8:00AM P23.00001 Strain tunability and domain structures of epitaxial (001) BiFeO3 thin films†. CHANG-BEOM EOM, University of Wisconsin-Madison — It was recently discovered that the spontaneous polarization (P_s) values determined in epitaxial BiFeO3 thin films, ~100 μC/cm^2, are over an order of magnitude higher than those previously measured in bulk samples. This raises a fundamental question: can the remanent polarization and other properties of BiFeO3 be tuned by strain? We studied the strain dependence of remanent polarization and domain structures of BiFeO3 through direct measurements on the same epitaxial (001)_p BiFeO3 thin-film capacitors before and after releasing them from an underlying Si substrate. Our measurements reveal that: (1) the large P_s of BiFeO3 is indeed intrinsic; (2) the out-of-plane polarization (P_P) of (001)_p-oriented BiFeO3 thin films has a strong strain dependence. These findings can be exploited in studying symmetry-dependent magnetoelectric coupling of BiFeO3, where strain and/or symmetry play a role in the coupling because the direction of magnetic spin ordering is not parallel to that of ferroelectric polarization switching.

8:36AM P23.00002 Local Electrical Conductivity of Multiferroic Domain Walls. QING HE, JAN SEIDEL, LANE MARTIN, YING-HAO CHU, QIAN ZHAN, FENG WANG, RAMAMOORTHY RAMESH, UC Berkeley — There is an intense interest in magnetoelectric coupling between electric and magnetic due to its potential to the revolutionary device architectures. Single-phase multiferroics - materials that show spontaneous magnetization and polarization simultaneously at ambient conditions - remain elusive as most systems (such as the manganites) exhibit magnetoelectric coupling between electric and magnetic due to its potential to the revolutionary device architectures. One multiferroic material, however, has played a key role in rejuvenating the field after a report of multiferroicity only at low temperatures. Alternatively, multiferroics can be synthesized as a composite system, e.g. as a product property of a composite phase consisting of a magnetostriective and a piezoelectric material. One multiferroic material, however, has played a key role in rejuvenating the field after a report of large ferroelectric polarization combined with interesting magnetic properties - BiFeO3, consisting of a magnetostrictive and a piezoelectric material. One multiferroic material, however, has played a key role in rejuvenating the field after a report of multiferroicity only at low temperatures. Alternatively, multiferroics can be synthesized as a composite system, e.g. as a product property of a composite phase consisting of a magnetostriective and a piezoelectric material. One multiferroic material, however, has played a key role in rejuvenating the field after a report of large ferroelectric polarization combined with interesting magnetic properties - BiFeO3. Here we provide evidence of a unique property of single domain walls in multiferroic BiFeO3. Unlike other multiferroic materials, e.g. PbTiO3, on which the electronic properties of the domain walls are not significantly different from the domain area, we observe a finite electric conductivity at room temperature in ferromagnetic domain walls using conductive atomic force microscopy. This intrinsic property of the domain wall is attributed to a changed crystallographic structure as revealed by high resolution transmission electron microscopy. Additionally, optical absorption measurements confirm a change in bandstructure at domain walls in BiFeO3.

8:48AM P23.00003 The multiferroic properties of Bi(Fe1/2Cr1/2)O3 compound. CHANGQING JIN, J.L. ZHU, H.X. YANG, S.M. FENG, L.J. WANG, R.C. YU, X.H. WANG, L.T. LI. Institute of Physics, Chinese Academy of Sciences, Beijing, China — Dense Bi(Fe1/2Cr1/2)O3 ceramics of R3c crystal structure were synthesized by solid state reaction under high pressure. TEM observations reveal superstructure characteristics in Bi(Fe1/2Cr1/2)O3. Magnetization as well as dielectric properties of Bi(Fe1/2Cr1/2)O3 ceramics were characterized over a broad temperature.
9:00AM P23.00004 Optical coupling to spin waves in the cycloidal multiferroic BiFeO₃. ROGERIO DE SOUSA, Department of Physics, University of California, Berkeley, CA, USA, JOEL E. MOORE, Department of Physics, University of California, and Department of Materials Science, Lawrence Berkeley National Laboratory, Berkeley, CA, USA — The magnon and optical phonon spectrum of an incommensurate multiferroic such as BiFeO₃ is considered in the framework of a phenomenological Landau theory. The resulting spin wave spectrum is quite distinct from commensurate substances due to soft mode anisotropy and magnon zone folding. The former allows electrical control of spin wave propagation via reorientation of the spontaneous ferroelectric moment. The latter gives rise to multiple magneto-dielectric resonances due to the coupling of optical phonons at zero wavevector to magnons at integer multiples of the cyclod wavevector. These results show that the optical response of a multiferroic reveals much more about its magnetic excitations than previously anticipated on the basis of simpler models.

4Current Address: Dept. of Physics and Astronomy, University of Victoria, B.C., Canada

9:12AM P23.00005 Electric Field Controlled Magnetism in BiFeO₃/Ferromagnet Films. M.B. HOLCOMB, Y.H. CHU, L.W. MARTIN, M. GAJEK, J. SEIDEL, R. RAMESH, UC Berkeley, A. SCHOLL, Advanced Light Source, LBNL, A. FRAILE-RODRIGUEZ, Swiss Light Source, PSI — Electric field control of magnetism is a hot technological topic at the moment due to its potential to revolutionize today’s devices. Magnetoelectric materials, those having both electric and magnetic order and the potential for coupling between the two, are a promising avenue to approach electric control. BiFeO₃, both a ferroelectric and an antiferromagnet, is the only single phase room temperature magneto-electric that is currently known. In addition to other possibilities, its multiferroic nature has potential in the very active field of exchange bias, where an antiferromagnetic thin film pins the magnetic direction of an adjoining ferromagnetic layer. Since this antiferromagnet is electrically tunable, this coupling could allow electric-field control of the ferromagnetic magnetization. Direction determination of antiferromagnetic domains in BFO has recently been shown using linear and circular dichroism studies. Recently, this technique has been extended to look at the magnetic domains of a ferromagnetic grown on top of BFO. The clear magnetic changes induced by application of electric fields reveal the possibility of electric control.

9:24AM P23.00006 Investigation of domain walls in multiferroic BiFeO₃. JAN SEIDEL, LANE MARTIN, YING-HAO CHU, QIAN ZHAN, QING HE, Department of Materials Science and Engineering and Department of Physics, UC Berkeley, FENG WANG, Department of Physics, UC Berkeley, RAMAMOORTHY RAMESH, Department of Materials Science and Engineering and Department of Physics, UC Berkeley, AXEL ROTHER, NICOLA SPALDIN, Materials Department, UC Santa Barbara, GUSTAV CATALAN, JAMES SCOTT, Department of Earth Science, University of Cambridge, UK — We present a thorough study of domain walls in multiferroic BiFeO₃ thin films using scanning probe methods, transmission electron microscopy, transport measurements coupled with theoretical studies. In rhombohedral BiFeO₃, three different domain wall orientations exist, namely 180, 109, and 71 degrees. We find that the domain configurations in thin films are strongly dependent on the processing conditions. Here we investigate electrical and structural properties of all three varieties. Atomic resolution STEM studies were used to reveal the structure across the domain walls, with a specific focus on 109°. We observe that the changed crystallographic structure in domain walls gives rise to a change in local properties. From the investigation of individual domain walls we also infer their relation to changed macroscopic properties in thin films. This work is supported by the US DOE, ONR MURI, NSF Chemical Bonding Center program, and the Alexander von Humboldt Foundation.

9:36AM P23.00007 Optical properties of BiFeO₃ thin films and single crystal. R.C. RAI, X.S. XU, T.V. BRINZARI, J.L. MUSFELDT, University of Tennessee, D.J. SINGH, Oak Ridge National Laboratory, S. LEE, S-W. CHEONG, Rutgers University, Y.H. CHU, R. RAMESH, University of California, Berkeley, S. MCGILL, National High Magnetic Field Laboratory — BiFeO₃ has been studied using optical and magneto-optical spectroscopy and the results are compared with first-principle calculations. The optical gap in thin films (2.7 eV) is much larger than that in the single crystal (1.3 eV), the evidence that this system has a novel transition between strongly correlated and band insulator behavior. Both magnetic field and temperature suppress the excitation between the strongly hybridized valence levels and Fe d levels near 1.5 eV. The temperature and magnetic field effects appear to scale energetically suggesting spin-charge coupling. The high energy magneto-electric contrast shows a jump at 18 T corresponding to the transition from toroidal to homogeneous antiferromagnetic phase.

3This work is supported by the U.S. Department of Energy.

9:48AM P23.00008 Magnetization manipulation in multiferroic devices. MARTIN GAJEK, LANE MARTIN, YING HAO CHU, MARK HUIJBEN, MICKY BARRY, RAMAMOORTHY RAMESH, UNIVERSITY OF CALIFORNIA, BERKELEY TEAM — Controlling magnetization by purely electrical means is a central topic in spintronics. A very recent route towards this goal is to exploit the coupling between multiple ferroic orders which coexist in multiferroic materials. BiFeO₃ (BFO) displays antiferromagnetic and ferroelectric orderings at room temperature and can thus be used as an electrically controllable pinning layer for a ferromagnetic electrode. Furthermore, BFO remains ferroelectric down to 2nm and can therefore be integrated as a tunnel barrier in MTJ’s. We will describe these two architecture schemes and report on our progresses towards the control of magnetization via the multiferroic layer in those structures.

10:00AM P23.00009 Electronic and magnetic structures of double perovskite multifunctional La₃NiMnO₁₀ thin films. HAIZHONG GUO, JIANDI ZHANG, Department of Physics, Florida International University, Miami, FL 33199, ARUNAVA DE SOUSA, Center for Materials for Information Technology and Department of Chemistry, University of Alabama, Tuscaloosa, Alabama 35487, M. VARELA, S.J. PENNYCOOK, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831 — Electronic and magnetic structures of the ordered double perovskite La₃NiMnO₁₀ (LNMO) thin films grown by pulsed laser deposition have been studied by x-ray absorption spectroscopy (XAS) and magnetic circular dichroism spectroscopy (XMCD). Based upon the results of XMCD, we find that the primary ion valence states to be Mn⁴⁺/Ni⁴⁺, and the ferromagnetism resulting from Mn⁴⁺ O 2⁻ Ni⁴⁺ superexchange interaction. Additionally, we show that the LNMO samples contain some Mn⁴⁺ and Ni³⁺ Jahn-Teller ions caused by oxygen or cation related defects. The orbital and spin magnetic moments of the Mn 3d and Ni 3d also have been deduced from the magneto-optical sum rules and compared with magnetization measurements.

10:12AM P24.00010 Influence of oxygen concentration on the magnetic properties of multi-functional La$_2$CoMnO$_6$, thin films. ARUNAVA GUPTA, Center for Materials for Information Technology and Department of Chemistry, University of Alabama, Tuscaloosa, Alabama 35487, HAIZHONG GUO, JIAN DI, JIANGI ZHANG, Department of Physics, Florida International University, Miami, FL 33199, M. VARELA, S.J. PENNYCOOK, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831 — The dependence of the magnetic properties on oxygen concentration in epitaxial La$_2$CoMnO$_6$(LCMO) thin films has been investigated grown by pulsed laser deposition (PLD). Using x-ray magnetic circular dichroism spectral microscopy (XMCD) at Mn$_{L2,3}$ and Co$_{L2,3}$ edges, we have determined that the primary ion valence state is Mn$^{3+}$/Co$^{3+}$. Additionally, we see evidence of some low-spin Co$^{4+}$ ions, corresponding to the existence of a second ferromagnetic (FM) phases in our samples. The existence of oxygen vacancies induces the local vibronic Mn$^{3+}$/Co$^{3+}$ superexchange interactions in direct competition with the static FM Mn$^{3+}$/Co$^{3+}$ interactions. This results in the appearance of a new low temperature FM phase and suppression of the high-temperature FM phase, creating two distinct magnetic phase transitions.

Wednesday, March 12, 2008 8:00AM - 10:36AM – Session P24 DMP: Focus Session: Optical Properties of Nanostructures V: Plasmonics and Metallic Nanostructures Morial Convention Center 216

8:00AM P24.00001 Calculations of second harmonic generation by nano-particles or holes. WILLIAM SCHAICH, Indiana University — We are setting up finite-difference time-domain (fDTD) calculations of second harmonic generation (SHG) by metallic nano-particles or at nano-holes in metallic films. This generation is driven by first order fields at the metal surfaces, using the phenomenological a and b parameters that have been used to describe shg at planar jellium-metal surfaces. Our interest is in locating and understanding the occurrence of resonances and hot-spots for shg.

1Research supported in part by NSF-CBET-0708590.

8:12AM P24.00002 Plasmonic bonding and anti-bonding forces in a bisphere. TSZ FAI (JACK) NG, C.T. CHAN, The Hong Kong University of Science and Technology — By exciting the surface plasmon resonance of a pair of nanoparticles using intense laser illumination, one can exploit huge optical forces on the nanoparticles. We calculate such resonant optical force using a multiple scattering and Maxwell stress tensor formalism, which is "exact" within the classical electrodynamics. It is shown that the full electrodynamic calculation can give results that differ significantly from those obtained by the quasi-static approximation. As the pair of nanoparticles approach each other, the individual particle's plasmonic modes hybridize and split into bonding and anti-bonding modes, which induced attraction and repulsion respectively. At very small separations, the bonding (anti-bonding) modes are forced to curve downward (upward) in frequency significantly, resulting in the formation of a low frequency attractive (high frequency repulsive) band. Consequently, a low frequency laser illumination will induce strong attraction, promoting particle clustering, and a high frequency illumination will induce strong repulsion, preventing particle aggregation. With high intensity, these resonant forces can dominate over the other relevant forces, including the van der Waals force, when the separation between the particles is several nanometers.

8:24AM P24.00003 Surface-enhanced Raman Scattering from Virus-like Particle Crystals. CHRISTOPHER DUFORT, BOGDAN DRAGNEA, Indiana University, Department of Chemistry — Recently, a method for the encapsidation of gold nanoparticles by an icosahedral virus protein coat, termed a virus-like particle (VLP), has been developed. Of particular interest is in observing their spectroscopic properties upon arrangement into a three-dimensional crystal lattice. Here we present the surface-enhanced Raman scattering spectrum of such an assembly. This is made possible by the plasmonic coupling of adjacent gold nanoparticles when excited near their plasmon resonant frequency. To determine whether the SERS effect is arising from isolated hot spots or a large number of junctions acting in unison we employed scanning confocal Raman spectroscopy. This seems to indicate the latter, as a uniform Raman intensity is observed across entire crystals.

8:36AM P24.00004 The effects of nanoparticle spacing on second-harmonic generation from gold nano-dimers. DAVON W. FERRARA, KEVIN A. TETZ, MATTHEW D. MCMAHON, RICHARD F. HAGLUND, JR., Vanderbilt University — Second-generation harmonic (SHG) is an important signature of electron dynamics in nanoparticles (NPs) as well as a sensitive probe of surface effects. In the gap between closely spaced pairs of NPs, or nanodimers (Nds), localized electromagnetic field energy creates a hot spot that has been shown to affect SHG from asymmetric Nds. We will present new experimental results demonstrating the role that gap size and field localization plays in SHG from centrosymmetric arrays of gold Nds. Using standard electron-beam lithography techniques, NPs were made 20 nm in height with varying areal aspect ratios. In the ND arrays, symmetry forbids SHG in the forward direction, but not at larger angles. Our experiments indicate suppression of SHG intensity with decreasing gap size and evidence of stronger long-range interactions between NPs with separation over 200 nm. Finite-difference time-domain simulations were also performed in order to correlate field localization with SHG. Our simulations show a strong dependence on the polarization of incident light.

1Supported in part by DOE grant DE-FG02-01ER45916.

8:48AM P24.00005 Optical Imaging Properties of Metal Nanoparticle Chains. DAVID CITRIN, Georgia Institute of Technology — Chains of noncontacting noble-metal nanoparticles are known to support coupled plasmonic-electromagnetic modes known as plasmon polaritons, in which those polarized perpendicular to the chain axis exhibit group and phase velocity in opposite directions. This in turn has attracted interest in nanoparticle chains and arrays as left-handed materials for optical applications. In this contribution, I discuss recent work in my group on the imaging properties of nanoparticle chains. In particular, I present work that demonstrates theoretically the focusing properties of nanoparticle chains. I further discuss possible applications in near-field optics.

9:00AM P24.00006 Plasmonic superfocusing on metallic tips for near-field optical imaging and spectroscopy. CATALIN C. NEACSU, ROB OLMON, SAMUEL BERWEGER, ALEXANDRIA KAPPUS, FRIEDRICH KIRCHNER, Department of Chemistry, University of Washington, Seattle, USA, CLAUS ROPERS, Max-Born Institute for Nonlinear Optics and Short Pulse Spectroscopy, Berlin, Germany, LAX SARAF, Pacific Northwest National Laboratory, Richland, WA, USA, MARKUS B. RASCHKE, Department of Chemistry, University of Washington, Seattle, USA — Realization of localized light sources through nonlocal excitation is important in the context of plasmon photonics, molecular sensing, and in particular near-field optical techniques. Here, the efficient conversion of propagating surface plasmons, launched on the shaft of a scanning probe tip, into localized plasmon at the apex provides a true nanoconfined light source. Focused ion beam milling is used to generate periodic surface nanostructures on the tip shaft that allow for tailoring the plasmon excitation. Using ultrashort visible and mid-IR transients the dynamics of the propagation and subsequent scattered emission is characterized. The strong field enhancement and spatial field confinement at the apex is demonstrated studying the coupling of the tip in near-field interaction with a flat sample surface. It is used in scattering near-field spectroscopic imaging (s-SNOM) to probe surface nanostructures with spatial resolution down to 10 nm.
Novel properties of nanostructured metal particles and films. SHENGLI ZOU, University of Central Florida — Using electromagnetic dynamics, we simulate the extinction spectra and enhanced electric fields of nanostructured metal nanoparticles and films. Their sensing and waveguide applications will be discussed. The sensing of molecules is achieved by the shift of the plasmon resonance wavelength of nanoparticles or enhanced Raman scattering or fluorescence signals, which are due to the enhanced local electric fields near or far away from the metal surface. The waveguide is achieved by the electromagnetic coupling in a one dimensional particle chain or a perforated metal film.

Resonance of metallic wire structures. LEI ZHOU, Y. ZHANG, Fudan University, SIU TAT CHUI, University of Delaware — Metallic wire structures form a common class of physical systems. We illustrate how to understand the general physics of the wire systems with a specific example, the split ring resonator. We derived simple polynomial equations to determine the entire resonance spectra of split ring structures, which can be analytically solved in the limit of narrow wires. A resonance spectrum very similar to that of a straight wire is obtained. For double stacking split rings made with flat wires, we showed that the resonance frequency depends linearly on the ring-ring separation. In particular, we found that the wavelength of lowest resonance mode can be made as large as 10^3, the geometrical size of the ring for realistic experimental conditions, whereas for current systems this ratio is of the order of 10. Finite-difference-time-domain simulations on realistic structures verify the analytic predictions.

Fabrication of Plasmonic Optical Probe and Its Characterization. SEONG SOO CHO, SunMoon University, D.W. KIM, VINAYAH JHA, O. SUWAL, SunMoon Univ, M.J. PARK, Korea Military Academy, RESEARCH CENTER FOR NANOSCIENCE, NATIONAL RESEARCH LAB TEAM — Recently, there have been tremendous interests about the nano-structured optical probe using surface plasmon polariton due to possible applications of the next generation local communication devices and nano-bio sensor technology. The nano-size metallic apertures such as metal-coated fiber probe and microfabricated pyramidal probe, have shortcomings of very low output intensities. With periodic groove or defects near the aperture on the microfabricated pyramidal probe, the huge output intensity enhancement has been reported [1]. In this talk, the fabrication with nano-flowers including metallic scattering centers around the nano-size aperture and its optical characterization of the pyramidal metallic probe will be presented. References: [1] The effect of groove shape on light transmission, S.S. Choi, etc., 3rd International Conference on Surface Plasmon Photonics, June 17-22, Dipon, France.

Inter-particle coupling and polarizability of silver nanoparticle dimers. KE ZHAO, CLAUDIA TROPAREVSKY, University of Tennessee & Oak Ridge National Laboratory, ADOLFO EGUILUZ, ZHENYU ZHANG, Oak Ridge National Laboratory & University of Tennessee, THEORETICAL CONDENSED MATTER PHYSICS AT UNIVERSITY OF TENNESSEE & OAK RIDGE NATIONAL LABORATORY COLLABORATION — Using a real-space implementation of density-functional theory, we investigate systematically the electronic/chemical coupling of two silver nanoparticles of varying sizes. The nanoparticles are allowed to approach each other along two distinct directions defined by, respectively, maximum and minimum static polarizabilities. We show that, as the inter-particle separation decreases, the static polarizability of the dimer shows signatures of crossover to a strong-coupling regime. Moreover, we analyze the connection between the crossover from weak to strong coupling regimes of the nanoparticles and the electron density overlap from the states contributed by the individual nanoparticles. The significance of these results will be discussed in connection with the prevailing theories of the electromagnetic enhancement of surface-enhanced Raman scattering.

Enhancement of Light Transmission through Bull’s Eye Structures. SINAN SELCUK, Department of Physics University of Florida, DANIEL ARENAS, DAVID B. TANNER, ARTHUR F. HEBARD, Department of Physics University of Florida — Optical transmission of a single hole in a metal film surrounded by concentric surface grooves is shown to have an enhanced transmission. We fabricated these structures in silver films which are thin enough to let light through without a center hole. We have measured the optical transmission and reflection in visible to near infrared spectrum observing enhanced transmission scaling with groove periodicity. Opening a hole in the center gives rise to destructive interference between the light passing through the structure and the light passing through the hole. We will discuss the mechanisms behind light transmission for the bullseye structure for varying hole size, groove periodicity, groove depth and the metal thickness.

Fluorescence enhancement from nominally flat surfaces. SHY-HAUH GUO, Department of Electrical and Computer Engineering, University Of Maryland, College Park, MD, 20742, HUNG-CHIH KAN, Department of Physics, University Of Maryland, College Park, MD, 20742, RAY PHANEUF, Department of Materials Science and Engineering, University Of Maryland, College Park, MD, 20742 — We report on experimental investigations of fluorescence enhancement from nominally flat silver and silicon substrates, in the presence of an oxide spacer layer. By varying the thickness of the oxide layer, we were able to change the spacing between the substrates and the oxide layer thickness. We find that the relative fluorescent intensity measured above Ag vs. Si substrates oscillates, indicating a resonant effect. We investigate the effect of nanoscale roughness on the observed fluorescent enhancement.

Anisotropic Light Scattering from Ferrofluids. CORNELIU RABLAIU, PREM VAISHNAVHA, Kettering University, Flint, MI, RATNA NAIK, GAVIN LAWES, RON TACKETT, C. SUDAKAR, Wayne State University, Detroit, MI — We have investigated the light scattering in DC magnetic fields from aqueous suspensions of Fe_3O_4 nanoparticles coated with tetra methyl ammonium hydroxide and γ-Fe_2O_3 nanoparticles embedded in alginate hydrogel. For Fe_3O_4 ferrofluid, anomalous light scattering behavior was observed when light propagated both parallel and perpendicular to the magnetic fields. This behavior is attributed to the alignment and aggregation of the nanoparticles in chain-like structures. A very different light scattering behavior was observed for γ-Fe_2O_3 alginate sample where, under the similar conditions, the application of the magnetic field produced no structured change in scattering. We attribute this difference to the absence of chain-like structures and constrained mobility of iron nanoparticles in the alginate sample. The observation is in agreement with our relaxation and dissipative heating results where both samples exhibited Neel relaxation but only the Fe_3O_4 ferrofluid showed Brownian relaxation. The results suggest that Brownian relaxation and nanoparticle mobility are important for producing non-linear light scattering in such systems. 3.P.P. Vaishnava, R. Tackett, A. Dixit, C. Sudakar, R. Naik, and G. Lawes, J. Appl. Phys. 102, 063914 (2007).

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P25 DPOLY DBP: Focus Session: DNA and Protein Analysis with Micro and Nanofluidics Morial Convention Center 217
8:00AM P25.00001 Learning from the Jersey Turnpike: Cell Lysis, Labeling and Washing with Microfluidic Metamaterials, ROBERT AUSTIN, Princeton University — Directing objects across functional streamlines at low Reynolds number is difficult but important since this motion can be used to label, lyse, and analyze complex biological objects on-chip without cross-contamination. Here we use an asymmetric post array to move cells across colloring reagents and show on-chip, immunofluorescent labeling of platelets with washing and E. Coli cell lysis with simultaneous separation of bacterial chromosome from the cell contents. Furthermore, we develop the concept of a microfluidic metamaterial by using the basic asymmetric post array as a building block for complex particle handling modes. These modular array elements could be of great use for developing robust techniques for on-chip, continuous flow manipulation and analysis of cells, large bio-particles, and functional beads.

8:36AM P25.00002 DNA Docking with Functionalized Colloidal Probes, LU ZHANG, YINGXI ELAINE ZHU, Department of Chemical and Biomolecular Engineering, University of Notre Dame — The docking of DNA with probe-functionalized microparticles remains inadequately understood, despite the significance of DNA hybridization-based technologies for high-throughput screening for genetic analysis and biomedical diagnostics. In this work, we employ fluorescence correlation spectroscopy (FCS) and confocal microscopy to examine DNA-colloid interaction and resulting conformational structures of DNA oligomers with oligonucleotide-functionalized colloidal probes, whose particle size varies from 100 nm to 3 um. We observe that the docking efficiency strongly depends on DNA length, colloid size and surface functionality. Optimal probe size and temperature are found for rapid hybridization. We conjecture that the resulting structure of DNA at the interface of colloidal probes is determined by both steric effects and DNA charge condensation. If time permits, we will discuss our recent work on the docking of elongated DNA with functional probes by imposed dielectrophoretic forces in the presence of AC fields.

8:48AM P25.00003 Confinement spectroscopy: A novel approach to force spectroscopy1, FREDRIK PERSSON, PAWEL UTIKO, WALTER REINSER, ANDERS KRISTENSEN, Technical University of Denmark — In physics DNA is readily described by its mechanical properties, neglecting its chemical composition. By studying variations in these properties conclusions can be drawn about the interaction between DNA and both its environment and also ligand binding to DNA. These investigations are normally performed by force spectroscopy using optical or magnetic tweezers associated with an elaborate experimental setup. We introduce confinement spectroscopy, as a complementary technique, where a continuously variable degree of spatial restriction is applied to the molecule in a fluidic funnel-like geometry. By driving the molecule along the funnel, an extension versus confinement curve is obtained. This curve contains not only information regarding the molecule elasticity, but also new details concerning the self- and surface-interactions of the molecule. It is also easily integrated into lab-on-a-chip devices.

9:00AM P25.00004 Fluorescence microscopy studies of the DNA motion near voltage biased solid-state nanopores, KAZUHIKO OBANA, YOICHI NAKAMURA, KAYA KOBAYASHI, TOSHIYUKI MITSUI, Aoyama Gakuin University — A solid state nanopore in a Si-based thin insulating membrane works as a single DNA molecule sensing device that provides the information of the length and the folding configuration of the DNA by measuring ionic currents when the DNA translocates through the pore [1]. These nanopores may play a significant role in molecular electronics and rapid DNA sequencing. Now one of the issues related to this nanopore sensing technique is clogging the nanopores by DNA molecules because it significantly extends the DNA translocation time. To elucidate this issue, we use time-resolved fluorescence microscopy to observe the DNA motion near voltage biased nanopores. We will discuss the DNA motion near nanopores under the various applied voltages. [1] J. Li M. Gershov, D. Stein, E. Brandin, and J.A. Golovchenko, Nature Materials 2: 611 (2003); T. Mitsui, D. Stein, Y.-R. Kim, D. Hoogerheide, and J.A. Golovchenko, Phys. Rev. Lett. 96: 036102-1 (2006)

9:12AM P25.00005 Influence of polymer-pore interactions on translocation, TAPIO ALA-NISSILÄ, Helsinki University of Technology, KAIYU LUO, Helsinki University of Technology, Finand, SEE-CHEN YING, Brown University, ANIKET BHATTACHARYA, University of Central Florida, TRK COLLABORATION, BROWN COLLABORATION, UCF COLLABORATION — We investigate the influence of polymer-pore interactions on the translocation dynamics using Langevin dynamics simulations2. An attractive interaction can greatly improve translocation probability. At the same time, it also increases translocation time slowly for weak attraction while exponential dependence is observed for strong attraction. For fixed driving force and chain length the histogram of translocation time has a transition from Gaussian distribution to long-tailed distribution with increasing attraction. Under a weak driving force and a strong attractive force, both the translocation time and the residence time in the pore show a non-monotonic behavior as a function of the chain length. Our simulations results are in good agreement with recent experimental data3.

9:24AM P25.00006 Nanofilters for high throughput DNA separation, NABIL LAACHI, University of Minnesota, CARMELO DECLET, University of Puerto Rico-Mayaguez, CHRISTINA MATSON, Mississippi State University, KEVIN DORFMAN, University of Minnesota — Nanofilters are a novel class of microfabricated devices for rapidly separating short, rigid DNA. The succession of alternating narrow slits (~50nm) and deep wells (~300nm) is used to trap the DNA, which then escape at a size-dependent rate. Experiments and near-equilibrium theoretical arguments both indicate that smaller DNA travel faster in a weak field, but the separation fails at around 100V/cm. We theoretically show that the speed and performance of the device can be enhanced using high fields of several hundred V/cm. Based on scaling arguments, the separation of short, rod-like DNA molecules at high fields occurs via "torque-assisted escape," which originates from the non-uniform electric field at the slit entrance. The quadratic dependence of the torque on the molecule size indicates that larger molecules will now emerge first; under a high field, the device operates in a band-inverted manner. Brownian dynamics simulation results confirm the mobility increase with size, with a quasi-plateau at very large fields.

9:36AM P25.00007 Rapid DNA Identification by Dielectrophoresis of Nanocolloids, ZACHARY GAGNON, SATYAJIYOTI SENAPATI, JASON GORDON, HSUEH-CHIA CHANG, Dept. of Chemical and Biomolecular Engineering, University of Notre Dame — Due to their size and number, dispersed oligo-functionalized nanocolloids can reduce the diffusion length/docking time and increase the sensitivity of ssDNA hybridization reactions by orders of magnitude compared to immobilized probes. We find that, for long target ssDNAs, their docked conformation is a sensitive function of the nanocolloid size, surface charge, functionalized probe density and number of docked DNAs per bead. Three distinct conformations (collapsed, stretched and condensed) are detected via independent light scattering, Zeta potential, dielectrophoresis (DEP) and electron micrograph techniques. By optimizing the hybridization conditions to produce a stretched conformation, we are able to significantly change the DEP cross-over frequency of hybridized beads, thus allowing rapid label-free detection of hybridization by simple impedance techniques down to pM concentrations.
9:48AM P25.00008 The non-driven polymer translocation through a nanopore: relaxation and translocation are not decoupled. GARY W. SLATER, MICHEL G. GAUTHIER, University of Ottawa — Most theoretical models describing the translocation of a polymer chain through a nanopore use the hypothesis that the polymer remains in an equilibrium random coil conformation during the process. In other words, models generally assume that the characteristic relaxation time of the chain is small enough compared to the translocation time that non-equilibrium polymer conformations can be ignored. We present Molecular Dynamics simulations that directly test this hypothesis by looking at the escape time of unbiased polymer chains starting with different initial conditions. We find that the chains are deformed for the systems studied, even though the translocation time is about 10 times larger than the relaxation time. Our most striking result is the observation that the last half of the chain escapes in less than 12% of the total escape time, which implies that there is a large entropy-driven acceleration of the chain at the end of its escape from the channel.

10:00AM P25.00009 Digital DNA: Physics of DNA in Nanoparticle Lattices. WALTER REISNER, Brown University Dept. of Physics, JONAS TEGENFELDT, Dept Physics / Solid State Physics Lund University, NIELS LARSEN, Biosystems/Polymer Dept. Risø National Laboratory Technical University of Denmark, HENRIK FLYVBJERG, Biosystems Dept. Risø National Laboratory Technical University of Denmark, DEREK STEIN, Dept. of Physics Brown University, ANDERS KRISTENSEN, MIC - Department of Micro and Nanotechnology Technical University of Denmark — Controlling the on-chip organization and conformation of DNA is important for a number of interrelated nanotechnology disciplines. We introduce a new type of nanostructure consisting of a nanoplat with a built in spatial modulation of confinement created by arrays of embedded nanoparticles. Nanoplates are square plates with 100 nm wide and 500 nm deep. We show that DNA molecules inserted into such nanostructures can adopt conformational states that can be used to store and retrieve information. A further application of this type of structures is that they will spontaneously adopt a 'digitized' conformation consisting of filled nanoplates connected by fluctuating links. By adjusting the spacing, organization and placement of the nanoparticles it is possible to immobilize DNA at predetermined regions of device without additional chemical modification and achieve a high degree of control over local DNA conformation. We will present results from fluorescence microscopy experiments on the equilibrium behavior and dynamics of DNA in such structures and interpret these results in terms of a simple statistical mechanical model.

10:12AM P25.00010 Dynamics of DNA molecules confined to slit-like nanofluidic channels. CHRISTINE MEYER, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands, DOUWE JAN BONTHUIS, present address: Technical University of Munich, Germany, DEREK STEIN, present address: Brown University, USA, CEES DEKKER, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands — We experimentally investigate the dynamics of DNA in confined spaces. This is not only important for a better understanding of the behavior of DNA as a biologically relevant molecule but also helps us to test general polymer dynamics models. Fluorescently stained DNA molecules are inserted into slit-like nanofluidic channels. The channel material is fused silica and the channels are fabricated using a bonding process. We take fluorescent images of the DNA in channels of different heights and measure the projected size of the DNA molecules fitted by an ellipse. Furthermore, we measure the relaxation times derived from the autocorrelation function of the size. If the channel height is smaller than twice the radius of gyration of the DNA molecules ($R_g = 700$ nm) both parameters agree with the predictions of de Gennes. For even smaller channels with a height less than twice the persistence length of stained DNA ($L_p = 60$ nm) the dynamics resemble the predictions made by Odijk for this regime.

10:24AM P25.00011 Electrokinetic transport at a nanocapillary/microchannel interface. JARROD SCHIFFBAUER, KATHLEEN KELLEY, BOYD EDWARDS, AARON TIMPERMAN, West Virginia University — Coupled electrokinetic transport phenomena play a central role in concentration polarization near the interface between a permselective nanocapillary membrane and a microchannel. Here the effects of ion concentration and potential distribution on transport through a single nanocapillary are studied using both semi-empirical and fundamental models. The fundamental models are developed within the context of the coupled electrohydrodynamic transport equations for multiple charged species in aqueous solution. The semi-empirical models describe average species and fluid fluxes through the respective regions.

10:48AM P25.00013 Separation of DNA in nanoscale devices with alternating channel depth. HENRY LAU, ELIZABETH STRYCHALSKI, HAROLD CRAIGHEAD, LYNDEN ARCHER, Cornell University — The size-dependent separation of DNA using nanofabricated devices consisting of alternating deep and shallow regions have been the subject of numerous experimental and theoretical works. Recent Brownian dynamics simulations suggest that the separation of rigid-rod DNA can be effected at high electric fields without a loss of resolution (PRL, 2007, 98, 098106). To study the dynamics of DNA separation at high fields, electrophoresis experiments were carried out using DNA fragments up to 753 bp in size. As the transport mechanism of DNA fragments in gels has been shown to be a strong function of topology (Electrophoresis, 2004, 25, 1772), electrophoresis of branched rigid-rod DNA molecules was performed to investigate the effects of aneute architecture on mobility in nanofabricated devices. By comparing the mobility of branched and linear DNA molecules of identical total molecular weight, we exclude the influence of size and charge and focus on the effects of branch size and location, and overall aneute topology. Our results help elucidate the electrophoretic migration mechanism of DNA molecules with complex architecture in sieving media with precisely-controlled internal structures.

Wednesday, March 12, 2008 8:00AM - 10:48AM — Session P26 DCP: Focus Session: Quantum Control III — Morial Convention Center 218

8:00AM P26.00001 Use of Ultrafast Molecular Dynamics and Optimal Control for Identifying Biomolecules. JEAN-PIERRE WOLF, University of Geneva — With F. COURVOISIER, L. GUUYON, V. BOUTOU, and M. ROTH, H. ROSLUND, H. RABITZ, Princeton University. The identification and discrimination of molecules that exhibit almost identical structures and spectra using fluorescence spectroscopy is considered quite difficult. In order to evaluate the capability of optimal control for discriminating between the optical emissions of nearly identical molecules, we developed a new approach called ‘optimal dynamic discrimination’ (ODD). A proof of principle ODD experiment has been performed using Riboflavin (RBF) and Flavin Mononucleotide (FMN) as model system. We used a complex multipulse control field made of a pair of pulses (UV and IR). The UV part ($\lambda = 400$ nm) is optimally shaped using a control learning loop while the IR component (800 nm) is FT-limited (100 fs) and set at a definite time delay with respect to the UV pulse. Clear discrimination was observed for optimally shaped pulses, although the linear spectra from both molecules are virtually identical. A further experiment showed that, by using the optimal pulse shapes that maximize the fluorescence depletion in FMN and RBF in a differential manner, the concentration of both molecules could be retrieved while they were mixed in the same solution. The ODD demonstration sets out a promising path for future applications, as for example fluorescence microscopy where endogenous fluorescence spectra of many biomolecules overlap.
isomers. The case of molecular isotopes is based on the mass difference between the molecular components which results in a slightly different revival period of excitation degree of the other. In our work we implemented this approach to molecular nitrogen, and study the cases of molecular isotopes and molecular spin using ultrashort laser pulses where the first pulse rotationally excites both components in a binary mixture, and the second pulse de-excites one, while enhancing the other. 

We experimentally demonstrate a new approach to selective excitation of close molecular species in mixtures. We apply two time delayed, YEHIAM PRIOR, SHARLY FLEISCHER, ILYA SH. AVERBUKH, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, and isomers diffusion-space pattern helps indicate the area in the search space that is most amenable to effective optimization. The diffusion-mapping algorithm is sufficiently effective in maximizing integrated intensity in a second harmonic generation experiment. The use of a sampling set of 1000 random pulses in the diffusion mapping detection space and to sample essential patterns in the lower-dimensional representation. The diffusion maps are constructed and analyzed for the case study here, we use the recently developed nonlinear statistical method of diffusion mapping to effectively reduce the combined dimensionality of the search and detection spaces are high-dimensional (with dimension $\sim$100 each). This poses considerable problems to analysis and interpretation of the process-related data. 

Photonics Research, Temple University, Philadelphia, PA 19122 — Strong-field control settings involve highly nonlinear processes. Typically, both search and detection spaces are high-dimensional (with dimension $\sim$100 each). This poses considerable problems to analysis and interpretation of the process-related data. 

Here, we use the recently developed nonlinear statistical method of diffusion mapping to effectively reduce the combined dimensionality of the search and detection space and to sample essential patterns in the lower-dimensional representation. The diffusion maps are constructed and analyzed for the case study of maximizing integrated intensity in a second harmonic generation experiment. The use of a sampling set of 1000 random pulses in the diffusion mapping detection space is sufficient for effective dimensionality reduction and for revealing the inherent structure of the process-related data. Extrapolation of the low-dimensional diffusion-space pattern helps indicate the area in the search space that is most amenable to effective optimization. The diffusion-mapping algorithm is sufficiently fast and robust that may make it a valuable preprocessing tool for optimal pulse searching.

Selective Rotational Manipulations of Close Molecular Species – isotopes and isomers, YEHIAM PRIOR, SHARLY FLEISCHER, ILYA SH. AVERBUKH, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel 76100 — We experimentally demonstrate a new approach to selective excitation of close molecular species in mixtures. We apply two time delay, ultrashort laser pulses where the first pulse rotationally excites both components in a binary mixture, and the second pulse de-excites one, while enhancing the excitation degree of the other. In our work we implemented this approach to molecular nitrogen, and study the cases of molecular isotopes and molecular spin isomers. The case of molecular isotopes is based on the mass difference between the molecular components which results in a slightly different revival period of the repetitive alignment that follows excitation by an ultrashort pulse. Following the revival process, one can distinguish between the isotopic components and selectively affect them. The case of spin isomers is more complicated since there are no differences in their mechanical or electrical properties. Here we utilize the symmetry and statistics of the specific molecular wavefunction and demonstrate highly selective ($\sim$18:1) excitation of Ortho/Para nitrogen. Numerical simulations agree very well with the observed results. Since this process is nonresonant and does not require any special conditions like temperature etc. this approach is general and can be applied to most symmetric molecules. 

Anti-Correlated Pigment Fluctuations of Allophycocyanin for Highly Efficient Photosynthetic Light Harvesting in Cyanobacteria, ANDREW MORAN, University of North Carolina, RENE NOME, NORBERT SCHERER, University of Chicago — The phycobiliprotein, allophycocyanin (APC), is an excellent model system for the study of light harvesting pigment interactions with a protein bath. This work investigates the relaxation of electronic excitations in APC with electric field–resolved transient grating and photon echo spectroscopies. Transient grating experiments observe a 35 fs internal conversion process between single exciton levels. Most importantly, our analysis shows that anti-correlated phycocyanobilin pigment energy level fluctuations cause the anti-diagonal orientation of the node in the measured dispersive photon echo spectrum. We believe this novel observation to reflect concerted protein bath fluctuations over the 2 nm length scale that separates the pigments. Consideration of the Forster energy transfer rate theory suggests that APC has evolved with this property to enhance its photosynthetic light harvesting efficiency. 

10:24AM P26.00007 ABSTRACT WITHDRAWN – 

Understanding the relaxation of excited-state cis-1,3,5-hexatriene in order to augment the preferred pathway for control, MICHAEL ORROZCO, KUO-CHUN TANG, ROSEANNE SENSION, Dept. of Chem., University of Michigan - Ann Arbor — A study of the ground and excited-state relaxation of cis-1,3,5-hexatriene in various solvents and temperatures has been performed. The role solvent plays in the relaxation dynamics and relaxation pathways has been assessed and modeled to achieve a better understanding of the energy landscape. This information will be used to determine the preferred relaxation pathways and inform efforts to use sculpted UV pulses to influence the excited state dynamics through pump-dump interactions. Finally, further experiments are proposed wherein UV pulse-shaping will used to study and control other reactive systems.
8:00AM P27.00001 Magnetic Stripe Phase at the Spin Reorientation Transition of an Ultrathin Magnetic Film†. Y.Z. WU, Surface Physics Laboratory (National Key Laboratory) and Advanced Material Laboratory, Fudan University, Shanghai 200433, China — Magnetic long-range order cannot exist in an isotropic 2D Heisenberg system at any finite temperature, but could be established by adding a magnetic anisotropy to the system. In experiment, this topic has been addressed by investigating the so-called spin reorientation transition (SRT) in magnetic ultra-thin films, where the perpendicular magneto-crystalline anisotropy cancels the in-plane magnetic shape anisotropy. In this talk, we present our study on the SRT of Fe/Ni/Cu(100) system using Photoemission Electron Microscopy (PSEM) chamber at beam line 7.3.1.1 of the Advanced Light Source. We show that (1) a homogenous magnetic state is energetically unstable against the formation of magnetic stripe domains, (2) the stripe domain width decreases exponentially towards the SRT point, and (3) the Curie temperature of the film is reduced to result in a paramagnetic phase within a narrow thickness gap in the SRT region. Using magnetic interlayer coupling to simulate the effect of an external magnetic field, we further studied the SRT in Co/Cu/(Fe/Ni)/Cu(100) system and revealed a universal behavior of the stripe domain width. Moreover a new metastable bubble domain phase was observed near the SRT point in Fe/Ni film, which enriches the magnetic phase diagram of a 2D magnetic system.

†Work was done in collaboration with C. Won, J. Choi, J. Wu, A. Doran, A. Scholl, and Z. Q. Qiu.

8:36AM P27.00002 Induced V magnetic polarization effects in V/Fe/V trilayers. ROSA A. LUKASZEW, CESAR CLAVERO, College of William and Mary, YONGSEONG CHOI, DANIEL HASKEL, APS-ANL, CECILIA SANCHEZ-HANKE, NSLS-BNL, BRIAN KIRBY, NIST, MIKE FITZSIMMONS, LANSCE-LANL — Understanding magnetic interactions at interfaces between nonmagnetic and magnetic elements and in some cases magnetic polarization of non-magnetic elements at these interfaces is a challenging topic. In addition these phenomena are interesting also due to their potential application in magneto-optical (MO) data storage devices and sensors. In the case of Fe/V interfaces, a fundamental question is the effect of interdiffusion on the magnetic moments of the intervening elements at the interface. Here, we present a structural, morphological and magnetic study of a V/Fe/V trilayer. While no significant diffusion of V into the Fe film was observed with x-ray reflectometry (XRR) and polarized neutrions reflectometry (PNR), x-ray magnetic circular dichroism (XMCD) and x ray resonant magnetic scattering (XMRSS) measurements reveal V magnetic polarization at both Fe/V interfaces. The magnetization profile in the Fe and V films was obtained by XRRMS and will be compared with that obtained with PNR. Our results show the complementarity of these techniques to further clarify V polarization phenomena in Fe/V interfaces.

8:48AM P27.00003 Structure and magnetism of Ni50Mn50 monolayers on Cu3Au(001). WALDEMAR MACEDO, REINALDO OLIVEIRA JR., MAXIMILIANO MARTINS, MANOEL PIRES, CDTN — The growth, structure and magnetism of equiatomic NiMn ultrathin films on Cu3Au(100) and the magnetism of Fe/Femn bilayers on this substrate were investigated. NiMn alloys in a concentration range around 50-50% have an L11 structure with lattice constants a and c of 3.74 Å and 3.52 Å, respectively. This NiMn-phase is antiferromagnetic (AFM), with high Néel temperature (∼1070 K), being very interesting for ferromagnetic / antiferromagnet systems with exchange bias effect and, therefore, for magneto-electronic devices. Cu3Au is an ordered fcc phase with lattice parameter of 3.75 Å, a substrate with very good epitaxial relationship with L11 NiMn. The NiMn monolayers were grown by coevaporation, under molecular beam epitaxy conditions, and characterized in situ by RHEED, LEED, XPS, AES and MOKE. Structural analysis revealed the epitaxy and layer-by-layer growth at room temperature. MOKE measurements suggest that the Fe/Ni50Mn50 bilayers present exchange bias, indicating that equiatomic NiMn films, as grown on Cu3Au(100) at room temperature, is AFM, as expected for the L11.

9:00AM P27.00004 Ab-initio simulation of magnetic exchange force microscopy of the antiferromagnetic Fe monolayer on W(001). CESAR LAZO, STEFAN HEINZE, Institute of Applied Physics, University of Hamburg, Germany, VASILE CACIUC, HENDRIK HOELSCHER, Institute of Physics, University of Muenster, Germany — Magnetic exchange force microscopy (MexFM) is a promising new technique to perform magnetic imaging with atomic resolution by measuring the magnetic exchange force between a magnetically coated tip and a magnetic sample [1]. Here, we apply density functional theory using the full-potential linearized augmented plane wave (FP-LAPW) method to investigate the exchange forces on the antiferromagnetic monolayer Fe on W(001) [2]. We use an Fe cluster as a tip model and include relaxations of the cluster and the surface. Surprisingly, relaxation effects of tip and sample depend sensitively on the local magnetic configuration. Therefore, relaxations play a crucial role for the magnetic signal. In particular, the onset of the exchange forces is shifted to larger distances, which facilitates their experimental observation. Based on the calculated force-distance curves we simulate MexFM images which display a competition of chemical and magnetic forces. Our simulations can explain the experimentally observed magnetic contrast [3]. [1] U. Kaiser et al., Nature 446, 522 (2007). [2] A. Kubetzka et al., Phys. Rev. Lett. 94, 087204 (2005). [3] R. Schmidt, C. Lazo, et al., submitted (2007).

9:12AM P27.00005 First-principles calculation of low-dimensional magnetic structures†. RUQIAN WU, University of California, Irvine — Magnetism in low dimensions is of great interest for fundamental and industrial research. Density functional calculations are important to provide clear physical insights for search, design and optimization of magnetic nanostructures that are essential in new technologies. We have recently performed systematic studies for search of giant magnetic anisotropy energies in single atom such as 3d on CuN, monatomic wires encompassing 3d-5d atoms, magnetic thin films such as 3d on Cu and Au. We will review the physics that governs the magnetic anisotropy and other phenomena driven by spin-orbit coupling. We will also discuss our recent results of spin dynamics in nanoentities.

†Work was supported by the DOE (grant No: DE-FG02-05ER46237).

9:48AM P27.00006 Shape Anisotropy and Magnetization Modulation in Hexagonal Cobalt Nanowires. ZUWEI LIU, PAICHUN CHANG, CHIA CHI CHANG, G E R D BERGMANN, JIA G. LU, University of Southern California — Ferromagnetic Co nanowires with diameter around 90 nm are synthesized via low voltage electrodeposition method. High resolution transmission electron microscopy and x-ray diffraction results show that the nanowires are uniform in size, and consist predominantly fcc structure with the magnetocrystalline easy axis (-axis) perpendicular to the wire axis. SQUID measurement illustrates the dominance of shape anisotropy, manifested by the weak temperature dependence of the enhanced coercive field along the nanowire axis. The magnetic domain structures of individual, segmented or multiple nanowires are studied via magnetic force microscopy. It shows a strong dipole at the two ends of the nanowire, together with a spatial magnetization modulation along the nanowire with a period around 700 nm. Based on theoretical modeling, such intrinsic modulation originates from the competition between the magnetocrystalline polarization along the easy axis and the shape anisotropy along the nanowire axis.
10:00AM P27.00007 Unique playground for complex magnetism: Fe monolayers on hexagonal transition-metal surfaces, STEFAN HEINZE, JOERG HARDRAT, PAOLO FERRIANI, Institute of Applied Physics, University of Hamburg, Germany, ALI AL-ZUBI, GUSTAV BIHLMAIER, STEFAN BLIEGEL, Institut fuer Festkuerperforschung, Forschungszentrum Juelich, Germany — Recently, the complexity of magnetic order even in single monolayer (ML) thick magnetic films on non-magnetic substrates has been dramatically demonstrated by the discovery of a spin-spiral state for a Mn ML on W(110) [1] and a nanoscale magnetic structure for an Fe ML on Ir(111) [2]. Here, we use density functional theory calculations based on the full-potential linearized augmented plane wave method to systematically study the magnetic order of an Fe ML on hexagonal hcp (0001) and fcc (111) surfaces of 3d- and 5d-transition metals. We show that due to substrate d-band filling the exchange coupling changes gradually from antiferromagnetic (AFM) on Tc, Ru, Re, and Os to ferromagnetic (FM) on Rh, Ir, Pd, and Pt. On Ru and Re the AFM coupling leads to a non-collinear Néel ground state due to topological frustration of exchange interaction. On Ru, Rh and Ir, the nearest-neighbor exchange coupling is small and exchange beyond nearest-neighbors, higher order spin interactions, and anisotropic exchange interaction compete making these systems a playground for intriguing magnetic order. [1] M. Bode et al., Nature 447, 190 (2007). [2] K. von Bergmann et al., PRL 96, 167203 (2006).

10:12AM P27.00008 Mean Field aspects of magnetic domain pattern evolution in ultrathin Fe/Cu(001) films, DANIO PESCIA, ALESSANDRO VINDIGNI, NICULIN SARATZ, OLIVER PORTMANN, Laboratory for Solid State Physics, ETH Zurich, PAOLO POLITI, Istituto dei Sistemi Complessi, CNR Firenze — Ultrathin Fe/Cu(001) films are magnetized out of plane and represent an experimental counterpart of the 2D Dipolar Frustrated Ising Ferromagnet. Indeed, one of the most attractive feature of these films is the occurrence of a variety of magnetic domain patterns; the last few consist of superstructures of positive and negative magnetization which originate from the competition between long-ranged antiferromagnetic dipolar interaction and nearest-neighbor ferromagnetic exchange interaction. The experimental patterns are relatively free to change their characteristic length of modulation as well as their overall structure (striped, labyrinthine, etc.) when the temperature is varied. The Mean Field theory is able to reproduce the temperature dependence of some important experimental observables like the domain width and the inside-domain magnetization profile (obtained by SEMPA images). We report on some Mean Field predictions for the 2D Dipolar Frustrated Ising Ferromagnet in close relationship with quantitative analysis of experimental SEMPA images recorded on Fe/Cu(001) films.

10:24AM P27.00009 Novel magnetism in gold and silver nanoclusters, WEIDONG LUO, STEPHEN J. PENNYCOOK, SOKRATES T. PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory — Ferromagnetic (FM) ordering in transition-metal systems (solids, surface layers, nanoparticles) arises from partially filled d shells. Thus, recent observations of FM Au nanoclusters were unexpected, and an explanation has remained elusive. We report first-principles density-functional spin-polarized calculations for Au and Ag nanoclusters. We find that in highly symmetric Au nanoclusters, the highest-occupied molecular orbital (HOMO) is highly degenerate and partially filled by Au 6s electrons with spins aligned according to Hund’s rule. The nanoclusters behave like “superatoms,” with the spin-aligned electrons being itinerant on the outer shell of atoms. Similar results obtain for Ag nanoclusters. In contrast, the same kind of calculations for Pt nanoclusters find that FM ordering is controlled by the partially filled d states in the usual way, and spin polarization generally occurs in many eigenstates of the Pt clusters. This research was sponsored in part by the DOE Office of Basic Energy Sciences, Division of Materials Sciences and Engineering and by the McMinn Endowment at Vanderbilt University. Computations were performed at the National Energy Research Scientific Computing Center.

10:36AM P27.00010 Non-Arrhenius Ferromagnetism In 1D Systems, LUCA SPADAFFORA, FAUSTO BORGONI, Dipartimento di Matematica e Fisica, Universita Cattolica, via Musei 41, 25121, Brescia, Italy, LUCA CELARDO, Department of Physics, Tulane University, New Orleans, LA 70118, BRUNO GONCALVES, Emory University, Atlanta, GA 30322 — Topological phase space disconnection has been recently found to be a general phenomenon in isolated anisotropic spin systems. This phenomenon sets a general framework to understand the emergence of ferromagnetism in finite magnetic systems. Here we study its relevance for finite systems in contact with a heat bath. The existence of this threshold, inducing extremely large magnetic reversal times, is shown to be able to determine metastable ferromagnetic behavior in finite samples. Also, it acts as a real energy barrier. Under suitable conditions the law for average reversal times can be obtained analytically and confirmed numerically. Consistent differences from the expected Arrhenius law of reversal times are shown for short rate interacting spin systems.

10:48AM P27.00011 Spin-orbit induced spin-spin coupling between electrons in coupled quantum dots, JIANMIN SUN, SUHAS GANGADHARIAH, OLEG STARYKH, University of Utah — We investigate spin-spin interaction between electrons localized in spatially separated quantum dots. We show that in the presence of single electron spin-orbit interaction (of Rashba type) in the dots and Coulomb interactions between electrons, a new anisotropic coupling of the van der Waals type between spins emerges. Unlike the standard exchange this coupling does not require overlap of the wavefunctions, and as a result becomes dominant for large distance between the dots. This ferromagnetic interaction is important in the Wigner crystal state where the exchange processes are severely suppressed.

Wednesday, March 12, 2008 8:00AM - 11:00AM – Session P28 DCMP: Superlattices and Nanostructures (Wires, Dots, etc.): Optical Properties

8:00AM P28.00001 Enhancement of optical sensitivity of quantum dots near metal-dielectric interface, PRABATH HEWAGEEGANA, VADYM APALKOV — We study theoretically the enhancement of the incident light transmitted through the diffraction grating. We are interested in the mid-infrared frequency range, corresponding to the intraband absorption by quantum dots. We show that for the s-polarized light the enhancement is much stronger than for p-polarized light. By tuning the parameters of the diffraction grating the enhancement of the light can be increased by a few orders of magnitude. The distribution of the transmitted light is highly nonuniform with very sharp peaks with the spatial width about 10 nm. Due to strongly inhomogeneous distribution of electromagnetic field the quantum dots should be placed at special points, i.e. hot spots, with large intensity of the field. We discuss the application of this effect to the quantum dot infrared photodetectors.

8:12AM P28.00002 Surface Enhanced Infrared Absorption Spectroscopy (SEIRA) using Infrared resonant Au-nanoshell based substrates, JANARDAN KUNDU, HUI WANG, Department of Chemistry, Laboratory for Nanophotonics, FEI LE, PETER NORDLANDER, Laboratory for Nanophotonics, Department of Physics and Astronomy, NAOMI HALAS, Department of Chemistry, Laboratory for Nanophotonics, Department of Electrical and Computer Engineering — Enhancements of the molecular signals are known to occur in the mid-IR region when the molecules are in close proximity to rough metal surfaces. This phenomenon, known as surface enhanced infrared absorption (SEIRA), is complementary to surface enhanced Raman scattering (SERS) and can be used for biochemical sensing. However, designing substrates for SEIRA that are resonant in the mid-IR has proven challenging. One solution is to use metal nanoshells, plasmonic nanoparticles with a wide plasmon tunability range from the visible to the mid-IR. Here, we exploit this tunability property of nanoshells to fabricate nanoshell aggregates and nanoshell arrays as SEIRA substrates. Para-aminophenol (pMA) is used as a test molecule for studying SEIRA activity of these substrates. SEIRA enhancement factors are evaluated to be in the 10000 range for these substrates. These strong enhancements allow for sensing of biologically relevant molecules such as adenosine. Spectral interpretation using SEIRA surface selection rule allows for insight into the molecule’s preferred orientation on the nanoparticle surface.
8:24 AM P28.00003 Polarization memory of charged excitons in vertically coupled InAs/GaAs quantum dots. SWATI RAMANATHAN, KUSHAL WIJESUNDARA, MAURICIO GARRIDO, ERIC STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio 45701-2979, USA. MICHAEL SCHEINBER, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375, USA. — Polarized photoluminescence of the InAs/GaAs coupled quantum dot system was studied, and circular polarization memory signatures of the neutral exciton, the positive trion and the negative trion are reported. Our samples are Stranski-Krastanow dots, vertically separated by a GaAs barrier. We obtain results for circular polarization memory that are consistent with previous polarization studies on single quantum dots, indicating that coupled dot systems have polarization signatures very similar to single dot systems. Due to their structure, our samples display hole level anticrossings. As the system shifts from one positive trion configuration to the other, a continuous change in circular polarization memory is observed. This change in polarization memory is explained by hole tunneling and exchange interactions. Identifying the two positive trion configurations as neutral exciton-like and positive trion-like provides a theoretical basis for understanding the circular polarization memory signature.

8:36 AM P28.00004 Spin interactions in a coupled InAs/GaAs quantum dot studied by polarization dependent photoluminescence. KUSHAL C. WIJESUNDARA, MAURICIO GARRIDO, SWATI RAMANATHAN, ERIC STINAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, OH 45701. MICHAEL SCHEINBER, ALLAN BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375. — In a quantum dot molecule, excitons and trions are relatively long-lived states that can be studied by optical spectroscopy and spin-resolved measurements. Recent experiments on InAs/GaAs quantum dot systems have demonstrated the feasibility of these approaches, and have revealed interesting physics. In this paper, we report on spin-resolved measurements on InAs/GaAs quantum dot systems, and discuss the implications of these results for the development of quantum dot devices.

8:48 AM P28.00005 THz Charge Oscillations in a Modulation Doped Parabolic Quantum Well. JAMES HEYMAN, LAURA BELL, JEFFERY ROGERS, Macla...
9:48AM P28.00010 Coherent coupling and energy transfer enhancement via multi-exciton levels in semiconductor nanocrystals, AMEENAH AL-AHMADI, Department of Physics, Umm Al-Qura University, SA, SERGIO ULLOA, Department of Physics and Astronomy, Ohio University, Athens, OH — The theory of coherent energy transfer (ET) in nanocrystal (NC) systems [1] is generalized for multie exciton levels. The relevant excitonic states in an isolated NC can be described by an effective four-level system, consisting of the ground level, two degenerate single exciton levels, and the biexciton level. We study the dynamics of a single donor-acceptor pair via the equation of motion for the density matrix of the system and consider analytical limits as well as numerical solutions. We show that the enhancement of the ET efficiency introduced by the biexciton levels is limited due to the coherent coupling of the exciton-biexciton levels in the donor-acceptor pair. The saturation of the ET rate in the donor-acceptor pair suggests a new mechanism to control the dipole-dipole coupling strength in NC systems, and we present here its dependence on structure parameters.

10:00AM P28.00011 Luminescence excitation of InAs/GaAs coupled quantum dots, MAURICIO GARRIDO, KUSHAL C. WIJESUNDARA, SWATI RAMANATHAN, ERIC A. STINIAFF, Department of Physics and Astronomy, and Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, Ohio 45701, MICHAEL SCHEIBNER, ALLAN S. BRACKER, DAN GAMMON, Naval Research Laboratory, Washington, DC 20375 — An understanding of the excited states in coupled quantum dots is a necessary step in the road towards a coherent control of this system. Photoluminescence excitation studies were performed on an InAs/GaAs coupled quantum dot system embedded in a Schottky diode structure. The ground states of the positive trion, negative trion and neutral exciton are first clearly identified by their photoluminescence spectra in bias maps. Preliminary results are reported on the luminescence excitation spectra of these charge configurations; both near and far away from the region where molecule-like behavior is observed.

10:12AM P28.00012 Record Extinction of a Laser Beam by a Single Quantum Dot, NICK VAMIVAKAS, METE ATATURE, University of Cambridge, JAN DREISER, TUNC YILMAZ, ANTONIO BADOLATO, Swiss Federal Institute - Zurich, ANNA SWAN, BENNETT GOLDBERG, Boston University, ATAC IMAMOGLU, Swiss Federal Institute - Zurich, SELIM UNLU, Boston University — The ability to efficiently couple far-field light to subwavelength light emitters is of critical importance for the rapidly growing field of nanophotonics. In this talk we present our recent work on the use of both index matched GaAs solid immersion lenses (SIL) and numerical aperture increasing lenses (NAIL) to improve far-field light coupling to and from single InAs/GaAs quantum dots. By incorporating a SIL\NAIL in resonant scattering measurements we find that a single InAs QD can extinguish nearly 12% of the exciting laser beam; a seven-fold improvement in extinction when compared to measurements made without a SIL\NAIL. The strong extinction makes it possible to measure a typical QD extinction using a dc power-meter without the need for phase sensitive lock-in detection.

10:24AM P28.00013 Quantum-mechanical description of Faraday rotation in a single quantum dot, YANJUN MA, JEREMY LEVY — Faraday rotation is one way to realize quantum non-demolition (QND) measurement of electron spin in a quantum dot. In the literature, it has been semiclassically modeled based on quantized electron spin states and classical electromagnetic fields. We have developed a fully quantum- mechanical model to describe Faraday rotation in single quantum dots, using an extension of the Jaynes-Cumming model which includes quantum Stokes operators. The intrinsic noise of Faraday rotation that results from the interaction between photon and electron is quantified under this model. Some effects, such as hyperfine interactions and transitions between off-resonant states such as light hole and conduction band electron states, and have not been included in our calculation. It is believed that these effects will affect the dynamics of spin and based on the current model, our calculation could be extended to examine the behavior of Faraday rotation with these effects included. This work was supported by NSF-DMR-0802846.

10:36AM P28.00014 Optical Aharonov-Bohm oscillations in DMS type-II ZnMnTe/ZnSe quantum dots, I.R. SELLERS, V.R. WHITESIDE, M. EGINLIGIL, University at Buffalo, W.-C. CHOU, National Chiao Tung University, China, I. KHAN, A. PETROU, University at Buffalo, A.O. GOVOROV, Ohio University, B.D. MCCOMBE, University at Buffalo — Low temperature magneto-photo luminescence studies of diluted magnetic semiconductor Zn(Mn)Te quantum dots (QDs) will be presented. As expected, the exchange interaction between the Mn spin and the electric charge carriers results in a strong optical polarization of the luminescence at low temperature. However, in addition, the sample geometry for the structure, which consists of five Zn(Mn)Te QD layers separated by narrow ZnSe spacer layers, will be shown to be particularly suitable for the observation of the optical Aharonov-Bohm effect. This is illustrated by the presence of strong Aharonov-Bohm oscillations in the photoluminescence intensity. Finally, although the (ZnMn)Te system is known to be paramagnetic, at low temperatures the QD structures described display evidence of spontaneous magnetization at zero applied magnetic field both in the optical circular polarization degree and the magnetization. The origin of this behavior will be discussed.

10:48AM P28.00015 Robust Aharonov-Bohm oscillations at elevated temperatures in type-II ZnTe/ZnSe quantum dots, V.R. WHITESIDE, I.R. SELLERS, University at Buffalo, I.L. KUSKOVSKY, Queens College CUNY, A.O. GOVOROV, Ohio University, B.D. MCCOMBE, University at Buffalo — The ZnTe/ZnSe material system is remarkable in that it is possible to study both Te-bound isoelectronic excitons and type-II ZnTe quantum dots (QDs) in the same sample. This is possible since with increasing tellurium deposition there is a clustering of the Te-atoms resulting in an evolution of Te isoelectronic centers, formed by Te-Se substitution, into ZnTe QD structures. The formation of columns of such QDs in multilayer superlattice structures has recently been shown to be particularly suitable for the observation of the optical Aharonov-Bohm effect. Here we present magneto-photo luminescence from such type-II ZnTe/ZnSe QDs that demonstrate large and persistent oscillations in both the exciton energy and intensity at high temperature indicating the formation of coherently rotating states. Furthermore, this high temperature Aharonov-Bohm effect is remarkably robust persisting until 180K despite significant quenching of the luminescence due to ionization of the type-II excitons.

Wednesday, March 12, 2008 8:00AM - 10:48AM — Session P29 DMP: Focus Session: Carbon Nanotubes and Related Materials IX: Graphene Electronic Structure Morial Convention Center 221
8:00AM P29.00001 Veselago lens and p-n junctions in graphene.1, VLADIMIR FALKO, Lancaster University — Both monolayer and bilayer graphene are gapless semiconductors. Their electrostatic modulation can be used to generate single and multiple p-n junctions. We have shown [V. Cheianov and V.I. Fal’ko - Phys. Rev. Lett. 97, 226801 (2006)] that p-n junctions in monolayer graphene are transparent for incident electrons. In particular, those electrons approaching the n-p interface in an almost perpendicular direction can cross it without reflection. Moreover, in graphene the transmission of charge through the n-p interface is quite similar to the refraction of electromagnetic waves at the interface where the refractive index inverts sign [J. Pendry - Nature 423, 22 (2003); J. Pendry - Phys. Rev. Lett. 85, 3966 (2000)]. This is because the electron dispersion in the conduction and valence bands in graphene is such that so that, after an electron crosses the n-p interface, from the n- to p-side, its wave vector becomes directed opposite to its velocity. As a result, n-p junctions in graphene possess intriguing and very promising transport properties: a single straight p-n interface can focus electrons [V. Cheianov, V.I. Fal’ko, B.L. Altshuler - Science 315, 1252 (2007)]. This situation is realised in the n-p junction with equal densities of carriers in the n- and p-regions. Also, we have shown that by varying the carrier density in, e.g., p-side of the junction the focus can be smeared into a pair of caustics meeting each other in a cusp, and calculated the characteristic interference pattern of electron waves in the vicinity of the cusp. Using the idea of fine-tuned focusing of electron flow by the p-n interface, we propose to use n-p-n junctions in a bipolar graphene-based transistor to create Veselago lens and focused beam splitters for electrons.

8:36AM P29.00002 Intradband Landau level transitions in monolayer graphene, ZHIGANG JIANG, Columbia University/NHMFL, E.A. HENRIKSEN, Columbia University, L.C. TUNG, NHMFL, M.E. SCHWARTZ, M. TAKITA, Columbia University, Y.-J. WANG, NHMFL, P. KIM, Columbia University, H.L. STORMER, Columbia University/Bell Labs — We study the cyclotron resonance of electrons and holes in monolayer graphene, via infrared transmission measurements in a magnetic field, $B$, up to 18 T. We find that, instead of having a single resonance energy as in a traditional two-dimensional system, a wide range of transitions between different sets of Landau levels (LLs) can be uniquely distinguished in monolayer graphene. We have observed intraband transitions between neighboring LLs up to $n = 7$, where $n$ is the LL index. As expected from the unusual linear dispersion of the low-energy electronic band of monolayer graphene, we show that the corresponding energies of all observed LL transitions are proportional to $\sqrt{B}$. In addition, beyond such a simple linear dispersion, we find that the measured band bending near the charge-neutral Dirac point ($E = 0$) is $\sim 12\%$ larger than that at higher energies. The LL transitions in the electron and hole bands of monolayer graphene show a considerable asymmetric behavior.

9:48AM P29.00003 High Field Magnetoresistance of Graphene at the Dirac Point1, JOSEPH CHECKELSKY, LU LI, N. P. ONG, Princeton University — The longitudinal and Hall resistance of graphene near the charge neutral point have been studied down to low temperature (20 mK) in high magnetic field (20 T). At issue is the nature of the ground state in the vicinity of the Dirac point in high magnetic fields. In samples in which the off-set voltage is small, we observe a highly unusual approach to an insulating state as the field increases. In samples with $\mu > 0.5$ T$^{-1}$ and $V_0 < 3$ V, the resistance at the Dirac point $R_0$ increases divergently to $M$ in fields of 14-20 T at temperatures $T < 2$ K. This divergent behavior is suppressed in samples with large $V_0$. Surprisingly, this rise shows little temperature dependence below 2 K. The acute dependence on magnetic field and accompanying lack of activated behavior with temperature provides evidence for an unusual cross-over or transition to the insulating state. Implications for theoretical models including gapless edge modes and Quantum Hall Ferromagnetism will be discussed in the context of these results.

9:00AM P29.00004 Effect of disorder on transport in a graphene p-n junction1, B. I. SHKLOVSKI, UMN, M. M. FOGLER, UCSD, L. I. GLAZMAN, D. S. NOVIKOV, Yale — We evaluate the resistance of a gate-tunable graphene p-n junction, in which the gradient of the carrier density is controlled by the gate voltage. Depending on this gradient and on the density of charged impurities, the junction resistance is suppressed in samples with large $V_0$, $\mu < 0$. For $V_0 > 0$, the resistance at the Dirac point $R_0$ increases divergently to $M$ in fields of 14-20 T at temperatures $T < 2$ K. This divergent behavior is suppressed in samples with large $V_0$. Surprisingly, this rise shows little temperature dependence below 2 K. The acute dependence on magnetic field and accompanying lack of activated behavior with temperature provides evidence for an unusual cross-over or transition to the insulating state. Implications for theoretical models including gapless edge modes and Quantum Hall Ferromagnetism will be discussed in the context of these results.

9:12AM P29.00005 Nonlinear screening and ballistic transport in a graphene p-n junction1, L. MATTHEW ZHANG, M. M. FOGLER, UCSD — Our theoretical work is devoted to a new class of graphene devices: lateral p-n junctions. Such structures have been recently realized experimentally by modulating the electron density in graphene samples with external gates. We study the charge density distribution, the electric field profile, and the resistance of such p-n junctions. We show that the proper treatment of the electrostatic screening, including nonlinear effects, is crucial for obtaining the correct results for all these quantities. In particular, we show that the total electric field at the interface of the electron and hole regions is strongly enhanced due to limited screening capacity of Dirac quasiparticles. Accordingly, the junction resistance is significantly lower than estimated in previous theoretical literature. At the same time, our new theory enables us to achieve a closer agreement with the recent experiments.

9:24AM P29.00006 Quantum Critical Scaling of Graphene1, DANIEL E. SHEEHY, Louisiana State University, JOERG SCHMALIAN, Ames Lab and Iowa State University — We show that the emergent relativistic symmetry of electrons in graphene near its quantum critical point (QCP) implies a crucial importance of the Coulomb interaction. We derive scaling laws, valid near the QCP, that dictate the nontrivial magnetic and charge response of interacting graphene. Our analysis yields numerous predictions for how the Coulomb interaction will be manifested in experimental observables such as the diamagnetic response and electronic compressibility.

9:36AM P29.00007 Atomic Collapse and Quasi-Rydberg States in Graphene1, ANDREY SHYTTOV, Brookhaven National Laboratory, LEONID LEVITOV, MIT, MIKHAIL KATSNELSON, Radboud University of Nijmegen — We demonstrate that graphene opens a way to investigate in the laboratory a fundamental quantum relativistic phenomenon, that is, atomic collapse in a strong Coulomb electric field, long-sought for, but still inaccessible in high-energy experiments. We consider charged impurities in graphene and show that an impurity can host an infinite family of Rydberg-like resonance states of massless Dirac particles. Strong coupling of these states to the Dirac continuum via Klein tunneling leads to striking resonance effects with direct signatures in transport and local properties.

1 preprint Arxiv.org:0708.0837
Institute — The dielectric storage (\(\epsilon\) and Conductivity of Multi-Wall Carbon Nanotubes), RAJRATAN BASU, GERMANO IANNACCHIONE, Worcester Polytechnic Center 222.

E conductivity analysis of MWCNT reveals possible mechanisms for how relaxation process (mode-2) is also observed that is independent of 10 branches is fixed by the topological vacuum charge of the insulating BLG state. We discuss how these chiral states can manifest experimentally, and emphasize conventional solitonic zero-modes, their properties are defined by the unusual chiral BLG quasiparticles, from which they derive. The number of zero-mode confinement. These states appear on the domain walls separating insulating regions experiencing the opposite gating polarity. While the states are similar to the measurement). A slow relaxation process (mode-1) is observed that increases in peak frequency with increasing \(E\) but is independent of \(\epsilon\) rot (in-phase and same frequency as the measurement) and \(\epsilon\) rot and shifts to higher frequency with increasing \(E\). A fast downshifts for the G mode and D mode respectively, the softening rate (\(\Delta\omega/\omega\)) is about 1% for both. This behavior is explained by the weakening of carbon-carbon bonds due to elongation, and is consistent with previous studies on carbon nanotubes.

10:12AM P29.00010 Structural and Electronic Properties of Bilayer Epitaxial Graphene, GREGORY M. RUTTER, PHILLIP N. FIRST, Georgia Institute of Technology, Atlanta, GA, JASON N. CRAPIN, JOSEPH A. STROSCIO. Center for Nanoscience and Technology, NIST, Gaithersburg, MD — Scanning tunneling microscopy (STM) and spectroscopy (STS) are used to study the structural and electronic properties of epitaxial graphene on SiC(0001) [1]. We address in this talk the surface morphology and stacking sequence of bilayer graphene. STM topographic images show that in the initial stages of growth, the surface morphology of graphene conforms to an underlying SiC interface reconstruction [1]. In bilayer epitaxial graphene, the top graphene layer forms a continuous sheet across steps separating adjoining terraces. A change in the apparent height between the two graphene basis atoms is observed as a function of tunneling bias. We model the relative heights based on a simple form for the local density of states in AB layer stacking (Bernal, as typical for bulk graphite) [2], and predict a smooth transition from imaging a single sublattice to imaging both sublattices. The experimentally-observed transition is consistent with Bernal stacking of the epitaxial bilayer, and an interlayer hopping energy of 0.4 eV. This work was supported in part by NSF grant ECS-0404084 and Dept. of Commerce/NIST grant 60ANABD6166. [1] G. M. Rutter et al., Science 317, 219 (2007); arXiv:0711.2523. [2] Z. F. Wang et al., Phys. Rev. B 75, 085424 (2007).

10:24AM P29.00011 Aharonov-Bohm effect and broken valley-degeneracy in graphene rings, PATRIK RECHER, U. Leiden, BJØRN TRAUZETTEL, U. Wuerzburg, ADAM RYCEK, U. Jagiellonian, YAROSLAV BLANTER, TU Delft, CARLO BEENAKKER, U. Leiden, ALBERTO MORPURGO, TU Delft — We analyze theoretically the electronic properties of Aharonov-Bohm rings made of graphene. We show that the combined effect of the ring confinement and applied magnetic flux offers a controllable way to lift the orbital degeneracy originating from the two valleys, even in the absence of intervalley scattering. The phenomenon has observable consequences on the persistent current circulating around the closed graphene ring, as well as on the ring conductance. We explicitly confirm this prediction analytically for a circular ring with a smooth boundary modelled by a space-dependent mass term in the Dirac equation. This model describes rings with zero or weak intervalley scattering so that the valley isospin is a good quantum number. The tunable breaking of the valley degeneracy by the flux allows for the controlled manipulation of valley isospins. We compare our analytical model to another type of ring with strong intervalley scattering. For the latter case, we study a ring of polygonal form with lattice-terminated zigzag edges numerically. We find for the hexagonal ring that the orbital degeneracy can still be controlled via the flux, similar to the ring with the mass confinement.

10:36AM P29.00012 Topological configuration in bilayer graphene, IVAR MARTIN, LANL, YAROSLAV BLANTER, ALBERTO MORPURGO, Delft — We study a new type of one-dimensional chiral states that can be created in bilayer graphene (BLG) by electrostatic lateral confinement. These states appear on the domain walls separating insulating regions experiencing the opposite gating polarity. While the states are similar to conventional solitonic zero-modes, their properties are defined by the unusual chiral BLG quasiparticles, from which they derive. The number of zero-mode branches is fixed by the topological vacuum charge of the insulating BLG state. We discuss how these chiral states can manifest experimentally, and emphasize their relevance for valleytronics.

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P30 DCMP: Electronic Properties of Graphene and Related Structures III Morial Convention Center 222

8:00AM P30.00001 Electric Field and Frequency Dependence of the Dielectric Storage, Loss, and Conductivity of Multi-Wall Carbon Nanotubes, RAJRATAN BASU, GERMANO IANNACCHIONE, Worcester Polytechnic Institute — The dielectric storage (\(\epsilon\)') and loss (\(\epsilon\)'') of the complex dielectric constant (\(\epsilon\)) are reported for multi-wall carbon nanotubes (MWCNT) up to 10^12 Hz as a function of ac-field amplitude E_{rod} (in-phase and same frequency as the measurement) and E_{ac} (fixed phase and frequency with respect to the measurement). A slow relaxation process (mode-1) is observed that increases in peak frequency with increasing E_{rod} but is independent of E_{ac}. A fast relaxation process (mode-2) is also observed that is independent of E_{rod} and shifts to higher frequency with increasing E_{ac} (opposite to that seen for mode-1). A conductivity analysis of MWCNT reveals possible mechanisms for how E_{rod} and E_{ac} can effect the dielectric dissipation differently.

8:12AM P30.00002 The genus g=2 problem- A solution of the Persistent current for the genus g=2 -An application to the Edge currents in Graphene, DAVID SCHMELTZER, CCNY — We report the first solution of Persistent currents for genus g = 2 Aharonov-Bohm coupled rings which form a character “8” structure. For two large coupled rings with equal fluxes, we found that the persistent current in the two coupled rings is equal to that in a single ring. For opposite fluxes the energy has a chaotic structure. This results are obtained within an extension of Dirac’s second class constraints.

1 Collaborative grant CUNY 2007-2008
8:24AM P30.00003 Potential barriers in graphene1, NIMROD STANDER, DAVID GOLDBERGER-GORDON, BENJAMIN HUARD, JOEY SULPIZIO, KATHRYN TODD, BO YANG, Stanford University — Graphene is a single sheet of graphite. Some of its remarkable electronic properties have been predicted over the past 6 decades, but only recently, the Geim group at Manchester succeeded in fabricating graphene and measuring the Quantum Hall effect. These measurements agreed with earlier predictions by observing plateaus at half-integer values and triggered an immense theoretical and experimental effort. It was also predicted that the tunneling through a potential step in graphene is highly anisotropic, and occurs with probability 1 at normal incidence, due to the chiral nature of its quasiparticles. This behavior can be investigated in different potential configurations, such as pn junctions or npm barriers in graphene. In this talk, I will present our experimental work on electronic transport through a tunable potential barrier in top gated graphene devices. I will show that the experiments we have done, depend on the disorder and on the profile of the potential rise across the graphene sheet. Therefore, they can also be seen as a tool to investigate scattering and screening properties in graphene.

8:36AM P30.00004 Effects on the electron conductivity emerging from Majorana zero modes, MIKLOS GULASCI, PASQUALE SODANO, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — The link between single particle random Hamiltonians and non-linear sigma models (NLSM) comes about when setting up a generating function for the mean value taken by the product of Green’s functions. Using the standard machinery of the replica trick we derived disorder averaged product of the retarded and advanced Green’s functions from an effective NLSM describing low energy physics of graphene films with both disorder and defects. We then compute the electron transport properties and we find remarkable effects arising when the defect topology is such that the Majorana fields acquire zero modes.

8:48AM P30.00005 BEC and Superfluidity of Magnetoexcitons in Graphene, OLEG BERMAM, NYC College of Technology of CUNY, GODFREY GUMBS, Hunter College of CUNY — We propose the experimental observation of Bose-Einstein condensation (BEC) and superfluidity of quasi-magnetoexcitons in bilayer graphene. Electrons are in one layer and holes in another which are controlled by an applied gate voltage. We describe the dilute gas of magnetoexcitons with dipole-dipole repulsion in a strong magnetic field $B$ by a $4 \times 4$ matrix Hamiltonian. This Hamiltonian is mapped on to a scalar effective mass Hamiltonian for a dilute gas of dipolar excitons without an applied magnetic field. However, the magnetic field enters through a $B$-dependent effective mass for magnetoexcitons. Moreover, for $N$ excitons, we reduced the problem in a space with $2N \times 2$ dimensions into one with $N \times 2$ dimensions. This is accomplished by integrating over the coordinates of the relative motion of electron and hole. We will present the energy spectrum of collective excitations, the sound spectrum as well as the effective magnetic mass of magnetoexcitons in the strong magnetic field limit. The superfluid density $n_s$ and the temperature of the Kosterlitz-Thouless phase transition $T_c$ are shown to be increasing functions of the excitonic density $n$ and decreasing functions of $B$ and the interlayer separation $d$.

9:00AM P30.00006 Fractionalization in a square-lattice model with time-reversal symmetry1, MARCEL FRANZ, CONAN WEEKS, BABAK SERADJEH, University of British Columbia — We propose a two-dimensional time-reversal invariant system of essentially non-interacting electrons on a square lattice that exhibits configurations with fractional charges ±e/2. These are vortex-like topological defects in the dimerization order parameter describing spatial modulation in the electron hopping amplitudes. Charge fractionalization occurs via a mechanism similar to that in graphene with the “Kekule” distortion and is established by a simple electron counting argument, analytical calculation within the effective low-energy theory, and by an exact numerical diagonalization of the lattice Hamiltonian.

9:12AM P30.00007 Dirac Fermions in a Magnetic Forest1, ANDRES CONCHA, Johns Hopkins University — Recent experimental progress have made it possible to study of a single layer of carbon atoms, i.e. graphene. This newly synthesized material seems to be a promising candidate for building up nano-devices as well as a useful experimental tool to study exotic properties of its low energy excitations. In this work we consider the effect of a vortex lattice in the adjacent superconductor on the transport properties of a graphene sheet. We show that the transport properties of graphene sheets of various geometries can be substantially altered and manipulated by changing the vortex lattice structure and the amount of magnetic flux. A relatively straightforward experimental test of our results is suggested.

9:24AM P30.00008 Phonon-induced many-body renormalization of graphene electronic properties1, WANG-KONG TSE, SANKAR DAS SARMA, University of Maryland — In this talk, we present a many-body theory for the electron-phonon interaction effects on the electronic properties of graphene. We provide analytical results for the electron self-energy, spectral function, and band velocity renormalization due to phonon-mediated electron-electron interaction, showing that phonon-mediated electron-electron coupling has a large effect on the graphene band structure renormalization. Our analytic theory successfully captures the essential features of the observed graphene electron spectra in the angle-resolved photoemission spectroscopy (ARPES) experiments, predicting a kink at $\sim 200$meV below the Fermi level and a reduction of the band velocity by $\sim 10$ – $20\%$ at the experimental doping level.

9:36AM P30.00009 The effect of electronic correlations on Josephson current and proximity effect in SNS graphene junctions, ANNICA BLACK-SCHAFFER, SEBASTIAN DONIACH, Stanford University — Using the self-consistent tight-binding Bogoliubov-de Gennes (BdG) formalism, we investigate the proximity effect and current-phase relationship in SNS graphene Josephson junctions. Both short and long junctions are considered, as well as different doping levels of the graphene. For short junctions at zero doping in the uncorrelated regime our results agree with those found using the non self-consistent Dirac-BdG formalism [1]. We introduce electronic correlations in the Hamiltonian by including the intrinsic nearest-neighbor spin-singlet coupling present in $sp$-bonded planar organic molecules. We study the possibility of coupling this intrinsic $s$- or $d$-wave superconducting pairing [2] to the extrinsic $s$-wave order parameter induced by the metal electrodes. The intrinsic $d$-wave solution, favored in doped graphene, appears for longer doped junctions. For short junctions, the $s$-wave solution can occur, although the result is sensitive to the type of interface. We also report on the two different intrinsic superconducting states’ influence on the supercurrent.

1Supported in part by NSF Grant DMR-0531159

2This work is supported by U.S. ONR.
Density is much weaker in these materials than in conventional porous materials. Our simulations show that this scaling occurs because the nanoscale structure can be used to make porous silica with mechanical properties that remain favorable as the porosity increases. In particular, the elastic modulus scaling with...
8:48AM P31.00003 Phase-field simulations of martensite-martensite nanocomposites 1, MATHIEU BOUVILLE, RAJEEV AHLUWALIA, Institute of Materials Research and Engineering — We study composites made of two martensite-forming materials, with different transition temperatures, $T_1 < T_2$. The system remains austenitic at high temperature, and if the temperature is very low then the difference between the two materials is negligible. We therefore focus on intermediate temperatures, i.e. $T_1 < T < T_2$. Then only one material can transform to martensite — the other transformation may occur only if it is triggered by the martensite already formed (volume changes will then play a key role). We study the effect of reducing the size of the system, in particular how martensite can form in nanocomposites at temperatures at which no martensitic transformation can exist at the macroscopic scale. This work has relevance to multiferroics, where the phase transformation in one material (e.g. ferroelectric) triggers a transformation in another material, for instance magnetostrictive.

9:00AM P31.00004 The dynamical activation-relaxation technique (DART): an on-the-fly kinematic Monte-Carlo algorithm 1, FADWA EL-MELLOUHI, MICHEL COTE, LAURENT J. LEWIS, NORMAND MOUSSEAU, Dep. de physique et RQMP, Univ. de Montreal, Quebec, Canada — We present DART, the dynamical activation-relaxation technique, that combines the activation-relaxation technique (ART) with a non-lattice KMC method that allows the on-the-fly identification of barriers and the full treatment of lattice deformations. Most KMC schemes rely on the use of a fixed list of events and barriers, which are drawn with the proper weight during the simulation. While this works well for a number of problems (such as metal-on-metal growth), it cannot be used for processes where the events may change with time. DART overcomes this limitation. ART nouveau has been used extensively for the study of activated mechanisms in different materials within both an empirical and an ab-initio description of the systems. In the DART implementation, KMC moves are based on a catalog of events constructed on-the-fly using ART. After each KMC move, this catalog is updated so as to take into account new environments that may appear. A topological description of the structure of the system at each moment allows the method to identify rapidly these new environments and to move forward efficiently. In this talk, we will describe the method and present the case of interstitial diffusion in Si. Our results are compared with previous molecular-dynamics and on-lattice KMC simulations.

9:12AM P31.00005 Charge patching method for the calculation of electronic structure of organic semiconductors 1, NENAD VUKMIROVIC, LIN-WANG WANG, Lawrence Berkeley National Laboratory — The electronic structure of organic semiconducting conjugated polymers and molecular crystals is essential in determining their optical and transport properties. Such organic semiconductor systems have potential applications for solar cells, field-effect transistors and luminescent devices. However, for such systems containing a large number of atoms, the direct calculations based on density functional theory (DFT) are often not feasible. Here we present the development of the charge patching method for the calculations of organic systems, a method which was previously successful in treating inorganic semiconductor materials [1]. The results of the calculations for alkane and alkene chains using this approach yield the difference in Kohn-Sham wavefunction eigenenergies of the order of only 30 meV compared with direct DFT calculations. Further investigations involving aromatic compounds, as well as elements such as sulfur, nitrogen, and oxygen, will be presented. [1] L.W. Wang, Phys. Rev. Lett. 88, 256402 (2002).

9:24AM P31.00006 Real-space grid representation of momentum and kinetic energy operators for electronic structure calculations 1, DOMENICO NINNO, GIOVANNI CANTELE, FABIO TRANI, Università di Napoli Federico II, Dip. di Scienza Fisiche, Via Cintia, I-80126, Napoli — The development of computational methods based on real-space grids is contributing to the advances and understanding of nanoscale materials. Real-space grids methods, particularly within the pseudopotential density functional theory, have the advantage of producing highly structured matrices paving the way towards grid-based O(N) methods for both DFT total energy and molecular dynamics calculations. However, a limitation seems to be the lack of a basis set putting these approaches on a different ground with respect to standard methods. We prove that this limitation is only apparent showing that the position operator eigenkets are the natural basis set for the finite difference representation of momentum and kinetic energy operators. Some conceptual points and unpublished results related to the connection between the discrete and the continuum representations will be discussed.

9:36AM P31.00007 Single molecular NDR: A first principles study 1, RANJIT PATI, Department of Physics, Michigan Technological University, Houghton, MI 49931 — The demonstration of single molecule switch with a negative differential resistance (NDR) feature has drawn considerable attention in recent years. The NDR feature is described by a steady increase followed by a decrease in current with the increase in applied bias. Here we report a single molecular NDR in a strongly coupled metal-molecule junction, with peak to valley ratio (PVR) of 2.7 at both positive and negative bias. The bias dependent screening effect is explicitly included in our calculation through a rigorous self-consistent many body approach. The non equilibrium Green function approach is used to calculate the quantum transport. The origin of high PVR will be discussed.

9:48AM P31.00008 Electron correlations in molecular wires: e-e interactionion both in leads and bridge 1, YURI DHANOVSKY, Department of Physics & Astronomy, University of Wyoming, Laramie, WY 82071, VINCE ORTIZ, Department of Chemistry & Biochemistry, Auburn University, Auburn — Molecular systems (molecules) with strong electron-electron interaction both in leads and a bridge are described in terms of the time-dependent electron Green functions. We prove that the Meir-Wingreen expression holds if one assumes that the bridge and lead electron subsystems are strongly separated. We develop a diagrammatic technique in a well determined, noncrossing cluster approximation. Within this approach, Dyson equations for various nonequilibrium Green functions are derived, and the validity conditions are found. In addition, we rigorously prove that despite strong electron-electron or electron-vibration interaction in the systems with the finite number of quantum states, the Landauer-Buttiker expression for electric current is true. The ab initio electron propagator method is applied to the calculations of I-V characteristics in molecular electronic devices with the bridge composed from 1,4-benzene–dithiolate molecule.

10:00AM P31.00009 Characterizing Capture-Zone Distributions: Generalized Wigner vs. Alternative Forms, and Experimental Fits\textsuperscript{1}, T.L. EINSTEIN, ALBERTO PIMPINELLI\textsuperscript{2}, U. of Maryland, College Park — In problems of growth of islands or of dots, it is often advantageous to consider the distribution of the areas of proximity (Voronoi) cells of nucleation sites, i.e. the capture zones (CZ). Extending results for terrace-width distributions on vicinal surfaces\textsuperscript{3} we have shown that the (non-equilibrium, steady-state) CZ distribution is well described by the generalized Wigner expression \( P_b(s) = a^b \exp(-bs^2) \) [with \( a \) and \( b \) being constants assuring normalization and unit mean, and \( s \) here the CZ area divided by its mean], which accounts for a strikingly broad range of fluctuation phenomena. For CZ distributions we find that the single adjustable parameter \( g = (2/d)(i + 1) \), where \( i \) is the size of the critical nucleus and \( d \) (= 1 or 2) the spatial dimensionality\textsuperscript{4}. We emphasize comparisons with other fitting expressions (esp. gamma functions), new applications to experimental data, and the generality of \( P_b(s) \).

10:12AM P31.00010 Molecular simulations of capillary adhesion\textsuperscript{1}, SHENGFENG CHENG, MARK ROBBINS, Johns Hopkins University — Adhesion due to capillary condensation is ubiquitous in nature, and dominates the adhesion force between particles in many experiments. Traditional models are based on continuum theory and may not describe nanoscale capillaries in microelectromechanical systems (MEMs) or at an atomic force microscope (AFM) tip. We employ molecular dynamics simulations to investigate the capillary adhesion between a nominally spherical tip and a flat substrate with a liquid bridge of fixed volume. The atomic scale roughness on the tip, contact angle and volume are varied. The adhesive force-distance curve and the separate contributions from Laplace pressure and surface tension are compared to continuum theory using independently measured parameters. Continuum theory provides a good description down to separations of a few molecular diameters. Atomic scale roughness affects the contact angle that enters the continuum theory and alters the adhesive force.

10:36AM P31.00012 An algebraic approach to computer program design and memory management\textsuperscript{1}, JAMES RAYNOLDS, University at Albany, State University of New York, LENORE MULLIN, National Science Foundation — Beginning with an algebra of multi-dimensional arrays and following a set of reduction rules embodying a calculus of array indices, we translate (in a mechanizable way) from the high-level mathematics of any array-based problem and a machine specification to a mathematically-optimized implementation. Raynolds and Mullin introduced the name Conformal Computing\textsuperscript{2} to describe this process that will be discussed in the context of data transforms such as the Fast Fourier, Wavelet Transforms and QR decomposition. We discuss the discovery that the access patterns of the Wavelet Transform form a sufficiently regular subset of those for our cache-optimized FFT so that we can be assured of achieving similar efficiency improvements to the Wavelet Transform as those that were found for the FFT. We present recent results in which careful attention to reproducible computational experiments in a dedicated/non-shared environment is demonstrated to be essential in order to optimally measure the response of the system (in this case the computer itself is the object of study) so as to be able to optimally tune the algorithm to the numerous cost functions associated with all of the elements of the memory/disk/network hierarchy. * The name Conformal Computing is protected: © 2003, The Research Foundation, State University of New York.

10:48AM P31.00013 Giant Hall Effect in Laterally Inhomogeneous 2D Electron Gas\textsuperscript{1}, HANG XIE, PING SHENG, Department of Physics, Hong Kong University of Science and Technology — Giant Hall effect has been observed in non-magnetic granular metals at concentration close to the quantum percolation threshold [1], attributable to quantum interference effect. In this work we numerically simulate the Hall effect for 2D electron gas in a laterally inhomogeneous structure. At scales smaller than the electron dephasing length, we obtain the Hall coefficient of 2DEG by solving Schrodinger’s equation, with 4 leads connected to the sample. It is shown that for special (laterally) nano-scaled structures, the Hall coefficient can be enhanced by at least 3 orders of magnitude. We have also simulated the effect of assembling such structures into a macroscopic sample, by solving the Laplace equation.

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P32 GMAG FIAP: Focus Session: Magnetic Media and Hard Magnetic Materials Morial Convention Center 225
8:00AM P32.00001 Magnetism of FePt nanoparticles and nanodot arrays.1 HAO ZENG, University at Buffalo-SUNY — L10 structured FePt materials show great potential for magnetic data storage media applications.1 The first part of this talk concerns the magnetism in chemically synthesized FePt nanoparticles. Discrete FePt nanoparticles with L10 structure have recently been realized by salt annealing, making it possible to study their size dependent magnetic properties.2 We have discovered a strong reduction of magnetization with decreasing FePt particle size and an unusual temperature dependent magnetization that deviates from the Bloch’s T²/² law at low temperatures. A model based on competing exchange interactions is proposed to explain this unusual behavior, considering explicitly the nanoparticle shape. FePt system has complicated exchange interactions, with interaction in the (100) plane being strongly ferromagnetic and inter-plane much weaker. The ferromagnetic and antiferromagnetic exchange interactions contribute differently at the nanoparticle surface and interior, leading to reduced ferromagnetic order at the surface terminated by facets. The model correctly explains the magnetization reduction with decreasing particle size, a surface paramagnetic phase as evidenced by Mossbauer spectroscopy and the unusual temperature dependent magnetization behavior. The second part of this talk will report our recent efforts in developing ordered FePt nanodot arrays using self-assembled porous templates as evaporation masks. The arrays possess perpendicular anisotropy, large coercivity and extremely high density, all of which are desirable features for future data storage media.

8:36AM P32.00002 Permanent-Magnetic Fe-Pt Nanoparticles1 RALPH SKOMSKI, D.J. SELLMYER, Department of Physics and Astronomy and NCMN, University of Nebraska — Recently, it has become possible to produce magnetically stable small-scale single-phase [1] and hard-soft [2] Fe-Pt nanoparticles with potential applications in permanent magnetism. The coercivity is largely determined by the degree of L10 ordering and the presence of the soft phase, respectively, and affected by surface anisotropy. We model the coercivity of the particles as a function of composition, structure, and particle diameter. The smallest particles reverse coherently, with renormalized anisotropy constants, but with increasing size, micromagnetic correlations become important. The reversal modes in the two-phase particles are reminiscent of p-state wave functions in atomic physics [2] and well described by second-order perturbation theory. We also discuss extensions involving semihard phases, which may be created by substitutions or coatings using heavy transition metals, such as Pt and W. One example is hexagonal Co1−xPtx, which exhibits a huge anisotropy per Pt atom and a substantial net anisotropy. - [1] C. B. Rong et al., Adv. Mater. 18, 2984 (2006). - [2] J. E. Shield et al., JAP 99, 08BS08 (2006). - [3] R. Skomski, Simple Models of Magnetism, University Press, Oxford 2008.

8:48AM P32.00003 FePt Nano-particles and Nano-wires1 LEVENT COLAK, GEORGE HADJIPANAYIS, UNIVERSITY OF DELAWARE TEAM — In this work, we have studied the microstructure and magnetic properties of FePt nano-particles, nano-rods, and nano-wires synthesized by modified chemical synthesis route described elsewhere[1,2]. The effect of synthesis parameters on the particle shape has been investigated for nanoparticles with sizes of 5-7 nm, for nano-rods and nano-wires with a diameter of 2-3 nm and a length of 20 and 100 nm, respectively. Low injection temperature for the iron precursor and usage of surfactants as reaction solvents resulted in 7 nm nano-cubes whereas a high heating rate to refluxing temperature and high injection temperature resulted in spherical shapes with 5 nm diameter. Nano-rods and nano-wires are formed by simply adjusting the relative ratios of surfactants to reaction solvents (oleic acid, oleyl amine and octadecene/benzylether) and the refluxing time. Transmission electron microscope (TEM) studies show that usage of high concentrations of oleyl amine and longer refluxing times induce nano-wire formation. HRTEM and magnetometry studies are currently in progress to investigate the development of morphology and microstructure during the synthesis and determine their influence on the magnetic properties. 1. C. Wang et. al. Angew. Chem. Int. Ed. 2007, 46,1-4. 2. M. Chen et. al. J. Am. Chem. Soc. 2007, 129, 6348-6349.

9:00AM P32.00004 Nanostructure and Magnetic Properties L10 FePt Films with Additions of Au and Cu. T. GEORGE, M. YAN, Y. XU, R. SKOMSKI, R. KIRBY, D. J. SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska — Non-epitaxially grown L10 FePt/Au and FePt/Cu films have been fabricated and investigated. All films are initially deposited with the structure [FePt]/[Au] and have individual layer thicknesses from about 0.1 nm to 1 nm. The L10 phase is achieved by post-deposition annealing at temperatures from 500 to 600 °C for varying times. XRD and TEM show that Cu enters the L10 lattice whereas Au segregates at the grain boundaries. Both types of films exhibit a decrease in M_s due to magnetic dilution. The coercivity (H_c) increases and decreases with the addition of Au and Cu, respectively. These changes are due to reduced anisotropy (Cu) and to reduced inter-granular exchange coupling (Au). In the FePtAu films, MFM shows a decrease in magnetic coherence length (L_M) from 90 to 74 nm and the M – H slope α = (dM/dH)_{sat} decreases from 5.7 to 0.9 for Au contents from zero to 32 vol%. A simple interaction model quantifies these trends by considering that intergranular exchange cooperatively enhances both α and L_M. In the FePtCu films, the addition of Cu yields a decrease in Curie temperature (574 K at 20 vol%). - Work supported by NSF DMR 0302544.

9:12AM P32.00005 Electric field assisted magnetization reversal in FePt films. PAVEL LUKASHEV, University of Nebraska, Omaha, KIRILL BELASHCHENKO, University of Nebraska, Lincoln, RENAT SABIRIANOV, University of Nebraska, Omaha — We propose to use strain assisted reduction in anisotropy of FePt in order to make magnetization reversal easier in the writing of the magnetic storage devices. We performed first-principles calculations of the magnetocrystalline anisotropy of FePt under bi-axial stress using full-potential LAPW implemented in FLEUR code. Magnetocrystalline anisotropy decreases by 25% with application of 1.5% tensile biaxial strain. This is partially due to the reduction of the c/a ratio by about 1.5% (calculated Poisson ratio is 0.33) in the tetragonal cell and partially due to the increase in volume by about 1.5%. Biaxial strain can be obtained by placing piezoelectric film under FePt layer, and by applying electric field on the system. Modern ferroelectric systems can provide stress up to 2%. Besides, we propose using thin ferroelectric films with asymmetric interfaces, which provides a simple way to generate bias field in the polarization reversal and related properties. The existence of the polar interfaces results in a different average polarization in the film upon reversal. As a result, the strain in the film depends on the direction of polarization. This asymmetric strain can be used do modulate magnetic properties.

9:24AM P32.00006 Influence of interfacial non-magnetic materials on soft-hard bilayer interaction. A. ZAMBAHO, H. OGUCHI, J. TAKEUCHI, Univ.of Maryland, S. LOFLAND, Rowan Univ., J. LIU, Univ.of Texas, D. JOSELL, L. BENDERSKY, NIST, Y. LIU, Z. WANG, Georgia Tech — Among the factors that affect this behavior and how the interface nonmagnetic material can significantly alter the nature of the interaction. Such behavior can have a pronounced effect on hard-soft bulk nanocomposite magnets. ONR MURI N00014-05-1-0497.

9:36AM P32.00007 Depth dependence of anisotropy in graded Co/Pd multilayers, S.M. WATSON, J.E. DAVIES, NIST, K. LIU, UC-Davis, G.T. ZIMANYI, B.J. KIRBY, J.A. BORCHERS, NIST — As the magnetic recording industry looks beyond perpendicular recording [1] multilayered media such as exchange coupled composite [2] and graded media [3] have the potential for increasing storage density by combining low and high anisotropy materials. The soft layer reduces the required write field while the hard layer helps to maintain the thermal stability. Recent work has shown further enhancements when the anisotropy is gradually increased up to the hard layer anisotropy [3]. Grading the media in this manner is difficult to do experimentally. Equally difficult is accurately measuring the properties that make these materials unique, namely the depth dependence of the anisotropy. In this study we used polarized neutron reflectometry to measure the in-plane magnetization depth profile of graded Co/Pd multilayers with perpendicular-to-plane easy axis as a function of in-plane applied field. This technique allowed us to observe the depth-dependent response of the spins as they were pulled away from their easy axis, thus allowing us to determine the depth dependence of the anisotropy field. 9:48AM P32.00008 Fast Reversal in Multilayer Exchange Spring Media, D. SUESS, Vienna University of Technology — Hard disk media that support ultra high densities require small grains in order to obtain high signal to noise ratios. The use of high coercive materials such as alloys in the L10 phase allow for thermally stable grains at grain diameters in the order of 4nm. However state of the art write heads produces too small fields to reverse these extremely hard magnetic grains. Recently composite media and exchange spring wire were proposed in order to decrease the write field requirements [1,2]. In exchange spring media an ultra hard magnetic storage layer is strongly exchange coupled to a softer magnetic nucleation host layer. The nucleation host decreases the switching field of the storage layer up to a factor of five without lowering the thermal stability of the entire structure. If the nucleation host is composed of multiple magnetic layers where the anisotropy increases from layer to layer it was shown that the resulting structure has a high thermal stability whereas at the same time the coercive field decreases with one over the total layer thickness [3]. Besides the previous results which were obtained in the quasi static limit, where the external field was applied slowly (several nanosecond) further surprising effects occur if the field rise time is in the order of several hundred picoseconds. These fast field rise times together with small damping constants in the media allow for precessional switching in composite media. It was demonstrated that precessional switching significantly lowers the coercive field [4] and also leads to ultra fast reversal modes [5]. We will present results on the reversal time of magnetic bilayers and magnetic trilayers in the precessional switching regime. Micromagnetic simulations show that a magnetic bilayer with a total thickness of 25 nm (hard layer anisotropy is $K = 1 \text{ MJ/m}^2$) can be reversed with a field pulse of 20 ps. Interestingly the reversal time increases to 0.5 ns as the field rise time is decreased from 0.1 ns to 0.01 ns.

10:24AM P32.00009 Role of dipolar interactions in the determination of intrinsic switching field distributions in perpendicular recording media1, YANG LIU, KARIN DAHMEN, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL 61801, USA, ANDREAS BERGER, CIC nanoGUNE Consolider, E-20009 Donostia - San Sebastian, Spain — The $\Delta H(M, \Delta M)$ method and its ability to determine the intrinsic switching field distributions of perpendicular recording media are numerically studied with the coupled hysteron model. It is found that the presence of dipolar interactions with strength of practical recording media enhances the reliability of the $\Delta H(f; \Delta M)$ method. The correlation between the fit quality measure and the deviation from redundancy measure indicates that the latter, which can be determined from experimental data alone, is a good predictor of the reliability.

10:36AM P32.00010 Chiral electrical DW injection and single shot detection for ultra-high density data storage, L. O’BRIEN, Imperial College London, D.E. READ, D. PETIT, A.-V. JAUSOVEC, E.R. LEWIS, H.T. ZENG, R.P. COWBURN — Ultra high density data storage devices based on magnetic domain walls (DWs) propagating through Permalloy (Py) nanowires have recently been proposed [Cowburn et al., Science 2005]. Controlling the chirality (defined as the sense of rotation of the magnetic moments within the DW) of the DW is of vital importance for proper functioning of these devices. Chiral DW injection can be achieved using global magnetic fields; however, technological applications require this to be carried out using independent, localised fields in multiple wires simultaneously. Using the Oersted field from pulsed electrical currents passing through gold wires (∼40µm wide, ∼200nm thick) fabricated at an angle over Py nanowires (100nm wide, 10nm thick) we inject transverse DWs. The chirality of the DWs is probed using spatially resolved MOKE measurements of their chirality dependent interaction with a cross-shaped trap. The results are consistent with chirally controlled DW injection. In addition, we are able to individually address four parallel wires and detect DW propagation using single shot MOKE measurements. Electrical readout was separately demonstrated by detecting the presence of single DWs at the end of a wire using Anisotropic Magnetoresistance (AMR) measurements.

10:48AM P32.00011 Effect of Grain size on the Giant Intrinsic Coercivity of High-Energy Milled Sm(Co,Cu,Fe)5 Alloys1, DILARA SULTANA, ALEXANDAR GABAY, GEORGE HADJIPANAYIS, University of Delaware, MAGNETICS LAB, UNIVERSITY OF DELAWARE TEAM — The giant intrinsic coercivity of multilayered Sm(Co,Cu)5 alloys have been known for a long time [1]. Previous studies suggested that this behavior is due to the crystal site disorder [2]. Our previous work has explained that the room-temperature intrinsic coercivity of 37 kOe after low-temperature aging is rather due to the intrinsic change in the Co atomic site occupation [3]. In this study, we investigated the effect of grain refinement through the high energy milling on the intrinsic coercivity of the Sm(Co,Cu,Fe)5 alloys. We have found that grain refinement does not affect the high coercivity of homogenized alloys, but strongly influences the onset of the giant coercivity during low-temperature aging. The microstructures of the samples are examined with TEM. [1] E.A. Nesbitt, R.H. Willens, R.C. Sherwood, E. Buehler, J.H. Wernick 1968 Appl. Phys. Lett. 12, 361. [2] H. Oesterriech, F.T. Parker, M. 8:00AM P33.00001 Generation, Modulation and Electrical Detection of Spin Currents in Silicon in a Lateral Transport Geometry1. BEREND JONKER, Naval Research Laboratory — The electron’s spin angular momentum is one of several alternative state variables under consideration on the International Technology Roadmap for Semiconductors. Electrical injection / transport of spin-polarized carriers is a prerequisite for developing such an approach. While significant progress has been realized in GaAs, little has been made in Si. Electrical injection of spin-polarized electrons is demonstrated in Fe/AlO3/Si (001) n-i-p structures by using the circular polarization of the electroluminescence (EL). The EL polarization tracks the Fe magnetization, confirming spin injection into the Si, and reflects Fe majority spin, consistent with the common delta-symmetry of the Fe and Si bands. The Si spin polarization is \( \sim \)30% at 5K, with significant polarization extending to at least 125K. These results are confirmed in Fe/AlO3/Si/AlGaAs/GaAs quantum well structures – the GaAs EL shows that spin transport occurs despite poor crystalline quality of Si epi-layers on GaAs, the 0.3 eV Si/AlGaAs CB offset, and air exposure of the interfaces. Lateral transport structures and non-local detection techniques are used to create a spin current which flows separately from the spin-polarized charge current. This spin diffusion current is sensitive to the relative magnetizations of the injecting and detecting contacts, and can be modulated by a perpendicular magnetic field (Hanle effect) which causes precession in the transport channel. The generation of spin currents, coherent spin precession and electrical detection using magnetic tunnel barrier contacts and a simple lateral device geometry compatible with “back-end” Si processing will facilitate development of Si-based spintronic devices.

8:36AM P33.00002 Electrical Spin injection into Silicon: a comparison between Fe/Schottky and Fe/AlO3 tunnel contacts. G. KIOSEOGLOU, A.T. HANBICKI, C.H. LI, P.E. THOMPSON, R. GOSWAMI, G. SPANOS, B.T. JONKER, Naval Research Laboratory — We have recently demonstrated successful electrical injection of spin-polarized electrons from an Fe film through an AlO3 tunnel barrier into Si [1]. The spin polarization in the Si is \( \sim \)30% at 5K, with significant polarization sustained to at least 125K. In this study we compare electrical spin injection from Fe into Si, using vertical device structures, with spin injection from Fe into Si using lateral structures by reverse biased Fe/Si Schottky contact and a Fe/AlO3 tunnel barrier. For both types of structures the electroluminescence (EL) spectra are dominated by transverse acoustic and optical phonon emissions in the Si. The emitted clear circular polarization of the EL due to radiative recombination in the Si tracks the Fe magnetization, confirming that the spin-polarized electrons originate from the Fe for both types of samples. However, the polarization is lower for the Fe/Si contact than that of the Fe/AlO3/Si system. Systematic TEM analysis has been performed to correlate the interface structure with the observed optical polarization, and reveals some Fe/Si intermixing which is absent in the Fe/AlO3/Si structure. [1] B.T. Jonker et al., Nature Physics 3, 542 (2007). This work was supported by ONR and core programs at NRL.

8:48AM P33.00003 Spin transport through n-type doped silicon using electrical methods1, H.-JAE JANG, BIQIN HUANG, IAN APPELBAUM, University of Delaware — In this presentation, we report on all-electrical injection, transport, and detection of spin-polarized electrons through a 3um n-type Phosphorus-doped single-crystal silicon device. Using our hot-electron methods, we demonstrate both spin-valve behavior in an in-plane magnetic field and spin precession in a perpendicular magnetic field. Voltage spectroscopy reveals the effects of charge screening and band bending in the spin transport layer which are not evident in the operation of our previously-studied undoped silicon devices [1,2].

9:12AM P33.00005 Spin Transport in Silicon1. IAN APPELBAUM, University of Delaware — Silicon has been broadly viewed as the ideal material for spintronics due to its low atomic weight, lattice inversion symmetry, and near lack of nuclear spin, resulting in exceptionally long spin lifetime. Despite this appeal, however, the experimental difficulties of achieving coherent spin transport in silicon were overcome for the first time only recently, by using unique spin-polarized hot-electron injection and detection techniques. [1] Our subsequent observations of very long spin lifetimes and transit lengths [2] have impact on prospects for Spintronics as the basis for a new paradigm of information processing.

9:48AM P33.00006 All-epitaxial heterostructure for tunneling spins into silicon. MAITRI WARUSAWITHANA, DARRELL SCHLORM, Department of Materials Science and Engineering, Penn State University, XUANGLIN KE, PETER SCHIFFER, Department of Physics, Penn State University. — An all-epitaxial spin-tunnel structure has been constructed using molecular-beam epitaxy (MBE). The structure consists of an epitaxial layer of iron (~100 Å thick) on commensurately strained SrTiO3 (~20 Å thick) on (100) Si. The thin SrTiO3 layer serves simultaneously as a tunnel barrier for spin polarized currents and as a protective layer preventing the reaction between iron and the underlying silicon which would lead to the formation of an undesired iron silicide. While the iron film was grown in ultrahigh vacuum, the growth of the SrTiO3 film on silicon was accomplished using molecular oxygen via a sequence of steps by which the formation of an interfacial amorphous silicon dioxide layer is kinetically suppressed. Magnetic measurements indicate strong magnetic anisotropy with the easy axis lying in the plane of the film and a curie temperature above 400 K. Electrical measurements probing spin injection and detection in microfabricated Fe-SrTiO3-Si-SrTiO3-Fe devices, where the ferromagnetic electrodes have different coercive fields due to size anisotropy, will be discussed.
10:00AM P33.00007 Tunneling Characteristics across Nano-Scale Metal Ferric Junction Lines into Doped Si1, JIANG-QING WANG, KEQIANG WANG, JIRI STEHLIK, Binghamton University — Tunneling properties were studied on nanofabricated metal ferric tunnel structures on phosphorus doped silicon by measuring $I-V$ characteristics and differential conductance versus bias over a wide temperature range between 80 K to 325 K. These properties were found to have very weak temperature dependences up to 250 K. Such temperature independencies in transport properties demonstrated tunneling characteristics from metal ferric nano-lines into Si via AlO$_x$ insulating barrier. Nanoscaled spin-dependent tunneling (STD) lines were patterned on doped Si with the injection contacts having the form of long strips with width and separation of 100 nm and several micron long patterned by e-beam lithography. The measured tunneling coefficient was nearly independent of the bias below 1.0 V, and abruptly increases above the threshold, indentifying such threshold as tunneling barrier height. The thermal transport of the active Si region demonstrated a direct correlation between thermal activation of deep levels (of 0.4 eV) in bulk Si and metal-semiconductor tunneling, revealing feasible mechanisms influencing the interfacial transport.

10:12AM P33.00008 Tunnel magnetoresistance of spin tunnel contacts to silicon, R. JANSEN, MESA+ Institute for Nanotechnology, University of Twente, B.C. MIN, R.S. PATEL, S.P. DASH, M.P. DE JONG — For the development of silicon-based spintronic devices, careful design of the contacts between ferromagnet and semiconductor is crucial, as the resistance and potential energy landscape critically affects spin flow across the interface. One approach to engineer spin tunnel contacts to Si uses low work function materials, inserted between the ferromagnet (FM) and the insulator of FM/Al2O3/Si tunnel contacts [1]. Here we present another route to tune the properties of FM/Al2O3/Si contacts by exposure of the Si surface to alkali metal atoms, such as Cs, prior to preparation of the tunnel barrier. This is surprisingly effective in reducing the Schottky barrier height, and will present a series of measurements that elucidate the mechanism. Moreover, we show that the band bending near the contact can be inverted, leading to the formation of a two-dimensional electron gas observable in tunneling spectroscopy, and giving rise to novel tunnel magnetoresistance. [1] B.C. Min et al. Nature Materials 5, 817 (2006).

10:24AM P33.00009 Spin blockade at semiconductor/ferromagnet junctions1, MASSIMILIANO DI VENTRA, YURIY PERSHIN, Department of Physics, University of California, San Diego, La Jolla, California 92093-0319, USA — We study theoretically extraction of spin-polarized electrons at nonmagnetic semiconductor/perfect ferromagnet junctions. The outflow of majority-spin electrons from the semiconductor into the ferromagnet leaves a cloud of minority-spin electrons in the semiconductor region near the junction, forming a local spin-dipole configuration at the semiconductor/ferromagnet interface. This minority-spin cloud can limit the majority-spin current through the junction, creating a pronounced spin blockade at a critical current. We calculate the critical spin-blockade current in both planar and cylindrical geometries and discuss possible experimental tests of our predictions. [1] Yu. V. Pershin and M. Di Ventra, Phys. Rev. B 75, 193301 (2007). [2] Yu. V. Pershin and M. Di Ventra, arXiv:0707.4475.

10:36AM P33.00010 Spin injection and transport in graphene layers1, WEIHUA WANG, KEYU PI, WENZHONG BAO, KATHY MCCREARY, WEI HAN, JEANIE C. N. LAU, ROLAND K. KAWAKAMI, Department of Physics and Astronomy, UC Riverside — Graphene is an intriguing material system for spintronics research. Due to its low atomic number and low spin-orbit coupling, graphene is an excellent candidate for spin transport. In our past study, we have demonstrated spin-polarized transport in mesoscopic graphite by two-probe spin-valve devices [1]. Recently, we further investigated this topic and fabricated non-local spin-valve devices consisting of single-layer and few-layer graphene. Ferromagnet (FM) and nonmagnetic electrodes are formed by using electron beam (e-beam) lithography and e-beam evaporation. Thin tunnel barriers consisting of magnesium oxide are inserted between graphene layers and FM electrodes to overcome conductivity mismatch and enhance spin injection efficiency. Atomic force microscopy and Auger spectroscopy are used to characterize their morphology and chemical composition. We performed magneto-transport using the Johnson-Silsbee geometry in a cryogenic environment and observed non-local spin signal up to room temperature. This unambiguously demonstrates the spin injection, transport and detection in graphene materials. [1] W.-H. Wang, et. al., Phys. Rev. B (Rapid Communications), in press.

Wednesday, March 12, 2008 9:00AM - 10:30AM – Session P34 Tutorial for Authors and Referees of Physical Review Morial Convention Center 226

9:00AM P34.00001 Tutorial for Authors and Referees — Editors from Physical Review Letters and Physical Review will provide useful information and tips for our less experienced referees and authors. The information presented will be relevant to anyone who is looking to submit to or review manuscripts for any of the APS journals, or to anyone who would like to add to their knowledge and experience of the authoring and refereeing processes. Topics for discussion will include: (1) how to write good manuscripts and useful referee reports; (2) differences between manuscripts and referee reports for PRL and PR; (3) the roles of authors and referees in the review process; etc. Following a short presentation from the editors, there will be a moderated discussion of these and other topics. Questions from the audience will be most welcome. Refreshments will be served.

Wednesday, March 12, 2008 8:00AM - 10:36AM – Session P35 DMP: Focus Session: Materials for Photovoltaics and Photocatalysis II Morial Convention Center 227

8:00AM P35.00001 Multijunction solar cells for concentrator systems: prospects and challenges, ANDREAS W. BETT, Fraunhofer-Institut fur Solare Energie Systeme — No abstract available.
8:36AM P35.00002 Photovoltaic properties of novel titanium oxide nanotubes. EUGEN PANAITESCU1, CHRISTIAAN RICHTER2, LATIKA MENON3, Northeastern University — Ultrafast synthesis of high aspect ratio titanate nanotubes by anodization in chloride ions containing solutions has been reported and furthermore optimized by our group. We are presenting in this paper the results of relative measurements on photovoltaic properties of the chloride nanotubes samples sensitized with ruthenium dye N3, comparing them with samples obtained by other anodization methods, and with anatase nanopowders. Photoreponse parameters like short circuit current, open circuit voltage, maximum power and overall conversion efficiency have been measured under simulated solar radiation. Preliminary results on absolute measurements on dye sensitized solar cells employing these samples will also be presented.

8:48AM P35.00003 Enhanced optical absorption by nanocavities inside titania. WEIQIANG HAN, LIJUN WU, ROBERT KLIB, YIMEI ZHU, Brookhaven National Laboratory — Titania, a wide band gap semiconductor, can generate powerful oxidants and reductants by absorbing photon energies. Titania has been extensively used in photoelectrochemical systems, such as dye-sensitized titania, a wide band gap semiconductor, can generate powerful oxidants and reductants by absorbing photon energies. To improve the photoelectivity of titania, several approaches, including doping and metal loading have been proposed. Nanocavities are isolated entities inside a solid and hence are very different from nanoporous, whose pores (often amorphous and irregular) connect together and open to the surface. Dense polyhedral nanocavities inside single-crystalline anatase titania nanorods were successfully synthesized by simply heating titanate nanorods. The size of the nanocavities is typically about 10 nm. The surfaces of the nanocavity polyhedron are determined to be the crystallographic low-index planes of the titania crystal. We found that these dense nanocavities significantly enhance the optical absorption coefficient of titania in the near-ultraviolet region, thereby providing a new approach to increasing the photoelectivity of the titania nanorods in the applications related to absorbing photons. This work is supported by the U. S. DOE under contract DE-AC02-98CH10886 and Laboratory Directed Research and Development Fund of Brookhaven National Laboratory (to W.H.).

9:00AM P35.00004 Charge Separation in layered Titanate Nanostructures: Effect of Ion Exchange induced Morphology Transformation1, O. DIWALD, A. RISS, H. GROTHE, Vienna University of Technology, Institute of Materials Chemistry. J. BERNARDI, Vienna University of Technology, USTEM, E. KNOEZINGER, Vienna University of Technology, Institute of Materials Chemistry, IMC TU WIEN TEAM — Morphology changes induced by surface chemistry can provide important insights into photoexcitation processes on solids which are critical to photovoltaic and photocatalytic applications. We investigated charge separation processes on Nb2Ti3O7 nanowires and scrolled up H2Ti3O7 nanotubes, two types of morphologies which by means of acid/base treatment can reversibly be transformed into each other. Some of the competitive processes photoexcited states undergo can be tracked by means of electron paramagnetic resonance and photoluminescence spectroscopy. A complementarity between efficient charge separation and radiative recombination of photoexcited states was observed and clearly demonstrates the critical influence of morphology and interlayer composition on the photoelectronic properties of layered oxide nanostructures [2]. [1] Riss et al. Nano Lett. 2007, 7, 433-438. [2] Riss et al. Angew. Chem. Int Ed. 2007, anie.200703817, in press

9:12AM P35.00005 Bandgap Narrowing of Titanium Dioxides via Non-Compensated n-p Co-Doping for Photocatalysis1, WENGUANG ZHU, University of Tennessee & Oak Ridge National Laboratory, BAOHUA GU, M. PARANS PARANTHAMAN, GYULA ERES, Oak Ridge National Laboratory, ZHENYU ZHANG, Oak Ridge National Laboratory & University of Tennessee — Titanium dioxide (TiO2) is a promising photocatalyst for solar hydrogen production from water, yet its photocatalytic efficiency is limited by its intrinsic wide-bandgap nature. In this talk, we present a conceptually new and intuitive approach, termed non-compensated n-p co-doping, to narrow the bandgap of TiO2. The validity of this approach has been demonstrated using first-principles calculations within density functional theory, showing that extra impurity bands are created in the gap region because of the non-compensated nature of the n-p co-doping, resulting in a narrowed bandgap around 2 eV. Moreover, the electrostatic attraction between the n and p dopants enhances their thermodynamic and kinetic solubility in the host semiconductors. Preliminary experimental results confirming the non-compensated n-p co-doping concept will also be presented, together with its applicability to other wide bandgap semiconductors.

9:24AM P35.00006 The role of bond switches in light-induced defects in amorphous silicon. LUCAS WAGNER, JEFFREY GROSSMAN, University of California, Berkeley — Amorphous silicon(a-Si) thin-film solar cells are promising materials for solar cells, but they suffer from the Staebler-Wronski effect, in which the efficiency degrades over the course of a few hours of light exposure. While there has been progress in mitigating this effect through sample preparation, there is still no clear microscopic explanation for the degradation. Using first principles density functional theory and highly accurate quantum Monte Carlo techniques, we investigate the simplest reaction in a-Si: a bond switch between two neighboring Si atoms. We find that these reactions can create defect states and can be light activated.

9:36AM P35.00007 Time-domain ab initio studies of photoexcited electron’s dynamics at chromophore-semiconductor interfaces. OLEG PREZHDO, University of Washington — No abstract available.

10:12AM P35.00008 First-principle study of the interfacial rehybridization in organic-inorganic composite photovoltaic devices1, GEORGY SAMSONIDZE, FILIPE J. RIBEIRO, MARVIN L. COHEN, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA 94720 — Composites of organic conjugated polymers and inorganic nanostructures offer cheap but at present inefficient photovoltaic materials. The efficiency of the photovoltaic device is critically dependent on charge transfer and orbital rehybridization at the donor-acceptor interface. In this work we investigate the P3HT/PCBM interface from density functional theory (DFT) based first-principles calculations. We find a strong rehybridization of the conduction band edge states suggesting an efficient route for exciton dissociation at the interface. Using many-body perturbation theory, we compute the quasiparticle corrections on top of the DFT results. These corrections are critical for accurate predictions and to reach agreement with experiment.

10:24AM P35.00009 Pulsed optically detected magnetic resonance of intrinsic a-Si:H at low excitation power. SANG-YUN LEE, THOMAS HERRING, University of Utah, CUNGENG YANG, Department of Medicine, University of Hawaii, HEATHER SEIFEL, CHRISTOPH BOEHME, University of Utah, CRAIG TAYLOR, Colorado School of Mines, JIAN HU, FENG ZHU, MV Systems, Golden, CO, ARUN MADAN — For more than 3 decades, there has been much effort devoted to the investigation of recombination processes in hydrogenated amorphous silicon (a-Si:H). Recently, low-temperature pulsed optically-detected magnetic-resonance (pODMR) studies have shown the presence of a variety of qualitatively different recombination mechanisms that influence the photoluminescence of this material [K. Lips, et. al., JOAM, 7, 13 (2005)]. Here, we present similar experiments with comparatively low light excitation densities (60(10) mW/cm², 514nm, cw Ar⁺ Laser). Qualitatively, our measurements confirm the presence of similar spin dependent recombination channels to those seen at high light excitation densities. However, due to the reduced densities of excess charge carriers, the dynamics of these processes are significantly slower. We attribute this behavior to the decreased transition probabilities at increased charge carrier separations.

Wednesday, March 12, 2008 8:00AM - 10:48AM — Session P36 GIMS: Focus Session: X-ray and Neutron Instrumentation and Science Morial Convention Center 228

8:00AM P36.00001 Advances in Neutron Scattering Instrumentation at Oak Ridge National Laboratory. DOUGLAS ABERNATHY, Oak Ridge National Laboratory — Oak Ridge National Laboratory hosts two world-class neutron sources for condensed matter research. The High Flux Isotope Reactor (HFIR) has recently added a cold source to augment the existing high-intensity thermal beams, and the Spallation Neutron Source (SNS) is the most powerful pulsed spallation neutron source in the world. Investments in neutron scattering instrumentation have come to fruition in a current set of high-performance scattering stations in the user program, covering a wide range of diffraction and spectroscopic techniques. Examples of current scientific results include reflectometry from bio-responsive polymer films and the spectroscopy of slow spin dynamics in frustrated magnetic systems. In 2008 an additional 6 instruments will start user operation or commissioning at the SNS, increasing the breadth and depth of scientific possibilities. Novel techniques and new devices in such areas as sample environment and neutron polarization are also under development.

8:36AM P36.00002 Recent developments on polarized neutron scattering at NIST. WANGCHUN CHEN, NIST, Gaithersburg, Maryland and Indiana University, Bloomington, Indiana, JULIE BORCHERS, ROSS ERWIN, JAMES MCVIER, THOMAS GENTILE, JEFFREY LYNN, NIST, Gaithersburg, Maryland, GORDON JONES, Hamilton College, Clinton, New York — ³He neutron spin filters (NSF) employ nuclear spin-polarized ³He gas, produced by optical pumping, and can be used to polarize or analyze neutron beams because of the strong spin dependence of the absorption cross section for neutrons by ³He. At the NIST center for Neutron Research, the polarized ³He NSF program has been developed to enhance the measurement capability in polarized neutron scattering. This technique has been applied in a number of neutron scattering experiments for user instrumentation and instrumentation development. Here we will discuss applications of the ³He NSF devices in polarized small-angle neutron scattering (SANS), polarized neutron reflectometry (PNR), and polarized triple-axis spectrometry (TAS). For these applications, we employ ³He NSF's as both neutron polarizers and neutron filters that are achieved using the adiabatic fast passage nuclear magnetic resonance technique. We will present the results in each of these applications from magnetic nanoparticles on SANS, patterned magnetic thin films on PNR, and the multiferroelectric system on TAS.

8:48AM P36.00003 Neutron detection in boron carbide/Si heterojunctions as functions of time constants and bias voltage¹. NINA HONG, JOHN MULLINS, S. ADENWALLA, Physics and Astronomy, Univ. of Nebraska-Lincoln — True solid-state neutron detectors have the potential to achieve high efficiencies at low mass, size and power. [1,2] Such detectors made from semiconducting boron carbide (BC) allow for neutron capture and charge collection in the same layer. Here we report neutron detection results from p-n heterojunction diodes of boron carbide on n-type Si. Neutron capture efficiency increases with time constant and reverse bias, from 0.15% at 0 bias and short time constant to 0.46% at 19 V and long time constant. Increasing reverse bias increases the depletion width in the BC layer, leading to a higher proportion of charge capture. The long time constants allow for the detection of charge capture in the BC-scope traces show charge capture times of ~ 30 μs (as compared to < 20 ns in Si). These results indicate that the BC layer is playing an active role in neutron detection, capturing neutrons as well as charge. [1] B. W. Robertson, S. Adenwalla, et al., APL, 80, 3644 (2002). [2] E. Day M. J. Diaz, and S. Adenwalla, J. Phys. D: Appl. Phys. 39, 2020 (2006).

9:00AM P36.00004 The effect of Gd doping on the atomic and electronic structure of HfO₂ thin films. IHOR KETSMAN, ANDREI SOKOLOV, KIRILL BELASHCHENKO, PETER DOWBEN, University Nebraska-Lincoln, YAROSLAV LOSOVYJ, Louisiana State University, JINKE TANG, ZHENJUN WANG, University of Wyoming — HfO₂ is a promising oxide for many applications, including high-k gate dielectric for CMOS devices. In addition, Gd-doped HfO₂ could lead to a dilute magnetic semiconductor and provide an efficient neutron detection medium due to huge neutron absorption cross section of Gd. Gd-doped HfO₂ films deposited on both p-type and n-type silicon by PLD retain monoclinic phase at small doping levels, but can be stabilized in fluorite phase by increased doping [1]. At small doping levels, photoemission measurements indicate the presence of similar spin dependent recombination channels to those seen at high light excitation densities. However, due to the reduced densities of excess charge carriers, the dynamics of these processes are significantly slower. We attribute this behavior to the decreased transition probabilities at increased charge carrier separations.

9:12AM P36.00005 Time-dependent small-angle X-ray and neutron scattering studies of solution-mediated nanoparticulate nucleation, growth and alignment. ANDREW J. ALLEN, VINCENT A. HACKLEY, NIST Ceramics Division, Gaithersburg, MD — A remote-controlled, isothermal, circulating fluid flow cell has been developed for small-angle X-ray and neutron scattering (SAXS and SANS) studies of suspensions with online monitoring of flow rate, temperature or conditions, e.g., pH. Used with the small X-ray beams available at 3rd generation synchrotron sources and the nanometer-to-micrometer scale range accessible in ultrasmall-angle X-ray scattering studies, structural characteristics ranging from 1 nm to several micrometers can be measured, in situ and in real time, as a function of changing physical or chemical conditions. Used with time-resolved pinhole SAXS instruments, rapid reaction precursor phenomena at the nanoscale level can be similarly studied. Used in SANS studies, a neutron-adapted version of the flow cell allows real-time contrast variation techniques to further elucidate the structural evolution. Applications will be discussed for real-time studies of solution-mediated nanocrystalline ceramic oxide formation, and Au nanowire alignment in extensional flow.

9:24AM P36.00006 ABSTRACT WITHDRAWN —
9:36AM P36.00007 Dynamical reconstruction of the valence exciton in LiF

PETER ABBAMONTE, University of Illinois, WEI KU, Brookhaven National Laboratory, TIM GRABER, University of Chicago, JAMES REED, SERBAN SMADICI, University of Illinois, ABHAY SHUKLA, Universite Pierre et Marie Curie, JEAN-PASCAL RUEFF, Synchrotron SOLIEL — We have used inelastic x-ray scattering, coupled with recently developed inversion techniques, to reconstruct the structure and dynamics of the valence exciton in the prototype alkali halide LiF. Our inversions, which yield resolutions $\Delta x = 0.533 \text{Å} \text{and } \Delta t = 20.67 \text{as} (2.067 \times 10^{-17} \text{s})$, reveal that the exciton forms in less than 50 as, oscillates with a period of 283 as, and decays after approximately 5 fs. It contains a pronounced $a/3$ internal periodicity, where $a = 4.027 \text{Å}$ is the crystal lattice parameter, that changes little during the course of its life, indicating that this exciton lies very close to the Frenkel limit. Our results resolve a 70 year old controversy about the valence exciton in alkali halides and, when compared to $ab$ initio calculations, demonstrate a simplified theoretical approach to describing excitons in the spirit of strong binding energy.

9:48AM P36.00008 Core-hole propagator and resonant inelastic X-ray scattering: exact results within a Baym-Kadanoff-Keldysh approach

ANDRUI SHVAIKA, TARAS MYSAKOVYCH, Institute for Condensed Matter Physics, 79011 Lviv, Ukraine, JAMES FREERICKS, Department of Physics, Georgetown University, Washington, DC 20057 — We solve for the core-hole propagator and the resonant inelastic X-ray scattering (RIXS) response functions in correlated materials by employing dynamical mean-field theory. We focus our attention on the spinless Falicov-Kimball model, where the problem can be solved exactly, and the system can be tuned to go through a Mott-Hubbard-like metal-insulator transition (the coupling with the core hole is also a Falicov-Kimball type of interaction). The core-hole propagator is expressed in terms of a continuous fermionic Toepplitz determinant defined only on the upper real-time branch of the Keldysh contour. We have derived exact large-time asymptotics for the core-hole propagator using the Wiener-Hopf finite sum equation technique which produces an efficient algorithm to obtain the density of states of the X-ray edge problem for any temperature and any interaction strength. We have also derived the two-particle vertices in a diagrammatic representation of the scattering processes (using a Baym-Kadanoff-Keldysh approach). As an example of this formalism, we show results for the L-edge contributions to RIXS. This work was supported by Award No. UKP2-2697-LV-06 of the U.S. Civilian Research and Development Foundation.

10:00AM P36.00009 Identification of Mn site in Pb(Zr,Ti)O$_3$

A. BOONCHUN, M. F. SMITH, S. RUJIRAWAT, B. CHERDHIRUNKORN, S. LIMPIJUMNONG, School of Physics, Suranaree University of Technology, Thailand — The impurity Mn in PbTiO$_3$ and PbZrO$_3$ has been studied by means of first-principles spin density functional theory. It is found that the Mn atom energetically prefers to substitute on the Ti/Zr site over other sites (i.e., Pb site, O site or interstitial) under all equilibrium growth conditions. The calculations predict that a majority of Mn atoms substitute for Ti/Zr and have neutral-charge state each with a total electron spin of $M = 3/2$. This prediction is supported by the combination of x-ray absorption near edge structure (XANES) experiment and first-principles simulation of the spectrum. The measured XANES of the Mn-doped Pb(Ti,Zr)O$_3$ within the concentration range of 0.5 - 2.0 at% yield the exact same features, indicating that the location of Mn in the crystal is independent of Mn concentration. The measured XANES is consistent with the partial density of states simulation of Mn atom on the Ti/Zr site and inconsistent with the simulations of Mn atom on other sites.

1Present address: Dept. of Physics, Case Western Reserve University, Cleveland, OH 44106

10:12AM P36.00010 Direct mapping of phonon dispersions in copper by x-ray thermal diffuse scattering

RUQING XU, HAWOONG HONG, TAI CHIANG, University of Illinois at Urbana-Champaign — X-ray Thermal Diffuse Scattering (TDS) arises from lattice vibrations. Measured TDS intensities can be used to extract phonon dispersion relations, as has been demonstrated in a number of systems. But most analysis methods so far have involved data fitting based on assumed atomic force constant models, and it is difficult to determine a priori the accuracy of the procedure. Methods of direct inversion, i.e., deterring k-space frequencies directly from x-ray TDS data without a presumed model, have been proposed in prior work, but most of the schemes involve absolute intensity measurements, which are difficult especially in the presence of an unknown background. Here we report an improved approach, in which phonon frequencies are determined through the temperature dependence of TDS intensities at each point in reciprocal space. Polarization selection rules are employed to disentangle contributions from different phonon branches. Results taken from a simple model material, copper, will be presented.

10:24AM P36.00011 Fractionation of uranium isotopes in minerals screened by gamma spectrometry

JEFFREY L. GEIGER, AUSTIN M. BALDWIN, CHARLES C. BLATCHLEY, Pittsburg State University — At least two groups have reported finding shifts in the ratio U-235/U-238 for sandstone, black shale, and other sedimentary samples using precision ICP-MS. These shifts were tentatively attributed to a recently predicted isotope effect based on nuclear volume that causes fractionation for U-235/238. However, fractionation of high Z elements may be less likely an explanation than U-235 depletion induced by galactic cosmic ray neutrons. Isotope depletion in marine sediments could therefore be an indicator of changes in cosmic ray flux due to nearby supernovae, gamma-ray bursts, or longer term changes during the 62 million year cycle of high Z elements. We report using a less precise approach than ICP-MS, but one which can quickly screen samples to look for anomalies in isotope ratios, namely HPGe gamma ray spectrometry. Various levels of depletion were measured for uranium rich minerals, including brannerite, carnottite, and pitchblende, as well as coal and limestone samples.

10:36AM P36.00012 Electronic Structure Study of Cerium Doped Scintillators

DA GAO, MICHAEL MCLIVAIN, Idaho National Laboratory — The interest shown in recent years related to cerium doped lanthanide halides, such as LaCl$_3$, LaBr$_3$, and LaI$_3$, is mainly due to their potential applicability as gamma ray scintillation detectors. We have performed a comprehensive theoretical study of these materials to better understand the scintillation process and define the nature of the self trapped exciton (STE) associated with thermally dependent scintillation process. The present work focuses on the study of the luminescence properties of cerium doped lanthanide halide scintillators from the point of view of solid state band structure calculations. Our calculated band structures are in good agreement with experimental values. For example, LaCl$_3$ band gap is calculated to be 6.85 eV as compared to approximately 7.0 eV for the experimentally determined value. The theoretically calculated excitation spectra are also compared with the experimental spectra. We find that scintillation efficiency is dependent on the location of the of Ce$^{3+}$ ground 4f and excited 5d levels with respect to the fundamental band gap of the host materials.

1This work was supported by the U.S. Department of Energy, Office of Biological and Environmental Research, Environmental Research Science Program under Contract No. DE AC07-05ID14517.
We report photoluminescence (PL) measurements of GaAs incorporation is predicted to mainly perturb the valence band and does not significantly affect the electron mobility, thus promising better device performance. Bi\textsubscript{GaAs} with small amounts of N or Bi results in a large reduction of the fundamental band gap, leading to the so called “giant band gap bowing”. GaAs doping with magnetic versus non-magnetic impurities. Effects of disorder, compensation, and doping in these samples. In addition, comparing Mn doped and Be doped films allows for distinguishing the effects of doping and compensation.

The work was supported by the Semiconductor Research Corporation. NCN computational resources were used.

3Supported by the NIH, the NSF, and the WU CMI

8:36AM P37.00004 Micro-spectroscopy of Ga\textsubscript{1−x}Mn\textsubscript{x}As and Ga\textsubscript{1−x}Be\textsubscript{x}As films with gradient doping and compensation, BRIAN CHAPLER, University of California San Diego, R.C. MYERS, D.D. AWSCHALOM, University of California Santa Barbara, M.C. MARTIN, Lawrence Berkeley National Laboratory, K.S. BÜRCH, Los Alamos National Laboratory, D.N. BASOV, University of California San Diego — A detailed study into the problem of carrier induced magnetism in ferromagnetic III-Mn-V semiconductors is being carried out using micro-infrared measurement techniques. Infrared micro-spectroscopy and broad-band micro-ellipsometry measurements have been performed on films of Ga\textsubscript{1−x}Mn\textsubscript{x}As, \( x = 0.03, 0.16\), as well as Ga\textsubscript{1−x}Be\textsubscript{x}As, \( x = 0.018\). The films were prepared using non-rotated molecular beam epitaxial growth. The results of this growth are films with a varying As:Ga ratio across the sample. Using the above experimental techniques, measurements can be taken at specific locations along the As:Ga gradient, which have shown to cause systematic changes in spectra as a function of As:Ga ratio. These experiments provide a unique opportunity to study the effects of disorder, compensation, and doping in these samples. In addition, comparing Mn doped and Be doped films allows for distinguishing the effects of doping with magnetic versus non-magnetic impurities.

8:48AM P37.00005 Slow light and anomalous pulse breakup near an exciton resonance in GaAs quantum wells, TIMOTHY SWEENEY, YAN GUO, SUSANTA SARKAR, HAILIN WANG, Department of Physics, University of Oregon, Eugene, OR 97403 — We report experimental studies of optical pulse propagation near an exciton resonance in GaAs quantum wells. The spectral dependence of the group velocity reveals a sharp decrease in the group delay when the spectral position of the optical pulse is varied from below to above the exciton absorption line center. The decrease in the group delay occurs in a spectral range that is small compared with the exciton absorption linewidth. Pulse breakups are also observed when input optical pulses with relatively low intensities are slightly below the exciton absorption line center. Detailed nonlinear optical studies suggest that these surprising behaviors arise from coherent population oscillation and especially a sharp increase of the exciton decoherence rate from below to above the exciton absorption line center.

9:00AM P37.00006 ABSTRACT WITHDRAWN —
9:24AM P37.00008 Effect of spin-orbit coupling on excitonic levels in layered chalcogenide-
fluorides, ANDRIY ZAKUTAYEV, ROBERT KYKYNESHI, JOSEPH KINNEY, DAVID H. MCINTYRE, GUENTER SCHNEIDER, JANET TATE, Department of Physics, Oregon State University — BaCuCHF (Ch=S,Se,Te) comprise a family of wide-bandgap p-type semiconductors. Due to their high transparency and conductivity, they have potential applications as components of transparent thin-film transistors, solar cells and light-emitting devices. Thin films of BaCuCHF have been deposited on MgO by pulsed laser deposition (PLD). Solid solutions BaCuSi$_1-x$Se$_x$Te$_x$ and BaCuSe$_1-x$Te$_x$ have been prepared by PLD of alternating thin BaCuCHF layers. All films were deposited at elevated substrate temperatures. They are preferentially c-axis oriented, conductive and transparent in the visible part of the spectrum. Double excitonic peaks have been observed in the absorption spectrum of these films in the temperature range from 80 to 300K. The separation between the peaks in the doublet increases with the increase of atomic mass of the chalcogen. It also increases with the increase of the heavy chalcogen component $x$ in the solid solutions. This separation most likely is caused by the effect of spin-orbit coupling in the chalcogen atoms on excitonic levels in BaCuCHF.

9:36AM P37.00009 Photocurrent-induced transport of exciton energy in a single heterojunction quantum well, PATRICK FOLKES, Army Research Laboratory, YINGMEI LIU, University of Pittsburgh — Excitons which coexist with a degenerate two-dimensional electron gas (2DEG) in the same quantum well subband have been observed in the photoluminescence (PL) from the recombination of electrons with localized photoexcited holes. Under pulsed photoexcitation at a critical applied voltage, the screening response of the 2DEG/exciton system to the appearance of a remote photocurrent filament in the 2DEG results in the existence of spatially direct and red-shifted indirect excitons in the photoexcitation region and the anomalously fast formation of in-plane spatially indirect excitons which are localized around the filament. Our data suggests the occurrence of a fast long range transport of exciton energy.

1Present address: Department of Physics, Massachusetts Institute of Technology

9:48AM P37.00010 Two-dimensional hole systems in InSb and In$_x$Ga$_{1-x}$As quantum wells, CHOMANI GASPE, MADHAVIE EDIRISOORIYI, TETSUYA MISHIMA, MICHAEL SANTOS, University of Oklahoma — CMOS circuits require $p$-type transistors with high hole mobility, in addition to $n$-type transistors with high electron mobility. In InSb, we have observed room-temperature electron mobilities of 10,000 and 40,000 cm$^2$/Vs in quantum wells made of In$_{0.5}$Ga$_{0.47}$As and InSb, respectively. To achieve high hole mobilities, strain and confinement must be maximized. Both parameters increase the energy splitting between holes with light in-plane mass and those with heavy in-plane mass. We have observed a room-temperature hole mobility of 600 cm$^2$/Vs in InSb quantum wells with remotely Be-doped Al$_x$In$_{1-x}$Sb barriers grown on GaAs substrates by molecular beam epitaxy. We will discuss the effects of strain, structural parameters, and defect density on hole mobility in InSb and In$_x$Ga$_{1-x}$As quantum wells.

10:00AM P37.00011 ABSTRACT WITHDRAWN —

10:12AM P37.00012 Non-Markovian damping of Rabi oscillations in semiconductor quantum dots, LUIZ E. OLIVEIRA, Instituto de Física - Unicamp - Brazil, DMITRI MOGILEVTSEV, A.P. NISOVTSEV, S. KILIN, Instituto de Física - NASB - Belarus, S.B. CAVALCANTI, Instituto de Física - UFAL - Brazil, H.S. BRANDI, Instituto de Física - UFRJ - Brazil — A systematic investigation is performed on the damping of Rabi oscillations induced by an external electromagnetic field interacting with a two-level semiconductor system. We have considered a coherently driven two-level system coupled to a dephasing reservoir, and shown that in order to explain the dependence of the dephasing rate on the driving intensity, it is essential to consider the non-Markovian character of the reservoir. Moreover, we have demonstrated that intensity-dependent damping may be induced by various dephasing mechanisms due to stationary as well non-stationary effects caused by the coupling with the environment. Finally, present results [1] are able to explain a variety of experimental measurements [2-4] available in the literature.

10:24AM P37.00013 Nonlinear Terahertz pump-Terahertz probe Measurements of Semiconductor Carrier Dynamics, HAIDAN WEN, AARON LINDENBERG, PULSE Center, Stanford Linear Accelerator Center, LINDENBERG LAB TEAM — A table-top terahertz (THz) source has been employed to study the nonlinear response of semiconductors to near-half-cycle femtosecond pulses in the THz regime. We report nonlinear field-induced changes in the far infrared absorption coefficient induced by THz pulses. The transmittance as the function of THz peak field was measured using a z-scan technique and it is observed that the absorption coefficient dramatically increases above a threshold field.

10:36AM P37.00014 Effect of Spin-Orbit Interaction on the Lattice Properties of Solids: Sb and Bi, M. CARDONA, MPI fuer Festkörperforschung, D-70569 Stuttgart, Germany, L. E. DIAZ-SANCHEZ, CINESTAV-Queretaro, 76230 Queretaro, Qro., Mexico, X. GONZE, Unite de Physico-Chimie et de Physique des Matériaux, Université Catholique de Louvain, B-1348 Louvain-la-Neuve, Belgium, R. K. KREMER, MPI fuer Festkörperforschung, D-70569 Stuttgart, Germany, A. H. ROMERO, CINESTAV-Queretaro, 76230 Queretaro, Qro., Mexico, J. SERRANO, ICREA, EPSC Universitat Politècnica de Catalunya, 08860 Castelldefels, Spain — We present measurements of the specific heat ($C$) vs. $T$ for Bi and Sb and vs. isotopic mass for Sb. The measurements are compared with $ab$-initio calculations performed with the ABINIT code, including spin-orbit (S-O) interaction. It is shown that the S-O interaction softens the lattice and thus increases the value of $C$ at the low $T$ maximum ($T_m \sim$8K for Bi, $T_m \sim$14K for Sb), improving agreement between theory and experiment. The effect of S-O interaction on other thermodynamic properties, such as the lattice parameter, $a_0$, and the cohesive energy, $E_c$, is also calculated. It is shown that this interaction decreases $E_c$ and, correspondingly, increases $a_0$. These effects are proportional to $c_2 \lambda^2 + c_3 \lambda^4$, where $\lambda$ is the S-O coupling constant, about twice as large for Bi as for Sb.

Wednesday, March 12, 2008 8:00AM - 11:00AM –
Session P38 DCMP: Relaxor Ferroelectrics and Piezoelectrics Morial Convention Center 230
We have discovered that by substituting the 'A' site with a smaller atom compared to Pb to apply “chemical pressure” and tune the morphotropic-phase boundary to lower pressures.

Laboratory, HAOSU LUO, Shanghai Institute of Ceramics — The lattice dynamics of PbMg1/3Nb2/3O3extremely high piezoelectric coefficient, higher electromechanical coupling, and larger attainable bandwidth. This will lead to enhanced agility of NEMS/MEMS devices. The main advantages are the materials are extremely important for applications in micro-electromechanical systems (MEMS) and nano-electromechanical systems (NEMS). Here, we will be presenting PMN-PT (Lead Magnesium Niobate-Lead Titanate) on SOI as a hyper piezoelectric material for NEMS devices. The main advantages are the materials are extremely important for applications in micro-electromechanical systems (MEMS) and nano-electromechanical systems (NEMS). Here, we will be presenting PMN-PT (Lead Magnesium Niobate-Lead Titanate) on SOI as a hyper piezoelectric material for NEMS devices.

Material Science and Engineering, Pennsylvania State University, PA 16802, VLADIMIR AKSYUK, Alcatel-Lucent Technologies, NJ 07974 — Piezoelectric BLICK, Department of Electrical and Computer Engineering, University of Wisconsin-Madison, WI 53706, SEUNG-HYUB BAEK, CHANG-BEOM EOM, MUHTAR AHART, RONALD E. COHEN, RUSSELL J. HEMLEY, Carnegie Institution of Washington — Motivated to determine and understand PMN-32%PT’s behavior under pressure, we employed the angular dispersive x-ray diffraction methods (Advanced Photon Source, Argonne National Laboratory) to investigate PMN-32%PT in a diamond anvil cell up to 15 GPa. The x-ray diffraction results show changes in Bragg peaks at 4 GPa which indicate that PMN-32%PT undergoes a ferroelectric rhombohedral to a paraelectric cubic phase transition. In addition, we investigated the pressure dependence of domain structure of PMN-32%PT up to 10 GPa; rhombohedral domains decrease with pressure and disappear above 4 GPa. These results are qualitatively consistent with earlier Raman study of B. Chaubane, (Phys. Rev. B 70, 134114, 2004). We suggest a phase diagram for PMN-PT system which is slightly different from the one predicted by B. Chaubane et al.

8:36AM P38.00004 Aging mechanisms in field cooled PMN-PT 12%, MATTHEW DELGADO, EUGENE COLLA, MICHAEL WEISSMAN, University of Illinois Urbana-Champaign — In the relaxor ferroelectric PMN-PT 12% ((PbMg1/3Nb2/3O3)0.98(PbTiO3)0.02) the dielectric susceptibility (ε″, ε′′) and pyroelectric current I₀ were measured after different field-temperature histories. As previously reported [1], when the sample was cooled in zero field, standard spinglass-like aging of ε″ was found in the glassy relaxor regime. Cooling in a DC electric field of 0.67 kV/cm drove a transition into a polarized ferroelectric-like state, which retained its polarization after the field was removed at low temperature. During 10 hours of subsequent zero-field aging at 160K, ε″ showed almost no change. This suggests that the mechanisms responsible for glasisy aging in the relaxor state are absent in the ferroelectric state. [1] L. Chao, et al. PRB 74, 014105 (2006).

8:48AM P38.00005 Hyper Piezoelectric Nano-Electromechanical Systems, DUSTIN KREFT, ROBERT BLICK, Department of Electrical and Computer Engineering, University of Wisconsin-Madison, WI 53706, SEUNG-HYUB BAEK, CHANG-BEOM EOM, Department of Material Science and Engineering, University of Wisconsin-Madison, WI 53706, V. VAITYHANATHAN, DARRELL SCHLOM, Department of Material Science and Engineering, Pennsylvania State University, PA 16802, VLADIMIR AKSYUK, Alcatel-Lucent Technologies, NJ 07974 — Piezoelectric materials are extremely important for applications in micro-electromechanical systems (MEMS) and nano-electromechanical systems (NEMS). Here, we will be presenting PMN-PT (Lead Magnesium Niobate-Lead Titanate) on SOI as a hyper piezoelectric material for NEMS devices. The main advantages are the extremely high piezoelectric coefficient, higher electromechanical coupling, and larger attainable bandwidth. This will lead to enhanced agility of NEMS/MEMS devices and lower energy consumption. The work will also have considerable impact for nanoscale mechanics.

9:00AM P38.00006 Zone Boundary Soft Modes in Relaxor PMN, PETER GEHRING, NIST Center for Neutron Research, JAN SWAINSON, NRC, Chalk River Laboratories, CHRIS STOCK, ISIS, Rutherford Appleton Laboratory, GUANGYONG XU, Brookhaven National Laboratory, HAOSU LUO, Shanghai Institute of Ceramics — The lattice dynamics of PbMg1/3Nb2/3O3, a prototypical relaxor, have been studied using neutron TOF techniques at the NIST Center for Neutron Research. Unusual “columns” of inelastic scattering are seen at the M and R-point zone boundaries of 300K. These columns are due to the superlattice peaks observed in the relaxor regime. Preliminary neutron structure factor calculations indicate that the corresponding ionic displacements involve the Mg/Nb and Pb atoms. This picture is consistent with x-ray studies according to which the superlattice peaks result from <110> correlated, anti-parallel Pb displacements. The potential relationship between the columns and superlattice peaks is intriguing because the temperature dependence of the M-point superlattice peak tracks that of the soft, zone center mode, which is associated with the development of short-range ferroelectric correlations. [1] A. Tkachuk and H. Chen, AIP Conf. Proc., 677, p. 55 (2003); [2] P. M. Gehring, S. Wakimoto, Z.-G. Ye, and G. Shirane, Phys. Rev. Lett. 87, 277601 (2001).

9:12AM P38.00007 Polar nanoregions and phase instability in relaxors, GUANGYONG XU, Brookhaven National Laboratory, JINSHENG WEN, Brookhaven National Lab/Stonybrook, CHRISTOPHER STOCK, Rutherford Appleton Lab, U.K., PETER GEHRING, NIST — Local polar clusters called polar nano-regions (PNR) are believed to play important roles in the electronic properties of relaxor ferroelectrics. Recent work has shown that the presence of PNRs in relaxor systems could also be related to the high piezoelectric response in these materials. Diffuse scattering studies on PNRs in PMN-xPT and PZN-xPT systems will be presented and their electric field response will be discussed. Our results suggest that there is an intrinsic phase instability in relaxor systems induced by the PNRs, which makes it easier for an (electric field) induced strain to develop. Possible scenarios for the further enhancement of the piezoelectric response near the morphotropic phase boundary (MPB) will also be discussed.
9:24AM P38.00008 First-Principles Investigations of Pb Anti-Site Defects in PbZrO$_3$ and Pb(Zr, Ti)O$_3$ Perovskites$^1$. RICARDO KAGIMURA, DAVID J. SINGH, Oak Ridge National Laboratory — Lead zirconate (PZ) and lead zirconate titanate (PZT) have the perovskite type structure, ABO$_3$. Bivalent lead (Pb$^{2+}$) ions occupy the A site, while tetravalent titanium and zirconium (Zr$^{4+}$, Ti$^{4+}$) ions occupy the B site at random of the PZT solid solution. Also, lead can be tetravalent (Pb$^{4+}$), such as in PbO$_2$ structure. Recent experimental work has reported that tetravalent Pb ions can locate at the B site of the PZT perovskite forming a lead zirconate-titanate-plumbate solid solution. The experimental results suggest that, based on a PbZrO$_3$-PbTiO$_3$-PbPbO$_{3}$ ternary solution phase diagram [G. Suchaneck et al., Ferroelectrics 318, 3 (2005)], the substitutional Pb atom prefers to occupy the Zr site instead of the Ti one. In this work, we report density functional supercell calculations for pure PbZrO$_3$ perovskite and for ordered Pb(Zr$_{1/2}$Ti$_{1/2}$)$_3$O$_9$ solid solution with different configurations for the Zr and Ti atoms. We investigate the anti-site defect energies and the effects on the electronic structure.

9:36AM P38.00009 Stability of point defects in SrTiO$_3$ substrates during thin film deposition. EMMANUEL TOWEY, SHEHNAZ JEDDY, GREGG JANOWSKI, Abant Izzet Baysal University, Department of Physics — We will report the results of a first principles investigation of the electronic and lattice dynamical properties of so-called giant dielectric compound Na$_{1/2}$Bi$_{1/2}$Cu$_3$Ti$_4$O$_{12}$ which was found to have a very high ‘extrinsic’ as well as ‘intrinsic’ dielectric constant. The calculations have been carried out within the local spin density functional approximation using norm-conserving pseudopotentials and a plane-wave basis. The electronic band structure suggests that, based on a PbZrO$_3$-PbTiO$_3$-PbPbO$_{3}$ ternary solution phase diagram [G. Suchaneck et al., Ferroelectrics 318, 3 (2005)], the substitutional Pb atom prefers to occupy the Zr site instead of the Ti one.

9:48AM P38.00100 Electron Beam Excitation Mechanism of Rare Earth Ions in LiNbO$_3$. T. TAFOIN PENN, V. DIEROLF, G.S. CARGILL III, Lehigh University — Many applications of ferroelectric materials in frequency conversion are based on precise engineering of the ferroelectric domains. Unfortunately, the quest for smaller feature sizes is slowed due to the lack of real-time local controls of the process. We explored the feasibility of using as local probes RE ions in LiNbO$_3$ that exhibit in their excitation and emission spectra linear Stark shifts making them sensitive to local electric fields such as local charging and fields from defect dipoles. We studied the feasibility of this approach for the domain writing process induced by an e-beam in a SEM. A necessary first step is a good understanding of the excitation mechanisms of RE:LiNbO$_3$ that leads to CL under e-beam irradiation. We observe a pronounced saturation already for moderate e-beam currents indicating that not all RE ions can be excited. This excludes the direct excitation pathway as a major contributor to the CL excitation. Our observations are explained by a defect trap mediated energy transfer between generated electron-hole pairs and the RE ions. Independent of the RE ion, we find that the energy transfer rate from the defect trap to the RE ion is less than 100 ns$^{-1}$.

10:00AM P38.00011 Raman study of the phonon modes in bismuth pyrochlores$^1$. DANIEL ARENAS, WEI QIU, JUAN NINO, DAVID TANNER, University of Florida, LEV GASPAROV, University of North Florida — The Raman Spectra of the cubic bismuth pyrochlores Bi$_2$Zn$_2$Nb$_2$O$_9$, Bi$_3$ZnTa$_3$O$_{12}$, Bi$_2$MgNb$_2$O$_{12}$, and Bi$_3$MgTa$_3$O$_{12}$ were measured. The samples, in ceramic form, were measured from 50 to 1000 cm$^{-1}$ at room temperature. The Raman bands were tentatively assigned to specific vibrational modes. Overall, the Raman spectra were similar for all four samples and the number of modes was affected by the displacement disorder in the bismuth-based compounds. The results will also be compared to published infrared data to gain insight into these additional modes. Last, the existence of an 860 cm$^{-1}$ mode in BiZn and BMNb will be discussed as it suggests influence of the lone pair character on the displacement disorder.

10:12AM P38.00012 A Low-Temperature Specific Heat Study of the Giant Dielectric Constant Materials. C. P. SUN, J. Y. LIN, H. D. YANG, Department of Physics, National Sun Yat-Sen University, Kaoshuing 804, Taiwan, Republic of China, JIANJUN LIU, CHUN-GANG DUAN, W. N. MEI, Department of Physics, University of Nebraska at Omaha, Nebraska, 68182-0266, USA — Low-temperature specific-heat study has been performed on the insulating giant dielectric constant material CaCu$_3$Ti$_4$O$_{12}$ and two related compounds, Bi$_2$Cu$_3$Ti$_4$O$_{12}$ and La$_2$Na$_{0.5}$Cu$_3$Ti$_4$O$_{12}$, from 0.6 to 10 K. From analyzing the specific heat data at very low-temperature range, 0.6 to 1.5 K, and moderately low-temperature range, 1.5 to 5 K, in addition to the expected Debye terms, we noticed significant contributions originated from the linear and Einstein terms, which we attributed as the manifestation of low-lying elementary excitations due to lattice vibrations occurred at the grain boundaries and induced by local defects. Together with the findings on electronic and mechanical properties, a phenomenological model is proposed to explain the high dielectric constant behaviors at both low and high frequency regions.

10:24AM P38.00013 First Principles Investigation of Electronic and Lattice Dynamical Properties of High Dielectric Constant Material Na$_{1/2}$Bi$_{1/2}$Cu$_3$Ti$_4$O$_{12}$. CIHAN PARLAK, RESUL ERYIGIT, Abant Izzet Baysal University, Department of Physics — We will report the results of a first principles investigation of the electronic and lattice dynamical properties of so-called giant dielectric compound Na$_{1/2}$Bi$_{1/2}$Cu$_3$Ti$_4$O$_{12}$ which was found to have a very high ‘extrinsic’ as well as ‘intrinsic’ dielectric constant. The calculations have been carried out within the local spin density functional approximation using norm-conserving pseudopotentials and a plane-wave basis. The ground state is found to be antiferromagnetic direct-band gap semiconductor. Lattice dynamical properties, such as Born effective charge tensors, dielectric permittivity tensors, and phonon frequencies at the Brillouin zone center were calculated using density functional perturbation theory and found to be similar to more studied CaCu$_3$Ti$_4$O$_{12}$ and CaCu$_3$Ti$_4$O$_{12}$ compounds. The calculated electronic ($\epsilon_{\text{el}} \approx 11.5$) and static ($\epsilon_{\text{st}} \approx 150$) dielectric constants indicate that the observed high dielectric constant is extrinsic in origin. The main contribution to the static dielectric constant is found to be due to a low frequency (50 cm$^{-1}$) IR-active mode which has a large mode effective charge.

Transition temperature of martensitic transformations in hafnia and zirconia

XUHUI LUO, UT Austin, A.A. DEMKOV, UT Austin — Transition metal oxides find applications in ceramics, catalysis and semiconductor technology. In particular, hafnium dioxide or hafnia will succeed silica as a gate dielectric in advanced transistors. However, thermodynamic properties of thin hafnia films are not well understood, despite their technological importance. We use density functional theory to investigate the tetragonal to monoclinic phase transition in hafnia and zirconia. We find that unlike the case of the cubic to tetragonal transition, this phase transition is not driven by a soft mode. We use transition state theory to identify the minimum energy path (MEP) employing first principle calculations for hafnia and zirconia, sow that both transformations are martensitic, and obtain the transition barriers. Martensitic transformations include both the internal coordinate transformation and deformation of the cell lattice vectors ("strain and shuffle”), therefore the potential energy surface and MEP are function not only of the internal atomic coordinates but also of the unit cell lattice vectors. Considering the simplest case of uniform strain the transition temperatures we then relate the barrier height to the transition temperature. As a self-consistency check, assuming the equality of thermodynamics potentials of the tetragonal and monoclinic phases during the transition, and using the difference in the internal energy calculated from first principles we estimate the entropy change associated with the transition which is found in good agreement with that calculated form the phonon spectra.

Correlation effects in charge-density wave insulator BaBiO3

CESARE FRANCHINI, MARTIJN MARSMAN, GEORG KRESSE, Faculty of Physics, University of Vienna and Center for Computational Materials Science — The negative-U nature of BaBiO3 leads to a charge-ordered insulating state in which pentavalent Bi5+ coexists with trivalent Bi3+. Despite the apparent absence of strong-correlation effects in BaBiO3 standard density functional (DFT) theory yields a much too small band gap of 0.14 eV. By means of an hybrid-DFT approach combined with self-consistent GW including vertex corrections we investigate the electronic, vibrational and dielectric properties of BaBiO3. We show that the inclusion of strong-correlation effects increases the band gap up to 1.2 eV, shifts the oxygen breathing modes upwards by ≈ 2 THz and reduces the dielectric constant by a factor of 3. The overall agreement with available experimental data is significantly improved.

Effects of quenched randomness on predator-prey interactions in a stochastic Lotka-Volterra lattice model

UWE C. TAUBER, Department of Physics, Virginia Tech, Blacksburg, VA 24061-0435, ULRICH DOBRAMYSL, Institute of Semiconductor and Solid State Physics, Johannes Kepler University, 4040 Linz, Austria — We study the influence of spatially varying reaction rates (i.e., quenched randomness) on a stochastic two-species Lotka-Volterra lattice model for predator-prey interactions using Monte Carlo simulations. The effects on the asymptotic population densities, transient oscillations, spatial distributions, and on traveling wave and invasion front speed are investigated. We find that spatial variability in the predation rate yields an increase in the asymptotic population densities of both predators and prey.

Effects of quenched randomness on predator-prey interactions in a stochastic Lotka-Volterra lattice model

PER ARNE RIKVOLD, VOLKAN SEVIM, Florida State University — We report very long kinetic Monte Carlo simulations of eco- systems generated by individual-based models of biological co-evolution, emphasizing the temporal fluctuations in community structure, diversity, and population sizes [1-3]. These multispecies coevolution models contain both producers that directly utilize an external resource, and consumers that must consume one or more other species for support. Time series of diversities and population sizes over tens of millions of generations display highly correlated fluctuations that give rise to power spectra of 1/f form. These model-intrinsic dynamic features correspond to large, correlated extinction events and similarly correlated bursts of new species, without the need for external catastrophic events. The communities generated by the evolution process take the form of simple food webs, whose species abundance distributions and degree distributions are consistent with data from real food webs.

Research in part funded through the National Science Foundation, NSF DMR-00755725, and supported through an IAESTE student exchange internship.

Dynamical Clustering in Reaction-Dispersal Processes on Complex Networks

VINCENT DAVID, MPI-DS, Gottingen, MARC TIMME, MPI-DS, BCCN, Gottingen, THEO GEISEL, University of Gottingen, MPI-DS, BCCN, Gottingen, DIRK BROCKMANN, Northwestern University, Evanston — We investigate nonlinear annihilation processes (e.g., A + A → 0) of particles that perform random walks on complex networks. In well mixed populations (mean field) this process exhibits t−1 decay behavior in the total number of particles. Additional dispersal of particles adds a second time scale and drastically changes the decay behavior. Here we study these changes for two types of hopping processes. First, if particles independently select one of the possible exit channels at each node their exit rates are given by the sum of all outgoing weights such that the waiting times are degree-dependent. We compare this to the popular ansatz of a uniform waiting time process. Derived mean field equations show that for large numbers of particles per node both processes exhibit nearly identical relaxation properties. However, below a critical particle number the processes deviate not only from mean field predictions but, more importantly, by orders of magnitude from one another. We attribute this to dynamical clustering effects in the uniform waiting time model, that is absent in the independent channel dynamics.

Fluctuations and Food-web Structures in Individual-based Models of Biological Coevolution

PER ARNE RIKVOLD, VOLKAN SEVIM, Florida State University — We report very long kinetic Monte Carlo simulations of eco- systems generated by individual-based models of biological co-evolution, emphasizing the temporal fluctuations in community structure, diversity, and population sizes [1-3]. These multispecies coevolution models contain both producers that directly utilize an external resource, and consumers that must consume one or more other species for support. Time series of diversities and population sizes over tens of millions of generations display highly correlated fluctuations that give rise to power spectra of 1/f form. These model-intrinsic dynamic features correspond to large, correlated extinction events and similarly correlated bursts of new species, without the need for external catastrophic events. The communities generated by the evolution process take the form of simple food webs, whose species abundance distributions and degree distributions are consistent with data from real food webs.

Metabolic disease network and its implication for disease comorbidity

DEOK-SUN LEE, Northeastern University, ZOLTAN OLTVAI, University of Pittsburgh, NICHOLAS CHRISTAKIS, Harvard Medical School, ALBERT-LASZLO BARADASI, Northeastern University — Given that most diseases are the result of the breakdown of some cellular processes, a key aim of modern medicine is to establish the relationship between disease phenotypes and the various disruptions in the underlying cellular networks. Here we show that the current understanding of the structure of the human metabolic network can provide insight into potential relationships among often distinct disease phenotypes. Using the known enzyme-disease associations, we construct a human metabolic disease network in which nodes are diseases and two diseases are linked if the enzymes associated with them catalyze adjacent metabolic reactions. We find that the more connected a disease is, the higher is its prevalence and the chance that it is associated with a high mortality. The results indicate that the cellular network-level relationships between metabolic pathways and the associated disease provide insights into disease comorbidity, with potential important consequences on disease diagnosis and prevention.
8:48AM P39.00005 The Human Phenotypic Disease Network, CESAR HIDALGO, Center for Complex Network Research, Dept of Physics, University of Notre Dame, NICHOLAS BLUMM, Center for Network Science, Dept of Computer Science, Northeastern University, ALBERT-LASZLO BARABASI, Center for Network Science, Dept of Physics, Biology and Computer Science, Northeastern University, NICHOLAS CHRISTAKIS, Dept of Health Care Policy, Harvard Medical School — We study the evolution of patient illness using a network summarizing the disease associations extracted from 32 million Medicare claims recorded from 13 million elders using the ICD9-CM format. We find that the evolution of patients’ illness is accurately described by a process in which once a patient develops a particular disease, subsequent disease are seen to occur among diseases lying close by in the network. In addition, we find that patients affected with diseases with high network connectivity are more likely to die during a follow-up period of eight years.

9:00AM P39.00006 Bilateral interactions in disease dynamics - Decreasing epidemic thresholds with facilitated contact rates, ALEJANDRO MORALES GALLARDO, MPI-DS, Gottingen, DIRK BROCKMANN, Northwestern University, Evanston, THEO GEISEL, University of Gottingen, MPI-DS, Gottingen — Compartmental epidemiological models are very successful modeling paradigms in epidemiology. Typically, they are employed for quantitative assessments of key parameters such as the basic reproduction number $R_0$. These models rest on two key assumptions: 1.) a population is well mixed 2.) transmission is triggered by a population averaged contact rate. However, experimental evidence shows that contact rates vary substantially, and it has been hypothesized that this variability can change the dynamics of population relevant disease dynamics. However, for inhomogeneous populations the translation of distributed contact rates into effective disease transmission events is non-trivial. Transmission may either depend only on the contact rate of the transmitting individual alone (unilateral transmission), or on the contact rates of transmitting and receiving individual (bilateral transmission). In the SIS model we show that in either systems the endemic state of a disease can be stable for values of $R_0 < 1$ unlike homogeneous systems with a critical value $R_0 = 1$. Furthermore, bilateral contact dynamics entail parameter regimes in which a stable endemic state can cease to exist if the mean contact rate is increased, an unexpected effect absent in homogeneous populations.

9:12AM P39.00007 Single species victory in a two-site, two-species model of population dispersion, JACK WADDELL, Department of Computer Science, University of Michigan, Ann Arbor, Michigan 48109-1043, LEN SANDER, Department of Physics, University of Michigan, Ann Arbor, Michigan 48109-1120, DAVID KESSLER, Department of Physics, Bar-Ilan University, Ramat-Gan ILS9200, Israel — We study the behavior of two species, differentiated only by their dispersal rates in an environment providing heterogeneous growth rates. Previous deterministic studies have shown that the slower-dispersal species always drives the faster species to extinction, while stochastic studies show that the opposite case can occur given small enough population and spatial heterogeneity. Other models of similar systems demonstrate the existence of an optimum dispersal rate, suggesting that distinguishing the species as faster or slower is insufficient. We here study the interface of these models for a small spatial system and determine the conditions of stability for a single species outcome.

9:24AM P39.00008 Color Triads in Complex Networks: Uncovering Racial Segregation Patterns in US High Schools, JULIAN CANDIA, MARTA GONZALEZ, Northeastern University — Introducing color subgraph analysis as a novel tool for characterizing complex network structures, we identify the basic racial patterns in a nationally representative sample of all public and private High Schools in the US. We apply this method on color triad subgraphs and obtain quantitative measurements on racial homophily effects, as well as on inter racial mixing patterns. Strongest homophily phenomena are observed within the white student population, followed in decreasing order by black, hispanic and asian students. Racial reciprocity measurements reveal that white students tend to form triads in which they constitute a racial majority. Black-hispanic triads are also observed to be non-reciprocal, while black-asian and hispanic-asian triads show a stronger tendency towards symmetric ties. Racial preference measurements show a rather weak white-black affinity. Since both white and black triad majorities prefer a hispanic third party, hispanic students may play the role of a bridge between white and black students. In order to design better integration strategies, quantitative observations on homophily and interracial mixing patterns could be used to redefine school organizational features. Moreover, the color subgraph analysis method can be applied to a large variety of complex network systems on other interdisciplinary fields of science.

9:36AM P39.00009 A Bayesian approach to network modularity, JAKE HOFMAN, Columbia University, Department of Physics, CHRIS WIGGINS, Columbia University, Department of Applied Mathematics and Applied Physics — We present an efficient, principled, and interpretable technique for inferring module assignments and identifying the optimal number of modules in a given network. Our approach is based on a probabilistic network model equivalent to an infinite-range spin-glass Potts model on the irregular lattice defined by a given network; the problem of identifying modules is then tantamount to inferring distributions over both the module assignments (i.e. spin states) and the model parameters (i.e. coupling constants) while also identifying the number of modules (i.e. number of occupied spin states) in the network. Using a variational approximation we derive a mean-field free energy, the minimization of which provides controlled approximations to the distributions of interest. We show how several existing methods for finding modules can be described as variant, special, or limiting cases of our work, and how related methods for complexity control — identification of the true number of modules — are outperformed. We apply the technique to synthetic and real networks and outline how the method naturally allows selection among competing network models.

9:48AM P39.00010 Distribution of Node Characteristics in Complex Networks, JULYONG PARK, A.-L. BARABASI, Northeastern University — Our enhanced ability to map the structure of various complex networks is accompanied by the capability to independently identify the functional characteristics of each node, leading to the observation that nodes with similar characteristics show tendencies to link to each other. Examples can be easily found in biological, technological, and social networks. Here we propose a tool to quantify the interplay between node properties and the structure of the underlying network. We show that when nodes in a network belong to two distinct classes, two independent parameters are needed. We find that the network structure limits the values of these parameters, requiring a phase diagram to uniquely characterize the configurations available to the system. The phase diagram shows independence from the network size, a finding that allows us to estimate its shape for large networks.

10:00AM P39.00011 The Modular Structure of Protein Networks, HERNAN D. ROZENFELD, DIEGO RYBSKI, Levich Institute, City College of New York, New York 10031, USA, SHLOMO HAVLIN, Minerva Center and Department of Physics, Bar-Ilan University, 52900 Ramat-Gan, Israel, HERNAN A. MAKSE, Levich Institute, City College of New York, New York 10031, USA — The evolution of the human protein homology network (H-PHN) has led to a complex network that exhibits a surprisingly high level of modularity. Topologically, the H-PHN presents well connected groups (conformed by proteins of similar aminoacid structure) and weak connectivities between the groups. Here, we perform an empirical study of the H-PHN to characterize the degree of modularity in terms of scale-invariant laws using recently introduced box covering algorithms. We find that the exponent that gives insight into the evolutionary process that led to the modular organization and dynamics of the present H-PHN.
10:12AM P39.00012 Synchronization behavior in linear arrays of negative differential resistance circuit elements, HUIDONG XU, STEPHEN TEITSWORTH, Duke University — We study the electronic transport properties in a linear array of nonlinear circuit elements that exhibit negative differential resistance, and find that state-cluster synchronization emerges when there is heterogeneity in the element properties. This type of synchronization is associated with a non-uniform spatial distribution of total applied voltage across the array elements, as well as the formation of multiple stable branches in computed current-voltage curves for the entire array. Unlike most synchronizing systems studied previously [1], this system possesses coupling between elements that displays both positive and negative feedback depending on the state of each element. An empirical order parameter is defined which quantifies the degree of synchronization. We also find that the degree of synchronization is strongly dependent on the ramping rate of the total applied voltage to the array, with complete synchronization observed in the limit of small ramping rate. This model provides a basis for describing related nonlinear phenomena in more complex electronic structures such as semiconductor superlattices [2]. [1] A. Pikovsky, M. Rosenbaum, and Jürgen Kurths, Synchronization: a universal concept in nonlinear sciences (Cambridge University Press, Cambridge, 2001). [2] M. Rogozia, S. W. Teitsworth, H. T Grahn, and K. H. Ploog, Phys. Rev. B65, 205303 (2002).

10:24AM P39.00013 Hierarchical, 4-connected Small-World Graph1, BRUNO GONCALVES, STEFAN BOETTCHER, Emory University — A new sequences of graphs are introduced that mimic small-world properties. The graphs are recursively constructed but retain a fixed, regular degree. They consist of a one-dimensional lattice backbone overlaid by a hierarchical sequence of long-distance links in a pattern reminiscent of the tower-of-hanoi sequence. These 4-regular graphs are non-planar, have a diameter growing as $2\sqrt{\ln N}$ or as $(\log N)^\alpha$ with $\alpha \sim (\log_2 N + \log_2 \log_2 N^2)$, and a nontrivial phase transition $T_c > 0$, for the Ising ferromagnet. These results suggest that these graphs are similar to small-world graphs with mean-field-like properties.

10:36AM P39.00014 Exact Renormalization of Super-Diffusion on the Tower-of-Hanoi Network, STEFAN BOETTCHER1, BRUNO GONCALVES2, Physics Department, Emory University — We propose the Tower-of-Hanoi network as a hierarchical, small-world network possessing both, geometric and long-range links. Modeling diffusion via a random walk on this network provides a mean-square displacement $\sqrt{\ln(2)} = 1.30576$. Here, $\phi = (1 + \sqrt{5})/2$ is the “golden ratio” that is intimately related to Fibonacci sequences. This may be the first solvable model with super-diffusion for any fractal structure. This appears to be also the first known instance of any physical exponent containing $\phi$. It originates from an unusual renormalization group fixed point with a subtle boundary layer. The connection between network geometry and the emergence of $\phi$ in this context is still elusive.

10:48AM P39.00015 Scaling behavior of the non-affine deformation of random fiber networks, HAMED HATAMI-MARBINI, CATALIN PICU, Rensselaer Polytechnic Institute — Random fiber networks exhibit non-affine deformation on multiple scales. This controls to a large extent their “homogenized” behavior on the macroscopic (system level) scale. It is currently believed that denser networks and networks in which the fibers have vanishing bending stiffness deform affinely. Here we show that these conclusions depend on the nature of the measure used to probe the non-affine. If a strain based measure is used, it can be shown that all networks, irrespective of the axial or bending behavior of their fibers are non-affine. Furthermore, the non-affinity decreases with the observation scale, exhibiting a universal power law scaling. The behavior of dense and sparse networks is shown to be similar if a scale renormalization is applied.

Wednesday, March 12, 2008 8:00AM - 10:48AM —
Session P40 DCMP: Surface Effects, Thermodynamics and Fabrication Morial Convention Center 232

8:00AM P40.00001 Surface core-level shifts and atomic coordination at the W(320) surface, XUBING ZHOU, J.L. ERSKINE, Department of Physics, University of Texas at Austin, O. KIZILKAYA, Center for Advanced Microstructures and Devices — High resolution 4f core-level photoemission spectra are reported from the W(110) and from the related vicinal W(320) surfaces. Curve fittings of the spectra permit tests of core-level binding-energy shift models that relate local atomic coordination to binding –energy differences associated with (for example) terrace and step-edge atoms. A well-resolved shoulder on the W(320) surface peak is attributed to step-edge atoms and contributions from surface atoms having higher atomic coordination are obtained from the curve-fitting exercises. The results are discussed in relation to prior core-level measurements, tight-binding models, and ab-initio calculations of core-level shifts for W(320).

10:12AM P40.00002 Secondary electron spectra of Au and Cu under bombardment by very low energy positrons, S. MUKHERJEE, A.H. WEISS, M.P. NADESLINGAM, U. Texas at Arlington, P. GUAGLIARDO, A. SERGEANT, J. WILLIAMS, U. Western Australia — Measurements of the secondary electron energy spectra resulting from very low energy positron bombardment of a polycrystalline Au and Cu (100) surfaces are presented. The low energy part of the secondary spectra contain significant contributions from two processes: 1. annihilation induced Auger electrons that have lost energy before leaving the surface and 2. secondary electrons resulting from direct energy exchange with an incident positron. Our data indicate that the second process (direct energy exchange with the primary positron) is still important at and below 3 eV incident beam energy. Since energy conservation precludes secondary electron generation below an incident beam energy equal to the difference between the electron and positron work functions (~3eV), the fact that we still observe significant secondary electron emission at energies at or below this value provides strong evidence that the incident positrons are falling directly into the surface state and transferring all of the energy difference to an outgoing secondary electron.

8:24AM P40.00003 Fermi-liquid effects in propagation of low frequency electromagnetic waves through thin metal films\(^1\). NATALYA ZIMBOVSKAYA, GRIGORY ZIMBOSKIY, University of Puerto Rico-Humacao — In the present work we theoretically analyze the contribution from a transverse Fermi-liquid collective mode to the transmission of electromagnetic waves through a thin film of a clean metal in the presence of a strong external magnetic field. We show that at the appropriate Fermi surface geometry the transverse Fermi-liquid wave may appear in conduction electrons liquid at frequencies \( \omega \) significantly smaller than the cyclotron frequency of charge carriers \( \Omega \) provided that the mean collision frequency \( \tau^{-1} \) is smaller than \( \omega \). Also, we show that in realistic metals size oscillations in the transmission coefficient associated with the Fermi-liquid mode may be observable in experiments. Under certain conditions these oscillations may predominate over the remaining size effects in the transmission coefficient.

8:36AM P40.00004 Ground-state structure of the hydrogen double vacancy on Pd(111). SUNGHO KIM, SEONG-GON KIM, Mississippi State University, STEVEN ERWIN, Naval Research Laboratory — We determine the ground-state structure of a double vacancy in a hydrogen monolayer on the Pd(111) surface. We represent the double vacancy as a triple vacancy containing one additional hydrogen atom. The potential-energy surface for a hydrogen atom moving in the triple vacancy is obtained by density-functional theory, and the wave function of the fully quantum hydrogen atom is obtained by solving the Schrödinger equation. We find that an H atom in a divacancy defect experiences significant quantum effects, and that the ground-state wave function is centered at the hcp site rather than the fcc site normally occupied by H atoms on Pd(111). Our results agree well with scanning tunneling microscopy images.

8:48AM P40.00005 Band Mapping in Higher-Energy X-Ray Photoemission: Phonon Effects and Comparison to One-Step Theory. JAN MINAR and Comparison to One-Step Theory. JAN MINAR, Ludwig Maximilian University, Munich, LUKASZ PLUCINSKI, IFF-9, Research Center Juelich, BRIAN SELL, Otterbein College, Westerville, Ohio, JUERGEN BRAUN, Hildesheim University, HUBERT EBERT, Ludwig Maximilian University, Munich, CLAUS SCHNEIDER, IFF-9, Juelich Research Center, CHARLES FADLEY, UC Davis and LBNL. Mat. Sc. Div. — In view of the present interest in more bulk sensitive band mapping via x-ray photoemission, we have studied the temperature dependence of W(110) angle-resolved spectra excited at photon energies of 260, 870 eV, and 1254 eV and between 300K and 780K. Experimental results are compared to both a free-electron final-state model and theoretical one-step model calculations. At 300K, clear band dispersions can be observed in the data. The ratio between direct and non-direct transitions is approximately estimated from a Debye-Waller factor. One-step theoretical calculations reproduce well band dispersions and matrix element effects in the measured spectra at room temperature, but including phonon effects via complex phase shifts does not predict density-of-states related features observed in higher-temperature spectra. We will also discuss the implications of this work for future experiments on other materials and at even higher photon energies up to 10 keV.

9:00AM P40.00006 Electronic Gr"uneisen Parameter In Paramagnetic Nickel\(^1\). SHOUHUA NIE, XUAN WANG, JUNJIE LI, RICHARD CLINITE, MARK WARTENBE, JIANMING CAO, Physics Department and National High Magnetic Field Laboratory, Florida State University — We have conducted the first measurement of electronic Gr"uneisen parameter \(\gamma_e\) in the paramagnetic state of ferromagnetic transition metal nickel by monitoring the laser-induced ultrafast stress dynamics using femtosecond electron diffraction. This method overcomes the restriction of traditional low-temperature methods and offers a unique path to study electronic thermal expansion in magnetic metals. Our measurement indicates that the local magnetic moment that persists in the paramagnetic state of nickel does not contribute significantly to electronic thermal expansion. This result would serve as an important test of current models regarding the magnetism in ferromagnetic transition metals.

9:12AM P40.00007 Generalized Surface Thermodynamics of Solids with Application to Nucleation\(^1\). ROBERT CAMMARATA, Johns Hopkins University — J.W. Gibbs formulated a general thermodynamics for surfaces in multicomponent fluid systems. For the case of solid-fluid surfaces, he restricted attention to single component solids. Attempts to generalize Gibbs’ results for surfaces between multicomponent solids and fluids are problematic owing to the difficulty that the surface chemical potentials in the solid are generally not well defined, and therefore any expressions involving these chemical potentials will also not be well defined. A formulation of a general surface thermodynamics that can take into account capillary effects in systems involving interfaces between multicomponent solids and fluids while avoiding the aforementioned difficulties will be discussed that utilizes the concept of thermodynamic availability. It will be shown how this approach allows Gibbs-Thomson effects for finite size solids, an adsorption equation for a solid surface, and the thermodynamics of nucleation during solidification to be treated in a straightforward manner that avoids all references to ill defined surface quantities. In particular, a derivation will be presented that is the first to properly generalize Gibbs’ analysis for the reversible work of nucleation to the case of solidification.

9:24AM P40.00008 Controlling precipitate growth in aluminum rich alloys via externally applied stress\(^1\). JACK FRANKLIN, JENNIFER LUKES, University of Pennsylvania — The material properties of metallic alloys are directly influenced by their microstructure. The final microstructure of bulk specimens is currently determined through specific heat treatments designed to control the homogenous precipitation of secondary phases from a saturated matrix. This talk will introduce a novel stress-based method of controlling the precipitation and directed growth of secondary phases to create desired microstructures on the surface of an aluminum-copper alloy. Microstructures obtained under different stress conditions will be presented and the mechanisms leading to their formation will be discussed.

9:36AM P40.00009 Bulk nanostructured alloys by large strain extrusion machining. WILFREDO MOSCOSO, CHRISTOPHER SALDANA, JON MADARIAGA, Purdue University, RAVI SHANKAR, University of Pittsburgh, SRINIVASAN CHANDRASEKAR, DALE COMPTON, Purdue University — Large strain extrusion machining (LESM) is presented as a method of severe plastic deformation for the creation of bulk nanostructured materials in a wide range of metal alloys. This method combines inherent advantages afforded by large strain deformation in chip formation by machining, with simultaneous dimensional control of extrusion in a single step of deformation. Bulk nanostructured materials in the form of foils, plates, and bars of controlled dimensions are shown to result by appropriately controlling the geometric parameters of the deformation in large strain extrusion machining.
9:48AM P40.00010 Engineering materials-design parameters of the Mg-Li Alloy System from ab initio calculations, WILLIAM COUNTS, MARTIN FRIAK, DIERK RAABE, JORG NEUGEBAUER, Max-Planck Institute for Iron Research — Ab initio calculations are becoming increasingly useful to engineers interested in designing new alloys because these calculations are able to accurately predict basic material properties only knowing the atomic composition of the material. Fundamental physical properties (like formation energy and elastic constants) of 11 bcc magnesium-lithium alloys were calculated using density-functional theory (DFT) and compared with available experimental data. These DFT determined properties were in turn used to calculate engineering properties like the bulk modulus/shear modulus (B/G) and Young’s modulus/density (E/ρ). From these engineering parameters, alloys with optimal mechanical properties need for a light weight structural material were identified. It was found that the stiffest bcc magnesium-lithium alloys contain about 70 at.% magnesium while the most ductile alloys have 0-20 at.% magnesium. In addition, the specific modulus for alloys with 70 at.% magnesium was found to be equal to that of aluminum-magnesium alloys and slightly lower than that of aluminum-lithium alloys.

10:00AM P40.00011 Testing the MacPherson-Srolovitz Theory in Simulations of 3D Grain Growth, ANTHONY ROLLETT, FATMA UYAR, SETH WILSON, JASON GRUBER, SUKBIN LEE, Carnegie Mellon University — The theory by MacPherson and Srolovitz provides an exact prediction of the growth rate of individual cells or grains in a space-filling network (microstructure). Testing the predictions of the theory requires measurement of mean width and edge lengths where three cells meet at triple line junctions. This is most easily accomplished in networks that are discretized with a mesh. A Moving Finite Element (MFE) model was used to simulate the evolution (growth) over short times of a network discretized on a tetrahedral mesh and growth rates. Volumes, mean widths and edge lengths were measured. The growth rates measured from the simulation were found to be in very good agreement with the predictions of the MacPherson-Srolovitz theory. The results from similar measurements in Monte Carlo and Phase Field models of grain growth will also be reported. In this case, measurement of mean width and edge length is complicated by use of a regular grid to discretize the network on a set of points or voxels. A modified algorithm by Ohser and Mücklich is used to measure mean width. Edge length measurement along triple lines requires conversion of the voxel image to a surface mesh.

10:12AM P40.00012 Phase-field Simulation for Analyzing Time Evolution of Grains of Precipitate in Phase Decomposition Processes of Magnetic Alloys, YOSHIHARU KANEGAI, Mechanical Engineering Research Laboratory, Hitachi, Ltd. — The time evolution of the average grain size and the number of grains of precipitate in phase decomposition processes of magnetic alloys in two-dimensional systems was investigated using phase-field simulation. Specifically, the phase decomposition processes of Fe-Cu and Fe-Cr systems were studied. Chemical free energy from a thermodynamic database of phase diagrams was used and magnetic contribution was considered. In appropriate compositions, these systems show spinodal decomposition followed by Ostwald ripening. In the long-time region of these processes, the time evolution of the average grain size and the number of grains of precipitate was evaluated by the power of time. The exponent of the power of time of the average grain size was $\alpha \sim 1/3$, consistent with the Lifshitz-Slyozov-Wagner theory. On the other hand, that of the number of grains $\beta$ was $\beta \sim 2/3$, inconsistent with the theory, which predicts $\beta \sim 1$. However, it was shown that in two-dimensional systems these results are reasonable.

10:24AM P40.00013 Modeling Digestive and Ostwald Ripening of Nanocrystals, MICHAEL TAMBASHCO, Columbia University, SANAT KUMAR — Ostwald and digestive ripening are two diametrically opposite phenomena that dramatically impact nanocrystal polydispersity. Ostwald ripening allows for large nanocrystals to grow at the expense of small ones, while digestive ripening involves the propulsion of small nanocrystals. Chemical free energy from a thermodynamic database of phase diagrams was used and magnetic contribution was considered. Chemical free energy from a thermodynamic database of phase diagrams was used and magnetic contribution was considered. In appropriate compositions, these systems show spinodal decomposition followed by Ostwald ripening. In the long-time region of these processes, the time evolution of the average grain size and the number of grains of precipitate was evaluated by the power of time. The exponent of the power of time of the average grain size $\alpha$ was $\alpha \sim 1/3$, consistent with the Lifshitz-Slyozov-Wagner theory. On the other hand, that of the number of grains $\beta$ was $\beta \sim 2/3$, inconsistent with the theory, which predicts $\beta \sim 1$. However, it was shown that in two-dimensional systems these results are reasonable.

10:36AM P40.00014 Mean-field Theory of Multicomponent Phase Coarsening, KE-GANG WANG, Department of Physics and Space Sciences, Florida Institute of Technology — Study of phase coarsening in multicomponent systems is rare. Morral and Purdy developed a general theoretical frame for phase coarsening in n-component alloys. However, all work considered only the effect of solution thermodynamics, and ignored the kinetic effect from non-zero volume fraction. Therefore, all studies are valid only in the case of vanishing volume fraction. When $V_{f}$ is not zero, the interactions among precipitates exist. The diffusion screening length is used to describe these interactions, and it is found that the growth rate of particle depends on the volume fraction through diffusion screening length. A mean-field theory of multicomponent phase coarsening will be presented, which includes effects of both multicomponent thermodynamics and kinetics from nonzero volume fraction.

Wednesday, March 12, 2008 11:15AM - 1:39PM — Session Q1 DCMP: Ballistic Charge and Spin Transport in Graphene Morial Convention Center LaLouisiane AB

11:15AM Q1.00001 Electronic spin transport and spin precession in single graphene layers at room temperature, BART VAN WEES, University of Groningen — I will give a review of our experiments on spin injection, spin transport and spin precession in field effect transistors based on single graphene layers. We have employed a four terminal non-local measurement technique which allows us to fully separate the electronic charge and spin circuits. One pair of ferromagnetic electrodes is used as spin injectors, the other pair as spin detectors. By using different widths for the ferromagnetic electrodes we are able to control the coercive fields and prepare the magnetization direction of each with an applied magnetic field (in positive or negative x-direction). We observe clear signals due to spin diffusion from injector to detector electrodes. From the dependence of the spin signals on electrode spacing we obtain a spin relaxation length of 1.5 to 2 micrometer, and a corresponding spin relaxation time of about 100 ps [1]. These measurements are confirmed by Hanle-type spin precession measurements where the injected spins precess around a magnetic field applied perpendicular to the graphene plane. The spin signals only weakly depend on temperature (between 4.2 K and 300K), and also change little when the gate voltage is tuned from the metallic electron/hole regimes to the Dirac neutrality point. Recent experiments show that the spin relaxation times/lengths are similar for spin directions pointing in the graphene plane and perpendicular to the graphene plane [2]. Also the presence of an Al$_2$O$_3$ layer on top of the graphene does not significantly change the spin relaxation length and time. I will discuss these results in the light of existing theories for spin-orbit interaction in graphene. The implications for graphene spintronics and graphene qubits will be discussed.

11:15AM Q1.00002 Phase coherent transport in graphene, ALBERTO MORPURGO, Delft University — The investigation of transport phenomena originating from quantum interference of electronic waves has proven to be a very effective probe of the electronic properties of conducting materials. Recent work has shown that this is also the case for graphene, a novel material consisting of an individual layer of carbon atoms, in which the electronic dynamics is governed by the Dirac equation. After introducing the peculiar aspect of the low-energy electronic properties of graphene that are important to understand quantum interference in this material, I will present our experimental work. I will first discuss our study of Aharonov-Bohm conductance interference in single- and bi-layer graphene devices, we show that the minimum conductivity value is geometry dependent and approaches the theoretical value of $4e^2/h$ only for wide and short graphene strips. Moreover, we observe periodic conductance oscillations with bias and gate voltages, arising from quantum interference of multiply-reflected waves of charges in graphene. When graphene is coupled to superconducting electrodes, we observe gate tunable supercurrent and sub-gap structures, which originate from multiple Andreev reflection at the graphene-superconductor interfaces. Our results demonstrate that graphene can act as a quantum billiard with a long phase coherence length. *This work was supported in part by DOD/DMEA-H94003-06-2-0608.*

1:03PM Q1.00004 Ballistic Transport in Graphene,1 MIKHAIL TITOV, Heriot-Watt University, Edinburgh — Charge transport in ballistic graphene-based microstructures is described within the scattering formalism, which takes into account evanescent modes induced by metallic contacts. We discuss in detail new theoretical predictions for the charge transport and shot noise in the models which include local potential inhomogeneities, next to the nearest neighbor coupling, or ripples in the graphene plane.

1 Support from the School of Engineering and Physical Sciences at Heriot-Watt University is gratefully acknowledged.

**Wednesday, March 12, 2008 11:15AM - 2:15PM**

Session Q2 DBP DMP: The Physics of Self-Assembled Protein Cages

LaLouisiane C

11:15AM Q2.00001 Packaging of Polyelectrolytes in Viral Capsids: The Interplay Between Polymer Length and Capsid Size1, CHARLES KNOBLER, UCLA, Dept. of Chemistry and Biochemistry — Each particle of the Cowpea Chlorotic Mottle Virus (CCMV) has a very small “parts list,” consisting of two components: a molecule of single-stranded RNA and a 190-residue protein that makes up the 28-nm diameter capsid. When purified viral RNA and capsid protein are mixed in solution at an appropriate pH and ionic strength, infectious wild-type viruses form spontaneously. Virus-like particles (VLPs) are formed when the protein self-assembles around other anionic polymers such as poly(styrene sulfonate) (PSS). Under different pH and ionic strength conditions the capsid protein can assemble by itself into empty capsids, multishell structures, tubes and sheets. To explore the effect on virion size of the competition between the preferred curvature of the protein and the size of the packaged cargo we have examined the formation of VLPs around PSS polymers with molecular weights ranging from 400 kDa to 3.4 MDa. Two distinct sizes are observed — 22 nm for the lower molecular weights, jumping to 27 nm at 2 MDa. While under given conditions the size of PSS in solution is directly determined by its molecular weight, the self-complementarity of RNA makes its solution structure dependent on the nucleotide sequence as well. We have therefore employed Small-Angle X-ray Scattering and Fluorescence Correlation Spectroscopy to examine the sizes of viral and non-viral RNAs of identical lengths. A model for the assembly that includes both the inter-self interactions of the polyelectrolyte and the capsid proteins and the interactions between them provides insight into the experimental results.

1 This work was supported by National Science Foundation Grant CHE-0400363

11:51AM Q2.00002 Diversity in virus assembly: biology makes things complicated, ADAM ZLOT-NICK, Biochemistry & Molecular Biology, OUHSC — Icosahedral viruses have an elegance of geometry that implies a general path of assembly. However, structure alone provides insufficient information. Cowpea Chlorotic Mottle Virus (CCMV), an important system for studying virus assembly, consists of 90 coat protein (CP) homodimers condensed around an RNA genome. The crystal structure (Speir et al, 1995) reveals that assembly causes burial of hydrophobic surface and formation of $\beta$ hexamers, the intertwining of N-termini of the CPs surrounding a quasi-sixfold. This structural view leads to reasonable and erroneous predictions: (i) CCMV capsids are extremely stable, and (ii) $\beta$ hexamer formation is critical to assembly. Experimentally, we have found that capsids are based on a network of extremely weak (4-5 kT) pairwise interactions and that pentamer formation is the critical step in assembly kinetics. Because of the fragility of CP-Cp interaction, we can redirect assembly to generate and dissociate tubular nanostructures. The dynamic behavior of CCMV reflects the requirements and peculiarities of an evolved biological system; it does not necessarily reflect the behavior predicted from a more static picture of the virus.

12:27PM Q2.00003 Dynamic Models for Templated Viral Capsid Assembly, MICHAEL HAGAN, Physics Department, Brandeis University — The replication of many viruses with single-stranded genomes requires the simultaneous assembly of an ordered protein shell, or capsid, and encapsidation of the genome. In this talk, I will present coarse-grained computational and theoretical models that describe the assembly of viral capsid proteins around interior cores, such as polymers and rigid spheres. These models are motivated by two recently developed experimental model systems in which viral proteins dynamically encapsidate inorganic nanoparticles and polyelectrolytes. Model predictions suggest that some forms of cooperative interactions between subunits and cores can dramatically enhance rates and robustness of assembly, as compared to the spontaneous assembly of subunits into empty capsids. For large core-subunit interactions, subunits adsorb onto a core en masse in a disordered manner, and then undergo a cooperative rearrangement into an ordered capsid structure. These assembly pathways are unlike any seen for empty capsids formation. While model predictions suggest that cooperative interactions between disparate assembling components can overcome some limitations of spontaneous assembly, the complexity of multicomponent assembly introduces new forms of kinetic traps that can frustrate assembly, and hence introduces new limitations. These findings have implications for a mechanism in which viruses use interactions between proteins and genomic molecules to promote and control assembly, and thereby control the replication process.

1:03PM Q2.00004 Self-Assembly of the HIV Virus, ROBINN BRUINSMA, University of California, Los Angeles — The talk will discuss the application of the continuum theory of elastic shells to understand the different morphologies of Retroviral capsids. Minor differences in molecular structure between different capsid proteins produce large changes in capsid morphology. Continuum elasticity theory can account for the capsid shape “phase-diagram.” The conical shape of the capsid of the HIV virus is the result of assembly “constraints” in the form of the enclosing lipid bilayer and the osmotic pressure of the encapsidated genome molecules.
11:15AM Q3.00001 Quasielastic scattering – theory and experiment hand in hand, JULIA HIGGINS, Imperial College, London — In his early career de Gennes worked with colleagues at the CEA Saclay and was familiar with the new possibilities offered for studying materials using neutron scattering techniques. He published a number of papers in this field, two of the most influential being in the field of polymer dynamics where he developed theoretical descriptions of quasi-elastic scattering from single polymer chains in solution. The first results were based on the Rouse model of a polymer chain with no dynamic interaction with the solvent. The second paper appearing a few years later extended the theory to take account of hydrodynamic interactions with the solvent (the so-called Zimm model). These papers appeared at the time when high resolution quasi-elastic scattering techniques were being developed at a number of neutron sources and were influential in driving some of the first experimental investigations of polymer dynamics using neutrons. As dynamic light scattering developed, particularly from large biological molecules the theory was also applied here. The subsequent development of the reptation model for polymer molecules in the dense phase, and the publication by de Gennes of the scattering law expected from a reptating chain also coincided with developments in experimental techniques, in particular the neutron spin-echo technique. This technique allowed the scattering from single polymer molecules in dense phases to be observed and provided some of the first direct experimental tests of the reptation model. Quasielastic scattering and particularly neutron spin-echo techniques have been continually developing in subsequent decades, and both local side group dynamics and main chain motion have been investigated in detail, as well as collective motions in these glass forming materials. Interpretation of the data has been considerably advanced by the parallel development of modelling, particularly molecular dynamic simulations. New neutron sources with even higher fluxes currently being commissioned include QENS in their portfolio of instruments so that we can anticipate further experimental investigation of polymer dynamics, to compare to ever more sophisticated modelling.

11:51AM Q3.00002 The Coil-Stretch Transition after more than 30 years, ERIC SHAQFEH, Stanford University — From the seminal paper of DeGennes (1974), there has been a long debate over the nature of polymer dynamics surrounding the “critical point” in flow strength where local fluid line extension rates (and the resulting drag created on a linear polymer) dominate over the entropic restoring force – the so-called coil-stretch transition. This debate has now essentially ended as a result of recent single molecule experiments and large scale molecular simulations which demonstrate that, for steady extensional flow, the basic tenets DeGennes put forth were correct, albeit with certain details which DeGennes did not foresee. However, for flows which are either not steady or which contain significant vorticity, there are qualitatively different features which have now been suggested and remain essential to understand. For example, molecular simulations of planar mixed flows demonstrate that conformational fluctuations play a key role in the coil-stretch transition especially for flows that are “near shear”. Finally, the application of the DeGennes’ ideas to turbulent drag reduction are far from clear, and new large scale molecular simulations have shed some light on polymer dynamics in this important application.

12:27PM Q3.00003 Dynamics of Polymer Solutions, WILLIAM GRAESSLEY, Princeton University — No abstract available.

1:03PM Q3.00004 Dynamics of Entangled Polymers, MICHAEL RUBINSTEIN. University of North Carolina — The effect of entanglements on polymer dynamics is one of the most interesting and most challenging areas of polymer physics. In 1967 Edwards introduced the confining tube model for polymer networks in which the effect of permanent entanglements from surrounding chains on a given one was replaced by the confining tube potential. In 1971 de Gennes proposed reptation model, suggesting that entangled chains diffuse along their confining tubes. This ingenious idea provided a simple explanation for strong molecular weight dependence of relaxation time and self-diffusion coefficient of entangled linear polymers. In 1975 de Gennes put forward the concept of constraint release that takes into account modifications of the confining tube caused by the motion of surrounding chains forming this tube. In the same paper de Gennes showed that dynamics of entangled branched polymers, such as stars, is qualitatively different from that of entangled linear polymers. Branch points do not allow these molecules to reptate along their confining tubes, as linear molecules do, but instead stars can only relax and move by a highly entropically unfavorable process of arm retraction. I will describe the development and modification of ideas put forward in de Gennes’ original models of dynamics of entangled linear and branched polymers. Some details of de Gennes’ constraint release model were modified and the concept of tube dilation was introduced couple of years later. For the following quarter of century scientists are debating whether constraint release or tube dilation is the dominant mechanism for relaxation of branched and linear polymers. The shape of the entropic potential for the arm retraction mechanism of branched polymers proposed by de Gennes was modified by Doi and Kuzuu in 1980. This potential is acting along the primitive path – the axis of the confining tube, and the resulting relaxation time of the branched polymers strongly depends on the precise definition of this primitive path. Unfortunately, the primitive path is still not clearly defined by any of the existing models and scientists are still arguing which definition is better. I will describe these and other challenges and open questions remaining in the field of entangled polymer dynamics.

1:39PM Q3.00005 Interdiffusion and disentanglement of polymer brushes, JACOB KLEIN, Weizmann Institute of Science — In the spirit of this symposium, I will briefly survey some of the main ideas on interdiffusion and interfacial relaxation put forward by de Gennes, then consider some recent experimental developments. A very attractive feature of the central tenets of polymer physics introduced by de Gennes is their versatility in different physical situations, so that a discussion of, for example, friction, will in a natural way involve reptation. A particular case in point concerns the relaxation of interdiffused, compressed polymer brushes undergoing shear, as when they are used as lubricating layers. Here the useful concept is, unexpectedly, that of relaxation of entangled star-branched polymers, introduced by de Gennes over 30 years ago for a totally different purpose: The main idea – and conceptually a beautifully simple one - is that in order for an entangled chain emanating from a fixed branch point to relax, it needs to retract back along its ‘tube’ and dissipate the stress by re-equilibrating in a new configuration. Compression of two polymer brushes, whether in a good solvent or in the melt, creates a model interdiffused interface, whose dynamic properties can be analyzed based on such star-branched relaxation models, and the talk will describe some recent results on these systems.

Wednesday, March 12, 2008 11:15AM - 1:39PM – Session Q4 DCMP: Pairing Fluctuations Near the Superconductor-Insulator Transition Morial Convention Center 206
11:15AM Q4.00001 Survival of superconducting correlations across the two-dimensional superconductor-insulator transition: A finite-frequency study

N. PETER ARMITAGE, The Johns Hopkins University

The complex AC conductivity of thin amorphous InO films was studied as a function of magnetic field through the nominal 2D superconductor-insulator transition. We have resolved a significant finite frequency superfluid stiffness well into the insulating regime, giving direct evidence for superconducting correlations in this insulating state. As these superconducting fluctuations are temperature independent at low temperatures, this also represents the first observations of quantum superconducting fluctuations around an insulating ground-state. A phase diagram is established that includes the superconducting state as a transition to a “Bose” insulator and an eventual crossover to a “Fermi” insulating state at high fields. We speculate on the consequences of these observations, their impact on our understanding of the insulating state, and its relevance as a prototype for the insulating states of matter that derive from superconductors.

11:51AM Q4.00002 Theory of the Nernst effect near quantum phase transitions in condensed matter, and in dyonic black holes

MARKUS MUELLER, Harvard University

We present a general hydrodynamic theory of transport in the vicinity of superfluid-insulator transitions in two spatial dimensions described by “Lorentz-invariant” quantum critical points. We allow for a weak impurity scattering rate, a magnetic field B, and a deviation in the density, ρ, from that of the insulator. We show that the frequency-dependent thermal and electric linear response functions, including the Nernst coefficient, are fully determined by a single transport coefficient (a universal electrical conductivity), the impurity scattering rate, and a few thermodynamic state variables. With reasonable estimates for the parameters, our results predict a magnetic field and temperature dependence of the Nernst signal which resembles measurements in the cuprates, including the overall magnitude. Our theory predicts a “hydrodynamic cyclotron mode” which could be observable in ultralow samples. We also discuss exact results for the zero frequency transport coefficients of a supersymmetric conformal field theory (CFT), which is solvable by the AdS/CFT correspondence, mapping the CFT to a black hole problem in 3+1 dimensional anti-de Sitter space. These exact results are found to be in full agreement with the general predictions of our hydrodynamic analysis.

12:27PM Q4.00003 Observation of the Nernst signal generated by fluctuating Cooper pairs

KAMRAN BEHNIA, LPEM (CNRS - ESPCI), Paris — Long-range order is destroyed in a superconductor warmed above its critical temperature (Tc). However, amplitude fluctuations of the superconducting order parameter survive and lead to a number of well-established phenomena such as paraconductivity: an excess of charge conductivity due to the presence of short-lived Cooper pairs in the normal state. According to a theory by Usyukhin, Sondhi and Huse, these pairs generate a transverse thermoelectric (Nernst) signal. In two dimensions, the magnitude of the expected signal depends only on universal constants and the superconducting coherence length, so the theory can be unambiguously tested. In a dirty superconductor, the lifetime of Cooper pairs exceeds the elastic scattering time of normal electrons in a wide temperature range above Tc and, consequently, their Nernst response dominates the one generated by the normal electrons. We studied the Nernst effect of amorphous superconducting films of Nb51.5Si48.5 and resolved a Nernst signal, which persists deep inside the normal state. The amplitude of the observed signal is in excellent agreement with the theoretical prediction [1].

1:03PM Q4.00004 Nernst effect and diamagnetism in phase fluctuating superconductors

ASHVIN VISHWANATH, UC Berkeley — We investigate the characteristic signatures that arise when superconductivity is destroyed by thermal phase fluctuations induced by a dilute mixture of mobile vortices. We find that the Nernst effect and diamagnetic response differ significantly from Gaussian fluctuations — in particular, a much sharper decay with temperature is obtained. We predict a rapid onset of Nernst signal at a temperature that tracks the transition temperature Tc, rather than the pairing temperature. We also predict a close quantitative connection with diamagnetism — the ratio of magnetization to transverse thermoelectric conductivity αEL is proportional to the temperature over a wide range of fields. We interpret Nernst effect measurements on the underdoped cuprates in terms of a dilute vortex liquid over a broad temperature range above Tc [1]. We also introduce a new formalism to study fluctuating superconductivity that deals directly with the vortex variables. This technique allows us to analyze the effect of vortex properties such as core energy on Nernst effect and diamagnetism. [1] D. Podolsky, S. Raghu and A. Vishwanath, ‘Nernst Effect and Diamagnetism in Phase Fluctuating Superconductors’, Phys. Rev. Lett. 99, 117004 (2007)

Wednesday, March 12, 2008 11:15AM - 2:15PM –
Session Q5 AIP APS: Panel Discussion: How Can Industry Best Support the Innovative Research That It Needs?
Morial Convention Center R01

11:15AM Q5.00001 Leveraging R&D Resources via the Joint LLC Model

MATTHEW W. GANZ, President and CEO, HRL Laboratories, LLC — Industrial scientific research labs have become increasingly stressed in recent years by a variety of external forces. Both corporations and government funding agencies have shifted their priorities from long-term fundamental research toward projects that have a high probability of shorter-term payoff. Industrial funding has been further stressed by an increasing demand for quarterly results and fierce global competition. Industry leaders are now asking their R&D labs for “home runs and not just a solid base in the physical sciences. The end of the Cold War has also left the US without a declared enemy whose overt intention was to defeat us through a mastery of large-scale weaponry based upon exploitation of fundamental physics. This, when combined with a bona-fide need for technology gap fillers to respond to on-the-ground threats in the current Middle East conflicts, has led to diminished government emphasis on long-term research in the physical sciences. Simultaneously, the global sources of R&D spending are expanding. The dramatic growth of private equity in the technology development arena has both drawn talent from industry and changed the expectations on researchers. R&D spending in China, India and many other countries is growing significantly. Thus, in order to become relevant, industry must now keep its finger on the pulse of the hundreds of billions of dollars being invested privately and publicly around the world. HRL Laboratories, LLC in Malibu, California represents a unique and successful new business model for industrial R&D. HRL was founded by Howard Hughes in 1948 as the Hughes Research Laboratory and for more than four decades was the internal R&D lab for the Hughes Aircraft Company. After a series of mergers, acquisitions and divestitures over the past 15 years, HRL is now a stand-alone LLC that is owned jointly by General Motors and the Boeing Company. HRL, with a staff of about 300, performs R&D services for GM and Boeing as well as for government and commercial entities. The central themes to HRLs business model are innovation, value and leverage. Leveraging is key to the companies success. HRLs business model has been carefully honed to allow its parent companies to perform proprietary R&D in certain areas and joint, collaborative R&D among the LLC members in others. The intellectual property arrangements are skillfully organized so that the LLC Members receive a greater than 4:1 leverage of their research dollars in terms of the IP rights gained. This briefing will describe an overview of the current industrial research environment, HRLs business model, and challenges to future success.

