisenberg models on the distorted kagome lattice appropriate for Zn-parataramite with small x. Our theory naturally explains the emergence of the valence bond solid phase. We suggest future inelastic neutron and elastic X-ray scattering experiments that can test our predictions.

12:03PM Y27.00005 New natural spin-1/2 kagomé systems — kapellansite Cu$_2$Zn(OH)$_6$Cl$_2$ and haydeeite Cu$_2$Mg(OH)$_6$Cl$_2$, OLEG JANSON, HELGE ROSNER, Max-Planck-Institute for Chemical Physics of Solids Dresden, Germany — New natural spin-1/2 systems with kagomé layers — kapellansite Cu$_2$Zn(OH)$_6$Cl$_2$ and haydeeite Cu$_2$Mg(OH)$_6$Cl$_2$ — are studied by full potential density functional calculations using the fpblo.00-24 code. The band structure, obtained by a paramagnetic calculation, was used to solve a tight-binding model. The transfer integrals were mapped subsequently to a Hubbard model and to a Heisenberg model, giving an estimate for the antiferromagnetic (AF) exchange. The total exchange, containing AF and ferromagnetic (FM) parts, was derived from LSDA + U supercell calculations. As the main result, we find that in both compounds only two exchange integrals are relevant: the nearest neighbour exchange $J_1$ and the interaction $J_2$ along the diagonals of the Cu$^{2+}$-hexagons. Surprisingly, the size of these integrals depends strongly on the O—H bond length which was therefor optimized with respect to the total energy, resulting in about 1 Å for both compounds. Using the optimized O—H bond length, we find $J_1 > J_2$ in kapellansite and $J_1 < J_2$ in haydeeite. According to our results, kapellansite can be described as a modified kagomé lattice, while interpenetrating chains should be considered for haydeeite. Our results should encourage new experimental studies of these interesting materials.

12:15PM Y27.00006 Classical antiferromagnet on a hyper-kagome lattice, JOHN HOPKINSON, Brandon University, SERGEI ISAKOV, ETH-Zurich, HAE-YOUNG KEE, YONG BAEK KIM, University of Toronto — Motivated by recent experiments on Na$_2$IrO$_4$ [Y. Okamoto et al., Phys. Rev. Lett. 99, 167402 (2007)], we study the classical antiferromagnet on a frustrated three-dimensional lattice obtained by selectively removing one of four sites in each tetrahedron of the pyrochlore lattice. This “hyper-kagome” lattice consists of corner-sharing triangles. We present (J. Hopkinson et al., Phys. Rev. Lett. 99, 037201 (2007)) the results of large-$N$ mean field theory and Monte Carlo computations on $O(N)$ classical spin models. We find the classical ground states to be highly degenerate. Nonetheless, at low temperatures, nematic order emerges via “order by disorder” in the Heisenberg model ($N=3$), representing the dominance of coplanar spin configurations. Above this transition, the spin-spin correlations show a dipolar form which can be understood to arise from a generalized “Gauss” law constraint. The relevance of these results to ongoing neutron scattering experiments will be discussed.

12:27PM Y27.00007 Tuning of the spin liquid ground state in the kagome system Pr$_3$Ga$_2$XO$_{14}$,‡ C. R. WIEBE, H. D. ZHOU, Y.-J. JO, M. A. CASTELLANO, L. BALICAS, M. J. CASE, Y. QIU, J. R. D. COPLEY, V. RAMACHANDRAN, N. S. DALAL, J. S. GARDNER — We report on the single crystal growth of the series of kagome oxides Pr$_3$Ga$_2$XO$_{14}$ ($X$ = Si, Ti, Ge, and Sn). The material Pr$_3$Ga$_2$SiO$_{14}$ has near neighbor antiferromagnetic interactions between the Pr spins ($\theta$ = -2.3 K), but there is no long range order down to 0.035 mK ($f$ = 66). The presence of 2D low energy spin excitations results in a strong $T^2$ component to the specific heat typical of other kagome systems such as SCGO. By tuning the size of the lattice through substitution on the Si site, one can adjust the exchange between the spins in a regular fashion. Our data shows a systematic decrease in the amplitude of the $T^2$ component of the specific heat as the magnetic exchange becomes weaker through Ti and Ge substitution. In the case of Sn doping, the system orders as the dipolar interactions dominate over the weak antiferromagnetic exchange. To our knowledge, this is the first example of a tunable spin liquid kagome system.

12:39PM Y27.00008 Thermodynamics of Ising Spins on the Triangular Kagome Lattice,‡ YEN LEE LOH, DAOXIN YAO, ERICA W. CARLSON, Purdue University — In the compounds Cu$_2$X$_2$O$_{16}$ ($X$=Zn, Cd, Ge, Mn) and Cu$_2$GeO$_3$, the Cu spins form a fascinating and unique pattern called a triangular kagome lattice (TKL). We present a detailed study of Ising spins on such a lattice using exact methods and Monte Carlo simulation. We calculate the free energy, internal energy, specific heat, entropy, sublattice magnetizations, and susceptibility, and we find a rich phase diagram as a function of coupling constants, temperature, and applied magnetic field. In the frustrated regime at $T=0$, the system effectively decouples into independent states of freedom, giving residual entropy $S_0 = \frac{1}{2} \ln 72$ per spin and correlation length $\xi = 0$ — an interesting contrast with the triangular and kagome lattice Ising models. Applying a field induces a critical phase (related to the honeycomb lattice dimer model) that has irrational $1/\sqrt{2}$ correlations that should be detectable by neutron scattering. 1

We gratefully acknowledge support from Research Corporation.

12:51PM Y27.00009 Spin Triplet Excitations of the Heisenberg Antiferromagnet on the Kagome Lattice,‡ KWON PARK, Korea Institute for Advanced Study, BOHM-JUNG YANG, Seoul National University, YONG BAEK KIM, University of Toronto, JAEJUN YU, Seoul National University — The Kagome lattice Heisenberg antiferromagnet is one of the most frustrated spin systems in two dimensions, with many generated various theoretical proposals for the ground state. While recent experiments strongly suggest that the ground state is not magnetically ordered, identification of the true ground state remains highly controversial. Possible candidate phases include various spin liquids and a valence bond solid, particularly with a 36-site unit cell. It is therefore important to theoretically explore decisive properties of the candidate ground states which can be directly compared with experiments. To this end, we investigate the low-energy spin triplet excitations of the valence bond solid state with a 36-site unit cell, which are gapped in contrast to spin singlet excitations. Implications to future experiments are discussed.

1:03PM Y27.00010 Multiple magnetic phases in the frustrated spin-dimer compound Ba$_2$Mn$_2$O$_4$,‡ E. C. SAMULON, Stanford University, Y.-J. JO, National High Magnetic Field Laboratory, P. SENGUPTA, Los Alamos National Laboratory, G. M. SCHMIEDEHOFF, Occidental College, C. D. BATISTA, M. JAIME, Los Alamos National Laboratory, L. BALICAS, National High Magnetic Field Laboratory, I. R. FISHER, Stanford University — Ba$_2$Mn$_2$O$_4$ is a spin-dimer compound based on S=1 3d$^3$ Mn$^{3+}$ ions on a triangular lattice. Antiferromagnetic intradimer exchange leads to a singlet ground state in zero-field. Here we present the first results of thermodynamic measurements for single crystals probing the high-field ordered states of this material. Specific heat, magnetocaloric effect, torque magnetometry and magnetotension measurements were performed in magnetic fields up to 32 T and temperatures down to 20 mK. These measurements reveal the presence of multiple ordered states for fields above $H_c1 \sim 8$ T. Both single-ion anisotropy and geometric frustration play crucial roles in determining the phase diagram.

‡Work at Stanford is supported by the NSF under grant DMR 0705087

1:15PM Y27.00011 135,137$^+$Ba NMR study of Ba$_3$Mn$_2$O$_7$. STEVE SUH, W.G. CLARK, GUOQING WU, S.E. BROWN, UCLA, E.C. SAMULON, I.R. FISHER, Stanford, C.D. BATISTA, LANL, A.P. REYES, P. KUHNS, L.L. LUMATA, NHMFL, Tallahassee — We report results from 135,137$^+$Ba NMR spectroscopy and relaxation rate ($1/T_1$) measurements in single crystal Ba$_3$Mn$_2$O$_7$, an S=1 dimer system with a singlet ground state. Thermodynamic measurements have shown it has multiple field-induced phase transitions for fields exceeding a critical field $H_c1 \sim 90$ K and varying with field orientation. We have evaluated the hyperfine couplings and electric field gradients in the normal phase for one of the two inequivalent Ba sites, and find a significant anisotropic component to the hyperfine coupling. Measurements of $1/T_1$ made at fixed fields down to temperatures $T < 0.4$ K are consistent with critical behavior in the vicinity of $H_c1$. However, lower temperatures are needed to clarify the universality class. Goals for upcoming experiments include a determination of the spectrum in the low-symmetry phases and an evaluation of $1/T_1$ for $T < 0.4$ K. This work is supported at UCLA by NSF Grants 0520552 (SEB), DMR-00334869 (WGC), Stanford by DMR-0134613 (IRF), and NHMFL by 0084173 and the State of Florida.
3+ evolution: (1) suppressed structural distortion leading to geometric frustration, and (2) the formation of $S=0$ Co centers that can break magnetic exchange pathways. The pitch of the spiral is substantially larger than when the chains are coupled in an unfrustrated square-lattice geometry. The CAF phase does not appear to be stabilized for any value of $J_1/J_2$ for the spin-one model.

1:39PM Y27.00013 Spin order and excitations of a model triangular antiferromagnet, WEI BAO, Los Alamos National Lab., YINGMING QIU, NIST, YINXIA WANG, KUO LI, JIANGHUA LIN, Peking University, ROSS ERWIN, NIST — The triangular antiferromagnet is a model system sittinguate close to the boundary between a three-sublattice order and a quantum-liquid state, due to delicate balance among magnetic interaction, quantum fluctuations and geometrical frustration. The unique topology of the non-collinear three-sublattice order has profound consequences in finite-temperature phase-transitions and spin excitations, which are not yet fully understood. Experimental investigation on such issues has been impeded by imperfect materials which fail to represent the theoretical model at low temperatures. Here we show by neutron scattering that the three-sublattice order in the exceptional new material La$_2$Ca$_2$MnO$_6$ remains two-dimensional down to 40 mK. The order parameter and critical spin fluctuations suggest a phase transition at 3.8 K, but the in-plane correlation length becomes resolution-limited only below 1.8 K. While the spin-wave cone at low energy and the softening of high-energy modes in current theories are supported by our observations, measured spectral intensity above the upper energy limit of spin-waves distribution and a pseudogap developing below 1.8 K are not anticipated.

11:15AM Y28.00001 Layer interdependence of transport in an undoped electron-hole bilayer, CHRISTIAN MAROTH, JOHN SEAMONS, JOHN RENO, MIKE LILLY, Sandia National Lab — Recently interest in the layer interdependence of a bilayer’s transport has emerged. To examine this dependence the layer transport properties in an undoped electron-hole bilayer (uEHBL) device were measured as a function of density, inter-layer electric field and temperature. The uEHBL device consisted of a tunable, independently-contacted two-dimensional electron gas (2DEG) and two-dimensional hole gas (2DHG) in direct GaAs quantum wells separated by a 30 nm Al$_x$Ga$_{1-x}$As barrier. At $T = 0.3$ K, the 2DHG mobility increased with increasing 2DEG density, while the opposite effect was not observed. Decreasing the inter-layer electric field also increased 2DHG mobility without affecting the 2DEG mobility. This also decreased 2DHG Coulomb drag suggesting the inter-layer separation was increased. Distinct temperature dependencies were also measured for each layer’s density and resistivity.

11:27AM Y28.00002 Electronic doping in heterostructures of strongly correlated materials, IVAN GONZALEZ, Department of Physics and Astronomy, The University of Tennessee, Knoxville, TN, ROGER G. MELKÓ, Department of Physics and Astronomy, University of California, Davis. — We have performed inelastic neutron scattering measurements on a single crystal sample of YBaCo$_4$O$_{10+δ}$, triangular lattice $(J_1 = 0)$, triangular lattice $(J_1 = J_2)$ and decoupled one dimensional linear chains $(J_2 = 0)$. Results are obtained by means of linked-cluster series expansions around the collinear antiferromagnetic phase (CAF) and the non collinear antiferromagnetic phase (NCAF), also known as the spiral phase. For the spin-half model, both phases can be stabilized within our calculations for small $J_2$. However, the NCAF phase always appears to have a lower energy. The pitch of the spiral is substantially renormalized from the classical values. For the spin-one model, we find a transition from the Haldane gap phase to the NCAF phase as a function of $J_1/J_2$. Interchain coupling required for this transition is more than a factor of 30 larger than when the chains are coupled in an unfrustrated square-lattice geometry. The CAF phase does not appear to be stabilized for any value of $J_1/J_2$ for the spin-one model.
11:51AM Y28.00004 Electronic states in magnetic quantum dots and quantum-dot molecules: Coulomb interaction effects and spontaneous symmetry breaking, ALEXANDER GOVOROV, Ohio University, WEI ZHANG, Ohio University & Institute of Applied Physics and Computational Mathematics, Beijing, China — We investigate theoretically few-electron states in semi-magnetic quantum dots and quantum-dot molecules [1,2]. A double quantum-dot system made of diluted magnetic semiconductor behaves unlike the usual molecules. In a semiconductor double quantum dot or in a diatomic molecule, the ground state of a single carrier is described by a symmetric orbital. In a magnetic material molecule, new ground states with broken symmetry can appear due to the competition between the tunneling and magnetic polaron energy. With decreasing temperature, the ground state changes from the normal symmetric state to a state with spontaneously broken symmetry. Interestingly, the symmetry of a magnetic molecule is recovered at very low temperatures. A magnetic double quantum dot with broken-symmetry phases can be used as a voltage-controlled nanoscale memory cell. [1] A. O. Govorov, Phys. Rev. B 72, 075359 (2005). [2] W. Zhang, T. Dong, and A. O. Govorov, Phys. Rev. B 76, 075319 (2007).

12:03PM Y28.00005 The Kondo Effect and Rashba Spin-Orbit Coupling, JUSTIN MALECKI, University of British Columbia — We present the results of a study of the influence that weak Rashba spin-orbit coupling has on the Kondo effect induced by a magnetic impurity in a two dimensional electronic system. It is shown that the Kondo effect is robust against such coupling of momentum and spin, despite the fact that the spin of the conduction electrons is no longer a conserved quantity. A proposal is made for how the spin-orbit coupling may change the value of the Kondo temperature \( T_K \) in such systems. Applications to semiconductor quantum dots and magnetic atoms on metallic surfaces are discussed.

12:15PM Y28.00006 Fano-Kondo effect in a two-level system with triple quantum dots, TETSUFI TANAMOTO, YOSHIFUMI NISHI, SHINOBU FUJITA, Advanced LSI Technology Laboratory, Toshiba Corporation — Quantum dot (QD) systems have been providing opportunities to probe a wide variety of many-body effects in microelectronic structures. Recently, the Fano effect, which appears as a result of quantum interference between a discrete single energy level and a major electronic system, has attracted the interests of many researches [1]. Here, we theoretically study the Fano-Kondo effect and Fano effect in a triple QD system, where two QDs constitute a two-level system and the other QD works in a detector with electrodes. When two QDs are coupled, bonding and anti-bonding states are formed. It is expected that the detector current reflects these electronic states. Indeed, we found that the Fano dip is modulated by strongly coupled QDs with a slow detector. We also compare noise properties of Fano-Kondo effect with those of Fano effect, and we found that, depending on the coupling strength among the QDs, noise and the Fano factor are greatly modulated for a slow detector. These suggest a new method of reading out qubit states [2]. 

12:27PM Y28.00007 Kondo physics with ac driving in the single electron transistor subjected to finite bias, ALI GOKER, Universite de Montreal — We employ the time-dependent non-crossing approximation to study the time averaged conductance for a single electron transistor in the Kondo regime when the dot level is sinusoidally driven from its equilibrium position by means of a gate voltage in finite bias. We find that the average conductance exhibits considerable deviation from the monotonous reduction when the applied bias is equal to the driving frequency of the dot level. We attribute this behaviour to the overlap of the satellite Kondo peaks with the split Kondo resonances formed at each lead’s Fermi level. We display the spectral function to put our interpretation into more rigorous footing. We also investigate the effect of the temperature and the driving frequency on the observed enhancement.

12:39PM Y28.00008 Interplay of Interactions and Phase Coherence in Open Quantum Dots, ILEANA RAU, MICHAEL GROBIS, RON POTOK, Stanford University, HADAS SHTRIKMAN, Weizmann Institute, DAVID GOLDHABER-GORDON, Stanford University — The effect of Coulomb interactions on the electronic properties of a confined quantum system greatly weakens when electrons are allowed to rapidly enter and exit the system. For electron transport through a quantum dot, increasing the coupling of the dot to nearby leads causes a transition from the Coulomb blockade regime to a regime dominated by interference phenomena. We have investigated this transition in large, micron-sized quantum dots and found that Coulomb blockade effects persist in a regime where they had generally been assumed absent: when a dot is coupled by one fully transmitting mode to each of two leads. We discuss the interplay of these residual Coulomb interactions with phase coherent transport through a dot. We also examine how the subtle suppression of conductance by these Coulomb interactions affects the electron dephasing rate at low temperatures in open quantum dots.

