surprising soft behavior with temperature changes: its energy increases with temperature and reaches the Zeeman energy for temperatures above 2K. These experiments [2] have suggested the possibility of observing a long range Skyrme crystal phase with non-collinear magnetic order at low temperatures. The magnetic properties of the 2DES close to \( \nu = 1 \) are studied by the direct measurement of the low-lying spin wave excitations by inelastic light scattering between 2.5K and 40mK. We discovered a very low energy spin wave that emerges on both sides of \( \nu = 1 \). The spin wave is well below the Zeeman energy and exhibit surprising soft behavior with temperature changes: its energy increases with temperature and reaches the Zeeman energy for temperatures above 2K. These results suggest an instability of the 2DES towards magnetic order at low temperatures and filling factors close to \( \nu = 1 \). The spin excitation spectra are consistent with the ordering of the in-plane components of spin in a square Skyrme crystal phase proposed in theoretical evaluations [3], but never fully confirmed by experiments. Our experiments create venues for the determination of Skyrme crystal phases from measurements of low-lying spin excitations by inelastic light scattering.

Supported by NSF Grant No. NMR-0352738 and by DOE Grant No. DE-AIO2-04ER46133.

Work performed at Columbia University (USA) in collaboration with J.Yan, A.Pinczuk, L.N. Pfeiffer and K.W.West.

8:36AM A1.00002 Soft spin waves and magnetic instability in Skyrmion systems\(^1\), YANN GALLAIS\(^2\).

Universite Paris 7 — In this work the highly correlated ground states of spin in 2D electron layers (2DES) near filling factor \( \nu = 1 \) are probed by inelastic light scattering [1]. In this filling factor region the ground state of the 2DES is affected by the proliferation of spin-charge textures known as Skyrmions. Recent experiments [2] have suggested the possibility of observing a long range Skyrmion crystal phase with non-collinear magnetic order at low temperatures. The magnetic properties of the 2DES close to \( \nu = 1 \) are studied by the direct measurement of the low-lying spin wave excitations by inelastic light scattering between 2.5K and 40mK. We discovered a very low energy spin wave that emerges on both sides of \( \nu = 1 \). The spin wave is well below the Zeeman energy and exhibit surprising soft behavior with temperature changes: its energy increases with temperature and reaches the Zeeman energy for temperatures above 2K. These results suggest an instability of the 2DES towards magnetic order at low temperatures and filling factors close to \( \nu = 1 \). The spin excitation spectra are consistent with the ordering of the in-plane components of spin in a square Skyrmion crystal phase proposed in theoretical evaluations [3], but never fully confirmed by experiments. Our experiments create venues for the determination of Skyrmion crystal phases from measurements of low-lying spin excitations by inelastic light scattering.

9:12AM A1.00003 High Resolution Spectroscopy of the Quantum Hall Liquid, OLIVER DIAL.

Massachusetts Institute of Technology — We present precise and unprecedentedly high resolution spectra of the tunneling density of states (TDOS) of a cold two dimensional electron system (2DES) in GaAs over an energy range from 15 meV above to 15 meV below the Fermi surface. The results provide the first direct measurements of the width of the single-particle exchange gap and lifetimes in the quantum Hall system. At higher energies, we show the first observations of exchange-induced spin-splittings in fully filled or unfilled Landau levels not at the Fermi energy. The results demonstrate a counter-intuitive fact: the high energy spectrum reflects correlations that only appear at very low temperatures. For instance, upon raising the temperature from 100 mK (0.01 meV) to 1 K (0.1 meV) changes are seen in the spectrum at 10 meV away from the Fermi energy. Along with measurements of exchange splittings and lifetimes, we observe an unpredicted new structure appearing only at high magnetic fields and low temperatures that appears to be a long lived quasi-particle. The results are made possible by a novel technique, time domain capacitance spectroscopy. It allows us to measure the TDOS of a 2DES with resolution only limited by temperature, even at large tunneling energies. In TDCS, sharp voltage pulses disequilibrate a 2DES from a nearby metallic contact inducing a tunnel current perpendicular to the plane of the 2DES. We detect this current by monitoring the image charge of the tunneling electrons on a distant electrode. No ohmic contact to the 2DES is required. The technique works even when the 2DES is empty or has vanishing in-plane conductivity, as frequently occurs in the quantum Hall effect. Importantly, we can eliminate the effects of ohmic heating in the experiment by using short duty cycle pulses, with currents flowing only 0.01% of the time. The obtained spectra reveal the beautiful and difficult to reach structure present far from the Fermi surface in the quantum Hall system.

9:48AM A1.00004 Magnetotunneling spectroscopy: Imaging electron wavefunctions and measuring electron dispersion curves in GaMnAs- and GaAsN-based heterostructures, LAURENCE EAVES.

School of Physics and Astronomy, University of Nottingham — Magnetotunnelling spectroscopy is a powerful tool for imaging the wavefunctions of electrons in quantum wires [1] and dots [2] and for measuring the energy-wavevector dispersion curves of holes [3] and electrons [4] in novel quantum well structures. It uses the effect of the Lorentz force to tune the in-plane momentum of a tunneling electron when it enters a quantum-confined structure [4]. This talk will describe recent work to spatially image the ground and excited state wavefunction of electrons confined in quantum dots in ferromagnetic GaMnAs tunnel diodes. These dots are formed by the electrostatic potential arising from clusters of charged Mn interstitial donors. It will also be shown how the fragmented conduction electron dispersion curves of GaAsN give rise to highly non-linear electron dynamics and a new type of negative differential conductivity effect.

8:36AM A2.00002 Dichroism in the pseudogap phase observed through high precision Sagnac interferometry, ELIZABETH SCHEMM, Department of Physics, Stanford University — Polar Kerr effect in the high-\(T_c\) superconductor \(\text{YBa}_2\text{Cu}_3\text{O}_{6+\delta}\) was measured at zero magnetic field with high precision using a cryogenic Sagnac fiber interferometer. We observed non-zero Kerr rotations on the order of \(\sim 1\) \(\mu\)rad appearing near the pseudogap temperature \(T^*\), and marking what appears to be a true phase transition. Anomalous magnetic behavior in magnetic-field training of the effect suggests that other high temperature superconductors will also be discussed.

Work done in collaboration with Jing Xia and Aharon Kapitulnik.

9:12AM A2.00003 Orbital-Current phases in one- and two-dimensional strongly correlated systems, THIERRY GIAMARCHI, University of Geneva — Although we now know that strongly correlated systems can have several type of conventional order ranging from charge or spin order to superconductivity, the possibility that they present also more exotic phases remains an elusive but very challenging question. In particular whether such systems can have orbital current order for realistic interactions has been strongly debated. Recently this question has come to attention again due to theoretical proposals and subsequent neutron scattering experiments suggesting that this could be the case in the pseudogap phase of High \(T_c\). Tackling this issue directly for the two dimensional case is difficult, since no uncontrolled method can be used beyond exact diagonalization for very small clusters. However this question can be looked at on the one dimensional (ladder) version of this problem, where such orbital current phases can be studied by well controlled methods such as bosonization. I will present the results we obtained on these systems and discuss in particular the comparison between the case of a simple Hubbard ladder [1] versus a three band model (\(\text{Cu-O ladder}\) [2].