11:51AM Q5.00002 The Value of Long Range R&D in the Information Technology Industry

PAUL M. HORN, Distinguished Scientist in Residence, NYU and Senior VP and Dir. of Research (retired), IBM — Examples from IBM and other IT companies will illustrate how long range physics research can be financially beneficial.
12:27PM Q5.00003 Creating Value with Long Term R&D: The life science industry. DARLENE J. S. SOLOMAN, CTO and Vice President, Agilent Technologies — Agilent Laboratories looks to the future to identify, invest and enable technologies and applications that will nurture the worlds people, environment and economies, and help ensure Agilents continuing leadership. Following a brief introduction to Agilent Technologies and Agilent Laboratories, Solomon will discuss how innovation and long-term R&D are transcending traditional boundaries. Focusing on the life sciences industry, she will discuss current trends in R&D and the importance of measurement in advancing the industry. She will describe some of the challenges that are disrupting the pharmaceutical industry where significant and sustained investment in R&D has not translated into large numbers of block-buster therapeutics. Much of this gap results from the profound complexity of biological systems. New discoveries quickly generate new questions, which in turn drive more research and necessitate new business models. Solomon will highlight examples of Agilents long-range R&D in life sciences, emphasizing the importance of physics. Shell conclude with the importance of creating sustainable value with R&D.

1:03PM Q5.00004 TBD, MARK R. PINTO, CTO and Senior VP & General Manager, Energy and Environmental Solutions, Applied Materials, Inc. — TBD

1:39PM Q5.00005 Panel Discussion: How can industry best support the innovative research that it needs? ABSTRACT APS — Four industrial physics leaders will discuss the future and value of innovative research in an industrial setting, and will share perspectives on how their companies address the challenge of supporting research operations. The speakers come from varied research settings and represent a cross-section of and scientific fields including bio-physics/life sciences, materials processing equipment, information technologies and electronics. This session includes an interactive panel discussion on overcoming the challenges and the circumstances confronting industrial R&D operations.

Wednesday, March 12, 2008 11:15AM - 2:15PM – Session Q6 GMAG: Artificial and Tunable Realizations of Spin Systems Morial Convention Center RO4

11:15AM Q6.00001 Frustration in a patterned array of nanoscale ferromagnetic islands: Artificial Spin Ice1, PETER SCHIFFER2, Dept. of Physics and Materials Research Institute, Pennsylvania State University — Geometrical frustration among spins in magnetic materials can lead to exotic low temperature states including “spin ice”, in which the local moments mimic the frustration of hydrogen ion positions in frozen water. Our group has performed extensive studies of spin ice materials, and we have developed and studied an artificial geometrically frustrated magnet which shares many of the properties of the spin ice materials. This artificial frustrated system is an array of lithographically fabricated single-domain ferromagnetic islands. The islands are arranged such that the dipolar interactions between them are analogous to those in spin ice. Images of the magnetic moments of individual elements in this correlated system allow us to study the local accommodation of frustration. We see both ice-like short range correlations and an absence of long range correlations, behavior which is very similar to the low temperature state of spin ice. We have extended these studies to include theoretical analysis of the disordered state of moments. We have also used these arrays to analyze the process of demagnetization, which is necessary to access low energy collective states in our arrays and in many other magnetic systems. Our results shed light on the nature of frustration in patterned arrays and correspondingly demonstrate that artificial frustrated magnets can provide a rich new arena in which to study the physics of frustration. References: R. F. Wang et al. (Nature 2006 and Journal of Applied Physics 2007); C. Nisoli et al. (Physical Review Letters 2007).

11:51AM Q6.00002 Artificial Kagome Spin Ice1, JOHN CUMINGS, Department of Materials Science and Engineering, University of Maryland — Recently, significant interest has emerged in fabricated systems that mimic the behavior of geometrically-frustrated materials. Here, I will present the full realization of such an artificial spin ice system on a two-dimensional kagome lattice, and I will present results obtained by directly counting individual pseudospins, demonstrating rigid adherence to the local ice rule. This adherence is maintained even when the lattice is randomized through a rigorous demagnetization process. The resulting spin configuration shows not only local ice rules and long-range disorder, but also correlations consistent with spin ice Monte Carlo calculations. Deviations in the correlation values suggest that dipolar corrections are significant in this system, as in pyrochlore spin ice. Because the pseudospins can be observed directly, the system also presents new routes for determining the entropy of such frustrated systems by direct observation, without heat-capacity background subtraction. I will also present the unique behavior of the system during magnetic reversal cycles, showing avalanche-like phenomena. Because of the simplicity of the structure and the robustness of its behavior, it serves as an ideal system for studying frustration in general, including the possible influences of controllable lattice imperfections.

12:27PM Q6.00003 Thermodynamics and dynamics of artificial square ice and related dipolar nanoarrays. GUNNAR MOLLER, University of Cambridge — Spin ice is a geometrically frustrated magnetic phase which has attracted much attention since the discovery of rare earth pyrochlores reproducing the zero-point entropy of ice found by Pauling in the 1930’s. Square ice is a two-dimensional analogue of this phase, sharing its algebraic correlations and finite entropy at zero temperature, as well as connections to exact solutions, quantum magnetism, unusual quasiparticles such as magnetic monopoles, exotic dynamics and gauge theories. Experimental realizations of two-dimensional magnetic systems could recently be achieved using lithographic fabrication techniques and local magnetic probes to detect and manipulate individual magnetic degrees of freedom [1]. We study the frustrated dipolar arrays recently manufactured by Wang et al. [1] in order to realize the square ice model in an artificial structure. In particular, we discuss models for thermodynamics and dynamics of this system [2]. We show that an ice regime can be stabilized by small changes in the array geometry; a different magnetic state, kagome ice, can similarly be constructed. At low temperatures, the square ice regime is frustrated by a thermodynamic ordering transition, which can be chosen to be ferro- or antiferromagnetic. We argue that the arrays do not fully equilibrate experimentally, and identify a likely dynamical bottleneck.

1:03PM Q6.00004 Realizing Colloidal Artificial Ice on Arrays of Optical Traps. CYNTHIA OLSON, Department, Center for the Semiconductor Physics in Nanosctructures, Fayetteville, Arkansas 72701 — Recent clever techniques for fabricating nanosize materials, one-atomic-layer-at-a-time, have simultaneously opened a door to a fantastic adventure at the frontier of physics, chemistry, biology, and engineering. Nanosize materials simply do not behave as the bulk. Indeed, the rules that govern the growth and behavior of these tiny structures are unexplored. In this talk we will discuss our recent efforts to be the architect of their shape, size, density, and position of nanostructures and along the way, the interactions between them that lead to their optical and electrical behavior. While self-assembly is providing exciting quantum dot (QD) structures to explore, like the QD molecules shown here, it is equally exciting to try to use the rules we uncover to encourage QD formation to take a desired path. Can we understand the formation of faceted nanostructures? Can we encourage or seed dot structures to form specific arrays? Is it possible to engineer greater homogeneity of dot shape and size? Can we design both the optical and electrical behavior of either individual or arrays of nanostructures to mimic those we find in nature? In this talk we will review our progress to answer these questions and discuss the possibilities and challenges ahead. For example, we will discuss the formation of individual faceted nanostructures as well as the fabrication of a vertically and laterally ordered QD stacks forming three-dimensional QD arrays. As another example, we will discuss the importance of surfaces with high Miller indices, as a template to the formation of nanostructures as well as their potential role in determining the shape and increased size uniformity of the confined structures. Importantly, these observations lead to an even more basic question of when and why high index surfaces are stable. Indeed, we have found that in order to understand the origin of high index surfaces that form nanostructures we have to study them directly.

1:39PM Q6.00005 Ultracold atomic gases in optical lattices: mimicking condensed matter and beyond. MACIEJ LIEWENSTEIN, ICFO - Institut for Photonic Sciences — I will present a short review of the newest developments of physics of ultracold atomic gases in optical lattices. After a short introduction about possibilities offered by such systems I will describe recent progress in physics of ultracold dipolar gases (generation and engineering of metastable states), ultracold disordered gases (interplay disorder-interactions, random field induced order), and ultracold gases inside an optical resonator (overlapping Mott zones). I will comment on challenging open questions concerning preparation, manipulation and detection of such systems, as well as possible applications in quantum information and precision metrology.

Wednesday, March 12, 2008 11:15AM - 2:15PM
Session Q7 FEd: Undergraduate Nanotechnology and Materials Physics Education II
Morial Convention Center R05

11:15AM Q7.00001 The Role of Engineering Design in Materials Science and Engineering Curricula. EMILY ALLEN, San Jose State University — Undergraduate materials engineering curricula diverge from materials science curricula in two important ways. An underlying requirement is to prepare the graduates for industrial positions, so they need a good grounding in processing and statistical methods, as well as a strong set of hands-on skills in materials characterization and metrology. The other distinguishing feature of an engineering education is the focus on design rather than research. In the case of materials science and engineering, the design deliverable is often a process design, a materials selection, or a failure analysis. Some of the features of education for design include the exercise of thinking about the customer's needs, functional requirements of the product, the cost of production, and the broader context of the design project in society. These ideas can be integrated or at least introduced early in the curriculum and in many different types of courses. Materials Science and Engineering programs have the dual requirement of educating both future scientists and future engineers. Graduating baccalaureate students need to be ready for engineering practice, yet many also are being readied for graduate study and research. One aspect of this ambiguity is that research and design activities are not always as clearly differentiated as they are in other engineering programs. How can one undergraduate curriculum be successful at both? One key distinguishing element in engineering practice is engineering design. Design activities occur in many aspects of the profession and may be practiced by both scientists and engineers; however it is engineering curricula, not science curricula, that tend to explicitly focus on developing the skills and methods of design practice in students. Accredited programs within colleges of engineering are required to emphasize engineering practice and design, while still providing the necessary conceptual development of the underlying science. Current practices and emerging ideas concerned with these aspects of materials education will be presented in this talk.

11:51AM Q7.00002 What Quantum Dots Can Do For You. GREGORY SALAMO, University of Arkansas, Physics Department, Center for the Semiconductor Physics in Nanosctructures, Fayetteville, Arkansas 72701 — Recent clever techniques for fabricating nanosize materials, one-atomic-layer-at-a-time, have simultaneously opened a door to a fantastic adventure at the frontier of physics, chemistry, biology, and engineering. Nanosize materials simply do not behave as the bulk. Indeed, the rules that govern the growth and behavior of these tiny structures are unexplored. In this talk we will discuss our recent efforts to be the architect of their shape, size, density, and position of nanostructures and along the way, the interactions between them that lead to their optical and electrical behavior. While self-assembly is providing exciting quantum dot (QD) structures to explore, like the QD molecules shown here, it is equally exciting to try to use the rules we uncover to encourage QD formation to take a desired path. Can we understand the formation of faceted nanostructures? Can we encourage or seed dot structures to form specific arrays? Is it possible to engineer greater homogeneity of dot shape and size? Can we design both the optical and electrical behavior of either individual or arrays of nanostructures to mimic those we find in nature? In this talk we will review our progress to answer these questions and discuss the possibilities and challenges ahead. For example, we will discuss the formation of individual faceted nanostructures as well as the fabrication of a vertically and laterally ordered QD stacks forming three-dimensional QD arrays. As another example, we will discuss the importance of surfaces with high Miller indices, as a template to the formation of nanostructures as well as their potential role in determining the shape and increased size uniformity of the confined structures. Importantly, these observations lead to an even more basic question of when and why high index surfaces are stable. Indeed, we have found that in order to understand the origin of high index surfaces that form nanostructures we have to study them directly.

12:27PM Q7.00003 An Interdisciplinary Program in Materials Science at James Madison University. CHRIS HUGHES, James Madison University — Over the past decade a core group of faculty at James Madison University has created an interdisciplinary program in materials science that provides our students with unique courses and research experiences that augment the existing, high-quality majors in physics and astronomy, chemistry and biochemistry, geology and environmental science, mathematics and statistics, and integrated science and technology. The university started this program by creating a Center for Materials Science whose budget is directly allocated by the provost. This source of funds acts as seed money for research, support for students, and a motivating factor for each of the academic units to support the participation of their faculty in the program. Courses were created at the introductory and intermediate level that are cross-listed by the departments to encourage students to enroll in them as electives toward their majors. Furthermore, the students are encouraged to participate in undergraduate research in materials since this is the most fundamental unifying theme across the disciplines. This talk will cover some of the curricular innovations that went into the design of the program to make it successful, examples of faculty and student research and how that feeds back into the classroom, and success stories of the interactions that have developed between departments because of this program. Student outcomes and future plans to improve the program will also be discussed.
1:03PM Q7.00004 Use of clickers and sustainable reform in upper-division physics courses. MICHAEL DUBSON, University of Colorado at Boulder — At the University of Colorado at Boulder, successful reforms of our freshmen and sophomore-level physics courses are now being extended to upper-division courses, including Mechanics, Math Methods, QM, E&M, and Thermal Physics. Our course reforms include clicker questions (ConcepTests) in lecture, peer instruction, and an added emphasis on conceptual understanding and qualitative reasoning on homework assignments and exams. Student feedback has been strongly positive, and I will argue that such conceptual training improves rather than dilutes, traditional, computationally-intensive and problem-solving skills. In order for these reforms to be sustainable, reform efforts must begin with department-wide consensus and agreed-upon measures of success. I will discuss the design of good clicker questions and effective incorporation into upper-level courses, including examples from materials science. Condensed matter physics, which by nature involve intelligent use of approximation, particularly lends itself to conceptual training. I will demonstrate the use of a clicker system (made by iClicker) with audience-participation questions. Come prepared to think and interact, rather than just sit there!

1:39PM Q7.00005 Thinking like a physicist: Condensed Matter and Materials Physics in the Paradigms in Physics Curriculum at Oregon State University1, JANET TATE, Oregon State University — The Paradigms in Physics Program at Oregon State University organizes the upper-division undergraduate physics curriculum to blur traditional subdisciplinary boundaries and makes use of many interactive pedagogic techniques. Condensed matter physics and materials science content appear in many places in the early curriculum, culminating in a capstone course in solid state physics where students calculate band structure of real materials related to their research projects. A mix of analytic, computational, and research approaches are employed to include, for example, traditional topics like doping in semiconductors and modern topics like carbon nanotubes.

Wednesday, March 12, 2008 11:15AM - 2:15PM – Session Q8 DFD: Colloidal Phase Behavior Morial Convention Center R06

11:15AM Q8.00001 Studies of colloids on spherical interfaces using digital holographic microscopy. JÉRÔME FUNG, RYAN J. MCCORTY, VINOTHAN N. MANOHARAN, Harvard University, Dept. of Physics — Colloidal particles pinned to the surface of an oil droplet in water form robust equilibrium structures at low area fractions. To better understand the interactions in this system, we are studying these structures and their dynamics during quasistatic changes in the area fraction. We do so by imaging the 3D structures with fast temporal resolution using digital holographic microscopy (DHM). To keep the particles in non-density matched colloidal samples in the field of view, we have constructed a new apparatus to perform DHM under time-averaged zero gravity using a rotating stage. In DHM, we illuminate a sample with a laser beam and then magnify and digitally record the interference patterns between the scattered and unscattered light. Subsequent numerical reconstruction of the recorded 2D holograms allows 3D particle tracking with millisecond time resolution and submicron spatial resolution.

11:27AM Q8.00002 Confinement Finds a Length Scale for the Colloidal Glass Transition. KAZEM EDMOND, ERIC R. WEEKS, Emory University — We study a colloidal suspension confined between two parallel walls as a model system for glass transitions in confined geometries. We use confocal microscopy to directly observe the motion of the colloidal particles, which are slower when confined. This slower motion produces glassy behavior in a sample that is liquid-like when not confined. Our results, from a range of volume fractions, demonstrate that the maximum thickness where confinement effectively defines a length scale for a given particle volume fraction. The length scale increases as the glass transition is approached. We observe that near the glass transition particle motion is strongly spatially correlated. We investigate the relationship between the length scales of these correlations and the established confinement length scale.

11:39AM Q8.00003 Dislocation nucleation and motion observed in a 2D Yukawa triangular lattice, V. NOSENKO, S. ZHDANOV, G. MORFILL, Max-Planck-Institute for extraterrestrial Physics — Dislocation nucleation and motion were studied experimentally in a 2D Yukawa triangular lattice. Edge dislocations were created in pairs in lattice locations where the internal shear stress exceeded a threshold and then moved apart in the glide plane at a speed higher than the sound speed of shear waves. The early stage of this process is identified as a stacking fault. At a later stage, supersonically moving dislocations generated shear-wave Mach cones. The experimental system, a plasma crystal, allowed observation of this process at an atomistic (kinetic) level. We used a monolayer suspension of microspheres in a plasma, i.e., a complex plasma, which is like a colloidal suspension, but with an extremely low volume fraction and a partially-ionized rarefied gas instead of solvent. At our experimental conditions, the suspension forms a highly ordered 2D triangular lattice. Dislocations were generated in this lattice due to the shear stress introduced by its differential rotation, with two “rigid” domain walls imbedded in it. We used digital video microscopy for direct imaging and particle tracking.

11:51AM Q8.00004 Low-electric-field phase behaviour of Brownian colloidal suspensions in sedimentation equilibrium. AMIT AGARWAL, NING LI, ANDAN YETHIRAJ, Department of Physics and Physical Oceanography, Memorial University of Newfoundland — We study the phase diagram of the suspension of micron-scale fluorescent labeled silica colloids in aqueous suspension as a function of concentration in the presence of a moderate (less than 1 volt per μm) AC electric field. Confocal microscopy was used to track three-dimensional structure and dynamics of colloidal suspensions in sedimentation equilibrium. We characterize thresholds for field-induced organization in monodisperse colloidal suspensions of two particle sizes using orientational order parameters. We then study structure formation at moderate fields above the field threshold. At concentrations greater than 10%, and electric fields much larger than the field threshold measured, the colloidal suspension crystallizes to form a body centered tetragonal structure as has been previously reported. At lower concentrations and moderate fields, we uncover complex structure formation phenomena that include equilibrium cellular structures.

12:03PM Q8.00005 Benchmarks for simulations of colloidal suspensions1, TONY LADD, University of Florida — There are now a number of methods available to investigate the dynamics of colloidal suspensions; among the most popular are Stokesian dynamics, the lattice-Boltzmann equation, dissipative particle dynamics, and stochastic rotation dynamics. One of the most commonly asked questions is how do the various methods compare in terms of accuracy and computational cost. At present there is no meaningful answer, in part because it is not straightforward to construct clean test calculations and obtain reference solutions to these problems. I will outline some principles that may be helpful in developing a basis for comparison and describe preliminary results obtained with the lattice-Boltzmann method.

1Research on aspects of the Paradigms in Physics Program is funded by the National Science Foundation under DUE 06-18877.

12:15PM Q8.00006 Non-equilibrium Crystallization Kinetics of an Induced Transition Observed in a Nano-Colloidal Liquid Crystal-Aerosil Dispersions 1, DIPTI SHARMA, Worcester Polytechnic Institute — A new transition feature, termed “Induced Crystallization” (IC), has been observed in a nano-colloidal liquid crystal (octyloxybenzophenyl, 8CB) and aerosol gel system dependent on silica content. This IC feature exhibits apparent activated kinetics following Arrhenius-like behavior. Temperature scans were performed on heating using a DSC technique at ramp rates from 1 to 20 K/min and the aerosol density varied from 0 to 0.2 g/cc. For the 8CB-sil, a well resolved exothermic peak was found as an additional feature on heating scan before the melting transition, absent in bulk 8CB. As the sil density increases, the observed the enthalpy increases while the effective activation energy decreases for this IC feature, eventually saturating at the highest density studied. This behavior appears consistent with molecular disorder imposed by the surface molecular interaction, inducing slow glassy crystallization of the 8CB liquid crystal.

1Author is grateful to Germano Iannacchione for many useful discussions.

12:27PM Q8.00007 Phase separation in asymmetric 2D binary hard-sphere mixtures 1, CAMILO GUAQUETA, ERIK LÜJTEN, University of Illinois at Urbana-Champaign — We investigate the phase behavior and structural properties of highly asymmetric binary mixtures of additive hard spheres in two dimensions, using Monte Carlo simulations in both the canonical and restricted Gibbs ensembles. To tackle large diameter ratios between the large and small species we use an efficient geometric cluster algorithm. Results for the pair correlation functions, compressibility, and depletion potentials are presented and compared to theoretical predictions, for diameter ratios from $q = 2$ to $q = 400$ and over a wide range of packing fractions. We explore and comment on the possibility of a demixing transition at high $q$ and total packing fraction.

This work is supported by the National Science Foundation through Grant No. DMR-0346914.

12:39PM Q8.00008 Experiments on a two dimensional lattice of charged colloids above a water-oil interface, WILLIAM IRVINE, YAEL ROICHMANN, ANDREW HOLLINGSWORTH, DAVID GRIER, PAUL CHAIKIN, Department of Physics and Center for Soft Matter Research, New York University — Charged hydrophobic (PMMA) colloids in an oil phase (cyclohexyl bromide) are attracted, without wetting, by image charge effects to an oil-water interface. The micron size spheres form a monolayer on the interface and interact via screened coulomb interactions to form a crystalline or hexatic lattice, depending on the tunable ratio of lattice spacing to screening length. We study the statics and dynamics of this system in periodic, commensurate, incommensurate, random and quasi-periodic potentials applied by holographic optical tweezers. The use of holographic tweezers allows considerable control over the character and strength of the applied potential. A similar system has been used to study the effects of a curved fluid interface on the particle density and on topological defects.

12:51PM Q8.00009 Nematic Order on Foams, BRYAN CHEN, RANDALL KAMIEN, University of Pennsylvania — We investigate the competition between nematic order and area minimization in nematic foams, in particular, how the structure is affected by the bending of the nematic director, and whether these systems will continue to obey Plateau’s laws. We study the minimum energy configurations of the director field on a one parameter family of perturbed Reuleaux tetrahedra with special attention to the location of topological defects. We determine the energy distribution at the Plateau borders versus the film surface and relate the change in structure to changes in elastic constants and surface tension.

1:03PM Q8.00010 Restricted Defect Dynamics in Colloidal Peanut Crystals, SHARON GERBODE, Physics - Cornell University, STEPHANIE LEE, Materials Science and Engineering - Cornell University, BETTINA JOHN, Chemical Engineering - Cornell University, ANGIE WOLFGANG, Physics - Cornell University, CHEKESHA LIDDELL, Materials Science and Engineering - Cornell University, FERNANDO ESCOBEDO, Chemical Engineering - Cornell University, ITAI COHEN, Physics - Cornell University — We report that monolayers of hard peanut-shaped colloidal particles consisting of two connected spherical lobes order into a crystalline phase at high area fractions. In this “lobe-closed-packed” (LCP) crystal, the peanut particle lobes occupy triangular lattice sites, much like close-packed spheres, while the connections between lobe pairs are randomly oriented, uniformly populating the three crystalline directions of the underlying lattice. Using optical microscopy, we directly observe defect nucleation and dynamics in sheared LCP crystals. We find that many particle configurations form obstacles blocking dislocation glide. Consequently, in stark contrast to colloidal monolayers of close-packed spheres, single dislocation pair nucleation is not the only significant energetic barrier to relieving an imposed shear strain. Dislocation propagation beyond such obstacles can proceed only through additional mechanisms such as dislocation reactions. We discuss the implications of such restricted defect mobility for the plasticity of LCP crystals.

1:15PM Q8.00011 Two-dimensional Dimer System, XIAOCHAO XU, DAVID PINE, Dept. of Physics and CSMR, New York University — We report on an experimental study of the two-dimensional phase behavior of colloidal dumbbells (dimers) trapped at a water-air interface. The dimers are made out of 1.6 μm silica microspheres that are fused together at a point. The water-air interface is very slightly concave so that the dimers are gently compressed by gravity towards the center of interface. The spheres form a stable dense state after a few days. For this dense phase, the location of peaks of both positional and angular pair correlation functions of the dimers reveals that many different orientations and configurations of the dimers are present and this is in agreement with the disorder crystal phase predicted by Monte Carlo Simulation. We found that there is a relatively long range angular correlation, but the positional correlation is short-ranged. This long range angular correlation is limited by the domain sizes which are determined by the density of the defects in the system.

1:27PM Q8.00012 Observing liquid-gas nucleation in a colloid-polymer solution using digital holographic microscopy, RYAN MCGORTY, VINOTHAN N. MANOHARAN, Harvard University — We study liquid-gas nucleation in a colloid-polymer solution. Though the colloidal particles are too small to resolve, we are able to observe nucleating droplets due to the refractive index mismatch between the two fluid phases. By using digital holographic microscopy we are able to observe the three-dimensional structure of the nucleating phase. The experimental setup and algorithms for reconstructing the holography data will be discussed. We hope that our data will allow us to better understand nucleation kinetics and that analysis of the fluctuating droplets will provide us with the surface tension between the two phases.

1:39PM Q8.00013 Soft Spheres Make More Mesophases, CHRISTIAN SANTANGELO, Department of Physics, University of Massachusetts, Amherst MA 01003, MATTHEW GLASER, Department of Physics, University of Colorado, Boulder CO 80309-0390, USA, GREGORY GRASON, Department of Polymer Science, University of Massachusetts, Amherst MA 01003, USA, RANDALL KAMIEN, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia PA 19104, USA, ANDREJ KOSMRLJ, Massachusetts Institute of Technology, Cambridge, MA 02139-4307, USA, PRIMOZ ZIHERL, Department of Physics, University of Ljubljana, Jadranska 19, SI-1000 Ljubljana, Slovenia — We use both mean-field methods and numerical simulation to study the phase diagram of classical particles interacting with a hard-core and repulsive, soft shoulder. Despite the purely repulsive interaction, this system displays a remarkable array of aggregate phases arising from the competition between the hard-core and shoulder length scales. In the limit of large shoulder width to core size, we argue that this phase diagram has a number of universal features, and classify the set of repulsive shoulders that lead to aggregation at high density. Surprisingly, the phase sequence and aggregate size adjusts so as to keep almost constant inter-aggregate separation.
1:51PM Q8.00014 Correlations between Dynamical Heterogeneities and Visco-elastic properties of Confined Colloidal Thin Films, PRASAD SARANGAPANI, Y. ELAINE ZHU, University of Notre Dame, Department of Chemical and Biomolecular Engineering, Notre Dame, IN 46556 — Our recent study on confined hard-sphere colloidal suspensions demonstrates that glass transition can be observed ‘sooner’ as film thickness approaches a critical value while volume fraction remains constant. In this talk, we present a new study of the rheological properties of strongly confined colloidal thin films by using a home-designed micro-rheometer interfaced with a confocal microscope. We visualize the shear-induced structural relaxation at a single particle level and measure the rheological properties of confined colloidal thin films between two surfaces at narrow gap spacing ranging from 50 μm to 1-2 μm. The application of shear excitation greatly accelerates structural relaxation compared to quiescent colloidal fluids and we visualize particle displacements during the “bond breakage” process in strongly confined thin films. Additionally, we characterize their patterns, size and lifetimes under varied shear rates, and correlate their behaviors to the measured visco-elastic and visco-plastic properties of confined colloidal thin films.

2:03PM Q8.00015 Direct Imaging of the Collapsed Langmuir Monolayers and Multilayer Formation, DOSEOK KIM, Department of physics and Interdisciplinary Program of Integrated Biotechnology, Sogang University, SANGJUN SEOK, Department of Physics, Sogang University, TAE JUNG KIM, YOUNG DONG KIM, Nano-Optical Property Laboratory and Department of Physics, Kyung Hee University, DAVID VAKNIN, Ames Laboratory, Iowa State University — In-situ ellipsometry imaging was used to monitor Langmuir monolayer of arachidic-acid spread on water and on CaCl2 solution before and after collapse. The Langmuir monolayer was collapsed by compressing it beyond the minimal closely-packed surface molecular area. The ellipsometry image showed clear domains of collapsed regions, and analysis of the image allowed determination of thicknesses of these domains. It was found that the structure of multilayer domains in the collapsed region was bilayer of arachidic acid on the surface of CaCl2 solution, while the trilayer was formed on the pure water surface.

Wednesday, March 12, 2008 11:15AM - 2:03PM — Session Q9 DFD: Focus Session: DNA and Biofluid Analysis with Micro and Nanofluidic Devices Morial Convention Center R07

11:15AM Q9.00001 Using hydrodynamics to control DNA conformation for genotyping, sorting, and analysis, SUSAN MULLER, Univ. of California, Berkeley — Understanding the dynamics of biopolymers in complex flows is critical for the successful design of lab-on-a-chip devices. Work by Chu, Shaqfeh, and others using both Brownian dynamics simulations and direct, single molecule visualization methods have yielded unprecedented insights into DNA dynamics in simple shear, planar extension, and a range of linear mixed flows. Here, we focus on two flows designed to stretch and manipulate DNA conformation for single molecule genotyping and analysis; that is, flows designed to produce specific conformation fields. First, we present results on DNA in pressure-driven flow through a post array, and discuss insights from direct comparisons with Brownian Dynamics simulations by Shaqfeh and co-workers. Second, we consider stagnation point flows and, through the use of sequence-specific probes, demonstrate the potential of these flows for target sequence identification, single molecule studies of enzyme kinetics, and sorting.

11:51AM Q9.00002 Droplet-based microfluidics for high-throughput scanning of a large probe library, ADAM ABATE, DAVE WEITZ, Harvard University — Droplet-based microfluidics can produce monodisperse picoliter size microreactors at 10 kHz speed. We use this technology to prepare and fuse two drop trains. The drops in one train each contain a unique biochemical probe. The drops in the other train contain a probe target, enzymes, and other biochemical reagents that are necessary to sufficiently mimic the cellular environment. We synchronize the trains hydrodynamically and use electro-coalescence to perform high-throughput controlled fusion of one of each type of droplet microreactor. Using a multicolor laser excitation and fluorescence polarization detector we monitor each fusion event to observe the state of the probe and extract information about the target. This allows us to scan through a large probe library in a matter of seconds using less than 1μL or reagent.

12:03PM Q9.00003 Distant-ion dragging of polarizable nanodroplets and solvated DNA on nanotubes, BOYANG WANG, PETR KRAL, University of Illinois at Chicago, PROF. KRAL’S RESEARCH GROUP TEAM — Long distance Coulombic coupling allows efficient molecular dragging at the nanoscale by moving electrons, ions and molecules [1]. We use molecular dynamics simulations to show that ions intercalated inside semiconducting single-wall carbon nanotubes (SWNT) can be solvated in polarizable nanodroplets adsorbed on the SWNTs, and the coupled systems can be dragged by electric fields [2]. We also demonstrated that solvated single-strand DNA molecules adsorbed on SWNTs can be driven by ionic solutions flowing inside the tubes. These phenomena could be applied in molecular delivery, separation, desalination and be integrated in modern lab-on-a-chip technologies. [1] Boyang Wang and Petr Kral, JACS 128, 15984 (2006). [2] Boyang Wang and Petr Kral, submitted.

12:15PM Q9.00004 Spontaneous and coherent Raman spectroscopy of microfluidic flows, RAJAN ARORA, GEORGI PETROV, VLADISLAV YAKOVLEV, University of Wisconsin-Milwaukee, UNIVERSITY OF WISCONSIN-MILWAUKEE TEAM — Identifying protein structure and understanding its conformational dynamics are the grand challenges for biomedical science. The advent and most recent progress of microfluidics holds a promise of successfully addressing the major issues of structure determination—protein crystallization—by greatly multiplexing the evaluated number of crystallization conditions and protein dynamics—protein folding—by achieving a microsecond scale mixing. The further success of these approaches will strangely depend on the availability of remote probes capable of non-invasive interrogating the structure of biological molecules. Vibrational spectroscopy offers superior structural and chemical sensitivity, which can be successfully applied for characterizing transitional kinetics in microfluidic channels. In particular Raman and CARS give the molecular fingerprint along with structural information that is not possible with conventional fluorescence measurements. Here we are investigating the potential applicability of spontaneous and coherent Raman spectroscopy for protein folding and crystallization. Under suitable experimental conditions coherent Raman is seen to be 100 times more efficient than conventional Raman.

12:27PM Q9.00005 Detection of Kinase Translocation Using Microfluidic Electropicative Flow Cytometry, CHANG LU, JUN WANG, NING BAO, LEELA PARIS, HSIIANG-YU WANG, ROBERT GEAHLLEN, Purdue University, West Lafayette, IN, BIOLOGICAL ENGINEERING COLLABORATION, PHARMACY COLLABORATION — Translocation of a protein between different subcellular compartments is a common event during signal transduction in living cells. Detection of these events has been largely carried out based on imaging of a low number of cells and subcellular fractionation/Western blotting. These conventional techniques either lack the high throughput desired for probing an entire cell population or provide only the average behaviors of cell populations without information from single cells. Here we demonstrate a new tool, referred to as microfluidic electropicative flow cytometry, to detect the translocation of an EGFP-tagged tyrosine kinase, Syk, to the plasma membrane in B cells at the level of the cell population. We combine electrophoresis with flow cytometry and observe the release of intracellular kinase out of the cells during electroporation. We found that the release of the kinase was strongly influenced by its subcellular localization. Cells stimulated through the antigen receptor have a fraction of the kinase at the plasma membrane and retain more kinase after electroporation than do cells without stimulation and translocation. This tool will have utility for kinase-related drug discovery and tumor diagnosis and staging.
12:39PM Q9.00006 DNA/Protein Concentration and Identification by Nano-Channel Electrokinet...
11:15AM Q10.00001 Vortex ratchets from asymmetric weak-pinning channels\(^1\), K. YU, T.W. HEITMANN, C. SONG, M.P. DEFEO, B.L.T. PLOURDE, Syracuse University, M.B.S. HESSELBERTH, P.H. KES, Leiden University — The dynamics of vortex flow in confined geometries can be explored with structured weak-pinning channels of superconducting a-NbGe surrounded by strong-pinning NbN channel edges. The lack of pinning allows the vortices to move through the channels with the dominant interaction determined by the shape of the channel walls. We have fabricated such weak-pinning channels with asymmetric sawtooth edges for controlling the motion of vortices. We present measurements of vortex dynamics in the channels and compare these with similar measurements on a set of channels with uniform width. While the uniform-width channels exhibit a symmetric response for both directions through the channel, the vortex motion through the asymmetric channels is considerably different, with substantial asymmetries in both the static depinning and dynamic flux flow. We report on the rich dependence on magnetic field and driving force amplitude for this vortex ratchet effect.

\(^1\)Supported by NSF DMR-0547147

11:27AM Q10.00002 Vortex dynamics in a single weak-pinning superconducting channel with a Corbino geometry\(^1\). T.W. HEITMANN, K. YU, C. SONG, M.P. DEFEO, B.L.T. PLOURDE, Syracuse University, M.B.S. HESSELBERTH, P.H. KES, Leiden University — We report transport measurements of vortex flow dynamics in nanofabricated weak-pinning channels of a-NbGe with strong-pinning NbN channel edges. The channels are arranged in circular patterns on a Corbino disk geometry with a radial bias current, thus eliminating the influence of edge barriers to vortex entry on the dynamics. We have developed a SQUID voltameter arrangement for resolving the flux flow voltage from a small number of vortices moving through such a single mesoscopic channel. We discuss the configuration of this measurement scheme, along with potential applications of this system for measuring the flow of vortices around single weak-pinning channels free from edge barriers.

\(^1\)Supported by NSF DMR-0547147

11:39AM Q10.00003 Spontaneous Transverse Voltage and Amplified Switching in Superconductors with Honeycomb Pinning Arrays, CYNTHIA OLSON REICHHARDT, CHARLES REICHHARDT, Theoretical Division, Los Alamos National Laboratory — Using numerical simulations, we show that a novel spontaneous transverse voltage can appear when a longitudinal drive is applied to type-II superconductors with honeycomb pinning arrays in a magnetic field near certain filling fractions. We find a coherent strongly amplified transverse switching effect when an additional transverse ac current is applied, even for very small ac current amplitudes. The transverse drive can also be used to control switching in the longitudinal voltage response. We discuss how these effects could be used to create new types of devices such as current effect transistors.

11:51AM Q10.00004 Anisotropic properties of superconducting niobium wire-networks, J. HUA, Z.L. XIAO, Department of Physics, Northern Illinois University, DeKalb, Illinois 60115, A. IMRE, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, U. PATEL, Department of Physics, Northern Illinois University, DeKalb, Illinois 60115, L.E. OCOLA, Center for Nanoscale Materials, Argonne National Laboratory, Argonne, Illinois 60439, V. NOVOSAD, U. WELP, W.K. KWOK, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439 — By utilizing focused ion beam (FIB) patterning technique we were able to fabricate hole-arrays with interhole spacing down to 150 nm into superconducting niobium (Nb) films. This enabled us to have a large temperature range to explore the properties of Nb wire networks in which the superconducting strips between neighboring holes are comparable to the superconducting coherence length. We studied the anisotropy of these superconducting networks by measuring the critical temperatures and magnetoresistances at various magnetic field directions respect to the film surface. The effect of film thickness, hole diameter, interhole-spacing and the symmetry of the hole lattice on the anisotropy will be reported.

12:03PM Q10.00005 Vortex Matter in Magnet — Superconductor Hybrids, IGOR LYUKSYUTOV, TAMU — Arrays of magnetic nanowires in alumina template can create highly inhomogeneous and 1 g STA strong magnetic fields on the template surface. We discuss properties of vortex matter created by such magnetic nanostructures and an external field in thin superconducting film on the template surface. This includes possible phase diagrams, pinning properties and critical current. We predict possible types of hysteresis curves and I-V curves in such magnet-superconductor hybrid in a broad temperature range.

12:15PM Q10.00006 Comparing computer simulations to measurements of slow moving vortices in NbSe\(_2\). MICHAEL DREYER, JONGHEE LEE, HUI WANG, University of Maryland, BARRY BARKER, Lab. for Phys. Sci. — We observed slow moving vortices in NbSe\(_2\) using scanning tunneling microscopy (STM) at a temperature of 4.2 K driven by the slow decay of the magnetic field of our superconducting magnet. The velocity of the vortices depends on the rate of field decay (0.4 mT/day) and the distance of the STM tip from the center of the sample. In our case the velocities of the vortices are in the range of \(\mu\)m/s allowing for high spatially and (relatively speaking) temporal data series. In order to understand the details of the measurements we wrote a simple 2D simulation for moving vortices in a static potential landscape. The simulation allows for a variety of scenarios such as periodic/fixed boundaries, constant variable driving force, insertion/extraction of vortices, point/line defects in order to match the behavior of the velocity with time, showing periodic ‘spikes’, so far defied explanation. The results of the simulation as well as possible reasons for the velocity vs. time data will be discussed in detail.

12:27PM Q10.00007 Towards ordered flux flow in A15 superconductor V\(_3\)Si at high fields\(^1\). R. KHADKA, A.A. GAPUD, University of South Alabama, A.P. REYES, L. LUMATA, P.L. KUHNS, National High Magnetic Field Laboratory, D.K. CHRISTEN, Oak Ridge National Laboratory — The motion of flux quanta is observed in a high-quality superconducting single crystal of V\(_3\)Si with weak pinning and significantly reduced thermal fluctuations due to a critical temperature of less than 17 K. This opens up the possibility of approaching ordered, Bardeen-Stephen flux flow (BSFF). The flux flow resistivity \(\rho_{ff}\) associated with dissipative flux motion is observed in V-I curves as a high current transition to an ohmic curve whose dissipation level is below the normal-state level. Details of overcoming technical difficulties of using high currents are described. BSFF is expected to be manifested by a linear dependence of \(\rho_{ff}\) on applied field \(H\). Measuring from fields of 6 T up to 20 T, an approach to ohmic curves characteristic of BSFF are clearly distinguishable, along with other interesting features such as the “peak” effect in critical current \(J_c(H)\) seen only when the pinning energy density is comparable to the elasticity of the flux medium. This and further data and their interesting ramifications are discussed.

\(^1\)Research funded by University of South Alabama startup funds and Summer Professional Development Award.
12:39PM Q10.00008 Time-resolved infrared spectroscopy of superconducting NbTiN film near Hc1. JUNGSEKE HWANG, University of Florida, HAILONG ZHANG, University of Nebraska, DAVID H. REITZE, CHRISTOPHER J. STANTON, D. B. TANNER, University of Florida, G. LAWRENCE CARR, Brookhaven National Laboratory — We use subnanosecond time-resolved, pump-probe infrared spectroscopy to study vortex dynamics of a conventional superconductor, Nb0.5Ti0.5N near Hc1. The measurements were performed at the National Synchrotron Light Source, Brookhaven National Laboratory; Picosecond pulses from a near-infrared Ti:Sapphire laser were used as a pump and, subnanosecond pulses of infrared synchrotron radiation as a probe. We report detailed magnetic field dependences of the amplitude of photoinduced quasi-particles and the effective lifetime of the quasiparticles and also discuss vortex dynamics in the system near Hc1. Near Hc1, we observe an interesting deviation from the field-independent behavior of the effective lifetime at lower fields.

The research has been supported by the DOE through grant DE-FG02-02ER45984 at Florida and contract DE-AC02-98CH10886 at BNL.

12:51PM Q10.00009 Imaging the dynamics of single vortices on grain boundaries in YBa2Cu3Oy+δ thin films. B. KALISKY, B. NOWADNICK, Geballe Laboratory for Advanced Materials, Stanford University, S. WENDERICH, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, E. ZELDOV, Department of Condensed Matter Physics, Weizmann Institute of Science, J. KIRTLEY, IBM Research Division, Yorktown Heights, A. ARIANDO, H. HILGENKAMP, Faculty of Science and Technology and MESA+ Institute for Nanotechnology, University of Twente, K. A. MOLER, Geballe Laboratory for Advanced Materials, Stanford University — We use a scanning Hall probe microscope with single vortex resolution to study the dynamics of single vortices on grain boundaries in YBa2Cu3Oy+δ thin films with 10 kHz bandwidth. In the presence of an applied current, we observe individual vortices hopping between pinning sites. Detecting the motion of individual vortices allows us to probe the very- low-voltage regime of the current -voltage (I - V) characteristic, at voltage levels of 2 . 10^-15 V. By scanning the grain boundary we show local I – V curves and investigate the statistical processes at the onset of vortex motion.

1:03PM Q10.00010 Imaging the Vortex Density of States in Bi2Sr2CaCu2O8+x. YI YIN, M. ZECH, T. L. WILLIAMS, Harvard University, GENDA GU, Brookhaven National Laboratory, J. E. HOFFMAN, Harvard University — We use a low temperature scanning tunneling microscope (STM) to image vortices in the high temperature superconductor Bi2Sr2CaCu2O8+x, in magnetic fields up to 9T. We locate the vortices via their increased local density of states near ±7 mV. We investigate the dependence of the vortex halo on several parameters, including applied magnetic field and proximity to surface impurities.

This work was supported by the Air Force Office of Scientific Research under grant FA9550-05-1-0371, and by the NSF under grant DMR-0508812.

1:15PM Q10.00011 Single Vortex Imaging and Shaking in a YBa2Cu3O6.991 Single Crystal. LAN LUAN, O. M. AUSLAENDER, Stanford University, E. ZELDOV, Weizmann Institute of Science, K. A. MOLER, Stanford University, D. A. BOÑN, RUIXING LIANG, W. N. HARDY, Department of British Columbia — We image and manipulate individual vortices in a detwinned YBa2Cu3O6.991 single crystal, using magnetic force microscopy (MFM). We observe a strong dynamic asymmetry between the fast and slow directions of the raster imaging pattern, when the MFM tip-vortex force exceeds the depinning force. The vortex can be dislodged hundreds of nanometers along the raster direction, while perpendicular to it, along the slow direction, it can be stretched up to several microns by the same applied force. We attribute this effect to single vortex shaking, in analogy with vortex matter shaking induced by an oscillating magnetic field or current. Here, we raster the tip, shaking the top of one vortex to help it explore different configurations, which are determined by the interplay between pinning and elasticity. In this process, elastic energy associated with stretching along the slow direction can be released, thus allowing the vortex to be dragged further. We are currently studying shaking in an underdoped YBa2Cu3O7-δ single crystal, where the Josephson coupling along crystal c-axis is much reduced, rendering elasticity weaker.

1:27PM Q10.00012 Tunneling of an extended object in a dissipative environment: suppression of tunneling of vortices caused by a remote gate. KAREN MICHAELI, Department of Condensed Matter Physics, The Weizmann Institute of Science, Rehovot 76100, Israel, ALEXANDER FINKEL’STEIN, Weizmann Institute of Science, Israel and Department of Physics, Texas A&M University, USA. A strong decrease of the resistance of a superconducting film measured in magnetic field has been observed when a metallic gate is placed above the film. We study how the magnetic coupling between vortices in a superconducting film and electrons in a remote unbiased gate affects the tunneling rate of the vortices. We examine two approaches to analyze tunneling in the presence of low-energy degrees of freedom: (i) the response of the electrons inside the metallic gate to a change in the vortex position is described as “tunneling with dissipation” (ii) the scattering of the electrons by the magnetic flux of the vortex leads to the Orthogonality Catastrophe that opposes the vortex tunneling. We show that the gate can cause a dramatic suppression of the vortex tunneling restoring the superconducting property in accord with the experiment.

1:39PM Q10.00013 Dynamics of vortices driven by magnetic field changes observed by LT-STM. JONGHEE LEE, MICHAEL DREYER, HUI WANG, University of Maryland, BARRY BARKER, Lab. for Phys. Sci. — When changing the magnetic field for a type two superconductor the vortex density has to change accordingly. Vortices have to enter/leave the superconductor to facilitate that change. Since vortex-defect interactions impede the vortex motion such a change does not happen instantaneously. Observing the vortex lattice at a given distance from the center by STM allows to study that behavior. The velocity usually decays close to exponentially. Although the first ‘fast’ phase (30 min) is unaccessible to STM due to its limited scan speed the tail section (˜5 h) can be studied in detail. We will present analysis of the data and compare it to previous results on slow moving vortices driven by a slowly decaying magnetic field.

1:51PM Q10.00014 h/e-Flux Periodicity in Superconducting Loops. ARNO KAMPF, FLORIAN LOBER, THILO KOPP, JOCHEN MANNHART, CHRISTOF SCHNEIDER, University of Augsburg, YURI BARASH, Russian Academy of Sciences, Chernogolovka — We apply the BCS theory to superconducting rings with unconventional order parameter symmetries. An external magnetic flux changes the character of the states in the condensate; as a consequence the energy of the superconducting ground state varies with a flux period of h/e. This h/e periodicity is caused by the flux-induced reconstruction of the supercurrent carrying condensate.

Supported by the Deutsche Forschungsgemeinschaft through SFB 484.

Wednesday, March 12, 2008 11:15AM - 1:39PM —
Session Q11 DMP: Focus Session: Hybrid Magnetic-Superconducting Systems II
Morial Convention Center R09
Curie's intriguing finding was the reduction in the $S$ ordering temperature of the SRO layer when $T$ regions, arranged along narrow strips, where a superconductor-like gap penetrates the SRO more than 25 nm. This is attributed to "crossed Andreev reflections" bilayers indeed show that on most of the junction area the $S$ order parameter vanishes in the SRO over a distance less than 8 nm. However, we find localized a superconductor-ferromagnet ($S$-$F$) junction is spin polarized, Andreev reflections are suppressed. Consequently, the induced $S$ order parameter in the $F$ is $\Delta_{0}$ enhancement in cuprate bilayers. We have also studied (110)YBCO-SRO bilayers, where, surprisingly, a clear penetration of the Andreev bound states (residing on the (110) YBCO surface) into the $F$ layer was revealed. The penetration is manifested in the density of states as a split zero bias conductance peak with an imbalance between peak heights. Our data indicate that the splitting occurs at the $S$ side, possibly as a consequence of induced magnetization, consistent with recent theoretical predictions. The imbalance is attributed to the spin polarization in SRO.

Superconductor-Ferromagnet Bilayers

Scanning Tunneling Spectroscopy Study of Bi-Layer

La$_{0.7}$Ca$_{0.3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-\delta}$ Thin Films

I. FRIDMAN, P. MORALES, J.Y.T. WEI, University of Toronto — Recent experiments have reported long-range proximity effect in ferromagnet/superconductor (F/S) heterostructures comprised of transition-metal perovskites. To look for direct evidence of this effect, we have performed scanning tunneling spectroscopy (STS) on La$_{0.7}$Ca$_{0.3}$MnO$_3$/YBa$_2$Cu$_3$O$_{7-\delta}$ (LCMO/YBCO) bi-layer thin films. The bilayer films were epitaxially grown on SrTiO$_3$ substrates using pulsed laser deposition. STS measurements were made at 4.2 K on bi-layer films with varying LCMO thickness (20 to 60 nm) and in a magnetic field parallel to the film. The STS data were analyzed for spectral signatures of a pairing gap on the LCMO layer induced by the YBCO layer, to determine the length scale of the F/S proximity effect and the role played by magnetic domain walls.

Work supported by NSERC, CFI/OIT and the Canadian Institute for Advanced Research.

Anomalous Sub-Gap features in Nb/Ni Tunneling DOS

PAUL SANGIORGIO, MALCOLM BEASLEY, Stanford University, JUNHYUNG KWON, KOOKRIN CHAR, Seoul National University — We report the existence of anomalous sub-gap features in tunneling DOS measurements of Superconductor/Strong Ferromagnet bilayers. By measuring the DOS as a function of ferromagnet thickness, $d_F$, we are able to document the spatial evolution of the Cooper pairs diffusing into the ferromagnet. This technique proves to be much less sensitive to variations in boundary conditions and provides more detailed information per sample than traditional $T_e$ or $J_c$ measurements. In addition to the sub-gap features, we find that the DOS shows the usual peaks at $\pm \Delta_0$, which "invert" at $d_F = 3.5$ nm. We analyze the results with the fully non-linear Usadel equation, including the effects of various scattering mechanisms and spin-dependent boundary conditions. We are able to quantitatively account for the features at $\pm \Delta_0$ through the addition of spin-orbit scattering in the F-layer, but we find that no known parameter recreates the sub-gap features. By examining the behavior of the sub-gap in magnetic field, we propose that it is a signature of a long-range triplet condensate.

Spin Polarization And Inelastic Scattering In High And Low Transparency Ferromagnet/Superconductor Point Contacts

PAUL J. DOLAN, JR., Northeastern Illinois University, CHARLES W. SMITH, University of Maine — For point contact spectroscopy studies of ferromagnet/superconductor charge transport, the effects of spin polarization and inelastic scattering can dominate conductance data. Model calculations show that accurate values of the spin polarization parameter can most easily be determined in high transparency contacts (the ballistic limit) when inelastic scattering is low, and in low transparency contacts (the tunneling limit) when inelastic scattering is high. Comparison with data for both contacts will be shown.

Electrical properties of interfaces in high-$T_c$ superconducting heterostructures

MAARTEN VAN ZALK, JOS BOSCHKER, MENNO VELDORST, ALEXANDER BRINKMAN, HANS HILGENKAMP, Condensed Matter Physics and Devices Group, MESA+ Institute for Nanotechnology, University of Twente — Electrical contacts between materials of different functionality are often required, both for technological applications as well as for fundamental research. However, contacts between different complex oxides frequently do not behave like expected. For example, it is well known that tunnel junctions are difficult to fabricate from high-$T_c$ superconductors, due to the presence of a degraded, non-superconducting layer underneath the tunnel barrier. We investigated the interface properties of a number of different oxide heterostructures, prepared by pulsed laser deposition. Specifically, the causes of non-ideal interface behavior, such as changes in the stoichiometry, oxygen deficiency, structural changes and electronic reconstruction, were investigated.

All-oxide inverse superconducting spin switch

JACOBO SANTAMARIA, GFMC, Fisica Aplicada III, Universidad Complutense de Madrid, 28040 Madrid, Spain, NORBERT NEMES, ICMC-CSIC, 28049 Cantoblanco, Spain, CRISTINA VISANI, JAVIER GARCIA-BARRIOCANAL, ZOUHAIR SEFRIOU, DIEGO ARIAS, CARLOS LEON, GFMC, Fis. Aplicada III, Univ. Complutense Madrid, Spain, MAR GARCIA-HERNANDEZ, ICMC-CSIC, Cantoblanco, Spain, SUZANNE TE VELTHUIS, AXEL HOFFMANN, Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA — In proximity coupled ferromagnet/superconductor/ferromagnet (F/S/F) structures the critical temperature is modulated by the relative orientation of the magnetization in the F layers (superconducting spin switch-SSS). A larger $T_{c}$, with antiparallel (AP) compared to parallel (P) magnetizations results from the averaging of the exchange field over the coherent volume. Recent reports have shown an SSS behavior in F/S/F structures with strong ferromagnets, where superconductivity is favored for $P$ orientation of the adjacent magnetizations. Its origin is a subject of debate. While some reports suggest enhanced pair breaking by spin-polarized quasiparticles in the AP configurations, others emphasize the effect of stray fields in depressing the superconductivity. Comparing data of bilayers and trilayers, we show that the SSS effect of our epitaxial LCMO/YBCO/LCMO structures is governed by spin transport within the F layers.

Covalent Bonding and Orbital Reconstruction at an Oxide Interface.

JAK CHAKHALIAN, University of Arkansas, JOHN FREELAND, Advanced Photon Source, Argonne National Laboratory, HANS-ULRICH HABERMEIER, GEORG CRISTIANI, G. KHALIULLIN, Max Planck Institute for Solid State Research, MICHEL VAN VEENENDAAL, Northern Illinois University, BERNHARD KEIMER, Max Planck Institute for Solid State Research — Atomically controlled interfaces between two materials can give rise to novel physical phenomena and functionalities. Modern synthesis methods have yielded high-quality heterostructures of oxide materials with competing order parameters. Orbital reconstructions and covalent bonding must be considered as important factors in the rational design of oxide heterostructures. Here we examine the interface between high-temperature superconducting (Y,Ca)Ba$_2$Cu$_3$O$_{7+\delta}$ and metallic La$_2$Cu$_3$O$_6$ by resonant x-ray spectroscopy. The resulting data show that electrons are transferred from Mn to Cu ions across the interface. This phenomenon is accompanied by the major reconstruction of the orbital occupation and symmetry in the CuO$_2$ plane. Specifically, we report the experimental finding that unlike bulk at the interface Cu d$_{3z^2-r^2}$ orbital is partially occupied and electronically active. This observation opens a path to orbital engineering of interface-controlled materials. J. Chakhalian et al, "Covalent Bonding and Orbital Reconstruction at an Oxide Interface," Science, v. 318, 1155 (2007).
observed in the resistivity data, the lower two transitions are suppressed by an applied magnetic field. At low temperatures metamagnetism is observed in the and high magnetic field measurements of the electrical resistivity and magnetization. For zero field, three magnetic transitions at 1 K, 1.5 K and 2.8 K are reveal that the superconductivity coexists with the hidden order but is suppressed by antiferromagnetic ordering. Here, we report charge and thermal transport by itself is an exceptional case of pairing among heavy electrons with a long Fermi-wavelength in a nearly semimetallic system. Moreover, pressure studies conductivity with such a low density is remarkable since the superfluid density is very low in some way reminiscent of underdoped cuprates; the superconductivity observations, most of the carriers disappear below \( T_\alpha \) alignment is changed from parallel to antiparallel in FSF. Moreover, the critical Josephson current in SFFS multilayers is also a monotonic function of \( \alpha \) when the junction is far enough from \( 0-\pi \) transitions. In contrast to the diffusive case, no substantial impact of long-range spin–triplet superconducting correlations neither on conductance nor on the Josephson current has been found in the clean limit.

1:15PM Q11.00009 Properties of Hybrid Superconductor/Half-metal Systems, MATTHIAS ESCHRIG, University of Karlsruhe and DFG-Center for Functional Nanostructures, D-76128 Karlsruhe, Germany, TOMAS LOFWANDER, Chalmers University of Technology, S-412 96 Gothenburg, Sweden — Interfaces between materials that exhibit different types of order present unique opportunities to study fundamental problems in physics. One example is the interface between a single superconductor and a half-metallic ferromagnet, where Cooper pairing occurs between electrons with opposite spin on one side, while the other displays 100% spin polarisation. New effects, like spin mixing and spin rotation are characteristic for such interfaces [1], providing a mechanism for conversion between unpolarized and completely spin polarized supercurrents. Our predictions have been confirmed in a recent experiment observing a supercurrent through half-metallic CrO\(_2\) [2]. The interface region exhibits a superconducting state of mixed-spin pairs with highly unusual symmetry properties that opens up new perspectives for exotic Josephson devices [3]. We present results for Andreev bound state spectra for point contact Andreev conductance spectra. The role of disorder and symmetry of the pairing amplitudes on the spectra and the temperature dependence of the Josephson current is elucidated.

1:27PM Q11.00010 Novel Josephson junctions of high-\( T_c \) cuprate using magnetic islands: Fabrication and Properties, A. MAEDA, L. GOMEZ, S. KITAMURA, Department of Basic Sciences, University of Tokyo — In spite of the potential high performance, no one has succeeded in fabricating good Joseph junctions of high-\( T_c \) cuprate superconductors with a large \( I_c R_N \) product and textbook like \( I_c - V \) characteristics. This is probably because the fabrications of the oxide barrier layer even on the almost perfect surface of the cuprate causes many unexpected troubles, suggesting that there are still many issues to be solved in the surface science of the cuprate superconductors. We have tried the high-\( T_c \) Junction fabrication with a novel method, where we do not need to fabricate oxide barrier layer; A small island of Fe was merely placed on a strip of a cuprate superconductor, LSCO. By measuring \( I_c - V \) characteristics, microwave radiation effect, and magnetic field effect, it turned out that this simple novel structure becomes a typical Josephson junction. What is remarkable is that the structure often exhibits a large \( I_c R_N \) value (\( \sim 10-20 \) meV), suggesting that our method is promising. Together with various kinds of comparative experiments, we will discuss the mechanism of the weak coupling.

Wednesday, March 12, 2008 11:15AM - 2:03PM
Session Q12 DCMP: Focus Session: Hidden Order and Heavy Fermions Morial Convention Center 203

11:15AM Q12.00001 Exotic Superconducting State Embedded in the Hidden Order Phase of URu\(_2\)Si\(_2\)\(^1\), YUJI MATSUDA, Department of Physics, Kyoto University, Kyoto 606-8502, Japan — The heavy-Fermion compound URu\(_2\)Si\(_2\) has mystified researchers since the superconducting state \( (T_c = 1.5\) K) is embedded within the “hidden order” phase \( (T_h = 17.5\) K). According to several experimental observations, most of the carriers disappear below \( T_h \), resulting in a density one order of magnitude smaller than in other heavy-Fermion superconductors. Superconductivity with such a low density is remarkable since the superfluid density is very low in some way reminiscent of underdoped cuprates; the superconductivity by itself is an exceptional case of pairing among heavy electrons with a long Fermi-wavelength in a nearly semimetallic system. Moreover, pressure studies reveal that the superconductivity coexists with the hidden order but is suppressed by antiferromagnetic ordering. Here, we report charge and thermal transport measurements on ultraclean single crystals of URu\(_2\)Si\(_2\) \( (RRR < 700) \) down to 30 mK \( (T_c/50) \), which reveal a number of unprecedented superconducting properties. The uniqueness is best highlighted by field-induced superconductor-insulator-like first-order transition at the upper critical fields, which is a direct consequence of the electronic structure imposed by the hidden order. The results provide strong evidence for a new type of unconventional superconductivity with two distinct gaps having different nodal topology. We propose a gap function with chiral \( d \)-wave form \( \Delta_k \propto k_c (\pm i k_y) \) [1]. We also report a distinct flux line melting transition with outstanding characters and a formation of the quasiparticle Bloch state in the periodic flux line lattice in this ultraclean system [2]. The intriguing superconducting state of URu\(_2\)Si\(_2\) adds a unique and exciting example to the list of unconventional superconductors.

1:27PM Q11.00008 Spin-triplet correlations in clean superconductor-ferromagnet multilayers, MATTHIAS ESCHRIG, MATTHIAS ESCHRIG, ZORAN RADOVIC, ZORICA PAJOVIC, MILOS BOZOVIĆ, Department of Physics, University of Belgrade, POB 368, 11001 Belgrade, Serbia, JEROME CAYSSOL, ALEXANDER BUZDIN, Univeristie Bordeaux I, CPMOH, UMR 5798, 33405 Talence, France — We study transport phenomena in clean superconductor-ferromagnet (S-F) multilayers for a general case of arbitrary relative orientation of in-plane magnetizations and interface transparencies. The scattering problem based on the Bogoliubov-de Gennes equation is solved, taking into account both spin-singlet and spin-triplet superconducting correlations in two geometries, FSF and SFFS. We find a monotonic dependence of conductance spectra on the angle of misorientation of magnetizations \( \alpha \) as their alignment is changed from parallel to antiparallel in FSF. Moreover, the critical Josephson current in SFFS multilayers is also a monotonic function of \( \alpha \) when the junction is far enough from \( 0-\pi \) transitions. In contrast to the diffusive case, no substantial impact of long-range spin–triplet superconducting correlations neither on conductance nor on the Josephson current has been found in the clean limit.

11:51AM Q12.00002 Neutron scattering studies of the quantum critical point of CeAuSb\(_2\), JOHN JANIK, CHRIS WEBE, NHMFL/FSU, HAIDONG ZHOU, NHMFL, BEN UELAND, YING CHEN, JEFF LYNN, NIST, ZACHARY FISK, University of California, Irvine, H. LE, WEI BAO, LANL, YOUN-JUNG JO, LUIS BALICAS, NHMFL — We present neutron scattering results on CeAuSb\(_2\), a quantum critical material whose critical point in revealed in magnetic field. We find incommensurate ordering, indicative of itinerant electron physics. The incommensurate feature seem to be directly related to metamagnetic transitions.

12:03PM Q12.00003 Magnetic and electrical transport study of single crystal Yb\(_2\)Au\(_3\), H. RYU, E.D. MUN, S.L. BUDKO, P.C. CANFIELD, Ames Lab / Iowa State University — Single crystals of Yb\(_2\)Au\(_3\) grown by flux method are studied by low temperature and high magnetic field measurements of the electrical resistivity and magnetization. For zero field, three magnetic transitions at 1 K, 1.5 K and 2.6 K are observed in the resistivity data, the lower two transitions are suppressed by an applied magnetic field. At low temperatures magnetism is observed in the magnetization and magnetoresistance data. Strong anisotropy between the tetragonal ab plane and c-axis, is revealed in both magnetization and transport measurements. The \( H - T \) phase diagram for applied field along the \( ab \) plane is constructed by electrical transport measurements. The anisotropy can be explained with a crystalline electric field (CEF) model. Yb\(_2\)Au\(_3\) can be characterized as Kondo lattice compound with strong CEF splitting.

\(^2\)Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.
12:15PM Q12.00004 A Novel Low-Temperature Phase in Strongly Correlated CePd$_3$Ga$_2$. QINC'AN LI, J.F. MITCHELL, K.E. GRAY, Argonne National Laboratory, ROBIN MACALUSO, Northern Colorado College — The specific heat, $C_p$, of CePd$_3$Ga$_2$ strongly supports the presence of two phase transitions, which are consistent with magnetization data. The 11 K transition (suppressed for fields, $B>3$ T) is also seen in the resistivity, whereas the 6 K transition is not. The resistivity is anisotropic both with respect to field and current directions, while its temperature dependence is similar to UCd$_3$ and CeAuSb$_2$. Both resistivity and $C_p$ are affected by magnetic fields up to about 30 K and possible connections will be discussed.

1Supported by US DOE, BES under contract DE-AC02-06CH11357.

12:27PM Q12.00025 Is the Low-Temperature Phase in CePd$_3$Ga$_2$ Fascinating or Just Novel? K.E. GRAY, J.F. MITCHELL, H. CLAUS, QINC'AN LI, Argonne National Laboratory, ROBIN MACALUSO, Northern Colorado College — Magnetization data for CePd$_3$Ga$_2$ strongly support the presence of two phase transitions, also seen in specific heat, $C_p$. The 11 K transition (suppressed for fields, $B>3$ T) has similarities to UCd$_3$ and CeAuSb$_2$, but the lower temperature phase ($T<6$ K, $B<2.5$ T) is novel and its nature is a mystery. Its uniaxial magnetic anisotropy implies that CePd$_3$Ga$_2$ is an effective Ising system for the Ce spins, likewise consistent with $C_p$. The phase diagram of this fascinating material will be discussed in terms of combined magnetization, conductivity, $C_p$ and neutron scattering data.

1Supported by US DOE, BES under contract DE-AC02-06CH11357.

12:39PM Q12.00006 Field-induced magnetic phase transition in antiferromagnetic YbPtSi$^1$. YURI JANSSEN, Brookhaven National Laboratory, YUEN YIU, Stony Brook University, PETER KHALIFA, MEIGAN ARONSON, Brookhaven National Laboratory, Stony Brook University, Berkeley National Laboratory, State University of New York at Stony Brook. — We have studied single crystals of the orthorhombic intermetallic compound YbPtSi. Here we present results of anisotropic field- and temperature dependent magnetization and specific heat. Magnetization isotherms measured between 1.8 K and the ordering temperature of 4.65 K show a sudden anomalous increase in magnetization. This phase transition becomes sharper and takes place at progressively higher fields as temperature decreases. Measurements of field- and temperature dependent specific heat above 0.4 K confirm this magnetic phase transition above 1.8 K, and allow us to draw anisotropic magnetic phase diagrams down to 0.4 K. These phase diagrams indicate that the magnetic phase transition in YbPtSi can be brought close to zero temperature in relatively modest applied fields, $\sim 3.5$ T for the hard magnetization direction. The critical line is well described by $Y_e/(H/T)^{1/2} = (1-(H_e(T)/H_e(0))^{2})^{0.3}$, very different from quasi-one-dimensional or two-dimensional quantum critical antiferromagnets.

$^1$This research is supported by US-DOE, under contract DE-AC02-98CH10886.

12:51PM Q12.00007 Magnetic Order in single-crystalline YbPtSi. YUEN YIU, State University of New York at Stony Brook, YURI JANSSEN, Brookhaven National Laboratory, PETER KHALIFA, MEIGAN ARONSON, Brookhaven National Laboratory, State University of New York at Stony Brook. MOOSUNG KIM, Brookhaven National Laboratory, MARCUS BENNETT, State University of New York at Stony Brook. — We report the first measurements on YbPtSi, which we synthesized as single crystals by means of flux growth from Indium. Single crystal x-ray diffraction measurements find that the YbPtSi crystal structure is the orthorhombic C$_2$Si$_2$-type, with one crystallographic site for Yb. Magnetic susceptibility measurements find Curie-Weiss behavior above 100 K with a moment of $3.45 \mu_B$, close to the 4.54 $\mu_B$ expected for trivalent Yb. Measurements of the heat capacity find a mean field-like magnetic ordering transition at $T=4.65K$. DC-susceptibility measurements show substantial single ion anisotropy, but also exhibit a peak at 4.65 K, indicating possible antiferromagnetic ordering. The electrical resistivity is metallic, and the magnetic ordering is accompanied by a change in slope. The magnetic entropy amounts to only about 65% of $Rln2$ expected from an ordering state doublet at the ordering temperature, suggesting a possible role for the Kondo effect. Our measurements indicate that YbPtSi is an unusual example of an Yb-based Kondo lattice system, ordering at an unusually high temperature.

1:03PM Q12.00008 Angle resolved photoemission studies of YbRh$_2$$_{1-x}$Ge$_x$_2. S.-K. MO, K. TANAKA, N. MANNELLA, Stanford University and Advanced Light Source, C. CAPAN, D.J. KIM, Z. FISK, UC Irvine, Z. HUSSAIN, Advanced Light Source, Z.-X. SHEN, Stanford University, YUEN YIU, Brookhaven National Laboratory. — YbRh$_2$_2 is a prototype system for 4f-based Kondo lattices and has attracted a lot of attention as the first Yb-based system with a quantum critical point (QCP) at $x \sim 0.05$. The QCP can be tuned by either magnetic field or chemical substitution, and non Fermi liquid properties have been observed in the vicinity of it. We present high-resolution angle resolved photoemission data on this compound as a function of Ge-doping. The result will be discussed in conjunction with various theoretical proposals on the Fermi surface topology of this material.

1:15PM Q12.00004 High Pressure Studies of CeIn$_3$ in High Magnetic Fields. JACOBY COOLEY, Los Alamos National Laboratory, RONGWEI HU, Brown University, ROSS MCDONALD, National High Magnetic Field Laboratory - LANL, CEDOMIR PETROVIC, Brookhaven National Laboratory, STANLEY TOZER, National High Magnetic Field Laboratory - FSU. — High pressure and strong magnetic fields are useful tools for studying the relationship between the antiferromagnetism and unconventional superconductivity observed in the heavy fermion superconductor CeIn$_3$. We report high pulsed magnetic field (up to 55 T) pressure studies of single crystal CeIn$_3$ utilizing the change in the resonant frequency of a tunnel diode oscillator (TDO) as a contactless means of measuring the skin depth of the crystal. An anomaly in the skin depth was observed at $\sim 42$ T and was found to be driven to lower fields with increasing pressure. The relationship of the observed anomaly with the nature of the Fermi surface and the formation of a superconducting state at $\sim 200$ mK and 27 kbar will be discussed. 1. N. Harrison et al, preprint arXiv:07062387 2. N. D. Mathur et al, Nature, 394, 39 (1998)
1:39PM Q12.00011 Unconventional Magnetic Scaling Exponents near a $T = 0$ Transition in URu$_2-x$Re$_x$Si$_2$\textsuperscript{1}, NICHOLAS P. BUTCH, BENJAMIN T. YUKICH, M. BRIAN MAPLE, Department of Physics and Institute for Pure and Applied Physical Sciences, University of California, San Diego — Substituting Re for Ru in the heavy fermion compound URu$_2$Si$_2$ suppresses the hidden order and superconducting transitions and gives rise to long range ferromagnetism. From electrical transport, specific heat, and magnetic susceptibility studies of single crystals of URu$_2-x$Re$_x$Si$_2$, $0 \leq x \leq 0.6$, it is apparent that the non-Fermi liquid behavior first observed in polycrystalline samples is indeed a robust phenomenon intrinsic to the bulk material. We present a recent investigation of the magnetization of URu$_2$Si$_2$ and find the magnetic transition from well into the ferromagnetic phase down to its onset. The variation of the exponents with $x$ is discussed within the context of the observed non-Fermi liquid behavior.

\textsuperscript{1}This research was supported by the US National Science Foundation and US Department of Energy.

1:51PM Q12.00012 The linear and non-linear magnetic susceptibility of URu$_2$Si$_2$ in hydrostatic pressure, G.J. MACDOUGALL, G.M. LUKE, McMaster University, T. GOKO, TRIUMF, J.D. GARRETT, McMaster University — The heavy-fermion material URu$_2$Si$_2$ has long been a topic of interest due to the mysterious 'hidden order' transition at $T_0=17.5K$. Though the exact nature of this order is still a matter of great debate, the transition has strong signatures in heat capacity, resistivity and linear and non-linear magnetic susceptibility. Interest in the material has increased in recent years, as high-pressure measurements have revealed a first-order quantum phase transition to an antiferromagnetically ordered state. However, the fate of the hidden-order, and how it relates to the anti-ferromagnetism is still unknown. With this in mind, we have measured the linear and nonlinear magnetic susceptibility of single-crystalline URu$_2$Si$_2$ under hydrostatic pressure. We will report the results of these measurements, with particular emphasis placed on the signatures of hidden-order and how they evolve as the system is driven into the antiferromagnetic state.

Wednesday, March 12, 2008 11:15AM - 1:51PM —
Session Q13 DCOMP: Ground State Density Functional Theory: Applications

11:15AM Q13.00001 Polarizabilities and Hyperpolarizabilities of Hydrogen Chains: Is Self-Interaction Correction the Key?, A. RUZINSZSKY, J.P. PERDEW, Dept. of Physics, Tulane U., G.I. CSONKA, Dept. of Chemistry, Budapest U. of Technology and Economics, G.E. SCUSERIA, Dept. of Chemistry, Rice U., O.A. VYDROV, Dept. of Chemistry, MIT — Semi-local density functionals like the local spin density and generalized gradient approximations are known to overestimate [1, 2] the polarizabilities and especially the hyperpolarizabilities of long-chain molecules, while these quantities are much better predicted by exact-exchange methods (Hartree-Fock or Optimized Effective Potential). The source of this failure of the semilocal approximations for the electric response is rooted in the self-interaction error inherent to the semilocal approximations. We show here that the semilocal functionals, after full or scaled-down Perdew-Zunger self-interaction correction [3, 4], are even better than the exact-exchange methods for these quantities.

11:27AM Q13.00002 Improved Description of Stereoelectronic Effects Using Semi-local Density Functional Theory, GABOR I. CSONKA, Dept. of Chemistry, Budapest U. of Technology and Economics, Budapest, Hungary, JOHN P. PERDEW, ADRIENN RUZINSZKY, Dept. of Physics, Tulane U., New Orleans LA 70118 — Proper description of stereoelectronic (SE) effects is desirable for any theoretical method to be used in organic chemistry. The SE design rules are frequently used in synthetic organic chemistry to design and explain new reactions by electron donating and withdrawing effects or steric interactions. These effects are often poorly described by standard generalized gradient approximations for exchange and correlation. Many popular exchange-correlation functionals are biased toward the correct description of free atoms and fail to improve upon LSDA for solids. Changing two parameters within the PBE form to satisfy different constraints leads to a new non-empirical GGA, PBEsol [1], that performs well for solids and improves the description of large organic systems and reactions. We present examples where this new non-empirical functional provides considerable improvements for molecules. [1] J.P. Perdew, A. Ruzinszky, G.I. Csonka, O.A. Vydrov, G.E. Scuseria, L.A. Constantin, X. Zhou, and K. Burke, http://arxiv.org/abs/0711.0156

11:39AM Q13.00003 Approximations in local hybrid density functionals, BENJAMIN JANESKO, Rice University, GUSTAVO SCUSERIA, Rice University — Hybrid density functionals incorporating a fraction of exact (Hartree-Fock-type) electronic exchange have become one of the dominant approximations for modeling the electronic structure of large molecules and solids. Generalization to a position dependent admixture of exact exchange provides a route to improved accuracy. However, such local hybrid functionals generally have a significant computational expense. We present work towards approximating density functionals that incorporate some of the desirable properties of local hybrids, without requiring explicit evaluation of exact exchange. These results show promise for extending the benefits of hybrid functionals to larger systems.

11:51AM Q13.00004 The role of middle-range Hartree-Fock-type exchange in hybrid functionals, THOMAS HENDERSON, ARTUR IMAYLOV, GUSTAVO SCUSERIA, Rice University, ANDREAS SAVIN, Universite Pierre et Marie Curie — While hybrid functionals are responsible for many successes in modern Kohn-Sham theory, they have several drawbacks. The slow decay of nonlocal exchange makes hybrids computationally demanding in extended systems with small bandgaps, while in finite systems the rapid decay of semilocal exchange causes errors in quantities sensitive to the long-range potential. Both problems can be addressed by range-separated hybrids which include nonlocal exchange only for some values of the interelectronic separation. Excluding long-range nonlocal exchange in extended systems improves computational efficiency without loss of accuracy, while including full long-range nonlocal exchange in finite systems improves accuracy without loss of efficiency. Both approaches use a significant fraction of nonlocal exchange for intermediate electronic separations. We show that a hybrid functional that uses nonlocal exchange only for this middle range has many advantages, properly describing thermochemistry, reaction barriers, and bandgaps in the same framework.

12:03PM Q13.00005 Molecular Crystals, a test system for weak bonding,\textsuperscript{1}, BERNARD DELLEY, Paul Scherrer Institut Switzerland, TEODORA TODOROVA, Paul Scherrer Institut Switzerland — Intermolecular binding in molecular crystals are due to electrostatic and Van-der-Waals interactions. Crystal parameters are crucially dependent on the accuracy of the electronic model. We investigate sets of molecular crystals, classified by the lowest non-vanishing molecular multipole moment, with density functional theory. We find that certain density functional approximations give an almost surprisingly good description of such lattices, deteriorating only moderately going from molecules with dipole moment, to ones with quadrupole and to even higher symmetry molecules, where finally Van-der-Waals interactions dominate at large distance. For the best performing density functional approximations, even the VdW subset has an error range of calculated lattice parameters comparable to crystals with covalent, ionic or metallic bonds.

12:39PM Q13.0008 Generalized LDA+U+V functional in DFT calculations for covalent systems
VIVALDO CAMPO, MATTEO COCCIONI, Computing and Materials Science Department, University of Minnesota, Minneapolis, MN 55455, USA — In this work, we introduce a generalized LDA+U+V functional that consists in both on-site (U) and inter-site (V) interactions. While V can be straightforwardly obtained from the same linear-response approach used to calculate U [1], its inclusion in the “+U” functional can improve the treatment of systems where electrons tend to localize on molecular states (bonds) rather than on atomic orbitals, and will extend the applicability of this approach to an even broader class of systems. Because of a better treatment of hybridization, this extension also helps avoiding well-known drawbacks of “standard” (atomic) LDA+U such as the exaggerated down-shift of the energy of localized filled orbitals. It thus results in an improved energetic description, which is crucial for studying structural relaxations, chemical reactions and phase transitions. Paradigmatic examples of application of this generalized approach will include diatomic molecules, TM oxides and group-IV solids. ¹ M. Cococcioni and S. de Gironcoli, Phys. Rev. B 71, 035105 (2005).

12:51PM Q13.0009 Comparative Study of the Performance of DFT B3PW91 for the Prediction of Electronic Properties of Molecules
JASMA BATHAM, PEDRO DEROSA, Louisiana Tech University — Density Functional Theory is a widely used and accepted tool for the prediction of ground state molecular properties. However and despite the fact that the hybrid GGA functional B3PW91 has proven to be successful for many application, its use seems not to be as widespread. In a paper by Zhang and Musgrave the HOMO, the LUMO and the energy difference between the two (HLG), is compared for a set of 27 molecules to the experimental ionization potential (IA), electron affinity (EA), and the lowest excitation energy respectively. The first two are inspired by the Koopman’s theorem that suggests that the HOMO is a good approximation of IP while the negative of the LUMO is an approximation of the -EA. Notably, in the mentioned paper, results for 11 different DFT functional are compared but B3PW91 is not one of them. In this work we compare the performance of B3PW91, to that of B3LYP, also a hybrid functional, and the corresponding non-hybrid GGAs BLYP and BPW91 for the same 27 molecules. For all the cases the 6-311+G** basis set is used. We compare HOMO, LUMO and HLG to the experimental IP, EA, and first excitation energy among the four methods. In addition we formally calculated the IP and EA as the difference in energy between the corresponding ion and the neutral. B3PW91 show at least comparable results to other methods more commonly used.

1:03PM Q13.0010 Relativistic Density Functional Theory Calculations of the Electron Paramagnetic Resonance Parameters for Vanadyl Acetyl Acetonate and Copper Acetyl Acetonate
LAXMAN MAINALI, INDIRA SAHU, KEITH EARLE, Department of Physics, SUNY at Albany — Relativistic density functional theory calculations of electron paramagnetic resonance (EPR) parameters using a variety of basis sets have been computed for the molecular systems Vanadyl acetyl acetone and Copper acetyl acetone using the ORCA program. The basis set dependence of g and A tensor calculations for Vanadyl acetyl acetonate and Copper acetyl acetone were studied using Pople Style and Ahirachs basis sets in Local and gradient corrected functionals (BP86 and PW91) and Hybrid functionals (B3LYP and PW1PW). The PW1PW hybrid functional gives the best values for VO(acac)2 using the TZV basis set and for Cu(acac)2 using the 6-311G(d) basis set. The calculated A values with PW1PW hybrid functional for VO(acac)2 and Local and gradient corrected functional (BP86) for Cu(acac)2, with same basis set (DZ) give better results than previously reported values using the Amsterdam Density Functional Theory (ADF) Software. Our calculated g and A tensor values are in good agreement with the values determined from experiment.

1:15PM Q13.00011 ABSTRACT WITHDRAWN —

1:27PM Q13.00012 Functional minimization scheme for first-principles electronic structure calculations with bi-orthogonal interpolating wavelets
WILLIAM GARBER, DMITRI VOLJA, WEI KU, Brookhaven National Laboratory — A new development of first-principles electronic method will be presented based on direct energy functional minimization and bi-orthogonal wavelet basis set. The employment of bi-orthogonal basis allows systematically controlled accuracy while benefiting from the compact support that allows O(N) algorithms. Furthermore, utilization of the interpolating nature of the wavelet, together with the effectiveness of multi-resolution of wavelet, enables very efficient calculation without compromising accuracy. By avoiding solving eigenvalue equation as in standard Kohn-Sham framework, the method is easily extended to parallel algorithms, and allows simple implementation of various non-local functionals. In case of crystals, our method goes directly as solution of Wannier functions, further utilizing their sparseness. This new development is ideal for easy implementation and accurate systematic benchmarking of various modern functionals, and holds the potential to attack very large systems such as nano-materials.

1:39PM Q13.00013 An implementation of LDA+DMFT within the PAW framework: Application to SrVO3.
BERNARD AMADON, CEA Bruyeres le Chatel, DPTA, France, FRANK LECHERMANN, University of Hamburg, Germany, ANTOINE GEORGES, Ecole Polytechnique, CNRS, France — The combination of LDA and DMFT has been used in the past ten years to understand properties of strongly correlated systems. Different interfaces have been used such as Linear Muffin Tin Orbitals and Maximally Localized Wannier Functions. Such schemes are however restricted to simple systems because the construction of wannier functions is demanding or because another simplification is used (such as the atomic sphere approximation). We present a new implementation of LDA+DMFT, which keeps the precision of the Wannier implementation, but which is lighter. It relies on the projection of Kohn-Sham states over localized orbitals to define the correlated subsystem. We have implemented this method within the Projector Augmented Wave Framework. This thus opens the way to electronic structure calculations within LDA+DMFT for more complex structures. We present an application to SrVO3. The results are compared to calculations done on the Wannier basis and we discuss the features of the total spectral function.
11:15AM Q14.00001 Control of Decoherence of Many-Body Excitations in a Bose-Einstein Condensate. NIR BAR-GILL, EITAN ROWEN, NIR DAVIDSON, Weizmann Institute of Science — In this work we discuss collective, many-body excitations of a BEC, and their decay into the condensate continuum. We measure the excitation spectrum of a BEC loaded into a 1D optical lattice, and the decoherence of these excitations due to Beliaev damping, as a function of the lattice depth. The cause for decoherence is the Beliaev decay of Bogoliubov quasi-particles, both of which (the excitation and decay products) are observable experimentally. The unique structure of the BEC reservoir, which is composed of a continuum of initially unoccupied quasi-particle modes, results from the quantum interference between the hole and particle amplitudes of these modes. This structure can be modified in a well-controlled manner by adiabatically loading the BEC into and optical lattice. Therefore, by changing the depth of the lattice, we can control the decoherence rate of the excitations. Our experimental results are compared to 1D calculations of the Bloch-Bogoliubov theory. We find that the rate of decay is either enhanced or suppressed as a function of lattice depth. These results can be explained in the framework of the general formula for decay, which also accounts for both the quantum zeno and anti-zeno effects. Such control of the coherence time could allow further studies of dynamics and phase fluctuations of this many-body system.

11:27AM Q14.00002 Investigating Universal Few-body Physics based on Bose-Einstein Condensates of Cesium Atoms in Optical Lattices. NATHAN GEMELKE, CHEN-LUNG HUNG, XIBO ZHANG, CHENG CHIN, University of Chicago — We present progress on an experiment designed to investigate universality in few-body systems based on Bose-condensed atoms in optical lattices. In particular, we describe how collapse and revival of matter wave coherence may be used as a sensitive probe for non-binary collisions and correlations. We discuss limitations on the technique due to lattice inhomogeneity and hydrodynamic time-of-flight, and suggest remedies based on Feshbach-mediated control of interactions, and application of spin-echo techniques to matter-wave revival. To reach this goal, we have recently demonstrated Bose-Einstein condensation of $3 \times 10^5$ cesium atoms in a crossed-beam dipole trap. A novel trapping geometry is adopted which allows us to smoothly convert the crossed-beam trap to a single layer of two-dimensional (2D) lattices. The single-layer 2D lattice will allow us to directly monitor the density distribution of atoms and identify domains with different atomic populations.

11:39AM Q14.00003 Temperature effects when adiabatically ramping up the optical lattice. LORE POLLET, ETH Zurich, CORINNA KOLLATH, Universite de Geneve, KRIS VAN HOUCKE, University of Massachusetts - Amherst, MATTHIAS TROYER, ETH Zurich — When atoms are loaded into an optical lattice, the process of gradually turning on the lattice is almost adiabatic. We calculate the entropy in the single band Bose-Hubbard model for various densities, interaction strengths and temperatures using Quantum Monte Carlo. This allows us to draw equi-entropy lines in order to study the adiabatic heating when going from the gapless superfluid phase to the gapped Mott phase. We present results in one and two dimensions for homogeneous and trapped systems. We find that current experiments remain in the quantum degenerate regime, and our theory can reproduce experimental time-of-flight images.

11:51AM Q14.00004 Bose-Einstein condensation and superfluidity in optical lattices and periodic porous media; a path integral Monte Carlo study. ALI SHAMS, HENRY GLYDE, University of Delaware — We evaluate the Bose-Einstein condensate density and the superfluid fraction of bosons in a periodic external potential using Path-Integral Monte Carlo (PIMC) methods. A unit cell containing a potential well is replicated into a lattice along 1D using periodic boundary conditions. The aim is to describe bosons in 1D optical lattice or helium confined in a periodic porous medium. The One-Body Density Matrix (OBDM) is evaluated and diagonalized to obtain the single boson natural orbitals (e.g. the condensate orbital) and the occupation of these orbitals (e.g. the condensate fraction). The superfluid density is obtained from the winding number. We investigate (1) the impact of the periodic external potential on the spatial distribution of the condensate, and (2) the correlation between localizing the condensate into separated parts and the loss of superflow along the lattice. For strongly interaction Bosons, as the well depth increases, the condensate becomes depleted in the wells (depletion by interaction). For weakly interacting bosons, as the well depth increases, the BEC is localized at the center of the wells (tightly binding). In both cases, the localization of the condensate suppresses superflow leading to a superfluid-insulator cross-over. The temperature dependence is investigated and comparison with Hubbard models and experiment is made.

12:03PM Q14.00005 Superfluid-Insulator and Roughening Transitions in Domain Walls. SEBNEM GUNES SOYLER, BARBARA CAPOGROSSO-SANSONE, NIKOLAY PROKOFOV, BORIS SVISTUNOV, University of Massachusetts at Amherst. We have investigated superfluid behavior of one and two dimensional interfaces separating solid domains. The system is described by the hard-core Bose-Hubbard Hamiltonian with nearest-neighbor interaction. We present the analysis of superfluid-insulator transition of the interface based on our quntantum Monte Carlo simulations. We also show that, in one dimension the transition is accompanied by the roughening transition, driven by proliferation of charge-1/2 quasiparticles. The temperature dependence is investigated and comparison with Hubbard models and experiment is made.

12:15PM Q14.00006 Ground state properties of one- and two-component Bose-Hubbard model. SEBNEM GUNES SOYLER, BARBARA CAPOGROSSO-SANSONE, NIKOLAY PROKOFOV, BORIS SVISTUNOV, Physics Department, University of Massachusetts, Amherst. We report results for the ground state properties of the single component Bose-Hubbard model and preliminary results for the two-component system at total unity filling factor. Our study is based on exact quantum Monte Carlo simulations by worm algorithm. We compare our answers with those of existing analytic calculations based on strong coupling expansion and mean field theory. This work was supported by the DARPA OLE program.

12:27PM Q14.00007 Mott-insulator mediated Josephson physics. COURTNEY LANNERT, Wellesley College, SMITHA VISHVESHWARA, University of Illinois, Urbana-Champaign — We investigate the phenomenon of Josephson tunneling between superfluid regions separated by Mott insulating regions in the context of the Bose-Hubbard model. Such systems can be realized when bosons on a lattice close to a commensurate filling are subject to a random potential or when bosons of sufficiently small hopping strength are trapped in an applied confining potential (i.e. in cold-atomic systems). Using a pseudospin approach valid at small t/U (large interaction strength or small hopping), we derive the equations of motion of the system and show that they lead to Josephson coupling between disjoint superfluid regions. We find expressions for the bulk energy and the Josephson tunneling energy and evaluate them numerically for realistic experimental parameters in a radially-symmetric parabolically-confined cold atom system. Partially supported by NSF grant DMR-0605871.
KUEI SUN, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign, COURTNEY LANNERT, Wellesley College — We study the inhomogeneous system of interacting bosons in an optical lattice trap. We focus on the weak tunneling region wherein a condensate is predicted to exist between two Mott insulating phases and we consider the effect of applying a radio-frequency (RF) magnetic field in this region. We find that the RF spectrum for driving transitions from one hyperfine species of bosons to another is markedly different between the Mott insulating phase and the condensed phase. In particular, the former has one resonant peak, while the latter has two peaks which show shifts of the order of the tunneling strength between lattice sites. Our results and analyses provide a means of verifying the existence of the condensate.

12:51PM Q14.00009 Bosons with three-body interactions on optical lattices, STEFAN WESSEL, Stuttgart University — Motivated by a recent proposal on using polar molecules in optical lattices driven by microwave fields to induce strong three-body interactions (H. P. Büchler et al., Nature Physics 3, 726 (2007)), we study the quantum phase diagram of the boson Hubbard model with nearest neighbor three-body repulsion using quantum Monte Carlo simulations. In particular, we consider the case of a one-dimensional system in the hard-core limit, and assess the nature of the phases that appear in this regime. Our exact numerical results are compared to analytical findings based on a bosonization approach to the same model. Extensions to higher-dimensional systems are mentioned.

1:03PM Q14.00010 Supersolidity from defect-condensation in the extended boson Hubbard model.
YU-CHUN CHEN, National Taiwan University, ROGER G. MELKÒ, University of Waterloo, STEFAN WESSEL, Universität Stuttgart, YING-JER KAO, National Taiwan University — We study the ground state phase diagram of the hard-core extended boson Hubbard model on the square lattice with both nearest- (nn) and next-nearest-neighbor (nnn) hopping and repulsion, using Gutzwiller mean field theory and quantum Monte Carlo simulations. We observe the formation of supersolid states with checkerboard, striped, and quarter-filled crystal structures, when the system is doped away from commensurate fillings. In the striped supersolid phase, a strong anisotropy in the superfluid density is obtained from the simulations; however, the transverse component remains finite, indicating a true two-dimensional superflow. We find that upon doping, the striped supersolid transitions directly into the supersolid with quarter-filled crystal structure, via a first-order stripe melting transition.

1:15PM Q14.00011 Bose Hubbard model in the presence of Ohmic dissipation.
DENIS DALIDOVICH, MALCOLM KENNÉTT, Simon Fraser University — We study the zero temperature mean-field phase diagram of the Bose-Hubbard model in the presence of local interactions between the bosons and an external bath. We consider a coupling that conserves the on-site occupation number, preserving the robustness of the Mott and superfluid phases. We show that this interaction with the bath shrinks the size of the Mott lobes, leading to superfluidity around the points where $\frac{n}{\mu/U}$ is integer, even in the absence of hopping between the sites. It also imposes an upper limit on the possible occupation numbers in the Mott phase, $n_{\text{max}}$ which is relatively small. We discuss the role that such a bath coupling may play in experiments that probe the formation of the insulator-superfluid shell structure in systems of trapped atoms.

1:27PM Q14.00012 Incommensurate superfluidity of bosons in the optical lattice of double-well potentials.
VLADIMIR M. STOJANOVIC, Carnegie Mellon University, CONJUN WU, University of California, San Diego, W. VINCENT LIU, University of Pittsburgh, SANKAR DAS SARMA, University of Maryland, College Park — We study the first excited band of the Bose-Hubbard model in a double-well optical lattice, a setup recently experimentally realized by a group at NIST. A unique feature of this system is the two lowest bands being far separated from the higher bands, which leads to a greatly reduced phase space for the decay of bosons initially occupying the first excited band. By calculating the parameters of the Bose-Hubbard model based on the nonseparable optical lattice potential used in the NIST experiments, we estimate that in the most favorable situations the lifetime of bosons in the first excited band can be several orders of magnitude longer than the characteristic time scales associated with nearest-neighbor tunneling. An additional novel feature of this system is that the band-minima of the excited band occur at an incommensurate finite crystal momentum, suggesting a new superfluid state of circulating currents that spontaneously breaks the time-reversal, rotational, and translational symmetries. We discuss possible physical consequences of this unconventional state.

1:39PM Q14.00013 Superfluid-insulator transition in Fermi-Bose mixtures and the orthogonality catastrophe.
GIL REFAEL, Caltech, EUGENE DEMLER, Harvard University — The superfluid-insulator transition of bosons is strongly modified by the presence of Fermions. Through an imaginary-time path integral approach, we account for the statics as well as the dynamical screening effects of the Fermions on the boson's superfluid transition line. We find that an effect akin to the fermionic orthogonality catastrophe, arising from the fermionic screening fluctuations, suppresses superfluidity. We analyze this effect for various mixture parameters and temperatures, and consider possible signatures of the orthogonality catastrophe effect in other measurements of the mixture.

1:51PM Q14.00014 Novel few- and many-body lattice methods for cold atoms.
DEAN LEE, North Carolina State University — We discuss general methods for measuring scattering phase shifts, spin-orbit coupling, and mixing angles for quantum particles on a lattice. We also present many-body lattice results for ground state properties at unitarity and deviations due to finite S-wave scattering length, S-wave effective range, and P-wave scattering volumes.

2:03PM Q14.00015 Cat state production with ultracold bosons in rotating ring superlattices.
ANDREAS NUNNENKAMP, Clarendon Laboratory, University of Oxford, ANA MARIA REY, ITAMP, Harvard University, USA, KEITH BURNETT, University of Sheffield, UK — Ultracold bosons in rotating ring lattices have previously been shown to form cat-like superpositions of different quasi-momentum states. We demonstrate that cat state production in slightly non-uniform ring lattices has several advantages: the energy gap decreases less severely with the number of particles, the sensitivity to detunings from the critical rotation frequency is reduced, and the scheme is not limited to commensurate fillings. We show that different quasi-momentum states can be distinguished in time-of-flight absorption imaging and propose to probe cat-like correlations via the many-body oscillations induced by a sudden change in the rotation frequency.

We acknowledge support from the Rhodes Trust (A.N.), ITAMP (A.M.R.), the Royal Society and the Wolfson Foundation (K.B.).

Session Q15 DMP: Focus Session: Semiconductor Qubit Approaches I Morial Convention Center 207
11:15AM Q15.00001 Spin Dependent Transport in Si/SiGe Few-Electron Quantum Dots
CHRISTIE SIMMONS, University of Wisconsin - Madison — Si/SiGe quantum dots are of interest for quantum information processing due in large part to the existence of spin zero isotopes of both Si and Ge. We present the results of transport measurements and integrated charge sensing in silicon double and single quantum dots.[1,2] We observe two effects arising from spin dependent transport in a double quantum dot. First, and as expected, for one direction of current flow we observe spin blockade – the canonical example of spin-to-charge conversion in transport. In addition, when current flow is reversed, we observe a second effect: strong tails of current extend from the sharp triangular regions in which current conventionally is observed. The presence of these tails is explained by a combination of long spin relaxation times and preferential loading of an excited spin state. We also present charge-sensing measurements of single and double quantum dots using an integrated quantum point contact. The charge sensor signal from single electron tunneling is well correlated with conventional transport through the system. When the tunnel barrier is large and transport through the dot is not measurable, charge sensing remains a viable means to track charge transitions and is used to confirm individual-electron occupation in a single quantum dot. Work performed in collaboration with Nakul Shaji, Madhu Thalakulam, Levente J. Klein, H. Luo, Hua Qin, R. H. Blick, D. E. Savage, M. G. Lagally, A. J. Rimberg, R. Joynt, M. Frieden, S. N. Coppersmith, M. A. Eriksson. Work supported by ARO, LPS, NSF and DOE. (1) Shaji, N. et al. e-print arXiv:0708.0794 (2) Simmons, C. B. et al. Appl. Phys. Lett. 91, 213103 (2007).

11:51AM Q15.00002 Coulomb Blockade in Double Top Gated Si MOS Nano-Structures, ERIC NORDBERG, University of Wisconsin - Madison and Sandia National Laboratories, MALCOLM CARROLL, MIKE LILLY, KENT CHILDS, LISAY TRACY, KEVIN ENG, ROBERT GRUBBS, JOEL WENDT, JEFF STEVENS, Sandia National Laboratories, MARK ERIKSSON, University of Wisconsin - Madison — Recent demonstrations of Pauli blocked transport in Si-based double quantum dots [1,2] have demonstrated that the basic processes involved in spin-to-charge conversion are observable in quantized quantum dots in Si. In this work, we will present results on the fabrication and electrical transport properties of novel double top gated Si MOS nano-structures. Potential advantages include: variable 2DEG density, CMOS compatible processes, and relatively small vertical length scales. A silicon foundry was used for initial processing steps and produced MOS structures with a peak mobility of 12000 cm2/V·s at electron densities of 1×1012/cm2. Resulting structures, demonstrate Coulomb blockade, and we will discuss the effect of different geometries (vertical top gate spacing, and single and double dot designs) on Coulomb blockade in these Si MOS structures. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000. 12:03PM Q15.00003 Dephasing of exchange coupled spin qubits by electron-phonon coupling in Silicon1, XUEDONG HU, University at Buffalo, The State University of New York — Silicon is regarded as one of the most promising host materials for solid state spin-based quantum information processing because of small spin-orbit interaction and the prospect of removing nuclear spins through isotopic purification. However, in a coupled spin system, charge and orbital fluctuations are as harmful to the spin qubits as in other semiconducting materials. Here we explore pure dephasing between the two-electron singlet and triplet states for two exchange-coupled spin qubits in a double quantum dot, with particular attention paid to the multi-valley nature of the silicon conduction band.

1This work is supported by NSA, LPS, ARO, and NSF.

12:15PM Q15.00004 Decoherence and Relaxation in Two-electron Si Quantum Dots, MARTA PRADA, University of Wisconsin Madison, MARK FRIESEN, ROBERT JOYNT — We study the relaxation process for a doubly-occupied silicon quantum dot from an excited (triplet) state to the ground (singlet) state. The dominant mechanism available in absence of an external magnetic field is the hyperfine coupling with nuclei via a virtual state. Since a direct transition is forbidden by energy conservation, (the energy associated with a nuclear spin is three orders of magnitude smaller than that of the electron spin), the change in energy of the electron spin has to be compensated by a lattice vibration, or emission of a phonon. On the other hand, in absence of time reversal symmetry, spin-orbit (SO) admixtures different spin states through the Rashba SO coupling. This leads to a non-vanishing matrix element for the phonon-assisted transition between a singlet and a triplet state, where the phonon provides only energy conservation, potentially increasing the relaxation rate, 1/ΓST. We find relaxation times TST of a few seconds for a 40×40×15nm3 Si quantum dot in a magnetic field of 1T.

12:27PM Q15.00005 Spin-singlet-triplet relaxation times in Si double quantum dots, ANTON VORONTSOV, MAXIM VAVILOV, University of Wisconsin - Madison — Recent observation of spin-sensitive transport in semiconductor quantum dots presents a new way of spin manipulation in nanoscale devices. Spin-flip processes are essential for understanding the potential of these systems. Following experiments by A. C. Johnson et al. Phys.Rev.B 72, 165308 (2005) and N. Shaji et al. [cond-mat/0708.0794] we calculate the relaxation times of different spin configurations in double quantum dots. For two-electron states, we evaluate the effects of leads on the spin-flip transitions, compare these effects with relevant spin-orbit and nuclear spin relaxation mechanisms, and calculate the electric current profile, including structure of the peaks and temperature dependence of the transport in the suppressed (‘valley’) region.

12:39PM Q15.00006 Spin resonance of 2D electrons in silicon MOS structures1, S. SHANKAR, A.M. TYRYSKIN, S. A. LYON, Princeton University — Metal-oxide-silicon (MOS) heterostructures are a well developed technology, but not much is known about the electron spin properties of this system. However the promise of utilizing electron spins in MOS structures as qubits for quantum information processing calls for detailed study of these properties. We have previously reported an ESR signal at g = 1.9999(1) originating from 2D electrons in a MOSFET. The signal arises from mobile 2D electrons at gate voltages above threshold and weakly confined electrons below threshold. The signal intensity for confined electrons follows the expected Curie-like 1/T temperature dependence characteristic of isolated, independent spins. At high electron densities, where the Fermi energy is large compared to the microwave frequency, one might expect a simple Pauli susceptibility temperature dependence. In particular, electron spin susceptibility is expected to become constant at low temperatures. Perhaps surprisingly, we find that below about 4 K, the spin susceptibility decreases as the temperature is lowered. At electron densities from 3×1011 to 10×1011 cm−2, the signal intensity falls by a factor of 5, as the temperature is reduced from 4 to 2 K. A more sophisticated analysis is required to explain the temperature dependence of the mobile 2D electron ESR signal.

12:51PM Q15.00007 Valley Splitting in Electrostatically Confined Structures at the Si/SiO2 Interface, L.A. TRACY, Sandia National Laboratories, E.P. NORDBERG, University of Wisconsin, K. ENG, M.P. LILLY, M.S. CARROLL, Sandia National Laboratories — Silicon is a promising material for qubits that use the spin degree of freedom for their encoding because of the anticipated long spin decoherence times. Electrostatic confinement of electrons at a Si(100)/dielectric interface splits the 6 fold conduction band degeneracy. However, 2DEGs are found to have a relatively small valley splitting between the two lowest levels, which is smaller than predicted for ideal interfaces. Small valley splitting is undesirable as it may detrimentally impact the spin decoherence time. Recent theory suggests that interface properties (e.g., miscut and disorder) can significantly change the valley splitting. Large splitting of the valley states has recently been observed in nanostructures formed in Si/SiGe heterostructures for which it is believed the electrons sampled a small number of atomic terraces [1]. In this talk, we will discuss valley splitting at a Si/SiO2 interface in both conventional MOSFETs, MOS- heterostructures and their dependence on effects such as interface roughness, fixed charge, trap density and strain. The valley splitting is characterized via activation energy measurements in the quantum Hall regime. [1] S. Goswami et al., Nature Physics 3, 41 (2007). Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States DOE under contract DE-AC04-94AL85000.
Substrate orientation dependence of valley-splitting in Silicon nanostructures | NEERAV KHARCHE, SEONGMIN KIM, School of Electrical and Computer Engineering, Network for Computational Nanotechnology, Purdue University, TIMOTHY BOYKIN, Department of Electrical and Computer Engineering, University of Alabama in Huntsville, GERHARD KLIMECK, School of Electrical and Computer Engineering, Network for Computational Nanotechnology, Purdue University — Si nanostructures are being actively perceived for Quantum Computing (QC) devices where valley-splitting (VS) is an important device design parameter. Si is desirable for QC due to its long spin decoherence times, scaling potential and integrability within the present microelectronic infrastructure. Six-fold degenerate valleys in Si interact with each other in the presence of confinements provided by physical dimensions of the nanostructures, and applied electric and magnetic fields. These interactions can result in very-different splittings depending on substrate orientations and inherently present disorders in nanostructures. Surface morphology of Si is highly dependent on substrate orientations and so is the VS. Such surface irregularities are automatically included in supercell tight-binding calculations due to atomistic nature of the Hamiltonian. VS calculations in the Si nanostructures grown on (100), (110), (111) and high index vicinal surfaces will be presented.

Why the Long-term Charge Offset Drift in Si SET Transistors is Much Better than Metal-Based Ones: TLF Stability | NEIL ZIMMERMAN, WILLIAM HUBER, STUART MARTIN, BRIAN SIMonds, EMMANOUEL HOURDAKIS, AKIRA FUJlWARA, YUKINORl ONO, YASUO TAKAHASHI, HIROSHI INOKAWA, CHRISTIAN HOF, MIHA FURLAN, MARk KELLER, JOSÉ AUMENTADO — The charge offset drift is a long-standing problem in metal-based single-electron tunneling (SET) devices, manifesting as a time-dependent instability. Through a compendium of drift measurements on SET transistors fabricated in five different laboratories, we can show that the drift is endemic in metal-based devices, but is absent in Si-based devices. Given that it is well-known that two-level fluctuators (TLF's) exist in Si devices the question naturally arises: why is the long-term drift so much better in the Si-based devices? Our answer: the TLF's in Si devices are stable over time, thermal cycling, etc., whereas the TLF's in the metal-based devices are unstable, and exist in interacting glass-like state. Following these observations, we have developed a model based on the theory of heat evolution in glasses that quantitatively agrees with the rate of charge offset drift in metal-based devices. Finally, we suggest some particular directions for future fabrication that may eliminate this problem.

Vertically coupled Al and Si SETs for characterization of MOS structures at low temperature | LUYAN SUN, B.E. KANE, Laboratory for Physical Sciences, University of Maryland — Due to impurities and interface states, a silicon metal-oxide-semiconductor field-effect transistor (MOSFET) channel is usually imperfect. A single electron transistor (SET) close to the channel provides a useful probe of some of these imperfections at low temperatures, the regime where Si devices may be used for quantum information processing. We incorporate an Al-AlO\textsubscript{2}-Al SET at the gate of a narrow MOSFET to induce a self-aligned and vertically coupled Si SET at the Si/SiO\textsubscript{2} interface [1]. We use this SET sandwich architecture to probe and identify sources of defect charge motion in MOS structures via a cross-correlation measurement between the two SETs. In particular, we will present preliminary data from these devices to study a single charge defect at the Si/SiO\textsubscript{2} interface. [1] L. Sun, K. R. Brown, and B. E. Kane, Appl. Phys. Lett. 91, 142117 (2007).

Gate control of single-electron spins: a multi-scale numerical simulation approach | SANJAY PRABHAKAR, JAMES RAYNOLDS, State University of New York University at Albany — Among recent proposals for next-generation, non-charged-based spintronics there is the notion that a single electron can be trapped and its spin manipulated through the application of gate voltages (Rev. Mod. Phys. 79, 1217 (2007)). In this talk we present numerical simulations of such Spin Single Electron Transistors (SSET) in support of experimental work at the University at Albany, State University of New York aimed at the practical development of post-CMOS concepts and devices. We use a multi-scale simulation strategy to self-consistently solve the Schroedinger-Poisson equations (with and without exchange-correlation effects) to obtain realistic confining and gating potentials for realistic device geometries. We discuss scaling of the equations in the various sub domains of a finite-element discretization to span the dimensions from the micron scale of the gate structures down the single-electron level. We will discuss the calculation of the gate-tuned “g-factor” for electrons and holes (Phys. Rev. B 68, 155330 (2003)) in electro-statically- and lithographically-defined quantum dots including the Rashba and Dresselhaus spin-orbit interactions computed numerically from realistic wave functions. This work is supported through funding from the DARPA/NRI INDEX center.

Negative-result evolution from continuous noisy measurement of a double-dot spin qubit | RUSKO RUSKOV, VIATCHELAV V. DOBROVITSKI, BRUCE N. HARMON, Ames Laboratory — We consider evolution of a double quantum dot (DQD) two-electron spin qubit that is continuously measured with a linear charge detector (quantum point contact). We identify the regime where a non-unitary negative-result evolution of the qubit emerges due to the fact that the system remains in the (1,1) charge state (each dot is occupied by one electron). In this case, the \(|T_0(1,1)|\) triplet spin state is spin-blocked, and the transition between \(|S(1,1)|\) and \(|S(0,2)|\) states is suppressed by the continuous measurement, due to the quantum Zeno effect. Moreover, unitary evolution between \(|T_0(1,1)|\) and \(|S(1,1)|\) states is induced by the negative-result measurement due to presence of \(|S(0,2)|\) state. We demonstrate that these effects exist for both strong and weak coupling between the detector and the DQD system. They can be observed with present-day technologies and can be used for coherent qubit manipulations complimentary to existing methods.

Atomistic calculation of electronic and optical properties of a single InAs quantum dots | M. ZIELINSKI, M. KORKUSINSKI, Institute for Microstructural Sciences, NRC, Ottawa, Canada, W. SHENG, Department of Physics, Fudan University, Shanghai, China, P. HAVRYLAK, Institute for Microstructural Sciences, NRC, Ottawa, Canada — We present an atomistic tight-binding (TB) theory of electronic structure and optical properties of a single self-assembled InAs quantum dot (SAD). In previous work an effective-bond-orbital model (EBOM) was used to calculate electron and hole states of the SAD. The strain distribution was calculated using the continuum elasticity theory and EBOM was coupled to the strain via the Bir-Pikus Hamiltonian. However, the properties of these multimillion-atom systems are influenced by the presence of crystal facets and the symmetry of underlying zinc-blende lattice. In current work we present a fully atomistic TB model, accounting for the atomistic symmetry, and extended to include d-orbitals for proper treatment of interband/intervalley couplings. Strain is included in the Hamiltonian via Slater-Koster rules and a generalized Harrison law, with the equilibrium positions of atoms calculated using the valence force field method. Coulomb matrix elements are found using the TB functions, and electronic properties of N confined excitons (N=1-6) are determined in the CI approach. Emission spectra of multieexcitons are also obtained. Comparison with the previous approach and the experimental results is presented.

Session Q16 DBP DPOLY DFD: Focus Session: Cytoskeletal Dynamics and Cell Motility II
11:15AM Q16.00001 Cell migration through connective tissue in 3-D. BEN FABRY, Department of Physics, University of Erlangen-Nuremberg, Germany — A prerequisite for metastasis formation is the ability of tumor cells to invade and migrate through connective tissue. Four key components endow tumor cells with this ability: secretion of matrix-degrading enzymes, firm but temporary adhesion onto connective tissue fibers, contractile force generation, and rapid remodeling of cytoskeletal structures. Cell adhesion, contraction, and cytoskeletal remodeling are biomechanical parameter that can be measured on single cells using a panel of biophysical methods. We use 2-D and 3-D traction microscopy to measure contractile forces; magnetic tweezer micro electromechanical systems to estimate adhesion strengths, cytoskeletal stiffness and myosin ATP turnover rates; and nanoscale particle tracking to measure cytoskeletal remodeling. On a wide range of tumor cell lines we could show that cell invasiveness correlates with increased expression of integrin adhesion receptors, increased contractile force generation, and increased speed of cytoskeletal reorganization. Each of those biomechanical parameters, however, varied considerably between cell lines of similar invasivity, suggesting that tumor cells employ multiple invasion strategies that cannot be unambiguously characterized using a single assay.

11:51AM Q16.00002 Dynamics of active cellular response under stress. RUMI DE, Weizmann Institute of Science, Israel, ASSAF ZEMEL, University of California, Davis, SAMUEL SAFRAN, Weizmann Institute of Science, Israel — Forces exerted by and on adherent cells are important for many physiological processes such as wound healing and tissue formation. In addition, recent experiments have shown that stem cell differentiation is controlled, at least in part, by the elasticity of the surrounding matrix. Using a simple theoretical model that includes the forces due to both the mechanosensitive nature of cells and the elastic response of the matrix, we predict the dynamics of orientation of cells. The model predicts many features observed in measurements of cellular forces and orientation including the increase with time of the forces generated by cells in the absence of applied stress and the consequent decrease of the force in the presence of quasi-static stresses. We also explain the puzzling observation of parallel alignment of cells for static and quasi-static stresses and of nearly perpendicular alignment for dynamically varying stresses. In addition, we predict the response of the cellular orientation to a sinusoidally varying applied stress as a function of frequency. The dependence of the cell orientation angle on the Poisson ratio of the surrounding material can be used to distinguish systems in which cell activity is controlled by stress from those where cell activity is controlled by strain. Reference: Nature Physics, vol. 3, pp 655 (2007).

12:03PM Q16.00003 Observation of Non-local Mechanical Responses to Locally Applied Forces in Cells using Magnetic Micropost Arrays. CORINNE LAMB, YAOHUA LIU, DANIEL REICH, Johns Hopkins University, NATHAN SNIADECKI, University of Washington, CHRISTOPHER CHEN, University of Pennsylvania — The process of force transduction by living cells is linked to changes in cell shape and function. To study this process in more detail, we have developed a novel force detection device, which can also be used to apply external forces to a cell. Cells are cultured atop an array of micrometer scale elasticostic posts, which act as independent sensors to cellular traction forces. An external force is applied to the adherent surface of the cell via a magnetic torque on a cobalt nanowire embedded in a single post. Results measuring the spatially resolved forces exerted by the cell over time indicate two responses: a sudden or a gradual global relaxation of the cell in response to a single force actuation. In both cases, the subcellular distribution of loss in traction forces was not concentrated near the point of stimulation but occurred instead at discrete locations around the cell’s periphery. Observation of these adaptive non-local responses is potentially important in understanding how external forces are transduced into biochemical regulators of cell function.

12:15PM Q16.00004 Substrate Stiffness Detection by Cellular Stress and Strain. SHANG-YOU TEE, PAUL JANMEY, University of Pennsylvania — Cells can detect the stiffness of their microenvironment and use this elasticity information to perform cellular functions. We grow cells in hydrogels of different stiffness. We embed particles in the hydrogels and measure the traction forces exerted on the hydrogel by tracking particle motions. We correlate these motions to protein dynamics and deduce the stress-strain relationship that cells use to measure elasticity.

12:27PM Q16.00005 Probing Eukaryotic Chemotaxis with Optically Manipulated Biomimetic Microparticles. HOLGER KRESS, CECILE MEJEAN, JIN GYU PARK, TAREK FAHMY, ERIC DUFRESNE, Yale University — Chemotactic cells are able to sense chemical gradients and to move towards the source of a chemical agent. Eukaryotic chemotaxis is an important part of the mammalian immune system and poses many questions about the cell's physical mechanisms to detect, process and respond to external stimuli. While an understanding of the balance between directional and random motion is necessary, few methods for precise, controlled and flexible quantitative cell stimulation are needed to test existing hypotheses. We present such a method which is based on optically manipulated biomimetic microparticles. We are developing colloidal particles that provide controlled release of a chemoattractant. These micro-sources of stimulating agents are positioned with optical tweezers at arbitrary locations close to chemotactic cells in order to apply flexible spatio-temporal stimulation patterns to the cells. We show that chemotactic cell response - directed cell polarization, motility and turning - can be induced by our novel stimulation method. In conjunction with live cell microscopy this method is suitable to study the dynamics of intracellular signaling loops.

12:39PM Q16.00006 Quantifying Dictyostelium discoideum Aggregation. COLIN MCCANN, University of Maryland, PAUL KRIEBEL, CAROLE PARENT, National Institutes of Health, WOLFGANG LOSERT, University of Maryland — Upon nutrient deprivation, the social amoebae Dictyostelium discoideum enter a developmental program causing them to aggregate into multicellular organisms. During this process cells sense and secrete chemical signals, often moving in a head-to-tail fashion called a 'stream' as they assemble into larger entities. We measure Dictyostelium speed, shape, and directionality, both inside and outside of streams, and develop methods to distinguish group dynamics from behavior of individual cells. We observe an overall increase in speed during aggregation and a decrease in speed fluctuations once a cell joins a stream. Initial results indicate that when cells are in close proximity the trailing cells migrate specifically toward the backs of leading cells.

12:51PM Q16.00007 Cell motility as a persistent random walk. SIMON NORTHELYKKE, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany. Department of Molecular Biology, Princeton University, FRANK JULICHER, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany — We study the stochastic properties of trajectories of individual keratocytes that move on a solid substrate. The distribution of observed velocities exhibits a characteristic maximum at finite speed and a local minimum at zero velocity. This velocity distribution depends on the averaging time during which velocities are measured. To characterize the stochastic properties of the system, we determine the correlations between longitudinal and transverse components of the acceleration with the instantaneous velocity. The experimental data can be captured by a simplified physical description of cell locomotion where random forces act on a system of two elastically coupled elements, one of which is driven forward by an active process, dragging the second behind.

1:03PM Q16.00008 Role of receptor patch geometry for cell adhesion in hydrodynamic flow. CHRISTIAN KORN, ULRICH SCHWARZ, University of Heidelberg — Motivated by the physiological and biotechnological importance of cell adhesion under hydrodynamic flow, we theoretically investigate the efficiency of initial binding between a receptor-coated sphere and a ligand-coated wall in linear shear flow. Using a Langevin equation that accounts for both hydrodynamic interactions and Brownian motion, we numerically calculate the mean first passage time (MFPT) for receptor-ligand encounter. We study how the MFPT is influenced by flow rate, receptor and ligand coverage, and receptor patch geometry. With increasing shear rate, the MFPT decreases monotonically. Above a threshold value of a few hundreds, binding efficiency is enhanced only weakly upon increasing the number of receptor patches. Increasing the height of the receptor patches increases binding efficiency much more strongly than increasing their lateral size. This strong dependence on out-of-plane geometry explains why white blood cells adhere to the vessel walls through receptor patches localized to the tips of microvilli, and why malaria-infected red blood cells form elevated receptor patches (knobs). [1] C. Korn and U. S. Schwarz, Phys. Rev. Lett. 97: 138103, 2006. [2] C. B. Korn and U. S. Schwarz. J. Chem. Phys. 126: 095103, 2007.
1:15PM Q16.00009 Dynamic friction measurements on living HeLa cells, MARC-ANTONI GOULET, MARIE-JOSE`EE COLBERT, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — The interaction of cells with various interfaces, and especially man-made surfaces, is an active field of research. In our experiment we use a micropipette to measure both the friction and normal force as a cell slides across a surface. A thin substrate, coated with Poly-L-Lysine is brought into contact with a HeLa cell. The adjustable substrate motion is used to study the response of the cell at various normal forces and speeds. Analysis of the micropipette provides dynamic measurements of both the friction and normal force. With our novel setup we are able to probe the attachment/detachment process of living cells.

1:27PM Q16.00010 AFM method to study mechanics of biological cells with real brushy surface, IGOR SOKOLOV, SWAMINATHAN IYER, RAVI GAIKWAD, VENKATESH SUBBA-RAO, CRAIG WOODWORTH, Clarkson University — AFM is particularly useful for studying biological systems because it can be used on viable cells directly in biological media. Most of the time, the deformation curves measured with AFM on cells have typical “two layer” behavior. As we see from confocal fluorescent images of cells, the cell surface is not flat and covered by a brush-like structure. Here we describe a simple two-layer model to decouple the force response of these two “layers”, the cell body and brush. In contrast with the existing biological methods, AFM is a highly sensitive technique that can provide precise quantitative data on both lengths and grafting densities of the brush while measured directly on viable cells. Moreover, it allows one to decouple true cell rigidity from the contribution of the brush layer. This novel method can be applied to virtually any kind of cells. Ignoring this layer may result in incorrect values of cell rigidity derived from the AFM measurements. We demonstrate the developed method on the example of cancerous and normal human cervical cells.

1:39PM Q16.00011 Dynamical measurement of the physical properties of single cells, MARIE-JOSE`EE COLBERT, CECILE FRADIN, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — The mechanical response of living cells to external forces has attracted the attention of many researchers. We have developed a new tool that takes advantage of an “L” shaped micropipette to micromanipulate a single cell and put it in contact with an adhesive surface mounted on a translation stage. The spring constant of the micropipette is carefully measured and its deflection is used to apply a calibrated force, and probe the mechanical properties of the cell. As the cell is compressed between the pipette and substrate, dynamical measurements of the elasticity of the cell and the adhesion of the membrane to the substrate are obtained by monitoring the displacement of the micropipette. This technique gives access to real time monitoring of the cell response to a constant applied force, thus exploring the relaxation processes of the cell when subjected to deformation.

1:51PM Q16.00012 Computational modeling of cell-cell adhesion and cell-endothelium peeling, KENG-HWE CHIAM, RAYMOND QUEK, A*STAR Institute of High Performance Computing — We describe the use of computational modeling to study the behavior of cells adhering to one another as well as to the circulatory endothelium. The cells are subjected to shear stress imposed by the circulatory plasma, and may peel from the endothelium as a result. Cells that peel have a higher chance to enter circulation and hence pose a greater threat in cancer metastasis. We use the immersed interface method to model the cells and solve for its biomechanical response. We quantitatively study the peeling dynamics as a function of the cells’ material properties and the surrounding fluid’s dynamics. We show how cell peeling from the endothelium is hampered by its adhesive interaction with surrounding cells. In addition, a larger aggregate of cells, such as a tumor embolus, peels more readily from the endothelium than smaller ones. These results may give us insight into the concept of cancer metastatic efficiency.

2:03PM Q16.00013 Implications of Cytoplasmic Streaming for Intracellular Transport and Micro-scale Mixing, JAN-WILLEM VAN DE MEENT, IDAN TUVAL, DAMTP, University of Cambridge, WIM VAN SAARLOOS, Lorentz Institute, Leiden University, RAY GOLDSTEIN, DAMTP, University of Cambridge — Found in many large eukaryotic cells, particularly in plants, cytoplasmic streaming is the circulation of their contents driven by fluid entrainment from organelles carried by molecular motors at the cell periphery. Streaming has frequently been conjectured to aid in transport and mixing of molecular species in the cytoplasm, and, by implication, in cellular homeostasis, yet no mechanism quantifying this enhancement has been demonstrated. We solve the flow and its associated advection-diffusion equations for the archetypal ‘rotational streaming’ found in Characean algae, where the cytoplasm streams up and down along helical bands on the surface of cylindrical internodal solute, allowing faster uptake and response to changes in external concentration. This effect constitutes a novel example of how high Pecl´ et number flows can facilitate diffusive transport and mixing at the micro-scale.

Wednesday, March 12, 2008 11:15AM - 2:15PM — Session Q17 DBP: Focus Session: Hydrophobic Interactions at Multiple Scales in Biology Morial Convention Center 209

11:15AM Q17.00001 Water, Hydrophobic Interactions, and Polymer Collapse, THOMAS TRUSKETT, The University of Texas at Austin — The collapse of a hydrophobic polymer in water is a basic model for many-body hydrophobic interactions, and it holds promise of providing fundamental insights into biomolecular folding transitions. Here, we discuss simulations that probe the effects of monomer length scale along with the strength of monomer-monomer and monomer-water interactions on the thermodynamics of the hydrophobic polymer collapse transition.

11:51AM Q17.00002 Comparing Nonaqueous against Aqueous Solution on the Basis of Scaled-Particle Theory, HENRY S. ASHBAUGH, Tulane University — Normal hexane is adopted as a typical organic solvent for comparison with liquid water in modern theories of hydrophobic hydration, and detailed results are worked out here for the C-atom density in contact with a hard-sphere solute, rho*G(R), for the full range of solute radii. The intramolecular structure of an n-hexane molecule introduces qualitative changes in G(R) compared to scaled-particle models for liquid water. Also worked out is a revised scaled-particle model implemented with molecular simulation results for liquid n-hexane. The classic scaled-particle model, acknowledging the intramolecular structure of an n-hexane molecule, is in qualitative agreement with the revised scaled-particle model results, and is consistent in sizing the methyl/methylene sites which compose n-hexane in the simulation model. The classic and revised scaled-particle models disagree for length scales greater than the radius of a methyl group, however. The liquid-vapor surface tension of n-hexane predicted by the classic scaled-particle model is too large, though the temperature variation is reasonable; this contrasts with the classic scaled-particle theory for water which predicts a reasonable magnitude of the water liquid-vapor surface tension, but an incorrect sign for the temperature derivative at moderate temperatures. Judging on the basis of the arbitrary condition that drying is indicated when G(R) < 1, hard spheres dry at smaller sizes in n-hexane than in liquid water.
and mixed aqueous solutions provide insights relevant to biological assembly. Chemistries (from hydrophobic to hydrophilic) and lengthscales. These simulations combined with those of folding-unfolding of hydrophobic polymers in water roles in biological and colloidal self assembly processes. More recently, lengthscale dependences and manybody effects in these interactions have received renewed attention. We will present results from theory and molecular dynamics simulations on hydration of and interactions between solutes and interfaces of varying chemistry (from hydrophobic to hydrophilic) and lengthscales. These simulations combined with those of folding-unfolding of hydrophobic polymers in water and mixed aqueous solutions provide insights relevant to biological assembly.

1:39PM Q17.00005 Depletion when Water meets a Hydrophobic Surface, ADELE POYNOR, Allegheny College, STEVE GRANICK, University of Illinois Urbana Champaign, PAUL FENTER, Argonne National Laboratory, IAN ROBINSON, University College London — What happens when water is forced into contact with a hydrophobic surface? Our previous synchrotron X-ray reflectivity experiments (Phys. Rev. Lett., 2006) reported strong evidence for the existence of an angstrom-thick region of low-density at this interface. Here we report fresh experiments in which ethanol, a wetting fluid, is studied at these same surfaces to quantify the contribution from terminal methyl groups on the hydrophobic surface that are invisible to X-rays. The existence of a depletion layer when water meets a suitably hydrophobic surface is confirmed. Better quantification of its thickness emerges.

1:51PM Q17.00006 Profile of the Interface between a Hydrophilic Surface and Water, URSULA PEREZ-SALAS, Argonne National Laboratory, JOHAN STALGREN, Stanford Linear Accelerator Center, CHARLES MAJKRZAK, FRANK HEINRICH, NIST Center for Neutron Research, MICHAEL TONEY, Stanford Linear Accelerator Center, DAVID VANDERAH, NIST — Aqueous interfaces are ubiquitous and play a fundamental role in biology, chemistry, and geology. The structure of water near interfaces is of the utmost importance, including chemical reactivity and macromolecular function. Theoretical work by Chandler et al. on polar-apolar interfaces predicts that a water depletion layer exists between a hydrophobic surface and bulk water for hydrophobes larger than \( \sim 20 \text{mm}^2 \) (a \( \sim 4A \) in radius apolar molecule). Until now, what the interface really looks like remains in dispute since recent experiments give conflicting results: from complete wetting (no water depletion layer) to a water depletion layer. Those experiments that have found a water depletion layer report 40-70% water in the depletion zone: 40 -70% and a width of \( \sim 3A \). However, an alternative interpretation to the profiles exists where no depletion layer is required. By studying hydrophobic SAM surfaces against several water mixtures we obtained the hydrophobic/water profile by phase sensitive neutron reflectivity. With this model independent technique we observe a 2 times wider and drier depletion water layer: 6A thick and 0-25% water. Given the level of disagreement, I will review the topic of immiscible interfaces and show how phase sensitive reflectometry is unique in obtaining nm resolution profiles without fitting bias.

2:03PM Q17.00007 Reconstructing the dynamics of water near a model charged surface using inelastic x-ray scattering, NATHAN SCHMIDT, ROBERT CORIDAN, GHEE HWEE LAI, PETER ABBAMONTE, GERARD WONG, University of Illinois at Urbana-Champaign, WONG RESEARCH GROUP TEAM — Understanding the behavior of water near hydrophobic surfaces is fundamental to many aspects in biology and surface. From high resolution inelastic x-ray scattering measurements of the dynamical structure factor at 3rd generation synchrotron sources, we reconstruct the longitudinal (density) response function of water. We use this data set to investigate how water behaves at polar and non-polar surfaces via linear response theory. Preliminary data on this and how water wets hydrophobic surface patches of different sizes will be presented.
11:39 AM Q18.00003 Improving the Dispersion and Interfaces in Polymer-Carbon Nanotube Nanocomposites by Sample Preparation Choice. CHANG-UK LEE, University of Tennessee, Knoxville, MARK DADMUN, University of Tennessee, Oak Ridge National Laboratory — Polymer nanocomposites composed of poly(styrene-vinyl phenol) (PSVP) copolymers and 5 wt % multi-walled carbon nanotubes (MWNTs) were prepared by three different methods, including melt-mixing and solution casting. The MWNTs were either oxidized to incorporate oxygenated defects or utilized as received. The mechanical properties of the nanocomposites were measured by DMA, and the extent of intermolecular hydrogen bonding between MWNTs and PSVP was quantified by IR. Our DMA results suggest that melt-mixing leads to more stable morphologies of the final nanocomposites than solution casting. Additionally, the IR analysis of the nanocomposites indicates melt-mixing can result in the formation of more intermolecular hydrogen bonding between the MWNTs and PSVP than solution casting, and thus suggests that melt-mixing leads to nanocomposites with more reproducible mechanical properties than solution casting. Our results thus provide guidelines to realize improved morphologies and properties of polymer carbon nanotube nanocomposites by optimizing intermolecular interactions between MWNTs and polymers using processing.

11:51 AM Q18.00004 Enhancing Dispersion and Properties of SWNT-polymer Nanocomposites by Controlled Non-covalent Interactions. DIAS LINTON, University of Tennessee — The enhancement of the dispersion and properties of singlewalled carbon nanotubes in a polymer nanocomposite via non-covalent interaction is studied. 1% w/w SWNT are dispersed in random copolymers of methyl methacrylate and 2-(dimethylamino)ethyl methacrylate (DMAEMA), where the composition of the copolymer varies from 0% to 50% DMAEMA. The resulting nanocomposites indicate the existence of interactions between the carbon nanotube and polymer matrix by a shift of the D* peak position (~2600-2700 cm⁻¹) of the polymer nanocomposite. The copolymer with 30% DMAEMA shows the smallest shift, suggesting that the nanotubes are debundled, where it is expected that this non-covalent interaction originate from the tertiary amino group in DMAEMA by formation of an electron-donor interaction with the SWNT.

12:03 PM Q18.00005 Spectroscopic Investigations on Polypropylene – Carbon Nanofibers Composites. MARCEA CHIPARA, The University of Texas at Pan American, JONES BRIAN, University of Nebraska Lincoln, KAREN LOZANO, JOHN R. VILLAREAL, ALIN CRISTIN CHIPARA, ANNA HERNANDEZ, MAGDALENA DORINA CHIPARA, The University of Texas Pan American, DAVID J. SELLMYER, University of Nebraska Lincoln — Nanocomposites were obtained by high-shear mixing of isotactic polypropylene (Marlex HLN-120-01; Philips Sulmika Polypropylene Compound) with various amounts of vapor grown carbon nanofibers (PR-24AG; Pyrograf Products, Inc) by utilizing a HAAKE Rheomix at 65 rpm and 180 °C for 9 min followed by an additional mixing at 90 rpm for 5 min. Composites loaded with various amounts of vapor grown carbon nanofibers have been prepared. Wide angle X-ray scattering investigations focus on the effect of carbon nanofibers on the crystalline phases of polypropylene and on the overall crystallinity degree of the polymeric matrix. Raman spectroscopy analysis concentrates on D and G bands. X-band electron spin resonance investigations aim at a better understanding of the purity of carbon nanofibers and of the ratio between conducting and paramagnetic.

12:15 PM Q18.00006 Simulation of Electrical Conductivity of Composites Containing Uniaxially-Aligned, Finite Rods above the Percolation Threshold. SADIE WHITE, University of Pennsylvania, BRIAN DIDONNA, LAI-CHING CHOU, TOM LUBENSKY, KAREN WINEY, University of Pennsylvania — Simulations probed the percolation behavior of composites containing isotropic and uniaxially aligned, conductive, cylindrical fillers with aspect ratios of 10, 20, and 80. In addition, the random resistor network model was used to calculate the electrical conductivity of these composites at concentrations above the percolation threshold. The observed trends compare favorably with our experimental results in carbon nanotube and carbon nanofiber polymer nanocomposites. For example, the electrical conductivity is highest when the fillers are slightly uniaxially aligned in both simulation and experimental results. In addition, the critical degree of filler orientational order at which the electrical conductivity abruptly decreases was found to depend on rod aspect ratio along the same trends noted for experimental data. This work represents the first simulations of electrical conductivity above the percolation threshold for oriented and isotropic composites containing permeable, conductive, finite-sized rods, and is pertinent to the rapidly expanding field of polymer nanocomposites.

12:27 PM Q18.00007 Polymer Dynamics in Single Wall Carbon Nanotube / Polystyrene Nanocomposites. MINFANG MU, RUSSEL COMPOSTO, Department of Material Science and Engineering, University of Pennsylvania, USA, NIGEL CLARKE, Department of Chemistry, Durham University, UK, KAREN WINEY, Department of Material Science and Engineering, University of Pennsylvania, USA — Polymer nanocomposites provide access to new regimes of polymer dynamics in which the impenetrable filler particles are comparable to and frequently smaller than the end-to-end distances of the polymer. In this study, single wall carbon nanotubes (SWCNTs) / polystyrene (PS) nanocomposites was prepared by a coagulation method. Rheological properties were measured in the linear viscoelastic regime and tracer diffusion coefficients were determined using an elastic recoil detection (ERD) method. The tracer diffusion coefficient first decreases and then increases with increasing SWCNT loading. Across this same range of filler concentration, the plateau modulus and the cross-over frequency are approximately constant. The transition from decreasing to increasing tracer diffusion corresponds approximately with the onset of rheological percolation and appears to increase with decreasing matrix molecular weight. A model is under development to describe the polymer dynamics is polymer nanocomposites.

12:39 PM Q18.00008 Periodic Patterning of Polyethylene Block Copolymers Directed by Carbon Nanotubes. BING LI, Drexel University, LINGYU LI, The Dow Chemical Company, CHRISTOPHER LI, Drexel University — Periodic patterning on one-dimensional carbon nanotubes (CNTs) is of great interest from both scientific and technological points of view. Although both chemical and noncovalent CNT functionalization have attracted extensive attention during the past decades, very few efforts have been dedicated to periodic patterning on individual CNTs. Recently, we demonstrated using a controlled polymer solution crystallization method to achieve periodically decorated CNTs. Polyethylene (PE) and Nylon 6,6 single crystals were controlled to grow on CNTs, forming a unique nanohybrid shish kebab (NHSK) structure. The periodicity was, however, not uniform because the concentration governed growth mechanism. Here we report improving the regularity of the periodic NHSK structures by employing block copolymers (BCPs), polyethylene-b-ethylene oxide (PE-b-PEO), to produce NHSKs on CNTs. By crystalizing BCP on CNTs via thin film crystallization, periodic structures were generated along CNTs. The characteristic microphase separation of BCP was clearly observed, forming the striking alternating stripes perpendicular to the axes of individual CNTs. Furthermore, by functionalizing the BCP blocks with thiol groups, Au nanoparticles were subsequently immobilized on the BCP domains of the hybrid nanomaterial, replicating the periodic patterns.
12:51PM Q18.00009 Clay dispersion and interaction effects in supercritical CO2 processed polystyrene-clay nanocomposites. • R. KANNAN, R. BELLAIR, M. MANITOU, S. HORSCH, Wayne State University, E. GYLAR, Clemson University — The major challenges in producing high performance nanocomposites are in effectively dispersing the clay layers in the matrix and in promoting interactions at the polymer-clay interface. A novel process exploiting the properties of supercritical CO2 (scCO2) has recently been shown to be an effective means to delaminate clay platelets with or without a polymer matrix present. In this study we demonstrate the ability of scCO2 to exfoliate commercial, organically modified clay and to produce nanocomposites with significantly improved properties. Rheology shows solid-like behavior in loadings as low as 2wt%, and elastic modulus improvements as high as 2.5 orders of magnitude in 5wt% nanocomposites. TEM images indicate a rich morphology for scCO2 processed composites, with a large fraction of dispersed platelets. In contrast, solution blended control samples display much larger tactoids and a lack of individual clay sheets. Unexpectedly, XRD shows a dramatic increase in the peak in specific heat during crystallization. Structural analysis shows that the additive particles are well-dispersed in the polymer matrix—-they are surrounded by both crystalline and non-crystalline chain segments, the relative proportions of which depend on x and y and strongly suppress the peak in specific heat during crystallization. The decrease in chain mobility correlates with lower crystallinity and smaller crystallite sizes. Further, the presence of additive particles also dramatically suppresses the peak in specific heat during crystallization. The degree of enhancement in the properties appears to be not only dependant on the degree of dispersion, but also on how polymer-clay interactions are promoted by the supercritical fluid.

1:03PM Q18.00010 Surface characterization of Laponite-Poly(ethylene oxide) nanocomposite films • EDUARD A. STAFANESCU, IOAN I. NEGULESCU, WILLIAM H. DALY, Department of Chemistry, Louisiana State University, Baton Rouge, LA 70803, BOGDAN C. DONOSE, ANH V. NGUYEN, School of Engineering, The University of Newcastle, Callaghan, NSW 2308, Australia — The aim of the present work is to understand how ionic strength of precursor polymer-clay gels influences the final structure of multilayered nanocomposite films fabricated from such gels. We have prepared three aqueous precursor gels containing 3wt% LRD, 2wt% PEO and 95wt% water, in which the salt concentrations were kept at 0X, 1X and 3X with X = 5.57 * 10⁻⁵ g NaCl/mL. The Laponite (LRD) - PEO multilayered films (LRD60%-PEO40%) were fabricated by manually spreading and drying each gel on a glass slide. Prior to the AFM measurements the polymer-clay composite films were freeze-dried by immersion in liquid nitrogen until they were totally degassed. Frozen samples then fractured and left for additional drying for 24 hours in a desiccator. The imaging procedure employed here is tapping mode AFM. Distinct features were identified on the layered transversal surface of the films, and were attributed to the different salt concentrations in the samples. Addition of salt increases the adhesion and compactness properties of the nanoparticles, as a more uniform side surface can be observed after freeze-fracturing the materials.

1:15PM Q18.00011 Viscoelastic Behavior of Polyhedral Oligomeric Silsequioxane (POSS)-Filled Epoxy Matrices • QINGXIU LI, STEPHEN HUTCHESON, GREGORY MCKENNA, Texas Tech University, KADINE MOHOMED, TAM Instruments-Waters LLC, SINDEE SIMON, Texas Tech University — Large residual stress in fiber-filled thermosetting resin composites is a major technological problem encountered during the development and applications of these materials. Strategies to reduce the residual stress of the composites include lowering the thermal stress coefficient by lowering the product of coefficient of thermal expansion and shear modulus (αG) and/or lowering the thermal pressure coefficient by lowering the product of coefficient of thermal expansion and bulk modulus (αK). Nanoparticles are unique fillers for resins used in composites and generally result in improved moduli and increased linear thermal expansion coefficient (CTE); however, the effect on the thermal residual stresses has not been addressed. This paper develops epoxy/polyhedral oligomeric silsequioxane (POSS) nanocomposites with mitigated residual stress. The effect of functionalized POSS loading on the viscoelastic properties, linear coefficient of thermal expansion, and glass transition temperature of epoxy/POSS nanocomposites is investigated. The outcome of the current study provides fundamental knowledge to the design criteria for nanoparticle-filled polymer matrix composites with mitigated residual stress and high shear properties.

1:27PM Q18.00012 Spectacular Improvements in Toughness of Poly(lactide-co-glycolide), PLG, Nanocomposites • HARIS RETSOS, MSEE CORNELL UNIVERSITY, ITHACA, NY TEAM — Poly(lactide-co-glycolide) (PLG), a biocompatible, biodegradable polymer, was toughened by adding small amounts of surface modified clay nanoparticles. The elongation of nanocomposite during tensile tests is highly increased in comparison with that of the pure polymer, while we observed also an increase in modulus. Electron microscopy, X-ray scattering, rheometry and dielectric spectroscopy were used to investigate the toughening mechanism. It is revealed that multiple crazing occurs in the clay nanocomposite right after the yield point. The fibrils in the crazes have the ability to be significantly extended before fracture, which translates into a dramatic increase in elongation before failure. Rheological studies show that the nanoclay particles act as physical crosslinks that increase the fracture strength of the polymer. Small angle x-ray scattering was used to investigate any orientation of nanoparticles during deformation and their mobility provided by the polymer matrix.

1:39PM Q18.00013 ABSTRACT WITHDRAWN —

1:51PM Q18.00014 Rheological Studies on the Quasi-quiescent Crystallization of Polypropylene Nanocomposites1 • XIA DONG, TONGCHEN SUN, FENGHUA CHEN, KE WANG, QIANG FU, CHARLES C. HAN, State Key Laboratory of Polymer Physics and Chemistry, Joint Laboratory of Polymer Science and Materials, ICCAS, Beijing, China — Isothermal crystallization of isotactic polypropylene/organic modified montmorillonite binary nanocomposite (IPP/OMMT) and IPP/OMMT/PEOc (poly(ethylene-co-octene)) ternary nanocomposites were investigated by polarized optical microscope, rheometer and scanning electron microscope. The modulus change which accompanying the crystallization growth was observed after freeze-fracturing the materials. We show that sticky interactions between polymers and clay nanoparticles suppress crystallization.

The authors thank the fund support from important project 20490220 of NSFC.

2:03PM Q18.00015 Effect of additive particles on the crystallization of homopolymers • ASHOK DASMAHAPATRA, Chemical Engineering, IIT Bombay and Polymer Division, National Chemical Laboratory, Pune, India, GURUSWAMY KUMARASWAMY, Polymer Division, National Chemical Laboratory, Pune, India, HEMANT NANAVATI, Chemical Engineering, IIT Bombay, India — The effect of additive particles on polymer crystallization has been investigated using lattice dynamic Monte Carlo simulation. Additives are compatible with the polymer matrix (viz. there is an attractive “sticky” interaction between additives and monomers) and, additive particles have the same size as a monomer. Polymer crystallization is strongly influenced by both additive fraction, x and the additive-monomer interaction strength, λ. While increase in x or λ the diffusivity of the polymer chain decreases dramatically. The decrease in chain mobility correlates with lower crystallinity and smaller crystallite sizes. Further, the presence of additive particles also dramatically suppresses the peak in specific heat during crystallization. Structural analysis shows that the additive particles are well-dispersed in the polymer matrix—they are surrounded by both crystalline and non-crystalline chain segments, the relative proportions of which depend on x and λ. We show that sticky additive particles suppress crystallization.

Wednesday, March 12, 2008 11:15AM - 2:15PM — Session Q19 FEd: Physics Education: In and Out of the Classroom Morial Convention Center 211
11:15AM Q19.00001 Changes in Student Models of Electric Current and Electric Potential in Activity-Based Physics1. C. TRECIA MARKES, University of Nebraska – Kearney — With a three-year FIPSE grant, it has been possible at the University of Nebraska at Kearney (UNK) to develop and implement activity-based introductory physics at the algebra level. It has generally been recognized that students enter physics classes with misconceptions about current and potential difference in simple series and parallel circuits. Many of these misconceptions persist after instruction. Pretest and posttest responses on the “Electric Circuit Concept Test” (ECC) are analyzed to determine the models that students use. Responses are divided into expert model (correct answer), one or more student models (approximately equally common incorrect answers), and null model (all other answers) categories. Students are categorized as being in an expert state (mostly expert model answers), a mixed state (a combination of expert model answers, student model answers, and null model answers), or a student state (mostly student model answers). The change (if any) of state is identified for each student. The changes are analyzed to determine the effectiveness of activity-based instruction.

This work was supported by the US DOE’s FIPSE Grant No. P116BS1449.

11:27AM Q19.00002 Do physics undergraduate students understand their strengths and weaknesses? R. MICHALAK, University of Wyoming — Physics and non-physics majors self evaluation and confidence responses to exams in undergraduate physics are analyzed with respect to the students’ actual success in the subject. The confidence was sampled in a variety of frequency and sophistication physics classes before and after the exams were taken. Undergraduate populations fall into two subgroups: Students who do have a general awareness whether they have comprehended a topic and students who have not. The divide is all the more surprising as there are students who excel and have no or little confidence that they do excel and as there are students who fail completely and do not see it coming. There is little change in student’s understanding of their comprehension during a given term or between terms.

11:39AM Q19.00003 Experimenting with the virtual environment Moodle in Physics Education. MARIA INES MARTINS, ADRIANA DICKMAN, Pontificia Universidade Catolica de Minas Gerais — The master’s program in Physics Education at the Catholic University in the state of Minas Gerais, Brazil, includes the discipline “Digital technologies in Physics education.” The main goal of this discipline is to discuss the role of Information and Communication Technology (ICT) in the process of learning-teaching science. We introduce our students to several virtual platforms, both free and commercial, discussing their functionality and features. We encourage our students to get in touch with computer tools and resources by planning their own computer based course using the Moodle platform. We discuss different patterns of virtual environment courses, whose proposals are centered mainly in the students, or teacher-centered or even system-centered. The student is free to choose between only one topic and a year course to work with, since their interests vary from learning something more about a specific subject to a complete e-learning course covering the entire school year. (The courses are available online in the address sitesinf01.pucmg.br/moodle. Participation only requires filling out an application form.) After three editions of this discipline, we have several courses available. We realize that students tend to focus on traditional methods, always preserving their role as knowledge-givers. In conclusion, we can say that, in spite of exhaustive discussion about autonomy involved with ICTs abilities, most of the students used the new virtual medium to organize traditional teacher-centered courses.

11:51AM Q19.00004 Writing and representation in liquid crystal physics research. CHAD WICKMAN, CHRISTINA HAAS, Kent State University, PETER PALFFY-MUHORAY, Liquid Crystal Institute, KSU — Public understanding of science is often shaped by semiotic systems—linguistic, mathematical, graphic, pictorial—deployed in the textual presentation of scientific findings. Nowhere is this more apparent, perhaps, than in recent debates over climate change where non-quantitative communication has played an integral role in shaping public discourse. This is one example of many, but it speaks to the need for research that examines how working scientists disseminate knowledge to expert and non-expert alike. Based on the study of text production in liquid crystal physics research, I will discuss the way in which physicists utilize multiple semiotic systems in their research and publications. Findings suggest that shared meanings are often created through a variety of semiotic forms—from linguistic script to equations to graphs to diagrams—and that these forms offer specific meaning potentials for communicating knowledge to different audiences. Ultimately, I argue that an improved understanding of scientific literacy practices is key to the effective communication of science to various constituencies.

12:03PM Q19.00005 Modeling cell membrane action potentials with RC circuits in a general physics teaching laboratory. M.S. RZCHOWSKI, Physics Dept., University of Wisconsin-Madison — Faculty in the physics department at the University of Wisconsin have been working in collaboration with colleagues in biological sciences to modify a large calculus-based general physics service course populated primarily by students pursuing a career in the biological sciences. Part of this effort involves introducing examples and laboratory experiments that students enter physics classes with misconceptions about current and potential difference in simple series and parallel circuits. Many of these misconceptions persist after instruction. Pretest and posttest responses on the “Electric Circuit Concept Test” (ECC) are analyzed to determine the models that students use. Responses are divided into expert model (correct answer), one or more student models (approximately equally common incorrect answers), and null model (all other answers) categories. Students are categorized as being in an expert state (mostly expert model answers), a mixed state (a combination of expert model answers, student model answers, and null model answers), or a student state (mostly student model answers). The change (if any) of state is identified for each student. The changes are analyzed to determine the effectiveness of activity-based instruction.

12:15PM Q19.00006 Two new experiments in physics based on electrospun polymer nanofibers. NICHOLAS PINTO, University of Puerto Rico – Humacao — Nanoscience and nanotechnology have been the focus of much scientific research worldwide and has great potential in enhancing the way we look at all of our present day electronic devices. If only part of this potential can be made into reality, the results will be phenomenal. Given the vast financial and scientific investment in nanotechnology that is tied to our future, it is important to expose undergraduate Physics and Engineering students to this field of study early in their career. Two experiments related to nanoscience that are currently part of our undergraduate Physics program will be presented. A simple to build and to operate electrospinning apparatus produces conducting polymer nanofibers that are then used in device fabrication. The devices include a nanoresistor and a Schottky nanodiode and yield themselves to straightforward data acquisition and analysis. A modification of the sample chamber can convert one of the experiments into a superabsorbent alcohol vapor sensor.

Work supported by NSF.

12:27PM Q19.00007 Animation of Early Cosmological Models. GREGORY TOPASNA, Virginia Military Institute — Early Greek and renaissance models of the solar system are usually presented as diagrams in most astronomy textbooks. While the intent of such diagrams is to illustrate how these models attempted to account for the motion of the planets, the static nature of the diagrams typically leaves students nonplussed and are often only viewed as mere curiosities. However, animating these earlier models vividly demonstrates the early attempts at cosmology and can reflect some of the accuracies our ancestors were able to achieve. While the complexity of some models may at first seem to make animation a difficult task, we show how such models can be written in a basic mathematical form suitable for animation in FlashMX. While these models are not extremely precise they are accurate enough to show the motion of celestial bodies and have an impact that static images alone can not achieve.
12:39PM Q19.00008 Revitalizing the Advanced Lab Course*, DAVID MARX, Illinois State University — As a hard science, physics is based in observation and experiment. Training of physicists at the undergraduate level must include the recognition that students need a solid foundation in experimental techniques used in the various sub-fields of physics, best practices, and a thorough understanding of data analysis and uncertainty. Recently, recognition of this importance has resulted in the creation of an AAPT task force on the advanced laboratory. An examination of advanced laboratory courses from dozens of universities from across the United States has been conducted by the author, the results of which will be presented. In addition, knowledge gained from this examination has recently been used in revitalizing the Experimental Physics course at Illinois State University.

12:51PM Q19.00009 Teaching a laboratory-intensive online introductory electronics course*, MARK MARKES, University of Nebraska-Kearney — Most current online courses provide little or no hands-on laboratory content. This talk will describe the development and initial experiences with presenting an introductory online electronics course with significant hands-on laboratory content. The course is delivered using a Linux-based Apache web server, a Darwin Streaming Server, a SMART Board interactive white board, SMART Notebook software and a video camcorder. The laboratory uses primarily the Global Specialties PB-505 trainer and a Tenma 20MHz Oscilloscope that are provided to the students for the duration of the course and then returned. Testing is performed using Course Blackboard course management software.

1:03PM Q19.00010 Harnessing the Efficiencies of Industry-Standard Tools in the Electronics Laboratory, MATTHEW VONK, University of Wisconsin River Falls — Powerful and flexible computer based tools have generated impressive productivity gains in the industrial sector. These innovations allow users to simulate the functionality of applications before they are built, to create custom integrated circuits on-the-fly, and to automate data acquisition. While these tools promise similar efficiency gains to student learning in educational settings, many physics classes have been slow to exploit them. This talk will illustrate how a number of these advances have been incorporated into an undergraduate electronics laboratory class. Special emphasis will be given to those tools that are low-cost and intuitive.

1:15PM Q19.00011 The Complete Undergraduate Research Experience Inspired by NASA’s Microgravity University, TIMOTHY RITTER, The University of North Carolina at Pembroke — In a typical undergraduate research experience the student is often assigned a small portion of a more comprehensive endeavor. While they may complete their assigned portion of the project, the larger investigation is usually one that was active prior to the student’s arrival in the lab and will continue once the student has left. What we present here are the results, lessons, and experiences from a multidisciplinary, multicampus, undergraduate microgravity research program. This unique experience requires a team of students to go from the idea stage to final report writing in one year. During the entire process the team is also conducting a vigorous outreach program. The research is conducted as part of NASA’s highly competitive Reduced Gravity Student Flight Opportunities Program. Because of its unique features, we believe our program provides the student with a broader, more comprehensive, and more stimulating research experience than a traditional undergraduate research experience.

1:27PM Q19.00012 Imhotep’s Legacy After School School Science Enrichment Program for African Nova Scotian Learners1, KEVIN HEWITT, Dalhousie Univ., Physics and Atmospheric Science, EMMANUEL NFONOYIM, Dalhousie Univ., BARB HAMILTON-HINCH, Dalhousie Univ., Black Students Advising Centre, MARGO HAMPDEN, Nova Scotia Office of African Nova Scotian Affairs, WAYN HAMILTON, Office of African Nova Scotian Affairs — Imhotep’s Legacy After-School Project (ILASP) is a provincial science and engineering after-school enrichment program established in 2003. It aims to redress the under-representation of African Canadians in postsecondary science studies. ILASP offers African Nova Scotian participants in Grade 7, 8 & 9 important academic and social opportunities at no out-of-pocket cost. It is guided by the fact that young learners will be motivated to regularly attend a program that features high-quality, interactive and fun learning activities that are distinct from but connected to their school curricula. The program is structured to sustain contact with the learners over three years (grade 7, 8, 9) during a crucial phase in their academic careers. University science and engineering students, acting as mentors, foster positive social interactions with young learners and deliver science enrichment activities in a participatory and casual atmosphere. Reasons for the high retention rate among participants will be discussed. Visit our website at http://ilasp.dal.ca/.

1The financial support of the Nova Scotia Dept’t of Education - African Canadian Services Division, Office of African Nova Scotian Affairs, Council on African Canadian Education and the Faculty of Science - Dalhousie University is gratefully acknowledged.

1:39PM Q19.00013 Teaching About Variables in Magnetism to Fifth and Sixth Graders, MICHAEL BIRNKRANT, MATTHEW CATHELL, Material Sci & Eng Dept., Drexel University, Philadelphia, PA, PRISCILLA BLOUNT, JEAN ROBINSON, Martha Washington Elementary School, Philadelphia, PA, ADAM FONTECCHIO, ELI FROMM, Electrical & Computer Eng Dept., Philadelphia, PA — Middle school students are very familiar with using computers, but many are unaware of how a computer stores information. We develop a module to explain how computers store and retrieve information from a hard drive. The module is part of the yearlong NSF GK-12 outreach program between Drexel University and local Philadelphia middle schools. The module complements the variables portion of their science and math curriculum. The module introduces magnetism as well as the link between the physical state of a hard drive and the picture on the screen. This module and others have contributed to improvements both in their classes and on their benchmark exams.

1:51PM Q19.00014 Use of media in introductory physics courses and public outreach, KHAZHGERY SHAKOV, Tulane University, ZALIMGERY SHAKOV, Kabardino-Balkar State University — Making the material presented interesting and exciting for the students has always been one of the main challenges in teaching introductory physics to students who have little or no background in physics (e.g. K-12 or undergraduate college). Many of the traditional teaching strategies consider physical systems (real or fictional) where the “level of distraction” is intentionally minimized or eliminated for the sake of better clarity. While it certainly allows a student to focus on important principles, it often leads to an impression that physics (and science in general) mostly operates with “artificial” systems that are not immediately relevant to everyday life. One of the ways to address this problem is to incorporate different forms of media that would “bring physics to life”. We discuss how one can use fragments of popular movies to enhance students’ interest in the subject.

2:03PM Q19.00015 Analytical Animations: New Views of Physics, DOUG SWEETSER, none — Analytical animation, like analytical geometry before it, opens new ways to look at physics. Systems with both spin 1/2 and spin 1 symmetry can be animated. The groups U(1), SU(2), and SU(3) of the standard model are viewed as animations, and together make visual sense. A new perspective on gamma matrices, a tool used in quantum field theory, is easy to understand based on images. All software used is open source.
11:15AM Q20.00001 Impurity Decoration for Crystal Shape Control: C_{60} on Ag(111)^1, T.J. STASEVICH^2, C.G. TAO, W.G. CULLEN, E.D. WILLIAMS, T.L. EINSTEIN, U. of Maryland. — The decoration of hexagonal Ag/Ag(111) monolayer islands by chains of C_{60}, observed via STM at 300K, dramatically changes their shape and fluctuations. We tune coverage so that a single C_{60} chain fully decorates each Ag island boundary. The C_{60} induced rounding appears due to competing energetic and entropic effects. We estimate the Ag - C_{60} attractions as -0.13 eV and -0.04 eV, respectively. The edge fluctuations are remarkable: 1) C_{60} decoration does not impede the step-edge diffusion (SED) and 2) while the bare-island fluctuations are driven by SED, the decorated island has the signature of non-conserved dynamics, even though the C_{60} remains at the island edge. We suggest that rapidly diffusing Ag atoms randomly attracting the nearby C_{60}s. Generalizations of our model show that both spherical and rectangular decorating molecules will similarly lower the energy of highly-kinked boundaries, leading to similar island shape changes.

11:27AM Q20.00002 Optical, Structural and Electrochemical Properties of CeO_{2–Al_{2}O_{3–}SiO_{2}} Thin Films, DURSEN SAYGIN HINCZEWSKI, Istanbul Technical University (I.T.U.), MICHAEL HINCZEWSKI, TUBITAK Bosphorus Univ. Feza Gursey Institute, IDRIS SORAR, ESAT PEHLIVAN, PATMA Z. TEPEHAN, I.T.U., GALIP G. TEPEHAN, Kadir Has Univ. — CeO_{2} thin films can be used as counter-electrodes in electrochromic devices, but have the disadvantage of slow reaction kinetics. Thus research has shifted to composite CeO_{2} films for predicting the properties of the surface-adsorbate complex.

100

11:39AM Q20.00003 Organic coverage of the silicon (100) surface: first-principles calculations, GIOVANNI CANTELE, CNR-INFM and University of Napoli “Federico II”, IVO BORRIELLO, University of Napoli “Federico II”, DOMENICO NINNO, CNR-INFM and University of Napoli “Federico II” — Interfacing semiconductor surfaces with organic molecule adsorbates is one of the most challenging aspects of the modern surface and interface engineering. Controlled and periodic surface coverage can have important implications in lots of technological applications, such as molecular sensing, molecular electronics, etc. One of the widely investigated surfaces is the silicon <100>. Such a surface shows a periodic arrangement of silicon dimers (induced by reconstruction) whose bonding has been extensively debated. It turns out that its properties are similar to those of a double carbon-carbon bond, and it is therefore suitable for attaching organic molecules, especially those containing a double bond. In this study we theoretically investigate from first principles the adsorption of ethylene, cyclopentene and a class of its chemical derivatives on the Si <100> surface, discussing the implications in tailoring the surface properties, such as the electron affinity and work function. Each molecular adsorbate induces a dipole layer on the surface, whose magnitude depends on the considered molecular species. Our findings demonstrate that, for this class of systems, it is not enough the knowledge of the isolated molecule properties for predicting the properties of the surface-adsorbate complex.

11:51AM Q20.00004 Ab initio calculations of BaTiO_{3}, PbTiO_{3} and SrTiO_{3} (001) and (111) surfaces, ROBERTS EGLITIS, DAVID VANDERBILT, RUTGERS UNIVERSITY TEAM — We present results of calculations of surface relaxations and rumpling of (001) and (111) surfaces of ATiO_{3} perovskites (A=Ba, Pb, Sr) using a hybrid B3PW description of exchange and correlation. On the (001) surfaces, we consider both AO and TiO_{2} terminations. In the former case, the surface AO layer is found to relax inward for all three materials, while outward relaxations of all atoms in the second layer are found for both kinds of (001) terminations. The surface relaxation energies of AO and TiO_{2} terminations are found to be comparable with each other for all three materials. For (111) surfaces, we consider terminations on a TiO layer, an A layer, or an O layer. The surface relaxation energies for BaTiO_{3}, PbTiO_{3} and SrTiO_{3} (011) surfaces for all terminations are considerably larger than for (001) surfaces. Among the (011) surfaces, the relaxation energy is much larger for the TiO-terminated surface than for the Ba- or Pb-terminated surfaces for the BaTiO_{3} and PbTiO_{3} perovskites. We predict a considerable increase in the Ti-O chemical bond covalency near the (111) surfaces as compared to both the bulk and the (001) surfaces.

12:03PM Q20.00005 Structure of the rutile TiO_{2}(011)-(2x1) surface, NAVID KHORSHIDI, ANDREAS STIERLE, VEDRAN VONK, CLAUS ELLINGER, HELMUT DOSCH, Max Planck Institute for Metals Research, Stuttgart, Germany, ULRIKE DIEBOLD, Tulane University, New Orleans, USA, XUEQING GONG, ANNABELLA SELLonI, Princeton University, Princeton, USA — TiO_{2} has various applications in technology and is one of the most investigated metal oxides. It is used in solar cells and its photocatalytic activity makes an understanding of the structure of diverse surface orientations desirable. Although there are many studies on TiO_{2} surfaces, the (011) surface has been rarely investigated. First principal DFT calculations predict the (011)-(1x1) face to have the third lowest energy and in a Wuiff Construction a large part of the surface is (011) oriented. TiO_{2} nanoparticle exhibit preferentially (011) oriented facets. Therefore a structure model of this surface is required to understand the photocatalytic processes on an atomic scale. We have investigated the TiO_{2}(011)-(2x1) surface using Surface X-Ray Diffraction (SXRD), Scanning Tunneling Microscopy (STM) and Low Energy Electron Diffraction (LEED). From our data we are able to derive a novel model for the (011) surface in combination with DFT calculations. The new model has a much lower surface energy than the one suggested previously and fits the X-Ray data very well.

12:15PM Q20.00006 Surface Reactivity, and Lead Sorption of Hydrated Alumina and Hematite Surfaces, SARA MASON, ANNE CHAKA, NIST — It is well known that polarity and structure of oxide surfaces have significant impacts on reactivity. Experimental and theoretical studies at solid-aqueous interfaces have revealed that hydrated oxide surface morphology can vary significantly from surfaces under high vacuum conditions. We apply a combination of density functional theory simulations and ab initio thermodynamics to hydrated structures of α-Al_{2}O_{3} and α-Fe_{2}O_{3} surfaces. While geometrically isostructural in the bulk, these two oxides have sharp contrasts in electronic structure and can have thermodynamically stable surface terminations which differ in both the number and type of exposed functional groups. We use the environmentally relevant interaction of Pb(II) with the hydrated surfaces to explore relationships between reactivity and both surface structure and identity.

12:27PM Q20.00007 Development of the EAM Potential for Fe-C Alloy Systems, BOHUMIR JELINEK, JEFF HOUZE, SUNGHO KIM, AMITAVA MOITRA, LAALITHA LIYAGNE, MARK HORSTMUEYER, SEONG-GON KIM, Mississippi State University — The ab-initio calculations based on density functional theory (DFT) are performed for Fe and C in their ground state crystal structures. Heats of formation are then calculated for different Fe–C alloy compounds. The lattice constant (volume), bulk modulus and shear moduli for cementite are determined from the total energy calculations for bcc Fe and fcc C. The results of the new potential are compared with the results of ab-initio calculations.

12:39PM Q20.00008 Embedded Atom Method (EAM) interatomic potential for Zinc (Zn)

AMITAVA MOITRA, SUNGHO KIM, JEFFRY HOUZE, BOHUMIR JELINEK, LAALITHA LIYANAGE, Dept. of Physics and Astronomy, Center for Advanced Vehicular System, Mississippi State University, MARK F. HORSTEMEYER, Dept. of Mechanical Engineering; Center for Advanced Vehicular System, Mississippi State University, SEONG-ONG KIM, Dept. of Physics and Astronomy; Center for Advanced Vehicular System, Mississippi State University — We developed a new spline-based embedded-atom method (EAM) interatomic potential for Zn by matching forces to those of ab-initio calculations. The material parameters such as cohesive energy, equilibrium atomic volume, and bulk modulus were used to optimize the potential. The applicability of the new potential was demonstrated by performing atomistic simulations for different surfaces. The formation energies, and various point defects were also calculated. The applicability of this EAM potential to the stability analysis of small clusters was also tested.

12:51PM Q20.00009 Calculation of Absorption Energies Using EAM Potential for Al-Mg alloy systems

LAALITHA LIYANAGE1, BOHUMIR JELINEK2, SUNGHO KIM, MARK F. HORSTEMEYER3, SEONG GON KIM4, Center for advanced vehicular system — Spline-based embedded-atom method (EAM) interatomic potentials for Al-Mg alloy systems are developed using existing EAM potentials. The lattice constant, bulk modulus and shear modulus for the alloy are determined to demonstrate the validity of the new potential. The absorption energies of Mg atoms on Al surfaces are also calculated and compared with the results of ab-initio calculations.

1:03PM Q20.00010 Ab initio study of the plutonium dioxide surfaces: role of electronic correlations

GERALD JOMARD, FRANCOIS BOTTIN, Commissariat a l’Energie Atomique — This ab initio study is performed in the framework of density functional theory (DFT) using the projected augmented wave method. Introducing the on-site Coulomb repulsion term U in the calculations, we found equilibration properties of both PuO2 and Pu2O3 in good agreement with experiments. At odds with conventional DFT calculations, these two compounds are no more metallic and recover their insulating behavior with an antiferromagnetic order. As concerns the surface properties of the plutonium dioxide PuO2, we perform an extensive study of eleven (1 x 1) (110), (100) and (111) terminations then compare their thermodynamic stability by computing their surface Grand potential. Whereas conventional DFT calculations predict that a few uncompensated polar terminations can be stable, in the stability domain of the PuO2 compound, the inclusion of the electronic correlations modify significantly these conclusions. We discuss this result by connecting the surface electronic structure to the polar or non-polar character of the termination.

1:15PM Q20.00011 Effect of Mg doping on the Structure and Reflectivity of Alumina surfaces

TIMOTHY PENNYCOOK, Vanderbilt University, JUAN C. IDROBO, Vanderbilt University, SOKRATES T. PANTELIODES, Vanderbilt University, and Oak Ridge National Laboratory, KALMAN VARGA, Vanderbilt University, SOKRATES T. PANTELIODES, Vanderbilt University, and Oak Ridge National Laboratory — Mg is used in the fabrication of Al alloys to increase the strength of the material. In typical applications, a layer of alumina is present on the surface. The high diffusivity and chemical reactivity of Mg means that Mg can migrate from the bulk alloy to the alumina film and the surface, where it can affect the structural and optical properties of the material. The doping of Al alloys with Mg is known to cause “darkening” and affect the coloration of the material. We will report results of first principles density functional theory calculations that explore the segregation modes of Mg in the near-surface region of alumina and the corresponding effect on optical properties, i.e., reflectivity. This work is supported in part by NSF grant DMR-0513048 and ALCOA Inc.

1:27PM Q20.00012 Down the primrose path of dalliance: how iterative structural determination routines for thin films may lead to partial or false solutions

NAJ JUSSEINI, CODRIN CIONCA, Department of Physics, University of Michigan, Ann Arbor, 48109, YIZHAK YACOBY, Racah Institute of Physics, Hebrew University, Jerusalem, Israel, 91904, ROY CLARKE, Department of Physics, University of Michigan, Ann Arbor, 48109 — Iterative methods are frequently used to solve thin film structures. Convergence, however, may terminate at partial or even incorrect solutions. Coherent Bragg Rod Analysis (COBRA), a direct phase retrieval method with minimal iterations, has had recent success with buried interfaces in perovskite oxides and semiconductors. Here, we investigate the role of iterations in COBRA by means of simulations on a model lattice-matched system of PbTiO3 on SrTiO3 with realistic stochastic noise. Out-of-plane atomic displacements were added in various monolayers of the PbTiO3 film. With increasing iterations the positions of the heaviest element (Pb) became more accurate at the expense of the lighter elements – particularly the oxygen sublattices. In addition, the error in the central monolayers of the film decreased while the error at both the film-substrate and film-air interface increased. Our results provide new insights on the influence of uncertainties in measuring subtle structural details at interfaces.

1:39PM Q20.00013 Effect of surface nanostructure on temperature programmed reaction spectroscopy

MICHAEL RIEGER, JUTTA ROGAL, KARSTEN REUTER, Fritz-Haber-Institut, Faradayweg 4-6, D-14195 Berlin (Germany) — Using the catalytic CO oxidation at RuO2(110) as a showcase, we employ first-principles kinetic Monte Carlo simulations to illustrate the intricate effects on temperature programmed reaction (TPR) spectroscopy data brought about by the mere correlations between the locations of the active sites at a nanostructured surface. Even in the absence of lateral interactions, this nanostructure alone can cause inhomogeneities that cannot be grasped by prevalent mean-field data analysis procedures, which thus lead to wrong conclusions on the reactivity of the different surface species. The RuO2(110) surface studied here exhibits only two prominent active sites, arranged in simple alternating layers. Yet, the mere neglect of this still quite trivial nanostructure leads mean-field TPR data analysis [1] to extract kinetic parameters that are in error by several orders of magnitude and that do not even reflect the relative reactivity of the different surface species correctly [2].

1:51PM Q20.00014 NMR Evidence of Cage-to-Cage Diffusion of H2 in H2-Clathrates

LASITHA SENADEHERA, MARK CONRADI, Washington University — H2 and heavy-ice at P > 1 kbar and T ~ 250 K form H2-D2O clathrate; four and one H2 may occupy each large (L) and small (S) cage, respectively. In H2-THF-H2O clathrate, H2 occupies singly and only S cages. Previous electronic-structure calculations estimate the barriers for H2 passage though hexagonal and pentagonal faces of cages as ~6 and ~25 kcal/mol, respectively. Our H2 NMR linewidth data reflect random crystal fields from frozen cage-wall D2O orientations. We find dramatic reductions in linewidth starting at 120 K (175 K) for H2-D2O (H2–TDF-D2O) indicating time-averaging of the crystal fields. Assuming Arrhenius behavior, our data imply energies for escape from L (S) cages of about ~4 (~6) kcal/mol. For L cages, the agreement with the calculated (cages were treated as rigid) barrier is reasonable. For H2 in S cages, in H2–TDF-D2O, the extreme disagreement with theory points to another mechanism of time-averaging, reorientations of the cage-wall D2O molecules, as suggested by previous work in TDH-H2O clathrate. Our limited NMR spectra at high T ~145 K in H2-D2O show evidence of distinct resonances from diffusionaly mobile and immobile H2 molecules, as expected.

11:15AM Q21.00001 ”Heterogeneous Electrocatalysis”, ANDRZEJ WIECKOWSKI, University of Illinois, Champaigne — No abstract available.

11:51AM Q21.00002 Tailoring Surface Reactivity of Metal Oxides. ULRIKE DIEBOLD, Department of Physics, Tulane University, New Orleans, LA 70118 — Titanium oxide is receiving continued attention because of its importance as catalyst support, as a material to harvest solar energy for chemical transformations, and as a model metal oxide. In this talk, I will focus on the structure and defects (extrinsic and intrinsic) of less-studied TiO2 surfaces; i.e., rutile (011)-2x1 and anatase (101), and their influence on surface reactivity.

12:27PM Q21.00003 ”Understanding Reaction Pathways on Model Catalyst Surfaces”, WILFRED TSYSOE, University Wisconsin Milwaukee — No abstract available.

1:03PM Q21.00004 Modulating the reactivity of Pt-based catalysts for PEMFC: A First Principles Study, HAI-YAN SU, XIN-HE BAO, WEI-XUE LI, Dalian Institute of Chemical Physics, CAS, Dalian, China — Low-temperature Polymer electrolyte membrane fuel cells (PEMFCs) have been regarded as one of the most promising candidates to produce heat and electricity, especially for electric vehicles or residential co-generation systems. However, the CO poison at the anode and the slow kinetics of the ORR at the cathode for Pt based-catalysts limit its widespread application, which motivated extensive research for more effective catalysts with CO tolerant, highly active and lower Pt loading, and/or highly selective for CO PROX. Density functional theory calculations have been used to screen Pt-based catalysts for PEMFC. It is found that the direct contact with Pt catalysts (so-called Pt-skim) is essential. The reactivity of Pt-skim catalysts towards the oxygen reduction reaction (ORR) and the hydrogen evolution reaction (HER) can be modulated by stepwise increase of Ni contents, which are accomplished by the modification of the reactivity through ligand and geometric effects. The overall reactivity is however balanced by effective adsorption and desorption of adsorbates. Our calculations show that among various Pt-Ni with Pt-skim, Pt3Ni1 is the catalyst with the highest overall reactivity. The present work indicates that it may be a good candidate for CO preferential oxidation (PROX) in excess of the hydrogen.

1:15PM Q21.00005 Surface Site Characterization of COads on Platinum1, PATRICK MCGRATH, AURORA MARIE FOJAS, ELTON CAIRNS, JEFFREY REIMER, University of California - Berkeley — Nuclear magnetic resonance (NMR) spectroscopy is used in conjunction with cyclic voltammetry (CV) to explore the surface chemistry of CO on platinum electrocatalysts. Electrochemically prepared CO ads adsorbed on Pt-skin, Pt3, Pt2, and Pt1 planes are investigated using the 13C-NMR of the adsorbed species resulting from electrochemically adsorbing labeled methanol provides direct insight into the surface electronic structure of the catalysts. We observe a shift in the 13C-NMR spectra associated with different surface preparations. These shifts correlate with the corresponding coverage of the adsorbate on different types of platinum sites. NMR is used to probe the dynamics of these species to elucidate the interaction of the adsorbate with the platinum surface.

1:27PM Q21.00006 Does Pauli repulsion induce the dissociation energy barriers? A first principles study. MASATO ITO, SHIGEYUKI TAKAGI, HIDEKAZU TOMONO, KAZUO TSUMURAYA, Meiji University, JAPAN — We elucidate the origin of the formation analyzing the dissociation process of oxygen molecule on bridge-top-bridge site of Pt(111). The charge state is analyzed by the Bader method together with the spin states of the two oxygen atoms. The charge transfers to the dissociated oxygen molecule from the Au surface. The potential energy variation is in agreement with the energy variation of the separated in distance, charged, and spin polarized oxygen molecules that is calculated with the origin of the formation analyzing the dissociation process of oxygen molecule on bridge-top-bridge site of Pt(111). The charge state is analyzed by the Bader

1:39PM Q21.00007 O2 Dissociative Adsorption on Cu2O(100) with O Vacancies1, DUY LE, SERGEY STOLBOV, TALAT RAHMAN, University of Central Florida — Cu2O surfaces and nanoparticles have been shown to have high activity for CO oxidation [1]. As a result of consumption of the surface oxygen during the CO oxidation process on Cu2O(100), the issue of restoration of the surface composition becomes critical. Through first principles electronic structure calculations of the geometry, activation energy barriers, reaction pathways, and the local densities of electronic states for O2 dissociative adsorption on the Cu2O(100) surface with O vacancies, we show that the healing of oxygen vacancies is accompanied by reconstruction of the surface. Our calculations are based on density functional theory in the generalized gradient approximation and usage of ultrasoft pseudopotential method in the plane wave representation. [1] B. White, M. Yin, A. Hall, D. Le, S. Stolbov, T. S. Rahman, N. Turro, and S. O’Brien, Nano Lett., 6, 2095 (2006).

2:17PM Q21.00008 Modeling the effects of the oxide substrate on O2 dissociative adsorption on Au nanostructures, SERGEY STOLBOV, TALAT S. RAHMAN, University of Central Florida — In this work we apply the density functional theory calculations to explore the mechanism of high reactivity of Au nanoparticles on oxide substrates. We test the idea that the substrate – nanoparticle interaction makes the O2 dissociative adsorption favorable on this system, in contrast to bulk Au, and then the O atoms, so adsorbed, are consumed by reactants for further oxidation. We exploit the observation that the 2-layer Au film on TiO2 displays an exceptionally high reactivity as compared to a monolayer Au film, as well as those with 3 or more layers [1]. We calculate the energy Eads of dissociative adsorption of O2 on the surfaces 1, 2, 3, and 5 Au(111) layer structures in two environments: 1) free standing layers, 2) on TiO2 fragments (modeling a substrate). We find Eads to be negative for the 2- and 3-layer Au films on the “substrate” while it is positive for all other systems under consideration. This result along with the experimental finding [1] point to the O2 dissociative adsorption as being the main mechanism for the observed reactivity of Au nanostructures. Calculated local densities of electronic states and local charges in the system will be presented for further insights into the nature of the effect. [1] M. S. Chen, D. W. Goodman, Science 306, 234 (2004).

Adaptable polymer particles that can change geometry, flow characteristics, and adsorption properties upon the stimulation of an environmental change, such as temperature, are of great interest in the fields of materials science and engineering. Georgia Institute of Technology, ALFRED J. CROSBY, Polymer Science and Engineering Department, University of Massachusetts, Amherst

1

Theoretical and experimental investigations have been carried out to develop adaptable polymer systems that can respond to changes in their environment. These studies have focused on the development of responsive materials that can alter their properties in response to stimuli such as temperature, pH, or light. The goal is to create materials that can be used in various applications, such as drug delivery systems, sensors, and smart materials. The responsive behavior of these materials is often achieved through the incorporation of stimuli-responsive polymers or the use of responsive building blocks that can change their conformation or state in response to the stimuli.

11:51AM Q22.00002 In-situ Liquid Volume Measurement of Polymer Films Using Surface Plasmon Resonance, YIBING ZHANG, MOHSEN YEGANEH, Corporate Strategic Research, ExxonMobil Research and Engineering Company — Many physical properties of a polymer in contact with liquid can be markedly affected by the amount of the liquid that can penetrate into the polymer matrix. The liquid accessible volume in a polymer matrix is difficult to determine at elevated temperatures and not possible with simple weight gain measurements. A high sensitivity optical Surface Plasmon Resonance (SPR) technique, which has been widely used in chemical and biomedical applications, was developed for determination of liquid accessible volume in a polymer matrix at both room and high temperatures (up to 150 °C). Experimental results and theoretical calculation are in excellent agreement. Hysteresis in liquid accessible volume as a function of organic liquid was observed when temperatures were cycled between room and high temperatures. The newly developed SPR technique for accessible volume determination has a great potential for in-situ characterization of a polymer matrix in contact with liquid.

12:03PM Q22.00003 Interface and dynamic indentation of crosslinked polyester films, SURESH AHUJA, Xerox Corporation — The nanoindentation technique has drawn much interest recently for both its efficiency and versatility in measuring the mechanical properties of small volumes of materials and thin films. Since the unloading curve of polymers depends not only on the holding time but also on the unloading rate, Hysitron Nanoindenter was used in our investigation of contact deformation of surfaces of polyester and polycarbonate supported on an aluminum substrate. Crosslinked polymers with different gel concentration were produced on aluminum surfaces. Inter-phase plays a crucial role in composites. Stiffening and strengthening rely on load transfer across the interface, toughness is influenced by crack deflection/fiber pull-out, and ductility is affected by relaxation of peak stresses near the interface. Instead of strain softening with indentation depth observed in linear polymers, cross-linked polymers showed strain hardening. The extent of diffusion determines the extent of the interfacial region with the conformation loss of large molecules being higher than that of small molecules. Besides, considering the strain hardening, an increasing stress is required to produce further plastic deformation after the material is strained beyond the yielding point, it is possible to separate the plastic deformation and the visco-elastic deformation and study them individually. Steady state deformation is compared with sinusoidal deformation relatable to differences in Tg from confinement effects. In cross-linked polymers, surface deformation is analyzed a three-layer model consisting of free surface layer, intermediate layer, and interface layer. Molecular relaxation dependence on molecular weight and cross-link density is shown.

12:15PM Q22.00004 Prediction of Zeolite Types Based on Structural Data, M. LACH-HAB, D.A. CARR, I. VAISMAN, E. BLAISTEN-BAROJAS, Computational Materials Science Center, George Mason University, Fairfax, VA — Application of knowledge discovery methods in the search of information contained in databases is an emerging field in materials science that plays an important role on facilitating data analysis. In this study we propose a model for identification of the zeolite mineral type based on the topological analysis of the underlying crystal structure. High-throughput generation of topological descriptors is derived from the Delaunay tessellation of zeolite supercells. Based on these descriptors, our Zeolite-Structure-Predictor is trained for classifying zeolite crystals into twenty two different types of minerals and is based on a random forest model constructed with attributes that include tetrahedrality index, in-sphere volume, average edge, frequency of occurrence and probability of oxygen rich selected simplices. The underlying crystal structure data used for this study are included in the Inorganic Crystal Structural Database (ICSD).

Acknowledgments: Supported by NSF grant CHE-0626111; the ICSD data is a courtesy from NIST.

12:27PM Q22.00005 Adaptable Polymer Microsrolls, KYRIAKI KALAITZIDOU, Woodruff School of Mechanical Engineering, Georgia Institute of Technology, ALFRED J. CROSBY, Polymer Science and Engineering Department, University of Massachusetts, Amherst — Adaptable polymer particles can change shape, flow characteristics, and adsorption properties upon the stimulation of an environmental change, such as temperature are of great interest in the fields of materials science and engineering. These studies have focused on the development of adaptable polymer systems that can respond to changes in their environment. The goal is to create materials that can be used in various applications, such as drug delivery systems, sensors, and smart materials. The responsive behavior of these materials is often achieved through the incorporation of stimuli-responsive polymers or the use of responsive building blocks that can change their conformation or state in response to the stimuli.

The method is applicable to any material combination that satisfies the design equations. The materials used in this work are gold/titanium (Au/Ti) and polydimethylsiloxane (PDMS). Initial demonstrations of this responsive control and its impact on properties of the adaptable polymer particles are also presented. These structures combined with their demonstrated reversibility have potential as capsules in drug delivery systems and novel conductive composites.
Ordered block copolymer thin films may have important applications in modern device fabrication. Current characterization methods such as conventional GISAXS have fixed electron density contrast that can be overwhelmed by surface scattering. However, soft x-rays have longer wavelength, energy dependent contrast and tunable penetration, making resonant GISAXS a very promising tool for probing nanostructured polymer thin films. Our preliminary investigation was performed using 290 eV resonant GISAXS on block copolymer films on beam-line 5-2 SSRF, and beam-line 6.3.2 at ALS, LBNL. The contrast/sensitivity of the scattering pattern varies significantly with photon energy close to the C K-edge (∼290 eV). Also, higher order peaks are readily observed, indicating hexagonal packing structure in the sample. Comparing to the hard x-ray GISAXS data of the same system, it is clear that resonant GISAXS has richer data and better resolution. Beyond the results on the A-B diblock copolymers, results on ABC block copolymers are especially interesting.

12:15PM Q22.00007 Orientation Distribution for Thin Film Block Copolymers, RONALD JONES, XIAOHUA ZHANG, SANGCHEOL KIM, ALAMGIR KARIM, NIST, ROBERT BRIBER, Univ. of Maryland, HO-CHEOL KIM, IBM Almaden Research Center — The directed self-assembly of nanostructured films with vertically oriented morphologies is a potential solution for manufacture of next generation data storage platforms, microelectronic devices, and nanoporous membranes. In many of these applications, the distribution of orientation must be tightly controlled to enable pattern transfer. This parameter is expected to depend on factors such as the Flory-Huggins chi parameter, but little data has been reported to date. We present results from tomographic small angle scattering on a series of block copolymer films whose assembly has been directed through solvent annealing. Films of poly(styrene-b-ethylene oxide) are cast as a function of annealing time and their orientation distribution reported. The results provide significant insight into the fundamental limits of line edge roughness and defect control possible using this fabrication technique.

1:03PM Q22.00008 Unusual Domain Morphology in PS-b-PFS Block Copolymer Films, SETH DARLING, MURUGANATHAN RAMANATHAN, Argonne National Laboratory, ELIZABETH NETTLETON, University of South Dakota — Gaining control over the structure and order of self-assembled domains is critical to the success of bottom-up fabrication methodologies. We focus on the self-assembly of polystyrene-block-poly(ferrocenylmethylsilane) block copolymers (PS-b-PFS). Thin films microphase separate to form nanoscale PFS cylinders within a PS matrix. Traditionally, order in such films is improved using thermal annealing, which has drawbacks including time requirements and possible thermal degradation. In this work, solvent annealing has been used, sometimes in concert with thermal annealing, to gain control over the microphase domain orientation. In addition to orientational control, novel domain morphologies have been observed. Thermochemical techniques and AFM and TEM imaging have been utilized to characterize these materials. Because of the comparatively high etch resistivity of the PFS block, this block copolymer holds potential in lithographic patterning of nanowires, nanopillar arrays, and nanofluidic channels. Some initial patterning results will also be presented.

1:15PM Q22.00009 Using Functional Small Molecules to Control Self-Assembly and Patterning in Block Copolymer Thin Films, C. GERALDINE BAZUIN, DAVID GASPARD, XIMIN CHEN, DAMIEN MAURAN, ROBERT E. PRUD'HOMME, CHRISTIAN PELLERIN, University of Montreal — Self-assembled thin films of block copolymers constitute an elegant means to obtain nanopatterns and nanotemplates on surfaces. Here, we demonstrate how interacting small molecules can be used to control the morphology of dip-coated block copolymer films. Such films obtained from THF solutions of styrene-4-vinylpyridine block copolymers (PS-b-PVP, ca. 29 wt percent VP) and naphthol (NOH), which hydrogen bonds to PVP, yield nanopatterns of quasi-hexagonally ordered nodules of PVP+NOH in a PS matrix. Washing in methanol removes the small molecules, leaving functional PVP-lined nanopores in the film. These nanopores are receptor sites for molecules with desired properties. In contrast, naphthoic acid (NCOOH), which differs from NOH only by the hydrogen-bonding group, leads to fingerprint morphology under the same initial dip-coating conditions. By changing the conditions, in particular reducing the dip-coating speed sufficiently, the fingerprint morphology can be converted to quasi-hexagonal. Reflection-absorption infrared spectroscopy indicates that the proportion of small molecule incorporated into the dip-coated film is about half that found in solution for both NOH and NCOOH.

1:27PM Q22.00010 Combinatorial Studies of Free Surface Effects on Block Copolymer Thin Films, THOMAS EPPS, JULIE LAWSON, THOMAS SCHERR, University of Delaware, MICHAEL FASOLKA, NIST, Polymers Division — To employ block copolymers for many nanoscale templating applications, it is essential to understand how the interfacial interactions originating from the substrate and free surface in ultrathin (∼nm) films affect block copolymer morphologies. In this work, we manipulated the free surface interactions of poly(styrene-b-isoprene-b-styrene) and poly(styrene-b-ethylene oxide) thin films using solvent vapor gradient libraries. These libraries were created using fluorinated acrylate microfluidic devices consisting of a two-input solvent vapor mixing tree and several discrete solvent vapor flow channels. Areas of the thin films exposed to vapor flowing through the channels were subsequently examined by AFM. Analysis along the discrete vapor gradients showed the expected results for the channels at the extremities (representing the approximately single component vapor streams); however, the channels at intermediate vapor compositions show time-dependent nanostructure behavior that was a function of both vapor composition and distance along the channel.

1:39PM Q22.00011 Self-assembly of Cylindrically Confined Block Copolymers in Core-Shell Electrospun Fibers, MINGLIN MA, GREGORY RUTLEDGE, Chemical Engineering, MIT — We report the development of electrospun fibers with internal nanostructure by two-fluid coaxial electrospinning of block copolymers. Microphase separated morphologies with a long-range order were obtained by electrospinning two-fluid coaxial block copolymers on beam-line 5-2 SSRF, and beam-line 6.3.2 at ALS, LBNL. The contrast/sensitivity of the scattering pattern varies significantly with photon energy close to the C K-edge (∼290 eV). Also, higher order peaks are readily observed, indicating hexagonal packing structure in the sample. Comparing to the hard x-ray GISAXS data of the same system, it is clear that resonant GISAXS has richer data and better resolution. Beyond the results on the A-B diblock copolymers, results on ABC block copolymers are especially interesting.

1P1PM Q22.00012 A Generalized Method for the Preparation of Neutral Brushes from Homopolymer Mixtures, SHENGXUAN JI, GUOLIANG LIU, Department of Chemical & Biological Engineering, University of Wisconsin-Madison, FAN ZHENG, FRANZ HIMPSEL, Department of Physics, University of Wisconsin-Madison, PAUL NEALEY, Department of Chemical & Biological Engineering, University of Wisconsin-Madison — We demonstrate a new, generalized approach for the formation of neutral surfaces that uses a ternary blend of hydroxyl-terminated homopolymers A-OH and B-OH and a low MW A-b-2VP block copolymer. The presence of the block copolymer effectively homogenizes the A/B homopolymer mixture before the homopolymers are grafted onto the substrate, thereby preventing macroscopic phase separation of the homopolymer mixture, and maintaining chemical neutrality over the length scales necessary for the self-assembly of block copolymer microdomains. The grafting ratios of the two homopolymers were varied simply by changing the blend ratios. Neutral compositions for P(S-b-MA) and P(S-b-2VP) were located using this binary homopolymer mixture strategy.
2:03PM Q22.00013 Centrifugal adhesion balance (CAB): A novel surface characterization technique, RAFAEL TAMDOR, LAN DANG, AISHA LEH, PRASHANT BAHAHADUR, KUMUD CHAURASIA — Drop lateral adhesion to a surface and the condition for drop sliding along a surface are key issues in many disciplines including biophysics, environmental science, fluid dynamics and agriculture. Yet, to date, except for the tilt stage method, which is extremely limited in range of forces, there is no systematic experimental instrumentation to measure the forces required for drop sliding. We present a new instrument that uses centrifugal forces to slide any drop along a surface. Beyond extending the range of measurable drop-surface interaction, the instrument enables decoupling of some parameters that are bound to be coupled with the simple tilt stage method. Specifically the tilt stage method has two variables varying at the same time: the lateral and normal forces. This violates a fundamental principle of experimental science which leads to obscured understanding of surface characteristics. The CAB avoids this problem.

Session Q3 DMP GMAG: Focus Session: Bilayer Manganites Morial Convention Center 215

11:15AM Q23.0001 Doping dependence of the bilayered colossal magnetoresistive manganites La(2-x)Sr(1+2x)Mn(2)O(7): Angle Resolved Photoemission studies1, NORMAN MANNELLA, University of Tennessee - Knoxville, KIYOHISA TANAKA, SUNG-KWAN MO, Advanced Light Source - Berkeley, ZHI-XUN SHEN, Stanford University — We have measured the doping dependence of the bilayer colossal magnetoresistive manganites La(2)Sr(1+2)Mn(2)O(7) with Angle Resolve Photoemission (ARPES). Our measurements reveal profound differences in the spectral features depending on the doping levels. Surprisingly, the spectra corresponding to x = 0.4 exhibit more similarities to those corresponding to x = 0.6 than the ones with x = 0.36 and x = 0.38. Further aspects of these data in relation to the physics of layered manganites will be discussed.

1DOE Office of Basic Energy Science, Division of Material Science, under contracts DE-FG03-01ER45929-A001 and DE-AC03-76SF00515

11:27AM Q23.0002 Non-monotonic Fermi surface geometry and its correlation with real-space ordering in the bilayer magnetoresistive oxide La(2−x)Sr(1+2x)Mn(2)O(7), ZHE SUN, J.F. DOUGLAS, Q. WANG, Department of Physics, University of Colorado, Boulder, CO 80309, USA, Y.D. CHUANG, A.V. FEDOROV, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, USA, H. LING, S. SAHRKORPI, B. BARBIELLINI, R.S. MARKIEWICZ, A. BANSIL, Department of Physics, Northeastern University, Boston, MA 02115, USA, H. ZHENG, J.F. MITCHELL, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, USA, D.S. DESSAU, Department of Physics, University of Colorado, Boulder, CO 80309, USA — Angle-resolved photoemission spectroscopy was used to study the Fermi surface and nesting effects for a wide range of doping levels (x) of La(2−x)Sr(1+2x)Mn(2)O(7). While band structure calculations indicate a monotonic trend in the size of each piece of the Fermi surface, our data indicates non-monotonic trends which are consistent with the evolution of the charge modulations, unequivocally confirming the direct connection between the nesting and the charge correlation vectors. This may be classified as a key example of a system with a strongly k-dependent self-energy.

11:39AM Q23.0003 Doping evolution of bilayered colossal magnetoresistive manganites: bilayer splitting and c-axis coupling, CHRIS JOZWIACK, Department of Physics, UC Berkeley, JEFF GRAF, Materials Science Division, LBNL, SHUYUN ZHOU, Department of Physics, UC Berkeley, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, LBNL, HONG ZHENG, Materials Science Division, ANL, JOHN MITCHELL, Materials Sciences Division, ANL, ALESSANDRA LANZARA, Department of Physics, UC Berkeley; MSD LBNL — We present a detailed momentum, doping and temperature dependent study of the electronic properties of bilayer manganites, La(2−x)Sr(1+2x)Mn(2)O(7), by means of angle-resolved photoemission spectroscopy. In particular, we will address both the in-plane bilayer splitting, as well as the out-of-plane band, as a function of doping. We will discuss possible implications for the role of inter-plane coupling in the CMR manganites.

11:51AM Q23.0004 Calculated properties of the La(2−x)Sr(1+2x)Mn(2)O(7) bilayer manganites, 0.30 ≤ x ≤ 0.501, ROLANDO SANIZ, ARTHUR FREEMAN, Northwestern University, MICHAEL NORMAN, Argonne National Laboratory — The low temperature properties of the La(2−x)Sr(1+2x)Mn(2)O(7) 0.30 ≤ x ≤ 0.50 bilayer manganites have been studied in the past using a host of experimental techniques in order to understand the outstanding properties they exhibit. To complement these investigations, we present a systematic study of their calculated ground state properties as a function of doping level, using the highly precise full-potential linearized augmented plane wave (FLAPW) method2 and focusing on magnetic order and optical and transport properties. Our results, which are in very good agreement with experiment in several respects, underline the correlation between the structural and orbital degrees of freedom and also shed light on many of the unexpected behaviors at low temperature in angle-resolved photoemission spectroscopy, optical conductivity, and resistivity measurements.

1Supported by the DOE (DE-FG02-88ER45372 and DE-AC02-06CH11357).

12:03PM Q23.0005 Magnetic State of La(1.36)Sr(1.64)Mn(2)O(7) Probed by Magnetic Force Microscopy1, JUNWEI HUANG, CHANGBAE HYUN, TIEN-MING CHUANG, JEEHOON KIM, ALEX DE LOZANNE, J.B. GOODENOUGH, J.S. ZHOU, U Texas at Austin, JOHN MITCHELL, ANL — We have investigated the evolution of the ferromagnetic (FM) domain structure of a single-crystal La(1.36)Sr(1.64)Mn(2)O(7) with temperature and external magnetic field by using low-temperature magnetic force microscopy. We observed that theFM domains form stable treelike patterns with out-of-plane magnetization below 65 K. As the temperature increases, the FM domains begin to change gradually. Around 88 K, the magnetization changes from the out-of-plane to an in-plane direction. The in-plane FM domains almost completely disappear near the Curie temperature of this sample (Tc ≈ 110 K). Interestingly, the evolution of the FM domain patterns with temperature was seen to coincide with the change in resistivity. We also observed large changes in the magnetic structures upon thermal cycling. We concluded that the formation of FM domains is determined by the competition between the magnetostatic energy and domain-wall energy and is also associated with the 2D character of the system.

1Supported by NSF DMR-0308575 (AdL).
12:15PM Q23.00006 Thermal Expansion, Heat Capacity and Magnetization Measurements of La$_1.25$Sr$_{1.8}$Mn$_2$O$_7$†, RICHARD K. BOLLINGER, J. J. NEUMEIER, Montana State University, H. ZHENG, J. F. MITCHELL, Materials Science Division, Argonne National Laboratory — La$_1.25$Sr$_{1.8}$Mn$_2$O$_7$ is a bi-layered ferromagnet of perovskite structure with two dimensional magnetic and electrical properties. In this presentation, we will show measurements of the specific heat, magnetization, and thermal expansion for single crystalline La$_1.25$Sr$_{1.8}$Mn$_2$O$_7$ in the temperature range 300 K < T < 5 K. The thermal expansion of this tetragonal crystal along the a and c directions will be presented, the anisotropy will be discussed, and the critical behavior near the magnetic transition will be evaluated.

†This material is based upon work supported by the US DOE (DE-FG-06ER46269) and NSF (DMR-0504769).

12:27PM Q23.00007 Thermal conductivity of layered La$_1.2$Sr$_{1.8}$Mn$_2$O$_7$, FILIP RONNING, Los Alamos National Lab, NAMJUNG HUR, NOBUYUKI KURITA, J.D. THOMPSON, ROMAN MOYSHOVICH — La$_1.2$Sr$_{1.8}$Mn$_2$O$_7$ has many similarities to underdoped cuprates: highly anisotropic transport, strong disorder in a charge reservoir layer, and even claims for Fermi arcs. Thus we measured the thermal and charge transport of this system to examine whether the Wiedemann-Franz law is violated in La$_1.2$Sr$_{1.8}$Mn$_2$O$_7$. The work focuses on the elastic properties of Ca$_2$RuO$_4$.

12:39PM Q23.00008 Temperature Dependent Raman Scattering in Layered Manganites, RAJEEV GUPTA, Department of Physics and Materials Science Programme, Indian Institute of Technology, Kanpur 208016, India, D. N. PATEL, S. L. GUPTA, Department of Physics, Indian Institute of Technology, Kanpur 208016, India — La$_2$MnO$_4$ is a perovskite system built up of New York — 99Ru Mössbauer Effect and magnetic measurements have been made on an enriched 99Ru sample of SrRu$_{0.06}$Mn$_{0.94}$O$_2$ which are compared with a series of measurements on compounds SrRu$_2$Mn$_{1-x}$O$_3$ made with natural Ru completed earlier. SrRu$_2$Mn$_{1-x}$O$_3$ is an antiferromagnet for x<0.06 and a ferromagnet for x>0.9. The change from the ferromagnet to the antiferromagnet is accompanied by a change in the hyperfine magnetic field from 420 K with saturation magnetizations depending on the degree of Fe$_{1+}$ lattice parameters are to be quite unusual and reflects the rich phase diagram of these materials. Almost all measured Ca$_2$RuO$_4$ and Re are ordered in a rock-salt type configuration, was prepared at a high pressure (6GPa) and high temperature (1000 C) condition. The crystal structure determined by the synchrotron X-ray powder diffraction was centrosymmetric with a space group I4/m. The critical behavior near the magnetic transition will be evaluated.

12:51PM Q23.00009 Optical Measurements of Transition from Insulator to Metallic Phases in LaxMnO$_3$: Evidence for Mixed Phases Below T_p, MICHAEL DELEON, PENG GAO, TREVOR A. TYSON, Physics Department, New Jersey Institute of Technology, ZHENXIAN LIU, Geophysical Laboratory, Carnegie Institution of Washington, CATHERINE DUBOURDIEU, LMGP-Minatc, France — Infrared measurements were conducted over the range 100 to 8000 cm$^{-1}$ on film of LaxMnO$_3$ ($x<0.8$). From these measurements we determined the temperature dependent conductivity, the effective number of carriers and the frequency dependence of specific phonon modes. The Drude model conductivity matches well with the measured DC resistance measurements. The bulk magnetization noset and resistance peak coincide near 25 K lower in temperature and saturates at 200 K. This indicates that a significant volume of the insulating phase exists below Tp.

This research was funded by NSF DMR-0512196, NSF INT-0233316, and CNR/NSF project No.14550.

1:03PM Q23.00010 Experimental Evidence for an Energy Gap in the Magnetic Insulator SrRu$_{0.06}$Mn$_{0.94}$O$_2$, M. DEMARCO, D. COFFEY, Dept. of Physics, Buffalo State College, NY 14222, B. DABROWSKI, S. KOLESNIK, M. MAXWELL, Dept. of Physics, Illinois Institute of Technology, Chicago, IL 60616. — The only copper-free superconductor isostuctural to the cuprates. Among the doped varieties of SrRuO$_3$, the Ca$_2$Sr$_{1.8}$Mn$_2$O$_7$ is an antiferromagnet for x=0.06 and a ferromagnet for x>0.9. The change from the ferromagnet to the antiferromagnet is accompanied by a change in the hyperfine magnetic field from 33T to 50T at 4.2K and also an isomer shift from a +4 to close to a +5 charge state. The measurements of the hyperfine field as a function of temperature show a change from 50T at 4.2K to 40T at 300K. Since the Néel temperature is about 160K for this compound, these small changes indicate that the thermal excitation of spin waves, which lead to the decrease of the hyperfine field with temperature, are strongly suppressed by a gap of order 100K in the spin wave spectrum. This indicates the presence of strong magnetic anisotropy in the material.

This work was supported by the USDOE(DE-FG02-03ER46064) at BSC and by the NSF(DMR-0302617) at NIU.

1:15PM Q23.00011 Elastic properties of the transition metal oxides Ca$_2$-$_x$Sr$_x$RuO$_4$, YANBING LUAN, VEERLE KEPPENS, The University of Tennessee, RONGYING JIN, DAVID MANDRUS, Oak Ridge National Laboratory, THE UNIVERSITY OF TENNESSEE TEAM, OAK RIDGE NATIONAL LABORATORY COLLABORATION — Layered perovskite ruthenates have attracted considerable interest since the discovery of superconductivity in Sr$_2$RuO$_4$. Among the doped varieties of SrRuO$_3$, the Ca$_2$Sr$_{1.8}$Mn$_2$O$_7$ series is heavily studied, as it connects the Mott insulator Ca$_2$RuO$_4$ with the superconductor Sr$_2$RuO$_4$ and exhibits a variety of physical properties. The current work focuses on the elastic properties of Ca$_2$-$_x$Sr$_x$RuO$_4$ Resonant Ultrasonic Spectroscopy (RUS) has been used to study the elastic response of the samples, and results are presented for single crystals with x = 0.2, 0.3, 0.4, 0.5, 1, 1.5, 1.9 and 2.0. The temperature-dependence of the elastic behavior is found to be quite unusual and reflects the rich phase diagram of these materials. Almost all measured Ca$_2$Sr$_{1.8}$RuO$_4$ samples show a soft phonon mode at low temperatures, which is believed to be associated with the dynamics of the RuO$_6$ octahedra.

1:27PM Q23.00012 Synthesis and Physical Properties of Double Perovskite Pb$_2$FeReO$_6$, KOUSUKE NISHIMURA, MASAKI AZUMA, MIKIO TAKANO, YUICHI SHIMAKAWA, Inst. Chem. Res., Kyoto Univ. — A double perovskite Pb$_2$FeReO$_6$, in which Fe and Re are ordered in a rock-salt type configuration, was prepared at a high pressure (6GPa) and high temperature (1000°C) condition. The crystal structure determined by the synchrotron X-ray powder diffraction was centrosymmetric with a space group I4/m with the Pb$^{2+}$ ion on the A-site. The lattice parameters are a = 5.6159(1) Å and c = 7.9455(3) Å. No structural transition to a lower symmetry was observed down to 23 K. The resistivity showed semiconducting behavior. This compound exhibited a ferrimagnetic transition at 420 K with saturation magnetizations depending on the degree of Fe$^{3+}$/Re$^{5+}$ ordering controlled by the cooling rate after the heat treatment.

Wednesday, December 12, 2008 11:15AM - 2:15PM – Session Q24 DMP: Focus Session: Transport in Nanostructures V: Optics, Mechanics, and Networks Morial Convention Center 216
11:15AM Q24.00001 Simultaneous measurements of single-molecule electrical conduction and Raman response, DANIEL WARD, NAOMI HALAS, DOUGLAS NATELSON, Rice University — Electronic conduction through single molecules is affected by the molecular electronic structure as well as by other information that is extremely difficult to assess, such as bonding geometry and chemical environment. The lack of an independent diagnostic technique has long hampered single-molecule conductance studies. We report on simultaneous measurements of single molecule electronic conduction and Raman response in a nanogap geometry using paramercaptoaniline. The measurements show strong correlations in the time variation of the conductance and the Raman spectrum. The Raman changes include "blinking", spectral diffusion, and changes in Raman mode structure. Conduction in nanogaps is known to be dominated by a single or at most a few molecules, demonstrating the correlated Raman response is also single molecule in nature. These observations establish that multimodal sensing of individual molecules is possible in dense mass-producible nanostructures.

11:27AM Q24.00002 Local luminescence characterizations of ZnO nanostructures and their electrical transport characteristics, JI-YONG PARK, YOUNG MU OH, KYUNG MOON LEE, Ajou University, KYUNG HO PARK, Korean Advanced Nanofab Center, YOUNG CHUL KIM, Y.H. AHN, SOONIL LEE, Ajou University — Local luminescence characterizations using cathodoluminescence (CL) emissions from individual ZnO nanostructures with diameters of 30-100 nm are investigated to correlate their optical and electrical properties. Two types of ZnO nanostructures with high and low light carrier densities are identified from electronic transport measurements and concomitant CL characterizations. The results demonstrate that local luminescence characterizations can provide information about inhomogeneities in electrical and optical properties among ZnO nanostructures.

11:39AM Q24.00003 Transport properties of a novel molecular rotor, MEI XUE, K.L. WANG, SANAZ KABEHEI, JEFFREY I. ZINK, UCLA — Rotary motion around a molecular axis has been controlled by electron transfer process and by photoexcitation. The basis of the motion is intramolecular rotation of a ligand (3,8-d-ethynyltrityl-1, 10-phenanthroline) around a copper axle. The asymmetric copper system is synthesized by immobilizing a "stator" to a silicon support. The "rotator," 3,8-di-ethynyltrityl-1, 10-phenanthroline is complexed to the metal center, Cu (I) or Cu (II) serving as an "axle". The Cu (I) system structure is tetrahedral, but that of Cu (II) is square planar. The interconversion of the two provides the basis for controlled, rotational motion. Hysteresis is observed in the different region of the applied voltage for different stators. The peak of the bis-P-Si shifts to the left compared to that of the phen-Si stator because of the larger energy gap of phen-Si. The energy states of the Cu (I) and Cu (II) are extracted from the transport measurement results.

11:51AM Q24.00004 Simultaneous Measurements of Force and Conductance through Single Molecular Junctions, MICHAEL FREI, Department of Applied Physics and Applied Mathematics, Columbia University, New York, New York, MARIA KAMENETSKA, MARK S. HYBERTSEN, Center for Functional Nanomaterials, Brookhaven National Labs, Upton, New York, LATHA VENKATARAMA-MAN — We measure the conductance of single molecules attached to gold electrodes by repeatedly forming and breaking junctions between a gold substrate and a gold-coated cantilever in a modified atomic force microscope (AFM). While transport through single molecular junctions has been investigated, we gain additional information through the simultaneous recording of the forces required to break these junctions. Specifically, the force traces show elastic and plastic deformation processes hidden in conductance measurements. Our single molecular conductance measurements reproduce the results obtained previously and we find that the forces required to break gold point-contacts is consistent with published results. Furthermore, we present a comparison of measured forces required to break the Au-N bond formed in our single molecule junctions and densities functional theory (DFT) results.

12:03PM Q24.00005 Dielectrophoretic Trapping of Au Nanoparticles using High Quality Nanogap Electrodes, YE LU, DANVERS E. JOHNSTON, DOUGLAS R. STRACHAN, BETH S. GUITON, PETER K. DAVIES, TAE-HONG PARK, MICHAEL J. THERIEN, A. T. CHARLIE JOHNSON, University of Pennsylvania — In the past decade, single molecule-based electronic devices have drawn enormous attention. One of the great challenges to be overcome is the fabrication of well-defined, uncontaminated nanogap electrodes, and the subsequent assembly of individual molecules or nanoparticles onto the contacts. A promising route to this goal is the feedback controlled electromigration (FCE) drawn enormous attention. One of the great challenges to be overcome is the fabrication of well-defined, uncontaminated nanogap electrodes, and the subsequent assembly. Methods for controlling DEP assembly by modification of the electrostatic interaction between NPs and substrate surfaces are explored. Funding: NSF-NSEC/NBIC DMR-0425780. 1D. R. Strachan et al., Appl. Phys. Lett. 86 043109 (2005). 2D. R. Strachan et al., Nano. Lett. 86 043109 (2006).

12:15PM Q24.00006 Nanomechanical Shuttling of Electrons, E. M. WEIG, D. R. KOENIG, J. P. KOTTHAUS, Center for NanoScience & Department of Physics, Ludwig-Maximilians University Munich, Germany — A nanoscale metal island that is oscillating between two opposing electrodes on a vibrating string can be used to mechanically actuate an electric current. We have realized such an electron shuttle on a doubly clamped high Q silicon nitride beam subject to high tensile strain. The shuttle is operated acoustically which guarantees complete decoupling of the measured signal from the drive at arbitrary source drain voltages. We have investigated the shuttling current across the island as a function of the applied voltage bias under resonant actuation. Since the tunnel resistance increases exponentially with distance, charge transfer between the island and an electrode only occurs at the turning points of the shuttle motion. Therefore transport across the island is strictly sequential, so that the shuttle can be theoretically described using a single electron box model during contact time. We have observed excellent agreement between our measured data and theoretical calculations which suggests that a crossover to the Coulomb blockade regime should be observed for smaller sample dimensions and lower temperatures.

12:27PM Q24.00007 Measuring the momentum of a nanomechanical oscillator using tunnel junctions, CHARLES DOIRON, Universitaet Basel, BJOERN TRAUZETTEL, Universitaet Wuerzburg, CHRISTOPH BRUDER, Universitaet Basel — We present a way to measure the momentum $p$ of a nanomechanical oscillator. The momentum detector is based on two tunnel junctions in an Aharonov-Bohm-type setup, where one of the tunneling amplitudes depends on the motion of the oscillator and the other one does not. The coupling between the first tunnel junction and the oscillator is assumed to be linear in the position $x$ of the oscillator $t(x) = t_0 + t_1 x$. However, the presence of two junctions can make the equation of motion for the density matrix of the coupled (oscillator+tunnel junction) system show that in this case the finite-frequency current noise of the detector is proportional to the momentum spectrum of the oscillator.

---

12:39PM Q24.00008 Vibronic enhancement of phonon heat conductance\(^1\). YOSHIHIRO ASAI, National Institute of Advanced Industrial Science and Technology (AIST), Japan — We have studied the electron transport and phonon heat transport through single molecular bridge-junctions in terms of a newly proposed self-consistent theory. Due to the inelastic coupling between electrons and phonons, the two transport properties are closely correlated, which are treated on an equal footing. By using the theory we have studied the two problems, i.e., (1) the non-equilibrium phonon effect on the electron transport and (2) the inelastic vibronic coupling effect on the phonon heat conductance. We have discussed dissipation processes of the inelastic energy accompanying the electronic conduction through the bridge-junction. Ref) Y. Asai, Phys. Rev. Lett. 93, 246102 (2004); 94, 099901(E) (2005). Y. Asai and H. Fukuyama, Phys. Rev. B 72, 085431 (2005). Y. Asai, submitted.

12:51PM Q24.00009 Anisotropic Phonon Propagation in Nanoporous Alumina\(^1\). AKIHIRO SATO, Max Planck Institute for Polymer Research, GEORGE FYTAS, F.O.R.T.H Institute of Electronic Structure and Laser Technology, BAHRAM DJAFARI-ROUHANI, YAN PENNEC, Institut d’Electronique, de Micro-électronique et de Nanotechnologie, MARTIN STEINHART, Max Planck Institute of Microstructure Physics, WOLFGANG KNOLL, Max Planck Institute for Polymer Research — Self-ordered nanoporous alumina membranes contain highly ordered hexagonal arrays of cylindrical holes. Phononic crystals based on nanoporous alumina with various porosities represent a composite medium for rich elastic wave propagation phenomena due to their periodicity and acoustic impedance contrast between alumina and infiltrated materials. It allows the manipulation of the high frequency acoustics as probed by Brillouin light scattering. In-plane and out-of-plane (perpendicular to the holes) propagation of the elastic waves are distinctly different. While the former reveals an effective medium and localization behavior, the latter selects the medium filling the holes. Band structure theoretical calculations provide a semiquantitative description of the new experimental findings.

\(^1\)This study was partially supported by a grant-in-aid from Marubun Research Promotion Foundation.

1:03PM Q24.00010 Phononic Properties of Periodic 1D Multilayer Polymer Films, NIKOLAOS GOMOPOULOS, WEI CHENG, Max Planck Institute for Polymer Research, GEORGE FYTAS, F.O.R.T.H Institute of Electronic Structure and Laser Technology, TARAS GORISHNYY, EDWIN THOMAS, Massachusetts Institute of Technology, ANNE HILTNER, ERIC BAER, Case Western Reserve University — The evolution of phonon dispersion relation with composition and periodicity in 1D periodic multilayer nanoscale polymer films is studied using high resolution Brillouin light scattering. An increase in complexity of the dispersion relation as the lattice constant \(d\) becomes comparable to the phonon wavelength \((q \sim 1)\) is observed. Films with large \(d\) include phonons propagating within individual layers, as opposed to delocalized phonons moving throughout an effective homogeneous medium in films with small \(d\). Temperature dependent measurements of the sound velocities reveal the presence of distinct glass transition temperatures in support of the distinct propagation of phonons through the periodic medium in agreement with theoretical predictions. The structure related elastic excitations are determined by the product of the layer thickness and the phonon wave vector \(q\) and hence all layer guided modes are superimposed in a reduced plot of the phase velocity \(v\) vs \(q\).

1:15PM Q24.00011 Dephasing of the weak localization correction in networks of quantum dots\(^1\). JOERN N. KUPFERSCHMIDT, PIET W. BROUWER, LASSP, Cornell University — We consider the corrections to the conductance of networks of quantum dots due to electron-electron interactions. Interaction corrections are calculated to first order in the propagator associated with the capacitive coupling among the dots. We focus in particular on calculating the dephasing correction to the weak localization correction and the Altshuler-Aronov correction to the conductance.

\(^1\)Supported by the Cornell Center for Materials Research

1:27PM Q24.00012 Fractal conductance fluctuations of classical origin, HOLGER HENNIG, RAGNAR FLEISCHMANN, MPIDS, Goettingen and University of Goettingen, Germany, LARS HUFNAGEL, Kavli Institute for Theoretical Physics, UCSB, USA, THEO GEISEL, MPIDS, Goettingen and University of Goettingen, Germany — The coherent conductance through mesoscopic structures is well known to show reproducible fluctuations with the variation of an external parameter (e.g. a magnetic field). These fluctuations are caused by interference effects and can be described semiclassically. In systems with mixed (regular and chaotic) classical dynamics fractal conductance curves are found. Experiments that study the transition from coherent to chaotic transport showing a change of the fractal dimension with the coherence-length\(^2\) however, seemed to contradict the semiclassical theory of the fractal scaling. We show that there is no contradiction but that the classical dynamics itself already leads to fractal conductance curves\(^3\) explaining the experimental observations. Moreover, we predict fractal classical conductance fluctuations not only in systems with mixed phase space but in purely chaotic systems.

1:39PM Q24.00013 Electron Transport through Models for Small-World Nanomaterials\(^1\). LAZARUS SOLOMON, MARK NOVOTNY, Mississippi State University — We investigate the quantum transport of (spinless) electrons through simplified models related to small-world nanomaterials. We employ a tight-binding Hamiltonian, and obtain the transmission coefficient from a matrix solution of the associated time-independent Schrödinger Equation. The system studied corresponds to \(d = 1\) semi-infinite input and output leads, connected to a 'blob' of \(N\) atoms. We first present exact results for \(N\) inter-connected atoms, a fully-connected graph. The exact solution, for any \(N\), is given both for symmetric and non-symmetric connections between the 'blob' and the input/output. We then present numerical results obtained by removing some of the connections within the \(N\)-site 'blob', thereby approaching transport through a small-world nanomaterial [1-4].