12:51PM Y28.00009 Numerical estimate of correlation energy for two electrons confined in 2D quantum dot, TAKUMA OKUNISHI, YUKI NEGISHI, MASAKAZU MURAGUCHI, KYOZABURO TAKEDA, Waseda University — Local density approximation (LDA) is now widely accepted to design the novel materials as well as to predict new phenomena. In practical use of LDA, estimate of correlation energy is crucial. Tanatar et al. have given the well-known comprehensive expression of LDA correlation energy for 2D electron gas [1]. However, a straightforward use of this correlation energy for two electrons confined in 2D quantum dot is not possible. We have obtained the correlation energy for two electrons confined in 2D QD by applying the improved LDA. [1] B. Tanatar and D. M. Ceperley, Phys. Rev. B 39, 5005 (1989).
to acknowledge support from DOE Award Nos. DE-FG02-07ER46376 and DE-FG02-07ER46377. I.K. Hsu contact resistances can also be differentiated via the offset of the temperature increase at the ends of the suspended CNT. The results show the ratio of the

Fourier heat transport equation, we determine the thermal contact resistance ($R C T$) and correlate the CTE with the tube atomic structure. All the 4 walls of this individual MWCNT show apparent radial diameter thermal contraction. Because of the small size, experimental measurement of individual CNTs is very difficult; So far only limited data was reported by X-ray (CNTs). The coefficient of thermal expansion (CTE) of CNTs has been a subject of considerable debate in the literature with more recent works predicting, J. ZHANG, L. JI, J. ZUO, Univ. of Illinois — It is of fundamental value to understand the thermo-mechanical properties of individual carbon nanotubes (CNTs). The coefficient of thermal expansion (CTE) of CNTs has been a subject of considerable debate in the literature with more recent works predicting such anisotropic Casimir interaction has not been considered before and may lead to an orientation of long flexible objects, like nanotubes, at polar substrates. The interaction energy is derived analytically for the case of a single-wall nanotube on the ST-cut quartz. Besides a material dependent energy constant, it is proportional to the ratio of the volume of interacting segment of the nanotube and cube of the distance to the substrate. The interaction energy is derived analytically for the case of a single-wall nanotube on the ST-cut quartz. Besides a material dependent energy constant, it is proportional to the ratio of the volume of interacting segment of the nanotube and cube of the distance to the substrate.

**11:15PM Y28.00011 Non-Markovian Dynamics of Charge Carriers in Quantum Dots at High Bias** EDUARDO VAZ, JORDAN KYRIAKIDIS, Dalhouse University — We have investigated the dynamics of bound particles in multi-level current-carrying quantum dots. We look specifically in the regime of resonant tunneling transport, where several channels are available for transport: Through the non-Markovian Born-Redfield formalism, we investigate the real-time evolution of the confined particles including transport-induced decoherence and relaxation. In the case of a coherent superposition between states with different particle number, we find that coherence may be preserved even in the presence of tunneling into and out of the dot. Real-time results are presented for various asymmetries of tunnel barriers and tunneling rates into different orbitals.

**11:15AM Y29.00001 Anisotropic Casimir interactions between a one-dimensional object (nanotube) and a polar substrate**, SLAVA V. ROTKIN, Physics Dept, Lehigh University, ALEXEY G. PETROV, Liffe Institute, JOHN A. ROGERS, Beckman Institute, UIUC — The energy of Casimir interaction of a polarizable one-dimensional object (1DO), e.g. a nanotube, and a polar substrate was estimated. Within our model the energy of the dipole moment induced in the 1DO by the external electric field of the fluctuations of the quantized surface optical phonon modes is evaluated. Such polaron modes are known to exist in polar insulators and have the electric field with an exponentially decreasing wing in vacuum. If the polarization tensor of the 1DO is not isotropic, an orientation dependent Casimir force may arise. To the best of our knowledge, such anisotropic Casimir interaction has not been considered before and may lead to an orientation of long flexible objects, like nanotubes, at polar substrates. The interaction energy is derived analytically for the case of a single-wall nanotube on the ST-cut quartz. Besides a material dependent energy constant, it is proportional to the ratio of the volume of interacting segment of the nanotube and cube of the distance to the substrate.

**12:27AM Y29.00002 Dynamics and energy dissipation of nano-graphite mechanical devices**, ZHIPING XU, Rice University — Controllable mechanical motion of nano-structures holds great interest because of their applications in the nano-electromechanical systems (NEMS). One of the novel models proposed was the nano-graphitic materials based devices, where planar or cylindrical graphene layers act as moving parts and the motion is managed by the van der Waals force between them. Comparing with the multi-walled carbon nanotubes, nano-graphite flakes have an accessible scale for current techniques. Recent experiments using nano-mechanical manipulator have shown self-retraction motion of micrometer graphite layers after mechanical extrusion (Zheng et al. submitted to PRL). However, persistent oscillation as expected was not observed. The short lifetime implies severe energy dissipation. Analysis based on MD simulation show that the coupling with rotation and lattice vibration contribute significantly. Furthermore we have discussed the effects of edge instabilities, surface contamination and non-planar deformation, which also introduce complexities into the dynamics as approved by the experimental observation.

**11:39AM Y29.00003 Large Negative Thermal Expansion of an Individual Carbon Nanotube**

J. ZHANG, L. JI, J. ZUO, Univ. of Illinois — It is of fundamental value to understand the thermo-mechanical properties of individual carbon nanotubes (CNTs). The coefficient of thermal expansion (CTE) of CNTs has been a subject of considerable debate in the literature with more recent works predicting thermal contraction. Because of the small size, experimental measurement of individual CNTs is very difficult; So far only limited data was reported by X-ray diffraction that measured the average CTE of many tubes. Here, we use nanoarea electron diffraction to measure the CTE of an individual Multi-walled carbon nanotube (MWCNT) and correlate the CTE with the tube atomic structure. All the 4 walls of this individual MWCNT show apparent radial diameter thermal contraction. Because of the small size, experimental measurement of individual CNTs is very difficult; So far only limited data was reported by X-ray diffraction that measured the average CTE of many tubes. Here, we use nanoarea electron diffraction to measure the CTE of an individual Multi-walled carbon nanotube (MWCNT) and correlate the CTE with the tube atomic structure. All the 4 walls of this individual MWCNT show apparent radial diameter thermal contraction from 297 to 827 K, and thermal expansion from 827 to 1027 K. The radial CTE has strong direction dependence between 297 and 827 K. It changes from (-6.48±0.46) E-5 (1/K) for the wall with the theoretical diameter 16.4 Å to (-2.37±0.77) E-5 (1/K) for the wall with the theoretical diameter 37.3 Å, which means smaller diameter wall contracts more. On the other hand, all 4 walls of this individual MWCNT show apparent axial thermal contraction from 297 to 1073 K. The axial CTE is independent of the diameter, and the average axial CTE for different walls is (-1.30±0.07) E-5 (1/K).

This work was supported by U.S. DoE Grant DEFG02-01ER45923. Microscopy was carried out at the CMM at the MRL, which is partially supported by the U.S. DoE under grant DEFG02-91-ER45439.

**11:51AM Y29.00004 Optical Measurement of Thermal Contact Resistance in Suspended Carbon Nanotubes** I-KAI HSU, RAJAY KUMAR, ADAM BUSHMAKER, MICHAEL T. PETTES, LI SHI, TODD BRINTLINGER, MICHAEL S. FUHRER, JOHN CUMINGS, STEPHEN B. CRONIN, University of Southern California — We observe the local temperature increase profile $\Delta T(x)$ along suspended carbon nanotubes (CNTs) by converting the shifts in the $G$-band Raman mode to temperature. By deconvolving the temperature profile using the Fourier heat transport equation, we determine the thermal contact resistance ($R C T$) relative to the intrinsic thermal resistance of the nanotube itself ($R_N T$). The curvature of the temperature profile is found to be dominated by the ratio of $R_N T$ to $R C T$. The contact resistance can also be differentiated via the offset of the temperature increase at the ends of the suspended CNT. The results show the ratio of the contact thermal resistance to the nanotube thermal resistance to range from 0.02 to 17. The measurement is also able to distinguish between ballistic and diffusive thermal transport. We find diffusive thermal transport to dominate the heat transport in all nanotubes measured in this study. The authors would like to acknowledge support from DOE Award Nos. DE-FG02-07ER46376 and DE-FG02-07ER46377. I.K. Hsu et al., Applied Physics Letters (in press).
12:03PM Y29.00005 Thermal Conductance Measurement of Metal-CNT Composites using Micro-Sized Suspended Structure, KI SUNG SUH, JUNG HOON BAK, BYUNG YANG LEE, SEUNGHUN HONG, YUN DANIEL PARK, FPRD Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea — As CNTs have a unique structure and remarkable physical properties, CNT composites have attracted much attention from many researchers. Especially the thermal properties of CNTs and their composite materials have been studied intensively, because CNT has very good thermal transport properties [1-5]. For example, thermal conductivity of CNT is known to be much larger than that of metals such as Ag, Au, Cu and Al. To study the thermal conductance of metal-CNT composites, we have fabricated the micro-sized suspended structures. By using e-beam lithography and metalization, two thermometers have been patterned on the GaAs substrates. Thermal links made of metal or metal-CNT composite also have been patterned between the two thermometers. Then GaAs substrate has been under-etched to form suspended structures. We will show the fabrication methods and measurement scheme using these microstructures. * parkyd@phy.snu.ac.kr [1] J.A. Eastman et al., Appl. Phys. Lett. 78, 718 (2001). Xia et al., Appl. Phys. Lett. 94, 4967 (2003).

12:15PM Y29.00006 Thermal conductivity of isolated and interacting carbon nanotubes, DAVIDE DONADIO, GIULIA GALLI, UC Davis — We have investigated the thermal conductivity of single wall carbon nanotubes (SWCNT) either isolated or in contact with external media, by using equilibrium molecular dynamics and the Boltzmann transport equation. We show that, contrary to existing controversies, both methods yield a finite value of the thermal conductivity for infinitely long tubes, as opposed to the case of 1D momentum conserving systems. Acoustic and flexure modes with mean free paths of the order of a few micron, as observed also in experiments, are identified as major contributors to the high value of SWCNT conductivity. We also find that the interaction with an external medium may substantially decrease the lifetime of the low frequency vibrations, reducing the thermal conductivity by up to two orders of magnitude.

12:27PM Y29.00007 Determination of carbon nanotube wall thickness and elasticity by atomic force microscopy, TRISTAN DEBORDE, CALEB JOINER, MATTHEW LEYDEN, ETHAN MINOT, Oregon State University — To understand the operation of carbon nanotube (CNT) devices it is important to determine whether nanotubes are single-walled or multi-walled. Transmission electron microscopy of CNTs has previously been the only tool available to count the number of graphene sheets forming the wall of a CNT. We show that atomic force microscopy can measure CNT wall thickness by squeezing individual nanotubes between a tip and a hard surface. Full compression of single-walled and double-walled CNTs can be achieved either by a static force or by ac-mode imaging, allowing clear determination of wall number. Direct measurements of compression forces are used to determine the elastic properties of the wall, yielding the bending modulus of graphene.

12:39PM Y29.00008 Pressure Induced Changes in the Atomic and Electronic Structure of Carbon Nanotubes, SUMIT SAXENA, TREVOR A. TYSON, New Jersey Institute of Technology - Newark — We present first principle density functional calculations on small diameter single walled carbon nanotubes to explore the changes in their electronic structure and atomic arrangement under hydrostatic compression. Simulations on zigzag (n, 0) SWCNT 6 ≤ n ≤ 9 using the full potential projector augmented wave and ultra-soft pseudo potentials were conducted. Large structure-related changes are found in the density of states at the Fermi energy. The cross sections of small tubes exhibits deformations not predicted by classical models. The structural cross sections of large diameter tubes calculated under moderate pressure are consistent with the reported results. The details of calculations and other results will be presented. This work is supported in part by NSF DMR-0512196.

12:51PM Y29.00009 Nanomechanical energy transfer in carbon nanotubes: fundamental insights from molecular dynamics simulations, GIOVANNA LANI, Politecnico di Torino, Torino, Italy and Center for Integrated Nanomechanical Systems (COINS), University of California, Berkeley., P. ALEX GREANEY, COINS, University of California, Berkeley, GIULIA GALLI, UC Davis, TRISTAN DEBORDE, CALEB JOINER, MATTHEW LEYDEN, ETHAN MINOT, Oregon State University — To understand the operation of carbon nanotube (CNT) devices it is important to determine whether nanotubes are single-walled or multi-walled. Transmission electron microscopy of CNTs has previously been the only tool available to count the number of graphene sheets forming the wall of a CNT. We show that atomic force microscopy can measure CNT wall thickness by squeezing individual nanotubes between a tip and a hard surface. Full compression of single-walled and double-walled CNTs can be achieved either by a static force or by ac-mode imaging, allowing clear determination of wall number. Direct measurements of compression forces are used to determine the elastic properties of the wall, yielding the bending modulus of graphene.

1.03PM Y29.00010 A Failure Criterion for Single-Walled Carbon Nanotubes Based on Molecular Mechanics, ANTONIO AVILA1, Univesidade Federal de Minas Gerais, GUILHERME LACERDA, Universidade Federal de Minas Gerais — Single-walled carbon nanotubes (SWNT) are the natural choice for high performance materials. The problem, however, arises when the experimental data are compared against each other. The large variability of experimental data lead to development of a new set of numerical simulations called molecular mechanics, which is a “symbiotic” association of molecular dynamics and solid mechanics. This paper deals with a molecular mechanics simulations of single-walled carbon nanotubes. Three SWNT configurations and their combinations were simulated, i.e. armchair, zigzag and chiral. The failure criterion introduced is based on modified Morse’s potential with dissociation energy of 124 Kcal/mol and an inflection point considered is around 13% of strain. The numerical data are in agreement with data from Belytschko et al. (2002) where the failure occurred at 10.6% strain at 65.2 GPa of stress. To be able to identify the highest stress concentration region, one end of the SWNT all degrees-of-freedom were fixed and a prescribed axial displacement was applied at the opposite end. The Sadoc (chiral-chiral) configuration had the highest stress at the smallest chiral SWNT. For the Dunlap configuration (chiral-zigzag) the highest stress occurred at chiral part close to the pentagon location.

1:15PM Y29.00011 Excitons in Single-Walled Carbon Nanotubes in Different Local Environments: Effects of Strain and Disorder on Magnetic Brightening

T. A. SEARLES, ECE Dept, Rice University, D.J. HILTON, J. SHAPER, W.D. RICE, Rice Univ, Y.-D. JOH, GIST, Korea, S.A. MCGILL, NHMFL, J.A. FAGAN, E.K. HOBIE, NIST, J. KONO, ECE Dept, Rice University — Recent experiments on single-walled carbon nanotubes (SWNTs) have shown that in the presence of a high magnetic field the two lowest-energy spin-singlet exciton states become bright [1]. Furthermore, this “magnetic brightening”, or increase in photoluminescence (PL) intensity as a function of magnetic flux through each SWNT, increases as the temperature decreases. Here, we report results of temperature-dependent magneto-PL from 2 to 200 K and up to 45 T on SWNTs of the same stock solution suspended in four different local environments. We compared both the brightening and temperature dependence of tubes stretch aligned and unaligned in poly-acrylic acid matrices. As expected, the tubes aligned at high magnetic field exhibited more brightening than those unaligned. We also investigated the behavior of SWNTs in two other matrices, iota-Carrageenan and gelatin. Along with the expected peak shifting and broadening from the effects of strain, we found that the temperature dependence changes with local environment. [1] S. Zaric et al., PRL 96, 016406 (2006); J. Shaver et al., Nano Lett. 7, 1851 (2007); I. B. Mortimer and R. J. Nicholas, PRL 98, 027404 (2007).

1:27PM Y29.00012 Carbon nanotube nanomechanical mass sensors

HSIN-YING CHIU, PETER HUNG, California Institute of Technology, HENK POSTMA, California State University Northridge, MARC BOCKRATH, California Institute of Technology — Single-walled carbon nanotubes are arguably the lightest and smallest wires in the world, and have recently been shown to act as nanomechanical resonators [1]. As a result, single-wall carbon nanotubes are excellent candidates for highly sensitive mass sensing [2]. We observed the down shift of the resonant frequency of a suspended double-clamped carbon nanotube resonator at cryogenic temperatures upon helium mass loading. Using a straightforward estimate of the nanotube mass, the observed frequency shift corresponds to the mass of ~1000 helium atoms, which is the zeptogram range. This is considerably smaller than found previously with nanotube resonators, and comparable to that found using nanowire resonators [3]. Our noise floor is currently ~1 Xenon atom per root Hz, which may enable single-atom detection in future experiments. [1] Vera Sazonova, et al., Nature 431, 284 (2004). [2] H. B. Peng, et al. Phys. Rev. Lett. 97, 087203 (2006) [3] Y. T. Yang, et al. Nano Lett. 6, 583 (2006).

1:39PM Y29.00013 Anharmonic phonon lifetimes in carbon nanotubes, graphene and graphite

NICOLA BONINI, Department of Materials Science and Engineering, MIT, Cambrige, MA, USA, MICHELE LAZZERI, FRANCESCO MAURI, Institut de Minologie et Physique des Milieux Condenses, Paris, France, NICOLA MARZARI, Department of Materials Science and Engineering, MIT, Cambridge, MA, USA — In this work we present a first-principles study of the anharmonic phonon lifetimes of the key vibrational modes that most strongly interact with electrons in carbon nanotubes, graphene and graphite. The calculations of both harmonic and anharmonic properties are performed using density-functional theory and density-functional perturbation theory. Our results—in excellent agreement with the available experimental data—provide a microscopic characterization of the energy relaxation mechanisms and of the relative importance of the individual decay channels. We will discuss the relevance of these results to elucidate the role of non-equilibrium phonon populations in high-field electronic transport.