In order to tackle these issues for the two-dimensional case, we have performed a variational Monte Carlo analysis for a three band Cu-O model. This technique although depending on the quality of the variational wave function has the advantage of being essentially free of numerical problems. I will discuss the phases obtained by this approach as well as the possible experimental consequences.

These works are a collaboration with E. Orignac; P. Chudzinski and M. Gabay; C. Weber, A. Laëuchli and F. Mila.

9:48AM A2.00004 Inhomogeneous Superconductivity in \(\text{YBa}_2\text{Cu}_3\text{O}_y\) and \(\text{La}_{2-x}\text{Sr}_x\text{CuO}_4\) Above \(T_c\), JEFF SONIER, Simon Fraser University — An exciting development in the immense research effort focused on resolving the origin of high-\(T_c\) superconductivity, is the growing evidence for signatures of superconductivity in cuprate materials at temperatures far above \(T_c\). Recent STM experiments on \(\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+\delta}\) have provided new insight into the precise nature of these pairing correlations, by revealing the occurrence of nanometre-sized pairing regions above \(T_c\). Whether nanoscale inhomogeneous superconductivity is universal to the cuprates, and whether \(T_c\) is driven by Kosterlitz- Thouless physics or Josephson coupling between nanometre-sized superconducting regions is matters of current debate. Very recently we have used \(\mu\)SR to probe the local response in the bulk of \(\text{YBa}_2\text{Cu}_3\text{O}_y\) and \(\text{La}_{2-x}\text{Sr}_x\text{CuO}_4\) single crystals to a large applied magnetic field (\(H = 7\) T). At temperatures above \(T_c\), we detect a spatially inhomogeneous magnetic field that tracks the hole-doping dependences of both \(T_c\) and the superfluid density at \(T = 0\) K. Our experiments are inconsistent with the field inhomogeneity above \(T_c\) being caused by electronic magnetic moments or a vortex liquid. Instead they are explained by the existence of nanometre-size superconducting regions with a local \(T_c\) that exceeds the bulk \(T_c\). In \(\text{YBa}_2\text{Cu}_3\text{O}_y\), we detect a spatially inhomogeneous response to field that persists beyond \(T = 200\) K, indicating that the basic ingredients for superconductivity near room temperature already exist in spatially localized regions of this material. A lingering question is the origin of the weak magnetism detected earlier in \(\text{YBa}_2\text{Cu}_3\text{O}_y\) by zero-field \(\mu\)SR, at temperatures below the pseudogap temperature \(T^*\).

This work was supported in part by the Swiss NSF under MaNeP and Division II.

10:24AM A2.00005 Observation of a Sharp Magnetic Transition at the Pseudogap Temperature in \(\text{YBa}_2\text{Cu}_3\text{O}_6\), HERB MOOK, Oak Ridge National Laboratory — Polarized neutron diffraction has been used to demonstrate magnetic order in a crystal of \(\text{YBa}_2\text{Cu}_3\text{O}_6\) that displays an exceptionally sharp superconducting transition. Earlier experiments showed a gradual increase of intensity of magnetically scattered neutrons from underdoped \(\text{YBa}_2\text{Cu}_3\text{O}_{6+\delta}\) crystals for reflections that do not break translational symmetry. The present experiment confirms this but displays a much sharper transition demonstrating that the width of the magnetic transition depends on the quality of the superconducting transition. This relationship is strengthened by the fact that other magnetic properties sensitive to the superconductivity, such the resonance and excitation spectra are also exceptionally well defined when measured with the same sample. The magnetic order is observed at the temperature of the pseudogap transition and the close relationship between the quality of the magnetic properties and the superconductivity suggests that the pseudogap is directly connected to the magnetic order.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A3 DCOMP TMS: Frontiers in Computational Materials

8:00AM A3.00001 Multi-Scale Modeling from First-Principles, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Berlin, Germany and UC Santa Barbara, USA — Electronic structure theory (the nature of the chemical bond) is the base on which the finest scale for multi-scale modeling of the function of materials. Frequently it is assumed that details at this base do not matter when length and time scales approach meso- or macroscopic proportions (e.g. \(\mu\)m and minutes). In this talk I will show for various examples that details matter indeed. When accuracy is lacking at the base, there is little hope for predictive results at any level of modeling that follows. I will also emphasize the importance of reversible mapping and error control between the different levels of multi-scale modeling when moving up the chain of methods to successively increasing spatial and temporal dimensions. — In this context I will also address the sometimes problematic accuracy of present day density functional theory methods and show how it can be determined and errors corrected.

8:36AM A3.00002 Computational Approaches for Strongly Correlated Materials: an Electronic Structure Theory Perspective, SERGEY SAVRASOV, University of California Davis — Density functional theory known to work well for weakly correlated materials fails to attack real strongly correlated phenomena, and recent progress in understanding those using many-body model-hamiltonian-based dynamical mean-field theory has triggered developments of new approaches for computational material science in searching for alternatives to DFT. In this talk I will discuss some such new techniques, a spectral density functional theory, which considers total free energy as a functional of a local electronic Green function, will be discussed. Applications of the method to compute energetics, spectroscopy, lattice dynamics and exchange interactions of classes of materials such as heavy fermion and high temperature superconductors as well as actinide systems will be given.
9:12AM A3.00003 First-principles studies of electrical transport in nanoscale molecular junctions1. J. B. NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — Understanding the conductance of individual molecular junctions is a forefront topic in theoretical nanoscience. The development of a general, efficient atomistic approach for treating an open system out of equilibrium with good accuracy, and then using it to inform experiment, is a significant open challenge in the field. Here I will describe studies where first-principles techniques, based on density functional theory (DFT) and beyond, are used to investigate some of the fundamental issues associated with single-molecule transport measurements. After a brief summary of previous work, a DFT-based scattering-state approach is presented and applied to H$_2$ and amine-Au linked molecular junctions [1], two systems for which there exist reliable data [2]. Similar to most ab initio studies, we rely on a Landaau approach within DFT for junction conductance. Using this framework, which has proven relatively accurate for metallic point contacts, good agreement with experiment is obtained for the H$_2$ conductance. For amine-Au linked junctions, however, the computed conductance is significantly larger than that measured, although structural trends are reproduced by the calculations. To explore this further, we draw on GW calculations of a prototypical metal-molecule contact, benzene on graphite, where interfacial polarization effects are found to drastically modify frontier orbital energies [3]. A physically motivated model self-energy correction is developed from our GW calculations, applied to the amine case, and shown to quantitatively explain the discrepancy with experiment. The importance of many-electron corrections beyond DFT for accurately computing molecular conductance and understanding experiments is thoroughly discussed. [1] S. Y. Quek et al., Nano Lett 7, 3482 (2007); K. H. Khoo et al., submitted (2007). [2] R. Smit et al., Nature 419, 906 (2002); L. Venkataraman et al., Nature 442, 904 (2006). [3] J. B. Neaton et al., Phys. Rev. Lett. 97, 216405 (2006).