\(^1\)Supported in part by NSF.
11:15AM Q25.00001 Structure and Assembly of Dense Solutions and Melts of Polymer Tethered Nanoparticles, ARTHI JAYARAMAN, KENNETH S. SCHWEIZER, University of Illinois, Urbana-Champaign — We generalize the microscopic Polymer Reference Interaction Site Model theory to study intermolecular pair correlation functions and collective structure factors of dense solutions and melts of polymer-tethered spherical nanoparticles. The complex interplay of entropy (translational, conformational and packing) and enthalpy (particle-particle attraction) leads to different structural arrangements with distinctive scattering signatures. Strong concentration fluctuations indicative of aggregate formation and/or a tendency for microphase separation occur as the total packing fraction and/or particle-particle attraction strength increase. A microphase spinodal curve is estimated by extrapolation of the inverse of the amplitude of the small angle scattering peak. For nanoparticles, twice the diameter of monomers, carrying a single tether the microphase spinodal temperature grows roughly as a power law function of packing fraction with an exponent much less than unity. Increasing the nanoparticle diameter lowers the microphase spinodal temperature and results in a qualitative change of its packing fraction dependence. The effect of nanoparticle size, number and length of tethers, position of the grafting sites, total packing fraction, and particle-particle attraction strength on the structure, scattering patterns and tendency for microphase ordering has been studied in detail.

11:27AM Q25.00002 Line shape analysis of dynamic light scattering results on polymeric microgel nanoparticles, KIRIL A STRELETZKY, IMAAN BENMERZOUGA, JOHN MCKENNA, Cleveland State University — Hydroxypropylcellulose (HPC) is nontoxic polysaccharide with temperature dependent water solubility. HPC polymer chains can be chemically cross linked into stable nanoparticles—microgels. HPC microgel properties depend on polymer and salt concentration and cross linking density. One of the most important properties of HPC is its critical temperature of 41°C, at which the polymer undergoes a reversible phase transition. HPC microgels also undergo a reversible volume phase transition in which particles shrink considerably. This property might lead to application of microgels as effective targeted drug delivery and release system. We used Dynamic Light Scattering to study microgels at different temperatures and applied line shape analysis algorithm to analyze resulting spectra. We found that the microgel initial size depends heavily on polymer concentration. We also found that varying salt concentration affects the dynamics of microgels. In addition, we were able to determine the effective cross linking density that yields relatively monodisperse microgels. We explored the structure of several microgel solutions by angular dependence analysis and found that most of them were spherical particles. In addition, we explored dynamics of the same microgels at different temperatures that enabled us to monitor their shrinking behavior.

11:39AM Q25.00003 Neutron Flow-Mapping of Controlled-Architecture Polymer Melts, TOM MCLEISH, Dept of Physics and Astronomy and Polymer IRC, Univ. of Leeds, NIGEL CLARKE, Dept of Chem./Polymer IRC, Univ. of Durham, PIERRE CHAMBON, Dept of Chem./Polymer IRC, Univ. of Sheffield, EDOARDO DE LUCA, Dept of Chem./Polymer IRC, Univ. of Durham, JOHN EMBERY, Dept of Physics and Astronomy and Polymer IRC, Univ. of Leeds, CHRISTINE FERNYHOUGH, Dept of Chem./Polymer IRC, Univ. of Sheffield, TIM GOUGH, Dept of Mech. Eng.,/ Polymer IRC, Univ. of Bradford, RICHARD GRAHAM, School of Mathematical Sciences, Univ. of Nottingham, ISABELLE GRUJO, Institut Laue-Langevin, France, LIAN HUTCHINGS, Dept of Chem./Polymer IRC, Univ. of Durham, KAMAKSHI JAGANNATHAN, HARLEY KLEIN, Dept of Physics and Astronomy and Polymer IRC, Univ. of Leeds — We report on results of a new method for probing complex flows of entangled polymer melts that is able to compare simultaneously chain configurations on different length scales and stress distribution in the flow with the predictions of molecular models. Controlled-architecture melts synthesised by anionic polymerisation and selectively deuterated are made in sufficient quantities to fill a recirculating flow device. The whole processing rig is scanned across a narrow neutron beam. The motion is then detected by measuring the induced e.m.f in the electrode. As a first step in understanding possible damping effects due to metal films, we have fabricated free standing metallic resonators. We have fabricated doubly clamped beams out of Al, Au, and Au/Pd alloys (dimensions length 3−5µm, thickness ≈ 100 nm, width 200 nm). Beams of this dimension have a resonant frequency around 5−10 MHz. We will report measurements, performed in a dilution refrigerator, of the quality factor Q in these resonators as a function of temperature and magnetic field (up to 15 T).

11:51AM Q25.00004 Chain dynamics in a semifluoropolymer solution under steady shear, PRASANTH JOSE, GRZEGORZ SZAMEL, Department of Chemistry, Colorado State University, Fort Collins, CO 80523 — We performed a series of Brownian dynamics simulations of sheared semifluoropolymer solutions of relatively short polymer chains and found that incomplete cancellation of intra and inter chain contributions to the steady state structure factors leads to anisotropic patterns that resemble those observed in light scattering experiments on sheared semifluoropolymer solutions (J. Chem. Phys. 122, 114905(2007)). Here we investigate the changes in the single-chain dynamics in sheared semifluoropolymer solutions. We study the shear-rate dependence of the end-to-end vector relaxation, Rouse modes' dynamics, etc. We correlate the changes in the chain dynamics with shear rate dependence of the anisotropic scattering patterns and shear thinning of the solution viscosity.
12:03PM Q25.00005 Investigation of Extensional Flow-induced Crystallization in Entangled Polymer Melts. JONG KAHK KEUM, YIMIN MAO, FENG ZUO, BENJAMIN S. HSIAO, Stony Brook University. TEAM — To investigate the extensional flow-induced crystallization of semidilute and concentrated polymer solutions, synchrotron X-rays have been used. The results show that the formation of crystallization precursor structure (i.e., shish-kebab structure) under extensional flow is strongly governed by applied strain as well as strain rate. A critical strain rate exists in the formation of flow-induced crystallization precursor structure. Below this critical strain rate, no shish-kebab structure can be formed even when the applied strain is higher than the critical strain rate. Results confirmed that the crystalline shish precursor structure is formed first and it induces the growth of folded-chain lamellae, i.e., kebabs.

12:15PM Q25.00006 Transport and rheology in block copolymer mesophases. XUSHENG ZHANG, JORGE VINALS, McGill University — Free energy functionals of an order parameter field are widely used to describe ordered phases and flows in block copolymer melts. We present a systematic derivation of the transport equations governing order parameter diffusion and hydrodynamic flows by considering the order parameter and the local deformation as the two independent variables. By studying the static and dynamic response of the copolymer, we derive expressions for the reactive and dissipative components of the stresses. We finally use these equations to study the low frequency rheology of the copolymer under an applied oscillatory shear.

12:27PM Q25.00007 Universal Scaling of Linear and Nonlinear Rheological Properties of Semidilute and Concentrated Polymer Solutions. RONALD LARSON, YOUNGSUK HEO, University of Michigan — We examine the validity of the de Gennes “blob” concept in predicting linear and nonlinear rheological properties of semidilute polystyrene solutions in tricresyl phosphate (TCP). At a fixed value of reduced concentration c/ce where ce is the entanglement concentration, below a critical value of around 2.0 for our polystyrene/TCP solutions, linear and nonlinear rheological functions superimpose after the modulus and the frequency (or shear rate) of each solution are respectively normalized with the concentration-dependent plateau modulus and the equilibration time obtained from the de Gennes scaling relationships using the literature value of the solvent-quality exponent 0.53. However, once the polymer volume fraction exceeds the “swelling volume fraction” above which the polymer takes on a random walk configuration on all length scales even in a good solvent, this universal scaling breaks down and the polymer conformation appears to be governed by Colby-Rubinstein’s scaling laws for theta solutions. We estimate that all polybutadiene solutions in phenyl octane (a good solvent) from the work of Colby et al. are above the swelling concentration and can be scaled using theta solvent scaling laws for concentrations ranging all the way up to the melt, showing universal behavior of melts and solutions above the swelling concentration.

12:39PM Q25.00008 The linear rheological responses of cyclic polyoctenamer melt. MIAO HU, GREGORY MCKENNA, Department of Chemical Engineering, Texas Tech University, YAN XIA, ROBERT GRUBBS, JULIE KORNFIELD, Division of Chemistry and Chemical Engineering, California Institute of Technology. — There is continuing interest in the dynamics of macrocyclic polymers or polymer rings. Here we are working with novel polyoctenamer rings synthesized by a ring opening metathesis polymerization (ROMP) route that precludes linear contamination when pure catalyst is used. While the rings are polydisperse in their molecular weights, the method permits synthesis of extremely high molecular weight entities. Here we report results on the dynamic moduli and the zero shear rate viscosities of both the cyclic polyoctenamer of Mw up to nearly 400,000 g/mol (which is nearly 50 entanglements) and the linear analogue. Comparisons will be made with prior literature results on rings made by ring closure methods in dilute solution where contamination with linear chains was problematic and where the entanglement density was less than 20.

12:51PM Q25.00009 Rheology and birefringence of Fomblin YR at very high shear rates. KHALED MRIZIQ, HANK COCHRAN, MARK DADMUN, University of Tennessee. — Simultaneous measurements of the rheological and structural properties of perfluoropolyether (PFPE) lubricant films were measured at relatively low to extremely high shear rates using a rotational optical rheometer. The viscosity of various films with different thicknesses exhibit Newtonian behavior up to a shear rate 1x10^4 s^-1, with a transition to shear-thinning behavior obvious at higher shear rates. Birefringence of these films was also measured, and these results indicate chain alignment with shear in the shear-thinning regime. The shear rate at which alignment occurs is similar to that of the onset of shear thinning. This correlation between chain alignment and shear thinning provides direct evidence that the ability of PFPEs to lubricate hard drives at high shear rates is a direct consequence of the ability of the applied shear field to align the molecules on a molecular level.

1:03PM Q25.00010 Rheo-Dielectric Studies of Concentrated Polysisoprene Solutions. JAI PATHAK, RICCARDO CASALINI, C. M. ROLAND, NRL, Chemistry, SIMONE CAPACCIOLI, University of Pisa, Physics, NIKOS HADJICHRISTIDIS, University of Athens, Chemistry. — We have performed dielectric spectroscopy on concentrated and well-entangled cis-1,4-polysoprene solutions in n-tetradecane while they undergo steady shear. The volume fraction of polymer is 0.2, and the number of entanglements per chain varies between 20 and 30. cis-1,4-Polysoprene is a Stockmayer Type-A dipole, with one dipole moment component along the chain backbone. Hence dielectric spectroscopy on it reveals the global chain relaxation (normal mode), in addition to its segmental mode relaxation. We critically examine the normal mode in strongly non-linear flows in the cone (22.8 mm diameter)-platen (25 mm) geometry. We work with a sea of fluid surrounding the cone, and the edge remains intact deeper into the shear thinning regime. In addition to visual inspection of the sample edge, we also check for validity of the Cox-Merz rule, finding good agreement between the two. Preliminary results indicate that the dielectric strength continually decreases well into the non-linear regime, perhaps a consequence of the orthogonal directions of the dielectric measurement (velocity gradient direction) and the chain stretching (flow direction).

1:15PM Q25.00011 Isothermal and Self-Seeding Crystallization from Polyethylene Solution. HOWARD WANG, NARAYAN CH DAS, KAIKUN YANG, Department of Mechanical Engineering and Institute of Materials Research, Binghamton University, SUNY, Binghamton, NY 13902, BOUALEM HAMMOUDA, National Institute of Standards and Technology, Gaithersburg, MD 20899. — We have applied time-resolved small angle neutron scattering (SANS) to studying self-seeding and isothermal crystallization kinetics of low molecular weight polyethylene in solution. In one example, SANS spectra of isothermal crystallization of 2.1 kg/mol PE at 78.8 °C from a solution containing 4.3% PE by mass show both the characteristic form and structure factors of stacked lamellae. The intensity hump around 0.025 Å^-1 indicates the correlation among lamellae. On the other hand, SANS from the same solution after quenched from melt to the room temperature, then stored at 90 °C for 5 min, followed by quenching to 78.7 °C are different from those of isothermal crystallization; the first correlation peak from the structure factor is not obvious, implying that crystals are dominantly in single or few lamellae forms. A morphological model that accommodates arbitrary distributions of structures from individual lamellae to infinite stacks has been used to analyze the SANS data. A possible lyotropic transition from isolated to stacked lamellae is suggested.

1This work is supported by the National Science Foundation.
1:27PM Q25.00012 Retention behavior of star-shaped polymers near the chromatographic critical condition. JESSE ZIEBARTH, YONGMEI WANG, University of Memphis, KYUHYUN IM, HAE-WOONG PARK, YOUNGTAK KIM, SUNYOUNG AHN, TAIHYUN CHANG, Pohang University of Science and Technology — The retention behavior of star-shaped polymers near the liquid chromatographic critical condition (LCCC) was investigated with 2-D liquid chromatography of polystyrene (PS) and lattice Monte Carlo simulations. At the LCCC for linear PS, stars with short arms elute after linear PS, while stars with long arms show a cross-over from late to early elution as branch number increases. Monte Carlo simulations show that two factors, excluded volume interactions and attractive end-effects resulting from initiator butyl groups, are required to explain the elution of star polymers. When polymers are modeled by random walk chains without excluded volume interactions, all stars are slightly more attracted to pores than corresponding linear chains. When polymers are modeled as self-avoiding walks (SAW) that include excluded volume interactions, stars with short arms elute later and stars with long arms elute earlier compared to linear chains. Incorporating more attractive-ends in SAWs results in more attractive to pores than corresponding linear chains. More attractive ends in PS star samples were confirmed through chromatographic retention of stars with short arms elute later and stars with long arms elute earlier compared to linear chains. In addition, no significant dependence of the hole burning event on entanglement density was observed.

1:39PM Q25.00013 Mechanical Hole Burning Spectroscopic Investigation. QIAN QIN, GREGORY MCKENNA, Texas Tech University — Mechanical spectral hole burning (MSHB) was previously applied to a densely entangled block copolymer and successfully distinguishes the heterogeneous from the homogeneous state. Here, we chose polystyrene (PS) solutions to further investigate the effect of entanglement density on mechanical spectral hole burning. The entanglement density was varied by changing either solution concentration or molecular weight of the PS. Dynamics in different regimes ranging from close to the Rouse regime into the terminal region were also examined. Our results are consistent with a heterogeneous dynamics over both entanglement (or plateau) and Rouse regimes. Terminal relaxation dynamics, on the other hand, were always found to be homogeneous for the PS/diethyl phthalate solutions investigated. In addition, no significant dependence of the hole burning event on entanglement density was observed.

1:51PM Q25.00014 Linking number of linear chain in polymer solution and melts. QI LIAO, Institute of Chemistry, Chinese Academy of Sciences, Beijing, 100080, China — We present the statistical results of linking number of linear chains prepared by Monte Carlo and molecular dynamics simulations of polymer solution and melts. Simulations were performed for a wide range of chain lengths covering both non-entangled and entangled polymer dynamics. The simulation results for linking number dependence on chain length and distribution function are compared with the prediction and conjecture of topology.

2:03PM Q25.00015 Computer simulation study on the shear-induced phase separation in semidilute polymer solutions by using Ianniruberto-Marrucci model. SHOTARO NISHITSUJI, MIKHITOK TAKENAKA, Graduate School of Engineering, Kyoto University, TAKASHI TANIGUCHI, Graduate School of Science and Engineering, Yamagata University, HIROKAZU HASEGAWA, Graduate School of Engineering, Kyoto University — When shear flow is imposed to a semi-dilute polymer solution at its one phase region, the solution exhibits strong turbidity. This phenomenon is called shear-induced concentration fluctuation and/or phase separation. Theoretically, Doi and Onuki submitted a two fluid model which incorporates the gradient term of the stress tensor into Ginzburg-Landau type free energy functional, and account for the spatial heterogeneity of the stress field by dynamic asymmetry. We developed the new computer simulation scheme with Doi-Onuki theory, where the Ianniruberto-Marrucci model (IM model) is employed as the constitutive equation, to simulate the dynamics of the shear-induced concentration fluctuation and/or phase separation in semi-dilute polymer solutions. In the simulation results, the concentration fluctuations appear and coarsen with time under shear flow and the change in shear stress with time exhibits the overshoot behavior due to the relaxation of entanglement. These results agree with the experimental results.

Wednesday, March 12, 2008 11:15AM - 2:15PM – Session Q26 DCP: Advances in Spectroscopy Morial Convention Center 218

11:15AM Q26.00001 IR and Raman spectroscopy of water and ice by ab initio simulations1. MANU SHARMA, DAVIDE DONADIO, GIULIA GALLI, UC Davis — We use ab initio molecular dynamics to compute the IR and Raman spectra of a variety of heavy water systems, ranging from pure water and ice, to liquid water confined between graphene foils and D-terminated diamond surfaces. The analysis of the simulated spectra provides the fingerprints of different hydrogen bonding environments, giving access to the complex structural and dynamical properties of water in various conditions. In addition our results provide a detailed, microscopic interpretation of IR and Raman experiments, as they allow us to assign univocally spectroscopic bands to specific vibrational modes, and to identify electro-dynamic coupling between water molecules and surfaces, in the case of confined water. Our MD simulations also give a quantitative assessment of the anharmonicities and lifetimes of various vibrational modes.

1This work was performed under the auspices of the DOE under contract no. W-7405-Eng-48

11:27AM Q26.00002 Infrared spectra of ice and water from first principles: intra vs. intermolecular dipole correlations1. WEI CHEN, Department of Physics, Princeton University, Princeton, NJ 08544, USA, MANU SHARMA, Department of Chemistry, University of California, Davis, CA 95616, USA, RAFFAELE RESTA, Dipartimento di Fisica Teorica, Università di Trieste, Strada Costiera 11, 34014 Trieste, Italy, GIULIA GALLI, Department of Chemistry, University of California, Davis, CA 95616, USA, ROBERTO CAR, Department of Chemistry, Princeton University, Princeton, NJ 08544, USA — We report simulated infrared (IR) spectra of deuterated ice and water using Car-Parrinello molecular dynamics with maximally localized Wannier functions. Experimental features of both ice and water are accurately reproduced within the harmonic approximation. Calculated line shapes are further decomposed in terms of intra and intermolecular dipole correlation functions with spatial resolution. This approach proves to be very useful to understand the origin of spectral features and the nature of the underlying hydrogen-bond (H-bond) network. We find that intermolecular dynamic charge fluctuations play a crucial role over the entire frequency range.

1This work is partially supported by NSF under the PCCM-MRSEC program with award number: NSF DMR 02-13706.
11:39 AM Q26.00003 Nuclear quantum effects in water. JOSEPH MORRONE, ROBERTO CAR, Dept. of Chemistry, Princeton University — In this work, a path integral Car-Parrinello molecular dynamics simulation of liquid water is performed. It is found that the inclusion of nuclear quantum effects systematically improves the agreement of first-principles simulations of liquid water with experiment. In addition, the proton momentum distribution is computed utilizing a recently developed “open” path integral molecular dynamics methodology. It is shown that these results, which are consistent with our computations of the liquid structure, are in good agreement with neutron Compton scattering data. The remaining discrepancies between the present results and experimental data are indicative of some degree of over-binding in the hydrogen bond network, likely engendered by the use of semi-local approximations to density functional theory in order to describe the electronic structure.

11:51 AM Q26.00004 ABSTRACT WITHDRAWN

12:03 PM Q26.00005 Fluorescence correlation spectroscopy with Gaussian-Lorentzian volumes. MICHELE MARROCCO, ENEA — Fluorescence correlation spectroscopy (FCS) is a fundamental technique of fluorescence microscopy used for many applications of chemical physics where molecular diffusion plays primary roles [see, for example, O. Krichhevsky and G. Bonnet, Rep. Prog. Phys. 65, 251 (2002)]. The milestone of FCS is called three-dimensional Gaussian (3DG) approximation. According to this assumption, the observation volume is modeled by Gaussian profiles along the main three spatial directions. This simplification is necessary to achieve analytical treatment of FCS measurements. In this work, analytical solutions are shown for another geometry corresponding to the fundamental mode of laser beams, i.e. the Gaussian-Lorentzian distribution, where Gaussian profiles are associated with the two transverse directions while a Lorentzian dependence characterizes the axial direction (coincident with the optical axis of the microscope). Analytical solutions are guaranteed only for both one-photon and two-photon excitations of diffusing molecules [one-photon excitation is considered in M. Marocco, Chem. Phys. Lett. 449, 227 (2007)]. Similarities and differences with respect to the 3DG approximation are discussed.

12:15 PM Q26.00006 Studying hydrogen bond by Quantum Monte Carlo: binding energy and dispersion curve of the water dimer. LEONARDO SPANU, SISSA-ISAS Trieste, Italy; Dept. of Chemistry UC Davis, FABIO STERPONE, LUCA FERRARO, Caspur Roma, Italy, SANDRO SORELLA, SISSA-ISAS Trieste, Italy, LEONARDO GUIDONI, Univ. La Sapienza Roma, Italy — We present a variational MonteCarlo (VMC) and lattice regularized diffusion MonteCarlo (LRDMC) study of the binding energy and dispersion curve of the water dimer. One the aim of the present work is to investigate how the bonding of two water molecules, as a prototype of the hydrogen-bonded complexes, could be described by a JAGP wave function, an implementation of the resonating valence bond idea. Using a Pseudopotential for the inert core of the Oxygen, with a full optimization of the variational parameters, we obtain at the VMC level a binding energy of -4.5(0.1) Kcal/mol, while LRDMC gives -4.9(0.1)Kcal/mol (exp. 5 Kcal/Mol). The calculated dispersion curve reproduces both at the VMC and LRDMC level the minimum position and the right curvature. The quality of the WF gives us the possibility to dissect the binding energy in different contributions by appropriately switching off determinantal and Jastrow terms in the JAGP: we estimate the dynamical contribution to the binding energy of the order of 1.4(0.2) Kcal/Mol whereas the covalent one about 1.0(0.2) Kcal/Mol. JAGP reveals thus a promising WF for describing systems where dispersive and covalent forces play an important role.

12:27 PM Q26.00007 Hydrogen bond network ordering of liquid water confined between two metallic plates studied by ab initio molecular dynamics. MARIVI FERNANDEZ-SERRA, Physics & Astronomy SUNY Stony Brook — We present an ab initio molecular dynamics study of liquid water confined between two palladium (111) surface slabs, at room temperature. We analyze in detail the layering and ice-Ih-type ordering of water molecules close to the metal interfaces. In particular we show how water molecules next to the metal surface display a very different structural and dynamic behavior as compared to those in the “bulk” regions, which can be easily characterized using infra-red spectroscopy. Hydrogen bonds near the metallic surfaces are strengthened, inducing a characteristic ordering which decays with de distance from the surfaces. Our preliminary results show that this confined water presents an asymmetrical and stable structure as a function of Z (axis perpendicular to the surfaces) which results in a characteristic ordering of the water molecules resembling that of ferroelectric systems.

12:39 PM Q26.00008 Quasiparticle lifetime and edge localized states of graphite studied by high-resolution ARPES. KATSUAKI SUGAWARA, TAKAFUMI SATO, SEIGO SOUMA, TAKASHI TAKAHASHI, Tohoku University, HIROHITO SUEMATSU, RIKEN, Spring-8 — We have performed an ultrahigh-resolution angle-resolved photoemission spectroscopy (ARPES) of high-quality graphite single crystal (kish graphite) to elucidate the band structure and many-body interaction. We clearly observed an extremely small hole-like Fermi surface centered at the K(H) point, a sharp quasiparticle peak in the vicinity of the Fermi level ($E_F$), and a kink in the dispersion at 0.18 eV. 1 We also found first evidence for the edge localized states near $E_F$, whose energy dispersion is markedly different from that of the bulk band. We will discuss the energy- and temperature-dependence of quasiparticle lifetime in relation to the strong electron-phonon coupling, the electron-plasmon interaction, and the electron-hole pair excitations. 2 K. Sugawara et. al., Phys. Rev. Lett. 98 (2007) 036801. 2 K. Sugawara et. al., Phys. Rev. B 73 (2006) 045124.

12:51 PM Q26.00009 Fully ab-initio study of the optical response of charged rare gas clusters. FERNANDO NOGUEIRA, Center for Computational Physics and Physics Department, University of Coimbra, Portugal, MICAELE OLIVEIRA, Center for Computational Physics, University of Coimbra, Portugal and European Theoretical Spectroscopy Facility, MIGUEL MARQUES, LPMCN, Universitè Lyon 1, Lyon, France and European Theoretical Spectroscopy Facility — Charged rare-gas clusters are markedly different from their neutral, van der Waals bonded counterparts. The removal of an electron from a strongly antibonding orbital causes the bonding to become much stronger and shifts the optical absorption to the visible region. We report a fully ab-initio determination of the geometry, electronic structure, and optical response of small singly charged Ne, Ar, Kr and Xe clusters. All calculations were performed using a pseudopotential based real space implementation of Time-Dependent Density-Functional Theory. We find that GGA leads, in general, to much better results than LDA, even though it predicts some absorption peaks at slightly higher energies than those found experimentally. The lighter elements show a single absorption peak but in the heavier elements spin-orbit interaction induces a splitting of the absorption peak, in good agreement with experiment.

1 This work was supported by Fundação para a Ciência e Tecnologia through grants #POCI/FIS/58309/2004 and #SFRH/BD/12712/2003.
the correlation length and the actual distance between two defects, the lattice spacing and the domain-wall size. Ad hoc directions and the crystal axes break the site-by-site translational invariance along the chain. Both these phenomena affect slow relaxation. We will show how...
11:27AM Q27.00002 Dynamical correlations of spin-1/2 chains . RODRIGO PEREIRA, University of British Columbia, STEVEN WHITE, UC Irvine, IAN AFFLECK, University of British Columbia — We show that the long-time behavior of the self-correlation function \( \langle S_i^z(t) S_j^z(0) \rangle \) of the S=1/2 XXZ model in the critical regime is dominated by high-energy excitations. We relate the exponents of the long-time decay to phase shifts which are known exactly from the Bethe ansatz. The same exponents are connected with the singularities of the dynamical structure factor \( S^{zz}(q, \omega) \). By combining the analytical results with the time-dependent density matrix renormalization group (tDMRG), we calculate \( S^{zz}(q, \omega) \) to very high precision.

11:39AM Q27.00003 Finite-temperature lineshapes in gapped quantum spin chains . ROBERT KONIK, Brookhaven National Laboratory, FABIAN ESSLER, University of Oxford — We consider the finite-temperature dynamical structure factor (DSF) of gapped quantum spin chains such as the spin one Heisenberg model and the transverse field Ising model in the disordered phase. At zero temperature the DSF in these models is dominated by a delta-function line arising from the coherent propagation of single particle modes. Using methods of integrable quantum field theory we determine the evolution of the lineshape at low temperatures. We show that the line shape is in general asymmetric in energy and becomes Lorentzian only at temperatures far below the gap. We discuss the relevance of our results for the analysis of inelastic neutron scattering experiments on gapped spin chain systems such as CsNiCl₃ and YBaNiO₅.

11:51AM Q27.00009 Magnetic field versus temperature phase diagram of the spin-1/2 bond-alternating-chain antiferromagnet \( F_{2}PNN \). YASUO YOSHIDA, Kyushu University; University of Florida, TATSUYA KAWAI, Kyushu University, BOHDAN ANDRAKA, YASUMASA TAKANO, University of Florida, YUKO HOSOKOSHI, Osaka Prefecture University, KATSUYA INOUE, Hiroshima University, NOBUYA MAESUMA, Tohoku University, Institute for Molecualr Science, KOUICHI OKUNISHI, Kanazawa University, KYOMI OKAMOTO, Tokyo Institute of Technology, TORU SAKAI, Japan Atomic Energy Agency — The S = 1/2 Heisenberg bond-alternating-chain antiferromagnet pentfluorophenyl nitronyl nitroxide (\( F_{2}PNN \)) exhibits Tomonaga-Luttinger-liquid behavior in the temperature dependence of the specific heat above the field-induced magnetic ordering temperature [1]. We have determined the magnetic phase diagram of this compound from the specific heat. For a single crystal, the boundary of the ordered phase in the field-versus-temperature diagram is symmetric with respect to the central field of the gapless region \( H_{c1} \leq H \leq H_{c2} \), whereas a distorted phase boundary is observed for a powder sample, whose ordering temperature is reduced. Calculations based on the finite-temperature density-matrix renormalization group suggest the possibility of a novel incommensurate phase due to frustration in the powder, in a narrow field range near the central field. [1] Y. Yoshida et al., Phys. Rev. Lett. 94, 037203 (2005).

12:03PM Q27.00005 Correlation amplitude and entanglement entropy in random spin chains¹ . JOSÉ HOYOS, Duke University, ANDRÉ VIEIRA, Universidade Federal do Ceará, NICOLAS LAFLORENCIE, CNRS-Orsay, EDUARDO MIRANDA, Universidade Estadual de Campinas — Using strong-disorder renormalization group, numerical exact diagonalization, and quantum Monte Carlo methods, we revisit the random antiferromagnetic XXZ spin-1/2 chain focusing on the long-length and ground-state behavior of the average time-independent spin-spin correlation function \( C(t) = \langle S_i(t) S_j(0) \rangle \). In addition to the well-known universal (disorder-independent) power-law exponent \( \eta = 2 \), we find interesting universal features displayed by the prefactor \( v = v_{l}/s \), if \( l \) is odd, and \( v = v_{o}/s \), otherwise. Although \( v_{l} \) and \( v_{o} \) are nonuniversal (disorder dependent) and distinct in magnitude, the combination \( v_{l} + v_{o} = -1/4 \) is universal if \( C \) is computed along the symmetric (longitudinal) axis. The origin of the nonuniversalities of the prefactors is discussed in the renormalization-group framework where a solvable toy model is considered. Moreover, we relate the average correlation function with the average entanglement entropy, whose amplitude has been recently shown to be universal. The nonuniversalities of the prefactors are shown to contribute only to surface terms of the entropy. Finally, we discuss the experimental relevance of our results by computing the structure factor whose scaling properties, interestingly, depend on the correlation prefactors.

12:15PM Q27.00006 Electronic and magnetic properties of the chain compounds K₃T₂O₄ (T=Ni, Pd, Pt) . KLAUS KOEPERNIK, IFW, Dresden, DEEPA KASINATHAN, WALTER SCHNELLE, HELGES ROSNER, MPI CPS, Dresden — Recent susceptibility measurements on the chain compound K₃Pd₂O₄ were interpreted in terms of localized spin 1/2 Pd moments on one of the two crystallographically different Pd sites, only [R. V. Pasin et al., J. Solid St. Chem. 180, 1566 (2007)]. The main exchange interaction was reported to be antiferromagnetic from the negative Curie-Weiss temperature \( \theta = -80K \). Earlier measurements for the isostructural and isovalent Ni and Pt compounds suggest an antiferromagnetic coupling for T=Ni as well as ferromagnetic for T=Pt. [H. Zentgraf et al., Z. Anorg. allg. Chem., 462, 92 (1980)] Here, we report an electronic structure study focusing on the interplay of covalency, spin-orbit coupling and correlation to describe the behavior of this compound family. The inclusion of strong Coulomb repulsion at the transition-metal sites is necessary to obtain the correct insulating ground state observed in recent measurements for the Pd system. The origin of the different magnetic behavior will be discussed.

12:27PM Q27.00007 ABSTRACT WITHDRAWN –

12:39PM Q27.00008 muSR study on quasi-one-dimensional cobalt/rhodium oxides . PETER RUSSO, TRIUMF, JUN SUGIYAMA, H. NOZAKI, Y. IKEO, K. MUKAI, Toyota CRDL, T. TAKAMI, University of Texas at Austin, H. IKUTA, DANIEL ANDREICA, ALEX AMATO, LMU-PSI — Thanks to the unique power of muon spin spectroscopy, we found that the quasi-one-dimensional Co-Rh oxides \( A_{n+2}CoRh_{n}O_{3n+3} \) \((A = Ca, Sr; n=1, 2, 3)\) exhibit a two-dimensional antiferromagnetic transition that ranges from approximately 185 K for \( n=1 \) to 125 K for \( n=3 \) with a transition width \( (\Delta T) \) of about 80 K. The variation of \( T_{N}^{c} \) with \( n \) is explained by the increase in the distance between the neighboring CoRh \( O_{3n+3} \) chains. Static magnetic order is observed below the endpoint of \( N = (T_{N}^{c} - \Delta T) \) for each of the three compounds. The existence of the two-frequency components in the ZF-spectrum indicates the appearance of ferrimagnetic order for \( A_{3}CoRhO_{6} \) below 20 K.
1:03PM Q27.00010 $^{51}$V NMR Study of a quasi-1D XXZ spin chain system BaCo$_2$V$_3$O$_8$, K.-Y. CHOI, NHMFL, FSU, Tallahassee, FL32306-4390, USA, N.S. DALAL, REYES COLLABORATION, P.L. KUHNS COLLABORATION, H.D. ZHOU COLLABORATION, C.R. WIEBE COLLABORATION — We present $^{51}$V NMR measurements on the quasi-one-dimensional $S=1/2$ XXZ antiferromagnet BaCo$_2$V$_3$O$_8$ along the chain. The $^{51}$V NMR spectrum shows that the quantum phase transition takes place from the Néel ordered phase to the incommensurately ordered phase around $T_C = 4$ T. In addition, we studied a spin-lattice relaxation rate, $1/T_1$, as a function of temperature and field. Our results are compared to a theoretical prediction and are discussed in terms of a softening of spinons in an external field.

1:15PM Q27.00011 Spin Supersolid in Anisotropic Spin-One Heisenberg Chain, PINAKI SENGUPTA, CRISTIAN BATISTA, LANL — We consider an $S = 1$ Heisenberg chain with strong exchange ($\Delta = J_s/J_1$) and single-ion uniaxial anisotropy ($D$) in a magnetic field ($B$) along the symmetry axis. The low energy spectrum is described by an effective $S = 1/2$ XXZ model that acts on two different low energy sectors for a finite range of fields. The vacuum of each sector exhibits Ising-like antiferro magnetic ordering coexisting with the finite spin stiffness obtained from the exact solution of the XXZ model. In this way, we demonstrate the existence of a spin supersolid phase. We also compute the full $\Delta - B$ quantum phase diagram using a quantum Monte Carlo (QMC) method.

1:27PM Q27.00012 Interacting vs. free quasi-particle description for the spin-1/2 chain, SEBASTIAN EGGER, MICHAEL BORTZ, University Kaiserslautern, MICHAEL KARBACH, University Wuppertal, IMKE SCHNEIDER, University Kaiserslautern — We consider the individual excitations of the antiferromagnetic spin-1/2 chain in the Luttinger Liquid formalism. The inclusion of Umklapp scattering and other irrelevant operators introduces an interaction between quasi-particles, which lifts the degeneracy in the linearized spectrum. So far this effect has been systematically understood only for the lowest excited state in each sector. We now show for a number of low lying excitations how rotations in the degenerate subspaces diagonalize the Umklapp term perturbatively. Our results are verified by taking advantage of the Bethe solution of the spin chain to perform an exact finite size scaling analysis for individual excited levels. From this we can identify the correspondence of quantum numbers between the bosonic and Bethe states. We also make contact to the well known quantum numbers at the non-interacting free fermion point.

1:39PM Q27.00013 Magnetic Susceptibilities of Finite Ising Chains in the Presence of Defect Sites, SERGEI GOUPALOV, University of Utah & Ioffe Institute, DANIEL MATTIS, University of Utah — Any antiferromagnet with zero net magnetic moment exhibits limited response to an external homogeneous magnetic field. This changes dramatically in the presence of defect sites, even those that carry no spin. We examine the excess susceptibilities, longitudinal and transverse, due to one or more defects at arbitrary separations in a finite Ising chain with nearest-neighbor couplings. Adapting matrix methods to finite chains we derive exact formulas valid at all $T \geq 0$.

1:51PM Q27.00014 Excitation spectrum and magnetic properties of the new Haldane-gap material NENB, SERGEI ZVYAGIN, Dresden High Magnetic Field Laboratory (HLD)/Research Center Dresden - Rossendorf (FZD), E. ČIŽMÁR, M. OZEROV, O. IGNATCHIK, T. PAPAGEORGIOU, J. WOSNITZA, NHMFL/Florida State University, Z. ZHOU, Wayne State University, J.L. WIKAIRA, University of Canterbury, C.P. LANDEE, M.M. THURNBULL, Clark University — Results of high-field ESR and magnetization studies of the new spin-1 Haldane-chain material $[Ni(C_{12}H_{12}N_2)_2NO_3(BF_4)]$ (NENB) are reported. A definite signature of the Haldane state in NENB was obtained. From the analysis of the frequency-field dependence of magnetic excitations in NENB, the spin-Hamiltonian parameters were calculated, yielding $\Delta/k_B = 17.4$ K, $\delta || = 2.14$, $D/k_B = 7.5$ K, and $E/k_B = 0.7$ K for the Haldane gap, $\delta$ factor and the crystal-field anisotropy constants, respectively. The presence of fractional $S = 1/2$ chain-end states, revealed by ESR and magnetization measurements, is found to be responsible for spin-glass freezing effects. In addition, extra states in the excitation spectrum of NENB have been observed in the vicinity of the Haldane gap, which origin is discussed.

2:03PM Q27.00015 Direct comparison of hole doping effects due to cation and to oxygen content on magnetic properties of the spin-chain system $Ca_{3+y}Y_{2-}^{+}Cu_{O_{10-}^{−}y}$, KEESEONG PARK, THEODORE CACKOWSKI, JOHN MARKERT, Department of Physics, The University of Texas at Austin — A quasi-one dimensional system, $Ca_{3+y}Y_{2-}^{+}Cu_{O_{10-}^{−}y}$ (CaY-CuO) is studied to compare the magnetic effects of cation doping with those of oxygen deficiency. Hole doping ($p$) due to cation concentration ($x$) and oxygen deficiency ($\delta$) in other copper oxides is often observed to obey $p = x - 2\delta$. CaYCuO has a simple edge shared CuO$_2$ structure and is hole dopable up to a formal copper valence of 2.4. Various Ca doped CaYCuO specimens were fabricated in different oxygen environments, including high pressure oxygen up to 170 atm. X-ray diffraction and iodometric titration were used to confirm phase and oxygen content. Samples are found to be more oxygen deficient with increasing cation doping. Magnetic moment and specific heat were measured. The antiferromagnetic phase was observed up to $x = 1.0$ doping for fully oxygenated specimens. Néel temperatures decreased with increasing cation doping and decreasing oxygen deficiency. The decrease in Néel temperature is found to be more than expected from hole doping $p = x - 2\delta$. A new quantity that describes all of the behavior of Néel temperature, $x = (2/3)\delta$, is proposed.

2:15PM Q28.00001 Thermoelectric Transport Coefficients in Correlated Condensed Matter, SRIRAM SHASTRY, University of California Santa Cruz — We present a recently developed formalism for computing thermoelectric transport coefficients for standard models of correlated matter, such as the Hubbard and the $t-J$ model. Successful predictions of this method in the context of the Hall constant are noted. This success helps to motivate the extension to the Seebeck coefficient, the Lorenz number $L$, and the figure of merit $ZT$. In terms of novel equal time correlation functions of two new fundamental operators, the thermal operator $\Phi^{xx}$ and the thermoelectric operator $\Phi^{xz}$. Along the way, we uncover a new sum rule for the dynamical thermal conductivity for many standard models, precisely analogous to the f-sum rule for the electrical conductivity. Also along the way, we throw light on Lord Kelvin's early ideas on reciprocity, worked out within the context of equilibrium thermodynamics. The precise connection between Kelvin's formulation, and the later and more rigorous formulation of Onsager is commented upon. The new formalism is tested in simple settings and recent computational results are displayed for testing the frequency dependence of these variables in certain standard models. Close agreement with existing transport experiments on sodium cobaltates Na$_{0.68}$CoO$_2$ in the Curie Weiss phase is found. Finally some new predictions are made regarding triangular lattice systems, motivated by the sodium cobaltate system.

11:15AM Q28.00001 Thermoelectric Transport Coefficients in Correlated Condensed Matter

1Supported in part by grants NSF-DMR-0706128, and DOE-BES DE-FG02-06ER46319
11:51 AM Q28.00002 Enhancing figure-of-merit of n-type Bi$_2$Te$_3$-$x$Sb$_x$. XIAO YAN, JIAN YANG, YI MA, BED POUEL, YUCHENG LAN, DEZHI WANG, ZHIFENG REN, QING HAO, GENG CHEN, MIT COLLABORATION — Thermoelectric materials with high dimensionless figure-of-merit (ZT) are greatly demanded in energy industry, among which bismuth telluride (Bi$_2$Te$_3$) exhibits decent ZT around room temperature. However, thermal conductivity of Bi$_2$Te$_3$ is still high which limits its wider use for low temperature cooling devices. Here we investigate nanostructured bulk n-type Bi$_2$Te$_3$-$x$Sb$_x$ by reducing the thermal conductivity via increased phonon scattering of the significantly increased grain boundaries due to nano size grains. We first made alloy nanocrystals by mechanical alloying a mixture of elements with the right ratio and then 100% nanostructured samples by hot press.

12:03PM Q28.00003 High pressure transport studies on Sb$_2$Te$_3$ and BiSbTe$_2$. MATTHEW JACOBSEN, ANDREW CORNELIUS, University of Nevada, Las Vegas — Interest regarding the abilities of thermoelectric materials has produced exciting results regarding their properties in the thin-film form [3]. However, little work has been done regarding the pressure tuning of the thermoelectric figure of merit for these materials. Some previous work has suggested that it would be useful to investigate this further using pressure tuning [1,2]. Based upon this interest, facilities have been developed in our laboratory for the study of the relevant properties under high pressure up to near 20 GPa. Results of this work on Sb$_2$Te$_3$ and BiSbTe$_2$ will be presented here from the use of these facilities. [1]Gény, G., Dresselhaus, M.S., Dresselhaus, G., Fleurial, J.-P., and Caillat, T. Recent developments in thermoelectric materials. International Materials Reviews, 48, 45-66 (2003). [2]Rowe, D.M. CRC Handbook of Thermoelectric Materials. CRC Press, 1995. [3]Venkataramanan, R., Silvola, E., Colpitts, T., and O’Quinn, B. Thin film thermoelectric devices with high room-temperature figures of merit. Nature, 413, 597-602, 2001.

12:06PM Q28.00004 Inelastic scattering on antimony bearing thermoelectric materials: rattlers revisited. R. P. HERMANN1, W. SCHWEIKA, Institut fuer Festkoerperforschung - Forschungszentrum Juelich, Germany, H.-C. WILLE2, ESRF, Grenoble, France — Antimony element specific measurements on EuFe$_2$Sb$_12$ and Zn$_2$Sb$_3$ will be presented in parallel with inelastic neutron scattering measurements on Zn$_2$Sb$_3$. These results yield new insight in the rattler concept. First, the antimony specific DOS in EuFe$_2$Sb$_12$ and Co$_2$Sb$_3$ provides experimental insight into the guest-host interaction mechanism which is required for a lowering of the thermal conductivity[1]. Second, the scattering vector dependence of the Zn$_2$Sb$_3$ inelastic response reveals that “rattling” behavior is not restricted to single atoms and that more complex structural units, such as dumbbells, can exhibit a similar behavior that is responsible for a low thermal conductivity.[2] The European Synchrotron Radiation Facility is acknowledged for provision of the synchrotron radiation facility at beamlines ID18 and ID22N and the European Community - ARI HPR-2001-00175 is acknowledged for provision of neutron scattering beam time at the FR-J-II research reactor in Juelich, Germany. [1] Schwei W. et al. Phys. Rev. Lett. 99, 125501 (2007). [2] Wille H.-C. et al. Phys. Rev. B 76, 140301(R) (2007).

12:27PM Q28.00005 ABSTRACT WITHDRAWN –

12:39PM Q28.00006 Lattice thermal conductivity of AgSbTe$_2$. DONALD MORELLI, Michigan State University, VLADIMIR JOVOVIC, SURAJ THIAGARAJAN, JOSEPH HEREMANS, The Ohio State University — The lattice thermal conductivity of high-quality crystals of AgSbTe$_2$ is nearly temperature-independent from 80 to 300 K, and has a value of 0.65±0.05 W/mK. This value corresponds to the minimum possible thermal conductivity, where the phonon mean free path equals the interatomic distance. The result is analyzed in terms of scattering mechanisms: Umklapp and Normal phonon-phonon scattering processes are the dominant mechanism. It is, to our knowledge, the first system in which intrinsic phonon-phonon interactions limit the lattice thermal conductivity to such a low value. This in turn results from the extreme anharmonicity of the chemical bonding in AgSbTe$_2$, which gives rise to one of the highest Gruneisen parameter of any solid. The phonon-phonon scattering rate being a function of the square of the latter, the lattice thermal conductivity is also one of the lowest.

12:51PM Q28.00007 Galvanomagnetic and thermomagnetic properties of AgSbTe$_2$. VLADIMIR JOVOVIC, JOSEPH HEREMANS, The Ohio State University — We report here data on the electrical resistivity, magnetoresistance, Hall effect, thermoelectric power, magneto-Seebeck and transverse Nernst-Ettingshausen coefficients of high-quality crystals of AgSbTe$_2$, measured from 77 to 400 K in magnetic fields up to 2 Tesla. Thermal conductivity data are also reported in samples with a much higher carrier concentration than those used in our other work. From an analysis of these data, we conclude AgSbTe$_2$ to be a very narrow-gap semiconductor (Eg≈ 7.6±3 meV) with ~5x10$^{19}$ cm$^{-3}$ holes in a valence band with a high density of states and thermally excited ~10$^{17}$ cm$^{-3}$ high-mobility (2.200 cm$^2$/Vs) electrons at 300 K. The estimated hole density-of-states effective masses, including Fermi pocket degeneracy, is 2.5±0.5 free electron masses; the electron mass is about two orders of magnitude smaller, but the exact value cannot be resolved. The lattice term dominates the thermal conductivity, and the electronic contribution in samples with both electrons and holes present is in turn dominated the ambipolar term. The low thermal conductivity and very large hole mass of AgSbTe$_2$ make it a most promising p-type thermoelectric material.

12:51PM Q28.00008 De Haas - van Alphen quantum oscillations in AgSbTe$_2$. JOSEPH HEREMANS, VLADIMIR JOVOVIC, The Ohio State University — Quantum oscillations are observed in the magnetic susceptibility of p-type single crystals of AgSbTe$_2$, at 5 K in magnetic fields up to 5 Tesla (the De Haas - van Alphen effect). The period of the oscillations is analyzed in terms of the cross-section of the hole Fermi surface. Recent band structure calculations illustrate the dependence of the hole Fermi surface structure on the ordering of the Ag and the Sb atoms on the metal sublattice, and provide guidance for the interpretation of the periods of the oscillations. Galvanomagnetic studies of the same sample provide a hole density of 5x10$^{19}$ cm$^{-3}$, so that an image for the valence band Fermi surface can be Reconstructed at that carrier density level. The measured Fermi surface cross-sections, together with the transport properties, give an overall picture that is consistent with the calculation valid for AgSbTe$_2$, with Ag and Sb ordered on the metal sublattice. [1] Khang Hoang, S. D. Mahanti, James R. Salvador, and Mercouri G. Kanatzidis, Atomic Ordering and Gap Formation in AgSb-Based Ternary Chalcogenides, Phys. Rev. Lett. 2007, accepted [2] V. Jovovic and J. P. Heremans, Galvanomagnetic and Thermomagnetic properties of AgSbTe$_2$, abstract here.

1:15PM Q28.00009 Precipitation anneals in the PbTe-PbS system\textsuperscript{1}. CHRISTOPHER JAWORSKI, VLADIMIR JOVOVIC, JOSEPH HEREMANS, The Ohio State University — Bulk samples of (PbS)\textsubscript{x}(PbTe)\textsubscript{1-x} have been prepared in the range 4\% < \< 15\%. There is a miscibility gap in the pseudo-binary PbTe/PbS phase diagram that enables the precipitation of a PbS-rich phase in a PbTe-rich matrix. To that effect, the samples were compounded in the liquidus, and then quenched, resulting in a supersaturated solution. Conditions for precipitation anneals were then developed, and samples with nano-precipitates of a PbS-rich phase in a PbTe-rich parent phase have been obtained, as evidenced by X-ray diffractions. This technique, previously applied to Pb-rich PbTe\textsuperscript{1}, is aimed at creating a bulk material containing a substantial fraction of nanometer-sized particles in order to mimic the morphology of quantum-dot superlattices that reached very high values of the thermoelectric figure of merit. Preliminary thermoelectric and thermal conductivity data will be presented, along with galvanomagnetic and thermomagnetic data aimed at identifying the electronic properties of the materials. [1] J. P. Heremans, C. M. Thrush and D. T. Morelli, Thermopower enhancement in PbTe with Pb precipitates, J. Appl. Phys. 98 063703 (2005) [2] T. C. Harman, M. P. Walsh, B. E. LaForge, and G. W. Turner, J. Electron. Mater. 34, L19 (2005).

\textsuperscript{1}This work is supported by BSST-Amerigon.

1:27PM Q28.00010 High-Resolution \textsuperscript{125}Te NMR of Novel Thermoelectric Materials, E.M. LEVIN, K. SCHMIDT-ROHR, B.A. COOK, Ames Laboratory DOE and Iowa State University, MI-KYUNG HAN, M.G. KANATZIDIS, Northwestern University — Several novel Te-based thermoelectric materials with extraordinary figure of merit ZT > 1.4 have been studied by high-resolution 25 kHz magic angle spinning \textsuperscript{125}Te nuclear magnetic resonance (NMR) in order to investigate variations in composition on the nano-scale. A 20-fold wider \textsuperscript{125}Te NMR signal of both AgSbGe\textsubscript{2}Te\textsubscript{5} and AgSbGe\textsubscript{5}Te\textsubscript{7} (\textgreek{g}= -90 kHz) compared to that of PbTe (4.5 kHz) indicates a variation of shifts due to local composition fluctuations. The similar total shift of the main peak in Ag\textsubscript{0.53}Pb\textsubscript{1.5}Sb\textsubscript{1.2}Te\textsubscript{20} (-1790 ppm) and PbTe (-1750 ppm) and similarly long T\textsubscript{2} relaxation time show that the majority of Te atoms in both materials has a similar environment. A second peak in Ag\textsubscript{0.53}Pb\textsubscript{1.5}Sb\textsubscript{1.2}Te\textsubscript{20} at -1600 ppm shows the presence of a second type of Te site, accounting for \textgreek{g}/3 of all Te. These are apparently located in (Ag, Sb)-rich inclusions, as indicated by a much shorter T\textsubscript{2}, which can be due to the effect of quadrupolar relaxation of \textsuperscript{125}Sb or \textsuperscript{125}Te (spin 5/2 or 7/2, respectively) on \textsuperscript{125}Te. Our data confirm suggestions made by Hsu et al., Science (2004) and by Chen et al., Appl. Phys. Lett. (2005) about the presence of nano-scale inclusions in Ag\textsubscript{0.53}Pb\textsubscript{1.5}Sb\textsubscript{1.2}Te\textsubscript{20}, which result in low lattice thermal conductivity and high ZT.

1:39PM Q28.00011 Substitution effects on the thermoelectric properties of Sr\textsubscript{3}IrO\textsubscript{4}, YANNICK KLEIN, ICHIRO TERASAKI, Waseda University, Tokyo — Layered cobalt oxides with the low-spin (LS) state, such as Na\textsubscript{2}CoO\textsubscript{2} and Ca\textsubscript{2}CoO\textsubscript{4}, have shown a good potential as p-type materials for thermoelectric applications [1, 2]. Layered rhodium oxides are also characterized by a high Seebeck coefficient and a low metallic resistivity [3, 4]. The LS configuration of the transition metal is considered to be at the origin of this unusual property. We have investigated the thermoelectric properties of Sr\textsubscript{3}IrO\textsubscript{4}, which is isostructural to the superconductors La\textsubscript{2}CuO\textsubscript{4} and Sr\textsubscript{2}RuO\textsubscript{4}. Contrary to the later ones, Sr\textsubscript{3}IrO\textsubscript{4} is a semiconductor with a narrow gap and a weak ferromagnetic ground state (T\textsubscript{c} \approx 240K, M\textsubscript{S} \approx 0.14\textmu B/\textmu m) [5]. For polycrystalline samples, the resistivity is of the order of 10\textsuperscript{11} cm and the thermoelectric power shows a broad maximum around 110K (S \approx 300\textmu V/K\textsuperscript{-1}) denoting the activation of minority carriers. In order to increase the carrier concentration, we tried many substitutions for Sr and Ir. Results of resistivity, thermoelectric power and susceptibility will be discussed.

1:51PM Q28.00012 Temperature - Concentration Phase Diagram from First Principles Calculations in P\textsubscript{2}-Na\textsubscript{2}CoO\textsubscript{4}\textsuperscript{1}. YING S. MENG, University of Florida, YOYO HINUMA, GERBRAND CEDER, Massachusetts Institute of Technology — The unusual electronic and magnetic properties of Na\textsubscript{2}CoO\textsubscript{4} are attracting considerable interest in recent years. At high sodium content, the system displays unusually strong thermoelectric effect and a low metallic effect. In this paper, we present temperature - concentration phase diagram for Na\textsubscript{2}CoO\textsubscript{4} (0 < x < \approx 0.5) obtained with first principles method of the Density Functional Theory (DFT) in the Generalized Gradient Approximation (GGA) scheme, where charge on Co is delocalized. In comparison we will also present the results obtained from the GGA with Hubbard U correction (GGA+U) scheme, where charge on Co is localized.

2:03PM Q28.00013 ABSTRACT WITHDRAWN —

11:15AM Q29.00001 Quantized transport in graphene p-n junctions, CHARLES MARCUS, Harvard University — No abstract available.

11:51AM Q29.00002 Local-Gating of Graphene Nanostructures, JAMES WILLIAMS, CHARLES MARCUS, Harvard University — We report on the fabrication and measurement of locally-gated single-layer graphene devices. Utilizing a non-covalent functionalization layer, the preservation of the unique electrical properties of graphene after deposition of the top-gate oxide is demonstrated. Novel top-gate geometries, including circular and multiple-rectangular gate designs, combined with oxygen-plasma etching allow for further elucidation of the unique transport properties of graphene p-n junctions and graphene constrictions. Research supported in part by INDEX, an NRI Center, and by the Harvard NSEC.
12:03PM Q29.00003 Scanning tunneling microscopy and spectroscopy of graphene.1, GUOHONG LI, ADINA LUCIAN, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — We report low temperature high magnetic field scanning tunneling microscopy and spectroscopy on a graphene sheet suspended above a graphite substrate by extended defects. The measurements provide the first observation of the V-shaped density of states in zero field and of the Landau level (LL) spectrum in finite fields. The LL spectrum consists of a single sequence exhibiting square root dependence on field and level-index, and contains a zero energy LL attributing to the chiral nature of the Dirac Fermi quasiparticles. The density of states reflects important effects due to electron-phonon interactions and to confinement. These include a reduced Fermi velocity, a small (10 meV) gap at the Dirac point, splitting of the n=0 LL at relatively low fields and a new negative energy state that emerges from the Fermi level and splits away linearly with increasing field.

12:15PM Q29.00004 Electronic properties of one-dimensional graphene bilayer ribbons1, BHA-GAWAN SAHU, Microelectronics Research Center, University of Austin, Austin TX 78758, HONGKI MIN, ALLAN MACDONALD, Department of Physics, University of Texas, Austin TX 78712, SANJAY BANERJEE, Microelectronics Research Center, University of Texas at Austin, Austin, TX 78758 — The electronic properties of armchair and zigzag bilayer graphene nanoribbons are studied using ab-initio density functional theory. We study the effect of width and the electric fields (up to the dielectric breakdown field of SiO2) on their energy gaps [Sahu 2007]. We find metallic and semiconductor arm-chair ribbons and electric field has the effect of increasing the gap in metallic ribbons. The zigzag ribbons due to the edge magnetism show opposite behavior: gap decreases with increase in the applied electric field. We studied small ribbons (below 1 nm) as well as large ribbons (5 nm). In small width arm-chair semiconductor ribbons, the gap decreases whereas in large width ribbons, the gap increases with applied electric field. Sahu B, Min H, MacDonald AH, and Banerjee SK “Electronic properties of one-dimensional graphene bilayer ribbons” (Submitted to Physical Review B).

12:27PM Q29.00005 Strong Coulomb interactions and weak disorder in graphene , MATTHEW FOSTER, IGOR ALEINER, Columbia University — We analyze the instabilities and compute the transport properties of the low-temperature conducting phase of graphene, using a renormalization group (RG) approach that incorporates both Coulomb electron-electron interaction and weak quenched disorder effects. Strong Coulomb interactions are treated within the large-N expansion. Using a perturbative renormalization group (RG) approach to study the effects of virtual processes, we find that at successively lower energy scales, for moderate to strong Coulomb interaction strengths, a type of non-Abelian vector potential disorder always asserts itself as the dominant elastic scattering mechanism for generic short-ranged microscopic defect distributions. Vector potential disorder appears in graphene due to, e.g., elastic lattice deformations (“ripples”). We combine the RG results with a quantum kinetic equation analysis of real processes, i.e. inelastic electron-electron scattering, which allows us to compute the temperature- and chemical potential-dependence of electronic and thermal transport coefficients due to elastic and inelastic scattering processes in various coupling regimes.

12:39PM Q29.00006 Electric Field Effect in Epitaxial Graphene Devices, XUEBIN LI, XIAOSONG WU, MICHAEL SPRINKLE, FAN MING, CLAIRE BERGER, RAGHUNATH MURALI, FARHANA ZAMAN, JAMES MEINDL, WALTER DE HEER, Georgia Institute of Technology — The electric field effect has been observed on epitaxial graphene multilayers grown on SiC substrates by thermal decomposition of SiC. Carriers mobilities up to 2.5×10^6cm^2/Vs have been measured. Both side-gated and top-gated graphene field effect transistors (FETs) have been fabricated using standard semiconductor processes on both the Si and the C face of the SiC substrates. In side-gated FETs, the gates are located on both sides of narrow graphene ribbons; source-drain resistance is measured by a gate bias of several volts. For top-gated FETs the resistance swing reaches a factor of 25. At the gate voltage corresponding to the maximum source-drain resistance, the Hall voltage changes sign indicating a transition from hole- to electron-carried transport, consistent with the graphene band structure. These results indicate the potential of epitaxial graphene as a platform for large-scale graphene based electronics.

12:51PM Q29.00007 Free-Standing 2-D Graphene Carbon Nanostructures, BRIAN HOLLOWAY, RONALD QUINLAN, Luna Innovations Incorporated, KUN HOU, College of William and Mary — Carbon nanosheets – a new, free-standing, two-dimensional carbon nanostructure – have been deposited on a metal, semiconductor, and insulating substrates by RF PECVD. Raman, SEM, TEM, SAED, XPS, AES, FTIR, and XRD all indicate that nanosheets are graphite sheets up to 8 µm in height and ≤1 nm in edge thickness. The nanosheets stand off the growth substrate in a manner similar to aligned nanotubes grown by CVD. In contrast to nanotubes, nanosheets do not require catalyst for growth and can be patterned after deposition using standard lithographic techniques. Hydrogen etching promotes the formation of the atomically thin structures while the anisotropic dipole created in the graphene planes by the plasma sheath promotes the vertical orientation. Due to their uniform height and the large number of edge emission sites, nanosheets have proven to be excellent field emitters. Nanosheet samples have produced up to 33 mA of current (32 mm^2 sample area); similar nanosheet samples have sustained 1.3 mA of current over 200 hours of testing with no degradation.

1:03PM Q29.00008 Superconducting Proximity Effect in Graphite Films, MASAHIKO HAYASHI, Akita University, HIDEO YOSHIOKA, Nara Women’s University, AKINOBU KANDA, University of Tsukuba — Theoretical analysis of superconducting current in graphite films (or graphen)in proximity to superconductors is presented. In this work, the band structure of the graphite film is treated seriously: because of the delicate band structure of graphite, the actual band structure of the film, which undergoes the effects of various external factors such as leads and gates, can show a wide variety. We introduce following three models: 1) graphen-like Fermi points, 2) semi-metal, 3) electron (or hole) pockets, and 4) semiconducting gap. The superconducting critical current Lc = \exp[-L/\xi(T)] is studied where L is the distance between two leads and \xi(T) is the coherence length in the graphite film. The temperature dependence of \xi(T) is largely affected by the band structure and by examining this dependence the electronic properties of the graphite film can be estimated. The results are compared with actual experiments.

1:15PM Q29.00009 Superconducting proximity effect in thin graphite films , A. KANDA, T. SATO, S. TANAKA, H. GOTO, Y. OOTUKA, Inst. Phys. and TIMS, Univ. Tsukuba and JST-CREST, K. TSUKAGOSHI, RIKEN, AIST, and JST-CREST, H. MIYAZAKI, RIKEN and JST-CREST, S. ODAA, Y. AOYAGI, RIKEN, Tokyo Inst. Tech. and JST-CREST — Gate-controlled superconducting proximity effect in thin graphite films is reported. A graphite film with thickness of 4 - 10 nm is connected to two aluminum superconducting electrodes, forming a SNS junction, and gate electric field is applied using a back gate. The critical supercurrent displays an ambipolar behavior, and for a fixed normal-state resistance the electron critical supercurrent with positive gate voltage is always larger than the hole critical supercurrent with negative gate voltage (electron-hole symmetry breaking). This effect is also observed in the critical temperature where the junction resistance vanishes. Furthermore, the critical supercurrent is proportional to \exp(-(T/Tc)^2), which has never been observed in other SNS systems. The details of the experimental results as well as their possible origins will be discussed.

1:27PM Q29.00010 Supercurrent in Graphene Josephson Transistors, WENZHONG BAO, UC-Riverside, FENG MIAO, GANG LIU, CHUNNING LAU — We investigate electrical transport in single or bi-layer graphene devices coupled to superconducting electrodes. In these two-dimensional Josephson junctions, we observed gate tunable supercurrent, multiple Andreev reflections and hysteretic current-voltage characteristics. Latest experimental progress on dependence of supercurrent on temperature, number of layers and source-drain separation will be discussed.
1:39PM Q29.00011 Conductance behaviors of point-contact graphene junctions with normal metal and superconducting tips\(^1\), W. K. PARK, S. WOLIN, C. CHIALVO, N. MASON, L. H. GREENE, Department of Physics and the Frederick Seitz Mater. Res. Lab., University of Illinois at Urbana-Champaign — The recent discovery of graphene, a truly two-dimensional carbon allotrope, has attracted great interest because of its novel physics and potential for new electronic device applications. Among a variety of theoretical predictions that await stringent experimental tests, reflectionless tunneling (Klein paradox) and specular Andreev reflection are most intriguing. Aiming at eventually probing such unique charge transport phenomena in graphene junctions, we first investigate conductance behaviors of the nanoscale graphene junctions made by point-contact techniques using simple metal (Au) and superconducting (Nb) tips. At low temperatures, the conductance data exhibit an inverse peak structure centered at zero bias, reminiscent of the theoretical density of states arising from the Dirac-like dispersion relation. Junctions with Nb show the additional superconducting gap feature. We will present sets of conductance spectra as a function of temperature, magnetic field, and gate voltage, and discuss possible mechanisms to explain the observed conductance behaviors.

\(^1\)Work supported by the U.S. DoE DEFG02-91ER45439 and by NSF-DMR-0706013 through the FSMLRL and the CMM at UIUC.

1:51PM Q29.00012 Josephson Current and Multiple Andreev Reflections in Graphene SNS Junctions\(^1\), IVAN SKACHKO, XU DU, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — The Josephson Effect and Superconducting Proximity Effect were observed in Superconductor-Graphene-Superconductor (SGS) Josephson junctions with coherence lengths comparable to the distance between the superconducting leads. By comparing the measured temperature and gate dependence of the supercurrent and the proximity induced sub-gap features (multiple Andreev reflections) to theoretical predictions, we find that the diffusive junction model yields close quantitative agreement with the results. This is consistent with the fact that the measured mean free paths in these junctions, 10 ~ 30 nm, are significantly shorter than the lead separation. We show that all SGS devices reported so far fall in the diffusive junction category.

\(^1\)Work supported by DOE DE-FG02-99ER45742, NSF-DMR-0456473 and ICAM.

2:03PM Q29.00013 Electric field effect modulation and hysteresis in thin graphite using ferroelectric gate oxides, X. HONG, K. ZOU, J. ZHU, Department of Physics, Penn State University, A. POSADAS, J. REINER, C. H. AHN, Department of Applied Physics, Yale University — We study the electronic properties of thin graphite field effect transistors (FETs) using ferroelectric gate oxide Pb (Zr,Ti)O\(_3\) (PZT). Thin graphite flakes (3-5nm) are exfoliated onto 300 nm PZT films epitaxially grown on doped SrTiO\(_3\) (STO) and fabricated into FET devices. Carriers are induced into the FETs by applying a voltage \(V_g\) on the STO substrate (backgate). We observe a maximum carrier density \((n)\) of \(\sim 4 \times 10^{13} \text{cm}^{-2}\) and a density modulation of \(\sim 2 \times 10^{12} \text{cm}^{-2}/\sqrt{V_g}\) (\(V_g\)).

11:15AM Q30.00001 Correlations in carbon nanotubes: A DMRG approach, ALEXANDER STRUCK, SEBASTIAN A. REYES, SEBASTIAN EGGERT, Department of Physics, University of Kaiserslautern, D-67663 Kaiserslautern, Germany — Single wall carbon nanotubes (SWCNT) are a paradigm for studying quasi-one-dimensional systems with strong correlations, both experimentally and theoretically. Considering the strong relevance of SWCNT, it is even more surprising that only few numerical calculations of correlation effects have been attempted. In this talk, we use the density-matrix renormalization group (DMRG) technique to treat a recently formulated one-dimensional tight-binding lattice model, which accounts for both the electron motions around the circumference and along the tube axis. We discuss the influence of interactions of variable strength and range on the electronic structure and the electron density and outline possible finite-size and boundary effects.

11:27AM Q30.00002 First-Principles Electronic Structure Calculations of \(\text{N}_2\text{H}_4\) Adsorbed on Single-Wall Carbon Nanotubes\(^1\), M. YU, W.Q. TIAN, C.S. JAYANTHI, S.Y. WU, University of Louisville — Recent experiments conducted by Desai et al.\(^1\) reveal that single-wall carbon nanotube (SWCNT) networks exposed to \(\text{N}_2\text{H}_4\) vapor at various pressures exhibit considerable drop in resistance with respect to the pristine sample. Experimental findings reveal: (i) n-type behavior for the adsorption of \(\text{N}_2\text{H}_4\)/SWCNT, and (ii) the binding of \(\text{N}_2\text{H}_4\) on SWCNT as chemisorption. In the present work, we have performed first-principles electronic structure calculations\(^2\) for the \(\text{N}_2\text{H}_4\) adsorbed on the (14, 0) SWCNT, where several orientations for the \(\text{N}_2\text{H}_4\) molecule were considered. Calculations for the combined system were performed using 3 unit cells with the DFT/GGA and ultra soft pseudo-potentials. Our calculations reveal: (i) the binding of \(\text{N}_2\text{H}_4\) on SWCNT as physisorption, and (ii) the electronic structure of SWCNT to be practically unaffected by the adsorption of \(\text{N}_2\text{H}_4\), suggesting that there will not be a dramatic drop in resistance for \(\text{N}_2\text{H}_4$/ SWCNT. This is in disagreement with the experimental findings. To further understand the experimental observations, we will discuss mechanisms that may alter the binding nature of \(\text{N}_2\text{H}_4\) on SWCNT.\(^1\) S. Desai, G. Sumanasekera, et al. (APS, March 2008).\(^2\) G. Kresse and J. Furthmuller, Phys. Rev. B 54, 11169 (1996).

11:39AM Q30.00003 First-principles calculations of effects of metallic electrode contacts on transport properties of carbon nanotubes, NOBUHIKO KOBAYASHI, Institute of Applied Physics, University of Tsukuba, TAISUKE OZAKI, Research Center for Integrated Science, Japan Advanced Institute of Science and Technology, KENJI HIROSE, Nano-Electronics Research Laboratories, NEC Corporation — Recently, considerable effort has been devoted to developing carbon nanotube devices. One of the important issues in the developments of carbon nanotube devices is the control of contact effects of the electrodes. To detect electric signals through nanotubes, electrodes must be connected to the nanotubes. Contact with the electrodes sensitively influences their electronic structures and transport properties. Therefore, it is important to discuss the transport properties on the basis of the detailed electronic state calculations that include the effect of contact with the electrodes. We have investigated quantum transport in carbon nanotubes bridged between metallic electrodes. The electronic states are calculated using a numerical atomic orbital basis set in the framework of the density functional theory, and the conductance is calculated using the Green’s function method. We have analyzed transport properties of the size of carbon nanotubes bridged between metallic electrodes, and discuss the contact effect of the electrodes on the transport properties. We reveal their dependency on the length and the electrode materials.
11:51AM Q30.00004 Effect of Phase-Breaking Events on Electron Transport in Single-Wall Nanotubes. THUSHARI JAYASEKERA, PAVAN PILLALAMARRI, J.W. MINTMIRE, Department of Physics, Oklahoma State University, Stillwater, OK, VINCENT MEUNIER, Oak Ridge National Laboratory, Oak Ridge, TN — Existing ballistic models for electron transport in single wall nanotube systems will break down as the size of the device becomes longer than the phase coherence length of electrons in the system. V. Krstic, et al. observed experimentally that the current in a SWNT system can be modified by a combination of a coherent and a non-coherent part. We analyze this problem in detail following Buttiker’s dephasing model. We investigate the effect of phase-breaking events on the electron transport in two-terminal single wall carbon nanotube systems, and discuss about more possible applications.

1The work carried out at Oklahoma State University is supported by the Department of Energy (DE-FG02-07ER46362) and the work at ORNL is supported by the Division of Materials Sciences and Engineering U.S. Department of Energy (DEAC05-00OR2272).

12:03PM Q30.00005 Local Gating in Carbon Nanotubes. JOSEPH SULPIZIO, Department of Physics, Stanford University, CHARIS QUAY, Stanford University, DAVID GOLDBADER-GORDON, Department of Physics, Stanford University — Single Wall Carbon Nanotubes (SWNTs) exhibit a host of remarkable physical properties. Their unique electronic structure suggests that SWNTs are ideal for studying the rich physics of one-dimensional (1D) quantum systems. Local gating enables the creation of tunable structures where such phenomena can be experimentally studied. We have fabricated locally-gated SWNT devices and have performed low-temperature electronic transport measurements. We present our recent data and discuss the results in the context of 1D mesoscopic systems.

12:15PM Q30.00006 Distinguishing the mechanisms of transistor-like switching in single-walled carbon nanotubes (SWCNTs). STEVEN HUNT, BRETT GOLDSMITH, PHILIP G. COLLINS — One of four mechanisms usually dominates the conductance switching of SWCNTs in field effect transistor geometries. In semiconducting SWCNTs, both the bandstructure and the Schottky barriers present at the SWCNT-electrode interface are sensitive to local electric fields. Disorder, too, leads to field sensitivity through SWCNT-SWCNT junctions and SWCNT defect sites. These four mechanisms can be distinguished by scanning gate microscopy, in which the local gating characteristics of interfaces, defects, and pristine sidewall can each be independently measured. We will demonstrate this separation and, in particular, focus on the gate sensitivity of sidewall defects produced by point functionalization. Scanning gate microscopy of SWCNTs before and after chemical attack allows us to visualize the electronic contributions of localized disorder and rank its contribution to three-terminal device characteristics.

12:27PM Q30.00007 Probing Vapor Phase Analytes with Single Walled Carbon Nanotube Biopolymer Hybrid Devices. SAMUEL KHAMIS, University of Pennsylvania Dept. of Physics and Astronomy, MICHELLE CHEN, University of Pennsylvania Dept of Materials Science and Engineering, A.T. CHARLIE JOHNSON, University of Pennsylvania Dept. of Physics and Astronomy — Single-Walled Carbon Nanotubes (SWCNTs) have attracted enormous interest due to their excellent electronic properties. The integration of SWCNTs into technologically relevant architectures is limited by the processing techniques available to address numerous integration challenges such as selective placement, doping and separation by electronic type. This talk will focus on using chemical methods to address the separation challenge by selectively functionalizing the metallic SWCNTs to fabricate field-effect transistors consisting of multiple SWCNTs. The process begins with a large-scale, low-loss purification of SWCNTs using a density step-gradient to allow for characterization of SWCNTs in large quantities. Once the material is purified, functionalized diazonium salts are used to selectively react with the metallic SWCNTs. Multiple SWCNT devices are then prepared and result in dramatically improved switching behavior. Methods to exploit the selective functionalization as a means of physically separating the material will also be discussed.

12:39PM Q30.00008 Selective Chemical Functionalization for the Fabrication of Single-Walled Carbon Nanotube Devices. GEORGE TULEVSKI, ALI AFZALI, PHAEDON AVOURIS, JAMES HANNON, IBM T.J. Watson Research Center — Single-Walled Carbon Nanotubes (SWCNTs) have attracted enormous interest due to their excellent electronic properties. The integration of SWCNTs into technologically relevant architectures is limited by the processing techniques available to address numerous integration challenges such as selective placement, doping and separation by electronic type. This talk will focus on using chemical methods to address the separation challenge by selectively functionalizing the metallic SWCNTs to fabricate field-effect transistors consisting of multiple SWCNTs. The process begins with a large-scale, low-loss purification of SWCNTs using a density step-gradient to allow for characterization of SWCNTs in large quantities. Once the material is purified, functionalized diazonium salts are used to selectively react with the metallic SWCNTs. Multiple SWCNT devices are then prepared and result in dramatically improved switching behavior. Methods to exploit the selective functionalization as a means of physically separating the material will also be discussed.

12:51PM Q30.00009 Electric Field Modulation of Thermoelectric Transport in Carbon Nanotubes and Graphene in the Quantum Transport Limit. YURI M. ZUEV, Applied Physics Department, Columbia University, PHILIP KIM, Physics Department, Columbia University — Mesoscopic thermoelectric power (TEP) measurements of nanometer scaled graphitic systems such as single walled carbon nanotubes (SWNTs) and graphene are reported. Highly transparent electrical contact was made to SWNTs using Pd electrodes. TEP was measured in-situ using a microfabricated heater and thermometers. Electrical conduction and TEP were observed at low temperature where both quantities were modulated by the gate voltage. At low temperatures, coherent quantum electric transport was observed as the conductance displayed oscillatory Fabry-Perot type interference. Simultaneously measured TEP provided corresponding oscillatory features. Deviations of the low temperature TEP gate dependence from the semiclassical Mott relation allows us to gain insight into the quantum transport regime in this one dimensional conductor. We compare these results with Butler’s dephasing model. We investigate the effect of phase-breaking events on the electron transport in two-terminal single wall carbon nanotube systems, and discuss about more possible applications.

1Work Supported by JSTO of the DTRA and the Army Research Office (W911NF-06-1-0462)

1:03PM Q30.00010 Thermal Conductivity of Single-Wall and Multi-Wall Carbon Nanotubes. NIHAR PRADHAN, Physics Department, WPI, MA, USA, HUANAN DUAN, JIANYU LIANG, Mechanical Engineering Department, WPI, MA, USA, GERMANO IANNACCHIONE, Physics Department, WPI, MA, USA — One-dimensional materials, such as nanotubes, and their composites attract interest due to their potential use in applications as well as model systems for understanding low-dimensional physics. There is a need for detailed measurements of the specific heat \(c_p\) and thermal conductivity \(\kappa\) in order to guide theoretical efforts. This talk presents \(c_p\) and \(\kappa\) using an ac-calorimetric technique for single-wall (SW) and multi-wall (MW) carbon nanotubes (CNT) in a composite sample-cell arrangement. From 300 to 400 K, \(c_p\) exhibits a linear behavior for both nanotubes. However, \(\kappa\) for MWNT and SWCNT with the heat flow perpendicular to the nanotube long-axis is bulk-like in behavior until \(\approx 370\) K, thereafter decreasing with increasing temperature, indicating the onset of phonon-phonon scattering. For samples where the heat flow is parallel to the nanotube long-axis, \(\kappa\) for the MWNT sample is consistent with ballistic phonon transport.
1:15PM Q30.00011 Efficient excitation energy transfer in single-walled carbon nanotube/porphyrin complexes, JOHN P. CASEY, SERGEI M. BACHILO, R. BRUCE WEISMAN, Department of Chemistry, Rice University — A novel method for generating single-walled carbon nanotube (SWNT) excited states by energy transfer from porphyrin molecules is presented. Addition of SWNTs to a series of micelle suspended porphyrins results in efficient quenching of porphyrin fluorescence. Analysis of concentration-dependent porphyrin quenching reveals that intermolecular energy transfer is associated with complex formation. Two-dimensional excitation/emission spectroscopy demonstrates that photosensitization of porphyrin absorption bands results in characteristic near-IR SWNT photoluminescence. The porphyrin/SWNT hybrid displays significantly shifted absorption and emission transitions as a result of strong electronic coupling between these two pi-conjugated systems. These interactions allow controllable tuning of SWNT transition energies. Complexation of SWNTs with organic photosensitizing molecules provides uniform excitation of a wide range of nanotube species in polydisperse samples using a convenient single excitation wavelength.

1:27PM Q30.00012 Heat Treatments In Situ and Noise Reduction in Metallic Single-Walled Carbon Nanotubes (SWCNTs), ALEXANDER KANE, PHILIP COLLINS, Department of Physics and Astronomy, University of California Irvine, Irvine, CA 92697-4576 — As fabricated, small diameter metallic SWCNTs have anomalously high contact resistances and noise amplitudes. High temperature treatments have been found to decrease both the resistance and noise through undetermined mechanisms. This work investigates this high temperature processing through in situ measurements in a UHV environment, focusing on small metallic SWCNTs contacted by Ti, Pt, or Pd electrodes. The role of the contact resistance and contaminants in the device fluctuations or noise is studied. The two mechanisms affect device noise differently, with the net effect that room temperature noise decreases can be more than proportional to resistance decreases. Annealing temperatures for ideal device performance are determined for all three contact metals.

1:39PM Q30.00013 Dependence of the Raman G’ band intensity on metallicity of single-wall carbon nanotubes, KI KANG KIM, Sungkyunkwan University, JIN SUNG PARK, Tohoku University, SUNG JIN KIM, HONG ZHANG GENG, Sungkyunkwan University, KAY HYE S. AN, Jeonju Machinery Research Center, CHEOL-MIN YANG, Sungkyunkwan University, KENTARO SATO, RICHIRO SAITO, Tohoku University, YOUNG HEE LEE, Sungkyunkwan University — We report the peculiar behavior of the G’-band Raman intensity, which is dependent on the metallicity of single-wall carbon nanotubes (SWCNTs). In the metallic SWCNTs, the G’-band intensity was enhanced relative to the G-band intensity, while the G’-band intensity was suppressed in the semiconducting SWCNTs. Resonance Raman spectroscopy (using laser energies of \( \nu_{\text{Laser}} = 2.41 \, \text{eV}, 1.96 \, \text{eV}, \) and \( 1.165 \, \text{eV} \)) showed these features on the metal-enriched and semiconducting-enriched SWCNTs samples that had been selectively separated while the G’-band intensity was suppressed in the semiconducting SWCNTs. The metallicity dependence was explained theoretically by calculating resonance Raman intensity within the extended tight-binding model. The calculated results confirm that the G’-band intensity of the metallic SWCNTs is stronger than that for the semiconducting SWCNTs because the electron-phonon matrix elements for the TO phonon at the K point is larger for metallic SWCNTs and the resonance window for \( \nu_{\text{Laser}} ^{2} \) is larger than that for \( \nu_{\text{Laser}} ^{2} \).

1:51PM Q30.00014 Stability of finite single-walled carbon nanotubes adsorbed on Si(001)\(^{1}\), WALTER ORELLANA, Facultad de Ciencias Fisicas, Universidad Andres Bello — The stability and bonding properties of capped single-walled carbon nanotubes (CNTs) adsorbed on the Si(001) surface are studied using ab initio methods. We report the peculiar behavior of the G’-band Raman intensity, which is dependent on the metallicity of single-wall carbon nanotubes (SWCNTs). In the metallic SWCNTs, the G’-band intensity was enhanced relative to the G-band intensity, while the G’-band intensity was suppressed in the semiconducting SWCNTs. Resonance Raman spectroscopy (using laser energies of \( \nu_{\text{Laser}} = 2.41 \, \text{eV}, 1.96 \, \text{eV}, \) and \( 1.165 \, \text{eV} \)) showed these features on the metal-enriched and semiconducting-enriched SWCNTs samples that had been selectively separated while the G’-band intensity was suppressed in the semiconducting SWCNTs. The metallicity dependence was explained theoretically by calculating resonance Raman intensity within the extended tight-binding model. The calculated results confirm that the G’-band intensity of the metallic SWCNTs is stronger than that for the semiconducting SWCNTs because the electron-phonon matrix elements for the TO phonon at the K point is larger for metallic SWCNTs and the resonance window for \( \nu_{\text{Laser}} ^{2} \) is larger than that for \( \nu_{\text{Laser}} ^{2} \).

2:03PM Q30.00015 Brownian Dynamics Simulations of Single-Wall Carbon Nanotube (SWNT) Separation by Type using Dielectrophoresis, MANUEL J. MENDES, Applied Physics, NOE ALVAREZ, Dep. Chemistry, HOWARD SCHMIDT, R. Smalley Inst., MATTEO PASQUALI, Dep. Chemical and Biomolecular Eng., Rice Univ. — We theoretically investigate the separation of individual metallic and semiconducting SWNTs in a dielectrophoretic (DEP) flow device. The SWNTs motion is simulated by a Brownian Dynamics (BD) algorithm including the translational and rotational effects of hydrodynamic, Brownian, dielectrophoretic, and electrophoretic forces. The device geometry is chosen to be a coaxial cylinder, because it yields effective flow throughput, and all fields can be described analytically. We construct a flow-DEP phase map, showing different regimes depending on the relative magnitudes of the forces in play. The BD code is combined with an optimization algorithm that searches for the conditions which maximize the separation performance. The optimization results show that a 99% performance can be achieved with typical SWNT parameters by operating in a region of the phase map where metallic SWNTs orient with the electric field, whereas the semiconducting SWNTs flow align. We show spectroscopic measurements of experimental tests which demonstrate metallic vs. semiconductor separation at frequencies in the MHz range. These results reveal crucial knowledge on the influence of the surfactant on the SWNTs effective conductivity.

Wednesday, March 12, 2008 11:15AM - 2:15PM – Session Q31 DMP DCOMP: Computational Nanoscience: Nanotubes and Graphene

11:15AM Q31.00001 Possible Precursors for Boron Nanotubes: A Novel Bonding Picture in Boron Sheets and Nanotubes, HUI TANG, SOHRAB ISMAIL-BEIHI, Department of Applied Physics, Yale University — Boron nanotubes (BNTs) have attracted a great deal of attention due to their unique properties: unlike carbon nanotubes (CNTs), all BNTs are predicted to be metallic regardless of chirality or radii. Based on density functional theory, we present a class of boron sheets, composed of mixtures of triangular and hexagonal motifs, that are more stable than any sheet-structures considered to date and thus are more likely to be the precursors of atomically thin BNTs [1]. We describe a picture of the nature of the bonding in these sheets which clarifies their stability. We further point out that our bonding picture, which focuses on the balance of two-center and three-center bonding, is crucial for the stability of other boron nanostructures. We also discuss BNTs made from our new boron sheets.

11:27AM Q31.00002 Boron Nanotubes: Characterization Through Theory  
ABHISHEK SINGH, ARTA SADRZADEH, Department of Mechanical Engineering and Materials Science, Rice University, Houston, TX 77005; BORIS YAKOBSON, Department of Mechanical Engineering and Materials Science Rice University, and Department of Chemistry, Rice University, Houston Tx 77005 — Boron nanotubes have been believed to be metallic irrespective of diameter and chirality, as opposed to carbon nanotubes (CNTs), which could be both metallic and semiconducting. However, the separation of metallic and semiconducting CNTs is still a challenging task, which eventually, plagues their applications. Using first principle calculations, we investigate mechanical and electronic properties of the BNTs and show that BNTs could also be semiconducting. We discuss the origin of semiconductivity in BNTs. Prospect of having only metallic BNTs is a great advantage over CNTs, however, having semiconducting BNTs could make them applicable in electronics, sensing and optoelectronics.

SOMILKUMAR RATHI, ASOK RAY, The University of Texas at Arlington — Ab initio calculations within the framework of hybrid density functional theory and finite cluster approximation have been performed for the electronic and geometric structures of three different types of armchair germanium carbide nanotubes from (3, 3) to (11, 11). Full geometry and spin optimizations with unrestricted symmetry have been performed. A detailed comparison of the structures and stabilities of the three types of nanotubes will be presented. The dependence of the electronic band gaps on the respective tube diameters, energy density of states, dipole moments as well as Mulliken charge distributions have been investigated. Radial buckling of tube along with bond length variations is also studied. All armchair GeC nanotubes investigated so far are semiconducting in nature. Applications in the field of nano-optoelectronic devices, molecular electronics and band gap engineering are envisioned for GeC nanotubes.

1:11PM Q31.00004 Water in nanoscale confinement: Insights into structure, dynamics, and H-NMR chemical shifts from first-principles theory  
PATRICK HUANG, ERIC SCHWEGLER, Physical Sciences Division, Lawrence Livermore National Laboratory, GIULIA GALLI, Department of Chemistry, University of California, Davis — The properties of water confined to nanoscale dimensions can differ markedly from bulk. Numerous studies of confined water focus on water in carbon nanotubes (CNTs), because CNTs provide a uniform environment with a well-defined geometry and chemical composition. However, the behavior of water in CNTs remains controversial. Here, we apply first-principles density functional theory (DFT) to study the structure and dynamics of water in CNTs, and relate our microscopic picture to experimentally-accessible observables. One such observable is H-NMR, a sensitive probe of atomic-scale structure and dynamics. While empirical procedures to relate chemical shifts to structure are known for organic molecules, analysis of NMR spectra of solids and liquids requires more sophisticated approaches. We evaluate chemical shifts of water in CNTs within periodic DFT, and relate our findings to experimental H-NMR measurements.

12:03PM Q31.00005 First-Principles Studies of Metal-Graphene and Metal-Nanotube Heterostructures  
ALEJANDRO LUGO-SOLIS, IGOR VASILIEV, Department of Physics, New Mexico State University, Las Cruces, New Mexico 88003 — Metal-nanotube heterostructures have attracted considerable interest due to their potential applications in catalysis, fuel cell technology, and hydrogen storage. We investigate the optical properties of alkali metal atoms and clusters adsorbed on graphene and single-walled carbon nanotubes. The geometries, binding energies, and optical absorption spectra of the modeled structures are calculated in the framework of ab initio density-functional and time-dependent density-functional methods combined with the local-density approximation for the exchange-correlation functional. Our calculations show significant differences between the structures and absorption spectra of isolated alkali metal clusters and those adsorbed on graphene and carbon nanotubes.

12:15PM Q31.00006 Linear plasmon dispersion in graphene and single-wall carbon nanotubes and the influence of interlayer interactions  
R. HAMBACH, C. GIORGETTI, F. SOTTILE, L. REINING, LSI, CEA-CNRS UMR 7642-Ecole Polytechnique, France and ETSF France, C. KRAMBERGER, M.H. RÜMMELI, M. KNUPFER, J. FINK, B. BÜCHNER, T. PICHLER, IFW Dresden, Germany, E. EINARSSON, S. MARUYAMA, The Univ. of Tokyo, Dept. of Mech. Eng., 7-3-1 Hongo, Bunkyo-ku, Tokyo, Japan, K. HANNEWALD, IFTO, Friedrich-Schiller Universitaet Jena, Germany, V. OLEVANO, Institut Neel, Grenoble, France and ETSF France, A.G. MARINOPOULOS, Department of Physics and Astronomy, Vanderbilt University, Nashville, USA — Using first principle calculations [1], we studied momentum resolved electron energy loss spectra (EELS) for isolated graphene in RPA. Correspondingly, we simulated the influence of interlayer interactions on the plasmon dispersion and the importance of local field effects (or depolarization effects). The latter cause a mixing of electronic transitions resulting in a nearly linear dispersion of the plasmon in graphene for in-plane momentum transfer. Corresponding EELS measurements on isolated, vertically aligned single-wall carbon nanotubes (SWCNT) show a very similar dispersion relation along the tube axis. This validates the use of graphene to understand electronic excitations of carbon nanotubes and vice versa.

12:27PM Q31.00007 Tuning Field-Induced Energy Gap of Bilayer Graphene via Interlayer Spacing  
YUFENG GUO, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, WANLIN QIU, Institute of Nanoscience, Nanjing University of Aeronautics and Astronautics, Nanjing, 210016, China, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154 — Using first-principles calculations, we demonstrate a sensitive dependence of the electric-field-induced energy gap of bilayer graphene on its interlayer spacing. The calculated results reveal surprisingly large (±50%) changes in the energy gap by relatively small (±10%) adjustments in the interlayer spacing near the equilibrium structure when the electric field is sufficiently high (above 3 V/nm). We elucidate the underlying mechanism by examining the response of the interlayer charge distribution to the interlayer spacing variation at different electric fields. These results suggest an effective way for reversible tuning of the field-induced energy gap of bilayer-graphene-based nanoelectronic devices through nanomechanical control.

12:39PM Q31.00008 Role of Surface Defects in the Carboxylation of Carbon Nanotubes: An Ab Initio Study1. NABIL AL AQTASH, IGOR VASILIEV, Department of Physics, New Mexico State University, Las Cruces, New Mexico — We investigate the mechanism of covalent sidewall functionalization of carbon nanotubes with carboxyl groups using first principles computational methods. The binding energies and equilibrium geometries of carboxylated nanotubes with no surface defects, Stone-Wales defects and vacancies are calculated in the framework of density functional theory combined with the generalized gradient approximation. Our calculations show that the binding of carboxyl groups with carbon nanotubes containing surface defects is stronger than that with defect-free nanotubes. Furthermore, the presence of carboxyl groups on the surface leads to a considerable change of the electronic and structural properties of defective nanotubes. Our results suggest that surface defects play an important role in the formation of chemical bonds between chemical groups and carbon nanotubes.

1Supported by NSF DMR-0505270.

12:51PM Q31.00009 An ab initio description of cleaning of SWNT with UV light. ABRAM VAN DER GEEST, Colorado School of Mines, KATHRINE HURST, NIST Boulder, MARK T. LUSK, Colorado Scool of Mines — The photodesorption of molecules and its application to the cleaning of single walled carbon nanotubes (SWNTs) has been experimentally demonstrated using a 248 nm laser. The excitation of the carbon nanotube π-plasmon is thought to couple to vibrational modes of the molecule-nanotube bond. An ab initio inquiry seeks to validate this hypothesis and optimize the process of nanotube cleaning. The response of SWNTs to an electric field, a description of the enhancement of surface plasmons, and the role of hot electrons are discussed.

1:03PM Q31.00010 Modeling and simulation of adhesion between carbon nanotubes and surfaces. ALPER BULDUM, NABA RAJ PAUDEL, Department of Physics, The University of Akron, Akron, OH 44325, TOSHIYUKI OHASHI, Honda Research Institute USA, Inc. Research Institute, OH 44325, COLIN BURTON, ULrice, Inc. COBE, Inc. COBE, Inc. — There have been also many experimental studies which were performed to compare the adhesion properties of carbon nanotubes with that of a gecko’s foot on smooth surfaces. Yurdumakan et al. measured the adhesive force of multiwalled carbon nanotube hairs and found it to be 200 times higher than that observed for gecko foot hairs. Here, we present theoretical investigations of CNTs interacting with surfaces. We study the deformation of CNTs and evaluate their adhesion similar to the experimental investigation of a gecko’s foot. To study the deformation behavior and adhesion of CNTs, atomistic simulations of capped armchair (10,10) nanotubes with two different lengths are performed on rigid and relaxed graphite surfaces. Simulations were also performed for different orientations of the nanotube with respect to the graphite surface to study the angular dependence of adhesion and deformation.

1:15PM Q31.00011 Monte Carlo simulations of the effect of nanotube length distribution on the percolation resistivity in single-walled carbon nanotube films. JEREMY HICKS, ASHKAN BEHNAM, ANT URAL, University of Florida — Employing Monte Carlo simulations, we generate and calculate the resistivity of multilayer films made up of single-walled carbon nanotubes with various nanotube length distributions. Each layer in the film acts as a charge-percolating 2D mesh with contacts to adjacent layers. First, we study the case when the tube-face contact resistance dominates the resistivity. For randomly oriented nanotubes, we find that, the resistivity of the film, as well as its overall percolation probability correlate strongly with the root mean square (RMS) length of the nanotubes near the percolation threshold regardless of distribution. As the nanotubes in the film become increasingly aligned, the resistivity correlation shifts to higher order in length. On the other hand, if the nanotube resistance dominates the resistivity, the resistivity of the film correlates strongly with the average nanotube length. These results, which can be explained by physical and geometrical arguments, show how individual nanotube parameters contribute to the macroscopic characteristics of the film. They also show that computational studies are an essential tool for providing insight into the percolation transport in single-walled carbon nanotube films.

1:27PM Q31.00012 Mechanism for Superelongation of Carbon Nanotubes at High Temperature1. CHUN TANG, Department of Physics & High Pressure Center, University of Nevada, Las Vegas, WANLIN GUO, Institute of Nano Science, Nanjing University of Aeronautics & Astronautics, CHANGFENG CHEN, Department of Physics & High Pressure Center, University of Nevada, Las Vegas — Recent discovery of super elongation of carbon nanotubes (CNTs) at high temperature raises fundamental questions about the deformation mechanism of these normally brittle materials. Here we report extensive molecular dynamics simulations that identify two key factors for this intriguing phenomenon: (1) activation of defects all over the tube at the elastic limit and continued emergence of additional defects at increasing strain that impede the formation of localized predominant instability and facilitate homogeneous deformation; (2) large-scale defect evolution that produces multistage necking and kink motion. Intricate interplay between CNT sizes and temperature activated defect nucleation and motion plays a key role in determining the overall deformation pattern.

1DOE Cooperative Agreement DE-FC52-06NA26274.

1:39PM Q31.00013 Mesoscopic model for CNT-based materials1. ALEXEY VOLKOV, KIRIL SIMOV, LEONID ZHIGILEI, University of Virginia — A mesoscopic computational model is developed for simulation of the collective mechanical and thermal behavior of carbon nanotubes (CNTs) in CNT-based materials. The model is based on a coarse-grained representation of CNTs as “breathing flexible cylinders” consisting of a variable number of segments. A novel effective “tubular” potential is developed for the description of van der Waals inter-tube interactions. Frictional forces and energy dissipation, as well as heat conduction along and between CNTs, are incorporated into the mesoscopic model and parameterized with the help of results from atomistic simulations. The developed model is used in calculations of the mechanical and thermal properties of CNT meshes and mats. The systems under consideration contain thousands of CNTs, allowing for investigation of the effective properties of CNT-based materials. The computational results are related to available experimental data.

1:51PM Q31.00014 First-principles studies of the switching performance of [2]rotaxane molecules and monolayers. KINYIP PHOA, Department of Electrical Engineering and Computer Sciences, University of California, Berkeley, J.B. NEATON, The Molecular Foundry, Materials Sciences Division, Lawrence Berkeley National Laboratory, VIVEK SUBRAMANIAN, Department of Electrical Engineering and Computer Sciences, University of California, Berkeley — Density functional theory calculations of [2]rotaxane, an organic molecule consisting of a linear (straight) backbone and an encircling ring, which was recently proposed as the basis of a molecular memory device, are presented. The energy landscape describing the shifting of the ring along the backbone is calculated and carefully investigated. Furthermore, to estimate the potential RC delays associated with this molecular memory circuit, the long-wave dielectric response of [2]rotaxane monolayers is explored by applying an external field. Our calculations shed new light on the underlying working principle of this system and build on previous studies.

2:03PM Q31.00015 Structure-property relations in electronic switches based on the rotaxane and catenane supramolecular framework , YONG-HOON KIM, University of Seoul — Mechanically interlocked bistable supramolecular complexes are promising candidates of molecular electronics. Applying a multiscale computational approach combining force-fields molecular mechanics, density-functional theory, and matrix Green’s function calculations, we study the structure-property correlations in nanoelectronic switches based on [2]rotaxane and [2]catenane supramolecules. Computational aspects that increase the efficiency of charge transport characteristics calculations while ensuring the numerical accuracy will also be discussed. (This work was supported by the Korea Research Foundation Grant KRF-2007-331-C00077)

Wednesday, March 12, 2008 11:15AM - 2:15PM –
Session Q32 GMAG DMP: Focus Session: Molecular Magnets II Morial Convention Center 225

11:15AM Q32.00001 Strongly Correlated Electrons in the [Ni(hmp)(ROH)X]₄ Single Molecule Magnet: A DFT+U Study , CHAO CAO, Quantum Theory Project and Department of Physics, University of Florida, STEPHEN HILL, Department of Physics, University of Florida, HAI-PING CHENG, Quantum Theory Project and Department of Physics, University of Florida — The single molecule magnet [Ni(hmp)(MoOH)Cl]₄ is studied using both density functional theory and the DFT+U method, and the results are compared. By incorporating a Hubbard-U like term for both of the nickel and oxygen atoms, the experimental ground state is successfully recovered, and the exchange coupling constants derived from the DFT+U calculation fit the experimental results very well. The results show that the nickel 3d electrons and oxygen 2p electrons in this molecule are strongly correlated, and thus the inclusion of on-site Coulomb energies is crucial to obtain correct results. This work is supported by DOE DE-FG02-02ER45995 (H.-P. Cheng and C. Cao), NSF/DMR/TR-0218957 (H.-P. Cheng and C. Cao), NSF DMR0299481 (S. Hill), and NSF DMR0506946 (S. Hill). The authors want to thank NERSC, CNMS/ORNL and the University of Florida High Performance Computing Center for providing computational resources and support that have contributed to the research results reported within this paper.

11:27AM Q32.00002 Spin excitations in the molecule Mn₁₉ with a record ground-state spin S = 83/2 , B. BURGER, Institut für Anorganische Chemie, Universität Karlsruhe, 76128 Karlsruhe, Germany, O. WALDMANN, Physikalisches Institut, Universität Freiburg, 79104 Freiburg, Germany, A.M. AKO, A.K. POWELL, Institut für Anorganische Chemie, Universität Karlsruhe, 76128 Karlsruhe, Germany, H. MUTKTA, Institut Laue-Langevin - 6 Rue Jules Horowitz, BP 156-38042, Grenoble Cedex 9, France, T. UNRUH, FRM-II, Technical University Munich, ZWE, 85747 Garching, Germany — In the magnetic molecule Mn₁₉, 12 Mn(III) and 7 Mn(II) ions are ferromagnetically coupled such as to yield a S = 83/2 ground state. We recorded Q-band ePR and inelastic neutron scattering (INS) spectra on powder samples of Mn₁₉. The ePR data is well interpreted by the model of an isolated S = 83/2 spin with uniaxial magnetic anisotropy, H = DS² + gpSB. We find D = 0.004 cm⁻¹, hence Mn₁₉ is not a single-molecule magnet. The INS spectra show a broad feature I at ca. 0.25 meV, which exhibits an uncommon temperature dependence, and two peaks II and III at ca. 3.0 and 5.7 meV. The analysis of the INS data is complicated by the huge Hilbert space of Mn₁₉, hence the behavior cannot be described in a single-spin picture, but requires an inherent many-body description.

11:39AM Q32.00003 Looking for higher anisotropy barriers in single-molecule magnets , SAIIT DATTA, University of Florida, CONSTANTINOS MILIOS, EUAÑ BRECHIN, The University of Edinburgh, U.K, STEPHEN HILL, UNIVERSITY OF FLORIDA COLLABORATION — We report single-crystal high-frequency electron paramagnetic resonance (HF EPR) studies of a series of recently discovered Mn₆ single-molecule magnets (SMMs) with large barriers to magnetization reversal. All of the complexes consist of Mn₆ triangles with a ferromagnetic interaction between them. Recent studies have shown that the exchange interactions within the triangular Mn₆ units can be switched from antiferromagnetic to ferromagnetic, resulting in a switching of the spin from S = 4 to 12 for many of the Mn₆ complexes. This strategy to “increase S” has resulted in the highest magnetic energy barrier and blocking temperature for any known SMM to date. Extensive frequency, temperature and field-orientation dependent HF EPR measurements were performed to determine the magnetic anisotropy parameters for each complex. These studies have contributed to important new insights concerning strategies for designing SMMs with high blocking temperatures, particularly for complexes containing manganese in its +3 oxidation state. 1 T. Stamatakos et al., J. Am. Chem. Soc. 129, 12505-12511, 2007.

11:51AM Q32.00004 Theory of tunneling spectroscopy in a Mn₁₂ single-electron transistor by DFT methods , LUKASZ MICHALAK, Lund University and Kalmar University, Sweden, CARLO M. CANALI, Lund University, Sweden, MARK R. PEDERSON, Naval Research Lab, Washington DC, USA, VINCENZO G. BENZA, Universita dell Insubria, Como, Italy — We present a theory of single-electron tunneling transport through a Mn₁₂ molecular magnet in the Coulomb blockade regime. We employ spin density functional theory to calculate the low-energy spin multiplet states for neutral and charged (anion and cation) Mn₁₂, split by spin-orbit interaction. Tunneling matrix elements between these states are the basic ingredients of a master equation formalism that gives the tunneling conductance as a function of the bias and gate voltage. We compare the results of this formalism with the ones obtained using a phenomenological giant-spin Hamiltonian and highlight the importance of the orbital degree of freedom included in our SDFT approach.

12:03PM Q32.00005 First-principles study of a monolayer of single-molecule magnets Mn₁₂ on a gold surface , SALVADOR BARRAZA-LOPEZ, MICHAEL C. AVERY, KYUNGWA PARK, Department of Physics, Virginia Polytechnic Institute and State University, Blacksburg VA, 24061 — Over the past decade, single-molecule magnets have drawn considerable attention due to observed magnetic quantum tunneling and interference and a possibility of using them very efficiently in devices. There have been significant experimental efforts to build and characterize thin films or monolayers of single-molecule magnets on surfaces or single-molecule magnets bridged between electrodes. In parallel, theoretical models have been proposed to understand the properties of single-molecule magnets coupled to a metal substrate. However, there do not exist atomic-scale simulations on this complex system. We simulate, within density-functional theory, prototype Mn₁₂ molecules adsorbed via a thiol group onto a gold surface. We investigate how strongly a Mn₁₂ molecule is coupled to the metal surface and how much charge and spin moments are transferred between a Mn₁₂ molecule monolayer and the metal surface. In particular, we compare the electronic and magnetic properties of the Mn₁₂ monolayer on a gold surface with those of an isolated Mn₁₂ in the presence of spin-orbit interaction. Our results may shed light into tailoring of the magnetic properties of nanomagnets as a result of electronic transfer from a proximal metallic surface.
12:15PM Q32.00006 Ignition of magnetic deflagration in Mn$_{12}$ acetate, SEAN MCHUGH, R. JAAFAR, M.P. SARACHIK, City College of New York, Y. MYASOEDOV, A. FINKLER, H. SHTIRIKMAN, E. ZELDOV, The Weizmann Institute of Science, R. BAGAI, G. CHRISTOU, University of Florida — We study the conditions for the ignition of two types of magnetic avalanches in the molecular magnet Mn$_{12}$-acetate corresponding to the major species and a fast-relaxing minor species. The major component, which has a lower anisotropy barrier, exists in these crystals at the level of 5 – 7%. The ignition temperatures are measured using small (30 × 30µm$^2$) Ge thermometers. In addition, the magnetization dynamics are measured using an array of Hall sensors of comparable size. Various aspects of the ignition will be discussed, including: the reduction of the ignition threshold due to quantum tunneling, the catalytic effect of the minor species, and the shift of the ignition point as a function of external magnetic field. The work at City College was supported by NSF grant DMR-00451605. E. Z. acknowledges the support of the Israel Ministry of Science, Culture and Sports. Support for G. C. was provided by NSF grant CHE-0414555.

12:27PM Q32.00007 Quantum Interference in the Longitudinal Oscillations of the Total Spin of a Dimeric Molecular Nanomagnet, CHRISTOPHER RAMSEY, ENRIQUE DEL BARCO, University of Central Florida, STEPHEN HILL, University of Florida, SONALI SHAH, CHRISTOPHER BEEDLE, DAVID HENDRICKSON, University of California at San Diego — The synthetic flexibility of molecular magnets allows one to systematically produce samples with desirable properties such as those with entangled spin states for implementation in quantum logic gates. Here we report direct evidence of quantum oscillations of the total spin length of a dimeric molecular nanomagnet through the observation of quantum interference associated with tunneling trajectories between states having different spin quantum numbers. As we outline, this is a consequence of the unique characteristics of a molecular Mn$_{12}$ wheel which behaves as a (weak) ferromagnetic exchange-coupled molecular dimer: each half of the molecule acts as a single-molecule magnet (SMM), while the weak coupling between the two halves gives rise to an additional internal spin degree of freedom within the molecule, namely that its total spin may fluctuate. This extra degree of freedom accounts for many magnetization tunneling resonances that cannot be explained within the usual giant spin approximation. More importantly, the observation of quantum interference provides unambiguous evidence for the quantum mechanical superposition involving entangled states of both halves of the wheel.

12:39PM Q32.00008 EPR Studies of Magnetically Dilute Ga-Doped Single Crystals of Fe$_{15}$ Antiferromagnetic Molecular Wheels, JOHN HENDERSON, CHRISTOPHER RAMSEY, ENRIQUE DEL BARCO, University of Central Florida, THEODOROS STAMATATOS, GEORGE CHRISTOU, University of Florida — Studies of the quantum dynamics of the electron spins in solid state systems has gained considerable interest recently due to their potential for use as quantum computing substrates. One class of materials, molecular magnets, are of particular importance, owing to the seemingly limitless array of spin configurations due to synthetic chemical flexibility. Efforts are currently devoted to minimizing decoherence times by diminishing dipolar effects. In this regard, we have carried out EPR measurements on small single crystals of 0.5% Ga doped Fe$_{18}$ molecular antiferromagnetic wheels at temperatures down to 300 mK using planar resonators patterned on GaAs wafers. This system constitutes a dilute sample of $S = 3/2$ molecules dispersed within a sea of $S = 0$ (at low temperature) molecules, which significantly reduces dipolar interactions and might provide a means of observing Rabi oscillations in crystals of molecular magnets. Detailed angular dependence studies reveal significant anisotropy with D = 500 mK and E = 20 mK. The presence of second order anisotropy (E) is very unusual for such a high symmetry system and its interpretation will be discussed. Pulsed-EPR measurements and doping concentration dependence will also be discussed.

12:51PM Q32.00009 Spin-Jahn-Teller effect in the antiferromagnetic molecular wheel CsFe$_8$, O. WALDMANN, Physikalisches Institut, Universität Freiburg, 79104 Freiburg, Germany, L. SCHNELZER, B. PILAWA, Physikalisches Institut, Universität Karlsruhe, 76128 Karlsruhe, Germany, M. HORVATIC, Grenoble High Magnetic Field Laboratory, CNRS, BP 166, 38042 Grenoble Cedex 9, France — In an antiferromagnetic (AF) molecular wheel, magnetic metal ions are clustered together by organic ligands such as to form rings. Due to AF Heisenberg interactions in the wheel, the molecule’s ground state at zero magnetic field is nonmagnetic with total spin $S = 0$. The higher lying states belong to $S = 1, 2, ...$. In this magnetic field these states are Zeeman split, leading to a series of level-crossings (LCs) at characteristic fields at which the ground state changes from $S = 0$, $M = 0$ to $S = 1$, $M = 1$, and so on. Hence, via the field, the magnetic ground state of the molecule can be tuned through a degeneracy at the LC. Field-dependent measurements of the magnetic torque and $^1$H-NMR on CsFe$_8$ single crystals were performed, which show clear indications of a phase transition at the LCs at low temperatures [PRL 96, 027206 (2006); PRL 99, 087201 (2007)]. These phase transitions are explained by a field-induced spin-Jahn-Teller effect (JTE) due to tunneling of the field and the lattice: For fields close to a LC, a spontaneous structural distortion of the CsFe$_8$ wheel occurs such as to lift the degeneracy in the magnetic energy spectrum, hence the spin-JTE.

1:03PM Q32.00010 Magneto-infrared investigations of $[\text{MoO}_4\text{O}_{30}(\mu_2-\text{OH})_{18}]^{8-}$, $\text{H}_2\{\text{Ni}^{II}_4(\text{H}_2\text{O})_4\}_4\}$, J. CAO, J.L. MUFSELD, University of Tennessee, M. PEDERSON, Naval Research Laboratory, R. KLEMM, University of Central Florida, P. KOGERLER, Ames Laboratory — We measured the magneto-infrared spectrum of $[\text{MoO}_4\text{O}_{30}(\mu_2-\text{OH})_{18}]^{8-}$, $\text{H}_2\{\text{Ni}^{II}_4(\text{H}_2\text{O})_4\}_4$ in order to test the suggestion that molecular structure (and thus interactions between spins) may be changing with applied magnetic field. Although this low-noise magneto-infrared work was done in a superconducting magnet (which limits the field range to only 18 T), these experiments do provide direct evidence for small field-induced local distortions of the lattice. The field-induced change in the localized $\text{H}_2\text{O}$ wagging mode on the O attached to the Ni sites is particularly evident. This result is consistent with previous magneto-optics work indicating a small change in the Ni$^{II}_4$ crystal field environment at 30 T. We also consider whether the magneto-infrared results and the consequent small implied changes in local structure with magnetic field are enough to account for the observed magnetization data, and we discuss complementary mechanisms based on more extended spin Hamiltonians that may also account for large changes in J and D in molecular-based magnets.

1:15PM Q32.00011 Dzyaloshinskii-Moriya interactions and multiferroic behavior in high-symmetry single molecule magnets, RICHARD KLEMM, University of Central Florida, DMITRI EFREMOV, Technische Universität Dresden — We study analytically the effects of the antisymmetric exchange, or Dzyaloshinskii-Moriya interactions in high-symmetry single molecule magnets with 2-4 magnetic ions per cluster. When the Moriya rules allow it, such as when an ionic bond does not contain a center of inversion, these interactions can lead to interesting observable effects, including the presence of an electric polarization driven by an applied magnetic field, and associated multiferroic behaviors. We will present our results for tetramers with the common $S_1$ molecular group symmetry, and for other ultrasmall single molecule magnets.

1:30PM Q32.00012 Spin echo experiments on dilute ensembles of single molecule magnets, GREGOIRE DE LOUBENS, ANDREW D. KENT, NYU, Physics, VLADIMIR KRYMOV, GARY J. GERFEN, Yeshiva University, AECOM, Physiology & Biophysics, CHRIS C. BEEDLE, DAVID N. HENDRICKSON, UCSD, Chemistry & Biochemistry — Single molecule magnets (SMMs) have been suggested as candidates for qubits in quantum processors. However, the coherence time ($T_2$) of high-spin molecules has not been determined. In SMM single crystals the strong dipolar interactions between molecules (separated by only 1 nm) is expected to drastically reduce the coherence time. In order to determine the coherence time, $T_2$, we undertook a series of experiments. In particular, dilute frozen solutions of the SMM Ni$_4$ have been studied using high frequency D-band (130 GHz) EPR setup [1]. Despite the random orientation of the molecules, well defined EPR absorption peaks are observed, due to the strong variation of the splittings between the different spin-states on magnetic field. Temperature dependent studies (> 4 K) and comparison with simulations enable identification of the spin transitions and determination of the Hamiltonian parameters, found to be close to those of Ni$_4$ single crystals. The absence of echo in pulsed experiments sets an upper bound of about 50 ns on the spin coherence time in Ni$_4$ at 130 GHz and T = 5.5 K. [1] G. de Loubens et al., arXiv:0709.2146.
1.39PM Q32.00013 Transition Metal Dimers and Physical Limits on Magnetic Anisotropy, TOR OLOF STRANDBERG, CARLO M. CANALI, Kalmar University, ALLAN H. MACDONALD, University of Texas at Austin — Recent advances in nanoscience have raised interest in the minimum bit size required for classical information storage, i.e. for bistability with suppressed quantum tunnelling and energy barriers that exceed ambient temperatures. In the case of magnetic information storage much attention has centred on molecular magnets with bits consisting of 100 atoms, magnetic uniaxial anisotropy energy barriers 50 K, and very slow relaxation at low temperatures. In our recent article (Nature Materials 6, 648 - 651 (2007)), we draw attention to the remarkable magnetic properties of some transition metal dimers which have energy barriers approaching 500 K with only two atoms. The spin dynamics of these ultra small nanomagnets is strongly affected by a Berry phase which arises from quasi-degeneracies at the electronic Highest Occupied Molecular Orbital (HOMO) energy. In a giant spin-approximation, this Berry phase makes the effective reversal barrier thicker.

1.51PM Q32.00014 Magnetic anisotropies of late transition metal atomic clusters, JAIME FERRER, LUCAS FERNANDEZ-SEIVANE, Departamento de Física, Universidad de Oviedo — We analyze the impact of the magnetic anisotropy on the geometric structure and magnetic ordering of small atomic clusters of palladium, iridium, platinum and gold. We have employed a non-collinear implementation of Density Functional Theory where the spin-orbit interaction has been included self-consistently. The size of the clusters range from two to five, six or seven atoms, depending on the element. Our results highlight the relevance of the spin orbit interaction in the magnetic properties of small atomic clusters made of fourth- and fifth-row elements [1].

2:03PM Q32.00015 Dirac Equation for Electrodynamical Model Particle, J.X. ZHENG-JOHANSSON, IOFPR — We set up the Maxwell’s equations and subsequently the classical wave equations for the electromagnetic waves which together with their generating source, an oscillatory charge of zero rest mass, make up a particle travelling at velocity $v$ as with the charge in the fields of an external scalar and vector potentials. The direct solutions in constant external field are Doppler-displaced plane waves propagating at the velocity of light $c$; at the de Broglie wavelength scale and expressed in terms of the dynamically equivalent and appropriate geometric mean wave variables, these render as functions identical to the space-time functions of the Dirac spinor, and these are identical to the de Broglie phase waves given previously from explicit superposition. For two spin-half particles of a common set of space-time functions constrained with antisymmetric spin functions as follows the Pauli principle for same charges and as separately indirectly induced based on experiment for opposite charges, the complete wave functions are identical to a Dirac spinor. The back-substitution of the so explicitly determined complete wave functions in the corresponding classical wave equations of the two particles, subjected further to reductions appropriate for the stationary-state particle motion and to rotation invariance when in three dimensions, give a Dirac equation set; the procedure and conclusion are directly extendible to arbitrarily varying potentials by use of the Furious theorem and to three dimensions (full paper: QT55).

Wednesday, March 12, 2008 11:15AM - 2:15PM –
Session Q33 GMAG FIAP DMP: Focus Session: Spin Polarization in Compound Semiconductors
Morial Convention Center 224

11:15AM Q33.00001 Boundaries Between Current Carrying Semiconductors and Metallic Contacts, INANC ADAGIDELI, Universitaat Regensburg — No abstract available.

11:51AM Q33.00002 Current-Induced Spin Polarization in Gallium Nitride, W. KOEHL, C. POBLENZ, M.H. WONG, U. MISHRA, J. SPECK, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Recent experimental studies have shown that when a current is passed through certain non-centrosymmetric semiconductors (GaAs, ZnSe), a net spin polarization may be generated throughout the material. However, the physical mechanism responsible for this phenomenon, known as current-induced spin polarization (CISP), is still poorly understood but known to exist at high temperatures in wide-bandgap semiconductors [1]. In order to further explore the degree to which CISP depends on the band structure and spin lifetimes of a material, we measure the phenomenon in GaN, a wide-bandgap, non-centrosymmetric semiconductor. A series of n-type GaN epilayers are grown in the wurzite phase via molecular beam epitaxy at a variety of doping densities chosen to modulate the transverse spin lifetime, $T_\perp$, across its full available range. Using the Kerr effect, CISP is then characterized in these epilayers as a function of excitation energy over a range of temperatures.

1Work supported by the NSF and ONR.

12:03PM Q33.00003 Spin polarization in quantum point contact structures, ANH NGO, SERGIO ULLOA, Department of Physics and Astronomy, Ohio University — One of the important goals in the field of spintronics is to produce spin-polarized currents in semiconductors [1]. The Rashba spin-orbit interaction is useful in this regard, because its strength is controllable by applying an electric field. In this work we study ballistic transport through semiconductor quantum point contact systems under different confinement geometries and applied fields. In particular, we investigate how the lateral spin-orbit coupling, as induced by the lateral confinement potential, plays a non-trivial role on the spin polarization of the current, even in the absence of magnetic field. We find that high spin polarization can be obtained by controlling the asymmetric shape of the confinement potential, and contrast our results with previous work in the literature [2]. This behavior suggests a novel scheme to implement spin-filters without external magnetic fields, and we present its dependence on structural parameters.

12:15PM Q33.00004 All-Electric Quantum Point Contact Spin Polarizer, PHILIPPE DEBRAY, SAY-DUR RAHMAN, University of Cincinnati, Cincinnati, OH 45221, STEVEN HERBERT, Xavier University, Cincinnati, OH 45207, MARC CAHAY, RICHARD NEWROCK, University of Cincinnati, Cincinnati, OH 45221 — The conductance of InAs quantum point contacts (QPCs), created by two side gates on InAs/InGaAs quantum-well structures, was measured at low temperatures (≤ 4.2K) as a function of Fermi energy. By tuning the bias voltages of the gates, we were able to make appear or disappear on demand a conductance plateau at $G \cong 0.5 (2e^2/h)$. The presence of this plateau indicates complete spin polarization in the fundamental mode of transport. The 0.5 plateau appears when the transverse confining potentials of the QPC are tuned to be highly asymmetric. We believe the spin polarization responsible for the 0.5 plateau is induced by the lateral spin-orbit coupling, which originates from the transverse electric field of the confining potentials at the edges of the QPC. In a strong perpendicular magnetic field the magnetic confinement screens out the electrostatic confinement and the 0.5 plateau disappears. Our results show that it is possible to use an InAs QPC as a spin polarizer of both spin species through appropriate tuning of the bias voltages of its side gates.

12:27PM Q33.00005 Nanomechanical spin-polarizer, ALEXEY KOVALEV, LIVIU ZĂRBO, Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA, YAROSLAV TŠERKVONYAK, Department of Physics and Astronomy, University of California, Los Angeles, California 90095, USA, GERRIT BAUER, Kavli Institute of NanoScience, Delft University of Technology, Lorentzweg 1, 2628CD Delft, The Netherlands, JAIRO SINOVA, Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA — We study the effects of time dependent strain on transport properties in a long semiconductor rod and predict a piezo-spin effect. Torsional oscillations of a free-standing semiconductor beam are shown to cause spin-dependent oscillating with time potentials that spin-polarize an applied charge current in the presence of intentional or disorder scattering potentials. One may apply AC voltage synchronized with the mechanical motion to obtain a DC spin current. The thus created spin accumulation in the leads can be detected by e.g. ferromagnetic side contact or by the optical Kerr rotation. We propose to build the mechanical spin generators and manipulators based on the piezo-spin effect.

12:39PM Q33.00006 Generation and Decay of Spin Flip Waves in a CdMnTe Quantum Well, P. JACOBS, R. MERLIN, U. Michigan, Ann Arbor, MI, C. AKU-LEH, F. PEREZ, INSP, UMR 7588, CNR/Paris VI et VII, France, G. KARCZEWSKI, Polish Academy of Sciences, Warsaw, Poland — Recently, two dimensional electron gases (2DEG) embedded in semimagnetic Cd$_{1-x}$Mn$_x$Te quantum wells have been introduced as a model for spin-polarized systems. The addition of a small amount of Mn induces a giant Zeeman splitting such that, under moderate magnetic fields, spin effects dominate over orbital quantization, providing the reverse situation to that of GaAs. Using Raman spectroscopy, both collective and single-particle spin excitations have been observed in CdMnTe [1]. We have used ultrafast pump-probe spectroscopy to study collective spin-flip excitations in modulation doped CdMnTe quantum wells. Oscillations due to the zone center spin-flip wave were generated by circularly-polarized 70fs pump pulses and detected by Kerr rotation of linearly-polarized probe pulses. The spin-flip lifetime has a strong dependence on the applied magnetic field and also by weak heating due to laser absorption. The dependence of the lifetime on excitation energy and magnetic field indicate that the optically-excited heavy holes and their spin orientation play an important role in the decay of the collective mode. [1] F. Perez et al., Phys. Rev. Lett. 99, 026403 (2007)

12:51PM Q33.00007 Quantum Anomalous Hall Effect in HgMnTe Quantum Wells, CHAOXING LIU, Center for Advanced Study, Tsinghua University, Beijing, 100084, China, XIAOLIANG QI, Department of Physics, McCullough Building, Stanford University Stanford, CA 94305, XI DAI, ZHONG FANG, Institute of Physics, Chinese Academy of Sciences Beijing, 100084, China, SHOUCHENG ZHANG, Department of Physics, McCullough Building, Stanford University Stanford, CA 94305 — Quantum Hall effect is usually observed in the two-dimensional electron gas with an external magnetic field, where the electronic states form Landau levels. In this work, we show that a new phenomenon, the quantum anomalous Hall effect, can be realized in HgMnTe quantum wells, without the external magnetic field and associated Landau levels. This effect originates purely from the magnetization of Mn atoms, and is closely related to the quantum spin Hall effect observed in HgTe quantum wells recently. The opposite signs of sp-d exchange coupling between the Mn atoms and conduction or valence band electrons is crucial for realizing this effect. The quantized Hall conductance is predicted for a range of Mn concentrations and the relative magnitude of Mn atoms. Between the experimentally accessible parameter regime, we propose an experiment to demonstrate that the quantized Hall conductance indeed arises from the Mn magnetic moments rather than Landau levels. This effect enables dissipationless charge current in spintronics devices.

1:03PM Q33.00008 The Effect of Detector Bias on Non-Local Measurements of Spin Transport, E.S. GARLID, T. KONDO, University of Minnesota, K.S.M. REDDY, Q. HU, P.A. CROWELL, C.J. PALMSTRØM, University of Minnesota — Previous studies of spin transport in Fe/GaAs heterostructures have observed a strong non-monotonic dependence of the spin polarization on the bias across the injector contact in a non-local measurement. We have studied the dependence of the non-local voltage signal in Fe/GaAs/Fe spin valves as a function of detector bias. Measurements were made on lateral devices fabricated from epitaxial Fe/n-/n-GaAs heterostructures that have observed a strong non-monotonic dependence of the spin polarization on the bias across the injector contact in a non-local measurement. We have studied the dependence of the non-local voltage signal in Fe/GaAs/Fe spin valves as a function of detector bias. A sign change was observed at both forward and reverse detector bias, and the detector sensitivity was enhanced by up to a factor of five under large forward bias. This enhanced sensitivity may reflect the energy dependence of the Fe/GaAs interfacial density of states, although the connection between charge and spin transport in the semiconductor channel must also be considered. This work was supported by ONR and the NSF MRSEC, IGERT, and NNNM programs.

1:15PM Q33.00009 Growth and Characterization of VLS-type (Zn,Mn)Se nanowires, BENJAMIN COOLEY, Dept. of Physics and Materials Research Institute, Penn State University, TREVOR CLARK, Materials Research Institute, Penn State University, NIRMAL P. SAMPARTH, Dept. of Physics and Materials Research Institute, Pennsylvania State University — Magnetically-doped semiconductor nanowires offer an interesting regime for exploring carrier-induced ferromagnetism in the presence of a 1D density of states. Measurements were performed by biasing the detector electrode with respect to a reference electrode and using lock-in techniques to measure the spin polarization generated from an AC biased injector electrode. The non-local voltage signal was found to have a very different dependence on detector bias than on injector bias. A sign change was observed at both forward and reverse detector bias, and the detector sensitivity was enhanced by up to a factor of five under large forward bias. This enhanced sensitivity may reflect the energy dependence of the Fe/GaAs interfacial density of states, although the connection between charge and spin transport in the semiconductor channel must also be considered. This work was supported by ONR and the NSF MRSEC, IGERT, and NNNM programs.

1:27PM Q33.00010 Enhancement of In-Plane Magnetic Anisotropy Through Compensation in Ga$_{1-x}$Mn$_x$P:S, P.R. STONE, O.D. DUBON, University of California, Berkeley and Lawrence Berkeley National Lab, K.M. YU, J.W. BEEMAN, Lawrence Berkeley National Lab, C. BIHLER, M.S. BRANDT, Walter Schottky Institut, Technische Universitat Munchen — Ga$_{1-x}$Mn$_x$P is a ferromagnetic semiconductor (FS) in which exchange is mediated by localized holes [Scarpulla et al., Phys. Rev. Lett. 95, 207204 (2005)]. As is the case for the prototypical FS Ga$_{1-x}$Mn$_x$As, there exists a uniaxial magnetic anisotropy between in-plane $<$110$>$-type directions with the magnetic easy axis lying near the in-plane [1-10] direction [Bihler et al., Phys. Rev. B 75, 214419 (2007)]. Here we report the effect of compensation of Mn acceptors by sulfur donors on the in-plane uniaxial magnetic anisotropy in Ga$_{1-x}$Mn$_x$P as measured by both ferromagnetic resonance (FMR) and SQUID magnetometry. Raising the S concentration increases the magnitude of the uniaxial magnetic anisotropy between in-plane $<$110$>$-type directions. While the [1-10] direction remains the easy axis in the plane of the film, “wasp-waisted” hysteresis loops develop in the [110] direction as the S concentration increases. The wasp-waisted loops are modeled whereby magnetization reversal occurs by a combination of coherent spin rotation and noncoherent spin switching. Finally, by comparing FMR and SQUID data we extract domain wall formation energies as a function of compensation.
1:39PM Q33.00011 Deposition and characterization of highly spin-polarized $\text{Co}_{1-x}\text{Fe}_x\text{S}_2$ thin films.\textsuperscript{1}, MICHAEL MANN0, C. LEIGHTON, University of Minnesota — Many spintronic devices could benefit from the use of a highly spin polarized ferromagnet. We have recently demonstrated tunable spin polarization of $-56 < P < +85\%$ by composition control of the Fermi level in bulk $\text{Co}_{1-x}\text{Fe}_x\text{S}_2$.\textsuperscript{1} Although this material offers great promise for fundamental studies of spintronic devices, integration in devices such as spin injectors requires deposition of thin films. We present here synthesis details, structural, electronic, and magnetic properties of polycrystalline $\text{Co}_{1-x}\text{Fe}_x\text{S}_2$ films successfully fabricated by \textit{ex-situ} sulfidation on $\text{Al}_2\text{O}_3$ (0001), $\text{SrTiO}_3$ (001), and GaAs (001). The synthesis involves exposure of sputter or MBE deposited Co and Co-Fe alloy films to a S atmosphere at various reaction temperatures. Significant reaction with S occurs only above 200°C, while at 350°C and above we observe single-phase $\text{Co}_2\text{S}_2$ XRD patterns, and S contents (from EDS) of 65-70%. The conversion process has been studied in detail using multiple probes. Optimal conditions produce films that are ferromagnetic with the bulk $T_C$, bulk magnetization, metallic transport, and the expected magnetotransport phenomena. [1] L. Wang et al., Phys. Rev. B. 73 144402 (2006).

\textsuperscript{1}Work supported by NSF MRSEC.

1:51PM Q33.00012 Spin-filtering properties of ultra thin Eu chalcogenide films\textsuperscript{1}, MARTINA MUELLER, MARIUS COSTACHE, JAGADEESH MOODERA, Francis Bitter Magnet Lab, MIT — Promising materials for the generation of nearly fully polarized current are the magnetic semiconductors $\text{EuO}$ and $\text{EuS}$ when used as tunnel barriers. The spin-filter effect is due to exchange splitting of their conductance band below the ferromagnetic transition temperature, $T_C$. Combined with a structural and electrical compatibility with Si, Eu chalcogenides can be recognized as potential materials to study spin injection into semiconductors. In this work, special attention was drawn to the magnetic and transport properties of thin (<6nm) $\text{EuO}$ and $\text{EuS}$ films to explore the feasibility of their integration into spin-injection devices. We investigated the magnetic, structural and transport behavior of $\text{EuO (EuS)}$ thin films with regard to thickness- and substrate-induced changes. The influence of reduced dimensionality on exchange splitting and spin filter efficiency was observed in transport experiments using $\text{EuO (EuS)}$ as a tunnel barrier. “The phenomena of spin filter tunneling”, J. S. Moodera, T. S. Santos and T. Nagahama, J. Phys.: Condens. Matter 18 (2007) 1–24 – A review

\textsuperscript{1}Work supported by NSF and ONR research funds.

2:03PM Q33.00013 Resonant spin dipole induced by an in-plane potential gradient spin-orbit interaction\textsuperscript{1}, C. S. CHU, K. Y. CHEN, Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan, A. G. MAL’SHUKOV\textsuperscript{2}, Institute of Spectroscopy, Russian Academy of Science, 142190 Troitsk, Moscow oblast, Russia — Spin-orbit interaction (SOI) arising from in-plane potential gradient is invoked for the generation of spin accumulation in a driven electric field. The SOI and a local in-plane potential pattern together bring about resonant spin dependent scatterings to electrons in a nonequilibrium distribution. In the vicinity of a ring-shaped potential barrier pattern, a spin dipole distribution with a resonant dipole strength characteristic is obtained. As the chemical potential $\mu$ dependent scatterings to electrons in a nonequilibrium distribution.

12:03PM Q35.00003 Electronic Structure of Conduction Bands in Strained Si Nanomembranes
C. EUARUKSAKUL, Z. LI, C.S. RITZ, B. TANTO, D.M. COTTRILL, M.-H. HUANG, F. CHEN, D.E. SAVAGE, University of Wisconsin-Madison, F. LIU, University of Utah, F.J. HIMPSEL, M.G. LAGALLY, University of Wisconsin-Madison — We observe energy shifts of several conduction bands and a splitting of the conduction band minimum in elastically strained Si(001) and Si(110) Si nanomembranes (NMs) using X-ray absorption spectroscopy from the Si 2p core level. The surface sensitivity of absorption spectroscopy with electron yield detection makes the method suitable for studying very thin strained layers. Elastically strained NMs are dislocation free and thus provide an excellent model for determining the relationship of energy levels and strain. We measure the change in the global conduction band minima near the six X-points and also higher minima at the L and I' points, which yield information about the direction of the absolute energy shift due to the strain. Quantitative values of the level positions, including the core levels, are provided and compared to theory.

1Research supported by DOE, NSF and AFOSR.

12:15PM Q35.00004 Inelastic Electron Tunneling Spectroscopy Study of MOS Diodes Based on High-k Gate Dielectrics
S.L. YOU, C.C. HUANG, C.J. WANG, H.C. HO, J. KWO, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, W.C. LEE, K.Y. LEE, Y.D. WU, Y.J. LEE, M. HONG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan — Inelastic electron tunneling spectroscopy was applied to characterize the microstructure, interface, and trap-related states in silicon MOS diodes made of high k gate dielectrics HfO₂, Y₂O₃, and stacked HfO₂/Y₂O₃ bilayers by molecular beam epitaxy and atomic layer deposition under various heat treatments. Reproducible vibrational modes of monolonic HfO₂ and cubic Y₂O₃ were identified from IETS spectra. The gate bias dependence of the spectrum enables to ascribe the phonon modes adjacent to the lower or upper interface. A simple modeling was employed to analyze the trap related features in the spectra of stacked HfO₂/Y₂O₃ bilayers, and showed that most traps are located near the HfO₂/Y₂O₃ interface due to dissimilar charge distributions of two ionic oxides of different cation valences, and the interfacial strains of dissimilar structures. Work is now extended to Y-doped HfO₂ films in cubic phase with an enhanced k over 30.

12:27PM Q35.00005 On the role of Al doping at the SiO₂/HfO₂ interface
ONISE SHARIA, A.A. DEMKOV, UT Austin, G. BERSUKER, B.H. LEE, SEMATECH — One of the main challenges associated with the integration of high-k gate dielectrics such as hafnia is the identification of metal electrodes exhibiting the work function aligned with Si band edges. Due to the inherent instability of metals in contact with hafnia under high temperature, the focus has recently shifted towards developing a metal gate stack with appropriate effective work functions (EWF), which would result in the required low transistor threshold voltage. In this talk we report the theoretical results on doping the SiO₂/HfO₂ gate stack with Al atoms which, as we show, controls the EWF. We consider several dopant-vacancy models in various positions with respect to the interface. The proper stoichiometry avoiding fixed charge is maintained in all models. We find that doping at the interface has lower energy than doping in the bulk of silica or hafnia, which suggests the segregation of Al atoms towards the interface. Importantly, in all cases Al-vacancy complexes at the interface significantly change the band alignment, reducing the valence band offset. Thus, doping the SiO₂/HfO₂ gate stack with Al atoms offers a consistent way to adjust the alignment. This increase of the EWF can be explained with our previously introduced model that suggests that an oxygen depleted interface provides less effective screening, which in turn increases the interface dipole.

12:39PM Q35.00006 Oxide charge and band alignments in Pt/epi-Lu₃O₅/Si (111) structures studied by Internal Photoemission and C-V measurements
W. CAI, J.P. PELZ, Ohio State Univ., C. ADAMO, D.G. SCHLOM, Pennsylvania State Univ. — A variety of rare-earth/transition metal oxide films (of interest as possible “high-k” gate dielectrics for future MOS devices) were found to have similar band gap and band alignments to Si, and “tailing” conduction band (CB) states extending ~1 eV below the “primary” CB [1]. We used internal photoemission/photoconductivity (Int-PE/PC) and capacitance-voltage (C-V) measurements to study 20 nm-thick epitaxial Lu₂O₃ film grown at 700 °C on Si(111). A ~1.5V difference between the oxide- and Si- flat band voltages (measured by PC and C-V respectively) indicates ~6 × 10¹² cm⁻² fixed positive oxide charge, which was mostly removed by a ~350 °C post-metallization vacuum anneal. Int-PE measurements indicate the CB measured from the metal-side lines up ~0.4 eV below the “primary” CB measured from the Si side, in contrast with our finding on Pt/epi-SiO₂/Si (111) [2] that the metal-side CB aligned with the tail-state CB. Also, Ballistic Electron Emission Microscopy of Pt/epi-Lu₂O₃/Si (111) found ~0.3 - 0.4 eV higher energy barrier than found by Int-PE, suggesting significant transient charge trapping in this sample. Work supported by NSF Grant No. DMR-0505165. [1] V. V. Afanas’ev et al., Appl. Phys. Lett. 85, 5917 (2004); 88, 032104 (2006). [2] W. Cai et al., Appl. Phys. Lett. 91, 042901 (2007).

12:51PM Q35.00007 Electrical and optical properties of Pt/Si thin films
HENDRIK BENTMANN, A.A. DEMKOV, UT Austin, STEFAN ZOLLNER, RICH GREGORY. Freescale Semiconductor — Metal silicides are used in complementary metal-oxide-semiconductor devices (CMOS) to form contacts between metal interconnects and source, drain, and gate silicon of the transistors. They offer important properties like low resistivity, low contact resistance to Si as well as excellent process compatibility with the standard Si technology. Recently, metal silicides have attracted renewed attention and they are a current research topic in the semiconductor industry. We report a joint theoretical and experimental study of thin Pt silicide films. Employing density functional theory (DFT) methods we have investigated the electronic structure as well as bonding and optical properties of PtSi and Pt₅Si. Additionally, we have calculated surface energies for various orientations and terminations of PtSi surfaces. Our results suggest the work function aligned with Si band edges. Due to the inherent instability of metals in contact with hafnia which yield information about the direction of the absolute energy shift due to the strain. Quantitative values of the level positions, including the core levels, which were identified with inter-band transitions in the d-manifold of platinum and compared to theory.

1:03PM Q35.00008 Ab-initio study of early stages of III-V epitaxy on Si: direct vs. buffer deposition on vicinal surfaces
A.A. DEMKOV, ONISE SHARIA, HENDRIK BENTMANN, UT Austin — III-V materials, such as GaAs or InSb as well as other compound semiconductors with high carrier mobility are considered as potential candidates for a channel material in future CMOS-type devices. The most promising route to incorporate these advanced materials into CMOS is by growing epitaxial thin films on Si, either directly or via a buffer layer. Direct deposition suffers from a large lattice mismatch, and domain formation caused by the presence of steps on the Si surface. Perovskite oxides such as SrTiO₃ (STO) offers a possibility to reduce the lattice mismatch between Si and, e.g. GaAs in a step-wise fashion, however, the steps on the semiconductor surface present a somewhat unusual challenge. On the other hand, the use of vicinal surfaces for the direct deposition of GaAs on Si may eliminate the problem of orthogonal domains. Thus understanding the role of steps during the crystal growth is key to both approaches. In this talk we report a theoretical study of STO epitaxy on the vicinal Si(001) surface. In particular, we find that at the early stages of growth, Sr adatoms segregate to the step edges. We also consider the direct epitaxy of III-V compound semiconductors on high index Si surfaces, specifically, the silicon (112) surface. We consider In adsorption on this surface and identify a stable 7x1 substitutional reconstruction which is fundamentally different from the 6x1 reported for Ga. 
1:15PM Q35.00009 Atomic-layer-deposited HfO$_2$ on In$_{0.53}$Ga$_{0.47}$As – passivation and energy-band parameters...Y.C. CHANG, K.Y. LEE, M.L. HUANG, Y.J. LEE, T.D. LIN, M. HONG, Dept. of Materials Science and Engineering, National Tsing Hua University, Taiwan, J. KWO, Dept. of Physics, National Tsing Hua University, Taiwan — High k dielectric HfO$_2$ films were deposited by atomic-layer deposition on air-exposed In$_{0.53}$Ga$_{0.47}$As/InP (100), and found to exhibit an atomicly sharp interface free of arsenic oxides, an excellent aspect for Fermi level pinning. Angular-resolved x-ray photoelectron spectroscopy (XPS) using synchrotron radiation, however, observed the existence of Ga$_2$O$_3$, In$_2$O$_3$, and In(OH)$_3$ at the interface. The I-V of the MOS diode for an HfO$_2$ 7.8 nm thick follows the Fowler-Nordheim tunneling mechanism with a low leakage $\sim 10^{-8}$A/cm$^2$ at V$_{FB}$+1V, and an interfacial density of states $D_{it}$ of $2x10^{12}$cm$^{-2}$eV$^{-1}$. A conduction-band offset of $\sim$ 1.8 eV, and a valence-band offset of $\sim$ 2.9 eV were derived from the transport, and XPS data, respectively. For another HfO$_2$ film 4.5nm thick we achieved a CET value as small as 1.0nm, and a leakage of 3.8x10$^{-10}$A/cm$^2$ at V$_{FB}$+1V. The good scalability of ALD grown HfO$_2$ film with low leakage makes it very promising for III-V MOSFET applications.

1:27PM Q35.00010 Interfacial-layers-free Ga$_2$O$_3$(Gd$_2$O$_3$)/Ge MOS Diodes, C.H. LEE, T.D. LIN, K.Y. LEE, M.L. HUANG, L.T. TUNG, M. HONG, Department of Materials Science and Engineering, National Tsing Hua University, Taiwan, J. KWO, Department of Physics, National Tsing Hua University, Taiwan — High k dielectric Ga$_2$O$_3$(Gd$_2$O$_3$) films were deposited directly on Ge by Molecular-Beam-Epitaxy without the employment of GeON interfacial layer. Excellent electrical properties, such as a high k value of 14.5, a low leakage current density of only 3x10$^{-9}$A/cm$^2$ at V$_{FB}$+1 V, and a high mobility of 800 cm$^2$/V·s were obtained after 530°C oxidation in N$_2$ ambient for 5 min. An abrupt Ga$_2$O$_3$(Gd$_2$O$_3$)/Ge interface was revealed by high-resolution transmission electron microscopy as well as in-situ x-ray photoelectron spectroscopy (XPS). Detailed XPS studies indicate that the oxide/Ge interface consists of mainly Ge-O-Gd bonding, distinctly different from that of native oxide. Furthermore, the 500°C annealing did not change the chemical bonding, implying a great thermodynamic stability of the hetero-structure. The outstanding electrical and thermodynamic properties qualified Ga$_2$O$_3$(Gd$_2$O$_3$) as a promising dielectric for Ge and proved the GeON interfacial layer to be unnecessary.

1:39PM Q35.00011 Aspect Ratio Study of Microstructures Formed using an Adaptable Photomask, ANNA FOX, ADAM FONTECCHIO, Drexel University — We present an aspect ratio study of microstructures fabricated using a holographically formed polymer dispersed liquid crystal (H-PDLC) adaptable photomask. Recently it has been shown that H-PDLC films can act as electrically controllable light valves to selectively allow transmission of UV exposure in the lithographic process, making it ideal for application as a reconfigurable photomask. This study focuses on comparing aspect ratios of structures patterned using this adaptable photomask and processed with wet etching and reactive ion etching techniques. Aspect ratio comparisons with structures fabricated using a binary mask and etched using an identical process are presented. Results indicate that features formed using an adaptable H-PDLC mask have comparable aspect ratios to features fabricated using a binary mask. H-PDLC is a polymeric material formed holographically to have periodically spaced stratified layers of cured monomer and liquid crystal droplets. Reflection of a particular band of wavelengths occurs due to the periodicity of the layers and the index mismatch of the randomly aligned liquid crystal droplets. Bias applied to the film electrically aligns the liquid crystal layers eliminating the index mismatch yielding a transparent film.

1:51PM Q35.00012 Characterization of surface and pore morphologies on nanoporous organosilicate films...JEEUN KIM, HEEJU LEE, SANGHOON SONG, WONSUK CHA, HYUNJUNG KIM, GUNWOO PARK, SUNGKYU MIN, TAEHON LEE, HEEWOO RHEE, Sogang University, Korea, GWANGWOO KIM, Pohang Light Source Pohang, Korea — We have fabricated nanoporous organosilicate films with reactive porous trimethoxysilyl-propyl-cyclodextrin(TMSCD). With same amount of porogen loading, the films with reactive porogen TMSCD have shown higher mechanical strength than with those other non-reactive porogen. We have measured the pore morphologies depending on the types of porogens and loading densities along the pore generation processes by the grazing incidence small angle x-ray scattering, x-ray reflectivity, and ellipsometry. We measured the porosity of the film as a function of time and the annealing condition. We determined the actual porosity by measuring electron density of the films. In low loading density (10%~20%) porosity is very small and porosity distribution is uniform. In high loading density (>50%) the pores start to aggregate. We found that the porosity of the films can be affected easily by moisture. The results will be discussed with the mechanical properties along the optimized conditions for the films with ultra low dielectric constant.

2:03PM Q35.00013 Trap densities in porous low-k dielectric thin films as determined by optical and electrical measurements, J. JOANNA ATKIN, DAOHUA SONG, ROBERT LAIBOWITZ, Columbia University, EDUARD CARTIER, THOMAS SHAW, IBM Yorktown Heights, TONY HEINZ, Columbia University — Low-k dielectric materials based on porous carbon-doped oxides (p-CDOs), with relative dielectric constants as low as k = 2.1, are of great interest in the microelectronics industry. Knowledge of their basic electronic properties, such as energy gaps, barrier heights, and trap states, is essential for developing an understanding of their electrical leakage and stability characteristics. In particular, conduction via traps is a dominant mechanism in N$_2$ ambient stress of p-CDOs. We have fabricated porous organosilicate films with reactive porogen TMSCD with same amount of porogen loading. The techniques used include photoinduced current transients, optical second-harmonic generation measurements, and C-V electrical characterization. The low-k materials are shown to have relatively high trap densities (as compared with silicon dioxide films). The different behavior of bulk and interface traps will be discussed, along with the effects of annealing in various ambients.

Session Q36 GIMS: Focus Session: Advances in Scanned Probe Microscopy III: Force Methods
Morial Convention Center 228

11:15AM Q36.00001 Three-Dimensional Force Imaging and Quantification with Atomic Resolution...UDDO D. SCHWARCH, Department of Mechanical Engineering, Yale University — Atomic resolution images in noncontact atomic force microscopy (NC-AFM) reflect planes of constant frequency shift. To draw conclusions on the chemical activity at specific surface sites, however, the force acting between tip and sample should be known locally rather than the frequency shift. This is not an easy translation due to the non-linear nature of the relationship between the two. To overcome this problem, several groups have developed an extension to NC-AFM, dynamic force spectroscopy, which allows the precise, distance-dependent measurement of tip-sample forces. The forces are determined from frequency shift versus distance curves by mathematical analysis. Even though this approach had some success, prior attempts resulted either only in two-dimensional atomic resolution force xz-maps or in data sets of relatively low resolution, as long-term drift stability has been a problem. Using our recently completed home-built low temperature, ultrahigh vacuum NC-AFM, we were able to map the complete three-dimensional (3D) force field over a surface. Simultaneously, the tip-sample interaction potential and the energy dissipation of the oscillation process were recorded. As a test material, we used highly oriented pyrolitic graphite (HOPG) in order to study the atomic-scale origins of its qualities as a solid lubricant. Individual data points have been acquired over a surface area comprising several unit cells in a 3D grid with less than 6 pm grid size in all directions. From this data set, representations of cuts in any direction can be produced. While constant height images show atomic resolution with pN force resolution, vertical cuts visualize how the attractive force fields of the atoms extend into the vacuum space. We expect that the technique will find applications in fields of science where a local knowledge of interaction forces is beneficial, such as catalysis, chemical imaging, thin film growth, device fabrication, and tribology.
11:51AM Q36.00002 Tuning the instability in Static Mode Atomic Force Spectroscopy by applying electric field 1, SOMA DAS, S.N. Bose National Centre for Basic Sciences, P.A. SREERAM, Indian Institute for Science Education and Research, ARUP K. RAYCHAUDHURI, S.N. Bose National Centre for Basic Sciences — We study the force-distance (f-d) curves in the absence and presence of a dc bias between the cantilever tip and sample using Atomic Force Microscope (AFM). We find a new kind of bistability in the f-d curves obtained from Atomic Force Spectroscopy. The experimental signatures for this bistability point to a hysteresis like phenomenon when the f-d curves are cycled through the approach and retract paths. Interestingly, it is also observed that on application of a dc bias between the cantilever tip and sample, this bistability in the f-d curves can be tuned. This means that the “jump-into-contact” and “jump-off-contact” positions in the f-d curves change with the applied dc bias while keeping the other parameters constant. We simulate a simple model for AFM and show that this bistability is a characteristic feature of the experimental procedure and it can be controlled by applying a bias externally between the tip and sample.

12:03PM Q36.00003 Theoretical simulation of tapping mode AFM in water, MASARU TSUKADA, Waseda University, NAOKI WATANABE, Mizuho Inf. & Res. Inst. — For the AFM of bio-molecules as proteins, the measurement in water is essential, since properties of bio-systems in vacuum are different from those in water. We developed a basic simulation method for the tapping mode AFM in water and applied to protein samples. First, the cantilever elastic body oscillation in water very close to the sample is analyzed, by solving the fluid dynamics of water simultaneously by a specially designed finite element method. The calculated resonance curve showed strong nonlinear features, as well as the reduction of resonant frequency and loss of the sharpness of the resonance. This method is useful for designing cantilever shapes. Next, the tapping process of the tip by the sample is simulated by a visco-elastic model of bio-samples obtained coarse graining the atomistic model. Sticking and detaching of the tip to the sample, which causes large disturbance of the cantilever motion, are also analyzed. With including these processes altogether, the frequency shift, dissipating energy, phase delay of the oscillation are obtained and used to calculate tapping mode images of proteins.

12:15PM Q36.00004 Functional probes for scanning probe microscopy, YUKIO HASEGAWA, Institute for Solid State Physics, The University of Tokyo, KOTONE AKIYAMA, Institute for Materials Research, Tohoku University, MASAYUKI HAMADA, TOYOAKI EGUCHI, TOSHU AN, Institute for Solid State Physics, The University of Tokyo, YASUNORI FUJIKAWA, TOSHIO SAKURAI, Institute for Materials Research, Tohoku University — In spite of importance of the probe in scanning probe microscopy (SPM), little attention was paid for the SPM probes for most of the measurements of SPM. We developed sharp metal-tip cantilevers with a typical curvature radius better than 5nm using focused ion beam (FIB) suitable for Kelvin probe force microscopy (KFM) 1. We obtained atomically resolved KFM images with an energy resolution less than 3meV with the probe 2. We also developed a glass-coated tungsten tip for synchrotron radiation-scanning tunneling microscopy with the FIB method 3 and obtained elementally resolved images in a resolution less than 20nm. We are now developing a precise atomic force microscope (AFM) lithography 4 with the FIB-milled tip attached to a quartz tuning fork controlled by non-contact AFM. We will present recent results of our AFM lithography such as an Au line with a width of 20~30 nm and characters drawn with Au nano dots on a Si surface. 1 K. Akiyama et al., RSI 76, 033705 (2005) 2 T. Eguchi, K. Akiyama et al., PRL 93, 266102 (2004) 3 K. Akiyama et al., RSI 76, 083711 (2005) 4 T. Eguchi, K. Akiyama et al., APL 89, 243119 (2006) 5 K. Akiyama et al., JP 61, 22 (2007).

12:27PM Q36.00005 Fabrication of a NEMS Resonator Over-shield for Mass Sensing, VINCENT T.K. SAUER, NINT, MARK R. FREEMAN, NINT and University of Alberta, WAYNE K. HIEBERT 1, NINT — The frequency shift of a resonating cantilever or bridge due to mass loading is dependent on the position of the loaded mass on the resonator. Therefore, for the purpose of accurate mass sensing, it is increasingly important to know the exact position of an added mass on a resonating mass sensor. Discussed is a novel technique to build over-shield structures on top of NEMS resonating devices to physically limit the position in which a loading mass can be deposited on a mass sensor. The over-shield is composed of a PECVD silicon nitride film which is supported by a sacrificial aluminum layer. Essentially, this MEMS over NEMS device acts as an integrated shadow mask for the resonator. With this over-shield device the effect of the position of added mass on a resonator is also examined.

1NINT is the National Institute for Nanotechnology, 11421 Saskatchewan Drive, Edmonton, AB, Canada, T6G 2M9

12:39PM Q36.00006 Ferromagnetic Resonance Investigation of an Individual Permalloy Dot Using Magnetic Resonance Force Microscopy, J. KIM, I.H. LEE, D. PELEKHOV, YU. OBUKHOV, P. BANERJEE, The Ohio State University, T. MARTIN, Los Alamos National Laboratory, P. WIGEN, P.C. HAMMEL, The Ohio State University — We report Ferromagnetic Resonance (FMR) investigations of individual 5.3 micron diameter permalloy dots using low temperature (4 K) Magnetic Resonance Force Microscopy (MRFM). The dot magnetization is saturated in the external magnetic field perpendicular to the plane of the sample. The evolution of the MRFM signal as probe-sample separation and the lateral probe position are varied reveals the shape of the magnetostatic modes excited in the dot in the presence of the strongly inhomogeneous magnetic field of the MRFM probe magnet. The experimental data agree excellently with micromagnetic modeling which suggests that localized FMR modes are excited in the sample. This effect opens the way for spatially resolved studies of ferromagnetic systems.

12:51PM Q36.00007 Detecting Few Electron Spins by Magnetic Resonance Force Microscopy with Potential Application for Donor Mapping in Semiconductor, KIN CHUNG FONG, PALASH BANERJEE, YURI OBUKHOV, DENIS PELEKHOV, P. CHRIS HAMMEL, Physics Department, Ohio State University — We report measurements of the statistical polarization of small electron spin ensembles by Magnetic Resonance Force Microscopy (MRFM). The experiments were conducted at T = 4 K using an IBM-style ultrasoft micromechanical cantilever outfitted with a high coercivity micromagnetic probe. Magnetic resonance signals from tens of electron spins with spin-correlation time of ~400 ns are obtained. In order to apply MRFM for spatial mapping of donor electrons in semiconductors, non-contact friction between the cantilever and the silicon surface is investigated. We found the combination of hydrogen passivation, gold coating, and shielding the sample surface from stray laser light reduces the non-contact friction by almost a factor of 100.

1:03PM Q36.00008 Force detected electron spin resonance from N@C₆₀ thin films, PALASH BANERJEE, K.C. FONG, D.V. PELEKHOV, P.C. HAMMEL, Dept of Physics, Ohio State University, Columbus OH 43210 — We report on force-detected electron spin resonance studies of thin films of endohedral fullerenes N@C₆₀. The electron spin associated with the nitrogen atom exhibits long spin-lattice relaxation times (T₁) at low temperatures. By combining microwave pulses with periodic adiabatic spin inversions in large gradients, we are able to selectively manipulate and detect the spins in submicron volumes. We also discuss our progress in detecting statistical fluctuations of the spin magnetization in this system using ultrasensitive force detection techniques.
1:15PM Q36.00009 Development of a $^3$He Nuclear Magnetic Resonance Force Microscope*, MARK MONTI, HAN-JONG CHIA, YONG LEE, JOHN MARKERT, Department of Physics, University of Texas at Austin — We report on construction of a $^3$He Nuclear Magnetic Resonance Force Microscopy (NMRFM) probe for nanoscale scanning and relaxation-time applications. Dual 3-axis piezo-driven stages yielded nanoscale positioning precision across several millimeters. We performed measurements on $^1$H nuclei in single crystal (NH$_4$)$_2$SO$_4$ in a sample-on-oscillator configuration at room temperature. A 0.25-mm-diameter permalloy magnet provided a field gradient of $\sim$500 T/m. The magnet position was scanned to achieve resonance; the RF frequency was also independently varied to verify the NMR nature of the force-detected signal. These first tests used a commercial AFM cantilever with a loaded resonance frequency of 2.0 kHz and spring constant of $\sim$0.03 N/m; motion was detected with a laser interferometer (1310 nm). Using cyclic adiabatic inversion (CAI), we detected a nuclear moment of $1.9 \times 10^{10}$ J/T with SNR $\approx 6$. By preceding the CAI sequence with a short, variable-length pulse, a spin-nutation signal was observed over several cycles of period 17 $\mu$s, implying a rotating RF field of 14 G. Using a $(\pi/2)$-r-$(\pi/2)$-CAI sequence, a spin-echo was mapped out, with a FWHM of 8 $\mu$s. We also discuss plans to extend measurements towards the base temperature of the probe, 0.3 K. *This work was supported by NSF Grant Nos. DMR-0605828 and DGE-0549417.

1:27PM Q36.00010 NMR Force Microscopy on Co/Cu interface , YU. OBUKHOV, D. V. PELEKHOV, P. BANERJEE, J. MARTINDALE, K. C. FONG, P. C. HAMMEL — We present our recent NMR Force Microscopy experiments, where we demonstrate the first detection of 63Cu and 65Cu NMR using Magnetic Resonance Force Microscopy (MRFM). The signals were detected at T = 5 K using a commercial Si3N4 cantilever with a spherical NdFeB probe magnet. We demonstrate MRFM detection sensitivity of 1.0e5 nuclear spins. We report measurements of the relaxation time, signal lifetime, and the results of nutation experiments. We also discuss the application of MRFM for spatially resolved mapping of the local hyperfine field variation in the vicinity of a buried Co/Cu interface arising from the RKKY interaction.

1:39PM Q36.00011 Micromagnetic Modeling of Localized Ferromagnetic Resonance Detected with Magnetic Resonance Force Microscopy, DENIS V. PELEKHOV, Ohio State University, IVAR MARTIN, Los Alamos National Laboratory, YURI OBUKHOV, JONGJOO KIM, INHEE LEE, Ohio State University, EVGUENI NAZARETSKI, ROMAN MOVSHOVICH, Los Alamos National Laboratory, P. CHRIS HAMMEL, Ohio State University — Magnetic Resonance Force Microscopy (MRFM) is a novel scanned probe technique based on mechanical detection of magnetic resonance. Its extreme sensitivity originates partially from the high magnetic field gradient of MRFM probe micromagnet which couples the MRFM probe to the magnetic moments in the sample. We report micromagnetic modeling of Ferromagnetic Resonance (FMR) performed in the local field of the micromagnetic MRFM probe: its strongly inhomogeneous field enables the excitation of localized FMR modes in the sample. This unusual effect provides a mechanism for spatially resolved FMR investigations of ferromagnetic systems. We discuss spatial resolution and results for both quasi 2D and 1D systems.

1:51PM Q36.00012 Magnetic Resonance Force Microscopy System Design for the Study of Organic Materials, DORAN SMITH, US Army Research Laboratory — We will present an overview of our program to study organic materials with MRFM.

2:03PM Q36.00013 Applications of scanning Kelvin probe microscopy in the characterization of photovoltaic materials and devices, CHUNSHENG JIANG, HELIO MOUTINHO, MOIMAF Ak-JASSIM, NATIONAL RENEWABLE ENERGY LABORATORY TEAM — We have in recent years developed scanning Kelvin probe microscopy (SKPM), and applied this nanometer resolution technique to the characterization of III-V, II-VI, and thin film Si-based single- and multi-junction solar cell devices. In this presentation, we will report our improvements of the SKPM technique and show three examples of the potential measurements. We will first show a Bi-incorporation-induced junction movement in a MBE-grown single-junction GaInNAs cell. This junction movement caused significant device degradation, especially in the short wavelength range. We then present potential distributions among the top and bottom junctions in a GaInP$_2$/GaAs tandem-junction cell. A light-induced potential flattening in the top junction and a potential accumulation in the bottom junction was clearly measured. Lastly, we will show a non-uniform distribution of the electric field across an a-Si:H $n$−$i$−$p$ junction, and this electric field was significantly improved by depositing buffer layers at the $n/i$ and $i/p$ interfaces.

Wednesday, March 12, 2008 11:15AM - 2:15PM –
Session Q37 FIAP: Magnetotransport in 2DEGs Morial Convention Center 229

11:15AM Q37.00001 Effective mass suppression in interacting, fully spin-polarized 2D electron systems in wide A1As quantum wells , MEDINI PADMANABHAN, T. GOKMEN, N.C. BISHOP, M. SHAYEGAN, Dept. of Electrical Engineering, Princeton University — We report effective mass measurements, via analyzing the temperature dependence of the Shubnikov-de Haas oscillations, in dilute two-dimensional electron systems (2DEGs) confined to wide A1As quantum wells. In this system electrons have an anisotropic in-plane Fermi contour. When the 2DEG is partially spin-polarized, the effective mass is larger than its band value and increases as the density is reduced, consistent with previous results in various 2DEGs. An unexpected trend emerges as we fully spin-polarize the 2DEG by subjecting it to a strong parallel magnetic field: the mass falls below the band value and tends to decrease with decreasing density.

11:27AM Q37.00002 Effective mass suppression in interacting, fully spin-polarized 2D electron systems in narrow A1As quantum wells , TAYFUN GOKMEN, MEDINI PADMANABHAN, K. VAIKILI, M. SHAYEGAN, Department of Electrical Engineering, Princeton University — Similar to the study described by M. Padmanabhan et al. (previous abstract), we perform effective mass measurements in a two-dimensional electron system (2DEG) confined to a narrow (45Å-wide) A1As quantum well. In contrast to the 2DEGs confined to wide A1As quantum wells, in this system the electrons occupy a single out-of-plane valley with an isotropic in-plane Fermi contour. We confirm that the effective mass for the fully spin-polarized 2DEG is suppressed compared to the partially spin-polarized value.
11:39AM Q37.00003 Effects of mass anisotropy, thickness and disorder on the spin susceptibility of the 2DEG in AlAs QWs. MARIAPA MARCHI, STEFANIA DE PALO, GAETANO SENATORE, Democritos IFNM-CN and Università di Trieste, SAVERIO MORONI, Democritos IFNM-CN and SISSA — We present predictions of the spin susceptibility $\chi^s$, obtained from extensive DMC simulations, for a two dimensional (2D) electron gas (EG) with mass anisotropy appropriate to AlAs QWs[1], both in the strictly 2D limit and with thickness included. We demonstrate that in the one-valley case anisotropy suppresses $\chi^s$ substantially at all densities and in particular at those relevant to experiments[1], the effect being larger at lower density. This suppression adds onto the one due to thickness[2,1]. The comparison of our results for a model EG including both thickness and anisotropy with experiments for AlAs QW’s[1] reveals the role of disorder in determining the measured spin susceptibility. In the two-valley case we find an interesting interplay of anisotropy and valley degree of freedom in determining the EG properties and in particular the spin susceptibility. [1] T. Gokmen et. al., Phys. Rev. B in press and cond-mat 0711.1294. [2] S. De Palo et. al., Phys. Rev. Lett. 94, 226405 (2005); and to be published.

11:51AM Q37.00004 Heat Transport Measurements on 2D Electron Systems at Zero Magnetic Field using Quantum Points Contacts. D.A. NICHOLS, G. GRANGER, J.P. EISENSTEIN, Caltech, J.L. RENO, Sandia, L.N. PFEIFFER, K.W. WEST, Bell Labs — Three adjacent quantum point contacts (QPCs) separated by 20 micrometers are fabricated along the edge of a GaAs/AlGaAs two-dimensional electron gas (2DEG). The 2DEG is heated locally by passing an alternating current through the middle QPC, which is tuned so only a few channels propagate. A thermovoltage develops across a detector QPC on either side of the heater, and its gate voltage dependence is related to the derivative of the conductance of the detector QPC as expected from Mott’s formula. The thermovoltage depends on power and temperature and are also investigated. These experiments illustrate the feasibility of using mesoscopic devices to study heat transport in 2D electron gases with various geometries.

This work was supported by Microsoft Research Project Q.

12:03PM Q37.00005 Observation of Chiral Heat Transport in the Quantum Hall Regime. G. GRANGER, D.A. NICHOLS, J.P. EISENSTEIN, Caltech, J.L. RENO, Sandia, L.N. PFEIFFER, K.W. WEST, Bell Labs — The nature and properties of heat transport at the edge of a quantum Hall state are investigated using three adjacent quantum point contacts (QPCs) separated by 20 micrometers fabricated along the edge of a GaAs/AlGaAs two-dimensional electron gas (2DEG). With the bulk of the device at filling factor $\nu=1$, a thermovoltage signal appears across a detector QPC only on one side of the heater QPC depending on the direction of the magnetic field. This behavior indicates that heat transport is chiral at this filling factor. Raising the temperature decreases the thermovoltage, as the electrons carrying the heat find more ways to cool off at higher temperatures. When the distance between the heater and the detector is doubled, the thermovoltage is reduced, meaning that the electrons cool significantly over distances on the order of tens of micrometers. These findings are qualitatively insensitive to the exact magnetic field over the field range corresponding to the $\nu=1$ minimum.

This work was supported by Microsoft Research Project Q.

12:15PM Q37.00006 Momentum resolved transport spectroscopy of quantum Hall edges in a bent quantum well. LUCIA STEINKE, A. FONTCUBERTA I MORRAL, M. BICHLER, G. ABSTREITER, Tech. Univ. Muenchen, M. GRAYSON, Northwestern University — A new magnetic field orientation is introduced for a bent quantum well, such that momentum-resolved edge-state spectroscopy is possible up to fractional filling factors. A bent quantum well (BQW) provides a unique way of coupling to quantum Hall edges when the junction length is reduced to the mean free path $\sim 10\mu m$, constituting a weak link between the two facets. With a magnetic field $B$ perpendicular to one facet, the other facet can probe momentum-resolved transport spectroscopy of the edge states even though no barrier is present. We measure the differential conductance $dI/dV$ across the BQW as a function of the dc bias voltage $V_d$ at fields below 3 T and $\nu < 1/3$. Above $1.5 T$ a conductance-suppression gap develops around zero bias, and resonance peaks are observed at the gap edges, reminiscent of previous momentum-resolved work. The gap size increases and at $6 T$ becomes asymmetric, with one of the flanking resonances becoming stationary and extremely sharp. These main features can be interpreted in terms of momentum resolved coupling, and the positions of these features are in good quantitative agreement with Hartree calculations of this system.

Supported by DFG GR-2618/1-1, work performed at NHMFL.

12:27PM Q37.00007 From insulating behavior to quantum Hall liquid at low magnetic fields. T.-Y. HUANG, CHI-TE LIANG, National Taiwan University, GIL-HO KIM, Sungkyunkwan University, CHUN FENG HUANG, CMS/NML, ITRI, C.-P. HUANG, J.-Y. LIN, H.-S. GOAN, National Taiwan University, D.A. RITCHIE, Cambridge University — It is an interesting, but unsettled issue whether a direct transition from an insulating (I) state to a quantum Hall (QH) liquid is a genuine phase transition where $\nu$ denotes the filling factor [1]. It is argued that the observed low-field direct transition is not a quantum phase transition, but can be ascribed to a crossover from weak localization to Landau quantization (LQ) [1]. We shall show that between the insulating region and the QH regime, multiple temperature (T)-independent points in the longitudinal resistance can be observed in a moderate-mobility two-dimensional electron system containing InAs quantum dots. Interestingly, the amplitudes of the accompanying resistance oscillations can be well approximated by the conventional Shubnikov-de Haas theory, suggesting metallic behavior. Moreover, our data show that LQ can modulate the density of states without causing the formation of a QH liquid, demonstrating that the crossover from insulating behavior to Landau quantization can occur over a wide range of magnetic field. We speculate that to obtain a correct insight into the low-field I-QH transition, the argument raised by Huckestein [1] ought to be modified. Ref: [1] B. Huckestein, PRL 84, 3141 (2000) and references therein.

12:39PM Q37.00008 In-plane field induced anisotropy in the microwave/rf resonances of 2D electrons at the second excited Landau level. HAN ZHU, Princeton Physics, G. SAMBANDAMURTHY, SUNY Buffalo, L. ENGEL, NHMFL/FSU, D. C. TSUI, Princeton EE, L. PFEIFFER, K. WEST, The Bell Labs, Alcatel-Lucent Technologies — We report measurements of the microwave/rf diagonal conductivity of ultrahigh mobility 2D electron systems in GaAs/AlGaAs quantum wells, at the second excited Landau level (LL), with in-plane magnetic field $B_{ip}$. Previous measurements [1] at $B_{ip} = 0$ have found an essentially isotropic pinning mode resonance of the bubble phase near LL filling $4.15$ to $4.4$. As $B_{ip}$ is applied, with the rf electric field $E$ either parallel or perpendicular to $B_{ip}$, the peak frequencies $f_{pk}$ and resonance widths almost identically increase, probably due to stronger pinning as the electron wavefunction is being pushed closer to the GaAs/AlGaAs interface. However, $B_{ip}$ is found to induce anisotropy in the ratio of the integrated intensity $S$ over $f_{pk}$, which is thought to be proportional to the participating carrier density. As $B_{ip}$ is applied, $S/f_{pk}$ increases with $E$ perpendicular to $B_{ip}$, and decreases with them parallel. Similar behavior is found in the resonances from the Wigner crystal phase formed with the same LL. [1] R. Lewis et al., PRL 89,136804 (2002).
12:51PM Q37.00009 Microwave modes of two dimensional electron systems near macroscopic ferromagnets
1. BRENDEN MAGILL, NHMFL and MARTECH, FSU. L. W. ENGEL, NHMFL/FSU, M. P. LILLY, J. A. SIMMONS, J. L. RENO, Sandia National Laboratory — We report on microwave measurements of a high mobility two dimensional electron system (2DES) in a homogeneous external field \( B_0 \), and with cylindrical ferromagnets of radii \( r_m \) placed on the surface of the sample with the long axis perpendicular to the 2DES. The magnet materials are Dy and permalloy, and \( r_m \) varies from 0.5 mm to 0.125 mm. Microwave spectra measured for transmission between two ohmic contacts show resonant absorption at peak frequency, \( f_{pk} \), decreasing as \( B_0 \) or \( r_m \) increase. We will interpret the data in terms of plasma excitations similar to edge magnetoplasmoids [1] confined under the edges of the magnets by the large magnetic field gradients there. [1] See, for example, V. A. Volkov and S. A. Mikhailov, Sov. Phys.-JETP 67, 1639 (1988).

1:03PM Q37.00010 Radiation-induced decay of Shubnikov-de Haas oscillations in the regime of the radiation-induced zero-resistance states in GaAs/AlGaAs devices.

1:15PM Q37.00011 Floquet Theory of Magneto-Resistance Oscillations in Microwave Irradiated 2DEGs.
ASSA AUERBACH, G. VENKETESWARA PAI, Physics Department, Technion — Some remarkable phenomena have been recently observed in semiconductor heterostructures: microwave induced resistivity oscillations (MIRO), Hall induced resistivity oscillations (HIRO), and zero resistance states (ZRS). These effects were seen at weak magnetic fields and high temperatures, where Shubnikov-de-Hass oscillations are thermally smeared and the transport is expected to be classical Drude-like. However microwave radiation, or large Hall currents expose the underlying Landau quantization and result in MIRO and HIRO. Theoretically, it is essential to get the full nonlinear current-field response in the presence of strong radiation fields and disorder to handle these effects. Here we generalize the Floquet operator approach to incorporate arbitrary large electric fields into the zeroth order evolution operator. We construct the disordered Floquet evolution operator which allows us to systematically calculate the nonlinear photocurrent to second order in short range disorder. We derive the magnitude of MIRO from the microscopic parameters. We deduce the optimal conditions for observing large MIRO and ZRS effects. We determine the characteristic Hall fields clarifying the HIRO, and the magnitude of spontaneous ZRS fields. Reference: A. Auerbach and G. V. Pai, Phys. Rev. B 76, 205318 (2007).

1:27PM Q37.00012 The origin of the stripes observed in scanning single-electron transistor and in mesoscopic transport measurements of quantum Hall samples
CHENGGANG ZHOU, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, MONA BERCIOU, Department of Physics and Astronomy, University of British Columbia — We analyze two seemingly unrelated types of experiments on quantum Hall samples. When the measured quantities (local compressibility and resistances) are plotted as a function of magnetic field (\( B \)) and electron density (\( n_e \)), both experiments exhibit stripes parallel to lines of integer filling factors on the \( B-n_e \) plane. Unlike the popular belief in Coulomb blockade physics, we explain this within the framework of non-interacting electron theory. Our numerical simulations and theoretical analysis demonstrate that new electronic states appear predominantly at the center of Landau levels, when the magnetic field increases. This leads to a certain “spectral ordering” of the localized states that is sufficient to explain the main features observed in the experiments.

1:39PM Q37.00013 External Field Effecting Excitonic Superfluid in Drag Geometry.
JUNG-JUNG SU, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin — We will report on transport properties of excitonic superfluid under the influence of external applied field in generalized drag geometries. In such geometry, voltages are applied to the driven layer and a tunnable load resistance is added across the drag layer, which enable current flows in the drag layer when an excitonic condensate is established. The physics of the excitonic superfluid is described macroscopically by classical model and justified by microscopic mean-field plus non-equilibrium Green’s function (NEGF) approach. We found that the excitonic superfluid only exist in the voltage configurations in which charge conservation law is satisfied, given a zero tunneling system. This system is then well described by a set of circuit, on the premise that the quasiparticle current can not flow through the system, and the current thus obtained is in great consistence with our NEGF calculation. Finally, we proposed a method of detecting tunneling strength by the non-conservation of charge in the presence of bare tunneling.

1:51PM Q37.00014 Supersolid of indirect excitons in electron-hole quantum Hall systems.
CHANG-HUA ZHANG, YOGESH N. JOGLEKAR, Indiana University—Purdue University Indianapolis — We investigate the ground state of a balanced electron-hole system in the quantum Hall regime using mean-field theory and obtain its phase diagram as a function of interlayer distance \( d \) and the filling factor within a layer. We identify an excitonic condensate phase, a supersolid phase, as well as uncorrelated Wigner crystal states. We find that balanced electron-hole system exhibits a supersolid ground state over a wide range of the filling factors. We obtain the ground state stiffness in the the excitonic phases and show that the phase transitions from a uniform condensate to a supersolid is accompanied by a marked change in the stiffness. Our results provide the first semi-quantitative determination and analysis of the supersolid of excitons.

2:03PM Q37.00015 Insulating, Metallic, and Superconducting Transport regimes of 2D Amorphous Superconducting Films in B-T-Disorder Space.
YIZE LI, JONGSOO YOON, University of Virginia — Amorphous tantalum thin films are known to exhibit a superconductor-metal-insulator transition in the zero temperature limit with increasing magnetic fields. The metallic phase intervening the superconducting and insulating phase is unexpected. Each phase is known to exhibit unique nonlinear transport properties[1] with intrinsic origins[2]. In order to study how the mechanism behind each phase is influenced by B, T, and disorder, we have measured the evolution of nonlinear transport properties by changing B, T, and disorder. The resulting “phase diagram” of a sample with normal state sheet resistivity of 2.3 kilo-ohm indicates that the superconducting phase is completely surrounded by metallic phase, and a direct superconductor-insulator transition is not allowed. Recently, we extend our study on other samples with different disorder that is controlled by film thickness. By combining these results, we can map out the 3D phase diagram in B-T-disorder space. [1] Y. Qin et al., Phys. Rev. B 73, 100505(R) (2006). [2] Y. Seo et al., Phys. Rev. Lett. 97, 057005 (2006).
11:51AM Q38.00002 Intrinsic Bipolar Carrier (e⁻/h⁺) Layer on Clean Surface of Insulating BaTiO₃, Y. WATANABE, D. MATSUMOTO, Y. URAKAMI, S. KAKU, Kyushu U, Japan — We show experimentally the electron/hole layer on the clean surface of insulating pure BaTiO₃ single crystals in ultra high vacuum, which is the first report of the bipolar surface carrier layer by the field effect on any oxide to our knowledge. The experiments here demonstrate that the surface carrier layer is not due to impurities or defects but is intrinsic due to the spontaneous polarization P₀. The surface carrier layer induced by P₀ was found to exist at least to 80K on atomically ordered surface of insulating BaTiO₃, which has become the basis of a recent new memory device. However, much skepticism about its intrinsic nature is unresolved. We report here the disappearance of the carrier layer above Curie temperature, its disappearance by the exposure to a low vacuum, which indicates its location as the top surface, and, both electron/hole carrier layers by P₀. Here, the control of the electron and hole surface layer is only through the direction of poling. The realization of the hole layer is clear evidence that oxygen vacancies are inessential to the formation of the carrier layer, because oxygen vacancies kill the hole carrier layers. The present results have various implications for the basis of ferroelectric materials such as nano-ferroelectrics, field effects and domains. “Watanabe et al., Phys. Rev. Lett. 86, 332 (2001).”

12:03PM Q38.00003 Contrast in ultrathin film ferroelectric behavior between air and vacuum environments, A. P. BADDORF, P. MAKSYMOWYCH, S. V. KALININ, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, R. RAMESH, Department of Materials Science, University of California, Berkeley — At nanoscale dimensions, ferroelectric properties of oxide materials are dominated by depolarizing effects which depend strongly on the electrostatic screening at the interfaces and the environment. Oxide surfaces readily react with adsorbed molecules that may chemically or electronically alter the ferroelectric behavior. We have examined ultrathin (5-20 nm) BiFeO₃ thin films grown on SrTiO₃(110) using ultra-high vacuum Piezoresponse Force Microscopy. All the films reveal a characteristic behavior trend that in air the films are uniformly polarized, while multiple domains are observed in vacuum. The monodomain to polydomain transition occurs via either annealing in oxygen or simple evaporation, which suggests that mole fraction of oxygen on the surface. Local ferroelectric switching behavior has also been compared for vacuum and ambient environments on the same substrate. Measurements were made at the Center for Nanophase Materials Sciences, sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. DOE.

12:15PM Q38.00004 X-ray Studies of Chemical Switching of PbTiO₃ on SrRuO₃, CAROL THOMPSON, Dept. of Physics, Northern Illinois Univ., R.-V. WANG, D.D. FONG, F. JIANG, S.K. STREIFFER, P.H. FUOSS, J.A. EASTMAN, G.B. STEPHENSON, Argonne National Laboratory — Recent studies have shown that monodomain polarization can be stabilized in thin films not only through the presence of electrodes that provide electronic compensation at the film interfaces but also through surface-adsorbed ions or charged interfacial defects/impurities. Here, we use real-time synchrotron x-ray scattering to investigate changes in the polarization of PbTiO₃ films induced by varying the chemistry of the vapor above the film surface. We observe the sign of the polarization can be reversibly switched by changing the partial pressure of oxygen (pO₂) in equilibrium with the film surface. The dependence of film lattice parameter on pO₂ is bistable, following a butterfly loop analogous to that observed under applied voltage. The large compressive strains observed in the thinnest films prior to switching indicate that the chemical switching process can result in electric fields approaching the intrinsic coercive field for PbTiO₃. Work supported by the U. S. Department of Energy under Contract No. DE-AC02-06CH11357.

12:27PM Q38.00005 First-principles prediction of switchable stoichiometry at interfaces, SERGEY V. LEVCHENKO, ANDREW M. RAPPE, University of Pennsylvania — We present a first-principles density functional theory (DFT) study of the relative thermodynamic stability of ferroelectric (FE) lithium niobate (LiNbO₃) (0001) surfaces of different stoichiometry. We predict that the equilibrium stoichiometries are different for the positively and negatively polarized LiNbO₃ surfaces under the same conditions. A correct way of calculating surface charges for ferroelectric materials with intrinsic polar stacking is developed. It is found that surface charge passivation by ions is thermodynamically favored over passivation by mobile carriers in a wide range of chemical potentials.

12:39PM Q38.00006 Phase Field Modeling of Ferroelectric Thin Films with Space Charge, RAJEEV AHLUWALIA, Instute of Materials Research & Engineering, Singapore, NATHANIEL NG, Institute of High Performance Computing, Singapore, HAIBIN SU, FREDDY BOEY, Nanyang Technological University, Singapore — The time-dependent Ginzburg-Landau (TDGL) equations and phase field modeling have been used to describe various phenomena in ferroelectric materials, such as domain nucleation and evolution, and hysteresis. This work applies the TDGL model to explain the behavior of perovskite ferroelectric thin film with space charge. Results show that the presence of space charge at the surface significantly influences the switching process and domain structures in ferroelectric thin films. The role of space charge on size effects is also studied.
12:51PM Q38.00007 One-dimensional polydomains in Ferroelectric thin films, MATIAS NUNEZ, North Carolina State University, MARCO BUONGIORNO NARDELLI, North Carolina State University — The local nature of the interface in metal/ferroelectric oxide junctions can drastically affect the polarization in the ferroelectric film. As the thickness of the film is reduced, the intensity of the depolarization field increases and the system will reduce its electrostatic energy in two ways, either by forming lateral 180° domains [1], or by reducing the ionic polarization while remaining in a monodomain state. Using DFT, maximally localized Wannier functions [2] and the layer polarization concept [3], we studied the ferroelectricity in thin layers of BaTiO$_3$ sandwiched between metal. Our results suggest that the structures associated with this spatial scale are more complex than previously thought, and we show how a pattern of the local polarization provides another way to minimize the internal energy below certain critical thickness. This pattern is characterized by the appearance of one-dimensional polydomains, consecutive dipoles with opposed orientations in the direction perpendicular to the ferroelectric thin film/metal interface.

1:03PM Q38.00008 Theory of Electric Polarization Induced by Inhomogeneity in Crystals, DI XIAO, The University of Texas at Austin, JUNREN SHI, Institute of Physics, Chinese Academy of Sciences, DENNIS CLOUGHERTY, The University of Vermont, QIAN NIU, The University of Texas at Austin — We develop a general theory of electric polarization induced by inhomogeneity in crystals. We show that contributions to polarization can be classified in powers of the gradient of the order parameter. The zeroth order contribution reduces to the well-known result obtained by King-Smith and Vanderbilt for uniform systems. The first order contribution, when expressed in a two-point formula, takes the Chern-Simons 3-form of the vector potentials derived from the Bloch wave functions. Using the relation between polarization and charge density, we demonstrate our formula by studying charge fractionalization in a two-dimensional dimer model recently proposed.

1:15PM Q38.00009 Ferroelectric Thin Films Under Inhomogeneous Electric Fields - Lateral Size and Thickness Dependence, NATHANIEL NG, Institute of High Performance Computing, Singapore, RAJEEV AHLUWALIA, Institute of Materials Research & Engineering, Singapore, HAIBIN SU, FREDDY BOEY, Nanyang Technological University, Singapore — Advances in nanoscale ferroelectric devices have led to interest in studying size effects in ultrathin films whose properties differ substantially from the bulk. We present our results from ferroelectric thin films on SrRuO$_3$/SrTiO$_3$ substrate for onset of (meta)stable memory should be in excess of 4.5 nm compared with critical thickness of 1.6 nm for existence of ferroelectric domains.

1:39PM Q38.00011 Transport properties of epitaxial ferroelectric trilayer heterostructures with BaTiO$_3$ barriers, D.A. FELKER, H.W. JANG, C.B. EOM, M.S. RZCHOWSKI, University of Wisconsin-Madison — We studied the influence of the polarization on the transport properties of epitaxial trilayer heterostructures with SrRuO$_3$ metallic oxide electrodes and ferroelectric BaTiO$_3$ barriers. The heterostructures were grown using atomic-layer controlled pulsed laser deposition, with barrier thickness ranging from 4 nm to 100 nm. We discuss the frequency and thickness dependence of the P-E loops, and both voltage-biased and current-biased current-voltage (I-V) characteristics. We find that the I-V curves of the thinnest barriers show a hysteresis due to the switching of the polarization in the ferroelectric barrier, leading to a change in the conductance of the junction. A ferroelectric junction with clear resistive switching is a candidate for nonvolatile memory applications.

1:51PM Q38.00012 $^{17}$O Nuclear Magnetic Resonance Chemical Shielding Calculations of PZT Solid Solutions, DANIEL L. PECHKIS, ERIC J. WALTER, HENRY KRAKAUER, College of William and Mary — First principles B3LYP calculations of $^{17}$O NMR in PbTiO$_3$, Pb(Zr$_{0.55}$Ti$_{0.45}$)$_3$O$_5$ (PZT), and PbZrO$_3$ will be presented. These systems were modeled with finite size quantum clusters embedded in point charge arrays. The embedding reproduces the Ewald Coulomb potential to better simulate the crystal environment. For polar systems, the calculations were performed in the presence of an external electric field to cancel surface depolarization effects. PZT was modeled using three chemically ordered structures: P4mm, P2mm, and R3m. Two groupings of $^{17}$O isotropic chemical shifts $\delta_{iso}$ are seen in all of our PZT calculations with [001] ordering. One is at $\delta_{iso}$ ≈ 400ppm and the other is at $\delta_{iso}$ ≈ 650ppm. We relate these to variations in the Ti-O and Zr-O bond lengths and use this to interpret recent experimental measurements.

2:03PM Q38.00013 First-principles calculation of phonon dispersions for Ba$_{1-x}$Ca$_x$TiO$_3$, TAICHI KOSUGI, SHINJI TSUNEYUKI, Department of Physics, University of Tokyo — Amongst perovskite oxides, BaTiO$_3$(BTO) is widely used for its distinct dielectric, piezoelectric and optical properties. Its lattice dynamics, associated with atomic displacements, have been intensively studied both theoretically and experimentally, since it is essential for the dielectric instability of this material. Recently Ca-doped BTO(BCTO) single crystal was synthesized by Fu et al. and found to have exotic natures. Using the direct method proposed by Parlinski, we calculated the phonon dispersions of BCTO in a fully ab initio manner, in which the force constants, the Born effective charges and the dielectric tensors are determined from first-principles.

11:15AM Q39.00001 Self-Organized Porous Nanostructures in Anodized Metal Oxide, LIAM STANTON, ALEXANDER GOLOVIN, Northwestern University — We consider the self-organization of porous nanostructures in anodized metal oxide. We have developed a mathematical model which incorporates the electro-chemical transport of oxygen anions within the oxide layer and the chemical reactions at the metal-oxide and oxide-electrolyte interfaces. It is shown through linear stability analysis, that a short-wave instability exists in certain parameter regimes which leads to the formation of hexagonally ordered pores observed in anodized aluminum oxide. Numerical simulations validate these results.

11:27AM Q39.00002 Intercalation of Li Ions into a Graphite Anode Material: Molecular Dynamics Simulations, IBRAHIM ABOU HAMAD, HPC², Mississippi State University, MARK NOVOTNY, HPC² and Department of Physics and Astronomy, Mississippi State University — Large-scale molecular dynamics simulations of the anode half-cell of a lithium-ion battery are presented. The model system is composed of an anode represented by a stack of graphite sheets, an electrolyte of ethylene carbonate and propylene carbonate molecules, and lithium and hexafluorophosphate ions. The simulations are done in the NVT ensemble and at room temperature. One charging scheme explored is normal charging in which intercalation is enhanced by electric charges on the graphitic sheets. The second charging mechanism has an external applied oscillatory electric field of amplitude A and frequency f. The simulations were performed on 2.6 GHz Opteron processors, using 160 processors at a time. Our simulation results show an improvement in the intercalation time of the lithium ions for the second charging mechanism. The dependence of the intercalation time on A and f will be discussed.

11:39AM Q39.00003 Aging processes in reversible diffusion-limited reactions, VLAD ELGART, MICHEL PLEIMLING, Virginia Polytechnic Institute and State University — Reversible diffusion-limited reactions display anomalous (i.e. slow) dynamics characterized by a power-law relaxation toward stationarity. In contrast to previous studies that focused on the time-dependence of this relaxation, we study here the nonequilibrium behavior of various simple reversible reaction-diffusion models in the aging regime. Starting from the exact Langevin equations describing these models, we derive expressions for two-time autocorrelation and autoresponse functions and obtain a simple aging behavior for these quantities. The autoresponse function is thereby found to depend on the specific nature of the chosen perturbation of the system.

11:51AM Q39.00004 Lyapunov modes in coupled map lattices¹, GUENTER RADONS, HONGLIU YANG, Institute of Physics, Chemnitz University of Technology — Hydrodynamic Lyapunov modes, which have recently been observed in many extended systems with translational symmetry, such as hard sphere systems, dynamic XY-models, or Lennard-Jones fluids, are nowadays regarded as fundamental objects connecting Nonlinear Dynamics and Statistical Physics. A solution to one of the puzzles, the appearance of good and of “vague” modes, is presented here for the model system of coupled map lattices: The structural properties of these modes are related to the phase space geometry, especially the angles between Oseledec subspaces, and to fluctuations of local Lyapunov exponents. The numerical calculation of these quantities is achieved with the new algorithm proposed in [1]. In this context we report also on the possible appearance of branches in the Lyapunov spectra of inhomogeneous systems [2], similar to acoustic and optical branches for phonons. [1] F. Ginelli et al., PRL 99, 130601 (2007). [2] H. Yang and G. Radons, PRL 99, 164101 (2007)

12:03PM Q39.00005 Simulation of nonlinear pattern formation dynamics in photoinduced structure change¹, KUNIO ISHIDA, Corporate R&D Center, Toshiba Corporation, Japan, KEIICHIRO NASU, Institute of Materials Structure Science, KEK, Japan — We study the nonlinear dynamics of pattern formation triggered by injection of photoexcited states. In order to describe the nonadiabatic relaxation during the relaxation process, we employ a model of localized electrons coupled with a fully quantized phonon mode, and the time-dependent Schrödinger equation for the model is numerically solved. We found that the photoinduced nucleation process is switched on only when certain amount of excitation energy is supplied in a narrow part of the system, i.e., there exists a smallest cluster of excited molecules which makes the nucleation possible. As a result, the portion of the cooperatively converted molecules is nonlinearly dependent on the photoexcitation strength, which has been observed in various materials.

12:15PM Q39.00006 A study of some non-equilibrium driven models and their contribution to the understanding of molecular motors, IRINA MAZILU, JOSHUA GONZALEZ, Washington and Lee University — From the point of view of a physicist, a bio-molecular motor represents an interesting non-equilibrium system and it is directly amenable to an analysis using standard methods of non-equilibrium statistical physics. We conduct a rigorous Monte Carlo study of three different driven lattice gas models that retain the basic behavior of three types of cytoskeletal molecular motors. Our models incorporate novel features such as realistic dynamics rules and complex motor-motor interactions. We are interested to have a deeper understanding of how various parameters influence the macroscopic behavior of these systems, what is the density profile and if the system undergoes a phase transition. On the analytical front, we computed the steady-state probability distributions exactly for the one of the models using the matrix method that was established in 1993 by B. Derrida et al. We also explored the possible features offered by the “Bethe ansatz” method by mapping some well studied spin models into asymmetric simple exclusion models (already analyzed using computer simulations), and to use the results obtained for the spin models in finding an exact solution for our problem. We have exhaustive computational studies of the kinesin and dynein molecular motor models that prove to be very useful in checking our analytical work.

12:27PM Q39.00007 Controlling surface morphologies by time-delayed feedback¹, BEATE SCHMITTMANN, Virginia Tech, MICHAEL BLOCK, ECKHERD SCHOELL, Technische Universitaet Berlin — We propose a new method to control the roughness of a growing surface, via a time-delayed feedback scheme. The method is very general and can be applied to a wide range of non-equilibrium growth phenomena, from solid-state epitaxy to tumor growth. Possible experimental realizations are suggested. As an illustration, we consider the Kardar-Parisi-Zhang equation in 1+1 dimensions and show that the effective growth exponent of the surface width can be stabilized at any desired value in the interval [0.25,0.33], for a significant length of time.

12:39PM Q39.00008 Schwoinger-Keldysh Formalism for Non-Hermitian Quantum Problems: A Case Study on Non-Equilibrium Steady State Transport, PAATA KAKASHVILI, C.J. BOLECH, Physics and Astronomy Department, Rice University, Houston, TX 77005, USA — Non-unitary quantum mechanics has been used in the past to study irreversibility, dissipation and decay in a variety of physical systems. In this presentation, we propose a general scheme to deal with systems governed by non-Hermitian Hamiltonians. We argue that the Schwinger-Keldysh formalism gives a natural description for those problems. To be concrete, we study a simple model inspired by mesoscopic physics – an asymmetric junction (relevant to spin-valve devices). The system is governed by a non-Hermitian Hamiltonian which captures essential aspects of irreversibility. Calculated steady state transport properties show behavior which is anticipated on physical grounds.

12:51PM Q39.00009 ABSTRACT WITHDRAWN

1:03PM Q39.00010 Caliber approach for non-equilibrium systems with a small number of states, JEREMY SCHMIT, KINGSHUK GHOSH, KEN DILL, University of California, San Francisco — We present a theory for the dynamics of systems with a small number of states based on E.T. Jaynes' principle of Maximum Caliber. We construct the full dynamical partition function using a transfer matrix formalism with the transition rates as input parameters. Using this partition function, we are able to calculate all moments of dynamical quantities, and thus are able to predict fluctuations around the average behavior. We compare our results to single molecule and microfluidics experiments and contrast our results to the predictions of Minimum Entropy Production.

1:15PM Q39.00011 Transition rates for a Blume-Capel model coupled to a phonon bath, KYUNGWHA PARK, Virginia Tech — In nanoscale systems ranging from semiconductor quantum dots to arrays of magnetic nanoparticles or nanoscale magnetic molecules, dynamic properties play a crucial role in understanding the underlying physics and in designing systems of interest for applications. Dynamic properties are highly sensitive to transition rates used, so it is crucial to use a physically correct stochastic dynamic to examine dynamic properties. However, spin Hamiltonians do not provide generic dynamics, so a dynamic should be determined from microscopic Hamiltonians. As the first step towards deriving a realistic spin dynamic of nanoscale systems, we consider the ferromagnetic S=1 Blume-Capel model on a square lattice in which each spin is weakly coupled to a d-dimensional phonon bath, and derive transition rates from a spin-phonon coupling Hamiltonian. Based on the derived transition rates, dynamical properties such as metastability and nucleation are studied in the low-temperature limit using kinetic Monte Carlo simulations. The properties obtained from the phonon-assisted transition rates are compared with those from the Glauber transition rate.

1:27PM Q39.00012 Statistical mechanics far from equilibrium: prediction and test for a sheared system1, A. BAULE, R. M. L. EVANS, R. A. SIMHA, P. D. OLMSTED, University of Leeds — Beginning from a description of the forces of interaction between microscopic particles in motion, equilibrium statistical mechanics can predict both the statistical properties of their resulting configurations and the properties of the fluid (or other material) that they constitute. Despite the existence of statistical steady states of complex fluids under continuous shear flow, with intriguing similarities to equilibrium phase behaviour, a similar complete statistical solution has hitherto been unobtainable away from thermodynamic equilibrium. Instead, theorists have had to resort to artificial models with simple dynamics (e.g. some invented set of microscopic transition rates) or, alternatively, to use near-equilibrium approximations. We report the first complete statistical treatment of a collection of particles interacting via Newtonian forces in the presence of continuous boundary-driven flow, arbitrarily far from equilibrium [1]. Our investigation is based on a non-equilibrium counterpart to detailed balance [2] which leads to a set of simple constraints for the driven transition rates in our model system. We have tested the predictions in simulations, by numerically solving and time-stepping the force-balance equations. [1] R. M. L. Evans, R. A. Simha, A. Baule and P. D. Olmsted, to be submitted. [2] R. M. L. Evans, Phys. Rev. Lett. 92, 150601 (2004).

1:39PM Q39.00013 Dynamic phase transitions in model glass formers1, FRÉDÉRIC VAN WIJLAND, Laboratoire Matière et Systèmes Complexes, Université Denis Diderot - Paris VII — Glassy dynamics is identified through a series of signatures, such as aging, slow relaxation and the presence of dynamical heterogeneities. Basing our considerations on kinetically constrained glass formers, we argue that these phenomena are the byproduct of an intrinsically dynamic phase transition. The latter can be unravelled by performing, in the spirit of Ruelle, a Gibbs-like statistical mechanics over the set of time realizations of the systems’ evolution, rather than over the conventional set of phase space configurations.

11:15AM Q40.00001 Sintering Behavior of Metallic Nanoparticles1, MARTIN FENDRICH, RALF MEYER, RUSLAN ZINETULLIN, DIETRICH E. WOLF, PETER ENTEL, Theoretical Physics, University of Duisburg-Essen, 47048 Duisburg, Germany — Novel technological applications call increasingly for the controlled production of nanoparticles with well-defined physical properties. An important subject in this field is the sintering of agglomerated particles. We employ two different computer-simulation techniques to simulate the sintering of metallic nanoparticles. Molecular-dynamics simulations are used to study the early stage (t < 100 ns) of the sintering of two Ni nanoparticles with a size of about 4 nm. These simulations make it possible to observe important metallurgical details, like the role of (partial) dislocations in the process of the alignment of the crystal lattices. The data of the molecular-dynamics simulations are then used to calibrate the time-scale of kinetic Monte-Carlo simulations which can follow the sintering process over a much longer time-scale. A special technique is used in these simulations which makes it possible to take the misaligned crystal lattices into account.

Nanocomposites, THOMAS EKIERT, GERALD POIRIER, KARL UNRUH, University of Delaware — Fe-Ag nanocomposites have been prepared by a transmutation reaction in which metallic Fe nanoparticles are used to reduce an aqueous solution of Ag+ ions. As the reaction proceeds, the Fe nanoparticles fragment into smaller particles and are reduced in size and metallic Ag nanoparticles are formed. The evolution in the structure and composition of the reaction products has been studied as a function of the time and the solution temperature by scanning and transmission electron microscopy, energy dispersive x-ray spectroscopy, and x-ray diffraction measurements. These measurements indicate that nearly all of the available Ag+ ions are reduced to metallic Ag within 5 minutes at solution temperatures between 5 °C and 35 °C. However, at higher solution temperatures the fragments of the Fe nanoparticles very quickly oxidize if the reaction is not carried out under anaerobic conditions. The magnetic properties of the Fe-Ag nanocomposites have also been studied by vibrating sample magnetometry. These measurements show a corresponding decrease in the saturation moment of those Fe-Ag nanocomposites not prepared under anaerobic conditions, with the majority of the change occurring within the first five minutes of exposure to the Ag+ solution.

Creation of low-energy twin lamellae for thermal stability in nanostructured materials, CHRISTOPHER SALDANA, TEJAS MURTHY, Purdue University, RAVI SHANKAR, University of Pittsburgh, SRINIVASAN CHANDRASEKAR, ERIC STACH, Purdue University — Intrinsic thermal instability of nanostructured metals have limited the applicability of these high-strength material systems. A novel stabilization route was discovered in these fine-grained systems when a high-density twin nano-lamella was introduced amongst nano-grain boundaries through SPD at cryogenic temperatures. The stabilization in such a composite microstructure was traced to the peculiar kinematic behavior of the twin-grain boundary triple junction. Copper was chosen as model material and deformed under cryogenic conditions using machining with varying deformation rates. The microstructure was investigated through HREM as a function of time and temperature. At small deformation rates, the SPD at cryogenic temperatures resulted in the creation of a nanostructured material with an unstable microstructure that coarsened even at room temperatures. At higher deformation rates under the same conditions, distribution of twin lamellae resulted in a thermally stable nanostructured material.

Electron-Phonon Interaction and High-Temperature Thermodynamics in Vanadium Alloys and Compounds, OLIVIER DELAIRE, MAX KRESCH, MATTHEW LUCAS, JORGE MUNOZ, CALTECH, JIAO LIN, BREN'T FULTZ, CALTECH, CALTECH TEAM — Inelastic neutron scattering was used to measure the phonon densities of states (DOS) for pure V and V-6%K solid solutions, and for the A15 compounds V3Si, V3Ge and V3Co, at temperatures from 10K to 1300K. Pure V and the A15 superconductors V3Si and V3Ge exhibit an anomalous anharmonic stiffening of phonons with increasing temperature up to 1000 K. In V, this anharmonicity is suppressed by Co and Pt, but not by iso-electronic Nb solutes. Non-superconducting V3Co exhibits a normal quasi-harmonic softening. The electronic density of states was calculated from first-principles DFT methods for all alloys and compounds. The materials whose phonons behave anomalously also exhibit sharp peaks below the Fermi energy in their electronic DOS. The phonon-enhanced thermal softening of these sharp features results in reduced screening of nuclear motions and stiffer phonons. These results show that the EPI can influence the phonon thermodynamics at temperatures up to 1000 K.

Remarkably large field dependences of the thermodynamic and transport properties of PtSn1, P.C. CANFIELD, S.L. BUD’KO, E.D. MUN, H. KO, G.D. SAMOLYUK2. Ames Lab / Iowa State University — PtSn1 is a known, binary, intermetallic compound that forms as a result of a deeply paritectic reaction. It’s reported to have an orthorhombic crystal structure with lattice parameters a = 6.42, b = 11.4, c = 6.39 Å. Exceptionally low residual resistivity single crystals of PtSn1 have been grown out of excess Sn (with RRR values larger than 1000) and a detailed study of their field dependent properties have been made. The highlights of our results can be summarized as follows: (a) PtSn1 manifests a huge, low temperature magneto-resistivity of 107 %, for an applied field of 5 T, that rises to 109 % for 14 T; (b) PtSn4 manifests dramatic and clearly resolved oscillations in the magnetization that, for fields below 7T, can be clearly resolved for temperatures as high as 20 K; (c) PtSn5 manifests dramatic and clear oscillations in electrical resistivity, that, for fields below 14 T, can be clearly resolved for temperatures as high as 10 K.

Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

Scanning Tunneling Microscopy Atomic Resolution of Uranium Compound, MARILYN HAWLEY, SHAO-PING CHEN, Los Alamos National Laboratory, PHILLIP VAN STOCKUM, Stanford University — Room temperature ultra-high vacuum scanning tunneling microscopy (STM) atomic resolution imaging has been achieved for the first time on a layered uranium compound, uranium antimony two. High quality single crystals were cleaved in situ then imaged by STM using PtIr tips. Atomic resolution images revealed an in-plane square lattice with an uranium-uranium interatomic spacing consistent with theoretical predictions for the lowest energy cleavage plane. The STM images revealed a number of, as yet, unexplained features suggestive of missing atoms and single atom wide rows of atoms aligned along the two a-lattice parameter directions, which will be discussed in this talk.
1:03 PM Q40.00010 Structure of Boron Carbide: Where's the Carbon? , DAVID MARX1, Illinois State University, GERALD SEIDLER, TIMOTHY FISTER, KENNETH NAGLE, University of Washington, CARLO SEGRE, Illinois Institute of Technology — Although the structure of the boron carbide series, B\textsubscript{12}C\textsubscript{x}, with 0.06 < x < 1.7, has been studied since the 1940s, the location of the carbon atoms has not been adequately determined. The recent development of the lower energy resolution inelastic x-ray scattering (LERIX) spectrometer on the PNC-CAT beamline at the Advanced Photon Source at Argonne National Lab has enabled differentiation of the boron and carbon absorption edge data for the various crystallographic sites. The structure (R-3m) consists of twelve-atom icosahedra and three-atom chains. Boron carbide may have a maximum of three carbon atoms, which may be located on the two end of chain sites and in one of two inequivalent sites on the icosahedra. At least one carbon atom must be present in the structure for it to be stable. In this presentation, structural results from non-resonant x-ray scattering for seven samples, ranging from B\textsubscript{12}C to B\textsubscript{10}C\textsubscript{1}, will be presented.

1:15 PM Q40.00011 Electronic structure and properties of lanthanum . LANE NIXON, DIMITRIOSS PAPA-CONSTANTOPOULOS, George Mason University — The total energy and electronic structure of lanthanum have been calculated in the bcc, fcc, keps and dhcp structures for pressures up to 50 GPa. The full potential linearized augmented-plane-wave method was used with both the local-density and general-gradient approximations. The correct phase order has been found, with lattice parameters and bulk modules in good agreement with experimental data. The GGA method shows excellent agreement overall while the LDA results show larger discrepancies. The calculated strain energies for the fcc and bcc structures demonstrate the respective stable and unstable configurations at ambient conditions. The calculated superconductivity properties under pressure for the fcc structure are also found to agree well with experiments. Both LDA and GGA, with minor differences, reproduce well the experimental results for T\textsubscript{c}.

1:27PM Q40.00012 High-Level Correlated Approach to the Jellium Surface Energy, Without Uniform-Electron-Gas Input1 , LUCIAN CONSTANTIN, Tulane University, LUCIAN CONSTANTIN COLLABORATION, M. PITARKE COLLABORATION, J.F. DOBSON COLLABORATION, A. GARCIA-LEKUE COLLABORATION, J.P. PERDEW COLLABORATION — We describe the long-standing controversy over the surface energy of simple metals: Density functional methods that require uniform-electron-gas input agree with each other at many levels of sophistication, but not with high-level correlated calculations like Fermi Hypernetted Chain and Diffusion Monte Carlo (DMC) that predict the uniform-gas correlation energy. Here we apply a very high-level correlated approach, the inhomogeneous Singwi-Tosi-Land-Sjölander (ISTLS) method, and find that the density functionals are indeed reliable (because the surface energy is "bulk-like"). ISTLS values are close to recently-revised DMC values. Our work also vindicates the previously-disputed use of uniform-gas-based nonlocal kernels in time-dependent density functional theory.

1:39PM Q40.00013 Magnetic, thermodynamic and transport properties of GdFe\textsubscript{x}(Al\textsubscript{1-x}Zn\textsubscript{1-x})\textsubscript{2}0\textsubscript{1} . M. LAMPE, N. NI, N. JIA, G.D. SAMOLYUK, A.S. SEFAT, S.L. BUD’KO, P.C. CANFIELD, Ames Lab / Iowa State University — The unusual physical properties of the dilute, rare-earth-bearing, intermetallic compound GdFe\textsubscript{x}Zn\textsubscript{1-x}20\textsubscript{1} have been explained as being the result of the Gd\textsuperscript{3+} moment being embedded in a nearly ferromagnetic Fermi liquid. To understand this in detail, single crystals of the pseudo ternary series GdFe\textsubscript{x}(Al\textsubscript{1-x}Zn\textsubscript{1-x})\textsubscript{2}0\textsubscript{1} (x < 0.05) grown out of Zn-rich solution. Magnetization, heat capacity and resistivity measurements on these compounds reveal a decrease of T\textsubscript{c} from 86 K (x = 0) to 4 K (x = 0.07) for GdFe\textsubscript{x}(Al\textsubscript{1-x}Zn\textsubscript{1-x})\textsubscript{2}0\textsubscript{1} and a decrease of the Stoner enhancement factor, Z, from 0.88 (x = 0) to 0.35 (x = 0.05) for YFe\textsubscript{x}(Al\textsubscript{1-x}Zn\textsubscript{1-x})\textsubscript{2}0\textsubscript{1}. Rigid band approximation and TB-LMTO-ASA calculation are used to explain this trend. These results, combined with earlier studies of the substitution of Co for Fe clearly indicate the importance of band filling and the applicability of even a simple rigid band model, to these compounds.

3Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

1:51PM Q40.00014 Magnetic properties of RT\textsubscript{2}Al\textsubscript{20} (R = Gd, Eu and Yb, T = Ti, V and Cr) . J. FREDERICK, Ames Laboratory, USDOE, SHUANG JIA, S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory, USDOE and Department of Physics and Astronomy, Iowa State University — Isotropical RT\textsubscript{2}Al\textsubscript{20} series of compounds contain less than 5 at. % of rare earth ions. Thermodynamic and transport measurements were performed on solution-grown, single crystals: both R = Gd and Eu series manifest clear local moment behavior with magnetic ordering below 10 K. These low transition temperatures are consistent with the dilute nature of the rare earth ions. Unlike the RT\textsubscript{2}Zn\textsubscript{20} series, we have not found enhanced magnetic order or near-Stoner like behavior for any member of the RT\textsubscript{2}Al\textsubscript{20} family of compounds. The R = Yb members, however, all manifest weak Pauli paramagnetism, consistent with a divalent state for the Yb ions.

R1.00001 POLYMERIC AND ORGANIC MATERIALS II —

R1.00002 Ultrafast dephasing processes in β-carotene homologues , MASAZUMI FUJIWARA, KENSEI YAMAUCHI, MITSURU SUGISAKI, HIDEKI HASHIMOTO. CREST-JST and Department of Physics, Graduate School of Science, Osaka City University, RICHARD COGDELL, Institute of Biomedical & Life Sciences, Glasgow Biomedical Research Centre, University of Glasgow — Carotenoids is an important pigment in a bacterial light-harvesting system together with bacteriochlorophyll (BChl). In the photosynthetic system, these two kinds of pigments cooperate to efficiently capture the solar energy and to transfer energy to the reaction site within a few picoseconds. In this study, transient grating signals in β-carotene homologues using sub-20 fs excitation pulses were measured in order to investigate the dependence of the coherence dynamics on the conjugation length of these carotenoids. The conjugation length is a decisive factor in determining the efficiency of energy transfer to BChls. Therefore, it is important to study how the conjugation length affects the coherence dynamics. The results show that the population-induced dephasing is a major factor in the total dephasing process in the longer-chain carotenoids. On the other hand, pure dephasing time, which indicates the strength of the system-bath interactions, does not depend on the conjugation length. It is also concluded that the central C=C stretching mode is the major channel for energy dissipation to the environment regardless of the conjugation length.
R1.00003 Characterization of Bioderived Polyhydroxyalkanoates by Size Exclusion Chromatography, JOAN NEGULESCU, RAFAEL CUETO, KELLY RUSCH, TERESA GUTIERREZ-WING, BENJAMIN STEVENS, Louisiana State University Macromolecular Science Group — The plant derived polyesters, better known as polyhydroxyalkanoates, PHAs, are renewable and sustainable. \(-\text{O-CH}(-\text{CH}_2)_x-\text{CO-}N\). If \(x = 0\) PHA is Poly(lactic acid), PLA; if \(x = 1\) or \(2\) it is Poly(hydroxy butyrate), PHB, or Poly(hydroxy valerate), PHV. SEC and light scattering have been used before for determination of the absolute molecular mass of PLA dissolved in CHCl3 (Malmgren et al., J. Thermal Anal. Calorim., 2006, 83, 35-40). To our best knowledge there is no publication on the determination of the absolute MW of other PHAs. The bioderived polymers analyzed in this work were four catalog PHA samples: PHB Fluka 81329, PHB Natural Aldrich 363502, 95PHB/5PHV Aldrich 403105, and 92PHB/8PHV Aldrich 403113. SEC/LS instrumentation used: three Phenogel (1K-1000K) columns — a guard column, an Agilent pump and Wyatt Heleos MALS, QUELS (DLS), ViscoStar and rEX DRI detectors, all in series. The experimental dn/dc of PHB in CHCl3 (0.0936 ml/g at 658nm) allowed the determination of absolute MW of all PHA samples: PHB Fluka Mw 345,100 Mn 218,400; PHB Aldrich Mw 335,700 Mn 185,000; 92PHB/8PHV Mw 144,700 Mn 91,970; 95PHB/5PHV Mw 253,000 Mn 193,800.

R1.00004 Assembly of functionalized dicomponent nanorods at liquid-liquid and -air interfaces, BOKYUNG KIM, University of Massachusetts Amherst, SOOJIN PARK, DIAN CHEN, THOMAS MCCARTHY, THOMAS RUSSELL — Nanoporous templates are used to fabricate nanorods which have attracted significant interest for the fabrication of functional materials with interesting optical, electrical and magnetic properties due to their shape. We investigated a method for preparing well-ordered Anodized Aluminum Oxide (AAO) template using block copolymer micelles to transfer block copolymer patterns to the surface of aluminum as a mask during RIE. Electrochemical deposition was used to deposit Au blocks and poly(pyrrole) blocks into AAO templates to prepare dicomponent nanorods. Varying the diameter and length of them can be easily controlled by the hole diameter of AAO templates and the electropolymerization. By taking advantage of the different properties and functions of the individual components for offering additional degrees of freedom in self-assembly, their distinct surface chemistry was prepared. At liquid-liquid and -air interfaces, functionalized nanorods were distinctly self-assembled to adjust the interfacial strengths and stabilize two phases.

R1.00005 Fabrication of Highly Ordered Silicon Oxide Dots and Stripes from Block Copolymer Thin Films, BOKYUNG KIM, University of Massachusetts Amherst, SOOJIN PARK, JIAYU WANG, THOMAS RUSSELL — A general route to fabricate highly ordered arrays of nanoscopic inorganic oxide dots and stripes from block copolymer thin films is described. Poly(styrene-b-4-vinylpyridine) (PS-b-P4VP) thin films with cylindrical microdomains oriented normal and parallel to the surface were used as templates for the fabrication of nanoscopic silicon oxide. A thin PDMS layer was spin-coated onto the nanopatterned film, followed by thermal annealing. The PDMS diffused into the pores by capillary action. PDMS was transformed to silicon oxide by oxygen plasma treatment, while PS-b-P4VP was completely degraded, resulting in ordered arrays of silicon oxide.

R1.00006 Oscillatory jet flow in electrospinning of polymer nanofibers, SUREEPORN TRIPATANASUWAN, Department of Polymer Science, TheUniversity of Akron, DARRELL RENEKER, Department of Polymer Science, The University of Akron — The flow of polymer solution into an electrospinning jet can be controlled, the pressure applied to the fluid, and the flow out can be controlled by the electrical potential of the fluid. When the average flow rate of solution carried away by the jet was smaller than the rate at which the liquid was forced through the orifice into the jet, the solution flow rate and the electrical current both oscillated in time. The amount of fluid near the orifice grew larger and caused the flow out of that region to increase, and the amount of fluid near the orifice decreased. Then the cycle repeated. The oscillatory phenomena were demonstrated using a jet of polyethylene oxide in water (Molecular weight, 400k, concentration about 5%) flowing through a tube with a diameter of 0.7 mm. The pressure was 500 to 2500 Pascal, and the applied potential was around 5 kV. The frequency of oscillation (about 0.5 Hertz) was affected by the resistivity of the polymer solution (around 4500 ohm-meters).

R1.00007 Interaction Chromatography of Random Copolymers with Tunable Monomer Sequence Distributions, CHANG Y. RYU, JUNJONG HAN, BYUNG HO JEON, Rensselaer Polytechnic Institute, JAMES J. SEMLER, YOUNG K. JHON, JAN GENZER, North Carolina State University — We demonstrate that high performance liquid chromatography (HPLC) in the interaction chromatography (IC) mode is capable of distinguishing among various comonomer sequences in random copolymers (RCPs). A series of poly(styrene-co-4-bromostyrene) (PBrS), where \(x\) is the mole fraction of 4-BrS, RCPs have been prepared by brominating parent monodisperse polystyrene (PS). The distribution of S and 4-BrS segments in PBrS was adjusted by varying the molar ratio of S to PBrS before the bromination reaction. We utilize both normal and reversed phase IC techniques to demonstrate that the adsorption-based retention of PBrS RCPs is affected not only by their chemical composition, but also by the comonomer distribution in the RCP. Thus, IC can be used as a tool for material characterization. They provide information on the interplay between the macromolecular collapse and segment blockiness affected by the adsorption-based retention times in HPLC.

R1.00008 Polymorphism Control of Poly(vinylidene fluoride), JIANFEN ZHENG, AIHUA HE, JUNXING LI, CHARLES C. HAN, STATE KEY LAB OF POLYMER PHYSICS AND CHEMISTRY, INSTITUTE OF CHEMISTRY, CHINESE ACADEMY OF SCIENCES TEAM — Poly(vinylidene fluoride) (PVDF) is well-known for its polymorphism, and can exhibit five different polymorphs depending on its processing conditions. The \(\alpha\)-phase is the most common and stable polymorph and the \(\beta\)-phase is the most important one due to its piezoelectric and pyroelectric properties. Polymorphism control of PVDF has been realized through electrospinning. PVDF fibrous membranes with fiber diameter in the range of 100 nm to several micrometers were produced by electrospinning and the crystal phase of electrospun PVDF fibers can be adjusted at the same time. Through the control of electrospinning parameters such as the solvent and electrospinning temperature, PVDF fibrous membranes containing mainly \(\alpha\)-or \(\beta\)-or \(\gamma\)-phase could be fabricated successfully.