1:51PM Y29.00014 Measurement of mechanical properties of graphene using nanoindentation

CHANGGU LEE, XIADONG WEI, JEFFREY KYSAR, JAMES HONE, Columbia University — Mechanical properties of graphene have been measured using AFM nanoindentation. Mono-, bi-, and tri-layer graphene sheets are suspended over micron-sized circular hole arrays. Force-displacement curves obtained by AFM nanoindentation allow the extraction of mechanical properties such as Young’s modulus and fracture strength using equations for thin circular membranes. In order to verify the validity of the equations, the experimental and analytical results were compared with finite element simulation. The analytical equations fitted to the measurements show that Young’s modulus is 0.9-1.2 TPa and the fracture strength is 90-150 GPa for up to 3 layers.

2:03PM Y29.00015 Electrical conductivity of individual, thermally reduced graphene oxide sheets

INHWA JUNG, DMITRIY DIKIN, Northwestern University, Evanston, Illinois, RICHARD PINER, ROD RUOFF, University of Texas at Austin — Electrical properties of individual graphene oxide sheets were investigated. Graphene oxide itself is insulating, but its conductivity is finite and measureable following heat treatment in vacuum. The dependence on temperature and time for reduction of graphene oxide were fit to a standard chemical kinetics rate law and from this an activation energy of 30 kcal/mole was found. I-V curves, obtained at several stages of the chemical reduction achieved by heating, are non-linear and slightly asymmetric. The effect of applying an electric field via a back gate and the resulting change in resistance was measured at different temperatures and at different stages of reduction. The maximum conductivity by thermal annealing graphene oxide sheets was 85 S/m at room temperature and zero gate potential. This value was determined based on 4-probe pseudo Van der Pauw measurements and numerical modeling and using 1.0 nm as the sheet thickness.

11:15AM Y30.00001 Inelastic neutron scattering from confined molecular oxygen

PAUL SOKOL, DUNCAN KILBURN, Indiana University — We report results from experiments measuring the generalized density of states in confined solid molecular oxygen. It is known from previous experiments that fundamental properties of liquids and solids, such as phase transition temperatures and intermolecular structure can be altered by confining them in porous media (pores typically in the angstrom to nanometer range). It is reasonable therefore to ask the question: what is the effect of confinement on collective excitations in the material, and can these changes be exploited in a technological setting? Using inelastic neutron scattering we find that both the structure and generalized density of states of solid molecular oxygen are altered by confining it in a templated porous glass with a mean pore diameter of 100 Angstroms. The structure, in the Q-range which we were able to measure, resembles that of an amorphous material and the density of states is shifted to lower energy excitations. One possible application for such a material is as moderator material in a very cold neutron source.

11:27AM Y30.00002 Imaging One-Electron Quantum Dots in InAs/InP Nanowires

HALVAR TRODAHL, ERIN BOYD, R.M. WESTERVELT, Harvard University, LINUS FROBERG, LARS SAMUELSON, Lund University — Quantum dots formed in InAs/InP heterostructure nanowires are attractive candidates for nanoelectronics, spintronics, and quantum information processing. It has been shown that with the use of a liquid helium cooled scanning probe microscope (SPM) the electronic charge state of a single quantum dot can be chosen by merely moving the tip of the SPM with respect to the dot [1]. Simulations show that this technique can also be implemented for double quantum dots with interdot separation less than 30nm. By applying a magnetic field the electronic states of a quantum dot can be split. It is possible to image this splitting with the local, movable electrostatic gating of the SPM. A magnetic field applied to a double dot system can be used to create a spin filter; a simple movement of the SPM tip with respect to the dot structure can determine which spin passes through the filter.

11:39AM Y30.00003 Imaging the Wavefunction of a One-Electron Quantum Dot

ERIN E. BOYD, HALVAR J. TRODAHL, Dept of Physics, Harvard Univ, PARISA FALLahi, Dept of Physics, ETH, R.M. WESTERVELT, Dept of Physics and Sch of Eng and App Sci, Harvard Univ, LINUS E. FROBERG, LARS SAMUELSON, Dept of Solid State Physics, Lund Univ — InAs quantum dots grown in InAs/InP nanowires are promising contenders for nanoelectronics. A fundamental understanding of the quantum behavior of the electron is important for the design of quantum devices. We have developed an imaging technique to image the electron wavefunction of a quantum state inside a long InAs dot (length>diameter) formed by InP barriers, using a liquid He-4 cooled scanning probe microscope [1]. The electrostatic potential of the tip dents the wavefunction and changes the energy of the quantum state by an amount proportional to the electron probability density at the tip position. Using Coulomb blockade conductance images of the dot, the energy change vis. tip position can be found. By deconvolving the measured energy shift with the tip potential, one can extract the electron probability density, using first-order perturbation theory. [1] P. Fallahi, PhD Thesis, Harvard Univ (2006).

11:51AM Y30.00004 Theoretical study of spin relaxation in a carbon nanotube quantum dot

BRIAN BEZANSON, XUEDONG HU, SUNY Buffalo — Carbon nanotubes offer an attractive environment for coherent spin manipulation due to the small population of nuclear spins and weak spin-orbit interaction. While a couple of specific spin relaxation mechanisms have been investigated theoretically[1][2], there is still no comprehensive study of spin lifetimes in carbon nanotubes. In the present study we calculate the spin decay rate for electrons in gate-defined quantum dots on carbon nanotubes due to the spin-orbit and electron-phonon interactions. More specifically, we explore effects of magnetic field strength and orientation, tube diameter and chirality, and confinement.

12:03PM Y30.00005 Analysis of unusual splitting of Kondo peak in the differential conductance of a carbon nanotube quantum dot

JEFFREY STEPHENS, JEROME LICINI, Lehigh University, A.T. CHARLIE JOHNSON, DOUG STRACHAN, DANVERS JOHNSTON, SAM KHAMIS, University of Pennsylvania — Carbon nanotubes grown by chemical vapor deposition on an oxidized silicon substrate were contacted to form a gated sample of parallel tubes. Testing was done at low temperature and high magnetic field using a dilution refrigerator and superconducting magnet. The current versus voltage graph shows asymmetry with respect to zero volts. The differential conductance (dI/dV) is computed and yields some intriguing behavior. The previous asymmetry is more apparent as is a sharp increase in conductivity near zero volts. Temperature data further suggests a conductance peak at near zero voltage consistent with the Kondo effect. High magnetic fields, 0 to 11 Tesla in 0.5 Tesla increments, are used to probe the conductance behavior. The magnetic field tests yield unusual shapes and splitting at two critical fields.

12:15PM Y30.00006 Probing edge-localized states of graphene quantum dots on Co(0001)

DAEJIN EOM, KWANG RIM, DUII ZHOU, MICHAEL LEFENFELD, LI LIU, SHENXIONG XIAO, COLIN NUCKOLLS, GEORGE FLYNN, TONY HEINZ, Columbia University — Two-dimensional graphene sheets of finite lateral extent are expected to show characteristic edge states at their boundaries. In particular, for zigzag edges, highly degenerate localized states have been predicted theoretically (Ref. 1) and probed by STM (Ref. 2). Such boundary effects are expected to be particularly prominent for nanometer-scale graphene quantum dots, structures for which the proportion of edge atoms is significant. In this paper we present investigations of graphene quantum dots that we have prepared by annealing carbon- bearing precursor molecules on a Co(0001) surface. Using scanning tunneling microscopy as a local probe of the physical and electronic structure, we report results on the nature of edge states for quantum dots of differing geometrical shape. We observed prominent edge-localized states for triangular quantum dots, whereas these features are suppressed for quantum dots of hexagonal shape. These observations are consistent with numerical simulations of the expected electronic structure. 1. M. Fujita et. al., J. Phys. Soc. Jpn. 65, 1920 (1996) 2. Y. Niimi et. al., Phys. Rev. B 73, 085421 (2006)

12:27PM Y30.00007 Surface Functionalized Carbogenic Quantum Dots

A. B. BOURLINOS, NCSR “Demokritos”, Greece, A. STASSINOPoulos, A. ANGLOS, S.H. ANASTASIADIS, Foundation for Research and Technology-Hellas, Greece, R. ZBORIL, Palacky Univ., Czech Republic, M. KARAKASSIDES, Univ. of Ioannina, Greece, E.P. GIANnELIS, Cornell Univ — Surface functionalized carbon-based quantum dots (C-QDs) are formed in-situ in a single-step process via thermal carbonization of suitable molecular precursors based on ammonium citrate salts. The as-synthesized nanoparticles have near spherical morphology and size around 7nm. Using different surface modifiers, we can form hydrophobic or hydrophilic capped C-QDs, which can be dispersed in organic or aqueous solvents, respectively. These C-QDs fluoresce strongly upon optical excitation. We believe that the fine size of the C-QDs combined with their disorder structure favor a high concentration of defect sites at the surface of the nanoparticles that, upon stabilization by the attached organic groups, give rise to the observed emissions. It is further noted that the emission band shifts to shorter wavelengths as the excitation is blue-shifted. In a series of studies, the emission quantum yield of C-QDs was found to be around 4%. These types of materials are promising as fluorescent tags for biological application. Sponsored by the UlfFORTH (Laserlab- Europe) and by the Greek GSRT.

12:39PM Y30.00008 Scanning Probe Microscopy Characterization of Electrical Properties of Bimetallic Core Shell Nanostructures, REGINA RAGAN, SANGYEOB LEE, ANIKAETA SHINDE, SATORU EMORI, UC Irvine — Metallic nanoparticles have shown enhanced catalytic activity compared to their bulk counterparts potentially due to changes in electronic properties at the nanoscale. Challenges in nanoscale catalysis studies include the fabrication of monodisperse nanostructures as well as a fundamental knowledge of the electronic properties at the nanometer length scale. Our group addresses these issues by fabricating dense ordered arrays of bimetallic core-shell nanostructures and characterizing structures with scanning tunneling spectroscopy and Kelvin probe force microscopy. Self assembled rare earth disilicide nanowires are used as templates for the growth of the structure. We will present results on the electronic and vibrational properties of these structures with nanometer scale resolution using STS and KPFM. STS measurements of RESi2 nanowires will be presented that show enhanced tunneling as compared to thin films as well as size dependant rectification ratios when comparing islands and wires of various width. KPFM is used to measure the work function of various sizes of RESi2 nanostructures providing a fundamental basis for understanding catalytic behavior in terms chemical activity of the nanostructures. KPFM data reveals a higher CPD for DySi2 nanowires than islands with Δφ nanoisland-nanowire found to be 230mEV.

12:51PM Y30.00009 Controlled fabrication and electrical properties of long quasi-one-dimensional superconducting nanowire arrays, KE XU, JAMES HEATH, Division of Chemistry and Chemical Engineering, California Institute of Technology — Quasi-one-dimensional superconducting nanowires are an interesting and ideal system to examine fundamental superconducting phase transition phenomena. We report a general method for reliably fabricating quasi-one-dimensional superconducting nanowire arrays, with good control over nanowire cross section and length, and with full compatibility with device processing methods. We investigate Nb nanowires with individual nanowire cross-sectional areas that range from bulk-like to 10 x 11 nm, and with lengths from 1 to 100 micrometers. Nanowire size effects are systematically studied. In particular, a comprehensive investigation of influence of nanowire length on superconductivity is reported for the first time. All results are interpreted within the context of phase-slip models.

1 This work was supported primarily by the Department of Energy (DE-FG02-04ER46175), with additional support from the Office of Naval research (N00014-07-1-0360) and the MARCO Center for Advanced Materials and Devices.

1:03PM Y30.00010 Optical Interferometry of Gas Pressure Damped Silicon Nanobridges and Nanocantilevers, O. SVITELSKY, N. LIU, V. SAUER, J. LOSBY, M. BELOV, E. FINLEY, K.M. CHENG, M. FREEMAN, W. HIEBERT, University of Alberta Physics Dept, and National Institute for Nanotechnology, Edmonton AB Canada — The growing interest in NEMS, in particular in nanobridges and nanocantilevers, is determined by the prospective of their use as highly sensitive sensors of various physical factors: mass, tension, pressure, viscosity, etc. In order to investigate their properties under damping, a series of NEMS with different sizes was prepared from standard SOI wafers by the chemical etching after electron beam lithography. The surfaces were coated by layers of Al, Au and/or Cr in different combinations. The quality of the fabricated NEMS was evaluated by SEM imaging. The resonant frequencies of the NEMS varied in the range of 10-1000 MHz. The damping was introduced by means of pressurized gas in specially built optical pressure chamber capable to hold up to 5 atmospheres with glass window and not less than 160 atmospheres if equipped with sapphire window. We demonstrate that the NEMS Q-factor, the amplitude and the frequency of their resonances show considerable dependence on the value of the pressure in the chamber.

1:15PM Y30.00110 Periodic and Quasiperiodic Nanostructures: Accessing Complex Architectures Through Designer Phase Masks, CHEONG YANG KOH, EDWIN THOMAS, Massachusetts Institute of Technology — In this work, we show how one may design phase mask architectures in order to achieve complex 3-dimensional periodic and quasiperiodic nanostructures through considerations of the symmetries of the phase masks. By making use of the fact that phase mask interference lithography is essentially a case of light propagation through the non-modulated direction of a finite photonic crystal slab, we show that the diffracted beams obey the symmetry restrictions of the corresponding phase mask, which allow us to determine and design the polarizations and directions of the exiting beams which interfere coherently in the substrate, subsequently leading to the formation of 3-dimensional nanostructures which are periodic or quasiperiodic. The extension of this approach towards quasiperiodic structures is straightforward when working in Fourier space, which identifies the propagating eigen-modes within the phase mask, or photonic crystal slab. This allows us to rationally design structures with targeted properties, utilizing this Fourier space approach. We show several examples of this approach in achieving this method of fabrication for both periodic and quasiperiodic nanostructures.

1:27PM Y30.00112 Field Emission Enhancement and the Field-Screening Effect Reduction using Carbon Nanopipettes as Cold Cathodes, ABDELILAH SAFIR, ElectroOptics Resarch Institute and Nanotechnology Center, University of Texas at Austin, THE CENTER FOR COMPLEX QUANTUM SYSTEMS TEAM — We compute the electron transmission through a bi-ripple waveguide. The dimensions of the bi-ripple waveguide is A) demonstrates promising emission properties of graphene.

1:39PM Y30.00013 Dicke effect in a multi-ripple electron waveguide, HOSHIK LEE, LINDA REICHL, The University of Texas at Austin, THE CENTER FOR COMPLEX QUANTUM SYSTEMS TEAM — We compute the electron transmission through a bi-ripple electron waveguide. We numerically observe a resonance splitting, in this open quantum system, which is analogous to the Dicke effect in quantum optics. We also plot S-matrix poles in the complex energy plane, and find that two symmetry related poles contribute to the resonance splitting. We find that the symmetric resonant states are easily coupled to the leads, but the anti-symmetric states are not. We show the resonance splitting is due to a indirect interaction between wavefunctions in each cavity using a simple model. We also show that one of S-matrix poles withdraws from the real axis as a ripple is added. It turns out that the width of the resonance for N-ripple waveguide is N times larger than the resonance width of a mono-ripple waveguide. It agrees with the result of the Dicke model.

1:51PM Y30.0014 What is Quantum in Quantum Pumping: The role of the Phase and Asymmetries, KUNAL NAS, Fordham University, TOMAS OPATRNY, Palacky University — By studying several examples, we show that quantum pumping does not always necessitate a strictly quantum description, neither is phase always a necessary concept. The same quantum mechanical picture of pumping encompass a variety of distinct mechanisms, some can be simulated by classical mechanisms while others can be explained only in a quantum picture; the role of the phase of the wavefunction is the crucial differentiator. We also show that most pumping processes have a previously unconsidered antisymmetric component which contributes significantly to the instantaneous current at each terminal but causes no net charge transfer. We have also computed the exact pumped current for arbitrary rates of time variation for certain potentials, not just in the adiabatic regime as has been previously studied.
2:03PM Y30.00015 Evanescent-wave current through nanometer-scale conductor with generalized channel decomposition in non-equilibrium Green’s function theory, HIROSHI SHIINOAKA, Dept. of Applied Physics, Univ. Tokyo, TAKEO HOSHI, Dept. of Applied Mathematics and Physics, Tottori Univ. and JST-CREST, TAKEO FUJIIWARA, Center for Reserch and Development of Higher Education, Univ. Tokyo and JST-CREST — In optics, evanescent wave is known as a decay mode without dissipation, which appears at total reflecting surfaces and surfaces of nanoparticles. Even though such decay mode can be found, in principle, also in electronic current in nanometer-scale conductors, the evanescent wave effect has not yet been investigated systematically, in materials with electronic structure. We present a new eigen-channel decomposition of Green’s function and the associated effective medium approximation. By applying this method and knowing the system is located at a nanometal wires, we found decaying behavior of electron density and backward current flows near electrodes, which is evidence of evanescent waves. We also found that the evanescent waves cause conductor-length dependence of the transmission, which is detectable in experiments. Dependence of the evanescent waves on materials and structures are also discussed from a point of view of band structures and their connectivity at electrodes.