9:48AM A3.00004 First-Principles Thermodynamics and Kinetics of Advanced Hydrogen Storage Materials1. VIDVUDS OZOLINS, Department of Materials Science & Engineering, University of California, Los Angeles — Hydrogen-fueled vehicles require a cost-effective, light-weight material that binds hydrogen strongly enough to be stable at ambient pressures and temperatures but weakly enough to liberate H$_2$ with minimal heat input. Since none of the simple metal hydrides satisfy all the requirements for a practical H$_2$ storage system, recent research efforts have turned to complex hydrides and advanced multicomponent material compositions. We will show that first-principles density-functional theory (DFT) calculations have become a valuable tool for understanding and predicting novel hydrogen storage materials. Recent studies in our group have used DFT calculations to (i) predict crystal structures of new solid-state hydrides, (ii) determine phase diagrams and thermodynamically favored reaction pathways in multinary hydrides, and (iii) study microscopic kinetics of diffusion, phase transformations, and hydrogen release.

10:24AM A3.00005 Liquid Metal Embrittlement: new understanding for an old problem. DAVID SROLOVITZ, Yeshiva University — When liquid metals are brought into contact with other polycrystalline metals, deep liquid-filled grooves often form at the intersections of grain boundaries and the solid-liquid interface. In some systems, e.g., Al-Ga, Cu-Bi and Ni-Bi, the liquid film quickly penetrates deep into the solid along the grain boundaries and leads to brittle, intergranular fracture under the influence of modest stresses. This is a form of liquid metal embrittlement (LME). This phenomenon is ubiquitous in material processing and is particularly important in nuclear reactor scenarios in which liquid metals are used as coolants and as spallation targets. The penetration of a liquid phase along the grain boundary is a complex phenomenon, involving several different types of simultaneous processes. The tendency for and rate of LME are also sensitive to externally controllable factors such as temperature and applied stress. Because of the interplay between the underlying phenomena that occur in LME, it has been difficult to perform experiments that can be interpreted to understand which processes control LME and which are simply parasitic. We study LME by performing molecular dynamics simulations of an Al bicrystal in contact with liquid Ga and investigate how Ga penetrates along the grain boundaries during the early stages of the wetting process. We use the simulation results to propose a new mechanism for LME and compare it with general trends gleaned from a series of LME experimental studies.

Monday, March 10, 2008 8:00AM - 11:00AM –
Session A4 DPOLY: Polymers at Surfaces: Adhesion, Tribology and Patterning Morial Convention Center 206

8:00AM A4.00001 Interfacial engineering using heteropolymers with adjustable monomer sequences (HAMS)1. JAN GENZER, Department of Chemical & Biomolecular Engineering, North Carolina State University — Heteropolymers with adjustable monomer sequences (HAMS) represent a new type of functional random copolymers that could play an important role in emerging areas pertaining to interfacial science and polymer assembly. Due to their disordered but tailorable co-monomer sequence distribution HAMS are capable of adsorbing selectively at interfaces and recognizing patterns on chemical targets (i.e., chemically patterned substrates). HAMS are synthesized in a laboratory by ‘coloring’ the segments of a collapsed homopolymer, A, with a functionalizing agent, B, and then unraveling the resultant polymer to yield a random sequence of A and B blocks, which ‘remembers’ its original collapsed conformation and hence prefers some conformations over others. In the presentation, we will provide details pertaining to the experimental formation of HAMS and studying their physico-chemical characteristics. We will also provide examples of a few case studies that unravel the tailorable interfacial and self-assembly character of HAMS made of poly(styrene-co-4-bromostyrene) and its derivatives. In addition, we present results of computer simulation studies providing molecular insight into forming HAMS.

8:36AM A4.00002 Carbon Nanotube-Based Synthetic Gecko Tapes, ALI DHINOJWALA, The University of Akron — Wall-climbing geckos have unique ability to attach to different surfaces without the use of any viscoelastic glues. On coming in contact with any surface, the micron-size gecko foot-hairs deform, enabling molecular contact over large areas, thus translating weak van der Waals (vdW) interactions into enormous shear forces. We will present our recent results on the development of synthetic gecko tape using aligned carbon nanotubes to mimic the keratin hairs found on gecko feet. The patterned carbon nanotube-based gecko tape can support a shear stress (35 N/cm$^2$) nearly four times higher than the gecko foot and stick to a variety of surfaces, including Teflon. Both the micron-size setae (replicated by nanotube bundles) and nanometer-size spatulas (individual nanotubes) are necessary to achieve macroscopic shear adhesion and to translate the weak vdW interactions into high shear forces. The carbon nanotube based tape offers an excellent synthetic option as a dry conductive reversible adhesive in microelectronics, robotics and space applications. The mechanism behind these large shear forces and self-cleaning properties of these carbon nanotube based synthetic gecko tapes will be discussed. This work was performed in collaboration with graduate students Liehui Ge, and Sunny Sethi, and collaborators from RPI, Lijie Ci and Professor Pulickel Ajayan.
9:12AM A4.00003 Polymer adhesion at surfaces: biological adhesive proteins and their synthetic mimics¹. PHILLIP MESSERSMITH, Northwestern University — Mussels are famous for their ability to permanently adhere to a wide variety of wet surfaces, such as rocks, metal and polymer ship hulls, and wood structures. They accomplish this through specialized proteins collectively referred to as mussel adhesive proteins (MAPs). The biophysical aspects of MAP adhesion is being revealed through the use of single molecule force measurements. The results provide insight into the adhesive roles of key amino acids found in these proteins, including the magnitude of adhesive forces, cooperative effects, and their self-healing properties. This molecular-level information is being incorporated into designs of biomimetic polymer coatings for a variety of applications. Our biomimetic approach to polymer design will be illustrated by a few examples where adhesive constituents found in MAPs are exploited to make wet-adhesive polymer coatings. In addition, small molecule analogs of MAPs can be used to apply thin functional films onto virtually any material surface using a facile approach. These coatings have a variety of potential uses in microelectronics, water treatment, prevention of environmental biofouling, and for control of biointerfacial phenomena at the surfaces of medical/diagnostic devices.

9:48AM A4.00004 Patterning inorganic nanoparticles in Polymer Films. EUGENIA KUMACHEVA, University of Toronto — No abstract available.

10:24AM A4.00005 Wrinkling, Crumpling and Snapping for Surface Property Control, ALFRED CROSBY, University of Massachusetts Amherst — Upon the development of a critical stress, many materials and geometries experience a mechanical instability, which produces significant changes in geometry with very small changes in stress. In nature, mechanical instabilities are ubiquitous with the definition of shape, morphology, and function. Examples range from wrinkles on human skin to the snapping of Venus Flytrap leaflets. Inspired by these examples and others, we use elastic instabilities to control the morphology and function of soft polymer surfaces. We present three strategies. The first is a novel approach for the development of surface wrinkles on a top-constrained elastomer surface. We demonstrate and understand the control of kinetically-trapped and equilibrium wrinkle morphologies associated with changes in the materials properties and geometric constraint. These structures are stabilized to create surfaces with enhanced adhesion and advantageous optical properties. A second strategy is based on the controlled buckling of surface attached sheets. This method allows the fabrication of responsive surface structures that are prone to snap-through instabilities and the fabrication of pattern features that are difficult, if not impossible, to achieve with any other method. The third strategy brings the bio-inspired surface control full circle with the use of mechanical instabilities to control and characterize monolayer sheets of biological cells.