R1.00009 Role of Crystallinity in CNT Dispersion and Electrical Conductivity of SWCNT-Thermoplastic Nanocomposites, ADE KISMARAHARDJA, JAMES BROOKS, Florida State University, KEESU JEON, RUFINA ALAMO, FAMU-FSU College of Engineering — Using a homopolymer iPP and a series of propylene-ethylene random copolymers with a content of ethylene from 7 to 21 mol% as matrices, SWCNT nanocomposites have been prepared in a range of CNT concentration from 0.15 to 1 wt%. The poly(propylenes) have crystallinities ranging from 70 to 10 %, and serve to test the role of CNTs acting as nucleants to preserve the uniform dispersion of CNTs after sonication in solution. Growth of the semicrystalline structure from the nanotubes is a barrier to prevent CNT clustering. Less crystallizable polymers lead to composites with poorer dispersion and lower electrical conductivity. At SWCNT concentrations of 0.15wt%, SEM images of nanocomposites with the highest crystallinity matrix indicate de-bundled and uniformly dispersed nanotubes, while CNT aggregates remain in the lowest crystallinity nanocomposites. Electrical conductivity in the former is relatively high, while the latter are insulators. Also discussed is CNT dispersion from analysis of Raman spectra and polymorphism of the nanocomposites in relation to the unblended matrix.
Self-Assembling Semicrystalline Polymer into Highly Ordered, Microscopic Concentric Rings by Evaporation, MYUNGHWAN BYUN, SUCK WON HONG, Materials Science and Engineering Iowa State University, LEI ZHU, Materials and Biomolecular Engineering University of Connecticut, ZHIQUN LIN, Materials Science and Engineering Iowa State University, MYUNGHWAN BYUN, SUCK WON HONG, AND ZHIQUN LIN TEAM, LEI ZHU COLLABORATION — A drop of semicrystalline polymer, poly(ethylene oxide) (PEO) solution was placed in a restricted geometry consisting of a sphere on a flat substrate (i.e., sphere-on-flat geometry). Upon solvent evaporation from the sphere-on-flat geometry, microscopic concentric rings of PEO with appropriate high molecular weight were produced via controlled, repetitive pinning (“stick”) and denpinning (“slip”) cycles of the contact line. The evaporation-induced concentric rings of PEO exhibited a fibrillar-like surface morphology. Subsequent isotothermal crystallization of rings at 40 °C and 58 °C led to the formation of multilayer of flat-on lamellae (i.e., spiral morphology). In between adjacent spars, depletion zones were developed during crystallization, as revealed by AFM measurements. The present highly ordered, concentric PEO rings may serve as a platform to study cell adhesion and motility, neuron guidance, cell mechanotransduction, and other biological processes.

Drying-mediated Formation of “Coffee Rings” of Regioregular Conjugated Polymers, MYUNGHWAN BYUN, SUCK WON HONG, ZHIQUN LIN, Materials Science and Engineering Iowa State University, MYUNGHWAN BYUN, SUCK WON HONG, AND ZHIQUN LIN TEAM — A drop of semicrystalline conjugated polymer, regioregular poly(3-hexylthiophene) (rP3HT) toluene solution was allowed to evaporate from a confined geometry consisting of either a spherical lens or a cylindrical lens on a Si substrate (i.e., sphere-on-Si or cylinder-on-Si geometry). As toluene evaporated, mesoscale concentric “coffee rings” and fingers of rP3HT were formed as a result of controlled, repetitive “stick” and “slip” motions of the contact line. By tuning the interfacial interaction between rP3HT and the Si substrate, different surface morphologies were obtained as revealed by AFM measurements. The P3HT patterns formed on native silicon oxide surface exhibited nearly amorphous morphology, while nanorod-like structures were emerged on either HMDS treated or HF treated Si substrate.

New insight into surface melting in ultrathin polymer films: a combined surface x-ray scattering study, TADANORI KOGA, Chemical and Molecular Engineering Program, Dept of Mat. Sci. and Eng., Stony Brook University, Y. WANG, M. RAFAILOVICH, J. SOKOLOV, Dept of Mat. Sci. and Eng., Stony Brook University, A. TIKHONOVA, D. SCHULTZ, M. LEE, ChemMatCARS, The University of Chicago, X. LI, J. WANG, Advanced Photon Source, Argonne National Lab. — The crystallization of ultrathin polymer films on solid substrates has been studied for decades due to its importance in determining interfacial properties of coatings. Numerous groups have demonstrated that the rate of crystallization, crystal orientation, and density of nucleation points can be very different from bulk. We previously observed that, by using the shear modulation force microscopy (SMFM) measurements, the surface melting temperature \( T_s \) of polyethylene (PE) thin films decreased by 40 °C relative to the bulk melting temperature \( T_m \) when the thickness was close to the lamellar domain spacing (~15 nm). This large depression can’t be explained by the classical Thomson-Gibbs equation. In order to delve deeper into the mechanism of the surface melting, we integrated a variety of in-situ surface-sensitive scattering techniques, i.e., grazing-incidence x-ray diffraction (GID), grazing-incidence small-angle x-ray scattering (GISAXS), and diffuse scattering. We will present the detailed x-ray results and shed new light on the mechanism.

The Equilibrium Amorphous Fraction of Polymer Crystals, BUCKLEY CRIST, Northwestern University — Knowledge about disordered surfaces is important to the understanding of both melting and crystallization of polymer crystals. The concept of a surface roughening transition is well documented in atomic crystals; at sufficiently high temperatures, the entropic effects of a rough surface overcome the enthalpic penalty associated with atomic scale asperities. Similar effects operate when chain-like molecules crystallize. We concentrate fist on the basal surface perpendicular, or nearly perpendicular, to the molecular axes in extended chain crystals. In one case the positions of the chains are ideal, but liquid-like conformational defects are permitted near the surfaces. In the second case we add axial positional disorder to individual chains. Both models predict temperature-dependent equilibrium amorphous fractions (i.e., 0%, 1%, etc.) and could very different values. The study concludes with some comments about the equilibrium non-crystalline component of folded chain crystals.

Asymmetrical Functionalization of Nanoparticles Mediated by Polymer Single Crystals, BING LI, CHRISTOPHER LI, Drexel University — Considerable attention has been paid to nanoparticle (NP) research because of their fascinating properties and potential applications in nanotechnology and biotechnology. Asymmetrically functionalizing NP is of particular interest because it could directly lead to controlled patterning of NPs into complex structures for a variety of applications. Herein we report using 2-dimensional thiol-terminated poly(ethylene oxide) (HS-PEO) lamellar single crystals to immobilize gold NPs (AuNPs). Furthermore, this unique technique also enables asymmetric functionalization of AuNPs. Free-standing bilayer AuNP/PEO films were obtained. Dissolving PEO single crystals led to free asymmetrically functionalized AuNPs and AuNP complexes. The degree of functionalization (number of polymer chains per particle) can be readily controlled by tuning the molecular weight. The low molecular weight PEO undergoes integral folding, which leads to high areal density of thiol groups and thus the higher degree of functionalization, and vice versa. We anticipate that this methodology could be applied to other metal or semiconductor NPs.

Periodic Modification of Nanofibers by Polymer Crystallization, BINGBING WANG, CHRISTOPHER LI, Drexel University — Electrospinning polymer nanofibers are one of the most useful 1D nanometer-scaled materials that have numerous potential applications in the fields of filter applications, and templates for tissue engineering. Herein we show that polymer nanofibers can be used as 1D nucleation agents to induce polymer crystallization. Poly(ethylene oxide) was electrospun into nanofibers which was used to induce PEO crystallization in solution. Shish kebab morphology was observed with the nanofiber as the shish and the PEO lamellar crystals as the kebabs. This unique morphology was named as nano fiber kebab (NFSK). We demonstrated that the structural parameters of the NFSK such as the fiber diameter, periods, the kebab size etc. could be readily controlled by the electrospinning and crystallization conditions. This NFSK also renders 3D features to the otherwise 1D nanofibers. It also serves as a vehicle for incorporating a variety of functional groups to the nanofiber systems, which, in turn, leads to numerous biomedical as well as electronic applications.

Shear-induced orientation of poly(vinylidene fluoride-co-trifluoroethylene) thin films, HEEJOON JUNG, JIYOUN CHANG, CHEOLMIN PARK, yonsei university, NANOPOLYMERS LABORATORY, YONSEI UNIVERSITY TEAM — Control of molecular and micro structures of crystalline polymers, in particular in organic electronics, has been widely studied because of the significant influence of the electrical performance of polymers by the controlled structures. Shear technique has been known as one of the most effective methods for manipulating micro structure of many different polymers. The application of the shear method to polymer films is, however, very difficult of the thickness of less than 200nm. In order to utilize the shear method for polymer film, we designed a new shear apparatus. We have demonstrated global ordering of semi-crystalline P(VDF-TrFE), well known crystalline polymer for in non-volatile ferroelectric polymer memory, using simple static shear in large area of a few centimeter squares. The orientation, systematically examined as a function of shearing temperature, rate and film thickness, was elucidated by Atomic force Microscope and Field-Emission Scanning Electron Microscope and related to the ferroelectric polarization of a metal/ferroelectric/metal capacitor. In addition, the globally ordered thin film P(VDF-TrFE) crystal was characterized by Grazing Incident Wide Angle X-rays.
R1.00017 Surface Orientation in Injection-Molded Thermotropic Liquid Crystalline Copolyester (TLCP) Plaques. ROBERT BUBECK, Michigan Molecular Institute, JUN FANG, WESLEY BURGHARDT, Northwestern University, SUSAN BURGARD, KATHERINE ROBERTSON, Impact Analytical, DANIEL FISCHER, NIST — Attenuated total reflection Fourier transform infrared (ATR-FTIR) and 2D WAXS in transmission were used to characterize surface orientation in thermotropic liquid crystalline copolyester (TLCP) injection-molded plaques to varying depths into the samples. Injection-molded TLCPs have bimodal orientation states due to contributions from “skin” and “core” regions resulting from extensional and shear flow, respectively, in the mold. The NEXAFS is sensitive to the orientation of the molecular pi orbital of backbone phenyl groups of the top 2 nm of a surface. ATR-FTIR obtained using a Herrick SeagullTM variable angle reflectance accessory is sensitive for dichroic ratios to a depth of 5 microns. Orientation parameters derived from the 1502/cm absorption band for equivalent positions are often typically about 5 to 10 percent less by ATR-FTIR than by NEXAFS. The orientational states are being correlated with physical properties of injection-molded TLCP samples.

1 Research is supported by NSF grant #0521771.

R1.00018 Synthesis and Self-Assembly of Amphiphilic Protoporphyrin-Based Oligomers. JIAN-JUN MIAO, LEI ZHU, Institute of Material Science and Department of Chemical, Materials and Biomedical Engineering, University of Connecticut, STORRS, CT 06269-3136 — An amphiphilic discotic molecule based on asymmetric protoporphyrin has been synthesized by attaching two triethylene glycol monomethyl ether (TEG) chains to the two vinyl groups in protoporphyrin via bromination and etherification, followed by attaching two octadecylamine (ODA) chains to the two carboxylic acid groups in protoporphyrin via amidization. The purity of the sample was verified by 1H NMR, size-exclusion chromatography, and mass spectroscopy. Self-assembly in the solid state was studied by differential scanning calorimetry and X-ray diffraction (XRD). A broad melting peak was observed at ca. 100 degC, and a weak ordering was observed by XRD. Self-assembly in selective solvents was studied by dynamic light scattering and transmission electron microscopy. Large vesicles of 120 nm with a narrow distribution were observed.

1 This work was supported by NSF CAREER Award DMR-0348724.

R1.00019 Nanomechanical Measurements on Ultra-thin Poly(n-butyl methacrylate) Films. SHANHONG XU, GREGORY MCKENNA, Texas Tech University, TEXAS TECH UNIVERSITY TEAM — The mechanical properties of ultra-thin poly (n-butyl methacrylate) (PBMA) films were investigated by the novel bubble inflation technique developed in our lab. Creep experiments were performed at temperatures above the glass transition temperature (Tg) of bulk PBMA. The deflection of the film is large enough to neglect the bending stiffness of the film. Surface effects were observed to play a much more important role in the inflation of the PBMA film, than had been observed for poly(vinyl acetate) (PVAc) and polystyrene (PS) previously investigated in our labs. Estimates of the surface energy contribution to film mechanical resistance for our measurements on PBMA are approximated 50% while those for PVAc and PS were between 8 and 31% depending on the details of the testing conditions including pressure and film thickness.

R1.00020 “Phase” Behavior of Aqueous Solutions of Poly(N-isopropylacrylamide). TOMOAKI KAWAGUCHI, Department of Polymer Chemistry, Kyoto University, Japan, KUNIHIKO KOBAYASHI, MASASHI OSA, TAKENAO YOSHIZAKI — A series of linear poly(N-isopropylacrylamide)(PNI Pam) samples were prepared by living anionic polymerization. The cloud-point curves for their aqueous solutions were determined by monitoring the transmittance of light through the solutions. The transmittance decreased monotonically with increasing temperature below the cloud point, as expected, but unexpectedly, it remained at a constant value if heating was stopped at a temperature. It means that the decrease in transmittance with increasing temperature does not necessarily correspond to the phase separation, i.e., the cloud-point curve for an aqueous solution of PNI Pam is not always identical with the coexistence curve.

1 This research was supported in part by the Global COE Program “International Center for Integrated Research and Advanced Education in Materials Science” from the Ministry of Education, Culture, Sports, and Technology, Japan.

R1.00021 Effect of Intermolecular Hydrogen Bonding on the Dynamics of Poly (2-vinylpyridine) Mixtures Containing Low Molecular Weight Phenolic Compounds. PORNPEN ATORNJAWAT, Burapha University, ROBERT KLEIN, Sandia National Laboratories, AMANDA MCDERMOTT, PAUL PAINTER, JAMES RUNT, Penn State University — The dynamics of poly(2-vinylpyridine) (P2VPy) mixed with a series of low molecular weight phenolic molecules (containing one to six hydroxyl groups) were investigated using broadband dielectric spectroscopy. All mixtures, FTIR spectroscopy indicates significant intermolecular H-bonding. All mixtures were single phase except for that containing 10 mol% hexahydroxybenzophenone, which formed a H-bonded complex with P2VPy. Intermolecular hydrogen bonding resulted in significant suppression of the P2VPy local relaxation in the glassy state. The segmental relaxations for mixtures containing 30 and 50% polyhydroxy compounds where broadened, indicating dynamic heterogeneity, whereas all P2VPy - ethylphenol mixtures exhibited dynamic homogeneity. Changes in relaxation strength of the segmental process are considered in light of calculated dipole moments for all species under investigation.

1 Supported by the NSF Polymers Program, DMR-0605027.

R1.00022 Small Angle Neutron Scattering of poly (ethylene oxide) ethyl alcohol / water mixtures. SANG HAK SHIN, ROBERT BRIBER, Materials Science and Engineering, University of Maryland, College Park, MD 20742, BOULEAM HAMMOUDA, DEREK HO, National Institute of Standards and Technology, Gaithersburg, MD 20899 — PEO solutions have interesting and complex features which arise from the interplay of the hydrophilic and hydrophobic sites on the chain (the oxygen atom and alkyl group respectively). PEO in ethanol forms an opaque gel-like mixture with a partial crystalline structure as confirmed by wide angle X-ray scattering. Addition of a small amount of water disrupts the gel: PEO in ethanol with 4 vol% water becomes a transparent solution. We confirmed the crystalline structure of PEO in ethanol and investigated the PEO chain conformation in mixed ethyl alcohol / water solutions using small angle neutron scattering (SANS). We also measured the phase behavior and spinodal temperature of PEO solutions in these mixed solvents with SANS. The phase behavior changes from an upper critical solution temperature (UCST) to a lower critical solution temperature (LCST) as the fraction of water is increased. The thermodynamic behavior changes from an UCST to LCST between 5~9% volume fraction water. PEO solutions which have more than 4~10 vol% water behave as an athermal polymer solution. The proposed origin of this unusual phase behavior comes from the formation of hydration layer around the PEO chain.
R1.00023 Multiscale Computer Simulation of Failure in Aerogels, BRIAN GOOD, NASA GRC — Aerogels have been of interest to the aerospace community primarily for their thermal properties, notably their low thermal conductivities. While such gels are typically fragile, recent advances in the application of conformal polymer layers to these gels has made them potentially useful as lightweight structural materials as well. We have performed computer simulations of aerogel thermal conductivity and tensile and compressive failure, with results that are in qualitative, and sometimes quantitative, agreement with experiment. However, recent experiments in our laboratory suggest that gels having similar densities may exhibit substantially different properties. In this work, we extend our original diffusion limited cluster aggregation (DLCA) model for gel structure to incorporate additional variation in DLCA simulation parameters, with the aim of producing DLCA clusters of similar densities that nevertheless have different fractal dimension and secondary particle coordination. We perform particle statics of gel failure on these clusters, and consider the effects of differing DLCA simulation conditions, and the resultant differences in fractal dimension and coordination, on gel strength and failure mode.

R1.00024 Active substrates through controlled creasing of surface-attached hydrogels, JUNGWOOK KIM, RYAN HAYWARD, University of Massachusetts, Amherst — A hydrogel film confined to a rigid substrate may undergo a mechanical instability to form sharp creases on its surface when placed under compressive stress. We will describe how this instability can be harnessed to generate substrates with surface chemical patterns that can be dynamically hidden and displayed. We employ lithographically micro-patterned underlying substrates as a route to spatially control the formation of creases. Using surface-bound hydrogels composed of poly(N-isopropylacrylamide), we prepare temperature-responsive dynamic substrates, whose surface reversibly fold and flatten as temperature is changed. Finally, deposition of polyelectrolytes on the hydrogel surface is exploited as a way to selectively pattern the surface chemistry of the gel. We focus on the use of poly(ethylene glycol) grafted polyelectrolytes with and without the integrin-binding peptide (RGD) as a route to dynamically control cell-substrate interactions.

R1.00025 Designing Surface Instabilities as Responsive Materials, EDWIN CHAN, JEFFREY KARP, ROBERT LANGER, Massachusetts Institute of Technology — Materials with surface properties that respond to external stimuli have potential applications as sensory devices, therapeutic materials and “smart” adhesive coatings. An example of a responsive material is a topographic surface whose pattern length-scale changes drastically in response to a stimulus. A potential approach to creating such a material is to take advantage of the morphological phase transition observed in elastic instability such as surface wrinkles. In this contribution, we present a general strategy to developing a responsive surface that takes advantage of this morphological transition in a poly(ethylene glycol) based elastomer. The responsiveness of this material is designed by the reversible transition between two distinct pattern length-scales; a small length-scale pattern of a microcels array that responds to an osmotic stress and leads to morphological phase transition to a large length-scale wrinkling pattern. Both these pattern length-scales are material’s defined since the microcels array forms naturally as a result of the residual stress that develops during polymerization, while the surface wrinkles forms due to the buckling stress that develops due to the applied osmotic pressure. Finally, we show that this phase transition occurs reversibly and demonstrate potential application of the material as an alternative design of a self-cleaning surface.

R1.00026 Correlation properties of dipole systems, YURI POPOV, PHILIP TAYLOR, Case Western Reserve University — We study theoretically the effects of electrostatic dipole-dipole interactions in ionomers, and the correlation properties of dipoles attached to either low-molecular-weight fluid or polymer chains. In particular, we study orientation-orientation correlations in systems of physical (extended) dipoles with relatively weak dipole moments. Correlation corrections to the free energy in such dipole systems are different from those in systems of point charges described by the Debye theory. The underlying physics, however, is similar: nearby dipoles rearrange around a given dipole in order to compensate for changes in its dipole moment and thus provide electrostatic screening. We develop both a simple Poisson-Boltzmann-like theory for such screening and a field-theoretic approach, which provides a natural language for describing such phenomena in a polymer context. New correlation lengths are obtained.

R1.00027 Micromechanics of Yielding for Ethylene / Methacrylic Acid Ionomers, ROBERT SCOGNA, RICHARD REGISTER, Princeton University — Partially neutralizing an ethylene/methacrylic acid copolymer (E/MAA) with either sodium or zinc leads to an increase in the yield stress, by an amount which increases with the level of neutralization. This is a direct consequence of increasing nanoscale heterogeneity: the formation of ion-poor and ion-rich domains within the amorphous phase of the ionomer. This segregation is evident by dynamic mechanical testing, which reveals that, upon neutralization, the $\beta$ relaxation peak of an unneutralized E/MAA copolymer splits into two parts which represent the relaxations in ion-poor and ion-rich regions. Though both sodium and zinc cations are capable of producing this segregation, the critical degree of neutralization required to produce the split relaxation is higher for zinc. The ion-poor relaxation occurs near the $T_g$ of low-density polyethylene while the temperature of the ion-rich relaxation increases monotonically with the degree of neutralization. Thus, increasingly higher temperatures or lower strain rates are needed to fully relax the ion-rich domains as the neutralization level is increased, resulting in the higher measured yield stress.

R1.00028 Ion Conduction and Polymer Dynamics of Poly(2-vinylpyridine) - Lithium Perchlorate Mixtures1, PORNKEN ATORNGITJAWAT, Burapha University, JAMES RUNT, Penn State University — Ion conduction and polymer dynamics of single phase mixes of poly(2-vinylpyridine) (P2VPy) with 0.1 to 10 mol% lithium perchlorate (LiClO$_4$) were investigated using broadband dielectric spectroscopy. Interpretation of the relaxation behavior was assisted by findings from wide-angle and small-angle X-ray scattering experiments, and other techniques. Five dielectric relaxations were observed: a local $\beta$ process in the glassy phase, a segmental relaxation, a slow segmental process, an ion-mode relaxation, and electrode polarization. The local P2VPy relaxation was strongly suppressed with increasing LiClO$_4$ content arising from the formation of transient crosslinks, which lead to a subsequent decrease in the number of free pyridine groups, and/or a reduction in the local free volume in the presence of LiClO$_4$. Ion conduction at low LiClO$_4$ concentrations (< 10 mol%) is governed by the diffusion of anions through the matrix, which is strongly coupled with the segmental relaxation. At relatively high LiClO$_4$ concentration (10 mol%), partial decoupling between ion motion and the segmental relaxation was observed, leading to increased conductivity.

1Supported in part by the NSF Polymers Program, DMR-0605627

R1.00029 Surface Structure of Ionic Liquids Determined by X-ray reflectivity and Sum-Frequency Generation Spectroscopy, DOSEOK KIM, YOONNAM JEON, JAEOH SUNG, Department of Physics and Program of Integrated Biotechnology, Sogang University, Seoul, Korea, WEI BU, DAVID VAKNIN, Ames laboratory and Department of Physics and Astronomy, Iowa State University, USA, YUKIO OUCHI, Department of Chemistry, Nagoya University, Japan — X-ray reflectivity and surface sum-frequency generation spectroscopy were used to study the surface of [BMIM][X] ionic liquids ([BMIM] = 1-butyl-3-methylimidazolium, X = BF$_4$, PF$_6$, and I). Sum-frequency signal strength from the terminal methyl groups of the cation at the surface indicates the topmost surface of these ionic liquids are occupied by polar-oriented hydrophobic butyl domains as the neutralization level is increased, resulting in the higher measured yield stress.
R1.00030 Surface Energy Effects on Polyelectrolyte Adsorption. RYAN J. MURPHY, VIVEK M. PRABHU, DENIS PRISTINSKI, ERIC K. LIN, N.I.S.T. - Polymers Division — Fluid-based directed assembly of functional nanoparticles is a promising approach to rapid fabrication of future devices. Current approaches of precise placement of these nanoscale building blocks onto pre-defined positions formed by lithography are of current interest. These methods allow for designer surfaces containing feature sizes both chemical and topological on the nanometer length scale. However, little is known about the kinetics of self assembly of charged macromolecular building blocks. Here, we investigate the adsorption kinetics of cationic polyelectrolytes as a function of surface energy, prepared by combinatorial methods. Ellipsometry and quartz crystal microbalance are used to understand the equilibrium and dynamic behavior. Constructing the adsorption phase diagram is a crucial first step towards developing a process mechanism for the directed assembly of nanoscale building blocks with polymers and nanoparticles as model systems.

R1.00031 Generating surface energy gradients for block copolymer thin film studies. JULIE LAWSON, THOMAS EPPS, Department of Chemical Engineering, University of Delaware — The development of block copolymer materials for future nanotechnologies requires an understanding of how surface energetics affect block copolymer thin film phase behavior. Surface energy gradients allow for combinatorial studies of these effects. In this work, surface energy gradients were created by vapor deposition of functionalized chlorosilanes on UVO-cleaned silicon substrates in a chamber under a dynamic vacuum process. The diffusion profiles of the chlorosilanes were controlled by the placement of the chlorosilane reservoirs in the chamber relative to the vacuum outlet and the substrate, allowing the profile of the surface energy gradient on the substrate to be tuned. X-ray photoelectron spectroscopy (XPS) was used to examine the results of the vapor deposition process. Additionally, thin films of a poly(styrene-b-methyl methacrylate) (PS-b-PMMA) block copolymer with a bulk cylindrical morphology were flow coated onto the gradient substrates, and the resulting phase behavior was characterized with atomic force microscopy (AFM).

R1.00032 Helix self-assembly through the coiling of cylindrical micelles. SHENG ZHONG, HONGGANG CUI, Department of Materials Science and Engineering and Delaware Biotechnology Institute, University of Delaware, ZHIYUN CHEN, KAREN WOOLEY, Center for Materials Innovation, Department of Chemistry and Department of Radiology, Washington University in Saint Louis, DARRIN POCHAN, Department of Materials Science and Engineering and Delaware Biotechnology Institute, University of Delaware — Both single and double helical superstructures with the length of several micrometers have been created through solution self-assembly of cylindrical micelles for the first time. Helical micelles which occur as a racemic mixture were formed from the co-assembly of poly(acrylic acid)-block-poly(methyl acrylate)-block-polystyrene triblock copolymers with triethylenetetramine or diethylenetriamine. Kinetic study reveals that the helix cylinders evolve from the stacking of intermediate micelle domains. The helix pitch could be efficiently adjusted by adjusting the amount and type of multiamine added. For example, the pitch distance would increase nearly 20% by increasing the relative molar amount of triethylenetetramine by 50% or substituting the tetraamine triethylenetetramine by the triamine diethylenetriamine. The helical structure exhibits unprecedented regularity for a nanostructure self-assembled from solution, which is proposed to be the result of long range electrostatic interactions coupled with uniaxial tension along the cylinder.

R1.00033 Self-assembled Patterns of Block Copolymer/Homopolymer Blends. DONG SIK PARK, EROL SANCÄKTAR, University of Akron, Poly. Eng. — The addition of homopolymer (Å) into an asymmetric triblock copolymer (ABA) increases the periodic orientation normal to substrate, enabling a directed self-assembly of the block copolymers into arrays of highly oriented, high-aspect ratio cylindrical nanostructure over large areas. The application of the physical properties of block copolymers provides substantial benefits in the nanotechnologies including nanostructured membranes, nanopatterns for nanoparticle synthesis, photonic crystals, and high-density information storage media.

R1.00034 UV-convergent One-loop Theory of Homogeneous Diblock Copolymer Melts. JIAN QIN, PIOTR GRZYWACZ, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota — A renormalized one-loop theory is used to analyze collective and single chain correlations in the disordered phase of diblock copolymer melts. For chains with intermediate lengths (N ~ 1000), the deviation of the scattering intensity from predictions of the random phase approximation is found to be significant even far away from the mean field MST. The decrease in the wavenumber q* at which the scattering intensity is the maximum is shown to be a result of inter-molecular correlations, which leads to wavenumber dependent apparent q parameter, and to be unrelated to fluctuation-induced changes in single-chain correlations. The relationship to the Fredrickson-Helfand-Barrat theory is discussed.

R1.00035 Thin film effects on the morphology of diblock and triblock copolymers. KAREN SOHN, UCBS, KEN KOJIO, Nagasaki, ROBERT COFFIN, UCBS, BRIAN BERRY, NIST, GUILLERMO BAZAN, EDWARD KRAMER, UCBS, MICHAEL SPRUNG, JIN WANG, ANL — Surface effects in block copolymer thin films cause variations in the morphology from what is expressed in the bulk. The SEBS and SEB systems being studied have a composition such that both spherical and cylindrical morphologies are present in the bulk, depending on the annealing temperature. The bulk order-transition from cylinders to spheres occurs at 140°C, but in thin films the morphology is more dependent on film thickness and substrate characteristics than the annealing temperature. The morphology of thin films was studied on silicon oxide and polystyrene brushes using SFM and GISAXS. The polystyrene blocks of the SEBS and SEB were deuterated and then studied with d-SIMS in order to determine which block wets the interface with the substrate. For samples annealed at 180°C, SFM shows a cylindrical morphology on SiO2 substrates in the SEB, but a spherical morphology on the PS brush. GISAXS is used to determine whether the morphology is spheres or perpendicular cylinders. The SEBS shows a spherical morphology by SFM on both substrates.

R1.00036 A Comparative Study of Microphase Separation of Polyurethane Multiblock Copolymers with Different Soft Segment Chemistries. REBECA HERNANDEZ, CSIC Madrid, TAEYI CHOI, Penn State University, JADWIGA WEIKSLER, AJAY PADSALGIKAR, AorTech Biomaterials, LICHONG XU, CHRISTOPHER SIEDELECKI, JAMES RUNT, Penn State University — We focus in this study on three series of chemically well-defined polyurethanes (PUs) with the same hard segments (MDI-BDO) but different soft segment chemistries of interest in biomedical applications: 1000 g/mol aliphatic polycarbonate, polytetramethylenoxide and a mixed macrolol of polydimethylsiloxane (PDMS) and polyhexamethylenoxide. Using quantitative small-angle X-ray scattering we demonstrate that the degree of hard/soft segment demixing varies greatly between the materials. For example, the PDMS-based copolymers exhibit a three phase, core-shell morphology, while the other copolymers exhibit a typical two phase structure. Additional analysis was conducted with a number of experimental probes including FTIR to assess inter- and intracomponent hydrogen bonding, and tapping mode AFM to characterize the nanoscale morphology.

R1.00037 Hierarchical Self-Assembly of Block Copolymers for Lithography-Free Nanopatterning. SANG OUK KIM, BONG HOON KIM, Materials Science and Engineering, KAIST, South Korea, SANG CHUL JEON, National Nanofab Center (NNFC), Daejeon, South Korea — Development of a truly macroscopic scale nanopatterning process applying self-assembling materials has proved limited success. Hierarchical self-assembly is an alternative approach, which may produce complex architectures accommodating diverse functionalities. The mutually interacting multi-scale orderings of a hierarchical assembly may provide an opportunity to control over the diverse length scales simultaneously. We present lithography-free, truly macroscopic scale nanopatterning process utilizing hierarchical self-assembly of block copolymers. A micropatterned block copolymer film was self-organized from an evaporating block copolymer solution over an arbitrarily large area. The thickness modulation of the patterned film directed the spontaneous alignment of nanoscale morphology, producing a marvelous hierarchical morphology comprising microscale and nanoscale orderings. This facile and robust nanopatterning process employing the two levels of spontaneous orderings represents a versatile pathway to control nanoscale morphology by manipulating microscale architecture. R1.00038 Block Copolymer Micelle Shuttles with Controllable Transfer Temperature between Ionic Liquids and Aqueous Solutions1. ZHIFENG BAI, YIYONG HE, TIMOTHY LODGE, University of Minnesota — Micelle shuttle is the term we used in our recent report that amphiphilic poly((1,2-butadiene)-block-ethylene oxide) (PB-PEO) block copolymer micelles (including spheres, cylinders, and vesicles) transfer, reversibly and with preservation of micelle structures, from an aqueous phase at room temperature to a hydrophobic ionic liquid at high temperature. We further found that the micelle shuttle could be realized in other ionic liquids, indicating its generality. The driving force for the transfer mainly originates from the deteriorating solvent quality of water for the PEO corona block at high temperature. The transfer temperature could be effectively tuned by adding ionic or non-ionic additives to the aqueous phase. Such an uncommon yet simple round-trip delivery system is of specific interest in quantitatively transporting solvophobic reagents, products, or byproducts between an ionic liquid reaction medium and an aqueous introduction or purification phase.

R1.00039 Sphere-Forming and Cylinder-Forming Block Copolymer Thin Films Aligned Under Oscillatory Shear. ANDREW MARENCIC, RANULFO ALLEN, RICHARD REGISTER, Princeton University, PAUL CHAIKEN, New York University — Large-amplitude oscillatory shear has been shown to orient bulk block copolymers of spherical, cylindrical, or lamellar morphologies; however, no such experiments have been described for block copolymer thin films. Using oscillatory shear to orient microdomains would be advantageous in the creation of complex patterns especially in constrained geometries where simple shear is not possible. Here we demonstrate the ability to orient sphere-forming (trilayer) and cylinder-forming (monolayer) block copolymer thin films using oscillatory shear. The shearing field was applied to the thin film through a viscous fluid using a parallel-plate rheometer, allowing for continuous range of strain and shear rate. Real-space images were taken using atomic-force microscopy. As expected, a minimum strain within the film is required to induce ordering. We also observed that a larger stress is required to orient these thin films using oscillatory shear when compared to simple shear experiments. We also investigated how the ordering evolves with the number of cycles of shear applied to the film.

R1.00040 Hydrogenated ROMP Block Copolymers as Thermoplastic Elastomers. JOHN BISHOP, RICHARD REGISTER, Princeton University — Thermoplastic elastomers (TPEs) are typically symmetric ABA triblock copolymers made up of a “soft” rubbery midblock (B) and “hard” endblocks (A) that are usually glassy. We have used living ring-opening metathesis polymerization (ROMP) and subsequent hydrogenation to synthesize TPEs with semicrystalline “hard” blocks. The hydrogenated ROMP polymers we use include hydrogenated poly(methylacrylate) (hPMA), a highly crystalline polymer with \( T_m = 143 \)C; hydrogenated polyhexylmethacrylate (hPHM), a rubbery amorphous polymer with \( T_g = -22 \)C; and hydrogenated polyethylene glycol (hPEG), a glassy polymer with \( T_g = 183 \)C. The mechanical properties of our amorphous hPMMA-hPN-hPMMA TPEs, where microphase separation is driven by interblock repulsion, are comparable to commercially-available TPEs (also amorphous) at room temperature. In analogous hPMA-hPMMA-hPMA triblocks, where the endblocks are crystalline instead of glassy, microphase separation is driven by crystallization from a homogeneous melt, resulting in materials that are much easier to process, and with superior solvent resistance. However, the hPN endblocks show plastic deformation at moderate strains, yielding tensile strengths for the semicrystalline TPEs below those of their amorphous counterparts.

R1.00041 Composition Distributions and Effective Concentration of Miscible Polymer Blends Probed by MD Simulation. WENJUAN LIU, RALPH COLBY, Department of Materials Science and Engineering, The Pennsylvania State University, DMITRY BEDROV, Department of Materials Science and Engineering, University of Utah, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, THE PENNSYLVANIA STATE UNIVERSITY TEAM, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING, UNIVERSITY OF UTAH TEAM — Using molecular dynamics we simulate the effects of thermally-driven concentration fluctuations and chain connectivity on segmental dynamics of miscible weakly interacting polymer blends. These naturally lead to local variations in glass transition temperature and hence, a distribution of segmental relaxation times. The self-convolution and pure component limits naturally truncate the Gaussian distribution of compositions surrounding a given segment. The most-probable composition differs considerably from the mean-field estimation of Lodge and McLeish for blend compositions that differ from 50/50, when we consider chain connectivity effects for all chains in the control volume.

R1.00042 Phase diagram of a binary liquid crystal mixture involving induced mesophase transitions1. TSANG-MIN HUANG, THEIN KYU, University of Akron, SHILA GARG, KATHY MCREARY, The College of Wooster, UNIVERSITY OF AKRON COLLABORATION, THE COLLEGE OF WOOSTER COLLABORATION — Phase transition temperature versus composition phase diagram of a binary nematic mixture (MBBA/5CB) has been established based on polarized optical microscopy and differential scanning calorimetry. The observed phase diagram is of an azeotrope type with a unique induced smectic phase, which is not present in neat constituents. This induced mesophase reveals a mosaic texture reminiscent of a smectic-B or a higher order smectic phase. At extreme compositions, the coexistence of nematic and solid crystal phases can be identified. Wide-angle x-ray diffraction was employed to determine the ordered mesophase structures. A theoretical model is being developed in the context of Flory-Huggins theory for liquid-liquid demixing in conjunction with a modified Maier-Saupe-McMillan theory to elucidate the interplay among nematics, higher order smectics, and eutectic crystals.

R1.00043 Dynamic Heterogeneity in Interacting Miscible Polymer Blends1. ASHISH GAIKWAD, TIMOTHY LODGE, University of Minnesota — Dynamic heterogeneity leading to time-temperature superposition (tTS) failure has been widely reported in non-interacting/weakly interacting miscible polymer blends. However, coupling of the component dynamic response in blends, even with a huge dynamic asymmetry in the pure components, is possible with H-bonding interactions. This study is focused on finding the minimum level of interaction necessary for thermo-rheological simplicity in blends. Blends of styrene-co-vinylphenol (PSVPh) and poly(vinyl methyl ether) (PVME) were chosen. Incorporation of styrene provides an effective way to modulate H-bonding interactions in the system. Linear viscoelastic data indicate that tTS fails for PS/PVME blends, whereas data obtained for different PVPh/PVME blends showed that tTS was obeyed over wide temperature range. For PVPh/PVME blends with low PSVPh content, tTS was successful. This suggests that the presence of alternating styrene and vinyl phenol units was insufficient for dynamic response decoupling. Further studies are in progress, with varying vinyl phenol content in PSVPh, to explore the influence of H-bonding on dynamic heterogeneity and blend dynamics.

R1.00044 Induced Mesophase in Mixtures of Photopolymerizable Hyperbranched Polyester and Liquid Crystal Mesogen

NAMIL KIM, THEIN KYU, University of Akron, MAMI NOOAKA, HIROTO KUDO, TADATOMI NISHIKUBO, Kanagawa University — Phase behavior of a mixture of eutectic liquid crystals (E7) and hyperbranched polyester (HBPEAc-CoOH) has been investigated using polarized optical microscopy and differential scanning calorimetry. The observed phase diagram is an upper azeotrope, exhibiting the coexistence of nematic + isotropic phase in the vicinity of 90–110°C above the clearing temperature of neat E7 (60°C). With decreasing temperature a focal-conic fan shaped texture develops in the composition range of 70–90 wt% of E7, suggestive of induced smectic S_{α}. A phase in the mixture containing no known smectic phase in their neat forms. Wide angle x-ray diffraction (WAXD) technique revealed the existence of higher order mesophase(s). The phenomenon of induced mesophase in the hyperbranched polyester/E7 system will be discussed.

R1.00045 Interfacial slip in polymer blends with nanoparticles

JOSEPH ORTIZ, Dept of Materials Science and Engineering, Stony Brook University, Stony Brook, NY 11794, EIHAB JABER, Dept. of Chemistry, Worcester State College, Worcester, MA 01602, DILIP GERSAPPE, Dept. of Materials Science and Engineering, Stony Brook University, Stony Brook, NY 11794 — The interfacial region in polymer blends has been identified as a low viscosity region in which considerable slip can occur when the blend is subjected to shear forces. Here, we use Molecular Dynamics simulations to establish the role that added nanoparticles play in modifying the interfacial rheology. By choosing conditions under which the fillers are localized either in the two phases, or at the interface we can look at the interplay between the strengthening capability of nanoparticles, and the change in the interfacial slip behavior. We examine particle size, attraction between the particle and the polymer component and the amount of filler in the material. Our studies are performed both above and below the point at which the filler particles form a transient network in the blend.

R1.00046 X-ray characterization of hybrid PEO-clay nanocomposite films

EDUARD A. STEFANESCU, IOAN I. NEGULESCU, WILLIAM D. DALY, Department of Chemistry, Louisiana State University, Baton Rouge, LA 70803 — The objective of the present contribution is to understand how clays with different chemistry, sizes and surface areas interact with each other and affect the structure and characteristics of polymer based nanocomposite multilayered films. In order to search for new synergistic properties and/or improve the properties of nanocomposite films already known, here we study polymer nanocomposites that have Laponite as well as Montmorillonite incorporated in various ratios. Although the polymer-clay solutions that are used to fabricate the nanocomposite films are completely exfoliated, XRD measurements confirm that all our dried multilayered films are highly exfoliated. Although the polymer-clay system per se has already been known, here we study polymer nanocomposites that have Laponite as well as Montmorillonite incorporated in various ratios. We use X-ray scattering to establish the role that the phase sequence of the multilayered samples plays in determining the mechanical properties of the multilayered films.

R1.00047 Interfacial and random field effects in polymers filled with nanoparticles

FOUAD ALIEV, VLADIMIR DOLIDZE, IVAN JOEL LOPEZ, University of Puerto Rico — We report on the influence of filling of poly(n-alkyl methacrylates) with nanoparticles on glass transition and relaxation processes, as investigated by dielectric spectroscopy and DSC. In order to estimate the role of interfacial effects at nanoparticle-polymer interface we used two types of Aerosil particles: with hydrophilic and hydrophobic surfaces. The agglomeration even of 2-3 volume percent of Aerosil particles in polymer forms a 3D-network dividing the polymer into random domains with liner size of several hundred nm, depending on the concentration of filling particles. The result of the filling of polymer is at least two fold: random field effects imposed by network and very developed area of the particles surface imposes interfacial effect on polymers. The relaxation times of α-relaxation process (sensitive to glass transition) in both filled polymers are faster than those of bulk polymers measured at the same temperatures. This might be interpreted as reduction of glass transition temperature in filled polymers. Semiquantitatively this reduction is in accordance with the Vogel-Fulcher data analysis of the temperature dependencies of bulk polymers measured at the same temperatures. Here, we extend these concepts to develop a model for the behavior of PNC T_{g}. The placement of impurities (nanoparticles) in a lattice (polymer matrix) changes the percolation threshold of the system, which we claim can be related to a change in T_{g}. Specific treatments of the impurities can result in either increases or decreases in T_{g} relative to the pure system, and the magnitude of the changes in T_{g} are related to the size and shape of the lattice impurities. We discuss the details of our results for such effects and compare them to experimental observations reported for PNCs.

R1.00048 Polymer nanocomposite (PNC) T_{g} from the perspective of percolation theory

JAMIE KROPKA, The University of Texas at Austin, PETER GREEN, The University of Michigan, VENKAT GANESAN, The University of Texas at Austin — A number of researchers have speculated on the connections between the liquid to glass transition and percolation concepts. Most recently, the film thickness dependence of T_{g} exhibited by polymers has been quantified in terms of the change in percolation threshold when transitioning from a 3D to 2D system. Here, we extend these concepts to develop a model for the behavior of PNC T_{g}. The placement of impurities (nanoparticles) in a lattice (polymer matrix) changes the percolation threshold of the system, which we claim can be related to a change in T_{g}. Specific treatments of the impurities can result in either increases or decreases in T_{g} relative to the pure system, and the magnitude of the changes in T_{g} are related to the size and shape of the lattice impurities. We discuss the details of our results for such effects and compare them to experimental observations reported for PNCs.

R1.00049 Effect of shear on the rheological and electrical properties of epoxy/MWCNTs dispersions

SAMEER S. RAHATEKAR, NIST, K. K. KOZIOL, ALAN H. WINdle, University of Cambridge, ERIK K. HOBie, Jeffery W. Gilman, NIST — We report the rheological, electrical and associated microstructural properties of multiwall carbon nanotubebased (MWCNTs) suspensions in an epoxy resin under shear. Above a critical concentration, we find a network of MWCNT aggregates with enhanced conductivity and viscosity. High shear results in MWCNT dispersion, with shear thinning and low electrical conductivity. The influence of MWCNT concentration and length on the scaling behavior of the elastic shear modulus is studied, and the role of individual MWCNTs is discussed. Further, we find significant differences in the scaling of the elastic shear modulus for different MWCNT lengths. Finally, we carry out small angle neutron scattering (SANS) in an attempt to establish a quantitative relationship between MWCNT microstructure and the corresponding rheological and electrical properties.

R1.00050 The amount of immobilized polymer in PMMA SiO\textsubscript{2} nanocomposites determined from caloricimetric data

CHRISTOPH SCHICK, ALBERT SARGSYAN, ANDREAS WURM, University of Rostock, Germany, SEVAN DAVTYAN, ANAHIT TONOYAN, SEUA, Yerevan, Armenia — The existence of an immobilized fraction in PMMA SiO\textsubscript{2} nanocomposites was shown on the basis of heat capacity measurements at the glass transition of the polymer. The results were verified by enthalpy relaxation experiments below the glass transition. The immobilized layer is about 2 nm thick at low filler content; agglomeration is not dominant. The thickness of the layer is similar to that found in semicrystalline polymers and independent of the shape of the nanoparticles. Nanocomposites therefore offer a unique opportunity to study the devitrification of the immobilized fraction (RAFT) without interference of melting of crystals as in semicrystalline polymers. It was found that no devitrification occurs before degradation of the polymer. No gradual increase of heat capacity or a broadening of the glass transition was found. The cooperatively rearranging regions (CCR) are either immobilized or mobile. No intermediate states are found. Sargsyan A, Tonoyan A, Davtyan S, Schick C. European Polymer Journal 2007-43:3113-3127.

R1.00051 ABSTRACT WITHDRAWN
R1.00052 “Cooperative” Relaxation Induced High Room-Temperature Dielectric
Constant in Supramolecular Diblock Copolymer Assembly

WEI CHEN, JIA-YU WANG, THOMAS RUSSELL, University of
Massachusetts, Amherst — The development of high-dielectric-constant polymers as active materials in high-performance devices is one of the challenges in
diﬀerent nanoscopic phases. Here, we report the development of high-dielectric-constant copolymers with a dielectric constant close to 50 at frequencies lower than 100 Hz. This is comparable with that of ferroelectric poly(vinylidene fluoride-
trifluoroethylene-chlorofluoroethylene) (PVDF-TrFE-CFE) terpolymer (40–60) and larger than those of PVDF (~10) and PVDF-TrFE (~20). Such a high
temperature-dielectric constant arises from the cooperative secondary relaxation between two blocks which increases the relaxation amplitude of CSA and
DY7, both of which have large dipole moments.

R1.00053 Electric Field Enhanced Diffusion of Salicylic Acid through Polyacrylamide Hydro-
gels
SUMONMAN NIAMLANG, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — The release mechanisms and the enhancement of salicylic acid - loaded polyacrylamide hydrogels were investigated experimentally by using a modified Franz-diﬀusion cell at 37 ◦ C to determine the eﬀects of crosslinking rate and electric field strength. A signiﬁcant amount of salicylic acid is released within 48 hours from the hydrogels of various crosslinking ratios, with and without electric ﬁeld. The release characteristic follows the Q vs. t^{1/2} linear relationship. Diﬀusion coeﬃcient initially increases with increasing electric
ﬁeld strength and reaches the maximum value at electric field strength of 0.1 V; beyond that, it decreases with electric ﬁeld strength and becomes saturated at electric field strength of 5 V. The diﬀusion coeﬃcient increases at low electric field strength (less 0.1 V) as a result of the electrophoresis of the salicylic acid, the expansion of pore size, and the induced pathway in pigskin. For electric field strength higher than 0.1 V, the decrease in the diﬀusion coeﬃcient is due to the pressure increase of the polyacrylamide pore size. The diﬀusion coeﬃcient obeys the scaling behavior D/D_0=(drug size/pore size)^m, with the scaling exponent m equal to 0.93 and 0.42 at electric ﬁelds of 0 and 0.1 V, respectively.

R1.00054 Induced Interaction of NH4NO3 With Poly(p-phenylene vinylene) by means of Ze-
olite Y. JIRARAT KAMONSANWAS, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — Conducting polymers are unique among the sensing materials known to us at present. They have many advantages over conventional metal sensors. Poly(p-phenylenevinylene) (PPV) can serve as the active material in sensor devices because PPV possesses good optical and electrical properties, and it can be synthesized by a relatively simple technique. Zeolite is chosen as inorganic ﬁller to be introduced into the conductive polymer matrix in order to increase electric sensitivity toward ammonium nitrate vapour. The objective of our work is to investigate the eﬀects of Si/Al ratio and cation type on the gas electrical conductivity sensitivity towards ammonium nitrate and corresponding interactions.

R1.00055 Styrene-Isoprene-Styrene Triblock Copolymer (SIS)/Polydiphenylamine Blends for
Actuator Application
KRAIPOP THONGSAK, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — Styrene-Isoprene-Styrene triblock copolymer (SIS) is a dielectric material exhibiting many properties similar to polystyrene elastomer, which has been widely studied for electroactive applications. In our work, SIS films were prepared via ﬁlm casting at various polystyrene (PS) contents (19 wt. %, 29 wt. %, and 44 wt. %), yielding three diﬀerent morphology ﬁlms as characterized by an optical microscope, SEM, and TEM. Polydiphenylamine (PDPA), a conductive polymer, was synthesized by the oxidative polymerization and doped with HCl. For electroactive applications, electrochemical properties of pure SIS films and SIS/PDPA blends under stretching at a ﬁxed temperature of 25 ◦ C were measured to determine the eﬀects of morphology (spherical, cylindrical, and lamella morphology), particle concentration, and doping level on the electrochemical properties measured: the storage and the loss moduli (′G′ and ′G′), the storage modulus responses (∆G/2kV/mm), and the storage modulus sensitivities (∆G/2kV/mm/G/0), under applied electric ﬁeld strength varying from 0 to 2 kV/mm.

R1.00056 The eﬀects of monomer sequence distribution and isotopic substitution on solution
phase behavior of random copolymers
YOUNG KUK JHON, NCSU, RAMANAN KRISHNAMOORTI, U. of Houston, JAN GENZER, NCSU — We report on the eﬀect of chemical composition, co-monomer distribution and H/D isotopic substitution on the phase behavior in copolymers of poly(styrene-co-4-bromostyrene) (PBrS), where x denotes the mole fraction of 4-bromostyrene (4-BrS), in cyclohexane. By adjusting the solvent quality during bromination of parent polystyrene, either random or random blocky PBrS, (r-PBrS or b-PBrS, respectively), were synthesized. We studied the temperature dependence of phase behavior of PBrS with various x in cyclohexane as a function of the polymer concentration using light scattering. Our results reveal that for a given 4-BrS content, the cloud points of b-PBrS solutions are consistently higher and broader than those observed in r-PBrS solutions. The transition temperature has also been found to depend on the isotope substitutions of H or D in the polymer or the solvent. Small angle neutron scattering measurements indicate signiﬁcant diﬀerences in the temperature dependence of the thermodynamic behavior for the random and blocky samples and the nature of the ﬂuctuations upon approaching the phase boundaries.

R1.00057 The Antimicrobial Activity of Porphyrin Attached Polymers
LESLEY THOMPSON — We are interested in testing the antimicrobial activity of a porphyrin that is attached to a polymer. The porphyrin (5-(4-carboxyphenyl)-10,15,20-tris-(4-pyridyl)) was synthesized from methyl 4-formyl benzoate, 4-pyridinecarbonaldehyde, and pyrrole and attached to a copolymer of poly(styrene/poly(vinyl benzyl chloride), which was synthesized by free radical polymerization. The antimicrobial activity of the polymer-attached porphyrin was then determined for gram-negative E. Coli grown to 0.80 OD. In this procedure, glass slides were coated with polymer-attached porphyrin via dip-coating, and the E. Coli bacteria were plated in Luria Broth media. The plates were subsequently exposed to light overnight before they were incubated as porphyrins act as photo-sensitizers when irradiated with light. The polymer-attached porphyrin did exhibit antimicrobial activity and parameters that aﬀect its eﬃciency will be discussed.

R1.00058 Mesoscale Patterns Formed by Evaporation of a Polymer Solution in the Proximity
of a Sphere on a Smooth Substrate: Molecular Weight and Curvature Eﬀects
SUCK WON HONG, JIANFENG XIA, MYUNGHWAN BYUN, QINGZE ZOU, ZHIQUN LIN, Iowa State University — A drop of polymer solution was constrained in a sphere-on-flat geometry, resulting in a liquid capillary bridge. As solvent evaporated, intriguing surface patterns of polymer formed, which were strongly dependent on the molecular weight (MW) of polymer. Dotted arrays were formed at low MW; concentric rings were produced at intermediate MW; concentric rings, rings with fingers, and punch-hole-like structures, however, were yielded at high MW. Rings with fingers as well as punch-hole-like structures were manifestations of simultaneous occurrence of the “stick-slip” motion of the contact line and the fingering instabilities of rings. In addition, the curvature of the sphere in the sphere-on-flat geometry was found to aﬀect the pattern formation. A decrease in the curvature of the sphere led to an earlier onset of the formation of punch-hole-like structures when high-MW polymer was employed as the nonvolatile solute.
R1.00059 Thermal-reversible, size-selective desorption of nanoparticles from polymer brushes. RICHARD VAIA, STEVE DIAMANTI, Air Force Research Lab, WPAFB, SHAFI ARIFUZZAMAN, JAN GENZER, Dept. Chem. & Biomolec. Eng, NCsu — The ability to reversibly modulate surface energy and chemistry will provide new opportunities for future separation and sensing technologies. Post-polymerization functionalization of covalently-tethered polymer brushes affords a robust platform technology for these goals. Using standard succionimide-based coupling, hydroxyl pendants of poly(2-hydroxyethyl methacrylate) (PHEMA) brushes were conjugated to oligo-peptides, alkanes, fluoroalkanes, and oligo(ethylene glycol) (OEG) through an alpha-terthienyl primary amine. Coupling of these three different chemical moieties allows tailoring of the surface energy ($\gamma_{LV}^{\infty}$) $\sim$ 40-110 mJ/m$^2$, that combined with PHEMA grafting density and molecular weight (MW), leads to tunable adsorption of analytes. OEG-modified PHEMA brushes exhibit thermal-reversible desorption of analytes that is size-selective. For example, Au NPs of larger size are liberated from the brushes at shorter heating times; hence mixtures of Au NPs of different sizes can be sequentially released by controlling substrate heating. The impact of electrolyte content, Au NP surface chemistry, coupling efficiency and OEG MW is discussed to elucidate the detailed molecular mechanisms dominating the size and temperature-dependent OEG-Au NP binding efficiency.

R1.00060 SANS from CO$_2$-saturated coals at conditions relevant to subsurface sequestration. YURI MELNICHENKO, ORNL, ANDRZEJ RADLINSKI, Geoscience Australia, GANG CHENG, ORNL, MARIA MASTALERZ, Indiana Geological Survey, GEORGE WIGNALL, ORNL. — Carbon dioxide (CO$_2$) is the greenhouse gas which makes the largest contribution to global warming and roughly one third of the United States’ CO$_2$ emissions are generated by fuel-burning power plants. Capture and storage of CO$_2$ in underground geologic structures may significantly reduce CO$_2$ emissions to the atmosphere. Sequestration of CO$_2$ in mineable deep coal seams is particularly attractive as many coal-burning power plants are located near sites potentially suitable for geological storage. It is widely assumed that CO$_2$ can be captured and retained in coals by virtue of several mechanisms, such as fluid trapping of an “imobile phase” inside the pore space, adsorption to the pore surface and chemical bonding inside the organic coal matrix in the vicinity of pore walls. We report the results of the first small-angle neutron scattering (SANS) studies of several coals saturated with CO$_2$ at temperatures and pressures similar to those found in deep coal seams which are likely to be used for industrial-scale underground storage of CO$_2$. We found that the porous coal matrix may work to create absorbed fluid phase with the physical density much exceeding the density of the bulk fluid at the same thermodynamic conditions. Fluid densification is different in different coals which may explain the observed differences in sorption capacity and migration rates.

R1.00061 Selective excitation of excitonic transitions in PTCDA crystals and thin films. V.R. GANGILENKA, A. DESILVA, LYUBOV V. TITOVA, L.M. SMITH, H.P. WAGNER, Department of Physics, University of Cincinnati, Cincinnati, Ohio 45221-0114, U.S.A., R. SCHOLZ, Walter Schottky Institute, Technical University of Munich, 80333 Munich, Germany. — We study various exciton transitions in PTCDA crystals and in thin films at low temperatures (≤ 5 K) by photoluminescence excitation spectroscopy (PLE) using DCM and RG6 dyes. The investigated PTCDA crystals are grown by sublimation and thin films are deposited on Si substrate by organic molecular beam deposition (OMBD) at high vacuum. The PLE excitation energy ranging from 1.878 to 2.172 eV enables the selective excitation of Frenkel excitons and of charge transfer transitions between PTCDA molecules in the same unit cell (CT1) as well as between stacked molecules along the growth direction (CT2). The observed excitation energy dependence of the emission bands supports the assignment of the different recombination channels obtained from time resolved PL measurements [1]. [1] A. Yu. Kobitski, R. Scholz, I Vragovic, H. P. Wagner, and D. R. T. Zahn, Phys. Rev. B 66, 153204 (2002).

R1.00062 Variable-Density Micelle Arrays in Block Copolymer Thin Films. JOHN PAPALIA, DOUGLAS ADAMSON, RICHARD REGISTER, Princeton University, PAUL CHAIRIN, New York University — Thin films of sphere-forming block copolymers are attractive templates for surface patterning and nanofabrication. Control over both the sphere (micelle) diameter and their average spacing (areal density). Within a given film, these quantities are statistically uniform: that is, there has not previously been a way to vary the number density of spheres across the film. By contrast, films having a thickness gradient are straightforward to prepare; however, regions of the film whose thickness is not commensurate with an integer number of layers of spheres will spontaneously form micron-scale islands or holes (terraces) of commensurate thickness, and a uniform areal density. By blending the block copolymer with matrix homopolymer, this terrace formation can be suppressed, so that creating a gradient in film thickness will also produce a gradient in micelle density. We employ a polystyrene-polysoprene diblock copolymer with block molecular weights of PS/PI 68/12 kg/mol, blended with PS homopolymer of varying molecular weights, in gradient films spanning thicknesses from 0-3 layers of spheres. At 50% PS homopolymer, terraces are still observed for homopolymer molecular weights in the “wet” brush region (9-50 kg/mol), but are completely suppressed when the homopolymer is excluded from the micelle corona (110 kg/mol).

R1.00063 ABSTRACT WITHDRAWN

R1.00064 Nanohole Structure in Polystyrene-block-poly(methyl methacrylate) Thin Film. WONCHUL JOO, SEUNG YUN YANG, JIN KON KIM, Pohang Univ. Sci. Tech., HIROSHI JINNAI, Kyoto Institute of Technology — Cylindrical nanoporous structures were prepared by using the mixture of polystyrene-block-poly(methyl methacrylate) (PS-b-PMMA) copolymer and PMMA homopolymer, and they were analyzed by using transmission electron microtomography and X-ray reflectivity. Two methods were employed for nanoporous structures: (1) whole PMMA phase was removed by UV irradiation and (2) only PMMA homopolymer was removed with selective solvent. We found that the nanoporous structure in the film prepared by method (1) exhibited cylindrical shape through the entire the film thickness. On the other hand, when the nanoporous film was prepared with the selective solvent, nanoporous structures exhibited a funnel-shape that the diameter of nanoholes located near the top of the film is larger than that located near the bottom of the film.

R1.00065 Thickness Dependence of Fluorescence Dynamics in Thin and Ultrathin Polystyrene Films. YOHEI TATEISHI, YOHEI OKADA, KEJII TANAKA, TOSHIHIKO NAGAMURA, Kyushu University — Fluorescence dynamics such as lifetime and rotational relaxation time for 6-(N-(7-nitrobenz-2-oxa-1,3-diazol-4-yl)amino) hexanoic acid (NBD) in polystyrene (PS) solid was examined as a function of film thickness, t. Both times decreased with decreasing thickness once the film became thinner than a critical value, t. Interestingly, in the case of ultrathin films, both times were insensitive to the film thickness. In addition, fluorescence intensity per unit thickness also decreased with decreasing thickness at t ≲ 50 nm, meaning that the fluorescence quantum yield was dependent on the thickness at t ≲ 50 nm. These results could be explained in terms of a simple three-layer model composed of surface, bulk and interfacial layers.

R1.00066 Interfacial Characterization of Poly(methyl methacrylate) with Non-solvents. YOSHI-HISA FUJII, HIRONORI ATARASHI, Kyushu University, MASAKIRO HINO, Kyoto University, KEJII TANAKA, TOSHIHIKO NAGAMURA, Kyushu University — Density profiles of a deuterated poly(methyl methacrylate) (dPMMA) film in water, hexane and methanol, which are “non-solvents” for dPMMA, were studied by neutron reflectivity (NR). The interfaces of dPMMA with the liquids were diffuse in comparison with the pristine interface with air; the interfacial width with water was thicker than that with hexane. Interestingly, in water, the dPMMA film was composed of a swollen layer and the interior region, which also contained water, in addition to the diffused layer. The interface of dPMMA with hexane was sharper than that with water. Although there were slight indications of a swollen layer for the dPMMA in hexane, the solvent molecules did not penetrate significantly into the film. On the other hand, in methanol, the whole region of the dPMMA film was strikingly swollen. The modulus of dPMMA in the vicinity of the interfaces with liquids was also examined on the basis of force-distance curves measured by atomic force microscopy. The modulus decreased closer to the outermost region of the film. The extent to which the modulus decreased in the interfacial region was consistent with the amount of liquid sorbed into the film.
R1.00067 Two photon absorption in PTCDA films using the z-scan technique, A.M. AWARD, V.R. GANGILENKA, Department of Physics, University of Cincinnati, Cincinnati, Ohio 45221, U.S.A., H. SCHMITZER, Department of Physics, Xavier University, Cincinnati, Ohio, 45207, U.S.A., H.P. WAGNER, Department of Physics, University of Cincinnati, Cincinnati, Ohio 45221, U.S.A. — The two-photon absorption coefficient of a polycrystalline PTCDA (pyrene-3,4,9,10-tetracarboxylic-3,4,9,10-dianhydride) thin film was measured at 880 nm using the z-scan technique. The 2 µm thick PTCDA film was grown by organic molecular beam deposition (OMBD) on Pyrex. For the z-scan measurements ~1 ps pulses were focused onto the thin film using a microscope objective lens (100x) of numerical aperture 0.55 and a beam waist of 1 µm. The films have been moved by a translation stage with a travel range of 100 µm and with a step size of 0.5 µm. The two-photon absorption coefficient of PTCDA obtained from a fit with open aperture measurements at different intensities results to ∼100 cm GW⁻¹. The z-scan measurements demonstrate that crystalline PTCDA films possess strong nonlinear optical properties that might be utilized for optical applications.

R1.00068 Chemical Branching/Crosslinking of Preformed Polymers Using bis-Benzophenone1, NICHOLAS CARBONE, Columbia University, MARY DICKSON, Columbia University, JEFFREY COBERSTEIN, Columbia University — We show that bis-benzophenone (bis-BP) is an effective method to photochemically crosslink essentially any reformed polymer system that contains abstractable hydrogen atoms. When bis-BP is mixed into a polymer and exposed to UV radiation, it absorbs hydrogen atoms from any chains in proximity, thereby initiating a cascade of free radical reactions that include several mechanisms that can lead to covalent polymer crosslinking. Herein we study the early stages of branching reactions that precede gelation by following molecular weight changes in bis-BP modified polystyrene (PS) by Gel Permeation Chromatography. Quantitative molecular weight changes in PS-bis-BP thin films are studied as a function of irradiation time, PS-bis-BP molar ratio, and film height. AFM studies are employed qualitatively to investigate the relationship between molecular weight and the degree of dewetting of thin PS films deposited on silicon wafers.

R1.00069 Toward a minimum criteria of multi dimensional instanton formation for condensed matter systems?, ANDREW BECKWITH, APS/ Contractor, FNAL — We present near the end of this document a promising research direction as to how to generalize a technique initially applied to density wave current calculations to questions of instanton formation in multi dimensional condensed matter systems. Initially we review prior calculations done through a numerical simulation that the massive Schwinger model used to formulate solutions to CDW transport in itself is insufficient for transport of soliton-antisoliton (S-S’) pairs through a pinning gap model of CDW transport. Using the Peierls condensation methodology is implemented. The methodology is found to produce KWW fits of high accuracy. Moreover, the stretching parameter, β, is found to

R1.00070 The Anomalous Translocation Dynamics of Long-Chain Molecules, SRABANTI CHAUDHURY, BINNY J. CHERAYIL, Dept. of Inorganic and Physical Chemistry, Indian Institute of Science, Bangalore 560012, India — Models of translocation based on simple Brownian diffusion mechanisms generally fail to account satisfactorily for anomalies in measured and simulated values of the average time of passage of long chain molecules through narrow pores. In an effort to rationalize these anomalies, we formulate an alternative model in which the time evolution of the number of monomers on one side of the pore is governed by the stochastic dynamics of a particle moving in a linear potential under the action of thermal fluctuations with long-ranged temporal correlations. We use this model in the limits of strong and weak diffusive bias to derive closed form expressions for the mean first passage time for pore crossing and the mean square displacement of a monomeric segment. These expressions, unlike those obtained from fractional Fokker-Planck formulations of the problem, are well-defined everywhere, and are also consistent with available numerical data.

R1.00071 Electric Field and Electron-Electron Interactions Effects on Bipolaron Transport in Polythiophene1, YAPING LI, JOLANTA LAGOWSKI, Memorial University of Newfoundland — Polythiophene is one of the most widely used organic conjugated polymer. Its charge transport mechanism has been a subject of many intensive studies. We employ the extended Su-Schriefer-Heeger’s theoretical model (SSH), including electric field and electron-electron interactions, to study bipolaron transport in polythiophene. This model involves the solution of coupled equations, consisting of the time-dependent Schrodinger equation and the classical motion equation for the lattice displacement, which are solved numerically in a self-consistent way. The time-dependent unrestricted Hartree–Fock approximation is also used. The parameters employed in the computations are determined by requiring good agreement with theoretical and experiment values for band gap and bond lengths. We find that a bipolaron does not distort significantly under weak electric field, however, a strong electric field can dissolve it, transforming localized charges into free charges. Electron-electron interactions do not significantly affect the nature of bipolaron transport in polythiophene.

R1.00072 Theoretical studies of the structures and optical properties of the dimers of the fluorene and carbazole derivatives, JOLANTA LAGOWSKI, Memorial University of Newfoundland, ZHIJUN GONG, Yangtze University — The intrinsic properties of the ground and excited states of fluorene, carbazole, fluorene-vinylene and fluorene-acetylene dimers and fluorene-carbazole unit are studied. The ground state optimized structures and energies are obtained using the molecular orbital theory and the density functional theory (DFT). The ground state potential energy curves of the dimers are also obtained. All molecules are nonplanar in their electronic ground states. The character and energy of the first 20 singlet-singlet electronic transitions are investigated by applying the time-dependent DFT approximations to the correspondingly optimized ground state potential energy curves of the dimers. The lowest singlet state is studied with the configuration interaction (singles) approach (CIS). CIS results suggest geometry relaxation in the first singlet excited state.

R1.00073 Orientational Relaxation in Simulated Polymer Melts, TAYLOR DOTSON, JOHN MCCOY, New Mexico Tech, JOANNE BUDZIEN, DOUGLAS ADOLF, Sandia National Laboratories, KEENAN DOTSON, JULIEANNE HEFFERNAN, New Mexico Tech — The orientational relaxation of simple polymer chains was studied using second Legendre polynomial autocorrelation functions. Such functions are commonly fit with a Kohlrausch-Williams-Watts (KWW) stretched exponential form. The value of the stretching parameter, β, and the degree that it changes as the glass transition is approached are both of physical interest. In the current project, a novel approach to determining the value and variation of β from molecular dynamics simulations is implemented. The methodology is found to produce KWW fits of high accuracy. Moreover, the stretching parameter, β, is found to collapse to a single-valued function of the decay timescale r regardless of thermodynamic path. Connections are drawn to experimental results and theoretical implications of the research are discussed.

R1.00076 Brownian dynamics simulations of tethered polymers on curved surfaces , MARGARET LINAK, MARTIN KENWARD, KEVIN D. DORFMAN, Department of Chemical Engineering and Material Science, University of Minnesota — Surface tethered polymers are an important component in many physical systems, including coating applications, microfluidic devices, drug delivery vehicles and molecular targets in DNA microarrays. The recent renewed interest in low-density tethered polymers (i.e., below the characteristic surface density of a polymer brush) is partially attributed to their applicability in the latter circumstances. We present a study of an isolated polymer chain tethered to a curved, impermeable surface, where the radius of curvature is varied from highly convex, through flat, to highly concave. Utilizing Brownian dynamics simulations, we examine the equilibrium properties of the polymer as a function of its stiffness and molecular size, as well as, the degree (and sign) of the surface curvature. Our results for curved surfaces have potential implications in a number of microfluidic and biological systems.

R1.00077 Phase Behavior of Polystyrene-block-poly(2-vinylpyridine) coordinated by Metal Chloride1 , DONG HYUN LEE, WONCHUL JOO, JIN KON KIM, Pohang Univ. Sci. Tech., JUNE HUH, Seoul National University, DU YEOL RYU, Yonsei University — The morphology and order-to-disorder transition (ODT) of asymmetric polystyrene-block-poly(2-vinylpyr dine) copolymers (PS-P2VP) varying chain length of P2VP coordinated with CdCl

R1.00078 Vibrational Spectroscopy of Polymers at High Pressures1 , ERIK EMMONS, K.C. CHIARTKUNC-HAND, RICHARD KRAUS, JEFFREY THOMPSON, AARON COVINGTON, Physics Department and Nevada Terawatt Facility, University of Nevada, Reno — Vibrational spectroscopy of polymers at high pressures (>1 GPa) is an interesting but relatively unexplored field. Early studies by Bridgman in the 1940s revealed a crystalline phase transition in only one polymeric material, poly (tetrafluoroethylene), at high pressures. Since that time, however, there have been relatively few studies of high-pressure polymorphism in polymers, with the exception of experiments on polyethylene. Hence, there is still not a clear picture of how common structural phase transitions are at high pressure in polymeric materials, in contrast to the situation for small organic molecules. The results of high-pressure vibrational spectroscopic studies of semi-crystalline polymeric materials such as α- and β-poly (vinylidene fluoride) will be presented.

R1.00079 ABSTRACT WITHDRAWN —

R1.00080 Evolution of multicompartiment micelles to mixed corona micelles2 , CHUN LIU, ZHIBO LI, MARC HILLMYER, TIMOTHY LODGE, Univ of Minnesota-Twin Cities — Multicompartiment micelles, self-assembled nanoscopic aggregates with subdivided solvophobic cores, have received great interest recently. This novel type of micelle was first realized by the micellization of triptych triblock copolymers—u-EOF (E: polyethylethylene; O: polyethylene oxide; F: polyperfluoropropylene oxide) in aqueous solutions. u-EOF micelles with the cores consisting of E and F blocks underwent a gradual transition from nanostructured vesicles to segmented worms, and finally to multicompartiment “hammers” as the ratio of the hydrophilic O block to the hydrophobic E/F block increased. Herein, we report on the further manipulation of their structures via the introduction of a second solvent—tetrahydrofuran (THF), which is selective for both E and O blocks. As THF content increases, the micelles evolve from multicompartiment micelles to mixed corona micelles with corresponding morphological changes, as evidenced in cryogenic transmission electron microscopy and dynamic light scattering.

R1.00081 Control of microdomain orientations in block copolymer thin films with chemically-patterned substrate , MIKIHIITO TAKENAKA, SATOSHI AKASAKA, Kyoto University, YASUHIKO TADA, Hitachi Ltd., TOMOHIRO INOUE, Kyoto University, HIROSHI YOSHIUDA, Hitachi Ltd., HIROKAZU HASEGAWA, Kyoto University — We demonstrate defect-free and well-aligned self-assembly of cylindrical microdomains in block copolymer thin films on chemically-patterned substrates in arbitrarily large areas. Poly(styrene-b-methyl methacrylate) (PS-PMMA) with weight average molecular weight and weight fraction of PS being 6.7×103 and 0.69, respectively, was spin coated on chemically nano-patterned substrate and annealed to undergo microphase separation. The chemically patterned substrate was prepared by patterning polystyrene grafted silicon wafer by conventional electron beam lithography, to form hexagonally arranged circular areas having higher affinity to cylindrical microdomain forming blocks. The epitaxially-grown cylinder structures were well aligned with defect-free hexagonal lattice, although the chemically-patterned substrate have some defects in its pattern. This result suggests that self-assembly of PS-PMMA can clean-up and interpolate the defects of patterned substrate while patterned substrate can align the orientation of block copolymer domain structures.
R1.00087 Control of the processing window for block copolymer nanostructures by the addition of a homopolymer. JUNHAN CHO, Dankook University, DU YEOL RYU, Yonsei University, KWANG HYUN SONG, SANG BO NA, Dankook University, YOUNGMIN KIM, Hongik University — Processing window for block copolymer nanostructures is often limited by a material at hand and effective intermonomer interactions. Taking polystyrene-b-poly(methyl acrylate) (PS-b-PMMA) as a model system, it is one of the most widely used passive electronic materials, we investigated how to control the processing window for fabricating nanostructures from PS-b-PMMA by the addition of PS homopolymer. The ordering transition points were measured for the neat copolymer and its mixtures by optical and radiation scattering methods. A molecular model based on a random-phase approximation theory was then used to elicit the effective interactions between constituent blocks and to predict the measured ordering transition temperatures for the design and fabrication of nanostructures from the copolymer system at desired processing condition.

R1.00083 Order-to-disorder Transition on PS-b-PI Copolymer Thin Film. CHANGHAK SHIN, HYUNGU AHN, DU YEOL RYU, Yonsei University, KWANG-WOO KIM, Pohang Accelerator Laboratory, YONSEI UNIVERSITY COLLABORATION, POHANG ACCELERATOR LABORATORY COLLABORATION — The phase separation transition in thin film system has been studied for diblock copolymers poly(styrene-isoprene) [PS-PI]. It has been broadly known that the microphase-separated or ordered state for block copolymers possesses a lower average density than the disordered state due to the dominant entropic contribution to the free energy. In this study, we used ellipsometry to probe transition temperatures in block copolymer thin films because it makes use of the change in polarization induced upon the reflection light from a covered substrate and allows the calculation of the thickness of the film. The phase behavior is compared based on the volumetric change on transition.

R1.00084 Surface Neutrality for PS-b-PMMA Copolymer Thin Film. SUJIN HAM, EUNHYE KIM, CHANGHAK SHIN, DU YEOL RYU, Yonsei University, CRAIG HAWKER, University of California, Santa Barbara, CA, THOMAS RUSSELL, University of Massachusetts, Amherst, MA, YONSEI UNIVERSITY COLLABORATION, UNIVERSITY OF CALIFORNIA, SANTA BARBARA COLLABORATION, UNIVERSITY OF MASSACHUSETTS, AMHERST COLLABORATION — Many attempts were made to control over the microdomain orientations of block copolymers in the thin films such as application of strong electric field, solvent annealing and chemical modification of the substrate surface because a variety of nanoscale periodic patterns of the block copolymers offers the potential use as nanolithographic templates, data storage, electronics and membranes. From this study, we suggest the experimental surface conditions for neutrality based on PS/PMMA. Lamellar or cylinder-forming PS-b-PMMA copolymers were used to investigate the thickness dependence of the perpendicular orientation of the microdomains by varying the chemical compositions (PS/PMMA) of underlying random copolymer brushes. The brush surfaces modified by the random copolymers were obtained by thermal annealing due to simple chemical reaction. From the thickness windows for the perpendicular orientation in PS-b-PMMA thin films, the real neutral surface could be observed.

R1.00085 Optical Absorption and Emission of Fully Conjugated Heterocyclic Aromatic Rigid-rod Polymers Containing Sulfonated Pendant Groups. SHIH JUNG BAI, SHEN-RONG HAN, INSTITUTE OF MATERIAL SCIENCE AND ENGINEERING, National Sun Yat-sen University — Fully conjugated poly(1,7-dihydrobenzo[1,2-d:4,5-d’]imidazole-2,6-diyi)-2-(2-sulfophenylene) (sPBI) has a para-catenated rod-like backbone, which was synthesized and fabricated for mono-layer polymer light-emitting diode (PLED) showing a threshold voltage of 4.5 V and a green light (530 nm) emission. Its SO₃H moieties attached to the p-phenyl ring improved electron delocalization along the backbone resulted in a red shift of absorption spectrum. sPBI was further derivatized for rigid-rod polyelectrolyte sPBI-PS(Li⁺) by attaching propanesulfonated pendant to the heterocyclic moiety of intractable sPBI for water solubility. This fully conjugated polyelectrolyte sPBI-PS(Li⁺) was fabricated for light-emitting electrochemical cells (PLECs) with a dopant of LiCF₃SO₃ or Li[N(CF₃SO₂)₂] for effects of propanesulfonated pendant and lithium dopants on luminescent emission and on room-temperature conductivity. sPBI-PS(Li⁺) PLECs doped with 0.41 and 1.01 wt.% of Li[N(CF₃SO₂)₂] showed higher green light (514 nm) electroluminescence emission intensity with a threshold voltage of 3.0 V and -4.6 V, respectively. Emission intensity of the sPBI-PS(Li⁺) PLEC did not raise upon increasing the conductivity of the luminescent layer.

R1.00086 Non-linear V-I Characters of LSMO/PAn/Co/Al Organic Spin-Valve. Z.L. LIU, H.G. CHENG, Z.H. QIN, J. CHEN, X.J. WANG, Huazhong University of Science and Technology — The present paper used the magnetron sputtering and Sol-Gel method to prepare the organic-spin valves composed of La₀.₇Sr₃₋ₓMnO₃ (LSMO)/polyaniline (PAN)/Co/Al. We adopted the four probe to study the MR of the spin valve and observed the non-linear V-I characters. The TMR effect in the organic spin valve was also studied.

R1.00087 Electroluminescence of Conjugated Rigid-rod Polymer Tuned by Emission Layer Thickness. SHIH JUNG BAI, HUA-WEI TSENG, Institute of Materials Science and Engineering, National Sun Yat-sen University, JEN-WEI HUANG, Department of Chemistry, ROC Military Academy — Bilayered light emitting diodes were fabricated with fully conjugated rigid-rod polymer poly-(p-phenylenebenzobisoxazole) (PBO) on top of hole conducting poly(3,4-ethylene-dioxythiophene:poly(styrene sulfonate) (PEDOT-PSS) using indium-tin-oxide on glass as the substrate and also the electron injecting cathode. The hole injecting anode was Al vacuum evaporated onto the PEDOT-PSS layer. Electroluminescence emission was obtained showing a blue shift in emission wavelength greater than a threshold voltage for the bayered polymer diodes having a smaller PBO layer thickness. When the PBO thickness changing from 90 nm to 27 nm with a constant PEDOT-PSS layer thickness of 54 nm, the ΔVthreshold were 70 nm and 3.5 V, respectively.

R1.00088 Growth Kinetics of Au Nanoparticles: Mean Field Modeling and SAXS. HILMAR KOERNER, AFRL, MICHAEL TAMBASCO, Columbia University, ROBERT MACCUSPIE, RICHARD VAIA, AFRL, SANAT KUMAR, Columbia University, AFRL, WPAPB, OH TEAM, COLUMBIA UNIVERSITY, NY TEAM — Gold (Au) nanoparticles (NPs) are a mainstay of current nanoscience and technology. With such a diversity of applications, developing a better understanding of the impact of macromolecular additives on single-phase fabrication routes, and ultimately on the resultant interfacial composition and structure (size, shape and dispersity), is critical to optimize performance and lower production cost. In-situ small-angle x-ray scattering (SAXS) is uniquely situated to directly monitor the morphological evolution of Au NPs from single phase reduction of Au(I) by tert-butylamineborane. Deconvolution of the in-situ SAXS profiles provides direct information on the evolution of NP size, polydispersity and relative number density, as well as the on-set of clustering and superstructure formation. The size-time profiles agree with mean-field calculations elucidating the role of ligands, their length and structure on the nucleation and growth kinetics as well as thermodynamic and structural characteristics of the Au NPs. In general, the combined approach provides new insights on the impact of additives on the various stages of NP formation and the ability to quantify particle-pair potentials and ascertain impact on assembly – de-assembly process of NP superstructures.
R1.00089 Effect of Ligand Molecular Weight and Nanoparticle Core Size on Polymer-Coated Gold Nanoparticle Location in Block Copolymers. JOSHUA PETRIE, UC Santa Barbara, BUMJOON KIM, UC Berkeley, GLENN FREDRIKSON, ED KRAMER, UC Santa Barbara — Gold nanoparticles modified by short chain polymer thioles [Au-PS] can be designed to strongly localize in either domain of a polystyrene-b-poly(2-vinylpyridine) [PS-PVP] block copolymer or at the interface. The P2VP block has a stronger attractive interaction with bare gold than the PS block. Thus, when the areal chain density $\Sigma$ of end-attached PS chains falls below a critical areal chain density $\Sigma_c$ the Au-PS nanoparticles adsorb to the PS-b-P2VP interface. The effect of the polymer ligand molecular weight on the $\Sigma_c$ has been shown to scale as $\Sigma_c \sim (R_g/R_{\Sigma_p})^2$, where $R$ is the curvature of the Au nanoparticle core radius. To test this scaling relation for $\Sigma_c$ further we are synthesizing gold nanoparticles with different core radii and will present preliminary results on $\Sigma_c$ as a function of $R$.

R1.00090 Patternning of Nano-Objects on PS-b-PMMA Thin Films by Selective Swelling. KOOKHEON CHAR, JEONG GON SON, Seoul National University, PAUL F. NEALEY, HUIMAN KANG, University of Wisconsin — Nano-objects have recently received great attention due to their unique photonic, electronic, and magnetic properties. However, in order to take full advantage of these properties of nano-objects, massively parallel assembly or integration of nano-objects is required. Block copolymers are well known to spontaneously form a wide range of nanostructures and block copolymer thin films can easily allow nano-scale patterns. In this presentation, we would like to introduce a new approach to realize nano-object patterning on perpendicularly oriented polystyrene-block-poly(methyl methacrylate) thin films. Our main idea is based on the properties of block copolymer thin films that simultaneously form the topographical and chemical patterns. We employed the annealing with selective solvents to realize topographical patterns of block copolymer thin films, from which we realized nano-object patterns either in the grooves of the patterns or on the top of the patterns. We verified the structures and mechanisms for the nano-object patterns on block copolymer thin films using Atomic Force Microscopy, Field-Emission Scanning Electron Microscopy and X-ray Photoelectron Spectroscopy.

R1.00091 Target site search strategy of gene regulatory proteins. ANDREW SPAKOWITZ, MARIO DIAZ DE LA ROSA, Stanford University — Gene expression is orchestrated by a host of regulatory proteins that coordinate the transcription of DNA to RNA. Regulatory proteins function by locating specific binding sequences of DNA and binding to these sequences to form the transcription initiation complex. In many instances, these regulatory proteins only have several specific copies that must efficiently locate target sequences on the genome-length DNA strand. The non-specific binding of regulatory proteins to random sequences of DNA is believed to permit the protein to slide along the DNA in a stochastic manner. Periodically, a thermal kick or an interaction with another bound protein will disengage the regulatory protein from the DNA surface, leading to three-dimensional diffusion. Eventually, the protein will reattach to the DNA at a new location that is dictated by both the diffusivity of the protein and the DNA configuration. Cycling through these random events constitutes a search strategy for the target site. We build a reaction-diffusion theory of this search process in order to predict the optimal strategy for target site localization. The statistical behavior of the DNA strand acts as a necessary input into the theory, and we consider several governing behaviors for the DNA strand. We explore the impact of DNA configuration on target site localization in order to predict how protein expression will vary under different experimental conditions.

R1.00092 Conformational Dynamics and Interactions of a DNA Aptamer Observed by Single Molecule Spectroscopy. JAMES TAYLOR, QOSAI DARUGAR, AJISH POTTY, RICHARD WILLSON, CHRISTY LANDES — Single molecule fluorescence resonance energy transfer (FRET) and fluorescence correlation spectroscopy (FCS) are used to study the interactions and structural dynamics of a DNA aptamer. Studies are performed in the presence of and in the absence of the aptamer’s binding target, the dimeric form of vascular endothelial growth factor (VEGF) protein. FRET and FCS experiments are conducted to determine the characteristics of conformational fluctuations by the “aptamer-VEGF” complex under different two- and three-dimensional conditions. It is shown that the VEGF has conformational fluctuations on a relatively fast time scale (single milliseconds to tens of milliseconds), and that these fluctuations are largely counterion dependent, being especially sensitive to Mg$^{2+}$ concentration. While these fluctuations also occur in the presence of VEGF, results show that the dynamics occur on a slower time scale (hundreds of milliseconds to seconds), indicating that there is indeed an interaction between the aV aptamer and its binding target, VEGF.

R1.00093 Scaling Exponents for Polymer Translocation through a Nanopore. KAIFU LUO, TAPIO ALA-NISSILA, Helsinki University of Technology, PAWEL POMORSKI, MIKKO KARTTUNEN, University of Western Ontario, SEE-CHEN YING, Brown University, ANIKET BHATTACHARYA, University of Central Florida – We present results of extensive computer simulations and scaling theory for computing the relevant scaling exponents associated with polymer translocation through a nanopore [1]. We present results for the scaling of the average translocation time and the fluctuation in the reaction coefficient for the case of spontaneous and field-driven translocation in 2D and 3D. The models used include: (i) the fluctuating bond model with single-segment Monte Carlo moves, (ii) Langevin dynamics, and (iii) GROMACS MD simulations using the bead-spring model for flexible polymers without an explicit solvent. We contrast our results to the recently presented alternate theories for polymer translocation [2,3].

R1.00094 Stretch-Induced Density fluctuations in glassy polymers. MIKIHITO TAKEKANA, SHOTARO NISHIT-SUJI, SHIMIZU HIRONOFUMI, Kansai University, SHIHYA YOSHIOKIO, Osaka City University — Glassy materials are hard but fragile. The fragileness of glass strongly depends on its processing and the heterogeneity developed during the processing in glass materials may be important in its destruction under deformation. However, the mechanism how the heterogeneity develops and leads to the fragmentation or cracking is not well understood. Here we show that the stretch induced the violent of the incompressibility by the coupling between the stretch and density fluctuations due to the strong density dependence of viscosity in glassy polymer. We demonstrate that the small-angle X-ray scattering intensity of a glassy polymer increases with stretch and exhibits so-called butterfly pattern. This butterfly pattern arises from the competition between the stretch and density fluctuations under different two- and three-dimensional conditions. It is shown that the VEGF in the absence of VEGF has conformational fluctuations on a relatively fast time scale (single milliseconds to tens of milliseconds), and that these fluctuations are largely counterion dependent, being especially sensitive to Mg$^{2+}$ concentration. While these fluctuations also occur in the presence of VEGF, results show that the dynamics occur on a slower time scale (hundreds of milliseconds to seconds), indicating that there is indeed an interaction between the aV aptamer and its binding target, VEGF.

R1.00095 Functionalized polymeric nanotubes. CECILE MALARDIER-JUGROOT, Royal Military College of Canada — New nanomaterials already play a key role in several emerging technologies such as nanomotors, nanoelectronics and drug delivery. The increased interest in nanotechnology comes from the fact that nanoscale materials have new physical and chemical properties compared to the bulk. Among the methods used to fabricate new nanomaterials, the most successful in producing precise structure, is the bottom-up method which builds the desired products from the atomic or molecular scale by self-assembly. We will present a new self-assembly process of amphiphilic alternating copolymers into nanotubes combining a computational (molecular modeling) and experimental (small angle neutron scattering, atomic force microscopy) characterization. The nanotubes will be illustrated by the association of poly(styrene-alt-maleic anhydride) and the effect of the functionalization of the polymer chain on the forces stabilizing the nanotubes (hydrogen bonds, π − π interactions) will be presented.
R1.00096 A New Design of Coiled-Coil Helix Bundle Peptide-Polymer Conjugates1. JESSICA SHU, CEN TAN, Department of Materials Science and Engineering, UC Berkeley, WILLIAM DEGRADO, Department of Biochemistry and Biophysics, University of Pennsylvania, TING XU, Department of Materials Science and Engineering, Department of Chemistry, UC Berkeley — Coiled-coil helix bundles, a common tertiary motif found in many natural proteins, underpins many structural and catalytic functions of natural proteins. De novo design has shown that the interior of the helix bundle can be tailored to perform well-defined functions, while the exterior dictates the environment in which it is situated. By attaching synthetic polymers to helix bundle-forming peptides, producing peptide-polymer conjugates, the polymer will mediate the interactions between the helix bundle and its environment, enabling the macroscopic self-assembly of the bundles, and potentially, give them function in non-biological environments. We report a novel design of peptide-polymer conjugates, where upon attachment of polymer to the exterior of the helix bundle stabilizes the peptide secondary and tertiary structures and preserves the built-in function of the bundle. This design strategy should be applicable to other coiled-coil peptides and shows great promise as an avenue toward peptide-based biomolecular functional materials.

3 C. Bertozzi and the Molecular Foundry at Lawrence Berkeley National Laboratory

R1.00097 Effects of molecular weight and entanglement on the dispersion of a layer of platelets in a polymer chain matrix1. BARRY FARMER, Air Force Research Laboratory, RAS PANDEY, University of Southern Mississippi — A stack of thin sheets (a model for clay platelets) is initially placed in a matrix of polymer chains. How does the dynamic polymer chain matrix (purely entropic constraints) affect the dispersion of sheets is the subject of this computer simulation study. A stack of four sheets constitutes the layer with a small initial inter-layer distance on a discrete lattice. A fraction of the lattice sites are randomly occupied by the polymer chains. Both sheets and chains are modeled by the bond-fluctuation mechanism. Coarse-grained chains and platelets interact and execute their stochastic motion via Metropolis algorithm. Dispersion of the sheets is examined by varying the molecular weight of the polymer chains which form the dynamic network, including entanglements. The relaxation time for dispersion increases on increasing the molecular weight. Exfoliation almost ceases in a matrix with chains beyond a certain length.

We thank AFRL for the support.

R1.00098 Numerical Self-Consistent Field Theory of Flat and Curved Polymer Thin Films TANYA L. CHANTAWANSRI, CARLOS J. GARCIA-CERVERA, HECTOR D. CENICEROS, GLENN H. FREDRICKSON, University of California, Santa Barbara — Using self-consistent field theory, we explore the numerical methods and boundary conditions involved in modeling the self-assembly of inhomogeneous polymer thin films deposited on flat and curved substrates. The model is simulated using a fourth-order accurate spectral collocation method first used by Cochran et al. [Macromolecules 2006, 39, 2449-2451] to model bulk polymeric systems, but where we apply finite difference approximations and non-periodic boundary conditions for the film in the direction normal to the substrate. Boundary conditions are employed to model experimentally relevant substrate conditions such as a "neutral" or attractive bounding surface. For a neutral surface where the substrate has no preferential attraction to either polymer segment, it is appropriate to utilize Neumann boundary conditions, while a surface with a preferential attraction can be modeled using Robin's or mixed boundary conditions.

R1.00099 Topologically constrained polymer collapse, ALEXANDER GROSBERG, University of Minnesota, THOMAS VETTOREL, KURT KRÉMER, Max Planck Institute for Polymer Research, Mainz, Germany — Linear polymer chains in an equilibrium melt are strongly entangled, and coils strongly overlap. Similarly, collapsed (globular) single chain is strongly self-entangled in equilibrium. It is a fundamental question of polymer physics - what happens if the formation of these entanglements or self-entanglements is either completely prohibited or strongly slowed down (like in a melt of unconcentrated rings, in a gel, etc). We address this question by massive Monte Carlo simulation based on the use of non-local moves which dramatically speed up relaxation while strictly preserving the topology. The effects of topologically supported separation of chains, or parts of the same chain, have far reaching applications ranging from gel collapse, to interphase chromosome territories, to statistics of knots in proteins.

R1.00100 Target Finding Time for Microtubules Interacting with Catastrophe-Suppressing Drugs MITRA SHOJANIA FEIZABADI, Canisius College — Target finding time for microtubules interacting with catastrophe-suppressing drugs is investigated in this study. In the steady state of microtubules interacting with catastrophe-suppressing drugs, two types of microtubules exist, one with drug tips and the second without drug tips. This work shows that microtubules in the first group are slower in finding a target than are those in the second group. This result is consistent with experimental findings.

R1.00101 Stability of Fddd structure in diblock copolymer, MYUNG IM KIM, SATOSHI AKASAKA, TSUTOMU WAKADA, MIKIHIITO TAKEKARA, HIROKAZU HASEGAWA, Department of Polymer Chemistry, Graduate School of Engineering, Kyoto University — Recently we reported a new bicontinuous microdomain morphology with the symmetry of Fddd space group found in a polystyrene-

R1.00102 Applications

R1.00103 Using radar waves to image subsurface heterogeneities: a case study from Randolph College, VA. TATIANA TOTeva, REEUJ POKHAREL, ARCHANa DATTA, Randolph College — A 2D ground penetrating radar survey at 250 MHz central frequency was conducted on Randolph College's campus, in Lynchburg, VA. The experimental setup consisted of three radar profile lines, each with length of 70 – 100 m. The goals of the project were to image subsurface heterogeneities, and define depth to bedrock. Conventional seismic refraction conducted earlier at the site revealed irregular topography of the subsurface and high degree of uncertainty in the arrival times of the elastic waves. Radar surveys have the potential to provide much higher resolution images. We observed a number of point reflectors and multiple layering of the subsurface soil.

R1.00104 Integrated Detector for Ballistic Electron Emission Luminescence, BIQIN HUANG, JING XU, IAN APPELBAUM, University of Delaware — Ballistic electron emission luminescence (BEEL) uses injected hot electrons to induce interband transitions and light emission in semiconductor collectors. Local hot electron injection and ratering from a scanning tunneling probe can therefore potentially provide a means to image buried luminescent layers. However, a sensitive photon detector is required to compensate for low external efficiency. We have designed integrated a Si photodetector to a GaAs/AIGAAs BEEL structure by UHV thin-film metal wafer bonding. This room-temperature technique overcomes index mismatch and numerical aperture problems associated with far-field detection. We expect this method will make BEEL microscopy generally applicable to the study of buried luminescent layers in light emitting devices based on arbitrary material systems. This work is funded by US DOE.
R1.00105 Reduced Contact Resistance in Quantum Cascade Lasers\textsuperscript{1}, MATTHEW ESCARRA, SCOTT HOWARD, ANTHONY HOFFMAN, CLAIRE GMACHL, Princeton University — Quantum cascade (QC) lasers have shown tremendous potential as powerful and compact mid-infrared light sources. However, improvement in the high-efficiency operation of these devices must be made for their transfer to real-world utilization. The internal, current, voltage, and optical efficiencies all must be maximized. In particular, high voltage efficiency requires minimizing the voltage defect in the quantum design and parasitic voltage dropped elsewhere in the device. The majority of this parasitic voltage lies in the metal-semiconductor contact junctions. To study this contact resistance, we designed and fabricated a QC laser structure without the active lasing region. Rapid thermal annealing (RTA) on this “empty” structure shows a 35.2\% reduction in contact resistance at room temperature, which would correspond with a 7\% improvement in laser wall-plug efficiency. Different annealing conditions were tested in order to optimize this reduction. Varying contact metallization and top growth also holds the potential for further reduction in contact resistance and improvement in QC laser efficiency.

\textsuperscript{1}This work is supported in part by DARPA-EMIL and MIRTHE (NSF-ERC).

R1.00106 Quantum-Dot Photodetectors: High Sensitivity due to Controllable Kinetics\textsuperscript{1}, ANDREI SERGEEV, LI-HSIN CHIEN, NIZAMI VAGIDOV, VLADIMIR MITIN, SUNY at Buffalo — Comparing to the quantum wells, the quantum-dot structures provide more opportunities to control electron kinetics and to optimize operating regimes of quantum-dot photodetectors. At room temperatures, the photoelectron capture in quantum-dot structures is determined by the electron diffusion in the potential of intentionally or unintentionally charged quantum dots. Therefore, the capture time can be drastically increased by a proper choice of the quantum-dot structure and modulation doping. Suppression of capture processes provides longer lifetimes of photoelectrons, thus increasing the photoconductive gain and responsivity. Here we exploit a model of the QD detectors operating at room temperatures and study electron diffusion in the self-consistent field of potential barriers surrounding quantum dots. Using the Monte-Carlo method and analytical evaluations, we investigate photoelectron capture and transit processes as functions of the quantum dot positions, sensor geometry, and external electric field applied. Finally, we calculate the photoconductive gain and discuss the optimal structures and regimes. [1] A. Sergeev, V. Mitin, and M. Stroscio, Physica B 316-317, 369 (2002).

\textsuperscript{1}This work was supported by AFOSR and NYSTAR grants.

R1.00107 Cascaded Emission Regions in 2.4 \(\mu\)m GaInAsSb Light Emitting Diode’s for Improved Current Efficiency , JOHN PRINEAS, JEFF YAGER, Dept. Physics and Astronomy, University of Iowa. JONATHON OLESBERG, Optical Science and Technology Center, University of Iowa, CHUANSHUN CAO, Dept. Physics and Astronomy, University of Iowa, MADHU REDDY, Dept. of Physics and Astronomy, University of Iowa, CHRIS CORETSOPOULOS, Optical Science and Technology Center, University of Iowa — Infrared optoelectronics play an important role in sensing of molecules through characteristic vibrational resonances that occur at those wavelengths. For molecules in aqueous and at room temperature, where optical transitions tend to be broad, the broadband emission of light emitting diodes (LEDs) are well suited for obtaining molecular absorption spectra. The 2-2.6 \(\mu\)m range is an advantageous range for sensing of glucose. Voltages available in batteries and control electronics are limited to much higher voltages than those required to turn on an infrared LED, and moreover have limited current supply. Here, we demonstrate room temperature operation of 5-stage cascaded emission regions in 2-2.6 \(\mu\)m GaInAsSb LEDs. We report three times higher turn on voltage, and nine times improved current efficiency compared to a single stage device.

R1.00108 Surface charge effects on the plasmonic band gap of metallodielectric gratings , IAN FOTI-LANDIS\textsuperscript{1}, PAUL WHITE\textsuperscript{2}, JENNIFER STEELE\textsuperscript{3}, Trinity University — Surface plasmon resonances of both metal nanoparticles and metal surfaces are highly sensitive to changes in their dielectric environment. The changes in surface plasmon resonance due to target molecules binding to the metal have been found to be caused by both a local change in dielectric environment as well as changes in the surface chemistry of the metal. The majority of investigations of these competing effects have primarily been limited to the localized surface plasmon resonances of metal nanoparticles. Here, the effects of surface chemistry on surface plasmons will be investigated using metallodielectric gratings. This periodic geometry supports traveling surface plasmon waves that show a plasmonic band gap in the dispersion relationship when two counterpropagating waves are simultaneously excited. The band gap energy changes in response to chemical functionalization, giving unique information on how the surface chemistry affects the surface plasmon resonance. This work focuses on the effect of charged species as a function of pH.

R1.00109 Electric field controlled left-handed-materials lens\textsuperscript{1}, S.V. BELY, R.V. PETROV, M.I. BICHURIN, A.V. FILIPPOV, Novgorod State University, Russia, G. SRINIVASAN, Oakland University, MI — Microwave lenses are useful for scanning and multi-beam antennas of radar systems, telemetries, and radio-astronomy of the cm and mm-wave bands. The development of electric and/or magnetic field controlled lenses using magnetoelectric material would facilitate improvement if the antenna technologies. We designed such lenses consisting of metal resonators on dielectric substrates with the control elements made of yttrium iron garnet and PZT. The control is based on the variation of magnetic permeability of the ferrite via the electric potential applied to piezoelectric. It results in change in the parameters of transmitted microwave—beam and focal length of the lens. The lens works in cm-wave band. The gain factor of the lens is 6 dB. Theoretical estimates and optimization of the lens parameters were also carried out.

\textsuperscript{1}Supported by grants from NSF, Russian Foundation for Basic Research and Russian Ministry of Education and Science.

R1.00110 Design, fabrication and FEM simulation of a novel Optical-MEMS sensor\textsuperscript{1}, VAIBHAV MATHUR, JIN LI, WILLIAM GOODHUE, Photonics center, University of Massachusetts, Lowell, PHOTONICS CENTER TEAM — Optical waveguides are used in a variety of telecommunications systems to route, add or drop optical signals from the network. Here a combination cantilever/waveguide structure is proposed as the core element of either a vibration/shock sensor or light modulator. An AlGaAs layered dielectric waveguide is fabricated on GaAs substrates and undercut to form a suspended beam. The suspended AlGaAs waveguide is micro-cleaved to produce cantilever segments of equal or unequal lengths, corresponding to either the same or different fundamental frequencies resonance (as the natural frequency is a function of length). The sample is vibrated using a piezo driver. If the vibration frequency supplied to the chip is near one of the resonances the waveguide becomes periodically misaligned as the cantilever displacement amplitude builds up causing a periodic loss in signal at the output end of the guide. In this work cantilever/waveguide structures are fabricated and a detailed FEM(Finite element method) analysis of the device carried out. Also wave propagation and subsequent optical misalignment simulation is carried out on the FEM based COMSOL Multiphysics Package.

\textsuperscript{1}We would like to acknowledge JPS Associates Inc. for laser cutting the samples.
R1.00111 Automation of analysis of electronic microscope images, GAGIK SHMAVONYAN, State Engineering University of Armenia — Many-sided analysis of multiple images of electronic microscope is a hard and time-consuming process. Besides, the analyses become more actual in the case of distorted, not high quality images of electronic microscopes, i.e. images of scanning tunneling microscope. To increase the accuracy and velocity of analyses a method is suggested, which allows analyzing the surface of semiconductor crystal. The method allows to get information on the position of the atoms of the 1\textsuperscript{st}, 2\textsuperscript{nd} and 3\textsuperscript{rd} crystallographic planes, analyze surface defects and dislocations, differentiate two and more materials on the surface, determine surface reconstruction or atomic structure, etc.

R1.00112 A 100 MHz antenna based on magnetoelectric composite materials\textsuperscript{1}, A.S. TATARENKO, R. PETROV, G. SRINIVASAN, Oakland University, M.I. BICHURIN, Novgorod State University — Results on miniaturization of a 100 MHz-antenna based on magneto-electric composites are presented. A composite with large and equal permittivity and permeability is sought for the task. In such composites both miniaturization and impedance match to free-space are possible. A sample of nickel zinc ferrite and bismuth strontium titanate prepared by the conventional ceramic processing is used. The dipole antenna operating at 100 MHz consists of a composite substrate 220 mm in diameter and 8.5 mm in width and a Cu-strip 6.5 mm in diameter. Antenna characteristics are measured with a vector network analyzer. Scattering parameter data indicates resonance at 98 MHz and an antenna miniaturization factor of 7-10, in agreement with theoretical estimates.

\textsuperscript{1}Supported by a grant from DARPA.

R1.00113 Magnetoelectric Composites for 1.3 GHz Antennas\textsuperscript{1}, R.V. PETROV, A.S. TATARENKO, G. SRINIVASAN, Oakland University, Rochester, MI, M.I. BICHURIN, Novgorod State University, Russia — A microstrip miniaturized antenna based on magneto-electric composite has been designed and characterized. Theoretical estimates of antenna properties are given. To miniaturize UHF antennas, one needs slow-wave topologies and magneto-electric (ME) materials with equal and high permeability and permittivity. Nickel Zinc Ferrites (Ni\textsubscript{1-x}Zn\textsubscript{x}Fe\textsubscript{2}O\textsubscript{4}, x=0-0.5, NZFO) are potential candidates for use as the magnetic phase in the composite since they have high permeability, in the range 4-50, and low magnetic loss tangent. The dielectric phase use is bismuth strontium titanates (Sr\textsubscript{1-\textit{r}}Bi\textsubscript{1.5}TiO\textsubscript{3}, 0.04<\textit{r}<0.25, BST) that have high permittivity and low dielectric loss tangent. A sample with nickel zinc ferrite and 2% BST is used. A microstrip dipole element of 47 mm in length and 2 mm in width is placed on a composite substrate with dimensions 65 x 40 x 2.2 mm\textsuperscript{3}. The other side of the substrate has a metal plate plane. Measurements of transfer scattering parameter S\textsubscript{21} are made. A miniaturization factor of 5-10 is achieved. The miniaturization methodology discussed here is useful for mobile communication platforms, radar systems, and remote-controlled ground based systems.

\textsuperscript{1}Supported by a grant from DARPA.

R1.00114 A magneto-electric composite based microwave phase shifter, M.I. BICHURIN, V.M. PETROV, Novgorod State University, Russia, G. SRINIVASAN, Oakland University, Rochester, MI — Magneto-electric (ME) properties of ferrite-ferroelectric composites arise from their response to elastic and electromagnetic force fields. The unique combination of magnetic, electrical, and ME interactions opens up the possibility of electric field tunable ferromagnetic resonance (FMR) based devices [1]. Here we discuss an ME phase shifter operating in the FMR region at 9.3 GHz. A slot line on a yttrium iron garnet film bonded to lead zirconate titanate (PZT) provides a basis for the phase shifter. The circularly polarized microwave magnetic field of the slot line interacts with the ferrite and causes variation of phase velocity with the controlling magnetic and electric fields. Electrical tuning is realized with the application of a control voltage due to PZT. The estimated phase shift per unit length and unit voltage is to 20 deg/cm kV for a PZT thickness of 0.5 mm. 1 S. Shastry and G. Srinivasa, M.I. Bichuri, V.M. Petrov, A.S. Tatarenko. Phys. Rev. B, 70 064416 (2004). - supported by grants from the Office of Naval Research and the Russian Foundation for Basic Research.

R1.00115 Development of a Capacitive Measurement Apparatus for Steel Alloy Magnetostriiction, CHRISTOPHER L. MILBY, JOSEPH L. WIEWEL, MATTHEW W. BECKNER, Department of Physics, Western Illinois University, MARK S. BOLEY, Dep’t of Physics, Western Illinois University — In our laboratory we have developed steel alloy torque transducers that operate via a magnetoelastic principle, converting applied stress to an external magnetic field signal subsequent to appropriate magnetic pre-conditioning. We have found that linearity, repeatability, and sensitivity of these transducers is highly dependent on the heat treatment to which the steel is subjected, which is severely limited by the minimum hardness coefficients that will be required in the actual technological application such as in a power delivery shaft. In our study, we focused on cases where Rockwell hardness coefficients in the forties or low fifties are expected, using a steel alloy with low nickel and chromium content. Austenitizing temperatures varied from 775 to 870 Celsius, whilst tempering temperatures varied from 205 to 540 Celsius, all in a helium atmosphere. The quenching medium following the austenitizing and tempering processes varied between oil and water. The study showed that a tempering temperature around 425 Celsius resulted in the best linearity and re-zeroing capabilities (repeatability) of the transducers, also corresponding to the least hysteresis. Additionally, water quench reduced sensitivity as compared to oil quench at the same temperature.

R1.00116 Determining Optimal Austenitizing and Tempering Temperatures and Quenching Media for a Steel Torque Transducer, JOSEPH L. WIEWEL, CHRISTOPHER L. MILBY, MATTHEW W. BECKNER, MARK S. BOLEY, Department of Physics, Western Illinois University — In our laboratory we have developed a series of high-stress steel alloy magnetoelastic torque transducers that convert applied stress to an external magnetic field signal. We have found that linearity, repeatability, and sensitivity of these transducers is highly dependent on the heat treatment to which the steel is subjected, which is severely limited by the minimum hardness coefficients that will be required in the actual technological application such as in a power delivery shaft. In our study, we focused on cases where Rockwell hardness coefficients in the forties or low fifties are expected, using a steel alloy with low nickel and chromium content. Austenitizing temperatures varied from 775 to 870 Celsius, whilst tempering temperatures varied from 205 to 540 Celsius, all in a helium atmosphere. The quenching medium following the austenitizing and tempering processes varied between oil and water. The study showed that a tempering temperature around 425 Celsius resulted in the best linearity and re-zeroing capabilities (repeatability) of the transducers, also corresponding to the least hysteresis. Additionally, water quench reduced sensitivity as compared to oil quench at the same temperature.

R1.00117 Liquid Supramolecular NanoStamping (LiSuNS), ARUM AMY YU, Massachusetts General Hospital, FRANCESCO STELLACCI, MIT — The development of high resolution bio-devices has generated a demand for the development of novel printing techniques able to minimize fabrication time and labor. Supramolecular NanoStamping (SuNS) is a stamping method that can copy single-stranded DNA features in a sequence specific way in only three steps: a master containing single stranded DNA features is immersed in a solution of complementary DNA (cDNA) molecules modified with a chemical group at the end (Hybridization). Another substrate is placed onto the hybridized master so that a chemical bond can form between cDNA and the secondary substrate (Contact). The two substrates are then separated by heating or mechanical force and a copy composed of cDNA is left on the secondary substrate (Dehybridization). However, like all other contact printing techniques, SuNS’ efficiency highly depends on the roughness of the substrates used. Here, we present an extension of SuNS, Liquid Supramolecular NanoStamping (LiSuNS). LiSuNS eliminates the need of contact between two solid substrates. Using a liquid prepolymer that is cured after contact, using LiSuNS, we achieved large coverage >10cm\textsuperscript{2}. Moreover, because LiSuNS prints 3-D physical information as well as 1-D chemical information (i.e DNA sequences), it can be used to generate a complete DNA-based bio-device with 3-D physical shape (e.g. channels) and chemically modified patterns.
The nanoparticles were exposed to soft x-rays of varying energy under ultra high vacuum, ∼\textit{(adsorbates)}, and we will describe our work to chemically modify the channel in order to control the surface scattering. (NTFETs), even at temperatures approaching 300 K. RTS arises from the population and depopulation of energy levels associated with charge traps along the channel and generate subwavelength patterns. Far-field origins were observed. We present a straightforward model for interference effects generated in our process, and discuss our ability to tune these effects with the fifth harmonic (213 nm) of an Nd:YAG source through metallized contact apertures in contact with resist. Interference patterns with both near- and far-field origins were observed. We present a straightforward model for interference effects generated in our process, and discuss our ability to tune these effects.

In this poster presentation, we discuss opportunities for direct-write UV photolithography through metallized apertures defined by focused ion beam on SPM cantilevers. This process offers subwavelength (<200nm) feature sizes without the need to generate a mask, and the writing process can take place in fully ambient conditions. In our preliminary work, we have patterned polymethyl methacrylate (PMMA) resist by exposing it with the fifth harmonic of a Nd:YAG laser. Experimental results show that the wavelength drift per milliampere of the VCSEL is 0.78 nm/mA.

A simple method for determining the wavelength drift of vertical-cavity surface-emitting lasers (VCSELs) has been studied extensively, and a cutoff frequency of 90 kHz constrained by the bandwidth of thermal response was reported. Results reveal that, with the assistance of polarization-selective optical feedback of about -15 dB, the cutoff frequency of the CDPS could be raised to 50 MHz. A set of rate equations was employed to simulate the enhancement of CDPS and to address the interaction of optical feedback with the PS. These results will help to extend the application of CDPS to even higher frequency.

The present spot size for DNA microarrays is on the order of micrometers. However, there is a need for smaller arrays to allow the detection of smaller volumes of analytes. Although, SPM-based techniques are capable of fabricating nanoscale bio-arrays, such fabrication methods are serial in nature and consequently slow and expensive. A recently introduced method, Supramolecular Nanostamping (SuNS) can overcome this problem by replicating DNA microarrays. In SuNS, a master (i.e. a DNA microarray made of DNA features immobilized onto a surface) is hybridized with its complementary DNA molecules terminated with ‘sticky’ ends to form a secondary structure. A secondary surface is then placed onto the hybridized master to allow for bond formation with the ‘sticky ends’ of the complementary DNA. Afterwards, the master and the secondary surface are separated using heat or mechanical forces effectively achieving a replica of the original DNA array. Here, we demonstrate the application of SuNS to DNA nanoarrays proving that SuNS can reproduce DNA arrays with features as small as 14 ± 2 nm spaced 77 ± 10 nm. Moreover, we show that hybridization of these nanoarrays can be detected using AFM in a simple and scaleable way that does not require labeling of the DNA strands.

R1.00125 First principles study of hydrogen storage in non-transition metal decorated graphitic materials, GYUBONG KIM, Department of Physics, Pohang University of Science and Technology, NOE JUNG PARK, Department of Applied Physics, Dankuk University, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology — Hydrogen has been considered an ideal material that can replace fossil-based fuels as its byproduct is simply water without emitting green house gases. Recently, transition metal (TM)-dispersed porous materials have been suggested as plausible candidates for hydrogen storages that possess optimal hydrogen binding characteristics. A serious problem in this approach is that TM atoms tend to aggregate instead of being atomistically dispersed, which results in the deterioration of hydrogen uptake. Here we study the hydrogen adsorption on non-transition metal (NTM) atoms dispersed on graphene using ab initio methods. We observe that the clustering energy of NTM atoms is much smaller than that of TM atoms, which indicates that NTM can be almost free of clustering on graphene. We also study hydrogen adsorption on those NTM atoms to find comparable storage capacity to that in TM dispersed graphene.

R1.00126 Theoretical study of the structural, mechanical, and electronic properties in hydrides, RYOJI SAHARA, BUN TSUCHIYA, HIROSHI MIZUSEKI, SHINJI NAGATA, TATSUO SHIKAMA, YOSHIYUKI KAWAOE, Institute for Materials Research, Tohoku University — Although an understanding of the mechanical behavior such as elastic properties and hardness of hydrides is important for their applications, theoretical studies have received little attention and only recently some progress has been made. In the present study, first-principles calculations have been performed on hydrides of Ti, Zr, and Hf. The elastic properties are estimated as a function of hydrogen concentration. Equilibrium lattice constants and the bulk moduli are estimated using Murnaghan EOS. While, the elastic constants, shear moduli, and Young’s moduli are estimated introducing the strain tensor. The origin of these properties is explained in terms of the changes in the bonding characters as well as cohesive energy. A semi-empirical relationship between the bulk modulus/shear modulus and the Vickers hardness is introduced to predict hardness of these materials from the present first-principles calculation results.

R1.00127 The crystal structure of $^7\text{Li}_2\text{ND}$, MASAMI TSUBOTA, Institute for Advanced Materials Research, Hiroshima University, MAGNUS H. SORBY, Institute for Energy Technology, Department of Physics, SATOSHI HINO, Graduate School of Advanced Sciences of Matter, Hiroshima University, TAKAKI ICHIKAWA, Institute for Advanced Materials Research, Hiroshima University, BJORN C. HAUBACK, Institute for Energy Technology, Department of Physics, YOSHIKICHI KOJIMA, Institute for Advanced Materials Research, Hiroshima University — Recently much attention has been given to reversible hydrogen storage materials possessing high gravimetric capacity. Lithium amide/imide systems are promising candidates. Chen et al.[1] found that a mixture of lithium amide and lithium hydride can reversibly store hydrogen up to 6.5 mass% forming lithium imide ($\text{Li}_2\text{NH}$). Among them, the crystal structure of $\text{Li}_2\text{NH}$ is still controversial. Balogh et al.[2] have reported a cubic structure model. However, this model differs significantly from theoretical structure models. In this work, the crystal structure of the isotopically substituted $^7\text{Li}_2\text{ND}$ has been investigated by powder neutron and synchrotron X-ray diffraction experiments. In our data some peaks, which should be a single peak for cubic symmetry, were obviously split indicating a lower symmetry than cubic for lithium imide. The structure of $^7\text{Li}_2\text{ND}$ will be described. [1] P. Chen et al., J. Phys. Chem. B 107 (2003) 10967. [2] M.P. Balogh et al., J. Alloys Compd. 420 (2006) 326.

R1.00128 Hydrogen Accumulation inside Single-Walled Carbon Nanotubes Encapsulated in a Pd Matrix, A. LIPSON, Department of Nuclear, Plasma and Radiological Engineering, University of Illinois at Urbana Champaign, C. H. CASTANO GIRELDO, Department of Nuclear Engineering, Missouri University of Science and Technology, B. F. LYAKHOV, E. I. SAUNIN, A. YU. TSIVADZE, A. N. Frumkin Institute of Physical Chemistry and Electrochemistry, Russian Academy of Sciences — Palladium metal possesses the unique property of dissociating molecular hydrogen into an atomic form while simultaneously exhibiting high H-diffusivity, while single-walled carbon nanotubes (SWCNTs) have been actively explored during the last decade as an effective hydrogen storage medium. We report a study of hydrogen storage in which electrochemical hydrogen loading of this material provides reproducibly high net capacity of SWCNT (reduced to hydrogen content in the Pd matrix). The synergistic effect has been achieved by encapsulating Single-Walled Carbon Nanotubes in thin Pd layers on a Pd substrate creates resulting from the combination of the Pd and the SWCNTs properties with regards to hydrogen.

R1.00129 Multimetal plasmonic nanomaterials for solar energy harvesting, RAMKI KALYANARAMAN, JUSTIN TRICE, Dept. of Physics, Washington University in St. Louis, RADHAKRISHNA SURESHKUMAR, Energy, Environmental and Chemical Engineering, Washington University in St. Louis, HERNANDO GARCIA, Dept. of Physics, Southern Illinois University in Edwardsville — Efficient broadband solar absorbing coatings could significantly enhance the performance of Si solar cells. Here, we present the design of novel SiO$_x$-based nanomaterial coatings based on multimetal plasmonic absorption. By implementing an efficient homogenization procedure based on the tight lower bounds of the Bergman-Milton formulation [Garcia et al. Phys. Rev. B, 75, 045439 (2007)], we have predicted the absorption coefficient of a quaternary nanocomposite consisting of Cu, Ag, and Au nanospheres embedded in a SiO$_2$ host matrix. A simulated annealing algorithm was used to predict nanocomposite properties (particle size and volume fractions) which result in a broadband absorption (350 - 800 nm) that matches the shape of the solar emission. These results show that novel optical materials can be made from multimetal-dielectric nanocomposites.

R1.00130 ABSTRACT WITHDRAWN

R1.00131 Relation between Packing Density and Thermal Transitions of Alkyl Chains on Layered Silicate and Metal Surfaces, HENDRIK HEINZ, University of Akron, RICHARD A. VAIA, BARRY L. FARMER, Air Force Research Laboratory, WPAFB — Characterization through experiment and simulation shows that the orientation of the alkyl layers and reversible phase transitions on heating are a function of the cross-sectional area of the alkyl chains in relation to the available surface area per alkyl chain (packing density). On even surfaces, a packing density less than 0.2 leads to nearly parallel orientation of the alkyl chains on the surface, conformational disorder, and no reversible melting transitions. A packing density between 0.2 and 0.75 leads to intermediate inclination angles, semi-crystalline order, and reversible melting transitions on heating. A packing density above 0.75 results in nearly vertical, lattice-like alignment of the surfactants on the surface and no reversible melting transitions. The same principle applies to curved surfaces, taking into account a local radius of curvature and a distance dependent packing density on the surface. The chain length (minimum C10) and interface chemistry have little impact on this behavior but determine chemical functionality and transition temperatures.
R1.00132 Characterization of iPP/CNT PCN through Transmission Ellipsometry1. GEORGI GEORGIEV, Assumption College, YANEIL CABRERA, TUFTS University, MARK CRONIN, CHRISTOPHER ROCHELEAU, Assumption College, BRIAN FEINBERG, PEGGY CEBE, TUFTS University, ASSUMPTION COLLEGE COLLABORATION, TUFTS UNIVERSITY COLLABORATION — Microscopic Transmission Ellipsometry is a fast and efficient technique for studying anisotropic organization in polymers. Polymer Carbon Nanotube Composites (PCNs) are the largest commercial application of carbon nanotubes (CNT) in nanotechnology. Isotactic Polypropylene (iPP) is one of the best model systems to study in this field because iPP/CNT PCNs can form alpha, beta, and gamma crystallographic phases under a variety of crystallization conditions: nonisothermal and isothermal melt crystallization, shear, stress, fiber extrusion, etc. The morphological structure and the orientation of the crystals can also be finely controlled under those conditions. We complement Microscopic Transmission Ellipsometry studies with other techniques: Differential Scanning Calorimetry, X-ray scattering and dielectric spectroscopy.

R1.00133 Effects of Molecule-Electrode Binding on Molecular Junctions, PETER DOAK, Chemistry UC Berkeley, JON MALEN, Mech. Eng, UC Berkeley, KANHYALAL BAHETI, Chemistry UC Berkeley, ARUN MAJUMDAR, Mech. Eng, UC Berkeley, RACHEL SEGALMAN, Chem. Eng, UC Berkeley, DON TILLEY, Chemistry UC Berkeley — Measurements of the Seebeck coefficient or thermopower of metal-molecule-metal junctions offer additional insight into single molecule transport. By applying a temperature bias across a junction created via an Au-Au STM break junction a thermoelectric voltage can be measured which is related to the transmission function through a derivative. Previously dithiol molecules have been studied by this method. Here, the effects of altering the binding to the electrodes will be demonstrated. When the binding group is altered to cyano or amine functionalities, the thermopower is greatly affected suggesting markedly different behavior in response to tuning of molecular energy levels. This indicates important changes in the junction transmission functions near the chemical potential of the contacts. For example, we show that measurements of dinitrile molecules cannot be interpreted as simple shifts of a single Lorentzian transmission peak across the contact chemical potential. Additionally these measurements show that the binding groups can have considerably more influence on junction behavior than other forms of molecular functionalization and provide a useful means to interrogate theories of junction transport.

R1.00134 Controlled one dimensional poly (3-hexythiophene) nano fiber for high performance organic field effect transistor, SUNG WON LEE, UNYONG JEONG, Yonsei University — We demonstrate here how to fabricate cylinder shape, one dimensional organic field effect transistor for high performance field effect transistor device. To reduce the size and increase component density in circuit we used electro-spinning as a fabrication method. Coaxial nozzle was used for cylindrical semiconductor and gate insulator defines. Regio-regular Poly (3-hexythiophene) and poly vinyl phenol was used as semiconductor and gate insulator respectively. Electrical performance is not reported here because of environmental instability. However, we expect good electrical performance will be shown shortly because this device form cylindrical conduction channel compare to thin film type field effect transistor. Here we propose electro-spinning is an easy one step process to fabricate one dimensional polymer field effect transistor.

R1.00135 Low-temperature characterization of organic conducting thin films, GREGORY TOPASNA, DANIELA TOPASNA, Virginia Military Institute — Conducting polymer thin films were investigated at low temperatures. We present results for such a spin coated film made of poly[2-methoxy-5-(2'-ethylhexyloxy)-p-phenylene vinylene] (MEH-PPV) which was tested for temperatures below 20 °C. The film was probed over several cycles of cooling then heating. For each cycle the results showed a similar temperature dependent resistance. Such polymer thin films have potential applications as flexible temperature sensors.

R1.00136 Electronic properties of adjoined TiO2 nanocrystals1, O. DIWALD, M.I. ELSER, N. SIEDL, Vienna University of Technology, Institute of Materials Chemistry, J. BERNARDI, Vienna University of Technology, USTEM — The discussion of particle attachment effects is indispensable for deeper insights into electronic conduction across grain boundaries and thus essential to photovoltaics. We investigated the condensation of isolated TiO2–nanocrystals [1] induced via the application of a simple hydration-dehydration cycle. The resulting particle network shows a mesoporous structure as well as significant changes in the optical absorption properties as investigated by UV-diffuse reflectance spectroscopy. In addition, polarizable conduction band electrons are only observed in the network which consists of adjoined TiO2–nanocrystals [2]. Since photo-assisted tunneling between localized states in the oxide particle network represents an important conduction mechanism in dye-sensitised solar cells, UV induced charge separation processes were studied on nanocrystal aggregates using EPR and IR spectroscopy. Corresponding results will be discussed in the light of associated structural data. [1] Berger et al. Chem. Phys. Chem. 2005 6 2104-2112 [2] Elser et al. J. Phys. Chem. B 2006, 110, 7605

R1.00137 Photooxidation of Acetone and Butanone on Rutile TiO2 (110)2, DANIEL P. WILSON, DAVID SPORLEDER, Stony Brook University, MICHAEL G. WHITE, Stony Brook University, Brookhaven National Laboratory, WHITE GROUP TEAM — Interest in the photooxidation of organic compounds on heterogeneous surfaces such as TiO2 has increased in recent years. Here, acetone and butanone, two common organic ketones, are studied under UHV conditions to determine what fragmentation occurs during photooxidation and to gain insight as to the predictability of desorbing species. The data was collected using a pump-probe time-of-flight (TOF) method. Excitation occurs via exposure to 3.7 eV photons followed by ionization with 13.05 eV photons. Preheating the surface to ~200K facilitated the formation of an organic-diatole species needed for photoactivity. During butanone photooxidation, different desorption mechanisms between mass 30 and masses 27-29 are evident. Background thermal results and preliminary translational energy distributions are calculated for acetone and some butanone fragments and are presented here.

R1.00138 Ultrafast Carrier Dynamics in Water-Splitting Photocatalysts, ELIZABETH CARROLL, OWEN COMPTON, MICHAEL SARAHAN, FRANK OSTERLOH, DELMAR LARSEN, Department of Chemistry, University of California — Semiconductors that photocatalytically split water into hydrogen and oxygen using solar energy represent promising renewable energy technologies. Charge carrier dynamics on sub-nanosecond timescales dictate the overall efficiency of charge separation, and consequently, photocatalytic activity of these materials. Using transient absorption spectroscopy, we investigated photoexcited carrier trapping, recombination, and interfacial charge transfer dynamics in water-splitting niobate nanosheets. Ca2Nb2O10 generated H2 from water with 0.22% quantum yield, but no O2 was formed. Carriers relaxed with second-order kinetics on a sub-nanosecond time scale that depended on the nanosheet size. Methanol was used as a sacrificial donor to separate electron and hole dynamics and identify absorption spectra for the trapped carriers. In aqueous methanol, hole scavenging was observed within 100 ps in direct competition with electron-hole recombination. The nanosheets were also functionalized with metal and semiconductor nanoparticles to form novel photocatalyst nanostructures. Colloidal IrO2 was attached to Ca2Nb2O10 to sensitize the catalyst for visible light absorption. Interfacial electron transfer stabilized the charge separation in IrO2, and O2 was generated.

R1.00139 Applications of Physics to Measuring and Improving the Performance of Buildings in Hot, Humid, Hurricane-Prone Climates1, NORMAN WITRIOL2, Building Science Innovators and The Regen Group, MYRON KATZ, NOLA Solar, Building Science Innovators and The Regen Group, CHRISTOPHER FAUST, NOLA Solar and The Regen Group, JINSION ERINJERI, Louisiana Tech University — In this presentation we will present topics showing how physics can be applied to measuring and improving the performance (energy efficiency and durability of the structure, health, safety, and comfort of the occupants) of buildings in hot, humid, hurricane-prone climates representative of the climate in New Orleans and the Gulf Coast.

1Retired, Louisiana Tech University

R1.00140 Modeling of Magnetic Field Assisted Assembly, RENE RIVERO, SHAMMUGAMURTHY FNU, GAURAV DEVRAHI, VIJAY KASISOMAYAJULA, MICHAEL BOOTY, ANTHONY FIORY, NUGGHELLI RAVINDRA, New Jersey Institute of Technology — A simplified model of the magnetic field assisted assembly process is presented and developed. Objects are moved by magnetic forces into an assembled pattern such as into an array of recesses. All the forces involved in the assembly process are considered in the model. An example in which an object comes in contact with the recess and settles into it in order to initiate the modeling process is illustrated. Experimental techniques for the assembly process with an optimal control system with feedback is described. The results of the study are analyzed in relation to applications in fabricating heterogeneous systems.

R1.00141 Probing molecules in integrated silicon-molecule-metal junctions by inelastic tunneling spectroscopy, WENYONG WANG, National Institute of Standards and Technology, ADINA SCOTT, Purdue, NADINE GERGEL-HACKETT, CHRISTINA HACKER, NIST, DAVID JANES, Purdue, CURT RICHTER, NIST — A hybrid technology where molecular devices are integrated with traditional semiconductor microelectronics is a promising approach for future electronic applications. Key challenges in this area include developing devices in which the molecular integrity is preserved and defining in-situ characterization techniques to probe the molecules within the completed devices. In this study, we present the first experimental report of inelastic electron tunneling spectroscopy of integrated metal-molecule-silicon devices with molecules assembled directly to silicon contacts. The results provide direct experimental confirmation that the chemical integrity of the monolayer is preserved and that the molecules play a direct role in electronic conduction through the devices. Spectra obtained under varying measurement conditions show differences related to the silicon electrode, which can provide valuable information about the physics influencing carrier transport in these molecule/Si hybrid devices.

R1.00142 Watching electrons tunnel, SIMON MOSER — To get insight to time resolved inner atomic or molecular processes, laser pulses of few femtoseconds or even attoseconds are needed. These short light pulse techniques ask for broad frequency spectra, control of dispersion and control of phase. Hence, linear optics fails and nonlinear optics in high electromagnetic fields is needed to satisfy the amount of control that is needed. One recent application of attosecond laser pulses is time resolved visualization of tunnel ionization in atoms applied to high electromagnetic fields. Here, Ne atom electrons are excited by an extreme ultraviolet attosecond laser pulse. After a while, a few cycles nearly infrared femtosecond laser pulse is applied to the atom causing tunnel ionization. The ion yield distribution can be measured as function of the delay time between excitation and ionization and so deliver insight to the time resolved mechanisms.

R1.00143 Application of the double and triple parabolic quantum well in a laser, MARTIN MOLINAR, GERMAN CAMPOY, Departamento de Investigacion en Fisica, Universidad de Sonora — Using a structure of two and three consecutive parabolic potentials (harmonic oscillator), enclosed in an infinite rectangular well, we solve the Schroedinger’s equation and get the eigenvalues for the Hamiltonian. Trying with a few periods of the structure, we can see the rise of subbands. This system can be used for the development of a semiconductor laser diode built with the deposition of semiconductors on a substrate. We calculate the energy differences between neighboring states and they are then compared with those values found in the literature for similar systems. The emission frequency, the gain and the efficiency of the periodic structure are calculated, for different widths of the parabolic wells and this let us to explore the possibility of use parabolic potentials instead rectangular wells for build a semiconductor laser diode.

R1.00144 ATOMIC, MOLECULAR & OPTICAL (AMO) PHYSICS –

R1.00145 Making BEC for study Quantum physics by modulating the Magnetic potential, JINAH PARK, DAHYUN YUM, WONHO JHE, Department of Physics and Astronomy, Seoul National University — The achievement of Bose Einstein Condensation (BEC) has opened a new chapter in atomic physics. With BEC in dilute atomic gases, quantum physics, solid state physics modeling and many physical phenomena, which has been hard to treat, could be studied beyond the research on BEC itself. In this sense, BEC in ultracold weakly interacting gases has been a very important meaning in recent years. Until now, many experimental results related with thermal atoms in the modulating potential have been carried out. It is no doubt that it is very interesting subject to study quantum mechanical phenomena in various potential configurations. We have been experimenting with the neutral rubidium 87 atoms for making BEC. Our experimental setup to obtain BEC is consisted of double Magneto-Optical Trap (MOT) system, Time Orbiting Potential (TOP) magnetic trap and evaporative cooling technique using rf-knife edge which is typical BEC setup. Here our experimental results are reported.

R1.00146 Superconducting atom chips: recent results and prospects, ADRIAN LUPASCU, CEDRIC ROUX, ANDREAS EMMERT, THOMAS NIRRENGARTEN, GILLES NOGUES, MICHEL BRUNE, JEAN-MICHEL RAIMOND, SERGE HAROCHE, Kastler-Brossel Laboratory, Ecole Normale Superieure (Paris) — Atom chips offer a very interesting set of tools for the magnetic trapping and manipulation of neutral atoms close to surfaces and on-chip optoelectronic devices. In our experiments we investigate atom chips built using superconducting wires in a cryogenic environment. We have recently produced the first Bose-Einstein condensate using this setup. We observe the onset of the Bose-Einstein condensation for 1 x 10^5 atoms at a temperature of 100 nK. This result opens the way for studies of ultra-cold atoms interacting with superconducting structures. We also envision to excite the dense atomic cloud towards long lived Rydberg states. Making use of the phenomenon of dipole blockade could lead to the deterministic production of a single atom in a Rydberg state.

R1.00148 Bose-Einstein condensation in low dimensional layered structures1. PATRICIA SALAS, Posgrado en Ciencia e Ingeniería de Materiales, UNAM, Mexico, M.A. SOLIS, Instituto de Física, UNAM, Apartado Postal 20-364, Mexico, D.F., Mexico — Bose-Einstein condensation critical temperature, among other thermodynamic properties are reported for an ideal boson gas inside layered structures created by trapping potential of the Kronig-Penney type. We start with a big box where we introduce the Kronig-Penney potential in three directions to get a honey comb of cubes of side a size and walls of variable penetrability ($P=mVab/h^2$), with bosons instead of bees. We are able to reduce the dimensions of the cubes to simulate bosons inside quantum dots. The critical temperature, starting from that of an ideal boson gas inside the big box, decreases as the small cube wall impenetrability increases arriving to a tiny but different from zero when the penetrability is zero ($P \rightarrow \infty$). We also calculate the internal energy and the specific heat, and compare them to the ones obtained for the case of the same Kronig-Penney potential in one direction (simulating layers), and two directions (nanotubes).

R1.00149 Spin Nematics and Quantum Fluctuation-Controlled Coherent Spin Dynamics of Hyperfine Spin F=2 Cold Atoms1. JUN LIANG SONG, GORDON SEMENOFF, FEI ZHOU, The Univ. of British Columbia — We show that quantum fluctuations lift the accidental continuous degeneracy that was found in the mean field analysis of spin nematic states of hyperfine spin F=2 87Rb. Two distinct spin nematic states with higher symmetries are selected out depending on scattering lengths: a uniaxial spin nematic and a biaxial spin nematic. Recently we also study coherent spin dynamics mainly driven by quantum fluctuations. Unlike the usual mean-field driven dynamics, quantum fluctuation-controlled spin dynamics are sensitive to the variation of fluctuations and the potential induced by quantum fluctuations can be tuned by four or five orders of magnitude in optical lattices. These dynamics have unique dependence on quadratic Zeeman fields and potential depth in optical lattices. We find that although these dynamics are difficult to observe in traps, it is possible to observe them in optical lattices; particularly they can survive in F=2 87Rb condensates with a relatively short life time.

R1.00150 Bose-Einstein Condensates of Cesium Atoms in an Optical Lattice1. CHEN-LUNG HUNG, XIBO ZHANG, NATHAN GEMELKE, CHENG CHIN, University of Chicago — The realization of the Mott-insulator to superfluid phase transition with neutral atoms in an optical lattice provides a rare opportunity to test many-body physics with accuracy. We report progress on an experimental and quantitative comparison of the superfluid to Mott-insulator phase boundary with results from the Bose-Hubbard model, using Bose-condensed cesium atoms confined to a thin layer of an optical lattice potential. Feshbach resonances with cesium atoms enable us to scan the on-site interaction over a wide range without modifying the tunneling rate and the overall trapping potential; chemical potential can be adjusted by loading a varied mean atomic density into the lattice. We describe the physical apparatus constructed for this investigation, including novel construction designed to achieve precise and agile control of the magnetic field used in tuning interactions, adiabatic loading and manipulation of the lattice potential, and tight two-dimensional confinement applied to negate the effect of gravity without sacrifice in system homogeneity.

R1.00151 Development of an apparatus for simultaneous trapping of 6Li—87Rb mixtures. QUN WEI, MICHAEL BROWN-HAYES, WOO-JOONG KIM, Dartmouth College, CARLO PRESILLA, University of Rome “La Sapienza” and INFM-CNR, ROBERTO ONOFRIO, Dartmouth College and University of Padova — Ultracold dilute atomic gases are providing a new window into quantum physics, with particular regard to the first-principle study of various superfluid phenomena. It is critical, in order to open this window, to reach deeper Fermi degeneracy, and this requires, for Fermi-Bose mixtures, to optimize the heat capacity matching between the Fermi and the Bose gases. After discussing a thermodynamic model showing that heat capacity matching is improved by using species selective traps, we discuss the status of an apparatus in which we trap fermionic 6Li and bosonic 87Rb in a magneto-optical trap.

R1.00152 Casimir forces in sphere-plane and cylindrical-plane geometries. QUN WEI, WOO-JOONG KIM, MICHAEL BROWN-HAYES, Dartmouth College. DIEGO DALVIT, Los Alamos, HAYDEN BROWNELL, ROBERTO ONOFRIO, Dartmouth College — We report on the status of an experiment aimed at measuring the Casimir force in cylinder-plane geometry. In order to characterize the apparatus, we have first performed small distance electrostatic calibrations in the sphere-plane geometry free from parallelism issues. This has allowed us to better identify various general issues on the measurement of the Casimir force, such as the distance dependence of the residual (contact) potential, and the delicate assessment of the absolute distance. Recent electrostatic calibrations in the cylinder-plane geometry after an upgrade of the parallelization system will be also reported.

R1.00153 Universal Dependence in Ultra-Cold Fermi Gases. SHIZHONG ZHANG, Department of Physics, University of Illinois at Urbana-Champaign — Over the last few years, there have been considerable efforts in understanding the physics of BEC-BCS crossover in ultra-cold fermi gases. Despite the fact that the problem can be easily formulated, it has not been amendable to analytic solutions. Various approximations have been used to address the problem especially around unitarity. Here we present some general considerations on the problem, relying on the fact that the system is dilute and thus the interaction effects comes only from two-body encounters. These enables us to express certain physical quantities(total energy, interaction energy, rf-spectroscopy shift and closed channel fractions) in terms of one universal function, depending only on temperature and interaction strength. The result obtained should be valid throughout the crossover and thus we expect it to have testable consequences in the future experiments.
R1.00154 Ultra-cold atom experiment and strongly interacting Fermi system. LI YAN, Stony Brook University, STONY BROOK COLLABORATION — Recent progresses in low temperature atomic experiment, especially the magnetic tunable inner-atom interaction via Feshbach resonance, give people a way to approach the study of low temperature and strongly interacting fermion system. In the strong interaction limit, i.e. the unitary limit range, system experiences BCS-BEC crossover, with universal thermodynamic properties. This kind of universality not only simplifies the theoretical research on strongly interacting fermion system but also help people to prove the uniqueness of strongly interacting system in ultra-cold atom experiment.

R1.00155 Emergent vortex dynamics in two-dimensional neutral superfluids. CHENG-CHING WANG, Dept. of Physics, Univ. of Texas at Austin, REMBERT DUNE, Inst. for Theoretical Physics, Utrecht University, MACDONALD ALLAN, Dept. of Physics, Univ. of Texas at Austin — We derive an effective action for the vortex translational zero modes of a superfluid by integrating out environmental modes which include phase and density fluctuations of the condensate. When the quantum dynamics of the fluctuations are treated as frozen with negligible Berry phases in adiabatic limit, we confirm the occurrence of vortex Magnus force and adiabatic vortex mass due to compressibility of the superfluids in agreement with earlier studies. In addition, we also show the results beyond adiabatic limit in which the quantum dissipative action can be derived and solved analytically. We show that the adiabatic approximation is only valid in large system with small coherence length $R \gg \xi$. Furthermore, we also build a numerical model based on discrete Gross-Pitaevskii equation to show the renormalization and broadening of the vortex cyclotron resonance peaks. It is demonstrated that well-defined cyclotron peaks in spectral functions can be sustained only when the condition $R \gg \xi$ is satisfied. With the mapping between discrete Gross-Pitaevskii equation and bosonic single-band Hubbard model, we propose that the adiabatic vortex dynamics can be realized by tuning the ratio between tunneling energy $J$ and on-site interaction energy $U$ such that $U N_a \gg J$ in cold atom systems with optical lattices, in which $N_a$ is the total number of bosonic atoms.

R1.00156 Violation of classical inequalities and EPR correlations in a two-mode three-level atomic system. EYOB SETE, New Mexico State University — We investigate violation of Cauchy-Schwarz and Bell inequalities in two-mode three-level atomic system show that this system can be used to prepare states that exhibits EPR correlations.

R1.00157 Fiber optic laser delivery system for planar ion traps. ELIZABETH GEORGE, DAVID LEIRANDT, ISAAC CHUANG, MIT — The use of trapped ions for quantum computation requires precise focusing and alignment of lasers for cooling the ions and performing logic gates. On-trap fiber optics would eliminate the need for alignment of lasers to the traps and allow scaling of surface-electrode ion traps on large chips to smaller sizes. We have developed a design for implementing on-trap fiber optics with an integrated beam focusing lens using microfabrication techniques. The design uses SU-8 photoresists structures to align the fiber and focusing lens to the trap. We present details of the design and the results of preliminary testing.

R1.00158 In-Situ Optical Heterodyne in time Resolved Coherent Anti-Stokes Raman Scattering. YEHIAHM PRIOR, ANDREY SHALIT, YURI PASKOVER, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel 76100 — We show both theoretically and experimentally that pure vibrational modes cannot be observed in the power spectrum of time resolved degenerate Coherent anti-Stokes Raman Scattering (CARS), unless the optical signal is linearized by an optical heterodyne detection scheme. A new heterodyne detection method is introduced, where the local oscillator is not provided externally, but is produced in-situ by the addition of small amounts of highly anisotropic molecules to the measured sample. The rotational anisotropy of the added molecules gives rise to a slowly evolving signal, which in turn serve as the local oscillator in heterodyned time resolved CARS. We have shown that the strength of the local oscillator can be controlled by amount of material added, in our experiments $C_3$ added to the measured chloroform or bromoform liquids. Small change of total anisotropy of the sample is expressed as dramatic changes in the intensity of the peaks corresponding to the fundamental vibrational frequencies. This method can be utilized for distinguishing of the fundamental frequencies from beats appearing in the signal due to quadratic (intensity) detection of the nonlinear signal.

R1.00159 Cold antiproton production in the ATRAP2 apparatus. JONATHAN WRUBEL, G. GABRIELSE, P. LAROCHELLE, D. LE SAGE, B. LEVITT, W.S. KOLTHAMMER, R. MCCONNELL, P. RICHERME, A. SPECK, Harvard University, M.C. GEORGE, D. GRZONKA, W. OELERT, T. SEFZICK, Z. ZHANG, Forschungszentrum Julich GmbH, A. CAREW, D. COMEAU, E.A. HESSELS, C.H. STORRY, M. WEEL, J. WALZ, Institut fur Physik, Mainz, ATRAP COLLABORATION — We have developed a new ATRAP2 experimental platform, which has succeeded in producing thousands of anthydrogen ($\bar{H}$) atoms in a combined Penning-Ioffe trap. The Penning trap provides confinement for charged particles needed for future laser cooling and precision spectroscopy of $\bar{H}$. As the $\bar{H}$ atoms are formed that by the addition of small amounts of highly anisotropic molecules to windows in the Ioffe trap to transmit Lyman-$\alpha$ radiation into the production space, which is needed for future laser cooling and precision spectroscopy of $\bar{H}$.

R1.00160 Density Matrix Descriptions for Pump-Probe Optical Phenomena in Moving Atomic Systems1, VERNE JACOBS, Naval Research Laboratory — Reduced density matrix descriptions are developed for pump-probe optical phenomena in moving many-electron atomic systems, taking into account atomic collisions and external magnetic fields. Time-domain (equation-of-motion) and frequency-domain (resolvent-operator) formulations are developed in a unified manner. In a semiclassical perturbative treatment of the electromagnetic interaction, compact Liouville-space operator expressions are derived for the linear and the general ($n$th order) non-linear electromagnetic-response tensors. These expressions are valid for coherent atomic excitations and for the full tetradic-matrix form of the collision operator in the Markov approximation.

R1.00161 Ab initio studies on molecules and clusters in external electrostatic fields. RAJEEV PATHAK, Department of Physics, University of Pune, Pune 411007, Maharashtra, India — Influence of a uniform static external electric field on some aliphatic and aromatic molecular species is studied within the density functional theory (DFT) employing the 6-311++G(2d,2p) basis-set with B3LYP exchange-correlation prescription. The electric field perturbs the molecular geometry; alters the dipole moments and engenders a molecular vibrational Stark effect. For polar molecules, significant frequency shifts are observed for field orientations both parallel and antiparallel to their permanent dipole moments; where HOMO-LUMO gaps alter significantly. Time dependent DFT analysis reveals that an increase in the applied field strength increases the excitation energies amongst frontier MOs with a concomitant decrease in oscillator strengths. Structural evolution of water clusters, ($H_2O)_n$, $n=6-8$ is studied within DFT: the intermolecular hydrogen bonds stretch, and eventually break at some threshold values, triggering a conformational transformation, with configurations appearing as local minima on the cluster’s potential energy landscape, with abrupt increase in the electric dipole moments and ‘opening up’ of three dimensional morphologies of water.
R1.00162 Analysis of the nuclear motion in a HeNe* transient molecule. CRISTIAN BAHRIM, JOSEPH HUNT, Department of Chemistry and Physics, Lamar University - Texas — Based on a model potential for describing the interaction between He and Ne* atoms during a collision [1] we predict a series of vibrational states within several electronic adiabatic potential wells of the HeNe* system for internuclear distances \( R < 6 \, \text{a}_0 \). The identification of vibrational states suggests the formation of a HeNe* transient molecule. In our study two theoretical approaches are employed: (1) the harmonic approximation is based on the assumption that during a collision (which is considered as being one period of vibration) the nuclear motion is harmonic, and (2) the anharmonic approximation which uses the best fit of the electronic adiabatic potential wells with a Morse anharmonic function, as is typically done for stable molecules [2]. A set of vibrational-electronic transitions which can be measured using IR spectroscopy is proposed. The relative population of Ne* atoms after collisions and various IR photo-absorption is predicted for experimental testing of the dominant character of the nuclear motion: whether harmonic or anharmonic. The existence of a HeNe* transient molecule could have a positive impact on improving the performance of He-Ne lasers. [1] Bahrim C, Kucal H and Masnou-Seeuws F 1997 Phys. Rev. A 56 1305. [2] Bahrim C and Hunt J 2006 J. Phys. B 39 4683.

R1.00163 Compton Profiles of Atoms and Ions. KHONDKAR KARIM, Illinois State University — We present momentum-space properties of several atoms and ions including He, Be, B, C, N, O, and Ne atoms, and the respective ions in many possible ionization stages. The calculations have been done using Hartree-Fock atomic models. The Compton profile data presented here could be used to obtain doubly differential cross section of electron production in ion-atom collision from electron-ion cross sections. The plots of electron distribution in momentum space reveal interesting features that are not apparent in electron’s radial probability distribution in coordinate space.

R1.00164 Fully Differential Cross Sections in Two-Photon Double Ionization of Helium. DANIEL HORNER, Theoretical Division, Los Alamos National Laboratory; THOMAS RESCIGNO, Chemical Sciences, Lawrence Berkeley National Laboratory; C. WILLIAM MCCURDY, Chemical Sciences, Lawrence Berkeley National Laboratory; Applied Science and Chemistry, U. California, Davis — We present total, single differential, and triple differential cross sections for two-photon double ionization of helium above and below the threshold for sequential ionization (54.4 eV). Sequential double ionization exhibits characteristic behavior seen in the total and differential cross sections. Evidence of this behavior also arises below the threshold through “virtual sequential ionization.” Using the method of exterior complex scaling, we compute numerically converged wave functions describing two unbound electrons on a large, but finite volume. From these wave functions, using formally exact integral methods, we extract ionization amplitudes, from threshold through “virtual sequential ionization.”

R1.00165 Adsorbates Effects in H−Na/Cu(111) collisions. BOGDANA BAHRIM, SONG YU, Department of Chemistry and Physics, Lamar University - Texas — The (111) faces of Cu, Ag and Au present a band gap that extends just below the vacuum level at the \( \Gamma \)-point [1]. The effect is to forbid electrons with energies in a certain range to be transferred into the metal along the surface normal. Thus, the presence of a band gap should dramatically influence various experiments in ion-surface collisions involving electron capture or loss. In recent years, this topic received a great interest [2 – 4]. Adsorbates deposition makes the electron dynamics at such surfaces to be even more complex. We analyze some interesting adsorbates of a band gap should dramatically influence various experiments in ion-surface collisions involving electron capture or loss. In recent years, this topic received a great interest [2 – 4]. Adsorbates deposition makes the electron dynamics at such surfaces to be even more complex. We analyze some interesting adsorbates of a band gap should dramatically influence various experiments in ion-surface collision with various ions in the target.

R1.00166 Spectroscopic and Magnetic Susceptibility Analyses of the \( \text{F}_J \) and \( \text{D}_4 \) Multiplet Manifolds of Tb\( ^{3+}(4\text{f}^8) \) in TbAlO\(_3\). KELLY NASH, JOHN GRUBER, DHIRAJ SARDAR, University of Texas at San Antonio, UYGUN VALIEV, ABDULLA UZOKOV, National University of Uzbekistan, GARY BURDICK, Andrews University — Detailed analyses of temperature-dependent spectroscopic and magnetic susceptibility data are reported for the crystal-field split energy levels of the \( \text{F}_J \) and \( \text{D}_4 \) of Tb\(^{3+}\) in TbAlO\(_3\). The spectroscopic data include absorption spectra obtained between 460 and 2920 nm from 8 to 300 K. High resolution fluorescence spectra are reported, representing transitions from \( \text{D}_4 \) to \( \text{F}_5 \) at a sample temperature of 85 K. Using crystal-field modeling techniques recently adapted for low symmetry systems, we have assigned all 5 experimental Stark levels within the \( \text{F}_J \) and \( \text{D}_4 \) manifolds, with a fitting standard deviation of 4.5 cm\(^{-1}\) (3.8 cm\(^{-1}\) rms error). Furthermore, the theoretical Stark levels and calculated wavefunctions were used to determine the temperature dependence of the magnetic susceptibility along the c-axis of the TbAlO\(_3\) crystal. Agreement is obtained between the calculated susceptibility and temperature-dependent magnetic data reported earlier. The susceptibility calculation also confirms the predicted ordering of states within the \( \text{F}_6 \) multiplet manifold.

R1.00167 Ultracold Cesium Feshbach Molecules. MICHAEL MARK, STEVEN KNOOP, FRANCESCA FERLAINO, MARTIN BERNINGER, HARALD SCHÖBEL, HANNS-CHRISTOPH NÄGERL, RUDOLF GRIMM, University of Innsbruck, Austria — We present our recent work on ultracold Cesium Feshbach molecules in an optical dipole trap. We have implemented a new crossed-beam laser trap, which traps atoms and molecules simultaneously. By scanning one laser beam the ellipticity can be dynamically tuned for an optimal trap configuration. We routinely prepare ultracold mixed atomic and molecular or pure molecular samples at temperatures down to 30 nK [1]. We selectively populate Feshbach molecules in various \( s-, d-, q- \) and \( q- \) l-wave states [2]. We have experimentally demonstrated that the \( q- \) dimers can be stable against spontaneous decay on the timescale of one second well above the dissociation threshold [3]. We have recently implemented the technique of resonantly modulated magnetic field spectroscopy [4]. Transitions between the atomic continuum and dimer states, and vice versa, as well as dimer-dimer transitions can be driven. Our main motivation is to apply this technique to search for trimer and tetramer states, whose presence has been indicated by resonances in collisional loss measurements.

R1.00168 Helium Spectra in Atomic Mechanics. ALFRED PHILLIPS, JR., SOURCE INSTITUTE — In our model of the helium atom, we postulate that the angular momentum of each electron divided by \( h \) equals an integer, \( n \), plus a fraction, \( \Delta n \). By minimizing the energy the energy of the helium atom, we find that the \( \Delta n \) values are a function of the total angular momenta, \( J \), irrespective of the integer, \( n \). We thus obtain a set of \( \Delta n \) values for the singlet and triplet states of helium. The \( \Delta n \) values are related to fractals. In our model, we made adjustments to the electron mass so that the calculated energy values agree with the seventeen values for the singlet \( ls \)-ns configurations listed in NIST Atomic Spectra Database Levels Data. The adjustments to the electron mass were very close to unity except for the ground state for which the adjustment was \(-5\%\). (Adjustments like these suggest that we may be able to study three-body effects with spectral accuracy.) By doing this, we had good agreement with all of the NIST spectral values for helium (191 lines of He I, and 243 lines of He II). This conceptually and mathematically simple procedure can be used for other atoms.
R1.00169 The Adiabatic-to-Diabatic Mixing Angle for the Inelastic Collision \( B(2P_{1/2}) \rightarrow H_2(j, n) \leftrightarrow B(2P_{3/2}) + H_2(j', n') \)

DAVID WEEKS, MATTHEW GARVIN, Air Force Institute of Technology — The Born-Oppenheimer approximation breaks down when two adiabatic potential energy surfaces become sufficiently close. Under these conditions, the nuclear dynamics are governed by a set of coupled diabatic surfaces. Derivative coupling matrix elements can be used to compute the transformation from the adiabatic to the diabatic potential energy surfaces. A line integral along various contours through the vector field defined by the derivative coupling matrix elements is used to compute the adiabatic-to-diabatic mixing angle. In particular, we investigate the path independence of this coupling angle for the inelastic collision \( B(2P_{1/2}) + H_2(j) \rightarrow B(2P_{3/2}) + H_2(j') \) collision (1). (1) D.E. Weeks, T.A. Niday, and S.H. Yang, J. Chem. Phys. 125, 164301 (2006).

R1.00170 Vibrational and Spin as well as Linear Kinetic Energies Should Be Included in Pair Production and Annihilation Energy Relations

STEWART BREKKE, Northeastern Illinois University (former grad student) — By including the vibrational and spin kinetic energies in Pair Production and Annihilation Formulas a closer reconciliation between theory and experimental results can result. The creating photon may create particle vibration and spin as well as mass and linear motion. In pair production:

\[ h\omega_{v0} + (n + 1/2)h\omega_{s0} + (n + 1/2)h\omega_{m0} \]

In pair annihilation at least two photons must be produced which get their energy from the linear, vibrational and spin kinetic energies as well as the mass-energy conversion. \( h\omega_{v1} + h\omega_{s1} + h\omega_{m1} = 2mgc^2 + 1/2ma_0v^2 + 1/2ma_0v^2 + 1/2I\omega_{v0} + 1/2I\omega_{s0} + (n + 1/2)h\omega_{m0} \). While these experiments were performed with a BEC healing length, \( V_D \) happens twice per every period of the mirror oscillation at non-equivalent positions (hysteresis effect), which leads to a non-zero net energy loss. The cooling devices, which is based on the phenomenon of optical bistability. These devices are modeled as a Fabry-Perot resonator with one fixed and one oscillating mirror. Using a magnetically-tuned Feshbach resonance, the \( m_1 \) is reduced to zero near which \( \xi \) becomes very large. Results of applying the disorder potential to this nearly non-interacting condensate, with \( a_s \) much less than the Bohr radius, will be reported.

R1.00171 Compton Effect Energy Formulas Should Include Vibrational and Spin as well as Linear Kinetic Energies

STEWART BREKKE

Northeastern Illinois University (former grad student) — In Compton scattering the incident photon affects not only the linear, but also the vibrational and spin kinetic energies after impact. \( h\lambda_1 + m_0c^2 + 1/2ma_0v^2 + 1/2ma_0v^2 + (n + 1/2)h\lambda_1 = \frac{hc}{\lambda_1 + m_0c^2 + 1/2ma_0v^2 + 1/2ma_0v^2 + (n + 1/2)h\lambda_1} \). If the incident photon produces a relativistic speed, the equation should be \( h\lambda_1 + m_0c^2 + 1/2ma_0v^2 + 1/2ma_0v^2 + (n + 1/2)h\lambda_1 = \frac{hc}{\lambda_1 + m_0c^2 + 1/2ma_0v^2 + 1/2ma_0v^2 + (n + 1/2)h\lambda_1} \). By including the other kinetic energies a closer reconciliation between theory and experiment will occur.

1.\(^{1}\) previous papers presented at earlier APS meetings

R1.00172 Feedback-controlled radiation pressure cooling

YEHIAM PRIOR, MARK VILENSKY, ILYA SH. AVERBUKH, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel 76100 — We propose a new approach to laser cooling of micromechanical devices, which is based on the phenomenon of optical bistability. These devices are modeled as a Fabry-Perot resonator with one fixed and one oscillating mirror. The bistability may be induced by an external feedback loop. When excited by an external laser, the cavity field has two co-existing stable states depending on the position of the moving mirror. If the latter moves slow enough, the field in the cavity adjusts itself adiabatically to the mirror’s instantaneous position. The mirror experiences radiation pressure corresponding to the intensity value. A sharp transition between two values of the radiation pressure force happens twice per every period of the mirror oscillation at non-equivalent positions (hysteresis effect), which leads to a non-zero net energy loss. The cooling mechanism resembles Sisyphus cooling in which the cavity mode performs sudden transitions between two stable states. We provide a dynamical stability analysis of the coupled moving mirror – cavity field system, and find the parameters for efficient cooling. Direct numerical simulations show that a bistable cavity provides much more efficient cooling compared to the regular one.

R1.00173 Effect of Disorder on a Bose-Einstein Condensate with Tunable Interactions

D. DRIES, YONG P. CHEN, J. HITCHCOCK, M. JUNKER, T. A. CORCOVILLOS, C. WELFORD, R. G. HULET, Rice University Physics and Astronomy and Rice Quantum Institute — We have investigated the effect of a disordered optical potential on the transport and phase coherence of a Bose-Einstein condensate (BEC) of \(^6\)Li. We observe damping of BEC dipole oscillations even when the disorder strength, \( V_D \), is small, while for large \( V_D \), transport is completely inhibited. Time-of-flight images show that the BEC gradually loses phase coherence for \( V_D > \mu/2 \), with coherence completely lost when \( V_D = \mu \), where \( \mu \) is the chemical potential of the BEC. We interpret this loss of coherence as resulting from fragmentation of the BEC as seen from in-situ measurements of the density distribution. While these experiments were performed with a BEC healing length, \( \xi \), that is small in comparison to the disorder length scale, we are currently attempting to observe the Anderson localization predicted to occur for large \( \xi \). Using a magnetically-tuned Feshbach resonance, the s-wave scattering length, \( a_s \), is reduced to near zero where \( \xi \) becomes very large. Results of applying the disorder potential to this nearly non-interacting condensate, with \( a_s \) much less than the Bohr radius, will be reported.

R1.00174 K-Shell Ionization of Atoms (2 \( \leq Z \leq 92 \))

M.A.R. PATOARY, Department of Physics, University of Rajshahi, Rajshahi, Bangladesh, M. ALFAZ UDDIN, Department of Physics, University of Rajshahi, Rajshahi, Bangladesh, A.K.F. HAQUE, Department of Physics, University of Rajshahi, Rajshahi, Bangladesh, A.K. BASAK, Department of Physics, University of Rajshahi, Rajshahi, Bangladesh, B.C. SAHA, Department of Physics, Florida A&M University, Florida-32307 — The electron impact ionization phenomenon have fundamental importance ranging from plasma to astro-physics. Reliable K-shell ionization cross sections (KICS) are needed for various quantitative analyses. Even the first order quantal calculations are rather both lengthy and not too easy to implement for various modeling calculations. We propose a parameter free model based on the widely used binary encounter approximation (BEA) [1,2] by incorporating both the ionic and relativistic corrections and have tested to evaluate KICS with considerable success as compared to experimental results even up to \( E = 1 \) GeV.

R1.00175 ARTIFICIALLY STRUCTURED MATERIALS –

R1.00176 Fabrication of metamaterials in THz region using ink jet system and characterization using THz-TDS

YEW LI HOR, HEE LIM, JOHN FEDERICI, NEW JERSEY INSTITUTE OF TECHNOLOGY TEAM — This article demonstrates the use of new fabrication techniques to fabricate metamaterials in THz range via a material deposition system. The patterns of these metamaterials follow the conventional designs which are single ring-SRR and double-Dots with varying conductivities. Highly conductive nano particle Ag and Pedot/PSS polymer inks are used as structural medium. The fabricated metamaterials of effective lattice sizes of 50 to 80 micron are then characterized using THz-TDS with 0.1 to 3 THz range in transmission mode. The detail steps of fabrication and THz-TDS experimental setup are elaborated. The absorption spectra of different thicknesses and different background substrate of these metamaterials are presented and discussed. Additional, the theoretical modeling of the fabricated samples are shown and compared with the experimental result.
A study of Diamond like Carbon films deposited by PECVD using DC and pulsed DC power supply.

R1.00187 Drift Instability of a 2D Magnetoplasma in a Periodic Potential. M. TAHIR, University of Sargodha, Sargodha, Pakistan, K. SABEEH, Quaid-i-Azam University, Islamabad, Pakistan, V. FESSATIDIS, Fordham University, Bronx, USA, N.J.M. HORING, Stevens Institute of Technology, Hoboken, USA — We examine the drift instability of a magnetized 2D electron plasma in a weak periodic potential, taking account of a steady current. In this, we treat a strong magnetic field inducing Landau quantization, and analyze both the inter- and intra-Landau band plasmon spectra within the framework of the random phase approximation, determining the occurrence of magnetoplasmon instability as a function of drift speed.

R1.00178 Stability and structure of free-standing III-V nanorods: An ab initio investigation. ROMAN LEITSMANN, FRIEDHELM BECHSTEDT, Institut für Festkörpertheorie und -optik, Friedrich-Schiller Universität Jena — The interest in anisotropic needlelike crystals has been recently stimulated by the potential need as building blocks for nanoscale electronic and photonic devices. Due to their considerable potential for optoelectronics or high-speed electronics nanorods (NRs) consisting of III-V semiconductors are of particular interest. In most cases the growth direction of III-V semiconductor NRs is parallel to the [111] axis of the bulk zinc-blende (zb) structure. However, the crystal structure of the NRs may change noticeably, depending on growth conditions and growth method. In particular, changes of the crystal symmetry from the cubic to the hexagonal (wurtzite - w) stacking of the carbon-anion bilayers have been observed in many cases. We report an investigation of hexagonal-shaped III-V III semiconductor NRs with varying crystal structure, varying surface passivation, and varying diameter [1]. Their stability is dominated by the free surface energies of the corresponding facets. We observe a phase transition between local zb and w geometry of the rods versus the preparation conditions of the surfaces [1] J. Appl. Phys. 102, 063528 (2007)

R1.00176 Bloch oscillation and Stark localization in graded lattices. KIN WAH YU, Chinese University of Hong Kong, K. YAKUBO, Hokkaido University, J. J. XIAO, Hong Kong University of Science and Technology — In this work, we report Bloch oscillation (BO) in graded elastic [1] and plasmonic [2] lattices. This is an unusual kind of oscillatory motion due to the band structure of graded lattices and is analogous to electronic BO in semiconductor superlattices. The study is related to the recently identified localized excitations called gradons which is peculiar to graded lattices [1,2]. We will use semiclassical theory to establish the conditions for BO and study the dynamics of BO in these systems. Moreover, we will confirm semiclassical solution by time-domain simulations of the propagation of wave packets. Results of these two methods will be compared. In this way, we can understand the origin of gradon localization more clearly. Results of the present research also offer great potential applications for controlling wave propagation by means of graded materials.

R1.00181 Modeling the self-assembly of nanoparticle and nanorod superlattices. ALEXEY TITOV, PETR KRAL, University of Illinois at Chicago, PROF. KRAL'S RESEARCH GROUP TEAM — Colloidl semiconductor PbSe/CdSE nanoparticles (NP) of the sizes of 3-10 nm can self-assemble in fcc, hcp and single-hexagonal (sh) superlattices [1]. We model the Coulombic, van der Waals and steric interactions between these NPs to understand the exact conditions under which they can self-assemble in these lattice structures. Our simulations show that non-local dipoles of the NPs and their screening by the conducting substrate are both crucial for the sh lattice formation. We model analogously the self-assembly of semiconducting CdSe nanorods (NRs), realized also in the presence of electric fields [2], and the binary semiconducting-metallic nanoparticle superlattices [3].

R1.00182 Experimental Study of Electrical Properties of ZnO Nanowire Random Networks for Gas Sensing and Electronic Devices. DAQING ZHANG, CSU Fresno, SIRISHA CHAVA, CHRIS BERVER, Univ. of Idaho, ANIRBAAN MUKHERJEE, VANVILAI KATKANANT, CSU Fresno — ZnO nanostructures are an attractive material for electronic and optical applications due to their many unique properties. Our research focuses on studying mats of ZnO nanowires as an electronic material with particular interest in their interaction with various gases. The ZnO nanowires were synthesized on sapphire substrates using a tube furnace at atmospheric pressure. Two-terminal current-voltage (I-V) measurements were used to examine the electrical conductivity of the ZnO nanowire mat as a function of temperature and exposure to various gases. The ZnO nanowires were synthesized on sapphire substrates using a tube furnace at atmospheric pressure. Two-terminal current-voltage (I-V) measurements were used to examine the electrical conductivity of the ZnO nanowire mat as a function of temperature and exposure to various gases. Temperature-dependent measurements were performed in vacuum using a continuous flow cryostat over ~150 K to ~ 300 K. Gas exposure experiments were conducted in a custom-built environmental chamber which was filled with various testing gases (Ar, CO, CO2, H2) at 30 bar or under vacuum. We observed reversible changes in the I-V characteristics as a function of gas exposure. For CO, the currents increased by a factor of about four. In addition, changes in the I-V behavior were found to be reversible after evacuation. Possible mechanisms for the gas-specific responses of the ZnO nanowire mat will be discussed.

R1.00183 CdSe, CdTe and core-shell CdSe-CdTe nanowires: A density functional study. R. RAMPRAASAD, TOM SADOWSKI, University of Connecticut — Semiconductor nanowires (NWs) are attractive in photovoltaic applications due to their ability to support a large number of electron-hole pairs (excitons) and the possibility of enhanced transport of dissociated charge carriers. To facilitate transport along the long axis of the nanowires, efficient charge separation of the exciton is desired. There is evidence suggesting that at a Type II band offset between two semiconductors enables charge separation more easily than in single component systems. The focus of this study is to provide an understanding of the tendency for electronic-hole separation in core-shell CdSe-CdTe NWs, which contain a radial Type II band offset. In particular, first principles computational methods have been applied to theoretically long CdSe-CdTe heterostructure NWs in the wurtzite crystal structure over a range of core and shell sizes. The interfacial energy of the nanorods, the band gaps, and the location of the electron and hole states are assessed as a function of the number of CdSe pairs, and core and shell radii. The overlap of the electron and hole wavefunctions, determined to quantify the extent of electron-hole separation, is differentiated with that for single-component CdSe and CdTe nanowires.
R1.00184 Fano effect in quantum wires with a uniform transverse electric field. V. VARGIAMLIS, Aristotle University, Thessaloniki, Greece, V. FESSATIDIS, Fordham University, Bronx, USA — We investigate the effect of an external uniform transverse electric field on the Fano resonance in electronic transport of a quantum wire with a finite range impurity. We employ the Feshbach coupled-channel theory for calculating the transmission probability. The attractive impurity is Pöschl-Teller along the propagation direction but is an arbitrary function of the lateral coordinate. For this type of impurity analytical solution to the scattering problem is possible. The Fano line shape resulting from the interference of direct transmission via a quasibound state created in the impurity, is shown to be strongly affected by the strength of the electric field. In particular, we show that as the strength of the electric field increases the resonance width continuously decreases and finally shrinks to zero. Consequently, the Fano line shape collapses. The vanishing of the resonance width indicates the transformation of the quasibound state into a true bound state in the continuum. Depending on the strength of the impurity, the collapse of the Fano line shape can even occur in the regime of weak electric field. This interesting collapsing behavior of the Fano resonance has also been shown to occur in purely one-dimensional systems (i.e., in 1D mesoscopic open rings). We also examine the role of the transmission amplitude, in the complex energy plane, as a function of the electric field strength.

R1.00185 Dynamics of an Electron in a Saddle Potential Subject to Crossed Electric and Magnetic Fields. K. SABEEH, A. YAR, Quaid-i-Azam University, Islamabad, Pakistan, V. FESSATIDIS, Fordham University, Bronx, USA, N.J.M. HOHLFELS, Stevens Institute of Technology, Hoboken, USA, M.L. GLASSER, Clarkson University, Potsdam, USA — We analyze the role of an electric field in the scattering/tunneling of an incident plane electron wave through a quantum point contact in a magnetic field. In this, the point contact is modeled as a saddle potential. We employ the Bogoliubov transformation and guiding center coordinates following the techniques of H. A. Fertig and B. I. Halperin (Phys. Rev. B 36, 7969 (1987)), but we expand the analysis to include the effects of the applied electric field here and examine the temporal development of the incident plane electron wave rather than that of a bath eigenfunction.

R1.00186 Magneto-optics of single Rashba spintronic quantum dots subjected to a perpendicular magnetic field. MANVIR KUSHWAHA, University of Puebla, Puebla, Mexico — We report on the theoretical investigation of the effect of the Rashba-type spin-orbit interaction (SOI) on the Fock-Darwin energy spectrum in the parabolically confined quantum dots in the presence of a perpendicular [to the original two-dimensional electron gas (2DEG)] magnetic field. The study is based on the exact analytical results obtained without any approximation and numerical simulation. We observe that the SOI modifies drastically the optical, thermodynamic, as well as magneto-optical properties of the (narrow-gap InAs) quantum dots. We discuss the dependence of the Fock-Darwin spectrum, Fermi energy, optical transitions, and magnetization on all the important parameters involved in the theory such as, for example, the orbital quantum number, the magnetic field, the confinement potential, and the Rashba parameter that characterizes the strength of the SOI. The illustrative examples include the results both with and without the SOI, for the sake of comparison. One of the most important observation is that the Rashba SOI causes the band mixing and band shifting in the quantum dots and the Fock-Darwin energy spectrum becomes richer but complex. This complexity seems to arise due to an intricate interplay between the SOI and the Zeeman energy.

R1.00187 Left-handed materials: detailed experimental parametric studies of the fishnet structure. V.D. LAM, J.B. KIM, J.W. PARK, N.T. TUNG, S.J. LEE, Y.P. LEE, q-Psi and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, Korea — Recently, a new area of research, called left-handed materials (LHMs), has attracted considerable interests due to their unusual physical properties and novel applications. The first experimental evidence for the existence of LH behavior was proposed by Smith et al., using the right-handed resonator combined with the continuous wire. Several different designs, utilizing this idea for the LHMs, have been reported. Zhou et al. investigated the LHMs based on the H-shaped wires, which exhibits a negative refraction index in the microwave range. Dolling et al. introduced a modification with rectangular structures (the so-called fishnet structure) and demonstrated the LH characteristics at a wavelength of 780 nm while S. Zhang et al. employed an array of elliptical apertures, showing the LH behavior in the near-infrared regime. The main purpose of these modified structures is to find out the optimized structure that can be easily fabricated and experimentally characterized, especially, LHM working at optical frequencies. In this report, we present the experimental results of the parametric study on the fishnet structure, which are also compared with the previous theoretical studies. These structures were designed, fabricated, and measured in the microwave frequency regime.

R1.00188 Nonlinear Fano effect in semiconductor quantum dots: Detecting weak interactions. ALEXANDER GOVOROV, Ohio University — The Fano interference effect appears when a discrete state of an atom or quantum dot couples with a continuum of states. In self-assembled quantum dots, the coupling may come from the tunnelling or Auger processes [1,2,3]. This study develops a theory of Fano effect in self-organized quantum dots under the condition of strong optical pumping. Our theory shows that the Fano effect becomes greatly enhanced in the nonlinear regime. In the linear regime, if the dot-continuum interaction is very weak, the optical detection of Fano effect is impossible because of the Heisenberg principle. In other words, in the linear regime, a finite lifetime of an exciton creates an energy uncertainty and the Fano interference effect becomes invisible. However, in the nonlinear regime, the natural radiative broadening does not play the main role and even a very weak dot-continuum interaction becomes apparent. This nonlinear method can be used to detect very weak interactions between a two-level system (or qu-bit) and a continuum of states of any nature. The nonlinear Fano effect in InAs quantum dots has been observed in the recent experiments performed in Munich and Edinburgh [3]. This study was performed in collaboration with W. Zhang, R. J. Warburton, K. Karrai, and R. J. Warburton. [1] A.O. Govorov, R. J. Warburton, and K. Karrai, Phys. Rev. B 67, 241307 (2003). [2] K. Karrai et al., Nature 427, 135 (2004). [3] M. Kroner et al., submitted to Nature.

R1.00189 Optically Injected Charge and Spin Density Patterns in Quantum Wells1. JOHN SIPE, RASHAD ABRAROV, EUGENE SHERMAN, Department of Physics and Institute of Optical Sciences, University of Toronto — We investigate the charge and spin dynamics following optical injection of currents in quantum wells taking into account momentum relaxation, electron-hole drag and the long-range Coulomb forces. Our numerical approach uses expansion of the investigated quantities in the Hermite-Gaussian basis. We find that on time scale of the order of one nanosecond the carrier and current densities demonstrate complex patterns even when the effects of the spatially nonuniform forces are expected to be weak. This behavior can be attributed to two different processes: the charge displacements seen in the THz radiation and optical pump-probe experiments can be sufficiently different. The resulting spin density patterns arising due to the spin-dependent electron-hole skew scattering are calculated and analyzed in terms of the spin-orbit coupling, Coulomb forces, and the carrier momentum relaxation effects.

1We are grateful to the NSERC (Canada) for support.

R1.00190 Computational Study on the Magneto-optical Effects from Gyrotropic Gratings. MIN HYUNG CHO, YUE HUI LU, Y. P. LEE, Quantum Photonic Science Research Center, Hanyang University, Seoul, Korea, J00 YULL RHEE, BK21 Program Division of Advanced Research and Education in Physics Research Division and Institute of Basic Sciences, Sungkyunkwan University, Suwon, Korea — Maxwell’s equations with non-diagonal complex dielectric tensor are numerically studied for the calculation of Magneto-optical(MO) effects from one-dimensional lossy gyrotropic or magnetic gratings. Owing to the periodicity of the structure, the dielectric tensor is expanded out in Fourier series and the electric and the magnetic vectors are written in terms of Bloch wave. Then, Maxwell’s equations are simplified as a system of ordinary differential equations, and the solutions can be simply written in terms of exponential function with the eigenvalue of system times the initial value. Finally, by considering the multiple reflection in the grating structure with Airy-like internal reflection series, the reflection and the transmission matrices are obtained and used to calculate the MO effect. The Kerr rotations of the 0th and the 1st diffracted orders are calculated as a function of various parameters. The calculated results agree excellently with the experimental data for permalloy gratings. This method can also be used for many interesting applications and easily extended to two-dimensional gratings.
Giant Photonic Band Gaps in one dimensional Photonic heterostructures. In this work we show that it is possible to design Giant Photonic Band Gaps in heterostructures via the determination of the group velocity. A photonic heterostructure is composed by the union of two or more distinct photonic crystals. We present the calculation of the heterostructure band structure implementing the supercell technique in the plane wave method. We show that even if the heterostructure presents a very complicated photonic band structure, it is possible to discriminate the regions of low transmission obtaining the group velocity. We verify the very existence of the forbidden allowed regions with the theoretical calculations of the light transmission.

Two-dimensional photonic crystal heterostructure with Omnidirectional band gap. We present the numerical determination of giant omnidirectional (3D) photonic band gaps calculated for a two-dimensional heterostructure, which are composed by the union of two photonic crystals. The photonic band structure is calculated via the implementation of the supercell technique on the the plane-wave method. We have optimized the structure in order to obtain the biggest band gap.

Synthesis and study of composite silver-polymer metamaterials. We have designed, synthesized and characterized a range of non-magnetic metamaterials with continuously tunable dielectric constant. Powders of 30 nm silver nanoparticles were suspended onto glass substrates and characterized in optical transmission and reflection experiments. Using known formula for reflectivity and transmissivity in three-layered structures, we extracted from the experimental data the spectra of real and imaginary parts of the effective dielectric constants. The experimental maximal value of $\varepsilon_{eff}'$ exhibited monotonous growth and reached $\varepsilon_{eff}'=12.8$ at $\lambda=2.4 \mu m$ at the maximal concentration of Ag nanoparticles. The demonstrated value of $\varepsilon_{eff}'$ exceeds that in Si and appears to be the highest in 1.5-2.5 $\mu m$ spectral range. The demonstrated easy-to-synthesize nanoparticle adds to the tool box of photonic metamaterials with extreme values of $\varepsilon$.

Magnetic dipole systems for probing optical magnetism. Powders of 30 nm silver nanoparticles were suspended in solution of Polymethylmethacrylate and exposed to Q-switched laser radiation in order to separate nanoparticles and/or reduce the degree of aggregation. The films of Ag-PMMA composites were deposited onto glass substrates and characterized in optical transmission and reflection experiments. Using known formula for reflectivity and transmissivity in three-layered structures, we extracted from the experimental data the spectra of real and imaginary parts of the effective dielectric constants. The experimental maximal value of $\varepsilon_{eff}'$ exhibited monotonous growth and reached $\varepsilon_{eff}'=12.8$ at $\lambda=2.4 \mu m$ at the maximal concentration of Ag nanoparticles. The demonstrated value of $\varepsilon_{eff}'$ exceeds that in Si and appears to be the highest in 1.5-2.5 $\mu m$ spectral range. The demonstrated easy-to-synthesize nanoparticle adds to the tool box of photonic metamaterials with extreme values of $\varepsilon$.

Artificial Molecules. Confinement of carriers in quantum dots results in hydrogenic like states for the exciton. Thus a single excitation in a quantum dot bears resemblance to a hydrogen atom; these materials are often referred to as ‘artificial atoms’. A pair of excitons will form a four body biexciton, akin to a hydrogen molecule. Quantum confinement increases the binding energy of the ground state of the biexciton. Quantum confinement should also produce bound states for the excited states of the biexciton. Thus the excitonic ‘hydrogen molecule’ should have an eigenstate spectrum in the vein of molecular orbitals. The eigenstate spectrum of the biexciton has remained elusive due to the ultrafast timescale of relaxation processes in quantum dots which mask observation of the excited states. Here, we show the first, direct observation of excited states of the biexciton, completing the analogy of excitons in quantum dots to atomic and molecular systems.

Hollow Quantum Dot Shells: Optical Response Function Analysis. We consider the response of finite two-dimensional lattice shells of coupled quantum dots, approximated as dipoles, to an applied external electric field. We assume that the lattice constant is much smaller than the wavelength of applied electric field, to provide a coherent exciton. Using the matrix Green's function and Coupled Dipole Hamiltonian, the response function is derived and analyzed numerically. Treating the dipole coupling as a parameter, the response function of an entirely decoupled lattice is calculated, from which the coherence effects are determined in the fully coupled case. The effect of hollowness is considered, in which optical resonator effects are determined, resulting from the matching of the radius of the cylindrical shell to the light wavelength. The response function is decomposed into partial response functions due to individual modes, in which the polarization dependence is determined by altering the orientation of the incident field.

Wave Transmission Through a Nano-hole. We have examined the integral equation for scalar wave transmission through a nano-hole modeled as a single point, employing a formal procedure for an exact analysis. The dependence is determined by altering the orientation of the incident field. The response function is decomposed into partial response functions due to individual modes, in which the polarization dependence is determined by altering the orientation of the incident field.

Nanostructured Silicon Optical Waveguides. We have measured the group index in both the TE and TM polarizations, and the experimental values agree closely with computational simulations using a fully-vectorial finite-difference mode-solver. We have fabricated and demonstrated multi-slot waveguides in silicon-on-insulator chips, with slot width 100 nm and slot-to-slot spacing of 150 nm. For chip-scale optical delay lines and compact waveguide-based polarization switches incorporating phase retardation. Using electron-beam lithography and dry etching, we have fabricated and demonstrated multi-slot waveguides in silicon-on-insulator chips, with slot width 100 nm and slot-to-slot spacing of 150 nm.

R1.00199 Förster Resonance Energy Transfer between Nanoparticles and Nanowires . PEDRO L. HERNANDEZ-MARTINEZ, ALEXANDER O. GOVOROV, Ohio University — We develop a theoretical model to describe Förster resonance energy transfer (FRET) between semiconductor nanoparticles (NPs) and nanowires (NWs). We obtain an analytical equation in the dipole limit and a numerical solution for the general case. We find that, for FRET between NPs and NW, the transfer time is proportional to 1/d^5, where d is the distance between NP and NW. The calculated transfer time between CdTe NPs and NWs is 16.9 ns. This number agrees well with the experimental value, 16 ns [1]. We also found good agreement with the experimental data [1] for other NP-NW distances. For a NW material, we explore a semiconductor (CdTe) and metals (Au and Ag) [2]. In a NP-NW bio-conjugate, excitons flow from NPs to a NW and then become collected in the NW. When voltage is applied across a NW, this system is expected to demonstrate enhanced photo-current and photo-voltage responses. The enhancement effect comes from energy channeling from NPs to a NW due to FRET. This system can be used in optoelectronic devices and energy conversion systems. [1] J. Lee, A. O. Govorov, and N. A. Kotov, Nano Letters 5, 2063-2069 (2005). [2] J. Lee, P. Hernandez, J. Lee, A. O. Govorov, and N. A. Kotov, Nature Materials, 6, 291 – 295 (2007).

R1.00200 Nanometer sized electrodes fabricated by electromigration of Au and Pd nanowires . ALEXANDRU VLAD, SÉBASTIEN FANIEL, BENOIT HACKENS, VINCENT BAYOT, SORIN MELINTE, DICE - Université Catholique de Louvain, Louvain la Neuve, Belgium — Electromigration-driven metallic nanowire failure is presented. Here, Au and Pd nanowires patterned by electron-beam lithography were electrically stressed up to their breaking point. Feedback control and simple voltage sweep techniques have been successfully used to form nanometer-sized gaps. We observe a decrease in residual resistance up to the breaking point. In contrast, Pd nanowires presented an anomalous resistance decrease close to their failure point. This was associated to the melting and agglomeration of metallic grains within the electrically stressed nanowires. The SEM images acquired at intermediate stages of electromigration agree with the electrical data findings. The influence of the nanowire geometry upon the morphology of fabricated nanoelectrodes is considered. Beside the morphological characterization of our break junctions, we also measured their current-voltage characteristics. We observed single electron tunneling effects, probably due to the presence of metallic clusters formed close to the nanoelectrodes during the electromigration. Our results are consistent with recent findings on Coulomb blockade phenomena in electromigrated gold break junctions.

R1.00201 Molecular spin clusters for quantum computation . MARCO AFFRONTE, CNR-INFM-S3 — Molecular spin clusters are prototypical systems exhibiting coherent dynamics of the electronic spin. The pattern of the lowest lying spin states is well defined and controlled at the synthetic level. The chemical bottom up approach used for the synthesis of molecules also allows to reduce intrinsic sources of decoherence and to build links between clusters, thus creating entanglement of spin states. Molecular spin clusters can be deposited at surfaces, thus forming scalable networks. Different molecules and ligands may be combined to exploit different functionalities, the latter being defined at molecular level. These facts provide extraordinary motivation to attempt the implementation of molecular quantum processors that, in turn, are test bench for novel quantum algorithms. Recent achievements obtained on antiferromagnetic molecular rings will be presented.

R1.00202 Quantum Computing using Rotational Modes of Dimers . KENJI MISHIMA, KOICHI YAMASHITA, Univ. of Tokyo — In this paper, we numerically constructed general-purpose phase-correct global quantum gates by using intermolecular rotational modes of two polar molecules coupled by dipole-dipole interaction to encode two qubits and implement the Deutsch-Jozsa algorithm. The calculations were based on the multi-target optimal control theory (MTOCT). The molecular systems we examined were NaCl-NaBr, NaCl-NaCl, and NaBr-NaBr dimer systems. The rotational states in the ground vibrational state of the ground electronic state of these pairs were taken as two qubits. When implementing the Deutsch-Jozsa algorithm by combining these elementary gates, we obtained a maximum probability 97.95 % for NaBr-NaBr system with the interval R=5.0 nm in the repulsive configuration, which is the best performance of the two-state Deutsch-Jozsa algorithm compared with intramolecular vibrational-vibrational, rotational-vibrational, and electronic-vibrational qubits reported so far.

R1.00203 Thermal conductivity of Si nanocrystals1 . SHANG-FEN REN, Illinois State University, WEI CHENG, Beijing Normal University — Thermal conductivities of spherical Si nanocrystals (NCs) are investigated with three different models: a macroscopic approximation, a semi-microscopic model that calculates the heat capacity of NCs with a microscopic Valence-Force-Field Model (VFFM), and a full microscopic description of phonon thermal conduction that calculate both heat capacity and phonon group velocity by the VFFM. The results are compared, and the advantages and limitations of each of these models are discussed. It is shown that for spherical Si NCs, the macroscopic approximation is quite good for NCs with a diameter larger than 1.33 nm. For smaller NCs, the VFFM predicts that the thermal conductivity increases quickly when the size decreases, opposite to the macroscopic approximation, and VFFM also predicts that the minimum of thermal conductivity for spherical Si NCs occurs at a diameter of 1.33 nm, the limit at which the macroscopic approximation applies.

R1.00204 Thermoelectricity in Ca$_3$Co$_4$O$_9$: An Atomic Structure Perspective1 , T. TYSON, Z. CHEN, New Jersey Institute of Technology, J. TU, City College of New York, Q. LI, Brookhaven National Laboratory — The temperature dependent local structure about the Co sites in the misfit system referred to as Ca$_3$Co$_4$O$_9$ was examined by x-ray absorption spectroscopy. Density Functional calculations utilizing a large cell were used to obtain the optimized atomic structure. The detailed atomic structure about the Co sites was determined from the XAFS measurements. The complementary density functional computations of the structure and atomic forces provide a new 3D model of the structure and point to a unique configuration which may be the origin of the high thermoelectricity in this material.

R1.00205 Maximizing thermoelectric figure-of-merit at high temperature in p-type Bi-Sb-Te system . BO YU, YI MA, JIAN YANG, BED POUDEL, YUCHENG LAN, DEZHI WANG, ZHIFENG REN, Dept. of Physics, Boston College, QING HAO, GANG CHEN, Dept. of Mechanical Engineering, Massachusetts Institute of Technology, DEPT. OF PHYSICS, BOSTON COLLEGE COLLABORATION, DEPT. OF MECHANICAL ENGINEERING, MASSACHUSETTS INSTITUTE OF TECHNOLOGY COLLABORATION — Bismuth telluride alloys and their derivatives are the most important thermoelectric materials used in refrigeration devices around room temperature. Using mechanical alloying and hot press, we have achieved 100% dense nano-structured p-type Bi$_3$Sb$_2$Te$_3$ samples. We demonstrated here that the enhanced dimensionless figure-of-merit (ZT) are due to enhanced phonon-scattering, and the ZT peak could be easily shifted to higher temperature by varying the composition and processing conditions.

R1.00206 Thermoelectric Properties Studies on n-type Bi$_2$Te$_3-x$Se$_x$ . JIAN YANG, XIAO YAN, YI MA, BED POUDEL, YUCHENG LAN, D.Z. WANG, Z.F. REN, Physics Department, Boston College, Chestnut Hill, MA02467, Q. HAO, G. CHEN, Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139 — Bi$_2$Te$_3-x$Se$_x$ is a classic room temperature n-type thermoelectric material. In spite of the long history of research, its ZT is still below 1. By directly making nano sized particles using mechanical alloy from element, then pressing the nanoparticles into 100% dense bulk sample with nano-structures by hot press, we expect to decrease the thermal conductivity by the increased grain boundary scattering of phonons so to improve the ZT above 1. The ratio of Te/Se was varied systematically to investigate its effect on thermal conductivity.
R1.00207 Thermionic cooling on barium strontium thin film surface\(^1\), FENG JIN, GUOGANG QIAN, SCOTT LITTLE, Ball State University — Strong thermionic emission was observed from low-work-function barium strontium oxide thin films. Such strong thermionic emission resulted from a cooling effect on the emitting surface. Temperature drops as high as 90 °C were obtained. Barium strontium oxide (BaSr\(_2\)O) thin films approximately 1 \(\mu\)m in thickness were deposited on tungsten substrates using RF magnetron sputter deposition. Thermionic emission from the thin film was characterized and the work function of the thin film was measured using Richardson line method. The temperature drop or cooling of the thin film surface at different emission current was measured using a high precision optical pyrometer.

R1.00208 Mn linear chains deposited on CuN/Cu(001): environment effects on the Mn-Mn interactions, MARIA ANDREA BARRAL, Departamento de Física, FCEyN, Universidad de Buenos Aires, ANA MARIA LLOIS, Departamento de Física, FCEyN, Universidad de Buenos Aires, RUBEN WEHT, Departamento de Física, CNEA, GUSTAVO LOZANO, Departamento de Física, FCEyN, Universidad de Buenos Aires — Scanning tunneling microscopy (STM) was used recently to study the interaction among manganese atoms deposited on thin insulating copper nitride islands grown on Cu(001). The value of the exchange interaction \(J\) among manganese atoms for different atomic arrangements was obtained, showing that it strongly depends on the Mn deposition sites. In this contribution we present the result of ab initio calculations for different arrangements of infinite Mn chains on CuN/Cu(001) to understand the influence of the environment on the Mn-Mn exchange interactions.

R1.00209 Photopatterning in phase separating reactive ternary systems, PRATYUSH DAYAL, OLGA KUKSENOK, ANNA BALAZS, University of Pittsburgh — We investigate a ternary ABC phase separating system in which components A and B undergo reversible photochemical inter-conversion reaction while component C remains non-reactive. We focus on systems with unequal forward and backward reaction rates. It has been well known that in such binary systems the competition between phase separation and chemical reaction results in hexagonal patterns contrary to lamellar structures for equal reaction rates. Since the chemical reaction favors miscibility a phase diagram is established to determine the phase boundary of such systems. We demonstrate that by confining chemical reaction to designated places using masks more complicated structures could be formed in the binary AB systems. We elucidate the scenarios in which the third non-reactive C component results in the displacement of AB domains from the reaction sites in favor of C. This migration is driven by difference in the free energies between the reaction sites and the masked regions. A rich variety of complex super-lattice patterns can be formed by changing the processing variables such as initial concentration, distance between the masks and rates of forward and backward reaction.

R1.00210 Self assembled silicon nanowire Schottky junction assisted by collagen\(^1\), DIDIER STIEVENARD, IEMN - DptISEN, BILLLE SAHIL, IEMN-Dpt ISEN, YANNICK COFFINIER, RABAH BOUKHERROUB, IRI FRE2963, OLEG MELNYK, IBL UMR8525, IEMN - DPTISEN TEAM, IRI TEAM, IBL TEAM — We present results on self assembled silicon nanowire Schottky junction assisted by collagen fibrous. The collagen is the principle protein of connective human tissues. It presents the double interest to be a low cost biological material with the possibility to be combed as the DNA molecule. First, the collagen was combed on OTS modified surface with gold electrodes. Second, silicon nanowires were grown on silicon substrate by CVD of silane gas (SiH\(_4\)) at high temperature (500 °C) using a vapor-liquid-solid (VLS) process and gold particles as catalysts. In order to increase electrostatic interaction between the collagen and the nanowires, these latters were chemically modified by mercaptopropylmethoxysilane (MTPS), then chemically oxidized. Therefore, the nanowires were transferred from their substrate into water and a drop of it deposited on the surface. Nanowires are only bound to collagen and in particular, in electrode gaps. The formation of spontaneous Schottky junction is demonstrated by current-voltage characteristics.

R1.00211 COMPUTATIONAL METHODS: DYNAMICS, TRANSFER, AND PLASMA —

R1.00212 Merging for Complex Particle Kinetic modeling of multiple plasma beams (inter-penetrating flows)\(^1\), ALEXANDER LIPATOV, GEST Center UMBC — We suggest a merging procedure for the Complex Particle Kinetic (CPK) model in case of inter-penetrating flow (multiple plasma beams). Each CPK macro-particle includes a Maxwellian distribution in velocity and Gaussian distribution in space with internal dynamics (see [Hewett, 2003], for details). It is assumed that an arbitrary distribution of real particles can be represented by such a superposition in phase space (moving—finite—element approach) at least as well as could be done with the standard particle in cell (PIC)/Monte Carlo (MC) delta functions and their associated “shape factors”. The CPK method allows us to provide a global simulation of the complex plasma objects on the Hall-MHD (fluid) scale (aggressive merging) with automatic incorporation of the kinetic/particle description of the particle-wave processes (aggressive fragmentation) where it is necessary. The CPK approximation works well for ions, electrons, dust grains and neutral components. This code was tested in the simulations for the study of the interaction of the plasma flow with comets and Io’s atmosphere. In this report we examine the standard (PIC) and the CPK methods in the case of the particle acceleration by shock surfing. The plasma dynamics is described by a standard (particle-ion– fluid- electron) hybrid model. While a particle-mesh study of the interaction of the plasma flow with comets and Io’s atmosphere is required to understand the high radiative power losses associated with tungsten. The energy loss due to radiative processes for high-Z ions can be critical in understanding the ionization balance of the plasma. We present non-local thermodynamic equilibrium (non-LTE) calculations for a tungsten plasma using the Los Alamos National Laboratory suite of atomic codes. We examine the radiated power losses and ion balance distributions for a variety of electron temperatures ranging from 2 keV to 30 keV and densities associated with conditions found in ITER.

\(^1\)This work was supported by the Department of Energy through Los Alamos National Laboratory.
or minor grooves. Differences between complexation with PEI and PLL will be discussed. The DNA does not undergo any major structural changes upon complexation and remains in the B-form. In the formed gene therapy vectors, with polycations emerging as promising candidates. Molecular dynamics simulations of the DNA duplex CGCGAATTCGCG in the presence to provide insight into the structure and formation of DNA polyplexes. After an initial separation of approximately 50 Å, the DNA and polycation come together to form a stable complex within 10 ns. The DNA does not undergo any major structural changes upon complexation and remains in the B-form. In the formed complex, the charged amine groups of the polycation mainly interact with DNA phosphate groups, and rarely occupy electronegative sites in either the major or minor grooves. Differences between complexation with PEI and PLL will be discussed.
Co-operative Macromolecular Disassembly via the Heat Shock Chaperone Hsc70. JASON PUCHALLA, KELLY KRANTZ, ROBERT AUSTIN, HAYS RYE, Princeton University — Many essential cellular functions depend on the assembly and disassembly of macromolecular complexes. A general class of protein known as molecular chaperones regulates several of these processes. How can complex protein structure be quickly and efficiently disassembled by the action of a small number of these proteins? One such example is that of clathrin: a ubiquitous protein that stabilizes vesicular trafficking by forming a scaffold onto the membrane surface. This scaffold must be removed before the vesicle can deliver its cargo. We report on the cooperative disassembly of yeast-derived GFP-labeled clathrin baskets via its interaction with Hsc70. We exploit the highest signal-to-noise light bursts from single fluorescent baskets transiting a confocal excitation spot to reversibly determine the brightness and size distribution of the baskets during the uncoating process. This minimal uncoating system demonstrates the ability of a surprisingly simple protein system to facilitate rapid structural changes through cooperative action.

R1.00229 Linking Inverse Square Law with Quantum Mechanical Probabilities, SHANTILAL GORADIA, Gravity Research Institute, Inc. — (©2007 by S Goradia) I modify the Newtonian inverse square law with a postulate that the probability of interaction between two elementary particles varies inversely as the statistical number of Planck lengths separating them. For two nucleons a million Planck lengths apart, the probability of an interaction is a trillionth (almost never), seemingly contradicting gravity. Likewise, statistical expression of the size of the universe implicitly addresses the issue of dark energy by linking fine-structure constant \( \alpha = 1/137 \) with the cosmological constant \( \lambda = 1/R^2 \) (abstract submitted 11/11/07 for APS APR2008 meeting). Since light travels one Planck length per Planck time, the radius \( R \) of the spherical shape of the universe is \( 10^{60} \) Planck lengths, linking the cosmological constant \( \lambda = 1/10^{120} \) (see equation 14 in Einstein’s 1917 paper) with \( \alpha \) by the relationship \( 1/\alpha \approx \ln(1/\lambda) \). Intuitive answers to the questions raised suggest that the elementary particles interact via Planck scale mouths \(^1\) with higher probabilities at smaller distances. This intuition may be supported by genetics, explaining issues such as DNA – nucleosome interaction \(^2\)(3). \[1\] http://www.arxiv.org/pdf/physics/0211040 [v. 3] \[2\] www.gravityresearchinstitute.org \[3\] Segal E. et al, A genomic code for nucleosome positioning. R1.00230 Fullerenes Can Induce Toxic Physical Changes of DNA, FABIAN C泽REWSKI, LENE B. ODDER-SHEDE, Niels Bohr Institute, Copenhagen, Denmark — Fullerenes are fascinating symmetric carbon nanostructures. Nowadays, they are widely used because of their characteristic physical and chemical properties. Until now research has mainly been focused on commercial applications of fullerenes. Only a few investigations have addressed the potential biological hazards, one of which is that fullerenes are believed to alter the elastic properties of DNA upon binding. In our experiments we use optical tweezers with sub-picoNewton and nanometer resolution to probe the structural changes and the potential damages which fullerenes might induce on single DNA molecules. Therefore, force-extension relations can be obtained under physiological conditions while varying the concentration of different types of fullerenes. It has theoretically been predicted \(^1\), that certain fullerenes can function as a minor-groove binder to double-strand DNA, thus altering its elastic properties significantly. Fullerenes are capable of causing severe damage inside living organisms by forming DNA regions which are not accessible for proper enzymatic functions. A further goal of the study is to establish fullerenes as a tool for a more detailed investigation of DNA-protein interactions, such as the trafficking of polymers or the packing by procaryotic proteins. \[1\] Zhao X, Striolo A, and Cummings PT: C60 Binds to and Deforms Nucleotides. BiophysJ (89):3856-62, 2005.

R1.00231 A study of the stability of the DNA double helix in complexes of DNA with the bipyridyl-(ethylenediamine)platinum(II) molecular ion, ATTILA SZABO, SCOTT LEE, University of Toledo — The DNA double helix is usually stabilized by the formation of a complex with a ligand. However, the exact nature of the complex can destabilize the double helix, as is well known in complexes of DNA with diaminedichloroplatinum(II). We report the results of our study of the complex of DNA with bipyridyl-(ethylenediamine)platinum(II), abbreviated [(bipy)Pt(en)]\(^2+\), via ultraviolet melting experiments. We find that the DNA double helix is stabilized by the formation of the complex: the temperature of the onset of melting of the DNA double helix increases with increasing amounts of [(bipy)Pt(en)]\(^2+\). The onset temperature is increased by about 14 °C for a ligand content of one [(bipy)Pt(en)]\(^2+\) for every three DNA base pairs.

R1.00232 From frontier states to an inter-nucleotide potential for DNA: a density functional theory based study, MARIA FYTA, Department of Physics, Harvard University, EFTHIMIOS KAXIRAS, Department of Physics and School of Engineering and Applied Sciences, Harvard University — We present results from accurate density functional theory based simulations of individual DNA bases and representative base-pairs in various relative configurations, as they are likely to appear in the equilibrium and stretched forms of DNA. Specifically, we extract the salient features of electronic structure of these molecules, and reveal that the frontier states in the base pairs are related to only one component of the pair. For all combinations of bases and base pairs studied here, the nature of these states was not affected by separation of the bases or base pairs along different directions or rotation along the helical axis. From the same calculations we were able to parametrize and construct an optimized intermolecular potential for DNA nucleotides, that accounts for hydrogen bonding, stacking interactions and the contribution from the sugar backbone. These calculations serve to set the stage for more extensive coarse grain calculations of DNA related biophysical phenomena.

R1.00233 Drug-Membrane Interactions Studied by Vibrational Sum-Frequency Spectroscopy , LAUREN WOLF, KIMBERLY BRIGGMAN, NIST — The activity of a number of drugs depends directly on their interaction with cell membranes and, thus, an understanding of drug-membrane interactions is necessary for improving their pharmacological performance. Drug molecules can interact with membranes by directly binding to membrane-bound proteins or by intercalating into the lipid matrix itself, altering membrane properties such as fluidity, thickness, internal pressure, and phase transition temperature. Here, we focus on the effects of local anesthetics incorporated into the lipid matrix, studying the structural changes induced in supported lipid bilayers by vibrational sum-frequency spectroscopy (VSFS). We find that in addition to depressing the phase transition temperature of the lipid bilayers, most anesthetics also sharpen the gel to liquid-crystalline transition, suggesting an increase in membrane constituent cooperativity. This behavior contrasts the effects of cholesterol on lipid bilayers, which increases membrane rigidity and broadens the phase transition. The structure of the membrane-intercalated anesthetics themselves will also be discussed. This work demonstrates the potential of using supported lipid bilayers and surface-sensitive techniques for future pharmacological studies.

R1.00234 Structure of Functional Staphylococcus aureus \( \alpha \)-Hemolysin Channels in Tethered Bilayer Lipid Membranes, FRANK HEINRICH\(^1\), Carnegie Mellon University, GINTARAS VALNICUS, Institute of Biochemistry, Vilnius, DUNCAN J. MCGILLIVRAY\(^2\), Carnegie Mellon University, JOSEPH W.F. ROBERTSON, NIST Electronics and Electrical Engineering Lab., ILJA IGNATJEV, Institute of Biochemistry, Vilnius, JOHN J. KASIANOWICZ, NIST Electronics and Electrical Engineering Lab., MATHIAS LOESCHE\(^3\), Carnegie Mellon University — We demonstrate the functional reconstitution of the Staphylococcus aureus \( \alpha \)-hemolysin channel in membranes tethered to gold. Electrical impedance spectroscopy measurements show that the pores have essentially the same properties as those formed in free-standing bilayer lipid membranes. Neutron reflectometry (NR) provides high-resolution structural information on the interaction between the channel and the disordered membrane, and validates predictions based on the channel x-ray crystal structure. NR also shows that the proximity of the solid interface does not affect the molecular architecture of the protein-membrane complex. The results suggest that this technique could be used to elucidate molecular details about the association of other proteins with membranes. It also may provide structural information on domain organization and stimulı-responsive reorganization for transmembrane proteins in membrane mimics.

R1.00235 Molecular Dynamics Simulated Annealing Study of Gramicidin A in Water and the Hydrophobic Environment. TAKAHARU MORI, YUKO OKAMOTO, Department of Physics, School of Science, Nagoya University and JST-BIRD — Gramicidin A is a hydrophobic 15-residue peptide with alternating D- and L-amino acids, and it forms various conformations depending on its environment. For example, gramicidin A adopts a random coil or helical conformations, such as \( \beta^{4.1}\text{-helix, } \beta^{6.3}\text{-helix, and double-stranded } \beta\text{-helix in organic solvents. To investigate the structural and dynamical properties of gramicidin A in water and the hydrophobic environment, we performed molecular dynamics simulated annealing simulations with implicit solvent based on a generalized Born model. From the simulations, it was found that gramicidin A has a strong tendency to form a random-coil structure in water, while in the hydrophobic environment it becomes compact and can fold into right- and left-handed conformations of \( \beta\text{-helix structures. We discuss the folding mechanism of the } \beta\text{-helix conformation of gramicidin A.} \)

R1.00236 Photo- and bio-physical characterization of novel blue and near-infrared lipophilic fluorophores for neuronal tracing. JEFF TONNIGES, MARIA HANSEN, Creighton University, Department of Physics, BERND FRITZSCH, Creighton University, Department of Biomedical Sciences, BRIAN GRAY, Molecular Targeting Technologies Inc., MICHAEL NICHOLS, Creighton University, Department of Physics. Lipophilic fluorescent dyes have been used to track neuronal connections because of their ability to diffuse laterally between nerve cell membranes. Given the large number of connections that a typical neuron makes with its neighbors, a diffusion-matched set of spectrally distinct dyes is desirable. Previously, a trio of dyes was developed with well-separated green, red and far red fluorescence emission that permitted triple labeling [1]. To extend this set to five, we have been characterizing the properties of novel blue and near-infrared candidates. By combining two-photon and confocal microscopy all of these candidates can be imaged using a single Ti:S laser. Here we present measurements of the absolute two-photon excitation spectra along with single- and two-photon fluorescence recovery after photobleaching measurements of the diffusion coefficient in spinal cord samples. [1] H. Jensen-Smith et al., Immunol. Invest., in press, 2007.

R1.00237 Coupled Translational and Rotational Fluctuations of Tethered Beads. ANDREW SPAKOWITZ, SHAFIGH MEHRAEEN, Stanford University — Single-molecule manipulation plays an important role in determining the physical mechanisms responsible for biological function. Establishing a robust method of predicting the fluctuating behavior of a tethered bead provides insight into how to maximize the signal-to-noise ratio to improve experimental resolution. We theoretically address the behavior of single-molecule experimental apparatuses. Our theory is amenable to addressing a variety of different bead-tether systems, thus providing a basis for comparing and contrasting these different experimental setups and for adapting the theory to the specific experimental system of interest. Fluctuations in both the location and orientation of the bead are incorporated in the theory; we explore their coupled effect on the observed behavior in single-molecule systems. The physical behavior of the tether molecule is described using the wormlike chain model. Making use of our exact solutions for wormlike chain model statistics, our current treatment achieves exact precision for the polymer behavior, apart from the approximations that are inherent to the wormlike chain model. We find that the impact of rotational fluctuations on the bead motion is largest when the radius of the bead is comparable to the length of the chain tether. We explore the impact that chain length and bead radius have on the resolution of single-molecule experiments and how to maximize the signal-to-noise ratio.

R1.00238 Formation of highly ordered self assembled monolayers of alkanethiol molecules on thermally annealed gold films. YOUNG-KYU HONG, HYUNYUNG YU, TAE GEOL LEE, NOAH LEE, JAE HO BAHNG, NAM WOONG SONG, WON CHEGAL, HYUN KYONG SHON, JA-YONG KOO, Korea Research Institute of Standards and Science — We controlled the ordering between alkanethiol molecules in self-assembled monolayers (SAMs) formed on a Au surface by modifying surface topography of Au films. The ordering between molecules was evaluated using Fourier Transform infrared (FTIR) spectroscopy. A thermal annealing in hydrogen environment removed the nm-scale protrusions from the surface of as deposited Au film resulting in an increase in grain size and a decrease in roughness. This process allowed the alignment of Au atoms in the (111) direction. Together with the aligned Au surface, Au nanoparticles were also prepared as a rough surface with tiny grain size of \( \sim 10 \) nm. The symmetric and asymmetric \( CH_2 \) vibrations in the FTIR spectra showed a larger blueshift from the SAMs on an flatter Au surface. Binding specificity of molecules was examined by Secondary Ion Mass Spectroscopy (SIMS) using a Au pattern formed on a SiO\(_2\)/Si wafer. The molecular signal matched with the Au pattern and the ratio of the signals on Au to SiO\(_2\) was larger than 1000, indicating that the level of non-specific binding was negligible. This method of improving and controlling the ordering between molecules in the SAMs can be applied to sub \( \mu m \) patterns on a SiO\(_2\)/Si wafer.

R1.00239 Detecting Low Levels of Cytochalasin B in 3T3 Fibroblast Cells by Analysis of Electrical Noise Obtained from Cellular Micromotion. DOUGLAS LOVELADY, DAVID RABSON, CHUN-MIN LO, University of South Florida — We performed several micromotion experiments using the electric cell-substrate impedance sensing (ECIS) apparatus on a confluent layer of 3T3 fibroblast cells exposed to differing, low-level amounts of the toxin cytochalasin B. We previously developed a technique to distinguish toxin levels in a single cell type. The noise of the time series extracted from these experiments is characterized by the power spectrum, Hurst exponent, DFA (detrended fluctuation analysis) exponent, first zero and first \( 1/e \) crossing of the autocorrelation function. These measures describe the long- and short-term correlations in the signal, which tell us something about the average behavior of these cells in culture. A change in the behavior of these cells is clearly revealed by an examination of these measures. A principal-component analysis shows a separation of the different toxin levels in the multidimensional space. To our knowledge, this is the most sensitive technique for detecting such a low level of cytochalasin B in 3T3 fibroblast cells.

R1.00240 Trapping Single Molecules With a Solid State Nanopore. MARC GERSHOW, DAVID HOOGHERHEIDE, Harvard University Dept. of Physics, ERIC BRANDIN, Harvard University Dept. of Molecular and Cellular Biology, JENE GOLOVCHENKO, Harvard University Dept. of Physics and School of Engineering and Applied Sciences — We demonstrate a single molecule trap based on a solid state nanopore. A single molecule of DNA is driven through a nanopore by an applied electric field. The passage of the molecule through the nanopore is detected by a decrease in the ionic current through the pore. After the molecule has passed through the pore, we reverse the applied field to recapture the molecule and drive it through the pore again. Upon detection of this second passage, we again reverse the applied field, leading to a third passage through the pore, and so on. Thus the molecule is continually confined by a \( \frac{1}{2} \) potential maintained by active feedback. Upon each passage through the pore, the state of the molecule is electronically interrogated via the measured current blockage. Molecules can be trapped, detected, and analyzed in free solution without any labels or chemical modifications. Repeated electronic interrogation of a single molecule provides a means for greatly enhancing the accuracy with which each molecule can be characterized by a nanopore and allows measurement over time of dynamical properties such as the molecule’s conformation and chemical state.
R1.00241 Subcellular modification of tissue by near-field laser ablation. M. E. REEVES, George Washington University, J. A. HOFFMANN, Applied Physics Laboratory. JASPER NUDAM, BENJAMIN CAMARI, George Washington University, PROTEIN MICROSCOPE COLLABORATION — We report on the development of a near-field approach to MALDI (Matrix-assisted laser desorption and ionization). In this technique analytes embedded in an energy absorbing matrix are ablated from the surface of a sample. In the infrared region, the matrix can be water by exciting the 3-micron vibrational mode of the water molecule. 3-micron wavelength lasers are available with sufficient power to ablate materials of interest, particularly biological samples, however, in most cases the spot size is fairly large, about 40 microns or more, due to the primitive optics available for this wavelength of light. In our laboratory, we have demonstrated near-field focusing of a 3-micron laser to a sub-wavelength spot size with energy sufficient to ablate material from the sample surface. We will review our findings and describe demonstrations of tissue modification by this approach at length scales comparable to the size of a single cell. This approach has the potential to allow the identification and mapping of proteins expressed in intact cells and tissues, which is of great interest as protein expression connects genomic information with the functioning of an organism.

R1.00242 Fluorescence spectroscopy investigation and molecular docking simulation of the interaction of β-lactoglobulin A (BLGA) with meso-tetraakis(4-sulfonatophenyl) porphyrin (TSPPP). IVAN SILVA, LORENZO BRANCALON, SAM SANSONE, University of Texas at San Antonio — The interaction of TSPPP and β-lactoglobulin A (BLGA) was studied as a function of pH (6.0-9.0). TSPPP is a dye that is currently in clinical trials for its application in photodynamic therapy of cancer, and BLGA is a well known globular protein. Binding to the protein affects the photochemistry of the dye, hence its potential in clinical applications. Data from TSPPP fluorescence experiments were analyzed and modeled by computational methods. Protein-dye interaction was studied using fluorescence spectroscopy to record the spectral shift (from 643nm to 649nm) to quantitatively bound and free dye with use of Gaussian curve fitting. TSPPP-induced quenching of protein fluorescence determined the binding constant and the number of binding sites through S-V and double-log plots. Fluorescence lifetime characterized the effects of the binding and the location of the binding site through FRET. Unlike the binding of protoporphyrin IX, pH dependence of the TSPPP binding to BLGA is not modulated by the pH conformational change of the protein. Molecular simulation of the docking of TSPPP monomers to BLGA dimers were done using the Arguslab software. Simulations reveal that the interaction is driven by the four negative charges on TSPPP which keep it on the surface of the protein.

R1.00243 The Peyrard-Bishop-Dauxois Model of DNA Dynamics. BOJAN ALEXANDROV, ALAN BISHOP, Los Alamos National Laboratory, ANNY USHEVA, Harvard Medical School, KIM RASMUSSEN, Los Alamos National Laboratory — This presentation details aspects of the rapid development of the connection between the dynamics of double strand DNA, and experimental findings that has occurred in the recent years. We will approach this topic by demonstrating the Peyrard-Bishop-Dauxois model’s ability to provide useful insight on several experimental observations. Specifically, we will focus on the melting behavior of various DNA sequences, and mechanical unzipping through dynamic force spectroscopy. Focusing on viral DNA structures and filters. Interestingly, chaotic behaviors were very rarely observed from analysis.

R1.00244 Design of new inhibitors for H5N1 avian influenza using a molecular dynamics simulation. JIN WOO PARK, WON HO JO, Seoul National University — Recently, there has been a growing interest in the treatment of H5N1 avian influenza. One of the most widely used viral agents is oseltamivir. However, it has been reported that oseltamivir is not as effective as against the neuraminidase subtype N1 as it is against subtypes N2 and N9. In our research we addressed this problem by designing new inhibitors and these altered inhibitor’s binding affinities were calculated. In this study, we introduced chemical groups to the existing oseltamivir, so to fit into the newly discovered cavity in the subtype N1. When the binding strengths of the oseltamivir and the newly designed inhibitors for N1 were calculated to examine the drug efficiency through a molecular dynamics simulation, then compared with each other, it was found that one of the designed molecules exhibited a strong binding affinity, with more than twice the binding strength than that of oseltamivir. Since the aforementioned designed inhibitor appears to have the possibility for oral activity according to the criteria of human oral bioavailability, we propose that the inhibitor is a promising antiviral drug for H5N1 avian influenza.