This work was supported by JSPS Research Fellowships for Young Scientists.

Friday, March 14, 2008 11:15AM - 2:03PM – Session Y31 DMP GMAG: Focus Session: Sodium Cobaltites Morial Convention Center 223

11:15AM Y31.00001 Charge order and anomalous magnetism in the Na cobaltates, HENRI ALLOUL, Physique des Solides, CNRS UMR 8502, univ. Paris-Sud, 91405 ORSAY — The layered Na cobaltates have some analogies with the cuprates as 2D conductivity occurs in the CoO planes and doping can be modified by changing the Na content. Also ordered magnetic phases have been evidenced, but unexpectedly for large values of x for which one would expect a hole doping of the band insulator NaCoO₂. Indeed, in the high crystal field on the Co sites in these compounds, an anionic picture for the Co states would correspond to low spin configurations Co³⁺, S=0 or Co⁴⁺, S=1/2. We shall present SQUID and $^{23}$Na and $^{59}$Co NMR data [1] taken on samples synthesized and characterized by X ray crystallography in LLB, Saclay. We evidence that the Co charge is uniform for x=0.35 as in the hydrated superconductive phase. For high Na contents the samples are found to display ordered Na structures or mixtures of those, with different x values. In pure phases isolated for specific x values, we evidence a charge disproportionation into non magnetic Co⁵⁺ and more magnetic Co sites with an average charge of about Co⁴⁺, except for x=0.5 [2]. This hole delocalization and charge order occur both for paramagnetic and AF phases [3]. NMR investigations of the dynamic susceptibilities allow us to characterize the nature of the in plane electronic correlations in most parts of the phase diagram. Contrary to the case of most cuprates for which dopant disorder is quite influential, the hole doping achieved in cobaltate samples is associated with the insertion of well ordered Na planar structures. They have to be taken into account to explain theoretically the metallicity, the magnetic properties and their evolution with doping.

11:51AM Y31.00002 Sodium Ordering Phase Transition in Sodium Cobaltate, D.J.P. MORRIS, HMI Berlin, Germany, M. ROGER, CEA Saclay, France, D.A. TENNANT, HMI Berlin and Technische Universitat Berlin, Germany, M.J. GUTMANN, ISIS Facility, UK., J.P. GOFF, Royal Holloway, University of London, UK., D. PRABHAKARAN, Clarendon Laboratory, Oxford, UK., J.-U. HOFFMANN, R. FEYERHERM, E. DUDZIK, K. KIEFER, HMI Berlin, Germany. — NaₙCoO₂ has emerged as a system of fundamental scientific interest because of its highly unusual electrical and magnetic properties. Using neutron and x-ray diffraction we have detected long-range 3D ordering of Na⁺ ions in single crystals, and demonstrate a kaleidoscope of Na⁺ ion patterns as a function of concentration and temperature [1]. Large scale numerical simulations reveal the ordering principle for this system, the formation of tri-vacancy charged droplets that then order long range, and the structure factors from these defect clusters are in good agreement with the observed neutron diffraction intensities. Superstructure transitions are observed in the diffraction data which are explained by a change from a stripe structure of tri-vacancies. The results readply explain many of the observed electrical and magnetic properties, including the formation of ferromagnetic sheets in the CoO₂ layers over this composition range, and the 3D nature of the magnetic excitations. [1] M. Roger et al. Nature 445, 631 (2007)

12:03PM Y31.00003 New magnetic states in Na₅CoO₂ induced by controlled Na order, T. F. SCHULZE, P. S. HAEFLIGER, Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland, CH. NIEDERMAYER, Laboratory for Neutron Scattering, ETH Zurich, CH-8093 Zurich, Switzerland and Paul Scherrer Institute (PSI), CH-5232 Villigen, Switzerland, K. MATTENBERGER, S. BUBENHOFER, B. BATLOGG, Laboratory for Solid State Physics, ETH Zurich, CH-8093 Zurich, Switzerland — We prove the direct link between low temperature magnetism and high temperature Na⁺ ordering in Na₅CoO₂ using the example of a so far unreported magnetic transition at 8K. The new magnetic state carries a weak ferromagnetic moment parallel to the CoO₂ layers. The 8K feature has been characterized in detail and its dependence on a diffusive Na⁺ rearrangement around 200K is demonstrated. The diffusive process is found to slow down around 200K, and the characteristic time scale reaches several hours at 195K. Applying muons as local probes this process is shown to result in a reversible phase separation into distinct magnetic phases that can be controlled by specific cooling protocols. Thus the impact of ordered Na⁺ Coulomb potential on the itinerant electrons in the CoO₂ layers is evident, and new ways to experimentally revisit the Na₅CoO₂ phase diagram are discussed.

12:15PM Y31.00004 Precise control of the Na nonstoichiometry in Na₅CoO₂, YOSHIIKO OKAMOTO, ATSUISHI NISHIO, YOKO KIUCHI, ZENJI HIROI, Institute for Solid State Physics, Univ. of Tokyo — Na₅CoO₂ has been attracting great interests in terms of a correlation between its electronic properties and Na nonstoichiometry. Many groups have reported that a Na rich phase (x ~ 0.7) is a Curie-Weiss metal and a poor phase (x ~ 0.3) is a Pauli paramagnetic metal. The origin of this difference, however, has not been confirmed yet, mainly because of difficulty in controlling precisely the Na nonstoichiometry. We succeeded in synthesizing a series of polycrystalline samples of Na₅CoO₂ with well-controlled Na content by the solid-state reaction instead of the solution reaction previously used. We prepared polycrystalline Na₅CoO₂ (0.58 < x < 0.63) by a solid-state reaction of Na₀.₆₂CoO₂ and Na₀.₅₃CoO₂ at 200°C. Furthermore, fine tuning of Na content in the range of 0.62 < x < 0.63 was carried out by a solid-state reaction of Na₀.₆₂CoO₂ and Na₀.₅₃CoO₂. Magnetic susceptibility of Na₅CoO₂ exhibited Curie-Weiss behavior at x > 0.62 while nearly temperature independent paramagnetic behavior at x < 0.61. Such a drastic change of magnetism clearly indicates that the magnetic phase boundary is located in an extremely narrow range around x = 0.62. We think that the difference originates from a change of the Fermi surface topology with electron filling probably associated with the dip in the a₁g band near the Γ point.

12:27PM Y31.00005 Systematic ARPES study on Na-rich Na₅CoO₂ (0.75<x<1) Y.-M. MU, Boston College, P. RICHARD, M. NEUPANE, F.-C. CHOU, C.-T. LIN, M. GAO, Z. WANG, H. DING — The phase diagram of the cobaltolate Na₅CoO₂ with varying Na concentration x is very rich and complicated. At the high-doping regime (x>0.75), the system was found to be more correlated, with a spin-density-wave state emerging at low temperatures. A stable phase was found with $\sqrt{13} \times \sqrt{13}$ symmetrical superstructure at Na-rich doping cobaltite. We will report our recent ARPES results of the Na-rich Na₅CoO₂ (0.75<x<1) samples.
12:39PM Y31.00006 Fermi surface pockets in Na$_x$CoO$_2$ for $x = 0.71$ and 0.84: Localization effects and emergence of a spin-liquid ground state. LUIS BALICAS, YOUNJUNG JO, National High Magnetic Field Lab, Florida State University, Tallahassee, FL 32310, FANGCHENG CHOU, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan. PATRICK LEE, Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139 — Here we report the observation of Fermi surface (FS) pockets via the Shubnikov de Haas effect in Na$_x$CoO$_2$ for $x = 0.71$ and 0.84, respectively. Our observations indicate that the FS of each compound can intersect their corresponding Brillouin zones, as defined by the previously reported superlattice structures, leading to small reconstructed FS pockets, only if a precise number of holes per unit cell is localized. For $0.71 < x < 0.75$ the coexistence of itinerant carriers and localized $S = 1/2$ spins on a paramagnetic triangular lattice leads, at low temperatures, to the observation of non Fermi-liquid behavior in the electrical transport and heat capacity properties. Namely, an anomalous exponent in the temperature dependence of the resistivity and a logarithmic divergence of the heat capacity divided by temperature as the temperature is lowered. These observations suggest the possibility of a unique quantum spin-liquid ground state resulting from the interplay between itinerant carriers and fluctuating $S = 1/2$ spins on a frustrated lattice.

12:51PM Y31.00007 ARPES investigation of the electronic properties of PdCoO$_2$\textsuperscript{1}, I.M. VISHIK, W.S. LEE, Stanford University, H. TAKATSU, Kyoto University, D.H. LU, R.G. MOORE, Stanford University, Y. MAENO, Kyoto University, Z.-X. SHEN, Stanford University — The triangular-lattice layered cobaltates have emerged as an exciting new correlated electron system. Although tremendous progress has been made with Sodium Cobaltate (Na$_2$CoO$_2$) there still remain disputes, most notably, the precise Fermi surface topology. In order to gain another perspective, we have studied a related compound, Palladium Cobaltate (PdCoO$_2$). This is a chemically stably metallic oxide that can be prepared with very high purity, allowing us to study a clean system that lacks the complications introduced by doping in Na$_2$CoO$_2$. We present the first ARPES measurements on PdCoO$_2$, focusing on determining the Fermi surface topology, comparing observed band structure to theory, and making connections with bulk measurements.

1:03PM Y31.00008 $a_1g$-$e_g$ splitting and the small Fermi surface pockets in Na$_x$CoO$_2$. MICHELLE JOHANNES, DEVINA PILLAY, IGOR MAZIN, Naval Research Laboratory, Washington D.C., OLE ANDERSEN, Max Planck Institute for Fekorporforschung, Stuttgart, Germany — Because DFT calculations and ARPES experiments disagree on the existence of six small Fermi surface pockets in NaCoO$_2$, it has been suggested that correlation effects neglected by the LDA may be responsible for suppressing the eg-derived pockets. Recent DMFT work has shown that such suppression is only possible if the position of the eg band is lower than that of the a1g band, prior to correlation effects. Here we show that the energy difference between band positions, $\Delta = e_{g1}-a_{1g}$ strongly depends on Na content, Na positions, and on whether bands stem from the surface or bulk. We show that the Coulomb of the Na ions is enough to shift the a1g band beneath the eg band, even though simple crystal field arguments would suggest the opposite.

1:15PM Y31.00009 Resonant Ultrasound Studies of Quasi-2D Na$_x$CoO$_2$ (0.7 < x < 0.77). TIMOTHY CABLE, VEERKE KEPPING, Department of Materials Science and Engineering, The University of Tennessee, RONGYING JIN, Materials Science and Technology Division, Oak Ridge National Laboratory — Cobalt-based oxides have been shown to represent a new paradigm for a good thermoelectric material. These materials violate all of the traditional guidelines to help identify a potentially good thermoelectric material. In order to obtain a better understanding of its physical properties, we have initiated the synthesis of layered Na$_x$CoO$_2$, and started a study of the elastic properties of these materials using Resonant Ultrasound Spectroscopy (RUS). In this work, we discuss our results for sodium cobaltate compounds with 0.7 < x < 0.77. Single crystals were successfully grown in a floating-zone furnace, and the elastic constants have been measured as a function of temperature (5-300K) and in magnetic fields up to 5 Tesla. The resulting plots of elasticity vs. temperature clearly reflect a transition below 50 K, which is believed to be associated with rearrangement of the Na-atoms between the Co$_2$ planes.

1:27PM Y31.00010 Thermo-magnetic effect of cobalt oxides. WATARU KOSHIBAE, Sendai National College of Technology, SADAMICHI MAEKAWA, IMR, Tohoku University, CREST-JST — The cobalt oxide, Na$_2$CoO$_2$, shows not only a large thermoelectric response but also an anomalous high-temperature Hall effect: The Hall coefficient increases linearly as a function of temperature and the magnitude comes to no fewer than 8 times as large as the expected Drude value. On the electron system with the large thermopower and the large Hall coefficient, an interesting behavior is expected in the response to a magnetic field upon a temperature gradient. We have studied the electronic state of the cobalt oxide and found that the electronic structure reflects the nature of the kagomé lattice hidden in the Co$_2$O$_3$ layer. We will show the importance of the hidden kagomé lattice structure in the emergence of the anomalous Hall effect and the close relationship between the Hall and Nernst coefficients.

1:39PM Y31.00011 Nodal $d+id$ pairing and topological phases on the triangular lattice: unconventional superconducting state of Na$_x$CoO$_2$ $\cdot$ $y$H$_2$O. SEN ZHOU, Florida State University, ZIQIANG WANG, Boston College — We show that the finite angular momentum pairing on the triangular lattice has point nodes in the complex gap function. A topological quantum phase transition takes place through a gapless critical state at a specific carrier density $x_c$ where the normal state Fermi surface crosses these isolated nodes. For spin singlet pairing, we show that the second nearest neighbor $d+id$ pairing is the dominate superconducting channel. The gapless critical state appears at $x_c \approx 0.25$ for the sodium cobaltates. It has six Dirac points and is topologically nontrivial with a $T^3$ spin rotation below $T_c$. This theory provides a consistent explanation for the unconventional superconducting state of Na$_x$CoO$_2$ $\cdot$ $y$H$_2$O.

1:51PM Y31.00012 Unusual Muon Spin Relaxation in Hydrated Cobaltite Superconductors. SCOTT L. STUBBS, JESS H. BREWER, Univ. of British Columbia, JUN SUGIYAMA, YUTAKA Y. IKEKO, Toyota CRDL, PETER L. RUSSO, TRIUMF, EDUARDO J. ANSALDO, Univ. of Saskatchewan, KIM H. CHOW, Univ. of Alberta, HIROTO OHTA, KAZUYOSHI YOSHIMURA, Dept. of Chemistry, Kyoto Univ. — Muon spin relaxation ($\mu^+$SR) was studied in zero (ZF) and weak magnetic field (TF) in Na$_x$(H$_2$O)$_3$CoO$_2$ $\cdot$ $y$H$_2$O and its deuterated analog. In ZF, the muon relaxes (surprisingly) faster for the deuterated sample. Detectable effects of superconductivity are also surprisingly subtle in both cases.

Session Y32 DCOMP DMP GMAG: Focus Session: Theory and Simulations of Magnetism II
Morial Convention Center 225
Determining the magnetic ground state of systems exhibiting metastable states close to the ground state. This freedom of the method might cause an ambiguity in chirality. For the linear and the isosceles Cr trimers we obtain collinear antiferromagnetic ground states. We also address the issue of choosing the reference state equations. In case of an equilateral Cr trimer we show that the Dzialoshinsky-Moriya interactions lift the degeneracy of the $120^\circ$ state.

The magnetic ground-state of the trimers are found as the solution of the Landau-Lifshitz-Gilbert equations. In addition, we show that the inclusion of fourth-order terms into the FLAPW code FLEUR which can cope with this challenge. We show by first-principles calculations based on the vector-spin density formulation of the density-functional theory (DFT) that that there are circumstances where the DM interaction is indeed sufficiently strong to compete with the interactions that favor collinear spin alignment causing magnetic phases of unique handedness e.g., homochiral magnetic phases such as a left rotation cycloidal spiral in Mn on W(110) [M. Bode et al., Nature 447, 190 (2007)] or favoring magnetic domain-walls with unique turning sense.

11:15 AM Y32.00001 Homochiral magnetic structures at surfaces. STEFAN BLUGEL, Institut für Festkörperforschung, Forschungszentrum Jülich, D-52425 Jülich, Germany — Electrons propagating in the vicinity of inversion asymmetric environments such as surfaces, interfaces, ultrathin films or nanostructures can give rise to an important antisymmetric exchange interaction, known as Dzyaloshinsky-Moriya (DM) interaction. Although this interaction, favoring spatially rotating spin structures, is in principle known for about 50 years, its consequences for the magnetic structure in low-dimensional magnets remained nearly unexplored and has been basically overlooked the past 20 years. Theoretical models considering isotropic exchange, magnetic anisotropy and the DM interaction display a rich phase diagram of complex magnetic phases on different length scales depending on the strength of the different contributions. Today, it is unknown how large is the strength of the DM interaction. Is this just a small perturbation to the collinear uniaxial ferro- or antiferromagnetic state, determined by exchange and magnetic anisotropy or is it strong enough to create new phases which had been overlooked? Surprisingly little first-principles calculations deal with the DM interaction. There might be several reasons for this: The investigation requires the treatment of non-collinear magnetism together with spin-orbit interactions of large magnetic structures in low-symmetry situations. We developed a perturbative strategy implemented into the FLAPW code FLEUR which can cope with this challenge. We show by first-principles calculations based on the vector-spin density formulation of the density-functional theory (DFT) that that there are circumstances where the DM interaction is indeed sufficiently strong to compete with the interactions that favor collinear spin alignment causing magnetic phases of unique handedness e.g., homochiral magnetic phases such as a left rotation cycloidal spiral in Mn on W(110) [M. Bode et al., Nature 447, 190 (2007)] or favoring magnetic domain-walls with unique turning sense.