Monday, March 10, 2008 8:00AM - 11:00AM
Session A5 DCMP: Supersolid 4He: A New State of Matter Morial Convention Center RO1

8:00AM A5.00001 Probable heat capacity signature of the supersolid transition¹. XI LIN, Penn State University — We report our heat capacity measurements [1] of solid ⁴He down to 40mK, well into the apparent supersolid region of the phase diagram. We observed a broad peak in the specific heat centered near 75mK in ⁴He samples containing 1ppb, 0.3ppm, and 10ppm ³He impurities. In addition, our measurements of samples containing 10ppm and 30ppm of ³He have revealed a temperature-independent contribution to the heat capacity that scales with the number of isotopic impurities. New measurements with higher resolution are in progress.

¹Experiment carried out in collaboration with A. C. Clark and M. H. W. Chan with support from NSF under grants DMR-0207071 and DMR-0706339.

8:36AM A5.00002 Probing the upper limit of the nonclassical rotational inertia². ANN SOPHIE C. RITTNER, Cornell University — Recently, we have used torsional oscillators to study the dependence of the nonclassical rotational inertia on sample confinement, expressed as surface to volume ratio S/V [1]. When we decreased the width of annular helium sample we observed an increase of the supersolid fraction by three orders of magnitude to 20 % in a 150 µm wide annulus. As an extension of those measurements, we have built torsional oscillators with even smaller gaps down to 25 microns. We will give a brief description of the experimental setup and present the results of those measurements.

²Work supported by NSF Grant DMR-0605864

9:12AM A5.00003 Frequency dependence and Hysteretic behavior in Non-Classical Rotational Inertia of Solid ⁴He³. YUKI AOKI², Rutgers University — We have constructed a compound torsional oscillator having two resonance frequencies for studying non-classical rotational inertia (NCRI) of solid ⁴He. The oscillator allows us to study NCRI and supersolid effects of the identical solid ⁴He sample grown in a cylindrical container at 496 and 1173 Hz. We have grown and studied solid samples with final solid pressures between 27 and 42 bar. The observed features are qualitatively similar in all solid samples. NCRI fractions at sufficiently low oscillation drive and at the lowest temperature are only about 0.1 % and consistent with cylindrical cells in other laboratories. NCRI fraction below 35 mK does not depend on frequency nor temperature. At T > 35 mK, NCRI fraction observed in the lower mode is smaller than that in the higher mode. “Transition” into supersolid state occurs at a higher temperature in the higher mode than the lower one. The peak in extra dissipation due to solid ⁴He is greater in the lower mode by a factor 1.7 than in the higher mode. The frequency dependence of the magnitude of NCRI will be compared with existing theoretical predictions. In addition to the frequency dependent effects at low oscillation drive, we have observed hysteretic behavior in NCRI fraction depending on the history of oscillation drive and temperature from the normal state above 300 mK to low temperatures. We find that the supersolid state below 40 mK can have different NCRI fractions depending on the particular sequence of oscillation amplitude. Above about 50 mK, however, NCRI fraction does not depend on the history of oscillation amplitude changes. We also observe a time dependent overshoot in the dissipation of solid when the NCRI fraction is increased by decreasing the oscillation drive. The general behavior of this relaxation phenomenon is rather complex depending on temperature, history of oscillation amplitude and memory effects. Some of the observations share common features with vortex motion and glassy behavior.

9:48AM A5.00004 Superfluid defects in solid Helium-4: grain boundaries, dislocations, superglass\textsuperscript{1}. NIKOLAY PROKOF'EV, University of Massachusetts, Amherst, MA 01003, USA — First principle quantum Monte Carlo simulations and recent experiments all point out that ideal, defect free, crystals of Helium-4 are not supersolid. Contrary to naive expectation that disorder inhibits superfluidity and suppresses superfluid response due to localization effects, disorder in quantum solids works in the opposite direction: if particles in the ideal crystal are already localized then defects can help to make the sample superfluid. The theory of superfluidity in lower dimensional defective structures embedded in a higher dimensional bulk has its own twists since such phenomena as superfluidity, roughening and defect mobility may be strongly linked. An unusual behavior is expected in the 3D network of 1D liquid channels when normal state at temperatures orders of magnitude above T\textsubscript{c} is indistinguishable from that of a superfluid. The possibilities for “designing” crystallographic defects are countless, and in the strongly correlated system each case (superfluid or not) has to be considered separately. We find that generic grain boundaries and the screw dislocation along the z-axis are superfluid, while special types of boundaries and edge dislocations are insulating [1,2]. We also find that Helium-4 can form a metastable superfluid glass [3]. Whether these findings are relevant for the explanation of supersolid and other experiments remains an open question.

NSF support

10:24AM A5.00005 Vortex liquid, PHILIP ANDERSON, Princeton University — No abstract available.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A6 FIAP: Novel Channel Materials for CMOS Technology Morial Convention Center R04

8:00AM A6.00001 III-V MOSFETs: From Materials & Physics to Devices, MATTHIAS PASSLACK, Freescale Semiconductor, Inc. — Gallium-Arsenide metal-oxide-semiconductor field-effect-transistors (MOSFET) have finally been demonstrated with performance metrics matching the predictions of semiconductor device models. Recent discoveries and inventions in many areas including materials and fabrication, semiconductor physics, interface chemistry, semiconductor interface analysis, and semiconductor device design and process have contributed to this success. In my invited talk, I will review some areas including the unique properties of interfaces formed between Ga\textsubscript{2}O\textsubscript{3} molecules and a GaAs surface, a high permittivity (\textit{\varepsilon} \geq 20) Ga\textsubscript{2}O\textsubscript{3}/Ga\textsubscript{2}O\textsubscript{3} dielectric stack providing both a device quality interface and band-offsets on GaAs required for MOSFET operation, a semiconductor heterostructure for mitigation of high band-edge interface-state density, and device design criteria for high electron channel mobility and MOSFET drive current. Performance metrics of present metal-gate GaAs enhancement-mode MOSFETs such as electron channel mobility, drive current, transconductance, and threshold voltage will be discussed. GaAs MOSFETs with In\textsubscript{0.35}Ga\textsubscript{0.65}As channel layers exhibit typical electron peak mobilities exceeding 5,000 cm\textsuperscript{2}/Vs, an improvement of a factor of 20 over silicon based high-\textit{\varepsilon} metal-gate inversion-mode MOSFETs. Even higher electron mobilities surpassing 12,000 cm\textsuperscript{2}/Vs have been measured in In\textsubscript{0.75}Ga\textsubscript{0.25}As channel layers. Beside the use of channel materials such as In\textsubscript{x}Ga\textsubscript{1-x}As with high bulk electron mobility, the physics of device operation is distinctively different from silicon inversion-mode MOSFETs. III-V MOSFET are now considered an option for CMOS based circuitry beyond the 22 nm node of the International Technology Roadmap for Semiconductors. High channel mobilities and the first successful implantation of III-V MOSFETs seem to justify such contemplation, however, many obstacles remain.