R1.00245 Phenotypic variability of growing cellular populations. TING LU, Princeton University, TONGYE SHEN, Los Alamos National Lab, MATTHEW BENNETT, PETER WOLYNES, JEFF HASTY, UCSD — The dynamics and diversity of proliferating cellular populations are governed by the interplay between the growth and death rates among the various phenotypes within a colony. In addition, epigenetic multistability can cause cells to spontaneously switch from one phenotype to another. By examining a generalized form of the relative variance of populations and classifying it into intracolony and cross-colony contributions, we study the origins and consequences of cellular population variability. We find that the variability can depend highly on the initial conditions and the constraints placed on the population by the growth environment. We construct a two-phenotype model system and examine, analytically and numerically, its time-dependent variability in both unbounded and population-limited growth environments. We find that in unbounded growth environments the overall variability is strictly governed by the initial conditions. In contrast, when the overall population is limited by the environment, the system eventually relaxes to a unique fixed point regardless of the initial conditions. However, the transient decay to the fixed point depends highly on initial conditions, and the time scale over which the variability decays can be very long, depending on the intrinsic time scales of the system.

R1.00246 Biomolecular Network Simulator: Software for Stochastic Simulations of Biomolecular Reaction Networks on Supercomputers. YAROSLAV CHUSHAK, Biotechnology HPC Software Applications Institute, US Army Medical Research and Materiel Command, BRENT FOY, Wright State University, Dayton, OH 45435, JOHN FRAZIER, Air Force Research Laboratory, Wright-Patterson AFB — At the functional level, all biological processes in cells can be represented as a series of biochemical reactions that are stochastic in nature. We have developed a software tool to simulate complex biochemical networks in order to predict and simulate complex biomolecular reaction networks. Two simulation algorithms - the exact Gillespie stochastic simulation algorithm and the approximate adaptive tau-leaping algorithm - are implemented for generating Monte Carlo trajectories that describe the evolution of a system of biochemical reactions. The software uses a combination of MATLAB and C-coded functions and is parallelized with the Message Passing Interface (MPI) library to run on multiprocessor architectures. We will present a brief description of the Biomolecular Network Simulator software along with some examples.

3 This work was supported by funds provided by the DoD High Performance Computing Modernization Program (HPCMP) and by the Air Force Office of Scientific Research (AFOSR).

R1.00247 Determining behaviors of biological networks with dynamic logic method. SUPING LYU, Medtronic Inc — Dynamic logic method was used to study dynamic behaviors of some network motifs. This method combines logic operations and kinetic parameters of biochemical reactions (response or delay times). The analysis is simple because it is pure symbolic operation without numerical calculation. We proved in general that if networks are cycles with an odd number of suppression interactions, the cycles will oscillate. Delay times are necessary for oscillatory networks. If delay times are zero, the systems stay at stable states. If there is an even number of suppression interactions, the cycles have two stable states. Signal travel in chain-like networks was also studied. The depths of travel depend on the pulse width of signals and the filters of chains. Same signals with different pulse widths can have different biological responses (one stimulation to multiple responses). When pulsive signal travel in cycles, they can remain to be pulses, die, or become flat (all active) depending on the filters of cycles. The coupled cycles have complicated behaviors that are determined by their intrinsic structures and filters. Interestingly, chaotic behaviors were very rarely observed from analysis.
R1.00248 Active Dynamics of Microtubule Bundles, ASSAF ZEMEL, Department of Neurobiology, Physiology and Behavior, University of California, Davis 95616, USA, ALEX MOGILNER, Department of Mathematics and Department of Neurobiology, Physiology and Behavior, University of California, Davis 95616, USA — Microtubule bundles play a central role in a variety of dynamical processes in cells such as cell division, neural growth and blood platelet formation. These processes are driven by the activity of molecular motors that exert sliding forces on the microtubules. In such bundles, motor proteins may crosslink two or more filaments, forming discrete clusters of microtubules whose dynamics is governed by a balance of the motor-generated forces. The connectivity of these microtubule-motor complexes is an essential property of the bundle and dictates its dynamics. We present a systematic computational study of these microtubule bundles based on force-balance computer simulations as well as a simplified analytical theory. This allows us to calculate the characteristic times of microtubule sorting and spreading, as well as the effective diffusion constants and drift coefficients as a function of the microtubule density and the polarity fraction of the microtubules. Application of our theory in the study of blood platelet formation is presented.

R1.00249 Preliminary comparative studies of Thermus aquaticus resilience to thermal and microwave heat input, KONRAD KABZA, Southeastern Louisiana University, KAREN GEORGE, Southeastern Louisiana University, STELLA VON MEER, ARMIN KARGOL, Loyola University New Orleans — Thermus aquaticus was grown using existing ATCC protocol. Bacteria were cultured in large batches and each batch partitioned into usable 250 mL aliquots. These samples were then tested using identical parallel experiments, one heated with a traditional thermal heat source, while the other was irradiated with a 2.45 GHz conventional microwave oven. Relative growth of the Thermus aquaticus was measured using UV visible spectroscopy at 400 nm. Multiple runs of the same experiments were averaged and the growth data for both modes of energization plotted. A unique low microwave exposure apparatus with a flow-through cell will be described and the entire experimental setup discussed.

R1.00250 Electroshock weapons can be lethal! MARJORIE LUNDQUIST, Bioelectromagnetic Hygiene Institute, P. O. Box 11831, Milwaukee, WI 53211-0831 USA — Electroshock weapons (EWs)—stun guns, tasers, riot shields—are electroconductive devices designed to safely incapacitate healthy men neuromuscularly, so they are called nonlethal or less-lethal. EW firms seeking large nonmilitary markets targeted law enforcement and corrections personnel, who began using EWs in prisons/jails and on public patrol in 1980 in the USA. This shifted the EW-shocked population from healthy soldiers to a heterogeneous mix of both sexes, ages 6-92, in a wide variety of health conditions! An EW operates by disrupting normal physiological processes, producing transient effects in healthy people. But if a person’s health is sufficiently compromised, the margin of safety can be lost, resulting in death or permanent health problems. 325 people have died after EW shock since 1980. Did the EW cause these deaths? Evidence indicates that EWs do play a causal role in most such deaths. EWs can be lethal for people in diabetic shock (hypoglycemia), which may be why Robert Dziekanski—a Polish immigrant to Canada—died so quickly after he was tasered at Vancouver Airport: not having eaten for over 10 hours, he likely was severely hypoglycemic. The EW death rate in North America is 30 times higher than need be, because EW users have not been properly trained to use EWs on a heterogeneous population safely! 1 J. Clinical Engineering 30(3):111(2005).

R1.00251 Analytic Thermodynamic Calculations for an Immobilized Molecule under Poisson-Boltzmann Interactions using a Spheroidal Geometry, JOAQUIN AMBIA-GARRIDO, MONTGOMERY PETTITT, UNIVERSITY OF HOUSTON TEAM — The change in some thermodynamic quantities such as Gibb’s free energy, entropy and enthalpy of the binding of a particle tethered to a surface or particle are analytically calculated. These particles are considered ellipsoids and submerged in a liquid. The ionic strength of the media allows the linearized version of the Poisson-Boltzmann equation (from the theory of the double layer interaction) to properly describe the interactions between an ion penetrable spheroid and a hard plate. We believe that this is an adequate model for a DNA chip and the predicted electrostatic effects suggest the feasibility of electronic control and detection of DNA hybridization and design of chips underlying avoiding the DNA folding problem.

R1.00252 ABSTRACT WITHDRAWN —

R1.00253 Kinesin motor protein as an electrostatic ratchet machine, GEORGE TSIRONIS, University of Crete and FORTH, ALEIX CIUDAD, JOSE MARIA SANCHO, University of Barcelona — Kinesin and related motor proteins utilize ATP fuel to propel themselves along the external surface of microtubules in a processive and directional fashion. We show that the observed step-like motion is possible through time varying charge distributions furnished by the ATP hydrolysis circle while the static charge configuration on the microtubule provides the guide for motion. Thus, while the chemical hydrolysis energy induces appropriate local conformational changes, the motor translational energy is fundamentally electrostatic. Numerical simulations of the mechanical equations of motion show that processivity and directionality are direct consequences of the ATP-dependent electrostatic interaction between the different charge distributions of kinesin and microtubule. Treating proteins as continuous dielectric media and using a Green’s function formalism we find analytical expressions for the electrostatic energy in the vicinity of the protein surfaces. We calculate the Bjerrum length in the interior of the protein and analyze the different charge distributions of kinesin and microtubule. We apply these results to kinesin and estimate the pure electrostatic ATP-ADP interaction to be larger than 2k T.

R1.00254 Efficiency optimization of the Buttiker-Landauer Heat Engine, RONALD BENJAMIN, RYOICHI KAWAI, University of Alabama at Birmingham — We study the energetic efficiency of a Brownian heat engine driven by spatially inhomogeneous temperature in presence of periodic potential, via Molecular Dynamics (MD) simulation as well as by numerically solving the inertial Langevin equation. We explore various potential shapes and different locations of the temperature boundary to identify the parameter regime in which the efficiency can be optimized. However the irreversible heat flow from the hot to the cold reservoir due to the particle’s kinetic energy severely limits the efficiency and is not very sensitive to variations of the parameters. We also investigated the heat engine when it works with maximum power and found that the efficiency is much lower than that of the corresponding endoreversible engine.

R1.00255 The anomalous polarization property in laser diode, TZU FANG HSU, YEN CHUN LIN, YUNG HSUN CHEN — We have experimentally found some anomalous polarization property in laser diode (LD). As laser beam was merely passing through a polarizer, the polarization curve acted as normal cosine function which obeyed the behavior of linear polarization, fitting the property of LD. However, the polarization curve that linear polarized beam reflected by a glass plate became the W shape, which is much more different to the curve of linear polarized light. By experimentally demonstrated, it is found that this anomalous curve was revealed as the linear polarized laser beam experienced the condition of second reflection, so that the curve of reflecting by mirror was normal cosine function and by prism was also the W shape.
R1.00256 Anomalous diffusion and passage time distributions of microscopic particles through biological layers¹. M. GREGORY FOREST, University of North Carolina at Chapel Hill, CHRISTEL HÖHENEGGER, Courant Institute, New York University, SCOTT MCKINLEY, Duke University, LINGXING YAO, University of North Carolina at Chapel Hill — The field of passive microrheology was launched by Mason and Weitz in 1997, and has subsequently advanced in a variety of experimental and theoretical directions. The original aim is to infer viscoelastic properties from mean-squared displacement statistics of Brownian particles (beads) dispersed in the material. Extensions to bead-bead correlations have been advanced to screen local particle-material chemical potentials. The experimental measurements are equally, if not more so, ideal for characterizing the anomalous diffusive transport properties of soft matter, which are fundamental to pathogen or drug carrier diffusion through biological layers. Direct and inverse modeling and simulation tools will be presented, together with an evaluation of how well mean squared displacement serves as a proxy for passage time distributions.

¹Research supported by NIH, NSF, and AFOSR.

R1.00257 Test of the noise-induced nonequilibrium kinetic focusing of voltage-gated ion channels¹. ARMIN KARGOL, Loyola University New Orleans, KONRAD KABZA, Southeastern Louisiana University, STELLA VON MEER, Loyola University New Orleans — It has been postulated [1] that voltage-gated ion channels can be focused into specific conformational states by application of fluctuating voltages, such as dichotomous noise. We conducted an experimental test on Shaker K+ channels. We applied the dichotomous noise, reproducing the conditions in [1] as close as is experimentally feasible. We also varied the frequency and the amplitude of the dichotomous noise within a certain range. We observed that in some cases, for intermediate noise frequencies (1-2 kHz) and large amplitudes, the probability for intermediate states in the Markov model of the ion channel gating kinetics can be significantly increased above the maximal value for any static voltages. However, so far the scale of the focusing effect observed experimentally is smaller than the numerical simulations predict.

¹This work was partially supported by a Lousiana Pfund grant (NSF/LEQSF(2005)-Pfund-21) (AK) and the Cottrell College Science Award (CC6481) from Research Corporation (AK).

R1.00258 Wavelet-based protocols for ion channel electrophysiology¹. ARMIN KARGOL, Loyola University New Orleans — Ion channel gating kinetics is usually represented as a discrete Markov model whose input is the applied membrane voltage and the output is the ionic current. A current paradigm in experimental ion channel electrophysiology is to subject the channels to static voltages, which results in equilibrium or near-equilibrium conditions. We implement a new type of rapidly fluctuating voltage inputs that drive ion channels into nonequilibrium distributions. We discuss an algorithm for generating time-varying voltage inputs as a composition of wavelets, which allows optimization of spectral and temporal properties of voltage inputs for specific purposes, such as model selection. The outputs of channel Markov models for the Shaker K+ channels are compared to the experimental data (whole cell ionic currents) recorded from these channels.

¹This work was partially supported by the Cottrell College Science Award (CC6481) from Research Corporation.

R1.00260 The Detection of Protein via ZnO Resonant Raman Scattering Signal. GUIYE SHAN, GUOLIANG YANG, Drexel University, SHUANG WANG, YICHUN LIU, Northeast Normal University — Detecting protein with high sensitivity and specificity is essential for disease diagnostics, drug screening and other application. Semiconductor nanoparticles show better properties than organic dye molecules when used as markers for optical measurements. We used ZnO nanoparticles as markers for detecting protein in resonant Raman scattering measurements. The highly sensitive detection of proteins was achieved by an antibody-based sandwich assay. A probe for the target protein was constructed by binding the ZnO/Au nanoparticles to a primary antibody by electrostatic interaction between Au and the antibody. A secondary antibody, which could be specifically recognized by target protein, was attached to a solid surface. The ZnO/Au-antibody probe could specifically recognize and bind to the complex of the target protein and secondary antibody. Our measurements using the resonant Raman scattering signal of ZnO nanoparticles showed good selectivity and sensitivity for the target protein.

R1.00261 Influence of dissolved gasses on hydrophobic interaction at different length-scales¹. ALENKA LUZAR, Department of Chemistry, Virginia Commonwealth University (VCU), 1001 West Main Street, Richmond, VA 23284-2006, D. BRATKO², University of California at Berkeley — Despite widespread experimental evidence of the influence of dissolved gases on hydrophobic interaction, the mechanism of observed effects are still unknown. We present direct calculations of the hydrophobic force between model hydrophobic surfaces in the presence and absence of dissolved gases, and varying surface separation up to 4 nm. We monitor gas adsorption at molecular resolution inaccessible to experiments. We find insignificant gas adsorption, confined to the first molecular layer, and no dependence of the width of the perturbed water layer on the amount and type of dissolved gas. The results offer a molecular-level interpretation for the lack of influence of dissolved gas on the short-range hydrophobic force, a finding that is consistently reported in experiments that show a dramatic gas effect at long-range, but minimal at short-range or in determining the adhesion force or interfacial energy. Finally, a coarse-grained approach is discussed to deal with apparent non-equilibrium effects at longer-range and implications to biological systems and nanoscience.

R1.00262 Imaging Applications of the Geant4 Simulation Toolkit. JOSEPH PERL, Stanford Linear Accelerator Center — Geant4 is a toolkit for the simulation of the passage of particles through matter. While Geant4 was originally developed for High Energy Physics (HEP), applications now include Nuclear, Space and Medical Physics. Medical applications of Geant4 in North America and throughout the world have been increasing rapidly due to the overall growth of Monte Carlo use in Medical Physics and the unique qualities of Geant4 as an all-particle code able to handle complex geometry, motion and fields with the flexibility of modern programming and an open and free source code. Many developers of imaging technology use Geant4 by way of GATE, the Geant4 Application for Emission Tomography, which comes around Geant4 to simplify use and add imaging features, while other imaging developers use Geant4 directly. This talk will provide an overview of these applications, with a focus on how Geant4’s unique qualities, such as its support for moving geometries and electric and magnetic fields, are applied to medical imaging.

R1.00263 Sequence effects on the translocation of heteropolymers through a small channel1. MICHEL G. GAUTHIER, GARY W. SLATER, University of Ottawa — Using a recently developed Monte Carlo algorithm and an exact numerical method, we calculate the translocation probability and the average translocation time for charged heteropolymers driven through a nanopore by an external electric field. The heteropolymer chains are composed of two types of monomers (A and B) which differ only in terms of their electric charge. We present an exhaustive study of chains composed of 8 monomers by calculating the average translocation time associated with the 256 possible arrangements for various ratios of the monomer charges ($\lambda_A / \lambda_B$) and electric field intensities, $E$. We find that each sequence leads to a unique value of the translocation probability and time. We also show that the distribution of translocation times is strongly dependent on the three parameters $\lambda_A$, $\lambda_B$ and $E$. Finally, we present results that highlight the effect of having repetitive patterns by studying the translocation times of various block copolymer structures for a very long chain composed of N = 218 monomers (with the same number of A and B monomers).

R1.00264 INSULATORS AND DIELECTRICS —

R1.00265 The new single crystals with alpha-quartz structure obtained by hydrothermal method , MICLAU MARINELA, BUCUR RAUL, POENAR MARIA, VLAZAN PAULINA, GROZESCU IOAN, Condensed Matter Research Department, National Institute R&D Electrochemistry and Condensed Matter, Pautuliu Andronescu 1, Timisoara, Romania, MUSCUTARIU IOAN, Baldwin-Wallace College, Berea, Ohio 44017-2088, U.S.A., MICLAU NICOLAE, “POLITEHNICA” University of Timisoara, Bd. Vasile Parvan, nr.2, Romania, INCERC TEAM, BALDWIN-WALLACE COLLEGE TEAM, POLITEHNICA UNIVERSITY TEAM — Interest of Si1-xGeO2 single crystal with alpha-quartz structure is connected to improvement of electromechanical coefficients and rise of alpha - beta phase transition of quartz one. Growth of alpha - Si1-xGeO2 single crystal was realized by a hydrothermal method of temperature gradient in autoclaves, made from Cr-Ni alloys. Nutrient material was prepared from synthetic quartz and placed in the bottom of autoclaves. There was loaded GeO2 powder additive in proportions to quartz nutrient. Single crystals were investigated by electron microscope analysis, X-ray diffraction and atomic force microscopy. The most important result, which was obtained during the investigations, is an experimental proof of growth of Si1-xGeO2 solid solutions single crystals (with quartz structure) under the hydrothermal conditions. The present results thus open the possibility to tune the piezoelectric properties of these materials by varying the chemical composition.

R1.00266 Anomalous relaxation of damped graded elastic lattices1, M.I. ZHENG, Chinese University of Hong Kong, J.J. XIAO, Hong Kong University of Science and Technology, K. YAKUBO, Hokkaido University, K.W. YU, Chinese University of Hong Kong — We study the relaxation of harmonic vibrational excitations of damped graded lattices with a mass gradient. In the previous work, no damping was considered [1]. In this work, we re-examine the vibrational modes in a rigorous quasi-normal mode approach. It is shown that both the damping positions and boundary conditions can affect the relaxation spectrum. Moreover, there exists a dip at the gradon transition frequency for one-dimensional (1D) damped chains with damping at two ends or on all the sites. In two-dimensional (2D) orthogonally graded squared lattices (OGSL), there exist a dip and a peak at the two boundary frequencies of soft-hard gradon region. Moreover, the dip and peak structures in the relaxation spectrum can be explained by the anomalous gradon wavefunctions.

R1.00267 Density of States of Silicon, Silicon Dioxide, Silicon Nitride and Silicon Carbide1 , HONG DONG, A.R. CHOIRASIA, Department of Physics, TAMU-Commerce, S.D. DESHPANDE, Department of Physics, Amravati University, India — The density of states of Si, SiC, Si3N4 and SiO2 have been studied using a DFT computational approach implemented in CRYSTAL06. This code employs linear combinations of Gaussian type functions to represent single particle wave functions. The Becke exchange and Lee, Yang and Parr correlation have been employed. The atomic basis sets with a polarization function have been optimized for each configuration in these materials. The unit cell parameters have also been optimized. The density of states in the valence and conduction bands have been computed in each case. The projected density of states of the constituents has also been computed. The band gap has been calculated for these materials. These values are compared with the available experimental data. The correlation between the electronic polarizability and the Auger parameter determined previously from x-ray photoelectron spectroscopy will be presented.

R1.00268 Spectral representation theory of graded composite materials , K.L. CHAN, C.M. KWOK, K.W. YU, The Chinese University of Hong Kong — In graded composite materials, the physical properties can vary continuously in space and it may give different physical phenomena when compared with homogeneous materials. The Bergman-Milton spectral representation is a rigorous mathematical formalism to express the effective dielectric constant of nongraded composite materials [1]. In this study, we consider a material (rather than microstructure [2]) graded composites, and generalize the Bergman-Milton spectral representation to extract the spectral density function for the effective dielectric constant of this graded composite material in the frequency domain [3]. Analytic and numerical solution will be presented for graded films and graded spheres.

R1.00269 Optical Trapping Forces from Electric Fields Inside Dielectric Materials1 , DOUGLAS BONESSI, KEITH BONIN, Wake Forest University, THAD WALKER, University of Wisconsin, Madison — We developed a method for computing forces from internal electric fields. The internal fields are found using discrete dipole approximation (DDA) and finite difference time domain (FDTD) approaches and the results are compared. We are interested in the results from an optical trapping viewpoint, though other simulations are used for benchmarks. This method can handle arbitrary input beams and particle sizes and shapes. We hope to report on similar calculations to calculate optical torques on birefringent particles in the Mie size regime.

R1.00270 DFT Ab initio Calculation of Vibrational Frequencies in AsSe glass, KESHAV SHRVASTAVA, HASAN KASSIM, AHMAD NAZRUL ROSLI, University of Malaysia, JABATAN FIZIK COLLABORATION — By using DFT double zeta wave functions, we calculated the structure, bond length (picometer, pm), frequencies (intensities) (degeneracy) for various clusters of arsenic selenide. Our results are as follows. (i) AsSe(diatomic) bond length 216 pm, 244.0 (1/cm). (ii) AsSe(2+) bond length 228.5 pm, frequencies 27.6 (1.9) and 387.6 (4.3). (iii) AsSe(2+) bond length 234.3 pm, As-As 223.3 pm, frequencies 237.3 (2.4) and 332.4 (0.05) (1/cm). (iv) AsSe(2+) bond length 238.4 pm, frequencies 107.5 and 296 (weak) (1/cm). (v) AsSe (square) bond length 250.2 pm, 58.5 (0.04), 241.3 (5.9) (1/cm). (vi) AsSe (triangular) bond length 231.2 pm, 75.9 (0.003), 103.5 (1.26) [2], 350.9 (33.2) [2]. From this study we identify that linear As-Se-As for which the calculated frequency is 27.6 (1/cm) is in agreement with the data of Nemamich, Phys. Rev. B 16, 1659 (1977). J. C. Phillips et al Phys. Rev B 21, 5724 (1980). We have successfully calculated several vibrational frequencies accurately which agree with the Raman data.

R1.00271 Raman spectroscopy of multiferroic trigonal boracite Cs$_3$B$_2$O$_5$Cl$^-$, MILKO ILIEV, VIKTOR HADJIEV, Texas Center for Superconductivity at the University of Houston, MARIA-EUGENIA MENDOZA, Instituto de Fisica, Universidad Autonoma de Puebla, Puebla, Mexico, JORDI PASCUAL, Institut Catal`a de Nanotecnologia (ICN) and Departament de Fisica, Universitat Autonoma de Barcelona, Barcelona, Spain. — Raman microscopy was applied to study the polarized Raman scattering from untwinned domains of Cs$_3$B$_2$O$_5$Cl$^-$ (Co-Cl) in the trigonal, R3$_c$, ferroelectric phase. The symmetry (A$_1$ or E) and mode polarization (LO or TO) for all observed Raman lines were determined from comparison of the spectra measured in several scattering configurations. It was found that as a rule the TO-LO splitting is small or negligible. A group of A$_1$ modes, characterized by a quasi-one-component Raman tensor, was tentatively assigned to stretching vibrations of Cl, O, or B along the trigonal axis, which in this material is parallel to the ferroelectric polarization direction.

R1.00272 Infrared spectroscopy of Dysprosium doped KPb$_2$Br$_5$ and KPb$_2$Cl$_5$, PETER AMEDZAKE, EI BROWN, UW HOMEIMERICH, Hampton University, SUDHIR TRIVEDI, Brimrose Corporation of America, JOHN ZAVADA, US Army Research Office — The infrared optical properties of rare earth doped crystals with narrow phonon spectrum (< 300 cm$^{-1}$) remains of current interest for applications in IR solid-state gain media. The maximum phonon energies of KPb$_2$Cl$_5$ and KPb$_2$Br$_5$ are only ~200 cm$^{-1}$ and ~150 cm$^{-1}$, which reduce non-radiative decay through multi-phonon relaxations. In this work, we present spectroscopic results of Dy: KPb$_2$Cl$_5$ and Dy: KPb$_2$Br$_5$ for possible applications in mid-infrared gain media. The investigated materials were grown by vertical Bridgman technique. Dy: KPb$_2$Cl$_5$ and Dy: KPb$_2$Br$_5$ exhibited characteristic Dy$^{3+}$ absorption bands in the visible and infrared regions. Optical excitation at ~800 nm resulted in the observation of a broad 4-5 $\mu$m mid-IR emission ($^{6}H_{11/2} \rightarrow ^{6}H_{3/2}$) at room temperature. The mid-IR emission lifetime was measured to be ~5.5 ms for Dy: KPb$_2$Cl$_5$ and ~3.8 ms for Dy: KPb$_2$Br$_5$, respectively. Based on temperature dependent lifetime studies and Judd-Olfet calculations, the emission quantum efficiencies for the 4-5 $\mu$m bands were estimated to be near unity. More details on the IR optical properties of Dy: KPb$_2$Cl$_5$ and Dy: KPb$_2$Br$_5$ will be presented at the conference.

R1.00273 Mid-infrared Emission and Energy Transfer Properties of Sensitized Rare Earth Ions in KPb$_2$Cl$_5$, ALTHEA BLUIETT, ERICA PINKNEY, Elizabeth City State University, EI BROWN, UW HOMEIMERICH, Hampton University, SUDHIR TRIVEDI, Brimrose Corporation of America, JOHN ZAVADA, US Army Research Office — Mid-infrared emission (4-5 $\mu$m) originating from the first excited state of Pr$^{3+}$ and from the first excited state of Nd$^{3+}$ were generated by means of Yb$^{3+}$ and Tm$^{3+}$ sensitization, respectively. The mechanisms involved in sensitizing Pr$^{3+}$ and Nd$^{3+}$ ions were determined by studying the decay kinetics of the $^2F_{5/2} \rightarrow ^2F_{7/2}$ transition of Yb$^{3+}$ and the $^4F_4 \rightarrow ^2H_6$ transition of Tm$^{3+}$ under 970 nm and 1750 nm laser excitation, respectively. It was observed that the emission lifetime of the $^2F_{5/2} \rightarrow ^2F_{7/2}$ transition and the $^4F_4 \rightarrow ^2H_6$ transition were reduced considerably in the presence of the activator ions Pr$^{3+}$ and Nd$^{3+}$, respectively. Strong 4-5 $\mu$m emission from Pr$^{3+}$ and Nd$^{3+}$ were observed in Yb, Pr: KPb$_2$Cl$_5$ and Tm, Nd: KPb$_2$Cl$_5$, respectively. These findings indicate that significant energy transfer was transpired. Concentration dependent studies will be conducted to ascertain the dopant concentrations for efficient MIR emission.

R1.00274 Rectifying Current-Voltage Characteristics of BiFeO$_3$/Nb-doped SrTiO$_3$ Heterojunction, HAO YANG, H.M. LUO, Superconductivity Technology Center, Los Alamos National Laboratory, H. WANG, Dept. of Electrical and Computer Engineering, Texas A&M University, D.M. FELDMANN, Q.X. JIA, Superconductivity Technology Center, Los Alamos National Laboratory — Epitaxial c-axis oriented BiFeO$_3$ (BFO) thin films were deposited on (001) Nb-doped SrTiO$_3$ (Nb-STO) substrates by pulsed laser deposition. Introducing Bi vacancies causes the BFO thin film to evolve to a p-type semiconductor and form a p – n heterojunction with n-type semiconductor Nb-STO. The current density vs voltage ($J$ – $V$) and capacitance vs voltage ($C$ – $V$) characteristics of the heterojunction were investigated. A typical rectifying $J$ – $V$ effect was observed with a large rectifying ratio of 5x10$^4$. Reverse $C$ – $V$ characteristics exhibit a linear 1/C$^2$ vs $V$ plot, from which a built-in potential of 0.6 V is deduced. The results show a potential application of BFO/Nb-STO heterojunction for oxide electronics.

R1.00275 Wet-chemistry synthesis and dielectric properties of pure and Rb and V doped Cs$_2$Nb$_2$O$_6$$_{11}$, JIANJUN LIU, Department of Physics, University of Nebraska at Omaha, ROBERT SMITH, Department of Chemistry, University of Nebraska at Omaha, WAI-NING MEI, Department of Physics, University of Nebraska at Omaha — Cs$_2$Nb$_2$O$_6$$_{11}$ (CNO) is an antiferroelectric compound whose single crystal structure and antiferroelectric properties have been recently reported [1]. It has a space group of Pnna and a phase transition temperature at 165 °C. In this study we synthesized CNO powdered samples, both pure and doped with rubidium and vanadium, by using a wet-chemistry method. Dielectric measurements showed that the phase transition temperature shifted with the doping. We analyzed the mechanism of this antiferroelectric phase transition based on the observed results. [1] Robert W. Smith, Chunhua Hu, Jianjun Liu, Wai-Ning Mei, Kuan-Jiuh Lin, J. Solid State Chem. 180 (2007) 1193-1197.

R1.00276 Effect of Pressure on the Atomic and Electronic Structure of Hexagonal YMnO$_3$, ZHIGLIANG CHEN, TREVOR TYSON, New Jersey Institute of Technology, SUNGBAEK KIM, SANG-WOOK CHEONG, Rutgers University — The multiferroic hexagonal system YMnO$_3$ is known to possess a significant polarization at room temperature. To understand the mechanism behind the polarization, we conducted high pressure x-ray diffraction measurements for pressures between ambient and 20 GPa. The powder diffraction data were refined to obtain the atomic level structure as a function of pressure. The pressure dependence of resistivity at room temperature (for pressures up to -6 GPa) was determined. Complementary density functional calculations were conducted to correlate the changes in electronic structure and polarization with the observed changes in atomic structure with pressure.

1 This work is supported by DOE Grant DE-FG02-07ER46402.
R1.00277 Acoustic and Optical Properties of Er$^{3+}$-doped LiNbO$_3$. ALEM TEKLU, NARAYANAN KUTHIRUMMAL, DANIEL MORRALL, JAY DANDREA, College of Charleston — Elastic constants of pure and Er$^{3+}$-doped lithium niobate (LiNbO$_3$) single crystals have been determined using resonant ultrasound spectroscopy (RUS). When comparing the elastic constants for pure and doped LiNbO$_3$ crystals, the bulk modulus was found to increase by 5.2% after doping. Also the elastic constants were compared. $C_{11}$ decreased by 4%, $C_{12}$ increased by 18% and $C_{44}$ increased by 16.6%. The surface-doping explains the decrease in elastic constant in only one direction. The presence of Er$^{3+}$ ions on the surface of LiNbO$_3$ has been monitored using photoacoustic spectroscopy. The photoacoustic spectrum revealed very weak absorptions corresponding to $4F^{7/2}$, $4F^{9/2}$ and $2H^{11/2}$ levels of Erbium, indicating the presence of Erbium.

R1.00278 Dielectric response in potassium tantalite/potassium niobate multilayers, M. E. REEVES, SHUOGANG HUANG, George Washington University, JENNIFER SIGMAN, Sandia national Laboratory, DAVID NORTON, University of Florida, HANS CHRISTEN, Oak Ridge National Laboratory — We report measurements of the dielectric response of thin-film multilayers of potassium tantalite/potassium niobate. The measurements were made by evanescent-probe microscopy, a technique that is quite sensitive to material placed in the near-field proximity of the sample probe. The measurements were performed at a frequency of 1.7 GHz with the electric field polarized perpendicular to the plane of the film. Our results show that there are two distinct phase transitions. The first coincides with a structural transition in the material and indicates the onset of coupling between the potassium niobate layers. The transition moves to higher temperature as the spacing between the layers in increased. A second lower temperature transition indicates the onset of anti-ferroelectric ordering in the sample. The temperature of this transition is nearly independent of layer thickness and is not connected with a structural transition. The mechanism for the transitions will be discussed and data measured on asymmetric multilayers will be presented.

R1.00279 Anomalous size dependence of inverse participation ratio of localized eigenfunctions in graded elastic lattices$^1$, M.J. ZHENG, Chinese University of Hong Kong, M. GODA, Niigata University, K. YAKUBO, Hokkaido University, K.W. YU, Chinese University of Hong Kong — Recently, we studied harmonic vibrational excitations in graded elastic lattices [1]. It is found that the eigenfunctions exhibit a transition from extended phonon states to localized gradon states when the frequency is increased beyond a critical frequency called the gradon transition frequency. At the same time, the inverse participation ratio (IPR) can exhibit a rapid increase at gradon transition. This unusual behavior prompts us to study the size dependence of the IPR of gradon wave function. A quantum analogue is established for the hump structure at the gradon front, via the fact that the probability of a quantum particle is inversely proportional to its volume. In this way, the envelope function can be determined analytically, and matches the gradon wave function quite well. We find that the size $N$ dependence can be captured by the relation: \( \text{IPR} = C_1 \log(N) + C_2 \), where $C_1$ and $C_2$ are constants. The interpretation is important in the understanding of a wide variety of properties of graded systems.

$^1$Supported by RGC and JSPS.

R1.00280 SUPPLEMENTARY ABSTRACTS —

R1.00281 Physics and Operational Research: measure of uncertainty via Nonlinear Programming. YASSER A. DAVIZON-CASTILLO$^1$, Arizona State University — Physics and Operational Research presents an interdisciplinary interaction in problems such as Quantum Mechanics, Classical Mechanics and Statistical Mechanics. The nonlinear nature of the physical phenomena in a single well and double well quantum systems is resolved via Nonlinear Programming (NLP) techniques (Kuhn-Tucker conditions, Dynamic Programming) subject to Heisenberg Uncertainty Principle and an extended equality uncertainty relation to exploit the NLP Lagrangian method. This review addresses problems in Kinematics and Thermal Physics developing uncertainty relations for each case of study, under a novel way to quantify uncertainty.

$^1$Department of Industrial Engineering

R1.00282 Physics of Large Scale Production Systems under Uncertainty. YASSER A. DAVIZON-CASTILLO, Department of Industrial Engineering, Arizona State University — Large Scale Production Systems (LSPS) are analyzed from the physics perspective based on the measure of uncertainty. A novel approach to quantify uncertainty is presented using Little’s law and Uncertainty Inequalities in Throughput and Work in Process. The extended version of an Uncertainty equality relation is used to measure the levels of uncertainty in the LSPS in a Nonlinear Programming context. Conservation of Energy Principle is used to determine the measure of uncertainty overall the system. The main contribution is the analogy from the physical phenomena to a LSPS arena using the Conservation of Energy Principle.

R1.00283 A High-resolution Rapidly-updated Meteorological Data Analysis System for Aviation Applications. CHI SHING LAU, MING CHUNG CHU, JONES TSZ-KAI WAN, The Chinese University of Hong Kong, PING WAH LI, Hong Kong Observatory — We present our work on the recent development of a high spatial- and temporal-resolution meteorological data analysis system for the identification and monitoring of mesoscale to microscale weather phenomena over the Hong Kong International Airport (HKIA) and its vicinity. The system can be updated minutely with a horizontal resolution of 150 m. The system is adapted from the Local Analysis and Prediction System (LAPS) from NOAA. Apart from conventional data such as automatic weather stations, wind profilers and satellite observations, automatic aircraft reports (AMDAR), LIDARs and Terminal Doppler Weather Radar (TDWR) data are ingested into the system. The LIDAR and TDWR data are complimentary to each other so that wind field can be identified in both clear and convective weather. Ingesting the above data into the system helps generate a comprehensive 3-dimensional structure of the atmosphere over the airport and nearby airspace. The analysis system would also be useful for newcast aviation-related weather after integrating with numerical weather prediction models. Several cases such as land-sea breeze, gust front and tropical cyclone are discussed. Our results could bring significant insights into aircraft safety and air traffic efficiency to the flights operating at other airports over the world.

R1.00284 Simulating a charged spherical pendulum in time-varying electric and magnetic fields$^1$, MARK WELLONS, FRANK KING, TODD MCALPINE, The College of Wooster — We simulate and analyze the dynamics of a charged spherical pendulum in time-varying electric and magnetic fields. The time-varying electric field is directed perpendicular to the gravitational field and serves as a driving force for the pendulum. The time-varying magnetic field is directed parallel to the gravitational field and serves to deflect the motion of the pendulum. We analyze the dynamics of the system to determine the conditions for which chaotic behavior is observed. We also include viscosity to look for strange attractors. The equations of motion are integrated using Objective C and the graphical user interface, including the three dimensional graphical representation of the system, is developed using Cocoa.

$^1$We thank NSF REU DMR-0649112 and The College of Wooster for their support.

R1.00285 POST-DEADLINE ABSTRACTS —
R1.00286 Electrode-side impedance nonlinearity in polycarbazole bioelectrodes quantifiable by a quaternion formalism, M. OVAHIA, D.H. ZAVITZ, UIC, Y.P. KAYNAMURA, J.F. RUBINSON, Georgetown — Nonlinear response to sinusoidal electrification is a phenomenon rarely observed for conductive interfaces. We report nonlinear response as an electrode phenomenon in a conjugated polymer electrode polycarbazole. While other semiconductors manifest an impedance quantifiable in the complex field (e.g., Warburg where complex $Z = Z_{W}^{\infty}$ and resistive with $Z = Z_{R}$ [HI-Hallblert]) the polycarbazole manifests no definable impedance due to essential nonlinearity. There is no description available for this form of pseudoconductivity. We introduce a quaternion formalism $Z_{Cg} = ai + bj + ck + dl$ [where $a, b, c, d$ are real and $i^2 = j^2 = k^2 = -1$ and $j = i$] that successfully describes all conductivity ($c = d = 0$) and pseudoconductivity presently known as a normed ring, and reduces to the complex field for conductivity. In this formalism, the normalized impedance of a capacitor is $Z = i$, the experimentally determined polycarbazole pseudoimpedance $Z_{Cg} = k$, that of a resistance is $Z = 1$ and that of the $Z_{W}^{\infty} = v/\sqrt{i}$. The non-Abelian character of $Z_{Cg}$ implies that the Onsager relation fails for some interfaces. Remarkably, certain Kramers-Kronig relations (Hilbert transformation in not only the complex but also the $[j, k]$ plane) still hold for certain experimental setups. Computation of the energy integral $\int_{DEdt}$ reveals that charge transport is lossless, similar to conduction in an ordinary capacitor.

R1.00287 Static And Dynamic Studies In Nonyloxycyanobiphenyl (9ocb) Confined To Anopore Membranes, SERGIO DIEZ BERART, Kent State university, MIGUEL ANGEL PEREZ JUBINDO, DAVID O. LOPEZ, M. ROSARIO DE LA FUENTE, JOSEP SALUD — We analyze and compare the static and dynamic properties of alkoxycyanobiphenyl (9OCB). This compound exhibits an I-N-SmA phase sequence. After confining into Anopore structures several phenomena can be seen: Both phase transitions change in their nature, $C_{p}$ peaks becoming lower, broader and shifted down in temperatures. A possible first-to-second order transition could be determined for the N-SmA. There develops a surface induced nematic layer that becomes larger when temperature decreases. Molecular dynamics out from the nematic layer is quite similar to that of the bulk.

R1.00288 ABSTRACT WITHDRAWN —

R1.00289 Electric Polarization and ME effect in layered iron oxide, SUMIO ISHIHARA, MAKOTO NAKA, JOYOI NASU, Department of Physics, Tohoku University — Rare-earth iron oxides $\text{R}Fe_{2}O_{4}$ (R: rare-earth elements) is an exotic dielectric material with charge-order driven electric polarization and magnetoelectric effect caused by spin-charge coupling. The crystal structure consists of paired Fe-O triangular lattices and $R$-O block ones alternately stacked. Since a nominal valence of Fe ion is 2.5+, an equal amount of $\text{Fe}^{2+}$ and $\text{Fe}^{3+}$ coexists in the paired triangular lattices. In the electron diffraction experiments, Bragg reflections at (h/3 h/3 m +1/2) appear below 320K($\equiv T_{C0}$) in $\text{LuFe}_{2}O_{4}$. This observation indicates a valence order of Fe ion, i.e. a charge order of the Fe $3d$ electrons. Around $T_{C0}$, a spontaneous electric polarization and dielectric anomalies turn up. Moreover, around the ferrimagnetic spin ordering temperature ($T_{C0} = 250K$), the gigantic ME effects are recently discovered. We present a theory of a dielectric magnet $\text{RFe}_{2}O_{4}$ as an electronic ferroelectric and multiferroic material [1]. We address the following issues: (i) origin of the electric polarization and the FE transition, (ii) mechanism of the coupling between electric polarization and magnetization. Present study shows that the novel dielectric properties in this material arises from interplay among the geometrical frustration and the multi-degrees of freedom of electron.

R1.00290 Fermi surface and local density of states of ordered and disordered stripes, MATS GRANATH, Goteborg University — For a doped antiferromagnet with short-range spin stripe correlations and long-range charge stripe order the manifestation of charge order changes abruptly as a function of momentum along the Fermi surface. The disorder averaged local density of states is isotropic when integrated only over states which contribute to the “antinodal” spectral weight. An effectively two dimensional nodal liquid can thus coexist with static charge stripes provided there is no static spin order. For commensurate spin and charge stripe ordered systems the Fermi surface consists of a nodal hole pocket and an open “stripe band” section. Due to the stripe order the relation between hole density and size of a pocket will be reduced compared to a paramagnet by a factor of two for even charge period and four for odd charge period and we find an estimated upper limit on the area fraction of a hole pocket of 1.6% for charge period four and 4% for charge period five. We also discuss why electron pockets are not expected for a stripe ordered system and show that the open Fermi surface section may be electron like with a negative Hall coefficient.

R1.00291 Modification of amorphous carbon film surfaces by thermal grafting of alkenes monolayer, HUSSEIN SABBAH, SOURAYA AABOULI-GIRARD, FRANCINE SOLAL, CHRISTIAN GODET, BRUNO FABRE, MARYLINE GUILLOUX-VIRY, ANDRE PERRIN, STEPHANIE DEPUTIER, PHYSIQUE DES ATOMES, LASERS, MOLECULES, SURFACES (PALMS, UMR 6627), UNIVERSITE RENNES 1 TEAM, SCIENCES CHIMIQUES DE RENNES (UMR 6226), UNIVERSITE DE RENNES 1 COLLABORATION — The integration of molecules and semi-conductors opens new possibilities for large area devices in the fields of biochemical sensors, molecular electronics. This work aims at improving the control of the surface of amorphous carbon thin films, in order to optimize molecular grafting processes and investigate the electronic properties of molecular assemblies. Robust devices are expected from this coherent grafting, through strong C-C interface bonds. A quantitative comparison of thermally assisted gas phase and liquid phase processes using linear alkenes has been performed using X-ray photoelectron spectroscopy (XPS). In order to understand the grafting mechanisms and the a-C surface reactivity towards alkenes at different temperatures (160 - 300 °C), surface coverage values are compared using a-C films, with different average C sp$^3$ / sp$^2$ hybridization, residual oxygen contamination, surface densities and surface energies, as obtained from XPS, grazing angle X-ray reflectivity and contact angle measurements.

R1.00292 Calculated Zhang-Rice Singlet Dispersion in Mott-Insulators, XIANGANG WAN, QUAN YIN, SERGEY SAVRASOV, University of California, Davis — Using a combination of local density functional theory and cluster exact diagonalization based dynamical mean field theory (LDA+DMFT), we calculated many body electronic structures of several Mott-insulating oxides including undoped prototype high Tc materials. The dispersions of the lowest occupied electronic states are associated with the Zhang-Rice singlets (ZRS) in cuprates, and with doublets, triplets, quartets and quintets in more general cases. The spectral weight of ZRS band decreases as it approaches the BZ center, as observed by many recent ARPES experiments. Our results are in good agreement with experiments.
R1.00293 Exploration of Strongly Coupled Plasma Dynamics and Equilibrium Using the Particle-in-Cell Methodology1, D.V. ROSE, D.R. WELCH, T.C. GENONI, Voss Scientific, T.A. MEHLHORN, R.B. CAMPBELL, Sandia National Laboratories — Particle-based numerical simulations are required to study the dynamics and evolution of inhomogeneous nonequilibrium multispecies strongly coupled plasmas. Molecular-dynamics (MD) and particle-in-cell (PIC) techniques have been compared previously [K. Y. Sanbonmatsu, et al., J. Phys. IV (France) 10, Pr5-259 (2000)], with the PIC methodology demonstrating the capability of improved accuracy over the MD simulations at high resolution. However, the PIC simulations were significantly slower, limiting their utility. Here we explore several schemes to improve the computational speed of such calculations including non-iterative, implicit EM field solvers and subgrid models. The simulations are compared directly with the results of Sanbonmatsu, et al., and a new theoretical analysis of the hypernetted chain model where all inter-species correlations are retained [V. Schowar, et al., Contrib. Plasma Phys. 47, 324 (2007)].

R1.00294 Ionic salt-bridge dependence of dimerization of the GCN4 Leucine zipper, YANXIN LIU, PREM CHAPACAIN, BERNARD GERSTMAAN, Department of Physics, Florida International University, University Park, Miami, FL 33199 — The role that ionic interactions, or salt-bridges, play in protein folding and dimerization is still controversial. We perform computational simulations on the GCN4 leucine zipper to investigate the effect of ionic interactions. A three dimensional lattice model incorporating a Monte Carlo Metropolis Algorithm is employed to simulate the dimerization process. Our results show that stronger ionic interactions result in more stable dimers, in agreement with experiments. Our simulations also show that increasing the strength of the ionic interactions does not lead to a monotonous increase in the speed of the dimerization process. We find an optimal intermediate ionic interaction strength at which the dimer is stable and the dimerization process proceeds at the maximum rate. We present quantitative results of dimerization rates, heat capacity, and free energy landscapes as a function of the ionic strength for the GCN4 leucine zipper.

R1.00295 Entanglement of Uniformly Accelerating Schrödinger, Dirac, and Scalar Particles, WAI LIM KU, MING CHUNG CHU, Department of Physics and Institute of Theoretical Physics, the Chinese University of Hong Kong — We study how the entanglement of an entangled pair of particles in two different modes is affected when one or both of the pair is uniformly accelerated, while the detector remains in an inertial frame. We find that the entanglement is unchanged if all degrees of freedom are considered. However, particle pairs are produced when a relativistic particle is accelerated, and more bipartite systems emerge. We identify the particle and antiparticle excitations in the asymptotic regions where there is no acceleration, which corresponds to detection by inertial detectors. We calculate the entanglements between particles/antiparticles in the two modes, and we find that the distribution of entanglements into the different biparticle systems varies as the acceleration. In particular, the entanglement of a pair of accelerating fermions is transferred preferentially to the produced antiparticles when the acceleration is large, and the entanglement transfer is complete when the acceleration approaches infinity. However, no such entanglement transfer to the antiparticles is observed for scalar particles.

R1.00296 Experimental observation of solitons propagating in a hydro-mechanical array of one-way coupled oscillators1, KELLY M. PATTON, JAMES GALLAGHER, JOHN F. LINDNER, The College of Wooster, Wooster OH 44691 — Arrays of two-way coupled oscillators are familiar and have been extensively studied. However, arrays of one-way coupled oscillators have been studied only in the last five years, mainly computationally and theoretically. One-way coupling seems impossible, because it appears to violate Newton’s third law (and energy conservation). However, we have constructed arrays of one-way coupled oscillators by enabling each oscillator to modify an external force that does work on a neighboring oscillator. We observe solitons propagating in our arrays and compare their behavior with computer simulations and theory.

R1.00297 Cyclotron radiation and emission in graphene, TAKAHIRO MORIMOTO, University of Tokyo, YASUHIRO HATSUGAI, University of Tsukuba, University of Tokyo, HIDEO AOKI, University of Tokyo — While the physics of “Massless Dirac” particles in graphene has been kicked off by the observation of an anomalous quantum Hall effect, interests begin to extend optical properties, which includes recent spectroscopy studies including the effect of disorder to show the following: (i) The unevenly spaced Landau levels do give rise to an interesting situation, As for the relaxation processes, which are examined with an extention of the treatment for ordinary quantum Hall systems, graphene’s peculiar cyclotron energy $\sqrt{\hbar/m_e}$ along with its 2D nature favor the cyclotron emission over other relaxation processes.

R1.00298 ABSTRACT WITHDRAWN —

R1.00299 Structural Phase Transitions induced by Compressive and Tensile Strains in Ordered Sc$_{0.5}$Ga$_{0.5}$N and Sc$_{0.5}$In$_{0.5}$N Alloys, AHMAD ALSAAD, AHMAD AHMAD, Department of Physics, Jordan University of Science & Technology (JUST), Irbid-22110, Jordan, CONDENSED MATTER GROUP TEAM — Local-density approximation calculations (LDA) within density functional theory (DFT), Berry phase approach within modern theory of polarization and phonon calculations within the density functional perturbation theory are performed to predict the existence of breaking-symmetry structural phase transitions in ordered Sc$_{0.5}$Ga$_{0.5}$N and Sc$_{0.5}$In$_{0.5}$N alloys. It has been demonstrated that the existence of strain-induced structural phase transition leads to optimized optical, electronic, acoustic, and piezoelectric properties of ordered Sc$_{0.5}$Ga$_{0.5}$N and Sc$_{0.5}$In$_{0.5}$N. In particular, it has been shown that ordered Sc$_{0.5}$Ga$_{0.5}$N and Sc$_{0.5}$In$_{0.5}$N alloys at fixed Ga, In and Sc compositions exhibit tremendous piezoelectric response (i.e., the e$_{ij}$ piezoelectric coefficient adopts a huge value as large as 8.3 C/m$^2$) as a function of the in-plane compressive and tensile strains. In addition, several optical, electric, acoustic anomalies are shown and discussed. We also reveal the reason behind, and consequences of, these unusual properties associated with the biaxial strain-induced structural phase transitions.

R1.00300 Characterizing soliton behavior in noise-mediated one-way coupled oscillators, CHRIS-TINE E. WEIDERT, BARBARA J. BREEN, University of Portland, JOHN F. LINDNER, The College of Wooster — While arrays of coupled bistable oscillators have been extensively studied, the unique behavior of such arrays under one-way coupling has been studied only in the last few years. Using numerical simulations run on a high-speed parallel computing cluster and theoretical arguments, we show that the speed of solitons propagating in these arrays is proportional to the coupling strength. In addition, we refine and improve a metric, the complexity, that quantifies the intricacy of the spatiotemporal behavior of the array as a function of coupling and noise.
R1.00301 Wetting-like phase transitions in a surface-enhanced type-I superconductor

VLADIMIR KOZHEVINIKOV, Tulsa Community College, MARGRIET VAB BAEL, Katholieke Universiteit Leuven, Belgium, PRATAP SAHOO, Paul Scherrer Institut, Switzerland, KRISTIAAN TEMST, CHRIS VAN HAESENDONCK, ANDRE VANTOMME, JOSEPH INDEKEU, Katholieke Universiteit Leuven, Belgium — Superconductivity in single crystal Sn samples with surface enhanced order parameter was studied experimentally. Controllable surface enhancement was achieved by mechanical polishing or by ion irradiation. A first-order surface superconductivity transition was found in parallel magnetic fields close to the bulk critical field Hc(T) and for temperatures above 0.8Tc up till a surface critical temperature Tcs higher than Tc, where Tc is the bulk critical temperature. The resulting phase diagram agrees with that predicted for interface delocalization or wetting transitions in type-I superconductors, based on the Ginzburg–Landau theory.

1This research has been supported by the K U Leuven Research Council (F/05/049, GOA/2004/02 and INPAC EF/05/005), project G.0237.05 of the FWO Vlaanderen, and IUAP P5/1.

R1.00302 Viscoelastic Relaxation of Molten Phosphorus Pentoxide

DAVID SIDEBOTTOM, Creighton University, JESSICA CHANGSTROM — We report the first ever dynamic light scattering study of the viscoelastic relaxation in anhydrous liquid P2O5. Properties of the time decay of the dynamic structure factor, including the average structural relaxation time and the stretching exponent, were obtained for temperatures from 850 °C to near the glass transition (Tg = 419 °C) using photon correlation spectroscopy. Analysis indicates that P2O5 is a strong glassforming liquid but one which exhibits an abnormal non-exponential relaxation near Tg. The viscoelastic behavior of P2O5 is compared with that of its metaphosphate counterpart to demonstrate how changes in bond connectivity influence both fragility and levels of dynamic heterogeneity.

R1.00303 Structural distortions in the spin-gap regime of the quantum antiferromagnet SrCu2(BO3)2

CARLO VECCHINI, IESL-FORTH, Heraklion, Greece, LAURENT CHAPON, ISIS Facility, STFC-RAL, Didcot,OX110QX, UK, HIROSHI KAGEYAMA, Chemistry Department, Kyoto University, Kyoto,606-8502, Japan, OTHON ADAMPOULOS, ALEXANDROS LAPPAS, IESL-FORTH, Heraklion, Greece — Since the so-called pseudo spin-gap was suggested to be relevant for the appearance of high-Tc superconductivity, a number of studies have been made on low-dimensional quantum spin systems with a singlet ground state. SrCu2(BO3)2 is an example of a 2D frustrated magnet in which a rectangular network of spin-1/2 Cu dimers displays a spin-gap (Tc<20K). Spin anisotropies are needed to describe accurately the dynamics of this 2D orthogonal dimer model. Accurate neutron lattice symmetry is necessary to rationalize the ground state properties. This is the first detailed crystallographic study within the gap region. Our powder neutron diffraction reveals distortions of the tetragonal structure that uncover an intimate spin-lattice coupling. The interdimer Cu-O-Cu angles increase abruptly by 0.4 deg, consistent with strengthening of the superexchange interaction. This is accompanied by a sharp reduction of the static buckling within the CuO2 planes and a contraction of the interlayer distances. We discuss the role of the structural deformations and the symmetry rules imposed for the development of the Dzyaloshinsky-Moriya exchange.

R1.00304 Hypervelocity Impact on Interfaces: A Molecular-Dynamics Simulations Study

MARTINA E. BACHLECHNER, Fairmont State University, ELI T. OWENS, ROBERT H. LEONARD, BRONWYN C. COCKBURN, West Virginia University — Silicon/silicon nitride interfaces are found in micro electronics and solar cells. In either application the mechanical integrity of the interface is of great importance. Molecular-dynamics simulations are performed to study the failure of interface materials under the influence of hypervelocity impact. Silicon nitride plates impacting on silicon/silicon nitride interfaces targets of different thicknesses result in structural phase transformation and delamination at the interface. Detailed analyses of atomic velocities, bond lengths, and bond angles are used to qualitatively examine the respective failure mechanisms.

R1.00305 Nanoscale X-ray Diffraction Microscopy at the Nanoprobe Beamline

MARTIN HOLT, ROBERT WINARSKI, JORG MASER, X-ray Imaging Group, Center for Nanoscale Materials, Argonne National Laboratory — The near-term completion of the Nanoprobe Beamline at the Advanced Photon Source as part of the Center for Nanoscale Materials Project will provide a dedicated facility for hard X-ray microscopy at a 30 nm spatial resolution. Integrating a high-flux synchrotron X-ray beamline with an advanced optomechanical experimental platform at an energy range of 3-30keV will make possible nanoscale studies of functional and biological materials with a high degree of precision and efficiency. The unique capabilities of hard X-ray microscopy techniques such as large penetration depths, experimental sensitivity to elemental composition, crystallographic phase, and strain when applied at this length scale offer unique opportunities for many fields of sciences. The challenges and scientific impact of extending X-ray microscopy techniques such as scanning probe X-ray fluorescence, scanning probe microdiffraction, spectroscopy, tomography, and full-field imaging to the nanoscale will be discussed.

R1.00306 Hard X-ray Nanoprobe Development at Argonne National Laboratory

ROBERT WINARSKI, MARTIN HOLT, JORG MASER, VOLKER ROSE, DEMING SHU, BRIAN STEPHENSON, Argonne National Laboratory, CENTER FOR NANOSCALE MATERIALS / ADVANCED PHOTON SOURCE COLLABORATION — The HarX-ray Nanoprobe beamline will explore nanoscale objects at a spatial resolution of 30 nanometers, using x-ray fluorescence spectroscopy, transmission imaging, diffraction, and scattering. X-ray fluorescence measurements will provide element-specific imaging of individual nanoparticles inside of samples. Transmission imaging will allow three dimensional mappings of thick specimens and devices. X-ray diffraction and scattering capabilities will examine strain states and ordering in nanoscale systems. The beamline is designed for two modes of operation: a scanning probe mode, where the spatially coherent fraction of the x-ray beam is focused by high-resolution x-ray optics onto a small area of a sample, and a full-field transmission mode, where the full, partially coherent x-ray beam is used to illuminate a sample for transmission imaging at high resolution.

2This research, including use of the Center for Nanoscale Materials, was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under contract DE-AC02-06CH11357.

R1.00307 Low temperature growth of boron nitride nanotubes

CHEE HUEI LEE, MING XIE, JIESHENG WANG, YOKE KHIN YAP — Boron nitride nanotubes (BNNTs) are promising nanostuctures that will complement the applications of carbon nanotubes in various emerging areas. However, the synthesis of BNNTs is still challenging and required high growth temperatures (1500 °C to 3000 °C). Here we will discuss about two approaches for low temperature growth of BNNTs. First, we have reported on the growth of pure BNNTs at 600 °C by a plasma-enhanced pulsed-laser deposition (PE-PLD) technique [1]. These BNNTs were grown vertically-aligned on substrates. Latest result on the effect of catalyst, growth temperatures, ambient gas pressures, substrate bias voltages and the growth mechanism will be discussed in the meeting. Secondly, effective growth of BNNTs is recently achieved by conventional thermal chemical vapor deposition (CVD). Our new CVD approach leads to effective growth of long and clean BNNTs at 1200 °C. SEM, TEM, EELS, Raman, FTIR, and UV absorption data indicate that these BNNTs are having high structural ordered and a energy band gap > 5.6 eV. [1].

R1.00308 Non-affine deformations in biological gels, QI WEN, ANINDITA BASU, JESSAMINE WINNER, ARJUN YODH, PAUL JANMEY, University of Pennsylvania — Compared to flexible polymer gels, filamentous biopolymer networks generally have larger elastic moduli, a striking increase in elastic modulus with increasing strain, and a pronounced negative normal stress when deformed under simple shear. Different theoretical models based on either entropic elasticity of semiflexible filaments or enthalpic bending and stretching of rods can under some conditions account for all three of these unusual features. An essential difference between theories that relate microscopic structural parameters such as persistence length and mesh size of biopolymer gels to their macroscopic rheology are predictions about whether deformation of these materials is affine. We test the validity of this affine assumption by embedding micron-sized fluorescent beads within the networks and quantifying their displacements under shear deformation. Measures of non-affine deformation are small for networks of thin relatively flexible filaments and get smaller as strain increases. The small non-affine measures are consistent with the entropic model for non-linear elasticity of semiflexible polymer networks. However, as filament stiffness and mesh size increases the deformations become more non-affine, these results are more possible consistent with enthalpic bending and stretching models.

R1.00309 Interference in the Mott Insulator State of Distinguishable Particles, LIN TIAN, FUMITAKA FUJIWARA, TIM BYRNES, National Institute of Informatics, 2-1-2 Hitotsubashi, Chiyoda-ku, Tokyo 101-8430, Japan, YOSHIHISA YAMAMOTO, Department of Applied Physics and E. L. Ginzton Laboratory, Stanford University, Stanford, CA 94305; National Institute of Informatics, Tokyo, Japan — Particle statistics plays a crucial role in strongly interacting quantum many-body systems. Here, we study the Hubbard model for distinguishable particles at unit filling. We show that when on-site repulsive interaction dominates over tunneling, the ground state is a Mott insulator state with higher order coherence between the particles. This result can be experimentally confirmed by the recovery of the interference pattern in the density correlation functions and is robust against non-uniformity of the interaction and tunneling parameters. We also show that this state is a maximally entangled state, in contrast to its bosonic counterpart. L. Tian, F. Fujiwara, T. Byrnes, and Y. Yamamoto, preprint, arXiv/0705.2023.

R1.00310 Spin-state polarons as a precursor to ferromagnetism and metallicity in hole-doped LaCoO\textsubscript{3}, A. PODLENSYAK, M. RUSSINA, Hahn-Meitner-Institut, Berlin, Germany, E. POMJAKUSHINA, K. CONDER, Paul Scherrer Institut, Switzerland, D. KHÖMISKII, Institute of Physics II, University of Cologne, Germany — Lightly doped cobaltites La\textsubscript{1-y}Sr\textsubscript{y}CoO\textsubscript{3} exhibit magnetic properties at low temperatures, in strong contrast to the diamagnetic LaCoO\textsubscript{3}. We undertook an inelastic neutron scattering study with the goal to identify the energy spectrum and magnetic state of cobalt ions in the doped system with x = 0.002. In distinguish to the parent compound, where no excitations have been found for T < 30 K, an inelastic peak at \Delta E \sim 0.75 meV was observed in La\textsubscript{0.998}Sr\textsubscript{0.002}CoO\textsubscript{3} at T = 1.5 K. The intensity of this excitation is much higher than what is expected from an estimated concentration of doped holes. Furthermore, strong Zeeman splitting of the inelastic peak corresponds to an unusually high effective magnetic moment \sim 15\mu_B. Neighboring low-spin (LS) Co\textsuperscript{3+} and intermediate-spin Co\textsuperscript{3+} ions can share an e\textsubscript{g} electron by swapping configuration. The two \textsubscript{t}_{2g} electrons, in their turn, couple ferromagnetically. Therefore, we propose that the holes introduced in the LS state of LaCoO\textsubscript{3} are extended over the neighboring Co sites forming spin-state polarons and transforming the involved Co\textsubscript{3+} to the higher spin state. Grows of spin-state polarons with hole doping finally results in a metallic ferromagnetic state for x > 0.3.

R1.00311 Metal-insulator transition in graphene oxide, GEUNSIK LEE, KYEONGJAE CHO, Department of Physics and Department of Electrical Engineering, University of Texas at Dallas, Texas 75080, USA — Using the first-principles density-functional theory method, we show that metallic graphene undergoes a metal-insulator transition upon adsorption of oxygen, and that the fully oxidized metastable graphene has a large energy gap of 3.27 eV. Graphene oxide (GO) shows the transition at the coverage of 1/3 - 1/2 monolayer of epoxide group. Each O atom saturates two \pi orbitals, and the GO band structure is determined by the connectivity of metallic channels of \pi orbitals. Although such directional conduction is verified for most of GOs that we considered, we have found that longer range interaction between \pi orbitals also plays an important role in the electronic structure of GOs. We apply our results to the implication on electrical conductions in dry and wet GO samples.

R1.00312 Tight-binding Calculation of Electronic Properties of Oligophenyl and Oligoacene Chains, ADAM HINKLE, ANTONIO C. CANCIO, MAHFUZA KHATUN, Ball State University — Within recent years, allotrophic structures of carbon have been produced in the forms of tubes and ribbons which offer the promise of extraordinary electronic and thermal properties. Here we present analyses of oligophenyl and oligoacene systems—finite, one-dimensional chains of benzene rings linked along the armchair and zigzag directions. These one-dimensional structures, which are amenable to calculation by analytical means, exhibit features very similar to carbon nanotubes and nanoribbons. Using a tight-binding Hamiltonian we analytically determine the energy bands of these systems. From these results we calculate the density of states and wavefunction symmetries for each structure. We also discuss the effect doping has on the energy as well as examine the transport properties.

R1.00313 Investigation of colloidal interactions in nanoparticle suspensions with a single optical trap, JOSEPH JUNIO, ERIC BLANTON, H. DANIEL OU-YANG, Lehigh University — Colloidal interaction parameters such as virial coefficients or bulk moduli are traditionally measured by scattering methods. However, experimental difficulties often limit the range of applications of these methods to idealized systems. Multiple optical tweezers have also been used to study interparticle forces, but this has been limited to micron size individual particles at infinite dilution. We propose a new approach to investigate many body deformations of sub-micron colloidal particles in native suspensions with a single optical trap. Using a blinking optical trap and confocal detection of optical signals, this approach can be used to measure many body interactions in suspensions of colloidal particles in the range of tens to hundreds nanometers in size. Theoretical calculation and preliminary experimental data will be presented at the talk.

R1.00314 3-D structure and dynamics of microtubule self-organization, JING WANG, H. DANIEL OU-YANG, Lehigh University — Laser scanning confocal microscopy was used to study the dynamics of 3D assemblies spontaneously formed in microtubule (MT) solutions. Microtubule solutions prepared by mixing and incubating tubulin in the presence of GTP and Oregon Green conjugated taxol in PM buffer were placed in long, sub-millimeter thin glass cells by the capillary action. Within 24 hours, starting with a uniform distribution, microtubules were found to be gradually separated into a few large “buckled” bundles along the long direction, and in the middle plane, of the sample cell. A well-defined wavelength of the buckling sinusoids along the short direction of the bundles was approximately 40 \mu m in diameter and the lengths were several centimeters. Detailed analysis of the 3-D image within the bundles revealed that each bundle seemed to consist of loosely packed MTs. It appeared that MTs were phase separated resulting from attractive interactions between charged MT fibers. The “buckling” behavior could be the result of geometrical constraints of the repulsive cell walls and the repulsive interaction between bundles. Detailed 3-D observations of the dynamic evolution of MT assembly could provide insight to the mechanisms of cellular MT organization and phase separation of charged colloidal rods.

R1.00315 Genetic Engineering of Optical Properties of Biomaterials\textsuperscript{1}, PAUL GOURLEY, Sandia Labs, ROBERT NAVIAUX, MICHAEL YAFFE, Univ. CA San Diego, SANDIA NATIONAL LABS COLLABORATION, U C SAN DIEGO COLLABORATION — Baker’s yeast cells are easily cultured and can be manipulated genetically to produce large numbers of bioparticles (cells and mitochondria) with controllable size and optical properties. We have recently employed nanoplasmonic spectroscopy to study the refractive index of individual cells and isolated mitochondria from two mutant strains. Results show that biomolecular changes induced by mutation can produce bioparticles with radical changes in refractive index. Wild-type mitochondria exhibit a distribution with a well-defined mean and small variance. In striking contrast, mitochondria from one mutant strain produced a histogram that is highly collapsed with a ten-fold decrease in the mean and standard deviation. In a second mutant strain we observed an opposite effect with the mean nearly unchanged but the variance increased nearly a thousand-fold. Both histograms could be self-consistently modeled with a single, log-normal distribution. The strains were further examined by 2-dimensional gel electrophoresis to measure changes in protein composition. All of these data show that genetic manipulation of cells represents a new approach to engineering optical properties of bioparticles.

R1.00316 Ambient-pressure thermodynamic measurements on UGe\textsubscript{2}, F. HARDY, C. MEINGAST, H. VON LOEHNEYSEN, Forschungszentrum Karlsruhe, Institut fuer Festkoerperfysik,76021 Karlsruhe, Germany, Physikalisches Institut, Universitaet Karlsruhe, 76128 Karlsruhe, F. FLOQUET, A. HUXLEY, SPMS-DRFM, CEA/ Service de Recherche en Matiere Condensee, France, J. LASHLEY, Materials Science Division and Technology Division, LANL, Los Alamos, New Mexico 87545, USA, R.A. FISHER, N.E. PHILLIPS, Materials Science Division, LBNL, Berkeley, California 94720, USA. — The pairing interaction leading to the formation of the Cooper pairs remains unidentified in the ferromagnetic superconductor UGe\textsubscript{2}. Nevertheless, there is strong experimental evidence that superconductivity is not mediated by the magnetic fluctuations that drive T\textsubscript{Curie} (p) to zero; it rather appears closely related to another phase boundary T\textsubscript{p} (p) that occurs at lower pressure. Theoretical works suggested that this additional phase boundary could arise either from a coupling between SDW and CDW orderings or from a peak in the electronic density of states. Although the existence of this anomaly is experimentally incontestable between 0.6 and 1.2 GPa, the situation at ambient pressure remains ambiguous. We discuss the aforementioned scenario in the light of recent high-resolution thermal expansion and calorimetric measurements realized under high magnetic fields at ambient pressure.

R1.00317 Ressonance Raman Excitation Energy Map and High Resolution Transmission Electron Microscopy of hundreds of (n,m) Single Wall Carbon Nanotubes\textsuperscript{1}, ADO JORIO, PEDRO B.C. PESCE, PAULO T. ARAUJO, Universidade Federal de Minas Gerais, STEPHEN K. DOORN, Los Alamos National Laboratory, PASHA NIKOLAEV, ERC/NASA-JSC, UFMG COLLABORATION, NASA COLLABORATION, LANL COLLABORATION — In this work we measure the Raman spectra of a single wall carbon nanotube (SWNT) sample with a wide diameter distribution - 1nm to 6nm - with closely spaced laser lines over the 1.26eV to 2.71eV energy range and did a thorough analysis of the observed features. The most intense peaks are assigned to the scattering of light by a single RBM phonon in resonance with the well-known excitonic E\textsubscript{11} transitions. Comparison of the Raman map with the diameter distribution of the sample, obtained from high resolution transmission electron microscopy (HRTEM) measurements of 395 different nanotubes allows us to determine the diameter dependence of the RBM cross section. Furthermore, a number of weaker features are identified with different mechanisms, such as the RBM overtone and cross polarized transitions.

\textsuperscript{1}Support from CNPq, Brazil.

R1.00318 Ripples in epitaxial graphene, FRANCOIS VARCHON, PIERRE MALLET, JEAN-YVES VEUILLEN, LAURENCE MAGAUD, Institut Neel CNRS/UJF — On the basis of extensive ab initio calculation supported by scanning tunneling experiments, we have elucidated the complex morphology of the graphene/SiC (0001) interface \textsuperscript{1}. We demonstrate that a carbon buffer layer is always present at the interface. It is a key characteristic of the system because this buffer layer electronically decouples the graphene layer from the substrate \textsuperscript{2}. It has a mosaic structure that is reminiscent of a graphene honeycomb lattice distorted by the formation of strong covalent bonds with the substrate. The substrate-induced nanostructuration extends up to the ontop graphene layer where it generates an incommensurate modulation of the honeycomb lattice. The possible opening of a gap induced by the substrate \textsuperscript{3} in the epitaxial graphene electronic structure will also be discussed. \textsuperscript{1}F.Varchon et al. cond-mat/0712.3394, (submitted to PRB) \textsuperscript{2}F.Varchon et al. Phys. Rev. Lett. 99, 126805 (2007) \textsuperscript{3}S.Y.Zhou et al. Nature Mat. 6, 771 (2007)

R1.00319 Phase transition via intermediate state and control of piezoelectric parameters in lead-zirconate-titanate based solid solutions\textsuperscript{1}, V. SOBOLEV, South Dakota School of Mines & Technology, V. ISCHCHUK, Institute for Single Crystals, NAS of Ukraine, 61001 Kharkov, Ukraine, N. SPIRIDONOV, STC “Reaktivelektron”, NAS of Ukraine, 83096 Donetsk, Ukraine — Presentation contains results of experimental investigation of the influence of external electric field on the stability of phases in antiferroelectric substances with a small difference in the free energies of the ferroelectric and antiferroelectric states. The composition-electric-field phase diagrams with intermediate states of coexisting domains of the ferroelectric and antiferroelectric phases are obtained for lanthanum-modified lead-zirconate-titanate based solid solutions. This intermediate state appears in the process of inducing of the ferroelectric state by an external electric field in antiferroelectric solid solutions. Peculiarities of the intermediate state caused by interphase interactions between coexisting ferroelectric and antiferroelectric domains are revealed. Analysis of the dependences of piezoelectric material parameters on external electric field at the phase transition via an intermediate state has been performed. It is demonstrated that within the interval of existence of the intermediate state the piezoelectric material parameters can be effectively controlled by an applied electric field.

\textsuperscript{1}Partially supported through ONR Grant No. N00014-06-1-0616 and STCU Grant No. 3898.

R1.00320 Entangled Photon Quantum Key Distribution: Theory and Experiment, ISRAEL OWENS, Los Alamos National Laboratory — Secure communications face growing challenges due to technological advances such as the anticipated arrival of quantum computers. Quantum key distribution offers a new method for the distribution of cryptographic key material that is secure against these challenges. I will describe a method of quantum key distribution that is based on using entangled photon pairs (EQKD). In particular, I will discuss and emphasize the key theoretical and experimental components of EQKD and the details of recent test-bed data results.

R1.00321 Zero dimensional area law in a gapless fermion system\textsuperscript{1}, GREGORY LEVINE, DAVID MILLER, Hofstra University — The entanglement entropy of a gapless fermion subsystem coupled to a gapless bulk by a “weak link” is considered. It is demonstrated numerically that each independent weak link contributes an entropy proportional to ln L, where L is linear dimension of the subsystem.

\textsuperscript{1}Supported by an award from Research Corporation CC6535

R1.00322 E=2mc\textsuperscript{2}, KWADWO DOMPREH, University of Cape Coast — The Albert Einstein mass-energy equation E=mc\textsuperscript{2} which is used primarily in the estimation of the amount of energy in fission reaction can be modified to give an equation which is used calculate the amount of energy in a fusion reaction. This theory is deduced using the Gedenken experiment used in special relativity and a computer simulation using the Matrix laboratory. The energy harnessed is non — radioactive and can be used to power our homes, industries and even our automobiles. When the equation is applied to cosmological bodies such as the Suns, Starts and others gives a better understanding of their origin.
R1.00324 Ion Size Effect on Glow Peak Temperature in Dielectric Binary Mixed Crystals Doped With Divalent Europium, RICARDO RODRIGUEZ-MIJANGOS, RAUL PEREZ-SALAS, Universidad de Sonora — Thermoluminescence measurements at room temperature of “beta” irradiated divalent Europium doped binary mixed alkali halides with RbCl and KBr components at several concentrations x in molar fraction are carried out. The experiments have been carried out to identify the effect of composition in thermoluminescence glow peaks. A typical glow peak has been distinguished for each composition. A linear dependence of its temperature on the composition x has been found. This is principally associated with the radii size change of halogen ions. Comparison with results in mixed KCl:KBr, KBr:RbBr and KCl:RbCl support that assertion.

R1.00325 Consistent Hybrid Simulation of MD and CFD, SHUGO YASUDA, RYOICHI YAMAMOTO, Department of Chemical Engineering, Kyoto University; CREST, Japan Science and Technology Agency — The idea of multi-scale hybrid simulation is expected to be very useful for overcoming several difficult problems remain unsolved in frontiers of computational science in general. A striking example is the case of hydrodynamics of complex fluids or soft matters, for which neither reliable constitutive relation is known explicitly. Our strategy to overcome this problem is very straightforward. We are developing a multi-scale hybrid method which combines computational fluid dynamics (CFD) as a fluid solver and molecular dynamics (MD) as a direct generator of constitutive relations in a consistent way. The numerical algorithm is rather simple. We perform usual lattice-mesh based simulations for CFD level, but each lattice is associated with a small MD cell which generates a “local stress” according to a “local flow field” given from CFD instead of using any constitutive functions at CFD level. Some algorithms to smooth out noses arising from MD simulations in a consistent way are being developed. Comparisons of the numerical results obtained by our hybrid-simulations and those by normal CFDs with a Newtonian constitutive relation are made in order to show the validity of our hybrid simulation method.

R1.00326 Manipulation of the vibration of cold ground-state Cesium molecules, MATTHIEU VITEAU, AMODEN CHOTIA, MARIA ALLEGRINI, DANIEL COMPARAT, PIERRE PILLET, Laboratoire Aimé Cotton, CNRS, Université Paris-Sud, Bâtiment 505, Campus d’Orsay, 91405 Orsay, France — Creating in an efficient way, a large and dense sample of ultracold molecules in their fundamental ground state, i.e. with neither vibration nor rotation, is an important step toward the realization in further experiments. Among them, cold collisions, controlled chemistry, or accurate spectroscopic measurement. One further motivation is the possibility to go towards the realization of a Bose-Einstein molecular condensate. But all existing experiments of cold molecules (Feshbach resonance, photoassociation) formed molecules in high vibrational state, mostly close to the dissociation limit. We want to explore different schemes to create or transfer cold molecules (Cs2) to the electronic and vibrational fundamental state (Σv=0). We have studied the photoassociation of cold atoms in a high vibrational level (1Σg+ or 3Σg−) follow by an optical pumping scheme. We use a shaped femtosecond laser to realize the optical repumping step in order to excite the molecules to a potential which have good decay to lower vibrational levels.

R1.00327 Thermodynamically stable noncomposite vortices in mesoscopic two-gap superconductors, LIUVI CHIBOTARU, VU HUNG DAO, University of Leuven and INPAC — Two-gap (or two-band) superconductors such as recently discovered MgB2 show new qualitative effects with respect to conventional ones. For example the fractionalization of the magnetic flux associated to individual vortices is predicted in massive two-gap superconductors. It can either result from the inequality of the winding numbers of the vortices in the two condensates (L1 ≠ L2) having a common vortex core (composite vortices), or the vortex cores in each of the two bands can be spatially separated (noncomposite or deconfined vortices). In both cases they never correspond to the ground state, i.e. are thermodynamically unstable. Thus only the usual Abrikosov vortices are experimentally observed in massive two-gap superconductors. Within the two-gap Ginzburg-Landau theory we have found the existence of thermodynamically stable noncomposite vortices in mesoscopic superconductors in a large domain of the T − H phase diagram. The appearance of these vortex phases is caused by a non-negligible effect of the boundary of the sample on the superconducting order parameter and represents therefore a genuine mesoscopic effect. For low values of interband Josephson coupling vortex patterns with L1 ≠ L2 can arise in addition to the phases with L1 = L2. The calculations show that noncomposite vortices could be observed in thin mesoscopic samples of MgB2.

R1.00328 Destruction of global coherence in long superconducting nanocylinders, VU HUNG DAO, LIUVI CHIBOTARU, University of Leuven and INPAC — Recent realizations of the Little-Parks experiment on long hollow cylinders with nanoscale diameter have shown the destruction of superconductivity at zero temperature around half quanta of applied magnetic flux. In addition the observed resistive transition unexpectedely broadens when departing from zero magnetic field. A quantum phase transition near half flux quanta has been argued to explain this anomalous behavior. However this theory does not explain the step-like features observed in the temperature variation of the resistance. We show here that the puzzling behavior of the resistance results from an alternation of normal and superconducting sections along the tube. First within the Ginzburg-Landau theory we have found that the transition is of second order if the studied cylinders are homogeneous, which precludes the existence of nonhomogeneous phases. From this we conclude that phase separation must be triggered by the tube inhomogeneities. Within a minimal model where cylinder properties vary along its axis, our BCS calculations of the superconducting state are in a good agreement with experimental data, in particular, the multistep transitions are naturally explained. A small discrepancy near half flux quanta may be ascribed to the charge imbalance induced by the normal electron flow.

R1.00329 Long Time Tail of the Velocity Autocorrelation Function in a Two-Dimensional Moderately Dense Hard Disk Fluid, MASAHARU ISobe, Nagoya Institute of Technology — Alder and Wainwright discovered the slow power decay 1/√t (d/dimension) of the velocity autocorrelation function in moderately dense hard sphere fluids using the event-driven molecular dynamics simulations. In the two-dimensional case, the diffusion coefficient derived using the time correlation expression in linear response theory shows logarithmic divergence, which is called the “2D long- time tail problem”. We revisited this problem to perform a large-scale, long-time simulation with one million hard disks using a modern efficient algorithm and found that the decay of the long tail in moderately dense fluids is slightly faster than the power decay (∼ 1/t). We also compared our numerical data with the prediction of the self-consistent mode-coupling theory in the long time limit (∼ 1/(tv/vT)).
R1.00330 First and second order coherence of exciton-polariton condensates, G. ROUMPOS, C.W. LAI, E.L. Ginztun Lab., Stanford University, USA, A. FORCHEL, Technische Physik, Universität Würzburg, Germany, Y. YAMAMOTO, E.L. Ginztun Lab., Stanford University, USA — The microcavity exciton-polariton system offers the possibility to study condensed matter physics with optical techniques. In particular, condensation of microcavity exciton-polaritons in momentum space, as well as spontaneous buildup of spatial and temporal coherence, were recently demonstrated. We investigate the first and second order coherence of exciton-polariton condensates both in coordinate and in momentum space. We measured the spatial coherence length of up to 20 \( \mu m \), while \( g^{(2)}(t = 0) \) was measured to be close to 2 for appropriate near- and far-field filtering. This experiment provides insights into the phase and intensity fluctuations induced by polariton interactions.

R1.00331 Effect of terminal functional group of self-assembled monolayers formed on gold surface on the adsorption of Amyroid fibrils by AFM, KOHEI UOSAKI, MASAYA TSUKAMOTO, KAZUYASU SAKAGUCHI, YUYA ASANOMI, Hokkaido University — Amyroid fibril, which is known to cause BSE and Alzheimer disease, is a solid and stable fiber of several tens of nm wide and several \( \mu m \) long and has a potential to be used as nano-materials because functional molecules and metal and semiconductor nano-particles can be attached. However, it is not yet possible to align the Amyroid fibrils on a solid surface as programmed. In this study, interaction between Amyroid fibrils and self-assembled monolayers (SAMs) with various functional groups constructed on a gold surface was investigated by in situ AFM. Amyroid fibril (Aβ1-35) peptide was synthesized and the peptide was incubated at 37 deg. for more than a week to obtain the fibril. SAMs of alkyliols with methyl, OH, COOH, NH2, and SO3 groups were formed on Au(111) surface and AFM images were obtained by MAC mode in a solution containing the fibrils. It was clarified that electrostatic and hydrophobic interactions play important roles in adsorption behavior of the fibrils.

This work was supported by MEXT, Japan for Promotion of Novel Interdisciplinary Fields

R1.00332 Effect of nickel doping on the magneto-transport properties of Sm\( _{0.55} \)Sr\( _{0.45} \)MnO\( _3 \) manganites, MAHER ABDELHADI, University of Hail — We studied the effects of nickel (Ni) doping on the magneto-transport properties of Sm\( _{0.55} \)Sr\( _{0.45} \)MnO\(_3 \) manganites near the metal-insulator transition. Various concentrations of Ni-doped Sm\( _{0.55} \)Sr\( _{0.45} \)MnO\(_3 \) samples up to 5% were prepared (Ni was partially substituted at the Mn-site). The temperature dependence of resistivity and magnetoresistance were measured as a function of Ni concentrations. We observed a nonlinear reduction of the metal-insulator transition temperature (MIT) and a decrease in the width of the peaks in the temperature dependence of resistivity with increasing concentration of Ni. The peaks become sharper at high Ni concentration. The resistivity peaks at various magnetic fields collapses on themselves at the high temperature ends above the MIT.

R1.00333 Biomimetic nucleation of calcium carbonate layers at the air-water interface, KYUNGIL KIM, Northwestern University — The interaction between calcium carbonate crystals and chitosan at the air-water interface was investigated. Chitosan was selected as an organic, pseudo-structural component of calcium carbonate biominerals in the subphase in the presence of octadecyl sulfate Langmuir monolayers. Calcite crystallization was studied using X-ray diffraction and optical microscope techniques; in-situ grazing incidence x-ray diffraction was performed at synchrotron sources. Calcite crystallization under octadecyl sulfate monolayers shows a superlattice structure. This chitosan system also results in ACC (amorphous calcium carbonate) formation in the early stage of crystallization.

R1.00334 1H-NMR Study of Silica-Poly(epsilon-carbobenzyloxy-L-lysine) Composite Particles as Function of Temperature, ERICK SOTO, JEROME KOCH, DALE TRELEAVEN, PAUL RUSSO, Louisiana State University — Nearly monodisperse silica-poly(epsilon-carbobenzyloxy-L-lysine) composite particles were synthesized. The hydrodynamic radius of the composite particles and silica core was 200 and 100 nm respectively. Separately, poly(epsilon-carbobenzyloxy-L-lysine) was synthesized having a molecular mass of 200 kDa and a polydispersity of about 1.08. 1H-NMR spectra of the untethered polypeptide dissolved in deuterated m-cresol was collected at different temperatures ranging from 15 to 40 °C. The sharp change in the chemical shift of several protons at around 27 °C suggests a coil-helix conformation transition. Similarly, 1H-NMR spectra of the composite particles exhibits a more subtle change in chemical shifts in the explored temperature range suggesting a conformation transition of the tethered polypeptide.

R1.00335 An improved algorithm for the functional renormalization group and its application to two-dimensional Hubbard model, HIROKAZU TAKASHIMA, University of Tokyo, RYOTARO ARITA, Riken, KAZUHIKO KUROKI, University of Electro-Communications, Hideo Aoki, University of Tokyo, Rikun, KAZUHIKO KUROKI, University of Electro-Communications, Hideo Aoki, University of Tokyo — Among the methods that treat strongly correlated electron systems, the functional renormalization group (fRG) method has desirable a feature that it can take account of the shape of the Fermi surface with an unbiased inclusion of diagrams up to the one-loop level. Specifically, the temperature-flow functional renormalization group (T-flow fRG), proposed by Honerkamp and Salmhofer[1], can be a powerful method. We adopted the equal interval patch discretization in the Cartesian coordinates, for which we have constructed a fast and stable algorithm. With the present algorithm we discuss spin, charge, and pairing susceptibilities and the spectral function at low T for the two-dimensional Hubbard model, including the effect of t' and t". [1] C. Honerkamp and M. Salmhofer, Phys. Rev. B 64, 184516 (2001).

R1.00336 Dynamic nuclear polarization in biased quantum wires using spin-orbit coupling, VIKRAM TRIPATHI, Tata Institute of Fundamental Research, Mumbai, ANSON C. H. CHEUNG, NIGEL R. COOPER, University of Cambridge, Cambridge, United Kingdom — We propose a new method for dynamic nuclear polarization in a quasi one-dimensional quantum wire utilising the spin-orbit interaction, the hyperfine interaction, and a finite source-drain potential difference. In contrast with current methods, our scheme does not rely on external magnetic or optical sources which makes local control much more feasible. Using this method, a significant polarisation of a few per cent is possible in currently available InAs wires which may be detected by conductance measurements. This may prove useful for nuclear magnetic resonance studies in nanoscale systems as well as in spin-based devices where external magnetic and optical sources will not be suitable.

R1.00337 Storage capacity and retrieval time of small-world neural networks. HIRAKU OISHIMA, TAKASHI ODAGAKI. Department of Physics, Kyushu University — To understand the influence of structure on the function of neural networks, we study the storage capacity and the retrieval time of Hopfield-type neural networks for four network structures: regular, small world, random networks generated by the Watts-Strogatz (WS) model, and the same network as the neural network of the nematode Caenorhabditis elegans. Using computer simulations, we find that (1) as the randomness of network is increased, its storage capacity is enhanced; (2) the retrieval time of WS networks does not depend on the network structure, but the retrieval time of C. elegans's neural network is longer than that of WS networks; (3) the storage capacity of the C. elegans network is smaller than that of networks generated by the WS model, though the neural network of C. elegans is considered to be a small-world network. Reference: H. Oshima and T. Odagaki, Phys. Rev. E 76, 036114 (2007).

R1.00338 Current-Induced Magnetic Domain Wall Motion at Low Current Density via Perpendicular Anisotropy. SOON-WOOK JUNG, POSTECH, WOOJIN KIM, TAEK-DONG LEE, KAIST, KYUNG-JIN LEE, Korea University, HYUN-WOO LEE, POSTECH — The current-induced motion of magnetic domain walls carries great potentials for applications such as nano-scaled logic and memory devices. To achieve this goal, a large reduction in the threshold current density Jth for the domain wall motion is highly desired. Here we show that by introducing and properly exploiting the perpendicular magnetic anisotropy, Jth can be reduced by one or even two orders of magnitude in experimentally accessible parameter regimes. Using the collective coordinate approach, we analyzed the physical origin of the reduction. The analytic result was also tested by micromagnetic simulations of the LLG equation with spin transfer torque terms. The resulting Jth is insensitive to domain wall pinning forces and also to the non-adiabaticity, both of which are hard to control in experiments.

R1.00339 Probing Micromechanical Properties of Biological Cells by Oscillatory Optical Tweezers1. ANGELA ZAORSKI, Lehigh University, MING-TZO WEI, National Yang-Ming University, Taipei, Taiwan, HUSEYN C. YALCIN, JING WANG, SAMIR N. GHADIALI, Lehigh University, ARTHUR CHIOU, National Yang-Ming University, Taipei, Taiwan, H. DANIEL OU-YANG, Lehigh University — We used oscillatory optical tweezers to probe the micromechanical properties of cultured alveolar epithelial cells in vitro. The frequency-dependent viscoelasticity of these cells was measured by optical trapping and forced oscillation of either a submicron endogenous intracellular organelle (intra-cellular) or a 1.5μm silica bead attached to the cytoskeleton through trans-membrane integrin receptors (extra-cellular). Both the storage modulus and the magnitude of the complex shear modulus followed weak power-law dependencies with frequency. These data are comparable to data obtained by other measurement techniques. The exponents of power-law dependencies of the data from the intra- and extra-cellular measurements are similar, whereas, the differences in the magnitudes of the moduli from the two measurements are statistically significant.

R1.00340 Molecular magnetic coupling at atomic scale. JINFENG JIA, Department of Physics, Tsinghua University, Beijing 100084, China, YINGSHUANG FU, SHUAIHUA JI, Institute of Physics, The Chinese Academy of Sciences, Beijing 100080, China, XI CHEN, Department of Physics, Tsinghua University, Beijing 100084, China, XUCUN MA, Institute of Physics, The Chinese Academy of Sciences, Beijing 100080, China, QIKUN XUE, Department of Physics, Tsinghua University, Beijing 100084, China — Understanding and manipulating magnetic interactions between molecules is not only meaningful to molecular electronics, but also expected to have profound impact on the development of molecular spintronics and quantum computation. Tunneling spectroscopy of CoPc multilayer prepared on nanometer-sized Pb islands on Si(111) were measured with a subkelvin temperature scanning tunneling microscope. We observed magnetic excitations of coupled molecular systems via inelastic electron tunneling microscopy, and determined the coupling strength between CoPc adjacent layers with Heisenberg model. We further demonstrate the coupling between molecules, and coupling of single-molecule spin with metallic host can both be manipulated by changing their stacking sequence via molecular manipulation.

R1.00341 Model of the magnetostrictic motion of planar domain walls in ferromagnets and antiferromagnets1. MIKHAIL INDENBOM, JIAN-JUN LI, Laboratory of magnetism of Brittany CNRS, Brest, France — Recently we have shown that all details of magnetisation of magnetic thin films and multilayers deployed onto thin substrates can be revealed by simultaneous measurements of the substrate flexion and torsion. This technique is complimentary to the ordinary vector magnetometer being capable to resolve the signal from a ferromagnetic (F) layer with the magnetisation negligible compared to one of the other layers or even from an antiferromagnetic (AF) layer and to study, for example, the formation of planar domain walls in a spring-magnet F/F bilayer or an exchange-bias F/AF bilayer. In the current presentation we are using a 1D model of the planar domain wall in order to demonstrate a variety of magnetostrictive signals which can be obtained in such systems. For clarity we neglect the thickness, magnetic anisotropy and magnetostriction of the control F layer (an ideal F-layer). We have calculated how spin rotation induced in this layer by the applied magnetic field penetrates into the magnetostrictive AF or F layer and forms the planar domain wall.

R1.00342 Heat Transport in Epoxy Networks: A Molecular Dynamics Study. VIKAS VARSHNEY, Universal Technology Corporation, Dayton OH, SOUMYA PATNAIK, BARRY FARMER, AJIT ROY, AFRL, Wright Patterson Air Force Base, OH — In this poster, thermal behavior of a crosslinked epoxy network along with its un-crosslinked counterpart is presented using atomistic molecular dynamics simulations. The simulations were performed on EPON-862 and curing agent-W (DETDA), used as a model system using consistent valence force field (CVFF). The thermal transport is discussed in terms of its thermal conductivity, as calculated using both equilibrium as well as non-equilibrium molecular dynamics approaches, based on Green-Kubo and Fourier law formalisms, respectively. The results are found to be in good agreement with respect to experimental findings. Different energetic contributions of heat flux towards thermal conductivity and their possible coupling in terms of kinetic energy, van der Waals and electrostatic interactions are also discussed. In addition, the broad distribution of low frequency vibrational modes from power spectrum of velocity autocorrelation function suggests their disordered and amorphous nature. The poster also presents heat movement across a crosslinked slab using thermal relaxation simulations and estimates the thermal diffusivity, thermal relaxation time and mean free path for epoxy networks.

R1.00343 Electron Spin Resonance Force Microscopy of Spin Probes. ERIC W. MOORE, SANGGAP LEE, STEVEN A. HICKMAN, SEPPE KUEHN, JOHN A. MAROHN, Cornell University — Nitroxide spin labels, such as 4-amino TEMPO can be used to probe environmentally, conformal and structural probes in biological and polymer systems. We report on our efforts to detect electron spin resonance of 4-amino TEMPO in a polymer matrix using the magnetic resonance force microscopy as a proof of concept for future experiments on spin labeled proteins. Our microscope operates at high vacuum and low temperature, using a custom fabricated single crystal silicon cantilever in the magneto-cantilever geometry. The applied field is provided by a microstripline resonator at 18 GHz.

R1.00344 Electrical Transport in Ultra Long Bundles of Carbon Nanotube. AMELIA CHURCH, RAKESH SHAH, XIANFENG ZHANG, SAIKAT TALAPATRA, Department of Physics, Southern Illinois University Carbondale. We will present electrical transport measurements performed on bundles of millimeter long multi walled carbon nanotubes (MWNT). These MWNTs were grown using air assisted floating catalyst chemical vapor deposition method. The temperature dependence of resistance of these MWNT bundles as a function of bundle length will be presented. The variation in the electrical transport properties as a function of MWNT lengths as seen from the current-voltage measurements will also be discussed.
R1.00345 Benzene confinement in single-walled carbon nanotubes: inelastic and quasielastic neutron scattering , N.R. DE SOUZA, A.I. KOLESNIKOV, N. VERDAL, Argonne National Laboratory, Intense Pulsed Neutron Source, A.P. MORAVSKY, MER Corporation — We characterize experimentally the dynamic properties of benzene confined in single-walled carbon nanotubes (SWNT) of diameter 14 Å. The presence of benzene inside the nanotubes is demonstrated by measuring the small-angle neutron scattering intensities from a properly prepared C6D6 benzene — SWNT sample. The incoherent inelastic neutron scattering spectra from C6D6 benzene in the nanotubes and in the bulk crystal are measured at 4 K, up to an energy transfer of 130 meV. The effective vibrational density of states reveals a significant redistribution of all intermolecular modes for the confined benzene, whereas the intramolecular modes are nearly unaffected. Incoherent quasielastic neutron scattering spectra from C6D6 benzene in the nanotubes were also collected from 9 K to room temperature, at an energy-transfer resolution of approx. 80μeV. The orientational and translational diffusive dynamics of confined benzene are discussed on the basis of these data.

R1.00346 Patterned nanoring magnetic tunnel junctions and current-induced magnetization switching , Z.C. WEN, H.X. WEI, Y.N. HAN, X.F. HAN, Institute of Physics, CAS — Patterned nanoring (NR) magnetic-tunnel-junctions (MTJs) with outer diameters between 100 and 400nm and narrow ring widths between 25 and 30nm were successfully fabricated. The NR structure consists of CoFeB electrodes and Al-oxide barrier. The tunnelling magnetoresistance (TMR) ratio of the patterned NR-MTJs is in the range of 20%-50% observed at room temperature with \( R_A \) lower than 500Ωμm². These NR- MTJs allow current-induced magnetization switching with a low switching current density of around \( 9 \times 10^4 A/cm^2 \). Due to the small stray field and high TMR ratio, NR-MTJs offer superior prospects for high density magnetic random access memory (MRAM), recording medium and other spintronics devices.

R1.00347 Spin waves in 2D classical XY-model , SNEHADRI OTA, Institute of Physics, Bhubaneswar, SMITA OTA, Institute of Mathematics and Applications, Bhubaneswar — The description of phase transition in the microcanonical formalism has gained growing interest in recent years for the calculation of thermostatic properties of physical systems and microcanonical entropy.\(^1\) We have carried out micro-canonical Monte Carlo simulations of the 2D XY-model using periodic boundary conditions.\(^2\) In case of microcanonical Monte Carlo simulation some thermodynamic-like relations apply that allow definition of variable by averaging, specifically, the temperature. The energy distributions of the spins have been obtained for the the Kosterlitz-Thouless situation.\(^3\) In this case, the energy distribution of vortices show features that is due to spin waves, which agrees with the spin wave theory which predicts that \( E_{vortex} = -2 + T/2 \). References: \(^1\) H.Behringer and M.Pleimling, Phys.Rev.E 74 (2006) 11108 \(^2\) M.Creutz, Phys.Rev.Lett. 50 (1983) 1411 \(^3\) S Ota and S B Ota, Phys.Lett.A 367 (2007) 35 \(^4\) J B Kagot, Rev.Mod.Phys. 51 (1979) 659

R1.00349 Fabrication and characterization of InAs/AlGaSb HEMTs with high-k gate insulators , TOSHIHIKO MAEMOTO, KENJI FUJIWARA, TATSUYA INOUE, NAOKI AMANO, MASATOSHI KOYAMA, SHIGEHIKO SASA, MASATAKA INOUE, OSAKA INSTITUTE OF TECHNOLOGY TEAM — We report on the fabrication and characterization of InAs/AlGaSb high electron mobility transistors (HEMTs) with high-k gate insulators (Al₂O₃ and HfO₂). InAs/AlGaSb quantum well structures were grown by molecular beam epitaxy on a semi-insulating GaAs substrate [1]. From Hall measurements at room temperature, the as-grown wafer showed an electron mobility of 20,000-25,000 cm²/Vs and a sheet carrier density of 1.0-2.0×10¹² cm⁻². InAs/AlGaSb HEMTs have demonstrated a maximum extrinsic transconductance of 181mS/mm at room temperature. The gate leakage current has been markedly decreased by using thin high-k gate insulators. A typical gate current density of less than 1 nA/mm at room temperature was measured at 4 K, up to an energy transfer of 130 meV. The effective vibrational density of states reveals a significant redistribution of all intermolecular modes for the confined benzene, whereas the intramolecular modes are nearly unaffected. Incoherent quasielastic neutron scattering spectra from C6D6 benzene in the nanotubes were also collected from 9 K to room temperature, at an energy-transfer resolution of approx. 80μeV. The orientational and translational diffusive dynamics of confined benzene are discussed on the basis of these data.

R1.00350 Phonon Transport in Carbon Nanotubes , G. PENNINGTON, S.J. KILPATRICK, A.E. WICKENDEN, Army Research Laboratory — An understanding of phonon transport in carbon nanotubes (CNTs) is important considering potential electronic and thermal management applications. Weak intrinsic phonon scattering in these quasi-one-dimensional materials allows unique properties including high thermal conductivity. Thus CNTs may provide novel thermal management solutions critical for many emerging electronics technologies, including the development of high-power, high-temperature transistors/lasers and the continued scaling down of feature sizes in high-performance microelectronics. Carbon nanotubes are also expected to exhibit relatively large optical phonon decay times. It is widely believed that non-equilibrium phonons lead to conductance degradation, negative differential conductance, and enhanced thermal breakdown of suspended CNTs.\(^1\) Furthermore, absorption of hot optical phonons by conducting carriers would significantly alter device characteristics in the low-field ballistic limit. Thermal properties are also affected as the slow decay of hot optical phonons is expected to lead to reduced thermal diffusivity, and the development of inhomogeneous heating within a nanotube. In this talk, we discuss simulations of CNT phonon transport based on Monte Carlo solution of the phonon Boltzmann transport equation.\(^1\) References: \(^1\) E. Pop, D. Mann, J. Cao, Q. Wang, K. Goodson, and H. Dai, “Negative Differential Conductance and Hot Phonons in Suspended Nanotube Molecular Wires,” Phys. Rev. Lett., vol. 95, pp. 155505-8, October 2005.

Wednesday, March 12, 2008 2:30PM - 5:30PM –
Session S1 DCMP: Diamond-based Quantum Information Processing Morial Convention Center
LaLouisiane AB
2:30PM S1.00001 Coherent control of single spins in diamond1. RONALD HANSON, Kavli Institute of Nanoscience Delft — Diamond-based materials have recently emerged as a unique platform for quantum science and engineering. Spins of single Nitrogen-Vacancy (N-V) color centers in diamond can be imaged, initialized and read out optically. These N-V center spins may allow for quantum information processing at room temperature, as measurements have shown long room-temperature electron spin coherence times well into the microsecond regime. We have investigated single N-V center spins that are coupled to electron spins of nearby nitrogen (N) defects, using magneto- optical imaging and coherent single-spin control at room temperature. Some of the N-V centers are strongly coupled to only one single N spin, allowing the controlled polarization and readout of this single ‘dark’ N spin. In contrast, other N-V centers couple to many N spins. We use these latter systems to study the canonical decoherence model of a single central spin coupled to a spin bath. By tuning the internal bath dynamics as well as the spin-bath coupling, we gain access to regimes with strikingly different behaviour. Finally, we have fabricated and characterized photonoc crystal microcavities in poly-crystalline diamond and observed quality factors up to 600. These structures are a first step towards controllable coupling of single N-V spins to single photons in a cavity-QED system in diamond.

1in collaboration with V.V. Dobrovitski, A.E. Feiguin, O. Gywat, C.F. Wang, E. Hu, and D.D. Awschalom. Financially supported by FOM, AFOSR and DARPA/CNID.

3:06PM S1.00002 Controlling individual electron and nuclear spins in diamond: from quantum registers to applications, MIKHAIL LUKIN, Harvard University — We will discuss our recent work involving the controlled manipulation of individual electron and nuclear spins in a high-purity diamond lattice. Our approach combines ideas from single molecule spectroscopy, quantum optical control techniques and the physics of mesoscopic spin ensembles. It allows us to isolate, polarize and manipulate single nuclear spins and use them to create quantum memory and small quantum registers. We will also describe novel applications of these techniques, including new approaches to quantum communication and computation as well as new quantum magnetic sensors with nanoscale resolution. Recent progress towards realization of these ideas will be discussed.

3:42PM S1.00003 Fabrication Strategies for Practical Diamond Based Quantum Information Processing Devices, STEVEN PRAWER, Centre of Excellence for Quantum Computer Technology and Quantum Communications Victoria, School of Physics, University of Melbourne, Australia — Optically emitting defect centres in diamond display a range of unique quantum properties that offer exciting possibilities for the construction of quantum devices which employ optical single-spin read-out. Indeed diamond is an ideal material for use in the fabrication of (i) single photon sources for quantum communications, (ii) optical fibre-based single spin read out systems, (iii) photonic platforms for the investigation of quantum entanglement in solid state systems and (iv) optical regenerators and non-linear quantum gates. The toolkit of available fabrication strategies which are used to engineer devices taking advantage of these unique properties will be presented. Our most recent results include demonstrations of (i) optical fibre based single photon sources based on Nickel and Nitrogen optical centres, (ii) waveguiding of light in structures hewn from single crystal diamond, (iii) Electrical Stark shift of the frequency of single optical emitters, (iv) coupling between the spins between single NV and N atoms in devices engineered by ion implantation, and (v) electromagnetically induced transparency in single NV centers. These crucial demonstrations establish the feasibility of a defect tolerant architecture for the fabrication of a few (~10-50) qubit diamond based quantum information processor. We will present one such possible architecture and explain the specific role for ion beam processing in the creation of qubits and the engineering of diamond photonic devices.

4:18PM S1.00004 Coherent Population Trapping of Single Spins in Diamond under Optical Excitation, CHARLES SANTORI, Hewlett-Packard Laboratories, Palo Alto, CA — The nitrogen-vacancy (N-V) center in diamond has long-lived electronic and nuclear spin coherence combined with optical addressability, making it an attractive candidate system for building a photonic network for quantum information applications. However, realizing such schemes will require control over the N-V energy level structure and integration into high-quality microphotonic structures operating at visible wavelengths. In this talk I will describe experiments on optical manipulation of N-V centers in low-nitrogen diamond samples. Typically the optical transitions of NV− are spin-conserving, so that if the N-V begins in the mS = 0 ground state, it can undergo many optical transitions before transitioning to mS = ±1. However, by applying stress to the crystal, or by using strain already present, it is possible to realize a Λ-type system with one excited state coupled by optical transitions to multiple ground states. By this technique we have observed coherent population trapping both in N-V ensembles and in single N-V centers. These results demonstrate the potential for all-optical spin manipulation in this system. I will also describe initial work on coupling N-V centers to photonic structures with the goal of enhancing emission into the zero-phonon line, as needed for applications such as quantum repeaters.

4:54PM S1.00005 Controlling single defects: Electric and magnetic fields, JOERG WRACHTRUP, Stuttgart University — Controlling the optical properties of single defects, e.g. its transition frequency and transition properties is an important prerequisite for their broad application. It is shown that external electric and magnetic fields allow for control over a broad range of parameters. The optical transition frequency can e.g. be controlled by an electric field. The same field determines whether the defect is driven cyclic or lambda transition behaviour dominates. The talk will describe current knowledge of the defect in this respect and show perspectives toward cavity coupling and entanglement of distant defects.

Wednesday, March 12, 2008 2:30PM - 5:30PM —
Session S2 FLAP: Can Power Dissipation in a Switch Be Significantly Lowered?
Morial Convention Center LaLouisiane C

2:30PM S2.00001 Will a New Milli-Volt Switch Replace the Transistor for Digital Applications? , ELI YABLONOVITCH, EECS Dept., University of California, Berkeley — In contemplating the headlong rush toward miniaturization represented by Moore’s Law, it is tempting to think only of the progression toward molecular sized components. There is a second aspect of Moores Law, that is sometimes overlooked. Because of miniaturization, the energy efficiency of information processing steadily improves. We anticipate that the energy required to process a single bit of information will eventually become as tiny as 1 electron Volt per function, truly a molecular sized energy. Inevitably most logic functions including storage, readout, and other logical manipulations will eventually be that efficient. However there is one information-processing function that bucks this trend. That is communication, especially over short distances. Our best projections of improvements in the short distance communication function show that it will still require hundreds of thousand of electron Volts, just to move one bit of information the tiny distance of only 10 micro meters. Why this energy per bit discrepancy for communications? It is caused by the difference in voltage scale between the wires and the transistor switches. Transistors are thermally activated, leading to a characteristic voltage $kT/q$. Wires are long and they have a low impedance, allowing them to operate efficiently even at 1-milli-Volt. The challenge then is to replace transistors with a new low-voltage switch, that is better matched to the wires. I will present some of the technical options for such a new switch.

3:06PM S2.00002 Use of negative capacitance to provide voltage amplification for ultra low power nanoscale devices, SAYEEF SALAHUDDIN, Purdue University — It is well known that conventional Field Effect Transistors (FET’s) require a change in the channel potential of at least 60 mV at 300K to effect a change in the current by a factor of ten, and this minimum subthreshold slope $S$ puts a fundamental lower limit on the operating voltage and hence the power dissipation in standard FET based switches. Here we show that by replacing the standard insulator with a ferroelectric insulator of the right thickness it should be possible to implement a step-up voltage transformer that will amplify the gate voltage thus leading to values of $S$ lower than 60 mV/decade and enabling low voltage/low power operation. The voltage transformer action can be understood intuitively as the result of an effective negative capacitance provided by the ferroelectric capacitor which arises from an internal positive feedback that in principle could be obtained from other microscopic mechanisms as well. Unlike other proposals to reduce $S$ this involves no change in the basic physics of the FET and thus does not affect its current drive or impose other restrictions.

3:42PM S2.00003 Nanowire Impact Ionization FETs, MIKAEL BJORK, IBM Research Zurich — One limiting factor in the scaling of transistor technology is the room temperature limit of 60 mV/decade of the inverse sub-threshold slope. As supply- and threshold voltages are scaled down leakage currents rise exponentially causing the standby power of highly integrated circuits to suffer. New types of devices based on band-to-band tunneling [1] or impact ionization [2] have recently been demonstrated that can circumvent the 60 mV/decade limit thereby offering lower leakage currents. We have demonstrated vertical integration [3] of a single surround-gated silicon nanowire field-effect transistor (NW FET) having an inverse sub-threshold slope as low as 6 mV/decade at room temperature that spans four orders of magnitude in current [4]. The transistor shows slopes below 60 mV/decade for supply voltages above 2 V. Due to the use of a top Schottky contact and two ungated regions the devices show ambipolar characteristics with impact ionization for both electron and hole branch. The rather small voltages reduce hot carrier injection into the gate dielectric making threshold voltage shifts and degradation of the performance minimal.

4:18PM S2.00004 Nanoelectromechanical switches, MARC BALDO, MIT, Department of Electrical Engineering and Computer Science — Power dissipation is perhaps the most important problem confronting the electronics industry. To address this issue, we investigate vertical nanoelectromechanical (NEM) switches suitable for complementary logic, reconfigurable interconnects, and static power management. NEM switches have the following advantages: (i) Near elimination of source-drain static tunneling losses, (ii) Improved subthreshold characteristics [1]— allowing lower operating voltage and hence lower dynamic power dissipation, (iii) Ability to run at much higher temperatures than Si-based CMOS. Our approach employs a carbon nanotube-based relay. We have prototyped this approach by inserting a tube into an etched gap between two contacts. Using a nanopositioner to align the tube, the prototype has demonstrated multiple switching at 5V. We will characterize this device and also integrated NEM switches.

4:54PM S2.00005 One-dimensional semiconductors for low-power electronic applications, JOERG APPENZELLER, School of Electrical and Computer Engineering and Birck Nanotechnology Center, Purdue University, West Lafayette, IN 47906 — Power dissipation is rapidly increasing from one to the next generation of silicon CMOS based chips. While following the ideal scaling rules should improve the performance without significantly increasing the power consumption, in particular the supply voltage has not been reduced in the past as required. Since the gate oxide thickness (SiO(N) in common CMOS applications) on the other hand has been decreased substantially, gate leakage currents have become a severe problem when the transistor is turned off. For logic applications, part of the applied voltage is used to switch the device from its off-state into its on-state while the other portion is used to drive the transistor into a regime of high transconductance. When asking the question about how to decrease the supply voltage to reduce power consumption of the device, both states have to be taken into account. Considering that currently more than 3 orders of magnitude current change are required to ensure proper circuit operation, already around 200mV of the supply voltage are used towards driving the transistor from the off-state to the on-state. This is true for charge-based devices that control current transport by means of a gate dependent barrier that can only be overcome by thermal emission. Those types of devices are characterized by an inverse subthreshold slope larger than around 60mV/dec. Altering the logic state by applying smaller voltages is highly desirable. My presentation will elucidate on the possibility of using band- to-band tunneling in carbon nanotubes as a viable approach to address both of the above aspects – the transistor off- and on-state performance. I will use the example of carbon nanotube based devices to discuss various switching concepts in these low-dimensional geometries and to argue why a certain device structure should be favored over another.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S3 GSNP: Aging, Shear and Rejuvenation: Mechanics of Glasses, Colloids and Granular Matter Morial Convention Center RO2 - RO3

2:30PM S3.00001 Jamming: Relating Shear and Effective Temperature1, TOM HAXTON, Department of Physics, University of Pennsylvania — In an equilibrium system, temperature not only influences the average properties of a system, such as its pressure or density, but also controls the fluctuations around those averages. In systems driven far from equilibrium, however, temperature is no longer well-defined, and fluctuations can be non-thermal in origin. I will discuss a class of such systems, namely steadily-sheared glasses, for which there is a considerable body of evidence that the idea of an effective temperature is useful, at least in certain regimes. Using nonequilibrium molecular dynamics simulations, we have now calculated seven different definitions that yield a consistent value for the effective temperature, which can be many orders of magnitude higher than the bath temperature. However, if we want to understand the behavior of a material, measuring its temperature is only a start. I will discuss recent results that show that when shear-induced fluctuations dominate over thermal fluctuations, the effective temperature controls materials properties such as the rheology and the extreme slowing down of the dynamics as the system jams.

1Supported by NSF-DMR-0605044
3:06PM S3.00002 Simulations of shear banding in metallic glasses. — Metallic glasses represent a promising high strength material, but their use is limited by the onset of a shear banding instability when their material strength is exceeded. Recent simulation studies of the initiation and development of localized deformation in molecular dynamics simulations of a number of amorphous systems reveal the structural changes that accompany plastic deformation and localization involve a decrease in the local short range ordering. We have simulated both two-dimensional and three-dimensional systems in nanoindentation [1,2], uniaxial tension [3] and compression [4] in plane strain. The degree of strain localization depends sensitively on the quench rate during sample preparation, with localization only arising in more gradually quenched samples. A systematic analysis of simulated systems in simple shear geometries [5] reveals that a Boltzmann-like relationship between strain rate and structure holds over large variations in both the applied strain rate and the initial structural state of the glass. Scaling is observed over eight orders of magnitude in strain rate. The consequences of this scaling for constitutive models of glass plasticity will be discussed.

1Supported by the National Science Foundation under award #0135009.

3:42PM S3.00003 Single particle dynamics of aging in colloidal systems. — When a liquid is quenched to form a glass it becomes trapped in a non-equilibrium state, and many of the system’s properties depend on the time elapsed since the quench. This phenomenon is known as aging. We study concentrated colloidal suspensions, a model system which has a glass transition when the particle concentration is increased. We use an optical confocal microscope to view the motion of these colloidal particles in three dimensions. Aging is most commonly detected by measuring the evolution of variables (such as the mean squared displacement) averaged over the entire system, but these quantities cannot yield information about the detailed, structural changes that occur during aging. In contrast, confocal microscopy lets us study the relationship between local structure and the motion of the colloidal particles, in both monodisperse and binary colloidal glasses. We find that particle motion occurs in cooperative groups, and that this motion is facilitated by the relatively poor packing of the particles in these regions. Work done with G. C. Cianci, J. M. Lynch, and R. E. Courtland.

4:18PM S3.00004 Aging dynamics and the mechanical behavior of glassy solids. — Aging dynamics and yielding also modify aging. This talk will present a series of molecular simulations that provide new insight into the complex, microscopic origins of the elastoplastic behavior of amorphous matter and its relationship to the macroscopic material response. In particular, we investigate the interplay between aging and plastic deformation in coarse-grained models for polymeric and metallic glasses. Molecular dynamics simulations are used to determine the macroscopic shear yield stress as well as the compliance of the model glasses for different loading conditions, temperatures, strain rates and aging times, as well as reveal their relationship to the underlying microscopic distribution of relaxation times. As in experiments on polymer glasses, we find that large stresses can decrease relaxation times and cause mechanical rejuvenation. Furthermore, we find new behavior when the aging glass undergoes more involved thermal protocols such as a temperature step. Phenomenological models will be developed that describe the data over a wide range of temperature, stress and strain rates. We also discuss how continuum models such as energy landscape pictures and the recently formulated shear transformation zone (STZ) theory of amorphous plasticity can account for the aging effects observed in the molecular simulations.

4:54PM S3.00005 Faults & Earthquakes as Granular Phenomena: Controls on Stick-Slip Dynamics. — Granular and continuous materials fail in fundamentally different ways, yet inherently discontinuous natural fault materials have often been modeled as continuum processes. Within a sheared or compressed granular material, the internal stresses take the form of a network of force chains. This network of strong connections among the particles is observed to be highly heterogeneous, and the magnitude of the stress varies widely over short distances. I will present the results of laboratory experiments which highlight the granular conrols on earthquake fault behavior. We perform experiments in a quasi-two-dimensional shear zone containing several thousand 5 mm circular and elliptical photoelastic plastic disks, allowing us to monitor the spatiotemporal evolution of both internal stress and strain. While the time, length, and strength scales are vastly different from the natural case, the frictional behavior is found to be in agreement. Therefore, the experiments allow us to isolate the effects of granular interactions and choice of boundary conditions on the fault behavior, through the observation of large populations of stick-slip and creep events.

Session S4 GIMS: Keithley Award Symposium Morial Convention Center 206

2:30PM S4.00001 Keithley Award Talk: Pushing the limits in ARPES. — A successively higher degree of parallelity in data acquisition has dramatically increased the information rate in angle resolved photoelectron spectroscopy (ARPES). This has been coupled to resolution improvements both in angle and energy. The development leading to the present state of the art is described, and recent results are presented. To extend the field further towards higher or lower energies, as well as higher resolution or larger acceptance angles, novel techniques are needed. Some recent and ongoing developments for this purpose will be described. It is also shown that the application of these techniques can be used to overcome some limitations in energy resolution even when the angular information as such is not important.

3:06PM S4.00002 High Resolution Angle-Resolved Photoemission Studies of Correlated Electron Systems. — DAN DESSAU, Department of Physics, University of Colorado, Boulder — Bjorn Wannberg’s invention of the “angle mode” for acquiring 2-dimensional ARPES images with both high energy and angular resolution has revolutionized the way modern ARPES experiments are performed. This advance has lead to both quantitative and qualitative improvements in the resolution as well as collection efficiency. In this talk I will give a few key examples of what has become possible using this new technology for the study of correlated electron systems. Particular focus is on high Tc superconductors, including a “fingerprinting” of electron-boson couplings using the isotope effect, and recent data on colossal magnetoresistive oxides which shows the critical aspect of the orbital degrees of freedom and k-dependent electron self energies.

3:42PM S4.00003 High Resolution Angle-Resolved Photoemission Studies of Correlated Electron Systems. — A successively higher degree of parallelity in data acquisition has dramatically increased the information rate in angle resolved photoelectron spectroscopy (ARPES). This has been coupled to resolution improvements both in angle and energy. The development leading to the present state of the art is described, and recent results are presented. To extend the field further towards higher or lower energies, as well as higher resolution or larger acceptance angles, novel techniques are needed. Some recent and ongoing developments for this purpose will be described. It is also shown that the application of these techniques can be used to overcome some limitations in energy resolution even when the angular information as such is not important.
4:18PM S4.00004 Angle-Resolved Photoemission Study of High Temperature Superconductors

ZHI-XUN SHEN, Stanford University — As a hybrid of spectroscopy and scattering experiments, angle-resolved photoemission spectroscopy reveals the direction, the speed, and the scattering mechanism of valence electrons. In the past two decades, enormously improved resolution and carefully matched experiments have elevated this technique to an important many-body spectroscopy. Today, ARPES experiments help setting the intellectual agenda by testing new ideas, discovering surprises, and challenging orthodoxies. This technique is at the focal point of the necessary debates leading to new paradigms of physics represented by the high temperature superconductors. In this talk, we will survey the progress of this field over the last two decades and the information we gained about the high temperature superconductors. However, the focus will be the latest ARPES data on the following subjects: i) New temperature and doping dependent data that provide insights on the relationship between pseudogap and superconducting gap; ii) New data on the Fermi surface dependent pairing and many-body interactions in self-doped multilayer cuprates. If time permits, we will also present new time resolved photoemission data from charge density wave systems.

3:06PM S5.00002 Optical sum rules for the interband MCD spectrum

The sum rule with \( p = 0 \) is the dichroic counterpart of the familiar \( f \)-sum rule for linearly-polarized light. I will show that it yields a contribution to the ground-state orbital magnetization which in insulators is associated with the circulation of the Wannier orbitals around their centers (more precisely, to the gauge-invariant part thereof). This differs from the net circulation, or total orbital magnetization, which has two additional contributions: (i) the remaining Wannier self-rotation, and (ii) the “itinerant” circulation arising from the center-of-mass motion of the Wannier orbitals. Contributions (i) and (ii) are not separately meaningful, since their individual values depend on the particular choice of Wannier functions. Their sum is however gauge-invariant, and can be inferred from a combination of gyromagnetic and magneto-optical experiments. The \( p = 1 \) sum rule is the dc limit of the dichroic Kramers-Kronig relation which yields \( \Delta \sigma \). The Karplus-Luttinger AHC. Ab-initio studies have shown that it is necessary to sample over millions of \( k \)-points to converge the calculation of this quantity. I will discuss recent first-principles calculations for ferromagnets as well as field-polarized solid and liquid heavy metals. The possible role of configurational disorder in enhancing the field-induced AHC of liquid metals by introducing low-frequency Drude-related features in the MCD spectrum will be explored.

3:42PM S5.00003 A converse approach to the calculation of NMR shielding tensors

TIMO THONHAUSER, Massachusetts Institute of Technology — We propose an alternative approach for computing the NMR response in periodic solids that is based on a recently developed theory of orbital magnetization [1]. Instead of obtaining the shielding tensor from the response to an external magnetic field, we derive it directly from the orbital magnetization appearing in response to a microscopic magnetic dipole [2]. Our new approach is very general, and it can be applied to either isolated or periodic systems. The converse procedure has an established parallel in the case of electric fields, where Born effective charges are often obtained from the polarization induced by a sublattice displacement instead of the force induced by an electric field. Our novel approach is simple and straightforward to implement since all complexities concerning the choice of the gauge origin are avoided and the need for a linear-response implementation is circumvented. We have demonstrated its correctness and viability by calculating chemical shieldings in simple molecular systems, finding excellent agreement with previous theoretical and experimental results. Applications to more complex systems are currently in progress.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S5 DCMP: Theory of Orbital Magnetization and Related Properties Morial Convention Center R01

2:30PM S5.00001 Theory of Orbital Magnetization and its Generalization to Interacting Systems

JUNREN SHI, Institute of Physics, Chinese Academy of Sciences, China — Recently, a new formula for the orbital magnetization was proposed. In this talk, I will review the original derivation of the formula based on the semi-classical wave-packet dynamics, as well as a general derivation based on the standard perturbation theory of quantum mechanics. The quantum derivation clarifies the origin of the novel aspects of the semi-classical derivation, such as the Berry phase correction to the density of states. It is valid for general systems including insulators with or without a Chern number, metals at zero or finite temperatures. More importantly, we are able to combine the quantum derivation with the exact current and spin density functional theory (SCDFT), proving the validity of the formula for interacting systems. With this development, the new magnetization formula, in combination with the recent advances in the construction of optimized effective potential for SCDFT, will turn out to be a powerful practical tool for the study of systems that have long defied traditional ab-initio methods.

4:18PM S5.00004 Non-perturbative ab-initio calculation of the g-tensor in periodic boundary conditions, DAVIDE CERESOLI, SISSA, Trieste — Electron Paramagnetic Resonance (EPR) spectroscopy is one of the most powerful and versatile analytic tools in materials science today. The wealth of important information available from EPR spectroscopy, however, cannot be extracted from experiments alone, rather from the combination of experimental date and theoretical calculations. To date, first principle methods for computing the EPR g-tensor rely on the linearization of the effective spin Hamiltonian with respect to spin orbit (SO) coupling [1]. While this approach gives good results for light atoms, it is insufficient when SO coupling is strong, as in transition metal compounds. We have derived a method to calculate the electronic g-tensor of paramagnetic defects from first principles in a non-perturbative way, based on the formula for the orbital magnetization [2]. The main advantage of his method, is that the external magnetic field do not enter the formula explicitly, showing that the g-tensor can be calculated as a ground state quantity by including the spin-orbit term in the SCF hamiltonian. We have found a perfect agreement with linear response calculations for bulk systems and molecular complexes containing light atoms. For heavier atoms, the agreement with experimental data is substantially improved.

4:54PM S5.00005 First-principles approach to Non-Collinear Magnetism: towards Spin Dynamics, E.K.U. GROSS, Institut für Theoretische Physik, Freie Universität Berlin, Arnimallee 14, D-14195, Germany — Most formulations of spin density functional theory (SDFT) restrict the magnetization vector field to have global collinearity. Nevertheless, there exists a wealth of strong non-collinearity in nature, for example molecular magnets, spin-spirals, spin-glasses and all magnets at finite temperatures. The local spin density approximation (LSDA) can be extended to these non-collinear cases [1] but this extension has the undesirable property of having the exchange-correlation (xc) field parallel to the magnetization density at each point in space. When used in conjunction with the equation of motion for the spin magnetization in the absence of spin currents and external fields [2,3], this local collinearity eliminates the torsional term, resulting in no time evolution. This severe shortcomings of LSDA, where the physical prediction is qualitatively wrong, opens up an important new direction for the development of functionals where this time evolution is correctly described. Towards this goal, I will describe our extension of the Kohn-Sham optimized effective potential (OEP) method to the non-collinear case and derive the corresponding integral equations, applicable to both finite and extended systems [3,4]. Most importantly I'll show that the resulting magnetization and xc field are not locally collinear to each other for real solids, and will therefore produce manifestly different spin-dynamics.

Wednesday, March 12, 2008 2:30PM - 4:54PM – Session S6 DCMP: Superfluid Density in Underdoped Cuprates Morial Convention Center RO4

2:30PM S6.00001 Quantum critical behavior in the superfluid density of strongly underdoped ultrathin copper oxide films, THOMAS LEMBERGER, The Ohio State University — The relationship between transition temperatures $T_C$ and superfluid densities $n_S(0)$ of cuprate superconductors has been a central issue in cuprate superconductivity from the beginning. When mobile holes are removed from optimally doped CuO$_2$ planes, $T_C$ and $n_S(0)$ decrease in a surprisingly correlated fashion. Recent measurements of the superfluid density of strongly underdoped YBa$_2$Cu$_3$O$_{7-\delta}$ films and crystals have found a square-root scaling, $T_C \propto n_S(0)^{\alpha}$ where $\alpha \approx 1/2$, which supplants the approximately linear proportionality that had been deduced long ago from less underdoped samples by Uemura et al. and had been ascribed to the quasi-2D structure of cuprates. This situation leads back to a basic question – what is the behavior of the fundamental structural unit, namely, a single CuO$_2$ layer or bilayer, which is truly two-dimensional by construction? To address this question, we studied 2D samples near the critical doping level where superconductivity disappears. We measured $n_S(T)$ in films of Y$_{1-x}$Ca$_x$Ba$_2$Cu$_3$O$_{7-\delta}$ as thin as two CuO$_2$ bilayers. $T_C$’s were as low as 3 K. We observed the 2D Kosterlitz–Thouless–Berezinski drop in $n_S$ at $T_C$, and we recovered the linear scaling $T_C \propto n_S(0)^{1/2}$ expected in 2D due to fluctuations in the phase of the superconducting order parameter. Taken together, results on 3D and 2D samples suggest that the disappearance of superconductivity with underdoping is ultimately due to quantum fluctuations near a quantum critical point.

*Work performed with I. Hetel and M. Randera; supported in part by NSF-DMR.*

3:06PM S6.00002 Superfluid density in the underdoped cuprates, DAVID BROUN, Simon Fraser University — This abstract not available.

3:42PM S6.00003 Two energy scales and the nodal-antinodal dichotomy in underdoped superconducting cuprates, ANTOINE GEORGES, CNRS and Ecole Polytechnique — Recent electronic Raman scattering experiments on hole-doped cuprates in the underdoped regime reveal that nodal and antinodal regions behave in very different manners. I will present the conclusions of a theoretical analysis of these experiments, based on a new sum-rule, and on Fermi liquid and phenomenological considerations, which lead to the conclusion that the superconducting state involves a hitherto hidden energy scale, which has the same doping-dependence than the superconducting transition temperature, in contrast to the pseudogap energy scale.

4:18PM S6.00004 Algebraic charge liquids and the underdoped cuprates, SENTHIL TODADRI, MIT — We describe a possible theoretical route for the evolution with doping of an antiferromagnetic Mott insulator into a gapless d-wave superconductor. Central to this description are “algebraic charge liquids” with power law correlations of gapless, spinless, charge e fermions. Based on this understanding a specific theory of the underdoped cuprates that naturally explains a number of puzzling phenomena including the doping and temperature dependence of the superfluid density, the photoemission spectra, and Shubnikov-de Haas oscillations is proposed. Experiments to test the theory are suggested.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S7 FGSA: Panel Discussion: Non-traditional Careers for Physicists Morial Convention Center R05
3:30PM S8.00006 Viscosity of confined suspensions. PHILIPPE PEYLA, JOHANN DAVIT, CLAUDE VERDIER, Université Joseph Fourier – Grenoble, LSP – CNRS – DYFCOM TEAM — In this work, we study experimentally and numerically the viscosity of non-brownian confined suspensions of hard spherical particles confined between two walls in a shear flow. By varying the wall-to-wall distance (gap), we show that the viscosity decreases with the gap. The deviation from this behavior is enhanced for smaller gaps. More precisely, when the wall-to-wall distance decreases, the linear term in volumic fraction decreases, which becomes increasingly shear banded with shear rate. We also confirm previous findings that monodisperse foam layers exhibit rate-independent viscosity profiles, which are quantitatively captured in a model that balances the viscous drag forces in the foam, provided that we assume the average drag force to be proportional to the number of bubbles in disordered foams.

3:42PM S8.00007 Rate dependence, drag balance and role of disorder in linearly sheared foams. GIJS KATGERT, MATTHIAS E. MÖBIUS, MARTIN VAN HECKE, Kamerlingh Onnes Laboratory, Leiden University — We linearly shear a bidisperse foam monolayer sandwiched between a glass plate and a fluid surface over 3 orders of magnitude in driving velocity. We find strongly rate-dependent velocity profiles, which become increasingly shear banded with shear rate. The shear rate is an important parameter for the shear modulus of the foam. We confirm previous findings that monodisperse foam layers exhibit rate-independent velocity profiles. We observe a transition from a 3D configuration to a quasi-2D one when the wall-to-wall distance becomes smaller than twice the spheres diameter. We find that the effective shear modulus for two particles which move perpendicularly to their connecting line is enhanced for smaller gaps. More precisely, when the wall-to-wall distance decreases, the linear term in volumic fraction decreases, which becomes increasingly shear banded with shear rate. We also confirm previous findings that monodisperse foam layers exhibit rate-independent viscosity profiles, which are quantitatively captured in a model that balances the viscous drag forces in the foam, provided that we assume the average drag force to be proportional to the number of bubbles in disordered foams.

3:54PM S8.00008 Shear Modulus of a Depletion-Induced Colloidal Gel. CHANJOONG KIM, DAVID A. WEITZ, Department of Physics and HEAS, Harvard University — Mechanical properties of a colloidal gel are of great interest because they are related to the processability of the colloidal dispersion and its stability. We measure the shear modulus for colloidal gel networks induced by depletion attraction and determine the relationship between the strength of the depletion attraction and the magnitude of the shear modulus.

4:06PM S8.00009 ABSTRACT WITHDRAWN

4:18PM S8.00010 Irreversible flow-induced vitrification of nanoemulsions by extreme droplet rupturing. JAMES N. VILKING, Dept. of Chemistry, University of California- Los Angeles, THOMAS G. MASON, Deps. of Physics and Chemistry, University of California- Los Angeles — Some materials weaken through fracturing when subjected to extreme stresses. However, breaking down repulsive bits of condensed matter that are dispersed in a viscous liquid can also potentially cause a dramatic and irreversible increase in the dispersion’s elasticity. Here, we demonstrate this principle using dispersions of one liquid in another immiscible liquid. Anionically stabilized microscale emulsions are subjected to a history of stresses, and we demonstrate that the dispersed phase can undergo a dynamical phase transition from an absorbing reversible steady state to a fluctuating irreversible state. For a given strain amplitude $\gamma$, this transition occurs at a critical volume fraction $\phi_c$. However, if the particles are not neutrally buoyant, they either sink to the bottom or float to the top of the container. New experiments and simulations show that under periodic shear, the particles resuspend, and that for a given strain amplitude $\gamma$, the particles evolve towards the critical concentration $\phi_c$ without any external intervention. In that case, particle collisions nucleated at the bottom of the shear cell propagate through the sample and keep the system suspended close to the critical volume fraction $\phi_c$.$\gamma$. Hence, slowly sedimenting particles under oscillatory shear appear as a new class of self-organized critical systems hitherto unreported.

4:42PM S8.00012 Self-organized criticality of slowly sedimenting shear suspensions. WEINING MAN, LAURENT CORTE, Physics Department, New York University, SHARON GERBODE, Department of Physics, Cornell University, DAVID PINE, PAUL CHAIKIN, Physics Department, New York University — Suspensions of neutrally buoyant particles driven by slow periodic shear can undergo a dynamical phase transition from an absorbing reversible steady state to a fluctuating irreversible state. For a given strain amplitude $\gamma$, this transition occurs at a critical volume fraction $\phi_c$. However, if the particles are not neutrally buoyant, they either sink to the bottom or float to the top of the container. New experiments and simulations show that under periodic shear, the particles resuspend, and that for a given strain amplitude $\gamma$, the particles evolve towards the critical concentration $\phi_c$ without any external intervention. In that case, particle collisions nucleated at the bottom of the shear cell propagate through the sample and keep the system suspended close to the critical volume fraction $\phi_c$. Hence, slowly sedimenting particles under oscillatory shear appear as a new class of self-organized critical systems hitherto unreported.

4:54PM S8.00013 Random organization: A dynamical phase transition. LAURENT CORTE, DAVID J. PINE, PAUL M. CHAIKIN, Center for Soft Matter Research, NYU — We introduce a simple model motivated by recent experiments in sheared suspensions. We show that randomly dispersed colloidal particles are sufficient to generate an organized state where further collisions are suppressed. This organization by self-activated random walkers presents a much more efficient process than when all particles are diffusing. It only occurs provided that the density in particle is lower than a critical value $p_c$ and is characterized by a dynamical phase transition. A mean-field description captures the existence of this transition. It suggests that the value of $p_c$ is determined by the ratio $p_c / p_s$, where $p_s$ is the probability that a “quiet” particle be collided. Our results also reveal that the ordering can be enhanced by straining the system periodically. However, these more organized states become less and less accessible as the strain amplitude is increased.
5:06PM S8.00014 X-ray photon correlation spectroscopy in a shear flow, ANDREI FLUERASU, European Synchrotron Radiation Facility — X-ray photon correlation spectroscopy was used to measure the diffusive dynamics of colloidal suspensions in a shear flow. The results presented here show how the intensity autocorrelation functions measure a coupling between the diffusive dynamics of the particles and their flow-induced, convective motion. However, in the limit of low flow/shear rates, it is possible to obtain the diffusive component of the dynamics. The conditions under which this is possible are easier to achieve at higher values of the scattering wavevector q and this may provide an advantage of X-ray over, for e.g. light, photon correlation spectroscopy. In recent work (A. Fluerasu et al., submitted, 2007) we have shown this result to hold for dillute (particle volume fraction Φ up to 50 %) suspensions when the correlation functions probe, basically, the self-diffusion of individual, non-interacting particles. Here we will also adress the collective motion of concentrated suspensions of hard-sphere systems (Φ up to 50 %) and study the coupling between the shear-induced response and the collective diffusion of the suspension. An important benefit of this experimental strategy over more traditional X-ray methods, is the minimization of X-ray induced beam damage, which makes the method suitable for the study of the dynamical properties of a large class of complex soft-matter and biological fluids.

5:18PM S8.00015 Electrophoretic “Equilibrium” Profile of Charged Colloids, ROMAIN PLANQUES, PAUL CHAIKIN, Dept. of Physics, New York University — We perform an electrophoresis experiment of a concentrated colloid against a semipermeable membrane. The electric field forces the charged particles against the membrane and sets up a concentration profile similar to that of a colloid in gravitational sedimentation equilibrium where gravitational forces compete against the osmotic pressure gradient. In the present case there is a current which flows through the electrolyte so the system reaches a steady state profile rather than equilibrium. The electric field, colloid and ionic concentrations adjust self consistently to produce the profile. We use 91 nm polystyrene spheres with sufficient charge that they crystallize and observe their Bragg scattering as a function of height to determine the lattice spacing and particle concentration. We also use 700nm spheres and obtain their concentration profile with X-ray absorption. The fluid flow is zero for a capped system. Connecting a return tube from the supernatant side above the electrophoretic sediment to below the filter yields an electroosmotic flow and circulation. The profile changes substantially and allows us to study the hydrodynamic interactions as a function of concentration for the electrophoresing particles.

Wednesday, March 12, 2008 2:30PM - 5:30PM — Session S9 DCMP: Optical Properties of Superconductors Morial Convention Center R07

2:42PM S9.00002 Investigation of the bosonic spectral density in highly under-doped YBa$_2$Cu$_3$O$_{6.35}$, JING YANG, THOMAS TIMUSK, Department of Physics and Astronomy, McMaster University, DOUGLAS BONN, RUIXING LIANG, WALTER HARDY, Department of Physics and Astronomy, University of British Columbia — We studied the doping dependence of the bosonic spectral function in nearly optimally-doped LSCO and highly under-doped YBa$_2$Cu$_3$O$_{6.35}$ single crystals by optical spectroscopy. With fixed oxygen content, the hole doping of the YBCO system can be fine-tuned by varying the degree of oxygen ordering. After annealing and quenching, we were able to make oxygen less ordered and obtain a highly under-doped YBa$_2$Cu$_3$O$_{6.35}$ sample with a very low transition temperature around 18K (about 20% of the optimal T$_c$). The a-axis reflectance data of this sample at nine temperatures between 30K and 295K was measured with an infrared spectrometer between 60 and 40 000 cm$^{-1}$ with the aid of three different infrared and optical polarizers. The optical properties of the highly under-doped YBCO sample show dramatic changes compared to the ortho-II YBCO sample. The strong sharp mode in the bosonic spectral function $\alpha^2 F(\Omega)$ in the ortho-II YBCO is absent in the highly under-doped sample.

2:54PM S9.00003 Optical conductivity of electron-doped cuprates, pseudogap and antiferromagnetic fluctuations, D. BERGERON, B. KYUNG, V. HANKEYCH, A.-M.S. TREMBLAY, Universite de Sherbrooke — Recent neutron scattering experiments on electron-doped cuprates have shown that the antiferromagnetic correlation length at the pseudogap temperature scales like the thermal de Broglie wavelength. This result, predicted by the Two-Particle Self-Consistent approach (TPSC), suggests that antiferromagnetic fluctuations are at the origin of the pseudogap in electron-doped cuprates. Clearly one needs to verify that other physical properties can also be explained within the same formalism. We thus derived, within TPSC, the formula appropriate for optical conductivity, including the first vertex correction. Our numerical calculations then show that, as observed experimentally, there is a transfer of spectral weight from low to high energy when antiferromagnetic fluctuations become important near the pseudogap temperature.

3:06PM S9.00004 Optical Properties of Organic Superconductor $\kappa$-(BETS)$_2$FeBr$_4$, M. REEDYK, N. HOSSEIN KHAIH, B. LIU, G.V. SUDHAKAR RAO, Brock University, St. Catharines, Canada, H. FUJIIWARA, Osaka City University, Japan, H. KOBAYASHI, M.A. TANATAR, K. YAKUSHI, T. NAKAMURA, Institute for Molecular Science, Okazaki, Japan — The optical response to far- and mid-infrared radiation has been measured for quasi two-dimensional plate-shaped crystals of $\kappa$-(BETS)$_2$FeBr$_4$ [where BETS = bis(ethylenedithio)-tetraselenafulvalene]. $\kappa$-(BETS)$_2$FeBr$_4$ is the first antiferromagnetic organic superconductor at ambient pressure with Néel temperature $T_N \approx 2.5$ K and superconducting transition temperature $T_c \approx 1.1$ K. Polarized thermal reflectance measurements were performed to compare the reflectance above and below $T_c$ and $T_N$ using a Martin-Puplett-type polarizing interferometer and $^3$He cryostat. In addition polarized absolute reflectance measurements in the far- and mid-infrared were carried out at temperatures in the natural state between 4 K and 300 K using a Michelson interferometer and cold finger cryostat. Kramers-Kronig analysis was then used to determine the optical conductivity of $\kappa$-(BETS)$_2$FeBr$_4$ at these temperatures.

3:18PM S9.00005 Optical properties of lattice/spin polarons in underdoped cuprates, SIMONE FRATINI, Institut Neel - CNRS, Grenoble, France, SERGIO CIUCHI, Research Center SMC, INFM-CNRS and Dept. Physics, Universita' dell'Aquila, I-Aquila, Italy, EMMANUELLE CAPPELLUTI, Research Center SMC, INFM-CNRS and Dept. Physics, Universita La Sapienza, Rome, Italy — In this contribution we investigate the optical spectra of one hole in the Holstein-\(J\) model. We employ a dynamical mean-field theory which becomes exact in the limit of infinite connectivity. This allows us to investigate the local (incoherent) features which are related to the internal structure of the polaron, disregarding coherent motion which might be reflected in the Drude-like peak. We show that magnetic and electron-phonon interactions sustain each other in establishing polaronic regime. Polaron formation is reflected in a peculiar mid-infrared (MIR) band which is however notably different in the case of a lattice or magnetic origin. The dependence of \(n(\omega)\) on the electron-phonon coupling constant \(\lambda\), on the exchange interaction \(J\) and on temperature \(T\) is investigated. We compare our results with experimental data in \(\text{Nd}_2\text{CuO}_4\) showing that the doping and temperature dependences of the optical conductivity in this compound is naturally reproduced by a spin/lattice polaronic model.

3:30PM S9.00006 Optical Conductivity and Correlation Strength of the High \(T_c\) Cuprate Superconductors, MASSIMO CAPONE, SMC, CNR-INFM and Dip. di Fisica, University of Rome “La Sapienza”, Piazzale A. Moro 2, I-00185, Rome, Italy, ARMIN COMANAC, Department of Physics, Columbia University, 538 W. 120th Street, New York, NY, LUCA DE’ MEDICI, Department of Physics, Rutgers The State University of NJ, 136 Frelinghuysen Road, Piscataway, NJ 08854, ANDREW MILLIS, Department of Physics, Columbia University, 538 W. 120th Street, New York, NY — High temperature copper-oxide-based superconductivity is obtained by adding carriers to insulating “parent compounds.” It is widely believed the parent compounds are “Mott” insulators, in which the lack of conduction arises from anomalously strong electron-electron repulsion, and that the unusual properties of Mott insulators are responsible for high temperature superconductivity. This paper presents a comparison of optical conductivity measurements and theoretical calculations based on Dynamical Mean-Field Theory which challenges this belief: the analysis indicates that the correlation strength in the cuprates is not as strong as previously believed, that the materials are not properly regarded as pure Mott insulators, that antiferromagnetism is essential to obtain the insulating state and, by implication, that antiferromagnetism is essential to the properties of the doped metallic and superconducting state as well.

3:42PM S9.00007 Is the Optical Sum Rule Violated in Cuprates?1, MICHAEL NORMAN, Materials Science Division, Argonne National Lab, ANDREY CHUBUKOV, Dept. of Physics, University of Wisconsin, Madison, ERIK VAN HEUMEN, ALEXEY KUZMENKO, DIRK VAN DER MAREL, University of Geneva, Switzerland — Much attention has been given to a possible violation of the optical sum rule in the cuprates, and the connection this might have to kinetic energy lowering. The true optical integral is composed of a cut-off independent term (whose temperature dependence is a measure of the sum rule violation), plus a cut-off dependent term that accounts for the extension of the Drude peak beyond the upper bound of the integral. We find that optical data in the normal state of the cuprates can be accounted for solely by the latter term, implying that the dominant contribution to the observed sum rule violation in the normal state is due to the finite cut-off.

3:54PM S9.00008 Sum rule analysis of \(\text{YBa}_2\text{Cu}_3\text{O}_y\) in magnetic field, ANDREW LAFORE, Univ. of California, San Diego, WILLIE PADILLA, Boston College, KENNETH BURCH, Los Alamos National Laboratory, ZHIQIANG LI, ALEXANDER SCHAFGANS, Univ. of California, San Diego, KOUI SEZAWA, YOICHI ANDO, Osaka University, Japan, DIMITRI BASOV, Univ. of California, San Diego — We present infrared magneto-optical reflectance measurements which characterize the interplane transport of three dopings of \(\text{YBa}_2\text{Cu}_3\text{O}_y\). An optical sum rule analysis reveals the field-evolution of the energy scale from which the superconducting condensate is drawn. We find that fields applied parallel to the \(c\) axis totally suppress high-energy contributions to the condensate in underdoped samples while only moderately reducing the superfluid density. For optimally doped crystals the sum rule is satisfied and not modified by field. These results point toward a more conventional, BCS-like condensation mechanism, and will be discussed in relation to the interlayer phase coherence.

4:06PM S9.00009 Illustration of advantages of optical self-energy for understanding conductivity data on superconductors, E.J. NICOL, University of Guelph, J.P. CARBOTTE, McMaster University — Over the last 20 years, it has become common to present optical data on exotic superconductors, such as high \(T_c\), and heavy fermions, in terms of a generalized optical self-energy. However, this quantity has never been fully examined in the context of conventional superconductivity and tested against experiment. We present a detailed study of the optical scattering rate and mass renormalization with emphasis upon the role of elastic and inelastic scattering, and make comparison with recent high quality data. This illustrates the usefulness of this approach and the new insights that can be obtained.

4:18PM S9.00010 Optical properties of underdoped high \(T_c\) superconductors from a phenomenological model, E. ILLES, E.J. NICOL, University of Guelph, J.P. CARBOTTE, McMaster University — We calculate the optical conductivity predicted by a phenomenological model for the pseudogap state given by Yang, Rice and Zhang [1]. In particular, we present results for both pseudogap and superconducting states as a function of doping. In addition to the conductivity, we examine the optical self-energy (i.e. the optical scattering rate and mass renormalization) and discuss our results in light of experiment.

4:30PM S9.00011 Signatures of superconducting gap inhomogeneities in the optical conductivity, J. LEBLANC, E.J. NICOL, University of Guelph, J.P. CARBOTTE, McMaster University — The observation of energy gap inhomogeneities in the \(\text{Bi}_2\text{Sr}_2\text{Ca}_2\text{Cu}_2\text{O}_{8+\delta}\) high \(T_c\) cuprates motivates studying such effects on other properties. We have calculated the optical conductivity using an effective medium approximation to mix superconducting regions with different energy gaps. We present our results and comment on possible signatures in the conductivity and optical self-energy.

4:42PM S9.00012 Time resolved Raman scattering on the pair-breaking peak in Bi-2212 — direct observation of the dynamics of the superconducting order parameter, PELANGI SAICHU, ILKA MAHNS, ARNE GOOS, STEPHAN BINDER, STEFAN SINGER, University of Hamburg, J. UNTERHINNINGHOFS, Max-Planck Institut fuer Festkoerperforschung, BENJAMIN SCHULZ, ANDRIVO RUSYDI, University of Hamburg, S.L. COOPER, M.V. KLEIN, University of Illinois at Urbana-Champaign, P. GUPTASARMA, University of Wisconsin-Milwaukee, DIRK MANSKE, Max-Planck Institut fuer Festkoerperforschung, MICHAEL RUEBHAUSEN, University of Hamburg — We employ a novel time resolved two-color pump probe Raman technique to study the electronic dynamics in the superconducting state of the high temperature superconductor Bi-2212. By studying the temporal evolution of the gap and the pair-breaking peak in the superconducting state, we reveal two contributions to the superconducting order parameter that respond within 1 ps and 7 ps, respectively. Both effects conserve spectral weight in the sense that the suppression of the pair-breaking peak appears concomitantly with the build up of in-gap states. The recovery times for both contributions to the gap are different by a factor of 4 outlining fundamentally different coupling mechanisms.
4:54PM S9.00013 Electronic Raman scattering in cuprates, WILLIAM GUYARD, Laboratoire Matériaux et Phénomènes Quantiques (Université Paris Diderot-Paris 7, CNRS), MATHIEU LE TACON, European Synchrotron Radiation Facility, MAXIMILIEN CAZA-VOYS, ALAIN SACUTO, Laboratoire Matériaux et Phénomènes Quantiques (Université Paris Diderot-Paris 7, CNRS), ANTOINE GEORGES, Centre de Physique Théorique, Ecole Polytechnique, DOROTHÉE COLSON, ANNE FORGET, Service de Physique de l’Etat Condensé, CEA-Saclay — We report electronic Raman response in mercury compound. In cuprates, the superconducting gap reaches its maximum values along the antinodal directions and vanishes along nodal directions corresponding respectively to the principal axes and the diagonal in the Brillouin zone. We will present both the antinodal $(B_{1g})$ and nodal $(B_{2g})$ responses as a function of doping and temperature. We will also report the full symmetric Raman response $(A_{1g})$ as a function of doping.

5:06PM S9.00014 Self Energy Corrections to Resonant Inelastic X-ray Scattering in the Cuprates, WAEL AL-SAWAIL, ROBERT MARKIEWICZ, ARUN BANSIL, Northeastern University — Resonant inelastic x-ray scattering (RIXS) is emerging as a powerful probe of strongly correlated systems by providing direct momentum-resolved information on charge excitations across the Mott gap. We have shown recently that long-range Coulomb interactions and self-energy corrections play an important role in modifying the electronic spectra of the cuprates. [1,2] Here we discuss model calculations to explore how plasmon and magnon corrections to the self-energy influence the RIXS spectra of the cuprates. [1] R.S. Markiewicz and A. Bansil, Phys. Rev. B 75, 020508(R) (2007).

1Work supported in part by the USDOE.

5:18PM S9.00015 Optical conductivity in strongly correlated electron materials, JIANMIN TAO, JIAN-XIN ZHU, Los Alamos National Laboratory — Ultrafast optical phenomena are of fundamental importance in the investigation of electronic structures of strongly correlated electron materials [1]. Starting from the Hamiltonian of a correlated electron material exposed to a time-dependent laser field, we formulate the particle current density. Within a mean-field approximation, we express the current density in terms of the expectation values of quasiparticle density operators by performing the canonical transformation. Within the Heisenberg picture, we solve a set of equations of motion for these quasiparticle densities. Finally we calculate the optical conductivity in several typical systems. [1] R. D. Averitt and A. J. Taylor, J. Phys: Condensed Matter 14, R1357 (2002).

Wednesday, March 12, 2008 2:30PM - 5:30PM –
Session S10 DCMP: Superconductors: Synthesis and Physical Properties  Morial Convention Center RO8

2:30PM S10.00001 Growth of MgB$_2$ Films by an Impinging Jet HPCVD Reactor Design, DANIEL LAMBORN, Department of Chemical Engineering, Penn State University Park, PA, USA, R.H.T. WILKE, QI LI, Department of Physics, Penn State University, University Park, PA, USA, XIAOXING XI, D.W. SNYDER, SHUFANG WANG, JOAN REDWING, Department of Materials Science and Engineering, Penn State University, University Park, PA, USA — An impinging jet hybrid physical-chemical vapor deposition (HPCVD) reactor design was used for the growth of both thin and thick MgB$_2$ films. This technique was able to independently control the substrate and Mg supply temperatures, and still maintained sufficient Mg overpressure to ensure phase stability. Thin films were predominantly axis oriented with the (0001) sapphire substrate while the thick films were either polycrystalline or showed preferred orientation. This technique was able to independently control the substrate and Mg supply temperatures, and still maintained sufficient Mg overpressure to ensure phase stability. Thin films were predominantly axis oriented with the (0001) sapphire substrate while the thick films were either polycrystalline or showed preferred orientation. Thick films (~10 µm) were deposited at a growth rate of ~110 µm/hr and showed a maximum T$_c$ of 39.8 K and residual resistivity ratio of 6.6. The thick films also showed a high J$_c$ of 2x10$^6$ A/cm$^2$ at low applied magnetic fields even at 20 K. The results indicate that the impinging jet HPCVD configuration shows promise for coated conductor processes.

2 Also with Department of Chemical Engineering, Penn State University, University Park, PA, USA

2 Films Fabricated by Ex Situ Annealing of CVD-Grown B Films in Mg Vapor

2:54PM S10.00003 High isostatic pressure synthesis of sonochemically modified MgB$_2$ superconductor, BRETT MCCARTY, JOSUA HUGEN, DANIEL STOECKLEIN, RUSLAN PROZOROV, Iowa State University — A study of the effects of high intensity ultrasound on MgB$_2$ precursors with different additives to improve pinning properties is reported. Additives were either co-sonicated with boron or mixed into sonoiced boron afterwards. Hot isostatic pressure (HIP) was used to form fully dense MgB$_2$ samples from precursors. Analysis of magnetization, microstructure and x-ray diffraction will be presented.

1Supported by the DOE-BES contract No. DE-AC02-07CH11358, NSF grant No. DMR 0603841 and Alfred P. Sloan Foundation
3:06PM S10.00004 Preparation and transport measurements of high Tc disordered MgB2 thin films1. LI ZHANG, WOLTER SIEMENS, NICHOLAS BREZNAY, AHARON KULPITULNIK, MALCOLM BEASLEY. Stanford University — In this talk we present a method using pulsed laser deposition to fabricate single-layer disordered MgB2 thin films. Both Mg and stoichiometric MgB2 targets are used during the deposition. The films have been characterized by AFM, XPS, and XRD to establish the quality of the surface and the structural and compositional uniformity of the films. Though the uniformity of the films is still under investigation, transport measurements show that the films exhibit behavior characteristic of the superconductor-insulator transition at relatively high temperatures (2 to 5K). We will also review some preliminary low temperature and high magnetic field transport measurement results. Also of interest is the very low spin-orbit scattering expected in MgB2 due to the low Z of Mg and B. This work is funded by DoE and NSF.

3:18PM S10.00005 Crystal growth of superconducting materials La2-xBaxCuO4, GENDA GU, J.S. WEN, Z.J. XU, J.M. TRANQUADA, BNL — Since the discovery of the superconductivity in high temperature superconducting oxide La2-xBaxCuO4 in 1986, a large number of groups have attempted to grow the single crystals. However, no single crystal La2-xBaxCuO4 with x<0.11 has been successfully grown. In this project, the effects of the growth condition and the compositions of a feed rod on the crystal growth of La2-xBaxCuO4 has been studied by an infrared image floating zone method. The experimental result shows that a planar solid-liquid growing interface tends to break down into a cellular interface when the growth velocity is more than 1 mm/h. When the planar solid-liquid growing interface break down into a cellular interface, the single crystal size decreases abruptly and the as-grown rod is not single phase. The large single crystals of La2-xBaxCuO4 with x=0 to 0.165 has been successfully grown. The single crystals of La2-xBaxCuO4 with x=0 to 0.165 up to 6 mm diameter and 150 mm length have been grown. The superconducting transition temperature Tc of as-grown single crystals of La2-xBaxCuO4 (x=0 to 0.165) have been measured.

3:30PM S10.00006 Superconductivity in La(Ni1-xTc)2C2 (T = Cu, Ti, and Pt)1. H.H. SUNG, S.Y. CHOU, Y.C. KUNG, H.K. KUO, K.J. SYU, W.H. LEE, Department of Physics, National Chung Cheng University, Ming-Hsiung, Chia-Yi, Taiwan, ROC, W.H. LEE TEAM — LaNiC2, which crystallizes in an orthorhombic CeNiC2 type structure with space group Ann2, is the first nickel-based ternary carbide superconductor with Tc ~ 2.7 K. Published results showed that about 50% substitution of La in LaNiC2 with the 5f thorium (Th) element could enhance the superconducting critical temperature Tc up to 7.9 K. Present results of static magnetization and electric resistivity data for fifteen polycrystalline La(Ni1-xTc)2C2 (T = Cu, Ti and Pt) compounds measured in the temperature range 1.8 ~ 4.4 K and 2.0 ~ 300 K, respectively. Discussion of the improvement, with respect to pure LaNiC2, on the superconducting critical temperature Tc, will be directed toward the changes of valence, lattice parameters as well as the effects of solubility limit in the pseudoternary La(Ni1-xTc)2C2 alloys. W.H. Lee, H.K. Zeng, Y.D. Yao and Y.Y. Chen, Physica C 266, 138 (1996). V.K. Pecharsky, K.A. Gschneidner, Jr., and L.L. Miller, Phys. Rev. B 58, 497 (1998). W.H. Lee and H.K. Zeng, Solid State Commun. 102, 433 (1997).

3:42PM S10.00007 ABSTRACT WITHDRAWN

3:54PM S10.00008 Magnetron sputter deposition of a 48-member cuprate superconductor library: Bi2Sr2YxCa1−xCuO8+d (0.5 ≤ x ≤ 1) linearly varying in steps of Δx = 0.01,2. KEVIN HEWITT, ROBERT SANDERSON, Dalhousie University — Using magnetron sputtering, a spatial composition spread approach was applied successfully to obtain 48-member libraries of the Bi2Sr2YxCaxCuO8+d (0.5 ≤ x ≤ 1) cuprate superconducting system. The libraries were deposited onto (100) single crystal MgO mounted on a water cooled rotating table, using two targets: the antiferromagnetic insulator Bi2Sr2YCuO8+d (P=98 W RF) and the hole doped superconductor Bi2Sr2CaCuO8+d (P=44 W DC). A low chamber pressure of 0.81 mTorr argon is used to reduce scattering by the process gas. To minimize oxygen resputtering a substrate bias of -20 V was used as well as a process gas free of oxygen. A rapid thermal processor is used to post-anneal the amorphous deposited films in a step annealing regime - ramp at 5 ◦C/s for heating and cooling, with a first plateau at 875 ◦C held for 200 s, and a second at 875 ◦C held for 480 s. X-ray diffraction reveals that the films develop crystalline order with the c-axis lattice parameter contracting linearly from 30.55 ˚A (x=0.5) to 30.24 ˚A (x=1.0) following a step annealing regime - ramp at 5 ◦C/s for heating and cooling, with a first plateau at 875 ◦C held for 200 s, and a second at 875 ◦C held for 480 s. In addition, surface morphology and grain connectivity of the samples were degraded and the high-Tc phase of the samples decreased with increasing Gd addition. The possible reasons for the observed degradation in microstructure, superconducting and mechanical properties due to Gd addition were discussed. Supported by the National Science Council of ROC under grant no. NSC 96-0212-M-194-008-MY3.

4:06PM S10.00009 Mechanical and superconducting properties of Bi1.8Pb0.35Sr1.9Ca2.1Cu3Gd4Oy system3. MUSTAFA AKDogan, Abant Izzet Baysal University, OZGUR OZTURK, Kastamonu University, HUSEYIN AYDIN, MURAT ERMED, CABIR TERTIOGLU, Abant Izzet Baysal University — The influence of addition of the rare earth ion Gd in Bi1.8Pb0.35Sr1.9Ca2.1Cu3Gd4Oy superconductor has been investigated by varying Gd addition (x=0, 0.1, 0.2, 0.3, 0.4 and 0.5). The samples were prepared by standard solid-state reaction methods. Phase analyses of the samples by X-ray diffraction (XRD), microstructure examination by scanning electron microscopy (SEM), superconducting properties by dc electrical resistivity and mechanical properties by static indentation were carried out to assess the effects of Gd addition. These measurements indicated that the superconducting transition temperature, Vickers hardness, Young’s modulus, yield strength, fracture toughness values of the samples strongly depend on the Gd addition. The values of Ti, He, E, Y and K1IC of the samples decreased with the increase in Gd addition. The hardness values of the samples are also found to be load independent, higher than the load independent) hardness, Young’s modulus, yield strength, fracture toughness of the samples. From XRD and SEM analyses, the addition of the sample by Gd degrades formation of the high-Tc Bi-2223 phase, and surface morphology and grain connectivity in comparison with undoped sample, respectively.

4:18PM S10.00010 Investigation of Some Physical Properties of Gd added Bi-2223 Superconductors, MURAT ERMED, Abant Izzet Baysal University, OZGUR OZTURK, Kastamonu University, HUSEYIN AYDIN, MUSTAFA AKDogan, CABIR TERTIOGLU, AHMET VARILCI, IBRAHIM BELENLI, Abant Izzet Baysal University — Static microindentation, XRD, SEM, DC electrical resistivity and critical current density measurements were performed to investigate some physical properties of Bi1.8Pb0.35Sr1.9Ca2.1Cu3Gd4Oy superconducting samples with x=0.0, 0.1, 0.3, and 0.5. The indentation load versus diagonal length of the samples under different indentation loads in the range of 0.245-2.940 N were presented. The microindentation measurements showed that, for the Gd added sample, the load dependent (apparent) microhardness value (Hap) is lower in comparison with that of the pure sample(x=0). The values of Hap were found to be load dependent. In addition, we extracted the load independent (true) microhardness using the Kick’s law, proportional specimen resistance (PSR), modified proportional specimen resistance (MPSR) model and the Hays-Kendall (HK) approach and compared the true hardness with the apparent hardness. We observed from the transport measurements that addition of Gd decreased Tc and Jc. In addition, surface morphology and grain connectivity of the samples were degraded and the high-Tc phase of the samples decreased with increasing Gd addition. The possible reasons for the observed degradation in microstructure, superconducting and mechanical properties due to Gd addition were discussed.
4:30PM S10.00011 Transport macroscopic and mechanical properties of Au diffusion-doped Bi-2223 superconductors. O. OZTURK, Kastamonu Univ. C. TERZIOGLU, A. VARLICI, I. BELENLI, Abant Izzet Baysal Univ. We have investigated the effect of the gold-diffusion on the mechanical properties of the Bi-2223 superconducting samples with different annealing times (10, 20 and 50 hours). The samples are prepared by the conventional solid-state reaction method in the polycrystalline bulk form. Doping of Bi-2223 was carried out by means of gold diffusion during sintering from an evaporated gold film on pellets. The experimental works in this study consist of dc electrical resistivity measurements for electrical and superconducting properties, microhardness measurements for mechanical properties, X-ray diffraction for phase analyses and lattice parameters, and scanning electron microscopy for microstructure examination. These measurements showed that Au-doping, in comparison with the undoped samples, increased the critical transition temperature and enhanced formation of high-Tc phase. Additionally, microhardness and grain size were also improved with increasing amount of diffusion. Moreover, the diffusion-annealing time decreased the number and size of voids and increased the transition temperature. The experimental results of hardness measurements were analyzed using the Kick’s law, modified proportioned specimen resistance (MPSR) model and the Hays-Kendall (HK) approach. Among them HK approach was the most successful.

This work is supported partly by the Scientific and Technological Council of Turkey (Project No: 104T325) and partly the Turkish State Planning Organization (DPT) (Project No: 2004K120200).

4:42PM S10.00012 Critical current density variations with increasing thickness in YBa₂Cu₃O₇₋ₓ + BaSnO₃ (BSO) films. CHAKRAPANI VARANASI, University of Dayton Research Institute (UDRI), JACK BURKE, LYLE BRUNKE, UDRI, HAIYAN WANG, Texas A&M, PAUL BARNES, Air Force Research Labs, UDRI TEAM, TEXAS A&M COLLABORATION, AFRL TEAM — To increase the engineering critical current density (Jc) of YBa₂Cu₃O₇₋ₓ (YBCO) films, it is of great importance to grow thicker films with high critical current density (Jc). However, it has been shown in YBCO films that the thickness is an essential factor for the increase of Jc, which is in contradiction to the previous work by this group showed that YBCO+BaSnO₃ (BSO) films of ~ 300 nm thickness can be grown with more than an order of magnitude increase in the Jc in applied magnetic fields using a dual phase sector PLD target approach. In the present work a systematic study of Jc, dependence on the thickness of YBCO+BSO thick films was undertaken by growing different films with thicknesses ranging from 300 nm to 4 µm. The Jc of these films was measured using a magnetometer indicated that high Jc at high fields can be maintained even in thicker films. The cross-sectional TEM analyses of the thick films showed that the BSO nanocolumns grow through out the entire thickness of the samples. Microstructural details and the superconducting properties of thick YBCO+BSO films will be presented.

5:06PM S10.00014 NbN films grown by chemical solution deposition. GUEIF ZOU, MENKA JAIN, HONGMEI LUO, S. A. BAILY, T. M. MCCLEESKY, E. BAUER, A. K. BURRELL, Q. JIA, Los Alamos National Lab. MPA TEAM — NbN films were grown on quartz substrate using a chemical solution technique of polymer-assisted deposition for the first time. The precursor films were annealed at different temperatures in ammonia atmosphere. X-ray diffraction and electron microscopy analysis indicated that the films were polycrystalline. Preliminary optical spectroscopy results of these films showed several strong peaks in the visible range that can be attributed to the NbN phase. Wide peaks in the photoluminescence spectrum suggest many defects in these films. The transition temperature (measured from SQUIDs) of these films also will be discussed in this paper.

5:18PM S10.00015 Superconductivity in YbGa₃Si₂₋ₓ with the AlB₂-type structure. N. TSUJI, M. IMAI, NIMS, Japan, H. YAMAOKA, RIKEN, H. OHASHI, NIMS, Japan, D. NAMOTO, SPring-8 Service Co., I. JARRIGE, Japan Atomic Energy Agency, H. YOSHIDA, Kyoto University, H. YOSHISAKURA, H. KITAZAWA, NIMS. Japan. In the magnetic susceptibility and the specific heat of the YbGa₃Si₂₋ₓ the gap structure has been obtained. Very recently, we discovered superconductivity in the AlB₂-type compound YbGa₃(Si₂O₈) below Tc = 2.5K. We report here on the structural and electronic properties of the YbGa₃Si₂₋ₓ series. XRD and TEM/EDS analysis suggested that the AlB₂-type phase is sustained for 1.0 ≤ x ≤ 1.4. Tc is found to decrease from 2.5K for x = 1.0 to 1.9K for x = 1.3 and eventually vanish for x = 1.4. High-resolution X-ray absorption spectra across the Yb-L₁₁₁ edge measured at SPring-8 on the beamline BL15XU. The valence of Yb was estimated to be 2.3+, suggesting a predominant Yb⁴⁺ character with minor importance of 4f electrons in the superconductivity.

Materials Physics and Applications Division, Los Alamos National Laboratory, Los Alamos, NM 87545 (USA).

Wednesday, March 12, 2008 2:30PM - 5:30PM — Session S11 DCP: Theory of Superconductivity in Cuprates I Morial Convention Center R09

2:30PM S11.00001 Cuprate higher harmonic gap structure: theory vs. experiment. DAVID PARKER, Max Planck Institute for the Physics of Complex Systems, ALEXANDER BALATSKY, Theoretical Division, Los Alamos National Laboratory. We present a detailed comparison to experiment of the generalized gap symmetry predictions of spin-fluctuation mediated superconductivity theory in the hole-doped and electron-doped cuprates, within a weak-coupling BCS framework. We comment on the implications of these results for the ongoing “one gap vs two gap” controversy in the cuprates, and discuss the impact of these results on the quasiparticle lifetime model of the cuprate Fermi arcs.

2:42PM S11.00002 Sublattice model of atomic scale pairing inhomogeneity in a superconductor. VIVEK MISHRA, P.J. HIRSCHFELD, Department of Physics, University of Florida, Gainesville, FL 32611, YURI S. BARASH, Institute of Solid State Physics, Russian Academy of Sciences, Chernogolovka, Moscow reg., 142432, Russia. We study a toy model for a superconductor on a bipartite lattice, where intrinsic microscopic inhomogeneity is produced by two different pairing couplings on a novel such sublattice. We discuss the effects of the inhomogeneity on the transition temperature, the density of states, the specific heat and superfluid density in the framework of the Bogoliubov-de Gennes equations, which may be solved analytically in several interesting cases. The phase diagram in the plane of two pairing constant is found to include a state of gapless superconductivity.
2:54PM S11.00003 Suppression of d-wave superconductivity in the weakly inhomogeneous checkerboard Hubbard Model. D.G.S.P. DOLWEERA, M. JARRELL, University of Cincinnati, TH. MAIER, Oak Ridge National Laboratory, A. MACRIDIN, University of Cincinnati, TH. PRUSCHKE, University of Goettingen, Germany — Using a dynamical cluster quantum Monte Carlo approximation we investigate the d-wave superconducting transition temperature $T_c$ of the doped 2D Hubbard model with a weak inhomogeneity in the form of checkerboard pattern in the hoppings. The hopping within a $2 \times 2$ cluster (plaquette) is $t$ and the hopping between the plaquettes is $t'$ ($0.8t \leq t' \leq t$). We find $T_c$ decreases monotonically with decreasing $t'$ for both fixed $U/t$ or $U/W$ ($U$ the on site Hubbard interaction and $W$ the bandwidth). The characteristic spin excitation energy scale and the strength of d-wave pairing interaction decrease with decreasing $T_c$, suggesting a strong correlation between these two quantities.

3:06PM S11.00004 Electronic properties investigation of YBaCuO using the PAW formalism. SIMON PESANT, MICHEL CÔTÉ, Département de physique et Regroupement québécois sur les matériaux de pointe (RQMP), Université de Montréal, Canada — Using density-functional theory (DFT) and the projector-augmented wave (PAW), we characterize the electronic properties of the YBa$_2$Cu$_4$O$_8$-$z$. These systems are metallic or antiferromagnet at room temperature depending on the hole doping induced by oxygen atoms in the basal plane. Also, the impact of an on-site coulomb repulsion term that we don’t know as LDA+$U$, is investigated in the different structures to take into account the highly correlated character of the electrons of those systems. The addition of an on-site coulomb repulsive term does not strongly alter the electronic properties of the YBa$_2$Cu$_4$O$_8$-$z$, and YBa$_2$Cu$_3$O$_{6.5}$ but gives more accurate details about the electronic structure. In the case of YBa$_2$Cu$_3$O$_6$, the impact of the U term is primordial, the anti-ferromagnetism phase being recovered when LDA+$U$ is used, compared to the standard LDA where it is metallic.

3:18PM S11.00005 Electronic properties and chain conductivity of underdoped YBa$_2$Cu$_3$O$_{6+x}$ by First-Principles calculations. VINCENZO FIORENTINI, ALESSIO FILIPPETTI, GIORGIA LOPEZ, MAURO MANTEGA, University of Cagliari, Italy — Metal-insulating transitions in cuprates represent an historical challenge for first-principles calculations. Here we present results obtained through the pseudo-self-interaction free density functional scheme (PSIC) that is capable to correct the gross failures of LSDA at just a moderate increase of computing effort, and works well in both strong-correlated and metallic limit. Here we describe the properties of the end-point systems YBa$_2$Cu$_3$O$_6$ and YBa$_2$Cu$_3$O$_7$ as well as the chemistry of insulating-metal transition occurring in the CuO chains of underdoped YBa$_2$Cu$_3$O$_{6.5}$ in the region $x=0.5$. Coherently with the one-dimensional metallic percolative regime observed at low-doping, we find that the metal-insulating transition occurring at low doping in the non-magnetic Cu(1)Ox chains is induced by chain-like alignment of the doping oxygens within the chains, whereas disorder (i.e. non chain-aligned) distributions are always insulating. In the Cu(2)O$_2$ planes the insulating antiferromagnetic state remains stable up to $x=0.25$, while at $x=0.5$ a normal-metal state, similar to that seen for YBa$_2$Cu$_3$O$_7$, take place. The in-plane antiferromagnetic- paramagnetic competition depends on $x$ but is almost unaffected by the intra-chain order-disorder competition.

3:30PM S11.00006 Holes localization and Fermi Surface morphology of Y$_{1-x}$Ca$_x$BaCu$_3$O$_6$ by First-Principles. GIORGIA LOPEZ, ALESSIO FILIPPETTI, VINCENZO FIORENTINI, University of Cagliari, Italy — The basic chemistry of underdoped Y$_{1-x}$Ca$_x$BaCu$_3$O$_6$ (and of high-$T_c$ superconductors) is permeated by unexplained features. One, in particular, concerns the nature of the non-superconducting phase and its Fermi Surface (FS) whose character is not univocally described by angle-resolved photoemission and Hall measurements, which detect disconnected arcs and pockets, respectively. But what is really missing for a sound interpretation of these data is a robust link between the observed FS and the corresponding electronic structure. As the description of the underdoped regime is hardly accessible through standard First-Principles calculations (FPC), here we use the innovative pseudo-self-interaction corrected local spin density (PSIC) approach to trace an accurate overview of underdoped Y$_{1-x}$Ca$_x$BaCu$_3$O$_6$, with special emphasis on the FS morphology. In particular, the PSIC can predict the formation of Zhang-Rice singlets (ZRS), and we show that electronic states characterized by a mixture of ZRS and antiferromagnetic CuO$_2$ units present, in fact, a variegated series of differently-shaped, disconnected FS that may reconcile the experimental data with a sound interpretation of the underdoped Y$_{1-x}$Ca$_x$BaCu$_3$O$_6$ properties.

3:42PM S11.00007 Nature of high-temperature superconductivity. JOHN D. DOW, Arizona State University, Tempe, AZ 85287-1504 USA, DALE R. HARSHMAN COLLABORATION — Using muon spectroscopy, the high-temperature superconductivity of YBa$_2$(Cu$_2$O$_7$)$_3$ is shown to reside in its BaO layers, not in its cuprate planes. The symmetry of the hole-pairing is s-like, not d-like. The family of superconductors Pb(2)Sr(2)(Y(1-x)R(x))Cu$_3$(O)(3) can be doped p-type (with $R=$Ca) or n-type (with $R=$Ce or Am). The n-type versions do not superconduct, but the p-type compounds do superconduct. The doped ruthenate Ba(2)YRuO(6) begins superconducting in its BaO layers at 92 K. A successful theory of high-temperature superconductivity must explain the ruthenates, the superconducting organic compounds, and the superconducting cuprates. Presently do not.

3:54PM S11.00008 Percolation Theory of the Pseudogap Phase. ALEXEI ABRIKOSOV, Argonne National Laboratory — A concept of the pseudogap state in high-$T_c$ layered cuprates on the basis of percolation theory is proposed. Contrary to the self-consistent BCS critical temperature, which defines $T^*$ - the upper boundary of the pseudogap state, the real critical temperature, $T_c$, is defined, as the percolation threshold, where the infinite cluster appears. This permits to obtain the exact formula for $T_c$, as function of doping and understand its “dome-like” shape.

4:06PM S11.00009 Pairing in Non-Fermi Liquids in Terms of Bethe-Salpeter Equation. YURI MALOZOVSKY, JD Duz Institute for Superconductivity, J.D. FAN, Southern University — The pairing between two fermionic excitations in a non-Fermi liquid is considered in terms of the Bethe-Salpeter equation. We consider the pairing in the Fermi systems with vanishing spectral weight. It is well known that the quasiparticle pole in the single-particle Green’s function in non-Fermi liquids is absent or weak. The examples of such systems can be viewed as the “Marginal” Fermi liquid and Luttinger liquid. Another example that has also been considered is the Fermi system with pseudogap behavior in the spectral weight. Although the pairing between two excitations in non-Fermi liquids is, in general, absent, yet we show that the Cooper’s type pairing can occur and the conditions for such pairing are discussed. The results have also application to the systems with smeared or non-monotonic Fermi distribution. The system that transmits from the Fermi type to Bose type behavior can be a showcase of such systems as discussed.

4:18PM S11.00010 Multiple Pairing in the BCS Model. J.D. FAN, Southern University, YURIY MALOZOVSKY, JD Duz Institute for Superconductivity — We study Cooper’s pairing for more than two particles in terms of the BCS model. We consider the multiple pairing in terms of the BCS Hamiltonian in a quiescent Fermi sea model and in the BCS ground state. Although there is no interaction between Cooper pairs in terms of the BCS Hamiltonian, yet we show that four particles are paired and form a bound state in the singlet state with just twice the bound state energy of a single Cooper’s pair. The four-particle bound state only exists as the result of the Pauli principle and the sharp Fermi edge. We have also shown that the smearing of the Fermi edge due to $\Delta (k)$ as it is in the BCS ground state weakens the pairing of either two or four particles. We show that in the particle-hole channel there exists the multiple particle-hole resonance for four particles and four holes in a quiescent Fermi sea model similar to the case of two particles and two holes resonance. There is no particle-hole resonance in the BCS ground state as shown, which means that the particle-hole resonance is removed by $\Delta (k)$ due to smearing of the Fermi distribution. The wave function for the multiple-pairing model is discussed as well.
4:30PM S11.00011 Extraction of the pairing glue spectra of high Tc superconductors, HAN-YONG CHOI, JAEHYUN YOON, SungKyunKwan Univ, TAKESHI KONDO, ADAM KAMINSKI, Iowa State Univ, CHANDRA VARMA, UC Riverside — We report the current progress of extracting the "pairing glue" spectra of high Tc superconductors. This is done by inverting the d-wave Eliashberg equation, which is an extension of the McMillan-Rowell analysis of the tunneling conductance for conventional s-wave superconductors. A major difference is that there are two distinct \( \alpha^F \) functions for the d-wave superconductors. Consequently, we need twice more experimental inputs to perform this analysis; the pairing function \( \Delta(\omega) \) and self-energy \( \Sigma(\omega) \). This experimental information is currently not available. We therefore first generate \( \Delta(\omega) \) and \( \Sigma(\omega) \) theoretically using the marginal Fermi liquid like glue spectra. Then, using the generated functions as "experimental inputs" we invert the Eliashberg equation to extract the glue spectra. We will compare the input and extracted glue spectra to demonstrate the applicability of the approach. We will next describe how to obtain experimental \( \Delta(\omega) \) and \( \Sigma(\omega) \) from ARPES data. Then, using the obtained experimental inputs we invert the Eliashberg equation to extract the glue spectra. The results will be reported for several temperatures above and below Tc.

4:42PM S11.00012 A competing order scenario of two-gap behavior in hole doped cuprates, TAMNOY DAS, R.S. MARKIEWICZ, A. BANSIL, Northeastern University — Angle-dependent studies of the gap function provide evidence for the coexistence of two distinct gap modes in hole doped cuprates, where the gap near the nodal direction scales with the superconducting transition temperature \( T_c \), while that in the antinodal direction scales with the pseudogap temperature. We present model calculations[1] which show that most of the characteristic features observed in the recent angle-resolved photoemission (ARPES) as well as scanning tunneling microscopy (STM) two-gap studies are consistent with a scenario in which the pseudogap has a non-superconducting origin in a competing phase. Our analysis indicates that, near optimal doping, superconductivity can quench the competing order at low temperatures, and that some of the key differences observed between the STM and ARPES results can give insight into the superlattice symmetry of the competing order. Work is supported in part by the USDOE.

4:54PM S11.00013 Local quasiparticle lifetimes in a d-wave superconductor, S. GRASER, P.J. HIRSCHFELD, Physics Department, University of Florida, Gainesville, FL 32611 USA, D.J. SCALAPINO, Department of Physics, University of California, Santa Barbara, CA 93106-9530 USA — Recently, scanning tunneling spectroscopy (STS) measurements have exhibited good fits to conductance spectra at the surface of Bi-2212 using a BCS-type model for a d-wave superconductor and assuming a local quasiparticle scattering rate varying linearly with energy. Employing a model of quasiparticle scattering by impurities and spin fluctuations we argue that the broadening of the local density of states is in general given by the self-energy of the system averaged over a small region. The size of this region at low energies is shown to be significantly larger than a gap "patch", a region over which the gap is roughly constant in this system; states measured by STS are therefore very homogeneous in this energy range. At energies above a scale determined by disorder, STS averages over states localized within a gap "patch", and lifetimes are correspondingly inhomogeneous. We show that the local self-energy in the impurity-plus-spin fluctuation model can explain the data as well as the phenomenological linear scattering rate extracted from experiment.

5:06PM S11.00014 Disordered superconductors: role of interaction strength, RAIMUNDO DOS SANTOS, FELIPE MONDAINI, THEREZEA PAIVA, Universidade Federal do Rio de Janeiro, RICHARD SCALETTER, UC-Davis — We have considered the half-filled disordered attractive Hubbard model, in which the on-site attraction is switched off on a fraction \( f \) of sites, while keeping a finite \( U \) on the remaining ones. The configurationally-averaged equal-time pair structure factor has been calculated as a function of temperature, through Quantum Monte Carlo simulations for several \( f \) and \( U \), and a finite-size scaling ansatz has been used for the zero-temperature gap. We have found that the system sustains superconductivity in the ground state up to a critical impurity concentration, \( f_c \), which increases with \( U \) at least up to the largest values of \( U \) we have considered. Also, the normalized zero-temperature gap as a function of \( f \), for fixed \( U \), shows a maximum near \( f_{\text{max}} \), within a range of \( U \) values, thus indicating that a small amount of disorder can initially enhance superconductivity. We argue that, overall, the observed behavior results from both the breakdown of CDW-superconductivity degeneracy and the fact that free sites tend to "push" electrons towards attractive sites.

5:18PM S11.00015 A singlet-pairing superconductor is always also a super-spin-current-conductor, CHIA-REN HU, Texas A&M University — A heuristic argument and a simple theory are used to show that, as a fundamental difference between BEC and BCS condensation of fermion pairs, the later, even for singlet pairing, can carry a sizable dissipation-less spin-current below practically the same \( T_c \). The heuristic argument is based on the similarity between a spin-current carried by a singlet-pairing condensate and (coherent) partner changing in a dancing hall. Simple theory: We consider singlet pairing in a normal metal carrying a moderate spin-current, which causes the spin-up- and -down Fermi surfaces (FSs) to be shifted in the momentum space by \( \pm q/2 \). \( (k,\uparrow),(k,\downarrow) \)-pairing is clearly still possible over the entire FSs. To favor a spin current in the system, we introduce a vector Lagrange multiplier \( \omega_{sp} \), and add \(-\omega_{sp} \sum_{k}\sigma h c_{k,\sigma}c_{-k,\sigma} \) to the Hamiltonian. Since time-reversal invariance is not broken, negligible changes to all properties of the singlet-pairing state follow, and the system remains fully gapped. No depairing can be induced even for a sizable spin current. Two experimental tests of this prediction will be discussed.

Wednesday, March 12, 2008 2:30PM - 5:30PM –
Session S12 DCMP: Strongly Correlated Quantum Phases
Morial Convention Center 203

2:30PM S12.00001 Fate of the Fermionic Quasiparticles at the Electronic Nematic-Smectic Quantum Critical Point, KAI SUN, BENJAMIN FREGOSO, EDUARDO FRADKIN, UIUC — We use the order-parameter theory of the electronic nematic-smectic critical transition of the fermionic liquid crystal phases, discussed in the previous talk, to study the effect of the low energy bosonic modes on the fermionic quasiparticles using RPA. Both the continuous model, which has a continuous rotational symmetry, and the lattice model, which has a discrete point group symmetry are studied. We find that at the nematic-smectic critical point, due to the critical smectic fluctuations, the dynamics of the fermionic quasiparticles near several points on the Fermi surface, which eventually become gapped under the development of CDW order, are not governed by a Landau Fermi liquid. Surprisingly, the fermions in the smectic phase also form a non-Fermi liquid. The transition between the quantum liquid crystal phases and the insulating CDW state is also discussed.
previous studies. The presence of a phase exhibiting both the plaquette and the columnar properties. This also presents a natural framework for resolving the disagreement between local constraint. By combining an analysis of the excitation gaps of different symmetry sectors with information on plaquette structure factors, we show the in the context of high-temperature superconductivity, and its descendants have taken on a central role in the study of quantum systems incorporating a hard charge density wave order, and construct an order-parameter theory. Its static part has the McMillan-DeGennes form of the classical smectic-nematic phase transition, while its quantum dynamics is dominated by the coupling to the electronic quasiparticles. Both, commensurate and incommensurate cases are studied. The spectrum of the nematic phase has low energy "fluctuating stripes". We also provide evidence that, contrary to the classical case, the gauge-type of coupling between the nematic and smectic at the critical point is irrelevant at this QCP. We discuss the relevance of these ideas to the phenomenology of the high $T_c$ superconductors. [1] S. A. Kivelson, E. Fradkin and V. J. Emery, nature 393, 550, 1998.

3:06PM S12.0004 Universal Scaling in the Fan of an Unconventional Quantum Critical Point, ROGER MELKO, University of Waterloo, RIBHU KAUL, Harvard University — We present the results of stochastic series expansion Quantum Monte Carlo simulations on a 2D S=1/2 Heisenberg model with additional four-spin interaction — the so-called ‘JQ’ model [1]. Using extensive simulations on lattice sizes containing in excess of $10^4$ spins, we examine the claim that the observed Néel to valence-bond-solid (VBS) quantum phase transition is consistent with the ‘deconfined’ quantum criticality scenario. We discuss finite-temperature properties of the conjectured quantum critical fan [2], including scaling behavior, the calculation of universal critical exponents, and the apparent emergence of a global U(1) symmetry in the VBS order parameter. Finally, we consider several extensions of the model that may help give further insight into the nature of this unconventional quantum phase transition.

3:18PM S12.0005 Quantum critical scaling behavior of deconfined spinons, FLAVIO NOGUEIRA, Institute for Theoretical Physics, Free University Berlin and Ames Laboratory, STEINAR KRAGSET, ASLE SUDBO, Department of Physics, Norwegian University of Science and Technology, Trondheim, Norway — The quantum scaling behavior of deconfined spinons for a class of field theoretic models of quantum antiferromagnets is considered. The competition between the hedgehogs and the Berry phases is discussed from a renormalization group perspective. An important result following from our analysis is the computation of the anomalous dimension for the decay of spin correlations. Our results confirm the expectation that the transition from a Néel to a valence-bond solid state belongs to a completely new universality class.

3:30PM S12.0006 Monte-Carlo simulations of su(2) symmetric deconfined criticality action, A.B. KUKLOV, CSI, CUNY, M. MATSUMOTO, Universite Paul Sabatier, Toulouse ; ETH Zurich, N.V. PROKOF’EV, UMASS, Amherst; ETH Zurich; Kurchatov Institute, Moscow, B.V. SVISTUNOV, UMASS, Amherst; ETH Zurich; Kurchatov Institute, Moscow, M. TROYER, ETH Zurich — We discuss results of Monte Carlo simulations of su(2) symmetric deconfined criticality action in $CP^1$ formulation proposed by T. Senthil, et. al, Science 303, 1490 (2004). Using high-temperature expansion we reformulate the partition function in terms of J-currents. The resulting configuration space is explicitly su(2) symmetric. Critical behavior in the region of possible deconfined critical point (DCP) is addressed by the flow method [A.B.Kuklov, et.al., Annals of Physics 321,1602(2006)] mapping critical properties of a system with small values of the gauge interaction $g$ at large sizes to a system with large $g$ and small sizes. We observe data collapse on a single master curve with the flow toward fluctuation induced I order transition. The unlikely possibility of existence of the lower tricritical point separating I order transitions from the DCP line is assessed in terms of disruption of the flow collapse.

3:42PM S12.0007 Phase diagram of the anisotropic two-dimensional bilinear biquadratic spin-1 Heisenberg model, CHRISTOPH PUETTTER, MICHAEL LAWLER, HAE-YOUNG KEE, Department of Physics, University of Toronto, Toronto, Canada M5S 1A7 — The anisotropic bilinear biquadratic Heisenberg model on a square lattice has been proposed to exhibit deconfined critical phenomena (DCP) based on QMC simulations and effective field theoretical studies [1, 2]. We investigate the phase transitions of the model using slave boson representation. Our mean field approach suggests a first order transition between the nematic and the disordered regime except at the tricritical SU(3) symmetric point. We will also discuss the relevance of our results to the DCP.

3:54PM S12.0008 Generic mixed columnar-plaque phases in Rokhsar-Kivelson models, RALKO ARNAUD, POILBLANC DIDIER, LPT - University of Toulouse, France, MOESSNER RODERICH, MPI-PKS, Dresden, Germany — We revisit the phase diagram of Rokhsar-Kivelson models, which are used in fields such as superconductivity, frustrated magnetism, cold bosons, and the physics of Josephson junction arrays. From an extended height effective theory, two simple generic phase diagrams are obtained. The first one is a first order transition scenario between the columnar and the plaquette phases, common in such models. The second, more exotic, exhibits a second order transition and contains a mixed phase that interpolates continuously between columnar and plaquette states. From exact diagonalization and Green’s function Monte Carlo techniques, we present evidence that a realization of the latter scenario occurs in the Rokhsar-Kivelson square lattice Quantum Dimer model. This model, originally proposed in the context of high-temperature superconductivity, and its descendants have taken on a central role in the study of quantum systems incorporating a hard local constraint. By combining an analysis of the excitation gaps of different symmetry sectors with information on plaquette structure factors, we show the presence of a phase exhibiting both the plaquette and the columnar properties. This also presents a natural framework for resolving the disagreement between previous studies.
4:06PM S12.00009 An exact chiral spin liquid with non-Abelian anyons, HONG YAO, STEVEN KIVELSON, Department of Physics, Stanford University — We establish the existence of a “chiral spin liquid” (CSL) as the exact ground state of the Kitaev model on a decorated honeycomb lattice, which is obtained by replacing each site in the familiar honeycomb lattice with a triangle [1]. This state spontaneously breaks time reversal symmetry but preserves other symmetries. There are two topologically distinct CSL’s separated by a quantum critical point. Interestingly, vortex excitations in the topologically nontrivial CSL (Chern number \( \pm 1 \)) obey non-Abelian statistics.

4:18PM S12.00010 Non-abelian topological phases and unconventional criticality in a model of interacting anyons, CHARLOTTE GILS, ETH Zurich, SIMON TREBST, Microsoft Research, Station Q, MATTHIAS TROYER, ETH Zurich, ANDREAS LUDWIG, UC Santa Barbara, ALEXEI KITAEV, Caltech — Non-abelian topological phases have recently attracted considerable interest in the context of fault-tolerant quantum computation. However, such phases have only been established in a small set of microscopic models, one of which involves interacting spin-1/2 degrees of freedom on a honeycomb lattice (Levin, Wen 2005). In particular, this model supports quasiparticle excitations that can be described as so-called Fibonacci anyons. We have reformulated this model in terms of anyonic degrees of freedom and consider the case of interacting anyonic quasiparticles by adding a magnetic field term to the Hamiltonian. Our analysis of a quasi-one-dimensional ladder model not only shows the (extended) stability of the topological phase when perturbed by such local terms, but also demonstrates the role of topology in determining the exact nature of these phases. Interestingly, the magnetic field can drive a phase transition between two distinct topological phases. Numerically, we establish that this critical point can be described by a conformal field theory with central charge \( c = 14/15 \). This observation has lead to an analytical understanding of this critical point which can be mapped to an exactly solvable transfer matrix representation in terms of a restricted-solid-on-solid (RSOS) model.

4:30PM S12.00011 Topological Mott Insulators, CHARLOTTE GILS, ETH Zurich, SIMON TREBST, Microsoft Research, Station Q, MATTHIAS TROYER, ETH Zurich, ANDREAS LUDWIG, UC Santa Barbara, ALEXEI KITAEV, Caltech — Non-abelian topological phases have recently attracted considerable interest in the context of fault-tolerant quantum computation. However, such phases have only been established in a small set of microscopic models, one of which involves interacting spin-1/2 degrees of freedom on a honeycomb lattice (Levin, Wen 2005). In particular, this model supports quasiparticle excitations that can be described as so-called Fibonacci anyons. We have reformulated this model in terms of anyonic degrees of freedom and consider the case of interacting anyonic quasiparticles by adding a magnetic field term to the Hamiltonian. Our analysis of a quasi-one-dimensional ladder model not only shows the (extended) stability of the topological phase when perturbed by such local terms, but also demonstrates the role of topology in determining the exact nature of these phases. Interestingly, the magnetic field can drive a phase transition between two distinct topological phases. Numerically, we establish that this critical point can be described by a conformal field theory with central charge \( c = 14/15 \). This observation has lead to an analytical understanding of this critical point which can be mapped to an exactly solvable transfer matrix representation in terms of a restricted-solid-on-solid (RSOS) model.

4:42PM S12.00012 Critical liquid phases for frustrated bosons in two dimensions, OLEXEY MOTRUNICH, California Institute of Technology, MATTHEW P.A. FISHER, Microsoft Corporation, Station Q, University of California Santa Barbara — An interesting question in strongly correlated systems is the possibility of a “metallic” bosonic liquid — a quantum liquid phase of bosons that is neither superfluid nor Mott insulator. We present an attempt to construct such states using slave particle technique borrowed from theories of spin liquids; the approach can be also be taken as a flux attachment treatment performed in the absence of time reversal breaking. We describe properties of such constructed boson liquid states, which support gapless boson excitations residing on “Bose surfaces” in the momentum space and exhibit power law correlations in various properties. We also suggest a promising model Hamiltonian of hard-core bosons hopping on a square lattice and with frustrating ring exchanges which may have such a phase.

4:54PM S12.00013 Pseudogap in strongly interacting and strongly disordered systems, SIMONE CHIESA, PRA Buddha CHAKRABORTY, WARREN PICKETT, RICHARD SCALETTAR, UC Davis — The interplay of disorder and correlation is known to give rise to anomalies in the density of states at the chemical potential of quantum and classical systems. In particular, in the quantum case, the diagrammatic calculation of Altschuler and Anson predicts a pseudo-gap for the case of a weakly disordered and weakly interacting metal. Here we report a numerical study suggesting that such anomalies are present also in the case of strongly interacting and strongly disordered systems. We consider the Hubbard model in the presence of diagonal disorder and diagonalize small clusters (up to 12 sites) in the framework of a grand canonical scheme involving twisting the boundary condition. For a given interaction and disorder strength we observe the formation of a pseudo-gap whose shape and depth is largely insensitive to the particle density. For a given particle density the pseudo-gap gets deeper as the interaction and the disorder are increased.

5:06PM S12.00014 Bose Metal Phase from Inhomogeneous Flow, GERGELY ZIMANYI, Physics Department, UC Davis, NIELS JENSEN, Department of Applied Science, UC Davis — Numerous experiments report a Bose Metal phase between the Superconducting (S) and the Insulating (I) phases at an SI transition. [1,2] However, theoretically the origin of the corresponding dissipation remains unclear. We propose a picture in which inhomogeneous superconducting flow occurs in channels/filaments, defined by islands of localized Bose Glass. The superconducting bosons interact with the localized bosons of the Bose Glass via the Coulomb interaction. This Coulomb drag generates an effective dissipation for the superflow. We developed a new numerical technique to simulate superconductivity by inertial dynamics and a current generator. We found a Bose Metal phase in a finite range of the disorder, bracketed by the superconducting and insulating phases. The noise spectrum was also determined and compared to recent experiments. [1] H.M. Jaeger, D.B. Haviland, B.G. Orr and A.M. Goldman, Phys. Rev. B 40, 182 (1989). [2] A. Yazdani and A. Kapitulnik, Phys. Rev. Lett. 74, 3037 (1995); M. Steiner, N. Breznay and A. Kapitulnik, arxiv: 0710.1822.

5:18PM S12.00015 Double Occupancy in low-energy theories of doped Mott insulators, PHILIP PHILLIPS, TING PONG CHOY, ROBERT LEIGH, University of Illinois, GEORGE SAWATZKY, University of British Columbia — We review how a proper low-energy theory can be constructed for the Hubbard model by explicitly integrating over the degrees of freedom far away from the chemical potential. A surprising feature of the exact low-energy theory is the emergence of an elementary charge 2e boson which mediates double occupancy much below the Mott scale. We show that within the standard canonical transformation formalism to derive the \( t - J \) model from the Hubbard model, a similar feature (double occupancy below the Mott scale) appears only if the electron creation and annihilation operators are properly transformed as well. By comparing precisely how the electron operators transform in both theories, we are able to show that the charge 2e boson mediates dynamical spectral weight transfer across the Mott gap. At half-filling, the interactions mediated by the charge 2e boson defeat the artificial local SU(2) symmetry found earlier in the projected \( t - J \) model. R. G. Leigh, P. Phillips and T. -P. Choy, Phys. Rev. Lett. 99 46404 (2007); arxiv:07071554 (PRB, in press).

Session S13 DCOMP DCP: Focus Session: Frontiers in Electronic Structure Theory I – Morial Convention Center 204
H. J. Kulik, M. Cococcioni, D. Scherlis and N. Marzari, PRL thus fruitfully employ GGA+U in the study of large-scale complexes which contain hundreds of atoms such as the active site of halogenating enzymes and will further highlight how our method affords substantial improvement in the physical description of hybridization and bonding irrespective of system size. We + approximation (GGA) with a Hubbard U which is obtained from a self-consistent linear response procedure can greatly improve the description of both spin state

Q.-M. Hu, K. Reuter, and M. Scheffler, PRL adsorption energetics from present-day DFT xc functionals with hybrid functional and Møller-Plesset perturbation theory calculations for small clusters. From untractable with correlated wave function techniques. We overcome these limitations with a recently introduced “local xc correction” scheme [1], correcting the is uncertain to properly account for this type of bonding, while the system sizes required to correctly grasp the metallic band structure are computationally severe challenge for accurate first-principles calculations. Density-Functional Theory (DFT) with local and semi-local exchange-correlation (xc) functionals a local exchange-correlation correction scheme

HEATHER KULIK, NICOLA MARZARI, DMSE, Massachusetts Institute of Technology — Despite the importance of transition metal centers in a variety of biological and inorganic chemical reactions, density functional theory calculations often fail quantitatively in describing both the stable intermediate electronic structures, splittings, and geometries as well as reaction barriers and geometries of transition states. We have shown that augmenting the generalized-gradient approximation (GGA) with a Hubbard U which is obtained from a self-consistent linear response procedure can greatly improve the description of both spin state splittings in the iron dimer as well as reaction barriers in the addition-elimination reaction of hydrogen and methane with FeO+2. This fully ab-initio GGA+U approach provides excellent agreement with accurate, correlated-electron quantum chemistry calculations but at a fraction of the cost of these methods. We will further highlight how our method affords substantial improvement in the physical description of hybridization and bonding irrespective of system size. We thus fruitfully employ GGA+U in the study of large-scale complexes which contain hundreds of atoms such as the active site of halogenating enzymes and various porphyrin complexes.

HEATHER KULIK, NICOLA MARZARI, DMSE, Massachusetts Institute of Technology — Despite the importance of transition metal centers in a variety of biological and inorganic chemical reactions, density functional theory calculations often fail quantitatively in describing both the stable intermediate electronic structures, splittings, and geometries as well as reaction barriers and geometries of transition states. We have shown that augmenting the generalized-gradient approximation (GGA) with a Hubbard U which is obtained from a self-consistent linear response procedure can greatly improve the description of both spin state splittings in the iron dimer as well as reaction barriers in the addition-elimination reaction of hydrogen and methane with FeO+2. This fully ab-initio GGA+U approach provides excellent agreement with accurate, correlated-electron quantum chemistry calculations but at a fraction of the cost of these methods. We will further highlight how our method affords substantial improvement in the physical description of hybridization and bonding irrespective of system size. We thus fruitfully employ GGA+U in the study of large-scale complexes which contain hundreds of atoms such as the active site of halogenating enzymes and various porphyrin complexes.

For molecules, the resulting numerical effort usually restricts these methods to Gaussian basis functions. We here show how all these methods can be handled accurately with efficient all-electron numerical atom-centered basis sets [1] by using a second, auxiliary basis for products of basis functions (resolution of the identity). For an extended set of finite systems spanning small molecules (water dimer, benzene), metal clusters (Na, ) and biomolecules (polyalanine peptides), we demonstrate that the efficiency of optimized numeric atom-centered basis sets is directly carried over into our new approach. Our approach is then applied to analyze the CO-adsorption problem (CO/Cu(111)). [1] V. Blum et al., The FHI-aims project, www.fhi-berlin.mpg.de/aims

2:42PM S13.00002 Order N Implementation of Exact Exchange XIFAN WU, Princeton University, ANNABELLA SELLONI, ROBERTO CAR — Exact (Hartree Fock) exchange is needed to overcome some of the limitations of local and semilocal approximations of density functional theory (DFT). Moreover exact exchange is a basic ingredient in modern approaches to compute excitation properties, like the GW and the OEP schemes. So far, however, computational cost has limited the use of exact exchange in plane wave calculations for extended systems. We show that this difficulty can be overcome by performing a unitary transformation from Bloch to Maximally Localized Wannier functions in combination with an efficient technique to compute real space Coulomb integrals. The resulting scheme scales linearly with system size and, when used in ab-initio molecular dynamics simulations, requires only a modest increase in computational cost compared to standard DFT implementations. We validate the scheme with representative applications.
4:06PM S13.00007 Transcorrelated method applied to covalent and ionic solids: total energy and band structure calculation. KEITARO SODEYAMA, SHINJI TSUNEYUKI, Department of Physics, University of Tokyo, REI SAKUMA, JST-CREST, AIST — To calculate the electronic structures of solids including correlation effects, we have developed the transcorrelated (TC) method, which was first proposed by Boys and Handy. In the TC method, the wave function is represented by a correlated wave function \( \Phi \), where \( \Phi \) is a single Slater determinant and \( F \) is a Jastrow function, \( F = \exp[-\sum_{i<j} u_{ij}] \), \( u_{ij} \) is a two-body function called Jastrow factor. The many-body Hamiltonian \( \hat{H} \) is similarity transformed to an effective Hamiltonian \( \hat{H}_{TC} = F^{-1} \hat{H} F \) with up-to-three-body interaction. One-electron orbitals and their orbital energies are optimized by solving a set of Hartree-Fock (HF)-like single particle equations derived by minimizing the variance of the \( \hat{H}_{TC} \). In this study, the band gaps and total energies of covalent and ionic solids were calculated by the TC method at various lattice constants. The local density approximation (LDA) and HF calculations were also performed to the same systems and compared to the TC results. In covalent solids such as silicon carbide, the lattice constant and bulk modulus calculated by the TC method were not largely different from the LDA results. In ionic solids such as lithium hydride, we found that the lattice constant, bulk modulus and band gap calculated by the TC method were closer to the experimental results than the LDA results.

4:18PM S13.00008 System-averaged exchange and correlation holes in third-row atoms. ANTONIO C. CANGIO, Ball State University — Recent work is presented on the theoretical calculation of system-averaged exchange and correlation holes (intracules) for a pseudopotential model of the valence shell of third-row atoms. Exchange holes are obtained from numerical fourier transform methods and correlation holes from variational quantum Monte Carlo calculations using the method of correlated estimates. We observe approximate scaling behavior in both exchange and correlation, following the known scaling of the valence density across the row. The holes are compared to density-functional models including LDA, GGA and meta-GGA approaches. Particular attention is paid to self interaction (SI) error; we find that a sizeable error occurs in the same-spin channel of the correlation hole which persists for the LDA and GGA even after standard SI corrections are applied. A simple SI correction that eliminates this error will be discussed.

4:30PM S13.00009 RPA Correlation Energy in ACFD Formalism with Thomas-Fermi-von Weizsäcker Approximation. VIET HUY NGUYEN, STEFANO DE GIRONCOLI, Intnl School for Adv Studies (SISSA), Trieste Italy — It is well known that LDA or GGAs approximations in DFT do not describe correctly systems where long range correlations are important. In the Adiabatic Connection Formalization-Dependence (ACFD) formalism correlation energy can be computed exactly from Kohn-Sham and interacting linear response functions. Although computationally very demanding, this formalism has shown to describe correctly systems where standard DFT fails qualitatively by combining RPA xc-kernel with short-range local-density corrections (RPA+). On the other hand, Thomas-Fermi-von Weizsäcker approximate kinetic response function can capture reasonably well asymptotic long range interactions via van der Waals coefficients, and has the computationally desirable feature that it only involves a single auxiliary wavefunction regardless of the number of electrons in the system. Here, we show how to use this approach to calculate approximate RPA correlation energies. Numerical results for atoms show that this approach gives approximate RPA correlation energies closer to the experimental values than those obtained by full RPA and, when combined with a short-range local-density correction, it gives results at least as good as those of full RPA+. The possibility is therefore open to address large systems where correlations need to be treated beyond LDA and GGAs.

4:42PM S13.00010 Generalized density functional theory for effective potentials in many-body electronic structure. F. A. REBOREDO, P. R. C. KENT, Oak Ridge National Laboratory — We demonstrate the existence of different density functionals that retain selected properties of the many-body ground state in the non-interacting density functional solution. We focus on diffusion Monte Carlo applications that require trial wave functions with Fermion optimal nodes. The theory can be extended and used to understand current practices in several electronic structure methods [GW-BSE,CLEPM] within a generalized density functional framework. The theory justifies and stimulates the search of optimal empirical density functionals and effective potentials but also cautions on the limits of their applicability. The theoretical concepts are tested against a near-analytic model that can be solved to numerical precision. Research performed at the Materials Science and Technology Division and the Center of Nanophase Material Sciences at Oak Ridge National Laboratory sponsored the Division of Materials Sciences and the Division of Scientific User Facilities U.S. Department of Energy.

5:06PM S13.00011 Real or artifactual symmetry breaking in BNB: A fixed-node diffusion Monte Carlo study1, WISSAM A. AL-SAIDI, CYRUS UMRIGAR, Cornell University — The linear BNB molecule represents one of the most challenging examples of symmetry-breaking effects because of its susceptibility to a second-order Jahn-Teller distortion along the antisymmetric stretching mode. This real symmetry breaking could be confused in calculations with an artifactual one caused by the approximate nature of the theoretical approach. Thus the debate of whether the ground state of BNB is symmetric in the positions of the boron atoms with respect to nitrogen or if this symmetry is broken. Our preliminary investigations with diffusion Monte Carlo shows that the symmetric and the broken symmetry geometries are nearly degenerate, which would suggest a highly floppy quasi-symmetric BNB ground state.

5:18PM S13.00012 Potential Energy Curves and Excited States of the C2 Molecule by Auxiliary-Field Quantum Monte Carlo (AFQMC)1, WIRAWAN PURWANTO, HENRY KRAKAUER, SHIWEI ZHANG, College of William and Mary, WISSAM AL-SAIDI, Cornell University — The accurate determination of potential energy curves (PECs) and excited states represents two difficult problems in electronic structure calculations. We present AFQMC PECs of the challenging C2 molecule, focusing on the ground state and two singlet low-lying excited states. AFQMC calculates a target many-body wave function (WF) by means of random walks in the space of Slater determinants. We employ truncated complete active space (CAS) trial WFs (\( \Psi_j \)) to guide the AFQMC projection to obtain the desired state. With the phase-free constraint, the CAS \( \Psi_j \) is effective in controlling the sign/phase problem, and filtering in the desired excited state. The AFQMC results are in very good agreement with exact results and in comparison with experimental spectroscopic constants will also be presented.

2:30PM S14.00001 Strongly interacting Fermi gases in an optical lattice. NIELS STROHMÄIER, ROBERT JOERDENS, ETH Zurich, KENNETH GUENTER, Ecole Normale Superieure, Paris, YOSUKE TAKASHI, Kyoto University, MICHAEL KOEHL, University of Cambridge, HENNING MORITZ, TILMAN ESSLINGER, ETH Zurich — When cold fermionic atoms are placed in the periodic potential of an optical lattice, they behave similarly to electrons in a crystal. However, the properties of this synthetic material can be changed at will. Here, we report on the experimental realization and investigation of strongly interacting Fermi gases with tunable interactions. By changing the interaction strength we are able to control the transport properties: while dipole oscillations are observed for a non-interacting gas, the atomic cloud relaxes very slowly to its equilibrium position for strong attractive interactions. We suggest an interpretation in the framework of the Hubbard model including external confinement: local fermionic pairing occurs, leading to a drastically reduced tunneling rate. Furthermore, experimental results on the behavior of repulsively interacting Fermi gases will be presented.

2:42PM S14.00002 Squeeing out the entropy of Fermions in an optical lattice. QI ZHOU, TIN-LUN HO, Physics Department, The Ohio State University, Columbus, OH, 43210 — We point out a new scheme for achieving the strongly correlated system in an optical lattice. By turning the bulk of the trapped fermions into a band insulator, the entropy of the system is expelled to the surface and removed by various means. Our scheme also illustrates a general principle of cooling in a many body system. That is, one can use a gapped state to squeeze out the entropy and then turn it into the desired state after the entropy is removed.

2:54PM S14.00003 Superfluid-insulator transitions of the Fermi gas with near-unitary interactions in a periodic potential. EUN-GOOK MOON, Harvard University, PREDRAG NIKOLIC, Rice University, SUBIR SACHDEV, Harvard University — We consider a gas of spin-1/2 fermions with interactions near the unitary limit. In an applied periodic potential, and with a density of an even integer number of fermions per unit cell, there is a second-order quantum phase transition between superfluid and insulating ground states at a critical amplitude of the lattice potential. We map out the universal phase diagrams at $N = \infty$ in a model with Sp(2N) spin symmetry, and compute the universal ratio between the critical lattice amplitude and molecule recoil energy. As the interactions between fermions are varied, the insulator evolves smoothly between a band insulator of fermions and a Mott insulator of fermion pairs. We discuss implications for recent ultra-cold atom experiments.

3:06PM S14.00004 Pattern formation in mixtures of different mass ultracold atoms in optical lattices: an inhomogeneous DMFT study. JAMES FREERICKS, Department of Physics, Georgetown University — Dynamical mean-field theory (DMFT) is generalized to include an inhomogeneous trap and applied to the problem of different mass spin-polarized fermionic atoms that have an interspecies interaction $U$. Such a system is described by the spinless Falicov-Kimball model in a harmonic trap (in the limit where the more massive atom is localized on the optical lattice); we examine atoms moving on a 51X51 two-dimensional square lattice. When the temperature is low enough, the system exhibits pattern formation with different types of order, ranging from checkerboard phases and phase separation to an analog of the viscous fingering seen in immiscible liquids. The temperature evolution of these ordered phases is interesting as well, as the system can form rings of ordered phases surrounding disordered phases, which expand in size as $T$ is lowered. These patterns can be detected with noise-correlation spectroscopy or Bragg scattering, and their evolution with $T$ could be employed for thermometry. The inhomogeneous DMFT algorithm parallels well and is quite efficient. The main difference with exact numerical solutions or the local density approximation is that the temperature scales for the ordering are significantly higher in the IDMFT solution.

3:18PM S14.00005 Fermion mixtures on an optical lattice. SHAN-WEN TSAI, University of California, Riverside, TUN WANG, Institute for Quantum Optics and Quantum Information of the Austrian Academy of Sciences — We investigate mixtures of two species of fermionic ultracold atoms loaded on an optical lattice. We consider fermions with unequal masses and also fermions with unequal spin populations. We discretize the two Fermi surfaces and employ a functional renormalization-group (RG) approach to calculate the flows of effective interaction vertices in order to identify the instabilities of the system. Without any interactions produced via tuning of Feshbach resonances, a question arises as to whether there can be BCS pairing from repulsive interactions (produced by the optical trap) combined with lattice effects. For spin-independent bare contact interaction, the RG flows for unequal spin populations generate effective spin-dependent interactions. We investigate cases with different interactions, both attractive and repulsive, and different shapes of the Fermi surfaces, in particular the case when one of the fermion species has a nested Fermi surface and the other one does not.

3:30PM S14.00006 Effects of frozen double occupancies in fermions in optical lattices. RAJDEEP SENARMU, EUGENE DEMLER, Harvard University, EHUD ALTMAN, Weizmann Institute — We study the effects of “frozen” double occupancies in metastable states of 3D fermionic Hubbard model in the strongly interacting regime. Such long lived states can be created with ultracold fermions in an optical lattice, as the lattice potential is ramped up to access strongly correlated regimes. We shall discuss how the presence of the double occupancies affect anti-ferromagnetism in these systems. We will also discuss possible “charge” orders in these systems.

3:42PM S14.00007 Dynamical instabilities of paired fermion superfluids in optical lattices. GANESH RAMACHANDRAN, University of Toronto, ANTON BURKOV, University of Waterloo, ARUN PARAMEKTANTI, University of Toronto — We report on a study of dynamical instabilities in cold atom fermionic superfluids in optical lattices. Of particular interest to us are the properties of such superfluids at fermion densities corresponding to noninteger average number of pairs per lattice site. In this case superfluidity competes with charge-density-wave ordered states, which has a profound effect on how such superfluids respond to flow. In particular, by varying the pairing momentum, we find a complex interplay between dynamical, pair breaking and Landau (phonon excitation) instabilities at different fillings and different magnitudes of the pairing interaction. Using insights from this study, we construct the “dynamical phase diagrams” of fermion superfluids, and discuss the experimental observability of the proposed effects.

3:54PM S14.00008 BCS-BEC Crossover of a Quasi-two-dimensional Fermi Gas: the Significance of Dressed Molecules. WEI ZHANG, GUIN-DAR LIN, LUMING DUAN, Department of Physics, University of Michigan — We study the crossover of a quasi-two-dimensional Fermi gas trapped in the radial plane from the Bardeen-Cooper-Schrieffer (BCS) regime to the Bose-Einstein condensation (BEC) regime by crossing a Feshbach resonance. Using an effective two-dimensional Hamiltonian with renormalized interaction between atoms and dressed molecules, we calculate the zero temperature cloud size and number density distribution and conclude that the results are consistent with the picture of BCS-BEC crossover. These results are in clear contrast to the predictions of an effective two-dimensional Hamiltonian with renormalized atom-atom interaction, where a constant cloud size and identical density profile are expected for arbitrary detunings. This inconsistency indicates that the inclusion of dressed molecules is essential to describe the two-dimensional Fermi systems, especially on the BEC side of the Feshbach resonance. 

Wednesday, March 12, 2008 2:30PM - 5:18PM — Session S14 DAMOP: Fermions in Optical Lattices Morial Convention Center 205

Supported by DARPA under grant number W911NF-07-1-0576.

Supported by NSF and Samsung Scholarship.
4:06PM S14.00009 Itinerant Ferromagnetism in an Atom Trap

ILYA BERDKIKOV, PIERS COLEMAN, Center for Materials Theory, Rutgers University, STEVE SIMON, Bell Labs, Alcatel-Lucent — Interest in ferromagnetism has prompted the development of many theoretical techniques to study the phenomenon. However, even the most sophisticated schemes, though well motivated physically, remain intrinsically uncontrolled. This is a clear signal that more experimental input is needed, and the rapidly developing field of ultra-cold atomic gases affords just such an investigation. We propose an experiment to explore the magnetic phase transition in interacting fermionic systems, and establish signatures of ferromagnetic correlations in the observed ground states. We find, that for large trap radii \( R > l \), in units of coherence length \( \xi \), ground states are topological in nature, a “skyrmion” in 2D, and a “hedgehog” in 3D. Finally, we describe how to obtain the ferromagnetic phase diagram of itinerant electron systems from these experiments.