11:51 AM Y32.00002 First-principles Calculation of Magnetic Anisotropy of a Single Atom on a Surface. CHIUNG-YUAN LIN, National Chiao Tung University, BARBARA JONES, IBM Almaden Research Center — Recent progress on scanning tunneling microscopy has made it possible to position (in atomic-scale accuracy) and probe single magnetic atom on material surfaces. Targeting the fabrication of a single-atom data storage bit, we perform first-principles calculations of single magnetic atoms (Fe and Mn) on a surface. Structure relaxation determines the binding structures of the magnetic atoms to its surroundings. Charge analysis indicates that the magnetic atoms form polar covalent bonds with the surface. Spin density is found to spread up to 4 Å from the magnetic atom, which is qualitatively similar to that reported in DFT calculations of molecular magnets. Total energies with spin-orbit interaction included are calculated in different spin orientations, and are compared to the anisotropy axes measured in the experiments.

Supported by Stanford University, Center for Probing the Nanoscale

12:03 PM Y32.00003 First-principles study on the surface half-metallicity of CaC in the zincblende structure. KAILUN YAO, GUOYING GAO, ZULI LIU, Huazhong University of Science and Technology — We investigate the electronic structure and the surface half-metallicity of CaC in the zincblende structure by using the first-principles full-potential linearized augmented plane-wave (FPLAPW) method. It is found that the (1 1 0) surface preserves the half-metallic character of the bulk, while in the case of the (0 0 1) surfaces including the Ca-terminated and C-terminated surfaces the surface states destroy the half-metallicity.

This work was supported by the National Natural Science Foundation of China under Grant Nos. 10574047, 10574048 and 20490210. It was also supported by National 973 project under grant No. 2006CB921600.

12:15 PM Y32.00004 Finite Hubbard clusters with large spin polarization. ERIK NIELSEN, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, R.N. BHATT, Department of Electrical Engineering, Princeton University; Princeton Center for Theoretical Physics, Princeton, NJ 08544 — A generalized Hubbard model can be used to characterize hydrogenic impurities in semiconductors. It has been shown that the ground state spin of such impurity clusters is very sensitive to a cluster’s electron number and geometry [1]. An understanding of how these factors affect cluster magnetization is particularly relevant in light of the current ability to position phosphorus donors with nanometer accuracy within bulk silicon [2]. We present numerical results for two-dimensional clusters showing the effect of geometry and electron-hole asymmetry present in real systems of hydrogenic donors. We also consider the robustness of high-spin cluster ground states to perturbations of site position, and discuss the general features of clusters found to possess a high-spin ground state, in particular the fully spin-polarized state.

Supported by NSF-MRSEC (DMR-0213706).

12:27 PM Y32.00005 Magnetic ground state of small nanoparticles: Cr trimers on Au(111). BALAZS UJFALUSSY, Research Institute for Solid State Physics — The development of scanning tunneling microscopy (STM) and the ability to build clusters with well-controlled structures permit the study of various effects induced by local interactions within magnetic nanoclusters. However, for a clear interpretation of experimental results, first principles studies are often required, even when they are sometimes too demanding. In this talk we show a new way to map the energy of supported magnetic nanoparticles obtained from first principles calculations onto a classical spin Hamiltonian. The half-filled valence configuration of Cr yields a large magnetic moment and strong antiferromagnetic inter-atomic bonding leads in turn to magnetic frustration and complex spin phenomena. The simplest system exhibiting such properties is a trimer. The electronic structure of the Cr trimers are calculated by means of a fully relativistic Green’s function embedding method. The relativistic treatment of the electronic structure leads to a proper account of spin-orbit coupling giving rise to tensorial exchange interactions and magnetic anisotropies influencing the formation of non-collinear ground states. In addition, we show that the inclusion of fourth-order terms into the spin-model largely enhance the accuracy of the mapping. The magnetic ground-state of the trimers are found as the solution of the Landau-Lifshitz-Gilbert equations. In case of an equilateral Cr trimer we show that the Dzialoshinsky-Moriya interactions lift the degeneracy of the $120^\circ$ Néel states with different chirality. For the linear and the isosceles Cr trimers we show collinear antiferromagnetic ground states. We also address the issue of choosing the reference state inherent to methods based on the magnetic force theorem in the context to the equilateral Cr trimer. This freedom of the method might cause an ambiguity in determining the magnetic ground state of systems exhibiting metastable states close to the ground state.

2:03PM Y32.00006 A Numerical Method to Study Highly Correlated Nanostructures: The Logarithmic Discretization Embedded Cluster Approximation, E. ANDA, G. CHIAPPE, C. BUSser, M. DAVIDOVICH, G. MARTINS, F. H-MEISNER, E. DAGOTTO, Oak蘭d University — A numerical algorithm to study transport properties of highly correlated local structures is proposed. The method, dubbed the Logarithmic Discretization Embedded Cluster Approximation (LDECA), consists of diagonalizing a finite cluster containing the many-body terms of the Hamiltonian and embedding it into the rest of the system, combined with Wilson’s ideas of a logarithmic discretization of the representation of the Hamiltonian. LDECA’s rapid convergence eliminates finite-size effects commonly present in the embedding cluster approximation (ECA) method. The physics associated with both one embedded dot and a string of two dots side-coupled to leads is discussed. In the former case, our results accurately agree with Bethe ansatz (BA) data, while in the latter, the results are framed in the conceptual background of a two-stage Kondo problem. A diagrammatic expansion provides the theoretical foundation for the method. It is argued that LDECA allows for the study of complex problems that are beyond the reach of currently available numerical methods.

1:15PM Y32.00007 Coulomb and spin-orbit effects in quantum dot molecules under harmonic fields, LILIA MEZA-MONTES, Instituto de Fisica B. Universidad Autonoma de Puebla, Mexico, AREZKY H. RODRIGUEZ, Universidad Autonoma de la Ciudad de Mexico, SERGIO E. ULLOA, Dept. of Phys. and Astron. CMS- NQPI Ohio University — The time evolution of a two-electron quantum dot molecule under strong harmonic electric fields is studied. The wave function is determined in terms of the single-electron orbitals using the Floquet approach. We pay particular attention to the evolution of the spin states of the system, as the surface inversion asymmetry (Rashba-type) and bulk inversion asymmetry (Dresselhaus-type) spin-orbit effects are known to introduce spin mixing. We also study the role of a perpendicular magnetic field, which is shown to have dramatic effects on the dynamics. We present an analysis of the physical behavior of the system in terms of the quasi-energy spectrum, and study the time evolution of the occupation probabilities of the dots. Conditions for singlet-triplet mixing, similar to the spin-flips observed in the single-electron case, are analyzed. These results are relevant for applications in spin-controlled devices.

1:27PM Y32.00008 Electron Transport in Nanogranular Ferromagnets, IGOR BELOBORODOV, University of Chicago, ANDREAS GLATZ, VALERII VINOKUR, Argonne National Laboratory — I will discuss electronic transport properties of ferromagnetic nanoparticle arrays and nanodomain materials near the Curie temperature in the limit of weak coupling between the grains. The conductivity is calculated in the Ohmic and non-Ohmic regimes and the magnetoresistance jump in the resistivity at the transition temperature is estimated. The results are applicable for many emerging materials, including artificially self-assembled nanoparticle arrays and a certain class of manganites, where localization effects within the clusters can be neglected.

1:39PM Y32.00009 Inverse band structure optimization of (InAs)/(GaAs) (001) nanostructures for thermophotovoltaics, PAULO PIQUINI, PETER GRAF, ALEX ZUNGER, National Renewable Energy Laboratory — Thermophotovoltaic materials converting black-body thermal radiation to electricity often require conversion efficiency for materials with direct band gaps of 0.6 eV. Random In$_{53}$Ga$_{47}$As alloy lattice matched to InP have a gap around 0.76 eV, too big for this application. Therefore, difficult to grow lattice-mismatched In-rich InGaAs alloys have been attempted in the past. Here we suggest to use (InAs)$_n$/(GaAs)$_m$ ordered superlattices (rather than random), lattice matched to InP substrates. Using empirical pseudopotential calculations and genetic algorithm methods we look for the sequence of InAs and GaAs pure layers that simultaneously lead to a target band gap of 0.6 eV and has a minimum in-plane stress (strain balance condition). Further, since for (InAs)$_n$ layers with $n>5$ the two-dimensional growth is unstable and SK quantum dots are seen to form, we restrict the value for the period of the InAs layers to be always lower than 5.

1:51PM Y32.00010 Spin-blockade in a Hubbard chain with spin-dependent impurities, CHANG-QIN WU, YAO YAO, Department of Physics, Fudan University, Shanghai, CHINA — We investigate the spin/charge transport in a one-dimensional strongly-correlated system using adaptive time-dependent density matrix renormalization group method. The model we consider is a non-half-filled Hubbard chain with spin-dependent impurities, which is found to display the blockade of spin current while little influence on charge current. We have considered (1) the spread of a wave packet of both spin and charge in the Hubbard chain and (2) the spin and charge currents induced by a spin-dependent voltage bias that is applied to the ideal leads attached at the ends of this Hubbard chain. It is found that the spin-charge separation plays a key role in the spin-blockade and a large on-site repulsion $U$ is required for more effective utilization of this phenomenon in some spin-related devices, like spin memory.

2:03PM Y32.00011 Signature of hyperfine interaction through current properties in quantum dots, ERNESTO COTA, FERNANDO ROJAS, Centro de Ciencias de la Materia Condensada, Universidad Nacional Autonoma de Mexico, SERGIO E. ULLOA, Ohio University — Several experiments have been carried out to observe and control spin properties of electrons in quantum dots subject to the hyperfine interaction due to nuclear spins. In this work, we study the manifestation of the hyperfine interaction through current calculations in one and two quantum dots. We use the density matrix master equation approach in the stationary regime taking into account an external magnetic field and the nuclear magnetic field in the quasistatic approximation characterized by the statistical fluctuations of the components of the nuclear field. As a first step, we study the case of a single quantum dot with one orbital. We study in detail the effects on the current of the hyperfine interaction, temperature and external magnetic field and we find that it is possible to obtain information on the hyperfine interaction directly from the differential conductance. We extend the model to study a double quantum dot with one and two electrons, including tunneling and exchange interactions, where the signature of the hyperfine interaction is more involved.

11:51 AM  Y33.00002 Insulator-ferromagnetic metal transition in anatase Fe:TiO$_2$. ENJU SAKAI, The University of Tokyo, YASUSHI HIROSE, KAST, TARO HITSUGI, TOSHIHIRO SHIMADA, TETSUYA HASEGAWA, The University of Tokyo, KAST — Local Fe valence states in Fe-doped anatase TiO$_2$ (Fe:TiO$_2$) were investigated in relation with transport and magnetic properties. Anatase Fe:TiO$_2$ films were deposited on LaAlO$_3$ (100) substrates by pulsed laser deposition technique. Amounts of oxygen vacancies in the films were controlled by varying partial oxygen pressure during deposition ($P_{O_2}$). Magnetic and transport properties of the synthesized Fe:TiO$_2$ films measured by SQUID and conventional four-probe measurements. An insulator-ferromagnetic metal transition was clearly observed between $P_{O_2} = 1 \times 10^{-6}$ and $3 \times 10^{-6}$ Torr. X-ray photoemission spectroscopy (XPS) measurements have revealed that the local Fe valence state changes from 3+ to 2+, accompanied with the insulator-ferromagnetic metal transition. These results strongly suggest that carriers bound to Fe-oxygen vacancy pairs form magnetic polarons, and that mutual overlap of magnetic polarons triggers the insulator to ferromagnetic metal transition in Fe:TiO$_2$.

12:03PM Y33.00003 Insights into magnetically doped semiconductors from soft x-rays$^1$. D.J. KEAVNEY, Argonne National Laboratory, D.B. BUCHHOLZ, Northwestern University, Q. MA, Northwestern University Synchrotron Research Center, R. CHANG, Northwestern University, T.C. DROUBAY, T.C. KASPAR, S. CHAMBERS, Pacific Northwest National Laboratory — Soft x-ray absorption and dichroism provide a crucial test of the intrinsic nature of magnetism in doped semiconductor. Experiments on Mn, Co, and Cu-doped ZnO reveal that the magnetic dopants have primarily paramagnetic field and temperature dependence regardless of whether the bulk behavior is ferromagnetic. In PLD-grown ferromagnetic Cu:ZnO, no zero-field dichroism is detected at the Cu L, O K, or Zn L edges. In MOVCD-grown Co:ZnO, we find a small remanent signal that is consistent with bulk magnetization measurements of $\sim 0.04 \mu_\text{B}/\text{Co ion}$, however the signal is insufficient to rule out metallic Co as its origin. These results suggest that the origins of ferromagnetism in doped oxides may be unrelated to the presence of magnetic dopants.

12:15PM Y33.00004 Structural, Magnetic and Transport Properties of a New Class of Ferromagnetic Semiconductors/Metals: (Ba, Sr)$_2$M$_{2+x}$Ru$_{1-x}$O$_{11}$ (M = Fe, Co)$.^2$ LARYSA SHLYK, LANCE DE LONG, SERGIY KRYUKOV, Dept. of Physics and Astronomy, University of Kentucky, BARBARA SCHÜPP-NIEWA, RAINER NIEWA, Department Chemie, Technische Universität München — Single crystals (mm size) of (Ba, Sr)$_2$Fe$_{2+x}$Ru$_{1-x}$O$_{11}$ and (Ba, Sr)$_2$Co$_{2+x}$Ru$_{1-x}$O$_{11}$ were grown for the first time. X-ray refinements confirmed a hexagonal space group (P6$_3$/mmc, No. 194) with two crystallographic sites having mixed Ru and Fe/Co occupation, and one site occupied exclusively by the 3d species. Structural parameters and charge balance suggest oxidation states Co$^{2+}$ and mixed Ru$^{3+}$/Ru$^{4+}$ in the Co compound, and mixed Fe$^{2+}$/Fe$^{3+}$ and Ru$^{4+}$/Ru$^{5+}$ in the Fe compound. The physical properties of these single crystals are sensitive to site disorder among the transition metal ions. Magnetic and transport measurements show the Co-bearing barium ferrite is a ferromagnetic metal below 105 K. In contrast, Fe-bearing barium and strontium compounds exhibit long-range ferromagnetic order at temperatures above 400 K, and narrow-gap semiconductor properties that include a large anomalous Hall conductance, low resistivity, and high carrier concentration. These characteristics make the Fe-bearing materials promising new candidates for spintronic applications.

12:27PM Y33.00005 Spin coherence of electrons in singly-charged quantum dots. DMITRI YAKOVLEV, Technical University Dortmund — We present experimental and theoretical study on electron spin coherence in ensemble of n-type doped InGaAs/GaAs quantum dots containing one electron per dot. A pump-probe time-resolved Faraday rotation technique is exploited. Long-lived spin precession of resident electrons in external magnetic fields is observed with the dephasing time of spin ensemble exceeding 6 ns. Rabi oscillations of the Faraday rotation amplitude have been detected confirming the suggested model of generation electron coherent via excitation of coherent superposition of the spin state and the resident electron [1]. We show that the ensemble dephasing can be overcome by using a periodic train of light pulses to synchronize the phases of the precessing spins. This mode-locking leads to constructive interference of contributions to Faraday rotation, and presents potential applications based on robust quantum coherence within an ensemble of dots [2, 3]. Under these experimental conditions spins of the dots nuclei are aligned in a way that all dots in the ensemble contribute to the coherent signal with a potential to focus the electron Larmor frequencies in the ensemble to a single mode [4]. The used optical technique allows to recover the coherence time of a single quantum dot. The measured spin coherence time is 3 microseconds, which is four orders of magnitude longer than the ensemble dephasing time of 400 picoseconds. This work is done in collaboration with A. Greilich, I. A. Yugova, R. Oulton, M. Bayer, A. Shabaev, Al. Efros, D. Reuter and A. D. Wieck.

1:03PM Y33.00006 Impurity-Ion pair induced high-temperature ferromagnetism in Co-doped ZnO. STEFANO SANTIVO, CHAITANYA DAS PEMMARAJU, RUAIRI HANAFIN, THOMAS ARCHER, School of Physics and CRANN, Trinity College Dublin, HANS BENJAMIN BRAUN, School of Physics, University College Dublin — Magnetic 3d-ions doped into wide-gap oxides show signature of room temperature ferromagnetism, although their concentration is two orders of magnitude smaller than that of conventional magnets. The prototype of these exceptional materials is Co-doped ZnO, for which an explanation for the room temperature ferromagnetism is still elusive. Here we demonstrate that magnetism originates from Co$^{2+}$ oxygen-vacancy pairs with a partially filled level close to the ZnO conduction band minimum. The magnetic interaction between these pairs is sufficiently long-range to cause percolation at moderate concentrations. However, magnetically correlated clusters large enough to show hysteresis at room temperature already form below the percolation threshold and explain the current experimental findings. Our work demonstrates that the magnetism in ZnO:Co is entirely governed by intrinsic defects and a phase diagram is presented. This suggests a recipe for tailoring the magnetic properties of spintronics materials by controlling their intrinsic defects.