8:36AM A6.00002 Stability of Metal Oxide/Ga and Metal Oxide/III-V Interfaces and Implications for Low Defect Density MOS Devices\textsuperscript{1}, PAUL MCINTYRE, Stanford University — The need to achieve high performance in MOS transistors as they scale to their ultimate size limits prompts interest in channel materials, such as Ge and III-V compound semiconductors, which exhibit larger intrinsic carrier mobilities than Si. Given the need to reduce gate leakage current density while maintaining electrostatic control of the devices, it is necessary to deposit high-\textit{\varepsilon} gate dielectrics onto these novel channel materials. Unlike silicon, high mobility channel materials do not form a highly-stable and stoichiometric native oxide; therefore, control of the state of oxidation at the metal oxide dielectric/channel interface during and after gate dielectric deposition is essential. This presentation will summarize findings reported to date on 1) chemical stability of Ge and III-V surfaces in the presence of oxygen and 2) oxide/channel defect formation and passivation. New results on pre-high-\textit{\varepsilon} chemical surface preparation, structural modification during metal oxide deposition and the resulting effects on MOS capacitor and transistor characteristics will also be presented, with emphasis on Al\textsubscript{2}O\textsubscript{3} and HFO\textsubscript{2} gate insulators grown by atomic layer deposition onto Ge and InGaAs channels. In situ and ex situ monitoring of chemical bonding at the gate insulator/channel interface by photoelectron spectroscopy will be correlated with the D\textsubscript{ltf}, fixed charge and charge trapping behavior of MOS devices.

9:12AM A6.00003 Dangling-bond defects and hydrogen passivation in germanium, JUSTIN R. WEBER, Department of Physics, University of California, Santa Barbara, California 93106-9530, USA — The application of germanium in complementary metal-oxide semiconductor (CMOS) technology is hampered by high interface-state densities, the microscopic origin of which has remained elusive. Using first-principles calculations, we have investigated the atomic and electronic structure of prototype germanium dangling-bond defects [1]. The computational approach is based on density functional theory, and in order to overcome band-gap problems we have also performed quasiparticle calculations based on the GW approach. Surprisingly, the germanium dangling bonds give rise to electronic levels below the valence-band maximum. They therefore occur exclusively in the negative charge state, explaining why they have eluded observation with electron spin resonance. The associated fixed charge is likely responsible for threshold-voltage shifts and poor performance of n-channel transistors. At silicon/silicon dioxide interfaces, hydrogen is successfully used to passivate dangling-bond defects. We have therefore also investigated the interaction of hydrogen with germanium. In contrast to silicon and other semiconductors in which hydrogen behaves as an amphoteric impurity, interstitial hydrogen in germanium is stable only in the negative charge state, i.e., it behaves exclusively as an acceptor. Passivation of dangling bonds by hydrogen will therefore be ineffective, again explaining experimental observations. Other cases where unusual interfacial defects and problems with hydrogen passivation may occur will be discussed.

Work performed in collaboration with A. Janotti, P. Rinke, and C. G. Van de Walle, and supported by the Semiconductor Research Corporation.

9:48AM A6.00004 Scanning-tunneling microscopy and spectroscopy of oxide deposition on III-V semiconductor surfaces, ANDREW KUMMEL, UCSD — The correlation between the atomic bonding structure and the electronic structure at oxide-semiconductor interfaces is critical to understanding how atomic scale changes in electronic structure can cause localization of electrons or holes at these interfaces. All logic devices function by having an electric field perturb the electronic structure of a semiconductor to change its resistance thereby activating the device. The key material in this process is the interface between the gate oxide and the semiconductor. Any fixed charge or defects which trap electrons or holes destroy the device operation because the electric field will be terminated by interface charges instead of being transmitted into the semiconductor. We have used atomically resolved scanning tunneling microscopy (STM) imaging and current-voltage (I-V) tunneling spectra (STS) to determine the atomic and electronic structure at the gate-oxide semiconductor interface. Our research focuses upon the group III-V semiconductors (GaAs, InGaAs, InAs) since they offer electron speeds up to 30x greater than silicon as well as germanium since it offers 3x higher hole speeds than silicon. In general, electronically passive interface forms are encountered when oxide deposition does not disrupt the semiconductor lattice but instead restores the semiconductor surface atoms back to more bulk-like electronic structure. Even in the absence of a lattice disruption, oxide deposition can create new states in the bandgap thereby pinning the Fermi level by two mechanisms: direct (the adsorbate induced states in the bandgap region) and/or indirect (generation of undimerized surface atoms).

Monday, March 10, 2008 8:00AM - 11:00AM — Session A7 DBP GSNP: Oscillations Without Transcription in Vivo and in Vitro Morial Convention Center R05

8:00AM A7.00001 Molecular synchronization, the Kai system, and biological oscillators, DAVID K. LUBENSKY, University of Michigan — In most textbook examples, oscillations in cell biology are driven by the periodic creation and destruction of one or more chemical species. The past few years, however, have seen growing interest in a different sort of oscillator. In these systems, the total concentrations of the major protein components are constant, but the molecules move sequentially through a cycle of different states (e.g., covalent modifications). Macroscopic oscillations appear when the progress of the many individual molecules becomes synchronized. The recently-characterized cyanobacterial circadian clock provides a particularly elegant example of such molecular synchronization. Remarkably, with only the 3 proteins KaiA, KaiB, and KaiC, a ~24 hour oscillation in KaiC phosphorylation can be reconstituted in vitro. We can thus dissect this biochemical circuit in almost unprecedented detail. Here, we give an overview of the Kai system and its relationship to other oscillators. We begin with a review of the major experimental facts about the Kai system, emphasizing possible mechanisms to synchronize KaiC phosphorylation. We then examine in more detail models in which this synchronization occurs through sequestration of KaiA via differential affinity: KaiA, which stimulates KaiC phosphorylation, has a higher affinity for KaiC during certain stages of the phosphorylation cycle; as long as some KaiC molecules at these stages are present in the reaction mixture, they bind all the available KaiA, thereby preventing the other KaiC’s from being phosphorylated and proceeding through the cycle. We also discuss the implications of this mechanism for phenomena such as temperature compensation. Finally, we suggest that, in light of lessons learned from the Kai system, a number of other biological oscillators can fruitfully be viewed as examples of molecular synchronization.

8:36AM A7.00002 Monomer exchange and the hourglass model of protein-based oscillators, ELDON EMBERLY, Physics, Simon Fraser University — Circadian rhythms in photosynthetic cyanobacteria are under the control of a three protein biochemical network that generates oscillations in the phosphorylation level of one of the proteins. This oscillatory signal has a period of roughly 24 hours and regulates many biological processes in the bacteria to the day and night cycle. The molecular view of the phosphorylation process is that one of the proteins forms a hexameric complex whose phosphorylation levels rise and fall based on the activity of the other two proteins. Each hexameric complex thus functions as an independent molecular clock. However the bacteria contains many such clocks and so how do they interact to generate a coherent oscillating signal? In this talk I will discuss a model that suggests that monomer exchange between hexamers helps to synchronize the population of clocks during the daylight portion of the oscillation. Other synchronizing mechanisms will be highlighted for the other portion of the cycle. Recent experiments will be discussed in light of the exchange model.

9:12AM A7.00003 Perfect Robust Network Architecture of a Bacterial Circadian Clock, MARKUS KOLLMANN, Humboldt Universität zu Berlin, Invalidenstr. 43, 10115 Berlin — The circadian core clock of cyanobacteria consists of only three proteins, KaiA, KaiB, and KaiC. The readout of the clock status is given by the phosphorylation level of KaiC hexamers that oscillates with 23 hour period even under in vitro conditions. We present a circadian clock model based on mass action kinetics that shows almost perfect agreement with the experimentally found phosphorylation dynamics. The model consists of two feedback loops, with the main oscillatory mechanism realised by a negative feedback via sequestration of the enhancer of KaiC autophosphorylation, that is KaiA. These feedbacks are the reason for the observed outstanding robustness of the KaiABC clock that keeps phase, frequency and amplitude even under concerted serveral fold changes of the Kai protein concentrations.