4:18PM S14.00010 The expansion of strongly interacting fermions after the release from a trap

FABIAN HEIDRICH-MEISNER, Institut fuer Theoretische Physik C, RWTH Aachen, Germany, MARCOS RIGOL, Department of Physics, University of California, Santa Cruz, CA, USA, ALEJANDRO MURAMATSUMU, Institut fuer Theoretische Physik III, Universitaet Stuttgart, Germany, ADRIAN FEIGJUN, Microsoft Q, University of California, Santa Barbara, CA, USA, ELBIO DAGOTTO, Materials Science and Technology Division, ORNL, and University of Tennessee, Knoxville, TN, USA — Both the recent experimental progress in cold atom gas realizations and developments in computational techniques has fueled interest in nonequilibrium properties of strongly correlated systems. Here we study the expansion of fermions in a one-dimensional lattice after released from a trap. Using the time-dependent density matrix renormalization group method, we analyze properties of the one-particle density matrix as well as the evolution of spin and density correlations. A comparison of particles escaping from a metallic region as compared to a Mott-insulating one shows that some memory on the initial state is preserved during the expansion. We further address the question to what extent the correlations measured during the expansion and thus in a non-equilibrium situation resemble those of appropriately chosen reference systems in equilibrium.

4:30PM S14.00011 Quantum Antiferromagnetism of Fermion in Optical Lattices with Half-filled p-band

HUI ZHAI, UC Berkeley, KAI WU, Center for Advanced Study, Tsinghua University — We study Fermi gases in a three-dimensional optical lattice with five fermions per site, i.e. the s-band is completely filled and the p-band with three-fold degeneracy is half filled. We show that, for repulsive interaction between fermions, the system will exhibit spin-3/2 antiferromagnetic order at low temperature. This conclusion is obtained in strong interaction regime by strong coupling expansion which yields an isotropic spin-3/2 Heisenberg model, and also in weak interaction regime, by Hatree-Fock mean-field theory and analysis of Fermi surface nesting. We show that the critical temperature for this antiferromagnetism of a p-band Mott insulator is about two orders of magnitudes higher than that of an s-band Mott insulator, which is close to the lowest temperature attainable nowadays.

4:42PM S14.00012 Stripe Formation and Superfluidity Correlation on Two-dimensional Optical Lattice: DMRG Studies for n-leg repulsive Hubbard model

MASAKI MACHIDA, MASAHIKO OKUMURA, SUSUMU YAMADA, CCSE, Japan Atomic Energy Agency — In order to predict strongly-correlated behaviors on two-dimensional (2-D) optical lattice, we employ the parallel density matrix renormalization group (p-DMRG) method and examine 2-D repulsive (square-lattice) Hubbard model. In the presentation, we firstly suggest that box shape trap enables to observe intrinsic properties of the Hubbard model in a fixed doping in contrast to the harmonic trap bringing about wide spatial variations of atom density profiles. Next, we show atomic density profile on 4-leg repulsive Hubbard model with the open boundary condition under the box trap. The variation parameters in the simulation are the doping rate below the half-filling and the repulsive interaction \( U/t \). As a result, we find that stripe formations are universal in a low hole doping regime and the stripe sensitively changes its structure with variations of \( U/t \) and the doping rate. A striking feature is that a stripe by a hole pair turns to one by a bi-hole pair when entering a limited strong \( U/t \) range. Furthermore, a systematic calculation reveals that the Hubbard model shows a change from the stripe to the Friedel oscillation with increasing the doping rate.

4:54PM S14.00013 Superfluidity of fermions with repulsive on-site interaction in an anisotropic optical lattice near a Feshbach resonance

BIN WANG, LUMING DUAN, University of Michigan, Ann Arbor — We present numerical analysis of ground state properties of the one-dimensional general Hubbard model (GHM) with particle assisted tunnelling rates and repulsive on-site interaction (positive-U), which describes fermionic atoms in an anisotropic optical lattice near a wide Feshbach resonance. Our calculation uses the time evolving block decimation algorithm, which is an extension of the density matrix renormalization group and provides a well controlled method for one-dimensional systems. We show that the positive-U GHM, when hole doped from half-filling, shows up a phase with coexistence of quasi-long-range superfluid and charge-density-wave orders. This feature is different from the property of the conventional Hubbard model with positive-U, indicating the particle assisted tunneling in the GHM could bring in qualitatively new physics.

5:06PM S14.00014 Predicted itinerant ferromagnetism with cold fermions in optical lattices

SHIZHONG ZHANG, Department of Physics, University of Illinois at Urbana-Champaign, CONGJUN WU, Department of Physics, University of California, San Diego — Itinerant ferromagnetism is one of the central topics in condensed matter physics. Ferromagnetism is intrinsically strong coupling physics which does not have a weak coupling limit, i.e., spontaneous spin polarization requires strong interactions to overcome the kinetic energy cost. In spite of its importance, ferromagnetism has not received enough attention in the cold atom community because the system is unstable to molecular formation if the interaction is tuned close to resonance from the positive side of the Feshbach Resonance. To overcome this difficulty, we instead propose to realize the ferromagnetic state in the p-orbital honeycomb lattice by taking advantage of its flat band structure. Due to the divergent density of states, even weak repulsions can drive the ferromagnetic transition while ensure the stability of the system. This will open up a new opportunity to investigate ferromagnetism with precise controllability and to realize spin transport and even spintronics applications with cold atoms.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S15 GQI: Superconducting Qubits III

Morial Convention Center 207

2:30PM S15.00001 Transmission line cavity as a quantum memory for superconducting phase qubits

K. CICAK, F. ALTMARE, J.I. PARK, M.A. SILLANPAÄ, R.W. SIMMONDS, National Institute of Standards and Technology, Boulder, CO 80305 USA — A superconducting transmission line cavity coupling two phase qubits has already proven useful as a bus for coherent state transfer\(^1\). In this talk we will discuss our efforts in extending the work of Sillanpäät al\(^2\) to use a transmission line as a short term memory element.

\(^1\)Current Address: Helsinki University of Technology, Low Temperature Laboratory, Finland

\(^2\)NATURE 449, 438-442 (2007)
2:42PM S15.00002 Coplanar resonators as computational elements in a superconducting qubit architecture, MAX HOFHEINZ, E.M. WEIG, R.C. BIALczAK, H. WANG, N. KATZ, M. NEELEY, E. LUCERO, A.D. O’CONNELL, M. ANSMANN, J. WENNER, D. SANK, I. STORCH, J.M. MARTINIS, A.N. CLELAND, UC Santa Barbara — We are coupling a superconducting phase qubit, implemented using a current-biased Josephson junction, to a high-Q coplanar waveguide resonator. The interaction between the qubit phase and the resonator can be controlled by tuning the qubit frequency into and out of resonance with the resonator, a tuning that can be achieved dynamically over times short compared to the Rabi time. By combining the quantum control flexibility of the phase qubit with the long coherence time and bosonic nature of the resonator, a number of interesting quantum operations can be explored, including long-term phase coherent quantum memory and two-qubit bus architectures. In this talk we will report on our recent progress with this experiment.

2:54PM S15.00003 Entangling phase qubits via a common transmission line cavity, JAE PARK, RAY SIMMONDS, NIST, Boulder — We consider ways of “distributing” entanglement to a number of qubits via a common superconducting transmission line cavity. We propose methods of preparing such states and verifying its preparation.

3:06PM S15.00004 Measuring the quantum states of a superconducting cavity, JAE PARK, FABIO ALTOMARE, KATERINA CICAK, NIST, Boulder, RAY SIMMONDS — We consider the prospects for preparing and measuring some basic quantum states (e.g. number states) of a superconducting transmission line cavity coupled to Josephson-junction qubits.

3:18PM S15.00005 Cooling of a Resonator with Microwave Induced Charge-Phase Qubit Transitions, JANI TUORILA, DAVID GUNNARSSON, ANTTI PAILA, JAYANTA SARKAR, EKRI THUNEBERG, YURIY MAKHLIN, PERTTI HAKONEN, Helsinki University of Technology and University of Oulu — We have studied a circuit QED experiment where a superconducting charge-phase qubit is coupled to an electric r-f-resonator via the phase degree of freedom. The resonator is coupled to a transmission line that allows reflection measurement with narrow band detection. Additionally, the charge degree of freedom is coupled to a mw-signal. The level spacing $\hbar \Delta$ of the qubit is controlled with constant shifts in both degrees of freedom. Multiphoton absorption from both drives can excite the qubit in the case the level separation is equal to the sum of the photon energies. The results of the measurements show asymmetry between the depths of the side-resonances of the basic resonance $\Omega = \omega_\mu$. Also, a non-monotonic AC-Stark shift is observed in the apparent resonance positions. Solutions of the semiclassical Maxwell-Bloch equations of the whole measurement apparatus show that the measured results can be considered as evidence of cooling/heating of the oscillator.

3:30PM S15.00006 Fast tuning of a high Q microwave cavity for qubit cooling, M. SANDBERG, C.M. WILSON, F. PERSSON, G. JOHANSSON, V. SHUMEIKO, T. DUTY, P. DELSING — In 2004 Wallraff et al. [1] demonstrated that an artificial atom in form of a superconducting qubit can exhibit coherent interaction with a superconducting high Q microwave transmissionline resonator. In recent experiments [2,3] similar resonators have been used for coupling and reading out qubits. In these experiments the resonance frequency of the resonator is fixed and the qubit frequency is tuned. Here we present measurements on a superconducting transmission line resonator with a tunable resonance frequency that could be used for qubit cooling [4]. With such a device, qubit gates can be performed while the qubits stay at their optimal points. We demonstrate a tunability of 700 MHz for a 4.8 GHz resonator with a linewidth of 500 kHz and that we can tune the resonance frequency by 330 MHz in a few ns. We show that if the resonator is detuned faster than its decay time the photons inside the resonator will shift their frequency with the resonator.

3:42PM S15.00007 Vacuum Rabi Mode Splitting at High Drive Powers and Elevated Temperatures, J.M. FINK, Department of Physics, ETH Zurich, A. BLAIS, Departement de Physique, Universite de Sherbrooke, R.J. SCHOELKOPF, Departments of Applied Physics and Physics, Yale University, A. WALLRAFF, Department of Physics, ETH Zurich, ETH QUANTUM DEVICE TEAM, YALE CIRCUIT QED TEAM — The circuit QED architecture [1,2] is ideal to probe the nonlinearity of a strongly coupled cavity QED system at high drive powers populating the cavity with a controllable average photon number in the range from $0.1 < n < 100$. While in atomic cavity QED the radiation pressure exerted on the atoms by the drive tends to expel the atoms from the cavity, superconducting qubits remain at a fixed position and maintain constant coupling. This enables us to explore the cross-over from the quantum to the classical regime in the single qubit-field interaction by measuring vacuum Rabi mode splitting spectra. We also investigate the effect of thermal radiation in the cavity leading to a thermal population of excited states in the Jaynes-Cummings ladder, which was theoretically studied in Ref. [3]. Simulations have been carried out in order to determine the optimal set of qubit and resonator parameters needed for first experiments.

3:54PM S15.00008 Observation of Berry’s Phase in a Superconducting Qubit, P.J. LECK, J.M. FINK, Department of Physics, ETH Zurich, A. BLAIS, Departement de Physique, Universite de Sherbrooke, R.J. SCHOELKOPF, Departments of Applied Physics and Physics, Yale University, A. WALLRAFF, Department of Physics, ETH Zurich, ETH QUANTUM DEVICE TEAM, YALE CIRCUIT QED TEAM — In quantum information science, the phase of a wavefunction plays an important role in encoding information. While most experiments in this field rely on dynamic effects to manipulate this information, an alternative approach is to use geometric phase, which has been argued to have potential fault tolerance [1]. Here we demonstrate the controlled accumulation of a geometric phase, Berry’s phase, in a superconducting qubit, manipulating the qubit geometrically using microwave radiation, and observing the accumulated phase in an interference experiment [2]. This is achieved utilizing the excellent phase coherence and qubit control possible in Circuit QED [3]. We find excellent agreement with Berry’s predictions, and also observe a geometry dependent contribution to dephasing.

4:06PM S15.00009 Cooper Pair Box Qubit in the Ultrastrong Coupling Regime, MARKUS BRINK, MICHAEL METCALFE, LUIGI FRUNZIO, VLADIMIR E. MANUCHARYAN, JENS KOCH, TERRI M. YU, STEVEN M. GIRVIN, ROBERT J. SCHOELKOPF, MICHEL H. DEVORET, Yale University — We propose a new superconducting qubit design, where a small Josephson junction is inserted in the central conductor of a coplanar waveguide resonator. In this distributed element design, the resonator provides a negative reactance for the junction, which modifies the charging energy $E_C$ of the junction and places the qubit far in the “Transmon regime”. $E_J \gg E_C$, where $E_J$ is the Josephson energy of the junction. We will discuss design details and show preliminary fabrication and measurement results.
4:18PM S15.00010 Homodyne detection of resonance fluorescence in circuit QED, LEV S. BISHOP, JENS KOCH, Yale University, ERKKI THUNEBERG, University of Oulu, JERRY M. CHOW, STEVEN M. GIRVIN, ROBERT J. SCHOELKOPF, Yale University, YALE CIRCUIT QED TEAM — In circuit QED, the transmon qubit[1] allows long coherence times and strong coupling. In this regime, tuning the qubit into resonance with the cavity leads to vacuum Rabi splitting[2] with two transition peaks very well-resolved in frequency (∼300 linewidths apart). At low probe power, these peaks have Lorentzian shape. As the probe power is increased, each Rabi peak is observed to split into two peaks. Approximating the combined effect for a single mode of the cavity does not account for T1s observed in our system. Here we show a semi-classical approximation for the Purcell effect for a multi-mode cavity which we compare with T1 measurements of several transmon qubits[1]. By designing an appropriate cavity we have improved T1 by a factor of 10.

4:30PM S15.00011 Purcell Effect Limits on the Lifetimes of Transmon Qubits, BLAKE JOHNSON, STEVEN GIRVIN, ROBERT SCHOELKOPF, Yale University, THE YALE CIRCUIT QED TEAM — Here we discuss coherence measurements of the transmon qubit, an optimized Cooper Pair Box geometry. We show experimental verification that sensitivity to 1/f charge noise was exponentially suppressed in the transmon qubit. As a result, the effects of gate charge noise and quasiparticle poisoning have been nearly eliminated, and the qubit was seen to be nearly homogeneously broadened. Following an improvement in relaxation times, dephasing times were measured at over a microsecond, nearly twice the relaxation time, without the need of an echo experiment while being tuned over a range of several GHz. The tuning of the qubit excitation energy shows strong agreement with a quantum mechanical calculation of the Purcell effect for a single mode of the cavity.

4:42PM S15.00012 Suppressing Charge Noise Decoherence in a Transmon Qubit, JOSEPH SCHREIER, STEVEN GIRVIN, ROBERT SCHOELKOPF, Yale University, YALE CIRCUIT QED TEAM — We show that charge noise is exponentially suppressed by employing a multi-mode cavity which we compare with T1 measurements of several transmon qubits[1]. By designing an appropriate cavity we have improved T1 by a factor of 10.

4:54PM S15.00013 Circuit QED with phase-biased qubits, JEROME BOURASSA, ALEXANDRE BLAIS, Universite de Sherbrooke, MICHEL DEVORET, ROBERT SCHOELKOPF, Yale University, YALE CIRCUIT QED TEAM — Coupling of a superconducting charge qubit to a transmission line resonator has been shown to lead to the very strong coupling regime of cavity qubit[1]. In this talk, we will discuss an alternative approach to circuit QED based on the cavity bifurcation amplifier[2] and where a qubit is directly embedded in the resonator’s center line. We will show that this type of phase bias leads to very strong coupling and/or non-linearities. Readout, decoherence rates and coupling of qubits in this architecture will be discussed. [1] A. Wallraff et al., Nature 431, 162 (2004). [2] M. Metcalf et al., PRB 76, 174516 (2007).

5:06PM S15.00014 Quantum walk on a circle in phase space via superconducting circuit quantum electrodynamics, BARRY SANDERS, PENG XUE, University of Calgary, ALEXANDRE BLAIS, KEVIN LALUMIERE, University of Sherbrooke — We show how a quantum walk, with a single walker and controllable decoherence, can be implemented for the first time in a quantum quincunx created via superconducting circuit quantum electrodynamics (QED). Two resonators are employed to provide simultaneously fast readout and controllable decoherence over a wide range of parameters. The Hadamard coin flip is achieved by directly driving the cavity, with the result that the walker jumps between circles in phase space but still exhibits quantum walk behavior over 15 steps.

5:18PM S15.00015 Quantum mirror transport of qudits and continuous variables and an implementation in Circuit-QED, JASON TWAMLEY, GERARDO ANDRES PAZ SILVA, STOJAN REBIC, Centre for Quantum Computer Technology, Macquarie University, Sydney — We expand on our previous work [J. Fitzsimons and J. Twamley, Phys. Rev. Lett. 97, 090502 (2006)], to derive a globally controlled automata-like protocol for the perfect transmission of quantum information in a chain made up of qubits or a chain made up of harmonic oscillators. The resulting protocol results in perfect spatial reflection of the entire quantum state of the chain about its midpoint. Quantum information can be encoded and then processed in continuous variables if one can engineer highly squeezed states [S. Lloyd and S. L. Braunstein, Phys. Rev. Lett. 82, 1784 (1999)]. We show that appropriately driving a superconducting coplanar microwave cavity coupled to a Cooper-pair box qubit can generate very high squeezings of the cavity mode. We consider a linear array of coplanar cavities nearest-neighbor coupled by Cooper-pair boxes. By controlling the coupling strengths of the cavities to the coupling-CPB qubits and the decoherence rates of the latter with time, we show that we can initialize the cavities to be in highly squeezed CV states, and then execute globally controlled quantum mirroring of the entire chain of CV qubits. We finally show that with extra control on the end cavities of the chain we can further execute universal CV quantum computation.

Wednesday, March 12, 2008 2:30PM - 5:30PM
Session S16 DBP: Focus Session: General Techniques and Radiation Therapies in Biological Physics
Morial Convention Center 208

2:30PM S16.00001 The Evolution of External Beam Radiation Therapy (EBRT) from a Technological Perspective, NICHOLAS DETORIE, Sibley Memorial Hospital, Washington, DC — Since the discovery of x-rays by Roentgen in 1895 ionizing radiations have been used as a treatment for cancer. Such treatments have been based on either implantation of radioactive materials at the site of disease or by aiming external radiation beams at the diseased site. This later method is referred to as teletherapy because the beams originate from a location outside of the body distant from the disease site itself. A brief review of the basic radiation biology will be given to illustrate the rationale for therapeutic use of ionizing radiation and the effects of beam energy and beam type— particulate or photon. The remainder of the presentation will focus on the technological developments supported by the required physical properties of the beams and their associated characteristics that make them suitable for patient treatments. Chronological highlights will include the following sources or devices: superficial x-rays, orthovoltage x-rays, megavoltage x-rays and Cobalt 60 photons, electron beams, neutron beams, negative pi mesons, protons, and heavy ions. The presentation will illustrate how the physical beam properties have been incorporated into modern radiation treatment devices, many of which are equipped with radiation imaging capability. Such devices include: linacs equipped with multileaf collimators for beam shaping and intensity modulation, the Gamma Knife for precise and accurate irradiation of brain tumors or arterial-venous malformations (AVM), the robotic arm based Cyber Knife, and the Helical Tomotherapy unit.
3:06PM S16.00002 State-of-the-Art External Beam Radiation Therapy: Challenges and Opportunities, JATINDER PALTA, University of Florida — Intensity-modulated radiation therapy (IMRT) and image-guided radiation therapy (IGRT) allow delivery of highly conformal non-convex dose distributions. However, these treatment modalities require precise knowledge of multimodality imaging, internal organ motion, tumor control probabilities, normal tissue complication probabilities, three-dimensional dose calculation and optimization, dynamic beam delivery of non-uniform beam intensities, and most importantly the knowledge of uncertainties in the radiation therapy planning and delivery process. These uncertainties arise from a variety of sources throughout the whole process that consists of three distinct steps: imaging, planning, and delivery. In the imaging step, 3D patient information is obtained for treatment planning. Any problem in the acquisition, transfer, conversion, registration, or use of imaging data can lead to increased geometrical uncertainties. Dose calculation algorithms have inherent errors, because they are based on approximate solutions to a complex physical situation. The assumptions of a RTP system in modeling a treatment machine significantly impact dose calculation accuracy. The accuracy of the beam geometry depends on the tolerance of each machine parameter and the magnitude of setup errors. Therefore, one must clearly identify and account for all sources of error in imaging, treatment planning, and delivery process to understand the uncertainty in dose delivered to a patient with IMRT/IGRT. It is necessary to properly account for these uncertainties in radiation therapy to improve the accuracy of the dose delivered to patients. This presentation will provide the framework and guidance to safely implement these technologies in the clinic.

3:42PM S16.00003 Technological Advances in Proton Therapy, JAMES MCDONOUGH, University of Pennsylvania — Proton therapy has interested radiation oncologists since the 1946 paper by Robert R. Wilson describing the energy deposition of proton beams and suggesting it would be more suitable for radiation treatments than beams of x-rays. For all its proposed benefits, only 25,000 or so cancer patients worldwide have been treated with high-energy proton beams over the last fifty years. However, during the past decade that number has started to rapidly increase. In the United States alone the number of dedicated facilities has grown from two to five in the last three years and will likely double again by the end of the current decade. We will soon be treating as many patients in one year as was treated during the first fifty years of proton therapy. Surprisingly, the reason is because of what has been happening in x-ray radiotherapy. Conventional radiotherapy underwent a dramatic change during the past decade with the introduction of multiple advances in imaging technology and beam delivery methods. The imaging advances include both imaging for treatment planning (multislice CT systems, high resolution MRI, and increasing use of PET) and imaging of the target location in the treatment room. The treatment delivery advances, dominated by methods that permit intensity modulated beam delivery, were made possible by increased computational power and more computer control of the treatment delivery. These imaging and beam delivery advances should benefit proton therapy treatments even more than x-ray treatments because of the better conformation of dose to the target that one can achieve with proton beams. However, because of the small size of the proton therapy community it has had difficulty implementing some of the advances made in x-ray therapy. The treatment planning imaging is also used by proton therapy but the on-treatment imaging and the intensity modulation often must be specially developed for each proton therapy system. This talk will present the developments in these areas that are expected to be implemented in the next few years.

4:18PM S16.00004 The active catheter: a novel approach for in-situ dose measurements in brachytherapy, PAUL GUEYE, Hampton University, CENTER FOR ADVANCED MEDICAL INSTRUMENTATION COLLABORATION — Radiation therapy is the primary method for combat cancerous tissues. However, although efficient, it still lacks from having a tool that can enable accurate measurement of the dose delivered to the tissue in-situ. The active catheter concept was taken from a common approach used in nuclear/high energy physics where the target is sometimes constructed so as to provide additional information on the scattering process (i.e., active target). By making the catheters used to transport radioactive sources during brachytherapy treatments becoming sensitive to radiation, one is able to extract dose information in-vivo with minimal to no modification during the treatment process. The technique relies on the use of thin (few 100s microns) scintillating fibers embedded within the brachytherapy device. We will report on two applications of such active catheters pertaining to breast and prostate cancer. The former was applied to the MammoSite® balloon from Cytyc, the accelerated partial breast irradiation technique that is becoming the preferred mode of radiation in breast brachytherapy. Results from water phantom data will be presented and discussed. For the latter, gel phantom tests were performed simulating prostate brachytherapy treatments. Comparison with a treatment planning to these data will be also presented and discussed.

4:30PM S16.00005 The proton and carbon therapy experience of the medical physics group at the Italian Southern Laboratories: Monte Carlo simulation and experiment, G.A. PABLO CIRRONE, C. AGODI, G. CANDIANO, G. CUTTONE, F. DI ROSA, E. MONGELLI, P. LOJACONO, S. MAZZAGLIA, G. RUSSO, F. ROMANO, L.M. VALASTRO, INFN-Laboratori Nazionali del Sud, Catania (I), S. LO NIGRO, Univ. of Catania (I), S. PITTERA, CSFNSM Catania (I), M.G. SABINI, A.O. Cannizzaro, Catania, L. RAFAELE, V. SALAMONE, A.O. Policlinico, Catania (I), C. MORONE, 2nd Univ. of Rome (I), N. RANDAZZO, V. SIPALA, INFN Section of Catania (I), M. BUCCiolini, I. BRUZZI, D. MINICHIELLI, Univ. of Florence — At the Italian Southern Laboratories (LNS) of the Italian National Institute for Nuclear Physics the first, and actually unique, Italian proton therapy center is installed and operating. Up to now, 140 patients have been treated. In this environment a big effort is devoted towards Monte Carlo simulation especially with the GEANT4 Toolkit. The authors of this work belong to the Geant4 collaboration and they use the toolkit in their research programs. They maintain a Monte Carlo application dedicated to the complete simulation of a generic hadron-therapy beam line and take active part in the study of fragmentation processes. Moreover they are working in the development of a prototype of a proton Computed tomographic system. In this work we will report our results in the field of proton and carbon therapy either in the simulation as well as in the experimental side of our activity.

4:42PM S16.00006 Real-time High Resolution Plasmonic nanosensors: pH modulated capta-vidin/biotin binding, JEFFREY ANKER, RICHARD VAN DUYNE, Northwestern University — The ability to observe real-time molecular binding kinetics is important for understanding the functions and interactions of biological molecules. Localized surface plasmon resonance (LSPR) nanosensors exhibit intense extinction and scattering spectra that redshift when molecules bind to their surface. Herein, we use an array of biotin functionalized silver nanoprisms to detect pH-modulated binding and dissociation of captavidin to biotin as a model system. The capta-vidin binds at neutral pH and dissociates at high pH. Spectral shifts are monitored in real-time at high resolution during pH-modulated binding and dissociation cycles over hours. After the first cycle, good reversibility is observed. We also observe pH modulated charging and nanoparticle etching effects which are important experimental parameters and also provide a means to control and modulate the nanoparticle spectra.

1This research was supported by the NSF (Grants EEC-0647560, CHE-0414554, DMR-0520513, and BES-0507036), the National Cancer Institute (1 U54 CA119341-01), and a Ruth L. Kirschstein National Research Service Award (5 F32 GM077020) to J.N.A.
4:54PM S16.00007 Electrical noise gives away presence of cancer or toxins in culture. DAVID RABSON, DOUGLAS LOVELADY, CHUN-MIN LO, University of South Florida — Since 1984, electric cell-substrate impedance sensing (ECIS) has been used to monitor cell behavior in culture and has proven sensitive to morphological changes and cell mobility. Several authors have associated fluctuations in the measured impedance with cellular micromotion; however we are unaware of any previous work applying statistical techniques in order to distinguish two different cell types. We have now demonstrated a method for distinguishing cancerous from non-cancerous cultures of human ovarian surface epithelial cells. Applying similar ideas, we have also determined the presence and concentration of the toxin cytochalasin B in cultures of 3T3 fibroblasts at levels lower than the detection thresholds of other techniques. Measures indicative of both short-time (autocorrelation) and long-time ($1/f^\alpha$ noise in the power spectrum and Hurst and detrended-fluctuation-analysis exponents) show statistically significant differences between the populations. Our measures confirm that the noise from non-cancerous cultures has a higher degree of temporal order, order which we argue must arise from greater coordination of motion between healthy cells than between cancerous ones.

5:06PM S16.00008 Delayed Luminescence and Biophotons from Biological Materials. ERNST KNOESEL, PATRICK HANN, MARIA GARZON, ERIK PFEIFFER, SAMUEL LOFLAND, Rowan University, ROWAN UNIVERSITY TEAM — There has recently been increased interest in the field of biophotonics, since it is a non-invasive technique. Many biological systems, such as yeast, bacteria, leaves, seeds, and algae display the unusual phenomenon of a weak, delayed luminescence on the timescale of seconds to minutes after transient illumination. It is also observed that the time decay of the biophotonic emission is not exponential, even after the delay, and that there can be oscillations in intensity with time, which depend on the duration of the illumination. Results from two types of yeast, i.e. bread yeast, and saccharomyces, as well as those from several types of algae are presented. Possible mechanisms for the source of the ultraweak photon emission are discussed.

5:18PM S16.00009 Dielectric Spectroscopy: noninvasive and fast method for measuring changes in the membrane potential. CORINA BOT, CAMELIA PRODAN, New Jersey Institute of Technology, EMIL PRODAN, Yeshiva University, Stern College for Women — We present a noninvasive and fast method, dielectric spectroscopy, to measure changes in the membrane potential of live cell suspensions, in particular to E. coli. This technique can be applied virtually to any cell suspension, regardless of size or shape and is tested against the traditional one, using voltage sensitive dyes. Precise measurements of the dielectric permittivity $\varepsilon$ and conductivity $\sigma$ of live cells suspensions require prior elimination of the polarization errors. Polarization errors are caused by the ionic content of a buffer, and they affect the total impedance in the low frequency limit. Here, $\varepsilon$ and $\sigma$ represent the fitting parameters; a higher weight is given to each of them for the high frequency domain (3kHz-10kHz), where polarization effects were proven negligible. Measurements were performed in a low electric field (1V/cm) and high frequency domain (3kHz-10kHz), where polarization effects were proven negligible. Measurements were performed in a low electric field (1V/cm) and different buffers are measured, such as HEPES, DMEM with different KCI concentrations. Adding different KCI concentration or ionophores triggers changes in the membrane potential of E. coli. Those changes are measured using dielectric spectroscopy and voltage sensitive dyes.

Wednesday, March 12, 2008 2:30PM - 4:54PM — Session S17 DCMP: Quantum Fluids and Solids II Morial Convention Center 209

2:30PM S17.00001 Phonon-roton modes and a Bose phase in nanoscale liquid $^4$He. JACQUES BOSSY, Institut Neel, CNRS-UJF, Grenoble, JONATHAN PEARCE, National Physical Laboratory, UK, SCHÖBER HELMUT, Institute Laue Langevin, Grenoble, HENRY GLYDE, University of Delaware — We present neutron scattering measurements of the elementary phonon-roton modes of liquid $^4$He confined in nanoporous media. The aim is to compare phonon-roton (P-R) and superfluid density measurements in helium at nanoscales and in disorder. A specific goal is to determine the region of temperature and pressure in which well defined phonon-roton modes (and therefore BEC) exist and compare this with the superfluid region. In 25 $\AA$ mean pore diameter gel similar Yamamoto et al.[1] find that the superfluid phase extends up to a temperature $T_s \approx 1.4$ K at saturated vapor pressure (SVP) (p = 0) and up to a pressure $p_s \approx 34$ bar (T ~ 0). There is apparently a Quantum Phase Transition at $p_s \approx 34$ bar[1]. We find well defined P-R modes (BEC) extend above $T_s$ at SVP (up to $T_s \approx 2.17$ K) and to pressures above $p_s$ (up to a pressure $p \approx 36.3-36.8$ bars at T ~ 0 but no modes above this pressure). This suggests that there is a Bose glass phase consisting of local regions of BEC (fragmented BEC) separated by regions with no BEC surrounding the superfluid phase at all p and T. We compare this phase diagram with other dirty Bose systems. [1] Yamamoto et al. Phys. Rev. Lett. 93, 075302 (2004).

2:42PM S17.00002 Elastic transmission of atoms through superfluid $^4$He, YAROSLAV LUTSYSHYN, J. WOODS HALLEY, University of Minnesota — We investigate completely elastic transmission of atoms through a slab of strongly interacting helium superfluid by diffusion Monte Carlo (DMC) method. Both quasiparticle and condensate mediated modes of transmission have been predicted[1,2] but only quasiparticle mode has been observed[3,4]. We performed numerical calculations of the transmission probability using DMC with a modified fixed-node approach to find the phase shifts of scattering states for elastic transmission process of atoms incident normal to the surface of a free standing helium slab. Transmission coefficients for different energies of the incident atom were computed. Preliminary results for the group velocity of a transmitted wave packet hint at rapid transmission with times characteristic of the virtual condensate mediated process. This work was supported in part by the University of Minnesota Supercomputing Institute.

2:54PM S17.00003 Experimental Observation of Quantized Vortex Reconnection and Turbulence in Superfluid Helium$^1$, MATTHEW PAOLETTI, University of Maryland, KATEPALLI SREENIVASAN, International Centre for Theoretical Physics and University of Maryland, DANIEL LATHROP, University of Maryland — We present experimental studies of the first direct visualization of reconnecting quantum vortices and the decay of superfluid turbulence in $^4$He. Micron-sized solid hydrogen particles are used for particle tracking. The cores of the superfluid vortices trap the hydrogen particles, thereby allowing direct visualization of the dynamics of the line-like defects. We generate superfluid turbulence by driving a thermal counterflow. After pulsing the counterflow, the system relaxes through a cascade of reconnection events. We examine the dynamics of pairs of particles trapped on reconnecting vortices and observe that these particles separate as power-laws in time with a scaling exponent distributed about the predicted value of $1/2$. We show that reconnection leads to power-law tails in the velocity probability distribution function, which is in stark contrast to the Gaussian tails that are ubiquitous in classical turbulence and thermal motion.

$^1$We would like to acknowledge support from NSF, NASA, and the Center for Nanophysics and Advanced Materials at the University of Maryland

3:06PM S17.00004 ABSTRACT WITHDRAWN
3:18PM S17.00005 Scanning Superfluid-Turbulence Cascade by Its Low-Temperature Cutoff, EVGENY KOZIK, Institute for Theoretical Physics, ETH Zurich, and Department of Physics, University of Massachusetts Amherst — Recent advances in experimental techniques have made it possible to explore highly non-trivial short-wavelength physics of low-temperature superfluid turbulence. We analyze the transformation of the (quasi-)classical Kolmogorov cascade into the Kelvin-wave cascade on individual vortex lines at high enough wavenumbers, revealing a chain of three qualitatively distinct intermediate regimes, supported by local-induction motion of the vortex lines, and distinguished by specific reconnection mechanisms. On the basis of this scenario, we develop a theory of low-temperature cascade cutoff, which predicts a peculiar behavior of the quantized vortex line density, $L$, controlled by the frictional coefficient, $\alpha(T) \ll 1$, responsible for the cutoff. Excellent agreement with a recent experiment by Walsme et al. [arXiv:0710.1033]—in which $L(T)$ has been measured down to $T \sim 0.08\,\text{K}$—validates our scenario and allows to quantify the Kelvin-wave cascade spectrum.

3:30PM S17.00006 ABSTRACT WITHDRAWN —

3:42PM S17.00007 Metastable Composite Vortices in Spinor Condensates, ARI TURNER, Harvard University, EUGENIE DEMLER — The ground states of condensates of atoms with spin have a variety of symmetries leading to many types of vortices. The quadratic Zeeman effect produces composite metastable vortices, which are configurations of vortices held together by a force resulting from the Zeeman effect as we explain. If the component vortices were to combine together and react to form a different set of components, then the composite vortex could break up. However, this is prevented by short-range repulsions. Our analysis focuses on the cyclic phase, where the chemistry of the vortices is regulated by the symmetry group of a tetrahedron.

3:54PM S17.00008 Quantum Monte-Carlo study of a two-band boson Hubbard model, SIEGFRIED GUERTLER, The University of Hong Kong, Department of Physics, MATTHIAS TROYER, ETH Zurich, Institute for theoretical Physics, FU-CHUN ZHANG, The University of Hong Kong, Department of Physics — We consider a two band boson Hubbard model, in which the on-site interaction is infinity for the intra-band bosons and repulsive for the inter-band bosons. The on-site inter-band boson interaction may facilitate condensation of vacancies of $a$-boson and interstitials of $b$-boson. We report results of large scale quantum Monte Carlo simulations to study possible supersolid phases of the model.

4:06PM S17.00009 A simple model of thermal conductivity in supersolid Helium, JOSHUA THIBODEAUX, ILYA VEKHTER, Louisiana State University, MATTHIAS GRAF, ALEXANDER BALATSKY, Los Alamos National Laboratories — The recent discovery of the decrease of the torsional oscillator period in solid Helium has led to a renewed interest in a supersolid state. The simplest model for this state is one in which the vacancies undergo Bose-Einstein condensation. Within this model we use the Boltzmann equation to investigate the thermal conductivity of normal $^4\text{He}$ and super solid by considering phonons interacting with a gas of vacancies. We analyze the temperature dependence of the thermal conductivity and specific heat for different vacancy concentrations. We will discuss the consequences of our calculations for existing and future experiments.

4:18PM S17.00010 Local melting at surface and isotope impurities in quantum solids, EMMANUELLE CAPPELLUTI, Research Center SMC, INFN-CNR and Dept. Physics, University La Sapienza, Rome, Italy, GIANLUCA RASTELLI, Laboratoire de Physique et Modélisation des Milieux Condensés, CNRS, Grenoble, France, SERGIO GAUDIO, Dept. Physics, University La Sapienza, Rome, Italy, LUCIANO PIETRONERO, Research Center SMC, INFN-CNR and Dept. Physics, University La Sapienza, Rome, Italy — Surface melting is a well-known phenomenon in classical solids, and it can be related to a local instability of the solid phase close to the surface truncation. In this contribution we employ a self-consistent harmonic approximation to investigate surface melting and local melting close to quantum impurities in quantum solids. We show that surface melting can occur at temperatures much lower than the critical temperature $T_\text{c}$ of the solid phase instability in the bulk. Similar effects are driven by the presence of an isotope substitution. In this latter case, we show that stronger local lattice fluctuations, induced by a lighter isotope atom, can induce local melting of the host bulk phase. Experimental consequences and the possible relevance in solid helium are discussed.

4:30PM S17.00011 A Kosterlitz-Thouless transition in solid $^4\text{He}$?, SERGIO GAUDIO, Dipartimento di Fisica, Universita di Roma, La Sapienza, EMMANUELLE CAPPELLUTI, Dipartimento di Fisica, Universita' di Roma, La Sapienza and ISC, INFN-CNR, Roma Italy, GIANLUCA RASTELLI, Universite' Joseph Fourier, Grenoble, France, LUCIANO PIETRONERO, Dipartimento di Fisica, Universita' di Roma, La Sapienza and SMC Research Center and ISC, INFN-CNR, Roma Italy — We show that the reproducible “Non-Classical Rotational Inertia” signals in solid Helium four are completely ascribable to a Kosterlitz-Thouless transition of liquid $^4\text{He}$ at the grain boundaries. Despite our toy model, we obtain a surprisingly good agreement with the experimental data when comparing the drop of the momentum of inertia. Within our model, we give an estimate of the average size of the grains, which we argue to be limited by the isotopic impurities and show that the signal is inversely proportional to the size of the average size of the grains.

4:42PM S17.00012 Disorder-induced Missing Moment of Inertia in Solid $^4\text{He}$, JIANSHENG WU, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — A microscopic model for the experimentally observed missing moment of inertia in the torsional oscillator experiments on partially-annealed solid $^4\text{He}$ is proposed. We argue that an ordered array of $^4\text{He}$ atoms is a Mott insulator. Disorder destroys the Mott state producing localized states in the gap which beyond a critical value of the disorder induce a superfluid state. Depending on the magnitude of the disorder, we find that the destruction of the Mott state takes place for $d \leq 3$ either through a Bose glass phase (strong disorder and weak disorder) or through a direct transition to a superfluid (intermediate disorder). The critical value of the disorder that separates three region of disorder is shown to be a function of the boson filling, interaction and the momentum cut off. We apply our work to the experimentally observed enhancement $^4\text{He}$ impurities has on the onset temperature for the missing moment of inertia. We find quantitative agreement with experimental trends.

1NSF DMR-0605769

Wednesday, March 12, 2008 2:30PM - 5:42PM –
Session S18 DPOLY: Hybrid Organic-Inorganic Nanomaterials II: Assembly and Fabrication
Morial Convention Center 210
2:30PM S18.00001 Transparent Organic Field-Effect Transistors with Carbon Nanotube Electrodes, ADRIAN SOUTHWARD, VINOD K. SANGUAN, TRACY L. MOORE, ELLEN D. WILLIAMS, MICHAEL S. FUHRER, Dept. of Physics, University of Maryland, College Park, MD 20742-4111 USA, DANIEL HINES, VINCE BALLARATTO, Laboratory of Physical Sciences at the University of Maryland — Carbon nanotube (CNT) films are promising as electrode material for organic field-effect transistors (OFETs). We have fabricated CNT films over large areas by airbrushing and patterned them either using shadow masks, or via photolithography and reactive ion etching. Pentacene thin film transistors bottom-contacted by CNT source/drain electrodes on Si/SiO₂ substrates show moderate mobility (up to 0.1 cm²/Vs) and contact resistance as low as 20 kΩ/cm. The contact resistance varies linearly with the gate voltage, eventually saturating at high negative gate voltage. OFETs were measured at temperatures from 228 to 353.5 K. After accounting for contact resistance, the intrinsic mobility of the transistors is found to be activated in temperature with activation energy between 0.137 and 0.151 eV in reasonable agreement with values in the literature. An all-carbon transparent OFET with CNT source, drain and gate electrodes and polymethylmethacrylate (PMMA) gate dielectric has been assembled on a polyethylene terephthalate substrate by transfer printing, with a field-effect mobility up to 0.06 cm²/(Vs).

1Supported by the Laboratory of Physical Sciences.

2:42PM S18.00002 Directed self assembly of macroscopic nanowires from single-wall carbon nanotubes suspended in aqueous bile-salt solutions, E. K. HOBIE, J. A. FAGAN, M. L. BECKER, S. D. HUDSON, J. CHUN, B. J. BAUER, NIST, M. PASQUALI, Rice — Length purified and chirality enriched single-wall carbon nanotubes (SWNTs) suspended in aqueous bile-salt solutions are found to spontaneously self assemble into macroscopically long straight nanowires, both in confined geometries and on patterned substrates. By patterning surfaces with ordered arrays of hydrophobic and hydrophilic regions, we tailor the self assembly of the nanowires for potential applications in the rapid and cheap fabrication of transparent films with strong directional conductivity. We report a phase diagram, and nanowire self-assembly. The predominant mechanisms for this phase behavior are identified as hydrogen-bonding interactions between contacted bile-salt micelles, which lead to the natural formation of macroporous fibrils, and entropic depletion interactions mediated by free surfactant micelles.

2:54PM S18.00003 Time and Temperature Dependent Rheological Behavior of Single-Walled Carbon Nanotubes Dispersed in Thermoreversible Acrylic Copolymer & Alcohol Solutions, ANDREW B. SCHOC, KENNETH R. SHULL, MSE, Northwestern University, L. CATHERINE BRINSON, MSE & ME, Northwestern University — SWCNT stabilized by A-B diblock and A-B-A triblock copolymers are excellent model systems for studying the relationship between nanotube dispersion and mechanical response. We have investigated the mechanical properties of these materials with low-amplitude oscillatory shear rheological measurements. The solvent used here, 2-ethyl-1-hexanol, is a poor solvent for PMMA (A) at low temperatures but a good solvent for PnBA (B) over the entire temperature range studied. The solubility of the PMMA blocks in 2-ethyl-1-hexanol drives the formation of an elastic gel in the ABA triblock copolymer at low temperatures. In these SWCNT/copolymer materials the storage and loss moduli have been observed to increase with time at fixed temperature. When triblock copolymer gels are used as the matrix, we find that the aging effect is erased by cycling the temperature through the gel transition. An increase in storage modulus is observed upon cooling before the gel formation. However, the moduli revert back to lower values when the gel dissolves on heating. We believe this is a result of semi-permanent nanotube junctions being pulled apart when the gel forms. This reversibility is not observed when the nanowires are dispersed in solutions of diblock copolymer, which do not form gels.

3:06PM S18.00004 Forces between nanorods with end-adsorbed chains in polymer melts, AMALIE FRISCHKNECHT, Sandia National Laboratories — Adsorbed or grafted polymers are often used to provide steric stabilization of colloidal particles. When the particle size approaches the nanoscale, the curvature of the particles becomes relevant. Here I use a classical density functional theory to study the polymer-mediated interactions between two nanorods. The rod are immersed in an athermal, melt polymer blend consisting of: 1) a small fraction of chains of length N=20 with “sticky” ends that are attracted to the rods with energy e/kT so that they form a polymer brush on the rods; and 2) a matrix of chains of length P which have no interactions with the rods. The structure of the brush depends on the nanorod diameter, P, and e/kT. There is an attractive well in the force between the rods near contact, followed by a strong repulsion as the brushes are compressed. The depth of the well increases with increasing P. I will discuss the implications for experimental systems. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

3:18PM S18.00005 Shape and size selection of Au nanorods by reversible flocculation, KYOUNG-WEON PARK, Air Force Research Laboratory, WEI LU, University of Michigan, HILMAR KOERNER, RICHARD VAIA, Air Force Research Laboratory — For gold nanorods (GNRs) synthesized by wet chemical method, spherical particles as a byproduct is inevitable. Efficient and rapid approaches to separate the NRs are critical to optimize the nanostructure-dependent optical properties and not bias conclusions due to existence of spherical impurities. Relatively monodisperse GNRs can be separated from smaller size spheres through repeated centrifugation steps. The number of centrifugation steps, though, must be minimized to avoid irreversible aggregation of rods due to the loss of their capping surfactant. As an alternative, we demonstrate that size selection of GNRs can be achieved by the formation of controlled flocculates of GNRs, driven by an attractive depletion interaction between the NRS induced by surfactant micelles above a critical concentration. The flocculates sediment after a few hours. Separation yields as high as 90 % in number of particles were obtained without any damage to the surface of NRS. Flocculation is reversible upon varying the concentration of surfactant. The effect of the aspect ratio of rods and surfactant micelle structure on the flocculation is discussed with regards to concentration, type and mixing ratio of binary surfactants. The effect of electrostatic interaction is also considered through the impact of different types of electrolytes.

3:30PM S18.00006 Industrial viable process of making nanoparticles of various shapes and interior structures, XIAORONG WANG, Bridgestone Americas, Center for Research and Technology — Over the past 10 years, we attempted to develop industrial viable processes which were of significance in manufacturing the nanoparticles in good quality and large volume. Our effort relied on the self-assembly concepts of block macromolecules in solutions to prepare particles with a hard core made of crosslinked plastics and a soft shell made of low Tg elastomer. Depending on the type and microstructure of the copolymers, the solvent concentration and other process parameters chosen, a variety of shell-core nano-particles of different shapes (spheres, hollow spheres, ellipsoids, cylinders, linear and branched strings, disks and etc.) and sizes (5-100 nm diameter) were reproducibly synthesized. Scale-up studies led to an optimization of the manufacturing process and the production of nanoparticles in large quantities for various product application efforts. The unique performance of those nanoparticles as performance tuning additives and novel rubber reinforcing elements was explored in rubber compounds. This review describes the synthesis methods used to produce the polymer nanoparticles, the technology to modify the particles through functionalization, the means to optimize their performance for specific applications, and the methods to use those particles in rubber compounds. Collaborators: Victor J. Foltz, Kurasch Jessica, Chenchy J. Lin, Jeff Magestrelli, Sandra Warren, Alberto Scuratti, James E. Hall, Jim Krom, Mindaugas Rackaitis, Michael W. Hayes, Pat Sadhu, Georg G. A. Bohm
3:42PM S18.00007 Performance of ZnO nanowire-based hybrid solar cells decorated with CdTe quantum dots deposited by a pulsed electron beam technique\textsuperscript{1}. ROBERTO AGA, RICHARD MU, Fisk University, Nashville TN 37208, KENNETH SINGER, Case Western Reserve University, Cleveland OH 44106 — More efficient nanocomposite hybrid solar cells require facile charge transport to the collecting electrodes as well as photon-to-electron conversion over the broad solar spectrum. In this work, we employ ZnO nanowires (ZnO-NW) as direct conduction pathways for electrons to the collecting electrode by growing them directly on ITO-coated glass substrates. Photovoltaic nanocomposites are then formed by spin-coating of poly(3-hexylthiophene). By decorating the ZnO-NW with CdTe quantum dots deposited by a pulsed electron beam technique, we have extended the photon-to-electron conversion sensitivity beyond 600 nm.

\textsuperscript{1}This research is supported in part by DOD/ARO contracts W911NF-05-1-0453, -05-1-0040, and -04-1-0400, NREL/DOE ACQ-4-33623-03 and NSF-CREST CA:HRD-0420516 and NSF-STC Clips under grant #0423914.

3:54PM S18.00008 Organic and Carbon-based Thin-film Transistors on Flexible Substrates.\textsuperscript{1}. DANIEL R. HINES, A. E. SOUTHARD, J.H. CHEN, M.S. FUHRER, E.D. WILLIAMS, Dept. of Physics, University of Maryland, College Park, MD — Fabrication of organic & carbon-based thin-film transistors (TFT) was achieved on plastic substrates using transfer printing. Each device component (Au electrodes, polymer dielectric layer and semiconductor layer) was printed using only pressure and temperature, eliminating all chemical processing on the device substrate. Pentacene (Pn), poly(3-hexylthiophene) (P3HT), carbon nanotube mats (CNTM) and graphene TFTs were all fabricated on polyethylene terephthalate (PET) substrates, yielding mobilities of 0.237 cm\textsuperscript{2}/Vs for Pn and 0.04 cm\textsuperscript{2}/Vs for P3HT. Bottom-gate CNTM TFTs are p-type, with mobilities of 13.7 cm\textsuperscript{2}/Vs, on/off ratio of 10\textsuperscript{7} and minimal hysteresis. Top-gate graphene TFTs have mobilities of 1.0x10\textsuperscript{3} cm\textsuperscript{2}/Vs for holes and 4x10\textsuperscript{3} cm\textsuperscript{2}/Vs for electrons. P3HT TFTs showed little variation in mobility, but strong variation in threshold voltage for different dielectric layers. These TFTs printed onto plastic substrates with a variety of polymer dielectric layers will be presented and discussed.

\textsuperscript{1}Supported by the Laboratory for Physical Sciences and the UMD-NSF MRSEC.

4:06PM S18.00009 Self-assembled contacts to nanoparticles using metallic Ga droplets. KAN DU, E. GLOGOWSKI, M.T. TUOMINEN, T. EMRICK, T.P. RUSSELL, A.D. DINSMORE, Department of Physics, Department of Polymer Science and Engineering University of Massachusetts Amherst — We demonstrate a pragmatic approach to forming electronic materials and devices, in which metal droplets serve as electrodes and their spacing is controlled spontaneously, via self-assembly, to allow tunneling contact with nanoparticles. We have fashioned devices consisting of droplets of molten metal (Ga). Ga is suspended in acidic solution. Ligand-stabilized Au nanoparticles in solution assembled on the metal surface, as shown by electron microscopy. Coated droplets which are then placed on a substrate and the solvent removed. Electron-transport measurements reveal the Coulomb blockade, in which current is suppressed below a tunable threshold voltage by the energy of charging individual nanoparticles. The threshold voltage for two different sizes of nanoparticles agrees with theory. Our approach provides a straightforward approach to creating nanoscale-precision contacts to nanoparticles and might lead to formation of a large number of microscopic devices from suspension.

4:18PM S18.00010 ATRP of MMA on Asymmetrically Functionalized Gold Nanoparticles. BINGBING WANG, BING LI, CHRISTOPHER LI, Drexel University — Metal nanoparticles have attracted enormous interest due to their unique optical and electronic properties. After the pioneer work of Brust and Schiffrin, a lot of reports have been focused on the modification of the surface of metal nanoparticles with functional groups. However, it still remains a challenging task to synthesize Janus metal nanoparticles, which could potentially lead to directed assembly of the functionalized nanoparticles, an essential step towards using these nanoparticles in real world applications. Asymmetrical gold nanoparticles (AuNPs) modified with two different kinds of polymers on the opposite sides were synthesized using poly(ethylene oxide) single crystals with thiol end groups as the substrate. After the immobilization of AuNPs, room temperature ATRP was performed using the ‘grafting from’ method to obtain asymmetrical AuNPs, which possess the ‘Janus’ nature, i.e. two types of polymer chains were selectively patterned on the different locations of the AuNPs. The asymmetric nature of these AuNPs was demonstrated by NP decoration.

4:30PM S18.00011 DNA guided assembly of well-organized nano-architectures. OLEG GANG, DMYTRO NYKYPANCHUK, MATHEW MÁYÉ, DANIEL VAN DER LÉLIE, Brookhaven National Laboratory — An incorporation of DNA in nano-object design provides a unique opportunity to establish reversible, chemically weak and highly selective interactions between the components of nanosystems. Assembly approaches based on this addressable interactions promise a possibility for creation of rationally designed multicomponent system. However, understanding interplay of interactions, cooperative phenomena leading to phase formation and experimental realizations of ordered phases has remained elusive. Using in-situ x-ray scattering methods, we have studied an assembly kinetics, structure development, and phase formation of DNA-capped nanoparticles on surfaces and in bulk for various DNA assembly schemes. The observed changes in the 2D DNA/nanoparticle array layer reveal an evolution of particle/surface separations and surface coverages. For 3D systems, formation of 3D assemblies with crystalline long-range order in two-component nanoparticle systems was observed. The DNA design, assembly schemes and thermodynamic pathway leading to this crystallization has been explored.

4:42PM S18.00012 Schottky nanodiodes based on electrospun polymer nanofibers: Effect of varying fiber diameter\textsuperscript{1}. RUT RIVERA, NICHOLAS PINTO, University of Puerto Rico - Humacao, ALAN JOHNSON JR., University of Pennsylvania — We report on a simple method to fabricate, under ambient conditions and within seconds, Schottky nanodiodes using electrospun polyaniline nanofibers and an inorganic n-doped semiconductor. The objective of the present work is to investigate the role of surface states on the device operation by fabricating Schottky nanodiodes using fibers of varying diameter. The standard thermionic emission model of a Schottky junction was utilized in analyzing the data. As the fiber diameter gets smaller, the diode rectification ratio and the diode turn-on voltage shifts to lower values, while the diode barrier height and the ideality factor increase. The simple construction and high surface to volume ratio of the nanofiber also makes these devices attractive candidates in the potential fabrication of low power, supersensitive and rapid response reusable sensors.

\textsuperscript{1}This work was supported by NSF.
4:54PM S18.00013 Effects of severe confinement on the structure and dynamics in polymer nanocomposites. S.H. ANASTASIADIS1, K. CHRISPOPOULOU, S. FOTIADOU, Foundation for Research and Technology - Hellas, K. ANDRIKOPoulos, G.A. KOUROUKLIS, Aristotle Univ. of Thessaloniki, Greece, B. FRICK, ILL, Grenoble, France — The structure and dynamics of PEO/Na+ MMT nanocomposites is investigated by XRD, DSC, Raman spectroscopy, and quasi-elastic neutron scattering (QENS). For concentrations up to 20 wt% PEO, the PEO chains within the galleries form either a single- or a double-layer structure of intercalated chains; at higher PEO content only double-layers of intercalated PEO chains are formed within the 0.9nm galleries. For PEO content below 70 wt%, the absence of XRD peaks that can be assigned to crystalline PEO and of any DSC melting transition as well as the observation of broad Raman lines reveal that the PEO chains remain liquid-like. It is only for PEO content higher than 70 wt% that diffraction peaks characteristic of bulk PEO are observed together with sharp Raman lines, proving crystallization of only the excess polymer outside the completely full galleries. QENS investigated the dynamics of PEO in bulk and in confinement. A jump of the bulk PEO dynamics at \( T_m \) is observed whereas the dynamics of confined PEO shows only weak temperature dependence and goes smoothly through the bulk \( T_m \). Sponsered by NATO’s Scientific Affairs Division, by the Greek GSRT and by the EU.

5:06PM S18.00014 pH and Protein Sensing with Functionalized Semiconducting Oxide Nanobelt FETs. YI CHENG, C.S. YUN, G.F. STROUSE, P. XIONG, Florida State University, R.S. YANG, Z.L. WANG, Georgia Institute of Technology — We report solution pH sensing and selective protein detection with high-performance channel-limited field-effect transistors (FETs) based on single semiconducting oxide (ZnO and SnO2) nanobelts.1 The devices were integrated with PDMS microfluidic channels for analyte delivery and the source/drain contacts were passivated for in-solution sensing. pH sensing experiments were performed on FETs with functionalized and unmodified nanobelts. Functionalization of the nanobelts by APTES was found to greatly improve the pH sensitivity. The change in nanobelt conductance as functions of pH values at different gate voltages and ionic strengths showed high sensitivity and consistency. For the protein detection, we achieved highly selective biotinylation of the nanobelt channel with through APTES linkage. The specific binding of fluorescently-tagged streptavidin to the biotinylated nanobelt was verified by fluorescence microscopy; non-specific binding to the substrate was largely eliminated using PEG-silane passivation. The electrical responses of the biotinylated FETs to the streptavidin binding in PBS buffers of different pH values were systematically measured. The results will be presented and discussed.1 Y. Cheng et al., Appl. Phys. Lett. 89, 093114 (2006). *Supported by NSF NIRT Grant ECS-0210332.

5:18PM S18.00015 On the Miscibility of Polymer / Layered Silicate Nanocomposites. K. CHRISPOPOULOU, I. ALTINTZI, I. ANDRIANAKI, N. KOUFAKI, S. FOTIADOU, S.H. ANASTASIADIS1, Foundation for Research and Technology-Hellas, Greece, E.P. GIANNELIS, Cornell University, Department of Materials Science and Engineering, U.S.A. — In the present work we attempt to control the structure in polymer / layered silicate nanocomposites by understanding and/or altering the interactions between the chains and the surfaces. In this respect, hydrophilic and organophilic systems have been utilized and the final structure of the composites is characterized by X-Ray Diffraction and Transmission Electron Microscopy. The effect of the solvent quality on the final structure, in the case of solution mixing, has been examined and the results are compared with the respective obtained from melt intercalation whereas the role of the chemical structure or of the different glass transition temperature of the polymer has been evaluated. In the case of very immiscible systems like for example polyolefin/silicate composites the effect of a more polar additive has been examined. Phase separated up to exfoliated structures can be obtained in a controlled way by varying the compatibilizer to organoclay ratio. Sponsored by NATO’s Scientific Affairs Division, by the Greek GSRT and by the EU.

Session S19 DMP: Focus Session: Dopants and Defects in Semiconductors III
Morial Convention Center 211

2:30PM S19.00001 Stoichiometry driven impurity configurations in compound semiconductors. A.K. RAMDAS, Purdue University — As is well known, crystal growth of defect-free compound semiconductors, in contrast to elemental, is inherently limited by non-stoichiometry. High resolution infrared spectroscopy of localized vibrational modes can display unique signatures which reveal the structure of stoichiometry related defect-impurity complexes. The talk will focus on II-VI semiconductors in which group II cations are replaced with a group IIA or a 3d-transition metal. The effect of the solvent quality on the final structure, in the case of solution mixing, has been examined and the results are compared with the respective obtained from melt intercalation whereas the role of the chemical structure or of the different glass transition temperature of the polymer has been evaluated. In the case of very immiscible systems like for example polyolefin/silicate composites the effect of a more polar additive has been examined. Phase separated up to exfoliated structures can be obtained in a controlled way by varying the compatibilizer to organoclay ratio. Sponsored by NATO’s Scientific Affairs Division, by the Greek GSRT and by the EU.

3:06PM S19.00020 ABSTRACT WITHDRAWN —
3:18PM S19.00003 Carrier compensation in semi-insulating CdTe1, MAO-HUA DU, DAVID SINGH, Materials Science & Technology Division and Center for Radiation Detection Materials and Systems, Oak Ridge National Laboratory — Carrier compensation in semi-insulating CdTe has been attributed to the compensation of surplus shallow acceptors by deep donors, usually assumed to be Te antisites. However, our first-principles calculations show that intrinsic defects should not have a significant effect on the carrier compensation due either to lack of deep levels near midgap or to low defect concentration. We demonstrate that an extrinsic defect, $O_{T\ell}$-$H$ complex, may play an important role in the carrier compensation in CdTe because of its deep electronic character and reasonably high concentration. Our findings have important consequences for improving device performance in CdTe-based radiation detectors.

3:30PM S19.00004 Gadolinium Doping in ZnTe1, Z.X. MA, Lawrence Berkeley National Lab., LEI LIU, LBNL, UC Berkeley, KIN MAN YU, WALADEK WALUKIEWICZ, DALE PERRY, LBNL, PETER YU, LBNL, UC Berkeley, SAM MAO, LBNL, UC Berkeley — We have investigated, experimentally and theoretically, the effects of Gd doping on the structural and optical properties of ZnTe films grown by pulsed laser deposition. A few % of Gd doping was found to reduce the ZnTe lattice constant with no change in the fundamental band gap. When the doping level is increased to >7%, the lattice constant becomes more or less constant, but the band gap increases abruptly by as much as 50 meV. First-principles calculations based on a density-functional theory using the linearized augmented plane wave method were performed using ZnTe supercells containing either isolated defects or defect complexes. The reduced lattice constant on Gd doping can be attributed to the presence of defect complexes involving substitutional Gd ions and neighboring vacancies. The insensitivity of the band gap at lower Gd concentration can be explained by self-compensation of these defects. The increase in the band gap energy at higher concentration is attributed to band-filling effect.

3:42PM S19.00005 First Principles Investigation of H in CdTe, HIROYUKI TAKENAKA, DAVID J. SINGH, MAO-HUA DU, Oak Ridge National Laboratory — CdTe and alloys particularly (Cd,Zn)Te are of interest for radiation detection and other applications. A key issue is obtaining high mobility compensated material with low concentrations of traps. Hydrogen has been shown to play an important role in various semiconductors with both beneficial and deleterious effects. We investigate the effect of H on vacancies in CdTe using supercells. Our results are obtained from the first principles density functional theory calculations using the full potential linearized augmented plane wave method including local orbitals and based on local density approximation. H atoms in Cd vacancies move toward one of Te atoms, which formTd symmetry with Cd in the bulk system. The bond length between H and Te is 1.7 angstrom. This corresponds to a closely spaced Te-H unit similar to OH. We also present H in Te vacancies. We report the electronic structures as well as positron lifetimes. This work was supported by DOE, NA-22.

3:54PM S19.00006 Origin of doping bottleneck in semiconductor quantum dots, SIU-HUIE WEI, National Renewable Energy Lab, JINGBO LI, SHU-SHEN LI, JIAN-BAI XIA, Institute of Semiconductors, Chinese Academy of Sciences — Doping difficulties in semiconductor nanocrystals have been observed and its origin is currently under debate. It is not clear whether this phenomenon is energetic or depends on the growth kinetics. Using first-principles method, we performed systematic study of defects (donors, acceptors, isovalent defects, etc.) in ZnSe quantum dots. We show that the transition energies and defect formation energies of the donor and acceptor defects always increase as the quantum dot sizes decrease. However, for isovalent impurities, the changes of the defect formation energies are rather small. Our study suggests that for donor and acceptor defects, the doping difficulty is mostly due to energetic effects, whereas for isovalent impurities, the doping difficulty is mostly due to kinetic effects. The origin of the calculated trends is explained using simple band-energy-level models.

4:06PM S19.00007 Increased binding energy of impurities near a semiconductor vacuum interface, . PAUL KOENRAAD, INEKE WIJNHEIJMER, JENS GARLEFF, Eindhoven University of Technology, KARIN TEICHMANN, MARTIN WENDEROTH, SEBASTIAN LOTH, R. ULRBRICH, University of Gottingen — We have recently shown that a STM tip can be used as a tool to manipulate the charge state of a single impurity below the cleavage surface of a semiconductor. This manipulation allowed us to determine the binding energy of single donors and acceptors as a function of their depth (up to 1 nm) below the surface. We found that the binding energy strongly increases near the surface. In the case of a Si-donor in GaAs the binding energy increases continuously from 5.6 meV in the bulk to more than 100 meV close to the surface. Our STM techniques also allowed for the determination of the size and shape of the Coulomb field of single ionized donors. We found that the range of the potential is strongly reduced relative to the bulk value. Both the reduced range of the Coulomb potential and the increased binding energy can be related to a reduced dielectric constant and increased effective mass near the surface. We will discuss the implications of these findings.

4:18PM S19.00008 First-principles simulations of GaAs defects: The challenge of Ga pseudopotentials, PETER A. SCHULTZ, O. ANATOLE VON LILIENTHAL, Sandia National Laboratories, Albuquerque, NM — Design of norm-conserving gallium pseudopotentials (PP) has been investigated for density functional theory calculations of defects in GaAs. A converged PP construction is described. We examined the performance in cubic zinc-blende structure phases of GaAs, GaP, and GaN. Computed lattice constants, bulk moduli, and, particularly, band gaps vary greatly depending on PP construction and exchange correlation functional. The Kohn Sham band gaps exhibit a distinctive sensitivity on lattice constant, direct with a strong near-linear dependence at larger lattice constants with crossover to indirect near (within 5%) of the equilibrium lattice constant. Gradient-corrected functionals with a converged PP give a near-zero GaAs gap, a problem for defect calculations. A 3d-core PP “fixes” the band gap, but predicts GaAs defect formation energies different from converged 3d-valence PP. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

4:30PM S19.00009 Computational studies of a 2D tight-binding model of randomly dispersed hydrogenic centers1, JAYSON PAULOSE, Department of Physics, Princeton University, Princeton, NJ 08544; School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, RAVINDRA BHATT, Department of Electrical Engineering and Princeton Center for Theoretical Physics, Princeton University, Princeton, NJ 08544 — The impurity band arising from s-orbitals of randomly dispersed hydrogenic dopants in semiconductors in two dimensions is studied via exact diagonalization of a tight-binding model. Ensemble averaged density of states (DOS) and inverse participation ratio (IPR) of eigenstates are obtained as a function of energy at low to intermediate doping densities, where small clusters of sites are most significant. A similar calculation is done for p-orbitals for comparison. A strong peak in the DOS is seen due to the impurity level. Increasing the density of sites weakens this peak and produces asymmetry in the DOS and the IPR. A nearest-neighbour pair approximation qualitatively explains several features in the DOS at low densities but does not reproduce the singularity. This motivates a comparison to a hierarchically constructed pair model, as well as random bipartite systems, which is pursued further via a renormalization group approach in a concurrent study.

1Supported by NSF Grant DMR-0213706.
4:42PM S19.00010 Quenched singularity in the density of states of 2D random hydrogenic systems1, R.N. BHATT, Department of Electrical Engineering, Princeton University; Princeton Center for Theoretical Physics, Princeton, NJ 08544, ERIK NIelsen, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, JAYSON PAULOSE, Department of Physics, Harvard University, Cambridge, MA 02138 — Delta-doped hydrogenic dopants in semiconductor heterostructures give rise to an impurity band which can be characterized by a two-dimensional tight-binding model with randomly positioned sites. At low densities, the density of states possesses a singularity about the impurity level, which can be understood in terms of the states of a hierarchically constructed set of impurity pairs. As the density is raised, this singularity is quenched due to further neighbors breaking the electron-hole symmetry. The quenching is accompanied by an asymmetry in the density of states, and pair approximations are insufficient to even qualitatively describe the system at higher densities. We motivate and outline a renormalization group technique that captures the quenched singularity and asymmetry in the density of states. This approach motivates the study of random bipartite systems [1], for which it is particularly suited. We compare the results of both types of systems.

1Supported by NSF-MRSEC (DMR-0213706).

4:54PM S19.00011 Negative magnetocapacitance and associated Schottky barrier height changes in lightly doped GaAs , SEFAATTIN TONGAY, ARTHUR HEBARD, University of Florida, Department of Physics, HEBARD LABORATORY TEAM — We investigate the magnetic field response of Schottky barriers formed on GaAs with Si dopant densities of ~3E16 cm⁻³ and ~9E16 cm⁻³. Negative magnetocapacitance of up to 21% at 20K and increasing Schottky barrier height as determined by various impedance measurement techniques are observed. We attribute these effects to a magnetic-field induced increase in the ionization energies of electrons bound to Si impurity atoms, causing shallow impurity electrons to hop to (ionization process) and from (capture process) the conduction band on longer time scales. The effective field at which these effects are seen is a factor of 10⁻³ smaller than it would be in vacuum because of the smaller effective mass and larger dielectric constant of the GaAs host. The dependence of interband hopping on magnetic field decreases the dipole response in the depletion region and gives a corresponding decrease in the measured capacitance. Magnetic field dependent Schottky barrier heights are inferred from linear 1/C² versus bias voltage plots. We note that these magnetic field dependent effects are occurring in the absence of magnetic impurities and thus need to be understood before characterizing the magnetic response of diluted magnetic semiconductors.

5:06PM S19.00012 Thermally activated persistent photoconductivity & donor binding energy in high mobility AlAs QWs , S. dasgupta, c. knaaK, a. Fontcuberta, m. bichler, g. abstreiter, Walter Schottky Institut, TU Munich, Germany, M. Grayson, Walter Schottky Institut and Dept. of Electrical Engineering and Computer Science, Northwestern University, USA — In AlAs, valley index is important quantum number which can help understand interactions. However, important parameters for growth such as donor binding energy and Si doping efficiency were unknown and AlAs quantum wells (QWs) typically did not conduct in dark. We grew series of (001) and (110) oriented double-sided doped n-type AlAs QWs and deduced Si donor binding energy ∆ in Al₀.₄₅Ga₀.₅₅ As and doping efficiency η. They work in dark possibly because dilute charge traps in substrate are screened by backside doping. From dark saturation density for doping series we deduced ∆₈₁₆=65.2 meV [1]. Our studies show thermally activated PPC where sample is illuminated at 4 K and returned to dark without appreciable density increase. As temperature is increased to 30 K, density doubles, indicating shallow binding energy ∆₈₅₁₄=0 meV post-illumination anneal (PIA). Doping efficiency after illumination for (001) facet was found to be η₈₅₁₄=25% and for (110) η₈₅₁₄=17%. With this understanding, we designed (001) AlAs QW with PIA density n=2.4×10¹¹ cm⁻² and mobility μ=4.3×10⁶ cm²/Vs(330 mK), improvement of almost an order of magnitude over published results. [1] Dasgupta, et al. APL (2007)

5:18PM S19.00013 The low-temperature 2D mobility for metallic p-type GaAs Quantum Well , THEODORE CASTNER1, University of Rochester — At T < 1.2K the mobility μ(T) is determined by charged trap ionized impurity scattering (is) and T-dependent screening [1]. μ(T) is calculated with <E(T)> given by an empirical expression T = τₐσ₀/[x + C tanh(η/2)] [x = E/kT, η = T/τ₀ and a 2D DOS that features a pseudogap. μ(T) exhibits a minimum at Tₘₙₐₜ = T/F/2.25 and increases slowly for T > Tₘₜ. The physical reason for this unusual increase in μ(T) is explained. The coefficient C is directly related to μ(T)/μ(Tₘₜ) [4.0 > ratio > 3.6 for p-type GaAs data [2]]. The T-dependent screening η₂(T) = s(T)/s₀ and s(T) is given by μ(T)/μ(Tₘₜ). This s(T) allows the determination of T* [dr/dT = 0] where T* is slightly less than Tₘₜ. The data [2] is an example of ideal 2D behavior. The role of interactions for T < Tₘₜ and T > Tₘₜ will be discussed. [1] F. Stern, PRL 44, 1469 (1980); [2] X.P.A. Gao et al., PRL 93, 256002 (2004).

Session S20 DMP: Focus Session: Engineering Interfaces for New Materials III: Heterogeneous Interfaces Morial Convention Center 212

2:30PM S20.00001 Epitaxial Growth of Iron and Iron Nitrides on Wurtzite Gallium Nitride (0001)1, WENZHI LIN, JENONGHAM PAK, KANGKANG WANG, ABHIJIT CHINCHORE, DAVID INGRAM, ARTHUR R. SMITH, Nanoscale and Quantum Phenomena Institute, Ohio University, Athens, OH 45701 — Magnetic transition metal-containing layers on GaN have potential spintronic applications. We explore the epitaxial growth of iron and iron nitride films on wurtzite (0001)GaN(0001). First, we investigate the growth of ∼1.1 nm iron nitride on w-GaN(0001) using rf N₂-plasma molecular beam epitaxy (MBE) and monitor growth with in-situ reflection high energy electron diffraction (RHEED). We find that Fe₃N grows epitaxially with zinc-blende structure and (111)-orientation on w-GaN(0001). To achieve high Fe content, such as Fe₃N₀.₅ and Fe₂N₀.₅, current efforts are aimed at reducing N content in the source gas. In the case of pure Fe deposition, x-ray diffraction and RHEED suggest the epitaxial relationship to be [110]Ga₃N₁₋₀ₓ/[000]GaN with Fe in bcc structure. The assignment is based on lattice spacing measurements as well as angular dependence of the RHEED pattern. In this presentation, most recent results for Fe and Fe₃Nₓ films grown on w-GaN(0001) will be presented.

1This work has been supported by DOE (grant #DE-FG02-06ER46317).

2:42PM S20.00002 Observation of Standing Waves on the GaN(0001) Pseudo (1x1) Surface by Scanning Tunneling Microscopy at Room Temperature , L. LI, Y. QI, G. SUN, M. WEINERT, University of Wisconsin, Milwaukee — The metallic pseudo-1x1 surface, consists of 2 to 2.5 ML Ga on top of the Ga-terminated GaN(0001), provides an ideally confined 2D electron gas (2DEG), which gives rise to complex standing wave patterns. Even at room temperature, these patterns can be observed by scanning tunneling microscopy (STM) and spectroscopy (STS). The analysis of the modulation of the local density of states within various confinement geometries as a function of the bias voltage shows that nearly free-electron like energy dispersive surface states are being probed.
2:54PM S20.00003 Surface Evolution During Sub-Monolayer Manganese Deposition onto Wurtzite Gallium Nitride (000-1) Surface. 

ABHIJIT CHINCHORE, KANGKANG WANG, WENZHI LIN, JEONGIHM PAK, ARTHUR R. SMITH, Nanoscale and Quantum Phenomena Institute - Ohio University — While transition metal (TM)-doped gallium nitride (GaN) films have been explored as potential spintronic materials, the structural and magnetic effects of various TM adatoms on GaN surfaces are not well understood. In this work, we investigate the deposition of sub-monolayer quantities of Mn onto the N-polar GaN(000-1) ×1 surface. First, the GaN surface is prepared by molecular beam epitaxy. The smooth surface is then annealed to remove excess Ga adatoms. Next, the surface is exposed to a dose [approximately 0.05-0.1 monolayer (ML)] of Mn at substrate temperature of 200 °C. Using in-situ reflection high energy electron diffraction (RHEED), we observe the onset of clear 2× periodicity along [1-100] but only 1× along [11-20]. Additional 0.05-0.1 ML Mn doses lead to increasing intensity of the 2/3-order RHEED streaks, while 1/3-order and 1/4-order streaks weaken. For Mn doses up to about 1/3 ML, the surface appears quite smooth, with the RHEED pattern stable upon heating the surface to 600 °C. The results suggest a surface evolution process leading to a well-ordered Mn-containing structure at the GaN(000-1) surface.

3:06PM S20.00004 Van der Pauw and Hall Measurements on Ultra Thin Silicon-on-Insulator.

WEINA PENG, HONGQUAN JIANG, SANGKEUN HA, MADHU THALAKULAM, DONALD SAVAGE, MARK ERIKSSON, MAX LAGALLY, University of Wisconsin Madison — Ultra-thin silicon-on-insulator (UTSOI) provides opportunities to study the role of the surface in electrical transport in Si. Because the Si layers can be as thin as 10 nm, surface states, surface induced band bending, and gap states at the oxide-Si interface dominate the carrier density. Transport measurements provide a sensitive probe of the carriers. Previous measurements of thin Si structures have shown that Si/SiO2 interfaces trap deplete Si of mobile carriers, and sheet resistances reach 1011 ohm/sq for a 20 nm thick sample [1]. Thus, any perturbation to the surface that induces even modest carrier densities can be detected in transport. We perform van der Pauw and Hall measurements on UTSOI structures with a variety of surface modifications, including hydrogen termination and epichlorohydrin surface attachment. UTSOI that was extremely resistive with oxide on both sides undergoes a drop in resistance of more than 3 orders of magnitude after surface modification. Hall and van der Pauw measurements, reveal the density and the sign of the carriers. We discuss the mechanisms for this increased conductivity. [1] Zhang P. et al. Nature 439 703 (2006)

R. RAMPASAD, C. TANG, University of Connecticut — Driven by a need for device miniaturization in the microelectronic industry, Hf-based high-permittivity materials, such as HfO2, have gained interest for their potential application as gate dielectrics. However, undesirable interfacial phases such as Hf silicides and SiOx are known to form and degrade the performance of devices. It has been postulated that these interfacial phases are related to the segregation of O defects (vacancy or interstitial) to the interface. In this work, we examine the thermodynamic and kinetic driving forces for the segregation of isolated and clustered O defects (vacancies and interstitials) to the Si:HfO2 interface. Using first principles density functional theory calculations, we have determined the formation and migration energies per O defect within bulk HfO2 and at the Si:HfO2 interface. Our results indicate that isolated as well as a distribution of point defects display large driving forces for interface segregation, allowing for the formation of silicides and silicates. Thus, while an abrupt Si:HfO2 interface may be stable in the absence of O defects, such an interface is unstable to the formation of other phases in the presence of O defects.

3:30PM S20.00006 Sub-Angstrom Distortions of an Epitaxial Oxide on Silicon (001).

YARON SEGAL, FRED WALKER, J.W. REINER, C.H. AHN, Department of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University, ZHAN ZHANG, Argonne National Laboratory — As metal oxide semiconductor field effect transistor (MOSFET) devices are reduced to the nanometer length scale, atomistic control of the silicon-oxide interface is needed in order to fabricate optimally functioning devices. In this work, we present synchrotron x-ray diffraction measurements of a model system, barium oxide grown epitaxially on Si (001), with an interface phase of submonolayer strontium on silicon. Diffraction results show that the 2×1 surface phase that promotes epitaxy transforms into an interface phase between the oxide and silicon, which also has a 2×1 symmetry on the Si (001) surface. Quantitative analysis of the diffraction is consistent with three classes of models; these involve a 2×1 arrangement of alkaline earth metal in the interface phase, sub-angstrom distortions of the oxide film, or a combination of both. These measurements demonstrate how this reconstruction is a true interface phase that can be used to test our current understanding of silicon-oxide interface physics.

3:42PM S20.00007 Experiment and theory on metal/ceramic interfaces.

MANFRED RHLE, Max Planck Institut fr Metallforschung — No abstract available.

4:18PM S20.00008 Theoretical investigation of the interface structure of θ-Al2O3/NiAl(001).

JHY-PIN CHOU, CHING-MING WEI, Institute of Atomic and Molecular Sciences, Academia Sinica, Taipei, 10617, Taiwan — The atomic structure of Ni-Alumina – Al(771) superlattice shows that the compliant oxide causes substantial disorder in the adjacent, soft metal layers. An H “probe atom” is found to bind best in the disrupted metal region, suggesting that this is the locus of initial failure of a protective oxide layer.

4:30PM S20.00009 Calculated atomic arrangement and impurity bonding at a κ-Alumina – Al(771) interface.

PETER J. FEIBELMAN, Sandia National Laboratories — First principles optimization of a κ-Alumina – Al(771) superlattice shows that the incompatible oxide causes substantial disorder in the adjacent, soft metal layers. An H “probe atom” is found to bind best in the disrupted metal region, suggesting that this is the locus of initial failure of a protective oxide layer.

Work supported by the DOE Office of Basic Energy Sciences, Division of Materials Science and Engineering. Sandia is operated by the Lockheed Martin Co. for the U.S. DOE’s National Nuclear Security Administration under contract DE-AC04-94AL85000.
4:42PM S20.00010 Local dielectric constants in metal-oxide and oxide-oxide interfaces: an ab initio approach to address interfacial effects, BORA LEE, CHOONG-KI LEE, SEUNGWU HAN, Ewha Womans Univ., SHANG-HO JEON, BAE-HO PARK, Konkuk Univ. — Recent experiments indicate that the dielectric constants of thin film oxides are strongly affected by interfaces formed between the oxide and metal or between different oxides. Such interfacial effects will be crucial to high-k dielectric stacks employing oxide materials with nanometer thickness. Therefore, systematic studies on interfacial effects are very important for materials selection and process design of gate stacks. In this presentation, we study on local dielectric constants in metal-oxide and oxide-oxide interfaces within the first-principles framework. Firstly, we introduce an efficient method to calculate local dielectric constants by employing slab models exposed to the vacuum. The static as well as optical dielectric constants are obtained from the change in electrostatic potentials upon the application of external electric fields. Our method can be easily adopted using conventional codes without any modification of the program. We apply this method to investigate interfacial dielectric constants in Au/MgO, Ni/ZrO2, Pt/HfO2, Ni/HfO2, Al/HfO2, SiO2/HfO2, and Al2O3/HfO2 interfaces. Our results show the presence of interfacial region with dielectric constants significantly different from that of the bulk. Microscopic explanations will be provided based on the dynamic charges and hardening/softening of phonons.

4:54PM S20.00011 The role of metal/transition metal oxide/organic interface, GUAN-RU LEE, CHIH-I WU, Graduate Institute of Photonics and Optoelectronics, National Taiwan University, Taipei, Taiwan 10617, Republic of China, TUN-WEN PI, National Synchrotron Radiation Research Center, Hsinchu, Taiwan 300, Republic of China — In this paper, we report a study with UPS and XPS data of metal/transition-metal-oxide/organic interfaces. Transition metal oxides are widely used in organic light-emitting (OLEDs) in recently years, such as WO3, ReO3, MoO3, and V2O5. These metal oxides have been proven to be good hole injection layers in OLEDs, interlayers in tandem OLEDs, and nanocomposite electrodes. Although a large number of studies have been made, little is known about the mechanism of metal/transition-metal-oxide/organic interfaces. UPS and XPS data performed by synchrotron radiation research show that these oxides would catch electrons from organic and results in p-type doping in organic material. In addition, there is a significant structure transition from insulating metal oxide to metallic metal oxide. As a result of high work function metallic metal oxides in anode structures and p-type doping organic hole transport layers (HTLs), holes can easily be injected from anode to HTLs. Current-voltage characteristics (I-V) and quantum-efficiency (\(\eta\)) measurements also show the improvement of device performance with insertion of thin transition metal oxides between anodes HTLs.

5:06PM S20.00012 Stability, structure, and electronic properties of chemisorbed oxygen and thin surface oxides on Ir(111), H. ZHANG, Sichuan University, China, A. SOON, The University of Sydney, Australia, B. DELLEY, Paul-Scherrer-Institut, C. STAMPFL, The University of Sydney, Australia — Iridium-based catalysts are widely used in several important chemical reactions. Despite this, very little is known about the surface structure of the catalyst and the atomic and molecular processes involved. As a first step towards a microscopic understanding, we use density-functional theory, coupled with ab initio atomistic thermodynamics [1], to investigate chemisorption of oxygen on Ir(111), and the stability of surface oxides. We find that for on-surface desorption, oxygen prefers the fcc-hollow site for all coverages considered, where with increasing coverage, the adsorption energy decreases substantially. Subsurface adsorption is found to be highly unfavourable. The most favourable surface-oxide-like structure has a tri-layer-like (OIrO) configuration, which however, the (p, T) phase diagram predicts is only metastable. For practically all conditions, except ultra-high vacuum, the bulk oxide is thermodynamically the most stable, and the only other stable phase predicted is the on-surface (2x2)-O structure for coverage 0.25 ML [2]. These studies point to the possible importance of oxidized iridium for heterogeneous oxidation reactions. [1] C. Stampfl, Catal. Today 105, 17 (2005). [2] H. Zhang, A. Soon, B. Delley and C. Stampfl, submitted to Phys. Rev. B.

Wednesday, March 12, 2008 2:30PM - 5:18PM –
Session S21 DCP: Focus Session: Fundamental Issues in Catalysis III

2:30PM S21.00001 Transient FTIR spectroscopy for probing reaction pathways on Au catalysts1, STEVEN H. OVERBURY, Oak Ridge National Laboratory — Au is now well known to be an active catalyst if the Au particles are sufficiently small, less than about 5 nm. The causes for this structure sensitivity are now beginning to be better understood. Computational modeling and measurements of size dependence on a single catalyst are consistent with activity at sites with low coordination numbers, due in part to flexibility of adsorbate geometry in these sites. Although small size and low coordinate sites are important in catalyzing, e.g. the CO oxidation reaction, there appear to be other factors which control the observed activity as demonstrated by catalyst deactivation and unusual temperature dependence. We have performed studies of CO oxidation over Au/TiO2, Au/SiO2, Au/ZnO/TiO2 and Au/FePO4 catalysts to explore reaction pathways and the causes for activation and deactivation. Three different reactor systems, a fast gas transient FTIR spectrometer, a slower transient DRIFTS cell and a steady state plug flow reactor have been used to correlate activity with surface species. Using this operando approach the elementary steps in the CO oxidation reaction have been explored. Striking differences between the supports are found. The effect of various pre-treatments, the evolution of the surface species during “steady state” reaction and the role of carbonate, oxygen storage, water, hydroxyl upon catalyst activation and deactivation have been explored and will be described. Reaction pathways and mechanisms will be proposed and compared for the different catalysts.

3:06PM S21.00002 TBD, BRIAN HAYDEN, University of Southampton — No abstract available.

3:42PM S21.00003 Molecular Factors Determining Selectivity in Catalysis1, FRANCISCO ZAERA, University of California — Achieving high selectivities is arguably the main challenge in heterogeneous catalysis for the 21st century. In complex reaction with competing parallel pathways, small changes in the relative values of the different activation energies are sufficient to switch the selectivity of those processes from one product to another. We in our laboratory have been carrying out mechanistic studies on model metal surfaces to try to identify the key factors that control such selectivity. In this talk we will present several examples of increasing subtlety from that work, with focus on the conversion of hydrocarbons. Specifically, we will discuss issues of regioselectivity and stereoselectivity in early dehydrogenation steps, and how those affect selectivity in the conversion of olefins. Time permitting, we will also discuss issues related to the bestowing of enantioselectivity on solid surfaces.

4:18PM S21.00004 The nucleation and growth of ordered Fe and FeO nanoparticles on reconstructed Au(111) surfaces, NEETHA KHAN, CHRISTOPHER MATRANGA, U.S. Dept. of Energy — Iron-based catalysts, including iron oxides, are an important class of materials with relevance to Fischer-Tropsch catalysis and gas-sensing applications. By growing nanostructured particles on single-crystal surfaces, we can create a model system to study size and shape effects on reactivity. We have studied the formation of monolayer thick iron oxide nanoparticles and thin films on the reconstructed Au(111) surface. STM, XPS, ISS, and LEED were used to evaluate the structure and composition of the iron oxide nanoparticles and films as a function of growth conditions. Iron oxide was grown by depositing iron on Au(111), followed by oxidation at room temperature and annealing to 700 K. XPS results indicate that the Fe is oxidized at room temperature, but the STM results indicate that the particles are not ordered until after annealing to 700 K. Atomically-resolved STM images show that at 0.3 ML Fe coverage, iron oxide nanoparticles, pseudo-hexagonal in shape, are formed, with large defects occurring in the corners. STM images of FeO particles over 0.5 ML Fe also show evidence of a non-coincidence overlayer lattice with a short periodicity of 0.25-0.3 nm modulated by a larger periodicity of approximately 3.5 nm. The larger periodicity results from a moiré pattern formed between the iron oxide overlayer and the underlying Au(111) surface.

4:30PM S21.00005 Dynamic structure in Pt nanoclusters on γ-alumina1, F. VILA, J.J. REHR, J. KAS, Dept. of Physics, U. of Washington, R.G. NUZZO, Dept. of Chemistry, U. of Illinois at Urbana-Champaign, A.I. FRENKEL, Yeshiva U. — Pt nanoclusters on γ-alumina exhibit a number of unusual phenomena including large structural disorder and bond-length contraction with increasing temperature. We investigate this behavior for a prototypical 10-atom Pt cluster using real-time, temperature-dependent simulations combining density functional theory/molecular dynamics and x-ray spectroscopy theory. We find that the cluster structure is dynamically varying in shape and topology on a time scale long compared with internal vibrations. Moreover, the clusters are not rigidly attached to the surface and occasionally pick up or discard a PtO bond. This real-time approach suggests that these nanoclusters are comprised of two distinct populations of Pt atoms depending on the charge transfer from the surface, and reproduces many of their unusual properties.

1Supported by DOE Grants DE-FG02-04ER15109 (FV and JJR), DE-FG03-97ER45623 (JJR), DE-FG02-03ER15476 (RGN and AIF), and NIH NCRR BTP Grant No. RR-01209 (JJK), and by DOE computer support at NERSC.

4:42PM S21.00006 In Situ Characterization of Ethylene Hydrogenation on Pt Powder Using Mass Spectrometry-Sum Frequency Generation Technique, BRYAN HSU, Department of Chemistry, Massachusetts Institute of Technology, SHAWN DOUGAL, PAUL STEVENS, MOHSEN YEGANEH, Exxonmobil Research and Engineering Company, Corporate Strategic Research — Bridging the pressure gap has been of paramount importance to the field of surface science. Unfortunately, the available techniques used to characterize catalytic surfaces have all been limited in some degree by a combination of factors (e.g. low pressure regimes, ex situ analysis, and low surface area catalysts), which do not fully replicate industrially relevant conditions. Here, we present in situ observation of ethylene hydrogenation of Pt powder in a high pressure regime. Using total internal reflection sum frequency generation (TIR-SFG) we are able to identify ethyl, ethylidyne, di-sigma-bonded ethylene, and pi-bonded ethylene surface intermediates and find that these are all present under reactive conditions as monitored with mass spectrometry (MS).

4:54PM S21.00007 Dissociation of water and Acetic acid on PbS from first principles1, ALESSANDRA SATTA, PAOLO RUGGERONE, CNR-INFN SLACS, GIOVANNI DE GIUDICI, Dept. Earth Science, University of Cagliari — The adsorption of complex molecules at mineral surfaces are crucial ingredients for understanding the mechanisms that rule the interaction between minerals and the biosphere and for predicting both the stability and the reactivity of minerals. The present work focuses mainly on the early stages of different adsorption reactions occurring at both the cleavage surface and a high-index vicinal surface of galena (PbS). We have studied the dissociation mechanism of water and acetic acid on the galena surfaces by means of ab initio calculations within the framework of density functional theory in the generalized gradient approximation and of pseudopotential approach. The calculated adsorption energies of the molecules indicate the stepped surface as the most reactive, as expected. The free energy surface during the reaction of ab initio calculations within the framework of the density functional theory in the generalized gradient approximation and of pseudopotential approach. The transition metal clusters generated in the gas-phase and deposited on a Au(111) surface. Using a magnetron cluster source, we are able to produce a wide range of heterogenous reactions such as hydrodesulfurization (HDS)2. However, understanding the role of size, structure, composition and support interactions of the MoS2 particles in these heterogenous reactions has not yet been resolved due to the inhomogeneity of commercial catalysts. Work done in our laboratory is geared towards preparing homogenous samples in ultra high vacuum that can serve as model systems for these types of catalytic reactions. We are currently investigating the reactivity of size-selected transition metal clusters generated in the gas-phase and deposited on a Au(111) surface. Using a magnetron cluster source, we are able to produce a wide range of nanocluster stoichiometries including the Mo9S82+ cluster, which has been observed as the metal core of the well-known Chevrel phase2. The work presented focuses on characterization of the Mo9S82+ cluster deposited on a Au(111) single crystal using techniques such as Auger, photoemission spectroscopy, and thermal desorption. In addition, preliminary reactivity studies will be presented of the supported Mo9S82+ cluster with small sulfur containing molecules. 1. Topsoe, H.; et.al; Hydrotreating Catalysis; Springer: New York, 1996. 2. Umarji, A. M.; et.al.; J. Phys. Chem. Solids 1980, 41, 421.

Wednesday, March 12, 2008 2:30PM - 5:30PM
Session S22 DMP DPOLY: Focus Session: Organic Electronics: Contacts and Interfaces
Morial Convention Center 214
2:30PM S22.00001 Energeterics of organic semiconductor interfaces: enhancing injection via chemical doping1. ANTOINE KAHN, Princeton University — Chemical doping of organic molecular films is a powerful way to improve charge injection and transport in organic devices, and to enhance device functionality. The formation of narrow depletion regions at doped organic-conductor interfaces facilitates injection via carrier tunneling through the barrier, and allows the use of moderate work function and non-reactive metals as efficient contacts. P-doping with the electronegative molecule, tetrafluoro-tetracyano-quinodimethane (F4TCNQ), has been used on a number of hole-transport materials. N-type doping is more challenging, often hindered by the energetic requirements of transferring an electron from the dopant HOMO to the host low lying LUMO. We recently demonstrated efficient n-doping of the electron transport material tris2,5-bis(3,5-bis-trifluoromethyl-phenyl)-thieno[3,4-b,h]-n,14,5,8,9,12-hexazatriphenylene (THAP), which has a 4.59 eV electron affinity (EA), with cobaltocene (CoCp, IE = 4.07 eV). We now introduce a stronger n-dopant, i.e. decamethycobaltocene (CoCp*2), and demonstrate n-doping of copper phthalocyanine (CuPc, EA = 3.25 eV). CoCp*2 is found to have a remarkably low IE of 3.30 eV. N-doping is evidenced by a large upward swing of the Fermi-level in the gap of CuPc, and confirmed by current-voltage (I-V) measurements. A 10^3- to 10^5-fold increase in current density of the interface-doped device is compared to the undoped CuPc device is due to enhanced injection. An additional 10^3-fold increase in current density is observed for the uniformly doped device and is attributed to enhanced conductivity of the bulk film. The application of p- and n-doping of CuPc to an organic homojunction p-n diode with a 1.47 eV built-in potential is demonstrated.

3:06PM S22.00002 Electronic Structure of Interfaces and Heterojunction Ambipolar Organic Thin Film Transistor. YONGLI GAO, HUANJUN DING, University of Rochester, HAIBO WANG, DONGHANG YAN, Institute of Applied Chemistry, The Chinese Academy of Sciences — There has been a considerable interest in forming ambipolar organic thin film transistors (OTFTs) due to their advantageous for integrated circuits. Recently, Shi et al. observed a substantial improvement for both the hole and the electron mobility in ambipolar OTFTs based on the heterojunction formed between copper-hexadecafluoro-phthalocyanine (F16CuPc) and 2,5-bis(4-biphenyl) bithiophene (BP2T). We examined the interface formation between F16CuPc and BP2T using ultraviolet photoemission (UPS) and inverse photoemission spectroscopy (IPES). It is observed that in F16CuPc/BP2T the heterojunction is characterized by band bending in both materials, while in BP2T/F16CuPc the band bending is confined in BP2T only. For F16CuPc/BP2T, the band bending of BP2T and F16CuPc are 0.40 and 0.35 eV, respectively. The band bending region is about 15 nm in both materials, from which the Debye lengths of the materials can be deduced. The combination of the band bending and finite Debye lengths may provide an explanation to the observed ambipolar behavior and improved mobility of the OTFTs based on such heterojunctions.

3:18PM S22.00003 Sub-100 nm Contact Effects in Poly 3-hexylthiophene (P3HT) JEFF WORNE, DOUGLAS NATELSON, Rice University — Poly 3-hexylthiophene (P3HT) is a widely studied, versatile material used in organic electronics. Important to understanding the behavior of P3HT lies in its interaction with metal contacts. Contact effects between P3HT and metal electrodes can influence charge injection into P3HT, giving rise to a contact resistance and thereby influencing device performance. The origin of this contact resistance still remains poorly understood, but may result from changes in film morphology near the metal contact, charge transfer and band bending near the contact, or both. Understanding the detailed behavior of the interface between P3HT and metal electrodes will allow for optimization of device behavior. Based on previous work, the voltage drop at the P3HT/silicon interface happens over 100 nm. We have fabricated devices on the tens of nanometer scale that directly probe this region, and present data on the effect of channel length versus device resistance as well as data on the temperature dependence of device resistance for gold and platinum electrodes. Implications for contact engineering will be discussed.

3:30PM S22.00004 ABSTRACT WITHDRAWN

3:42PM S22.00005 Infrared study of charge injection in organic field-effect transistors, ZHIQIANG LI, University of California, San Diego — We present a systematic infrared (IR) spectroscopic study of charge injection in organic field-effect transistors (FET). These experiments have revealed new unexpected aspects of both polymers and molecular crystals. IR spectromicroscopy was employed to image the charges in poly(3-hexylthiophene) (P3HT) FETs. The charge density profile in the conducting channel uncovers a density-dependent mobility in P3HT due to disorder effects. Our IR studies of single crystal rubrene based FETs show that charge transport in these devices at room temperature is governed by light quasiparticles in molecular orbitals. This result is at variance with the common beliefs of polaron formation in molecular solids. The above experiments have demonstrated the unique potential of IR spectroscopy for investigating physical phenomena at the semiconductor-insulator interface in FET devices. This work is in collaboration with G. M. Wang, D. Moses, A. J. Heeger (UCSB), V. Podzorov, M.E. Gershenson (Rutgers), Z. Hao, M. C. Martin (ALS), N. Sai, A. D. Meyerholen, M. F. Calhoun, J. Sanchez, D. Olaya, M. E. Gershenson and V. Podzorov (Rutgers), M. E. Gershenson (Rutgers).

4:18PM S22.00006 Studies of Au/SAMs/PEDOT-PSS/Au tunnel junctions, NAN SUN, MARYA LIEBERMAN, STEVEN RUGGIERO, University of Notre Dame — We report on tunneling through thin organic films. Junctions of the form: Au/SAMs/Polymer/Au were prepared on electronic-grade Si substrates with Self-Assembled Monolayers (SAMs) including octanedithiol (HS-C16H33-COOH). A transitional conducting polymer film PEDOT-PSS was spun on to the SAMs layer, and junctions were completed with a gold film. X-ray photoelectron spectroscopy (XPS) was employed to monitor the quality of the SAMs films. The electron tunneling properties including dI/dV and d2I/dV2 versus bias for the SAMs are discussed.

4:30PM S22.00007 Electronic functionalization of organic semiconductors with self-assembled monolayers VITALY PODZOROV, Rutgers University — Self-assembled monolayers (SAM) are widely used in a variety of emerging applications for surface modification of metals and oxides. Here, we demonstrate a new type of molecular self-assembly: the growth of organosilane SAMs at the surface of organic semiconductors. Remarkably, SAM growth results in a pronounced increase of surface conductivity of organic materials, which can be very large for SAMs with a strong electron withdrawing ability. For example, the conductivity induced by perfluorinated alkyl silanes in organic molecular crystals approaches 10^5 S per square, two orders of magnitude greater than the maximum conductivity typically achieved in organic field-effect transistors (OFETs). The observed large electronic effect opens new opportunities for nanoscale surface functionalization of organic semiconductors with molecular self-assembly. In particular, SAM-induced conductivity exhibits sensitivity to different molecular species present in the environment, which makes this system very attractive for chemical sensing applications [1, 2]. M. F. Calhoun, J. Sanchez, D. Olaya, M. E. Gershenson and V. Podzorov, “Electronic functionalization of the surface of organic semiconductors with self-assembled monolayers”, Nature Materials, Nov. 18, (2007).

4:42PM S22.00008 Impedance Spectroscopy of Organic Thin Film Transistors and Contacts1, DANIEL LENSKI, ADRIAN SOUTHERD, MICHAEL S. FUHRER, Department of Physics and Center for Nanoscience and Applied Materials, University of Maryland, College Park, MD 20742 USA — We have developed a novel method of characterizing organic thin films using a 2- or 3-contact transmission line configuration, in which an AC voltage is applied to the thin film and the phase and magnitude of the current are measured. This simple method can shed light not only on the bulk properties of the semiconductor film, but also on the contacts, by varying the effective length scale probed in the sample. We present the results of transmission line measurements of pentacene thin films, with several types of contacts including thin films of carbon nanotubes.

1This work has been supported by the Laboratory for Physical Sciences.
5:06PM S22.00009 Cross-sectional Imaging of Organic Optoelectronic Devices and Molecularily Assembled Nanostructures1, D.W. STEUERMAN, A. GARCIA, R. YANG, D.S. SEFERSOS, H. WU, D. KORYSTOV, A. MIKAHOLOVSKY, J.P. LOVFANDER, G.C. BAZAN, D.D. AWSCHALOM — As the science of organic optoelectronic devices continuously matures, performance often improves at the expense of molecular and architectural complexity. One widespread approach toward optimization is the use of several polymers and hybrid materials, either as blends or in multiple layers. Tools to provide a thorough understanding of interfacial structure are lacking. Therefore, we employed a dual beam scanning electron microscope/focused-ion beam (SEM/FIB) to create device cross-sections that we subsequently investigated by transmission electron microscopy (TEM). High resolution images of an assortment of devices will be presented, including: interfaces of polymer-electrode, polymer-polymer, polymer-nanoparticles, and oligomer-nanoparticles in fully fabricated devices and optical cavities. We directly observed a variety of polymer-polymer interfaces depending upon solvent casting conditions, annealing treatments, and molecular functionality.

1 We would like to acknowledge support from the NSF and CNID.

5:06PM S22.00010 Trapping carriers in organic field-effect transistors by metal nanoparticles1, YU CHEN, MASAYA NISHIOKA, ALLEN GOLDMAN, School of Physics and Astronomy, University of Minnesota — A thin layer of metallic Au nanoparticles was coated on substrates that were used for organic field-effect transistors, in order to study how the motion of carriers in the organic was affected by metal/organic coupling. A huge reduction of mobility was observed, due to the increase of the characteristic activation energy. We speculate that this follows from the polaronic motion of carriers resulted from the organic/metal coupling, similar to the organic/dielectric coupling. Further experiments demonstrate that the performance of those devices can be adjusted by changing the configurations of nanoparticles.

1 This work was supported by the National Science Foundation through the University of Minnesota Materials Research Science and Engineering Center under Grant NSF/DMR-0212032 and by the U. S. Department of Energy under grant DE-FG02-02ER46004.

5:18PM S22.00011 Charge-retraction time-of-flight technique for mobility measurements in organic materials, JASON WALLACE, University of Rochester, RALPH YOUNG, University of Rochester and Eastman Kodak Company, CHING TANG, University of Rochester, SHAW CHEN, University of Rochester and Laboratory for Laser Energetics — This presentation will explore a recently reported, all-electrical technique, charge-retraction time-of-flight (CR-TOF), for the measurement of charge carrier mobility through an organic layer. Carriers are injected and accumulated at a blocking interface, then retracted. The retraction current transient is nearly indistinguishable from a traditional time-of-flight photocurrent. The CR-TOF technique is validated by measurement of the hole mobility of two well-known compounds using a common hole-blocking layer. An advantage of all-electrical technique is the applicability to sample layers less than 300 nm in thickness. This method also offers new opportunities such as catching charges in the middle of the sample layer and an alternate determination of the transition voltage of organic-organic interfaces.

Wednesday, March 12, 2008 2:30PM - 5:30PM — Session S23 DMP GMAG: Focus Session: Nanostructured Oxides and Thin Films Morial Convention Center 215

2:30PM S23.00001 Synthesis, structure and properties of nanostructured manganites1, ARUP KUMAR RAYCHAUDHURI, S.N. Bose National Centre for Basic Sciences, Salt Lake, Kolkata -700098, India — Manganites form a fascinating class of multifunctional perovskite oxides with competing interactions that couple the charge, spin and the lattice. The presence of competing interactions (that often have a comparable energy scale) leads to presence of variety of phases in the manganites that can be tuned by substitution (hole concentration), pressure and magnetic field. Interesting classes of phenomena arise when the size is taken to nanoscales where the ground state can be tuned by the size. The size also tunes the nature of the phase transition and the nature of the electronic transport. Interestingly, the primary change in the lattice structures on size reduction that weakens the orthorhombic distortion. The physical properties of the nanostructured manganites are very distinct and different from that seen in related nanostructured transition metal ferromagnetic oxides like the cobaltates. In this talk we will first describe the methods of synthesis of nanostructured manganites in the form of nanocrystals, nanowires and nanostructured films using soft chemical routes. Arrays of the nanostructured manganites can also be made using such techniques as dip-pen lithography using an Atomic Force Microscope. This will be followed by presentation of results on structures using synchrotron X-rays and neutrons that establish the nature of structural changes on size reduction. The structural changes (as established through the above studies) on size reduction tend to enhance the ferromagnetic interaction in the system. Next we will report a number of physical phenomena that arise as a consequence of the size reduction. This will include destabilization of the charge ordered state, change in the nature of the ferromagnetic transition and non-linear conduction that arises in the nanostructured films due to presence of a large number of grain boundaries. At very low temperatures the transport in the manganites become dominated by such effects as intergrain tunneling and Coulomb blockade.

3:06PM S23.00002 Epitaxial growth of complex oxide films by a chemical solution method, Q.X. JIA, M. JAIN, H. LUO, E. BAUER, Los Alamos National Lab, H. WANG, Texas A&M University, A.K. BURRELL, T.M. MCCLESKEY, Los Alamos National Lab — In the last several years, complex oxides have become the basis for many revolutionary electronic devices because they exhibit a wide range of electronic properties that conventional metallic elements and covalent semiconductors do not possess. Complex oxide films can be grown by physical vapor deposition, chemical vapor deposition, and chemical solution deposition techniques. One of the challenges in solution-based processes of oxide films has been to produce high quality films and at the same time to control the stoichiometry. Here we describe a new chemical solution method called polymer-assisted deposition (PAD) to grow epitaxial oxide films (such as Ba1-xSrTiO3 and La0.7Sr0.3MnO3). We use a new strategy to control the distribution of metals in solution at a molecular level and a mixture of metal precursor and soluble polymer to form a solution with desired viscosity. By actively binding the metal, the polymer serves to encapsulate the metal to prevent chemical reaction while maintaining a uniform distribution of the metal in solution. This ensures a homogeneous metal distribution and prevents unwanted reactivity that can lead to the formation of undesired phases. The successful growth of epitaxial complex oxide films by PAD suggests that PAD is a feasible alternative approach to the growth of high quality films with desired properties.

3:18PM S23.00003 Tailoring The Magnetic Properties of TiO2 Nanobelts, SHEN V. CHONG, KAZUHIO YAMAKI, KAZUO KADOWAKI, Institute of Materials Science, University of Tsukuba — Over the past decades, titanium dioxide has been discovered to exist in various novel nano-structural forms with high aspect-ratio and good crystallinity. Moreover, the addition of dopants and the self-assembling of foreign molecules on the surface can enrich the physical and chemical properties of this semiconductor, enhancing its versatility and further promoting this metal oxide to be an important nano-based functional material. Herein we report on the doping of TiO2 nanobelts with small amount of cobalt, producing a diluted magnetic semiconductor which display a Curie temperature well above room temperature. Co-doped TiO2 nanobelts were prepared hydrothermally by powdering a piece of CoO, TiO2, and O2 single crystal. The magnetic properties of these nanobelts could be tailored via different heat treatment procedure. Annealing the as-synthesized cobalt titanate in air at 1000 K produced nanobelts which are paramagnetic, while evidence of room temperature ferromagnetism could be observed after the same sample was annealed under vacuum at length. An even more pronounce ferromagnetic behavior was observed when the nanobelts were vacuum annealed direct from the titanate phase. These results again show the importance of oxygen vacancies in unison with the presence of cobalt in inducing room temperature ferromagnetism in this semiconductor.
3:30PM S23.00004 Surface anisotropy and orbital moment in Fe$_3$O$_4$ nanoparticles, X. BATILLE, N. PEREZ, P. GUARDIA, O. IGLESIAS, A. LABARTA, IN2UB-UB. Barcelona, A.G. ROCA, M.P. MORALES, C.J. SERNA, ICMMA-SIC, L.M. GARCIA, F. BARTOLOME, J. BARTOLOME, ICMA-CSIC and U. Zaragoza, J.C. CEZAR, ESRF-Grenoble — Fe$_3$O$_4$ nanoparticles (NP) in the 5-20 nm range were synthesised in the presence of a variety of surfactants (oleic acid, PVA, ...). Saturation magnetization $M_s$ almost reaches the expected bulk value for those surfactants covalently bonded to the NP, being much larger than in those NP with just a protective coating. Thermo-remanence and ac susceptibility demonstrate that the surface anisotropy constant in covalently bonded NP is similar to the bulk value. XMCD confirms the dependence of the magnetic moment on the surface bond and suggests that the orbital contribution is smaller in covalently bonded NP. The occurrence of bulk $M_s$ in Fe$_3$O$_4$ NP may thus be related to the crystal and magnetic state at the surface. This is of relevance in biomedical applications to reduce the strength of the magnetic field required to obtain a high magnetic response, while the issue of the orbital contribution in Fe$_3$O$_4$ is under hot debate. Work funded by Spanish NAN2004-08805-C04-02, NAN2004-08805-C04-01, MAT2006-03999, MAT2005-02454 and CONSOLIDER CSD2006-12, and Catalan 2005SGR0969.

3:42PM S23.00005 Novel Oxide Glass-Based Nanocomposites: Development and Structural Characterization, KRISTINA LIPINSKA-KALITA, Department of Chemistry, University of Nevada Las Vegas, Las Vegas, NV, USA, CARLO SEGREG, Physics Division, UCPS Department, Illinois Institute of Technology, Chicago, IL, USA, PATRICIA KALITA, Department of Physics, University of Nevada Las Vegas, Las Vegas, NV, USA, OLIVER HEMMERS, Department of Chemistry, University of Texas at Austin, Austin, TX, USA, YOSHIMICHI OHKI, Department of Electrical Engineering and Bioscience, Waseda University, Tokyo, Japan, J. CECIL, M. CHAVARIA, Physics Division, UCPS Department, Illinois Institute of Technology, Chicago, IL, USA — Glasses can gain new functionalities when specific crystalline phases of nanometer dimensions are nucleated in them. We have developed a series of optically transparent glass-based composites, containing nanometer-sized crystals dispersed within the isotropic host matrix. The composites were characterized using conventional and synchrotron x-ray diffraction as well as synchrotron x-ray absorption spectroscopy. EXAFS studies of Er-doped, gallium-silica glasses and composites will be presented. As the glasses are treated at elevated temperatures, long-range beta-Ga$_2$O$_3$ is observed to evolve from the initially amorphous local structure. However, the same samples show no significant change in the Er local structure, possibly indicating clustering or preferential of Er in proximity to Ga atoms.

3:54PM S23.00006 A Memristive Switching Model of Two-Terminal Programmable Nanodevices, DMITRI STRUKOV, Hewlett Packard Labs, JULIEN BORGHETTI, DUNCAN STEWART, GREGORY SNIDER, R. STANLEY WILLIAMS, HEWLETT PACKARD LABS PACK — The existence of a fourth passive circuit element was proposed by Chua in 1971 from fundamental symmetry arguments. Although he showed that such a device, which he called a ‘memristor’ (acronym for memory resistor), had many interesting and useful circuit properties, until now no one has presented a physical model or example of such an element. We show here using a simple analytical example that memristance arises naturally in systems for which electronic and atomic transport are coupled under an external bias, and we explore the range of validity of the basic nonlinear circuit model of a more general class of dynamical devices called memristive systems. These results serve as the theoretical foundation for understanding a wide range of hysteretic current-voltage behavior observed in next-generation non-volatile resistive RAM devices, including nanoscale titanium oxide crosspoint switches built in our laboratory.

4:06PM S23.00007 Nano-crystalline structure and catalytic activity of TiO$_2$ supported manganese oxide catalysts, SERGEY MAMEDOV, Horiba Jobin Yvon Inc., PADMANABHA REDDY ETTIREDDY, NEERAJA ETTIREDDY, Chemical and Materials Engineering Department, University of Cincinnati, Cincinnati, OH, USA, PUNIT BOOCHLAND, Department of Electrical and Computer Engineering, University of Cincinnati, Cincinnati, OH, USA — A series of TiO$_2$ supported manganese oxide catalysts were prepared by wet-impregnation method. Raman spectroscopy was used to characterize the structure and chemical environment of these catalysts as well as manganese oxides. Spectra of different Mn-oxides are presented. It was found that there is strong correlation of the position and the width of E$_g$ mode of anatase at 146 cm$^{-1}$ and Mn-oxide(s) concentration. Evolution of Raman spectra described in the frame of the optical confinement model. In this model, the position and width of the Raman band depend on structural disorder and size of nano-crystals. Size of nano-crystal was estimated.

4:18PM S23.00008 Very Low Frequency (<1 mHz) Magnetic Noise in La$_{0.67}$Ca$_{0.33}$MnO$_3$ Films, SUDESHNA SAMANTA, ARUP KUMAR RAYCHAUDHURI, S. N. Bose National Centre for Basic Sciences — We report an occurrence of very low-frequency (<1 mHz) resistance fluctuations (noise) in a rare-earth perovskite manganite film. This fluctuation is distinct from 1/f noise and is larger than that. The fluctuation arises due to coupling to magnetization fluctuation. It reaches a peak close to the ferromagnetic Curie temperature $T_c$. The magnetic nature of the transition has been established by sensitivity of the noise to a very low applied magnetic field (<0.1 Tesla). The magnetization fluctuation has been calculated from the resistance fluctuation using the directly measured magnetoresistance. The magnetization fluctuations show peak at a temperature close to but lower than $T_c$ and shows a nontrivial dependence on the applied magnetic field.

3:30PM S23.00009 Film Growth and Surface Energy of (100) CrO$_2$, HUNTER SIMS, KRISHNA CHetry, MAIRBEK CHSHIEV, MINT Center and Department of Physics, University of Alabama, ARUNAVA GUPTA, MINT Center and Department of Chemistry, University of Alabama, WILLIAM BUTLER, MINT Center and Department of Physics, University of Alabama — Rutile structure CrO$_2$ can be grown epitaxially on a rutile TiO$_2$ substrate. Surprisingly, growth in the (100) direction is layer by layer even though surface energies evaluated using the VASP code [1] indicate that the surface energy of TiO$_2$ is less than the sum of the surface energy of CrO$_2$ and the CrO$_2$-TiO$_2$ interface energy. It is known however, that CrO$_2$ (100) surfaces spontaneously decompose to form an epitaxial Cr$_2$O$_3$ phase. We have investigated the conjecture that the layer by layer growth of CrO$_2$ results from the formation of a surface layer substoichiometric in oxygen. If the conjectured substoichiometric layer forms, it must be converted to CrO$_2$ on a rutile TiO$_2$ surface. This is of relevance in biomedical applications to reduce the strength of the magnetic field required to obtain a high magnetic response, while the issue of the orbital contribution in Fe$_3$O$_4$ is under hot debate. Work funded by Spanish NAN2004-08805-C04-02, NAN2004-08805-C04-01, MAT2006-03999, MAT2005-02454 and CONSOLIDER CSD2006-12, and Catalan 2005SGR0969.

4:42PM S23.00010 Study of Magneto-Transmission Spectra of La$_{0.7}$Pb$_{0.3}$MnO$_{3-\delta}$ Epitaxial Thin Film$^1$. SIDNEY MALAK, Binghamton University, RYAN CLAYTON-COX, JIRI STEHLIK, JIAN-QING WANG, Binghamton University — Magneto-transmission (MT) of epitaxially grown La$_{0.7}$Pb$_{0.3}$MnO$_{3-\delta}$ was measured. ThermoElectron Nexus 670 FT-IR spectrometer equipped with an electromagnet was used to obtain IR spectra in the range of 350 to 15000 cm$^{-1}$ in various applied magnetic fields up to 1.0 Tesla. For optimal magneto-spectroscopic measurements in transmission, the studied film had a thickness of 190 nm, with a maximum value up to 80% at 320 K in the colossal magnetoconductance (CMR) effect in 5.5 Tesla. It was observed that the MT scale proportionally with the applied magnetic field and was largest at longer wavelengths below 4000 cm$^{-1}$. In this far infrared range, the maximum observed MT value was 4.0 % at 1.0 Tesla. Beyond FIR range the MT curves monotonically decrease with frequency, until the effect vanishes at 12,000 cm$^{-1}$. Such crossover of magneto-spectroscopic responses from IR to optical frequencies is the first evidence of gradual disappearance of the magneto-dynamics at higher frequencies. Compared with the CMR effect, the measured MT property resembled that of the CMR closely in the field range and frequency ranges studied.

4:54PM S23.00011 Ferromagnetism in Co doped anatase TiO$_2$ thin films mediated by Co-Ti$^{3+}$O$_3$ complexes. MARIA VARELA, Oak Ridge National Lab, KELLI GRIFFIN-ROBERTS, University of Washington, SERGEY RASHKEEV, Idaho National Lab, MATTHEW PANTELIDES, Vanderbilt University, STEPHEN PENNYCOOK, Oak Ridge National Lab, KANNAN KRISHNAN, University of Virginia — The correlation of spherical aberration in the STEM has enabled sub-Angstrom imaging and spectroscopy, and, in favorable cases, direct imaging of light atoms and interstitials. We identify the origin of ferromagnetism in Co$_{0.03}$TiO$_2$ anatase thin films by combining STEM, EELS and DFT calculations. The films are insulating and ferromagnetic at room temperature. Ferromagnetism is enhanced by a post growth vacuum annealing suggesting a defect-mediated mechanism in these films. DFT finds interstitial Co to be energetically preferred over substitutional Co. STEM imaging reveals the interstitials in the predicted sites, and EELS finds reduced Ti in adjacent columns, also predicted by DFT. The combination of STEM-EELS-DFT therefore identifies the defect responsible for the magnetism: an O vacancy binds to the interstitial Co to form a Co-Ti$^{3+}$O$_3$ complex, with a magnetic moment in good agreement with the observed value. Research sponsored by Div. of Materials Sciences and Engineering US DOE, and NSF/ECS 0224138.

5:06PM S23.00012 Nonmetal-metal transition in anatase Nb-doped TiO$_2$. TARO HitsuSUGi, Advanced Institute for Materials Research, Tohoku University, HIDEYUKI KAMISAKA, KOICHI YAMASHITA, HIROYUKI NOGAWA, TETSUKAZU TSURUHAMA, Univ. of Tokyo, SHOICHIRO NAKAO, YUTAKA FURUBAYASHI, NAOMI YAMADA, Kanagawa Academy of Science and Technology (KAST), YUSUHI HIROSE, TOSHIHIRO SHIMADA, TETSUYA HASEGAWA, Univ. of Tokyo — Anatase TiO$_2$ show nonmetal-metal transition on Nb doping. Epitaxial Ti$_{0.94}$Nb$_{0.06}$O$_2$ (TNO) thin film exhibits low electrical resistivity, $\rho \sim 1.7 \times 10^4 \ \Omega$$cm$ at 300 K, comparable to highly-conducting transition metal oxide, ReO$_3$ and Na$_2$WO$_3$. This TNO is an n-type degenerate semiconductor with carrier density exceeding 10$^{21}$ cm$^{-3}$. We have studied the electronic structure of this TNO system using resonant photoemission spectroscopy and compared with first-principles calculations. The first-principles calculations reveal that there is no impurity state arising from Nb doping, and partial density of states of Nb contribute to both valence band and conduction band. These results imply that Nb is highly-hybridized with Ti and O orbitals, resulting in high activation efficiency of Nb which leads to high carrier density in the TNO system. Resonant photoemission spectra clearly show wide band gap without impurity state with Fermi level located in the conduction band.

5:18PM S23.00013 Carrier mediated Ferromagnetism in Cr: In$_2$O$_3$. RAGHAV PANGULURI, P. KHAREL, C. SUKAKAR, R. NAiK, B. NADGORNlj, G. LAwES, Department of Physics and Astronomy, Wayne State University, Detroit, MI 48201, R. SURYANARAYANAN, LPCES, Cr$_2$O$_3$, ICMnO, Universite Paris-Sud, 91405 Orsay, France, V. M. NAiK, Department of Natural Science, University of Maryland-Dean, Dearborn, MI 48128 — While a number of Dilute Magnetic Semiconducting Oxides (DMSO), when doped with transition metals, exhibit ferromagnetism well above room temperature, most of them are insulating and hence the relationship between the charge carriers and ferromagnetism remains unclear. Here, we investigate a high Curie temperature DMSO, Cr:In$_2$O$_3$, which is made conductive down to low temperatures. Films of various thicknesses ranging from 200 nm to 1100 nm were grown on sapphire substrate by rf sputtering. Upon vacuum annealing, the samples became both magnetic (with the saturation magnetization $\sim 0.07 \mu_B$/Cr) and highly conductive, in contrast to as-prepared samples which were both non-magnetic and insulating. Point Contact Andreev Reflection (PCAR) spectroscopy with the superconducting Sn tip demonstrated significant (50 % ± 5%) transport spin polarization, strongly suggesting that ferromagnetism in Cr:In$_2$O$_3$ is carrier-mediated. We will discuss the implications of these results on our understanding of the nature of ferromagnetic interactions in DMSOs, as well Cr: In$_2$O$_3$ potential applications as a spin injector.

Wednesday, March 12, 2008 2:30PM - 4:54PM — Session S24 DCMP: Fullerenes (not nanotubes) Morial Convention Center 216

2:30PM S24.00001 Magnetic molecules made of nitrogen or boron-doped fullerenes$^1$. CHIH-KAI YANG, Chang Gung University — By using density functional theory we investigate the electronic structure of a fullerene C$_60$ molecule doped with nitrogen atoms. We find that as long as the number of the impurity atoms is odd the doped fullerene turns magnetic, with its magnetic moment determined by the way the impurities are bonded with the carbon cage. For even number of impurities the pairing of the electrons exclude the appearance of magnetism. Similar results can be deduced by Raman and PES measurements which can then be used to assess the density-functional theory results. Although experimental and computed electron-phonon coupling agree on the total magnitude of the coupling, they do not on the contributions of the individual vibrational modes. Density-functional theory calculations indicate that high frequency modes are responsible for most of the coupling whereas experiments suggest that low frequency modes are the dominating contribution. Up to now, only calculations using the local density approximation (LDA) were performed. In this study, we investigate the effect of exact-exchange functionals, such as B3LYP, on the computed electron-phonon coupling of the different vibrational modes.

$^1$Supported by the National Science Council of the Republic of China

2:42PM S24.00002 Electron-phonon coupling in C$_{60}$ using exact-exchange functional. JONATHAN LAFLAMME JANSEN, MICHEL CÔTÉ, Département de physique et Regroupement québécois sur les matériaux de pointe (RQMP), Université de Montréal, Canada — The superconductivity in C$_{60}$ doped crystals is now well understood as a phonon mediated interaction. The strength of the electron-phonon coupling can be deduced by Raman and PES measurements which can then be used to assess the density-functional theory results. Although experimental and computed electron-phonon coupling agree on the total magnitude of the coupling, they do not on the contributions of the individual vibrational modes. Density-functional theory calculations indicate that high frequency modes are responsible for most of the coupling whereas experiments suggest that low frequency modes are the dominating contribution. Up to now, only calculations using the local density approximation (LDA) were performed. In this study, we investigate the effect of exact-exchange functionals, such as B3LYP, on the computed electron-phonon coupling of the different vibrational modes.
2:54PM S24.00003 Electron Transfer and Localization in Endohedral Metallofullerenes

SHENYUAN YANG, ICQS and Institute of Physics, Chinese Academy of Sciences; U of Tennessee; ORNL, MINA YOON, ORNL; U of Tennessee, CHRISTIAN HICKE, Michigan State U, ZHENYU ZHANG, ORNL; U of Tennessee, ENGE WANG, ICQS and Institute of Physics, Chinese Academy of Sciences — Endohedral metallofullerenes constitute an appealing class of nanoscale building blocks for fabrication of a wide range of nanomaterials. One open question of fundamental importance is the precise nature of charge redistribution with the carbon cages (C_{60}) upon metal encapsulation. Using ab initio density functional theory, we systematically study the electronic structure of metallofullerenes, focusing on the spatial charge redistribution. For all large metallofullerenes (n > 32), the valence electrons of the metal atoms are all transferred to the fullerene states. Surprisingly, the transferred charge is found to be highly localized inside the cage near the metal cations, rather than uniformly distributed on the surfaces of the carbon cage as traditionally believed. This counterintuitive charge localization picture is attributed to the strong electrostatic-molecular interactions within the systems. These findings may prove to be instrumental in the design of novel fullerene-based functional nanomaterials.

3:06PM S24.00004 Light Alkaline-Earth-Metal Coated Carbon Fullerenes as Effective Hydrogen Storage Media

MINA YOON, ORNL/U; of Tennessee, SHENYUAN YANG, Chinese Academy of Sciences/U. of Tennessee, CHRISTIAN HICKE, Michigan State U, ENGE WANG, Chinese Academy of Sciences, DAVID GEOHEGAN, ORNL; SHENYUAN YANG, ORNL/U. of Tennessee — We propose functionalizing carbon nanostructures with light alkaline-earth metals for use as hydrogen storage media. To support this idea, we investigate the feasibility of coating C_{60} fullerenes with light alkaline-earth metals and analyze the hydrogen storage capacities of the resulting compounds. We find a new and unique binding mechanism responsible for the strong binding between Ca or Sr atoms and C_{60}. Our theory explains experiments showing that C_{60} can be easily covered by a monolayer of Ca or Sr atoms. The coating results in a charge redistribution leading to electric dipolar fields around the metal atoms through which the fullerene becomes a ideal hydrogen-attractor with a binding strength larger than that of alkali carbon complexes but small enough to prevent hydrogen dissociation in the case of transition metal decorated fullerenes. With a hydrogen uptake of more than 8.4wt% and a binding energy of \approx 0.46eV/H2 on C_{60}, Ca is superior to currently used coating elements.

3:18PM S24.00005 An Investigation of Magnetic, Electronic and Structural Properties of Metallofullerenes

S. VINCENT ONG, MEICHUN QIAN, SHIV KHANNA, Dept. of Physics, Virginia Commonwealth Univ., Richmond, VA 23284 — Gadolinium based endohedral metallofullerenes Gd_{x}N@C_{60} functionalized with OH radicals have been found to enhance the relaxivity by orders of magnitude over conventional agents and are being sought as new contrast agents in magnetic resonance imaging (MRI). Using state of the art density functional theory (DFT) in the regime of the local density approximation with the on-site Coulomb interaction (LSDA + U), we have carried out theoretical studies to determine the electronic and magnetic properties of gadolinium-based and lutetium-based nitride fullerenes, namely Lu_{x}Gd_{x}N@C_{60} (x = 1-2). While Gd_{x}N@C_{60} has previously shown promising features as a contrast agent, the idea of replacing gadolinium atoms by lutetium has been proposed to result in a mixed-metal species for multi-modal imaging. Our results indicate that Lu_{2}GdN@C_{60} is the most stable of all possible configurations with a binding energy 16.57 eV, can be considered for use as both an MRI contrast agent, due to gadolinium’s high magnetic moment, and as a potential radioactive therapeutic or diagnostic agent, by neutron activation of a lutetium radioisotope. These results along with details of electronic structure will be presented.

3:30PM S24.00006 First-Principles Investigation of C_{60}-Pd Interface

LAN LI, HAI-PING CHENG — Conductivity and hybridization of C_{60}-Pd nano-system have been investigated using density functional calculations. From analysis of geometry, energetics and electronic structures, the interaction of C_{60} mono-layer and Pd clusters gives rise to electronic charge transfer at the interface and facilitates the dissociation and uptake of hydrogen, which lead to hydrogen storage. The first-principles studies are carried out by self-consistent plane-wave method. The interaction between ions and electrons is described by projector-augmented wave (PAW) approach. In our calculations, the C_{60} monolayer is doped by the Pd_{n} atoms on h-BN with n = 1-4 and 15, but it also forms a metal-C_{60} nano-array with the Pd clusters. Charge transfer occurs at the interface, from the Pd atoms towards the C_{60} monolayer. This electronic property strongly depends on the nature and number of metal atoms. A large amount of charge transfer between the Pd atoms and the C_{60} monolayer indicates a strong interaction under the ionic effect, in contrast with the interaction of the C_{60} monolayer and a metallic surface. The h-BN surface merely gains 0.1 electrons via C_{60}, proving that h-BN is an insulating material. We also find that Pd is a good catalyst for dissociation and storage of hydrogen on the C_{60} molecules. Hydrogen is sufficiently dissociated in the presence of the Pd atoms/clusters, which assists in bonding of the individual H atoms to C_{60}. Dehydrogenation of C_{60}Pd is also discussed in energetics.

3:42PM S24.00007 Investigation of Trapping Positions for Beryllium Atom in C_{60} Fullerene and Electron Densities at 'Be Nucleus

LEE CHOW, ARCHANA DUBEY, H.P. SAHA, UCF Orlando, GARY S. COLLINS, Washington State University, Pullman, R.H. SCHEICHER, Uppsala University, Sweden, N.B. MAHARJAN, Tribhuvan University Nepal, SUNY Albany, S.R. BADU, R.H. PINK, M.B. HUANG, SUNY Albany, T.P. DAS, SUNY Albany, UCF Orlando — We are investigating, using first-principles Hartree-Fock Roothaan procedure, the trapping sites for 'Be atom in C_{60} Fullerene, following broadly the same procedure as in earlier work by our group for trapping of muonium [1]. A number of possible sites, including the center of the C_{60} mono-layer, the position near the fullerene surface both outside and inside C_{60} are being studied including the effect of relaxation in the positions of neighboring C atoms. Electron densities at the 'Be nucleus will be presented for the sites where the binding energy is positive to attempt to understand the observed anomalous electron capture rate compared to other systems where trapped 'Be atom has been studied [2]. Results of our investigations for 'Be atom in graphite and graphene will also be presented for comparison with 'Be in C_{60}. Possible influence of many-body effects will be discussed. [1] O. Donzelli, T. Biere, T.P. Das, Sol. St. Comm. 90 663(1994), Indian J. Phys. 67 (Special Issue) 35 (1993) [2] Ohtsuki et al, Phys. Rev. Lett. 93,112501, (2004)

3:54PM S24.00008 Transfer of a Single Carbon Fullerene at Small Nano-Gap

YOSHIFUMI OSHIMA, YOSHIHIKO KURUI, KUNIO TAKAYANAGI, Tokyo Institute of Technology, PRESTO-JST COLLABORATION, CREST-JST COLLABORATION — A single carbon fullerene shows jump-to-contact behavior in conductance evolution when bringing an electrode close to it. Theoretically, the jump-to-contact behavior has been explained by deformation of the fullerene, but, it has not been proved experimentally. In this study, we investigated the geometry of the fullerene at the moment of jump-to-contact using transmission electron microscope – scanning tunneling microscope system. A single carbon fullerene was synthesized in-situ [1]. We sometimes observed that the single carbon fullerene was transferred back and forth between both electrodes at the bias voltage of 0.6 V when the gap distance became almost 1nm which was still tunneling regime in conductance. Such a transfer was never observed when the bias voltage was lower than 0.1 V. Since the conductance showed the order of 10^{-11} G0 in pulse at the moment of transfer, the fullerene was suggested to be expanded along the gap to have a contact with the opposite electrode. [1] M. Yoshida et al., Jpn. J. Appl. Phys. 46, L67 (2007).
4:06PM S24.00009 Boron Fullerenes: An Electronic Structure Study, ARTA SADRZADEH, OLGA PUPY-SHEVA, Rice University, IHSAN BOUSTANI, Berg Univ Gesamtsch Wuppertal, BORIS YAKOBOSON, Rice University, BORIS I. YAKOBOSON TEAM, IHSAN BOUSTANI COLLABORATION — Using ab initio calculations, we study electronic structure and frequency modes of $C_{60}$, a member of boron fullerenes family made from boron isomorphs of carbon fullerenes with additional atoms in the centers of hexagons. We also investigate geometrical and electronic structural properties of double-rings with various diameters, which are important as building blocks of boron nanotubes, and as the most stable clusters among the studied isomers with more than 36 atoms. Double-rings also appear as building blocks of $C_{60}$. Furthermore, we investigate the possibility of further stabilizing some of fullerenes by depleting them.

4:18PM S24.00010 Magic Number of a Spherical Ca Cluster on $C_{60}$, SUNGJONG WOO, YOUNG-KYUN KOWN, University of Massachusetts Lowell — Since the discovery of fullerenes, there have been a lot of interest in investigating the metal-fullerene clusters. Mass spectrum on the metal(M) covering on a $C_{60}$ complex showed a peak at $M_2C_{60}$. This magic number was theoretically explained using the geometry based on the C-Ca binding. However, such theories could not clearly reveal why the peak at $M_2C_{60}$, especially for calcium clusters, is so prominent compared to smaller number of metal atoms. Using ab initio MD simulations, we have found that for Ca covering with less than 32 atoms, Ca atoms tend to be retracted to a cluster rather than to be bound on each face of $C_{60}$, even though the Ca atoms are deposited symmetrically. Such a cluster does not have specific number of atoms and it is bound to $C_{60}$ through van der Waals interaction. However, once Ca forms a spherical shell with 32 atoms, the structure is quite rigid so that it will not be retracted to a cluster. We have also found that the interaction between an individual Ca atom and each $C_{60}$ face gets loosen so that $C_{60}$ can rotate within a solid phase. The phonon spectrum has been obtained by spectral analysis and electronic orbitals of $Ca_{32}C_{60}$ will also be presented.

4:30PM S24.00011 First principles study of cubane and alkali doped $C_{60}$ solids, YOUNG-MOO BYUN, VINCENT CRESPI, Department of Physics, Penn State University — Alkali doped fullerene ($C_{60}$) solids have been studied widely due to their interesting physical properties. Lately, an experimental group succeeded to dope cubane ($CBH_8$) into the octahedral voids of face-centered-cubic (FCC) $C_{60}$ solids, demonstrating that not only atoms (and polyatomic cations), but also small neutral molecules can intercalate into $C_{60}$ solids. We study the electronic properties of cubane-doped $C_{60}$ solids using first-principles techniques and show that $C_{60}$ solids doped with cubane and alkali metals, in which alkali metals such as K and Rb occupy the tetrahedral voids are energetically favorable. Cubane molecules substantially dilate the $C_{60}$ lattice, resulting in a very large density of states in a single-particle treatment and pronounced tendency towards electronic instability.

4:42PM S24.00012 First principles electronic structure calculation of interstitial P doped $C_{60}$ solid, SHIZHONG YANG, GUANG-LIN ZHAO, DIOLA BAGAYOKO, Physics Department, Southern University and A&M College, Baton Rouge, LA70813 — $C_{60}$ solid has a very low thermo-conductivity that can be utilized to improve the figure-of-merit of thermo-electric devices. The selection of suitable doping elements and doping concentrations in $C_{60}$ bulk semiconductors, for best performance in thermoelectric applications, is of great interest. In this work, we calculated the electronic structure of solid $C_{60}$, interstitially doped with P, at concentrations varying from 1.240 to 1.60. We employed a density functional potential and the plane wave method. Both local density approximation (LDA) and generalized gradient approximation (GGA) potentials were considered. The stability, the electron densities of states, dopant location, carrier type, volume change, and charge transfers of P doped $C_{60}$ were calculated and compared to those of B, N, and Co doped $C_{60}$ solids. In the 1.60 doping case, we found that P doped $C_{60}$ solid is an n-type semiconductor with the dopant energy levels in the band gap, close to the top of conduction band. This work was supported in part by the Department of the Navy, Office of Naval Research (ONR, Grant No. N00014-4-1-0067) and by the National Science Foundation (Award No. HRD050362).

Wednesday, March 12, 2008 2:30PM - 5:42PM – Session S25 DPOLY: Gels and Elastomers Morial Convention Center 217

2:30PM S25.00001 Large strain deformation of hydrophobically modified polyelectrolyte hydrosols, GUILLAUME MIQUELARD-GARNIER, COSTANTINO CRETON, DOMINIQUE HOUDRET, ESPCI — Hydrosols made from charged polyelectrolytes have been widely studied for their ability to absorb large amounts of water. However this occurs usually at the expense of mechanical properties. Because of recent reports describing very tough charged hydrosols, we have investigated the large strain and fracture resistance of novel chemically and physically crosslinked hydrosols. The backbone was polyacrylic acid modified with hydrophobic side groups and subsequently chemically crosslinked with thiol-ene chemistry. We performed compression/decompression experiments up to large strains and found that at polymer concentrations of 5-8 wt% these gels depart significantly from Gaussian behaviour at strains above 150% showing a pronounced strain hardening. We argue that this hardening leading also to a significant increase in ionic strength or the substitution of water with an organic solvent reduces or eliminates the effect implying that it is the charges that cause the hardening and the hysteresis.

2:42PM S25.00002 Creasing instability of surface-attached hydrogels, RYAN C. HAYWARD, VERONICA TRUJILLO, JUNGWOOK KIM, ANESIA BURNS, University of Massachusetts, Amherst — Surface-attached hydrogels provide a convenient means to tune physical properties. Lately, an experimental group succeeded to dope cubane (C8H8) into the octahedral voids of FCC $C_{60}$ solids, demonstrating that not only atoms (and polyatomic cations), but also small neutral molecules can intercalate into $C_{60}$ solids. We study the electronic properties of cubane-doped $C_{60}$ solids using first-principles techniques and show that $C_{60}$ solids doped with cubane and alkali metals, in which alkali metals such as K and Rb occupy the tetrahedral voids are energetically favorable. Cubane molecules substantially dilate the $C_{60}$ lattice, resulting in a very large density of states in a single-particle treatment and pronounced tendency towards electronic instability.

2:54PM S25.00003 Swelling-Induced Deformation of Nanopatterned Polymer Lines, VIJAY TIRU-MALA, CHRISTOPHER STAFFORD, RUI HUANG, LEONIDAS OCOLA, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM, UNIVERSITY OF TEXAS AT AUSTIN TEAM, ARGONNE NATIONAL LABORATORY TEAM — The deformation behavior of isolated poly(N-isopropylacrylamide) nanolines due to swelling is studied to quantitatively establish the parameters governing their mechanical stability. The features are patterned using electron-beam lithography and are supported on a rigid substrate. In the range of 50-250 nm linewidth, we show that the swollen lines undergo Euler buckling with stable higher order modes due to the constraint for polymer chain expansion at the substrate interface. The critical wavelength for buckling surprisingly increases with decreasing line length. The critical wavelength thus becomes a function of the initial length and decreases dramatically as the line length approaches twice the buckling wavelength for infinitely long lines. A critical length, larger than the buckling wavelength for infinitely long features, exists below which the lines remain mechanically stable regardless of their crosslink density. For sufficiently long lines with height-to-width aspect-ratio in the range 0.5-1.7, the scaling relationship for buckling wavelength vs. linewidth suggests that swelling is anisotropic and is more dominant through height than width. The results established in this study are more generally applicable to nanopatterned polymer lines since buckling instabilities involve simultaneous bending and compression, which deform the material with equal force but in opposite directions.
3:06PM S25.00004 Drop spreading and resorption on gel surfaces1, MEHDI BANAHAD, ADRIAN DAERRD, MSC* Denis-Diderot-University of Paris, LAURENT LIMAT, MSC* CNRS & Denis-Diderot-University of Paris — We have studied the dynamics of liquid drops on agar gels, using a visualisation method which captures the evolution of the free surface. A first remarkable observation is that drops of water deposited on the surface do not spread, although the gel consists of up to 99.7% water and as low as 0.3% agarose. Instead, the drop slowly de-wets and resorbs into the gel which swells locally. If the deposited drop contains surfactants, the dynamics is very different. A sharp circular swelling front develops and progressively invades the whole surface. We study the propagation of this front as a function of surfactant and agarose concentration, and compare its typical properties to similar fronts appearing during mass swelling events of bacterial colonies under the same conditions. The observations reveal the complex nature of gel surface physico-chemistry and its aging, and may be related to recent friction measurements at gel interfaces.

3:18PM S25.00005 Anomalous Composition-Dependent Swelling Behavior of Photocrosslinked VP/AA Copolymeric Hydrogels, J. HANNAH LEE, DAVID BUCKNALL, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology — We are investigating the swelling behavior and network structure of vinylpyrrolidone (VP)/acrylic acid (AA) copolymeric hydrogels synthesized using ultraviolet (UV) initiated polymerization. The goal of this work is to develop hydrogels with large expansion volumes but low expansion rates for use in tissue expander applications. In a number of reports, hydrogels composed of VP and AA units have shown that with increasing AA content higher equilibrium swelling ratios (equ) are produced. This behavior is due to higher osmotic pressure induced by the dissociation of carboxyl groups in the AA units into carboxylate anions and hydrogen ions during the swelling. In contrast, in our UV-cured system we found that the value of equ showed a distinct maximum at approximately 50 wt% AA. This anomalous swelling behavior has been studied by measuring the modulus and investigating swelling kinetics as a function of AA content, in addition to the composition and thermal analysis of the dried VP/AA gels. These measurements provide detail of the effective crosslinking density as well as weight between crosslinks for these hydrogels. From these results we propose a model which describes this anomalous behaviour based on the molecular chain structure of the hydrogels.

3:30PM S25.00006 Organogels from Polypeptide-based Block Copolymers, DANIEL SAVIN, DANIEL BERCOCI, SANDEEP NAIK, Department of Chemistry, University of Vermont — A series of AB diblock and ABA triblock copolymers consisting of poly(Lysine) (A) ( = P(Lys(Z)) ) and poly(propylene oxide) (B = PPO) were synthesized and found to form stable, rigid organogels in THF (ca. 1.5 wt.% solutions) at room temperature. In these systems, the protecting group on the P(Lys) side-chains remains intact. As such, the secondary structure of the polypeptide chains retains its helicity over a wide range of solution conditions. Gel formation in these systems results from the assembly of the solvethenphobic P(Lys(Z)) chains, which pack densely in an anti-parallel fashion, minimizing interfacial curvature. These gels exhibited shear-thinning behavior, and as the temperature was heated to 77°C exhibited a gel-sol transition. The gels formed over a time scale of about 10 minutes and had a modulus on the order of 55 Pa. The molecular weight dependence of the gel formation and rheological properties was studied in THF, dioxane and toluene.

3:42PM S25.00007 Soft random solids and their spatial elastic heterogeneity, XIAOMING MAO, PAUL GOLDBART, University of Illinois at Urbana-Champaign, XIANGJUN XING, Syracuse University, ANNETTE ZIPPELIES, University of Goettingen — As a consequence of the disorder that is quenched in at synthesis, random solids are spatially heterogeneous, not only in their structure but also in their response to external conditions. For the case of soft random solids, the heterogeneity in the elasticity is particularly intriguing, owing to its entropic origin and the interplay with incompressibility. We have examined the issue of heterogeneity in the elastic properties of soft random solids by applying replica statistical mechanics to a semi-microscopic model of a random network medium [1]. We have characterized the elastic heterogeneity by random residual stress and Lame coefficient fields, and have determined the statistics of these quantities. We have found that correlations involving the residual stress field are long ranged, and are governed by a universal parameter that also determines the mean shear modulus. Non-affine elastic deformations in soft random solids can also be also studied within this framework. [1] X. Mao, P. M. Goldbart, X. Xing and A. Zippelius, Europhys. Lett. 80, 26004 (2007).

3:54PM S25.00008 Effective removal of entanglement points by network dilution, JOSHUA D. MCGRAW, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — A polymer system in which the chains are much longer than the entanglement molecular weight, Ms >> Mw, is well entangled. When a thin polymer film is uniaxially strained below the glass transition temperature crazes are formed. Measurements of the volume fraction of the deformed versus the undeformed framework. [1] X. Mao, P. M. Goldbart, X. Xing and A. Zippelius, Europhys. Lett. 80, 26004 (2007).

3:30PM S25.00006 Organogels from Polypeptide-based Block Copolymers, DANIEL SAVIN, DANIEL BERCOCI, SANDEEP NAIK, Department of Chemistry, University of Vermont — A series of AB diblock and ABA triblock copolymers consisting of poly(Lysine) (A) ( = P(Lys(Z)) ) and poly(propylene oxide) (B = PPO) were synthesized and found to form stable, rigid organogels in THF (ca. 1.5 wt.% solutions) at room temperature. 3:54PM S25.00008 Effective removal of entanglement points by network dilution, JOSHUA D. MCGRAW, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — A polymer system in which the chains are much longer than the entanglement molecular weight, Ms >> Mw, is well entangled. When a thin polymer film is uniaxially strained below the glass transition temperature crazes are formed. Measurements of the volume fraction of the deformed versus the undeformed regions can give information on the entanglement density of the system[1]. We present results of such deformation experiments, probing using atomic force microscopy, in which well entangled networks have been diluted with chemically identical species of molecular weight, Mw << Ms, which results in a decrease in the entanglement density. Varying the length of the diluted chains provides molecular information on how the entanglement network is swollen.

4:06PM S25.00009 Advances in elastomer reinforcement: slow dynamics, PAUL SOTTA, CNRS/Rhodia Research and Technology, France, STÉPHANE DUPRES, PIERRE-ANTOINE ALCOUY, CNRS/university Paris-Sud, Orsay, France, DANIEL LONG, CNRS/Rhodia Research and Technology, France — Elastomers reinforced with nanometric solid particles or aggregates exhibit remarkable properties which are still far from being completely understood: reinforcement, non linear effects, irreversibility. Important progress has been achieved recently in modeling these properties, based on glassy layers around filler particles. In some cases, reinforcement as a function of temperature and filler volume fraction was explained quantitatively. We shall present an ensemble of experimental results obtained in various filled elastomers, which give some new insight on the microscopic mechanisms of reinforcement. We shall focus on two aspects: local strain measured by combining various techniques (NMR, mechanics, onset of strain-induced crystallization), indicate the level of stress heterogeneity in the elastomer matrix in the presence of reinforcing fillers; slow relaxation phenomena which occur in these systems: stress relaxation, memory effects and irreversibility effects -such as plasticity- indicate the importance of glassy regions within the matrix. Refs: J Berriot et al., Europhys. Lett. 2003, 64, 50-56; D. Long and P. Sotta, Macromolecules 2006, 39, 6282.

4:18PM S25.00010 Polydomain-Monodomain Transition of Randomly Disordered Nematic Elastomers with Different Crosslinking Histories, KENJI URAYAMA, ETSUKO KOHMON, RYO MASHITA, TOSHIKAZU TAKIGAWA, Kyoto University — When the mesogenic molecules (polymers) are crosslinked without a special care for global alignment, the resultant networks have a polydomain structure with local orientational order (in the order of micron) but without macroscopic order. It is well known that such polydomain liquid crystal elastomers (PLCE) exhibit a transition to the monodomain state with global orientation under a finite stretching stress. In present study, we examine the polydomain-monodomain (PM) transition of the two types of PLCE (I-PLCE and N-PLCE) that are originally formed in the high-temperature isotropic or low-temperature polydomain nematic states. They show no appreciable difference in the equilibrium properties such as transition temperature and swelling degree. In contrast, their transition behaviors are significantly different: The transition in I-PLCE occurs sharply at a critical stress whereas that in N-PLCE proceeds gradually over a wide range of stress.
4:30PM S25.00011 New Insights Regarding the Polydomain-to-Monodomain Transition in Smectic Elastomers1, RONALD HEDDEN, HARSHAD PATIL, DANIEL LENTZ, Penn State University — Smectic elastomers are rubber-like networks characterized by lamellar mesophases. Crosslinking a smectic polymer in the absence of an aligning field produces a polydomain elastomer containing numerous randomly oriented microdomains. Under uniaxial tension, polydomain smectic elastomers undergo a transition to a globally oriented “monodomain” state, which may proceed by rotation and/or transient disordering of microdomains. New studies of smectic main-chain elastomers suggest that disordering of microdomains via unfolding of hairpin structures is the dominant mechanism for elongation at intermediate strains. A “plateau stress” is found in plots of the nominal stress vs. strain, which correlates with the average domain size. At very high strains, elastic chains approach the finite extensibility limit, and layer buckling becomes the predominant mechanism for elongation. The elongation mechanism differs significantly from that in mesomorphic poly(diethyldisiloxane) elastomers, which also exhibit a “plateau” in the nominal stress vs. strain curve due to spontaneous random coil-to-helix transition. Because of chain-folding in main-chain smectics, the P-M transition may exhibit some similarities with the cold drawing of semicrystalline polymers.

1Supported by U.S. National Science Foundation grant DMR-0733658.

4:42PM S25.00012 Nematic elastomers: From a microscopic model to macroscopic elasticity theory, PAUL GOLDBART, University of Illinois at Urbana-Champaign, XUANGJUN XING, Syracuse University, STEPHAN PFÄHL, University of Mainz, SWAGATAM MUKHOPADHYAY, Rutgers University, ANNETTE ZIPPELIUS, University of Goettingen — A Landau theory is constructed for the gelation transition in cross-linked polymer systems possessing spontaneous nematic ordering, based on symmetry principles and the concept of an order parameter for the amorphous solid state. This theory is substantiated with help of a simple microscopic model of cross-linked dimers. Minimization of the Landau free energy in the presence of nematic order yields the neo-classical theory of the elasticity of nematic elastomers and, in the isotropic limit, the classical theory of isotropic elasticity. These phenomenological theories of elasticity are thereby derived from a microscopic model, and it is furthermore demonstrated that they are the universal mean-field descriptions of elasticity for all chemical gels and vulcanized media.

4:54PM S25.00013 Elasticity of a Chiral elastomer, APRANA BASKARAN, XUANGJUN XING, Syracuse University — We study the nonlinear elasticity of an elastomer made by crosslinking a chiral polymer melt in its isotropic state. It is shown that such an elastomer is unstable to uniaxial extension/compression and tends to develop a twist along the axis of deformation. Both phonon correlation functions and polarization dependent sound velocity are calculated. Furthermore, when such an elastomer is cooled below the isotropic-nematic transition of the underlying polymer melt, it develops inhomogeneous spontaneous deformations to accommodate the emergent chiral ordering of the polymers. We perform variational analysis of these spontaneous deformation in different regimes of system parameters.

5:06PM S25.00014 Determination of the refractive indices of liquid crystal elastomers1, ISRAEL LAZO, PETER PALFFY-MUHORAY, Liquid Crystal Institute, KSU — Liquid Crystal Elastomers (LCEs) are fascinating materials due to the coupling between orientational order and mechanical strain. We investigate this coupling by studying the optical properties of LCEs. We have measured the ordinary and extraordinary refractive indices of nematic LCEs as function of strain using two different techniques. In both cases, the strain is applied along the nematic director. The first technique is a Brewster’s angle measurement which is based on reflection of the incident light and the second is a conoscopic Mach-Zehnder interferometer based on transmission. We present our experimental results and methods of analysis. We compare our observations with theoretical predictions.

5:18PM S25.00015 Magnetooactive Liquid Crystal Elastomers, MORITZ WINKLER, Heinrich Heine Universitaet Dusseldorf, ANDREAS KAISER, Heinrich Heine-Universitaet Dusseldorf, SIMON KRAUSE, HEINO FINKELMANN, Albert Ludwigs-Universitaet Freiburg, ANNETTE SCHMIDT, Heinrich Heine-Universitaet Dusseldorf, DUESSELDORF TEAM, FREIBURG TEAM — Liquid crystal elastomers (LCEs) offer an interesting spectrum of properties, including temperature induced, fully reversible shape changes connected with considerable development of pulling force, and synthetic diversity. In order to take advantage of LCEs for an extended number of viable devices, it is desirable to trigger such shape changes with electromagnetic fields rather than temperature changes. Magnetooactive LCEs are accessible by the incorporation of superparamagnetic Fe3O4 nanoparticles into oriented nematic side-chain LCEs and offer a contactless activation pathway to activate the nematic-to-isotrope transition by local magnetic heating in external fields due to relaxation processes. In magnetomechanical measurements at 300 kHz and 43 kA m−1, a sample contraction of up to 30 % is observed under field influence, that is fully released when the field is switched off. The load evolved reaches 60 kPa and more. The materials’ ability to respond to a contactless electromagnetic stimulus with a well-defined contraction can be of use for various actuator applications.

5:30PM S25.00016 Calamatic liquid crystal elastomers swollen with bent-core liquid crystals, M. CHAMBERS, Liquid Crystal Institute, Kent State University, Kent, OH, J.T. GLEESON, S. SPRUNT, Department of Physics, Kent State University, Kent OH, A. JAKLI, Liquid Crystal Institute, Kent State University, Kent OH. — Liquid crystal elastomers are composed of a chemically bonded liquid crystal mesogen and an elastomeric polymer network. They exhibit both the properties of rubber elasticity, liquid crystallinity and their interplay, giving rise to unique systems rich in physics. Additionally, bent-core ("banana") liquid crystals are also of interest exhibiting rich phase behaviour and non-classical properties such as flexoelectricity. Here we examine the swelling of calamatic liquid crystal elastomers with various bent-core mesogens and the intriguing properties of the resulting system. The consequential swollen liquid crystalline elastomer systems, can imbibe many times their weight and volume in bent core mesogens until saturated. The homogenous system displays new properties (transition temperatures and phases) depending strongly on the interaction of the elastomer mesogen and bent-core mesogen. Strangely, for some bent-core mesogens this leads to higher temperature phase behaviour than both compounds originally possess. The authors would like to acknowledge support from ONR (N00014-07-1-0440) and NSF (DMR-0606160).

Wednesday, March 12, 2008 2:30PM - 4:54PM — Session S26 DCP: Focus Session: Advances in Atmospheric Aerosol Science — Morial Convention Center 218
2:30PM S26.00001 Tropospheric Aerosol Chemistry via Aerosol Mass Spectrometry. DOUGLAS WORSNOP, Aerodyne Research, University of Helsinki — A broad overview of size resolved aerosol chemistry in urban, rural and remote regions is evolving from deployment of aerosol mass spectrometers (AMS) throughout the northern hemisphere. Using thermal vaporization and electron impact ionization as universal detector of non-refractory inorganic and organic composition, the accumulation of AMS results represent a library of mass spectral signatures of aerosol chemistry. For organics in particular, mass spectral factor analysis provides a procedure for classifying (and simplifying) complex mixtures composed of the hundreds or thousands of individual compounds. Correlations with parallel gas and aerosol measurements (e.g. GC/MS, HNMR, FTIR) supply additional chemical information needed to interpret mass spectra. The challenge is to separate primary and secondary, anthropogenic, biogenic and biomass burning sources and subsequent transformations of aerosol chemistry and microphysics.

In collaboration with: Tim Onasch, Manjula Canagaratna, John Jayne, Jesse Kroll, Achim Trimborn, Aerodyne Research; Ingrid Ulbrich, Allison Aiken, Peter DeCarlo, Jose Jimenez University of Colorado; Qi Zhang, SUNY Albany.

3:06PM S26.00002 The Dynamic Interaction of Chemistry and Phase Partitioning in Atmospheric Organic Aerosols. NEIL DONAHUE, Carnegie Mellon University — Atmospheric organic aerosols are a dynamic, chemically evolving mixture in equilibrium between the gas and condensed phases. This applies equally to primary emissions, which span a huge range in volatility, as well as secondary oxidation products generated by chemical reactions in both phases. The degree of volatility of primary emissions has been historically underappreciated, and the role of oxidation reactions has been considered in almost all cases only through their first or two generations. We have recently developed a ‘volatility basis set’ to address both primary volatility distributions and secondary volatility evolution (sometimes called primary organic aerosol and secondary organic aerosol). Here we will discuss both facets of this framework and apply to organic aerosols on all scales, from emissions measurements to global organic aerosol loadings. We shall describe ongoing experimental work to constrain volatility distributions and volatility evolution through chemistry as well as extensions to the basis-set framework to more fully describe evolving aerosol properties.

In collaboration with Allen Robinson, Carnegie Mellon University.

3:42PM S26.00003 Tandem mass spectrometry of single organic aerosol particles: A promising approach for in-situ analysis of mixtures. PEDRO CAMPUZANO JOST, SARAH HANNA, EMILY SIMPSON, DAMON ROBB, MICHAEL BLADES, JOHN HEPBURN, ALLAN BERTRAM, University of British Columbia — We have built a new single particle mass spectrometer for organic aerosol analysis that combines different previously tried approaches into one single instrument. We use soft, wavelength tunable desorption by using a dedicated pulsed CO2 laser, (Prather, Baer & coworkers) and soft ionization by tunable VUV radiation (Baer, Wilson & coworkers)) to ensure a minimum of fragmentation. By ionizing the aerosol plume in the center of an ion trap both high sensitivity and the ability to elucidate structure by tandem mass spectrometry (Reilly & coworkers) can be achieved. The analytical performance of the instrument as well as the detection geometry has first been validated by using simple ionization techniques, 70 eV El and REMPI, on a suite of aromatic and aliphatic compounds and simple mixtures. The novel tunable VUV laser system has been thoroughly characterized with a host of gaseous organic compounds that has proven both the ability to determine ionization energies with high accuracy and the possibility in many cases to minimize fragmentation by tuning the VUV source close to the ionization threshold. The VUV source has been integrated into the aerosol mass spectrometer and first VUV single aerosol spectra will be presented.

3:54PM S26.00004 A novel flow reactor for studying the hydrolysis of N2O5 on aqueous H2SO4 solutions coated with organic surfactants. DANIEL KNOPP, Institute for Terrestrial and Planetary Atmospheres, Stony Brook University, LORI COSMAN, ALLAN BERTRAM, Dept. of Chemistry, UBC, PAYAM MOUSAVI, SATYA MOKAMATI, Dept. of Mech. Eng., UBC — A flow reactor has been developed which allows the study of heterogeneous kinetics on an aqueous surface coated by organic monolayers. Computational fluid dynamics simulations have been used to determine the flow characteristics for various experimental conditions. A mathematical framework has been developed which allows the study of heterogeneous kinetics on an aqueous surface coated by organic monolayers. Computational fluid dynamics simulations have been used to determine the flow characteristics for various experimental conditions. A mathematical framework has been developed which allows the study of heterogeneous kinetics on an aqueous surface coated by organic monolayers. Computational fluid dynamics simulations have been used to determine the flow characteristics for various experimental conditions.
2:30PM S27.00001 Probing Magnetic Nanostructures on the Atomic Scale. CYRUS F. HIRJIBEHELIN, London Centre for Nanotechnology, Deps. of Physics & Astronomy and Chemistry, University College London — Magnetic nanostructures are increasing data storage capacities and are promising candidates for implementations of novel spin-based computation techniques. The relative simplicity and reduced dimensionality of nanoscale magnetic structures also make them attractive model systems for studying fundamental interactions between quantum spins. We used a scanning tunneling microscope to build individual magnetic nanostructures one atom at a time. By measuring their spin-excitation spectra with inelastic electron tunneling spectroscopy, we determined the orientation and strength of the anisotropies of individual Fe and Mn atoms on copper nitride. First-principles calculations indicate that the magnetic atoms become incorporated into a polar covalent surface molecular network, making them similar to the building blocks of magnetic rare earths. In linear chains of up to 10 Mn atoms, we observed excitations of the coupled atomic spins that can change both the total spin and its orientation. The large magnetic anisotropy and strong spin-coupling manifested in these structures, which provide atom-by-atom accessibility via local probes, have the potential to produce atomic-scale magnetic structures that have a stable magnetization at low temperatures.

* This work was done in collaboration with C.-Y. Lin, A.F. Otte, M. Ternes, C.P. Lutz, B.A. Jones, and A.J. Heinrich at the IBM Almaden Research Center, San Jose, CA 95120 USA.

3:06PM S27.00002 Initial Metallization and Transition Metal Diffusion in ZnO Single Crystals, CVD-Grown Films, and Nanostructures. SENIA KATALINIC, SYLVIE RANGAN, RODNEY GATEAU, PAN WU, YICHENG LU, ROBERT BARTYNSKI, Rutgers University — Transition metal doped ZnO is a promising candidate room temperature dilute magnetic semiconductor for spintronic applications. In previous studies indicate Fe or Mn dopants exhibit significantly different diffusion properties in ZnO. To explore whether this is an inherent property of ZnO or if it is related to non-related aspects of the films or nanostructures, we have studied the initial stages of Mn, Fe, and Cu metallization of the single crystal ZnO(0001)[Zn-terminated] and (11-20) surfaces, as well as MOCVD-grown epitaxial a-plane films using scanning tunneling microscopy and spectroscopy (STM and STS). While deposited Cu forms well defined islands, all three surfaces exhibit substantial disruption upon Fe deposition, including significant change in terrace widths and a markedly smaller fraction of atomic height steps. Upon annealing, Cu islands become mobile and coarsen, but the underlying ZnO structure is not strongly affected. Annealing with Fe on the surface, significant coarsening and roughening of the substrate occurs even at the modest annealing temperature of 200°C, and this effect is enhanced upon annealing to 400°C. Initial results suggest that uptake of metals into the epi-film is predominantly determined by the properties of the (11-20) surface that terminates the film.

3:18PM S27.00003 Unusual size-dependent magnetic anisotropy in Co nanomagnets made from self-organized fast laser processing1, H. KRISHNA, Dept. of Physics, Washington University in St. Louis, MO, C. MILLER, Dept. of Electrical and Systems Engineering, Washington University in St. Louis, MO, Z. NUSSINOV, A.K. GANGOPADHYAY, R. KALYANARAMAN, Dept. of Physics, Washington University in St. Louis, MO — Unusual size-dependent magnetic anisotropy has been observed in hemispherical polycrystalline Co nanomagnet on SiO2 substrates produced by fast pulsed-laser-induced self-organization. The magnetic states of these particles have been characterized by using magnetic force microscopy (MFM) and hysteresis measurements. The results for single domain particles up to a diameter of 180 nm, the magnetization direction of smaller sized particles tends to be in-plane, while the larger particles tend to have out-of-plane orientation. This finding is not consistent with shape anisotropy which predicts a size-independent in-plane alignment. Microstructural analysis revealed that particles had a granular microstructure with the grain size increasing with particle size. This unusual behavior has been attributed to large residual tensile strain in the hemispherical nanoparticles due to the large heating/cooling rates (∼1010 K/s) under ns laser self-organization, the large thermal expansion mismatch and the negative magnetostricitive constant for polycrystalline Co.

3:30PM S27.00004 Magnetocaloric effect (MCE) in ferrite nanoparticles1, JAMES GASS, HARIHARAN SRIKANTH, University of South Florida — Enhancement of the magnetocaloric effect (MCE) in nanostructured materials is important for refrigeration applications particularly in potential spot cooling of MEMS and NEMS devices. We have investigated MCE in various classes of polydisperse and monodisperse soft ferrite nanoparticles with different blocking characteristics. Our observations indicate that in some systems, surface properties such as spin disorder and anisotropy lead to considerable enhancement of MCE. This is promising for potentially increasing MCE in nanoparticle systems through systematic engineering of the surfaces via core-shell or other approaches. We report on the magnetocaloric effect (MCE) in several ferrite nanoparticle systems and compare them. Characterization of structural and magnetic properties was done using XRD, TEM, DC and AC magnetization, and transverse susceptibility. The change in entropy was calculated using the thermodynamic Maxwell relation from the family of M-H curves taken at different temperatures. The specific role of surface anisotropy and surface structure in ferrite nanoparticles and correlation to the MCE will be discussed.

3:42PM S27.00005 A magnetic nanoparticle as an ultimate voltage-controlled nanomagnet1, IGOR OVCHNIKOV, E&E Dept. UCLA, KANG WANG, E&E Dept. UCLA, FENA, WIN, CNSI — We argue that when the conduction band edge of a semiconductor is aligned with the Fermi level, the valence band states have a high probability of being occupied. By controlling the voltage on the semiconductor surface, we can control the occupation of these states and thus control the magnetization of a magnetic nanoparticle. This concept is demonstrated using ZnO nanocrystals grown on Si substrates. The nanocrystals are grown using a self-organized wet chemical method and are characterized by scanning tunneling microscopy and spectroscopy (STM and STS). The nanocrystals are then functionalized with a magnetic layer, and the magnetic properties are measured using magnetic force microscopy (MFM) and hysteresis loops. The results show that the magnetic properties of the nanocrystals are highly dependent on the voltage applied to the semiconductor surface. This work is supported by the NSF and DOE.

3:54PM S27.00006 Anisotropy-Compensated Magnetic Nanostructures1, RALPH SKOMSKI, TOM ALGER, GEORGE, D.J. SELLMYER, NCMN and Dept. Physics & Astronomy, University of Nebraska — Nanostructuring can be used to tailor the magnetic anisotropy K1 as function of temperature, which is important in permanent magnetism and magnetic recording. Anisotropy is an atomic quantity, but the ferromagnetic exchange ensures an anisotropy averaging over a few nanometers, in contrast to the absence of nanoscale Curie-temperature averaging [1]. An intriguing and largely overlooked feature is the possibility of temperature-dependent anisotropy zeros, which yields a potential write-field reduction in magnetic recording. On an atomic scale, this effect is well-known but limited to a relatively narrow range of rare-earth transition-metal intermetallics. Nanostructuring greatly extends the range of materials. Explicitly considered materials are thin films, where the determination of the anisotropy zero (s) yields algebraic equations whose roots depend on the thicknesses, Curie temperatures, and zero-temperature anisotropies of the involved phases. On a somewhat larger length scale (j 5 to 10 nm), there is no longer a well-defined anisotropy, but the corresponding micromagnetic corrections are easily incorporated into the theory. - [1] R. Skomski, “Simple Models of Magnetism,” University Press, Oxford 2008.

4:06PM S27.00007 Lattice Induced Configurational Anisotropy in Nanomagnets\textsuperscript{1} 1, WEN ZHANG, NOAH BRAY-ALI, STEPHAN HAAS, University of Southern California — The study of magnetic nanoparticles is evolving into a rich and rapidly growing area, featuring many novel phenomena and potential applications. One of the most important properties of these systems is the magnetic anisotropy, which determines the blocking temperature. Besides the well-known crystalline and shape anisotropies, the competition of exchange and magneto-static interactions in nanomagnets leads to the formation of a configurational anisotropy, resulting from small deviations of the magnetization from uniformity within the nanostructures. In this talk, I discuss a new type of anisotropy, i.e. the lattice induced configuration anisotropy, which we have studies using Monte Carlo simulations. In particular, a scaling approach has been shown to be effective in obtaining the magnetic properties of nanoparticles. The relationship between anisotropy and blocking temperature will also be discussed. Understanding the influence of anisotropy opens up a new path to designing nanostructured magnetic materials with novel functionalities.

4:18PM S27.00008 Between ferro- and para-magnetism. Electron magnetic resonance and quantal effects in superparamagnetic nanoparticles, NATALIA NOGINOVA, Norfolk State University, Norfolk VA, MAXIM NOGINOV, Cornell University, Ithaca, NY, VADIM A. ATSarkin, IRE, Moscow, Russia — Nanometer-scale magnetic objects are at the interface between quantum dynamics of several interacting spins and classical thermodynamics of multi-particle systems. We present results of electron magnetic resonance (EMR) studies in suspensions of two different systems with superparamagnetic iron oxide nanoparticles with average size of 5 nm and 9 nm correspondingly. It is shown that both types of particles demonstrate common EMR behavior, including the broad spectral component, temperature-dependent narrow component with g-factor of $\sim 2$, and additional low-field signals observed at the fields $B_{\text{B1}} = B_0/k$, where $B_0$ is the resonance field of the main resonance, and $k = 2, 3$, and 4. These lines correspond to the transitions at the double, triple, etc., resonance frequencies and can be described in terms of the non-secular spin operators arising from the single-particle magnetic anisotropy or inter-particle dipole-dipole interactions. These features are common for small quantum systems and not expected in classical case. The relative intensity of the narrow component and low-field signals rapidly decreases with cooling or increase of particle size, marking gradual transition to classical FMR behavior.

4:30PM S27.00009 Finite size effect in shell nanoparticles, JOSHUA KOCH, RENAT SABRIANOV, University of Nebraska Omaha — The magnetic properties of single layer shell particles studied as function of the particle’s size using Monte Carlo method with free boundary conditions. We formed truncated octahedron shell-nanoparticles of 4-30 lattice spacings across mimicking particles from 2-12 nm in size. The classical Heisenberg model with nearest neighbor ferromagnetic (FM) and antiferromagnetic (AFM) exchange interactions shows the existence of the well defined ground state. FM nanoparticles have susceptibility maximum decreasing with the increase of the nanoparticle size. Finite size scaling analysis predicts small Curie temperature for shells of the large size. The AFM particles built as truncated octahedron with (001) and (111) planes of the cubic lattice show freezing in the noncollinear structure with very low magnetization. The freezing temperature determined as maximum in specific heat in particles with AFM does not change strongly with the size of the shell in the studied particle sizes. We clearly observe the effects of edges and corners on the properties of shell particles resulting in deviation from simple scaling behavior. We fit the size dependence variation of thermodynamic properties maxima using the idea of the continuous dimensionality and the fact that infinite 2D systems do not exhibit long range order at finite temperature in the continuous symmetry.

4:42PM S27.00010 Low T magnons condensation in FePd and FePt nano-particulate films, R. A. LUKASZEW, K. YANG, J. R. SKUZA, C. CLAVERO, The College of William and Mary, VA — Recently there have been interesting reports on experimental deviations from the Bloch T$^{3/2}$ law at low temperature in magnetic nanostructures. Specifically it has been reported an “upturn” of the T$^{3/2}$ law in the magnetization in some nanomagnetic materials. [1] This behavior has been attributed to a Bose-Einstein Condensation of magnons in the nanostructured materials due to more disorder in the spins at finite entropy as opposed to the case of crystalline bulk ferromagnets where it can be assumed that all the spins are in the direction of a saturating magnetic field and hence perfectly ordered. In order to further test these ideas, we have carried out systematic low temperature magnetization studies (SQUID) on FePd and FePt nano-particulate thin films. The microstructure and morphology of the thin films have also been extensively characterized with X-Ray, TEM and AFM/MFM. We will show our experimental data and point out significant differences and also similarities in the analyzed samples. [1]. Extension of the Bloch T$^{3/2}$ Law to Magnetic Nanostructures: Bose-Einstein Condensation, E. Della Torre, L. H. Bennett and R. E. Watson, Phys. Rev. Lett. 94, 147210 (2005).

4:54PM S27.00011 Strong-field interactions between a nanomagnet and a cavity mode, O. SOYKAL, M. E. FLATTE, OSTS and Department of Physics and Astronomy, University of Iowa — We analyze the interaction of a nanomagnet with a single mode of a microcavity in a fully quantum-mechanical treatment. We consider a spherical cavity roughly 1 mm\textsuperscript{3} in volume, and a nanomagnet consisting of 10\textsuperscript{10} spins treated as a macrospin, in the presence of a static magnetic field. For an initial configuration of no photons in the cavity and the macrospin oriented antiparallel to the field, the interaction Hamiltonian contains magnet-microwave mode coupling terms that exceed several GHz. Thus for quality factors in excess of 100, strong-field effects should be observable in the nanomagnet/cavity dynamics. Coherent states of the nanomagnet/photon system are characterized by large oscillations in the photon number (and nanomagnet spin), and are characterized by exceptionally long dephasing times.

5:06PM S27.00012 Magnetism of Fe double wires deposited on Ir(100), RICCARDO MAZZARELLO, SISSA, Trieste, Italy, ANDREA DAL CORSO, SISSA and DEMOCRITOS-INFM, Trieste, Italy, ERIO TOSATTI, SISSA, ICTP and DEMOCRITOS-INFM, Trieste, Italy — Bulk bcc Fe is a prototypical ferromagnet (FM), but a single monolayer of Fe on W(001) has been known to be antiferromagnetic (AFM). Very recent spin-polarized STM experiments on Fe double chains deposited on Ir(100) 5x1 [1] showed that these adsorbed nanowires are AFM too [2]. We study the magnetic properties of this system using ab-initio density functional theory and both scalar-relativistic and fully-relativistic ultrasoft pseudo-potentials. In particular, we address the energetics of FM and AFM configurations of several experimentally relevant structures. The AFM configuration is always energetically favored, which is in agreement with experiment but does not yet allow to distinguish between different structures. Investigation of the magnetic anisotropy induced by the spin-orbit interaction is in progress. [1] L. Hammer, W. Meier, A. Schmidt, and K. Heinze, Phys. Rev. B 67, 125422 (2003). [2] R. Wiesendanger, private communication.

5:18PM S27.00013 Tailoring magnetic order in nanowires by alloying 5d Transition Metal elements, JAVIER GUEVARA, Escuela de Ciencia y Tecnologia-UNAMS e INN-CNEA, TRISTANA SONDON, Departamento de Fisica e INN-CNEA, ANDRES SAUL, CRM CNRS, Marseille, Francia — The magnetism of pure-element nanowires have been theoretically studied and show, in the case of Au, Pt, and Ir, nanomagnets with anisotropic magnetic properties of A$_1$, B$_2$, C$_3$; nanowires being A$_1$, B$_2$, O$_3$, Ir, or Pt, by using the ab-initio Wien2k code. These alloyed nanowires have large magnetic moment values, and also giant MAE of different signs. We show the evolution of the spin and orbital magnetic moments as the magnetization axis is being varied.
2:30PM S28.00001 Design of uniaxial metallodielectric metamaterials having large optical nonlineairities. JOSEPH GEDDES, ERIK NELSON, PAUL BRAUN, University of Illinois at Urbana-Champaign — We describe how the intrinsically large optical nonlinearities of metals could be accessed and increased by fabrication of uniaxial homogenized composites comprising alternating metal and dielectric layers of subwavelength thickness. Such composites are predicted to exhibit effective third-order nonlinear susceptibilities of magnitude larger than those intrinsic to the metallic component. The enhancement is due to a resonance effect, and is limited to the direction perpendicular to the layer interfaces. We illustrate our predictions with calculations for several metallodielectric systems, including those consisting of copper and titanium dioxide components.

2:42PM S28.00002 Spectroscopic and thermal studies of L-arginine doped Potassium Dihydrongen Phosphate crystals. JAYESH GOVANI, FELICIA MANCIU, Department of Physics, University of Texas at El Paso, El Paso, TX 79968, U.S.A, MIHIR JOSHI, KETAN PARIKH, DIPAK DAVE, Department of Physics, Saurashtra University, Rajkot, Gujarat-360 005, India — We have used IR transmission and Raman spectroscopy to study the active doping of potassium dihydrogen phosphate (KDP) crystals with L-arginine amino acid. In the present investigation, pure and doped KDP crystals were grown by slow evaporation solution method. Although the dominant bands observed in the infrared absorption spectra correspond to KDP crystals, the existence of vibrational lines at 1401 cm⁻¹ (CH₂), 1637 cm⁻¹ (COO⁻), 1716 cm⁻¹ (NH₃⁺), and 3127 cm⁻¹ (NH₄⁺) indicate that successful doping was achieved. This affirmation is further corroborated by the FT-Raman data, where strong lines are observed in the 2800 cm⁻¹ – 3100 cm⁻¹ region, which is associated with C-H stretching modes of amino acids. The crystal structure and the thermal stability of the samples were also examined by powder X-ray diffraction and thermogravimetric techniques, respectively. Thermogravimetric analysis demonstrates a decrease of the thermal stability with increasing doping amount. An increase of second harmonic generation efficiency was found with more L-Arginine doping.

2:54PM S28.00003 Optical properties in the visible range of Co clusters capped by Pd under hydrogen. 1. A.L. CARRERA, J.I. AVILA, Facultad de Fisica, Pontificia Universidad Catolica de Chile, C.P. ROMERO, M.J. VAN BAEL, P. LIEVENS, Laboratorium voor Vaste-Stofsysca en Magneteisme, Katholieke Universiteit Leuven — Co clusters with mean size of 1.8 nm were deposited to form a 25 nm thick cluster assembled film on glass, capped by a continuous 15 nm Pd film. The light transmission and reflection, in the visible range (400 to 1000 nm), were measured when the sample was exposed to different hydrogen pressures up to 120 Torr. Measurements on 15 nm continuous Pd film were done for comparison. Electrical resistance of the films was also measured as an independent parameter to determine hydrogen absorption by the samples. In both samples the transmission and resistance of the films increase, reaching saturation at 30 Torr hydrogen pressure. Increase of the light transmission and electrical resistance on the pure Pd film indicates absorption of hydrogen in the bulk of the film. Smaller relative change of the resistance and reflection of light on the Co cluster sample capped by Pd indicates that hydrogen absorption is limited to the Pd capping layer only. This work is supported by the Fund for Scientific Research-Flanders (FWO), by the Flemish Concerted Action (GOA), and by the Belgian Interuniversity Poles of Attraction (IAP) programs.

3:06PM S28.00004 Novel optical signatures of sub-3 nm rare earth sesquioxide nanocrystals. JAMES DICKERSON, Department of Physics and Astronomy, Vanderbilt University, Nashville TN, SAMEER MAHAJAN, Interdisciplinary Program in Materials Science, Vanderbilt University, Nashville, TN — Europium and terbium based sesquioxide nanomaterials, known for their characteristic red and green luminescence, respectively, have recently garnered much research attention due to their size-dependent optical properties. Here, we present systematic investigation of the size-dependent optical properties Eu₂O₃, Tb₂O₃, and Gd₂O₃Eu³⁺ / Tb³⁺ nanocrystals (NCs) in the size range of 1-3 nm in diameter. We observe a new luminescence peak at 620 nm in Eu₂O₃ and Gd₂O₃Eu³⁺ NCs, which represents modulation of the 5F₂ transition in Eu³⁺ ion. Intensity modulation with respect to the 612 nm is observed as a function of nanocrystal size. For the Tb₂O₃ NCs, a new luminescence signature at 548 nm characterizes modulation of the 5F₄ transition in Tb³⁺ ion. In addition, we probe the effect of NC size on the luminescence efficiencies of the doped and pure sesquioxide NCs. The concentration quenching effect, which leads to low luminescence efficiencies in bulk, pure sesquioxides, is explored in sub-3 nm sesquioxides.

3:18PM S28.00005 Far-infrared Magneto-Spectroscopic Studies of Ca₃CoO₄ Thin Films and Single Crystals. 1 JIUFENG TU, DAMITR DIMITROV, CCNY, WEIDONG SI, QIANG LI, BNL — In recent years, the 2D-layered cobaltates have emerged as promising p-type thermoelectric materials due to their unique combinations of high thermo-coefficient and good metallic transport properties. These systems show high thermoelectric figure of merit and are ideal candidates as the materials of choice at elevated temperatures. We have carried out far-infrared magneto-spectroscopic studies of Ca₃CoO₄ thin films in Faraday geometry as a function of frequency, magnetic field and temperature with the emphasis on the coupling between the lattice, the charge and the spin degrees of freedom. Far infrared transmission reduces at low frequencies in the presence of magnetic field corresponding to negative magneto-resistance. Below 20K, hysteresis occurs. However, the spectral responses to magnetic field and temperature are different. This indicates that the negative magneto-resistance is due to reduced magnetic scattering when Co spins become aligned. Further infrared studies will be performed with magnetic field parallel to the CoO₄ layers. A good understanding of our infrared results should shed light on the origin of high thermo-power in these 2D-layered cobaltates.

3:30PM S28.00006 Ultrafast Time Resolved Transient Absorption and Photoluminescence (PL) Studies of In₅₀Ga₅₀As/GaAs Quantum Wells in High Magnetic Fields. 1 JINHO LEE, X. WANG, D.H. REITZIE, Physics Dept., University of Florida, S. MCGILL, NHMFL, Y.D. JHO, Dept. of Information and Communications, GIST, J. KONO, Dept. of Electrical and Computer Engineering, Rice University, A.A. BELYANIN, Physics Dept., Texas A&M University, G. SOLOMON, NIST — We investigate the temporal dynamics of dense magneto-plasmas excited by intense femtosecond laser pulses in In₅₀Ga₅₀As/GaAs multiple quantum wells in high magnetic fields. To fully fill the Landau levels (LLs), we pump to carrier densities near 10¹³ cm⁻² using 150 fs pulses. Time-resolved transient absorption experiments probe the occupancy of each e₁h₁ LL, revealing a dramatic decrease in decay times above the zero field e₁h₁ transition dynamics. Our PL results reveal evidence for multiple short bursts of emission pulses at the highest fields (17.5T) from in-plane PL emission compared with zero field emission. In addition, qualitatively different temporal dynamics from in-plane and out-of-plane collection geometries are observed. Our results are analyzed in the context of ultrafast cooperative emission mechanisms from dense electron-hole plasmas.

3:42PM S28.00007 Magneto-photoluminescence studies of CdTe/CdSe/ZnS nanoparticles. Y.H. CHANG, C.C. HUANG, L.W. CHANG, C.H. HSU, Department of Physics, National Taiwan University, CHIH-WEI LAI, CHIEN-LIANG LIU, PI-TAI CHOU, Department of Chemistry, National Taiwan University, Y.W. SUEN, Department of Physics, National Chung Hsing University — Recently, the effect of the magnetic flux on the excitonic energy has received much attention. Optical Aharonov-Bohm was observed on negatively charged exciton in InGaAs/GaAs quantum ring as well as neutral exciton in type-II InP-GaAs heterostructure. In this talk we will present our magneto-photoluminescence studies on the optical properties of CdTe/CdSe/ZnS system. The nanoparticles that were grown by chemical method have size of about 6 nm and the band alignment between the core (CdTe) and the shell (CdSe) is type-II band alignment. The addition of a ZnS layer is to passivate the surface of CdSe and to enhance the light emitting efficiency. Magneto-photoluminescence experiment was performed at T = 1.4 K with a 14 T superconducting magnet in conjunction with a green diode laser and a monochromator. Oscillation on the peak energy of the photoluminescence spectra as well as oscillation in the integrated intensity as a function of magnetic field were observed and are attributed to the optical Aharonov-Bohm-like effect.

3:54PM S28.00008 Absorption and photocurrent of semiconductor quantum wells: a multiband NEGF study. URS AEBERHARD, Paul Scherrer Institut — Interband photoexcitation of carriers in semiconductor quantum wells is exploited in various optoelectronic devices such as photodetectors or quantum well solar cells. For a quantitative prediction of the photocurrent, realistic models for the (sub)bandstructure as well as for the transport properties are required. In the present approach, the development of optical properties based on a multi-band empirical tight-binding Hamiltonian is combined with the non-equilibrium Green’s function formulation of quantum transport. The photocurrent is calculated in presence of elastic andinelastic electron-phonon scattering from the self-consistent Born approximation of the self energy for carrier-light interaction, while the absorption is obtained from the transverse interband polarization function. Since the absorption is observed experimentally by the excitonic contribution, the inclusion of this feature into the calculation of photocurrent and interband polarization via the respective many-body corrections is discussed.

4:06PM S28.00009 Magneto-infrared study on 2-dimensional electrons and holes in GaSb-InAs-AlSb coupled quantum wells. LI-CHUN TUNG, NHMFL, P.A. FOLKES, Army Research Laboratory, WEN XU, Australian National University, YONG-JIE WANG, NHMFL — InAs-AlSb heterostructures have been a subject of interests for their unusual type-II band alignment between InAs and AlSb. The spatially separated 2-dimensional electron and hole gases are confined in different layers and in equilibrium with each other at the InAs/GaSb interface. This unique circumstance has led to several predicted many-body effects, as well as possible applications as infrared detectors and sources. In the past, magneto-infrared studies on InAs-AlSb single quantum wells have revealed a range of phenomena arising from the electron-hole binding. We have carried out an infrared optical study up to 30T on a series of GaSb-InAs-AlSb coupled quantum well structures, in which the electrons and holes are separated by a thin barrier and the Fermi level is tuned by the thickness of the GaSb cap layer. In addition to the electron cyclotron resonance (CR), another transition has been observed at the fields higher than 13 T. The linewidth of the CR shows the oscillatory behavior with the filling factor that is consistent with the electron densities obtained from the transport measurements. The transition energy of this line is close to the energy difference between the lowest Landau level (LL) in the InAs layer and the highest LL in the GaSb layer, which suggests that the it might result from an excitonic transition across the barrier.

4:18PM S28.00010 Infrared dielectric properties and optical magnetoconductivity of CaRuO$_3$/CaMnO$_3$ superlattices. A.V. BORIS, P. YORDANOV, P. POPOVICH, B. KEIMER, Max Planck Institute for Solid State Research, Stuttgart, Germany, J.W. FREELAND, Argonne Nat. Lab., J. CHAKHALIAN, Univ. of Arkansas, Fayetteville, H.N. LEE, Oak Ridge Nat. Lab. — Spectroscopic ellipsometry and magneto-reflectivity in the far-infrared spectral range is used to study the electronic properties of [CaRuO$_3$]$_n$[CaMnO$_3$]$_{10n}$ superlattices (SLS). The nonlinear regression procedure is employed to extract the dynamical conductivity and dielectric permittivity of bare SLS within the effective medium approximation with a mixture of the ruthenate and manganite layers (N = 4-10 unit cells). This implies no major charge transfer effects between non-Fermi liquid metal CaRuO$_3$ and antiferromagnetic insulator CaMnO$_3$. While the low-energy electronic spectra of the SLSs is governed by CaRuO$_3$ layer behavior, we find a negative contribution, the inclusion of this feature into the calculation of photocurrent and interband polarization via the respective many-body corrections is discussed. The transition energy of this line is close to the energy difference between the lowest Landau level (LL) in the InAs layer and the highest LL in the GaSb layer, which suggests that the it might result from an excitonic transition across the barrier.

4:30PM S28.00011 Observation of coherent high-wavevector acoustic vibrations in a bulk material using time-resolved X-ray diffraction. MARIANO TRIGO, YU-MIIN SHEU, EMILY PETERSON, DAVID REIS, MATTHEW REASON, RACHEL GOLDMAN, ROBERTO MERLIN, University of Michigan, ERIC LANDAHL, Argonne National Laboratory, DONALD WALKO, DOHN ARMS, Argonne National Laboratory — We report on the observation of high-wavevector acoustic phonons in bulk InP that originate from folded phonons in the InAs layer and the highest LL in the GaSb layer, which suggests that the it might result from an excitonic transition across the barrier.

4:42PM S28.00012 Fröhlich phonon modes in PbSe and PbS colloidal quantum dots. JONATHAN WRUBEL, Harvard University, BYUNG-ROYOL HYUN, NIKOLAY AGLADZE, ALBERT SIEVERS, FRANK WISE, Cornell University — The measured infrared absorption of colloidal PbSe and PbS quantum dots in hexane is shown to be dominated by absorption near the Fröhlich mode frequency position. However, in both sets of quantum dots the mode is at a higher frequency than calculated from the bulk dielectric constant, and shifts to still higher frequency with decreasing diameter of dot. This behavior is shown to be consistent with a decreasing contribution of the near-infrared and visible exciton absorption to the dielectric constant at far infrared frequencies as the particle size decreases and the band gap increases. The unique presence of Fröhlich mode absorption in a wide range of dot sizes suggests that the mechanical boundary condition of the quantum dot is a “soft” one in which vibrational amplitudes do not go to zero at the boundary.

4:54PM S28.00013 Coherent defect-assisted multiphonon intraband carrier relaxation in semiconductor quantum dots. ALEXANDER PODDUBNY, Ioffe Institute, SERGUEI GOUPALOV, University of Utah & Ioffe Institute — A new defect-assisted mechanism of multiphonon intraband carrier relaxation in semiconductor quantum dots, where the carrier is found in a coherent superposition of the initial, final, and defect states, is proposed. It is shown that this mechanism is capable of explaining the observed trends in temperature dependences of the intraband relaxation rates for PbSe and CdSe colloidal nanocrystal quantum dots.
5:06PM S28.00014 Raman-Brillouin electronic density in GaAs/AlAs superlattices. NICOLAS LARGE, CEMES, Toulouse and DIPC, San Sebastian, ADNEN MLAYAH, CEMES, Toulouse, JAVIER AIZPURUA, DIPC, San Sebastian, JEAN-ROCH HUNTZINGER, GES, Montpellier, BERNARD JUSSERAND, INSIP, Paris — Raman-Brillouin scattering by acoustic phonons is an accurate experimental method to characterize vibrational states of nanostructures and understand their optical properties. Many nanoscaled systems such as quantum dots, wires, wells and membranes have been studied by the means of this technique. We present here a theoretical and experimental study of the Raman-Brillouin scattering in GaAs/AlAs superlattices. Within third order perturbation theory, we describe the Raman-Brillouin scattering process by introducing a Raman-Brillouin Electronic Density (RBED). The RBED is constructed by combining the superlattice electronic states according to their optical transition rates. This approach is useful when numerous intermediate electronic states are involved in the scattering process. It has been proven to successfully interpret the Raman-Brillouin scattering in quantum dots[1] and membranes[2]. We calculate the RBED for specific GaAs/AlAs superlattices and study the dependence of the Raman-Brillouin spectra on the GaAs/AlAs layer thickness ratio and incident photon energy. Comparison with experiments will be discussed. [1] J.R. Huntzinger et al, Phys. Rev. B 74, 115308 (2006) [2] A. Mlayah, J.R. Huntzinger and N. Large, Phys. Rev. B 75, 245303 (2007)

5:18PM S28.00015 Measured and Calculated Properties of n- and p-type PbTe-Based Materials for High-Performance Thermoelectrics1, C. VINEIS, T. HARMAN, S. CALAWA, M. WALSH, R. REEDER, W. GOODHUE, MIT Lincoln Laboratory — Recent advances in PbTe and other material systems for thermoelectric applications are based on nanostructuring, with a specific goal of substantially reducing lattice thermal conductivity while maintaining good electrical properties. Our work has focused on developing PbTe/PbSe1−xTex (x ~0.02-0.04) nanodot superlattices (NDSLs) for improved thermoelectric performance. In this presentation we will compare the electrical and thermal properties of n- and p-type NDSLs to baseline homogeneous PbTe, and also compare the electrical data to calculations performed using the Boltzmann transport equation with the relaxation time approximation. Compared to PbTe at the same carrier concentration, NDSL samples generally have reduced mobilities (~25-35%), the same Seebeck coefficients, and substantially reduced (~4-6x) lattice thermal conductivities, resulting in a large increase in ZT. Specifically, a 300-K in-plane power factor of ≥25 µW/cm-K² has been repeatedly achieved for both n- and p-NDSLs, while the cross-plane lattice thermal conductivity has been measured as ~0.35-0.4 W/m-K using various techniques. We will also present recent power generation results where 9.9 W/cm² was obtained from a 1 mm², 100-µm-thick stand-alone n-NDSL thermoelement, at a ΔT of 202 K.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S29 DMP: Focus Session: Carbon Nanotubes and Related Materials XI: Optical Spectroscopy

2:30PM S29.00001 In situ Raman Spectroscopy of Suspended Carbon Nanotubes under High Voltage Bias1, STEPHEN CRONIN, University of Southern of California — We report recent results of Raman spectroscopy taken of individual suspended single-walled carbon nanotubes exhibiting negative differential conductance (NDC) in situ under high voltage biases [1]. The transverse and longitudinal optical phonon modes (G+ and G− band) are found to respond differently to the applied voltage bias. We observe preferential downshifting of only one optical phonon mode while the other remains largely unchanged, indicating a non-equilibrium phonon population caused by the preferential electron-phonon coupling of only one optical phonon polarization. This preferential coupling is caused by the differences between the two Kohn anomalies in the TO and LO phonon branches [2]. Surprisingly, in most metallic nanotubes, the narrow G− band (TO band) is more strongly heated by electron-phonon scattering at high biases. The non-equilibrium phonon populations produced under high biases are corroborated by anti-Stokes Raman spectroscopy. We correlate the optically measured phonon population to the electrically measured resistivity using a Landauer model to determine key scattering parameters. The electron-phonon scattering mechanism revealed by these measurements and this analysis show the importance of electron-phonon scattering from absorption from the large non-equilibrium phonon population in explaining the observed negative differential conductance [3].

The authors would like to acknowledge DOE Award No. DE-FG02-07ER46376.

3:06PM S29.00002 Measurement of the absorption cross section of individual single walled carbon nanotubes. STÉPHANE BERCLAUD1, LAURENT COGNET, Centre de Physique Moléculaire Optique et Hertzienne, Université Bordeaux (France), R. BRUCE WEISMAN, Department of Chemistry, Rice University, Houston ,Texas, BRAHIM LOUNIS, Centre de Physique Moléculaire Optique et Hertzienne, Université Bordeaux (France) — We combined time–resolved and cw luminescence studies on highly luminescent individual (6,5) single walled carbon nanotubes in aqueous environments to yield the first experimental determination of the absorption cross section of individual nanotubes. Luminescence decays systematically exhibited a bi-exponential behavior with a short component (mean 45ps) accounting for most of the integrated signal, followed by a weak tail decaying on a 250 ps timescale. We obtained a mean statistical value of 1.0 10⁻¹⁷ cm² per carbon atom for nanotubes resonantly excited at their second order optical transition, a value independently obtained by photothermal absorption measurements also performed on individual (6,5) nanotubes. Precise knowledge of the absorption cross section of individual nanotubes is essential for the determination of nanotube quantum yield as well as in quantitative studies of multi-excitonic processes.

The authors would like to acknowledge DOE Award No. DE-FG02-07ER46376.

1present address: Department of Chemistry, Columbia University
3:18PM S29.00003 Length-dependent optical properties of single-walled carbon nanotubes. J. R. SIMPSON, J. A. FAGAN, B. J. BAUER, E. K. HOBBIE, A. R. HIGHT WALKER, NIST, Gaithersburg, MD 20899 — Length proves to be an important physical characteristic of single-wall carbon nanotubes (SWCNTs) strongly affecting optical absorption, photoluminescence, and resonance Raman spectroscopies. Our samples include HiPCo, CoMoCat, and arc-discharge SWCNTs dispersed in aqueous solutions by wrapping with either DNA or surfactant and exhibiting an exceptionally low degree of SWCNT bundling/clustering. Size-exclusion chromatography or density sorting ultracentrifugation collect length fractions ranging in size from approximately 50 nm to 1000 nm. The optical spectral weight specific to the SWCNT electronic states and photoluminescence peak emission intensity, compared to their underlying backgrounds, scale approximately linearly with length. All observed Raman vibrational modes exhibit a monotonic increase of scattering intensity with nanotube length. Resonance Raman of the radial breathing mode reveals a blueshift of the excitation energy for shorter nanotubes. Localization of bound excitons along the nanotube may explain the observed length-dependent optical properties.

3:30PM S29.00004 Reflectance spectra of individual single walled carbon nanotubes. HUALING ZENG — We report back scattering spectroscopic measurements on individual single walled carbon nanotubes (SWNTs). The reflectance spectra show geometry-dependent resonant peaks corresponding to optical transitions between Van Hove singularities in SWNTs’ joint density of states. All nanotubes display certain colours as their reflectance spectra demonstrate strong energy dependence. This approach was proved to be an effective tool to probe geometric structures and optical properties of individual SWNTs.

3:42PM S29.00005 Inverted spectra of SWCNT films. JOHN LEHMAN, KATHERINE HURST, LARA ROBERSON, NIST, KATHRYN NIELD, JOHN HAMLIN, MSL-New Zealand — Diffuse Reflectance for purified single wall carbon nanotube (SWCNT) films and its relation to absorptance in the wavelength range 0.6 µm to 2 µm are inverted when compared to absorptivity data in the literature. This surprising behavior has been corroborated by diffuse reflectance measurements and shows that the reflectance is a substantial part of the unique optical behavior. Typically, the absorptance is fairly assumed to be complementary to the transmittance, while the reflectivity is insignificant. Only in certain instances (see for example, Barnes, et al[1], Wang, et. al[2]), is the small reflectance explicitly accounted for. In the present work, we present diffuse reflectance and specular absorptance at normal incidence of SWCNT films.

3:54PM S29.00006 Broadband Rayleigh Scattering and Photoconductivity Spectra of Individual Semiconducting Single-Walled Carbon Nanotubes. MATTHEW SFEIR, Brookhaven National Laboratory, SAMI ROSENBLATT, YANG WU, HUGEN YAN, CHRISTOPHE VOISIN, BHUPESH CHANDRA, ROBERT C. C. CALDWELL, YUYAO SHAN, JAMES HONE, TONY F. HEINZ, Columbia University, JAMES A. MISIEWICH, Brookhaven National Laboratory — Combining a Fourier-transform measurement of photoconductivity with Rayleigh spectroscopy, we have identified the four lowest-lying optical transitions from specific, individual single-walled carbon nanotubes. In these investigations we made use of the previously reported transfer technique [1] to obtain samples with optimized arrangements both for Rayleigh (freely suspended) and photoconductivity (transistor geometry) spectroscopy. The combination of these two optical characterization techniques yields high-resolution spectra of the electronic transitions of individual nanotubes over a spectral range extending from 0.3 – 2.7 eV. We will discuss the details of the spectra that we have obtained for individual single-walled nanotubes of defined chiral index, including the observation of asymmetric lineshapes for the lowest-lying optical transition. [1] X. M. H. Huang, et al, Nano Lett. 5, 1515 (2005).

4:06PM S29.00007 Optical phonon and hot carrier lifetimes in single-walled carbon nanotubes by time-resolved anti-Stokes Raman scattering. KWANGU KANG, DAVID CAHILL, TANER OZEL, MOONSUB SHIM, Frederick Seitz Materials Research Laboratory, and Department of Materials Science and Engineering, University of Illinois — The lifetimes of optical phonon and photoexcited carriers in both semiconducting and metallic single-wall carbon nanotubes are determined by time-resolved Raman scattering using a subpicosecond pump-probe method. Non-equilibrium populations of electronic and phonon excitations are observed by incoherent anti-Stokes Raman scattering from a broad continuum and the G mode, respectively. HiPCo nanotubes with E_{22} transitions and arc-discharge nanotubes with E_1 transitions dominate the spectra because of their resonance with the photon energy. To separate Raman scattering created by the probe beam from scattering created by the pump beam, we have developed a two-color pump-probe technique based on the broad bandwidth of the Ti:sapphire laser oscillator and narrow bandpass optical filters. For semiconducting tubes, the optical phonon lifetimes decrease from 1.2 ps to 0.9 ps with increasing laser fluence. The optical phonon lifetimes of metallic tubes, on the other hand, increase from 0.6 ps to 1.1 ps. The hot carrier lifetime is approximately 0.3 ps.

4:18PM S29.00008 Raman Spectroscopy of isolated Double Wall Carbon Nanotubes (DWNT). FEDERICO VILLALPANDO-PAEZ, ALFONSO REINA CECCO, Massachusetts Institute of Technology, DAISUKE SHIMAMOTO, Shinshu University, Japan, ANTONIO G. SOUZA FILHO, Universidade Federal do Ceara, Brazil, HYUNGBIN SON, Massachusetts Institute of Technology, YOONG A. KIM, ENDO MORINOBU, Shinshu University, Japan, MAURICIO TERRONES, Instituto Potosino de Investigacion Cientifica y Tecnologica, Mexico, MILDRED DESSELSHAUS, Massachusetts Institute of Technology — We have developed a method to perform Raman spectroscopy on isolated double wall carbon nanotubes (DWNT). By identifying isolated DWNTs and obtaining their Raman spectra using different laser lines, we are able to find DWNTs whose inner and outer walls are in resonance with the same laser line or with more than one laser lines ranging from 514nm to 785nm. The inner and outer walls of a DWNT can be metallic (M) or semiconducting (S) and each of the four possible configurations (M/M, M/S, S/S, S/M) has different electronic properties. The obtained Raman spectra show simplified radial breathing mode (RBM), G and G’ line shapes that allow us to study the inter layer interactions and make comparisons to previous experiments on DWNT bundles and double layer graphene.

We study the transport properties of a long non-uniform quantum wire where the electron-electron interactions are treated in a tight binding formalism which includes bond-stretching, in-plane and out-of-plane bond-bending, and bond-twisting interactions. Equations of motion for the coherent phonon amplitudes are obtained in a density matrix formalism and we find that the coherent phonon amplitudes satisfy driven oscillator equations. In coherent phonon spectroscopy the coherent phonons are detected by ultrafast pump probe differential transmission measurements. We find that for uniform illumination with a 5 fs pump pulse only the q = 0 radial breathing mode and a high frequency G mode are strongly excited. We will discuss excitation strengths for different coherent phonon modes and compare to recent experiments.

1Supported by NSF DMR-0325474.

4:30PM S29.00009 Theory of coherent phonon spectroscopy in carbon nanotubes1. G. D. SANDERS, C. J. STANTON, University of Florida, Y. S. LIM, Konkuk University, K. J. YEE, J. H. KIM, Chungnam National University, E. H. HARZO, L. G. BOOSHEHR, J. KONO, Rice University — We develop a theory for the generation and detection of coherent phonons in single wall carbon nanotubes. Coherent phonons are generated in the nanotube by ultrafast laser pulses via the deformation potential electron-phonon interaction with the photogenerated carriers. The electronic states are treated in a tight binding formalism which gives a description of the states over the nanotube Brillouin zone while the nanotube phonon modes are treated in a valence force field model that includes bond-stretching, in-plane and out-of-plane bond-bending, and bond-twisting interactions. Equations of motion for the coherent phonon amplitudes are obtained in a density matrix formalism and we find that the coherent phonon amplitudes satisfy driven oscillator equations. In coherent phonon spectroscopy the coherent phonons are detected by ultrafast pump probe differential transmission measurements. We find that for uniform illumination with a 5 fs pump pulse only the q = 0 radial breathing mode and a high frequency G mode are strongly excited. We will discuss excitation strengths for different coherent phonon modes and compare to recent experiments.

4:42PM S29.00010 Stability of carbon nanotubes to laser irradiation probed by Raman spectroscopy. ALEXANDER SOLDATOV, DAVID OLEVKI, Dept. of Physics, Lulea University of Technology, MANUEL DOSSOT, Dept. of Chemical Physics, Nancy University, EDWARD MCRRAE, Lab. of Solid State Chemistry, Nancy University — CNTs in a bundled state suffer from overheating effects — exposure to laser irradiation leads to a reversible shift of the RBM resonance window at a moderate laser fluence [1] or even to damaging of certain nanotube types at higher fluences. Here we report on our systematic study of the influence of laser irradiation on the Raman spectra of HiPCO-produced single wall CNTs. Specifically, we have examined Raman response of bundled CNTs to: i) laser power density; ii) exposure time and iii) photon energy (1.96 and 2.33 eV). Our results show that irreversible destruction of CNTs in the bundles takes place at even a moderate laser power density (~500 W/cm²). Notably, the tubes with smaller diameters are influenced first and the rate of CNT damage increases with photon energy. Finally, we determined that the threshold for the RBM spectrum profile to change at ~200 W/cm², which is apparently below the laser fluencies used typically in Raman experiments on CNT bundles. Based on these results we developed a regime of Raman data collection which was recently used to identify functionalization of different types of CNTs [2] from their Raman spectra. [1] C. Fantini, et al. Phys. Rev. Lett., 93, 147406 (2004). [2] J. Liu, et al. Carbon, 45, 885, (2007).

5:45PM S29.00011 Surface Enhanced Raman Spectroscopy (SERS) and Scanning Electron Microscopy of Individual SERS Hot Spots. RAJAY KUMAR, STEPHEN CRONIN — We measure Raman spectroscopy and scanning electron microscopy before and after depositing silver nanoparticles on carbon nanotubes. Individual SERS ‘hot spots’ are identified with respect to a lithographically defined grid and using a cross-mapping technique. Carbon nanotubes’ extremely large aspect ratio enables subsequent imaging of the nanoparticle geometry together with the SERS active molecule. The SERS enhancement factor is determined by comparing the Raman intensity of an individual nanotube before and after nanoparticle deposition. The data, published in R. Kumar et al., Appl. Phys. Lett., 91 (2007), reports SERS enhancement factors up to 134,000 and nanoparticle heating exceeding 600°C, as evidenced by the local burnout of nanotubes in SERS hot spot regions.

5:06PM S29.00012 Electrical Transport Studies of (n,n) Armchair Carbon Nanotubes. ROBERT CALDWELL, BHUPESH CHANDRA, CHRISTOPHE VOISIN, TONY F. HEINZ, JAMES HONE, Columbia University — By using Rayleigh scattering spectroscopy, a simple mechanical transfer process, and standard E-beam lithography fabrication of metallic leads, we can probe the electrical properties of individual single-walled carbon nanotubes of known chiral indices (n,m) on the substrate of our choosing. Using these techniques, we have discovered that (n,n) ‘armchair’ nanotubes consistently deviate from the predicted metallic behavior, specifically showing a gap in current – gate voltage curves. We present detailed studies of the transport behavior of these devices, including conductivity as a function of bias, length, and temperature.

5:18PM S29.00013 Supercurrent in Single Wall Carbon Nanotube Josephson Junctions. GANG LIU, YONG ZHANG, CHUNNING LAU — We investigate transport in highly transparent single-wall carbon nanotube Josephson Junctions. Gate tunable supercurrent, multiple Andreev reflections and hysteresis current-voltage characteristics are observed, corresponding to on- and off-resonance transmission of charges via the nanotube’s quantized energy levels. In the talk we will discuss the dependence of supercurrent on temperature, source-drain separation and gate voltage, and compare with various theoretical models.
3:06PM S30.00009 Microwave Kinetic Inductance Measurement of a Carbon Nanotube

Y. YIN, J. CHUDOW, J. MANO ORTEGA, A. TRUE, C. A. SCHMUTTENMAER, Dept. of Chemistry, Yale Univ., B. REULE, LPS, Université Paris-Sud, Orsay, France. — The single-wall metallic carbon nanotube is a model molecular nano-system, and has also been proposed as a candidate for future IC interconnects. For both these reasons, measurement of the kinetic inductance is desirable. This inductance arises from the kinetic energy of electrons in the four quantum channels. It is fundamental to the prediction of the Luttinger liquid theory. Direct measurements at room temperature have been reported by Intel. That measurement is very challenging due to the large resistance compared to 50 ohms, and the small inductive impedance. We propose and demonstrate a new approach which uses two on-chip transmission line resonators to transform the nanotube impedance to nearly match the 50 ohm range of the microwave network analyzer. Simulations and cryogenic measurements will be presented.

This research was supported by NSF-CHE and NSFDMR.
4:42PM S30.00013 Zone Unfolding and Approximate Bandstructure Calculations in Tight-Binding
1, TIMOTHY BOYKIN, University of Alabama-Huntsville, NEERAJ KHARCHE, Purdue University, MATHIEU LUSIER, ETH Zurich, GERHARD KLMEEK, Purdue University — Tight-binding electronic structure calculations for periodic systems are often carried out in non-primitive unit cells, or for imperfect (e.g. random-alloy) nanostructures, such as nanowires. In the first case bands exist but they are difficult to identify due to the choice of unit cell for the calculation, while in the second case bands only exist in an approximate sense. The Brillouin zone unfolding technique applied to tight-binding calculations provides a powerful tool for extracting the true primitive-cell bands from non-primitive cells. Also, it is the starting point for approximate nanowire band calculations. We discuss zone unfolding in tight-binding and its application to both perfect and imperfect systems.

1Supported by Semiconductor Research Corporation.

4:54PM S30.00013 Gate Voltage Dependent Raman Scattering from Semiconducting Carbon Nanotube FETs, JAMES TSANG, MARCUS FREITAG, VASILI PEREBEINOS, PHAEDON AVOURIS, IBM T. J. Watson Research Center — The Raman spectrum of the carbon nanotube in a carbon nanotube FET changes reversibly as a gate voltage is applied, modifying the charge density in the channel. We show that the intensity of the G-line Raman scattering from semiconducting CNTFETs can decrease with applied gate voltage. This is in addition to our previously reported shift of the G-line to higher energies with no change in spectral width as the channel charge density increases. The spectral shift has been explained by gate voltage induced changes in the electronic excitations of the carbon nanotube which interact with the G-line. The gate voltage induced G-line shift and intensity changes observed in CNTFETs are similar to the changes observed for the G-line scattering between a suspended carbon nanotube over a trench, and the same tube on the substrate, where the G-line scattering from tube on the substrate shifts to higher energies and is weaker than the G-line scattering from the suspended tube. Gate voltage or substrate induced doping effects can modify the measured intensity of the Raman spectrum of a semiconducting carbon nanotube.

5:06PM S30.00014 Directed Assembly and Electrical Characterization of Carbon Nanotube-Molecule-Metal Junctions, KANSHENG CHEN, P. XIONG, Florida State University, S.A. MCGILL, National High Magnetic Field Laboratory — Molecular-template directed assembly has been shown to be an effective method for bottom-up assembly of high-performance single-walled carbon nanotube field-effect transistors (SWNT-FETs) 1. Here, we utilize this platform to carry out a systematic study of the electron transport behavior through SWNT-molecule-metal junctions. The devices were fabricated on doped-Si/SiO2 substrates: Au source/drain electrodes were first defined by electron beam lithography. Self-assembled monolayers (SAMs) of thiol molecules with polar ends were then created on either electrode by immersing the sample in molecule solution or on one of the electrodes by dip- pen nanolithography. Finally, SWNTs were selectively self-assembled onto the electrodes by putting a drop of SWNT solution on the template. The electron transport through the molecular SAM between the SWNT(s) and the Au electrodes were characterized through gated I-V measurements. The same devices were measured before and after the desorption of the molecular SAM(by baking) to directly elucidate the role of the molecules on the electron transport. The results will be presented and discussed.

5:18PM S30.00015 Thermal Imaging of Electrically-Heated Carbon Nanotubes using Raman Spectroscopy, SCOTT HSIIE, VIKRAM DESHPANDE, California Institute of Technology, ADAM BUSHMAKER, STEVE CRONIN, University of Southern California, MARC BOCKRATH, California Institute of Technology — Suspended carbon nanotubes have been known to exhibit striking negative differential conductance under high bias voltages1. To better probe the physics underlying this phenomenon, we have recently developed techniques to measure Raman spectra simultaneously with electrical transport, resulting in the direct observation of mode selective electron-phonon coupling2. Using similar techniques, we present spatially resolved data taken from long, suspended, and electrically contacted individual carbon nanotubes. Along with electrical transport, Raman spectra are taken at several points along the spatial coordinate, creating a spatial map of the Raman-active phonon populations and the lattice temperature profile. We use a finite element simulation to corroborate our data with a Landauer model and extract numerical values for key scattering and relaxation rate parameters and thermal contact resistances. This use of Raman spectroscopy constitutes a novel non-contact technique for probing local thermal data in nanosstructures.

Wednesday, March 12, 2008 2:30PM - 5:30PM — Session S31 DMP GMAG: Focus Session: Multiferroics I: 113 and 125 Morial Convention Center 223

2:30PM S31.00001 Dynamics and Phase Transitions in Multiferroic Helimagnets, HOSHI KATSURA, Department of Applied Physics, University of Tokyo, SHIGEKI ONODA, Condensed Matter Theory Laboratory, RIKEN, JUNG HOOON HAN, Department of Physics and Institute for Basic Science Research, Sungkyunkwan University, NAOTO NAGAOSA, Department of Applied Physics, University of Tokyo, CERC, CREST — The strong coupling between magnetism and ferroelectricity in multiferroics has recently been attracting much attention due to the fundamental physics involved and promising applications. The representative materials are helical magnets RMnO3 (R =Gd,Tb,Dy) and they have been extensively studied experimentally. We theoretically studied the dynamics and phase transitions in cycloidal helical magnets showing the multiferroic behavior. Our approach reproduces several novel features such as the anomalous dielectric response revealed by recent experiments on RMnO3 [1,2]. We also study the nature of the phase transition from collinear to helical spin structure. [1]N. Kida, Y. Ikebe, Y. Takahashi, J. P. He, Y. Kaneo, Y. Yamasaki, R. Shimano, T. Arima, and Y. Tokura, [arXiv:0711.2733]. [2]A. Pimenov, A. Loidl, A. A. Mukhin, V. D. Travkin, V. Yu. Ivanov, and A. M. Balbashov, [arXiv:0707.3614].

2:42PM S31.00002 Novel coupling of Tb- and Mn-magnetic orders in multiferroic TbMnO3, D.N. ARGIYROU, O. PROKHENKO, R. FEYERHERM, Hahn-Meitner-Institut, Glienicker Str. 100, Berlin D-14109, Germany, M. MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, 9747 AG Groningen, Netherlands, N. ALIOUANE, E. DUDZIK, A.U.B. WOLTER, A. MALJUK, Hahn-Meitner-Institut, Glienicker Str. 100, D-14109 Berlin, Germany — We report on diffraction measurements on multiferroic TbMnO3 which demonstrate that the Tb- and Mn-magnetic orders are coupled below the ferroelectric transition TF,E =28 K. For T < TF,E the magnetic propagations vectors (τ) for Tb and Mn are locked so that τTb=τMn, while below TFB=E =7 K we find that τTb and τMn lock-in to rational values of 3/7b* and 2/7b* respectively, and hold the relationship 3τTb+τMn = 1. We explain this novel matching of wave vectors within the frustrated ANNNI model coupled to a periodic external field produced by the Mn-spin order. The τTb=τMn behavior is recovered while the τTb=3/7 regime is stabilized by an optimal Tb spin-density wave ordering with 6 domain walls, superimposed on the τMn=2/7 Mn-ordering.

Wednesday, March 12, 2008 2:30PM - 5:30PM — Session S31 DMP GMAG: Focus Session: Multiferroics I: 113 and 125 Morial Convention Center 223
Electric polarization reversal in multiferroic TbMnO$_3$ with rotating magnetic field direction. NOBUYUKI ABE, SHINTARO OHTANI, Department of Physics, Tohoku University, KOUJI TANIGUCHI, TAKA-HISA ARIMA, IMRAM, Tohoku University, TAISHI TAKENOBU, YOSHIHIRO IWASA, IMR, Tohoku University — Recent extensive studies of magneto-electric multiferroics have revealed that the magnitude and direction of electric polarization can be considerably modified by the application of a magnetic field. TbMnO$_3$ is a prototypical multiferroic which shows the electric polarization flop from $P // c$ to $P // a$ by the application of magnetic field along the $b$ or $a$ axis. We have found that the direction of the magnetic-field induced polarization along the $a$-axis ($P_a$) is memorized even in the zero field where $P_a$ is absent. The polarization direction can be reversed by rotating the magnetic field direction in the ab plane. For the memory application of the multiferroic material, such a bistability in zero field and a switching between the bistable states with some nonoverlapping stimulus are essential.