1:15PM Y33.00007 Magnetic 3d interactions in ZnO and In$_2$O$_3$ in a band-gap corrected approach. STEPHEN LANY, H. RAEBIGER, A. ZUNGER, Natl. Renewable Energy Lab — The electronic and magnetic configuration of 3d transition metal (TM) impurities in wide-gap oxides like ZnO and In$_2$O$_3$ is misrepresented in the standard LDA and GGA approximations to density functional theory: Because the conduction band minimum lies energetically much too low, the spin-polarized impurity states wrongly occur as resonances inside the conduction band rather than as gap states. Due to spurious “charge spilling” from the TM impurity state into the host conduction band, the magnetic moment and the occupancy of the TM impurity state is incorrect, and the TM state becomes partially occupied, which is prone to cause overestimated ferromagnetic interactions. These errors in the LDA+U or GGA+U methods often applied to TM-doped states. In our band-gap corrected approach, we augment the GGA+U functional by empirical non-local external potentials (NLEP) for the $s$- and $p$-states of Oxygen and the cations. In this approach the correct spin and orbital configuration of the TM impurity-states is recovered. In the absence of additional doping, we find generally short-ranged magnetic interactions, and pronounced Jahn-Teller effects in case of partially occupied gap states. Additional electron-doping can lead to more long-range ferromagnetic interactions for those TM-dopants that have unoccupied d-states which hybridize strongly with the conduction band.
1:27PM Y33.00008 Study of the anomalous Hall effect, magnetoresistance, and magnetic anisotropy in ZnO:Co and ZnO:Mn thin films. Z. YANG, Z. ZUO, Y. PU, M. BIASINI, W. BEYERMANN, J. SHI, J. LIU, QUANTUM STRUCTURES LABORATORY, DEPT OF ELECTR ENGR, UNIV OF CALIFORNIA, RIVERSIDE, CA TEAM — ZnO-based diluted magnetic semiconductor (DMS) materials have attracted much attention in these years due to the theoretical prediction of above room-temperature ferromagnetism. So far, most of the experiments were focused to the study of the magnetization of the ZnO DMS materials. However, the magnetization study, by only providing a global information on the moment of the material, cannot distinguish the intrinsic magnetic properties from the extrinsic contributions. The ZnO thin films were grown on sapphire substrates by molecular-beam epitaxy. The Co- and Mn-implantations were performed on the as-grown ZnO samples with different free carrier concentrations. Anomalous Hall effect (AHE) and magnetoresistance measurements were performed on the ZnO:Co and ZnO:Mn thin films. AHE hysteresis loops were observed in both ZnO:Co and ZnO:Mn thin films, which confirm the intrinsic ferromagnetism in both films. However, the AHE hysteresis loops are distinctly weaker than the magnetization hysteresis loops (\(M - H\)) measured by SQUID. Therefore we conclude that both intrinsic and extrinsic ferromagnetism co-exist in the samples.

1:39PM Y33.00009 Influence of oxygen partial pressure on structural, transport and magnetic properties of Co doped TiO2 films. BAKHTYAR ALI, Department of Physics and Astronomy, University of Delaware, Newark DE, 19716, USA, ABDUL RUMAIZ, ARIF OZBAY, S. ISMAT SHAH, EDMUND NOWAK — Crystal structure, transport and magnetic properties of Co doped TiO2 laser ablated thin films are investigated and are found to have a strong dependence on the oxygen partial pressure. X-ray diffraction reveals the presence of mixed phase material containing anatase and rutile. However, these phases intertransform with the change in the oxygen partial pressure in the chamber during the growth of the films under the same temperature and other growth conditions. Electrical conductivity enhances as more oxygen vacancies are created. Concomitantly, the magnetization increases with increased vacancy concentration. The electrical transport data is suggesting that the conduction is dominated by polarons. The activation energies obtained are in the range from 100 to 150meV, typical for semiconducting oxides. 11:15AM Y36.00001 Understanding the dynamical control of animal movement. DONALD EDWARDS, Georgia State University — Over the last 50 years, neurophysiologists have described many neural circuits that transform sensory input into motor commands, while biomechanicians and behavioral biologists have described many patterns of animal movement that occur in response to sensory input. Attempts to link these two have been frustrated by our technical inability to record from the necessary neurons in a freely behaving animal. As a result, we don’t know how these neural circuits and patterns are structured, or how they change with context change or time-scale. To address this problem, we have developed a software package, AnimatLab (www.AnimatLab.com), that enables users to reconstruct an animal’s body and its relevant neural circuits, to link them at the sensory and motor ends, and through simulation, to test their ability to reproduce appropriate patterns of the animal’s movements in a simulated Newtonian world. A Windows-based program, AnimatLab consists of a neural editor, a body editor, a world editor, stimulus and recording facilities, neural and physics engines, and an interactive 3-D graphical display. We have used AnimatLab to study three patterns of behavior: the grasshopper jump, crayfish escape, and crayfish leg movements used in postural control, walking, reaching and grasping. In each instance, the simulation helped identify constraints on both nervous function and biomechanical performance that have provided the basis for new experiments. Colleagues elsewhere have begun to use AnimatLab to study control of paw movements in cats and postural control in humans. We have also used AnimatLab simulations to guide the development of an autonomous hexapod robot in which the neural control circuitry is downloaded to the robot from the test computer.

11:51AM Y36.00002 Biomechanical Analysis of Locust Jumping in a Physically Realistic Virtual Environment. DAVID COFER, GENNADY Cymbalyuk, Georgia State University, WILLIAM HEITLER, Univ. of St. Andrews, DONALD EDWARDS, Georgia State University — The biomechanical and neural components that underlie locust jumping have been extensively studied. Previous research suggested that jump energy is stored primarily in the extensor apodeme, and in a band of cuticle called the semi-lunar process (SLP). As it has thus far proven impossible to test this hypothesis directly, after the locust has been killed and placed in a dissecting pan, we have been able to test whether the energy stored in the SLP has a significant impact on the jump. To address problems such as this we have developed a software toolkit, AnimatLab, which allows researchers to build and test virtual organisms. We used this software to build a virtual locust, and then asked how the SLP is utilized during jumping. The results show that without the SLP the jump distance was reduced by almost half. Further, the simulations were also able to show that loss of the SLP had a significant impact on the final phase of the jump. We are currently working on postural control mechanisms for targeted jumping in locust.

12:03PM Y36.00003 Design of real-time locomotion generator with map-based neuronal models. NIKOLAI RULKOV, UCSO, JOSEPH AYERS, NEU, MARK HUNT, Ariel Inc. — We are developing an electronic nervous system for a biomimetic robot based on an established neurobiological model system, the Sea Lamprey. Undulatory locomotion of the lamprey is coordinated by a concatenated network of over 100 segmental central pattern generators (CPGs). To achieve real time operation in a DSP chip, we are using simple phenomenological models of neurons and synapses based on the dynamics of nonlinear maps. CPG networks based on known neuronal circuitry have replicated main properties of the dynamical behavior of the animal model. The results of numerical studies of the neuronal activity coordinating various swimming patterns in the reduced model of the CPG are considered. Both ascending and descending connections between segmental CPGs can mediate both forward and backward propagating flexion waves based on anterior or posterior bias by descending premotor commands. Bilaterally asymmetric biases of descending commands can mediate turning. The CPG outputs control 5 shape memory alloy actuators on each side to generate coordinated undulations. Two dorsal and ventral pitch actuators control the angle between the hull and undulator to control dive and climb. Descending commands are modulated by an analog compass, inclinometers, accelerometers and other sensory feedback to mediate hovering by the vehicle on a sonar beacon.

1:51PM Y33.00010 Spin-polarized tunneling study of the room temperature spin filter CoFe2O4. ANA RAMOS, JEAN-BAPTISTE MOUSSY, DSM/DRECAM/SCPSI, CEA Saclay, France, RICHARD MATTANA, Unité Mixte de Physique, CNRS/Thales, Palaiseau, France, FREDERIC PETROFF, Unité Mixte de Physique, CNRS/Thales, Palaiseau, France, TIFFANY SANTOS, Argonne National Laboratory, Argonne, IL, USA, GUO-XING MIAO, JAGADEESH MOODERA, Francis Bitter Magnet Lab, MIT, Cambridge, MA, USA — The spin filter effect has the potential of generating highly spin-polarized electron currents across the spin selective transport of electrons across a ferromagnetic tunnel barrier. In this work, we investigate the spin-polarized tunneling characteristics of cobalt ferrite (CoFe2O4), which we show is a room temperature spin filter. Tunnel junctions containing epitaxial CoFe2O4(111) tunnel barriers have been grown by oxygen plasma-assisted molecular beam epitaxy. Their structural, chemical and magnetic properties have previously been optimized by a number of in situ and ex situ methods, we focus on the spin-polarized tunneling in the CoFe2O4-based systems using different measurement techniques. Following the demonstration of spin filtering by TMR measurements, both at low temperature and at room temperature, we further investigate the spin filter characteristics of CoFe2O4 in detail. In particular, we pay special attention to the influence of defects on the spin polarization, as well as the role of different spin-detecting electrodes.

12:15PM Y36.00004 Genesis and synchronizion properties of fast neural oscillations\textsuperscript{1}, MAXIM BAZHENOV, Salk Institute, NIKOLAI RULKOV, UCSD — Fast neural network oscillations in gamma (30-80 Hz) range are associated with attentiveness and sensory perception and have strong relation to both cognitive processing and temporal binding of sensory stimuli. These oscillations are found in different brain systems including cerebral cortex, hippocampus and olfactory bulb. Cortical gamma oscillations may become synchronized within 1-2 msec over distances up to a few millimeters. In this study we used computational network models to analyze basic synaptic mechanisms and synchronization properties of fast neural oscillations. Using the network models of synaptically coupled pyramidal neurons (up to 500,000 cells) and fast spiking interneurons (up to 125,000 cells) we found that the strength of feedback inhibition determined the network synchronization state: either global network oscillations with near zero phase lag between remote sites or waves of gamma activity propagating through the network. Long-range excitatory connections between pyramidal cells were not required for long-range synchronization. The model predicts that local inhibitory circuits can mediate global network synchronization with phase delays being much smaller than activity propagation time between remote network sites.

12:27PM Y36.00005 Periodic vs. Transient Estimation of Phase Response Curves\textsuperscript{1}, JIANXIA CUI, Georgia Institute of Technology, SRISAIRAM ACHUTHAN, CARMEN CANAVIER, LSU Health Sciences Center, ROBERT BUTERA, Georgia Institute of Technology — Phase response curves (PRCs) for a single neuron are often used to predict the synchrony of mutually coupled neurons. Previous theoretical work on pulse coupled oscillators used single pulse perturbations. We propose an alternate method in which functional PRCs (FPRCs) are generated using a train of pulses applied at a fixed delay after a spike. Experimental FPRCs in \textit{Aplysia} pacemaker neurons were different from single pulse PRCs because of adaptation. Adaptation was incorporated by plotting the effective period, observed just after the pulse train is terminated, as a function of the entrained period during the pulse train. The effective intrinsic period was used iteratively in the prediction method instead of the unperturbed intrinsic period. Incorporating adaptation improved the accuracy of prediction of phase-locked modes in a model network of adapting oscillators characterized by both single pulse and multiple pulse PRCs compared to those characterized by single pulse PRCs alone.

12:39PM Y36.00006 Homoclinic Spike adding in a neuronal model in the presence of noise\textsuperscript{1}, IBINYINKA FUWAPE, ALEXANDER NEIMAN, Ohio University, Athens, Ohio, ANDREY SHILNIKOV, Georgia State University, Atlanta — We study the influence of noise on a spike adding transitions within the bursting activity in a Hodgkin-Huxley-type model of the leech heart interneuron. Spike adding in this model occurs via homoclinic bifurcation of a saddle periodic orbit. Although narrow chaotic regions are observed near bifurcation transition, overall bursting dynamics is regular and is characterized by a constant number of spikes per burst. Experimental studies, however, show variability of bursting patterns whereby number of spikes per burst varies randomly. Thus, introduction of external synaptic noise is a necessary step to account for variability of burst durations observed experimentally. We show that near every such transition the neuron is highly sensitive to random perturbations that lead to and enhance broadly the regions of chaotic dynamics of the cell. For each spike adding transitions there is a critical noise level beyond which the dynamics of the neuron becomes chaotic throughout the entire region of the parameter transition. Noise-induced chaotic dynamics is characterized in terms of the Lyapunov exponents and the Shannon entropy and reflects variability of firing patterns with various numbers of spikes per burst, traversing wide range of the neuron’s parameters.

12:51PM Y36.00007 Adaptive Neurotechnology for Making Neural Circuits Functional\textsuperscript{1}, RANU JUNG, Arizona State University, Center for Adaptive Neural Systems, Ira A. Fulton School of Engineering — Two of the most important trends in recent technological developments are that technology is increasingly integrated with biological systems and that it is increasingly adaptive in its capabilities. Neuroprosthetic systems that provide lost sensorimotor function after a neural disability offer a platform to investigate this interplay between biological and engineered systems. Adaptive neurotechnology (hardware and software) could be designed to be biomimetic, guided by the physical and programmatic constraints observed in biological systems, and allow for real-time learning, stability, and error correction. An example will present biomimetic neural-network hardware that can be interfaced with the isolated spinal cord of a lower vertebrate to allow phase-locked real-time neural control. Another will present adaptive neural network control algorithms for functional electrical stimulation of the peripheral nervous system to provide desired movements of paralyzed limbs in rodents or people. Ultimately, the frontier lies in being able to utilize the adaptive neurotechnology to promote neuroplasticity in the living system on a long-time scale under co-adaptive conditions.

1:27PM Y36.00008 Investigating the Dynamics of Functional Brain Networks with MRI, SHELLA KEILHOLZ, Emory University, WAQAS MAJEED, Georgia Institute of Technology — Functional Magnetic Resonance Imaging (fMRI) is sensitive to changes in blood oxygenation levels. While fMRI has traditionally mapped changes in these levels that localize to brain areas activated by an external stimulus, recent work has focused on detecting correlated, non-stimulus-related fluctuations in the fMRI signal throughout the brain. These fluctuations are believed to arise from spontaneous variations in local neural activity, and so correlated fluctuations from different brain areas may indicate coordinated activity. Maps of “functional connectivity” based upon these fluctuations show reproducible patterns of correlated signals. To date, research has focused on steady-state networks that persist over the entire imaging session (minutes). We are exploring the possibility of detecting changes in network activity on much shorter time scales (seconds). Preliminary analysis shows that power in the frequency band used to map functional connectivity varies over time, and that power differences correspond to changes in correlation between areas. We also detected phase differences in fluctuations that are consistent with propagating waves. These results indicate that time-varying analysis of fMRI data may provide insight into the dynamics of functional networks in the brain.

1:39PM Y36.00009 Estimating Granger causality from Fourier and wavelet transforms of time series data, MUKESH DHAMALA, Georgia State University — Experiments in many fields of science and engineering yield data in the form of time series. The Fourier and wavelet transform-based nonparametric methods are used widely to study the spectral characteristics of these time series data. We have recently extended the framework of nonparametric spectral methods to include the estimation of Granger causality spectra for assessing directional influences. We illustrate the utility of the proposed methods using artificial data and real brain data.

1:51PM Y36.00010 Anomalous Effect of Surface Diffusion on NMR Signal: Tracing the Fiber Geometry, VADYM APALKOV, NERANJAN EDIRISINGHE, GENNADY CYMBALYUK, Georgia State University — We show the strong qualitative effect of the surface diffusion channel on the echo attenuation of the NMR signal from restricted geometry, e.g., fiber system. In some range of parameters of the system the residual echo signal, which is obtained by subtracting the background value, can have anomalous behavior, which means that the echo signal has a maximum value at some finite value of the magnitude of the gradient pulses. This fact can be used to enhance the accuracy of the measurements by studying the echo signal around the maximum value. Effect described here could be also used for tuning the MRI measurements to trace fibers with particular characteristic diameters or for timely detection of changes in the diffusion coefficients and fiber diameters.
near room temperature. The hybrid system consists of a living neuron and a model neuron (or an artificial silicon neuron) interacting in the real time. Dynamic clamp is used to implement artificial ionic currents and synapses in the system (Sharp et al. 1993). Our study determines the mechanisms underlying and regulating bursting activity, based on intrinsic membrane dynamics and network interactions. The complexity of endogenous dynamics originates from the divergence of potential modes and different types of excitations and underlying patterns. Similar findings derived from the analysis of bursting, its origin and transformations are common in heart interneurons both as single cells and in the mutually inhibitory configuration.