9:48AM A7.00004 Stability and Noise in the Cyanobacterial Circadian Clock, IRINA MIHALCESCU, Université Joseph Fourier — Grenoble — Accuracy in cellular function has to be achieved despite random fluctuations (noise) in the concentrations of different molecular constituents inside and outside the cell. Single cell in vivo monitoring reveals that individual cells generate autonomous circadian rhythms in protein abundance. In multi-cellular organisms, the individual cell rhythms appear to be noisy with drifting phases and frequencies. However, the whole organism is significantly more accurate, the temporal precision being achieved most probably via intercellular coupling of the individual noisy oscillators. In cyanobacteria, we have shown that single cell oscillators are impressively stable and a first estimation rules out strong intercellular coupling. Interestingly, these prokaryotes also have the simplest molecular mechanism at the heart of their circadian clock. In the absence of transcriptional activity in vivo, as well alone in vitro, the three clock proteins KaiA, KaiB and KaiC generate a self-sustained circadian oscillation of autophosphorylation and dephosphorylation. Recent chemical kinetics models provide a possible understanding of the three-protein oscillator, but the measured in vivo stability remains yet unexplained. Is the clock stability a built-in property of the cyanobacterial clock mechanism? Recent experiments will be discussed in light of the diffusion constant. These results therefore confirm that the cyanobacterial clock stability is a built-in property: the cyanobacterian clock mechanism is not only the simplest but also the most robust.
10:24AM A7.00005 Chromosome oscillations in mitosis. OTGER CAMPAS, Harvard University — Successful cell division necessitates a tight regulation of chromosome movement via the activity of molecular motors. Many of the key players at the origin of the forces generating the motion have been identified, but their spatial and temporal organization remains elusive. In animal cells, chromosomes periodically switch between phases of movement towards and away from the pole. This characteristic oscillatory behaviour cannot be explained by the current models of chromosome positioning and congression. We perform a self-contained theoretical analysis in which the motion of the kinetochore and chromokinesins results from the competition between the activity of the kinetochore and chromokinesins motors on the chromosome arm. Our analysis, consistent with the available experimental data, proposes that the interplay between the aster-like morphology of the spindle and the collective kinetics of molecular motors is at the origin of chromosome oscillations, positioning and congression. It provides a natural explanation for the so-called chromosome directional instability and for the mechanisms by which chromosomes sense their position in space. In addition, we estimate the in vivo velocity of chromokinesins at vanishing load and propose new experiments to assess the mechanism at the origin of chromosome movement in cell division.

Monday, March 10, 2008 8:00AM - 11:00AM –
Session A8 DFD: Colloidal Self-Assembly | Morial Convention Center R06

8:00AM A8.00001 Directed Self-Assembly of Spherical Particles , NATALIE ARKUS, GUANGNAN MENG, VINOTHAN MANOHARAN, MICHAEL BRENNER, Harvard University — We examine the kinetics and energetics of self-assembly in systems containing a small number of spherical colloidal nanoparticles using a combination of theory, simulation, and experiment. We then explore how the addition of spherically symmetric binding specificity can be used to direct the self-assembly of a given structure. Using graph theoretic, numerical, and algebraic geometric techniques, we enumerate all possible packings for a system of n particles. We map out the energetic landscape of these packings, which is determined not only by the value of the potential energy at these minima, but also by the vibrational normal modes of the structures. Experiments for a 6 particle system show that the likelihood of a given packing follows this expected equilibrium distribution. To explore the kinetics of packing formation, we simulate the self-assembly of these systems in the irreversible binding limit. For the 6 particle system, this reveals that the kinetics required to form one of the packings is highly unlikely, resulting in the other packing forming with 100% probability. With the addition of binding specificity however, we can cause the unlikely packing to form with 100% probability. We show how the addition of binding specificity effects the energetic landscape of these systems, and that it alone is sufficient to direct self-assembly.

8:12AM A8.00002 Controlling assembly of micro- and nano-particle systems with DNA. , DMYTRO NYKYPANCHUK, MATHEW MAYE, DANIEL VAN DER LELIE, OLEG GANG, Brookhaven National Laboratory — Addressable biological interactions provide attractive platform for rational self-assembly, however the strength of such interactions are often difficult to control. Here we present an approach where DNA molecules are used to balance attractive and repulsive interactions during particle assembly while preserving the interaction addressability. We show, that by changing the composition and structure of DNA shall of micro- (2 um) or nanoparticles (10 nm), assembly kinetics, aggregate sizes, and the systems melting properties can be tuned. At constant environmental conditions, this strategy allows for rational control of interaction energy landscape for nano- and micro-systems in a wide dynamic range.

8:24AM A8.00003 Evaporation-Driven Assembly of Microspheres with Polymer in Emulsion Droplets1, KENG-HUI LIN, Institute of Physics, Academia Sinica, Taipei, Taiwan, LIANG-JIE LAI, Dept. of Physics, National Central University, Chung-li, Taiwan, CHIH-CHUNG CHANG, HUI CHEN, Dept. of Chemical and Materials Engineering, National Central University, Chung-li, Taiwan — We study the packing of colloidal microspheres mixed with polymer in oil-in-water emulsion droplets through evaporation. The addition of polymer produce non-unique configurations of final clusters when the number of particles N inside the droplet is larger than 4. The cluster configurations are classified into three categories based on the symmetry. Stabilized colloidal clusters of spherical packings are observed. Observation on packing process shed light to the mechanisms which cause different and non-unique structures. The osmotic pressure and interparticle interaction due to polymer play important roles in packing.

8:36AM A8.00004 Entropy-driven self-assembly of dimers , ISSEI NAKAMURA, AN-CHANG SHI, McMaster University — Supramolecular self-assembly is an important phenomenon with applications ranging from chemical synthesis to biological systems. Although the driving force of assembly is the weak non-covalent intermolecular interaction such as hydrogen bonding and dispersion force, the self-assembly is a result from balancing the enthalpic and entropic contributions. In general, the disassembled/disordered phase is expected as temperature is raised because of the entropic gain from the components of the aggregate. However, it has been observed that the self-assembled/ordered phase can be promoted with increasing temperature. This implies that the self-assembly is driven by entropy. In order to provide a better understanding of this entropy-driven transition, we have studied a statistical mechanical model for the aggregation of macromolecular dimers immersed in solvents. The model demonstrates that solvent molecules absorbed on the surface of the solution are released with increasing temperature, leading to an increase of the total entropy of the system. Consequently, the cooperative stability of the dimeric state is induced. The thermodynamic features of this transition are analyzed.

8:48AM A8.00005 Hydrodynamic interactions effects on the dipole-induced self-assembly of β-peptides and Brownian-induced polymer pore translocation , JUAN HERNANDEZ-ORTIZ, Departamento de Materiales, Universidad Nacional de Colombia, Sede Medellín, MICHAEL GRAHAM, JUAN DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — A novel method that scales linearly with the number of particles is used to study Brownian-systems considering fluctuating hydrodynamic interactions. The method is demonstrated in the concept of two applications: the dipole-induced self-assembly of β-peptides and the Brownian-motion-induced translocation of a polymer thought a rectangular pore. The method includes the long-range interactions by the Green’s function formalism. It allows the consideration of peptides at intermediate concentrations and the inclusion of the non-periodic domain of the translocation. The hydrodynamics interactions affect the dynamics of the peptides agglomeration and the mean-square-displacement indicates significant changes in the long-time diffusion coefficient. The polymer translocation is study using a transition path sampling based methodology. In particular it is used to calculate the translocation rate constant. Even for a single bead there are differences once hydrodynamics are included. These differences are due to the changes of mobility near walls and the change in polymer chain diffusion coefficient.