Spiral magnetic order in the ferroelectric phase of Gd$_{0.7}$Tb$_{0.3}$MnO$_3$. YUCHI YAMASAKI, Y. TOKURA, K. SASAI, M. MATSUURA, K. HIROTA, University of Tokyo, 6-7-1 Hongo, Bunkyo-ku, Tokyo 113-0033 Japan, KOUJI TANIGUCHI, TAKA-HISA ARIMA, Y. NODA, Tohoku University — Perovskite manganite Gd$_{0.7}$Tb$_{0.3}$MnO$_3$ possesses a ferroelectric phase with an electric polarization along the $a$ axis ($P||a$) in zero magnetic field, while RSmMnO$_3$ ($R$=Tb and Dy) undergo ferroelectric transitions with $P$ along the $c$ axis ($P||c$). The $P||a$ phase emerges upon the incommensurate to commensurate transition of the lattice modulation in a similar way of the magnetic field induced $P||a$ phase of TbMnO$_3$. The polarized neutron diffraction and the magnetic structure analysis of the $^{155}$Gd$_{3+}$-enriched single crystal of Gd$_{0.7}$Tb$_{0.3}$MnO$_3$ were performed to uncover the coupling between the magnetic order and the ferroelectric polarization $P||a$ on a microscopic level. We found that the ferroelectric transition occurs concomitantly with the collinear to spiral spin transformation and the spin helicity can be controlled by the electric field applied on cooling. Namely, the ferroelectric polarization in the $P||a$ phase can be explained by the spin current model as well as the $P||c$ phases known for TbMnO$_3$.

Reentrant electromagnons in multiferroic Eu$_{0.75}$Y$_{0.25}$MnO$_3$ in the H-T phase diagram. ROLANDO VALDES AGUILAR, A.B. SUSHKOV, H.D. DREW, MRSEC, Department of Physics, University of Maryland, College Park, MD 20742, J.Y. CHOI, C. ZHANG, S-W. CHEONG, Rutgers University, Piscataway, NJ 08854 — The electromagnon spectra of Eu$_{0.75}$Y$_{0.25}$MnO$_3$ has been measured as a function of magnetic field $H$ || c up to 8 T and temperature between 5 and 300 K. Three magnetic induced electric dipole features reported earlier are observed to weaken simultaneously but not shift for increasing field. These electromagnons features all show reentrant behavior as a function of temperature for $H > 6$ T and with the anomalies in the static dielectric constant, confirming their electromagnon origin. While the magnetic structure of Eu$_{0.75}$Y$_{0.25}$MnO$_3$ is unknown, it is assumed that it is a cycloidal magnet where the spins lie in the crystallographic a-b plane, based on the behavior of the magnetic susceptibility and the direction of static polarization $P$. Therefore, it appears that the electromagnon selection rule, $|\epsilon\alpha\alpha|$, in all the multiferroic RSmMnO$_3$ magnetics is independent of the spin plane and polarization direction. We will compare the phase diagrams of Eu$_{0.75}$Y$_{0.25}$MnO$_3$ and TbMnO$_3$ where similar anomalies are observed.

Reentrant electromagnons in multiferroic Eu$_{0.75}$Y$_{0.25}$MnO$_3$. DIYAR TALBAYEV, ANTOINETTE J. TAYLOR, Los Alamos National Laboratory, RICHARD D. AVERITT, Boston University, CHENGLIN ZHANG, SANG-WOOK CHEONG, Rutgers University — Dynamical studies of multiferroic materials help unravel the fundamental interactions between various degrees of freedom and answer technological questions such as achievable switching speeds in multiferroic-based memory elements. We report the results of the ultrafast pump-probe reflectance study of multiferroic Eu$_{0.75}$Y$_{0.25}$MnO$_3$. The material undergoes antiferromagnetic ordering and, upon further cooling, ferroelectric ordering that strongly couples to the material’s magnetic state. We measured the relaxation time of the pump-probe reflectance in this compound using 800-nm pump and probe pulses. The temperature dependence of the relaxation time follows that of the low-energy spectral weight that includes phonons and electro-active magnons [1]. This suggests a strong coupling between electronic (1.55 eV) and low-energy electro-active excitations in Eu$_{0.75}$Y$_{0.25}$MnO$_3$ that can be tuned by magnetic field. The relaxation time increases upon the application of magnetic field along the crystal’s c-axis in the ferroelectric phase, but exhibits no change in the paraelectric phase. Our results indicate the importance of multiple energy scales (electronic, lattice, and magnetic) for the multiferroicity of Eu$_{0.75}$Y$_{0.25}$MnO$_3$. 1. R. Valdes Aguilar et al, Phys. Rev. B 76, 060404(R) (2007)

Theory of terahertz absorption spectra due to two-magnon processes in cycloidal spin magnets. SHIN MIYAHARA, Multiferroics Project (MF), ERATO, Japan Science and Technology Agency (JST), NOBUO FURUKAWA, Aoyama Gakuin University — Perovskite manganites $RMnO_3$ have an attraction both experimentally and theoretically after the discovery of the ferroelectric polarization and its flop by external magnetic field. Recently the measurements by the terahertz time-domain spectroscopy have been investigated with the several sets of light polarization, and novel magnon states induced by the electric field are observed. Such a spin excitation is called an electromagnon. However, the origin of the electric-dipole active absorption is not clarified yet. We calculated the absorption of light due to the electric dipole transitions associated with two-magnon excitations in cycloidal spin magnets. The theory is applied to the ferroelectric magnets $RMnO_3$, and absorption peaks in terahertz time domain spectroscopy, which correspond to electromagnons, are interpreted with reasonable parameter sets.

Resonant magnetic scattering of multiferroic HoMnO$_3$ in an applied electric field. S. NANDI, A. KREYSSIG, L. TAN, J.W. KIM, J.Q. YAN, Ames Laboratory and Dept. of Physics and Astronomy, Iowa State Univ., J.C. LANG, D. HASKEL, Advanced Photon Source, Argonne National Laboratory, R.J. MCQUEENEY, A.I. GOLDMAN, Ames Laboratory and Dept. of Physics and Astronomy, Iowa State Univ. — The multiferroic material HoMnO$_3$ displays electrical polarization $P_c = 5.6 \mu$C cm$^{-2}$ along the hexagonal c axis below the Curie temperature $T_C = 875$ K and antiferromagnetic Mn$^{3+}$ ordering at the Néel temperature, $T_N = 75$ K. The recently reported ferromagnetic response of Ho$^{3+}$ by an applied electric field opens up the possibility of electric field controlled magnetic data storage. However, both the role of Ho$^{3+}$ in magnetism and details of the magnetic structure of Ho$^{3+}$ have been topics of significant debate. Using element specific x-ray resonant magnetic scattering and x-ray magnetic circular dichroism, we have focused on resolving this controversy. Both quadrupole and dipole Ho $L_{111}$ resonances were observed below 40 K. In zero field, Ho$^{3+}$ orders antiferromagnetically with moments along the c direction below 40 K and undergoes a transition to a different magnetic order below 4.5 K. The role of Ho$^{3+}$ upon the application of an external electric field in the temperature range 1.7-80 K will be discussed. – The support by U.S. DOE (DE-AC02-07CH11358 and DE-AC02-06CH11357) is acknowledged.
measurements suggest that Dy plays an active role in enhancing the ferroelectric polarization in multiferroic DyMnO$_3$.

Hahn-Meitner-Institut, Glienicker Str. 100, Berlin D-14109, Germany — Neutron powder diffraction and single crystal x-ray resonant magnetic scattering evolution of an incommensurate ordering of Dy moments with the same periodicity as the Mn spiral ordering. It closely tracks the evolution of the ferroelectric polarization. Below $T_{N}^{Dy}$, where Dy spins order commensurately, the polarization decreases to values similar for those of TbMnO$_3$. The higher $P_s$ found just above $T_{N}^{Dy}$ arises from the contribution of Dy-spins so as to effectively increase the amplitude of the Mn spin-spiral.

4:18PM S31.00010 Electrically driven spin excitation in a ferroelectric magnet DyMnO$_3$. N. KIDA, Multiferros Project, ERATO, JST, Y. IKEBE, Univ. Tokyo, Y. TAKAHASHI, J.P. HE, Y. KANEKO, Multiferros Project, ERATO, JST, Y. YAMASHI, Univ. Tokyo, R. SHIMANO, Multiferros Project, ERATO, JST and Univ. Tokyo, T. ARIMA, Tohoku Univ., N. NAGAOUSA, Univ. Tokyo and RIKEN, Y. TOKURA, ERATO-JST, Univ. Tokyo, and RIKEN — In multiferroic manganites, there have been recent experimental and theoretical arguments on the possibility of the presence of the low-lying spin excitation, called electromagnon, where the spin excitation electrically becomes active [1]. Here we report on a complete set of low-energy (1–10 meV) electrodynamics of spin excitations for a multiferroic DyMnO$_3$ with variations of the light polarization in a variety of phases tuned by both temperature (5–250 K) and magnetic field (0–70 kOe) [2]. We identify the pronounced absorption continuum (1–8 meV) with a peak feature around 2 meV, which is electric-dipole active only for the light E-vector along the a-axis. This absorption band grows in intensity with lowering temperature from the spin-collinear paraelectric phase above the ferroelectric transition, but irrespectively of the direction of the bc or ab spiral spin plane. The possible origin of this electric-dipole active band is argued in terms of the gigantic fluctuations of spins and spin-current. [1] A. Pimenov et al., Nat. Phys. 2, 97 (2006). [2] N. Kida et al., arXiv:0711.2733

4:30PM S31.00011 Spin structures of magnetic phases in YMn$_2$O$_5$. J.-H. KIM, S.-H. LEE, University of Virginia, S. WAKIMOTO, M. MATSUDA, JAE, H. KIMURA, Y. NODA, Tohoku University, S. JUERG, PSI, M. KENZELMANN, ETH/PSI, C.F. MAJKRZAK, NIST, S.-I. PARK, KAERI, S. PARK, S.W. CHEONG, Rutgers University — A magnetic ferroelectric material, YMn$_2$O$_5$, undergoes several magnetic phase transitions at low temperatures and develops spontaneous electric polarization along the b-axis in a commensurate magnetic phase with a characteristic wave vector of (0.5,0.0,0.25). We have determined the commensurate spin structure by performing four circle neutron diffraction (FCD) and three-dimensional polarization analysis (CRYOPAD) on a single crystal of YMn$_2$O$_5$. In the spin structure, Mn$_4^+$ moments form a transverse (cycloidal) spiral structure along the c-axis that can induce the spontaneous electric polarization along the b-axis.

4:42PM S31.00012 Magnetic domains in multiferroic YMn$_2$O$_5$ probed by Spherical Neutron Polarimetry under electric field. CARLO VECCHINI, LAURENT CHAPON, PAOLO RADAELLI, AZIZ DAOUD-ALADINE, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot, Oxfordshire, UK11 0QX, UK, JANE BROWN, TAPAN CHATTERJI, Institut Laue-Langevin, 6, rue Jules Horowitz, BP156-38042 Grenoble Cedex 9 - France, SOONYONG PARK, SANG-WOOK CHEONG, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — Precise determination of the magnetic structures in multiferromagnetic materials, YMn$_2$O$_5$, can be obtained by single crystal neutron diffraction. The analysis shows the presence of zig-zag antiferromagnetic chains in the ab-plane. An additional weak magnetic component parallel to the c-axis was detected which is modulated in phase quadrature with the a-b components. The nature and population of the coexisting antiferromagnetic domains in YMn$_2$O$_5$ have been determined by Spherical Neutron Polarimetry under an external electric field. We have proved that reversing the electrical field results in the inversion of the population of two types of antiferromagnetic domains, with opposite in-plane spin components. This analysis strongly supports theories in which the coupling of the magnetic configuration to the ferroelectric polarization is due to magnetic exchange striction and likely not related to the small cycloidal modulation in the bc-plane.

5:06PM S31.00013 Electromagnon H-T phase diagram of multiferroic TbMn$_2$O$_5$. DENNIS DREW, ANDREI SUSHKOV, ROLANDO VALDES AGUILAR, Department of Physics, University of Maryland, College Park MD, SOONYONG PARK, SANG-WOOK CHEONG, Rutgers University, Piscataway, New Jersey 08854, USA — We report the results of infrared (5–250 cm$^{-1}$) transmission study of multiferroic TbMn$_2$O$_5$ as a function of temperature (3–300 K) and H on magnetic fields up to 8 T. Our major observation is that the main electromagnon feature softens without splitting with increasing field at T = 5 K. This observation is in contrast with the gradual suppression of electromagnons without shifting by magnetic field in RmnO$_3$ compounds. Also, it is in agreement with the theoretical prediction of Fang and Hu [2] for this system. In this talk, we will also discuss other features of the magnetic field dependence of the low energy electromagnon excitations in multiferroic TbMn$_2$O$_5$.

5:50PM S31.00014 Far Infrared Anomalies in Orthorhombic Multiferroics (Bi,Pr)Mn$_2$O$_5$. N.E. MASSA, LANIS EFO-CEQUINOR, UNLP, CP 962, 1900, La Plata, Argentina, D. DE SOUSA MENESES, P. ECHEGUT, CNRS- CRMHT-F45071, Orleans, France, M.J. MARTINE-LOPE, J.A. ALONSO, CSIC-ICMM-Cantoblanca, E28049 Madrid, Spain — We report on far infrared reflectivity between 4 K and 300 K of polycrystalline BiMn$_2$O$_5$ and PrMn$_2$O$_5$ known to sustain orbital, lattice, charge, and spin interactions. After conventional temperature mode stiffening band profiles undergo a relative intensity raise with maximum in the interval ~40K to ~30 K (magnetic ordering temperature, T_N, and the onset of ferroelectricity, T_{C2}) indicative of a general electric polarization. We do not observe on cooling, in agreement with our high resolution neutron diffraction patterns, new phonon patterns which might be associated to structural changes. Below 30 K there is a weak reflectivity attenuation at about the temperature in which the spin glass sets in. In contrast, in PrMn$_2$O$_5$, we found a Drude shaped overdamped band centered at zero frequency that, active at all temperatures, develops substructure below 15 K. We associate this feature to collective modes responsible for ferroelectricity of magnetic origin ascribed to coupling spins with electronic polarization without atomic displacement. In overall, our spectra suggest a qualitative agreement with magnetoferroelectricity originating in spin dislocation and commensuration.

5:18PM S31.00015 Magnetic X-ray scattering in multiferroic HoMn2O5. LAURENT CHAPON, ISIS, Rutherford Appleton Laboratory, GUILLEAUME BEUTIER, ALESSANDRO BOMBARDI, Diamond Light Source, Rutherford Appleton Laboratory, CARLO VECCHINI, PAOLO RADAELLI, ISIS Facility, Rutherford Appleton Laboratory, S. PARK, SANG-WOOK CHEONG, Rutgers University — The commensurate magnetic phase of multiferroic HoMn2O5 has been identified by magnetic scattering off resonance and at the L3 edge of Holmium. The magnetic ordering of the Manganese ions below 40 K induces a magnetic order of Ho. Due to the element selectivity of the technique we were able to extract the temperature dependence of the Ho ordering up to temperature very close to TN. Azimuthal scans confirm the recent model of the magnetic structure determined from single neutron diffraction data, for both the Manganese and Holmium ions. The d-f coupling is discussed in the light of these results.
2:30PM S32.00001 Bound states in electronic transport through Fe/MgO tunnel junctions. IVAN RUNGER, NADJIB BAADJI, STEFANO SANVITO, School of Physics and CRANN, Trinity College, Dublin 2, Ireland — Using the ab initio code Smeagol we calculate the electronic transport properties of Fe/MgO/Fe(100) tunnel junctions for applied bias up to 2 Volt. The correct bias-dependent occupation of the interface states (IS) in the Fe/MgO junction is crucial to obtain a physically meaningful potential drop. The coupling of the IS to the Fe electrodes varies strongly for different k-points, and bound states are found along the high symmetry lines and at those k-points where there are no open channels in the Fe leads. A general method for setting the occupation of both weakly-coupled and bound states, based on the notion of a local Fermi energy and a finite relaxation time, is presented. For parallel alignment of the Fe leads the current through the IS is quenched above 20 mV, whereas for the anti-parallel alignment the current flows mainly through IS up to about 0.4 V. In this bias range the TMR shows a pronounced bias dependence, at higher voltages it decays smoothly. If the transmission through the IS is suppressed, for example by adding a finite imaginary part to the energy, the TMR decays monotonically with bias even at low voltage. Finally we show that oxygen vacancies inside the MgO barrier quench the TMR if they are within the first few layers from the interface, and that a similar reduction is achieved by partially oxidizing the Fe interface layer.

2:42PM S32.00002 Fabrication and characterization of fully epitaxial Fe/MgO/Fe magnetic tunnel junctions on Si(100) and the influence of MgO buffer layer1. G. X. MIAO, M. V. VEENHUIZEN, MIT, M. MUNZENBERG, Universitat Gottingen, J. S. MOODERA, MIT — Spin injection into Si can integrate the spin degree of freedom into future semiconductor technology. Coherent tunneling through epitaxial MgO barrier due to symmetry filtering is expected to yield large spin polarization [1]. Here we report the MBE growth of fully epitaxial Fe/MgO/Fe MTJ stacks on top of Si(100) with epitaxial MgO buffer layer giving rise to a large TMR. Due to the large lattice mismatch between Si and MgO (~9.6%), the crystalline structure of MgO is critically dependent on its thickness, and the influence is subsequently passed on to the MTJ structure. We observe a systematic change of TMR with the buffer layer thickness, which we attribute to the effect of dislocations. Coherent growth of MTJ on top of Si is a significant step toward spin injection into Si [2]. 1. W. H. Butler et al., Phys. Rev. B, 63, 054416 (2001).

2:54PM S32.00003 Temperature and Angular Dependences of Dynamic Spin-Polarized Resonant Tunneling1. CASEY W. MILLER, University of South Florida, Tampa FL 33620, USA, JOHAN ÅKERMANN, YAN ZHOU, Royal Institute of Technology, Electrum 229, 164 40 Kista, Sweden, RENU DAVE, JON SLAUGHTER, Technology Solutions Organization, Freescale Semiconductor, Inc., Chandler AZ 85224, USA, IVAN K. SCHULLER, UC San Diego, La Jolla CA 92039, USA — The bias dependence of tunneling magnetoresistance oscillations due to dynamic resonant tunneling in CoFeB/MgO/NiFe magnetic tunnel junctions was studied as functions of temperature and the relative magnetization angle of the two magnetic layers. The effect of temperature is consistent with thermal smearing, while that of the relative magnetic orientation was typical of a spin valve. A model of tunneling between spin-split free electron bands using the exact solution of the Schrödinger equation for a trapezoidal tunnel barrier agrees with experiment.

3:06PM S32.00004 Transport and spin transfer torques in Fe/MgO/Fe tunnel barriers. CHRISTIAN HEILIGER, CNST, NIST, Gaithersburg, MD / NanoCenter, UMD, College Park, MD — The prediction of very high tunneling magnetoresistance (TMR) ratios in crystalline Fe/MgO/Fe [1,2] tunnel junctions has been verified by a number of experiments [3,4]. The high TMR can be understood in terms of the electronic structure of the system. In MgO the Δ±1 states at the Brillouin zone center decay the most slowly and dominate the tunnelling current. For coherent interfaces, which are affected more strongly by the small lattice mismatch between Fe and MgO, these Δ±1 states at the Brillouin zone center are half-metallic in the Fe layers. The dominance of the Δ±1 states and their half-metallicity cause the high tunneling magnetoresistance measured in Fe/MgO/Fe tunnel junctions [5]. For the spin transfer torque, we calculate the linear response for small currents and voltages. Our calculations show that the half-metallicity of the Fe Δ±1 states leads to a strong localization of the spin transfer torque to the interface. As a result, the linear current dependence of the torque in the plane of the two magnetizations is independent of the free layer thickness for more than three monolayers of Fe. For perfect samples we also find a linear current dependence of the out-of-plane component. However, this linear piece oscillates rapidly with thickness and averages to zero in the presence of structural imperfections like thickness fluctuation, in agreement with experiment [6].

3:09PM S32.00005 Tunneling Magnetoresistance in MgO based double-barrier Magnetic Tunnel Junctions1. WEIGANG WANG, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716, CHAOYING NI, Department of Materials Science and Engineering, University of Delaware, Newark, Delaware 19716, Q. WEN, H.W. ZHANG, University of Electronic Science and Technology of China, Chengdu, 610054, China, TAKAHIRO MORIYAMA, JOHN XIAO, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716 — Double-barrier magnetic tunnel junctions (DMTJs) have attracted much attention due to their fertile physics and promising applications in spintronics devices. Here we report the fabrication and characterization of DMTJs of Si/ SiO2/Ta 7/Ru 20/Ta 7/CoFe 2/IrMn 15/CoFe 2/Ru 1.7/CoFeB 3/MgO 2/CoFeB 3/MgO 2/CoFeB 3/Ru 1.7/CoFe 2/IrMn 15/Ta 8/Ru 10, where the numbers are layer thickness in nanometers. Single barrier MTJs with similar structure were also fabricated. While the DMTJs exhibit the tunnel magnetoresistance (TMR) of 185 % at room temperature, which is the highest value in DMTJs reported to date, the corresponding single barrier MTJ shows 300% TMR. The reduction of TMR in DMTJs is understood in terms of sequential tunneling through two junctions in series. The effects of annealing temperature and bias voltage on the TMR of DMTJs will also be discussed.

This work is supported by NSF DMR Grant No. 0405136.
3:54PM S32.00006 Influence of spin accumulation on superconducting properties of aluminum layers in magnetic double tunnel junction devices. SEE-HUN YANG, HYUNSOO YANG, IBM Almaden Research Center, 650 Harry Road, San Jose, California 95120, USA, SABURU TAKAHASHI, SADAMICHI MAEKAWA, [1] Institute for Materials Research, Tohoku University, Sendai 980-8577, Japan, STUART PARKIN, IBM Almaden Research Center, 650 Harry Road, San Jose, California 95120, USA, IBM ALMADEN RESEARCH CENTER TEAM, TOHOKU UNIVERSITY COLLABORATION — We discuss the influence of spin accumulation on the superconducting (SC) properties of thin aluminum layers in crystalline MgO barrier based magnetic double tunnel junction devices composed of ferromagnet-insulator-superconductor-insulator-ferromagnet (FISIF) structures. Below the Al SC transition temperature, when the magnetization directions of the two outer CoFe ferromagnetic layers are antiparallel, the SC energy gap of the Al layer is suppressed, as compared to the case for parallel orientation of these same layers. This is consistent with theoretical models in which spin polarized quasi-particles are accumulated in the SC layer. The accumulated spin depends on the rate at which spin polarized current is injected and leaves and, most importantly, on the spin relaxation rate of the injected quasi-particles. We discuss the dependence of the spin accumulation on the spin-injection rate, which can be varied at a fixed voltage, by varying the MgO barrier thickness.

4:06PM S32.00007 Enhanced tunneling spin polarization by amorphizing usually crystalline CoFe alloys without any glass forming additives. LI GAO[1], XIN JIANG, SEE-HUN YANG, PHILIP M. RICE, STUART S.P. PARKIN, IBM RESEARCH DIVISION, ALMADEN RESEARCH CENTER, SAN JOSE, CA 95120, USA COLLABORATION — Ferromagnetic alloys of Co and Fe are particularly useful electrodes in magnetic tunnel junctions because they exhibit high spin polarization and high Curie temperatures as well as high thermal stability. These alloys are crystalline but they can be made amorphous by adding suitable glass-forming elements such as Boron. Here we show that films of pure CoFe alloys can be made amorphous, without the need of any additives, by sandwiching them between two amorphous layers, a tunnel barrier formed from amorphous Al2O3 and an amorphous overlay layer. The films are amorphous when thinner than ~25 Å but are crystalline for thicker layers. We find that both the tunneling magnetoresistance and the tunneling spin polarization (measured using superconducting tunneling spectroscopy in related junctions) are significantly enhanced when the alloy is amorphous. However, by heating the alloy above its glass crystallization temperature the enhancement is observed to vanish. Possible reasons for this behavior are discussed.

4:18PM S32.00008 Tunneling Anisotropic Magnetoresistance in Co/AIOx/Au Tunnel Junctions[1]. RUISHENG LIU, Halmstad University and Lund University, Sweden, LUKASZ MICHALAK, CARLO CANALI, Kalmar University, Sweden, LARS SAMUELSON, Lund University, Sweden, HANAN PETTERSSON, Halmstad University, Sweden — We observe spin-valve-like effects in nano-sized thermally evaporated Co/AIOx/Au tunnel junctions. The tunneling magnetoresistance is anisotropic and depends on the relative orientation of the magnetization direction of the Co electrode with respect to the current direction. We attribute this effect to a two-step magnetization reversal and an anisotropic density of states resulting from spin-orbit interaction. The results of this study points to future applications of novel spintronics devices involving only one ferromagnetic layer.

4:30PM S32.00009 Transport Studies of reduced RA product MTJs produced by highly charged ion irradiation. JOSHUA POMEROY, HOLGER GRUBE, National Institute of Standards and Technology — As is commonly known, magnetic tunnel junctions (MTJs) are used for hard drive read heads and are actively being developed for MRAM. In both of these cases, the resistance-area (RA) product is a critical parameter for device speed and bandwidth as well as total power dissipation (particularly for current driven devices). We present transport studies of MTJs whose barrier oxide has been partially reduced by highly charged ions (HCIs). The bias, temperature, and applied field dependence of these devices will be discussed. Beyond magnetic memory applications, HCI modified MTJs provide a compelling new route for preparing order THz spin torque oscillators.

4:42PM S32.00010 Large voltage from spin pumping in magnetic tunnel junctions. ZHIFANG LIN, Fudan University, SIU TAT CHUI, University of Delaware — We studied the response of a ferromagnet-insulator-normal metal tunnel structure under an external oscillating radio frequency (R.F.) magnetic field. The D.C. voltage across the junction is calculated and is found not to decrease despite the high resistance of the junction; instead, it is of the order of μV to 100μV, much larger than the experimentally observed value (100 nano-V) in the "strong coupled" ohmic ferromagnet-normal metal bilayers. This is consistent with recent theoretical results in tunnel structures, where the voltage is larger than μV.

5:06PM S32.00012 Space-Charge Induced Pauli Blockade Effect in Tunnel Junctions with Half-Metallic Electrodes[1]. A. P. LI, T.-H. KIM, X.-G. ZHANG, Oak Ridge National Laboratory, J. F. FENG, X. F. HAN, Chinese Academy of Science, Y. WANG, J. ZOU, The University of Queensland, D. B. YU, Grien Advanced Materials Co., Ltd., H. YAN, Beijing University of Technology — A space-charge induced Pauli spin blockade effect has been observed in the magnetic tunnel junction consisting of La0.95Sr0.05MnO3 (LSMO) and SrTiO3 barrier at temperatures up to 100 K. The blockade voltage under zero magnetic field provides a direct measurement of the energy gap between the Fermi energy and the top of the minority spin valence band of the LSMO. Outside the spin blockade regime, the low temperature conductance oscillates with the bias voltage as the trap centers are charged by electrons. The spin blockade can be lifted when the trap levels are thermally activated or when a large magnetic field lowers the LSMO minority spin mobility edge to below the Fermi energy. A very large magnetoresistance up to 10000% is observed and is correlated to the blockade effect. *Email: apli@ornl.gov

5:18PM S32.00013 First-principles theory of nonequilibrium vertex correction: disordered magnetic tunneling junction. YOUGI KE, KE XIA, HONG GUO, McGill University, HONG GUO TEAM, KE XIA TEAM — The Kubis-Nash Green's Function (NEGF) formalism has been developed within DFT to calculate the electronic structure of disordered systems. The conditionally averaged NEGF is evaluated by the vertex correction. The disordered Fe/Va/Fe tunneling junctions are investigated with present first principle method, the vertex correction shows important role in both the electronic structure and transport calculations. The bias dependence of Tunneling Magnetoresistance (TMR) in the disordered Junctions and the disordered dependence of TMR at a finite Bias were illustrated.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S33 GMAG FIAP DMP: Focus Session: Mostly III-V Semiconductors

2:30PM S33.00001 Strain-induced Fermi contour anisotropy of GaAs (311)A 2D holes. JAVAD SHABANI, MANSOUR SHAYEGAN, Department of Electrical Engineering, Princeton University, ROLAND WINKLER, Department of Physics, Northern Illinois University — There is considerable current interest in electronic properties of two-dimensional (2D) carriers whose energy bands are split at finite values of in-plane wave vector, thanks to the spin-orbit interaction and the lack of inversion symmetry. We report experimental and theoretical results revealing that the spin-subband Fermi contours of the heavy and light heavy-holes (HHh and HHH) can be tuned in high mobility GaAs (311)A 2D hole systems via the application of symmetry-breaking in-plane strain. Our calculations show that the HHH spin-subband Fermi contour is circular but the HHh spin-subband Fermi contour is distorted. Experimentally, we prove the Fermi contour anisotropy by measuring the magneto-resistance commensurability peaks induced by square arrays of antidots. When the spin splitting is sufficiently large, the magneto-resistance trace exhibits two peaks, providing clear evidence for spin-resolved ballistic transport. The experimental results are in good agreement with the calculations, and confirm that the majority spin-subband (HHH) has a severely distorted Fermi contour whose anisotropy can be tuned with strain while Fermi contour of the minority spin-subband (HHH) remains nearly isotropic.

2:42PM S33.00002 Strain-induced spin splittings in III-V and II-VI semiconductors. B.J. MOEHLMANN, MICHAEL E. FLATTÉ, OSTC and Department of Physics and Astronomy, University of Iowa — We have calculated the strain-induced spin splittings in III-V and II-VI semiconductors using a fourteen-band basis for a strain-dependent k - p Hamiltonian. Using deformation potentials from pseudopotential calculations we find quantitative agreement with the precessional rates observed in [1]. For GaAs, the contribution of upper-conduction-band deformation potentials to the strain-induced spin splitting is not negligible. The ratio of the strain-induced spin precession frequency to the drift velocity is similar for GaAs and InAs, but is an order of magnitude larger for GaSb and InSb. For ZnSe it is a factor of 2 smaller than GaAs. This work was supported by an ONR MURI. [1] Kato et al., Nature 427, 50 (2004).

2:54PM S33.00003 Electric field dependent g tensor modulation for a hydrogenic Si donor in bulk GaAs1. AMRIT DE, CRAIG E. PRYOR, MICHAEL E. FLATTÉ, Department of Physics and Astronomy and Optical Science and Technology Center, University of Iowa — We present calculations demonstrating the feasibility of electrical manipulation of a donor bound electron spin using g tensor modulation resonance. We calculate the electron g factor as a function of applied electric field, and show that dxy/dE is largest when the applied magnetic and electric fields are parallel. Unlike quantum dots, the donor’s g factor is highly nonlinear as a function of the applied magnetic field, and the anisotropy of the g tensor also has a strong magnetic field dependence. The calculations are for a Si impurity in GaAs, and are done using real-space 8-band k-p theory in the envelope approximation.

3:06PM S33.00004 Gilbert Damping in (Ga, Mn) As , ION GARATE, ALLAN MACDONALD, University of Texas at Austin — We examine Gilbert damping in (Ga,Mn)As by using a p-d mean-field theory model for the ferromagnetic ground state and a four-band spherical model for the host semiconductor band structure. Within this model it is possible to calculate impurity vertex- corrections to the long-wavelength spin-spin response functions to all orders. Because of spin-orbit coupling in the band structure, beyond leading order vertex corrections make significant contribution to the damping. We comment on the non-monotonic dependence of damping on impurity strength.

3:18PM S33.00005 Magnetic patterning of GaMnAs layers by hydrogen passivation. L. THEVENARD, A. LEMAITRE, G. FAINI, Lab. Photonique et Nanostructures, N. VERNIER, J. FERRE, Lab. Physique des Solides, S. FUSIL, UMR CNRS Thales — In order to study the magnetic switching behavior of diluted magnetic semiconductor (DMS) microstructures, we have patterned thin layers of (Ga,Mn)As by an original method. We have used local hydrogen passivation to locally suppress the carrier-mediated ferromagnetic phase. This purely diffusive process maintains the continuity of the film and smooths border effects. Two types of structures were examined by Kerr microscopy, and their magnetic behavior compared to that of structures made by dry etching1. On hydrogenated arrays of micron-sized magnetic dots, the switching fields were closer to the continuous film coercivity, and with a smaller dispersion. On micron-wide magnetic stripes, current-induced domain wall (DW) propagation was observed with typical currents as low as j = 4×107 A·cm⁻², a result of the low edge roughness induced by the patterning, and the low density of magnetic atoms. Local hydrogen passivation therefore appears as a viable route towards lower injection currents in DMS spintronics devices based on DW manipulation. 1 L. Thevenard et al., Appl. Phys. Lett. 91, 142511 (2007)

3:30PM S33.00006 Infrared longitudinal and Hall conductivities in Ga1−xMnx As films. HEORGHIE AGBAS, M.-H. KIM, J. CERN, Physics Dept. Univ. at Buffalo, SUNY, Buffalo, NY, M. CUKR, V. NOVAK, T. JUNGWIRTH, Institute of Physics, Acad. of Sciences of the Czech Republic, Prague, Czech Republic, J. SINOVÁ, Physics Dept., Texas A&M Univ., College Station, TX — We determine the complex infrared (0.1-1.2 eV) magneto-conductivity tensor of a series of Ga1−xMnx As films from the complex Faraday and Kerr angles as outlined in M.-H. Kim, et al., Phys. Rev. B 75, 214416 (2007). A systematic series of samples with varying Mn and hole concentrations is studied. The samples range from insulating to metallic. The frequency dependence of the real part of the longitudinal conductivity σxx is consistent with the values determined from transmission and reflection measurements. The complex transverse (Hall) conductivity σyz shows resonances associated with the inter-valence band transitions. As the Mn concentration decreases these transitions become broadened due to increased disorder. The temperature dependence shows non-monotonic behavior with sign changes at certain wavelengths. The data is compared with predictions from a disordered valence band model (T. Jungwirth, et al., Phys. Rev. B 76, 125206 (2007)). This work is supported by the Research Corporation Cottrell Scholar Award (Buffalo and Texas A&M), NSF-CAREER-DMR0449899 (Buffalo), an instrumentation award from the CAS, Univ. at Buffalo, ERAS-CT-2003-980409 (Prague) and NSF-CAREER-DMR-0547875 (Texas A&M).
3:42PM S33.00007 An n-type tunable two-dimensional ferromagnetic semiconductor. ANGELO BOVE, F. ALTOMARE, N. KUNDTZ, A. CHANG. Physics Department, Duke University, Durham, NC 27708. — In the past two decades ferromagnetic semiconductors have been a focus of intense study because of their potential technological application for spintronics. Particular attention has been dedicated to III-V Diluted Magnetic Semiconductors (DMS), where the ferromagnetism (FM) is hole-mediated and the Curie temperature can therefore be tuned by changing the concentration of free carriers. In these structures, the Anomalous Hall Effect (AHE) has played a key role in establishing that FM is hole-mediated. We will present data that show the first evidence of electron-mediated FM in GaMnAs. Our heterostructure has a low carrier density (\(\sim 1.1 \times 10^{12} \text{cm}^{-2}\)), a mobility of \(\sim 600 \text{cm}^2/\text{V} \cdot \text{s}\) and excellent gating capabilities. We will also present data that show the first clear bound on the AHE in an electron-mediated DMS and find it much reduced in magnitude when compared to the case of hole-mediated FM.

3:54PM S33.00008 Electrically-induced Spin Coherence by Ultrafast Electrical Spin Injection. B. BESCHLEROß, L. SCHREIBER, J. MORITZ, C. SCHWARK, G. GUENTHERODT. Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN — Efficient electrical spin injection from a ferromagnet into a semiconductor has been demonstrated for various material systems by steady-state experiments. We introduce a novel time-resolved technique based on electrical pumping and optical probing. As a pump we apply ultrafast current pulses (\(\sim 200 \text{ps}\)) to electrically inject spin packets from an iron layer through a reverse biased Schottky barrier into a n-GaAs layer. Spin coherence in the semiconductor is probed by subsequent spin precession in a transverse magnetic field using time-resolved Faraday rotation. We observe spin precession for current pulse widths down to 200 ps. The spin polarization of the spin packets is directly measured by Faraday rotation and is found to increase linearly with the current pulse width for pulses shorter than 3 ns at small magnetic fields. This finding together with independent measurements of the samples' high frequency bandwidth indicate that even shorter than 200 ps pulses might be used for generating coherent spin currents in our devices. Work supported by BMBF, DFG and HGF.

4:06PM S33.00009 Electrical detection of spin polarized current in semiconductors using Andreev reflection. PARTHA MITRA, MENG ZHU, NITIN SAMARTH. Department of Physics, The Pennsylvania State University — Electron transport across the interface between a superconductor and a normal conductor is sensitive to the spin populations of electrons in the conduction band of the latter, leading to the phenomenon of Andreev reflection. A characteristic non-linear behavior in differential conductance is observed in superconductor/ferromagnet bilayers, with a suppression of the conductivity below the superconducting gap. This allows the carrier spin polarization in the normal conductor to be extracted. We attempt to exploit Andreev reflection for measuring hole spin diffusion lengths in p-GaAs by studying a series of hybrid heterostructures of superconducting metal (In or Nb) and a ferromagnetic semiconductor (GaMnAs), separated by p-GaAs spacer layers of different thickness. Qualitatively, our data show evidence for a finite spin polarization in the current that decreases with spacer thickness.

4:18PM S33.00010 Reconfigurable spin logic gate in Gallium Arsenide. C. AWO-AFFOUDA, O.M.J. VAN ’T ERVE, M. HOLUB, C.H. LI, A.T. HANBICKI, G. KIOSEOGLIOU, B.T. JONKER. Naval Research Laboratory, Washington, DC 20375 — Electrical injection and detection of pure spin currents has recently been shown in semiconductors. Here we concentrate on the realization of spin-based logic circuits in semiconductors. We report on the electrical injection and detection of spin polarized currents using reconfigurable magnetic contacts. Fe/GaAs Schottky contacts are used to create and analyze the spin current in a GaAs transport channel. Non-local detection techniques show that the circuit output voltage can be modulated using current carrying wires that independently switch the magnetization of the contacts. We use this effect to generate a logic function based on pure spin transport in semiconductors. The realization of this integrated spin-based structure may facilitate the development of pure spin-based logic gates.

4:30PM S33.00011 Inversion of Ferromagnetic Proximity Polarization in GaAs by MgO Interlayers. Y. LI, Y. CHYE, Y.F. CHIANG, K. PI, W.H. WANG. Department of Physics and Astronomy, UC Riverside, J.M. STEPHENS, S. MACK, D.D. AVSCHALOM, Center for Spintronics and Quantum Computation, UC Santa Barbara, R.K. KAWAKAMI, Department of Physics and Astronomy, UC Riverside — Ferromagnet/semiconductor hybrid structures are building blocks for spin transport devices and spin-based logic gates for large- scale circuits. Recent experiments achieved success in making a lateral Fe/GaAs spin transport device, but anomalous bias dependence of the spin injection signal demand an understanding of the role of atomic-scale interfacial structure in determining the spin dependent reflection and transmission coefficients. In our studies, we incorporate a spin-filtering material MgO in the Fe/GaAs structure, and directly study the spin dependent reflection properties of the interface, or the ferromagnetic proximity polarization (FPP) effect, through ultrafast optical measurements. We find that the FPP in Fe/MgO/GaAs can be tuned by controlling MgO thickness, and we observe a sign change by MgO interlayers. Through study of the related nuclear spin polarization, we also observed sign change of FPP with laser intensity when MgO thickness is in the transition range of sign change. By modification of the interface, mainly changing oxygen partial pressure during MgO growth, we find that the Fe-Mg bond is a key factor in the sign change. Supported by CNID, ONR and NSF.

4:42PM S33.00012 GaMnAs-based hybrid multiferroic memory device. M. OVERBY, A. CHERNYSHOV, L.P. ROKHINSON, Department of Physics, Purdue University, West Lafayette, IN 47907, J.K. FURDYNA, X. LIU. Department of Physics, University of Notre Dame, Notre Dame, IN 46556 — In a ferromagnetic semiconductor GaMnAs grown on GaAs there are two equivalent easy axes of magnetization along the [100] and [010] crystallographic directions. These two directions can form a basis for a memory device with the binary state being encoded in the direction of the magnetization. The state can be electrostatically controlled by introducing a compressive (tensile) strain along one of the easy axes. We demonstrate a novel non-volatile hybrid multiferroic memory cell with electrostatic control of magnetization based on strain-coupled GaMnAs and a piezoelectric material. The magnetization direction is monitored via planar Hall effect, which changes sign when magnetization rotates. At zero voltage on the piezoelectric magnetization can be oriented either along [100] or [010], when voltage on piezoelectric is swept between positive and negative values magnetization forms a hysteresis loop with abrupt transitions between the two orientations.
4:54PM S33.00013 Reversal of spin polarization in Fe/GaAs (001) driven by resonant surface states: First-principles calculations, A.N. CHANTIS, Theoretical Division, Los Alamos National Laboratory, K.D. BELASHCHENKO, Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, D.L. SMITH, Theoretical Division, Los Alamos National Laboratory, E.Y. TSYMBAŁ, Nebraska Center for Materials and Nanoscience, University of Nebraska-Lincoln, M. VAN SCHILFGAARDE, Arizona State University, R.C. ALBERS, Theoretical Division, Los Alamos National Laboratory — A minority-spin resonant state at the Fe/GaAs(001) interface is predicted to reverse the spin polarization with voltage bias of electrons transmitted across this interface. Using a Green’s function approach within the local spin density approximation we calculate spin-dependent current in a Fe/GaAs/Cu tunnel junction as a function of applied bias voltage. We find a change in sign of the spin polarization of tunneling electrons with bias voltage due to the interface minority-spin resonance. This result explains recent experimental data on spin injection in Fe/GaAs contacts [1,2] and on tunneling magnetoresistance in Fe/GaAs/Fe magnetic tunnel junctions [3].

5:06PM S33.00014 Spin-Polarized Edge-Emitting Lasers¹, M. HOLUB, A.T. HANBICKI, C.S. KIM, G. KIOSEOGLOU, O.M.J. VAN ’T ERVE, C.H. LI, I. VURGAFTMAN, J.R. MEYER, B.R. BENNETT, B.T. JONKER, Naval Research Laboratory — Semiconductor lasers driven by a spin-polarized current are expected to provide a threshold current reduction, optical polarization control, and intensity stabilization. We explore these possibilities in edge-emitting lasers where the low switching fields of in-plane magnetized Fe thin films should enable electronic modulation of the output polarization. Fe/GaAs/GaAs heterostructures are designed, grown, and fabricated into surface-emitting light-emitting diodes (LEDs) and double heterostructure lasers. The LED emission is dominated by an H-band feature at 5 K and by the bulk recombination feature at 20 K. An electron spin polarization of 24% is measured in the Faraday geometry. Oxide-stripe lasers are fabricated with and without an Fe capping layer. Lasing is observed at low temperatures with threshold current densities of ∼100 A/cm². Magnetic field-dependent studies to examine the effects of spin injection on laser performance will be discussed.

5:18PM S33.00015 Spin Injection into Co₂MnAl by Optical Absorption in GaAs¹, S. ISBER, American University of Beirut, Y.J. PARK, KIST, J.S. MOODERA, MIT, D. HEIMAN, Northeastern University — Ferromagnet-semiconductor heterostructure devices have been made with half-metallic ferromagnets, which have larger spin polarizations than transition metal based ferromagnets. Spin-polarized electrons generated in the semiconductor by circularly polarized light are injected across a Schottky barrier into the ferromagnet and detected as photocurrent. In this technique, the optically pumped semiconductor is the source of spin polarized electrons, and the ferromagnet is the detector of spin polarized electrons. The heterostructures consist of MBE-grown Co₂MnAl Heusler ferromagnets which are lattice matched to n⁺GaAs, forming a Schottky barrier. A magnetic field is applied parallel to the light and perpendicular to the ferromagnetic layer, allowing the magnetization to be switched from parallel to antiparallel to the light direction, thus switching the direction of the detected spin polarization. Spin-dependent photocurrent was measured as a function of applied voltage bias across the Schottky barrier. The injection of spin-polarized electrons was determined after subtracting the magnetic circular dichroism (MCD) effect.

Wednesday, March 12, 2008 2:30PM - 5:30PM – Session S35 FIAP: Focus Session: Nanotechnology I Morial Convention Center 227

2:30PM S35.00001 Deep UV Pattern Definition in PMMA, BRIAN BURKE, TIMOTHY HERLIHY, ANDREW SPIKAS, KEITH WILLIAMS, University of Virginia — We have patterned polymethyl methacrylate (PMMA) resist by exposing it with the fifth harmonic (213 nm) of an Nd:YAG source through metallized apertures in contact with the resist. Interface patterns with both near- and far-field origins were observed. In order to test the contrast and uniformity of exposure, we deposited germanium onto developed areas to form arrays with feature sizes of approximately 200 nm. We present a straightforward model for interference effects generated in our process, and discuss opportunities for direct-write lithography through single apertures.

2:42PM S35.00002 Low Temperature Growth of ZnO Nanorods by Chemical Bath Method, MATT BAUMER, PARAMESWAR HARI, DARYL SPENCER, University of Tulsa — ZnO nanorods grown by chemical bath deposition (CBD) methods are of great interest in photonic and electronic device applications because they offer low cost, low temperature techniques compared to conventional vapor deposition and sputtering methods. Our past studies of ZnO nanorods were grown by CBD on indium tin oxide (ITO) coated glass substrates employed heating of an equimolar solution of Zinc (II) nitrate and hexamethylenetetramine solution at 95 C. Morphology of ZnO nanorods exhibited both open and closed hexagonal shape under various deposition conditions at or above 95 C. Currently we are studying the effect substrates on the morphology of the nanorods grown by chemical bath technique. We are using glass coated with tin oxide, aluminum, as well as solid molybdenum as substrates. We will use scanning electron microscopy and atomic force microscopy to map the changes in morphology of nanorods grown on various substrates. We will present quantitative data on changes in cluster size and shape of nanorods as the growth substrate is varied.

2:54PM S35.00003 Nano-assembly and Controlled Release Kinetics of Nanoelements from Nanoporous Templates, E. GULTEPE, D. NAGESHA, J. MCNULTY, S. SRIDHAR, eMRI, Dept. of Physics and Nanomedicine Consortium, Northeastern University — Nanotemplates and nanoparticle成長 potential for use in the area of nanomanufacturing and biomedical applications. We are using highly ordered nanoporous alumina as a template for drug delivery and to assemble nanoelements such as latex beads and single wall carbon nanotubes (SWNT) by the means of electrophoresis and/or dielectrophoresis. The results of 100% assembly of latex beads and controlled elution of drugs from nanoporous templates will be discussed. Vertically assembled SWNT and I-V characteristic as 3D interconnects, will also be presented. We have developed a variety of platforms incorporating superparamagnetic iron oxide nanoparticles for targeted delivery, magnetic hyperthermia and as a contrast agent for magnetic resonance imaging. The results of cell studies on these platforms will be discussed.

on the nanowire mat about showed reversible response to CO exposure. The sensor is a two-terminal design, where the terminals consist of two 25 \( \mu \)m of ZnO nanostructures. Here, we report the electrical properties of a gas sensor constructed from mats of ZnO nanowires grown on sapphire substrate that were produced by a conventional mechanical test. The presence of the nanowires is directly related to the one-dimensional meniscus configuration with a small viscosity at high temperatures and to the wide supercooled liquid region of the metallic glass. The electron microscopic observations demonstrate the diameters, the lengths, and the dimorphs in structural states, and the energy dispersive X-ray reveals the chemical components. In addition, we found that round ridges are constructed from nanotubes. The finding of amorphous nanostructures provides not only fundamental understanding of fracture processes but also give a new insight into nano-science and engineering.

ZHANG, California State University, Fresno, CHRIS BERVEN, University of Idaho — In the past decade, significant advances have been made in the synthesis of ZnO nanostuctures. Here, we report the electrical properties of a gas sensor constructed from mats of ZnO nanowires grown on sapphire substrate that were produced by a conventional mechanical test. The presence of the nanowires is directly related to the one-dimensional meniscus configuration with a small viscosity at high temperatures and to the wide supercooled liquid region of the metallic glass. The electron microscopic observations demonstrate the diameters, the lengths, and the dimorphs in structural states, and the energy dispersive X-ray reveals the chemical components. In addition, we found that round ridges are constructed from nanotubes. The finding of amorphous nanostructures provides not only fundamental understanding of fracture processes but also give a new insight into nano-science and engineering.

The dynamics of the deposition of nanotubes under different CMOS compatible manufacturing conditions was modeled using 2D and 3D finite element analysis. Bell Laboratories — The accurate positioning of an individual vertically aligned carbon nanotube (CNT) is a challenge for nanofabrication. We have successfully deposited individual CNT’s into sub-100nm diameter SiN windows on metal interconnects using electrophoresis in conjunction with the nanoscopic lens effect. The dynamics of the deposition of nanotubes under different CMOS compatible manufacturing conditions was modeled using 2D and 3D finite element analysis. Surface charge accumulation and saturation is the key determinant of the strength of the nanoscopic lens. The modeling predicts that there is an easily obtainable range of conditions where only one nanotube will be deposited in round windows using current generation lithography. Deposition in a slotted window geometry yields a limited number of nanotubes that have an average spacing which is a function of the geometry of the slot and randomly approaching nanotubes. Early integration of vertical carbon based logic with CMOS is feasible.

3:06PM S35.00004 Ionic PN and PNP junctions – Diodes and Transistors, ERIC KALMAN, UC Irvine, IVAN VLASTIOUK, PAVEL APEL, ZUZANNA SIWY — There are well-known devices for controlling the transport of electrons, but very few control ions in a solution. We have prepared ionic diodes and transistors that function in a similar manner to their semiconductor analogues. Ionic PN junctions were created by surface patterning single conical nanopores in polymer films, so that the pore walls are split into two sections: one with positive charge, and the other with negative. These diodes can achieve rectification degrees of several hundreds. Ionic PNP junctions were created by surface patterning single double-conical nanopores in polymer films with tip diameters between 2 and 6 nm, so that the pore walls are split into three sections: the two areas near the large pore openings which are positively charged, while the center of the pore, near the pore tip, is negatively charged. This device works in a similar fashion to a semiconducting BJT transistor, and we show that we can control the electric potential chemically in a manner sufficient to gate the ion current through the device.

3:18PM S35.00005 Metallic glass nanowire, KOJI NAKAYAMA, Tohoku University, YOSHIHIKO YOKOYAMA, GUOQIANG XIE, QINGSHENG ZHANG, MINGWEI CHEN, TOSHIO SAKURAI, AKIHISA INOUE — Metallic glass nanowires were spontaneously created on the fracture surfaces that were produced by a conventional mechanical test. The presence of the nanowires is directly related to the one-dimensional meniscus configuration with a small viscosity at high temperatures and to the wide supercooled liquid region of the metallic glass. The electron microscopic observations demonstrate the diameters, the lengths, and the dimorphs in structural states, and the energy dispersive X-ray reveals the chemical components. In addition, we found that round ridges are constructed from nanotubes. The finding of amorphous nanostructures provides not only fundamental understanding of fracture processes but also give a new insight into nano-science and engineering.

3:30PM S35.00006 CO Gas Sensing with ZnO Nanowire Mat, SIRISHA CHAVA, University of Idaho, DAQING ZHANG, California State University, Fresno, CHRIS BERVEN, University of Idaho — In the past decade, significant advances have been made in the synthesis of ZnO nanostructures. Here, we report the electrical properties of a gas sensor constructed from mats of ZnO nanowires grown on sapphire substrate that were produced by a conventional mechanical test. The presence of the nanowires is directly related to the one-dimensional meniscus configuration with a small viscosity at high temperatures and to the wide supercooled liquid region of the metallic glass. The electron microscopic observations demonstrate the diameters, the lengths, and the dimorphs in structural states, and the energy dispersive X-ray reveals the chemical components. In addition, we found that round ridges are constructed from nanotubes. The finding of amorphous nanostructures provides not only fundamental understanding of fracture processes but also give a new insight into nano-science and engineering.

3:42PM S35.00007 Mechanical Properties of Nanometric Wire of Water, MANHEE LEE, BAEKMAN SUNG, WONHO JHE, Department of Physics and Astronomy, Seoul National University, Seoul 151-742, Korea, CNL TEAM — Water has been one of the perfect newtonian viscosious liquids, which are exactly described by navier-stokes equations. Recently, it, however, was found that the effective shear viscosity of water confined between mica crystals at 10nm thickness is very different from the one of 3-dimensional bulk water. While some researchers have measured very high viscoelasticity of the confined liquid, the other researchers reported the fluidic nature of water confined between mica surfaces at <3.5 nm interfacial separation (bulk-like water-viscosity). These conflicting results concerning the mechanical properties of nanometric water have been continually reported for the past several years. None of them clearly clarified the mechanical properties of nanometric water, and the detailed behavior of the viscoelasticity within a tip-sample separation less than 1 nm has not been measured. We present the mechanical properties of nanometric water with a spatial resolution less than 0.1nm such as viscoelasticity, dissipation energy, and phase transitions.

3:54PM S35.00008 Growth of Vertically Aligned Carbon Nanotube on Glass, TRILOCHAN PAUDEL, JAKUB RYBCZYNSKI, ZHIFENG REN, BOSTON COLLEGE TEAM — Periodic arrays of vertically aligned carbon nanotubes on glass have been grown by dc plasma enhanced chemical vapor deposition on patterned Nickel dots prepared by polystyrene nanosphere lithography. A thin buffer layer of Titanium was first coated on cleaned high temperature C1737 Aluminosilicate glass substrates and then a monolayer of self-assembled polystyrene buffer layer of Titanium was first coated on cleaned high temperature C1737 Aluminosilicate glass substrates and then a monolayer of self-assembled polystyrene spheres was deposited on the glass. Through the polystyrene spheres, a hexagonal pattern of triangular Nickel dots was obtained after removing the spheres. The sphere size and Nickel thicknesses consequently determine the diameter and the site density of carbon nanotubes. The successful growth of carbon nanotubes on glass substrates with good periodicity and alignment are crucial to bio-sensor and solar cell applications.

4:06PM S35.00009 Feedback Cooling of a Massive Resonator, Quartz Tuning-fork, in Air, BAEKMAN SUNG, MANHEE LEE, WONHO JHE, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, CNL TEAM — Recently, the cooling of a mechanical resonator through active feedback control has been interested for many researchers and the experiment for a cantilever cooling by using a resonator in an air control [1]. While the recent cooling experiments have been done by tiny cantilever in vacuum, we performed the feedback cooling experiment in air by using a very massive harmonic oscillator, a tuning fork, which has been used as an useful force sensor due to its high stiffness and dynamic oscillation property in scanning probe microscopy (SPM) such as near field scanning optical microscopy, atomic force microscopy (AFM) [2]. This technique is expected to study the low temperature micro scale effect of macroscopic object in air. // [1] M.Poggio, C.L.Degen, H.J.Mamim, and D.Rugar, PRL 99,017201 (2007). [2] F. J. Giessibl, S. Hembacher, M. Herz, Ch. Schiller, and J. Mannhart, Nanotechnology 15, S79 (2004).

4:18PM S35.00010 Molecular quantum-dot cellular automata–from molecular structure to circuit dynamics, YUHUI LUI, CRAIG LENT, Unv. of Notre Dame — Quantum-dot cellular automata (QCA) [1] provides a transistor-less paradigm for molecular electronics. In the QCA approach, binary information is stored in the charge configuration of single cells, and transferred via Coulomb coupling between neighboring cells. Single-molecule QCA cells can be realized by using as quantum dots the localized states of mixed-valence complexes. Several candidate QCA molecules have been synthesized and shown to have the required field-induced switching properties [2]. We report progress towards a hierarchic dynamic theory of QCA circuits. We use ab initio techniques to calculate the relevant molecular electronic structure, and extract parameters for a simpler Hamiltonian to describe switching behavior. We then apply a coherence formalism to model interaction with the thermal environment and generate a circuit-dynamic description. [1] C. S. Lent, P. D. Tougaw, W. Porod, and G. H. Bernstein, Nanotechnology, vol. 4, pp. 49, 1993. [2] H. Qi, S. Sharma, Z. Li, G. L. Snider, A. O. Orlov, C. S. Lent, and T. P. Fehlner, J.Am.Chem.Soc., vol. 125, pp. 15250, 2003.

4:30PM S35.00011 Theory of Individual Carbon Nanotube Deposition by Nanoscopic Lenses, SHENG LIU, AMIT GOYAL, ZAFAR IQBAL, GORDON A. THOMAS, REGINALD C. FARROW, New Jersey Institute of Technology, LINUS A. FETTER, Bell Laboratories — The accurate positioning of an individual vertically aligned carbon nanotube (CNT) is a challenge for nanofabrication. We have successfully deposited individual CNT’s into sub-100nm diameter SiN windows on metal interconnects using electrophoresis in conjunction with the nanoscopic lens effect. The dynamics of the deposition of nanotubes under different CMOS compatible manufacturing conditions was modeled using 2D and 3D finite element analysis. Surface charge accumulation and saturation is the key determinant of the strength of the nanoscopic lens. The modeling predicts that there is an easily obtainable range of conditions where only one nanotube will be deposited in round windows using current generation lithography. Deposition in a slotted window geometry yields a limited number of nanotubes that has an average spacing which is a function of the geometry of the slot and randomly approaching nanotubes. Early integration of vertical carbon based logic with CMOS is feasible.

include the generally low H \(_2\) adsorption uptake. To improve the H \(_2\) adsorption affinity in MOFs, our previous work has shown that the coordinatively unsaturated adsorption sites in a Cl-MOF as an example, here we show that the H\(_2\) binding with the exposed TM site is not of the expected Kubas type, in strong contrast to "similar" ion−metal interactions. We also study the H\(_2\) binding with Mn-\(d\) orbitals and find no evidence of any H\(_2\)-\(σ^*\)-Mn orbital hybridization. We also study the H\(_2\) binding as a function of Mn-\(σ\) magnetic spin configurations, and find no significant effect of the magnetic state on the binding energy. We further reveal that the major contribution to the overall binding is classical Coulomb interaction arising from the small charge overlap of H\(_2\)-\(σ\) and Mn-\(d\) orbitals. This coulomb interaction is very anisotropic, and when the quantum nature of H\(_2\)-orientation is taken into account, the actual binding energy is significantly reduced from the calculated classical binding energy. [1] J. Am. Chem. Soc. 128, 16876 (2006).

4:42PM S35.00012 CMOS based fabrication of single electron devices on a large scale. VISHVA RAY, RAMKUMAR SUBRAMANIAN, PRADEEPI BHADRACHALAM, SEONG JIN KOH, The University of Texas at Arlington — Fabrication of single electron devices requires device components (a Coulomb island, source and drain electrodes) to be arranged with nanoscale precision. This has been so far carried out utilizing techniques such as e-beam lithography, shadow evaporation, electromigration, and scanning probe microscopy, which are not suitable for large-scale fabrication for practical use. Here we present new single electron device architecture and its large-scale fabrication within the framework of CMOS fabrication technology. This has been done by employing vertical electrode configuration where the source and drain electrode separation is controlled with nanoscale precision over an entire wafer. Colloidal Au nanoparticles of 10-20 nm diameter were used as Coulomb islands positioned between the source and drain electrodes. We observed clear Coulomb blockade and Coulomb staircase at room temperature for 10 nm Au nanoparticles with charging energies of ~50 meV, in good agreement with self-capacitance values of 10 nm Au particle. The experimental I-V characteristics also agree well with simulated I-Vs carried out using the orthodox theory.

4:54PM S35.00013 A QCM study of the dynamics and frictional properties of physisorbed polysytrene microspheres on a Au(111) Surface\(^1\), IYAM LYNCH, JACQUELINE KRIM, North Carolina State University, JESSICA MCNUTT, University North Carolina Asheville — The notion of transporting micro/nano objects has been of interest to the scientific community since the early days of nanotechnology. Progress in this area requires an understanding of the frictional behavior of these objects when they are in motion. In this study we have analyzed the behavior of 5μm diameter polysyrene spheres physisorbed on the electrode of a quartz crystal microbalance (QCM) in orientations normal and parallel to gravity. By varying the driving voltage of the QCM, the samples exhibit a frequency response with respect to the crystal amplitude ("decoupling curve"). This decoupling curve gives information about the motion of the spheres on the surface and leads to the calculation of the particles sliptime which gives rise to the frictional forces between the particles and surface. Optical observations show that the particle motion is dependent on the oscillation direction of the QCM and gravity to a lesser extent. Quantitative comparisons of the friction force and the optically observed sliding motion have been performed and will be reported on.

\(^1\) NSF and NTC are thanked for their support.

5:06PM S35.00014 Dynamic behavior of inter-pulse timing intervals of neuron-like pulses in a GaAs/InGaAs multi-quantum well structure.\(^2\), ARUNA WEERASEKARA, STEVEN MATSUK, GENNADY CYMBALYUK, A. G. UNIL PERERA, Georgia State University — Neuron-like triggered pulses in a GaAs/InGaAs multi-quantum well (MQW) structure, which shows an s-type negative differential resistance (SNDR), was investigated. Dynamic behavior of inter-pulse timing intervals (IPTIs) was studied by analyzing first return maps, power spectra, and correlation dimensions. First return maps of the IPTIs show an interesting grouping pattern at slower pulse rates. The grouping behavior can be empirically modeled using oscillatory behavior of the pulsing threshold level of the MQW structure. This pattern of IPTIs is similar to that of thermoreceptors in fish and mammals. Under different operational conditions, correlation dimension of 8.0, 8.5, and 10.0 were obtained by calculating the correlation integrals. The obtained correlation dimensions suggest that this system possesses a higher dimensional behavior.

5:18PM S35.00015 Using a quantum point contact as a sensitive detector of cantilever motion. M. POGGIO, M.P. JURA, C.L. DEGEN, M.A. TOPINKA, H.J. MAMIN, D. GOLDBERG-GORDON, D. RUGAR, IBM RESEARCH DIVISION, ALMADEN RESEARCH CENTER, 650 HARRY RD., SAN JOSE, CA COLLABORATION, CENTER FOR PROBING THE NANOSCALE, STANFORD UNIVERSITY, 476 LOMITA HALL, STANFORD, CA COLLABORATION — We demonstrate the use of a GaAs quantum point contact (QPC) as a sensitive displacement detector with the ability to resolve the thermal motion of an ultrasoft micromechanical oscillator. The displacement measurement is made by positioning the tip of a metal-coated Si cantilever ~100 nm above a QPC. The application of a small voltage to the lever causes it to gate the conductance through the QPC. As a result, motion of the cantilever’s tip modulates the conductance. By measuring this modulation, we achieve a displacement resolution better than 10-12 m/Hz\(^{1/2}\), which is comparable to the resolution achieved by low power optical interferometry. The flexibility of an on-chip QPC as a sensor of cantilever displacement has a number of potential applications including magnetic resonance force microscopy, the detection of displacement for cantilevers with dimensions smaller than the optical diffraction limit, and the cooling of mechanical resonators through feedback.

Wednesday, March 12, 2008 2:30PM - 5:30PM –
Session S36 DMP FIAP: Focus Session: Hydrogen Storage III: Novel Porous and Sorbent Materials Morial Convention Center 228

2:30PM S36.00001 Enhancing the interaction strength and capacities of hydrogen storage via surface adsorption. CRAIG BROWN, NIST Center for Neutron Research — Storing Hydrogen molecules in porous media based on a physisorption mechanism is one possible approach to reach the US Department of Energy targets for on-board hydrogen storage. Although the storage capacities of metal centers (CUMCs) can greatly enhance the H\(_2\) storage capacity, this has been done by employing vertical electrode configuration where the source and drain electrode separation is controlled with nanoscale precision over an entire wafer. Colloidal Au nanoparticles of 10-20 nm diameter were used as Coulomb islands positioned between the source and drain electrodes. We observed clear Coulomb blockade and Coulomb staircase at room temperature for 10 nm Au nanoparticles with charging energies of ~50 meV, in good agreement with self-capacitance values of 10 nm Au particle. The experimental I-V characteristics also agree well with simulated I-Vs carried out using the orthodox theory.

3:06PM S36.00002 Nature of the Hydrogen Binding in Metal Organic Frameworks with Exposed Transition Metal Sites. WEI ZHOU, NIST and UMD, TANER YILDIRIM, NIST and UPENN — MOFs with exposed transition metal (TM) sites were recently found to exhibit significantly larger experimental heat of H\(_2\) adsorption than classical MOFs, thus attracted great attention. [1, 2] Understanding the nature of the H\(_2\) interaction with the exposed metal sites is of critical importance for the further development of these materials. Using Mn-Cl-MOF as an example, here we show that the H\(_2\) binding with the exposed TM site is not of the expected Kubas type, in strong contrast to "similar" systems investigated previously (e.g., ref. [3] and [4]). In Mn-Cl-MOF, there are a) no charge transfer from TM to H\(_2\), b) no significant H-H bond elongation, and c) no evidence of any H\(_2\)-\(σ^*\)-Mn orbital hybridization. We also study the H\(_2\) binding as a function of Mn-\(σ\) magnetic spin configurations, and find no significant effect of the magnetic state on the binding energy. We further reveal that the major contribution to the overall binding is classical Coulomb interaction arising from the small charge overlap of H\(_2\)-\(σ\) and Mn-\(d\) orbitals. This coulomb interaction is very anisotropic, and when the quantum nature of H\(_2\)-orientation is taken into account, the actual binding energy is significantly reduced from the calculated classical binding energy. [1] J. Am. Chem. Soc. 128, 16876 (2006).
3:18PM S36.00003 Kinetic and steric differences in adsorption in two porous metal-organic frameworks. KATHLEEN LASK, VAIVA KRUNGLEVICTE, MURAT BULUT, ALDO MIGONE, Southern Illinois University, J.-Y. LEE, JING LI, Rutgers University — Kinetic and steric differences are two of the three fundamental mechanisms underlying the use of adsorption in applications to gas mixture separations. We present experimental results on kinetics and equilibrium adsorption measurements of tetrafluoromethane and argon on two metal-organic framework (MOF) materials: RPM1-Co or [Co3(bpdc)3(bpy)]·4DMF·H2O (bpdc = biphenyldicarboxylate, bpy = 4,4′-bipyridine, DMF = N,N′-dimethylformamide) and Cu-BTC or Cu2[BTC]2·(H2O)3 (BTC = benzene-1,3,5-tricarboxylate). The adsorbates display significant differences in their kinetics on RPM1-Co (i.e., there are sizable differences in the time required for each gas to reach equilibrium after it is allowed access to the substrate). Our equilibrium measurements show that CF4 is sterically precluded from adsorbing in the small tetrahedral-shaped side pockets present in Cu-BTC. We will compare our experimental results with predictions for how adsorption kinetics depends on the size of the adsorbate and on those of the pores present in the substrate.

3:30PM S36.00004 A theoretical and experimental study of hydrogen storage in metal organic framework materials. VALENTINO R. COOPER, JEONG YONG LEE, JING LI, YVES CHABAL, DAVID C. LANGRETH, Rutgers University — Metal-organic framework (MOF) materials, assembled by linking metal ions or clusters through molecular bridges, have been shown to be good candidates for H2 storage. We have been successful in fabricating and characterizing MOFs with increased H2 uptake though still too low for commercial applications. Here we present a coordinated theoretical-experimental effort to understand the mechanism of H2 adsorption in true MOF materials. Using the completely ab initio van der Waals density functional (vdW-DF), we simulate the interactions of H2 within Zn2(bdc)$_2$(tead). We demonstrate that modeling the entire MOF structure can result in different H2 adsorption geometries, binding energies and vibrational frequencies than observed in calculations on fragments of the MOF. Combining these results with experimental IR vibrational frequency studies may provide insights into modifying MOF structure and composition for enhanced H2 uptake. 

3:42PM S36.00005 The flexibility of zeolites for Hydrogen storage. ASEL SARTBAEVA, Oxford University, STEPHEN ANTHONY WELLS, Warwick University, PETER P. EDWARDS, Oxford University — The flexibility window is a newly discovered theoretical measure which can provide a valuable selection criterion when evaluating hypothetical zeolite framework structures as potential synthetic targets. Today synthetic zeolites are the most important catalysts in petrochemical refineries. There have been considerable efforts to synthesize new zeolites with specific pore geometries, to add to the 167 available at present. Millions of hypothetical structures have been generated on the basis of energy minimization, and there is an ongoing search for criteria capable of predicting new zeolite structures. The flexibility window appears to be a property of existing zeolite frameworks not shared by many hypothetical structures. It provides a valuable selection criterion when evaluating hypothetical zeolite framework structures as potential synthetic targets. We are investigating the use of zeolites as hydrogen storage materials, as small molecules such as molecular hydrogen and ammonia can be easily absorbed into a flexible framework of zeolites. An exiting possibility is the use of framework flexibility to control hydrogen uptake, storage and release. This would allow a safe use of hydrogen for fuel cells.

3:54PM S36.00006 Inelastic Incoherent Neutron Scattering Studies of the Ti-doped hydrogen-adsorbed SBA-15. ALICE I. ACATRINEI, LUKE L. DAEMEN, MONIKA A. HARTL, Los Alamos National Laboratory, LANSCE-LC — The discovery in 1998 of the hydrothermally stable SBA-15 by Zhao et al. [1] represents a great advance in the synthesis of ordered mesoporous materials. The high porosity, good thermal stability, and low specific weight of these materials makes them good candidates for hydrogen storage research, and metal doping shows an enhancement of their properties and gas storage capabilities. We used inelastic incoherent neutron scattering to look at both Ti-doped and undoped hydrogen adsorbed SBA-15. Powder XRD measurements confirmed the mesoporosity of the material. Adsorption isotherm showed that a significant amount of hydrogen was adsorbed in the compound. Our results indicate that hydrogen binds to the Ti centers in the material. [1]. D. Zhao, J. Feng, Q. Huo, N. Melosh, G.H. Fredrickson, B.F. Chmelka, G.D. Stucky, Science 279 (1998) 548.

4:06PM S36.00007 Hydrogen Storage in Mesoporous Materials under High Pressure. MICHELLE WEINBERGER, MADDURY SOMAYAZULU, RUSSELL HEMLEY, Geophysical Lab, Carnegie Institution of Washington — To date, the materials considered best candidates for hydrogen storage fuel cells include activated carbon and metal organic frameworks. Both very high surface area activated carbon and MOF-S have been shown to adsorb around 4.5 wt % of hydrogen gas at 78 K. We have investigated the fundamental structural response of these materials to high pressure, as well as their behavior at high pressure when packed with dense hydrogen. Further investigation of these materials at low temperatures while still at elevated pressures may in fact provide a route for recovery of these hydrogen-packed materials to near ambient conditions. Covalent organic frameworks offer the potential for even better hydrogen storage capacity. These materials have significantly lower densities than the MOF materials and offer a significantly larger number of adsorption sites. Diamond anvil cells are uniquely suited for the study of these materials, allowing in situ measurements at high pressure as well as at low temperatures. Using X-ray diffraction and Raman spectroscopy and Infrared Spectroscopy we probe the behavior of the hydrogen confined in these porous materials at high pressure by tracking changes in the in situ high pressure x-ray diffraction patterns and shifts in the hydrogen vibrion peaks.

4:18PM S36.00008 A combined pressure-temperature synthesis approach towards novel hydrogen storage materials1. RAJA CHELLAPPA, MADDURY SOMAYAZULU, VIKTOR STRUZHKIN, RUSSELL HEMLEY, Carnegie Institution of Washington — There is a growing need to explore synthesis of novel hydrogen storage materials with very high hydrogen content (> 30 wt.%) as well as tuning materials in order to facilitate reversible hydrogen desorption and absorption. A combined pressure-temperature (P − T) approach holds considerable promise towards achieving these objectives. In this talk, we will present results from our on-going efforts to synthesize hydrogen clathrates with very high hydrogen content that can be recovered at moderate P − T conditions based on simple molecular systems including clathrates and van der Waals compounds, specifically H2O, CH4, NH3, and boron containing systems. The use of suitable additives to enhance stability will also be explored. Results will also be presented from the direct P − T synthesis of metastable light metal (Li, Mg, B-based) complex hydrides.

---

4:30PM S36.00009 Structure of Nanoporous Biocarbon for Hydrogen Storage as Determined by Small Angle X-Ray Scattering. MIKAEL WOOD, J. BURRESS, J. POBST, S. CARTER, P. PFEIFER, C. WEXLER, University of Missouri-Columbia, Department of Physics, P. SHAH, G. SUPPES, University of Missouri-Columbia, Department of Chemical Engineering — As a member of the Alliance for Collaborative Research in Alternative Fuel Technology (ALL-CRAFT) our research group studies the properties of nanoporous biocarbon, produced from waste corn cob, with the goal of achieving the Department of Energy’s gravimetric and volumetric standards for both hydrogen and methane gas storage. Small Angle X-Ray Scattering (SAXS) is a valuable tool in our investigation of the geometry of the pore space in our carbon samples. In this talk, we will compare the experimental SAXS data with theoretical results for various pore geometries to determine which pore models are consistent with experiment. Using data from nitrogen adsorption isotherms, along with SAXS, yields significant structural information about the pore space. This analysis allows us to fully optimize our production process and to achieve the DOE’s target storage capacities. This work supported by: 1. National Science Foundation (PFI-0438469) 2. U.S. Department of Education (P200A040038) 3. U.S. Department of Energy (DE-AC02-06CH11357) 4. University of Missouri (RB-06-040) 5. U.S. Department of Defense (N00164-07-P-1306) 6. U.S. Department of Energy (DE-FG02-07ER46411)

4:42PM S36.00010 High Capacity Hydrogen Storage on Nanoporous Biocarbon1. JACOB BURRESS, MIKAEL WOOD, MICHAEL GORDON, University of Missouri-Columbia, PHILLIP PARILLA, NREL, MICHAEL BENHAM, Hiden Isochema, CARLOS WEXLER, FRED HAWTHORNE, PETER PFEIFER, Univ. of Missouri-Columbia — The Alliance for Collaborative Research in Alternative Fuel Technology (http://all-craft.missouri.edu) has been optimizing nanoporous biocarbon for high capacity hydrogen storage. The hydrogen storage was measured gravimetrically and volumetrically (Sievert’s apparatus). These measurements have been validated by NREL and Hiden Isochema. Sample S-33/k, our current best performer, stores 73.91 g H2/kg carbon at 77 K and 47 bar, and 1.0-1.6 g H2/kg carbon at 293 K and 47 bar. Hydrogen isotherms run by Hiden Isochema have given experimental binding energies of 8.8 kJ/mol compared to the binding energy of graphite of 5 kJ/mol. Results from a novel boron doping technique will also be presented. The benefits and validity of using boron-doping on carbon will also be discussed.

1Optimal pore sizes and volumes will be presented for hydrogen storage nanoporous carbon.

4:54PM S36.00011 Preparation and Cryogenic Hydrogen Storage Capacity of Nanoporous Carbon Materials Synthesized using an Aerosol-Assisted Approach. QINGYUAN HU1, Purdue University, YUNFENG LU, Univ. Cal. Los Angeles, GREGORY P. MEISNER, GM Research and Development Center — Spherical nanoporous carbon particles were synthesized from carbon precursor solutions of sucrose with either silica sols, colloidal silica particles, or both, in a direct one-step aerosol-assisted process, followed by carbonization and then removal of the silica template. The resulting particles show very high porosity with narrow pore size distributions, surface areas up to 2000 m2/g, and pore volumes up to 4.0 cm3/g. The porosity and pore sizes depend on the type and amount of silica template precursor added to the sucrose precursor solutions. The carbon particles were characterized by transmission electron microscopy, field emission scanning electron microscopy, and nitrogen sorption surface area measurements. Hydrogen adsorption was measured at various temperatures between 77 K and room temperature and at pressures up to 50 bars. The maximum hydrogen uptake of up to 4.0 wt% at 77 K and >20 bar was found for nanoporous carbon particles made using the silica sol template.

5:06PM S36.00012 NMR Characterization of Hydrogen Adsorption and Pore Structures of Carbon-Based Materials1. B.J. ANDERSON, ALFRED KLEINHAMMES, YUE WU1, Department of Physics and Astronomy, University of North Carolina, Chapel Hill, NC 27599-3255, UNIVERSITY OF PENNSYLVANIA DEPARTMENT OF CHEMISTRY COLLABORATION, LAWRENCE LIVERMORE NATIONAL LABORATORY COLLABORATION — Hydrogen adsorption in carbon-based materials such as boron-doped graphite and carbon aerogels was investigated by nuclear magnetic resonance (NMR). 1H NMR is shown to be a sensitive and quantitative probe for detecting adsorbed gas molecules such as H2, methan, and ethane. NMR measurements were carried out in-situ under given H2 pressure up to a pressure of over 100 atm, at room temperature and 100 K. From such 1H NMR measurement, the amount of adsorbed H2 molecules was determined versus pressure. In addition to measuring adsorption binding energies via isotherms, the structure and distribution of the nanopores within the material were characterized in order to relate the size of the pores to the rate of diffusion of the H2 to the adsorption sites.

Principle Investigator

5:18PM S36.00013 Fabrication Procedures and Material Properties of Activated Carbon for Hydrogen and Methane Storage1. JEFFREY POBST, JACOB BURRESS, MIKAEL WOOD, MATTHEW BECKNER, PARAG SHAH, MICHAEL GORDON, Univ. of Missouri-Columbia, PHILLIP PARILLA, NREL, SARAH BARKER, SARA CARTER, LAUREN ASTON, GALEN SUPPES, PETER PFEIFER, Univ. of Missouri-Columbia — The Alliance for Collaborative Research in Alternative Fuel Technology (http://all-craft.missouri.edu) has developed nanoporous biocarbons with interesting pore characteristics. These carbons are being optimized for hydrogen and methane vehicular storage. Our current best performer stores 73-91 g H2/kg carbon at 77 K and 47 bar, and 1.0-1.6 g H2/kg carbon at 293 K and 47 bar. The validity of using methane storage as a predictor for hydrogen storage will be presented. Recent carbons have achieved porosities as high as of 0.8 and BET surface areas of 3,500 m2/g. Optimal pore sizes and volumes will be presented for hydrogen storage nanoporous carbon.

Wednesday, March 12, 2008 2:30PM - 5:30PM
Session S37 DCMP: Effect of Strain on Ferroelectrics Morial Convention Center 229

2:30PM S37.00001 First-principles study of novel routes to ferroelectricity using strain. ALISON HATT, NICOLA SPALDIN, University of California, Santa Barbara — We use first-principles density functional theory (DFT) to explore the use of strain to induce ferroelectricity in otherwise non-polar materials. First, we investigate the polarization induced in LaAlO3 by changing in-plane bondlengths while constraining the unit cell to tetragonal symmetry. We then relax the symmetry constraint to examine the effect of oxygen octahedra rotations on the polarization. Next we explore whether epitaxial strain in the pseudocubic [100] direction can lift the inversion center in otherwise centrosymmetric BiMnO3 and induce the small polarization reported in thin films. By studying these systems with DFT calculations, we have the ability to finely vary the system constraints, predicting new functional materials and providing insight into the underlying physics.
quasirandom structures. In agreement with the literature, 
(PZT) depend upon epitaxial strains ranging from epitaxial strain, which is controlled by substrate selection. Here, using ab initio interest in ferroelectric perovskite thin films, alloys, and superlattices. Engineering of FeRAMs requires the control of both the spontaneous polarization and dielectric constant on strain will be discussed in terms of a theoretical model of the phenomenological thermodynamics of the film strain effect.

BILT, Rutgers University — The potential for creating ferroelectric-based devices such as ferroelectric random-access memories (FeRAMs) has led to an intense engineering oxide films. Work supported by the U. S. Department of Energy under Contract No. DE-AC02-06CH11357.

3:06PM S37.00004 In situ LEED-IV characterization of polar distorted ultra-thin BaTiO3 films VON BRAUN NASCIMENTO, E. WARD PLUMMER, University of Tennessee, JUN-SOO SHIN, A.Y. BORISEVICH, ARTHUR P. BADDORF, SERGEI V. KALININ, Oak Ridge National Laboratory — Ferroelectric phase stability in nanoscale ferroelectrics is governed by the interplay of electrostatic depolarization energy, domain formation, adsorption, and surface band bending. Predictions for the minimum critical film thickness for ferroelectricity in BaTiO3 have continuously decreased with more complex models to a current value of 6 layers. The thinnest experimental value is 12 layers. Using in situ low energy electron diffraction (LEED) - IV, we have characterized the structure of 4 and 10 ML BaTiO3 films, grown using molecular beam epitaxy with fully compressive strain on a SrRuO3/SrTiO3 substrate. Analysis of the LEED-IV reveals a surface dead layer with a single-domain upward (out of surface) polarized state below. Intrinsic asymmetry and the stability to compensation of depolarizing charges by dipoles induced by surface stress can explain the single domain scenario. Research was sponsored by the Division of Materials Sciences and Engineering and the Center for Nanophase Materials Sciences, Office of Basic Energy Sciences, U.S. Department of Energy with Oak Ridge National Laboratory, managed and operated by UT-Battelle, LLC.

3:18PM S37.00005 Phase diagram of Ba0.5Sr0.5TiO3 thin films KRISTOPHER E. ANDERSEN, Northern Arizona University, C. STEPHEN HELLBERG, Naval Research Laboratory — Ba0.5Sr0.5TiO3 (BST) thin films are a promising material for tunable microwave applications, which require large, tunable dielectric constants and low loss. By controlling the (i) substrate and (ii) oxygen partial pressure, it is possible to tune the tetragonal strain of these films. For example, in-plane strains between -0.48% (highly compressive) and +0.30% (highly tensile) have been reported for BST thin films grown on MgO(001) using rf magnetron sputtering. The ability to control the strain makes it possible to optimize the dielectric properties of the film for microwave (and other) applications; however, the strain-temperature phase diagram has not been systematically explored to-date. In this talk, the phase diagram of BST is studied using first-principles calculations, focusing initially on the T = 0 phases. Results for displacive as well as coupled ferroelectric/antiferroelectric phases (recently discussed by Zhang, Cagin, and Goddard in connection to BaTiO3) will be presented.

3:30PM S37.00006 Influence of strain relaxation and atomic interface configuration on the dielectric response of BST thin film capacitors REGINA DITTMANN, RAFAEL PLOKKA, PATRICK SCHÜTZENDORF, PERTSEV NIKOLAY, SHAOBO MI, CHUNLIN JIA, RAINER WASER, Research Centre Juelich — The collapse of the dielectric response which is commonly observed in Ba0.5Sr0.5TiO3 (BST) thin films is a topic of general physical interest as well as a key issue in terms of a possible application of this material in future DRAM storage capacitors. We address the influence of substrates-imposed strain and electrode interface configuration on the dielectric collapse in epitaxial SrRuO3/BST/SrRuO3 thin film capacitors. The growth mode of BST thin films was analyzed by RHEED and HRTEM from the thickness range of a few unit cells up to hundreds of nanometers where plastic strain relaxation occurs. The crystalline quality of our ultrathin samples enabled us to resolve the atomic arrangement and to identify the terminating layers at the SrRuO3/BST interface by STEM. We obtained bulk-like permittivities in the order of 5000 and its thickness dependence can be well described by an extended Ginzburg-Landau-D Devonshire model by taking into account plastic strain relaxation in BST thin films and finite screening of depolarizing fields by the SRO electrodes. We will furthermore present relaxor-type behavior of the BST thin films that becomes visible only in samples with sufficient interface quality and hints on nanoscale structural inhomogeneities.

3:42PM S37.00007 Strain Effects in Barium Strontium Titanate Thin Films for Tunable Microwave Applications LISA ALLDREDGE, WONTAE CHANG, Naval Research Laboratory, JOSEPH WOICIK, National Institute of Standards and Technology, STEVEN KIRCHOFER, JEFFREY POND, Naval Research Laboratory — Recently, it has been demonstrated that control of lattice structure can improve dielectric tuning in epitaxial ferroelectric (FE) films. Understanding the coupling of strain and lattice structure to the dielectric properties is important for FE-based tunable microwave applications. Ba0.5Sr0.5TiO3 films on (001) MgO substrates were grown by sputter deposition with <c> a > and c> a tetragonal distortions, where a and c are the in-plane and out-of-plane lattice parameters, respectively. The dielectric properties were significantly affected by the type of lattice distortion and the interplay of strain and orientation. X-ray absorption near edge structure (XAFS) measurements were taken in several orientations. The anisotropy in the spectra with orientation was used to determine the FE phases of the films. The dependence of the in-plane dielectric constant on strain will be discussed in terms of a theoretical model of the phenomenological thermodynamics of the film strain effect.

3:54PM S37.00008 An ab initio study of strained PZT films SCOTT BECKMAN, KARIN RABE, DAVID VANDER-BILT, Rutgers University — The potential for creating ferroelectric-based devices such as ferroelectric random-access memories (FeRAMs) has led to an intense interest in ferroelectric perovskite thin films, alloys, and superlattices. Engineering of FeRAMs requires the control of both the spontaneous polarization and the barrier for polarization reversal. The two parameters that are simplest to modify are the composition, which is controlled during the film deposition, and the epitaxial strain, which is controlled by substrate selection. Here, using ab initio methods, we investigate how the ferroelectric properties of (PZT) depend upon epitaxial strains ranging from -0.02 ≤ x ≤ +0.02. Compositions ranging from 0.0 ≤ x ≤ 0.5 are examined by the creation of special quasirandom structures. In agreement with the literature, the effect of strain on the polarization is found to be small. We also examine the strain dependence of the barrier for polarization reversal, and discuss the results in the context of experimental measurements of coercive fields and polarization retention.1

4:06PM S37.00009 High pressure x-ray diffraction study of single crystal Pb(Sn0.5 Nb0.5)O3, MADDURY SOMAYAZULU, MUHTAR AHART, RONALD COHEN, Geophysical Laboratory, RUSSELL HEMLEY, Geophysical Laboratory, GEOPHYSICAL LABORATORY TEAM — We employed high pressure single crystal x-ray diffraction to investigate the pressure-induced phase transition in Pb(Sc0.5Sn0.5)O3 (PSN). At 2 GPa and 300 K, PSN undergoes a phase transition as deduced from earlier dielectric measurements. The pressure dependence of diffuse scattering observed around the (110) Bragg peaks indicates that pressure suppresses the local distortion that is coupled to the polar nanoribbons. We have monitored the pressure dependence of diffuse scattering at temperatures between 300 - 4 K and used this to understand the P-T phase diagram of PSN. In addition, we also investigated the equation of state at various temperatures. Observed changes in the isothermal compressibility at low temperatures indicate that the first order phase transition changes character at 200 K and 4 GPa. The results can be understood in terms of a pressure-induced decrease in the correlation length among polar nanoribbons, which is a unique property of relaxor ferroelectrics.

4:18PM S37.00010 Strain induced relaxor behavior in PbSc0.50Nb0.25Ta0.25O3 thin films: A comparison with the nanocrystallites, MARGARITA CORREA, ASHOK KUMAR, RAM KATIYAR, University of Puerto Rico — A comparative study of the microstructure, micro Raman spectroscopy and dielectric properties of PbSc0.50Nb0.25Ta0.25O3 thin films and ceramics were carried out over a wide range of temperature 100-520 K and frequency 100Hz to 1MHz. Microstructure of PSNT films revealed an in-plane compressive strain whereas PSNT ceramics showed an average 10-15 nm size nanoribbons. We observed a shift of 65 K in dielectric maxima temperature towards the lower temperature and frequency dispersion of the dielectric constant in PSNT films compared to bulk that does not exhibit relaxor behavior. We addressed this different dielectric response due to the in-plane compressive strain in the films. Temperature dependent micro Raman spectroscopy revealed that the ferroelectric state in PSNT ceramics were accompanied by pronounced changes in both the lowest frequency F_{2g} and highest frequency A_{1g} modes. Micro Raman spectra of the thin films compared to nanocrystalline showed shifting of the Raman modes to lower frequencies that confirms the strain state of the films. The in-plane compressive strain, dipole arrangement and the size of nanoribbons change the dielectric response of the PSNT films compared to nanocrystallites.

4:30PM S37.00011 First Principles Theory of Sub-Monolayer Strontium on Silicon (001), KEVIN GARRITY, Yale University Department of Physics, JAMES REINER, FREDERICK WALKER, CHARLES AHN, SOHRAB ISMAIL-BEI, Yale University Department of Applied Physics — Conventional attempts to continue transistor scaling consistent with Moore's law will soon result in unacceptable quantum mechanical leakage currents across the dielectric oxide layer. One promising solution to this problem is to replace the current silicon dioxide layer with a thicker crystalline oxide with a higher dielectric constant, grown epitaxially on silicon. Although there has been progress in growing high quality epitaxial interfaces for some materials, the initial stages of growth, including the deposition of the initial metal layer, are not well understood. Using ab initio density functional theory, we study the initial stages of the deposition of strontium titanate on silicon (001), a good model system due its successful epitaxial growth. We present the binding energies of several new low energy structures with sub-monolayer coversages of strontium which differ significantly from the conventional view of this surface. Additionally, to include finite temperature effects, we calculate vibrational free energies. We compare our results to experimental samples grown by molecular beam epitaxy.

4:42PM S37.00012 Sub-monolayer Strontium Phase Diagram on Silicon (100), JAMES REINER, KEVIN GARRITY, FRED WALKER, SOHRAB ISMAIL-BEI, C. H. AHN, Yale University — Crystalline oxides manifest a number of important phenomena, including magnetism, ferroelectricity, superconductivity, and colossal magnetoresistance. Recently, it has become possible to integrate these materials onto a silicon platform in a fully epitaxial structure. These crystalline oxide-silicon heterostructures bring the promise of integrating the rich functionality present in crystalline oxides with modern silicon device technology. The most successful fully epitaxial oxide-silicon (100) heterostructures have been achieved through a deposition recipe that involves manipulating substrate temperature and oxygen pressure on a layer by layer basis during the deposition of an alkaline earth metal. Motivated by a desire to develop a fundamental understanding of this important transition layer between silicon and oxide, we have mapped out the phase diagram of strontium on silicon as a function of temperature and coverage. In particular, recent work on sub-monolayer strontium deposition on the silicon surface suggests the conventional picture of this structure, upon which the entire crystalline oxides on silicon framework is built, is only a low-temperature phase which plays no role in enabling epitaxial oxide growth. Instead, there is strong evidence that a different high temperature phase is the crucial template for epitaxial oxide growth on silicon.

5:06PM S37.00014 Polarization of strained SrTiO3 films grown on Si (001), F. J. WALKER, YARON SEGAL, Yale University, J. W. REINER, C. H. AHN, Yale University, ZHAN ZHANG, Argonne National Laboratory — Perovskite oxides grown on silicon provide powerful new functionalities for device components built upon the ubiquitous silicon platform. A rich set of applications results from the combination of the perovskite’s diverse electrical and physical structures and the semiconducting properties of silicon. Understanding how to develop new functionalities, however, requires detailed knowledge of the real space positions of atoms with sub-angstrom resolution. In this work, we have carried out synchrotron x-ray diffraction studies of crystal truncation rods on 4-5 unit-cell-thick SrTiO3 films grown epitaxially on silicon, which have been terminated with different gate materials. We determine the precise atomic structure of these materials, in particular the displacements of the TiO2 planes relative to the SrO planes that make up the perovskite structure. We show how that the polarization and structure of commensurately strained films depend critically upon the electrical and chemical properties of the terminating metal.

5:18PM S37.00015 Writing and Reading of Ultrathin Ferroelectric Domains on Commensurate SrTiO3 on Silicon, JEREMY LEVY, YUN JIN PARK, JEREMY LEVY, KYUNGJIN LEE, KUSHAL SRIVASTAVA, JEREMY LEVY, CHENG CEN, CHARLES R. SLEASMAN, MAITRI WARUSAWITHANA, DARRELL G. SCHLOM — Ferroelectricity in ultrathin epitaxial SrTiO3 grown commensurately by oxide-molecular beam epitaxy (MBE) on silicon substrates was investigated using piezoresponse force microscopy (PFM). A series of samples containing n multilayers (ML) of SrTiO3 (n = 3, 4, 5, 6, 8, 10, 20) was grown on silicon substrates. Room-temperature ferroelectricity was observed for all samples containing n = 5, 6, 8, 10 ML. Temperature-dependent measurements indicate that the sample with n = 5 exhibits a ferroelectric phase transition at T_C = 317 K. Sample with n = 6 remains ferroelectric up to at least 393K. Polar domains created on the n = 6 was found to be stable at room temperature for more than 72 hours. The implications of these results for fundamental and device-related applications will be discussed briefly.

This work was supported by NSF-0704022 (JL) and Office of Naval Research (ONR) through grants N00014-03-1-0721 (DGS) and N00014-04-1-0426 (DGS) monitored by Colm Wood.
2:30PM S39.00001 Absorbing-state phase transitions: exact solutions of small systems. RONALD DICKMAN, UFMG — I derive precise results for absorbing-state phase transitions using exact (numerically determined) quasistationary (QS) probability distributions for small systems. Analysis of the contact process on rings of 23 or fewer sites yields critical properties (control parameter, order-parameter ratios, and critical exponents $\alpha$ and $\beta/\nu$) with an accuracy of better than 0.1%; for the exponent $\nu$, the accuracy is about 0.5%. Good results are also obtained for the pair contact process. The QS kurtosis exhibits a sharp minimum at the critical point.

$^1$This work was supported by CNPq and FAPEMIG, Brazil.

2:42PM S39.00002 Displacement and velocity correlation functions of magnetic particle chains undergoing Brownian dynamics. YUK KWAN HO, MINGJIE ZHENG, KIN WAH YU, The Chinese University of Hong Kong — Brownian dynamics of physical systems has been studied for a long time since Einstein in 1905. In this work, we report the study of a magnetic particle chain in ferrofluid, with hydrodynamic interactions and harmonic interactions included, by using Rice method [1]. We will focus on the correlation functions and relaxation time of the chain. As qualitative account for the effect of system parameters, analytic solutions of the displacement and velocity correlation functions of a two-body system have been studied. In the case of an over-damped system, very long relaxation time for the displacement correlation function can be obtained from the analytic solutions. Moreover, the size dependence of the relaxation time is also studied numerically for moderate chain sizes.

2:54PM S39.00003 Theory of Zener tunneling and breakdown in solids. NAOYUKI SUGIMOTO, Department of Applied Physics, University of Tokyo, SHIGEKI ONODA, RIKEN, NAOITO NAGAOASA, Department of Applied Physics, University of Tokyo, CERC, CREST — Tunneling and breakdown phenomena are among of the most important problems in condensed matter physics. We study the Zener tunneling and breakdown phenomena in a bulk system taking into account the dissipation due to impurity scatterings in terms of the Keldysh formalism. Three distinct regions are recognized for the current-field characteristics, which are identified as the impurity-conduction, the Zener tunneling, and the Zener breakdown, respectively. The crossovers among them are described in a unified fashion. By examining the local density of states, which can be measured by scanning tunneling spectroscopy, we find that the Zener tunneling and breakdown can be understood as the conductance due to the finite local density of states at the Fermi energy originating from the hybridization between the conduction and valence bands induced by the electric field.

3:06PM S39.00004 Domain Structure Universality in Coarsening. BENJAMIN VOLLMAYR-LEE, Bucknell University, ANDREW RUTENBERG, Dalhousie University, SOHEI YASUDA, Bucknell University — Coarsening systems ubiquitously exhibit power law growth $L \sim t^{\alpha}$ with self-similar domain morphology, and much progress has been made in mapping out universality classes of the growth exponent $\alpha$. It has been commonly argued that these universality classes should apply well to the scaled domain structure, but recent evidence has appeared to the contrary. In particular, surface tension anisotropy has been found numerically and by exact solutions in the dilute limit to modify the domain morphology and structure factor, while leaving growth exponents unchanged. Thus the universality classes of the domain morphology remains an open question. We present a conjecture that the morphology universality is a consequence of the asymptotic trajectories of the topological defects, and then map out the universality classes that follow. Our prediction, in the case of scalar, conserved order parameter coarsening, is that the domain structures depend on surface tension anisotropy and mobility asymmetry, but nothing more. To test this prediction we have conducted extensive simulations of coarsening with mobility asymmetry and have demonstrated its influence on the scaled domain structure.

3:18PM S39.00005 Exact Solutions for Anisotropic Coarsening in the Dilute Limit. WILLIAM ROSENBAUM, Reed College, MELINDA GILDNER, BENJAMIN VOLLMAYR-LEE, Bucknell University — We study the influence of anisotropy on coarsening dynamics via two dilute coarsening models: Lifshitz-Slyozov theory for locally conserved order parameter dynamics, and Wagner theory for the globally conserved analog. We adopt a perturbative approach to analyze the effect of surface tension anisotropy on drop shapes and the scaled drop size distribution. In both models we find that coarsening solutions exhibit growth laws that are unchanged from the isotropic theories, $L \sim t^{1/3}$ and $L \sim t^{1/2}$ respectively, and drop shapes that are in general nonspherical and non-Wulffian. We also determine that the drop size distribution varies from the isotropic case.

3:30PM S39.00006 Domain Morphology and Structure Factor in the Asymmetric Cahn-Hilliard equation. SOHEI YASUDA, BENJAMIN VOLLMAYR-LEE, Bucknell University, ANDREW RUTENBERG, Dalhousie University — The Cahn-Hilliard equation for conserved order parameter coarsening is modified to allow for unequal mobilities in the two equilibrium phases. This asymmetric Cahn-Hilliard equation is then simulated using an unconditionally stable algorithm, which enables reaching times well into the $L \sim t^{1/3}$ dynamic scaling regime. Our goal is to address questions of the universality of the scaled domain morphology; in particular, to test our conjecture that the morphology should depend on the mobility asymmetry. We study mobility ratios of 1, 2, 4 and 8 and find that the domain size distribution depends strongly on the mobility asymmetry: the higher (lower) mobility phase forms a smaller (larger) backbone cluster with more (fewer) smaller domains, and the magnitude of the effect grows with the mobility ratio. Interestingly, the structure factor shows no discernible dependence on the mobility asymmetry.

3:42PM S39.00007 Non-trivial statistics crossover in random sequential adsorption due to the presence of a pattern. NUNO A.M. ARAUJO, GCEP-Centro de Física da Universidade do Minho, 4710 Braga, Portugal; T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, ANTONIO CADILHE, T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA; GCEP-Centro de Física da Universidade do Minho, 4710 Braga, Portugal, VLADIMIR PRIVMAN, Department of Physics, and Center for Advanced Materials Processing, Clarkson University, Potsdam, NY 13699, USA — The random sequential adsorption (RSA) on a lattice approaches the jammed state exponentially, while in the off-lattice version approaches the jammed state as a power-law. In this presentation, we focus on the kinetics leading to the jammed state. The presence of pattern influences the kinetics of approach to the jammed state. Namely, a pattern consisting of equal size squares embedded on a square matrix lattice provides a rich set of regimes. Measurements of the distribution of areas available for adsorption during the process make possible to predict how the jammed state is attained: power-law or exponential. Finally, we associate these two different kinetic regimes with the breakdown of Pommeau statistics near the jammed state.
apparently cannot be rigorously derived by any existing technique. The checkerboard formula that we find is same as that conjectured by Wu (Rev. Mod. Phys.

3:54PM S39.00008 Dephasing and the steady state in quantum many-particle systems. THOMAS BARTHUL, ULRICH SCHOLLWÖCK, Institute for Theoretical Physics C, RWTH Aachen, Germany — We discuss relaxation in many-particle systems. For integrable systems, the time-evolution from an arbitrary initial state can lead, for a given finite subsystem, to a definite steady state. We give an explicit derivation of the steady state ensemble and devise sufficient prerequisites for the dephasing to take place. We also find surprisingly simple scenarios, in which dephasing is ineffective and discuss the dependence on dimensionality and criticality. It also follows that, after a quench of system parameters, entanglement entropy will become extensive.

4:06PM S39.00009 Assembly and control of self-propelled structures in driven suspensions of magnetic microparticles. MAXIM BELKIN, Illinois Institute of Technology / Argonne National Lab, ALEXEY SNEZHKO, IGOR ARANSON, WAI-KWONG KWOK, Argonne National Lab — Magnetic microparticles suspended on the surface of liquid and subjected to periodic vertical magnetic excitations form a non-trivial dynamic snake-like pattern accompanied by large-scale surface flows. Apparently, controlled suppression of vortices at one end of the snake may lead to a formation of a self-propelled structure. We demonstrate that the suppression of the vortex pair can be implemented by the mechanical disturbance of the one end of the structure by means of the floating particle with characteristic size comparable to the width of the snake’s segment. The snake structure with the particle attached to its end becomes a swimmer with parameters effectively controlled by the external driving magnetic field. Experimental studies of such self-propelled structures are presented.

4:18PM S39.00010 Avalanches of Bose-Einstein-Condensates from open optical lattices. TSAMIKOS KOTTOS, Department of Physics, Wesleyan University, Connecticut-USA and MPI for Dynamics and Self-Organization, Gottingen-Germany, GIM SENG NG, Department of Physics, Wesleyan University, Connecticut-USA, HOLGER HENNIG, RAGNAR FLEISCHMANN, THEO GEISEL, MPI for Dynamics and Self-Organization, Gottingen-Germany — We investigate, the outgoing atomic flux of BECs loaded in large OLs using a mean field (Discrete Non-Linear Schroedinger Equation—DNLSE) approach. We show that for some critical values of the rescaled (with respect to the lattice size) interatomic interaction strength, the current decays in avalanches that follow a power-law distribution indicating the existence of a novel phase transition. The origin of this phenomenon is identified to be the collisions between stable and moving breathers which co-exist at the lattice. Using a reduce map we are able to provide bounds for the power law exponent of the avalanche distribution which reflect the complexity of the underlying classical phase-space. Due to the inter-disciplinary nature of the DNLS, we expect that the same phenomenon will be observed in several other branches of nonlinear physics, ranging from nonlinear optics to polaron and biological molecules.

4:30PM S39.00011 Study of universality and critical behavior in periodically driven interacting cold atomic system. MYOUNG-SUN HEO, YONGHEE KIM, WONHO JHE, Seoul National University, HEUNG-RYOL NOH, Chonnam National University — Strongly driven nonlinear oscillators show a variety of interesting phenomena such as period doubling, bifurcation, chaos. Since their resonant behaviors are very sensitive to external perturbation, they have now been widely adopted for the precise determination of physical quantities. The key concept to these researches is the development of bistable or period-2 states, which are, in most cases, energetically degenerate. If particles interact each other, however, this degeneracy of two attractors can be lifted up. For example, in the simple case of all-to-all attractive interaction, particles will be preferably directed into more populated attractors. Being incorporated with random fluctuation which tries to equilibrate population in each attractor, this lifting-up becomes dependent on the system size, or the total number of particles, as recently observed as spontaneous symmetry breaking in cold atomic system which inherently possesses the light-induced attractive interaction. In particular, this dependence seems to show a sort of critical behavior. Here we have elucidated the criticality existing in the strongly driven interacting many-particle system consisted up of cold atoms from static and dynamic perspectives.

4:42PM S39.00012 Transition of Electromechanical Pendulum into Nonlinear Response. CHULKI KIM, Physics, University of Wisconsin-Madison, HUA QIN, HYUN-SEOK KIM, ROBERT BLICK, Electrical & Computer Engineering, University of Wisconsin-Madison — We present measurements on a macroscopic electron shuttle in the regime of nonlinear response. The shuttle is formed by a classical mechanical pendulum situated between two capacitor plates. The main advantage of this macroscopic setup is that we can directly measure the onset of nonlinear response of thiselectromechanical pendulum exhibiting period doubling. The results will find use in application such as bifurcation amplifier in nanoscopic versions of the device. A model nanoelectromechanical device based on the macroscopic experiment has the potential to reveal nonlinear quantum mechanical effects.

4:54PM S39.00013 Harmonic measure of DLA and percolation clusters. ROBERT ZIFF, LEONARD SANDER, DAVID ADAMS, University of Michigan — The problem of efficiently finding the harmonic measure of DLA and percolation clusters is addressed. Deep inside fjords and inlets of irregular surfaces, traditional methods of solving Laplace’s equation become very inefficient. A new numerical algorithm that efficiently solves for those measures is developed. The technique uses a step-by-step approach that adds a shell at each time step to the diffusion front, and is essentially linear in the number of sites considered. The method works for lattice systems and discretized versions of continuum systems. With it, we have solved for the multifractal exponents of the fractal surfaces. For DLA, we address the controversy of the behavior of the harmonic measure deep inside the fjord. For percolation, we consider both the relatively smooth accessible hull (D = 4/3), and the very invaginated regular hull (D = 7/4).

5:06PM S39.00014 Critical surfaces for general two dimensional bond percolation problems. CHRIS SCULLARD, University of Chicago, ROBERT ZIFF, University of Michigan — We present a general method for deriving approximate bond percolation critical surfaces for general two dimensional lattices. Our approach is to assume that the critical surface is at most first order in its arguments and then to impose symmetries and known special cases until the function is completely determined. We show also that allowing higher powers of the arguments gives increasingly accurate approximations. For the Archimedean lattices the critical thresholds we find by this method are accurate to at least 4 significant figures. In two other cases, the checkerboard and inhomogeneous bow-tie we find critical surfaces that appear, from our numerical investigation, to be exact but that apparently cannot be rigorously derived by any existing technique. The checkerboard formula that we find is same as that conjectured by Wu (Rev. Mod. Phys. 54, 235 – 265 (1982)).
5:18PM S39.00015 Nonuniversal Deviations From Predictions of the Random Matrix Theory of Wave Chaotic Scattering: Theory and Experiment1. STEVEN ANLAGE, JAMES HART, ELLIOTT BRADSHAW, THOMAS ANTONSEN, EDWARD OTT, Physics Department, University of Maryland — The eigenfunctions and spectra of chaotic billiards are notoriously sensitive to small perturbations. Thus statistical approaches have been developed to model such systems. In recent work, we used random matrix theory to develop statistical models for the impedance of a chaotic microwave cavity coupled to a small number of antennas, with the only parameters being the radiation impedance of the antennas, the area of the cavity and a uniform loss parameter Q [S. Hemmady, et al., Phys. Rev. Lett. 94, 014102 (2005); X. Zheng, et al., Electromagnetics 26, 3 (2006)]. The theory generally agrees well with experiment, but under some circumstances the experimental and numerical results deviate significantly from the Random Matrix Theory predictions. We have derived a method of accounting for these deviations and have experimental and numerical results which agree well with our new, non-universal, predictions.

2:54PM S40.00002 Magnetism in matter before the discovery of quantum spin: Bohr’s less well-known contribution to the transition from classical to quantum physics. JEAN-FRANCOIS VAN HUELLE, Brigham Young University — How does one explain magnetic effects in matter when one views matter as a collection of classical charges in motion? The answer is: not at all! This is one of the points that Niels Bohr made in his doctoral dissertation in 1911, two years before addressing the issue of the stability of the hydrogen atom. The result, later rediscovered by H.J.van Leeuwen was amplified and formalized in Van Vleck’s 1932 text on electric and magnetic susceptibilities and it is currently known as the Bohr-van Leeuwen theorem. We will review Bohr’s two derivations, one statistical and one based on the motion of individual electrons. We will then propose reasons why this result, unlike that on the stability of hydrogen, did not lead to a major development in quantum theory but, instead, had to wait until after the introduction of spin and exchange forces in quantum mechanics to become generally known.

3:18PM S40.00003 Epistemological Dimensions in Niels Bohr’s Conceptualization of Complementarity, GREGORY DERRY, Loyola College In Maryland — Contemporary explications of quantum theory are uniformly ahistorical in their accounts of complementarity. Such accounts typically present complementarity as a physical principle that prohibits simultaneous measurements of certain dynamical quantities or behaviors, attributing this principle to Niels Bohr. This conceptualization of complementarity, however, is virtually devoid of content and is only marginally related to Bohr’s actual writing on the topic. Instead, what Bohr presented was a subtle and complex epistemological argument in which complementarity is a shorthand way to refer to an inclusive framework for the logical analysis of ideas. The important point to notice, historically, is that Bohr’s work involving complementarity is not intended to be an improvement or addition to a particular physical theory (quantum mechanics), which Bohr regarded as already complete. Bohr’s work involving complementarity is actually an argument related to the goals, meaning, and limitations of physical theory itself, grounded in deep epistemological considerations stemming from the fundamental discontinuity of nature on a microscopic scale.

3:42PM S40.00004 Paradox, Natural Mathematics, Relativity and Twentieth-Century Ideas, JOHN RYSKAMP — We are enjoying a renaissance in the historiography of set theory which allows us to pinpoint the effect of Poincare’s writing on the development of Einstein as an advocate of natural mathematics (what he called practical geometry). I will briefly describe the importance of Garciadiego’s landmark work on Russell (1992), and Grattan-Guinness’ epic recounting of the history of set theory (2000). I will present something for which historians of physics have searched but have not previously identified: the precise step at which Einstein incorporated practical geometry into his formulation of the relativitity of simultaneity. This leads to a troubling conclusion, at least for those who look to relativity for internal consistency. However, the trouble is not restricted to physics. We suggest that natural mathematics finds its way into the major twentieth-century ideas.

Session T1 Quarks to Cosmos: Breaking News at the Interface of Particle, Nuclear and Astrophysics New Orleans Marriott Carondelet (3rd floor)

7:30PM T1.00001 Quarks to Cosmos: Breaking News at the Interface of Particle, Nuclear and Astrophysics, MICHAEL TURNER, University of Chicago, JOSEPH LYKKEN, Fermi National Accelerator Laboratory, MICHAEL WIESCHER, University of Notre Dame — Profound connections join scales all the way from the very smallest to the very largest that we can explore, and these connections now link the fields of astrophysics, cosmology, nuclear physics and particle physics. Research that crosses these traditional field boundaries are beginning to reveal new states of matter, how the Universe began, the role of neutrinos in shaping the Universe, how massive stars explode and the elements in the periodic table were made, how Nature’s most powerful accelerators work, the nature of space and time and the unification of the forces, and the nature of dark matter and dark energy. These three talks will showcase these connections, highlight recent exciting results, and look toward the future.

8:36AM U1.00002 Frank Isakson Prize Talk: Using ultrafast to probe the slow1, JOSEPH ORENSTEIN, UC Berkeley and LBNL — The field of ultrafast optics exploded on the scene with the development of mode-locked lasers, and continues to grow as technology evolves. Although often associated with highly-nonequilibrium phenomena, ultrafast experiments can be performed in a low-power regime in which electronic systems are tickled, rather than blasted. The amplitude and phase stability of today’s laser oscillators allows detection of very small changes in optical response that result from weak laser excitation. While these changes can be viewed as a form of linear response, they often reveal properties that are not detected by traditional probes such as electrical conductivity or magnetic susceptibility. In this talk I will describe two examples of this approach, in the fields of high-Tc superconductivity and spin propagation in semiconductors. Somewhat paradoxically, the use of ultrafast techniques allows the observation of some rather slow effects. In the high-Tc materials, the lifetime of the photoexcited state diverges as the optical energy per laser pulse is lowered. The slow dynamics in this regime provide a window to the intrinsic inelastic scattering rate of quasiparticles, a new collective mode, and an abrupt transition in dynamics that takes place as a function of doping. In GaAs quantum wells the stability of the laser oscillator enables phase-sensitive detection of a transient spin-polarization wave that result from weak laser excitation. While these changes can be viewed as a form of linear response, they often reveal properties that are not detected by traditional probes such as electrical conductivity or magnetic susceptibility. In this talk I will describe two examples of this approach, in the fields of high-Tc superconductivity and spin propagation in semiconductors. Somewhat paradoxically, the use of ultrafast techniques allows the observation of some rather slow effects. In the high-Tc materials, the lifetime of the photoexcited state diverges as the optical energy per laser pulse is lowered. The slow dynamics in this regime provide a window to the intrinsic inelastic scattering rate of quasiparticles, a new collective mode, and an abrupt transition in dynamics that takes place as a function of doping. In GaAs quantum wells the stability of the laser oscillator enables phase-sensitive detection of a transient spin-polarization wave generated by the interference of two excitation pulses. Measuring dynamics as function of wave vector fully characterizes the spin propagation, revealing effects such as ballistic to diffusive crossover and spin Coulomb drag. In these systems we again have focused on “slow” phenomena. I will describe some of our recent attempts to create and detect a long-lived, “persistent spin-helix” state, predicted to occur at special points in the spin-orbit coupling parameter space.

9:12AM U1.00003 Frank Isakson Prize Talk: Optical Probes of π-Conjugated Polymers1, Z. VALY VARDENY, University of Utah — We review several optical probes that have been applied to π-conjugated polymers over a time period of ~30 years. These include linear and nonlinear optical spectroscopies, resonant Raman scattering, transient and steady state photodynamics, photoinduced electron and hole action, and optically detected magnetic resonance spectroscopy. The application of these techniques has revealed a myriad of important information on the interaction that govern the optical, electrical and magnetic properties of these materials; including electron-phonon interaction, electron-electron (e-e) and electron-hole (e-h) interactions, interchain coupling, spin-lattice and spin-orbit coupling. These properties are very important for various optoelectronic applications, in which the polymers serve as active layers. The following picture of the excited state properties of these polymers has emerged. (i) The e-e and e-h interactions are substantial, and as important as the electron phonon interaction. This leads to relatively large intrachain exciton binding energy of ~0.5 eV, and exchange energy between the singlet and triplet lowest states of ~0.7 eV. (ii) There are few important excited states with odd and even parity symmetry that govern the nonlinear optical spectra of these materials. (iii) The primary photoexcitations are intrachain excitons in isolated chains, and both excitons and polaron pairs in chains coupled by interchain interaction. (iv) The most strongly coupled phonons are amplitude modes of which frequencies and oscillator strengths are very sensitive to the existence of excess charges on the chains. (v) Excite changes are accommodated on the chains in the form of polarons with relatively large relaxation energy ranging from 0.1 to 0.5 eV. (vi) The spin orbit coupling is very weak in these materials, but can be tuned by involving heavy atoms in the polymer building blocks. (vii) The spin relaxation time for spin 1/2 polarons is relatively long of ~1 microsecond. The two latter properties may lead to new applications in the field of Organic Spintronics.

9:48AM U1.00004 David Adler Lectureship Award Talk: Lattice instabilities and ferroelectricity in complex oxides, KARIN M. RABE, Rutgers University — In perovskite oxides, layered perovskites and other complex-structured oxide families, a wide variety of distorted equilibrium structures can be realized, including ferroelectric, antiferroelectric, antiferrodistortive, and mixed-character structures. For an individual material, the equilibrium structure can be understood as being produced by the freezing-in of one or more lattice instabilities of the high-symmetry reference structure. This concept is central to the long-established soft-mode theory of ferroelectricity. In fact, first-principles phonon-dispersion calculations show that the high-symmetry reference structures of many complex oxides have entire ranges of instabilities that do not contribute to the bulk ground state structure. In this talk, we discuss how the information from first-principles studies of these systems provides guidance for altering the balance of the competition of instabilities of different character through changes in electrical and mechanical boundary conditions characteristic of epitaxial thin films, superlattices, and nanoparticles, leading to the realization of non-bulk phases. For example, it has been shown both theoretically and experimentally that SrTiO3, which has a nonpolar bulk ground state, can be driven ferroelectric by epitaxial strain. To illustrate the further development and application of these ideas, we present results for CaTiO3 and discuss other materials which, while nonpolar in bulk, can be driven in this way through a phase boundary to become ferroelectric. New ferroelectrics thus obtained could have combinations of tunable properties, including switchable polarization, magnetic ordering, and dielectric and piezoelectric response, desirable for current and future technological applications.

hole-doped region grows below ~150 K with decreasing temperature, similar to the case in 2DEGs, albeit the much higher temperature scale. In those

samples, the easy transport axis was apparently dictated by the orthorhombic crystal structure; however, the orthorhombicity η was only up to 1.5%, while the resistivity anisotropy was up to a factor of 3, which was obviously too large for the small η. Furthermore, the anisotropy in YBCO was found to be enhanced with decreasing y below ~0.5 despite the decreasing η until the crystal structure turns to tetragonal at y = 6.30. While this result gave strong evidence for the self-organization of the EN in high-Tc superconductors, it was not completely conclusive because of the existence of the orthorhombicity that chooses the preferred direction; also, the lack of support from neutron scattering kept the skepticism remain. However, very recently, neutron scattering has finally found corroborating

anisotropy in YBCO and convincing evidence for EN in a related oxide Sr3Ru2O7 was obtained, which together strengthened the case for cuprates considerably.

In collaboration with Kouji Segawa, Seiki Komiya, and A. N. Lavrov.

Session U2 DCMP: Electron Nematics

Morial Convention Center LaLouisiane C

8:00AM U2.00001 Transport anisotropy as a signature of electron nematicity

YOICHI ANDO,

Institute of Scientific and Industrial Research, Osaka University — Strong electron correlations often give rise to novel phenomena that are never found in ordinary materials. One of such phenomena is the emergence of electron nematicity (EN), which was theoretically proposed in 1998 to occur due to a combined effect of electron self-organization and quantum fluctuations. Experimentally, the EN was first discovered in 1999 in the two-dimensional electron gas (2DEG) at high Landau levels, where a clear transport anisotropy was found to grow upon lowering temperature in the mK region. In search for the signatures of the EN in cuprates, we have done extensive transport measurements of La2−xSrxCuO4 (LSCO) and YBa2Cu3O7 (YBCO) systems using high-quality single crystals. We discovered in 2001 that the in-plane resistivity anisotropy in untwinned single crystals of LSCO and YBCO in the lightly hole-doped region grows below ~150 K with decreasing temperature, similar to the case in 2DEGs, albeit the much higher temperature scale. In those samples, the easy transport axis was apparently dictated by the orthorhombic crystal structure; however, the orthorhombicity η was only up to 1.5%, while the resistivity anisotropy was up to a factor of 3, which was obviously too large for the small η. 8:36AM U2.00002 Theory of the nematic quantum critical point in a nodal superconductor

EUN-AH KIM, Stanford University — In the last several years, experimental evidence has accumulated in a variety of highly correlated electronic systems of new quantum phases which (for purely electronic reasons) spontaneously break the rotational (point group) symmetry of the underlying crystal. Such electron "nematic" phases have been seen in quantum Hall systems[1], in the metamagnetic metal Sr3Ru2O7[2], and more recently in magnetic neutron scattering studies of the high temperature superconductor, YBCO[3]. In the case of a high Tc superconductor, the quantum dynamics of nematic order parameter naturally couples strongly to quasiparticle (qp) excitations. In this talk, I will discuss our recent results on the effects of the coupling between quantum critical nematic fluctuations and the nodal qp's of a d-wave superconductor in the vicinity of a putative quantum critical point inside the superconducting phase. We solve a model system with N flavors of quasiparticles in the large N limit[4]. To leading order in 1/N, quantum fluctuations enhance the dispersion anisotropy of the nodal excitations, and cause strong scattering which critically broadens the quasiparticle peaks in the spectral function, except in the vicinity of the NWissenstein, L.N. Pfeiffer, and K.W. West, PRL 83, 824 (1999).

9:12AM U2.00003 Metamagnetic Nematic Phase of Sr3Ru2O7, ANDREW MACKENZIE, University of St Andrews — In this talk I will review our group's recent observations that a quantum phase with pronounced electrical transport anisotropies forms in the vicinity of a metamagnetic quantum critical point in Sr3Ru2O7. The behaviour, which is strongly dependent on disorder and is only seen in the highest purity crystals, has phenomenological similarities with prior observations on two-dimensional electron gases in semiconductor devices [1, 2]. Its appearance in bulk in Sr3Ru2O7 has allowed us to perform a number of thermodynamic measurements, and also offers the promise of study using modern surface-based spectroscopies such as angle resolved photoemission and spectroscopic imaging scanning tunneling microscopy. 9:48AM U2.00004 Electronic Nematic Liquid in Correlated Systems, HAE-YOUNG KEE — It was proposed that the electronic nematic phase with a broken rotational symmetry is a generic ground state of a doped Mott insulator, and it has attracted much attention with the discovery of anisotropic quantum Hall phases in GaAs-heterostructures in large magnetic fields. A series of recent experiments on the bilayer ruthenate Sr3Ru2O7 also suggest the existence of an anisotropic metallic phase which is uncovered by tuning the magnetic field. In this talk, I will show that two consecutive metamagnetic transitions, a large residual resistivity, and an anisotropic magnetoresistance observed in the bilayer ruthenate can be understood via the electronic nematic order and its domains. I will also discuss an SO(4) invariance at the critical point between the electronic nematic and d-wave superconducting states, and its relation to the similar SO(4) invariance between the d-density wave and d-wave superconducting states.

1NSERC of Canada, Canadian Institute for Advanced Research, Canada Research Chair
10:24AM U2.00005 Spins in cuprates near the edge of the superconducting phase - incoherent pairing, fluctuations on all timescales and observation of pseudogap energies. BILL BUYERS, National Research Council, Chalk River — When doping is just enough to create the superconducting phase spins behave very differently from heavily doped cuprates. Nonetheless low doping reveals the key ingredients for the coherence of superconducting pairs. The ordered spins of the insulating antiferromagnet are replaced by a hedgehog phase with isotropically polarized spins, and a commensurate central mode with slow short-range spin correlations extending over four planar unit cells. A subcritical 3D enhancement is destroyed by temperature and energy. The spins follow not via the coherence of charge pairs but the structures caused by hole doping, so that glassy short range spin orders within both the superconducting and normal phase. The tumbling regions of spins exhibit a power-law spectrum similar to 1/f noise down to microeV energies. Excitations are overdamped with a milliEV relaxation rate a thousand times faster, unlike the well-defined resonance familiar at large doping. Below 50 K the scale length is geometric and not linked by velocity to dynamic widths. As excited states are depopulated spin weight transfers to the central mode. At energies 300,000 times larger, decay of paramagnons into pseudogap states has been detected [1], a strong indication that it is the large density of high-energy spin states that provides the superconducting glue, rather than the resonance which is absent as a sharp spectral feature.

Thursday, March 13, 2008 8:00AM - 11:00AM –
Session U3 DPOLY: Simple Views on Polymers at Surfaces and Interfaces: Symposium Honoring P G de Gennes 
Morial Convention Center R02 - R03

8:00AM U3.00001 Polymer adsorption , JEAN-FRANCOIS JOANNY, Institut Curie Paris France — The aim of this talk is to review Pierre-Gilles deGennes’ work on polymer adsorption and the impact that it has now in our understanding of this problem. We will first present the self-consistent mean-field theory and its applications to adsorption and depletion. De Gennes most important contribution is probably the derivation of the self-similar power law density profile for adsorbed polymer layers that we will present next, emphasizing the differences between the tail sections and the loop sections of the adsorbed polymers. We will then discuss the kinetics of polymer adsorption and the penetration of a new polymer chain in an adsorbed layer that DeGennes described very elegantly in analogy with a quantum tunneling problem. Finally, we will discuss the role of polymer adsorption for colloid stabilization.

8:36AM U3.00002 Polymer brushes , EKATERINA ZHULINA, Institute of Macromolecular Compounds, Russia — The polymer brush is an ensemble of macromolecules end-tethered to a substrate. The so-called Alexander-de Gennes polymer brush model (S. Alexander, J. Physique 1977, and P.-G. de Gennes, Macromolecules 1980) opened a new field in polymer science and provided a theoretical framework to look at brush-like polymer systems. In this presentation, we will first briefly review the ideas and concepts behind the Alexander-de Gennes model of a planar polymer brush and summarize its major findings. We will then focus on the general impact of this seminal work by demonstrating numerous theoretical developments initiated by the Alexander-de Gennes model with specific emphasis on polyelectrolyte brushes and biological brush-like systems.

9:12AM U3.00003 Adhesion , HUGH BROWN, University of Wollongong — Adhesion is a highly practical subject in which the vast majority of published work is either chemical in nature, concerned with chemistry that is thought to occur at an adhesive junction or chemistry of adhesives, or essentially mechanical, concerned with the mechanics of testing and failure of adhesive systems. The role of polymer physics in general and de Gennes’ work in particular is to discover what happens at the scale of the polymer chain and hence form a bridge between these two approaches. A distinguishing feature of Gennes’ work in adhesion is the way he developed simple models that permitted us to see the essential physics of the situation. This is particularly true in his work in viscoelastic effects on toughness (the de Gennes trumpet) where more sophisticated mechanics had been done but the physical situation was obscure. Much of his work was concerned with the effects of connector molecules in toughening an interface in both elastomeric and glassy materials. This work has been extended by a number of authors and forms the basis of our current understanding of the area.

9:48AM U3.00004 Slippage , LILIANE LÉGER, Université Paris Sud XI — After a brief overview of the usual assumptions made to fix the boundary conditions for the flow velocity at a solid wall, we shall present the early conjecture made by Pierre Gilles de Gennes in 1979, predicting huge slip at the wall for polymer melts flowing against smooth non adsorbing surfaces. We shall then discuss how interplay between theory and experiments has allowed to produce a refined picture of the molecular mechanisms of friction at polymer interfaces, which quantitatively accounts for the three different friction regimes which have been experimentally identified when increasing the shear rate in simple shear experiments of polymer melts. The key idea (Brochard and de Gennes, 1992) focuses on the effect of a few surface anchored chains. If these chains are not rigid, they will deform under the effect of the friction forces resulting from entanglements between surface and bulk chains. When increasing the shear rate, the surface chains are thus progressively stretched, and can disentangle from bulk chains: a dynamic decoupling between surface and bulk polymer occurs. We shall discuss the available sets of experimental data (and the corresponding techniques which have been developed to either directly characterize wall slip or yield friction forces measurements). At present, the low surface density regime is fully understood, while series of data in the case of large grafting densities are available, but still lack of an adequate model. We shall finally draw lines of possible extensions of the ideas to other systems which start to be investigated as regards to friction: polyelectrolyses - grafted polyelectrolyte chains, rigid polymers, other complex fluids. We will also discuss experiments inspired by his work on confined polymers, in the last thirty years.

10:24AM U3.00005 Polymers in Confined Geometry , FRANCOISE BROCHARD-WYART, Institut Curie — Thanks to P. G. de Gennes’ famous “n = 0” theorem (relating the configuration of a polymer chain to a magnetic phase transition with an order parameter of n = 0 component), the swelling exponent ν (R = N^ν) was calculated in terms of space dimension d and fitted the qualitative Flory calculation. Using scaling laws, or the “blob” picture, it became possible to derive the configuration of a chain confined in a tube or a slit. The dynamics of confined polymers followed immediately. The new feature was the screening of the hydrodynamic interactions in confined geometry leading to Rouse-like behaviour. In a third step, de Gennes focused on the forced penetration of polymers (linear, branched, stars, neutral or charged) in narrow tubes, when they are submitted to a flow (or an electrical field for DNA). From all these calculations, the conclusion was that the threshold velocity (or field) corresponds to the penetration of the first blob. Afterwards, the friction force increases linearly with the penetrated length, whereas the confinement force remains constant. In the last few years, with his collaboration we studied the penetration of DNA in “soft” tubes. We predicted a transition from extended to globular DNA observed experimentally. We also showed that semi flexible polymer chains, like DNA, are ideal in 3d, but swollen effects are more pronounced in confined geometries. We will also discuss experiments inspired by his work on confined polymers, in the last thirty years.
and inelastic tunneling spectroscopy measurements of the electronic and dielectric properties of these high-k oxide-semiconductor systems. Using synchrotron crystal truncation rod analysis and reflection high energy electron diffraction, we place constraints on the detailed positions of the atoms at the oxide-semiconductor interface. This research has in part been motivated by a significant effort has been devoted to understand the nature of crystalline oxide-semiconductor interfaces. This research has in part been motivated by the potential applications in mind, I will also address interferometric measurements of states having superpositions of anyonic charges and discuss their non-Abelian anyonic statistics, such interferometric experiments would provide the most promising route to qubit read-out in a topological quantum computation. With these potential applications in mind, I will also address interferometric measurements of states having superpositions of anyonic charges and discuss their non-Abelian anyonic statistics, such interferometric experiments would provide the most promising route to qubit read-out in a topological quantum computation. With these potential applications in mind, I will also address interferometric measurements of states having superpositions of anyonic charges and discuss their non-Abelian anyonic statistics, such interferometric experiments would provide the most promising route to qubit read-out in a topological quantum computation. The observed quantum oscillations thus fundamentally differs from that of Aharonov-Bohm effect which has a period of one flux quantum, \( \Phi_0 \). The observed quantum oscillations in the quantum Hall corrals can be understood within the Coulomb blockade model of quantum Hall interferometers [1] as forward tunneling and backscattering, respectively, through the center island of the corral from the bulk and the edge states. In the second Landau level, we observe an extended series of oscillations with flux period of \( \Phi_0/2 \). The Aharonov-Bohm-Like oscillations are found to coexist with the \( \nu = 5/2 \) fractional quantum Hall effect. We detail the transport properties of the \( \nu = 5/2 \) fractional quantum Hall state and the mesoscopic quantum Hall corral in the second Landau level. [1] R. Rosenow and B.I. Halperin, Phys. Rev. Lett. 98, 106801 (2007).
activities taking place at IBM Zurich. It will also put them in perspective with the new rules the microelectronic industry might follow.

structures might indeed be seen as a logical conclusion for this evolution. This presentation will review the latest developments in the field, with a focus on the years ago, molecular beam epitaxy allowed band-gap engineering in compound semiconductors to build new devices and, more recently, was successfully used to explore the physics and chemistry of complex perovskites. During the last years, new developments have been made to combine oxides and semiconductors. In particular, many groups have reported the growth of oxides on silicon surfaces. The recent and renewed interest in compound semiconductor MOSFET structures might indeed be seen as a logical conclusion for this evolution. This presentation will review the latest developments in the field, with a focus on the activities taking place at IBM Zurich. It will also put them in perspective with the new rules the microelectronic industry might follow.

9:12AM U5.0003 First-principles modeling of functional oxides-semiconductor interfaces1. NA SAI, University of Texas at Austin — Search is ongoing for new classes of materials and structures based on complex oxides. One important example is the multiferroics which combine ferromagnetism or antiferromagnetism and ferroelectricity in a single phase. The coexistence, and occasionally the coupling of the two order parameters, has opened new opportunities for multifunctional applications. A promising route for practical applications is to employ thin films and multilayered structures, the properties of which can be readily manipulated at the nanoscale. Epitaxial multiferroic films are currently being developed through integration with semiconductors. Despite the progress in synthesis and experimental characterization, the roles of the interface phenomena, including strains, chemistry, etc., on the ferroelectric and magnetic properties of multiferroic thin films is not fully understood and difficult to differentiate experimentally. In this talk we illustrate the utility of theoretical methods based on density functional theory in understanding these technologically relevant structures. We describe examples of oxide-semiconductor interfaces based on YMO3 on GaN that have been synthesized recently and show how interfacial spins behave differently from those in the bulk. The interfacial effects lead to an intriguing behavior of the band offsets. We also discuss our ongoing investigation of electric field doping interfaces.

1Research in collaboration with Alex Demkov, Jaekwang Lee (University of Texas) and Craig Fennie (Argonne National Laboratory). Work at U. Texas was supported by Office of Naval Research Grant No. N000 14-06-1-0362.

9:48AM U5.0004 Thin Film Synthesis of New Complex Titanates. PAUL SALVADOR, Carnegie Mellon University — Thin film deposition methods allow for one to synthesize rationally specified compositions in targeted crystal structures. Because most of the thermodynamic and kinetic variables that control the range of materials that can be synthesized are unknown for specific compounds/processes, epitaxial stabilization and design of artificial layered crystals are driven through empirical investigations. Using examples taken primarily from the family of complex titanates, which exhibit a range of interesting physicochemical behaviors, the thermodynamic and kinetic factors that control materials design using thin film deposition are discussed. The phase competition between the pyrochlore and the (110) layered perovskite structure in the RE2Ti2O7 family (RE = rare-earth, Bi) will be explored, using pulsed laser deposition as a synthesis method. For RE = Gd, Sm, Nd, and La, the phase stability over a wide range of conditions is dictated entirely by substrate choice, indicating that the free energies of the phases are similar enough such that by controlling nucleation one controls the phase formation. In a related fashion, the growth of AE2Ti2O7 films (AE = Ba or Sr) will be discussed with respect to the formation of single-phase films or films that phase separate into AETiO3 and TiO2. The entire Ba1−xSr−xTiO3 series was grown and will be discussed with respect to growth technique (using MBE and PLD) and/or substrate choice. In this case, rock-salt substrates, which are not expected to interact strongly with any phase in the system, allow for the formation of single-phase films. Finally, several examples will be discussed with respect to the (SrO)0.5(TiO2)1.5 system, which includes the perovskite SrTiO3 and the Ruddlesden-Popper phase Sr2Ti2O5 grown using layer-by-layer molecular beam epitaxy. The solid phase epitaxial formation of the perovskite SrTiO3 from superlattices of rock-salt SrO and anatase TiO2 is discussed from both a kinetic and thermodynamic perspective by exploring the growth of a range of m and n values. Using similar arguments for stability, new layered intergrowths in the Sr2−3mTi2O5+n family are presented and their structures are discussed.

10:24AM U5.0005 Semiconductor-on-epitaxial insulator: towards ultrathin and nonclassical semiconductor devices1 ALEXANDER ZASLAVSKY, Brown University — The microelectronics industry is currently moving from bulk Si field-effect transistors (FETs) with silicon-dioxide gate insulators to high-k gate dielectric FETs and semiconductor-on-insulator (SOI) substrates, with alternative non-Si channel materials and nonplanar device layouts on the horizon. The possibility of integrating epitaxial insulator layers with well-controlled bandgaps and near-monolayer thickness control may open up new opportunities for nonclassical devices and possibly optical sources. Unlike their III-V counterparts, where epitaxial heterostructures have been available for decades, epitaxial oxide-based SOI devices have the crucial advantage of potential integrability with dominant silicon technology. This talk will discuss the examples of tunneling FETs and real-space transfer devices, as well as a proposed tunneling-based SOI intersubband laser. At this point, all of the proposed devices require epitaxial control and material quality that exceeds the state-of-the-art. Still, the unique characteristics derived from quantum mechanical tunneling make such devices an interesting playground for innovative device research, essentially replicating the III-V heterostructure device platform in the silicon-dominated microelectronics industry just as standard Si FET technology heads towards the long-predicted end of the miniaturization paradigm.

Thursday, March 13, 2008 8:00 AM – 10:24 AM
Session U6 DCOMP: Computational and Theoretical Challenges in Predicting Climate Change
Morial Convention Center R04

8:00AM U6.00001 Radiative Transfer in Climate Models. VENKATACHALAM RAMASWAMY, NOAA/ GFDL Princeton University — Radiation is a key physics element in both the maintenance of the climate as well as in driving climate change. The absorption of the Sun’s radiant energy by the atmosphere- system in the ultra-violet, visible and near-infrared spectral regions, and the absorption and emission of infrared radiation by the surface and atmosphere, together govern the planetary energy balance. The importance of radiative processes enters in both the “forcing” of the climate system and in the “feedbacks” that amplify the response to perturbations of the energy balance. As examples, we will examine the natural and anthropogenic radiative forcings that have occurred over the 20th century, our understanding of the governing processes and the challenges in representing them in climate models. The quantitative description comprises the determination of the forcing at the surface and in the atmosphere due to: emissions of the long-lived greenhouse gases (e.g., carbon dioxide), ozone precursors, and pollution particulates (e.g., sulfate and black carbon); changes in land surface properties; changes in solar irradiance; and particulates arising due to episodic volcanic eruptions. The various types of forcings are governed by fundamentally different underlying mechanisms, have distinct space-time dependencies and uncertainties, and exert varying signatures in terms of the climate system responses.
8:36AM U6.00002 Climate Feedbacks and Their Simulation in Coupled Ocean Atmosphere Models, BRIAN SODEN, University of Miami — The response of Earth’s climate to an increase in greenhouse gases depends on a complex superposition of feedback processes. These processes act to either amplify or dampen the climate’s response to an initial perturbation in the Earth’s radiative energy budget. Differences in the representation of these feedback processes in current models represent a primary source of uncertainty in model projections of future climate change. Progress in reducing uncertainties in model predictions of climate change therefore requires an accurate assessment of the differences in various feedback strengths between models. In this talk I will review the key climate feedback processes and assess their range of values in current models. Attention will be focused on the feedbacks from water vapor and clouds, which represent the most important climate feedbacks in current models. My presentation will describe the prevailing view behind these feedbacks and review observational evidence used in assessing the fidelity of their representation in current models.

9:12AM U6.00003 Objective methods for detecting climate change and attribution of causes, BENJAMIN SANTER, Lawrence Livermore National Laboratory — No abstract available.

9:48AM U6.00004 Predicting climate change: Uncertainties and prospects for surmounting them, MICHAEL GHL, Ecole Normale Supérieure, Paris, France, and University of California, Los Angeles, USA — General circulation models (GCMs) are among the most detailed and sophisticated models of natural phenomena in existence. Still, the lack of robust and efficient subgrid-scale parameterizations for GCMs, along with the inherent sensitivity to initial data and the complex nonlinearities involved, present a major and persistent obstacle to narrowing the range of estimates for end-of-century warming. Estimating future changes in the distribution of climatic extrema is even more difficult. Brute-force tuning the large number of GCM parameters does not appear to help reduce the uncertainties. Andronov and Pontryagin (1937) proposed structural stability as a way to evaluate model robustness. Unfortunately, many real-world systems proved to be structurally unstable. We illustrate these concepts with a very simple model for the El Niño–Southern Oscillation (ENSO). Our model is governed by a differential delay equation with a single delay and periodic (seasonal) forcing. Like many of its more or less detailed and realistic precursors, this model exhibits a Devil’s staircase. We study the model’s structural stability, describe the mechanisms of the observed instabilities, and connect our findings to ENSO phenomenology. In the model’s phase-parameter space, regions of smooth dependence on parameters alternate with rough, fractal ones. We then apply the tools of random dynamical systems and stochastic structural stability to the circle map and a torus map. The effect of noise with compact support on these maps is fairly intuitive: it is the most robust structures in phase-parameter space that survive the smoothing introduced by the noise. The nature of the stochastic forcing matters, thus suggesting that certain types of stochastic parameterizations might be better than others in achieving GCM robustness. This talk represents joint work with M. Chekroun, E. Simonnet and I. Zaliapin.

Thursday, March 13, 2008 8:00AM - 11:00AM — Session U7 Fed: Physics Demonstrations and Strategies for Teaching and Public Outreach Morial Convention Center R05

8:00AM U7.00001 Bringing Nano to the Public through Informal Science Education, WENDY CRONE, Univ. of Wisconsin - Madison — Researchers in nanoscale science and engineering communicate all the time. We give talks, present lectures, and write papers regularly. But the general public—the consumers who will use the products of our work and the voters who indirectly set the national research agenda—do not often hear us. Informal science education—including museums, TV, public lectures, popular press, etc.—is a way to connect with broader audiences in a variety of fun and effective ways. Museums, which are visited by hundreds of millions of people each year in the U.S., are popular because they are skilled at making abstract and complex phenomena comprehensible to people from all walks of life and at making the whole experience fun. This talk will provide an introduction the “informal science education” field, discuss the art of honing your message into clear and realistic learning goals, describe methods for understanding your audience and their background, and help researchers to appreciate the limits of what can be learned in one experience. It will also review what the public currently understands about nanoscale science and engineering and the challenges that these (mis)understandings create for museums and researchers.

8:36AM U7.00002 Preparing minority undergraduate students for successful science careers, MURTY AKUNDI, Xavier University of Louisiana — Xavier University of Louisiana is well known for being number one in graduating the most minority students in physical and biological sciences. The reason for this success is built on the concept of Standards with Sympathy in the Sciences (Triple S). This is an outgrowth of over twenty years of planning and development by the Xavier science faculty to devise a program for preparing and retaining students in the sciences and engineering. Xavier has been successfully conducting for over ten years, Summer Science Academy (SSA) for middle and high school students; Science Technology, Engineering and Mathematics (STEM) Scholars and Howard Hughes Biomedical programs for in-coming freshmen. Recently, through a grant from NSF, we have developed the Experiential Problem-solving and Analytical Reasoning (EPsAR) summer bridge program for in-coming freshmen who were given conditional admission to the university (i.e., those students who scored below the acceptable range for placement into degree mathematics courses). In this program, EPsAR participants will be engaged in problem-solving and critical thinking activities for eight hours per day, five days per week, for six weeks. Additionally, an interdisciplinary approach is taken to convey the mathematical skills learned to relate to physics, chemistry, biology, and computer science. Sixty-six students have participated in the last two years in the EPsAR program. During the first year 23 of 28 students successfully bi-passed the algebra review course and were placed into a degree credit course in mathematics. In the second year, thirty-one (31) of the 38 were advanced to a higher-level mathematics course. Twenty-three (23) out of 38 went on to degree credit math course. To retain students in the sciences peer tutoring in all the science disciplines are provided. Objective methods for detecting climate change and attribution of causes, BENJAMIN SANTER, Lawrence Livermore National Laboratory — No abstract available.

9:12AM U7.00003 “Wow” is good, but “I see” is better - techniques for more effective Physics demonstrations, STEPHEN COLLINS, Academy of the Sacred Heart — The use of demonstrations to assist in Physics education at all levels is commonplace, but frequently lacks optimal effectiveness. In many cases, the choice of demonstration is not at issue, but rather the manner in which it is presented to the audience. Modern educational research reveals a number of simple ways to improve instruction of this kind, including objective setting, audience evaluation, concept building, and promoting engagement. These techniques and considerations will be reviewed, explained, and modeled through a demonstration of “Why Mr. Fork and Mr. Microwave Oven don’t get along.”

9:48AM U7.00004 Gravity - The Engine of the Universe, JOHN THACKER, California Institute of Technology — The pervasive nature of gravity ought to give us pause. Since gravity is inescapable, one could reasonably claim that it is an overarching theme in our universe. In this session we will investigate some demonstrations and strategies for teaching gravity concepts. We will use education research results on student misconceptions related to gravity to focus the activities.
Local perturbation caused by a particle driven through a 2-D colloidal suspension, CARA HAGEMAN, VIKRAM PRASAD, ERIC R. WEEKS, Emory University — When polystyrene colloids are placed at a decane-water interface they form different phases based on their area fraction. These phases are: liquid, liquid-hexatic, hexatic and crystalline. In particular, the hexatic-crystal transition is characterized by a change in the functional form of the correlation functions and the density of defects. We study this system for area fractions near the hexatic-crystal transition. Using a laser tweezer we trap and drag a particle along the interface and observe its effect on the surrounding colloids. We observe a change in the local density of defects and a decay in the perturbed motion of colloids away from the trapped particle, revealing a length scale. We measure this length scale as a function of area fraction of the colloids and the applied velocity of the trapped particle.

Micro rheology of a sticking transition, SHOBO BHATTACHARYA, PRERNA SHARMA, SHANKAR GHOSH, Tata Institute of Fundamental Research, Mumbai, India 400005 — The phenomenon of colloidal deposition in presence of shear is studied by using an optical tweezer to hold a colloidal particle in close proximity of a plate subject to a sinusoidal in-plane shaking. Through the measurement of the real and imaginary parts of the particle’s response function, the coupling between the particle and the plate is found to evolve from a viscous regime to an elastic regime through an intermediate regime of time-dependent enhancement of viscoelasticity, reminiscent of aging in glasses. The sticking transition can be described in a scenario of hindered Stokes-Einstein diffusion and the Maxwell model of viscoelasticity. Upon changing the bead-plate interaction or the strength of the drive, three regimes of response: stick, stick-slip and slip are observed. The observed behavior has analogies to jamming in granular materials and the glass transition in viscous liquids.

A New Diffusion NMR Experimental Model System for Studies of Bidisperse Colloids, ANAND YETHIRAJ, SWOMITRA PALIT, Department of Physics and Physical Oceanography, Memorial University of Newfoundland — A method to prepare monodisperse colloidal particles that are simultaneously NMR-visible and fluorescent is described. A systematic approach to obtain spectrally resolved diffusion coefficients for every component (colloid and solvent) in a monodisperse colloidal suspension is presented. We also prepared bidisperse colloidal suspensions where each colloid component has a distinct NMR spectral signature, and obtained the diffusion coefficient of both colloid species and solvent simultaneously, in concentrated colloidal suspensions with volume fractions between 20 and 50%. This colloidal model system enables the study of bidisperse colloids at different size ratios and number ratios.

Universal exponential tails in the displacement distribution observed in an attractive colloidal glass, YONGXIANG GAO, MARIA KILFOIL, McGill University — Dynamical heterogeneities exist ubiquitously in glassy materials. They manifest themselves as a non-Gaussian distribution of the constituent particle displacements, that is, the self part of the van Hove correlation function. Though the shape of the tail of the distribution looks exponential or nearly exponential, not until recently has serious attention been paid to it. We observe pure exponential behavior—neither stretched nor compressed—over a wide range of volume fractions and time scales in an attractive colloidal system on the route to attractive glass transition. We observe universal behavior as all the distributions over a wide range of \( r \) and \( \phi \) can be scaled together. The tails arise from the mobile sub-component of the constituent particles. If time permits, I will also show our studies on the structure of colloidal gels and attractive glasses in terms of a translational order parameter and an orientational order parameter, under different interaction strength, volume fraction and buoyancy matching conditions.

Point response of a 2D packing of soft colloidal spheres near the jamming transition, PETER J. YUNKER, DANIEL T. N. CHEN, ZEXIN ZHANG, ARJUN G. YODH, University of Pennsylvania — We have created a 2D jammed packing by confining a bidisperse mixture of thermo-responsive NIPA microgel spheres between two glass slides with a thickness of roughly the larger sphere diameter. The packing is subjected to a point compression created by local heating with optical tweezers. We use particle tracking microscopy to characterize the response as a function of particle volume fraction both above and below the jamming transition.

Local perturbations of dense colloidal suspensions, GIANGUIDO C. CIANCI, ERIC R. WEEKS, Department of Physics, Emory University — A rapid temperature quench can transform a liquid into a disordered solid: a glass. We model glassy materials using the mobile sub-component of the constituent particles, where the transition is induced by increasing the number density rather than decreasing temperature. This transition has drawn significant attention because it poses numerous fundamental questions. For example, close to the glass transition temperature a small decrease in temperature can cause the viscosity of the liquid to increase by 14 orders of magnitude. Meanwhile the structure remains essentially unchanged — there is no growing static length scale accompanying the transition. Fast laser scanning confocal microscopy allows us to directly observe and track thousands of colloidal particles in real time. We add a small number of superparamagnetic colloids in the sample and pull them with an external magnet. The motion of a magnetic probe locally perturbs the dense suspension and highlights its heterogeneous structure. We examine the dependence of the affected region’s size on density and applied magnetic force.

Understanding the dynamics of closely packed microgel particles, MELAKU MULUHE, HANS WYSS, GIOVANNI ROMEO, JOHAN MATTSSON, ALBERTO FERNANDEZ-NIEVES, JINWOONG KIM, DAVID WEITZ, Harvard University, WEITZ COLLABORATION — Soft particles such as microgel suspensions have important applications in industry, which exploit their unusual structural and rheological properties. Despite their relevance, the fundamental physics that controls their behavior remains poorly understood. Intriguingly, microgels act as fluid even at high density. Techniques such as rheology, microscopy, and light scattering have been used to probe the macroscopic properties of these materials — however, the underlying physical mechanisms demand further investigation. We use confocal microscopy to image the local dynamics of highly packed microgels. The gel particles are tracked over time to obtain information about the short and long range correlations of the local particle motion. We probe their response to changes in environmental factors such as temperature or pH using light scattering. The results obtained not only help us understand the origins of the observed macroscopic behavior, but also give us information on the dynamics of glassy arrest in general.
9:24AM U8.00008 Colloidal Particle Geometry and Its Effect on Optical Trapping. RACHAEL HARPER, ALEX LEVINE, Department of Chemistry & Biochemistry, University of California Los Angeles — Recent experiments by Wilking and Mason (Europhysics Letters, in press) on the laser trapping of colloids of various shapes (the letters of the alphabet) show that for identical chemistries the trapping force varies wildly with particle shape. In fact, certain shapes do not trap at all. Motivated by these experimental results, we explore the trapping of particle of variable shape using a ray-optics simulation. This numerical tool allows us to perform Monte Carlo integrations of the total trapping forces and torques for a series of objects such as a cross (the letter “x”) or a beam (the letter “I”). We find that certain shapes feature bi-stable trapping positions/orientations, and some, indeed, do not allow for trapping at all.

9:36AM U8.00009 Modeling pore formation in lipid membranes via Janus nanoparticles. ALEXANDER DEXEY, Georgia Institute of Technology, WILLIAM E. USPAL, MIT, ANNA C. BALAZS, University of Pittsburgh — Phospholipid membranes, which separate the cytoplasm from the extracellular environment in biological cells, embed a large diversity of proteins. Some proteins form pores for the free transport of small molecules and ions across the membrane. Here, we use coarse grained numerical simulations to design a synthetic membrane, where pores can be formed “on demand.” Specifically, we use dissipative particle dynamics to probe the interaction between bilayer membranes and nanoparticles. The particles are nanoscopic Janus beads that comprise both hydrophobic and hydrophilic portions. We demonstrate that when the membrane is ruptured due to an external stress, these nanoparticles diffuse to the free edge of the membrane and form stable pores, which persist after the stress is released. Pore size depends on the architecture and concentration of the nanoparticles. Once a pore is formed, a small increase in membrane tension readily reopens the pore allowing rapid transport through the membrane.

9:48AM U8.00010 Three Dimensional Rotational Motion of Colloidal Clusters. JUSTIN CARAM, Harvard University, Department of Chemistry and Chemical Biology, VINOTHAN MANOHARAN, Harvard University, Department of Physics and School of Engineering and Applied Sciences — We will present the results of a study into the three dimensional rotational and translational diffusion of colloidal clusters, especially dimers and trimers. We will have accomplished this study using both diffraction pattern and holograph analysis, as well as depolarized dynamic light scattering. We believe that trimers break into discrete rotational diffusion constants dependent on their geometries. These findings can be matched to the results for the rotational decay in the correlation function generated by DDLS. Understanding these diffusion constants is important to the understanding of protein and liquid crystal dynamics in solution. Furthermore, developing depolarized dynamic light scattering experimental strategy for non ellipsoidal systems may help to determine 3-dimensional hydrodynamic extent of such systems in solution.

10:00AM U8.00011 Anomalous Rotation of a Pair of Spherical Particles in AC Electric Fields. PUSHKAR LELE, ERIC FURST, University of Delaware — Suspensions of colloidal particles are observed to form angled bands and vortices near surfaces in AC electric fields. We map the critical frequencies and field biases at which particles phase separate into to bands and the vortices gradually set in. The results from such mapping experiments are interpreted based on measurements of anomalous rotation on a pair of colloidal particles held in blinking optical tweezers. Our observations suggest that particle pair rotation is the characteristic motion in vortices and that the polarization of double layer around the particles influences the angular velocity of the vortex evolution. Increasing the electrolyte concentration of the medium or the frequency of the electric field results in reduction of the rotation. Based on these results, the suspension behavior can be “tuned” by changing the ionic strength, field strength, field frequency and particle size.

10:12AM U8.00012 Interferometric and holographic imaging combined: correlating interface deformations with 3D tracking of interfacial particles. DAVID KAZ, VINOTHAN MANOHARAN, Harvard University — We employ the techniques of digital holography and interference phase mapping to investigate particles on interfaces. Digital holography is used to track the positions of small (micron sized) particles to within a few nanometers in three dimensions, while optical interferometry maps interfacial deformations to within a few tens of nanometers. By utilizing both techniques simultaneously, we correlate the 3D position of particles trapped on an interface with deformations of that interface at up to 1000 frames per second. Such comprehensive data will serve to answer questions regarding the capillary interactions of particles on an interface.

Thursday, March 13, 2008 8:00AM - 11:00AM — Session U9 DCMP: Fluctuations, Phase Transitions and the Polar Kerr Effect Morial Convention Center RO7

8:00AM U9.00001 Fluctuations, mean-field $T_c$ and energy gaps in cuprate superconductors. JEFFERY TALLON, Industrial Research Ltd, JAMES STOREY, Victoria University of Wellington, JOHN LORAM, Cambridge University — We have carried out an analysis of Gaussian fluctuations about $T_c$ in the specific heat of (Y,Ca)Ba$_2$Cu$_3$O$_{y-3}$ and Bi$_2$Sr$_2$CaCu$_2$O$_{y+1}$. The analysis employs a full ARPES derived dispersion, including the pseudogap. This enables us to calculate the doping dependence of the mean-field transition temperatures, $T^{mf}_c$, in the absence of fluctuations. The values lie well above $T_c$, especially for lower doping where $T^{mf}_c$ is trending towards 180K. As a result, while the observed $T_c$, follows the well-known parabolic doping dependence, the values of $T^{mf}_c$ decrease monotonically with doping along with the superconducting gap parameter, $\Delta_0$, such that $2\Delta_0/k_BT_c \sim 0.3$. Using this result, we offer explanations for a number of anomalous observations. The line $T^{mf}_c(p)$ should not however be confused with the $T^*(p)$ line which is associated with the pseudogap and falls abruptly to zero at critical doping ($p_{crit}=0.19$ holes/Cu).

8:12AM U9.00002 Universal values for the static and dynamic critical exponents in thin-film and bulk crystalline YBCO. C.J. LOBB, SU LI, HUA XU, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park, M.C. SULLIVAN, Department of Physics, Ithaca College, Ithaca, NY. K. SEGAWA, YOICHI ANDO, ISIR, Osaka University, Ibaraki, Osaka, Japan, S.M. ANLAGE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park — Many researchers have used scaling of current vs. voltage curves to study the normal-superconducting phase transition of the high-temperature superconductors, searching for the static and dynamic critical exponents; however, there is little consensus among experimentalists as to the values of the exponents. We have studied this phase transition in optimally-doped YBa$_2$Cu$_3$O$_{y-3}$ thin films and bulk crystals. We consistently find $\nu = 1.5 \pm 0.2$ for the dynamic critical exponent in films (when finite-size effects are taken into consideration) and in crystals (where there are no finite size effects). We also find for the static critical exponent $\nu = 0.63 \pm 0.1$ for crystals and $\nu = 0.63 \pm 0.1$ for films. The failure to account for finite-thickness effects in thin films may account for the wide ranges of values for $\nu$ and $\Delta$ previously reported in the literature.}

1Supported by NSF grants DMR-0302596 and DMR-0706557.
8:24AM U9.00003 Dynamic critical behavior of YBCO thin films/crystals. HUA XU, SU LI, CHRISTOPHER LOBB, STEVEN ANLAGE, Center for Nanophysics and Advanced Materials, University of Maryland, College Park — The zero-field phase transition of high-Tc superconductors has been studied by a number of techniques. However transport properties (such as the conductivity) which probe the dynamics near Tc are less explored, and a wide range of critical exponents have been reported experimentally. We studied fluctuation effects of YBa2Cu3O7-δ thin films around Tc by doing frequency-dependent microwave conductivity and DC nonlinearity measurements. The length scales involved in the measurements and their influence on the fluctuation conductivity have been examined systematically, and this helps to clarify the historical discrepancy between experimental results and scaling predictions. Our results give a dynamical scaling exponent $z = 1.55 \pm 0.15$, which indicates the superconducting to normal phase transition of high-Tc materials likely belongs to the model E-dynamics.

This work was supported by NSF grant number DMR-0302596.

8:36AM U9.00004 Two-Dimensional Superconducting Fluctuations in Stripe-Ordered La$_2$-xBa$_x$CuO$_4$. QIANG LI, Brookhaven National Laboratory, MARKUS HUCKER, GENDA GU, ALEXEI TSVELIK, JOHN TRANQUADA — Recent spectroscopic observations of a d-wave-like gap in stripe-ordered La$_2$-xBa$_x$CuO$_4$ with x=1/8 have led us to critically analyze the anisotropic transport and magnetization properties of this material. The data suggest that concomitant with the spin ordering is an electronic decoupling of the CuO$_2$ planes. We observe a transition (or crossover) to a state of two-dimensional (2D) fluctuating superconductivity. Thus, it appears that the stripe order in La$_2$-xBa$_x$CuO$_4$ frustrates three-dimensional superconducting phase order, but is fully compatible with 2D superconductivity and an enhanced $T_c$ — [Ref. Q. Li et al., PRL 99, 067001 (2007)]

8:48AM U9.00005 Disorder-induced quantum critical point in an anisotropic gap superconductor. VICTOR GALITSKI, Physics Department and Joint Quantum Institute, University of Maryland — We consider an inhomogeneous anisotropic gap superconductor in the vicinity of the quantum critical point, where the transition temperature is suppressed to zero by disorder. Starting with the BCS Hamiltonian, we derive the Ginsburg-Landau action for the superconducting order parameter. It is shown that the critical theory corresponds to the marginal case in two dimensions and is formally equivalent to the theory of an antiferromagnetic quantum critical point, which is a quantum critical theory with the dynamic critical exponent, $z=2$. This allows us to use a parquet method to calculate the non-perturbative effect of quantum superconducting fluctuations on thermodynamic properties. We also discuss mesoscopic disorder fluctuations, which lead to the spatial variations of the local pairing temperature and the formation of superconducting islands above the mean-field transition. This disorder-induced Griffiths phase is described by a network of superconducting islands and metallic regions with a strongly suppressed density of states due to superconducting fluctuations. We argue that the phenomena associated with mesoscopic disorder fluctuations may also be relevant to high-temperature superconductors, in particular, to recent STM experiments, where gap inhomogeneities have been explicitly observed.

9:00AM U9.00006 Fermi arcs in phase fluctuating d-wave superconductors. EHUD ALTMAN, Weizmann Institute, EREZ BERG, Stanford University — One of the most puzzling aspects of the high-Tc superconductors is the appearance of Fermi arcs in the normal state of the underdoped cuprate materials. These are loci of low energy excitations covering part of the Fermi surface, that suddenly appear above $T_c$ instead of the nodal quasiparticles. Based on a semiclassical theory, we argue that partial Fermi surfaces arise naturally in a d-wave superconductor that is destroyed by thermal phase fluctuations. Specifically, we show that the electron spectral function develops a square root singularity at low frequencies for wave-vectors positioned on the bare Fermi surface. We predict a temperature dependence of the arc length that can partially account for results of recent angle resolved photo emission (ARPES) experiments.

9:12AM U9.00007 Vortex dynamics and Nernst effect in fluctuating superconductors. DANIEL PODOLSKY, University of Toronto, SRINIVAS RAGHU, Stanford University, ASHVIN VISHWANATH, University of California at Berkeley, DAVID HUSE, Princeton University — We present a new method to study the Nernst effect and diamagnetism of an extreme type II superconductor dominated by phase fluctuations. We work directly with vortex variables and our method allows us to tune vortex parameters (eg. core energy and number of vortex species). We find that diamagnetic response and transverse thermoelectric conductivity ($\sigma_{xy}$) persist well above the Kosterlitz-Thouless transition temperature, and become more pronounced as the vortex core energy is increased. However, they weaken as the number of internal vortex states are increased.

9:24AM U9.00008 Nernst effect in the phase-fluctuating superconductor InO. PANAYOTIS SPATHIS, HERVE AUBIN, ALEXANDRE POURRET, CIGDEM CAPAN, KAMRAN BEHNIA, ESPCI — We present a study of the Nernst effect in the amorphous superconductor InO. The low carrier density in this system implies a weak superfluid stiffness and consequently, strong phase fluctuations of the superconducting order parameter are expected. Measurements as function of temperature show that the Nernst signal evolves continuously through the superconducting transition as previously observed in underdoped cuprates. This contrasts with the abrupt jump expected at a BCS transition, as observed previously in Nb$_{0.15}$Sn as. In the last system, the Nernst signal due to vortices below $T_c$ and by Gaussian fluctuations above are clearly distinct [1]. The behavior of the ghost critical field in InO points to a correlation length which does not diverge at the Cooper-pair forming temperature $T_c$, a temperature below which the amplitude fluctuations freeze, but phase fluctuations survive. [1] Pourret et al, Nature Physics 2, 683 (2006)

9:36AM U9.00009 Bosonic Field Driven Superconductor-Insulator Transitions in Amorphous Nano-honeycomb Films. M.D. STEWART, JR., AIJUN YIN, J.M. XU, JAMES M. VALLES, JR., Brown University — We have observed multiple magnetic field driven superconductor-insulator transitions (SIT) in amorphous Bi films perforated with a nano-honeycomb (NHC) array of holes. The magneto-resistance across the SITs is periodic, with a period $H = H_M = h/2eS$, where $S$ is the area of a unit cell of holes. These transitions are, therefore, boson dominated. In constant field the temperature dependence of the resistance can be parameterized by $R(T) = R_0(T) \exp(T_c(T)/T)$ on both sides of the transition so that the evolution between the superconducting and insulating states is controlled by the vanishing of $T_c(T)$. We compare these data to the thickness driven transition in NHC films and the field driven transitions in unpatterned Bi films, other materials, and Josephson junction arrays. Our results suggest a structural source for similar behavior found in some materials and that despite the clear bosonic nature of the SITs, quasiparticle degrees of freedom likely also play an important part in the evolution of the SIT.

This work supported by the NSF through DMR-0606597 and DMR-0203608 and by the AFRL and ONR.

9:48AM U9.00010 Excess Voltage Noises in the Superconducting Transition in Thin Films. HENGSONG ZHANG, FULIN ZUO, University of Miami — We report voltage noise studies in the superconducting transition of thin Sn films. Voltage noises are measured as a function of temperature and applied current. The noise spectral power $S^{1/2}$ is peaked during the superconducting transition, with the peak temperature shifted downward from that of dR/dT. Comparison with the dc noise measurement shows the $S^{1/2}$ is much larger with ac current than dc. I-V characteristics and voltage noises are measured simultaneously to correlate the voltage noise with the vortex motion. The noise depends on the voltage with a characteristic $\sqrt{V}$ dependence for small V, suggesting shot noise nature for the excess noises.
10:12AM U9.00012 Kerr Effect in Superconductor. SANG BOO NAM — A magnetic field \( H \) is to make the time reversal symmetry break. By using the formulation [1], neglecting \( H \) dependence of \( \Delta(T) \) and for the pair cyclotron frequency \( \Omega = (2e/2m)h/c \) less than the photon frequency \( 2\pi c/\lambda \), the Kerr angle is obtained as \( \theta_K(T) = \theta_K(0)[(\Delta(T)/\Delta(0))\tanh(\Delta(T)/2k_BT)] \), where \( \theta_K(0) = \Delta^3 / \Omega^2 / (8\pi^3 N \lambda^2) \), \( \lambda = (3\delta/4, L)\delta_{BCS} \) in the (non-local, local) limit, with mean free path length \( L \) and BCS coherence length \( \xi_{BCS} \) for the pair in the normal state. We consider the effects of the Berry phase on the formation of the flux patterns in mesoscopic type-I SC using the phenomenological Ginzburg-Landau theory. We carry out simulations on three-dimensional samples of different geometries. We show that in the samples with sharp boundaries the amplitude of the \( d_{xy} \) admixture is quite small compared to the ordered DDW component.

10:24AM U9.00013 Possible Weak Ferromagnetism in Time Reversal Violating State of Underdoped Cuprates. VIVEK AJI, CHANDRA VARMA, University of California, Riverside — Recent polar Kerr effect measurements on underdoped \( \text{YBCO} \) have provided evidence for time reversal symmetry breaking near the pseudogap temperature. These results are consistent with the existence of a ferromagnetic moment of order \( 10^{-11} \) Bohr magneton along the \( c \)-axis. We discuss the conditions for the possible occurrence of ferromagnetism with moments perpendicular to the Copper-Oxideplanes, accompanying the loop current orbital magnetic order, in the underdoped phase of Cuprates.

10:36AM U9.00014 Electromagnetic response of a chiral \( p \)-wave superconductor. RAUL ROY, JOHN BERLINSKY, CATHERINE KALLIN, McMaster University — We study the response of a time-reversal symmetry breaking \( p_x + ip_y \) superconductor to an external electromagnetic wave and calculate the ac Hall conductivity, paying particular attention to the Kerr angle. For the topological Chern Simons term in the effective action and contributions from collective modes. We also consider the effects of a long range interaction such as the Coulomb interaction on the collective modes and the Hall conductivity. These results will also be discussed in the context of recent Kerr rotation experiments on Strontium Ruthenate by Xia et al. [1].

10:48AM U9.00015 Absence of magnetic field \( (B \leq 33 \text{ T}) \) induced effects in the mid-infrared properties of \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) films with \( 0 \leq x \leq 0.16 \). S.V. DORDEVIC, L.W. KOHLMAN, The University of Akron, A. GOZAR, G. LOGVENOV, I. BOZOVIC, Brookhaven National Lab, L.C. TUNG, Y.-J. WANG, National High Magnetic Field Lab — We have performed magneto-transmission measurements on a series of \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) films with magnetic fields up to 18 Tesla. Studied samples include doping levels \( x = 0 \), \( 0.1 \), \( 0.3 \), \( 0.45 \), \( 0.6 \), \( 0.8 \), \( 0.10 \). In addition, an optimally doped film \((x=0.16)\) was studied in magnetic fields as high as 33 Tesla, both below and above its superconducting critical temperature \( T_c = 41 \text{ K} \). In neither of the studied samples we could detect any field-induced changes of transmission in the mid-infrared energy range (between about 1000 and 3500 cm\(^{-1}\)). We discuss how these observations can enhance our current understanding of energy range excitations in the cuprates, and their relation to high temperature superconductivity.

Thursday, March 13, 2008 8:00AM - 10:48AM - Session U10 DCMP: Superconductivity: Magnetic Field Effects

8:00AM U10.00001 Peak Effect in \( \text{Co}_x\text{NbSe}_2 \) Single Crystals. MARIA IAVARONE, Argonne National Laboratory, R. DI CAPUA, Universita’ degli Studi del Molise, Italy, G. KARAPETROV, Argonne National Laboratory, A. KOSHELEV, D. ROSENMANN, H. CLAUIS, W.K. KWOK, Argonne National Laboratory — We report a pronounced peak effect in the magnetization of \( \text{Co}_x\text{NbSe}_2 \) single crystals having critical temperatures ranging between 7.1 K and 5.0 K. Magnetization studies reveal that the magnetic irreversibility below the peak effect regime is higher in samples with lower concentration of Co while exhibits a nearly reversible magnetization over a wide range of magnetic field for samples with higher concentration of Co. However, in the peak effect regime the situation is different. The irreversibility is a non-monotonic function of the Co content, and therefore of the critical temperature of the sample. This behavior cannot be explained as a crossover between collective to single pinning regimes as suggested for \( \text{NbSe}_2 \), since this should be a monotonic function of number of pinning centers. Furthermore, we investigated the peak effect regime with low temperature STM at 4.2 K and 1.8 K. [1] This work was supported by UChicago Argonne, LLC, Operator of Argonne National Laboratory ("Argonne"). Argonne, a U.S. Department of Energy Office of Science Laboratory, is operated under Contract No. DE-AC02-06CH11357

8:12AM U10.00002 Effect of the sample geometry on the intermediate state in mesoscopic 3D Type-I superconductors. GOLIJBON JERDiyorov, Departamento Fisica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium, ALEXANDER HERNANDEZ, Centro Atómico Bariloche, 8400 San Carlos de Bariloche, Rio Negro, Argentina, FRANCOIS PEETERS, Departement Fysica, Universiteit Antwerpen, Groenenborgerlaan 171, B-2020 Antwerpen, Belgium — The intermediate state (IS) of type-I superconductors (SC) has recently became a topic of increasing interest. [1,2]. Direct imaging of type-I SC reveals two distinct topologies of the intermediate state: flux tubes are formed upon magnetic field penetration and laminar patterns appear upon flux exit [2]. However, spheres and cones show no hysteresis with flux tubes dominating the IS [1]. In this work we investigate the effect of the sample topology on the formation of the flux patterns in mesoscopic type-I SC using the phenomenological Ginzburg-Landau theory. We carry out simulations on three-dimensional samples of different geometries. We show that in the samples with sharp boundaries (cubes and disks) laminar structures are mostly located along the boundary, whereas radial distribution of the flux patterns is obtained for cones and spheres. The effect of the edge defects on the observed structures will also be studied. [1] R.Prozorov, Phys. Rev. Lett. 98, 257001 (2007). [2] M. Menghini et al., Phys. Rev. B 75, 014529 (2007).
8:24AM U10.00003 Pauli Paramagnetic Effects on the Vortices in Superconducting TmNi$_2$B$_2$C, L. DEBEER-SCHMITT, M.R. ESKILDSEN, University of Notre Dame, M. ICHIOKA, K. MACHIDA, Okayama University, Japan, N. JENKINS, University of Geneva, Switzerland, C.D. DEVHURST, Institut Laue-Langevin, France, S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory and Iowa State University — The magnetic field distribution around the superconducting vortices in TmNi$_2$B$_2$C in the paramagnetic phase above $T_N$ was studied experimentally as well as theoretically. Using small-angle neutron scattering we imaged the vortex lattice (VL). Using the magnitude of the VL scattering vector, we obtain a direct measure of the magnetic induction, $B$, which is found to exceed $\mu_0 H$ at all fields up to $H_{c2}$. Measurements of the VL reflectivity yielded a form factor which remains essentially constant up to $\sim 0.6 H_{c2}$, above which it decreases rapidly but remains measurable up to the upper critical field. This field dependence of the form factor is in striking contrast to the usual exponential suppression. The measured form factor is well fitted by model based on the Eilenberger equations, extended to include paramagnetic effects due to the exchange interaction with the localized 4$f$ Tm moments. The model shows how the induced paramagnetic moments around the vortex cores act to maintain the field contrast probed by the form factor. The results will be compared to our recent measurements of the VL form factor in CeCoIn$_5$, which also indicate strong paramagnetic effects.

8:36AM U10.00004 Pauli-Limited Superconductors with Magnetic Fluctuations, ROBERT BEAIRD, Louisiana State University, ANTON VORONTSOV, University of Wisconsin-Madison, ILYA VEKHTER, Louisiana State University — We examine the full wave vector $q$ dependence of the expansion coefficients and examine the onset of both the uniform and spatially modulated superconducting phases along critical magnetic field $B_c(T)$. In the absence of fluctuations, both superconducting transitions are second order in 2D and meet at a tricritical point $B_c(T^*)$. We find that including magnetic fluctuations introduces first order transitions into the superconducting phase. We find the tricritical points where these transitions meet and determine $B_c(T)$ and $q(T)$ as functions of the coupling between superconducting order and the fluctuating magnetization.

8:48AM U10.00005 Evidence for Field-Induced Quantum Criticality in an Overdoped Cuprate, TAKASADA SHIBAUCHI, Dep. of Physics, Kyoto University, LIA KRUSIN-ELBAUM, IBM T. J. Watson Research Center, MASASHI HASEGAWA, Department of Materials Science and Engineering, Nagoya University, YUICHI KASAHARA, RYUJI OKAZAKI, Dep. of Physics, Kyoto University, YUJI MATSUDA, Dep. of Physics, Kyushu University, and ISSP, University of Tokyo — In current views, the putative quantum critical point in high-$T_c$ superconductors is understood to be driven by charge doping. Here we uncover an unexpected transition from a non-Fermi- to a Fermi-liquid state driven by magnetic field in a highly overdoped Tl$_2$Ba$_2$CuO$_{6+x}$ with $T_c \geq 15$ K. From the $c$-axis resistivity measured up to 45 T, we show that the Fermi-liquid $\rho_c = \rho_c(0) + A T^2$ features, accompanied by a (quantum) field-linear magnetoresistance, appear above a temperature-dependent field $H_{FL}(T)$, which decreases linearly with decreasing temperature and points to a quantum critical point near the upper critical field $H_{c2}(0)$. The observed field-induced quantum criticality with a power-law diverging $\rho_c(H)$ bears a striking resemblance to that of heavy-fermion superconductor CeCoIn$_5$, suggesting a common underlying physics in these strongly correlated electron systems.

9:00AM U10.00006 Superconducting Vortices in CeCoIn$_5$: Beyond the Abrikosov-Ginzburg-Landau Paradigm, A. D. BIANCHI, Dpt. de physique, U. de Montréal, Montréal, QC, Canada, M. KENZELMANN, J. MESOT, M. ZOLLIKER, J. KOHLBRECHER, LNS ETHZ & PSI, PSI, Switzerland, L. DEBEER-SCHMITT, M. R. ESKILDSEN, Dept. of Physics, U. of Notre Dame, Notre Dame, IL, USA, J. S. WHITE, E. M. FORGAN, School of Phys. and Astro., U. of Birmingham, Birmingham, UK, Z. FISK, Dep. Phys. & Astro., UC Irvine, Irvine, CA, USA, R. MOVSHOVICH, E. D. BAUER, J. L. SARRAO, MPA-10, LANL, Los Alamos, NM, USA, C. PETROVIC, Cond. Matt. Phys., BNL, Upton, NY 11973, USA — We report on the magnetic field ($H$) dependence of the form factor $|F|^2$ of the vortex lattice (VL) in CeCoIn$_5$ obtained by small angle neutron scattering for $H$ applied along the crystallographic $c$-axis. Superconductivity (SC) in CeCoIn$_5$ has several unconventional aspects to it: The $d$-wave SC is in competition with antiferromagnetic order, as suggested by the presence of an magnetic QCP located at the upper critical field $H_{c2}(0)$. The observed field-induced quantum criticality with a power-law diverging $|F|^2$ in CeCoIn$_5$ bears a striking resemblance to that of heavy-fermion superconductor CeCoIn$_5$, suggesting a common underlying physics in these strongly correlated electron systems.

9:12AM U10.00007 Reversal of specific heat oscillations with planar magnetic field in 2D d-wave superconductors: Doppler shift beyond the nodal approximation., G.R. BOYD, P.J. HIRSCHFELD, University of Florida, ILYA VEKHTER, Louisiana State University — Experiments on several novel superconducting compounds found oscillations of the specific heat when an applied magnetic field is rotated with respect to the crystal axes. The results are commonly interpreted as arising from the nodes of an unconventional order parameter, but the identifications of nodal directions are sometimes controversial. While the semiclassical method predicted the minima of $c^2$ near $\pm \pi/2$ in the $(T, c^2)$ phase diagram of a paramagnetically-limited superconductor in the presence of fluctuating magnetic moments. We derive the Landau- Landau free energy functional for the superconducting order from microscopics and include classical fluctuations of the magnetization. We consider the full wave vector $q$ dependence of the expansion coefficients and examine the onset of both the uniform and spatially modulated superconducting phases along critical magnetic field $B_c(T)$. In the absence of fluctuations, both superconducting transitions are second order in 2D and meet at a tricritical point $B_c(T^*)$. We find that including magnetic fluctuations introduces first order transitions into the superconducting phase. We find the tricritical points where these transitions meet and determine $B_c(T)$ and $q(T)$ as functions of the coupling between superconducting order and the fluctuating magnetization.

9:24AM U10.00008 Effect of Charge Carrier Density on the Vortex Regimes in Y$_{1-x}$Pr$_x$Ba$_2$Cu$_3$O$_{7-\delta}$ Single Crystals, P. GYAWALI, V. SANDU, C.C. ALMASAN, Kent State University, B.J. TAYLOR, M.B. MAPLE, University of California at Davis — We report the evolution of the vortex matter state in the temperature and field range where the second magnetization peak SMP is present by studying the magnetization and magnetic relaxation of a series of Y$_{1-x}$Pr$_x$Ba$_2$Cu$_3$O$_{7-\delta}$ ($x = 0.13$, $T_c = 82$ K; $x = 0.34$, $T_c = 50$ K; $x = 0.47$, $T_c = 34$ K) single crystals. Our study has shown that the main ingredient that controls the evolution of the vortex matter through the different regimes is the charge carrier density. The SMP is first enhanced and then suppressed as Pr concentration increases. The reason for this behavior is the softening of the elastic moduli, which makes the vortex lattice less stable to defect invasion. Within the collective creep theory, we determined the apparent activation energy. Its evolution with current density has shown that the vortex system is predominantly elastically pinned below the SMP, while above there is a smooth crossover to a vortex regime most likely dominated by the proliferation of dislocations.
9:36AM U10.00009 Skyrmmion Flux Lattices and their μSR signature1, QI LI, JOHN TONER, DIETRICH BELITZ, University of Oregon — Recently, topological excitations known as skyrmions were predicted to exist in p-wave superconductors [1]. The elastic theory of an induced skyrmion lattice was developed in [2], and its melting curve was found to be qualitatively different from that for vortex lattices. Here we show that the muon spin resonance (μSR) signatures of the two types of lattices are also very different. μSR has been applied extensively to study the magnetic properties of vortex flux lattices [3]. The observable in this technique is the μSR line shape \( n(B) \), which is the probability density that a muon experiences a local magnetic induction \( B \). In a vortex lattice, for small \( B \), \( n(B) \propto \ln(1/B)/B \). By contrast, for a skyrmion lattice we predict \( n(B) \propto B^1 - 3/2 \). This difference provides another way to easily distinguish between vortex and skyrmion flux lattices, and can thus help to identify p-wave superconductors. [1] A. Knigavko, B. Rosenstein, and Y.F. Chen, Phys. Rev. B 60, 550 (1999). [2] QI Li, John Toner, and D. Belitz, Phys.Rev. Lett. 98, 187002 (2007). [3] J. E. Sonier, J.H. Brewer, and R. F. Kiefl, Rev. Mod. Phys. 72, 769 (2000).

9:48AM U10.00010 Non-linear magnetization effects within the Kosterlitz-Thouless theory, LARA BENFATTO, Centro Fermi and University of Rome “La Sapienza”, CLAUDIO CASTELLANI, University of Rome “La Sapienza”, THIERRY GIAMARCHI, University of Geneva — Recent experiments in cuprate superconductors have attracted the attention on the role of vortex fluctuations. Measurements of the field-induced magnetization showed that the correlation length diverge exponentially, as predicted within the Kosterlitz-Thouless (KT) theory. However, it is somehow puzzling the persistence of non-linear magnetization effects at low field. Here we address this issue by means of a new theoretical approach to the KT transition at finite magnetic field, based on the sine-Gordon model. This approach is particularly useful in two respects. First, it leads to a straightforward definition of the field-induced magnetization as a function of the external magnetic field \( B \) instead of the magnetic induction \( B \), which is crucial to get a consistent description of the Meissner phase. Second, it allows us to identify the cross-over field \( H_{cr} \) from non-linear magnetization both below and above the transition. Above \( T_{KT} \), \( H_{cr} \) turns out to scale as the inverse correlation length, so that it decreases as the transition is approached. As a consequence, the fact that the only non-linear regime is accessible experimentally should be interpreted as a typical signature of the fast divergence of the correlation length within the KT theory. L.Benfatto, C.Castellani and T.Giamarchi, Phys. Rev. Lett. 99, 207002 (2007).

10:00AM U10.00011 Theory of diamagnetic response in layered superconductor above “Tc”, PEIJEN LIN, Electrophysics department, National Chiao Tung University, DINGPING LI, Beijing University, BARUCH ROSENSTEIN, Electrophysics department, National Chiao Tung University — Recent work by Wang et al. (Phys. Rev. Lett. 95, 247002) on field induced diamagnetic properties above Tc attracted a lot of attention from both theoretical and experimental physicist. In this talk, we will show that this phenomenon can be understood using conventional Ginsburg Landau theory for anisotropic materials. Above Tc, where the thermal fluctuations are strong, the effective description based on GL becomes non trivial due to the important contribution of higher landau levels. In previous works, some progress was achieved when certain additional assumptions (such as Lowest Landau Level approximation) were made. However, the validity of these assumptions is under debate. In our study of this system, we include the contribution of higher landau levels with nonperturbative method.Comparison will be made with Varlamov-Larkin results.

10:12AM U10.00012 Theory of quantum magneto-oscillations in underdoped cuprate superconductors1, SASHA ALEXANDROV, Loughborough University — Magneto-oscillations in kinetic and magnetic response functions of a few underdoped cuprates are perhaps one of the most striking observations since many probes of underdoped cuprates clearly point to a non Fermi-liquid normal state. Their observation in the vortex state well below the upper critical field raises a doubt concerning their normal state origin. Here I propose an explanation of the magneto-oscillations as emerging from the quantum interference of the vortex lattice and checkerboard modulations of the electron density of states revealed by STM with atomic resolution in some cuprate superconductors. The checkerboard effectively pins the vortex lattice, when the period of the checkerboard is commensurate with the period of the vortex lattice. This condition yields a periodicity of the response functions, rather than periodicity of conventional normal state oscillations periodic versus inverse magnetic field \( B \). Our solution of the Gross-Pitaevskii-type equation for composed charged bosons accounts for the \( d \)-wave symmetry of the order-parameter and its checkerboard modulations, and describes well changes in resonant frequency of the tunnel-diode oscillator circuit with \( \text{YBa}_2\text{Cu}_3\text{O}_6 \) and the oscillatory part of the Hall resistance in the mixed state of \( \text{YBa}_2\text{Cu}_3\text{O}_6 \).

10:24AM U10.00013 Enhanced tunneling in a magnetic field, BORIS IVLEV — As known, a probability of quantum tunneling through a static potential barrier \( U(x) \) can be substantially reduced by a static magnetic field \( H_z \). This happens due to increase of the effective barrier height caused by Landau’s gauge potential in a magnetic field (the same potential results in Landau levels). There is an exponentially small current in the direction of tunneling, \( x \). An underbarrier current in the direction perpendicular to tunneling, \( y \), is not small. If the potential barrier \( U(x, y) \) depends also on the coordinate \( y \), a new unexpected scenario can occur. Now the partial de Broglie waves, generated under the barrier, are not collected to the current in the \( y \) direction only but can be reflected by the potential \( U(x, y) \). An interference of those underbarrier waves after reflections can result in a peak of the particle density at a classically allowed region close to the conventional exit point from under the barrier. At the critical magnetic field, \( H_z = H_{cr} \), the peak amplitude is not exponentially small (Euclidean resonance). The same phenomenon can occur in tunneling through nonstationary barriers and is expected for photon tunneling when a refractive index is slightly inhomogeneous in the tunnel region.

10:36AM U10.00014 Current induced properties in bulk YBCO above the transition temperature, GEORGE ZIMMERMAN, Boston University, Emeritus — Simultaneous measurement of the electrical resistivity at high current densities and magnetic susceptibility of YBCO superconducting material reveals interesting behavior of the samples above the transition temperature. In addition to anomalies which appear at temperatures between 85K and 140K, the susceptibility seems to be affected by the electrical current up 200K. The electrical current, of density between 8 and 400 A/cm², seems to induce the behavior, with a lowered resistivity, which suggests a first order phase transition, possibly meta-stable, and persists despite the repeated cycling between 77K and 300K. The samples of bulk polycrystalline cylindrical rods 1.22 mm diameter and between 6cm and 20 cm long have a density of 5.4 gm/cm³ and were prepared sintering and annealing from a YBCO powder. Most were 10 to 15 years old. At 77K most samples exhibit relaxation times of several minutes in their magnetic and resistive behavior. The details of the measurements as a function of temperature, current density, and low magnetic field, will be described along with possible implications as to the nature of the pseudo-gap and other competing theories.

Thursday, March 13, 2008 8:00AM - 11:00AM –
Session U11 DMP: Focus Session: MgB2-like: Enhancement of Superconducting Properties
Morial Convention Center Room 909
8:00AM U11.00001 Introduction of Carrier Scattering in MgB$_2$, and its Effect on both Normal and Superconducting Properties, especially Hc$_2$. N. NEWMAN, Y. SHEN, R. SINGH, J. ROWELL, ASU, D. LARBALESTIER, F. HUNTE, FSU — The low Hc$_2$ values seen in pure and well ordered MgB$_2$ can be raised dramatically, to 35 T or more, by introducing carrier scattering by native and impurity defects. We describe three means to do this. First, He ion irradiation is used to tune Tc from 39K to less than 10K, while at Tc near 33K, Hc$_2$ reached a maximum value. Similar behavior has been reported for neutron damage and carbon doping. Second, we introduced oxygen in the films, either in-situ or ex-situ, and again, high Hc$_2$ values were seen and in these films, very high Jc values as well. Finally, a novel route has been investigated. We deposited MgB$_2$ films on room temperature substrates, then annealed at temperature just sufficient to produce crystallinity, giving Tcs in the range of 10 to 30K. Such films exhibit large dHc$_2$/dT values near Tc, sometimes larger than 2 T/K. This work is of practical importance and gives an improved understanding of how intraband and interband carrier scattering in the “2-gap” superconductor MgB$_2$ determine its Hc$_2$, resistivity and Tc.

8:12AM U11.00002 Upper critical field enhancements of TMB HPCVD magnesium diboride, F. HUNTE, J. JAROSZYNSKI, A. GUREVICH, D.C. LARBALESTIER, Applied Superconductivity Center, NHMFL, Florida State University, Y. ZHU, P.M. VOYLES, University of Wisconsin, Madison, R.H. WILKE, X.X. XI, The Pennsylvania State University — The H$_c2$ of four well textured carbon-doped-MgB$_2$ films grown by HPCVD from tri-methyl boron (TMB) at flow rates from 2.5 to 10 sccm was measured in fields up to 45T. H$_c2$ derived from low-current, four-point magnetoresistance clearly increases with increasing TMB flow rate. TMB appears to be a more uniform dopant than the (C$_x$H$_{2-x}$)$_2$Mg used earlier. These earlier films exhibited H$_c2$($0$) up to 70 T but also were imperfectly connected ($\rho$(50K) $\approx$ 200 – 800 $\mu\Omega$cm) due to excess amorphous C-rich phases observed between the MgB$_2$ grains. In strong contrast, $\rho$(50K) was only 10 – 20 $\mu\Omega$cm for the TMB films. When first measured, the linearly extrapolated H$_c2$($0$) reached $\sim$40 T for the film with the highest TMB flow rate, but after about 3 months of aging, this value rose to $\sim$50 T. The angular dependence of H$_c2$ for this sample was measured up to 45 T yielding H$_c2$(4.2 K) = 45.8 T and showing the good Ginzburg-Landau scaling with an H$_c2$ anisotropy of 2.88 at 4.2 K. These results are discussed in terms of the theory of dirty two-gap superconductors as a part of an in-depth study of the effect of ternary doping of magnesium diboride.

8:24AM U11.00003 Kinetic roughening of magnetic flux penetration in MgB$_2$ thin films, ANDREA LUCARELLI, GUNTER LUEPKE, College of William and Mary, BRIAN MOECKLY, Superconductor Technologies, Inc., YUE ZHAO, SHI DOU, University of Wisconsin, Madison, Wisconsin, R. ANSCHITZ, and L. KOWALSKI, University of Wisconsin, Madison — MgB$_2$ thin films exhibit pronounced instabilities such as finger-like structures, flux jumps or dendritic patterns, which endanger electronic devices at high field. This effect can be correlated to the defects that were induced by irradiation. In fact TEM images show the presence of amorphous regions whose sizes are compatible with the coherence length and such as to act as pinning centers through two different mechanisms. The influence that longitudinal and transverse resistivity of seven different samples with variable disorders characterized by the residual resistance ratio ($\rho$(0)/$\rho$(T)) measured in fields up to 45 T at different temperatures.

8:36AM U11.00004 Evidence of new pinning centers in irradiated MgB$_2$, C. TARANTINI, A. MARTINELLI, P. MANPRINNETTI, A. PALENCIO, I. PALLECHI, M. PUTTI, C. FERDEGHI, CNR-INFN-LAMIA, University of Genova, Via Dodecaneso 33, 16146 Genova, Italy, M.R. CIMBERLE, CNR-IMEM, Via Dodecaneso 33, 16146 Genova, Italy — It has been shown that C or SiC additions can strongly enhance upper critical field of MgB$_2$, leading to an in-field increase of critical current, but without introducing pinning centers other than grain boundaries. On the contrary neutron irradiation introduces new pinning centers, as highlighted by a significant shift of the maximum of pinning force and by a strong improvement of Jc at high field. This effect can be correlated to the defects that were induced by irradiation. In fact TEM images show the presence of nanometric amorphous regions whose sizes are compatible with the coherence length and such as to act as pinning centers through two different mechanisms. The influence that neutron irradiation induces on MgB$_2$ is also confirmed by magnetization decay tests that, differently by doped samples, show an important enhancement of pinning energies at high field. These measurements highlight as the increase of pinning energy with irradiation flux is strongly correlated with Jc improvement.

8:48AM U11.00005 Flux Pinning and Connectivity in MgB$_2$, M.D. SUMPTION, M. SUSNER, M. BHATIA, E.W. COLLINGS, Materials Science Department, Ohio State University — The transport and pinning properties of in-situ MgB$_2$ bulks and strands are discussed. The influence of SiC, excess Mg, B4C, TiC, and their combination on Brr and Bc2 as distinct from connectivity and flux pinning is the focus of the work. SiC dopants increase Bc2 and Brr exhibit prominent, with little influence on connectivity or flux pinning. Excess Mg improves the transport current, changes the grain connectivity and lead to energy dissipation. We investigated the magnetic field behavior of MgB$_2$ thin films samples grown by in situ pulsed laser deposition and in situ reactive deposition technique on different substrates. We performed time-resolved magneto-optical imaging (TRMOI) measurements as a function of applied static field and for a static filed plus ac current to visualize the kinetic roughening of the flux penetration front. The TRMOI images are analyzed by employing dynamic scaling concepts used in the studies of interface roughening of stochastic systems. For both static field and ac current the resulting critical state shows self-affine structure characterized by universal exponents. [1] Dynamic scaling-laws determined in both cases are consistent with the directed percolation model, placing the vortex dynamics of MgB$_2$ in the same universality class as YBCO and Nb.

9:00AM U11.00006 Upper critical field study of MBE grown MgB$_2$ thin films, J. JAROSZYNSKI, F. HUNTE, A. GUREVICH, D.C. LARBALESTIER, Applied Superconductivity Center, NHMFL, Tallahassee, Y. ZHU, P.M. VOYLES, University of Wisconsin, Madison, Y. SHEN, R. GANDIKOTA, R. SINGH, J. ROWELL, N. NEWMAN, Arizona State University, Tempe — “Normal” alloying of MgB$_2$ enhances the electron scattering, as does radiation damage. As a result, the upper critical field Hc2($0$) parallel to the ab planes doubles from about 18 to 35 T. ASU has been growing films by non-equilibrium MBE methods and either intentionally doping with oxygen during growth, or by deposition at room temperature with subsequent annealing ex situ at rather low temperature: e.g. 350 °C for 36 hrs followed by 600 °C for 30 min. The resistive transitions of the films have been measured in fields up to 45 T at different temperatures. The measurements revealed strong enhancement of Hc2($0$). In particular, the cold-deposited film remains superconducting at 45 T at 5 K, while extrapolation yields Hc2($0$) higher than 65 T, almost as high as the best C-doped HPCVD films. At the same time, the film is strongly inhomogeneous, the resistivity is as high as 30 m$\Omega$cm, while the transitions are very broad, and the critical temperature is lowered to 24 K. However, dHc2/dT at Tc reaches a record high value of 2.7 T/K. These observations open up another way to get exceptional values in MgB$_2$ films.

9:12AM U11.00007 Novel properties in the normal state and the mixed state due to multiband effect in MgB$_2$, HAI-HU WEN, Institute of Physics, Chinese Academy of Sciences — Based on high quality MgB$_2$ thin films, we measured the longitudinal and transverse resistivity of seven different samples with variable disorders characterized by the residual resistivity ratio (RRR) ranging from 4.0 to 33.3. Strong nonlinear Hall effect and strong magneto-resistance have been found in clean samples and they decrease gradually with the increase of scattering centers or temperature. By fitting to the theoretical model for a four-band system, for the first time, we derived the scattering rates for each band. Non-trivial difference between the transport properties of these four bands are unraveled. In the mixed state, a non-vanishing dissipation has been observed in the low temperature regime. The Hall Effect measurement confirms that it is induced by the vortex motion. Together with the data of I-V curves, point-contact tunneling and the magnetization relaxation, we conclude that this non-vanishing dissipation in the zero temperature limit is induced by the proliferation of the pi-band quasiparticles, in association with the multigap feature. In collaboration with H. Yang, Y. Jia, J.R. Shi, L. Shan, C. Ren and Y.Z. Zhang at IOP, CAS and C.G. Zhuang, Z.K. Liu, Qi Li, Yi Cui, and X.X. Xi at Penn State University.
9:48AM U11.00008 Structural-Microstructural Characteristics and its Correlations with the Superconducting Properties of in-situ PIT Processed MgB\textsubscript{2} Tapes with Ethyltoluene and SiC Powder added, ANJANA ASTHANA, Superconducting Materials Center, National Institute for Materials Science, 1-2-1, Sengen, Tsukuba, Ibaraki, H. YAMADA, N. UCHIYAMA, Central Japan Railways Company, Oyama, Japan, A. MATSUMOTO, H. KITAGUCHI, Y. MATSU, H. KUMAKURA, Superconducting Materials Center, National Institute for Materials Science, 1-2-1, Sengen, Tsukuba, Ibaraki — The structure and microstructures of pure MgB\textsubscript{2}, ethyltoluene and ethyltoluene + SiC added MgB\textsubscript{2} tapes have been investigated by using selected area electron diffraction, bright field, dark field and high resolution electron microscopy. As reported, the Jc values of the ethyltoluene and ethyltoluene + SiC added MgB\textsubscript{2} tapes are much higher than the pure MgB\textsubscript{2} tape sample. Analysis of the microstructures shows that pure MgB\textsubscript{2} tape sample consist of grains of 100-200nm. With the addition of ethyltoluene and ethyltoluene + SiC to the starting powder of in situ processed MgB\textsubscript{2} tapes, the grain size decreases drastically to an average size of about 20-50nm. The higher Jc value of the ethyltoluene and ethyltoluene + SiC added MgB\textsubscript{2} tapes as compared to the pure MgB\textsubscript{2} tapes has been attributed to the decrease in grain size and better connectivity of the grains and presence of pinning centers as some precipitates and Mg\textsubscript{2}Si particles of size less than 100nm.

10:00AM U11.00009 Properties of MgB\textsubscript{2} Thin Films Grown at Different Temperatures by Hybrid Physical-Chemical Vapor Deposition\textsuperscript{1}, MENNO VELDHORST\textsuperscript{2}, KE CHEN, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania, USA, CHE-HUI LEE, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, Pennsylvania, USA, QI LI, XIAOXING XI, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania, USA — MgB\textsubscript{2} films grown by Hybrid Physical-Chemical Vapor Deposition (HPCVD) at high temperature excel in $\mathbf{T}_\mathbf{c}$ values as high as 20 K are obtained, comparable to the highest values observed for the A15 compounds. These studies thus allow an investigation of any known binary compound, but the $T_c$ values of elemental superconductors under extreme pressures are not far behind. We have recently used pressures as high as nearly 2 Mbar to induce superconductivity in Sc, Y, Lu, and CaLi\textsubscript{2}. In situ X-ray diffraction and atomic force microscopy show that the film is polycrystalline. The low-temperature grown MgB\textsubscript{2} films are promising as the top electrode for sandwich-type all-MgB\textsubscript{2} junctions to preserve the integrity of the barrier layer.

10:12AM U11.00010 Superconductivity in Sc, Y, Lu, and CaLi\textsubscript{2} under Extreme Pressures\textsuperscript{1}, M. DEBESSAIJ, J.J. HAMLIN, A.K. GANGOPADHYAY, J.S. SCHILLING, Dept. Physics, Washington U, St. Louis, MO, USA, T. MATSUOKA, K. SHIMIZU, KYOKUGEN, Osaka U, Japan — Following the first experiments by Sizoo and Onnes in 1925 on Sn, studies of superconductivity under high pressures have made important contributions by furthering our understanding of this exotic state and creating many new and novel superconducting materials, including O, Si, Fe, I, and Cs. Indeed, the number of elemental superconductors across the periodic table has almost doubled through the application of extreme pressures. MgB\textsubscript{2} exhibits the highest value of $T_c$ of any known binary compound, but the $T_c$ values of elemental superconductors under extreme pressures are not far behind. We have recently used pressures as high as nearly 2 Mbar to induce superconductivity in Sc, Y, and Lu, as well as to search for superconductivity in CaLi\textsubscript{2}. $T_c$ values as high as 20 K are obtained, comparable to the highest values observed for the A15 compounds. These studies thus allow an investigation into the question: what is the maximum possible value of $T_c$ in a phonon-mediated superconductor?

10:24AM U11.00011 ABSTRACT WITHDRAWN

10:36AM U11.00012 Superconductivity in MgCNi\textsubscript{3}, Tunneling and heat capacity on single crystals\textsuperscript{1}, PETER SAMUELY, ZUZANA Pribulova, JOZEF KACMARCik, PAVOL SZABO, Centre of Low Temperature Physics at the IEP Slovak Academy of Sciences and P.J. Šafárík University, Watsonova 47, 040 01 Košice, Slovakia, CHRISTOPHE MARCENAT, CEA-Grenoble, Département de Recherche Fondamental sur la Matière Condensée, F-38054 Grenoble Cedex 9, France, THIERRY KLEIN, Institut Néel, CNRS, BP166 38042 Grenoble Cedex 9, France, D.-J. JANG, H.-G. LEE, H.-S. LEE, S.I. LEE, NVCRICS and Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Republic of Korea — MgCNi\textsubscript{3} reveals superconductivity despite a large molar volume of Ni atoms. The origin of superconductivity in this material has not yet been clarified. There is a lot of discrepancy in experimental results and physical interpretation where even unconventional pairing or a two-band model have been proposed for the system, but these suggestions are based on measurements on polycrystalline samples. Here we present the point-contact tunneling spectroscopy and ac-calorimetry measurements on single crystals of very good quality. Measurements have been performed in the temperature range from 0.7 K and in magnetic fields up to 8 T. The temperature dependence of the energy gap of the system is presented and compared to the BCS model.

\textsuperscript{1}This work has been supported by 6th FP EU grant No. MTKD-CT-2005-03002 and the Slovak Research and Development Agency contract No. LPP-0101-06.

10:48AM U11.00013 No Evidence for Spin Density Waves in Pb using Phonon Imaging\textsuperscript{1}, TIMOTHY HEAD\textsuperscript{2}, JAMES WOLFE, University of Illinois Urbana-Champaign — Phonon-imaging in superconducting Pb has proven to be a sensitive probe of quasiparticle density due to the highly anisotropic absorption of ballistic phonons by quasiparticles. Slower than expected temperature dependences of quasiparticle density observed previously by Wolfe and Short (Physica B 316, 107 (2002)) are explained here by taking into account the effects of nonequilibrium quasiparticles. Minimizing the effects of nonequilibrium quasiparticles enables us to extract a value of the zero-temperature superconducting gap parameter. We measure $\Delta = 1.32 \pm 0.07$ meV consistent with tunneling measurements in Pb and the conventional BCS picture, and inconsistent with earlier specific heat data that motivated the proposal of a spin-density wave ground state in Pb (Overhauser and Daemen, PRL 61, 1885 (1988)).

Thursday, March 13, 2008 8:00AM - 11:00AM — Session U12 DCMP: Strongly Correlated Electron Systems: Quantum Phase Transitions Morial Convention Center 203
8:00AM U12.00001 Quantum phase transition of a magnetic impurity in a dissipative environment¹, MENGXING CHENG, KEVIN INGERSENT, University of Florida, MATTHEW GLOSSOP, Rice University — We study the quantum phase transition (QPT) induced by dissipation in the Bose-Fermi Anderson model of a magnetic impurity that hybridizes with a metallic host and is also coupled (via its charge) to a bosonic bath having a spectral density proportional to $\omega^s$. For sub-Ohmic bath exponents $0 < s < 1$, numerical renormalization-group calculations show that upon increasing the coupling to the bosonic bath from zero, there is a crossover from a conventional (spin-sector) Kondo effect to a charge-Kondo effect. Further increase of the bosonic coupling results in a zero-temperature transition to a phase in which charge fluctuations on the impurity site are frozen out. Critical exponents describing the response of the impurity charge to a locally applied electric field are found to obey the hyperscaling relations characteristic of an interacting critical point. The numerical value of these exponents suggests that the QPT lies in the same universality class as that of the sub-Ohmic spin-boson model. Results for the Ohmic case $s = 1$ will also be presented.

¹Supported by NSF Grants DMR-0312939 and DMR-0710540.

8:12AM U12.00002 Quantum Criticality of the Pseudogapped Kondo Problem: Finite Temperature Scaling and Conformal Invariance, MATTHEW T. GLOSSOP, STEFAN KIRCHNER, QIMIAO SI, Department of Physics and Astronomy, Rice University — The critical destruction of the Kondo effect is of interest as a potential mechanism for quantum-critical heavy-fermion metals. Here, we study the pseudogapped Kondo model [1], with a conduction-electron density of states proportional to $\mid\tau\mid$, which provides a paradigm for understanding critical moment fluctuations. In general, an interacting quantum critical point (QCP), at a finite critical Kondo coupling $J_0$, separates Kondo-screened and free local-moment phases [2]. We focus on finite-$T$ scaling properties in the vicinity of the QCP, obtained using a dynamical large-N method for an SU(N) generalization of the model. Though the bulk lacks conformal invariance for $r > 0$, we show that correlation functions assume the form expected of a boundary conformal field theory, implying an enhanced symmetry at the QCP. We also address these and related issues in the N=2 model using a continuous-time quantum Monte Carlo impurity solver [3], which involves a stochastic evaluation of an expansion in the host-impurity hybridization. [1] D. Withoff and E. Fradkin, Phys. Rev. Lett. 64, 1835 (1990) [2] K. Ingersent and Q. Si., Phys. Rev. Lett. 89, 076403 (2002). [3] P. Werner et al., Phys. Rev. Lett. 97, 076405 (2006)

8:24AM U12.00003 Quantum-criticality in models of an impurity coupled to fermionic and bosonic baths¹, KEVIN INGERSENT, U. of Florida, MATTHEW GLOSSOP, Rice U. — Impurity models exhibiting quantum phase transitions (QPTs) have attracted interest in connection with impurities in cuprate superconductors, heavy-fermion quantum criticality, and quantum-dot devices. This talk focuses on three models describing an impurity level coupled both to a band of fermions (either spinful or spinless) with a density of states varying as $\mid\tau\mid$. However, for sufficiently strong fermionic pseudogaps (large values of $\tau$), new universality classes of QPT emerge.

¹Supported by NSF Grants DMR-0312939 and DMR-0710540.

8:36AM U12.00004 The Two-Impurity Anderson Model at Quantum Criticality¹, DAVID MROSS, Bonn University, Germany, HENRIK JOHANNESSON, Göteborg University, Sweden — We propose a realization of the two-impurity Anderson model in a double quantum-dot system. When charge transfer between the dots is suppressed the system exhibits a non-Fermi liquid critical line parameterized by the amount of charge localized on the dots. Employing conformal field theory techniques we identify the critical exponents that govern transport and thermodynamics in the vicinity of the critical line. We also determine the dynamical exponent that sets the time scale for buildup of the non-Fermi liquid state after the system is shifted into the critical region, e.g. by a sudden change of a nearby gate voltage.

9:12AM U12.00007 Kondo destruction in the Bose-Fermi Kondo model with a singular dissipative spectrum: Exact solutions and their implications¹, JIANHUI DAI, Zhejiang University, C.J. BOLECH, QIMIAO SI, Rice University — Quantum dissipation induces a critical destruction of the Kondo screening, which is of interest in the contexts of quantum critical heavy fermions and magnetic mesoscopic structures. The sub-Ohmic Bose-Fermi Kondo (BFK) model provides a setting to study such an effect. Here, we show that this many-body problem is exactly solvable when the spectrum of the dissipative bosonic bath, $J(\omega)$, is singular, such that $J(\tau) = \text{const.}$. We determine the exact results for the local spin correlation functions, which imply that the singular longitudinal fluctuations of the bosonic bath play a dominant role. We also demonstrate how the large-N limit of an SU(N) generalization of the same model fails to capture the $N = 2$ physics in the cases of a singular dissipative bosonic spectrum, due to an interesting under-treatment of the longitudinal fluctuations. Our results resolve an apparent inconsistency between the previous results respectively found using numerical renormalization group and large-N treatments, providing evidence that the local quantum critical solution of the extended dynamical mean field approach to the Kondo lattice model indeed has a zero residual entropy.

9:24AM U12.00008 ABSTRACT WITHDRAWN —
Quantum Criticality out of Equilibrium: Kondo Destruction and V/T Scaling in a Magnetic Single-Electron Transistor. STEFAN KIRCHNER, QIMIAO SI, Rice University — Non-equilibrium quantum phase transitions have so far received only limited attention despite the long-standing strong interest in classical out-of-equilibrium phase transitions. This is in part due to the fact that dynamics and statics are already intermixed at an equilibrium quantum phase transition. Nanostructured devices constitute simplified systems, both theoretically and experimentally, to study well-defined out-of-equilibrium states that give rise to unique steady-state limits. We recently showed that such a system, a magnetic single-electron transistor, can be tuned through a continuous quantum phase transition as the applied gate voltage is tuned [1,2]. The Kondo effect is critically destroyed across the quantum critical point, an effect that is also of interest in some bulk strongly correlated systems such as heavy fermions [3].

Current-Flow-Driven Nonequilibrium Paramagnetic-Ferromagnetic Phase Transitions. ADITI MITRA, New York University, IGOR ALEINER, ANDREW MILLIS, Columbia University — We study a 2d itinerant electron system near a ferromagnetic-paramagnetic quantum critical point, which has been driven out of equilibrium by current flow through its bulk. The lack of Galilean invariance in physically realistic models implies that there is no co-moving frame of reference where the physics is identical to that in the absence of current. In the vicinity of the equilibrium critical point the main effect of current flow is shown to be an effective temperature, with current induced drift giving subleading corrections. The current can also destabilize a classical order, and may give rise to new kinds of ordered or quasi-ordered phases.

Criticality in Inhomogeneous magnetic systems: Applications to Quantum Ferromagnets. R. SAHA, Dept. of Physics, Univ. of Oregon, Eugene, OR 97403 & Dept. of Physics, Univ. of Maryland, College Park, MD 20742, T. R. KIRKPATRICK, Dept. of Physics, Univ. of Maryland, College Park, MD 20742, D. BELITZ, Dept. of Physics, Univ. of Oregon, Eugene, OR 97403 — In standard phase transitions such as the liquid-gas transition, a homogeneous order parameter (OP) vanishes as one crosses from the ordered phase to the disordered one. An external field may preclude a macroscopic OP. This happens for a fluid in a gravitational field, where the transition becomes smeared [1] in the sense that the OP is nonzero everywhere, albeit very small in some regions of the phase diagram. A ferromagnet (FM) subject to mechanical stress is another realization of a system in an external field that has an inhomogeneous OP. We first investigate a classical Heisenberg FM, which is modeled by a $\phi^4$ theory with a spatially dependent mass $m(r)$. In contrast to the fluids case, we find a sharp phase transition where the envelope of the local magnetization vanishes uniformly, and mean-field critical exponents. The first order transition in quantum itinerant FMs also remains sharp and the fluctuation effects leading to a tricritical point are suppressed, and one recovers a quantum critical point with mean field exponents [2]. Non-Ginzburg-Landau Type Universality in Quantum Metamagnetism Induced by Topological Change of Fermi Surface: Applications to a Weak Itinerant-Electron Ferromagnet ZrZn$_2$. YOUEHI YAMAJI, TAKAHIRO MISAWA, Dept. of Applied Physics, Univ. Tokyo, MASATOSHI IMADA, Dept. of Applied Physics and JST-CREST, Univ. Tokyo — We clarify that metamagnetic transitions show unconventional properties as quantum phase transitions if they are accompanied by changes in Fermi-surface topology. Topological change of the Fermi surface makes the phase diagram qualitatively different from that of the conventional metamagnetic transitions; the quantum critical endpoint becomes not only the terminal of the finite-temperature critical line, but also the terminal of a quantum critical line of continuous Lifshitz transitions. Around the quantum critical terminal, power-law singularities of thermodynamic quantities are determined by the Fermi-surface topology and, therefore, are characterized neither by the Ising symmetry breaking nor by the Ginzburg-Landau-Wilson scheme proposed by Moriya, Hertz andMillis for the conventional quantum criticalities. We propose that such an unconventional universality indeed accounts for the metamagnetic transitions observed in ZrZn$_2$.

8:00AM U13.00001 Self-consistent van der Waals density functional: Development and Applications, VALENTINO COOPER, Rutgers University — The inability of density functional theory (DFT), with standard exchange-correlation functionals, to correctly describe van der Waals/Dispersion (vdW) interactions has severely limited its applicability to sparsely packed systems, such as organic and biological molecules. Numerous attempts have been made to correct these deficiencies; however, many of them either require extensive reparameterization for each new situation or scale poorly with system size. In this paper, I will discuss the development and implementation of an exchange-correlation functional which correctly incorporates non-local vdW interactions within DFT (vdW-DF). In addition, I will present our recent development of the corresponding exchange-correlation potential (Vxc). The Vxc gives us the ability to compute Hellmann-Feynman forces, allowing for structural relaxations and molecular dynamics simulation. Using the Vxc, I will examine the nature of the van der Waals bond between molecules. Finally, to demonstrate the power of the vdW-DF, I will discuss our relatively large-scale application of the functional to study the influence of stacking interactions on the structure and stability of DNA. Here, I will show how these interactions are crucial for defining the twist and base pair separation in DNA and how methyl-nucleobase and methyl-methyl interactions give additional stability to DNA.

8:36AM U13.00002 Stochastic Time-Dependent Current-Density Functional Theory, ROBERTO D’AGOSTA, University of California - San Diego — Static and dynamical density functional methods have been applied with a certain degree of success to a variety of closed quantum mechanical systems, i.e., systems that can be described via a Hamiltonian dynamics. However, the relevance of open quantum systems - those coupled to external environments, e.g., baths or reservoirs - cannot be overestimated. To investigate open quantum systems with DFT methods we have introduced a new theory, we have named Stochastic Time-Dependent Density Functional Theory (S-TDDFT) [1]: starting from a suitable description of the system dynamics via a stochastic Schrödinger equation [2], we have proven that given an initial quantum state and the coupling between the system and the environment, there is a one-to-one correspondence between the ensemble-averaged current density and the external vector potential applied to the system. In this talk, I will introduce the stochastic formalism needed for the description of open quantum systems, discuss in details the theorem of Stochastic TD-CDFT, and provide few examples of its applicability like the dissipative dynamics of excited systems, quantum-measurement theory and other applications relevant to charge and energy transport in nanoscale systems.

9:12AM U13.00003 Investigating interaction-induced chaos using time-dependent density functional theory, ADAM WASSERMAN, Harvard University — Systems whose underlying classical dynamics are chaotic exhibit signatures of the chaos in their quantum mechanics. In this talk I will discuss the possibility of using time-dependent density functional theory (TDDFT) to study the case when chaos is induced by electron interaction alone. Nearest-neighbor level- spacing statistics are in principle exactly and directly accessible from time-dependent density functional theory (TDDFT). Can the linear response formalism of TDDFT reveal the mechanism of chaos induced by electron-interaction alone? A simple model of a few-electron quantum dot highlights the necessity to go beyond the adiabatic approximation in TDDFT.

9:48AM U13.00004 Time-dependent NEGF calculations of extended systems, ALEXANDER PROCIUK, BARRY DUNIETZ, University of Michigan — A non-equilibrium GF (NEGF) model based on time dependent perturbation theory is developed to propagate electronic structure and molecular conductance of extended electrode-molecule-electrode nanostructures. In this model, we take advantage of the two time variable nature of the KB equations in order to formulate a mixed time-frequency representation for the lesser GF. This allows us to include bulk affected electrodes with non-trivial energy representations in our propagation. It also allows us to express dynamical observables such as current with highly informative Wigner distributions that shed light on the physical causes for certain dynamic features. Preliminary calculations, performed on simple systems, reveal that the dynamic current has both a direct and an alternating contribution. The direct current is due to a bulk affected state and the alternating component is due to a superposition of states. The amplitude of the alternating current can be changed dramatically by adjusting the bias pulse.

10:00AM U13.00005 Many-Body Density Matrix Perturbation Theory, C.J. TYMCGZAK, Texas Southern University — One fundamental limitation of quantum chemical methods is the accuracy of the approximate many-body theoretical framework that is utilized. Accurate many-body formalisms for quantum chemical methods do exist, but these methods are computationally very expensive. Methods also exist that are much less computationally expensive such as Hatree-Fock, Density Functional and the Hybrid Functional theories, but at a reduced representation of the exact many-body ground state. This severely limits their use to the system size. In the absence of an accurate representation of the many-body ground state. What is essential is a method which represents the many-body ground state accurately, but with a low computational cost. Recently, a method for determining the response, to any order of the perturbation, within the density matrix formalism has been discovered. This method is very simple and computationally efficient, and it immediately opens up the possibility of computing the variational many-body ground state to unprecedented accuracy within a simplified computational approach. Within this article, we report on the theoretical development of this methodology, which we refer to as Many Body Density Matrix Perturbation Theory. This theory has many significant advantages over existing methods. One, its computational cost is equivalent to Hartee-Fock. Two it is a variational upper bound to the exact energy. And three, it has no self-interaction.