Brains and Behavior Program at GSU

Friday, March 14, 2008 11:15AM - 2:03PM
Session Y37 FLAP: Thermodynamic and Transport Properties of Semiconductors

11:15AM Y37.0001 Impact ionization rate calculation based on GW approximation , TAKAO KOTANI, MARK VAN SCHILFGAARDE, Arizona State University — Impact ionization (IMI) means the electron-hole pair production due to high energy electron (or hole). It can control the performance of devices related to the high-field transport process. For solar cell, it was proposed to use IMI for efficient energy conversion. The IMI rate can be identified as the lifetime of an electron (imaginary part of the self-energy). Since the electron-hole pair spectrum is included in the screened Coulomb interaction W , it should be important to use full W for the calculation of the lifetime. However, to our knowledge, no such calculation has been presented for semiconductors until now. For example, Ref.[5] uses a model W . In addition, the conventional formalism of Ref.[1] contains some double-counting problem. We will show our calculation for the IMI rate based on our recently-developed quasi-particle self-consistent GW method for semiconductors. Our calculation predicts a rather smaller IMI rate. [1] A. Kuligk, N. Fitzer, and R. Redmer, PRB71, 085201(2005) [2] T.Kotani. M. van Schilfgaarde, and S.V. Faleev, PRB76, 165106 (2007)

11:27AM Y37.0002 First-principles calculations of mobilities in ultra-thin double-gate MOSFETs , OSCAR D. RESTREPO, KALMAN VARGA, Vanderbilt University, BLAIR TUTTLE, Vanderbilt University & Penn State Erie, SOKRATES T. PANTELIDES, Vanderbilt University & Oak Ridge National Laboratory — Carrier mobilities in MOSFETs are usually simulated by employing empirical scattering models. These methods do not take into account quantum mechanical effects with atomic-scale structural resolution, which are key elements to describe transport at the nano-scale. We use a novel first-principles approach to calculate mobilities in ultra-thin SOI MOSFETs [1]. For this report, we newly constructed interface models of Si(100) and amorphous SiO₂. Straining the silicon lattice results in significant increases in carrier mobility. We distinguish between the strain enhancement due to the change in velocities and the enhancement coming from the change in scattering potential. We also compare our calculations with experimental values for mobility degradation caused by radiation induced Coulomb scattering centers. We are able to quantify the contribution to the total mobility from various types of scattering centers, namely, from atomic-scale interface roughness (oxide protrusions, suboxide bonds) and scattering from point defects (dangling bonds, hydrogen). This work was supported by NSF Grant ECS-0524655. [1] M. H. Evans et al., Phys. Rev. Lett. 95, 106802 (2005)

11:39AM Y37.0003 Composition Dependence of the Hole Mobility in Dilute GaSb,As₁₋ₓ , KIRSTIN ALBERI, O.D. DUBON, U.C. Berkeley, Berkeley, CA 94720; Lawrence Berkeley National Laboratory — Carrier mobilities in MOSFETs are usually simulated by employing empirical scattering models. These methods do not take into account quantum mechanical effects with atomic-scale structural resolution, which are key elements to describe transport at the nano-scale. We use a novel first-principles approach to calculate mobilities in ultra-thin SOI MOSFETs [1]. For this report, we newly constructed interface models of Si(100) and amorphous SiO₂. Straining the silicon lattice results in significant increases in carrier mobility. We distinguish between the strain enhancement due to the change in velocities and the enhancement coming from the change in scattering potential. We also compare our calculations with experimental values for mobility degradation caused by radiation induced Coulomb scattering centers. We are able to quantify the contribution to the total mobility from various types of scattering centers, namely, from atomic-scale interface roughness (oxide protrusions, suboxide bonds) and scattering from point defects (dangling bonds, hydrogen). This work was supported by NSF Grant ECS-0524655. [1] M. H. Evans et al., Phys. Rev. Lett. 95, 106802 (2005)

11:51AM Y37.0004 Enhanced Hall coefficient in InAs/AlSb μ-Hall bars induced by ballistic electron scattering from interfacial impurities , GORAN MIHAJLOVIC, JOHN E. PEARSON, AXEL HOFFMANN, SAMUEL D. BADER, Materials Science Division, Argonne National Laboratory, MARK FIELD, GERARD J. SULLIVAN, Teledyne Scientific Company — We fabricated micrometer-sized Hall bar channels of variable width w from an InAs/AlSb quantum-well, two-dimensional electron system and studied their electrical response in perpendicular magnetic fields. For the narrowest channels (w ~ 1 μm) at low fields (<0.5 T) and 5 K, we observed that the Hall coefficient increases above its classical value. This increase persists up to temperatures of order 100 K, but its magnitude decreases with increasing channel width and disappears for w ~ 4 μm. At the same time, the longitudinal resistance decreases with increasing magnetic field. The strong negative magnetoresistance is present even for the widest channels, suggesting that boundary scattering is only partially responsible for its observation. We show that both results can be explained by a mechanism of large-angle scattering of ballistic electrons from non-ionized impurities residing at the InAs/AlSb interfaces.

Work supported by DOE under contract No. DE-AC02-06CH11357.

12:03PM Y37.0005 Superradiance And Electron Transport Through Nanosystems , LUCA CELARDO, LEV KAPLAN, Department of Physics, Tulane University, New Orleans, LA 70118 — Electron transport through a sequence of potential wells characterized by strong tunneling between them is investigated. Using the effective non hermitian Hamiltonian approach to open systems, the transition to a superradiance regime is shown to occur. The consequences of the superradiance transition on the conductance, including negative differential conductance, are investigated.

12:15PM Y37.0006 Thermal conductivity of amorphous silicon films , JOSEPH FELDMAN, XIAO LIU, Naval Research Laboratory, R. CRANDALL, National Renewable Energy Laboratory, N. BERNSTEIN, M. MEHL, D. PAPACONSTANTOPOULOS, Naval Research Laboratory — We measured the thermal conductivity of an 80 μm thick amorphous silicon film from 80K to room temperature. The amorphous silicon sample was prepared by hot-wire chemical-vapor deposition with 1 at. % hydrogen, which was found previously to contain almost no atomic tunneling states that is common in amorphous solids. The value of the thermal conductivity is about a factor of two larger than previous results. To explain this unusually large thermal conductivity, we report on a Kubo theory that makes use of a tight binding electronic structure of a 1000 atom model. We conclude that the large thermal conductivity of our film is attributed to the lack of scattering of the low frequency modes by the tunneling states. Therefore, low frequency modes can make significant contribution to heat transport even at near room temperature.
12:27PM Y37.00007 Thermoelectric properties of nanoporous Si , JOO-HYOUNG LEE, JEFFREY C. GROSSMAN, University of California-Berkeley, JOHN REED, Lawrence Livermore National Laboratory, GIULIA GALLI, University of California-Davis — Improvements in thermoelectric (TE) materials could lead to efficient solid-state energy-conversion for environmentally benign power generation and refrigeration. This realization would require a large increase to ∼ 3 in the thermoelectric figure of merit ZT at room temperature. Recent experiments have shown promise for practical applications of TE materials such as Bi$_2$Te$_3$/Sb$_2$Te$_3$ superlattices and PbS/Te/PbTe quantum dot superlattices, yielding ZT of 2.4 and 1.3 – 1.6, respectively. In addition, there have been recent attempts to use Si for TE applications due to its structural simplicity and the possibility of utilizing existing Si-based manufacturing processes. In the present work, we report theoretical studies on thermoelectric properties of Si with periodically arranged nanometer-sized pores (nanoporous Si). Specifically, we calculate the electrical conductivity, Seebeck coefficient and figure of merit of nanoporous Si for a range of configurations using a combined ab initio electronic structure calculation and Boltzmann transport approach at room temperature. The results show a substantial increase in ZT compared with that of bulk Si, similar to recent findings for ZT in Si nanowires. Approaches for increasing ZT further in this porous material will also be discussed.

12:39PM Y37.00008 ac conductivity in low dimensional structures: acoustic study, A. SUSLOV, NHMFL, Tallahassee, FL 32310, USA, I. DRICHKO, I. SMIRNOV, A. DYAKONOV, YU. GALPERIN, Joefe PTI, St Petersburg, 194021, Russia, V. VINOKUR, ANL, Argonne, IL 60439, USA — Surface acoustic waves (SAWs) were used for contactless measurements of ac conductivity in low dimensional structures. The value of complex ac conductivity was extracted from simultaneous measurements of the sound attenuation and velocity. The measurements were performed in the frequency range 17-300MHz, at temperatures down to 0.3K and in the magnetic fields up to 18T. Such measurements allowed to study, for example, mechanisms of conductivity in a dense array of SiGe quantum dots and localization of the 2D carries in GaAs/AlGaAs and Si/SiGe heterostructures in the ultraquantum limit. An extended list of coauthors will be presented during the presentation.

12:51PM Y37.00009 Effects of capture, escape and confinement on SAW-dragged photocurrents in a single QW, GODFREY GUMBS, Hunter College of CUNY, DANHONG HUANG, USAF Research Lab, MICHAEL PEPPER, Cavendish Lab of Univ. Cambridge, UK — A dual-plasma model is developed for studying the steady-state transport of SAW-dragged photocurrents of 1D confined-state carriers. This model includes the effects of the quantum confinement and the tunneling escape of SAW-dragged 1D carriers, as well as the effects of the inelastic capture of 2D continuous-state carriers and the space-charge field. The numerical results uncover a high photocurrent gain due to suppressed recombination of 1D carriers in a crossover region of the sample between an absorption strip and a surface gate. Based on a discrete model, responsibilities for the SAW-dragged photocurrents in a quantum well are calculated as functions of the gate voltage, photon flux, SAW power and frequency and temperature, respectively.

1:03PM Y37.00010 Evidence of Real-Space Transfer in Buried-Channel Ge$_x$C$_{1-x}$ Devices , EN-SHAO LIU, Microelectronic Research Center, University of Texas at Austin, DAVID KELLY, Texas Instruments, JOSEPH DONNELLY, EMANUEL TUTUC, SANJAY BANERJEE, Microelectronic Research Center, University of Texas at Austin — We present experimental evidence of real-space transfer (RST) in buried-channel Ge$_x$C$_{1-x}$ p-type metal-oxide-semiconductor field effect transistors (MOSFET) containing a Si cap layer. The output characteristics of these devices reveal a negative differential resistance (NDR) below 150K, at the onset of the saturation regime. This observation indicates a charge transfer from Ge$_x$C$_{1-x}$ layer into the Si cap at sufficiently large drain bias values. The lower hole mobility of the Si cap with respect to the Ge$_x$C$_{1-x}$, translates into a drain current reduction, hence the observed NDR. Our low-field, temperature-dependent mobility measurements indeed reveal a higher effective carrier mobility in the buried-channel Ge$_x$C$_{1-x}$ layer with respect to a Si-reference sample, which suggests that the observed NDR is caused by RST of holes from the Ge$_x$C$_{1-x}$ into the Si layer.

1:15PM Y37.00011 Tunable Channel Interference in an Aharonov-Bohm Ring , YIPING LIN, PEI-JUNG WU, KUAN TING LIN, J. C. CHEN, Dep. of Physics, National Tsing Hua University, Hsinchu, Taiwan, T. UEDA, S. KOMIYAMA, Dep. of Basic Science, University of Tokyo, Meguro-ku, Tokyo, Japan — We have investigated the Aharonov-Bohm effect in a quasi one-dimensional ring on a GaAs/Al$_{0.33}$Ga$_{0.67}$As heterostructure, which is defined by two metallic arc gates coupled to each branch of the ring. Each gate can be separately biased to uniformly squeeze the channel width of electrons, thereby externally tuning the transverse modes in the interference paths. The oscillatory magnetococonductance of the device is systematically studied by varying the number of channels in each path. We have observed the evidence of phase shifts in the magnetococonductance oscillations due to the suppression of the mode numbers on the ring path. Though the periodicity is not well resolved, qualitatively our data support the random phase shifts between the successive modes.

1:27PM Y37.00012 Energy Relaxation in the Bloch-Gruneisen Regime Probed by Weak Antilocalization (WAL) Measurements in GaN Heterostructures , HAILING CHENG, CAGLIYAN KURDAK, Physics Department, University of Michigan, NECMI BIYIKLI, JINQIAO XIE, HADIS MORKOC, Department of Electrical Engineering, Virginia Commonwealth University — Electron-phonon (e-p) interaction was investigated in wurtzite Al$_{0.15}$Ga$_{0.85}$N/AIn/GaN and Al$_{0.83}$In$_{0.17}$/N/AIn/GaN heterostructures with polarization induced two dimensional electron gases in the Bloch-Gruneisen regime. WAL and Shubnikov-de Haas measurements were performed on gali Hall bar structures at temperatures down to 0.3 K. With gate voltage, we cover a carrier density range from $3.41 \times 10^{12}$ cm$^{-2}$ to $4.92 \times 10^{12}$ cm$^{-2}$. Moreover, we used the WAL as a thermometer to measure the electron temperature $T_e$, as a function of the bias current. We find the power dissipated per electron $P_e$ is proportional to $T_e^3$ due to piezoelectric acoustic phonon emission by hot electrons. We calculated $P_e$ as a function of $T_e$ without using any adjustable parameters for both static and dynamic screening cases of piezoelectric e-p coupling. In the dynamic range of this experiment, the static screening case is expected to be applicable; however, our data are in better agreement with the dynamic screening case.

1:39PM Y37.00013 Bloch Oscillations and Saturation to a Steady-State Current of an Electron Gas in a Modulated Quantum-Wire Superlattice in a High Electric Field, S.K. LYO, Sandia National Laboratories, D. HUANG, Air Force Research Laboratory, W. PAN, Sandia National laboratories — We present rigorous theoretical results for the time-dependent and steady-state nonlinear DC current of an electron gas in a periodically modulated one-dimensional semiconductor quantum wire in a high electric field. The theoretical model considers electron-phonon and impurity scattering microscopically in the degenerate and the nondegenerate regime in a tight-binding model. The time-dependent oscillatory and saturation (i.e., steady-state) currents are studied as a function of the field, the radius of the wire, the elastic scattering rate, the lattice period, and the temperature. The radius controls the inelastic scattering rate. The distinctive roles of elastic and inelastic scattering for the current are contrasted and examined. Finally, we compare the results with those from an exact analytic formalism based on a relaxation-time model.

the aeroelastic response of the flat plate is a function of Reynolds number. Also, the aeroelastic response of the flat plate influences the vortex shedding between a subsonic flow and a flexible flat plate. The results of the present analysis indicate that there is a strong fluid-structure coupling. It was observed that can be excited, causing damaging instabilities. In the present analysis, the dependence of vortex shedding on the aeroelastic response of a vertical flat plate in body locations determined by the forcing geometry; when the driving is strong, they wander over the flow domain and interact pairwise. By comparing the behavior of several base flows, we show that our methods are robust even for complex flow situations.

11:27AM Y39.00002 ABSTRACT HAS BEEN MOVED TO SESSION D9 –

11:39AM Y39.00003 The dependence of vortex shedding on the aeroelastic response of a bluff body. MARCEL ILIE, Carleton University — Airflow over a vertical flat plate is investigated as a function of Reynolds number, using Large Eddy Simulation. It is generally known that the structure of the wake, behind a bluff body, exhibits very complex turbulent flow patterns. In many practical applications the bluff bodies are flexible structures and this characteristic enables them to respond to the aerodynamic loads. The fluid-structure interaction phenomenon is of critical importance due to the inheriting danger associated with the vortex induced vibrations. The periodic shedding of vortices may result in significant fluctuating loading on the body. When the shedding frequency is close to one of the characteristic frequencies of the body, the resonant oscillations of the body can be excited, causing damaging instabilities. In the present analysis, the dependence of vortex shedding on the aeroelastic response of a vertical flat plate in cross-flow is investigated. A CFD based algorithm, using Large Eddy Simulation, is developed for the investigation of a strong (two-way) aeroelastic coupling between a subsonic flow and a flexible flat plate. The results of the present analysis indicate that there is a strong fluid-structure coupling. It was observed that the aeroelastic response of the flat plate is a function of Reynolds number. Also, the aeroelastic response of the flat plate influences the vortex shedding.

VKS: a turbulent homogeneous dynamo with liquid sodium1, MICHAEL BERHANU, Ecole Normale Superieure — The magnetic field of the earth and of most astrophysical objects result from turbulent flows of electrically conducting fluids: the kinetic energy of the flow is converted into magnetic energy by dynamo effect. In September 2006 we observed this effect for the first time in a closed homogeneous turbulent flow of liquid sodium at very high Reynolds number in the Von-Karman Sodium (VKS). Despite the strong level of the fluctuations of the flow, we observed the growth and saturation of a stationary global mode of the magnetic field at the experiment’s characteristic length. Does turbulence act as noise or does it participate in the magnetic generation process? If we modify the global properties of the flow, we observe transitions between different magnetic field modes, going from stationary to oscillatory, and, near the frontiers between these modes, interesting dynamical behaviours occur, such as bursts and relaxations cycles. In particular we found a state with reversals of the magnetic field similar to those of the Earth recorded on geological time scale. These evolutions present some features of low dimensional chaos, compatible with the interaction between few modes. Finally we observe for the first time bistability from a stationary dynamo to an oscillatory one.

12:03PM Y39.00005 Dynamical Phase Transitions and Scaling Laws in the Response of a Rhythmically Perturbed Neuron. JAN ENGELBRECHT, RENATO MIROLLO, Boston College — In order to explore how a local rhythm influences the timing of a neuron’s spikes, we study the dynamics of an integrate-and-fire model neuron with an oscillatory stimulus. The frustration due to the competition between the neuron’s natural firing period and that of the oscillatory rhythm leads to a rich structure of asymptotic phase locking patterns and ordering dynamics. The phase transitions between these states can be classified as either tangent or discontinuous bifurcations, each with its own characteristic scaling laws. The discontinuous bifurcations exhibit a new kind of phase transition that may be viewed as intermediate between continuous and first order, while tangent bifurcations behave like continuous transitions with a diverging coherence scale.

12:15PM Y39.00006 Correlations, fluctuations and stability of a finite-size network of coupled oscillators1, MICHAEL BUICE, CARSON CHOW, National Institutes of Health — The incoherent state of the Kuramoto model of coupled oscillators exhibits marginal modes in mean field theory. We demonstrate that correlations due to finite size effects render these modes stable in the subcritical case, i.e. when the population is not synchronous. This demonstration is facilitated by the construction of a non-equilibrium statistical field theoretic formulation of a generic model of coupled oscillators. This theory is consistent with previous results. In the all-to-all case, the fluctuations in this theory are due completely to finite size corrections, which can be calculated in an expansion in 1/N, where N is the number of oscillators. The N → infinity limit of this theory is what is traditionally called mean field theory for the Kuramoto model.