9:00AM A8.00006 Self-assembly of complex shaped colloidal particles , ADELINA PERRO, VINOTHAN N. MANOHARAN, Harvard School of Engineering and Applied Sciences — We have developed a new method to produce hybrid particles with polyhedral shapes in very high yield (liter quantities at up to 75% purity) using a combination of emulsion polymerization and inorganic surface chemistry. The optical properties of these particles are tailored for studying their dynamics and self-assembly. For example, we produce systems that consist of index-matched sphere doublets with a small strongly scattering inorganic core between the two spheres, allowing us to track the center of mass of each doublet. We have generalized the preparation procedure to create even more complex geometries, including hybrid tetrahedra and octahedra. We present some preliminary studies on the self-assembly of these systems based on various optical experiments, including confocal microscopy, light scattering, and digital holographic microscopy.
9:12AM A8.00007 Progress on systems of DNA modified colloidal particles for self-replication, PAUL CHAIKIN, MIRIAM LEUNISSEN, REMI DREYFUSS, ROUJIE SHA, NADRIAN SEEMAN, DAVID GRIER, DAVID PINE, New York University — Our goal is to create new materials that can self-replicate and self-assemble. For this, we modify the interactions between micrometer-sized colloids by coating them with single-stranded DNA ‘sticky ends’, which specifically recognize complementary sequences on other colloids. We find that the aggregation-dissociation behavior is fully reversible for at least tens of temperature cycles. Using magnetic beads or optical tweezers, we form a chain-like ‘seed’ structure, which acts as a template to assemble colloids. The system is collimated by a high degree of orientational organization. Factors that determine the crystal structure are investigated, especially the dependence on ionic strength and on Janus balance. Contrary to the transverse linkers, the longitudinal linkers form AT/TA bonds, which can be crosslinked with an intercalator and UV irradiation. In this way, we permanently fix the seed and its copies.

9:24AM A8.00008 Binary Colloidal Assembly by Dielectrophoresis, PETER HOFFMAN, YINGXI ELAINE ZHU, University of Notre Dame — Dielectrophoresis (DEP)-driven colloidal assembly has been recently explored as a new route to manipulate colloids and rapidly form nanostructured materials. In this talk, we demonstrate that colloidal particles of varied sizes can be assembled with controllable packing configurations in the presence of AC-electrical fields. We investigate binary latex particles of varied size ratios from 0.25 to 0.8 and directly monitor the dynamic assembly process with final structural characterization by using high-speed confocal microscopy. We observe rich phase behaviors of binary colloidal assembly with a strong dependence of applied AC-field frequency and medium conductivity. The obtained structural phase diagram can be well predicted by the DEP mobility and the Peclet number. We also present a mechanism that underlies the colloidal charge polarization due to charge segregation and entrainment within the double layer at several distinct frequencies, which cannot be explained by the classical Maxwell-Wagner theory. We recently also employ the same mechanism to form binary colloidal crystals.

9:36AM A8.00009 Unusual aggregation behavior of colloids coated with palindromic DNA, MIRIAM LEUNISSEN, REMI DREYFUSS, DAVID PINE, PAUL CHAIKIN, New York University — Coating particles with single-stranded DNA ‘sticky ends’ gives excellent control over the specificity, strength and range of their interactions. Usually, a pair of complementary ‘Watson-Crick’ sequences is used to obtain thermoreversible binding of different colloids. However, for certain purposes one could also use self-complementary ‘palindrome’ sequences. Using light microscopy, we studied the aggregation behavior of micrometer-sized palindromic-coated colloids. Unlike Watson-Crick sticky ends, we found that it is of great importance whether the palindrome sticky end is attached to a flexible single strand or a rigid double-stranded ‘rod’. While the latter system displayed normal dissociation at elevated temperature, the former system showed enhanced aggregation with increasing temperature and no aggregation during fast temperature quenches. We explain these unusual observations by a competition between intra- and interparticle bonds. This provides us with an additional level of control over the interparticle bonding, besides the sequence of the sticky ends, the salt concentration and the DNA density on the beads.

9:48AM A8.00010 Functionalized Au nanoparticles in solution, GARY S. GREST, J. MATTHEW D. LANE, Sandia National Labs — The properties of functionalized Au nanoparticles in decane and water were studied by large-scale explicit atom, molecular dynamics simulations. Gold nanoparticles functionalized with S-(CH$_2$)$_n$-X alkanethiol chains (X = COOH or CH$_3$) were studied at the liquid-vapor interface and in the bulk. The structure of the functional groups on the nanoparticle was found to depend strongly on the end group and solvent. At the interface methyl terminated nanoparticles repel the water and move toward the vapor while in decane, the decane molecules engulf the nanoparticle. In the bulk, results for the nanoparticle/ nanoparticle pair correlation function and nanoparticle diffusion will be presented as a function of nanoparticle concentration. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04- 94AL85000.

10:00AM A8.00011 DNA-Grafted Janus Particles, CHING HSUEH, Department of Physics, National Central University, Chungli, Taiwan, KENG-HUI LIN, WEN-TAU JUAN, Institute of Physics, Academia Sinica, Taipei, Taiwan — Recently there have been advances in generating Janus microspheres whose two hemispheres have different chemical compositions [1-4]. The new types of particles open up possibilities for assembly of complex structures. Here we attach DNA molecules onto one side of Janus microspheres. The new type of colloidal particles resembles surfactant molecules and may provide us interesting new structures.

10:12AM A8.00012 The importance of repulsion in the aggregation-dissociation behavior of DNA coated colloids, REMI DREYFUSS, MIRIAM LEUNISSEN, ROUJIE SHA, NADRIAN SEEMAN, DAVID GRIER, DAVID PINE, PAUL CHAIKIN, New York University — Coating particles with DNA gives excellent control over the specificity, strength and range of their interactions. In our experiments, a pair of complementary ‘Watson-Crick’ sequences is used to obtain thermoreversible binding of different colloids. Colloids coated with such complementary ‘sticky’ DNA aggregate when they are mixed together, the aggregates dissolve again when they are heated. We investigate the melting behavior of colloids coated with both sticky and non-sticky DNA. By changing the ratio between the sticky and non-sticky DNA, the obtained melting curves have very different melting temperatures, but almost the same sharpness. We show that the sharpness does not change because a high number of bonds bridges the particles, and that the strong shift in melting temperature is due to a repulsive interaction induced by the confinement of the non-sticky DNA when the particles come close together.

10:24AM A8.00013 Self Assembly of Colloidal Particles at Small N, GUANGNAN MENG, NATALIE ARKUS, RYAN MCGORTY, MICHAEL BRENNER, VINOTHAN MANOHARAN, Harvard University — We confine a small number (N ≈ 10) of micron-sized colloidal particles within micro-wells, and we use this finite system to study the process of self-assembly. The reversible aggregation of colloidal particles is controlled by a short-range depletion attraction, which is induced by poly(N-isopropylacrylamide) nano particles. We use digital holographic microscopy to monitor the structural and kinetic properties of self-assembled colloidal clusters, and we use micro-wells to collect ensemble statistics. We compare our experimental results with theory and simulations, which probe how energetics and kinetics affect the packing structures.