10:12AM U13.00006 Conformational hierarchies of weakly bonded systems: Accuracy of dispersion corrected DFT, ALEXANDRE TKATCHENKO, VOLKER BLUM, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany — It is well known that long-range dispersion interactions, important for stabilization of, e.g., molecular crystals, biomolecules and physisorption, are badly described by state-of-the-art xc functionals in DFT, but naturally included in post-HF methods or empirically in force field simulations. We have implemented a semi-empirical C6/R6 correction [1,2] in the numeric atom-centered orbital based code FHI-aims [3] and obtained correction parameters by fitting to a database of high quality ab initio calculations [2], improving on previous results due to the more accurate basis set (0.5 kcal/mol average error for binding energies using PBE0+P86). We assess the accuracy and impact of the correction on conformational energy hierarchies of (i) H2O6+ clusters (n=2-6), (ii) Al2 and Al2+, and (iii) infinite polyaniline conformers, comparing to published post-HF results for (i) and (ii). Even though the relative energies are not changed for small H2O clusters and Al2 compared to DFT-GGA, the impact of dispersion on the conformation hierarchy of larger systems is surprisingly large, reaching ~1-4 kcal/mol for different polyaniline conformers. 10:24AM U13.00007 Iterative computation of dielectric eigenmodes, HUGH WILSON, FRANCOIS GYGI, GIULIA GALLI, University of California, Davis — We present an iterative method for the calculation of the eigenvectors of dielectric matrices of materials and nanostructures, based on Density Functional Theory, within a linear response framework. We show that by computing a relatively small number of eigenvectors via iterative dielectric response calculations, one may reconstruct the full dielectric matrix of a given system to high accuracy. The proposed method bypasses the need for the calculation of a large number of excited states required by earlier dielectric matrix computations based on the Random Phase Approximation. The scaling of the algorithm and the efficiency of the approach will be demonstrated by the calculation of the static dielectric properties of a variety of nanostructures, including silicon rods and slabs.

10:36AM U13.00008 Comparison of vibrational and electronic contributions to van der Waals interactions, MARK R. PEDERSON, Naval Research Laboratory, KYUNGWHWA PARK, Virginia Polytechnic Institute, AMY Y. LIU, Georgetown University — The van der Waals interaction can be caused by either ionic vibrations or instantaneous electronic motion relative to the atomic center. In this study, the vibrational contribution to the van der Waals interaction is formulated by considering the interaction between induced dipoles caused by the infrared-active normal modes of a neutral molecule. Using the derived formula, the contribution is quantified, within the density-functional theory formalism, using a screened, i.e., self-consistent, vibrational polarization. Applications for several neutral nonpolar dimers are presented. It is found that the vibrational contributions for the dimers are substantially smaller than their electronic contributions. The ratio of the vibrational to electronic contributions depends strongly on the ratio of the screened vibrational to electronic polarizabilities and on the ratio of the frequency of the strongest infrared-active mode to an ionization energy.

10:48AM U13.00009 Recent progress in ab initio density matrix renormalization group methodology, JOHANNES HACHMANN, JONATHAN J. DORANDO, GARNET KIN-LIC CHAN, Cornell University — We present some recent developments in the ab initio density matrix renormalization group (DMRG) method for quantum chemical problems, in particular our local, quadratic scaling algorithm [1] for low dimensional systems. This method is particularly suited for the description of strong nondynamic correlation, and allows us to compute numerically exact (FCI) correlated energies for large active spaces, up to one order of magnitude larger than can be done by conventional CASCI techniques. Other features of this method are its inherent multireference nature, compactness, variational results, size-consistency and size-extensivity. In addition we will review the problems (predominantly organic electronic materials) on which we applied the ab initio DMRG: 1) metal-insulator transition in hydrogen chains [1] 2) all-trans polyacetylene [1] 3) acenes [2] 4) polydiacetylenes [3]. Thursday, March 13, 2008 8:00AM - 11:00AM — Session U14 DAMOP: Focus Session: Exotic Phases in Ultracold Fermi Gases Morial Convention Center 205

8:00AM U14.00001 FFLO states in resonant Fermi gases, SUNKGIT YIP, Academia Sinica, Taiwan — We discuss the possible phases of two-component Fermi gas with population imbalance. In particular, we consider the various states proposed by Fulde-Ferrell and Larkin-Ovchinnikov. We distinguish between the plane-wave state Delta ~ e^{i\eta}, where the magnitude of the order parameter is uniform in space but the phase varies continuously in space, from those where the order parameters are real but change sign from one spatial region to the other. The later states, considered first by Larkin and Ovchinnikov, occupy a much larger region in the uniform phase diagram than previously suggested by other authors. If time permits, we shall discuss also the situation in a harmonic trap.

8:36AM U14.00002 Is There an FFLO Region in a Polarized Trapped Unitary Fermi Gas?, WILLIAM SCHNEIDER, The Ohio State University, RAJDEEP SENSARMA, Harvard University, ROBERTO DIENER, MOHIT RANDERIA, The Ohio State University — We have studied strongly interacting polarized gases in a harmonic trap beyond the local density (LDA) approximation using the Bogoliubov-deGennes equations. In particular, we are interested in the region separating an unpolarized superfluid core in the center and a fully polarized majority gas in the intermediate lattice limit, where the anisotropy in the atomic motion enhances Fermi surface 'nesting', but there is still a small amount of tunneling between tubes to provide long-range order. Finally we discuss the spatial arrangement of phases in a trap: in 3D the homogenous superfluid phase sits in the center of the trap, while in 1D it lies on the edge. We explain how this pattern evolves as one changes the lattice intensity.

8:48AM U14.00003 Polarized Fermi superfluids between one and three dimensions, MEERA PARISH, Princeton University, STEFAN BAUR, ERICH MUELLER, Cornell University, DAVID HUSE, Princeton University — We theoretically explore the phase diagram of a polarized two-component Fermi gas divided into an array of tubes by a two-dimensional optical lattice. By increasing the intensity of the optical lattice one suppresses the inter-tube hopping, and one can drive a crossover from three to one-dimensional behavior. We show that the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) inhomogeneous superfluid phase is stabilized by the lattice, and we argue that the most promising parameters for observing the FFLO phase are in the intermediate lattice limit, where the anisotropy in the atomic motion enhances Fermi surface 'nesting', but there is still a small amount of tunneling between the tubes to provide long-range order. Finally we discuss the spatial arrangement of phases in a trap: in 3D the homogeneous superfluid phase sits in the center of the trap, while in 1D it lies on the edge. We explain how this pattern evolves as one changes the lattice intensity.

9:00AM U14.00004 Dimensional crossover from Quasi-1D to 3D in spin-polarized Fermi superfluids, STEFAN BAUR, Cornell University, MEERA PARISH, Princeton University, ERICH MUELLER, Cornell University, DAVID HUSE, Princeton University — We use a zero temperature Bogoliubov de Gennes mean field theory to study the evolution of the exotic FFLO superfluid in a spin-imbalanced Fermi gas as one progresses from quasi-1D to 3D by changing the coupling between an array of tubes. The boundary between the uniform BCS superfluid and the FFLO state is determined by examining the energetics of a single π-domain wall in the superfluid order parameter. In the quasi-1D limit, each tube contains a single excess particle at the center of each domain wall and the spectrum of single particle excitations is gapped. As one approaches 3D there is a phase transition where this commensurability condition is relaxed and gapless single particle excitations can be found. [1] M. M. Parish, S. K. Baur, E. J. Mueller, and D. A. Huse, arXiv:0709.1120

10:00AM U14.00009 P-wave Pairing in Two-Component Fermi System with Unequal Population near Feshbach Resonance.1 RENYUAN LIAO, FLORENTIN POPESCU, KHANDKER QUADER, Kent State University — We explore p-wave pairing in a single-channel two-component Fermi system with unequal population near Feshbach resonance. Our analytical and numerical study reveal a rich superfluid (SF) ground state structure as a function of imbalance. In addition to the state $\Delta_{k\uparrow} \propto Y_{l\downarrow}, a$ multitude of “mixed” SF states formed of linear combinations of $Y_{l\downarrow}$’s give global energy minimum under a phase stability condition; these states exhibit variation in energy with the relative phase between the constituent gap amplitudes. States with local energy minimum are also obtained. We provide a geometric representation of the states. A $T=0$ polarization vs. p-wave coupling phase diagram is constructed across the BEC-BCS regimes. With increased polarization, the global minimum SF state may undergo a quantum phase transition to the local minimum SF state.

1This work is partially supported by funding from ICAM.

10:12AM U14.00010 P-wave Paired Ground state Structure of Two-component Population Imbalanced Fermi Systems with Unequal Mass1. FLORENTIN POPESCU, RENYUAN LIAO, KHANDKER QUADER, Kent State University — Effects of unequal mass on p-wave pairing in population imbalanced two-component Fermi systems is studied using a single-channel fermionic Hamiltonian. Provided certain phase criteria are satisfied among the orbital gap parameters, a rich structure of the ground state is obtained. The global and local minima ground state energies are determined analytically. By numerically solving the gap and number equations, we construct $T=0$ polarization vs. p-wave coupling phase diagram across the BEC-BCS regime for different mass ratios. This shows the existence of two superfluid phases, SF1 is enhanced; SF2 is not significantly affected. Competition between mass ratio and polarization is studied; the superfluid transition temperature shows interesting behavior versus the mass ratio at high polarizations. At large polarizations, a stable p-wave superfluid would survive only for small mass ratios, and for mass ratios close to unity.

1The work is partially supported by funding from ICAM.

10:24AM U14.00011 Orbital ordering in an atomic Mott insulator of p-band fermions. ERHAI ZHAO, W. VINCENT LIU, University of Pittsburgh — We derive the low energy effective model describing the orbital degrees of freedom of strongly interacting spinless p-orbital fermionic atoms in 2D optical lattices. Virtual hopping processes of $p_x$ and $p_y$ fermions give rise to direct and multi-particle orbital exchanges in the strong coupling regime. For the square lattice, we show that the effective orbital Hamiltonian is equivalent to a quantum spin-1/2 XXZ model. In the limit where the transverse hopping is much smaller than the longitudinal hopping, the XXZ model reduces to an antiferromagnetic Ising model. Thus the atomic Mott insulator is antiferro-orbitally ordered. We also present results for other simple 2D lattices and discuss the experimental signatures of various orbital orderings.
10:36AM U14.00012 Density waves and superconductivity in rapidly rotating atomic Fermi gases. GUNNAR MOLLE, NIGEL R. COOPER, University of Cambridge — We study theoretically the low-temperature phases of a two-component atomic Fermi gas with attractive s-wave interactions under conditions of rapid rotation [1], a problem related to the discussion of high-field superconductivity in the solid state [2]. The regime of interest for atomic gases differs substantially from solid state conditions: the rotation does not lead to any Zeeman splitting which might suppress high-field SC order; the short-range interactions allow density wave order to develop (contrary to long-range Coulomb interactions). We show that the low-temperature phases of an atomic Fermi gas with attractive interactions involve an interesting interplay between CDW and superconducting phases. In the extreme quantum limit, when only the lowest Landau level is occupied, we employ a renormalization group approach [3] to show that the system is unstable to CDW order along the rotation axis. At lower rotation rates, we show how CDW and SC can coexist, leading to supersolid behaviour.

10:48AM U14.00013 Quantum Hall Transition near a Feshbach Resonance in Fast Rotating Fermi Gases1, KUN YANG, National High Magnetic Field Lab and Florida State University, HUI ZHAI, UC Berkeley and Lawrence Berkeley Lab — We consider two-species of fermions in a rotating trap that interact via an s-wave Feshbach resonance, at total Landau level filling factor two (or one for each species). We show that the system undergoes a quantum phase transition from a fermion integer quantum Hall state to a boson fractional quantum Hall state as the pairing interaction strength increases, with the transition occurring near the resonance. The effective field theory for the transition is shown to be that of a (emergent) massless relativistic bosonic field coupled to a Chern-Simons gauge field, with the coupling giving rise to semionic statistics to the emergent particles.

Thursday, March 13, 2008 8:00AM - 11:00AM –
Session U15 GQI: Focus Session: Open Quantum Systems and Decoherence
Morial Convention Center 207

8:00AM U15.00001 Coherence and control of single electron spins in quantum dots1, LIEVEN VANDERSYPEN, Kavli Institute NanoScience TU Delft — Following our earlier work on single-shot read-out and relaxation of a single spin in a quantum dot, we now demonstrate coherent control of a single spin (detection is done using a second spin in a neighbouring dot). First, we manipulate the spin using conventional magnetic resonance. Next, we show that we can also rotate the spin using electric fields instead of magnetic fields. In both cases, 90 rotations can be realized in about 50 ns or less. We use these control techniques to probe decoherence of an isolated electron spin. The spin dephases in about 30 ns, due to the hyperfine interaction with the uncontrolled nuclear spin bath in the host material of the dot. However, since the nuclear spin dynamics is very slow, this dephasing can be largely reversed using a spin-echo pulse. Echo decay times of about 0.5 us are obtained at 70 mT. In parallel, we have started work on quantum dots in graphene, which is expected to offer superior coherence times. As a first step, we have succeeded in opening a bandgap in bilayer graphene, necessary for electrostatic confinement of carriers.

8:36AM U15.00002 Non-Markovian thermalization for a few qubit system, PEDER MANRIQUE, FERNEY RODRIGUEZ, Universidad de los Andes — Non-Markovian dynamics in the thermalization process of a single and coupled-qubit systems are analyzed by means on an effective master equation. Memory effects are included in a time dependent relaxation constant which is obtained from a proper bosonic bath spectral function. For different initial states, the population and coherence are studied as a function of the qubit-bath coupling strengths and bath temperature. Clear signatures of non-exponential decays for the qubit density matrix elements are found in a short-time regime corresponding to the back action of the qubit system on the bath dynamics. In the case of realistic two-qubit systems, such as quantum dots, entanglement oscillations should be observable.

8:48AM U15.00003 Decoherence of coupled electron spins via nuclear spin dynamics in quantum dots1, WEN YANG, REN-BAO LIU, Department of Physics, The Chinese University of Hong Kong, Shatin, N. T., Hong Kong, China — Decoherence of coupled electron spins due to electron-nuclear hyperfine interaction in double quantum dots is a major issue of solid-state quantum computation. Using an interacting nuclear spin bath model, we show theoretically that the exchange interaction between the two electron spins renormalizes the pair- flip excitation energy in the bath and modifies the non- Markovian bath dynamics, which in turn changes the electron singlet-triplet (S-T) decoherence arising from electron-nuclear entanglement. As the energy renormalization varies with the Overhauser field mismatch between the quantum dots, the S-T decoherence depends on the sampling of nuclear spin states from an ensemble, leading to the transition from super-exponential decoherence in single-sample dynamics to power-law decay under ensemble average,[1] in contrast with the sample-independent super-exponential decoherence of a single electron spin in one dot.

9:00AM U15.00004 Rabi oscillations decay from interaction with dynamical spin environments1, V.V. DOBROVITSKI, Ames Laboratory and Iowa State University, Ames, IA 50011, A.E. FEIGUIN, University of Maryland, College Park, MD 20742, and Microsoft Station Q, University of California, Santa Barbara, CA 93106 — Studying decoherence of spins/qubits interacting with a spin bath is important for quantum computation, high-precision metrology, coherent spintronics. Measurements of the Rabi oscillations decay provide much information about the decoherence dynamics and properties of the spin in single-spin quantum dots, dopant spins in a solid-state matrix, etc. [1] Also, for a static bath, application of a large Rabi field suppresses decoherence, changing fast exponential decay into slow power-law one. [1] However, internal dynamics of spin environment is important in such systems as NV centers in diamonds, magnetic molecules, and rare-earth dopant spins in solid state, but decay of Rabi oscillations for dynamical spin bath has been little studied. We present a detailed theoretical investigation of Rabi oscillations decay for a spin bath dynamical system, demonstrating new unusual decay regimes useful for characterization of the bath and decoherence suppression.

The paths difference, together with a phase rigidity. The solution shows that the interference visibility has a lobe pattern with applied bias with a period proportional to the average path length (and independent of the non-interacting Hamiltonian. It causes correlations inside each of the two MZI arm, resulting in the electrons affecting each other’s phase. An approximate difference. We argue that these effects have a fundamental reason. A simple invariance argument leads to an additional interaction term that must be added to interference visibility showed an unexplained lobe pattern behavior with a peculiar phase rigidity. Moreover, the effect did not depend on the MZI paths theoretically the behavior of the current oscillations in an electronic Mach-Zehnder interferometer (MZI) as a function of its source bias. Recently, The MZI has been shown to exhibit periodic oscillations in the output current as the source bias is varied. These oscillations are due to quantum interference effects and are of fundamental importance in quantum computing and quantum information processing.

Boundary Conditions for Open Rotating Quantum Systems, ARTHUR DAVIDSON, Carnegie Mellon University, ECE Dept, Pittsburgh PA 15213 — The customary boundary conditions for a 1D rotational system (e.g. a rigid rotor on a surface) are continuity of the complex wave function and its gradient. These four boundary conditions are sufficient if the potential energy satisfies rotational symmetry, but fall for non-rotational potentials. However, classical systems with a rotational coordinate and non-rotational potential are easily solved if the gradient of the potential, the force, is rotational. A solution is thus required for Schroedinger’s equation with a rotational coordinate and force, but non-rotational potential. Such solutions exist only in some spherical coordinate systems. However, the non-rotational potential will lead to non-rotational solutions which will not be rotational. It will be shown that the modified boundary conditions are continuity of three real quantities: the probability density, the gradient of the probability density, and the probability current density. Moreover, with these boundary conditions and non-rotational potential, energy can flow both ways between the system and its environment. The discontinuous wave functions obey the new boundary conditions, but nonetheless are not generally superposable. A subset of the discontinuous wave functions can be superposed, however, yielding the usual result for angular momentum states. The non-supersposable wave functions offer an alternate interpretation of the Schroedinger’s cat paradox.

Non-Markovian Open Quantum Systems, CESAR RODRIGUEZ-ROSARIO, E.C.G. SUDBAN, The University of Texas at Austin — A generalized non-markovian master equation is derived from the dynamical map of systems initially correlated with their environment. We study the connection between the initial correlations and the non-markovian memory effects. The significance of not-complete positive maps in order to obtain a consistent theory of non-markovian quantum dynamics is discussed. Previous specific instances of non-markovian master equations are examined in this framework.

Finite representations of continuum environments, MICHAEL ZWOLAK, Los Alamos National Laboratory — Understanding dissipative and decohering processes is fundamental to the study of non-equilibrium systems and quantum computing, and such processes can even induce quantum phase transitions. A typical construction is to have a system connected to a continuum environment, which acts as the source of dissipation or decoherence, or as a reservoir of particles. If the connection is strong or the environment has long-range correlations in time, the system dynamics are not easily separated from the dynamics of the environment. To study this situation numerically, one option is to simulate both the system and environment. This is a viable option so long as an efficient finite representation of the environment can be constructed. We will discuss a procedure to construct finite representations based on the concept of two-site recurrence and increasing smoothness. For solvable cases of non-interacting bosons, the procedure gives an exponential reduction in the number of discrete modes necessary to achieve some given accuracy in a real-time simulation. We will also discuss application of this procedure to interacting systems.

Induced decoherence and entanglement by an interacting spin chain, POCHUNG CHEN, Nat’l Tsing-Hua Univ, Hsinchu, CHENG-YAN LAI, JO-TZU HUNG, CHUNG-YU MOU — We study the reduced dynamics of a single or two qubits coupled to an interacting spin chain using time-dependent density matrix renormalization group (TD-DMRG) technology. By using TD-DMRG we can go beyond the uniform coupling central spin model and evaluate nonperturbatively the reduced dynamics even when the coupling between qubits and the chain is non-uniform. Furthermore, the qubit-bath interaction can be of Ising, XY, or Heisenberg type. This allows us to go beyond pure dephasing model. For single qubit we use Loschmidt echo to gauge the decoherence and investigate how the short time decay parameter and large time behavior are linked to the phase of spin chain. We use concurrence to quantify the (dis)-entanglement process of two qubits due to spin chain. We show that one can induced entanglement for an initially disentangled pair of qubit. The competition between induced decoherence and entanglement is discussed.

Temperature Exchange in a System of Two Harmonic Oscillators, ANTONIA CHIMONIDOU, GEORGE SUDARSHAN, University of Texas at Austin — We study the process by which quantum correlations are created when an interaction Hamiltonian is repeatedly applied to a system of two harmonic oscillators for some characteristic time interval, under what we call the “interact-refresh-repeat” scheme. We show, for example, that the oscillator frequencies are equal, the initial Maxwell-Boltzmann distributions of the uncoupled parts evolve to a new Maxwell-Boltzmann distribution that is not rotationally symmetric. Furthermore, we discuss why the equilibrium reached when the two oscillator frequencies are unequal, is not a thermal one. More specifically, we show that the ratio of the harmonic oscillator temperatures at the new equilibrium state is completely determined by the ratio of the inverse harmonic oscillator frequencies. We conclude that the selection rules imposed by the interaction Hamiltonian override the expected statistical mechanical effects. All the calculations are exact and the results are obtained through an iterative process, without using perturbation theory.

Impact of classical forces and decoherence in three-terminal Aharonov-Bohm devices, ELIA STRAMBINI, VINCENTO PIAZZA, FABIO BELTRAM, NEST INFN-CNR & Scuola Normale Superiore, I-56126 Pisa, Italy, GIOVANNI BIASIOL, Laboratorio Nazionale TASC INFN-CNR, I-34012 Trieste, Italy, LUCIA SORBIA, NEST INFN-CNR & Scuola Normale Superiore, I-56126 Pisa, Italy & Laboratorio Nazionale TASC INFN-CNR, I-34012 Trieste, Italy — Multi-terminal Aharonov-Bohm (AB) rings are ideal building blocks for quantum networks (QNs) thanks to their ability to transform input states into controlled coherent superpositions of output states. We report on experiments performed on three-terminal GaAs/AlGaAs AB devices and compare our results with a scattering-matrix model of our device including Lorentz forces and decoherence. Our devices were studied as a function of external magnetic field (B) and gate voltage (V g) down to a T=350 mK. The total output current from two terminals while applying a small bias to the third lead was found to be symmetric with respect to B with clear AB oscillations showing abrupt phase jumps between 0 and 2g differing due to the Lorentz force. Surprisingly, the individual outputs show an almost linear dependence of the oscillation phase on the external electric field. We emphasize that a simple scattering-matrix approach does not explain the observed behavior and show how to extend this model in order to fully describe the observed phenomena.

The Behavior of Electronic Interferometers in the Non-Linear Regime, IZHAR NEDER, ERAN GINOSSAR, Department of Condensed Matter Physics, The Weizmann Institute of Science, Rehovot 76000, Israel — We investigate theoretically the behavior of the current oscillations in an electronic Mach-Zehnder interferometer (MZI) as a function of its source bias. Recently, the MZI interference visibility showed an unexplained lobe pattern behavior with a peculiar phase rigidity. Moreover, the effect did not depend on the MZI paths difference. We argue that these effects have a fundamental reason. A simple invariance argument leads to an additional interaction term that must be added to the non-interacting Hamiltonian. It causes correlations inside each of the two MZI arm, resulting in the electrons affecting each other’s phase. An approximate solution shows that the interference visibility has a lobe pattern with applied bias with a period proportional to the average path length (and independent of the paths difference), together with a phase rigidity.
10:48AM U15.00013 What is quantum about quantum trajectory equations?, JAY GAMBITTA, Institute of Quantum Computing, HOWARD WISEMAN, STÈVE JONES, ERIC CAVALCANTI, Griffith University — Quantum trajectory equations are stochastic equations for the state of an open quantum system conditioned on a monitoring i.e. a continuous-in-time measurement of a bath to which it is coupled. They are closely related to classical stochastic equations for classical probability distributions called filtering equations (e.g. the Kalman filter). Given this close relation, the question arises: what is quantum about quantum trajectory equations? In this talk I suggest that the answer lies in the ability of an experimenter to choose different monitoring schemes. Moreover, I propose that there is an experimental way to distinguish between cases where this choice does demonstrate the quantum nature of the noise, and the cases where it does not.

Session U16 DBP: Focus Session: Medical Physics and Radiation Biology
Morial Convention Center

8:00AM U16.00001 Image-Guided Radiation Therapy: the potential for imaging science research to improve cancer treatment outcomes1, JEFFREY WILLIAMSON2, Virginia Commonwealth University — The role of medical imaging in the planning and delivery of radiation therapy (RT) is rapidly expanding. This is being driven by two developments: image-guided radiation therapy (IGRT) and biological image-based planning (BIBP). IGRT is the systematic use of serial treatment-position imaging to improve geometric targeting accuracy and/or refine target definition. The enabling technology is the integration of high-performance three-dimensional (3D) imaging systems, e.g., onboard kilovoltage x-ray cone-beam CT, into RT delivery systems. IGRT seeks to adapt the patient’s treatment to weekly, daily, or even real-time changes in organ position and shape. BIBP uses non-anatomic imaging (PET, MR spectroscopy, functional MR, etc.) to visualize abnormal tissue biology (angiogenesis, proliferation, metabolism, etc.) leading to more accurate clinical target volume (CTV) delineation and more accurate targeting of high doses to tissue with the highest tumor cell burden. In both cases, the goal is to reduce both systematic and random tissue localization errors (2-5 mm for conventional RT) conformity so that planning target volume (PTV) margins (varying from 8 to 20 mm in conventional RT) used to ensure target volume coverage in the presence of geometric error, can be substantially reduced. Reduced PTV expansion allows more conformal treatment of the target volume, increased avoidance of normal tissue and potential for safe delivery of more aggressive dose regimens. This presentation will focus on the imaging science challenges posed by the IGRT and BIBP. These include: Development of robust and accurate nonrigid image-registration (NIR) tools: Extracting locally nonlinear mappings that relate, voxel-by-voxel, one 3D anatomic representation of the patient to differently deformed anatomies acquired at different time points, is essential if IGRT is to move beyond simple translational treatment plan adaptations. NIR is needed to map segmented and labeled anatomy from the pretreatment planning images to each daily treatment position image and to deformably map delivered dose distributions computed on each time instance of deformed anatomy, back to the reference 3D anatomy. Because biological imaging must be performed offline, NIR is needed to deformably map these images onto CT images acquired during treatment. Reducing target and organ contouring errors: As IGRT significantly reduces impact of differences between planning and treatment anatomy, RT targeting accuracy becomes increasingly dominated by the remaining systematic treatment-preparation errors, chiefly error in delineating the clinical target volume (CTV) and organs-at-risk. These delineation errors range from 1 mm to 5 mm. No single solution to this problem exists. For BIBP, a better understanding of tumor cell density vs. signal intensity is required. For anatomic CT imaging, improved image reconstruction techniques that improve contrast-to-noise ratio, reduce artifacts due to limited projection data, and incorporate prior information are promising. More sophisticated alternatives to the current concept fixed boundary anatomic structures are needed, e.g., probabilistic CTV representations that incorporate delineation uncertainties. Quantifying four-dimensional (4D) anatomy: For adaptive treatment planning to produce an optimal time sequence of delivery parameters, a 4D anatomic representation, the spatial trajectory through time of each tissue voxel, is needed. One approach is to use sequences of deformation vector fields derived by non-rigidly registering each treatment image to the reference planning CT. One problem to be solved is prediction of future deformed anatomies from past behavior so that time delays inherent in any adaptive replanning feedback loop can be overcome. Another unsolved problem is quantification 4D anatomy uncertainties and how to incorporate such uncertainties into the treatment planning process to avoid geometric ‘miss’ of the target tissue.

8:36AM U16.00002 Bridging the Gaps between IGRT Systems and R&V Systems, YULONG YAN, XUEJUN WENG, JOSE PENAGARICANO, VANÉERAT RATAÑATHARATHORN, University of Arkansas for Medical Sciences — Image Guided Radiation Therapy (IGRT) is the next-generation of technology for high precision radiotherapy. BrainLAB ExacTrac and Tomotherapy are two of them. Unfortunately, neither of the two communicates with any Record and Verify (R&V) system for seamless radiation therapy workflow. So two dedicated software systems, iPump and ScreenBee, have been developed respectively to bridge the gaps between IGRT systems and the R&V systems to allow remote image reviewing as well as paperless future. Both iPump and ScreenBee have been extensively tested and evaluated in our clinic. They reduce the cost and improve the efficiency and the safety of clinical procedures. They also act as key integral components of our facility on its way toward the digital and paperless future.

8:48AM U16.00003 Hyperthermal heavy ion damage to DNA bases1, SARVENAZ SARABIPOUR, ZONGWU DENG, MICHAEL HUELS, Ion Reaction Laboratory, Dep. of Nuclear Medicine & Radiobiology, Univ. of Sherbrooke, QC, Canada — Ionization and fragmentation of DNA is a key step in biological radiation damage. When heavy ions cross the cell, secondary ballistic ions, electrons and radicals are generated along the ion tracks. Here we report measurements of ionic fragments induced by 1-100eV Ar$^+$ irradiation of Adenine, Guanine and Cytosine films on Pt. Experiments are conducted with a UHV ion-beam apparatus consisting of a low energy ion source, a beam line with high resolution magnetic mass spectrometer (MS), a biomolecular film preparation system, and a reaction chamber with high-resolution quadrupole MS to monitor desorbing ion yields. Among the major fragments, NH$_2^+$ was identified in the desorption mass spectra of all bases examined, indicating efficient de-amination; in cells this results in pre-mutagenic lesions. Several important factors, e.g. intra/inter-molecular proton/hydrogen tunneling, tautomeric equilibrium and the molecular geometry of the bases in the films likely contribute to ion induced de-amination, and will be discussed here.

9:00AM U16.00004 Physical and Clinical Evaluation of Standardized uptake values
Cristina Lois, University of Tennessee, Knoxville, TN, Bjoern W. Jakoby, University of Surrey, Guildford, UK, Karl Hubner, University of Tennessee, Knoxville, TN, Mario Canadas, CIEMAT, Madrid, Spain, David W. Townsend, University of Tennessee, Knoxville, TN — The Standardized Uptake Value (SUV) is often used in postion emission tomography (PET) to differentiate malignant from benign tumors, and to monitor the progress of the patient’s response to therapy. Despite its name, SUV may depend on both PET scanner hardware and software details, and will depend on the imaging protocol. In this paper, we present a study of the SUV variability according to these external factors. To study the influence of the PET device, phantom studies were performed on two different PET/CT scanners. SUVs were obtained using several reconstruction algorithms and different reconstruction matrix sizes. To study the influence of the imaging protocol, patients were injected with 370 MBq of 18F-FDG and scanned at 60 and 90 min post-injection. SUVs were obtained applying several clinical image reconstruction algorithms. Significant differences in SUVs were obtained depending on the PET scanner, reconstruction method, and imaging protocol. It is essential, therefore, to follow a strict protocol in order to reliably compare FDG uptake with SUVs. Our results may have a significant clinical impact in order to provide an unbiased SUV threshold to determine malignancy.

9:12AM U16.00005 The Dose Response Relationship for Radiation Carcinogenesis
Eric Hall, Columbia University — Recent surveys show that the collective population radiation dose from medical procedures in the U.S. has increased by 750% in the past two decades. It would be impossible to imagine the practice of medicine today without diagnostic and therapeutic radiology, but nevertheless the widespread and rapidly increasing use of a modality which is a known human carcinogen is a cause for concern. To assess the magnitude of the problem it is necessary to establish the shape of the dose response relationship for radiation carcinogenesis. Information on radiation carcinogenesis comes from the A-bomb survivors, from occupationally exposed individuals and from radiotherapy patients. The A-bomb survivor data indicates a linear relationship between dose and the risk of solid cancers up to a dose of about 2.5 Sv. The lowest dose at which there is a significant excess cancer risk is debatable, but it would appear to be between 40 and 100 mSv. Data from the occupation exposure of nuclear workers shows an excess cancer risk at an average dose of 19.4 mSv. At the other end of the dose scale, data on second cancers in radiotherapy patients indicates that cancer risk does not continue to rise as a linear function of dose, but tends towards a plateau of 40 to 60 Gy, delivered in a fractionated regime. These data can be used to estimate the impact of diagnostic radiology at the low dose end of the dose response relationship, and the impact of new radiotherapy modalities at the high end of the dose response relationship. In the case of diagnostic radiology about 90% of the collective population dose comes from procedures (primarily CT scans) which involve doses at which there is credible evidence of an excess cancer incidence. While the risk to the individual is small and justified in a symptomatic patient, the same is not true of some screening procedures is asymptomatic individuals, and in any case the huge number of procedures must add up to a potential public health problem. In the case of radiation oncology, modern innovations such as Intensity Modulated Radiation Oncology or Proton Therapy both result in a substantial total-body dose to the patient, which must result in an increased incidence of second cancers. The technology exists to reduce these total body doses and the problem needs to be addressed.

9:48AM U16.00006 Panel Discussion on Medical Physics and Radiation Biology and pathways to these fields
Paul Gueye, Hampton University — Medical Physics is one of the less know physics field but one that has the most impact on our daily life. It is intrinsically linked to radiation biology as the latter provides crucial inputs to the former including treatment planning software packages, understanding of cancer treatment optimization, etc. This panel discussion, composed of renown experts in these fields and who are part of the four medical physics sessions to be presented during this 2008 APS March meeting, will provide an environment for the audience to fully understand what medical physics and radiation biology are about and the various pathways to become a successful practitioner or researcher for contributing in these fields.

10:24AM U16.00007 Anomalous Effect of Surface Diffusion on NMR Signal in Restricted Geometry
Neranjani Edirisinghe, Vadym Apalkov, Gennady Cymbalyuk, Georgia State University — The diffusion of magnetic molecules along the surface of restricted media and the coupling on the surface will strongly modify the echo attenuation NMR signal in the pulse field gradient measurements. The origin of this strong effect is the change of the symmetry of the lowest diffusion eigenmode of the system. We illustrate the effect of surface diffusion for cylindrical symmetric system. We find the parameters of the system under which the anomalous behavior of echo signal can be observed.

8:00AM U17.00001 Hierarchy of Specific Lipid-Peptide Interactions Produces the Activity of Cell-penetrating and Cell-permeating Peptides
Matthew Davis, Daniel Parente, Vernita Gordon, Abhijit Mishra, Nathan Schmidt, Lihua Yang, Robert Cordon, Abhigyan SOM, Gregory Teiw, Gerard Wong, University of Illinois, Urbana-Champaign — Protein transduction domains can cross cell membranes with high efficiency, even when carrying a variety of cargos, and thus has strong biotechnological potential. The molecular mechanism of entry, however, is not well understood. We use small-angle x-ray scattering (SAXS) and confocal microscopy to systematically study the interaction of the TAT and ANTP PTD with model membranes of variable composition. Their membrane transduction activity requires the presence of both PE and PS lipids in the membrane. Antimicrobial peptides (AMP’s) are cationic amphiphiles that comprise a key component of innate immunity. Synthetic analogs of AMP’s, such as the family of phenylene ethynylene antimicrobial oligomers (AMO’s), recently demonstrated broad-spectrum antimicrobial activity, but the underlying molecular mechanism is unknown. PE lipid greatly enhances permeating activity of AMO in these membranes, synthetic analogs of AMP’s, such as the family of phenylene ethynylene antimicrobial oligomers (AMO’s), recently demonstrated broad-spectrum antimicrobial activity, but the underlying molecular mechanism is unknown. PE lipid greatly enhances permeating activity of AMO in these membranes, and rapidly increasing use of a modality which is a known human carcinogen is a cause for concern. 8:12AM U17.00002 Simulations of the pore structures for a M2GlyR derived channel forming peptide in membrane
Ahlam N. Al-Rawi, Asma Al-Rawi, Jianhan Chen, Alvaro Herrera, John Tomich, Kansas State University, Talat S. Rahman, University of Central Florida — In an effort to develop a peptide-based compound suitable for clinical use as a channel replacement therapeutic for treating channelopathies such as cystic fibrosis, we present a reductionist model that appears to capture many of the biophysical properties of an intact ion channel using short channel-forming peptides. We have developed two anion selective channel-forming peptides with near native and altered properties from the peptides derived from the glycine receptor: NK-I-M2 GlyR-P22 WT (KKKPPPVRVGLGTTTMATTTQG) and NK-I-M2 GlyR-P22 S22W (KKKPPPVRVGLGTTTMATTTQW), respectively. Starting with the two structures determined by solution multidimensional NMR (800 MHz) in SDS, we used CHARMM and NAMD to perform molecular dynamics simulations on the monomers. Using the existing experimental data, we then built an initial 5- helix assembly by altering the tilted angle, rotational angle and pore radius. We investigated the impact of the single mutation at position 22 on the structure and dynamics of the pore formed in a membrane build in a hydrated POPC lipid bilayer. Probable structures for both assemblies are presented.
8:24AM U17.00003 Membrane-mediated mechanism of amyloid oligomer toxicity in Alzheimer’s Disease. FRANK HEINRICH, Carnegie Mellon University, YURI SOKOLOV, JAMES E. HALL, University of California, Irvine, RIMA BUDVYTYTE, GINTARAS VALIUNCIS, Institute of Biochemistry, Vilnius, MATHIAS LOESCHE, Carnegie Mellon University. There is strong evidence, that soluble amyloid β (Aβ) oligomers, involved in Alzheimer’s Disease, are the primary toxic species of Aβ, although the mechanism of cell toxicity is very much debated [1]. Neuron reflectivity and electrical impedance spectroscopy assess the structural impact of Aβ (1-42) oligomers and their effect on the electrical properties of a tethered phospholipid model membrane. Two distinct and reversible peptide – membrane interactions were revealed: At low Aβ concentrations an equal incorporation of Aβ into both lipid leaflets and a compaction of the lipid membrane takes place. Aβ locally lowers the dielectric barrier for ion transport and the activation energy for ion transport through the bilayer remains significantly above that of a water-filled transmembrane pore. At high Aβ concentrations, an additional membrane thinning is observed. [1] D. E. Eliezer, J. Gen. Physiol. 128:631 (2006).

8:36AM U17.00004 Molecular target of synthetic antimicrobial oligomer in bacterial membranes. LIHUA YANG, VERNITA GORDON, Department of Materials Science and Engineering, University of Massachusetts, Amherst, JOHN CRONAN, David Schwab, Robijn Bruinsma, UCLA. Antimicrobial peptides consist of a key component of innate immunity for a wide range of multicellular organisms. It has been shown that natural antimicrobial peptides and their synthetic analogs have demonstrated broad-spectrum antimicrobial activity via permeating bacterial membranes selectively. Synthetic antimicrobial peptides, on the other hand, are tunable to interact with bacterial membranes through a variety of selectivity mechanisms. We investigate interactions and self-assembly using a prototypical family of antimicrobialbased on phenylene ethynylene. Results from synchrotron small angle x-ray scattering (SAXS) results and in vitro microbidassal on genetically modified ‘knock-out’ bacteria will be presented.

8:48AM U17.00005 Interaction of Arginine-Rich Peptides with Model Cell Membranes, ABHIJIT MISHRA, NATHAN SCHMIDT, VERNITA GORDON, JIANJUN CHENG, University of Illinois at Urbana-Champaign, TIMOTHY DEMING, University of California, Los Angeles, GERARD WONG, University of Illinois at Urbana-Champaign. WONG RESEARCH GROUP TEAM. — Cell-penetrating peptides have the ability to traverse the plasma membrane of eukaryotic cells. Furthermore, these peptides can transport cargo across a range of cell membranes, implying they have many potential biotechnological applications. In this study we compare the interaction of three commonly used arginine-rich cell-penetrating peptides, TAT, Penetratin, and pVEC, with model cell membranes of variable charge density and intrinsic curvature, using synchrotron small angle x-ray scattering (SAXS). To better understand the respective roles of arginine and hydrophobic residues in membrane reorganization we also examine the interaction of arginine-leucine (R60L20) block copolyptides with model membranes, as well as the relationship between membrane composition and peptide induced changes in membrane topology.

9:00AM U17.00006 Lipid and Protein Sorting during Membrane Tube Formation, HONGYUAN JIANG, THOMAS POWERS, Division of Engineering, Box D, Brown University, Providence, RI 02912 — Motivated by recent experiments that implicate the mechanical properties of membranes in lipid sorting, we examine the interplay of lipid composition and curvature in membrane tubes. We study how the dependence of bending stiffness and surface tension on membrane lipid and protein composition affects tube formation. Drawing a tube from a vesicle leads to a rearrangement of composition in which the phase of higher flexibility segregates in the tube, the region of high mean curvature. For point forcing, the force vs. extension curve can have a sharp drop just as the tube begins to form.

9:12AM U17.00007 Equilibrium Stability of Transmembrane Proteins : A Hard-Core Gas Problem. KARIM WAHBA, DAVID SCHWAB, ROBIJN BRUINSMA, UCLA. — Hydropathy plots, a moving average of amino acid hydrophobicity over a sequence, can be used to predict potential protein structure, in particular transmembrane proteins. Traditionally transmembrane regions are identified by peaks above an empirical cutoff. We treat the transmembrane segments as a one-dimensional gas of hard rods in a correlated random energy landscape. At zero temperature, where the entropic contribution due to the loops is negligible, we calculate the density profile as a function of the chemical potential in the case of the original as well as randomly generated landscapes. The density profile exhibits plateaus indicating regions where a transmembrane segment has been established. For designed versus random sequences we explore the distribution of the sizes of these plateaus and attempt to infer characteristic features that may be interpreted in terms of the stability of the protein in its inserted state.

9:24AM U17.00008 Diffusion of Transmembrane Proteins: Beyond the Saffman-Delbrück Model, TATIANA KOURIJOBA, MARK HENLE, ALEXANDER J. LEVINE, University of California, Los Angeles — The hydrodynamic model of Saffman and Delbrück [PNAS 72 311.1975] predicts that the diffusion constant D of proteins embedded in a fluid membrane exhibits a weak logarithmic dependence on the radius σ of the protein. However, recent experiments by Gambin et al. [PNAS 103 2098 (2006)] have observed a much stronger 1/2 dependence for proteins embedded in model membranes. Local interactions between a transmembrane protein and the lipids that surround it can cause the lipids to deform by, for example, stretching or compressing their tails, or by tilting their long axis with respect to the membrane’s surface. In this talk, we show that these deformations lead to additional sources of energy dissipation which cause the protein diffusion constant D ~ σ/a, as observed by Gambin et al. Our model incorporates the lipid stretch and tilt degrees of freedom into a traditional hydrodynamic model by introducing additional scalar and vector fields, respectively.

9:36AM U17.00009 Lateral organization of a non-equilibrium membrane model with immobile randomly-distributed impurities, ANDREW P. PARADIS, SUSAN R. MCKAY, Department of Physics and Astronomy, University of Maine, Orono, Maine 04469, SAMUEL T. HESS, Department of Physics and Astronomy, Institute of Molecular Biophysics, University of Maine, Orono, Maine 04469 — Cell membranes are dynamic, far-from-equilibrium systems; transport, signaling, and other membrane functions ensure that membrane lateral organization is heterogeneous across several length scales. However, many studies and simulations consider membranes as equilibrium systems. Here, we present a model of cell membranes that includes simplified endo- and exocytosis and immobile randomly-distributed impurities. The impurities take the form of fixed protein sites within the membrane, which act as potential localization zones for micro-domain rafts. We analyze the lateral organization in terms of spatial statistics through a modified Ripley K-test. This model illuminates the role of protein in a 1:1:1 mixture of saturated lipids, unsaturated lipids, and cholesterol. Additionally, this model exhibits a realistic heterogeneity of cluster sizes and shapes, and suggests conditions under which we may observe a partitioning of cholesterol in the membrane. Such simulated observations of the direct interactions between cholesterol, lipids, and protein on the molecular scale can enhance our understanding of all biophysical processes occurring within cell membranes.
action under Osmotic Pressure successfully explains a large number of experimental observations, such as density of formin speckles and variance of actin cable density. The model predicts nucleators, the actin cable dynamics are subject to spatial and temporal fluctuations. We studied actin cable dynamics with simple analytical models and whole flow of polymerized actin toward the cell center, and cable disassembly. Formin for3p associates with actin at the cable tip where it transiently polymerizes actin...

8:36AM U18.00002 Studies of Protein Folding in Non-Funneled Free Energy Landscapes1, COREY O’HERN, GREGG LOIS, JERZY BLAWZDZIEWICZ, Department of Mechanical Engineering and Department of Physics, Yale University — A theoretical framework is developed to understand the dynamics of protein folding. The key insight is that the search for the optimal conformation of the protein is influenced by the rate at which external parameters are adjusted to induce folding. A theory based on this insight predicts that (1) proteins with non-funneled free energy landscapes can fold reliably, (2) reliable folding can occur in equilibrium or out-of-equilibrium, and (3) reliable folding only occurs when the quench rate is below a limiting value, which can be calculated from measurements of the free energy. We test these predictions against numerical simulations of heteropolymers with hydrophobic and hydrophilic interactions and a single energy scale.

8:48AM U18.00003 Exploring HP protein models using Wang-Landau sampling, THOMAS WUEST, DAVID P. LANDAU, The University of Georgia, USA — The hydrophobic-polar (HP) protein model has become a standard in assessing the efficiency of computational methods for protein structure prediction as well as for exploring the statistical physics of protein folding in general. Numerous methods have been proposed to address the challenges of finding minimal energy conformations within the rough energy landscape of this lattice heteropolymer model. However, only a few studies have been dedicated to the more revealing — but also more demanding - problem of estimating the density of states which allows access to thermodynamic properties of a system at any temperature. Here, we show that Wang-Landau sampling, in connection with a suitable move set (“pull moves”), provides a powerful route for the ground state search and the precise determination of the density of states for HP sequences (with up to 100 monomers) in both, two and three dimensions. Our procedure possesses an intrinsic simplicity and overcomes the inevitable limitations inherent in other more tailored approaches. The main advantage lies in its general applicability to a broad range of lattice protein models that go beyond the scope of the HP model.

9:00AM U18.00004 ABSTRACT WITHDRAWN —

9:24AM U18.00006 Crowding Effects on the Thermodynamics of Apoflavodoxin Folding, DIRAR AL HOMOUZ, Univ of Houston — The thermodynamics of folding in Apoflavodoxin protein are studied using coarse-grained molecular dynamics simulations as a function of volume fraction of crowding agents. The stability of the folded state is enhanced in the presence of crowding agents as can be seen from the free energy diagrams. The changes in the transition state ensemble are analyzed under different crowding conditions.

9:36AM U18.00007 Protein Folding Simulation of Mutant Go Models of the Wild-Type Trpcage Protein, APICHART LINHANANTA, JUNMIN LIU, Department of Physics, Lakehead University — For the past three decades, Go models of protein folding have played important roles in the understanding of how proteins fold from random conformations to their unique native structures. Unfortunately Go models rely on known NMR or x-ray structures to construct Go interaction potentials potentially severely limit their predictive powers. In this work, we introduce a novel method for constructing Go interaction potentials of mutant proteins based on Go interaction potentials of wild type proteins. As a template we employ the all-atom Go model of the 20-residue Trp-cage protein (A. Linhananta, J. Boer and I. MackKay, J. Chem. Phys., 2005, 122, 114901) as the wild type Go model. Trp-cage mutants are constructed by replacing a Trp-cage residue with a different residue. In particular the Pro-12 residue of the Trp-cage is substituted by Trp-12 to produce the Trp2-cage mutant, whose native structure is not yet known. Monte Carlo simulations, using CHARMM force fields, are performed to determine the ground-state structure mutant. The resulting mutant structures are used to construct the Go interaction potential of the Trp2-cage mutant model.
9:48AM U18.00008 Statistical features of the rough energy landscape of proteins emerging from single-molecule force-clamp spectroscopy. JASNA BRUJIC, MAXIME CLUSEL, ERIC CORWIN, New York University. Following the complete folding trajectories of single ubiquitin molecules opens an unique window into the detailed mechanisms of protein folding. The biological importance of this problem motivated extensive studies using macroscopic biochemistry experiments and molecular dynamics simulations at the atomic scale, while little is known about the mesoscopic mechanisms of folding. To this end, our recent experiments combined with the tools of modern statistical mechanics reveal a wealth of new information. Using this single molecule approach, we have observed physical features reminiscent of glassy systems, exemplified by a power-law distribution of the rates of protein unfolding under a stretching force [1]. To further probe the signs of complexity in protein dynamics, we investigate memory effects and the influence of force on the folding trajectories, and more specifically the mechanism of formation of native interactions. The general aim of this research is to build a self-consistent picture of the free energy landscape of proteins. [1] J. Brujic et al., Nature Physics, vol 2, 282 (2006).

10:00AM U18.00009 Asymmetrical collapse of charged heterogeneous macromolecules. NATALIJA DENESYUK, JOHN WEEKS, Institute for Physical Science and Technology, University of Maryland, College Park. We propose a new method based on local molecular field (LFM) theory to treat Coulomb interactions in simulations of ionic fluids. This method has been tested in Langevin dynamics simulations of a model protein, which consists of a random sequence of charged hydrophilic and neutral hydrophobic monomers, in salt solution. The concentration of salt ions in the simulation box is maintained by grand canonical Monte Carlo. Our general strategy is to perform averages over an ensemble of sequences in order to identify those general properties that are sequence independent. We find that, independently of their random sequence, heterogeneous polyelectrolytes undergo the asymmetrical collapse in which one of their quadrupole moments vanishes.

10:12AM U18.00101 A Model for the Thermally Induced Polymer Coil-to-Globule Transition. DAVID SIMMONS, Univ. of Texas, ISAAC SANCHEZ, Univ. of Texas. A quantitative mean-field model for the thermally-induced (heating-induced) polymer coil-to-globule transition (HCGT) is developed with no adjustable parameters. The transition temperature $\Theta$ is given for a long chain by the equation $\Theta = T_p^* \left( 1 - \tilde{\rho}(\Theta) \right)$ where $T_p^*$ is the characteristic temperature of the polymer for the lattice fluid model and $\tilde{\rho}(\Theta)$ is the reduced solvent density at the transition temperature $\Theta$. Calculated HCGT temperatures show good agreement with experimental LCSTs. The physics of the HCGT transition is shown to be consistent with the physics of the LCST transition. The predicted globular state is characterized by the dominance of attractive polymer self interactions over excluded volume interactions. This model can be easily generalized to treat cross-linked gels and their contraction-expansion characteristics.

10:24AM U18.00111 Force Induced Globule-to-Coil Transition of Single Polymer Chains. NIKHIL GUNARI, University of Pittsburgh, GILBERT WALKER, University of Toronto. Force induced structural transitions of individual homopolymer chains have been studied in different solvent conditions using single molecule force spectroscopy. Single molecule mechanics in the “fly-fishing” mode showed a first-order like transition for polystyrene (PS) in water exhibiting a characteristic three regime force extension curve. In contrast, poly methylmethacrylate (PMMA) showed a characteristic saw-tooth pattern reminiscent of multidomain disassembly behavior similar to that seen in modular protein mechanics. The plateau force for PS and the saw-tooth pattern for PMMA disappear when measured in aqueous guanidine hydrochloride solution and in other non-solvents showing that the characteristic deformational behavior observed for the two polymers in water may be due to hydrophobic interactions.

10:36AM U18.00112 Wang-Landau sampling for homopolymer collapse. DANIEL T. SEATON, STEVEN J. MITCHELL, DAVID P. LANDAU, University of Georgia. We explore the behavior of a continuum-homopolymer model using the Wang-Landau algorithm, concentrating on phase transitions such as the coil-globule and solid-liquid transitions. Using the density of states generated by the Wang-Landau algorithm, we calculate various thermodynamic quantities, e.g., the internal energy and specific heat. We also study how algorithmic parameters, such as sampling boundaries (maximum and minimum energies for random walks) and the final value of the modification factor, affect these quantities. In particular, we observe how the sampling boundaries can significantly alter the transition behavior. Our results are compared with two recent studies that yielded contradictory results, one using the bond-fluctuation model and the other using a continuum model similar to our own. We find that the transitions seen in our model are much more similar to those in the bond-fluctuation study. The careful analysis of the effects of algorithmic parameters on thermodynamic quantities should be relevant to the study of other polymeric/protein models.

10:48AM U18.00113 Stimuli-Responsive, Concentrated Aqueous Solutions of DMAEMA-containing Amphiphilic Di- and Triblock Copolymers. KYLE GUICE, Department of Chemical Engineering, University of Texas at Austin, YUEH-LIN LOO, Department of Chemical Engineering, Princeton University. Poly(dimethyoaminoethyl methacrylate), poly(DMAEMA), has generated considerable interest due to its responsiveness to changes in temperature and pH. The pendant tertiary amine groups of DMAEMA are easily protonated below its pKa, and the polymer undergoes a hydrophilic-to-hydrophobic transition when heated above its lower critical solution temperature (LCST) in water. We have investigated di- and triblock copolymers containing statistical copolymers of DMAEMA and hydroxethyl methacrylate (HEMA), a biocompatible but nonresponsive monomer, as stimuli-responsive concentrated aqueous solutions. The swelling characteristics of these concentrated aqueous block copolymer solutions depend highly on the DMAEMA composition. Further, by selecting an appropriate hydrophobic block, we are able to design stimuli-responsive concentrated aqueous solutions that undergo reversible phase transformations over a narrow temperature window.

8:12AM U19.00002 Charged particle and neutron energy deposition in an inertial confinement fusion plasma leading to internal tritium breeding. KARABI GHOSH, S.V.G. MENON, Theoretical Physics Division, Bhabha Atomic Research Centre. Plasma heating by charged particles and neutrons, energy exchange between ions and electrons and radiative losses are the primary mechanisms determining the ignition conditions in a thermonuclear plasma. In this work the energy leakage probability has been obtained numerically by including the effect of nuclear scattering, small and large angle Coulomb scattering and collective plasma effects. A simple multigroup approach has been developed for energy deposition by neutrons due to nuclear interaction with the ions. Using this accurate model for energy deposition, the concept of internal tritium breeding in DT fusion pellet has been re-evaluated by numerically solving the rate equations for various participating species and energy balance equations for ions, electrons and radiation within the three temperature model. Internal tritium breeding is found to occur even when all the radiation loss mechanisms such as bremsstrahlung and inverse compton scattering are fully accounted for.
8:24AM U19.00003 Breakeven Fusion in Staged Z Pinch1, HAFIZ RAHM AN, University of California, PAUL NEY, Mount San Jacinto College, NORMAN ROSTOKER, FRANK WESSEL, University of California — We are studying the prospect for breakeven thermonuclear fusion considering a Mega joule (MJ) class, 100 ns, impulse generator using a modified version of MACH2, a 2-1/2 D, radiation-code. The load is a cylindrical, xenon plasma shell that implodes radially onto a co-axial, deuterium-tritium plasma target. Optimized plasma density and pinch radius lead to a fusion-energy output that is many times the stored capacitor bank energy. In this “Staged Z-pinch” shock fronts form that preheat the DT plasma to several hundred eV, before adiabatic compression. During compression, the Xe liner becomes Rayleigh-Taylor (RT) unstable while the DT target remains stable. Proper selection of the initial pinch radius and plasma density is crucial for optimum implosion efficiency.

8:36AM U19.00004 Intensity correlations in wave transport through complex media. GABRIEL CWILICH, Department of Physics - Yeshiva University, LUIS FROUFE-PEREZ, Laboratoire EM2C, Ecole Centrale Paris, ANTONIO GARCIA-MARTIN, Instituto de Microelectronica de Madrid, CSIC, JUAN JOSE SAENZ, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid — The intensity-intensity correlations that appear when a wave propagates coherently through a random medium will be discussed within the framework of the random matrix theory (RMT) of transport. We will consider the case of transmitted-transmitted, reflected-reflected and transmitted-reflected correlations. In the case of transmission the spatial correlations can be expressed as the sums of three terms with distinctive spatial dependences. This result coincides with the one obtained in the diffusive regime from perturbative calculations, but here its validity is extended from the quasi ballistic to the localized regime. In the RMT framework, approximate solutions of the DMPK equations allow us to study the dependence of the correlations with the length of the system.

8:48AM U19.00005 Modified Transition Matrix Methods1, DAVID YEVICK, MICHAEL REIMER, BJARNE TROMBORG, University of Waterloo — Recently we adapted the transition matrix Monte-Carlo method to general communication systems problems [D. Yevick and M. Reimer, Photon. Technol. Lett. 1529 (2007), IEEE Trans. Commun., submitted, (2007)]. In this presentation, we compare the accuracy and parameter dependence of different multicanonical and transition-matrix methods. We find that the standard multicanonical method can be reformulated more simply and accurately for a single system observable (output variable) within a transition matrix formulation by constructing the intermediate probability density function (density of states) after a small number of Markov transitions from the ratios of the elements of the transition matrix between adjacent histogram bins. Further, we consider an alternative procedure in which transitions only occur either from a given state to itself or to states that have previously been less frequently sampled. Here we show that the numerical error is small unless the self-transition probability is considerable. In this case, despite the violation of detailed balance, numerical precision can be effectively restored by ensuring that the random walker thermalizes within each histogram bin before effecting a transition to a different bin.

9:00AM U19.00006 ABSTRACT WITHDRAWN —

9:12AM U19.00007 Critical phenomena of Site-Percolation Models with Two Different Sizes of Particles on a Square Lattice, RYOJI SAHARA, HIROSHI MIZUSEKI, Institute for Materials Research, Tohoku University, KIYOSHI KANIE, ATSUSHI MURAMATSU, Institute of Multidisciplinary Research for Advanced Materials, Tohoku University, YOSHIIKI KAWAZOE, Institute for Materials Research, Tohoku University, IMR, TOHOKU UNIVERSITY TEAM — The concept of percolation plays an important role in explaining various important physical phenomena, including transport, mechanical, and electromagnetic properties of disordered systems. To date, many percolation models have been developed. Contrary to the ordinary site percolation models with homogeneous particles, systems have a certain particle-size distribution. Such a distribution may affect the properties of the system in certain ways. In the present study, site-percolation models with two different sizes of particles are systematically introduced on a square lattice to understand the effect of nonhomogeneity of the particles in the system. To estimate the critical phenomena with high accuracy, a finite-size scaling analysis is performed with a Monte Carlo simulation. The critical coverage at the percolation threshold is examined as a function of the size distribution of elements in the system. Fractal dimension and the critical exponents are also estimated.

9:24AM U19.00008 Development of a Simple Sintering Law for Fractal Aggregates Composed of Unequal Sized Primary Particles1 , TAKUMI HAWA, MICHAEL ZACHARIAH, University of Maryland and National Institute of Standards and Technology — Sintering of silicon nanoparticle chain aggregates composed of unequal sized primary particles are investigated using molecular dynamics (MD) simulations at 1500 K. We consider straight chain aggregates consisting of up to 40 2.5 and 5.4 nm primary particles. The sintering time increases with increase in the total volume of the chain aggregate or with increase in the exposed initial surface area of the chain. A mathematical model was developed to describe the dynamics of sintering of such chain aggregates. The model is a power law modification of the Frenkel sintering equation with the Koch-Friedelander model to include primary particle size dependence. We found that the particle size effect is a local process, and important only at the initial stage of the sintering. Thus, the effect is not significant when the aggregate becomes large. The model is amenable for use in aerosol models that might include sintering effects.

9:36AM U19.00009 Toward a new criteria of soliton/ domain wall creation in condensed matter systems?, ANDREW BECKWITH, APS/ Fermi contractor — We do an extension of prior work where we applied a quasi 1-Dimensional wavefunctional formulation of tunneling Hamiltonians to a physical transport problem characterized by a perturbed washboard potential. To do so beforehand in the quasi one dimensional situation, we considered tunneling between states that were modeled as wavefunctionals of a scalar quantum field. I-E curves that matched Zener curves — were used to fit data from an experimental standpoint with quasi one dimensional wavefunctionals congruent with the false vacuum hypothesis. We generalize this to the case of higher dimensional formulations of the wave functions, and also present a minimum criteria for the formation of soliton/ instanton structure in higher dimensions.
9:48AM U19.00010 Use of Space-Time Basis Sets for Solving Initial-Value Problems\textsuperscript{1}, CHARLES WEATHERFORD, XINGJUN ZHANG, Florida A&M University — A new algorithm for solving Quantum Mechanical initial-value problems such as the time-dependent Schrödinger equation and the Liouville equation is described. The method avoids the use of the time-translation operator which inevitably results in an essentially sequential algorithm and instead turns the problem into the solution of simultaneous equations, which produces a highly parallelizable algorithm. A basis set in time as well as spatial degrees of freedom is used. The basis may be spectral, finite element, or spectral element and may be continuous or discrete (discrete variable representation–DVR). The time-axis may have an arbitrary size of time element including only one element. The larger the time step, the larger the size of the time basis that is required. The Hamiltonian may be time-independent or time-dependent. In the case of a time-independent Hamiltonian, an extremely efficient algorithm results. For the time-dependent case, the problem of time-ordering does not arise. Several applications involving laser-atom interactions will be given.

10:00AM U19.00011 Propagating the nonlinear Schrödinger equation, FREDERICK STRAUCH, Gettysburg College — We derive an exact propagation scheme for nonlinear Schrödinger equations. This scheme, analogous to the propagation of linear Schrödinger equations, results from a special operator whose properties ensure the correct propagation. Using this scheme we prove the correctness of higher-order integrators for the Gross-Pitaevskii equation and its multi-component generalizations.

10:12AM U19.00012 Reconstructing the dynamics of water sheared between charged plates using inelastic x-ray scattering, GHEE HWEE LAI, ROBERT H. CORIDAN, NATHAN W. SCHMIDT, PETER M. ABBAMONTE, GERARD C. L. WONG, UIUC — Understanding the dynamical behavior of water under confinement or near surfaces is fundamental to tribology and many transport processes in cell biology. To achieve angstrom and femtosecond resolution in water dynamics, we reconstruct the space-time longitudinal (density) response function from high-resolution inelastic x-ray scattering (IXS) studies of water and, together with linear response theory, investigate how water behaves between two moving 2-D charge lattices at different charge densities and inter-plate separations. We find that the density profile varies with plate separation with a periodicity close to the diameter of a water molecule (~2.6Å), in agreement with surface forces apparatus measurements, and that the hydration patterns of charges on the surfaces are strongly velocity dependent.

10:24AM U19.00013 Ergodicity of Isothermal Molecular Dynamics Method\textsuperscript{1}, HIROSHI WATANABE, Nagoya University — A condition for equations of motion for isothermal dynamics is derived, and the Nosé–Hoover method is generalized on the basis of this condition. The ergodicity of the one-variable thermostats are studied, and it is shown that the one-variable thermostat coupled with the one-dimensional harmonic oscillator loses its ergodicity with large enough relaxation time. A stochastic process of the Nosé–Hoover method is also discussed based on the Markovian approximation.

10:36AM U19.00014 Statistical Mechanics of the Fluctuating Lattice Boltzmann Equation, BURKHARD DUENWEG, ULF SCHILLER, Max Planck Institute for Polymer Research, Mainz, Germany, ANTHONY J.C. LADD, Chemical Engineering, University of Florida, Gainesville, USA — The statistics of the occupation variables of a stochastic lattice Boltzmann simulation is analyzed in terms of a generalized lattice gas. We show that the most probable state of this model corresponds to the equilibrium distribution of the lattice Boltzmann equation. Stochastic collision rules are described in terms of a Monte Carlo process satisfying detailed balance. This allows a straightforward derivation of the discrete Langevin equation for the fluctuating modes. Detailed balance requires to thermalize all non-conserved modes. A Chapman–Enskog analysis shows that the approach is fully consistent with macroscopic fluctuating hydrodynamics.

Thursday, March 13, 2008 8:00AM - 11:00AM – Session U20 DMP: Focus Session: Metal Surfaces, Interfaces, and Thin Films Morial Convention Center 212

8:00AM U20.00001 Surface islands nucleated by a beam of energetic self-ions on Pt(111): A low-energy electron microscopy study\textsuperscript{1}, MICHAL ONDREJCEK, C. PETER FLYNN, WACEK SWIECH, University of Illinois at Urbana-Champaign — Using low energy electron microscopy (LEEM), we observe the adatom and advacancy islands nucleate and evolve when clean Pt(111), in the temperature range 750-1300K, is bombarded by a beam of Pt\textsuperscript{+} ions of various energies. The source of negative ion beam is incident on the sample at normal incidence with impact energies selectable in the range of 0 to 5 keV, and with current densities up to 40 µA/cm\textsuperscript{2}. We describe briefly initial experiments done with LEEM-ion accelerator tandem namely the investigations of relaxing steps extending the range over which surface mass diffusion coefficient D\textsubscript{a} is

8:12AM U20.00002 The effect of Fe atoms on the adsorption of a W atom on W surfaces, JEFFERY HOUZE, SUNGKYO KIM, SEONG-JIN PARK, RANDALL GERMAN, MARK HORSTEMEYER, SEONG-GON KIM, Mississippi State University — We report ab-initio calculations on the effect of iron (Fe) atoms on the adsorption of a tungsten (W) atom on W(100), W(110), and W(111) surfaces. The adsorption of a W atom on the clean W surfaces is compared with the adsorption of a W atom on a monolayer of Fe atoms covering the W surfaces. The total energy of the system is computed as the function of the height of the W adatom. For the W(100) surface I will show that the W atom first adsorbs onto the Fe monolayer. Then the W atom can replace one of the Fe atoms through a path with a moderate energy barrier and reduce its energy further. This intermediate site makes the adsorption (and desorption) of W atoms a two-step process in the presence of Fe atoms and lowers the overall adsorption energy by nearly 2.4 eV. Similar processes for adsorption will be presented for the (110) and (111) surfaces. Our result provides a fundamental mechanism that can explain the activated sintering of tungsten by Fe atoms.
8:24AM U20.00003 Stability of V and Ti on Al surfaces: Searching for suitable interlayer materials to stabilize the Fe-Al interface. WEERASINGHE PRIYANTHA, HUI CHEN, MICHAEL KOPCZYK, KASEY LUND, DAN TOWN, RICHARD SMITH, Montana State University, Bozeman, MT. PONNUSAMY NACHIMUTHU, VAITHYALINGAM SHUTTHANANDAN, Pacific Northwest National Laboratory, Richland, WA — There is considerable interest in fabricating thin film multilayer structures with sharp interfaces for a wide variety of applications. Interface intermixing may degrade the desired physical properties of a structure, but this may be reduced in some cases using stabilizing interlayers at the interface. Model calculations predict that both V and Ti will be effective stabilizing interlayers for the Fe-Al interface, a system well known for considerable intermixing at room temperature. We have used X-ray reflectometry (XRR) and Rutherford backscattering spectrometry (RBS) to characterize bilayers and trilayers of the Fe-V-Al and Fe-Ti-Al systems prepared using dc magnetron sputtering. Our analysis revealed that Fe-Al bilayer systems showed considerable intermixing, especially when the Fe layer was deposited on top of the Al. It was also found that with V or Ti as an interlayer at the interface, the intermixing of Fe and Al was reduced.

8:36AM U20.00004 Magic planar Ag clusters. Y.P. CHIU, C.M. WEI, C.S. CHANG, TIEN. T. TSONG, DEPARTMENT OF PHYSICS, NATIONAL SUN YAT-SEN UNIVERSITY, KAOSHIUNG, TAIWAN, ROC COLLABORATION, INSTITUTE OF PHYSICS, ACADEMIA SINICA, TAIPEI, TAIWAN, ROC COLLABORATION, INSTITUTE OF ATOMIC AND MOLECULAR SCIENCES, ACADEMIA SINICA, TAIPEI, TAIWAN, ROC COLLABORATION — The spontaneous assembly of atoms and molecules in a system has attracted many research interests and created numerous potential applications. Utilizing the periodic pattern found on the Pb quantum islands, which are grown on the Si(111) surface, we have recently discovered that self-organized Ag planar clusters formed on these templates exhibit enhanced stability at some particular sizes. Detailed calculations based on ab initio density functional theory have also been performed. The use of a density-functional optimization in geometrical structures and the corresponding binding energy support an examination of the genesis of these magic Ag nanoclusters and their relative stability. When the Ag nanopuck grows to a certain size, the geometrical effect takes hold from the electronic effect as the major attribute, which drive the Ag nanopucks towards well defined hexagonal crystalline structures. The theoretically related electronic and geometrical structures are also correlated with the experimentally energetically favorable structures of these magic clusters.

8:48AM U20.00005 Crucial electronic contributions to measures of surface diffusion by He atom scattering. GUIDO FRATESI, ETSF and Dipartimento di Scienza dei Materiali, Università di Milano-Bicocca, Milano, IT. GIL ALEXANDROWICZ, Cavendish Laboratory, University of Cambridge, Cambridge, UK, MARIO ITALO TRIONI, ETSF and CNISM, UdR Milano-Bicocca, Milano, IT, GIAN PAOLO BRIVIO, ETSF, CNISM, and Dipartimento di Scienze dei Materiali, Università di Milano-Bicocca, Milano, IT, WILLIAM ALLISON, Cavendish Laboratory, University of Cambridge, Cambridge, UK — In a He atom scattering (HAS) experiment, the position and motion of atoms or molecules at a surface is inferred indirectly, through the electron distribution at the sample surface. Nevertheless, surface diffusion measurements are typically analyzed assuming that the electron distribution simply follows the position of the surface atoms. We have examined theoretically recent HAS measurements of Na/Cu(001), identifying a non trivial relation between the dynamics of the electron distribution and that of the Na ions. The magnitude of the calculated variations in the charge density, and their dependence on the atomic density of adsorbates, account for the correlated 3D motion experimentally observed. The results of this study further highlight the sensitivity of HAS to the electron distribution of the sample and point out the role of electronic contributions in high-resolution measures of surface dynamics.

9:00AM U20.00006 Sapphire Surface Polymorphs and The Growth of Pb Overlayers. HAWOONG HONG, Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana-Champaign, AARON GRAY, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana-Champaign, T.-C. CHIANG, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois, Urbana-Champaign — The surface structure of sapphire (α-alumina) is an issue of long-standing interest, both scientifically and technologically. Molecular dynamics simulations showed the γ-alumina structure to have a lower energy than that of α-alumina [1], thus suggesting a possibly modified surface structure when sapphire is treated at high temperatures. We have performed x-ray reflectivity measurements at the Advanced Photon Source to address this issue. Standard sapphire substrates were prepared by furnace annealing at 1600° C in air. The resulting surfaces showed large terraces with straight step edges. The substrates were then annealed in a UHV chamber at increasingly higher temperatures. Many new features emerged in the reflectivity curves, which could be attributed to various transition alumina structures, including the δ-, θ-, and θ' polymorphs [2]. Pb films were grown on these surfaces. The resulting structure and morphology was characterized. This talk will summarize our findings. [1] S. Blonski and S. H. Garofalini, Surf. Sci. 295, 263 (1993). [2] I. Levin and D. Brandon, J. Am. Ceram. Soc. 81, 1995 (1998).

9:12AM U20.00007 Molecular dynamics simulations of low temperature Cu/Cu(100) growth. VALERY BOROVIKOV, YUNISC SHIM, JACQUES G. AMAR, University of Toledo — Recent X-ray scattering studies [1] of Cu/Cu(100) growth indicate the existence of a sharp transition from epitaxial growth at high temperatures to growth with a high vacuum concentration at lower temperatures (T < 150 K). Here we present the results of molecular dynamics (MD) simulations carried out in order to understand the detailed mechanisms of incorporation of vacancies and voids (vacancy clusters) into the growing film during low temperature deposition. The dependence of compressive strain, vacancy concentration and vacancy-cluster size distribution in deposited thin film, as well as the surface roughness and morphology on deposition conditions, such as the growth temperature, deposition angle, and incident kinetic energy will be discussed and compared with experiments. [1] C. E. Botez, K. Li, E. D. Lu, W. C. Elliott, P. F. Miceli, E. H. Conrad, and P.W. Stephens, Appl. Phys. Lett. 81, 4718 (2002).

9:24AM U20.00008 Parallel temperature accelerated dynamics simulations of vacancy formation in low temperature Cu/Cu(100) growth. YUNISC SHIM, VALERY BOROVIKOV, JACQUES G. AMAR, University of Toledo, BLAS P. UBERUAGA, ARTHUR F. VOTER, Los Alamos National Laboratory — While molecular dynamics simulations may be used to study thin-film growth at very low temperatures and at very high deposition rates, in order to study growth over time scales close to experiment, accelerated dynamics simulations are needed. Here we present the results of parallel temperature-accelerated dynamics simulations of low-temperature Cu/Cu(100) growth carried out using our recently developed parallel temperature-accelerated dynamics (parTAD) method, in order to understand recent X-ray diffraction experiments showing a surprisingly large vacancy concentration in Cu(100) growth at low temperature. In general, we find that, due to the existence of increased surface relaxation and activated events, the vacancy concentration obtained in our parTAD simulations is smaller than the corresponding concentration obtained in molecular dynamics (MD) simulations. The dependence of compressive strain and vacancy concentration, as well as the surface roughness and morphology, on growth temperature and deposition angle will also be discussed and compared with experiments.
9:36AM U20.00009 Atomic Processes responsible for the diffusion of 2D Cu islands on Ag(111): results from self learning KMC. O. TRUSHIN, Institute of Microelectronics, ASR, Yaroslavl, H. YILDIRIM, A. KARA, T.S. RAHMAN, Department of Physics, University of Central Florida — Diffusion on Ag(111) of small 2D-Cu clusters (4 to 30 atoms) is examined using embedded atom method potentials, as a first step towards understanding hetero epitaxial growth. A combination of an Off-Lattice Self-Learning Kinetic Monte Carlo and spherical repulsion scheme for saddle point searches, has revealed novel diffusion mechanisms. For this size range, the diffusion of islands involves 3 classes of processes: i) collective concerted motion (gliding), found to be dominant for small sized islands (4-9); ii) processes involving shear mechanism in which some of the Cu island atoms are commensurate with the substrate and others are not (≥ 9 atoms), finally iii) processes involving a “breathing” mechanism in which the island “shrinks” as a whole before “relaxing” to a less compact shape with a net displacement of the whole cluster equivalent to an fcc-hcp hop (≥ 12 atoms). These processes were revealed during the first 100 KMC steps for each island. Diffusion coefficients as a function of temperatures, effective diffusion barriers and frequencies of the responsible events will be presented.

9:48AM U20.00010 Semi-coherent Fe(001)/MX(001) interfaces, DAN FORS, GÖRAN WAHNSTRÖM, Chalmers University of Technology — Using ab initio calculations we investigate interface energies and structures for the semi-coherent Fe(001)/MX(001) interface systems. We apply a continuum approach using the Peierls-Nabarro model in order to account for the elastic displacements arising from the lattice mismatch and the periodic misfit dislocations in the interface. The chemical part of the interface energy is obtained by using density functional theory calculations. We find that the Fe/MN systems show decreasing trends along the 3d, 4d and 5d element rows corresponding to stronger bonding to Fe. In contrast the Fe/MC systems show a maximum for the Ti group. The trends and differences have been explored using projected density of states and charge density analysis. The results show a strong covalent bonding between Fe and C(N) when the two atoms are aligned on top of each other, but the hybridization itself can’t account for the differences along the rows. Instead the trend appears to be due to the metallic interaction between the Fe atom and M atom in the interface layer. We also find that the Fe/MX-interfaces have large misfits, which causes that many atoms will be unfavorable positioned and the elastic energy will constitute a significant part of the interface energy.

10:00AM U20.00011 Unstable and metastable states of dynamics governed by surface diffusion, B. DAVIDOVITCH, H. KING, C.D. SANTANGELO, UMass — Under certain kinetic conditions, the dynamics of solid surfaces is governed by surface diffusion processes. This type of dynamics is relevant, for example, in high-temperature sintering processes, and in the coarsening of nanorods metals coated by catalytic elements. For compact surfaces, the fixed points of this dynamics are surfaces of constant mean curvature (CMC). It is thus natural to ask whether there exist nontrivial CMC’s which are stable under dynamics governed by surface diffusion. This question will be addressed in this talk. We will discuss some subtleties concerning an analytic approach to the problem, and will present some numerical results for simple CMC surfaces.

10:12AM U20.00012 Morphology evolution of solid thin films in the presence of long range de-wetting interactions, ADI CONSTANTINESCU, West Virginia University, ARTEM LEVANDOVSKY, University of California Riverside, LEONARDO GOLUBOVIC, West Virginia University — The thin films of metals, such as cobalt or silver on substrates such as sapphire exhibit a striking formation of multilayered islands that reach heights many times larger than the initial film thickness. Here, we theoretically elucidate these phenomena within an interface dynamics model which incorporates both Mullins type surface diffusion relaxation and long range de-wetting forces acting across the film, such as Van der Waals forces and Ferminomial Casimir forces (Quantum size effect). The model is used to explore the scaling laws of multilayered island height growth as well as the coarsening laws governing surface evolution. At early times, the surface evolution is dominated by strong up-hill surface currents caused by long range Casimir-like forces. At late times however, the surface coarsening laws are universal and dominated by surface tension effects.

10:24AM U20.00013 Charge Transfer Model for Dissociative Barrier Formation; A First Principles Study, SHIGEYUKI TAKAGI, HIDEKAZU TOMONO, KAZUO TSUMURAYA, Meiji University — The origin of the formation of the barriers has been explained, for two decades, using Pauli repulsion, i.e., exchange term, by Hammer et al.[1] Excluding the exchange term in the electronic total energy calculation, we have however obtained the monotonic increase of the potential energy surface in the dissociation process of the H₂ molecule on Au(111) system. So we propose another origin for the formation focusing on the charger transfer induced by electronegativity differences between the hydrogen molecule and Au metal surfaces using density functional calculations. We evaluate the charges that belong to atoms in the system during the dissociation process using Bader analysis. The calculated dissociation energy curve along the reaction path coincides with that of the isolated, separated and positively charged hydrogen molecule using the linear combination of the atomic orbital method in real space. No interaction between the hydrogen molecule and the Au surface has been found in the initial stage of the dissociation. The transfer elongates the inter-atomic distance of the hydrogen molecule that raises the energy of the molecule, leading to the formation of the energy barrier in the present case. This charge transfer model is confirmed to be applicable to not only the present system but also H₂/Mg, H₂/Pt, O₂/Pt systems. [1] B. Hammer and J.K. Nørskov, Nature 376, 238 (1995).

10:36AM U20.00014 A Density Functional Study of Atomic Hydrogen and Oxygen Chemisorptions on the (0001) Surface of Double Hexagonal Close Packed Americium, PRATIK DHOLABHAI, RAYMOND ATTA-FYNN, ASOK RAY, The University of Texas at Arlington — Ab initio total energy calculations within the framework of density functional theory have been performed for atomic hydrogen and oxygen chemisorptions on the (0001) surface of double hexagonal packed americium using a full-potential all-electron linearized augmented plane wave plus local orbitals (FLAPW+lo) method. The three-fold hollow hcp site was found to be the most stable site for O adsorption. Chemisorption energies and adsorption geometries for different adsorption sites will be discussed. The change in work functions, magnetic moments, partial charges inside muffin-tins, difference charge density distributions and density of states for the bare Am slab and the Am slab after adsorption of the adatom will be discussed. The implications of chemisorption on Am 5f electron localization-delocalization will also be discussed.

10:48AM U20.00015 Simulations of adsorption of hydrocarbons on decagonal AlNiCo quasicrystal surfaces, WAHYU SETYAWAN, Duke University, RENEE D. DIEHL, MILTON W. COLE, Pennsylvania State University, STEFANO CURTAROLO, Duke University — Classical many-body interatomic potentials for hydrocarbon adsorptions on Al-Ni-Co systems are developed by using the Embedded-Atom Method. The potentials are fit to ab-initio energies of Al-Ni-Co ternary phases and hydrocarbons adsorbed on decagonal surface of Al-Ni-Co (d-AlNiCo) approximants. First principle data show that no dissociation occurs for all systems in the training set, indicating no chemisorptions. We extend the study and use the potentials to simulate adsorption of simple hydrocarbons on d-Al2Ni3Co13 quasicrystal surfaces using Grand Canonical Monte Carlo method. Research sponsored by ACS and NSF.

8:36AM U21.00004 Binary mixture study of CF\textsubscript{4} and CF\textsubscript{3}Cl on graphite\textsuperscript{1}, PETROS THOMAS, DANIEL VELAZQUEZ, GEORGE HESS, University of Virginia — In a binary mixture adsorption study of CF\textsubscript{4} and CF\textsubscript{3}Cl on graphite from 60 K to 105 K, both the CF\textsubscript{3}Cl - ν\textsubscript{as} and the CF\textsubscript{4} - ν\textsubscript{as} frequency shifts are measured using IRAS as the spreading pressure (chemical potential) of CF\textsubscript{4} is increased. Even though CF\textsubscript{4} has a much lower saturation vapor pressure (SVP) compared to CF\textsubscript{3}Cl (at 80 K, SVP of CF\textsubscript{4} is ∼ 70 mT and that of CF\textsubscript{3}Cl is ∼ 0.1 mT), the CF\textsubscript{4} either continuously dissociates or adsorbs on top of CF\textsubscript{3}Cl depending on the initial coverage of CF\textsubscript{3}Cl on the graphite surface. For temperatures between 70 K and 105 K we also lower coverage of CF\textsubscript{3}Cl, where the molecules lie with their C – Cl axis nearly parallel with the surface, the CF\textsubscript{3}Cl continuously displaces CF\textsubscript{4} from the surface. For saturated monolayer coverage of CF\textsubscript{4}Cl, where the C – Cl axis of the molecules is tilted relative to the surface, the CF\textsubscript{4}Cl molecules adsorb on top of the CF\textsubscript{3}Cl – HOPG template. At 60 K, the displacement of the low-coverage CF\textsubscript{3}Cl is only partial and the orientation of the remaining CF\textsubscript{4}Cl is tilted relative to the surface from a nearly flat position.

8:48AM U21.00005 DFT Estimation of Lateral Interactions in Lattice-gas Models of Br and Cl on Ag(100)\textsuperscript{1}, T. JUWONO, P.A. RIKVOLD, Florida State University — We studied Br and Cl chemisorbed on a Ag(100) surface, using a lattice-gas model and the Density Functional Theory (DFT) method. In this model the Br and Cl ions adsorb at the fourfold hollow sites of the Ag(100) surface, which yields a square lattice of adsorption sites. Five different coverages for each kind of adsorbate were calculated. For each adsorbate and coverage, we obtained the minimum-energy configuration, its energy, and its charge distribution. From these data we calculated dipole moments, lateral interaction energies, and binding energies. Our results showed that for Br the lattice-gas model obtained by fitting to the adsorption energies from the DFT calculation is consistent with long-range dipole-dipole lateral interactions using the dipole moments calculated from DFT charge distribution. For Cl we found less consistency, which indicates that long-range dipole-dipole interactions are not sufficient to describe the Chlorine system.

9:24AM U21.00008 Dissipation at Moving Contact Lines: Effect of Interface Width and Slip

MARK ROBBINS, SHENGFENG CHENG, Johns Hopkins University, COLIN DENNISTON, University of Western Ontario — Continuum mechanics predicts a diverging stress and total dissipation when the contact line between a fluid interface and a solid substrate is advanced. Several models for removing this divergence have been advanced. One is that the divergence is cutoff by a finite slip length. Another is that diffusion can remove the singularity for fluid interfaces of finite width. Extensive molecular dynamics simulations of partially miscible binary fluids were used to test these two pictures. The interfacial tension was changed by a factor of 20 and the interfacial width by an order of magnitude. The interface width had no direct effect on the dissipation and diffusion was orthogonal to the predicted direction. The dissipation only depended on system size, the dimensionless capillary number, and the slip length $S$ associated with the flow boundary condition in the fluid far from the contact line. The divergence in stress is cut off at the sum of $S$ and a distance of order the molecular diameter. The dissipation rises rapidly as the amount of slip is decreased. In all cases there is a first order transition where the advancing contact line becomes unstable and a film is entrained.

9:36AM U21.00009 Counterintuitive connection between layering and mobility in confined fluids

GAURAV GOEL, WILLIAM KREKELBERG, University of Texas at Austin, JEFFREY ERRINGTON, State University of New York at Buffalo, THOMAS TRUSKETT, University of Texas at Austin — Fluids confined to narrow spaces adopt a spatially inhomogeneous distribution of density due to the interactions between the fluid particles and the boundaries. This “density profile” is the most common measure of inhomogeneous structure in confined fluids, but its connection to fluid transport coefficients is poorly understood. We explore via molecular simulations how tuning particle-wall interactions to flatten or enhance the particle layering of a model Weeks-Chandler-Andersen (WCA) confined fluid impacts its self-diffusivity, viscosity, and entropy. Counterintuitively, interactions that eliminate particle layering significantly reduce confined fluid mobility, while those that enhance layering have the opposite effect. Excess entropy helps to both understand and predict these trends.

9:48AM U21.00010 Effective interfacial tension between miscible fluids

JOHN POJMAN, The University of Southern Mississippi, NICK BESSONOVI, Institute of Problems of Mechanical Engineering, GLORIA VINER, The University of Southern Mississippi, VITALY VOLPERT, Université Lyon I — Isobutyric acid (IBA) and water have an Upper Critical Solution Temperature of 27 Celsius. Using spinning drop tensiometry, we were able to demonstrate the existence of an effective interfacial tension by preparing a drop of isobutyric acid-rich phase below the UCST and then raising the temperature above the UCST. The capillary instability was also observed by rapidly reducing the rotation rate. We also demonstrated that such an effective interfacial tension is not unique to the IBA-water systems but can also occur in the cyclohexane – aniline, which has a Lower Critical Solution Temperature.
Driving proteins and DNA with mechanical forces: Pushing, pulling, and squeezing molecules using computer simulations.\textsuperscript{1} \textsuperscript{1}NSF, Welch Foundation

Fluorescent resonant energy transfer: Correlated fluctuations of donor and acceptor\textsuperscript{2}. ZHI-GANG YU, SRI International — Mounting evidence suggests that in single-molecule fluorescent resonant energy transfer (FRET) measurements, correlation between fluctuations in donor and acceptor may be important. We present a general theory to describe this correlation and its effect on the FRET rate\textsuperscript{1}. The correlation arises from low-energy excitations (e.g. acoustic phonons) of the molecule to which a donor-acceptor pair is attached, and results in an effective interaction between local environments or baths associated with the donor and the acceptor. The correlation is found to reduce the transfer rate, in particular at short donor-acceptor distances. The theory can quantitatively explain recent measurements of polyproline peptides.\textsuperscript{1} Z. G. Yu, J. Chem. Phys. 27, 20xxxx (Communications) (2007).

The water effects on long-distance charge transfer in polypeptides. NIKOLAISERGUEEV, ALEXANDERDEMKOV, The University of Texas at Austin — Long-range electron transfer (ET) is one of the most intriguing reactions occurring in biological systems. Recent experiments indicate that water play an important role in the mechanism of charge transfer in proteins. In this talk we present the first-principles study of the effect of intervening water molecules on the electron tunneling processes in simple polypeptide bridges. The ET rate is related to the probability current flow which is computed using density functional theory and nonequilibrium Green’s function formalism which takes into account the inelastic electron-phonon scattering in the bridge. Our results suggest that the effect of water is two fold. First, the insertion of water molecules changes the conformational probability current that is computed using density functional theory and nonequilibrium Green’s function formalism which takes into account the inelastic electron-phonon scattering in the bridge. Our results suggest that the effect of water is two fold. First, the insertion of water molecules changes the conformational

In\textsubscript{2}O\textsubscript{3} nanowire based field effect transistor for biological sensors. ZHONGMINGZENG, KAIWANG, WEILIEZHOU, Advanced Materials Research Institute, University of New Orleans, New Orleans, LA 70148 — Semiconductor nanowires (NWs) are attracting considerable attention due to their nanoscale dimensions and enormous surface-to-volume ratios. Many applications have been demonstrated in toxic gas, protein, small molecule and viruses sensing because of their superior sensing performances. Indium oxide (In\textsubscript{2}O\textsubscript{3}) NWs are working as n-type channel with obvious back-gate effect, which is much stronger than the reported results. The nanodevices used as virus detection will be also discussed.

Messenger RNA sequence and the translation process—a particle transport perspective\textsuperscript{1}. JIAJIA DONG, BEATE SCHMITTMANN, ROYCEK.P. ZIA, Virginia Tech — The translation process in bacteria has been under intensive study. A key question concerns the quantitative effect of different elongation rates, associated with different codons, on the overall translation efficiency. Starting with a simple particle transport model, the totally asymmetric simple exclusion process (TASEP), we incorporate the essential components of the translation process: Ribosomes, cognate tRNA concentrations, and messenger RNA (mRNA) templates correspond to particles, hopping rates, and the underlying lattice, respectively. Using simulations and mean-field approximations to obtain the stationary currents (the protein production rates) associated with different mRNA sequences, we are especially interested in the effect of slow codons, i.e., codons which are associated with rare tRNAs and are therefore translated very slowly. As a first step, we look at a “designed sequence” with one and two slow codons and quantify the marked impact of their spatial distribution to the currents. Extending the results to several mRNA sequences taken from real genes, we argue that an effective translation rate including the information from the vicinity of each codon needs to be taken into consideration when seeking an efficient strategy to optimize the protein production.

Sticky-sphere model for phase separation of mixtures of the eye lens proteins gamma-B and alpha crystallin: non-monotonic dependence on mutual attraction. GEORGETHURSTON, MAURINOBAUTISTA, DAVIDROSS, VERNLINDBERG, HOSSEINSHAHMOHAMAD, Rochester Institute of Technology — We apply a multi-component extension of the Baxter sticky-sphere model to aqueous solutions of the eye lens proteins gamma-B crystallin and alpha crystallin. These mixtures show liquid-liquid phase separation induced by gamma-B/gamma-B attraction, gamma-B/alpha size disparity and gamma-B/alpha attraction. We examine the dependence of the upper-critical spinodal temperature surface on gamma-B/alpha attraction, previously found to influence stability. Gamma-B crystallin is modeled with a temperature-dependent stickiness parameter that reproduces both static light scattering and small-angle neutron scattering near its critical point. Alpha crystallin is modeled as a hard sphere. We find that the Barbo-Teene model shows a non-monotonic dependence of the spinodal temperature surface on gamma-B/alpha attraction that is qualitatively consistent with recent molecular dynamics simulation results. Hard-sphere or very attractive gamma-B/alpha interactions lead to instability, and the spinodal surface shows a minimum in an intermediate range of gamma-B/alpha attraction strength. We examine the nature of the two types of instability.
9:36AM U22.00007 Structural Isotopic Effects in the smallest chiral amino acid: Observation of a structural phase transition in fully deuterated alanine. HELIOISA BORDALLO1, HMI, JOELMA DE SOUZA, PAULO DE TARSO, Universidade Federal do Ceará, DIMITRI ARGYRIOU, HMI — A first study of possible changes instigated by deuteration in amino acids was carried out using neutron diffraction, inelastic neutron scattering and Raman scattering in L-alanine, C\textsubscript{2}H\textsubscript{4}(NH\textsubscript{2})COOH. Careful analysis of the structural parameters shows that deuteration of L-alanine engenders significant geometric changes as a function of temperature, which can be directly related to the observation of new lattice vibration modes in the Raman spectra. The combination of the experimental results suggests that C\textsubscript{2}D\textsubscript{4}(ND\textsubscript{2})COOD undergoes a structural phase transition (or a structural rearrangement) at about 170 K. Considering that this particular amino acid is a hydrogen-bonded system with short hydrogen bonds (O...H \sim 1.8 Å), we evoke the Ubbelohde effect to conclude that substitution of hydrogen for deuterium gives rise to changes in the hydrogen-bonding interactions. The structural differences suggest distinct relative stabilities for the hydrogenous and deuterated L-alanine. De Souza et al. - Journal of Physical Chemistry B (Letters) 111, 5034-39 (2007)

9:48AM U22.00008 Exploring the Electrical Conductivity of Myoglobin\textsuperscript{1}. DEBIN LI, DAVID LEDERMAN, Dept of Physics, West Virginia University, PETER M. GANNETT, Basic Pharmaceutical Sciences, West Virginia University — The electrical conductance of single myoglobin proteins was measured to study its electron transfer properties. We examined the electronic properties of myoglobin, using apomyoglobin (myoglobin without a heme group) as a reference. The differential conductivity of the proteins deposited on Pt nanometer-scale electrodes was measured using a lock-in technique as a function of bias and gate voltages. Nano- electrodes were fabricated by creating small Pt channels 100 nm - 300 nm wide via e-beam lithography and then creating a break junction by electromigration at low temperatures (4 K - 77 K). The conductance of apomyoglobin was very different from that of myoglobin, with a predominant peak at 50 meV. On the other hand, myoglobin had a rich structure that we surmise results from the presence of the heme group.

10:00AM U22.00009 Selective binding affinity of cationic antimicrobial peptides for lipid membranes: roles of peptide charge and hydrophobicity\textsuperscript{1}. SATTAR TAHERI-ARAGHI, BAE-YEUN HA, Department of Physics and Astronomy, University of Waterloo, Ontario N2L 3G1, Canada — Antimicrobial peptides selectively disrupt microbial membranes through hydrophobic insertion into the outer layers, which are known to carry a large fraction of anionic lipids. When the peptides are cationic, as is often the case, the interplay between hydrophobic and electrostatic interactions determines the selective binding affinity (thus antimicrobial activity) of the peptides. Here we present a detailed theoretical picture of how the selective binding is influenced by such factors as the charge and hydrophobicity of the peptides and the elasticity of target membranes. This effort not only accounts for some of the general trends observed in experimental studies, but it also leads to a theoretical model for optimizing the selectivity and antimicrobial activity.

10:12AM U22.00010 Excitation dynamics in purple bacteria photosynthetic membranes under different light adaptation conditions . FELIPE CAYCEDO, FERNEY RODRIGUEZ, LUIS QUIROGA, Universidad de los Andes — Photosynthetic membranes in \textit{R. Sphaeroides} purple bacteria adapt to light growth conditions such as the intensity level of radiation, which determine their amount of Reaction Centers (RCs), and also their global architecture. In any case, for both high and low intensity conditions the trend for core (LH1) and outer (LH2) complexes clustering is maintained. Using a Förster hopping model for excitation transfer, we analyze different adapted membranes for which we report results for the yield and lifetime of excitations under continuous illumination levels. We show that complexes stoichiometry obey to efficiency optimization amount of Reaction Centers (RCs), and also their global architecture. In any case, for both high and low intensity conditions the trend for core (LH1) and outer (LH2) complexes clustering is maintained. Using a Förster hopping model for excitation transfer, we analyze different adapted membranes for which we report results for the yield and lifetime of excitations under continuous illumination levels. We show that complexes stoichiometry obey to efficiency optimization

10:24AM U22.00011 Microscopic Electrohydrodynamics of DNA electrophoresis\textsuperscript{1}. ALEKSEI AKSENTIEV, BINQUAN LUAN, Department of Physics, University of Illinois at Urbana-Champaign — Gel electrophoresis is currently the most successful yet costly method to sequence DNA. Electrophoresis of DNA through solid-state nanopores holds promise for reducing the costs and making personal genomics a reality. The underlying physics of DNA electrophoresis, however, remains controversial. Theoretical models of this process often invoke the notion of the effective charge of a DNA molecule \(q_{\text{eff}}\) to account for the reduced electric force on DNA in an external field \(E\), i.e. \(F = q_{\text{eff}}E\). However, experimental estimates of \(q_{\text{eff}}\) can differ from each other by as much as ten times. To clarify the physical origin of the reduction of an electric force on DNA in electrophoresis, we investigated this process through extensive all-atom molecular dynamics simulations. Our results demonstrate that the effective screening of the DNA charge arises from the hydrodynamic drag of the electroosmotic flow, not from the counterion condensation. We show that the effective driving force \(F\) of an applied electric field \(E\) in a nanopore obeys the same law as in a bulk electrolyte: \(F = \xi \mu E\). Here, \(\xi\) and \(\mu\) are, respectively, the friction coefficient and electrophoretic mobility of DNA that depend on the surface properties of a nanopore, such as its roughness. Based on the above law, a method for determining the effective driving force is suggested that does not require a direct force measurement.

10:36AM U22.00012 Multivalent counterions inhibit DNA ejection from viral capsid . TOAN NGUYEN — Viral DNA packaged inside a bacteriophage is tightly bent. This stored bending energy of DNA is believed to be the main driving force to eject viral DNA into host cell upon capsid binding. One can control the amount of ejected DNA by subjecting the virus to a solution of PEG8000 molecules. The molecules cannot penetrate the viral capsid, therefore, they exert an osmotic pressure on the virus preventing DNA ejection. Experiments showed that for a given osmotic pressure, the degree of ejection also depends on the concentration of small ions in solution. Interestingly, for multivalent ions (such as Mg\textsuperscript{2+}, Spd3+ or HexCo3+), this dependence is non-monotonic. We propose a simple electrostatic theory to explain this non-monotonic behavior. This is based on the fact that DNA molecules can invert their net charge at high enough multivalent counterion concentration. In other words, as multivalent counterion concentration is increased from zero, charge of DNA molecules change from negative to positive. At the concentration where DNA net charge is zero, the DNA molecules experience an attraction between different segments and DNA ejected amount is reduced. At low or high counterion concentration, DNA segments are charged (negatively or positively), repel each other and DNA ejected amount is increased. Fitting the result of the theory to experimental data, we obtain a numerical value for Mg\textsuperscript{2+} mediated DNA - DNA attraction energy to be \(-0.008\text{kJ} \text{per base}\).

Thursday, March 13, 2008 8:00AM - 10:48AM – Session U23 DMP GMAG: Focus Session: Manganite Thin Films Morial Convention Center 215
8:00AM U23.00001 Thickness dependence of the exchange bias in epitaxial manganite bilayers*, ALEXEY KOBRINSKII. University of Minnesota, MARIA VARELA, Oak Ridge National Laboratory, ALLEN GOLDMAN, University of Minnesota, U OF MN OXIDE MBE TEAM, OAK RIDGE NATL LAB COLLABORATION — A series of thin ferromagnetic/antiferromagnetic (F/AF) bilayers of doped lanthanum manganites La$_2$/3Ca$_1$/3MnO$_3$ (F) and La$_1$/3Ca$_2$/3MnO$_3$ (AF) have been grown by ozone-assisted molecular beam epitaxy (OAMBE). The lattice of the substrate material (001) SrTiO$_3$ is a good match to that of the manganites. Growth by the OAMBE method results in samples with sharp interfaces, which are suitable systems to study the interfacial phenomenon of exchange bias (EB). We present present EB as a function of the AF layer thickness and determined two critical values of the thickness for the onset and for the saturation of the hysteresis loop shift which is traditionally used to measure the effect. The observed dependence of EB on the AF layer thickness can be described within the original or generalized Meiklejohn-Bean model. Using this simple approach we have estimated the interfacial coupling energy and the antiferromagnetic anisotropy constant.

*This work was supported by the NSF through the University of Minnesota MRSEC under Grant NSF/DMR-0212032.

8:12AM U23.00002 Infrared studies of Phase Separated (La$_{1-x}$Pr$_x$)$_{0.67}$Ca$_{0.33}$MnO$_3$ Thin Films*, NAVEEN MARGANKUNTE, TARA DHAKAL, AMLAN BISWAS, D.B. TANNER, Dept of Physics, University of Florida — We report optical spectroscopy studies of phase separated (La$_{1-x}$Pr$_x$)$_{0.67}$Ca$_{0.33}$MnO$_3$ thin films grown on the substrate NdGaO$_3$. Reflectance measurements in the far and mid infrared were performed for a range of temperatures from 10 to 300 K. Particular attention was given to the narrow temperature range where the insulator-metal transition occurs. The optical constants were extracted by fitting the measured reflectance to a Drude-Lorentz dielectric function in conjunction with thin film optics and the measured properties of the substrate. Spectral weight analyzes show that the growth of low energy oscillator strength occurs well above the Curie temperature, indicating phase coexistence in the hysteresis regime seen in resistivity measurements. The optical conductivity results are contrasted with existing models for free carrier electrodynamics in manganites.

8:24AM U23.00003 Anisotropic Magnetoresistance in (La,Pr)$_{0.67}$Ca$_{0.33}$MnO$_3$ Films, MEGUMI YAMAMOTO, CHUHEE KWON, California State University Long Beach, ANTHONY DAVIDSON, SANJAY ADHIKARI, RAJESWARI KOLAGANI, Towson University — The out-of-plane anisotropic magnetoresistance (AMR) was measured in mixed phase manganite (La,Pr)$_{0.67}$Ca$_{0.33}$MnO$_3$ (LPCMO) films. Two samples with different film thicknesses (~30 nm and ~150 nm) on LaAlO$_3$ substrate were compared for the effects of stress on AMR. The thicker sample exhibits an insulator-metal resistive transition with a hysteresis typical of LPCMO with the peak temperature of 175 K and 250 K at H = 0 T and 8 T, respectively. While the resistance of the thinner sample is too high for our system to measure (Quantum Design PPMS) below 140 K at H = 0 T, the peak temperature at 8 T is 105 K. AMR shows a sinusoidal angular dependence typical of a ferromagnet for both samples. In this talk, we will present systematic AMR measurements of the LPCMO samples. We found that the peak position of AMR depends both on film thickness and on temperature. In addition, we observed time-dependent changes in resistance at lower temperatures indicating a long relaxation time for spins.

8:36AM U23.00004 Interface magnetism in complex oxide heterostructures*, HARIRAN SRIKANTH, University of South Florida — Magnetic oxides are an important class of materials from the perspectives of fundamental physics and technological applications. Advances in growth of high quality thin films and epitaxial oxide heterostructures over the years, have led to the realization of ideal condensed matter systems in which the complex and rich physics associated with cooperative phenomena can be explored. Examples of coupled phenomena in heterostructures include exchange bias effects, magneto-electric coupling and interplay between magnetism and superconductivity. In this talk, I will focus on three classes of oxide heterostructures – PLD-grown M-type barium hexaferrite (BaM)/barium strontium titanate (BST), CVD-grown CrO$_2$/CrO$_3$ bilayers and high-pressure sputtered LCMO/YBCO films. The common theme is the magnetic coupling across the interfaces. I will demonstrate that dynamic susceptibility and kinetic inductance experiments using a sensitive tunnel-diode oscillator (TDO) are effective probes of such coupled effects. In the case of CrO$_2$/CrO$_3$ and LCMO/YBCO, the interface coupling results in anomalous anisotropy, exchange bias in the former and complex interaction between the LCMO magnetism and YBCO vortex lattice in the latter. In BaM/BST heterostructures, I will discuss how interfacial coupling influences the microwave response that is both electrically and magnetically tunable.

9:12AM U23.00005 Atomic resolution STM study of Perovskite Manganite Thin Films, KENNJI FUCHIGAMI, University of Tennessee, ORNL and IHI Co. Ltd., Japan, ZHENG GAI, ORNL, ZHENGMING YIN, ORNL, E. WARD PLUMMER, University of Tennessee and ORNL, LIFENG YIN, ORNL, E. WARD PLUMMER, University of Tennessee and ORNL, JIAN SHEN, ORNL and University of Tennessee — The perovskite manganites have attracted huge interest due to their intriguing electronic inhomogeneous nature which is believed to be responsible for colossal magnetoresistance. Scanning tunneling microscope (STM) is one of the most promising techniques for studying such electronic inhomogeneity in real space. In order to investigate electronic property at the surface of non-layered perovskite manganite, we have synthesized single crystal La$_{5/8}$Ca$_{3/8}$MnO$_3$ (LCMO) thin film by laser MBE technique. In-situ thin film growth enables us to obtain atomically resolved STM image which has c-2x2 superlattice unit cell. In this talk, we will discuss the electronic properties as well as lattice structures of the LCMO surfaces. This research is sponsored by the Laboratory Directed Research and Development Program of Oak Ridge National Laboratory (ORNL), managed by UT-Battelle, LLC for the US Department of Energy under Contract No. DEAC05-00OR22725.

9:24AM U23.00006 Linear Crack Arrays and Resistive Anisotropy in Nd$_{0.2}$Sr$_{0.8}$MnO$_3$ Thin Films Under Tensile Strain*, KRISHNA NEUPANE, JOSHUA COHN. University of Miami, JOHN NEUMEIER, Montana State University — The structure, morphology, and electrical properties of epitaxial c-axis oriented thin films of Nd$_{0.2}$Sr$_{0.8}$MnO$_3$ are reported for thicknesses 10 < t < 150 nm. Films with t ≥ 20 nm grown under tensile stress on NdGaO$_3$ (100) and LSAT (110) substrates develop uniform linear crack arrays (cracks running along film c axis) with a crack spacing (0.3-10 μm) that decreases with increasing thickness. Films grown under compression on LaAlO$_3$(110) substrates exhibit no cracks. The room-temperature in-plane electrical resistance ratio, ρc/ρa, increases approximately exponentially with increasing film thickness to values of ~1000 in the thickest films studied. The temperature dependencies for ρc and ρa are approximately identical, suggesting that very long effective transport paths perpendicular to the cracks are responsible for enhanced values of ρc.

* This material is based upon work supported by the National Science Foundation under grants DMR-0072276 (Univ. Miami) and DMR-0504769 (Montana State Univ.), the Research Corporation (Univ. Miami), and the U.S. DOE Office of Basic Energy Sciences (Grant No. DE-FG-06ER46269).
9:36AM U23.00007 Effect of strain and disorder in manganite thin films, SUNG HEE YUN, RAJIV MISRA, BEN DEGLEE, JACOB TOSADO, TARA DHAKAL, ARTHUR HEBARD, AMLAN BISWAS. Department of Physics, University of Florida — We have studied the effect of strain and disorder on the phase separated state in thin films of the manganite (La_{1-x}Pr_{x}0.67Ca_{0.33}MnO_3 (LPCMO), y = 0.4, 0.5, 0.6) grown on (110) NdGaO_3 substrates using pulsed laser deposition. Due to the competition between the charge-ordered insulating and ferromagnetic metallic phases, thin films of LPCMO display a fluid-like phase separation (FPS) near the insulator-to-metal transition temperature. By applying direct mechanical stress on the LPCMO thin films using a three-point beam bending technique, we observed a colossal piezoresistance in the FPS state of these materials. Our observations show that a small amount of strain (~10^{-3}) can move the phase boundaries in the FPS state. We then modified the extrinsic disorder in the thin films by bombarding them with Ar-ions. Our measurements show a reduction of piezoresistance in the ion-bombarded samples which suggests that such extrinsic disorder can pin the phase boundaries and reduce the fluidity of the FPS state.

9:48AM U23.00008 Low Temperature Magneto-transport Measurements on Multilayered Manganese Films1, J. M. SPENCER, P. BHUPATHI, S. H. YUN, A. BISWAS, Y. LEE. Department of Physics, University of Florida, Gainesville, FL 32611-8440 — We have performed out-of-plane resistance measurements on a micro-fabricated multilayered manganite thin film structure down to 50 mK. The structure is composed of a 26 nm thick (La_{0.67}Pr_{0.33}Ca_{0.33}MnO_3 (LPCMO) film on top of a 60 nm thick (La_{0.67}Ca_{0.33}MnO_3) (LCMO) layer grown on an (110) NdGaO_3 (NGO) substrate. Two gold electrodes were deposited on the LPCMO layer and the exposed LCMO layer was then etched by ion plasma etching technique. We observed an upturn in resistance below 30 K for various current excitations ranging from 0.2 to 100 µA. Based on the electric and magnetic field dependence of the resistance, we attribute the upturn to the disorder-induced static phase separation of the LPCMO thin film at low temperature.

10:00AM U23.00009 The influence of growth temperature on the physical properties of La1-xSrxMnO3 thin film by rf magnetron sputtering, YONHANG PEI, JIWEI LU, STUART WOLF — Perovskite La_{1-x}Sr_{x}MnO_{3} has been of interest for such diverse applications as a spin injector for spintronic devices and for fuel cell electrodes due to its magnetic and transport properties, namely high spin polarization and ionic conduction. In this work, we prepared La_{1-x}Sr_{x}MnO_{3} thin films by rf-magnetron sputtering. LSMO films were deposited on single crystal SrTiO_{3} (100) substrates and platinized Si wafers concurrently in the temperature range from 450 to 600 °C. X-Ray diffraction (XRD) determined that the LSMO film was epitaxial on either substrate. Magnetic hysteresis loops were measured at temperatures between 10 and 300K and the saturation moment was significantly improved by increasing the growth temperature. In addition, the Curie temperature of LSMO was between 150 and 250 K and was also strongly dependent on the growth temperature. We will also discuss the impact of growth temperature on the temperature dependent transport and magnetic properties of LSMO.

10:12AM U23.00010 Current-induced and Photoinduced Effects in Annealed Bi1−xCa0.5MnO3 Thin Films1, VERA SMOLYANINOVA, K. KARKI, RAJESWARI KOLAGANI, G. YONG, R. KENNEDY. Towson University — Doped rare-earth manganese oxides exhibit a wide variety of physical phenomena. Application of magnetic field, electric field, or electromagnetic wave irradiation drastically modifies electrical conductivity and refraction index of these materials. A photoinduced and current-induced insulator to metal transition in charge-ordered (CO) manganese oxides is especially interesting from the point of view of photonic and opto-electronic device development. We have found that 50 nm Bi_{0.4}Ca_{0.6}MnO_{3} thin film grown on NdCaAlO_{4} substrate is very susceptible to increase of current and illumination with laser light (λ ~ 500 nm) [1]. Application of these stimuli partially destroys CO and produces charge-disordered conductive phase. Combined application of illumination and current completely destroys the charge ordering in this material, while the application of one of these factors separately is not sufficient to produce such effect. Current-induced and photoinduced properties of the Bi_{0.4}Ca_{0.6}MnO_{3} thin films grown on different substrates will also be presented and current-voltage characteristics will be discussed. 10:24AM U23.00011 Enhancement of Photoinduced Effects in Annealed Bi1−xCa0.5MnO3 Thin Films, K. KARKI, RAJESWARI KOLAGANI, G. YONG, R. KENNEDY, K. DEMARCHI, VERA SMOLYANINOVA, Towson University — Doped rare-earth manganese oxides (manganites) exhibit a rich variety of interesting physical phenomena including their sensitivity to application of magnetic, electric fields, and electromagnetic wave irradiation. A photoinduced insulator to conductor transition in charge-ordered (CO) manganites is especially interesting from the point of view of creating photonic devices. Thin films of Bi_{0.4}Ca_{0.6}MnO_{3} exhibit large photoinduced effects associated with melting of the charge ordering by visible light and can support conducting and insulating phase coexistence on a submicron scale [1]. We have found significant increase of the photoinduced resistivity changes and the life time of the photoinduced conducting phase after annealing. The changes in current-induced effects in annealed films will be also reported, and the possible origin of these effects will be discussed. [1] V. N. Smolyaninova at al., Phys. Rev. B 76, 104423 (2007).

10:36AM U23.00012 Insulating Domain Walls in Mixed Phase Manganite, GUNEETA SINGH BHALLA, S. SELCUK, T. DHAKAL, A. BISWAS, A.F. HEBARD. — We present here evidence of novel insulating domain walls (IDWs) which allow direct tunneling of spin polarized currents in thin films of the mixed phase ferromagnet (La_{0.4}Pr_{0.6}Ca_{0.3}MnO_{3}). Elastic interactions in the distorted perovskite structure of (La_{0.4}Pr_{0.6}Ca_{0.3})MnO_{3} coupled with magnetostatic interactions give rise to coexisting ferromagnetic metallic and insulating regions near the Curie temperature, T_{C}. Well below T_{C}, magnetization measurements reveal that the mixed phase metal/insulator state evolves into a fully saturated ferromagnetic metallic state. However, when either the film thickness is reduced, or a thicker film is patterned into a nanometer wide bridge structure, the formation of domain structure is modified as theoretically predicted for mixed phase ferromagnets, resulting in thin IDWs separating adjacent half-metallic domains. Experimentally we observe that upon cooling below T_{C}, a predominantly ferromagnetic supercooled state persists where remnants of the insulating regions behave as IDWs within the bridge. Tunneling across IDWs results in metastable, temperature-independent, high-resistance plateaus over a large range of temperatures below T_{C}. Upon application of fields on the order of the coercive field, neighboring domains align and the IDWs are extinguished resulting in sharp, collosal resistance drops. The presence of IDWs offers rich physical insights into ferromagnetic domain formation in mixed phase systems.

Thursday, March 13, 2008 8:00AM - 10:48AM — Session U24:DMP: Focus Session: Transport in Nanostructures VI: Nonequilibrium Phenomena and Noise. Morial Convention Center 216
8:00AM U24.00001 Imaging hot-electron transport using chemical reactions on metal surfaces

PETRO MAKSYMOWICH, Oak Ridge National Laboratory — We have investigated a new regime of single-molecule excitation in the scanning tunneling microscope, where hot electrons locally injected from the STM tip spread out via surface resonances over length scales of up to 100 nm and electronically excite surrounding molecules causing chemical reactions. Such non-local reactions were observed for several different molecules on the (111), (110) and (100) terminated surfaces of gold and copper. The hot-electron origin of these reactions was differentiated from the possible electric field effect in the tip-surface junction on the basis of the statistical analysis of the dissociation yield as well as the non-local excitation in the presence of artificially fabricated nanoclusters. One of the new opportunities provided by the non-local excitation is a direct measurement of hot-electron transport on a metal surface. Using a phenomenological kinetic model for the statistical analysis of the non-local reactions, it is shown that the reaction rate increases linearly with tunneling current and decays exponentially with the distance from the excitation pulse. Since the attenuation length of the non-local reaction has little dependence on the STM-tip and the parameters of the excitation, we argue that it is proportional to the inelastic mean-free path of hot-electrons in the surface resonance. The angular distribution of the reaction events is isotropic on Au(111), which is consistent with the symmetry of its surface resonances in the energy range of the non-local reaction. It is also shown that the total yield of the non-local reaction provides a measure of hot-electron transport across single-atom steps. Although the reflectance of the hot-electrons by single atom steps on Au(111) is less than 20% at energies above 1.5 V, the yield of the reaction becomes surprisingly asymmetric if hot-electrons are injected in the immediate vicinity of the step.

8:36AM U24.00002 Electromigration force, surface resistivity and low-frequency noise

ALEXANDER ABANOV, Stony Brook University, DMITRI IVANOV, Ecole Polytechnique Fédérale de Lausanne — We derive constraints on the statistics of the charge transfer between two conductors in the model of arbitrary time-dependent instant scattering of non-interacting fermions. ALEXANDER ABANOV, Stony Brook University, DMITRI IVANOV, Ecole Polytechnique Fédérale de Lausanne — Scattering of charge carriers from surface structures will become an increasing factor in the resistivity as the structure decreases in size to the nanoscale. The measured effects of scattering at the most basic surface defect, a kink in a step edge, are 5x larger than for a freely diffusing surface atom. For thermally active materials, this yields a corresponding contribution of the fluctuating steps to the surface resistivity, which will exceed 1% of the bulk resistivity as wire diameters decrease below 10s of nanometers. The temporal fluctuations of kink density will cause resistivity noise. Relating the known fluctuation spectrum of the step displacements to fluctuations in their lengths, the corresponding resistivity noise is predicted to show spectral signatures of $\sim f^{-1/2}$ for step fluctuations governed by random attachment/detachment, and $\sim f^{-3/4}$ for step fluctuations governed by step-edge diffusion.

9:00AM U24.00004 Frequency-dependent counting statistics in interacting nanoscale conductors

RAMON AGUADO, DAVID MARCOS, CSIC, CLIVE EMARY, TOBIAS BRANDES, TU Berlin — Following the considerable success of shot-noise in the understanding of transport through mesoscopic systems, attention is now turning towards the higher-order statistics of electron current. The so-called Full Counting Statistics (FCS) of electron transport yields all moments (or cumulants) of the probability distribution $P(n,t)$ of the number of transferred electrons during time $t$. The theory of FCS is now well established in the zero-frequency limit. However, this is by no means the full picture, since the higher-order current correlators at finite frequencies contain much more information than their zero-frequency counterparts. In this work [1], we present a formalism to calculate finite-frequency current correlations in interacting nanoscopic conductors. We work within the n-resolved density matrix approach and obtain a multi-time cumulant generating function that provides the fluctuation statistics solely from the spectral decomposition of the Liouvillian. We apply the method to the frequency-dependent third cumulant of the current through a single resonant level and through a double quantum dot. Our results, which show that deviations from Poissonian behaviour strongly depend on frequency, demonstrate the importance of finite-frequency higher-order cumulants in fully characterizing transport.

9:12AM U24.00005 ABSTRACT WITHDRAWN

9:24AM U24.00006 Nonequilibrium elastic quantum transport using plane waves

ARAN GARCIA-LEKUE, Donostia International Physics Center (DIPC), Donostia, Spain, LIN-WANG WANG, Lawrence Berkeley National Laboratory (LBNL), Berkeley, USA — In this work, we present an ab initio nonequilibrium electronic structure method for modeling the elastic electron transport through a nanostructure coupled to semi-infinite external electrodes and with an applied bias voltage. Our method is based on the scheme presented in Ref. [1], where the coherent quantum transport is calculated by means of the exact scattering states of the system obtained using plane waves and for zero applied bias voltage. In the case of a finite bias voltage, the electronic system is in a nonequilibrium situation, and the problem needs to be solved self-consistently. Here, we present an approach to obtain the self-consistent charge density and potential of the system, which are then employed in the calculation of the nonequilibrium transmission coefficient and conductance. As an illustration, results for a model system made up of a di-thiol-benzene (DBT) molecule connected by two Cu wires are provided. [1] A. García-Lekue and L.W. Wang, Phys. Rev. B, 74, 245404 (2006).

9:36AM U24.00007 Allowed charge transfers between coherent conductors driven by a time-dependent scatterer

ALEXANDER ABANOV, Stony Brook University, DMITRI IVANOV, Ecole Polytechnique Fédérale de Lausanne — We derive constraints on the statistics of the charge transfer between two conductors in the model of arbitrary time-dependent instant scattering of non-interacting fermions at zero temperature. The constraints are formulated in terms of analytic properties of the generating function: its zeroes must lie on the negative real axis. This result generalizes existing studies for scattering by a time-independent scatterer under time-dependent bias voltage. We discuss the meaning and possible extensions of our results.

9:48AM U24.00008 Ab-initio formulation of the 4-point conductance of interacting electronic systems and its implementation in the GWST method

PETER BOKES, Dept. of Physics, University of York, York, U.K. and Dept. of Physics, Slovak University of Technology, Bratislava, Slovakia, MATTHIEU VERSTRAETE, Dept. of Physics, University of York, York, U.K., REX GODBY, Dept. of Physics, University of York, U.K. — The commonly employed linear-response expression for the conductance of quantum junctions suffers from an ambiguity of the definition of the applied potential difference. We show how this is resolved in terms of the formally as well as physically well defined 4-point conductance [P. Bokes, J. Jung, and R. W. Godby, Phys. Rev. B 76, 125433 (2007)]. Furthermore, expressing the 4 point conductance solely in terms of the density response function or polarizability, we obtain a computationally viable approach to go beyond mean-field, Green’s function based descriptions of realistic ab initio models of quantum junctions. We will discuss the numerical implementation of the formalism within the GWST code for the real-space imaginary-time GW method [N. Rojas, R.W. Godby and R.J. Needs, Phys. Rev. Lett. 74 1827 (1995)] and present results for several simple systems.

Comparison of transport calculations using complex absorbing potentials and the Non-equilibrium Green's function formalism. Kalman Varga, Joseph Driscoll, Vanderbilt University, Nashville — In the Non-equilibrium Green's formalism (NEGF) the system is divided into left and right leads and a central region. To avoid spurious reflections from the boundaries one has to treat the leads as semi-infinite systems. Various efficient recursion methods are developed [1] for this purpose. Alternatively, one can use a complex absorbing potential (CAP) that absorbs the outgoing waves and one only has to deal with short finite leads. In this work we have compared the NEGF recursion and CAP approaches (1) on a simple analytically solvable example and (2) by calculating the transmission coefficients for a carbon nanotube device using a density functional Hamiltonian. Both approaches give very accurate results but the CAP method is orders of magnitude faster in calculating the self-energies. This work was supported by NSF grant ECS 0622146.

Systematic Study on Quantum Confinement and Waveguide Effects for Elastic and Inelastic Currents in Atomic Gold Wire: Importance of the Phase Factor for Modeling Electrodes, Hisao Nakamura, Koichi Yamashita, Univ. of Tokyo — Quantum confinement of the electrodes is an important issue for electron transport through molecular or atomic wire junctions. To assess the importance of waveguide effects by quantum confinement of the electrodes, we have calculated elastic and inelastic conductance and inelastic electron tunneling spectra of atomic gold wire with gold electrodes for several models. The results show the quite important role of the phase factors between the modeled electrodes and the contact region.

Nonlinear transport properties of model metal–Mott-insulator–metal heterostructures, Satoshi Okamoto, Materials Science and Technology Division, Oak Ridge National Laboratory — Transport properties of heterostructures in which a finite number of correlated-insulator or correlated-metal layers are sandwiched by semi-infinite metallic leads are investigated by using the layer dynamical-mean-field method combined with the Keldysh Green’s function technique. We use as impurity solvers the equation-of-motion decoupling method, the noncrossing approximation and the iteration perturbation method. Electron spectral functions in the interacting region are shown to evolve by an applied bias voltage. These effects control the current-voltage characteristics of the heterostructures. It is also shown that the deformed spectral functions strongly affect the optical response. These features differentiate a correlation-induced Mott insulator and a conventional band insulator.

Phonon Effects on Charge Transport Through a Two State Molecule, Sergio E. Ulloa, Efta Yudiarsha, Ohio University — We study the effect of local and non-local phonon on the transport properties of a molecule model described by two electronic states. The local phonon interaction is tackled by means of a Lang-Firsov transformation [1,2]. The interaction with non-local phonons (phonon-assisted hopping) is considered perturbatively up to the first nonzero order in the self energy. The presence of different kinds of electron-phonon interaction open new transmission channels. In addition to the polaron shift and replicas due to local phonons, non-local phonons cause the appearance of new satellite states around the initial states. In the weak coupling regime of non-local phonon and electrons, states are shifted an amount proportional to square of the interaction. However, in the strong coupling regime, the non-linear effects emerge and display more interesting features on transport properties. Additional features on transport properties due to new transmission channel are shown to appear at finite temperatures. [1] G. D. Mahan, Many-particle physics, 3rd ed. (Plenum Publishers, New York, 2000). [2] R. Gutierrez et al., Phys. Rev. B. 74, 235105 (2006).

Monte Carlo simulations of a coarse-grain model for block-copolymer melts: method and application, Francois Detcheverry, Darin Pike, Paul Nealey, Juan De Pablo, Department of Chemical and Biological Engineering, University of Wisconsin - Madison, Madison, WI 53706, Marcus Mueller, Institut fur Theoretische Physik, Georg-August Universitat, 37077 Goettingen, Germany — A new Monte Carlo based approach has been developed for simulation of polymeric systems, including block copolymers. The approach represents the system at the level of a coarse-grain Hamiltonian, akin to that employed in widely used self-consistent field theoretic (SCFT) treatments. In contrast to traditional implementations of SCFT, however, molecules are treated explicitly and fluctuations are taken into account. We present two distinct implementations of the method; the first relies on a grid and the second does not. While the grid-based method is highly computationally efficient, the gridless implementation permits simulations in arbitrary ensembles, including the grand-canonical and Gibbs ensembles, thereby facilitating study of phase transitions. The gridless implementation also gives access to the local mechanical properties. The performance of the two implementations is discussed in the context of several applications, including the directed assembly of multi-block copolymer thin films on patterned substrates, either chemical or topographical. In both cases we examine the ordering of the material and the effect of pattern or surface roughness.

Interaction between Polymer Grafted Particles: Self-Consistent-Field Study, Jaeup Kim, Mark Matsen, University of Reading — Recently, there has been an ongoing debate regarding a possible attraction between two polymer grafted nanoparticles. Using numerical self-consistent field theory (SCFT) we investigate the inter-particle potential, showing that only a monotonically increasing repulsive force is expected between the two particles regardless of the particle size and brush thickness. We also compared the exact mean-field result to approximate solutions using the Derjaguin approximation. The previously reported attraction is thought to be an anomaly caused by the use of bispHERical coordinates. We avoid this problem by developing a new SCFT scheme using two separate spherical coordinate systems centered on each particle. The idea of using multiple coordinate systems is applicable for many polymeric problems involving complicated geometries. In this scheme, two or more coordinate systems share an overlapping volume. Then the statistics of the polymers belonging to a certain coordinate system are solved in trial fields, and the resulting polymer concentration is shared by all coordinate systems to find a self-consistent solution. This method has been tried for other problems such as the behavior of a Janus nanoparticle (solved in spherical coordinates) in block copolymer lamellar phase (solved in cylindrical coordinates).

constant $T = 0.8$ by changing the LJ well depth ($\epsilon$).

This observation is confirmed by calculating the density profile of each cylinder and Fourier transform of the density distribution. We also performed jumps at

8:36AM U25.00004 Cylindrical phase of diblock copolymers in thin films. MARIANNE BREUER, BARBARA DROSSEL, Technical University of Darmstadt — We investigate the microphases of diblock copolymers confined in a thin film with walls attracting one of the monomer types. We focus on the possible structures of copolymers that form cylindrical phases in the bulk. We employ both self-consistent field theory and strong segregation theory to obtain the concentration profile minimizing the free energy of the system and to compare the free energy of possible morphologies. We present a phase diagram showing the possible microphases for a diblock copolymer with fixed volume fraction and fixed segregation parameter in dependence of the film thickness and the affinity of the walls. We study the effects of numerical inaccuracies on the appearance of different morphologies and their free energies.

8:48AM U25.00005 Cubic Micellar Crystals of $A_nB_mA_n$ Block Copolymers from MD. CHRIS LORENZEN, Kings College London, JOSHUA ANDERSON, ALEX TRAVESSET, Iowa State University and Ames Laboratory — Amphiphilic block copolymers exhibit a wide variety of phases in solution. One common phase of $A_nB_mA_n$ polymers is made up of spherical micelles with hydrophobic (B) cores and hydrophilic (A) coronas. At high enough concentrations, these micelles order on a lattice forming a micellar crystal. The dynamics during the formation of this phase are fascinating, being controlled almost entirely by the polymer transfer between micelles, as shown in Molecular Dynamics simulations. Application of a standard nucleation and growth analysis shows that the micellar crystals grow extremely rapidly and are probably aided by the periodic box in the simulation. A study of the dynamics at equilibrium shows that polymer transfer is still a continuing process and can be understood in the context of transition state theory.

9:00AM U25.00006 Brownian Dynamics Simulation of Kinetics of HEX Cylinders to FCC Spheres Transition in ABA Triblock Copolymer in Selective Solvent. MINGHAI LI, Boston University, RAMA BANSIL2, Boston University and National Science Foundation — We report Brownian Dynamics simulations on 400 bead-spring chains of triblock copolymer, $A_1B_2A_1$, in a selective solvent for the A block using a FENE potential together with Lennard-Jones (LJ) for B-B attraction and a Weeks-Chandler-Anderson potential for A-B and A-A repulsions. On varying volume fraction and temperature $T$ (in units of $\epsilon/k_B$, where $\epsilon$ is the well depth of the LJ interaction and $k_B$ the Boltzmann constant) we observe spheres in cubic phases, HEX cylinders, worm-like and disordered micelles. The time evolution following a quench from $T=0.0$ to a temperature $T>0.0$ shows a nucleation and growth mechanism where one cylinder breaks into spheres and induces neighboring cylinders to break into spheres. This observation is confirmed by calculating the density profile of each cylinder and Fourier transform of the density distribution. We also performed jumps at constant $T=0.8$ by changing the LJ well depth ($\epsilon$) from 1 to various higher values. We found that for $\epsilon > 4$ the cylinders are kinetically trapped, and the transition is fastest for $\epsilon = 1.5$.

9:12AM U25.00007 Thermal and Mechanical Properties of Polymer Nanofibers from Molecular Simulations. SEZEN CURGUL, KRYSYNY J. VAN VLJET, GREGORY C. RUTLEDGE, MIT — Polymer nanofibers exhibit new, emergent behavior as the diameter of the fibers are decreased from macroscopic to nanometer length scales. Since individual nanofibers are challenging to characterize experimentally due to their small size, computer simulations can be helpful in predicting the properties. We present the results of molecular dynamics (MD) simulations of polymer nanofibers to study their size-dependent properties. The fibers mimic the prototypical polymer polyethylene and have diameters in the range 2.0 to 23.0 nm. The fibers have been analyzed size dependent behavior in their thermal and mechanical properties. The glass transition temperature ($T_g$) of these amorphous nanofibers decreases with decreasing fiber diameter, and is independent of molecular weight over the range considered. Application of a volume averaged layer model for $T_g$ shows that the cooperativity length scale compares well with previous estimates for polyethylene. Young’s moduli of these nanofibers also decrease with decreasing fiber diameter, in agreement with $T_g$ depression. There is a significant decrease in modulus when the temperature increases above the glass transition temperature of the surface layer.

9:24AM U25.00008 ABSTRACT WITHDRAWN —

9:36AM U25.00009 Predicting glass transition temperatures from simulation studies. SOLOMON DUKI, PHILIP TAYLOR, Case Western Reserve University — We have been seeking techniques by means of which the glass transition temperature $T_g$ of a polymer can be predicted with minimal computational effort. With this goal in mind, the glass transition in syndiotactic poly(methyl methacrylate) was studied through atomistic molecular-dynamics simulations performed at temperatures in the range from 320 K to 700 K. The mean squared deviations of atoms, monomers, and molecules from their initial positions were analyzed by several different techniques. The most direct method looks at the long-time diffusive motion, and detects a characteristic change in the diffusion constant at $T_g$. This approach required lengthy computer runs to achieve meaningful results. Other techniques study the velocity correlation functions and the short-time translational motion. All three yield identical values for $T_g$, but it is found that the method that is most economical of computing resources is the analysis of the short-time departure from ballistic behavior. The apparent softening of the “cage” in which a monomer or chain segment oscillates coincides with the onset of diffusive motion.

9:48AM U25.00010 Band Structure Controlled by Chiral Imprinting. ADRIAN REYES CERVANTES, Universidad Nacional Autonoma de Mexico, P. CASTRO-GARAY, RUBEN RAMOS-GARCIA, Instituto Nacional de Astronomía Óptica y Electrónica — Using the configuration of an imprinted cholesteric elastomer immersed in a racemic solvent, we find the solution of the boundary-value problem for the reflection and transmission of incident optical waves due to the elastomer. We show a significant width reduction of the reflection band for certain values of nematic penetration depth, which depends on the volume fraction of molecules from the solvent, whose handedness is preferably absorbed. The appearance of nested bandgaps of both handednesses during the sorting mixed chiral process is also obtained. This suggests the design of chemically controlled optical filters and optically monitored chiral pumps.
The static properties of equilibrium polymer melts confined in ultrathin films are studied by means of Monte Carlo simulations of a lattice model: the bond fluctuation model. In this work we focus on the effects of ultrathin film confinement between two parallel and neutral walls on chain size and molecular weight distribution. We compare our numerical results to analytical calculations by Semenov and Johner [Eur. Phys. J. E, 12, 469 (2003)] which predicted for ultrathin films, logarithmic corrections to the leading mean-field behavior. Our simulation data are compatible with the theoretical results.

**10:24AM U25.00013 Promotion of the Polyfluorene Beta-Phase: A First Principles Study**

ELIZABETH M. LUPTON, FENG LIU, Department of Materials Science and Engineering, University of Utah, Salt Lake City UT-84122; DAVID G. PRENDERGAST, JEFFREY B. NEATON, The Molecular Foundry, Lawrence Berkeley National Laboratory, 1 Cyclotron Road, Berkeley CA-94720

Two configurations of polyfluorenes - potentially important for their blue emission properties in organic devices - have been identified in single molecule spectroscopy experiments: a glassy phase with random torsional angles between fluorene units, and a planar beta-phase. The twisted conformation is known to be the lowest energy structure, and the factors which promote the stabilization of the beta-phase are unclear. We present a density functional theory study of ways in which polyfluorenes could be manipulated to favor the formation of the photosynthetically more stable beta-phase. Extension along the molecular axis, which increases the stability of the planar conformation relative to the glassy phase, and the role of side groups are examined in fluorene oligomers and a polyfluorene infinite in the molecular axis. Implications for excited state properties, including fluorescence, will be discussed in the context of these results.

**10:36AM U25.00014 Atomic structures and electronic properties of poly(3-hexyl thiophene) on ZnO(110-1) surface.**

SEFA DAG, LIN-WANG WANG, Lawrence Berkeley National Laboratory — The atomic structures of adsorbed poly(3-hexyl thiophene) (P3HT) polymers on the non-polar ZnO surface (110-1) are studied with molecular dynamics using ab initio adjusted atomic force fields, and the electronic structures of the resulting systems are studied with direct ab initio calculations. We investigated different P3HT attachment orientations on the ZnO surface. We also studied the influence of the crystallization among the P3HT polymers to the polymer-ZnO attachment. We found that the strength of the attachment depends strongly on the P3HT crystal orientation, and to the partial charge of the surface Zn, O atoms and the end atoms of the P3HT. We studied the temperature dependence of the attachment, and the effects of the details of the attachment atomic structures to the electronic properties of the interface. This work is supported by U.S. Department of Energy, BES, under contract No. DE-AC02-05CH11231 and it used the resource of the National Energy Research Scientific Computing Center.

**10:48AM U25.00015 Ab initio study of a promising class of copolymers for application to high-efficiency photovoltaics.**

JEAN FRÉDÉRIC LAPRADE, MICHEL CÔTÉ, Département de physique and Regroupement québécois sur les matériaux de pointe (RQMP), Université de Montréal, Canada — In order to achieve high power conversion efficiency in bulk-heterojunction solar cells using PCBM as electron acceptor, it is essential to identify an electron donor polymer which i) harvests the largest part of the solar spectrum and ii) shows an electronic structure appropriate to PCBM. In the last few years, different groups synthetized copolymers based on either fluorene or dibenzosilole with interesting results. This presentation will report the results of density-functional theory (DFT) and time-dependent density-functional theory (TDDFT) calculations on those copolymers and their units in order to better assess the impact of changing the fluorene's 9-atom on the electronic properties. We will focus our discussion on the interplay of the counts on the energy levels and on the oscillator strength of the oligomers. O. Ingañäs & al. Appl. Phys. A, 2004, 79, 31 N. Blouin & al., Adv. Mater., 2007, 19, 2295 P.L.T. Boudreaulet & al, Macromol. Rapid Commun., 2007, 28, 2176
8:48AM U26.00003 Oxidation of the PAH Coronene by Ozone and OH Radical. ERIN MYSAK, JARED D. SMITH, JOHN T. NEWBERG, KEVIN R. WILSON, HENDRIK BLUHM, Lawrence Berkeley National Laboratory, LAWRENCE BERKELEY NATIONAL LABORATORY TEAM — Reactivity of the polycyclic aromatic hydrocarbon (PAH) coronene to oxidation sources ozone and OH radical is examined. To probe the extent of chemical reaction, product formation, and change in surface morphology as a function of reaction, we examine coronene, adsorbed onto various substrates, from both a surface and bulk perspective, with ambient pressure photoemission spectroscopy (APPEX) and aerosol mass spectrometry (AMS), respectively. For bulk on-line analysis, a 20nm thick layer of coronene adsorbed onto NaCl seed particles and reacted with either oxidant in a flow tube showed very little reactant conversion to product in the AMS. However, surface analysis by the APPEX of the same reaction where coronene was adsorbed onto model substrates showed up to 50 per cent conversion of the carbon species to oxidized carbon, depending on coronene layer thickness (about 1.5-14Å). Data obtained with these complimentary techniques provide evidence for a surface selective reaction.

9:00AM U26.00004 Morphological effects on coated aerosol kinetics. ELIAS ROSEN, EVA GARLAND, TOMAS BAER, University of North Carolina at Chapel Hill — The fate of organic material in the atmosphere can be strongly dependent on the chemical environment under which oxidation takes place. We have investigated the reaction of gas-phase ozone and oleic acid adsorbed to the surface of polystyrene latex spheres and silica aerosols to better understand how the substrate influences heterogeneous kinetics. Flow tube experiments were performed with an Aerosol Time of Flight Mass Spectrometer using a two-laser vaporization/ionization scheme to minimize analyte fragmentation. Pseudo-first-order rate coefficients suggest that ozonolysis of oleic acid proceeds differently on the hydrophobic latex and hydrophilic silica particles. Mechanistic interpretation of these results has been complicated by the discovery that the morphology of oleic acid vapor deposition onto both particle types is non-uniform, which results in the formation of discrete areas of organic material on the particle surface as evidenced by AFM and SEM/EDS measurements.

9:12AM U26.00005 Optical and microphysical properties of organic multicomponent aerosol particles. YINON RUDICH, Weizmann Institute — Atmospheric aerosols affect Earth’s climate in direct and indirect manners. The direct effect of aerosols on climate is by scattering and/or absorbing incoming solar and outgoing terrestrial radiation, which strongly modify Earth’s radiation budget. In addition, aerosols acting as cloud condensation nuclei (CCN) indirectly affect climate and precipitation by modifying the microphysical properties of clouds and cloud coverage. These climate effects depend on the chemical composition, size and morphology. We will present laboratory studies aiming at understanding how the organic component of atmospheric affect the climate system. Specifically, we present the use of cavity ring down (CRD) spectrometer to derive the extinction and complex refractive index of aerosols containing a significant organic component. By precisely measuring extinction as a function of particle size the real and imaginary refractive indices are obtained, and the single scattering albedo can be calculated. We will present results on aerosol particles containing humic like substances (HULIS). HULIS are a common component of aerosols in the atmosphere. They contribute to the CCN activity, hygroscopic properties and the density of aerosols. In addition, HULIS absorb throughout the visible range, and hence contribute to the direct climatic effect of aerosols. The absorption by organic aerosols is largely unaccounted for in models. Specifically, we will present how the absorption of aerosols containing HULIS and inorganic salts varies with wavelength, test various optical mixing rules and will present results on the extinction of core-shell particles. In addition, we will discuss how the presence of HULIS affects the surface tension of CCN at activation and of cloud droplets and its implications.

9:48AM U26.00006 Oxidation of oleic acid monolayers at air/liquid interfaces. LAURA VOSS, Bowdoin College — Field studies of marine and continental aerosols find that fatty acid films form on aqueous tropospheric aerosols. Oxidation of oleic acid monolayers by ozone was studied to understand the fate of fat-coated aerosols from both fresh and salt water sources. Using vibrational sum frequency generation spectroscopy and reflection absorption infrared spectroscopy, we present a molecular-level investigation of fatty acid monolayers at the air-water and air-sodium chloride solution interface and explore reactions with atmospheric oxidants by these model systems. Coupling sum frequency generation spectroscopy with a Langmuir trough, concurrent spectroscopic and thermodynamic data were collected to obtain a molecular picture of the monolayers. No substantial difference was observed between oxidation of monolayers spread on water and on 0.6 molar sodium chloride solutions. Results indicate that depending on the size of the aerosol and the extent of oxidation, the subsequent oxidation products may not remain at the surface of these films, but instead be dissolved in the aqueous sub-phase of the aerosol particle. Results also indicate that oxidation of oleic acid could produce monolayers containing species that have no oxidized acyl chains.

10:00AM U26.00007 Chemical and Spatial Microscopy of Individual Organic Aerosols. ALEXEI V. TVANSKI, Department of Chemistry, University of Iowa, REBECCA J. HOPKINS, MARY K. GILLES — Carbonaceous particles originating from biomass burning can account for a large fraction of organic aerosols in a local environment. Presently, their composition, physical, and chemical properties as well as their environmental effects are largely unknown. A distinct type of biomass burn particles, called “tar balls”, have been observed in a number of field campaigns, both in fresh and aged smoke. They are characterized by their spherical morphology, high carbon content and ability to efficiently scatter and absorb light. Here, a combination of scanning transmission x-ray microscopy and near edge x-ray absorption fine structure spectroscopy is used to determine the shape, structure and size-dependent chemical composition of 150 individual tar ball particles ranging in size from 0.15 to 1.2 μm. Oxygen is present primarily as carboxylic carboxyls and oxygen-substituted alkyl functional groups. The observed chemical composition is distinctly different from black carbon and more closely resembles high molecular weight humic-like substances. A detailed examination of the carbonyl intensity as a function of particle size reveals the presence of a thin oxygenated interface layer on the tar balls, indicative of atmospheric processing of biomass burn particles.

10:12AM U26.00008 OH oxidation of organic aerosols. JARED SMITH, ERIN MYSAK, MUSA AHMED, LBNL, CHRISTOPHER CAPPA, UC, Davis, STEPHEN LEONE, UC, Berkeley and LBNL, KEVIN WILSON, LBNL — Ambient aerosols play a significant role in a variety of atmospheric processes such as direct and indirect effects on radiative forcing. Chemical composition can be an important factor in determining the magnitude of these effects. However, a major fraction of organic aerosols (OA) can not be resolved on a molecular level. Recent identification of high mass oligomeric species as a major component in laboratory and ambient OA has received much attention due to the possibility that these species may account for much of the unknown organic mass in ambient aerosols. Although, a few mechanisms have been proposed, the origin and formation processes of these compounds remain largely unknown. Here we provide strong evidence for a previously unidentified mechanism of extremely rapid oligomer formation, via OH radical initiated oxidation of OA. This process appears capable of converting a sizable fraction of an organic particle to higher mass oligomers within a day of exposure to OH radicals at typical atmospheric concentrations. Furthermore, we have found that rapid volatilization is also important for specific reaction systems, and can lead to the loss of a large fraction of the particle mass. We propose that such a rapid processing is possible due to a radical chain reaction which quickly propagates throughout the entire particle and is only initiated by the surface OH reaction.

Thursday, March 13, 2008 8:00AM - 10:48AM – Session U27 DCMP: Correlated Electrons: Theory, Actinides, and Ising Systems Morial Convention Center 219
8:00AM U27.00001 Quantitative Calculation of the Spatial Extension of the Kondo Cloud . BERGMANN GERD, University of Southern California — A recently developed compact solution for the singlet state of the Friedel-Anderson and the Kondo impurity is applied to investigate the old question of a Kondo cloud in the Kondo ground state. Wilson’s states with an exponentially decreasing frame of energy cells towards the Fermi level are used. The Wilson states are expressed as free electron waves with a linear dispersion and integrated over the width of their energy cells. For the magnetic state of the Friedel-Anderson impurity one finds essentially no spin polarization in the vicinity of the d-imurity. However, for intense magnetic fields the electron spin (magnetization) becomes not only a function of the d-electron component but also of the f-electrons. The spatial range of the correlation effect of the f-electron spin is investigated in detail for the Kondo impurity. The range is inversely proportional to the Kondo energy \( \Delta K \). The extent of the electron density in real space is a detector for a resonance in energy. The spatial extension \( \xi \) and the resonance width \( \Delta \) are reciprocal and given by the relation \( \Delta \approx \hbar v \epsilon \).

8:12AM U27.00002 Perturbative Cumulant Monte Carlo Study of LiHoF\(_4\) in a Weak Transverse Magnetic Field . S.M. ALI TABELI, MICHEL GINGRAS, University of Waterloo, YING-JER KAO, Theoretical Sciences, National Taiwan University, TARAS YAVORSKII — Results from a recent quantum Monte Carlo (QMC) study of the LiHoF\(_4\) ising magnetic material in an applied transverse magnetic field \( B_z \) show a discrepancy with the experimental results, even for small \( B_z \) where quantum fluctuations are small. This discrepancy persists asymptotically close to the classical ferromagnet to paramagnet phase transition. We numerically investigate and compare this behavior with the similar diagram of LiHoF\(_3\) in the regime of weak \( B_{\|} \). In this regime, we numerically determine the effective magnetic field \( B_{\|} \) which incorporates perturbatively the small quantum fluctuations in the vicinity of the classical phase transition at \( B_{\|} = 0 \). Via this effective classical Hamiltonian, we study the \( B_{\|} - T \) phase diagram via classical Monte Carlo simulations. In particular, we investigate the influence of various effects that may be at the source of the discrepancy. We also show how our method can be generalized to numerically study the diluted LiHo\(_{1-x}\)F\(_3\) in the small \( B_{\|} \) regime.

8:24AM U27.00003 A New Heavy Fermion Compound Yb\(_3\)Pt\(_4\)\(^+\). MARCUS BENNETT, Stony Brook University, PETER KHALILFAR, DAMIRY SOKOLOV, YIUI YUEN, MOOSUNG KIM, CARL HENDERSON, WILLIAM GANNON, MEIGAN ARONSON — We report the synthesis of single crystals of a new binary heavy fermion system, Yb\(_3\)Pt\(_4\). Magnetic susceptibility measurements find Yb\(_3\)Pt\(_4\) local moment behavior above 150 K. Heat capacity measurements find a large weakly first order anomaly at 2.4 K, and the associated entropy indicates that magnetic order emerges from a doublet ground state. Magnetic field suppresses both the magnitude of the anomaly and the temperature at which the anomaly occurs, mapping out a first order phase line that ends at a tri-critical point, 1.75 T, 1.3 K. A weak cusp in the AC magnetic susceptibility indicates antiferromagnetic ordering. Above 0.2 T, the cusp becomes a step, which increases in height with increasing field indicating ferromagnetic order. The electrical resistivity of Yb\(_3\)Pt\(_4\) is that of a good metal, and the quadratic temperature dependence of a Fermi liquid is found throughout the antiferromagnetically ordered state and continues into the high field paramagnetic state. Both the magnitude of the quadratic temperature dependence of the resistivity and of \( \gamma \) are comparable to that found in heavy fermion compounds, indicating substantial quasiparticle mass enhancement. The Sommermer-Wilson ratio approaches 30 in the ordered state, suggesting strong fermionic correlations among the quasiparticles.

1Work at Stony Brook performed under NSF-DMR 0405961.

8:36AM U27.00004 Pressure and magnetic field effects in heavy-fermion UC\(_{1.5}\)Al\(_{1.5}\). A. ALSMADI, Physics Department, the Hashemite University, Jordan, H. NAKOTTE, Physics Department, NMSU, Las Cruces, NM, V. ZAPF, F. FABRIS, T.D. DIDN, A. LACERDA, NHMF, LANL, Los Alamos, NM, J. KAMARAD, Institute of Physics, CAS, Czech Republic — UC\(_{1.5}\)Al\(_{1.5}\) crystallizes in the hexagonal CaC\(_2\) structure and is described as a heavy fermion, which shows non-Fermi liquid behavior [1]. Here, we report on electrical resistivity, magnetic susceptibility, and magnetization results on polycrystalline UC\(_{1.5}\)Al\(_{1.5}\). The resistivity was measured under hydrostatic pressure up to 10kbar and in fields up to 18T. At ambient pressure and in zero field, the resistivity shows an anomaly at \( T_1 \approx 19K \) and then it goes through a maximum at \( T_{\text{max}} \approx 2K \). These two anomalies were also observed in the susceptibility data. The anomaly in the resistivity at \( T_1 \) goes to lower values with increasing fields and disappear at fields about 12T. \( T_{\text{max}} \) on the other hand goes to higher values with increasing fields. We find relatively weak pressure dependence, where both \( T_1 \) and \( T_{\text{max}} \) go down with increasing pressure. In the field scan at 2K and at ambient pressure, we find a change in the slope of the magnetoresistance at about 6.9T. Application of pressure causes a reduction of the magnetoresistance effect.

8:48AM U27.00005 Optical spectra of the heavy fermion uniaxial ferromagnet UGe\(_2\). VIOLETA GURITANU, PETER ARMITAGE, RICCARDO TEOLESI, SIDDHARTH SAXENA, ANDREW HUXLEY, DIRK VAN DER MAREL, DPMC, UNIVERSITY OF GENEVA, 24, TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY, COLLABORATION, DEPARTMENT OF PHYSICS, CAVENDISH LABORATORY, COLLABORATION, DEPARTMENT DE RECHERCHE FONDAMENTALE SUR LA MATIERE CONDENSEE - SPSMS, COLLABORATION — We report on a detailed study of UGe\(_2\) single crystalline material using infrared reflectivity and spectroscopic ellipsometry. The optical conductivity suggests the presence of a low frequency interband transition ( ~300 cm\(^{-1}\)) and a narrow free-carrier response with strong frequency dependence of the scattering rate and effective mass. We observe sharp changes in the (300 cm\(^{-1}\)) low frequency mass and scattering rate below the upper ferromagnetic transition \( T_C \). They recover their unrenormalized value above \( T_C \) and for \( \omega > 250 \text{ cm}^{-1} \). In contrast no sign of an anomaly is seen at \( T_C \approx 30K \), which is the lower transition of unknown nature. These observations are consistent with the weak anomaly observed at \( T_C \) in transport and thermodynamic experiments.

9:00AM U27.00006 Ferromagnetism of Silicon Doped with Uranium Investigated to Extremes of Magnetic Field (Beyond 100 tesla). CHARLES MIELEKE, MPA-NHMF, Los Alamos National Laboratory, JASON COOLEY, WILLIAM HULTS, MST-6, Los Alamos National Laboratory — The ferromagnetic (FM) phase of Si:U \( x \times A t \% \) (where \( x \approx 0.25, 0.5, 0.75, 1.0, \) and 50.0 (i.e. US)) were studied in high magnetic fields as a function of temperature and U concentration. The effect of doping U into Si is investigated using a vis a vis the FM transition temperature (127K for \( x = 50.0 \)) and high magnetic field saturation is discussed. The effect of the FM transition temperature is approached from the point of view of correlation effects in f-electron systems. Attention to the high magnetic field saturation is investigated as it is unusually high in the \( x = 50.0 \) intermetallic compound. Ultra-high fields extending to 185 tesla is reported for the system. Issues with homogenization of the dilute samples are presented as well.

3This work was funded by LANL-LDRD20070013DR

9:12AM U27.00007 Electronic Structure of Actinide Materials 1. J.J. JOYCE, Los Alamos National Laboratory, T. DURAKIEWICZ, K.S. GRAHAM, D.P. MOORE, L.A. MORALES, J.M. WILLS, R.L. MARTIN, J.-X. ZHU, E.L. ROY, C.G. OLSON, Ames Laboratory, USDOE, G.E. SCUSERTIA, I.D. PRODAN, Rice University — Photoelectron spectroscopy results for both metallic and insulating actinide materials are reviewed and compared against model calculations. The dual nature of S f electron characteristics is discussed for photoemission results and three different electronic structure calculations. Magnetic configurations as a means of f-electron localization are discussed for metallic materials. The photoemission results for U and Pu intermetallics are compared against mixed-level-model and dynamical-mean-field-theory calculations. The experimental results for the actinide oxide Mott insulators are compared against screened hybrid functional calculations.

1Work supported by the US DOE, Office of Science, Campaign II, and the LANL LDRD program.
9:24AM U27.00008 Effects of full Coulomb interactions on electronic structure of $\delta$-Pu. EUGENY GORELOV, TIM WEHLING, HARTMUT HAFFERMAN, ALEXANDER LICHTENSTEIN, University of Hamburg, ALEXEY RUBTSOV, Moscow State University, ALEXEY LANDA, CHRIS MARIANETTI, MICHAEL FLUSS, Lawrence Livermore National Laboratory, ALEXEY SHORIKOV, ALEXEY LUKOYANOV, MICHAEL KOROTIN, VLADIMIR ANISIMOV, Institute of Metal Physics — We used the CTQMC method for the realistic simulation of electronic properties of correlated actinides. In particular, we focus on the spectral function of $\delta$-Pu, which is described in terms of a 7-orbital $f$-impurity model interacting with a metallic bath. Our CTQMC implementation solves this model by calculating a weak coupling expansion of the partition function in the fermionic multiorbital path-integral representation and provides numerically exact results for relatively high temperature. We discussed how different terms in the full on-site Coulomb vertex affect the local density of states. The comparison of CTQMC results with only diagonal density-density like Coulomb interactions and with additional non-diagonal terms in the interaction part of the Hamiltonian related with so-called spin flips terms shows the importance of the full rotationally invariant Coulomb vertex on the electronic structure of $\delta$-Pu. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

9:36AM U27.00009 First-principles study of electronic structure and local moment interactions in PuAm alloy. MYUNG JOON HAN, XUANGANG WAN, SERGEJ Y. SAVRASOV, Department of Physics, University of California, Davis — Expected to provide a clue about the origin of zero moment in the bulk phase of Plutonium, Pu$_{1-x}$Am$_x$ alloy has attracted a great attention, in which as Am ratio, $x$, increases, Pu approaches from bulk to atomic limit. To understand the electronic structure and the magnetic properties of Pu in different crystal environments, we perform fully self-consistent first-principles calculations of the PuAm system based on the density functional theory. Electronic structure strongly depends on the level of approximation for correlation effects. The exchange interactions between Pu 5f electrons and the Kondo screening strength were estimated and compared, which provide a new insight to Pu magnetism.

9:48AM U27.00010 Knight shifts around nonmagnetic impurities in a triangular lattice spin 1/2 antiferromagnet: Case of $k$-(ET)$_2$Cu$_2$(CN)$_3$. KAROL GREGOR, OLEXEI MOTRUNICH, California Institute of Technology — We study effects of nonmagnetic impurities in a spin-1/2 frustrated triangular antiferromagnet with the aim of understanding the observed broadening of $^{13}$C NMR lines in the organic spin liquid material $k$-(ET)$_2$Cu$_2$(CN)$_3$. For high temperatures down to $J/2$, we calculate local susceptibility near a nonmagnetic impurity, and we find a broadening of the Knight shift decays to the uniform one very quickly (few lattice spacings), and with the suggested density of impurities would not explain the observed line broadening present already at elevated temperatures; more extended defects and/or longer-ranged interactions are probably needed. At low temperatures, we assume a gapless spin liquid with a Fermi surface of spinons. We calculate the local susceptibility in the mean field and also go beyond the mean field by Gutzwiller projection. Here the Knight shift decays with a power law and oscillates at $2k_F$. However, with single site impurities the results fall short of the observed inhomogeneous broadening, calling for a better understanding of the appropriate models for the spins and impurities and of the possible ground states that are probed by such experiments.

10:00AM U27.00011 Excitons in the 1D Hubbard Model: a Real-Time Study. KHALED AL-HASSANIEH, Los Alamos National Laboratory, ADRIAN FEIGUIN, The University of Maryland, FERNANDO REBOREDO, IVAN GONZÁLEZ, ELBIO DAGOTTO, Oak Ridge National Laboratory — We study the real-time dynamics of a pair hole/doubly-occupied-site, namely a holon and a doublon, in a 1D Hubbard insulator with on-site and nearest-neighbor Coulomb repulsion. Our analysis shows that the pair is long-lived and the expected decay mechanism to underlying spin excitations is actually inefficient. For a nonzero inter-site Coulomb repulsion, we observe that part of the wave-function remains in a bound state. Our study also provides insight into the holon-doublon propagation in real space. Due to the one-dimensional nature of the problem, these particles move in opposite directions even in the absence of an applied electric field. The potential relevance of our results to solar cell applications is discussed.

10:12AM U27.00012 Investigation of Dipole-Forbidden $d-d$ Excitations in Strongly Correlated Transition-Metal Oxides Using Higher-Order Multipole, Non-resonant Inelastic X-Ray Scattering. B.C. LARSON, J.Z. TISCHLER, ORNL, C.-L. YEH, Tamkang Univ., Taiwan, C.-C. LEE, WEI KU, BNL — We have shown that quadrupole and higher order multipole non-resonant inelastic x-ray scattering (NIXS) at large wavevectors, $q$, provides direct access to dipole-forbidden $d-d$ excitations (Larson et al. Phys. Rev. Lett. 99, 026401 (2007)). NIXS measurements using the XOR/UNI beamline at the APS have shown that the large-intensity of on-site excitons in NiO and CoO is highly anisotropic in $q$ and dominates the energy loss spectrum. Energy-resolved Wannier function analyses have shown that the anisotropies, including a nodal direction for NiO, provide direct information on the point-group symmetry of the particle-hole wave functions for transition-metal oxides. The interpretation of these large-$q$ NIXS measurements will be discussed in connection with energy-resolved Wannier function analyses and LDA+$U$ dynamical response calculations. Implications for the extension of such investigations to manganite systems will be considered.

3Research sponsored by the DOE-BES Division of Materials Sciences and Engineering; the APS is supported by the DOE Office of Science.

10:24AM U27.00013 Exact many-electron ground states on the diamond Hubbard chain. ZSOLT GULACSI, Department of Theoretical Physics, University of Debrecen, Debrecen, Hungary, ARNO K AMPF, DIETER VOLLHARDT, Theoretical Physics III, Center for Electronic Correlations and Magnetism, Institute for Physics, University of Augsburg, Augsburg, Germany — Exact ground states of interacting electrons on the diamond Hubbard chain in a magnetic field are constructed which exhibit a wide range of properties such as flat-band ferromagnetism, correlation induced metallic, half-metallic, or insulating behavior [1]. In particular, the properties of these ground states can be tuned by changing the magnetic flux, local potentials, or electron density. The results show that the studied simple one-dimensional structure displays remarkably complex physical properties. The virtue of tuning different parameters points to new possibilities for the design of electronic devices which can switch between insulating or conducting and metallic bath. Our CTQMC implementation solves this model by calculating a weak coupling expansion of the partition function in the fermionic multiorbital path-integral representation and provides numerically exact results for relatively high temperature. We discussed how different terms in the full on-site Coulomb vertex affect the local density of states. The comparison of CTQMC results with only diagonal density-density like Coulomb interactions and with additional non-diagonal terms in the interaction part of the Hamiltonian related with so-called spin flips terms shows the importance of the full rotationally invariant Coulomb vertex on the electronic structure of $\delta$-Pu. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

10:36AM U27.00014 Phonon effect on elementary excitations in one-dimensional Mott insulators. HIROKO MATSUEDA, Sendai National College of Technology, AKIHIRO ANDO, Institute for Materials Research, Tohoku University, TAKAMI TOHYAMA, Yokohama Institute for Theoretical Physics, Kyoto University, ŠÁDAMICHI MAEKAWA, Institute for Materials Research, Tohoku University — We examine the interplay among phonons and elementary excitations in one-dimensional Mott insulators. For this purpose, we perform dynamical density matrix renormalization group calculations for the single-particle excitation and optical absorption spectra in the extended Hubbard-Holstein model. We find that the elementary excitations in the Mott insulators are quite easily modified by the phonons. In particular, the spinon branch in the single-particle excitation spectrum can be broadened, even when the phonons only couple with charge degrees of freedom. In addition, the exciton in the photoexcited state becomes polaronic, and this polaronic feature is enhanced by increasing the on-site Coulomb repulsion. We show the origins of these novel properties, and discuss implications of the present results in light of spectroscopic measurements in 1D cuprates.
A device incorporating a micromagnet exhibits a magnetic field difference between dots, allowing electrons in either dot to be addressed selectively. Experimentally and theoretically, the magnetic field dependence and absence of associated Rabi oscillations are consistent with a novel hyperfine mechanism.

Department, University of California at Santa Barbara — An all-electrical spin resonance effect in a GaAs few-electron double quantum dot is investigated.

8:12AM U28.00002 Decoherence of coupled spin qubits due to charge fluctuations1, GUY RAMON, Department of Physics, Santa Clara University, XUEDONG HU, Department of Physics, University of Buffalo, SUNY — One of the significant advantages of using the spin of quantum dot electrons as a qubit rather than their charge is their relative insolation from the environment. A number of recent works have utilized two-spin singlet and unpolarized triplet states in biased configuration to encode a logical qubit, which offer better control and coherence properties as compared with single spin states. When spin states are exchange coupled, however, they are potentially vulnerable to environmental fluctuations affecting charge qubits, since exchange coupling is electrostatic in nature. Here we carry out a quantitative calculation of the coupling between a biased two-spin qubit and a nearby charge fluctuator represented by a two-level-system (TLS), utilizing a multipole expansion up to and including the Quadrupole-Quadrupole order. The resulting coupling terms are used in a master equation formalism to study the dynamics of the open system that is formed by the spontaneous emission of the TLS coupled to the vacuum. We are thus able to provide a reliable estimate of the decoherence effects during various gate operations on the spin qubit as a function of the geometry and other characteristics of the system. Possible ways to alleviate the sensitivity of coupled spin qubits to charge fluctuations are also discussed.

9:24AM U28.00006 Time-Reversal Symmetry and Electron Spin Relaxation of Lithium Donors in Silicon1. V.N. SMELYANSKIY, NASA Ames Research Center, A.G. PETUKHOV, South Dakota School of Mines and Technology, A.M. TYRYSKHIN, S.A. LYON, Princeton University — The exchange interaction (J-coupling) between electron spins provides a natural way to accomplish two-qubit operations in a spin-based, solid-state quantum processor. The J-coupling, because of its electrostatic (Coulombic) nature, is susceptible to charge noise in the environment, and hence turning on the J-coupling may cause fast decoherence of the interacting spin qubits. To clarify the effect of J-coupling on spin coherence, we performed spin relaxation measurements for exchange-coupled donors in dimers and trimers randomly formed in bulk-doped natural silicon and isotopically-purified 28Si. The longitudinal relaxation time, $T_1$, for donors in exchange-coupled dimers is found to be identical to that of isolated donors at temperatures 8-15K, solely determined by a two-phonon Orbach mechanism. The transverse relaxation time, $T_2$, for dimers is even longer than that of isolated donors because of the lower density of the dimers in our samples and thus substantially reduced dipole-dipole interactions. In natural silicon containing $5\%$ 29Si magnetic nuclei, an additional decoherence results from the nuclear-induced spectral diffusion. The spectral diffusion decoherence of J-coupled dimers and trimers is also identical to that of isolated donors. We conclude that J-coupling does not induce any additional decoherence in bulk donors in Si. However, the situation may change for donor dimers placed closer to the surface where more charge noise is expected. Supported by LPS/ARO.

9:36AM U28.00007 Spin relaxation of exchange-coupled donors in silicon. A.M. TYRYSKHIN, S. SHANKAR, S.A. LYON, Princeton University — The exchange interaction (J-coupling) between electron spins provides a natural way to accomplish two-qubit operations in a spin-based, solid-state quantum processor. The J-coupling, because of its electrostatic (Coulombic) nature, is susceptible to charge noise in the environment, and hence turning on the J-coupling may cause fast decoherence of the interacting spin qubits. To clarify the effect of J-coupling on spin coherence, we performed spin relaxation measurements for exchange-coupled donors in dimers and trimers randomly formed in bulk-doped natural silicon and isotopically-purified 28Si. The longitudinal relaxation time, $T_1$, for donors in exchange-coupled dimers is found to be identical to that of isolated donors at temperatures 8-15K, solely determined by a two-phonon Orbach mechanism. The transverse relaxation time, $T_2$, for dimers is even longer than that of isolated donors because of the lower density of the dimers in our samples and thus substantially reduced dipole-dipole interactions. In natural silicon containing $5\%$ 29Si magnetic nuclei, an additional decoherence results from the nuclear-induced spectral diffusion. The spectral diffusion decoherence of J-coupled dimers and trimers is also identical to that of isolated donors. We conclude that J-coupling does not induce any additional decoherence in bulk donors in Si. However, the situation may change for donor dimers placed closer to the surface where more charge noise is expected. Supported by LPS/ARO.

9:48AM U28.00008 Solid state quantum memory using the $^{31}$P nuclear spin. J.J.L. MORTON, Oxford University, A.M. TYRYSKHIN, S. SHANKAR, Princeton University, A. ARDAVAN, Oxford University, T. SCHENKEL, J.W. ÄGER, Lawrence Berkeley National Lab, S.A. LYON, Princeton University — Nuclear spins benefit from long coherence times compared to electron spins, but are slow to manipulate and suffer from weak thermal polarisation. A powerful model for quantum computation is thus one in which electron spins are used for processing and readout while nuclear spins are used for storage. Here we demonstrate the coherent transfer of an electron spin superposition to the nuclear spin using a combination of microwave and radiofrequency pulses applied to $^{31}$P donors in a passively-cooled pure $^{28}$Si crystal. The state is left in the nuclear spin on a time scale long compared with the electron $T_2$ and then coherently transferred back to the electron spin, thus demonstrating the $^{31}$P nuclear spin as a solid-state quantum memory. The transfer fidelity is about 84% each way, attributed to imperfections which could be corrected using composite pulses [J.J.L. Morton et al., Phys Rev Lett 95, 200501 (2005)]. Varying the time for which the state is stored in the nuclear spin permits the direct measurement of the nuclear spin $T_2$, which we have studied in the range 6.5 to 10 K.

10:00AM U28.00009 Detection of low energy single ion impacts in silicon transistors. CHRISTOPH WEIS, ARUNABH BATRA, STEFANO CABRINI, LBNL, JEFFREY BOKOR, CHEUK LO, UC Berkeley, THOMAS SCHENKEL, LBNL — We report a technique for single ion doping of field effect transistors through monitoring of changes in the source-drain currents at room temperature [1]. Implant apertures are formed in the interlayer dielectrics and gate electrodes of planar, micro-scale transistors by electron beam assisted etching. Device currents increase due to the generation of positively charged defects in gate oxides when ions (121Si12+, 14+, Xe6+; 50 to 70 keV) impinge into channel regions. Implant damage is repaired by rapid thermal annealing, enabling iterative cycles of device doping and electrical characterization. We discuss integration of single ion doping for the development of silicon based quantum computer structures with donor electron and nuclear spin qubits. [1] A. Batra et al., Appl. Phys. Lett. 91, 193502 (2007)

10:12AM U28.00010 Real-time decoherence of hyperfine-coupled electrons in quantum dots. JORDAN KRYIAKIDIS, JEAN-MARC SAMSON, Dalhousie University, Halifax, Canada — We approach the study of the electron spin decoherence due to the Fermi contact hyperfine interaction with the density matrix formalism of quantum relaxation. We consider an s-type electron in the ground state of a quantum dot interacting with a thermal distribution of nuclear spins. We directly compute the time dependence of the reduced density matrix by solving the system of integro-differential equations resulting from the Liouville equation at the Born (but not Markov) approximation. We show how the spin precession can, under certain circumstances, slow down and even reverse its rotation sense.

10:24AM U28.00011 Coupling of Mechanical Modes and Shot Noise in a Radio Frequency Quantum Point Contact. J. STETTENHEIM, FENG PAN, Dartmouth College, Z. JI, Rice University, MUSTABA BAL, W.W. XUE, Dartmouth College, MADHU THALAKULAM, Rice University, L.N. PFEIFFER, K.W. WEST, Bell Laboratories, Lucent Technologies Inc., Murray Hill, NJ 07974, A.J. RIMBERG, Dartmouth College — Interesting interactions exist between the electrical and mechanical degrees of freedom in GaAs quantum nanostructures due to the piezoelectric nature of the substrate. Here, we report measurements in radio-frequency quantum point contacts (RF-QPCs) in which the photon assisted tunneling is mediated by a piezoelectric substrate. The RF-QPC has a unique ten-fold (near) degeneracy which is only slightly lifted by stresses, magnetic field and spin-orbital interaction. Despite this degeneracy, we predict, on the basis of the time-reversal symmetry and weakness of the umklapp phonon processes, an extraordinarily long relaxation time for lithium donor electron spin for the temperatures below 0.3 K. Strong temperature dependence of the spin relaxation time is due to activation-type processes with several activation exponents. Experimentally observed traces of magnetization reversal and longitudinal spin relaxation times at $T = 2.1$ K and $\alpha = 4.5$ K are in remarkably close agreement with the theory.

10:36AM U28.00012 Intrinsic noise measurement of an ultra-sensitive radio-frequency single electron transistor1, W.W. XUE, Dartmouth College, Z. JI, Rice University, FENG PAN, A.J. RIMBERG, Dartmouth College — The radio-frequency single electron transistor (rf-SET) has been the focus of intense interest since its invention in 1998[1]. Using cryogenic ultra-thin film evaporation techniques [2] and an improved on-chip superconducting matching network [3], we have consistently fabricated rf-SETs with charge sensitivity of 1.7–5µe/√Hz and uncoupled energy sensitivity 1.1–5.1µe/√Hz. Using our 1GHz resonant circuit, intrinsic noise in the SET arising from a dc voltage bias was measured in the white noise limit. We measured the offset charge dependence of the intrinsic noise in the vicinity of the Josephson-quasiparticle and double Josephson-quasiparticle transport cycles. In regions for which the offset charge and resistance noise are strongly suppressed, we can determine the SET shot noise in the sup-gate regime. We discuss the effects of correlations between charge carriers on the measured Fano factor. [1] R.J. 10:48AM U28.00013 Coherent electron-phonon states in suspended quantum dots: decoherence and dissipation effects1, LUIS G.C. REGO, Univ. Fed. Santa Catarina, Department of Physics — The dynamics of coherent electron-phonon (el-ph) states is investigated for a suspended quantum dot structure. Exact quantum dynamics calculations reveal that electron and phonons (comprising a thermal bath) couple quantum mechanically to perform coherent oscillations with periods in the range of tens of nanoseconds, despite the finite temperature of the phonon bath. Mechanical energy dissipation due to clamping loss is taken into account in the calculations. Although the lifetime of the coupled el-ph states decreases with the temperature, well defined Rabi oscillations are obtained for temperatures up to 100 mK. The dynamics of the coupled electron-phonon state is susceptible to various forms of external control. For instance, a weak external magnetic field can be used to control the dynamics of the system, by decoupling the electron from the phonon bath. The results cast light upon the underlying physics of a yet unexplored system that could be suitable for novel quantum device applications.

9:24AM U29.00006 Mesoscopic valley-Hall effect in graphene, JOHAN NILSSON, Leiden University — An intriguing property of graphene is the existence of a degree of freedom associated with the two inequivalent valleys in the Brillouin zone. A controlled manipulation of this degree of freedom may potentially be used in novel electronic devices. We study the mesoscopic valley-Hall effect that may provide a route toward the desired control. The effect appears when the inversion symmetry of the crystal is broken, and it can generate a transverse valley current in response to an applied electric field. We look at a few sample setups and discuss the dependence on the geometry and the appearance of valley-Hall edge states. We also compare and contrast our results with those obtained from linear response theory in bulk samples.

9:36AM U29.00007 Electronic screening in graphite, JAMES REED, YOUNG IL JOE, PETER ABBAMONTE, University of Illinois at Urbana-Champaign — Nonlocal screening in highly-oriented pyrolytic graphite was investigated with inelastic x-ray scattering. Measurements were performed over a sufficiently broad range of momentum and energy to permit complete inversion of the loss function, \(-Im[\epsilon(k, \omega)]\), allowing real-time, microscopic imaging of the induced electron density around a charged impurity. In addition, we found evidence for a sign change in the zero-frequency dielectric function, \(\epsilon(k, 0)\), over a sizeable range of momentum. This “antiscreening” should cause the Coulomb interaction to be attractive, perhaps assisting superconductivity in this system.

9:48AM U29.00008 Band Structure of K(2x2) on graphene, JESSICA MCCHESEY, AARON BOSTWICK, TAISUKE OHTA, Lawrence Berkeley National Laboratory, THOMAS SEYLLER, K.V. EMTSEV, Universitt Erlangen-Nnber, KARSTEN HORN, Fritz Haber Institute, ELI ROTENBERG, Lawrence Berkeley National Laboratory — The electronic structure of K(2x2) on graphene, the same stochiometry as bulk KC8, was studied using angle-resolved photoemission spectroscopy (ARPES). In addition to bands derived from the graphene \(\pi\) states an intercalant induced “interlayer band” is observed centered at \(\Gamma\). Of these two bands, the dominant mass renormalization occurs in the \(\pi\)-derived bands, as determined by characterization of the “kinks” in the dispersion measured by ARPES. This suggests that the superconductivity in bulk KC8 has a more important role than the interlayer band.

10:00AM U29.00009 Coulomb scattering and transport in graphene1, DMITRY NOVIKOV, Yale University — The exact transport cross-section off a Coulomb impurity in graphene [1] is proportional to the carrier wavelength. Unexpectedly, the relativistic Coulomb scattering also exhibits a pronounced attraction-repulsion asymmetry [1,2]. Massless carriers are scattered more strongly when they are attracted to a charged impurity than when they are repelled from it. This finding, confirmed recently [3], can be used to separately determine the surface density of donors and acceptors in a graphene monolayer [2]. I will outline quantitative and qualitative differences between the exact result [1] and the commonly used Born approximation for charged impurity scattering. [1] D. S. Novikov, arXiv:0706.1391, Phys. Rev. B (in press); [2] D. S. Novikov, Appl. Phys. Lett. 91, 102102 (2007); [3] J. H. Chen, C. Jang, M. S. Fuhrer, E. D. Williams, M. Ishigami, arXiv:0708.2408v2.

10:12AM U29.00010 Resonance Raman investigation of monolayer and bilayer graphene, MARCOS PIMENTA, LEANDRO MALARD, DANIELA MAFRA, JULIANA BRANT, DANIEL ELIAS, Departamento de Fisica, UFMG, Brazil, GEORGII SAMSONIDZE, Berkeley University, JOHAN NILSSON, ANTONIO CASTRO NETO, Boston University, FLAVIO PLENTZ, ELMO ALVES, Departamento de Fisica, UFMG, Brazil — The Raman spectra of graphene samples exhibit a band around 2700 cm\(^{-1}\), the so called G’ band, that is ascribed to a double resonance Raman process involving electrons and phonons in the vicinity of the Dirac point. A dispersive behavior in the position and shape of this band is observed when we change the laser energy used in the Raman experiment, showing that it can be used to probe experimentally the dispersion of electrons and phonons near the Dirac point of graphene. We will present a resonance Raman investigation of monolayer and bilayer graphene using many different laser lines in the visible and near IR range. By the analysis of the dispersive behavior of the G’ band we can obtain information about the electronic structure of monolayer and bilayer graphene, such as the intralayer and interlayer tight-binding parameters. Our results reveal a significant asymmetry between the electronic dispersion in the valence and conduction bands of bilayer graphene. We are also able to obtain experimental values for the velocity of the TO and LA phonons near the Dirac point of graphene.

10:24AM U29.00011 Effect of contact induced states on minimum conductivity in graphene, ROKANSA GOLIZADEH-MOJARAD, SUPRIYO DATTA, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN-47906, USA — Recent experiments show that the conductivity of graphene tends to a minimum value in the range of \(~2-12\Omega^{-1}\) as the Fermi energy \(E_F\) approaches the charge neutral Dirac points \((E = 0)\). We point out that contact induced states can help explain the structure dependence of the minimum conductivity observed experimentally even if the samples were purely ballistic. Contact induced states are similar to the well-known metal induced gap states (MIGS) in metal-semiconductor Schottky junctions, which typically penetrate only a few atomic lengths into the semiconductor, while the depth of penetration decreases with increasing band gap. However, in graphene we find that these states penetrate a much longer distance of the order of the width of the contacts. As a result, ballistic graphene samples with a length less than their width can exhibit a resistance proportional to length that is not ‘Ohmic’ in origin, but arises from a reduced role of contact-induced states. While actual samples are probably not ballistic and involve scattering processes, our results show that these contact induced effects need to be taken into account in interpreting experiments and minimum conductivity depends strongly on the structure and configuration (two- vs. four-terminal).

10:36AM U29.00012 Theory of superconductivity by the edge states in graphene, KEN-ICHI SASAKI, MASAHIRO SUZUKI, RICHIRO SAITO, Tohoku University — Superconductivity in graphite intercalation compound and carbon nanotubes has been attracting much attention due to its high superconducting transition temperature above 10 K. However, the density of states (DOS) near the Fermi level of graphene is not sufficient to explain the observed high transition temperature. Thus, the mechanism of the superconductivity is an important issue. The STS measurements (Kobayashi et al., PRB73.125415, Niihi et al., PRB73.085421) show an anomalous DOS near the Fermi level of graphene which is relevant to localized edge states. The edge states significantly enhance the local DOS near the zigzag edge. Thus, it is valuable to examine the effect of the edge states on the superconductivity. Using the Eliashberg equation, we obtain an appreciable transition temperature for the edge states. We found that the effects of the Coulomb interaction and Fermi energy position are sensitive to the formation of superconducting gap. We will discuss the condition for observing the edge state superconductivity. (Sasaki et al., J. Phys. Soc. Jpn. 76, 033702 (2007))
10:48AM U29.00013 Ground-state carrier density in graphene, ENRICO ROSSI, SANKAR DAS SARMA, Condensed Matter Theory Center, University of Maryland, College Park, MD 20742-4111, USA — We calculate the carrier density spatial distribution for the ground state of a single layer graphene sheet in presence of randomly distributed charged impurities. In our calculation we include the effects due to the exchange and correlation energy. We carefully study how the distance $d$ of the charge impurities from the graphene layer and an external bias affect the spatial distribution of the carrier density. At zero bias we find that the carrier density is characterized by the presence of electron and hole puddles with equal probability and that, for $d \approx 1$, the typical size of the puddles is of the order of 30 nm in agreement with recent experiments. With the same approach we study the situation when a tunable barrier potential is applied locally and a bipolar junction within the graphene sheet is formed. This work is supported by NRI-NSF.

8:00AM U30.00001 Ab-initio study of polarization in graphene films, ERIC YU, Department of Electrical and Computer Engineering, Cornell University, DEREK STEWART, Cornell Nanoscale Facility, Cornell University, SANDIP TIWARI, Department of Electrical and Computer Engineering, Cornell University — We present an ab-initio analysis of polarization of multilayer graphene systems under applied electric fields. The effects of applied electric fields are calculated using a Berry phase approach with a plane-wave density functional formalism. We have determine polarization values for graphene films and carbon nanotubes and find that the polarizability of graphene films follows a linear relationship with the number of layers. We also examined changes in the induced charge distribution as a function of graphene layers. We focus in particular on bilayer graphene and find that the induced charge accumulates primarily on the B sublattice sites. This induced charge distribution was also confirmed by a separate tight-binding Green’s function calculation.

8:12AM U30.00002 Large-Scale Self-Consistent Simulation of Multilayered Graphene Devices, DENIS ARESHKIN, BRANISLAV K. NIKOLIC, University of Delaware — We use the Density Functional Theory-based Self-Consistent Environment-Dependent Tight-Binding (SC-EDTB) and self-consistent Non-equilibrium Green function formalism (NEGF) to test the all-graphene multilayer circuit concept. The key element of multi-layered circuits, which is to become available through high-speed graphene research, is the highly perforated graphene layer. The latter serves as an electrical insulator due to its relatively large band gap, and poor ballistic coupling to the conductive parts of the circuit. High bias $V − V'$ characteristics for various normally-on and normally-off transistor configurations were simulated, and transistor tolerance to manufacturing defects and imperfections was tested. The usage of SC-EDTB-NEGF makes it possible to model quantum transport through realistic devices composed of large number of carbon atoms ($\sim 10^6$), which are within the reach of presently available processing techniques. Other circuit elements, such as electric interconnects between different layers, wires crossings, and electric interconnects within the same layer are also considered.

8:24AM U30.00003 Energy bands of multilayer graphenes, WEN-YING RUAN, JIA-AN YAN, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology — The energy bands of L-graphene have been obtained using first-principles calculations. We found that after the introduction of interlayer coupling the linear valence and conduction bands of isolated layers can either remain or develop into parabolic bands or bands with a very flat top(bottom), depending on the stacking geometry. A theoretical explanation and some general rules have been developed based upon the tight-binding model with only the nearest-neighbor interactions.

8:36AM U30.00004 Effect of strain on the electronic structure of graphene, EDGAR MARTINEZ, Departamento de Fisica de Aplicada, Cinvestav-Merida, Yucatan, Mexico A.P. 73 Cordemex 97310 Merida, Yucatan, Mexico, EDUARDO CIFUENTES, Facultad de Ingenieria, Universidad Autonoma de Yucatan, Mexico, ROMEO DE COSS, Departamento de Fisica de Aplicada, Cinvestav-Merida, Yucatan, Mexico — Graphene has been attracting interest due to its remarkable physical properties resulting from an electron spectrum resembling relativistic dynamics (Dirac fermions). Thus, is desirable to know methods for controlling the charge carriers in graphene. In this work, we propose that the electronic properties of graphene can be modulated via isotropic and uniaxial strain. We have studied the electronic structure of graphene under mechanical deformation by means of first principles calculations. We present results for the charge distribution, electronic density of states, and band structure. We focus the analysis on the behavior of the Dirac cones and the number of the charge carriers as a function of strain. We find that an isotropic tensile strain increases the effective mass of carriers and an isotropic compression strain decrease it. Uniaxial tensile strain induce a similar behavior, as strain increase effective mass increase. Thus, our results show that strain allows controllable tuning of the graphene electronic properties. This research was supported by Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grant No. 43830-F.

8:48AM U30.00005 Band-gap engineering in graphene systems for electronic applications, SUJATA PAUL, MARCO BUONGIORNO-NARDELLI, NC State University — Ultrasound graphene films including monolayers, bilayers and graphene nanoribbons are intensely studied for the development of future electronic and optoelectronic devices. In this work we will present first principles electronic/phonon structure calculations to elucidate the role of geometry and interactions (electric field, edge functionalization, gating etc.) in the determination of the electronic properties of a wide variety of graphene systems (multi-layers, ribbons etc.). One preliminary objective of this task is to explore ways to accurately control the band gap through the careful design of the active graphitic systems. The coupling between electron and lattice dynamics will be analyzed via the evaluation of the electron-phonon coupling parameters and phonon dispersions calculations. We will discuss the growth of graphene layers on a preferred substrate e.g. SiC an Si.

9:00AM U30.00006 Effect of Disorders in Graphene Nanoribbon Field-Effect Transistors, YOUNGKI YOON, U of Florida, GIANLUCA FIORI, Università di Pisa, SEOKMIN HONG, U of Florida, GIUSEPPE IANNACCONE, Università di Pisa, JING GUO, U of Florida — Recent progress on the graphene and graphene nanoribbon (GNR) has provoked strong interests in GNR field-effect transistors (FETs) for future digital and analog nanoelectronics applications. In this work, device characteristics of GNRFETs are calculated by solving the non-equilibrium Green's function (NEGF) transport equation in an atomicistic $p^2$ orbital basis set self-consistently with three-dimensional (3D) Poisson equation. The effects of a lattice vacancy, ionized impurity, and edge roughness on transistor performance and characteristics are examined by the atomistic simulations. We show that even a single disorder can have a significant effect on the device characteristics of GNRFETs due to the atomically thin and nanometer-wide channel geometry. For example, a single lattice vacancy can affect the on-current of a GNRFET by 40%. Localized states in the GNR band gap energy range can be induced by the disorders, which affect quantum transport and self-consistent electrostatics. Significant variations between devices are expected due to disorders, but the GNRFETs still switch in the presence of moderate amount of disorders.
investigating the edge states of the Z-BGNR, we notice that the trigonal warping of the bilayer graphene sheets are reflected on in the edge state structure of the parameter bilayer graphite nanoribbons (Z-BGNR) with various ribbon width.

There exist many one-dimensional energy bands. The low energy bands are drastically changed by the interlayer atomic hoppings, such as the destruction of state degeneracy, alteration of Fermi-momentum states, creation of extra band-edge states, and modulation of energy gap. The composite systems are metals or semiconductors, which depends on the alignment and the geometry of carbon nanotube. The main characteristics of electronic structures are directly reflected in the electronic switch.

Based on this study, only the two-layer FLG is useful as a nanoscale electronic switch.

**9:12AM U30.00007 Diluted Graphene Antiferromagnet**, HERBERT FERTIG, Indiana University, LUIS BREVY, Instituto de Ciencia de Materiales de Madrid, SANKAR DAS SARMA, University of Maryland — We study RKKY interactions between local magnetic moments for both doped and undoped graphene. We find in both cases that the interactions are primarily ferromagnetic for moments on the same sublattice, and antiferromagnetic for moments on opposite sublattices. This suggests that at sufficiently low temperatures dilute magnetic moments embedded in graphene can order into a state analogous to that of a dilute antiferromagnet. We find that in the undoped case one expects no net magnetic moment, and demonstrate numerically that this effect generalizes to ribbons where the magnetic response is strongest at the edge, suggesting the possibility of an unusual spin-transfer device. For doped graphene we find that moments at definite lattice sites interact over longer distances than those placed in interstitial sites of the lattice (1/R^2 vs. 1/R^3) because the former support a Kohn anomaly that is suppressed in the latter due to the absence of backscattering.

**9:24AM U30.00008 Magnetization measurement of highly oriented pyrolytic graphite surface with a spin-polarized metastable helium beam**, SHIRO ENTANI, MITSUNORI KURAHASHI, YASUSHI YAMAUCHI — Magnetic ordering in nanometerscale graphic materials has attracted much interest in recent years. Some theoretical studies have predicted that the origin of ferromagnetism in these materials was attributed to defects in graphic structures, such as edges and topological defects. Employing surface analytical technique is favorable for elucidation of these predictions by experimental studies, because there exist a number of pores and steps at the graphite surface and the structure not in an equilibrium phase might be realized at a surface state. In this work, we have successfully detected the magnetization in highly oriented pyrolytic graphite (HOPG) surface using a spin-polarized metastable helium (He*) beam under high magnetic field up to 5 T. The He* beam is an extremely surface-sensitive probe and the surface magnetization can be analyzed by measuring the asymmetry of sample current induced by the He* spin direction [1]. The observed value of the asymmetry shows a clear temperature dependence and is much larger than that of magnetic impurities measured by Auger electron spectroscopy. Thus, we could conclude that this surface magnetism is an intrinsic property of the HOPG itself other than the diamagnetism.

---

**9:48AM U30.00010 Band structure engineering of graphene by strain**, JIANXIN ZHONG, GUI GUI, JIN LI, Department of Physics, Xiangtan University, Hunan 411105, China — We have investigated the electronic structure of graphene under different planar strain distributions using the first principles pseudopotential plane-wave method and the tight-binding approach. We found that graphene with a symmetrical strain distribution is always a zero band gap semiconductor and its pseudogap decreases linearly with the strain strength in the elastic regime. However, asymmetrical strain distributions in graphene result in opening of band gaps at the Fermi level. For the graphene with a strain distribution parallel to C-C bonds, its band gap continuously increases to its maximum width of 0.486 eV as the strain increases. For the graphene with a strain distribution perpendicular to C-C bonds, its band gap continuously increases only to 0.170 eV. The anisotropic nature of graphene is also reflected by different Poisson ratios in different directions. We found that the Poisson ratio is 0.079 and 0.255 for the strain distributions parallel to or perpendicular to C-C bonds, respectively. These findings are important for understanding and controlling the transport properties of graphene systems.

**10:00AM U30.00011 Electronic properties of nanotube-graphene composite carbon systems**, YEN-HUNG HO, Department of Physics, National Cheng Kung University, C.P. CHANG, Center of General Education, Tainan University of Technology, M.F. LIN, Department of Physics, National Cheng Kung University — Band structures of nanotube-graphene hybrid carbon systems are calculated by the tight-binding model. The Lennard-Jones potential is used to determine the optimal geometry for a single-walled carbon nanotube and a monolayer graphene. There exist many one-dimensional energy bands. The low energy bands are drastically changed by the interlayer atomic hoppings, such as the destruction of state degeneracy, alteration of Fermi-momentum states, creation of extra band-edge states, and modulation of energy gap. The composite systems are metals or semiconductors, which depends on the alignment and the geometry of carbon nanotube. The main characteristics of electronic structures are directly reflected in density of states. DOS exhibits a lot of asymmetric prominent peaks. The predicted results could be verified by the experimental measurements from the scanning tunneling spectroscopy.

---

**10:12AM U30.00012 Edge states of zigzag bilayer graphite nanoribbons**, JUN-WON RHIM, KYUNGSUN MOON, Department of Physics, Yonsei University, Seoul, South Korea, CONDENSED MATTER THEORY GROUP TEAM — Electronic structures of the zigzag bilayer graphite nanoribbons (Z-BGNR) with various ribbon width N are studied within the tight binding approximation. Neglecting the small inter-layer hopping parameter γ_z, there exist two fixed Fermi points ±k∗ for the ribbon width with the peculiar energy dispersion near k∗ as ε(k) ~ ε(k−k∗)^N. By investigating the edge states of the Z-BGNR, we notice that the tringular warping of the bilayer graphene sheets are reflected on the edge state structure of the Z-BGNR. With the inclusion of γ_z, the two above Fermi points are not fixed, but drift toward the vicinity of the Dirac point with the increase of the width N as shown by the finite scaling method and the peculiar dispersions change to the parabolic ones.

Morial Convention Center 223
8:00AM U31.00001 Spontaneous currents and charge redistribution in Mott insulators, DANIEL KHOMSKII, Universitaet zu Koeln, LEV BULAEVSKI, CHRISTIAN BATISTA, Los Alamos National Laboratory, MAXIM MOSTOVOY, Groningen University — The standard view is that at low energies Mott insulators exhibit only magnetic properties while charge degrees of freedom are frozen out as the electrons become localized by a strong Coulomb repulsion. We demonstrate that this is in general not true: for certain spin textures spontaneous circular electric currents or nonuniform charge distribution exist in the ground state of Mott insulators. The latter can give a purely electronic mechanism of multiferroic behaviour. In addition, low-energy "magnetic" states compare to the dielectric and magnetic phenomena, leading to interesting states like the electric field-induced "ESR" transitions, rotation the electric field polarization and resonances which may be common for both functions producing a negative refraction index in a window of frequencies.

8:12AM U31.00002 First-Principles Study of Large MagnetoElectric Coupling in Triangular Lattices, KRIS T. DELANEY, Materials Research Laboratory, UC Santa Barbara, MAXIM MOSTOVOY, Zernike Institute for Advanced Materials, University of Groningen, The Netherlands, NICOLA A. SPALDIN, Materials Department, UC Santa Barbara — We investigate, using density functional theory, the magneto-electric coupling in a frustrated antiferromagnet in which the combination of frustration with magnetic interactions mediated by Anderson superexchange leads to a unconventional and large coupling between polarization and magnetic order. The nature of the superexchange mechanism can be manipulated through polarization of the lattice upon application of an electric field, leading to a strong magnetoelectric effect. We demonstrate the effect in a Mn-based triangular lattice that is closely related to the Kagomé structure, with modifications to avoid self-compensation of the induced magnetic order. For our study, we employ the VASP software package with LSDA+U for describing electron exchange and correlation effects. A fully noncollinear treatment of the spinors is essential to describe the complex spin structures that the system adopts.

8:24AM U31.00003 Trends in spin exchange interactions and ferroelectric polarization in the orthorhombic $R\text{MnO}_3$ series, SILVIA PICOZZI, KUNIHIKO YAMAUCHI, CNR-INFM L Aquila, Italy, BIPAL SANYAL, Uppsala Univ., Uppsala, Sweden, FRANK FREIMUTH, STEFAN BLÜGEL, Forschungszentrum Julich, Germany, ELBIO DAGOTTO, Oak Ridge Natl. Lab. and Univ. Tennessee, TN — Recently, magnetic ferroelectricity induced by Heisenberg-type interactions has been theoretically predicted in E-type antiferromagnetic (AFM) $R\text{MnO}_3$. In order to fully clarify this unconventional microscopic mechanism, we have studied the structural, magnetic and ferroelectric properties for the entire family of orthorhombic $R\text{MnO}_3$ ($R=$ rare earth ions), based on first-principles density functional calculations. The ferromagnetic exchange interaction between nearest-neighbor Mn sites decreases with the ionic radius of $R$ (concomitantly with the in-plane Mn-O-Mn bond angle), whereas the anti-ferromagnetic next-nearest neighbor interaction rather stays constant in the series. The competition of these exchange interactions results in a complicated magnetic phase diagram. The decrease in the Mn-O-Mn angle also affects the hopping integrals between Mn ions (as determined from Wannier functions), so that the calculated electric polarization in E-type AFM $R\text{MnO}_3$ is remarkably reduced throughout the rare earth series.

8:36AM U31.00004 First-principles study of magneto-electric coupling in TbMnO$_3$, ANDREI MALASHCHEVICH, DAVID VANDERBILT, Rutgers University — At room temperature, the perovskite TbMnO$_3$ forms an orthohombically distorted lattice with the $Pbnm$ space group. Below $\sim$27 K the magnetic moments on the Mn atoms develop incommensurate cycloidal order, and simultaneously a polarization appears. We present a first-principles study of this low-temperature phase in which the ordering of the Mn$^{3+}$ moments is forced to be commensurate in a 60-atom supercell, approximating the experimental wavevector. The calculations are based on a non-collinear spin treatment of density-functional theory in the local-density approximation, with the polarization computed using the Berry-phase technique. We confirm that the electric polarization appears only when the spin-orbit coupling is turned on. Both electronic and lattice-mediated contributions to the polarization appear, the latter being dominant. We make a normal-mode analysis of the lattice contribution and discuss the ability of a model based on local Dyzaloishinski-Moriya interactions to reproduce the computed pattern of forces.

8:48AM U31.00005 MagnetoElectric Chains: Quasi-One-Dimensional Multiferroics, TURAB LOOKMAN, AVADH SAXENA, Los Alamos National laboratory — Recently discovered pyrochlores represent an example of a multiferroic containing quasi-one dimensional (Q1D) building blocks of zig-zag chains of edge-sharing octahedra along the c-axis of the crystal. This leads us to the natural question: what types of Q1D symmetries would allow for the simultaneous presence of polarization and magnetization? Moreover, what kinds of phase transitions can exist between two different Q1D magnetic phases? From this perspective we study quasi- one-dimensional magnetic symmetry in 3D space (magnetic rod groups), enumerate Q1D magnetic point groups that allow for magneto-electricity and illustrate their role in low-dimensional multiferroic phase transitions.

9:00AM U31.00006 Influence of oxygen defects and lattice distortions on the energy gap formation and magnetic properties of multi-ferroic materials, JUJI PULIKKOTIL, VLADIMIR ANTROPOV, Ames Laboratory — Full potential density functional calculations are performed to study the effects of O-vacancies on the structural parameters and electronic properties of $R\text{MnO}_4$ ($R=$ Y, rare-earths). We find that vacancies at the 2a-position of the hexagonal unit cell can introduce a small gap of magnitude $0.2\text{eV}$. Although significantly lower than the experimentally observed value of $2.5\text{eV}$, we claim that already such defects, which in general are inevitable in oxides, can introduce the energy gap in addition to the most commonly accepted Coulomb correlation mechanism. Besides, the off-plane O-vacancies modify the magnetic properties of the system and induce small magnetic polarization on the in-plane O-sites and at the interstitials. The electronic structure and magnetic properties modifications as a function of several lattice distortions have been analyzed. We also discuss the mechanisms of the exchange coupling and its most effective path. In addition we compare previously known results of the electronic structure calculations for these systems.

9:12AM U31.00007 Domain structure and magnetization reversal in multiferroic LuFe$_2$O$_4$, WEIDA WU, SOONYONG PARK, CHENGLIN ZHANG, S.-W. CHEONG, Department of Physics and Astronomy, Rutgers University — We report real space magnetic imaging of single crystal multiferroic LuFe$_2$O$_4$ via variable temperature magnetic force microscopy (VT-MFM). The magnetization reversal of LuFe$_2$O$_4$ is investigated in detail with MFM in magnetic fields up to 8 tesla at several temperatures below $T_N=230\text{K}$. Our results suggest that the domain structure and the magnetization reversal of LuFe$_2$O$_4$ are different from those of conventional FM magnets with a uniaxial anisotropy. These unconventional behaviors may originate from the low dimensional and the unusual spin-charge frustration of LuFe$_2$O$_4$.

9:24AM U31.00008 Interplay of charge order and magnetism in LuFe$_2$O$_4$, M. ANGST, Oak Ridge National Laboratory, Oak Ridge TN, R.P. HERMANN, Institut fuer Festkoerperforschung, Forschungszentrum Julich, Germany, A.D. CHRISTIANSSON, W. TIAN, R. JIN, B.C. SALES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge TN — Ferroelectricity in LuFe$_2$O$_4$ may originate from charge order and seems to be coupled the magnetism as well. Both charge order and magnetism, conflicting reports have been published. We have recently grown single crystals exhibiting features in magnetization sharper that previously reported and suggesting an additional transition around 175 K. Neutron scattering experiments have revealed Q1D magnetic and charge order. We will also present recent growth, characterization and magnetization measurements on these crystals, which indicate a subtle interplay of magnetism, charge order, and structural distortions. Superstructure reflections studied include (1/3,1/3,n and n/2) (exhibiting small systematic deviations away from 1/3), satellites to (0,0,3/2n) and (1/3,1/3,n and n/2), and two other types of reflections. Supported by the Division of Materials Sciences and Engineering, Office of Basic Energy Sciences, US Department of Energy.
9:36AM U31.00009 Three dimensional magnetic correlations in LuFe$_2$O$_4$. M.D. LUMSDEN, A.D. CHRISTIANSON, M. ANGST, Oak Ridge National Laboratory, Oak Ridge TN 37831, Z. YAMANI, Canadian Neutron Beam Centre, NRC, Chalk River, Canada, W. TIAN, R. JIN, S.E. NAGLER, B.C. SALES, D. MANDRUS, Oak Ridge National Laboratory, Oak Ridge TN 37831 — LuFe$_2$O$_4$ has recently attracted much attention due to a novel electronically driven ferroelectric transition and concomitant indications of coupling between magnetic degrees of freedom and a large spontaneous polarization. To examine the behavior of LuFe$_2$O$_4$ in further detail, we have performed extensive polarized and unpolarized neutron diffraction experiments on high quality single crystal specimens. These measurements reveal two phase transitions involving magnetic degrees of freedom below 300 K. At 240 K we find the onset of three dimensional ferrimagnetic order. The refined ferrimagnetic spin structure is a symmetry allowed magnetic structure of the parent R-3m space group with a propagation vector of (1/3 1/3 1/3). Below 175 K many of the magnetic Bragg peaks become significantly broadened and a broad diffuse component to the magnetic scattering becomes evident. In addition, a new set of satellites is observed indexed as (1/3 ±δ 1/3 ±δ 3L/2) where δ ≈ 0.027. Polarized neutron diffraction measurements indicate that these satellites have a substantial magnetic component.

9:48AM U31.00010 Optical properties of LuFe$_2$O$_4$. XIAOSHAN XU, TATIANA BRINZARI, JANICE MUSFELDT, University of Tennessee, Knoxville, MANUEL ANGST, DAVID MANDRUS, Oak Ridge National Laboratory — We measured the optical properties of single crystalline LuFe$_2$O$_4$ as a function of temperature and compared the results with recent electronic structure calculations. The 300 K optical gap is found to be ~ 0.4 eV. The optical conductivity is very sensitive to temperature and shows a sharp transition at around 170 K structural transition. The Fe$^{2+}$ to Fe$^{3+}$ charge transfer transition (at approximately 1.5 eV) sharpens dramatically at low temperature, a trend that may be connected with the complex charge order of handedness.

10:00AM U31.00011 Effect of oxygen deficiencies on charge ordering in RFe$_2$O$_4$−δ (R=Lu and Y). Y. HORIBE, Rutgers University, S. MORI, S. SHINOHARA, Y. MATSUO, Osaka Prefecture University, N. IKEDA, Okayama University, S-W. CHEONG, Rutgers University — Charge ordering (CO) of Fe$^{2+}$ and Fe$^{3+}$ on the triangular lattice in RFe$_2$O$_4$−δ (R=Lu and Y) is suggested to play an important role in the physical properties such as ferroelectricity. Herein, we report changes in the CO structures due to the oxygen deficiencies in RFe$_2$O$_4$−δ by transmission electron microscopy. At room temperature, characteristic superlattice reflections at (1/3 1/3 1/2)-type positions can be observed in the nearly stoichiometric YFe$_2$O$_4$−δ, where the diffuse streaks along c*-axis can be seen clearly in the non-stoichiometric YFe$_2$O$_4$−δ. It is suggested that the correlations between the Fe-O bilayers are suppressed due to the oxygen vacancies and therefore the two-dimensional charge ordering appears in the non-stoichiometric samples at room temperature.

10:12AM U31.00012 Ferroelectricity in an Ising Chain Magnet. V. KIRYUKHIN, Y.J. CHOI, H.T. YI, S. LEE, S-W. CHEONG, Rutgers Univ., Q. HUANG, NIST — The concept of magnetism-driven ferroelectricity has recently drawn significant attention. Among the simplest model systems showing this effect are magnetic spiral compounds, and frustrated collinear chain magnets with alternating charge order. While many experimental realizations of the former systems exist, no undisputed examples of the latter have been reported so far. Herein, we report discovery of an experimental realization of this model in an Ising chain compound with an up- down-down magnetic order. Unlike in the spiral magnetoelectrics where antisymmetric exchange coupling is active, the symmetry breaking in this system occurs through exchange striction associated with symmetric superexchange coupling. Since the latter can be large, this observation may help identify candidate systems with large magnetoelectric coupling and significant magnetoelectric effects.

10:24AM U31.00013 Magnetoelastic effect in Cr$_2$O$_3$ thin films. XI HE, University of Nebraska-Lincoln, YI WANG, SARBESWAR Sahoo, CHRISTIAN BINEK — Magnetoelastic materials experienced a recent revival as promising components of novel spintronic devices [1, 2, 3]. Since the magnetoelastic (ME) effect is relativistically small in traditional antiferromagnetic compounds like Cr$_2$O$_3$ (max. $\alpha_{xx} \approx 4\mu m$) and also cross-coupling between ferroic order parameters is typically small in the modern multiferroics, it is a challenge to electrically induce sufficient magnetization required for the envisioned device applications. A straightforward approach is to increase the electric field at constant voltage by reducing the thickness of the ME material to thin films of a few nm. Since magnetism is known to be affected by geometrical confinement thickness dependence of the ME effect in thin film Cr$_2$O$_3$ is expected. We grow (111) textured Cr$_2$O$_3$ films with various thicknesses below 500 nm and study the ME effect for various ME annealing conditions as a function of temperature with the help of Kerr-magnetometry. 10:36AM U31.00014 First-principles approach to lattice-mediated magnetoelectric effects. JORGE IGÜNEZ, ICMAB-CSIC — I will present a first-principles scheme for the computation of the magnetoelectric (ME) response of magnetic insulators. The method focuses on the lattice-mediated part of the magnetic response to an electric field, which can be expected to be the dominant contribution in materials displaying a strong coupling, thus avoiding the technical difficulties associated to the treatment of a purely electronic ME effect. I will describe results of calculations for Cr$_2$O$_3$ and other model magnetoelastic compounds.

10:48AM U31.00015 Chirality, Handedness and Pseudovectors. THOMAS A. KAPLAN, Michigan State University, S. D. MAHANTI, Michigan State University, KYLE WARLOW, Iowa State University — Chirality has been, to our knowledge, universally defined as a symmetry property, namely, lack of mirror symmetry of a physical object (e.g. a molecule) or, more generally, a physical situation (e.g. light propagation). It is understood that the mirror can be followed by a proper rotation and/or translation. The word chirality (Greek: hand), was added by Lord Kelvin after Pasteur noted the physical importance of right- and left-handed molecules, and, in this context, is considered identical to handedness. However, there is another context, equally important, where handedness has a different meaning, namely the handedness associated with the definition of the cross-product of two vectors. We call the former def. 1, the latter, def. 2. We show that the two meanings are essentially different by giving examples which are simultaneously handed (def. 2) and not chiral. These are drawn from light waves, spin spirals and multiferroics. Thus we show that there must be a distinction between chirality and the general idea of handedness.

Thursday, March 13, 2008 8:00AM - 11:00AM — Session U32 GMAG DMP: Focus Session: Magnetic Multilayers and Nanostructures Morial Convention Center 225
8:00AM U32.00001 Unusual resonant response in [Fe(001)/Cr(001)]10/ MgO(001) magnetic multilayers in magnetic field. VLADIMIR PRYADUN, FARKHAD ALIEV, Departamento de Fisica de la Materia Condensada, Universidad Autonoma de Madrid, Spain, ETIENNE SNOECK, Groupe NanoMateriaux, CEMES-CNRS, Toulouse, France — We report on experimental observation of unusual electromagnetic resonances in [Fe/Cr]10 multilayers epitaxially grown on MgO(001) substrates and measured by using balanced excitation and detection schemes. Electric voltage resonances with quality factor exceeding $10^3$ induce strong enhancement of Hall resistance for specific frequencies. Surprisingly, the continuum mechanics model for suspended Fe/Cr layers accounts well for the observed phenomena. Cross-sectional electron microscopy analysis of the multilayers confirms that we could be dealing with non-suspended nanoelectromechanical system.

8:12AM U32.00002 Field Dependence of the Magnetic Roughness of CoFe(B)/MgO.1. ¶ YVES IDZERDA, JOE DVORAK, EZANA NEGUSSE, ALEX LUSSIER, Montana State University, S.R. SHINDE, Y. NAGAMINE, S. FURUKAWA, K. TSUNEKAWA, D.D. DJAYAPRAWIRA, Canon-ANELVA Corporation — We have measured the field dependent roughness of the magnetic interface of CoFe and CoFeB films covered by MgO by using diffuse X-ray resonant magnetic scattering (diffuse-XRMS) of circular polarized light. The samples studied were 3.0 nm of either a Co(70)/Fe(30) or a Co(60)/Fe(20)/B(20) film covered by 1.8 nm MgO created by UHV sputtering system (ANELVA C-7100). By comparing the specular scattering map and the diffuse scattering map for a large range of incidence angles for photons resonantly tuned near the Co L3-edge as the applied magnetic field is swept through the coercive field, we have determined the chemical and magnetic roughness as a function of applied field. For the CoFeB films, the magnetic scattering of the X-rays increases significantly as the film passes through the coercive field where the magnetic in-plane correlations are relatively short range, indicating the presence of small magnetic domains during moment reversal. For the CoFeB films, there is no significant increase in magnetic scattering at the coercive field, consistent with large domain switching.

8:24AM U32.00003 Enhanced Electronic Density of States Observed in Fe-Cr Magnetic Multilayers1. ¶ DAVID W. COOKE, FRANCES HELLMAN, Physics Dept., University of California at Berkeley, MATTHEW CAREY, Hitachi Global Storage Technologies San Jose Research Center — Magnetic multi-layer structures have garnered much interest over the past two decades particularly because of the giant magnetoresistance (GMR) effect and its application to information storage technology. Iron-chromium multi-layer structures have been studied extensively, but there remain many questions in the field due to the complex behavior of the anti-ferromagnetic layer (Cr). Using our silicon micro-machined calorimeters, we examine the low temperature specific heat for a range of sputtered MML films grown under similar conditions to those used in industry. We have observed an enhanced electronic density of states in the Fe-Cr MMLs far beyond that of the iron or chromium individually. We compare this enhancement to the observed GMR behavior through a systematic study varying the thickness of the spacer layer.

8:36AM U32.00004 High bias voltage effect on spin-dependent conductivity and low frequency noise in epitaxial Fe/MgO/Fe magnetic tunnel junctions. FARKHAD ALIEV, RUBEN GUERRERO, DAVID HERRANZ, RAUL VILLAR, Universidad Autonoma de Madrid, Spain, FANNY GREULLET, CORIOLAN TIUSAN, MICHEL HEHN, FRANCOIS MONTAIGNE, Nancy Universitie, France — Low temperature (10K) high voltage bias dynamic conductivity (up to 2.7V) and shot noise (up to 1V) were studied in epitaxial Fe(100)/Fe-C/MgO(100)/Fe(100) magnetic tunnel junctions, as a function of the magnetic state. The MTJs show large TMR (185% at 300K and 330% at 4K). Multiple sign inversion of the magnetoresistance is observed for bias polarity when the electrons scan the electronic structure of the bottom Fe-C interface. The shot-noise shows a Poissonian character validating the high structural quality of the MgO barrier [1]. We have found that the normalized I/f noise (Hooge factor) asymmetry between parallel and antiparallel states may strongly depend on the applied bias and its polarity. These MTJs exhibit record low Hooge factors being at least one order of magnitude smaller than previously reported [2]. [1] R. Guerrero, et al., Appl. Phys. Lett. 91, 132504 (2007); [2] F.G. Aliev, et. al., accepted to Appl. Phys. Lett.).

8:48AM U32.00005 Giant Magnetoresistance in Nanoparticulate Magnets. ANDREAS GLATZ, Argonne National Laboratory, IGOR BELOBORODOV, Universidad de Chicago, VALERII VINOKUR, Argonne National Laboratory — I discuss the giant magnetoresistance (GMR) effect and its application to information storage technology. Iron-chromium multi-layer structures have been studied extensively, but there remain many questions in the field due to the complex behavior of the anti-ferromagnetic layer (Cr). Using our silicon micro-machined calorimeters, we examine the low temperature specific heat for a range of sputtered MML films grown under similar conditions to those used in industry. We have observed an enhanced electronic density of states in the Fe-Cr MMLs far beyond that of the iron or chromium individually. We compare this enhancement to the observed GMR behavior through a systematic study varying the thickness of the spacer layer.

9:00AM U32.00006 Influence of dipolar interactions on the formation of domains in layered Ni/Al2O3 nanocomposites. R. DAS, A. HEBARD, University of Florida, A. GUPTA, D. KUMAR, North Carolina Agricultural and Technical State University, S. OH, S. PENNYCOOK, Oak Ridge National Laboratory — Pulsed laser deposition has been used to fabricate Ni/Al2O3 multilayer composites in which Ni nanoparticles of uniform size in the range of 3-60 nm are embedded as layers in an insulating Al2O3 host. At fixed temperatures, the coercive fields show a well-defined critical size that delineates a crossover from single domain (SD) to multiple domain (MD) behavior. Most applications require that the particles be single domain with a uniform magnetization that remains stable with a sufficiently large anisotropy energy to overcome thermal fluctuations and beat the superparamagnetic limit, which establishes a temperature-dependent lower bound to the particle size (superparamagnetic limit). These considerations must take into account the effect of interactions on magnetic properties as is evident for high-density recording media where particles are very close to each other. The effect of dipolar interactions on the establishment of an upper bound to particle size ($d_c$), which defines the crossover from SD to MD behavior will be discussed. We show using coercivity measurements that, with increasing temperature, $d_c$ increases and then saturates due to attenuated dipolar interactions from thermally induced motions of neighboring randomly oriented particles.

9:12AM U32.00007 An investigation of quantum well states and magnetic properties of Co/Au/Ru(0001). J. CHOI, J. WU, Dept. of Physics, Univ. of California, Berkeley, CA 94720, F. EL GABALY, A.K. SCHMID, NCEM, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, Z.Q. QIU, Dept. of Physics, Univ. of California, Berkeley, CA 94720 — Quantum well state of Co/Au/Ru(0001) was investigated using Spin Polarized Low Energy Electron Microscopy (SPLEEM). Epitaxially grown Au on Ru(0001) at room temperature was annealed to $\sim$300 °C. Upon annealing, Au forms islands with atomically flat tops across stepped regions of Ru, forming local wedges of different Au thickness. Energy scans reveal clearly the existence of quantum well states in Au/Ru(0001). After depositing Co film on top of the Au, we found that the Curie temperature and the spin reorientation transition of Co film on the flat-top Au islands are different from that on the Au wetting layer. However the quantum well states of the Au layer have no effect on the Curie temperature and the spin reorientation transition of Co film.
9:24AM U32.00008 Angular Dependent Magnetic Susceptibility with Photoexcitation Studies on Prussian Blue Analog Thin Films¹, D.M. PAJEROWSKI, J.-H. PARK, M.W. MEISEL, Physics Department, University of Florida, F.A. FRYE, D.R. TALHAM, Chemistry Department, University of Florida — Prussian blue analog systems are the topic of ongoing research because of their novel physical effects. One such effect is persistent photoinduced magnetization, found in CoFe analogs. For such an optical system, in an attempt to maximize the material's interaction with incident photons, a thin film geometry is often utilized; this geometry can produce new effects [1]. Samples of different starting materials have been characterized with respect to photoinduced states, angular dependent susceptibility, film thickness, and chemical formula. Notably, magnetic anisotropies present in the systems show a dependence on the studied factors. One class of interesting starting materials are $\text{Rb}_2\text{Ni}_2[\text{Cr}(_3\text{Ni})_2]_3$, $\text{H}_2\text{O}$ and $\text{Rb}_2\text{Co}_2[\text{Fe}(_5\text{Co})_2]_3$, $\text{H}_2\text{O}$ heterostructures, generated by sequential adsorption on a Melinex substrate, that display behavior different than a noninteracting admixture of the two materials by themselves.

9:36AM U32.00009 Ferroelectric control of magnetism in BaTiO$_3$/Fe heterostructures¹, SARBESWAR SAHOO, University of Nebraska-Lincoln, SRINIVAS POLISETTY, CHUN GANG DUAN, SITARAM JASWAL, EVGENY TSYMBAL, CHRISTIAN BINEK — Multiferroics can offer the possibility to manipulate the cross coupled order parameters by conjugate electric and magnetic fields. Switching off ferroelectric order by an electric field for instance promises significant impact in the design of novel spintronics devices. Here we report on the reversible control of magnetism for a Fe thin film in proximity of a BaTiO$_3$ single-crystal. Large magnetization changes emerge in response to ferroelectric switching and structural transitions of BaTiO$_3$ controlled by applied electric fields and temperature, respectively. Interface strain coupling is the primary mechanism altering the induced magnetic anisotropy. As a result, coercivity changes up to 120% occur between the various structural states of BaTiO$_3$. Up to 20% coercivity change is achieved via electrical control at room temperature. Our all solid state ferroelectric-ferromagnetic heterostructures open viable possibilities for new technological applications.¹

9:48AM U32.00010 Griffiths phase and paramagnetism in ErCo$_2$³, FERNANDO BARTOLOME, LUIS M. GARCIA, ICMA, CSIC - Universidad de Zaragoza, JULIA HERRERO-ALBILLOS, Materiomics Science Dept., Cambridge University, ANTHONY T. YOUNG, Advanced Light Source, BLNL, TOBIAS FUNK, UCSF Physics Research Laboratory — A systematic study of the paramagnetic phase of ErCo$_2$ has recently allowed to identify the inversion of the net magnetization of the Co net moment with respect to the applied field well above the ferrimagnetic ordering temperature, $T_U$. This phenomenon, which we have denoted paramagnetism, may be related with the onset of a Griffiths-like phase in paramagnetic ErCo$_2$. We have measured SANS and ac susceptibility on ErCo$_2$ as a function of temperature, applied field, and excitation frequency. Several characteristics shared by systems showing a Griffiths phase are present in ErCo$_2$, namely the formation of ferromagnetic clusters in the disordered phase, the loss of analyticity of the magnetic susceptibility and its extreme sensitivity to an applied field. Our XMCD study of the Co magnetic moment flipping process show the occurrence of a pseudo-violation of the third Hund’s rule at the para- to paramagnetic “transition.”