12:27PM Y39.00007 Time-Shifts and Correlations in Synchronized Chaos. JONATHAN BLAKELY, NED CORRON, US Army RDECOM — We introduce a new method for predicting characteristics of the synchronized state achieved by a wide class of uni-directional coupling schemes. Specifically, we derive a transfer function from the coupling model that provides estimates of the correlation between the drive and response waveforms, and of the time shift (i.e., lag or anticipation) of the synchronized state. Notably, this approach does not require modeling or simulation of the full coupled system. To demonstrate the method, we compare its predictions to simulations of a variety of different coupled oscillator systems as well as to an experimental system of coupled chaotic electronic circuits. Finally, we show that the transfer function can be exploited to design novel coupling schemes that significantly improve the correlation and increase the maximum achievable time shift.
A linear reformulation of the Kuramoto model of self-synchronizing coupled oscillators. David Roberts, Los Alamos National Laboratory — This talk will present a linear reformulation of the Kuramoto model describing a self-synchronizing phase transition in a system of globally coupled oscillators that in general have different intrinsic frequencies. The reformulated model provides an alternative coherent framework through which one can analytically tackle synchronization problems that are not amenable to the original Kuramoto analysis. It allows one to 1) find an analytic solution for a new class of continuum systems and 2) solve explicitly for the synchronization order parameter and the critical point of the phase-locking transition for a system with a finite number of oscillators (unlike the original Kuramoto model, which is solvable implicitly only in the mean-field limit). It also makes it possible to probe the system’s dynamics as it moves towards a steady state. While this talk will cover only systems with global coupling, the new formalism introduced by the linear reformulation also lends itself to solving systems that exhibit local or asymmetric coupling.

Constructing almost invariant sets for multi-stable systems, Gabriele Migliorini, NCRG - Aston University - UK — We present a renormalization group study of two dimensional arrays of oscillators, with dissipative, short range interactions. We consider the case of non-identical oscillators, with distributed intrinsic frequencies within the array and study the steady-state properties of the system. In two dimensions no macroscopic mutual entrainment is found but, for identical oscillators, critical behavior of the Berezinskii-Kosterlitz-Thouless type is shown to be present. We then discuss the stability of (BKT) order in the physical case of distributed quenched random frequencies. In order to do that, we show how the steady-state dynamical properties of the two dimensional array of non-identical oscillators are related to the equilibrium properties of the XY model with quenched randomness, that has been already studied in the past. We propose a novel set of recursion relations to study this system within the Migdal-Kadanoff renormalization group scheme, by mean of the discrete clock-state formulation. We compute the phase diagram in the presence of random dissipative coupling, at finite values of the clock state parameter. Possible experimental applications in two dimensional arrays of microelectromechanical oscillators are briefly suggested.

Correlations of Coupled Logistic Maps, John Harrison, Richard Taylor, Gus Hart, Brigham Young University — Many systems in the world are non-linear and therefore often chaotic. Moreover, many systems influence or are influenced by other physical systems. That is, systems are often coupled to other systems. In an effort to uncover the fundamental issues of coupled systems, we have studied a system of coupled logistic maps. The logistic map, arguably the simplest chaotic system, shows unusual correlations when coupled to a second logistic map. We use a master–slave coupling, where the first map influences the second, but not the other way around. At low coupling strengths the correlations are complex but the two maps do not completely synchronize. At higher coupling strengths, the two maps “lock”, becoming synchronized. The value of coupling that causes the two maps to lock can be determined analytically. Intriguingly, at intermediate couplings strengths, periodic forcing by the master can result in chaotic behavior in the slave.

11:45AM Y40.00008 A computer simulation of polymer reversal inside a pore, Lei Huang, Dmitrii E. Makarov, University of Texas at Austin — Translocation of biopolymers through pores is implicated in many biological phenomena. Confinement within pores often breaks ergodicity on biological time scales by creating large entropic barriers to rearrangements of the chain. We study one example of such hindered rearrangement, in which the chain reverses its direction inside a long pore. Our goal is two-fold. First, we study the dependence of the polymer reversal timescale while the transmission factor, i.e., the ratio of the exact rate and the TST one, has a much weaker, power law dependence on the pore size and on the polymer length. Second, we examine the ability of simple theories, such as transition state theory (TST) and Kramers’ theory to quantitatively describe a transition in a system with a complex energy landscape. We find that one-dimensional TST using the polymer extension along the pore axis as the reaction coordinate adequately accounts for the exponentially strong dependence of the reversal rate on the pore radius $r$, and the polymer length $N$, while the transmission factor, i.e., the ratio of the exact rate and the TST one, has a much weaker, power law $r$ and $N$ dependence.

Refoldable Peptide Barrel – Carbon Nanotube Junctions, Alexey Titov, Boyang Wang, Petr Kral, University of Illinois at Chicago, PROF. KRAL’S RESEARCH GROUP TEAM — We design hybrid bio-nano-junctions formed by cylindrical peptide structures covalently attached to carbon nanotubes. The cylinders are composed of 5 pairs of antiparallel peptide strands that are “one-to-one” matched and covalently bonded through ester and amide bonds to the terminal C atoms in two (20,0) carbon nanotubes. The remaining terminal carbons in the CNTs are replaced by nitrogens, forming embedded quinoline-like structures. The used peptide strands are composed of charged amino acids that form cylindrical patterns with preferred stable configurations. By applying a torque to the nanotubes, we can reversibly fold and control the overall structure of the peptide barrels. The junctions might allow the collection and delivery of drugs and activation of biological molecules attached to them.

12:39PM Y39.00008 A linear reformulation of the Kuramoto model of self-synchronizing coupled oscillators, David Roberts, Los Alamos National Laboratory — This talk will present a linear reformulation of the Kuramoto model describing a self-synchronizing phase transition in a system of globally coupled oscillators that in general have different intrinsic frequencies. The reformulated model provides an alternative coherent framework through which one can analytically tackle synchronization problems that are not amenable to the original Kuramoto analysis. 12:03PM Y40.00005 In vitro optical measurements of the interaction between human lung cells and single-wall carbon nanotubes, M. L. BECKER, J. A. FAGAN, J. CHUN, B. J. BAUER, E. K. HOBBIE, NIST — The intrinsic band gap fluorescence of individual semiconducting single-wall carbon nanotubes (SWNTs) stabilized with single-stranded DNA and deoxycholate surfactant is exploited to optically measure the interaction between human lung cells and length-fractionated SWNTs. Using near-infrared (NIR) fluorescence microscopy in microfluidic flow platforms, live human lung fibroblasts (IMR-90) are exposed to controlled quantities of length-sorted single wall nanotubes, and the cellular interaction and uptake of the SWNTs is optically monitored in real space-time. Cell mortality is shown to result from the uptake of shorter nanotubes and is correlated with both SWNT length and concentration. The NIR optical measurements are used to identify potential uptake mechanisms and quantify the kinetics of the interaction.

12:15PM Y40.00006 AFM and XPS Studies of Oligodeoxyribonucleotides associated with Single Walled Carbon Nanotubes, ROYA R. LAHJII, B. D. DOLASH, D. ZEMLYANOV, D. E. BERGSTRÖM, R. REIFENBERGER, Birck Nanotechnology Center, Purdue University — Oligodeoxyribonucleotide (ODN) disperse single wall carbon nanotubes (SCWNTs) in aqueous solution via sonication. By developing procedures that produce ODN:SWCNT hybrids uniformly dispersed in an aqueous solution, new biological applications will emerge. We have studied ODN T30:SCWNT hybrids that form after different preparation techniques. Deposition of the resulting ODN T30:SCWNT hybrids onto both insulating and conducting substrates have been studied. AFM under ambient conditions reveals localized features decorating individual SWCNTs having an approximate height consistent with the dimensions of single stranded T30 ODN. XPS confirmed the decorative features are ODN. Taking advantage of the ODN negative charge, we studied the deposition of ODN:SCWNT hybrids on Au substrates using electrophoretic deposition techniques. Electrodeposition has advantages since it does not require functionalization of ODN or the substrate prior to deposition. Applying a positive potential to the Au substrate can produce a uniform deposit of T30 ODN:SCWNT hybrids. The electrodeposited ODN:SCWNTs were further studied using AFM and XPS. [1] M. Zheng et al, Nat Mater 2003, 2, 338. [2] R. R. Lahiji et al, Small 2007, 3, 1912.

12:27PM Y40.00007 Atomic Scale Spectroscopy of Protein Active Sites, J.T. SAGE, Northeastern Univ., B.M. LEU, W. STURHAHN, E.E. ALF, Argonne Natl. Lab — We use nuclear resonance vibrational spectroscopy (NRVS) to investigate $^{57}$Fe embedded in protein matrices. Access to the complete spectrum of Fe vibrations allows experimental determination of effective local force constants. The stiffness reflects the force required to displace the probe nucleus with respect to its nearest neighbors and provides a direct probe of local structure. In contrast, the resilience describes the force required to displace the probe atom with neighboring atoms free to respond, and determines the thermal fluctuations of the Fe. We find that additional covalent links to the protein increase the resilience of the Fe site in cytochrome c as compared to myoglobin.

12:39PM Y40.00008 The Directed Assembly of Conducting Polymer Nanowires¹, BRENT FLANDERS, PREM THAPA, Oklahoma State University, RAY BAUGHMAN, NORMAN BARISCI, University of Texas at Dallas — The Directed Electrochemical Nanowire Assembly (DENA) technique is a single-step approach to fabricating metallic nanowires and interconnecting them with external circuitry or other objects. Here we expand this technique to include the growth of non-metallic wires. From aqueous pyrrole solutions, individual wires were grown from the tip of one electrode across a 30 µm electrode gap and into contact with the tip of the other electrode. Energy dispersive spectroscopy is used to show that the wires are composed of doped polypyrrole. The conductance of these nanowires will be discussed, as well as the interfacing of DENA nanowires with biological cells for cell stimulation studies.

¹This research was supported by funding from the National Science Foundation (PHY-646966).

12:51PM Y40.00009 Directed Electrochemical Nanowire Assembly¹, PREM THAPA, BRENT FLANDERS, Oklahoma State University — Directed Electrochemical Nanowire Assembly (DENA) technique is a single-step approach to fabricating metallic nanowires and interconnecting them with external circuitry. We have previously shown that these are near single crystalline metallic nanowires and that they interconnect with on-chip electrodes with very small contact resistances. Here we discuss the user-directed growth of these nanowires up to inter-electrode targets, such as biological cells. Recent results on the delivery of small voltages to these targets will be discussed, as well.

¹This research was supported by the National Science Foundation (PHY-646966).

1:03PM Y40.00010 Electrochemical measurement of DNA in a nanofluidic channel, CHIH-KUAN TUNG, Dept of Physics, Princeton University, ROBERT RIEHN, North Carolina State University, ROBERT H. AUSTIN, Dept of Physics, Princeton University — The elongation of genomic length DNA in confining nanochannels is not only a fascinating exercise in polymer dynamics, but also is of great interest in biotechnology because the elongation of the confined molecule is directly proportional to the actual length of the molecule in basemaps. We will present a way to construct nanochannels using sacrificial PMMA ebeam lithography and to measure non-immobilized DNA molecules inside such a channel electrochemically. This kind of measurements can lead us to fast and precise electronic length measurement, which will open the door to a number of important areas in genomics such as gene exchange and evolution dynamics of single cells.

1:15PM Y40.00011 A nanofluidic lateral Coulter counter, YONG SUN, JUNHAN PAN, ROBERT RIEHN, North Carolina State University — Optical detection has been the mainstay of detection in many micro-and nanofluidic systems. However, the need for labeling and alignment of detectors or registration of images has slowed transition to application and increased cost. On the other hand, when traditional Coulter counters that detect along the axis of a fluidic channel are integrated with nanofluidics on a chip, leakage and limited resolution often present problems. For that reason, we are developing an electronic detection mechanism that is based on the impedance change of an electrode pair that is laterally integrated with a nanochannel. We will present detection of 50 nm polystyrene beads, and will discuss possible applications in the detection of biological molecules such as DNA.

1:27PM Y40.00012 On the virus capsid assembly and encapsulation of foreign materials, CHAO CHEN, Ph.D. Candidate, Chemistry Department, Indiana University, BOGDAN DRAGNEA, Assistant Professor, Chemistry Department, Indiana University, CHENG KAO, Professor, Department of Biochemistry and Biophysics, Texas A&M University, ADAM ZLOTNICK, Associate Professor, Biochemistry & Molecular Biology, Health Sciences Center, the University of Oklahoma, BOGDAN DRAGNEA TEAM, C. CHENG KAO COLLABORATION, ADAM ZLOTNICK COLLABORATION — Icosahedral virus capsids are one of the simplest biological structures, yet poorly understood from a molecular physics point of view, e.g., the paradox between its stability and flexibility, its interaction with the virus genome, and its assembly thermodynamics and kinetics. In the hope of elucidating these problems, we have created a study platform based on virus-like particles (VLPs) – inorganic nanoparticles encapsulated inside icosahedral virus capsids in place of their genomic core. These nanoparticles were successfully incorporated when coated with carbonate-terminated poly-ethyleneglycols, implying a dominating electro-static interaction between the virus capsid and the core. The nano-particle size determines the T number of the icosahedral cage and the efficiency of encapsulation. The current work seeks to understand the mechanism of capsid assembly process using VLP as a model system. Empty capsid assembly kinetics has been also studied for comparison. A simplified kinetically limiting model based on a previously reported master equation model is proposed.
1:39PM Y40.00013 Assembly and Characterization of NanoComplexes: Quantum Dot Encapsulated Liposomes, ANGELA HIGHT WALKER, EMREN ESENTURK, PETER YIM, JEESEONG HWANG, Physics Laboratory, National Institute of Standards and Technology (NIST) — Liposome complexes have received significant attention for a variety of biochemical and biomedical applications including drug targeting and drug delivery and tumor imaging and diagnostics. Semiconductor nano-crystals, also known as quantum dots, are now beginning to be used in similar biochemical experiments. Like fluorescent dyes, these quantum dots have the ability to reliably fluoresce at pre-engineered wavelengths. However, these nano-crystals have lifetimes significantly longer comparable to fluorescence dye counterparts. We have successfully encapsulated approximately 10nm CdSe nano-crystals inside approximately 100nm liposomes and studied the resulting complex using fluorescence resonance energy transfer (FRET) microscopy. Further studies were performed using transmission electron microscopy (TEM) showing the details of the encapsulation, and Raman spectroscopy to examine their structural details. Our nano-manufactured quantum dot liposome complexes do not bleach over periods of hours and are general enough to allow the addition of drugs targeted for the vectored cells thus offering the ability to both image and medicate simultaneously over a long period of time.

1:51PM Y40.00014 Selective Cell Growth on Fibronectin-Carbon Nanotube Hybrid Nanosstructures, SEON NAMGUNG, SUNG YOUNG PARK, BYUNG YANG LEE, MINBAEK LEE, Department of Physics and NANO Systems Institute, Seoul National Univ., Korea, JWA-MIN NAM, Department of Chemistry, Seoul National Univ., Korea, SEUNG-HUN HONG, Department of Physics and NANO Systems Institute, Seoul National Univ., Korea — Carbon nanotubes (CNT) have been considered a promising material for biological applications including biosensors, therapeutic application, and nano-structured scaffolds. However, there are still controversies associated with toxicity and biocompatibility of CNTs on live cells. Here, we report general strategy to functionalize CNTs with cell adhesion molecules (fibronectins) for selective and stable adhesion of cells on CNTs. Interestingly, more fibronectins were adsorbed and activated on CNTs rather than on hydrophobic self assembled monolayers (SAMs) or bare substrates (SiO$_2$). We demonstrate the functionality of fibronectins on CNTs with immunofluorescence and molecule-level force measurement study using atomic force microscopy (AFM). These fibronectin-CNT hybrid nanostructures were successfully applied to attract cells selectively onto predefined regions on the substrate. Our strategy was generally available on various cell types including mesenchymal stem cells, KB cells, and NIH3T3 fibroblast cells (Advanced Materials 19, 2530-2534 (2007)). We will also discuss about its impacts on cell biology combined with CNTs.

2:03PM Y40.00015 Large-Scale ‘Linker-Free Assembly’ of SWCNT-Based Biosensor Arrays, DONGHEE SOHN, BYUNG YANG LEE, SEUNGHUN HONG, Department of Physics and NANO Systems Institute, Seoul National University, Seoul, Korea — Biosensors based on single-walled carbon nanotubes (swCNTs) have received a great deal of attention due to their potential applications such as genotyping, disease diagnosis, food analysis, etc. However, a lack of reliable mass-production method for such swCNT-based biosensor has been holding back their practical applications. One promising mass-production method for such swCNT-based biosensor arrays can be ‘linker-free assembly’ process (Nature Nanotechnology 1, 66 (2006)), where non-polar patterns guide the ‘selective assembly’ and ‘precision alignment’ of carbon nanotubes on bare substrates without using any external forces such as liquid flow, etc. We used this method to fabricate large-scale assembly of swCNT-based integrated devices on virtually general substrates including SiO$_2$, Si, Al, Au, etc. To utilize swCNT devices for biosensors, we functionalized swCNT devices on SiO$_2$ with receptor biomolecules such as enzyme L-glutamate oxidase or biotin. And then, we could detect the target biomolecules (L-glutamate or streptavidin, respectively) with high sensitivity and selectivity by monitoring the conductance change of swCNT junctions in aqueous environment. These studies provide biological implications on neurotransmitters and proteins onto swCNT patterned surface.