10:36AM A8.00014 2D crystals of Janus amphiphilic colloidal spheres, SHAN JIANG, STEPHEN ANTHONY, University of Illinois at Urbana-Champaign, ANGELO CACCIUTO, Columbia University, ERIK LUIJKEN, STEVE GRANICK, University of Illinois at Urbana-Champaign — Colloidal spheres with one side hydrophilic and the other side hydrophobic form 2D crystals with hexagonal translational order complemented by a high degree of orientational organization. Factors that determine the crystal structure are investigated, especially the dependence on ionic strength and on Janus balance. Depending on these variables, patches of the orientational order can be altered: from doublets to extended lines containing dozens of particles. Janus particles with different geometry (Janus balance) self-assemble into different cluster structures. Collective motion is evident from time-resolved optical microscopy.
which point the efficiency is also predicted to reach a maximum. Operating range, and show excellent agreement with the experiments. The propulsive force is predicted to increase sharply after the shape transformation, at is complete. Calculations based on slender body and resistive force theory predict the torque-speed relationship and the filament shape throughout the entire by a sharp increase in the rotational speed. As the torque is decreased, the shape change exhibits hysteresis, transitioning back to the splayed form at a lower . rod rotating in a viscous fluid and set at an angle to the axis of rotation. In the experiments, two modes of operation are studied: constant torque and constant .

E. coli in a viscous fluid

Lagrangian methods in combination with the Maxey-Riley equations for inertial particles in fluid flow.

used to illustrate the proposed approach. We also show that predator-prey interactions during jellyfish swimming can be addressed using the aforementioned underwater velocimetry apparatus (SCUVA). Case studies of jellyfish and other aquatic animals observed in the laboratory and in marine environments are subsequently interrogated using dynamical systems tools in order to quantitatively resolve the dynamics of animal swimming. The Lagrangian methods are shown to be readily extended to time-dependent measurements in three spatial dimensions and to in situ field measurements using a recently developed self-contained underwater velocimetry apparatus (SCUVA). Case studies of jellyfish and other aquatic animals observed in the laboratory and in marine environments are used to illustrate the proposed approach. We also show that predator-prey interactions during jellyfish swimming can be addressed using the aforementioned Lagrangian methods in combination with the Maxey-Riley equations for inertial particles in fluid flow.

8:24AM A9.00003 Effects of hydrodynamic interactions in bacterial swimming,1, SUDDHASHIL CHATTOPADHYAY, Xiao Lun Wu, University of Pittsburgh — The lack of precise experimental data has prevented the investigation of the effects of long range hydrodynamic interactions in bacterial swimming. We perform measurements on various strains of bacteria with the aid of optical tweezers to shed light on this aspect of bacterial motility. Geometrical parameters recorded by fluorescence microscopy are used with theories which model flagella propulsion (Resistive force theory & Lighthill’s formulation which includes long range interactions). Comparison of the predictions of these theories with experimental data, observed directly from swimming bacteria, led to the conclusion that while long range interactions were important for single polar flagellated strains (Vibrio Alginolyticus & Caulobacter Crescentus), local force theory was adequate to describe the swimming of multi-flagellated Escherichia Coli. We performed additional measurements on E. Coli minicells (miniature cells with single polar flagellum) to try and determine the cause of this apparent effect of shielding of long range interactions in multiple flagellated bacteria.

9:12AM A9.00005 Shape transformations and propulsion due to an elastic filament rotating in a viscous fluid, BIAN QIAN, THOMAS POWERS, KENNETH BREUER, Brown University — The deformation of an elastic filament in a viscous liquid is central to the mechanics of motility in cells ranging from E. coli to sperm. We use experiments and theory to study the shape transition of a flexible rod rotating in a viscous fluid and set at an angle to the axis of rotation. In the experiments, two modes of operation are studied: constant torque and constant speed, and the shape of the filament is measured using stereoscopic imaging. At low applied torque, the rod bends gently, while at high torque, the rod adopts a helical shape with the tip close to the axis of rotation. At constant torque, the transition from the splayed form to the helical form is abrupt, accompanied by a sharp increase in the rotational speed. As the torque is decreased, the shape change exhibits hysteresis, transitioning back to the splayed form at a lower torque. At constant speed, the transition is continuous characterized by a region of decreasing torque that persists until the transition to the helical form is complete. Calculations based on slender body and resistive force theory predict the torque-speed relationship and the filament shape throughout the entire operating range, and show excellent agreement with the experiments. The propulsive force is predicted to increase sharply after the shape transformation, at which point the efficiency is also predicted to reach a maximum.
9:24AM A9.00006 Propulsion by directional adhesion. JOHN BUSH, MANU PRAKASH, MIT — The rough, hairy integument of water-walking arthropods is well known to be responsible for their water-repellency; we here consider its additional propulsion role. We demonstrate that the tilted flexible leg hairs of water-walking arthropods render the leg cuticle directionally anisotropic: contact lines advance most readily towards the leg tips. The dynamical role of the resulting unidirectional adhesion is explored, and yields new insight into the manner in which water-walking arthropods generate thrust, glide and leap from the free surface. We thus provide new rationale for the fundamental topological difference in the roughness on plants and insects, and suggest novel directions for biomimetic design of smart, hydrophobic surfaces.

9:36AM A9.00007 The role of the ventral pedal waves in the locomotion of terrestrial gastropods, JANICE LAI, ROBERT D. SHEPHERD, JUAN C. DEL ALAMO, JAVIER RODRIGUEZ-RODRIGUEZ, JUAN C. LASHERAS, University of California San Diego — The locomotion of terrestrial gastropods exhibits unique characteristics which allow these animals to crawl on steep surfaces. Gastropods move by gliding over a ventral foot lubricated by mucus. The phasic movements of the foot produce periodic suction at its tips, which persist long after the foot has left the substrate. The present work develops an analytic model for the forcing of the ventral foot, producing a forward traction, while the rim of the foot adheres to the substrate and generates suction forces. We analyzed the kinematics and dynamics of locomotion by conducting two sets of experiments. In the first set, we used digital image processing to correlate the frequency and wavelength of the pedal waves to the migration velocity. In the second set, we computed the traction and adhesion forces produced by these animals from measurements of the deformation of an elastic substrate of known properties. We found that the strain energy exerted by the animal on the substrate is quasi-periodic, and explored a possible correlation between the mean speed of migration and the period of this energy fluctuation. In addition, we found that the pedal waves accelerate as they move forward along the ventral foot producing the symmetry break necessary for the generation of a net traction force.

9:48AM A9.00008 Flying, swimming and fluttering in 3D: potential flow around a rectangular deformable plate, CHRISTOPHE ELOY, LIONEL SCHOUVEILER, IRPHE, Marseille, France — The interaction between a flexible rectangular plate and the flow around it can serve as a model for several phenomena. This situation arises in many problems of animal locomotion as well as industrial ones such as airfoil flutter. So far, most models have assumed a 2D problem for the sake of simplicity. We show here how to extend these models to include the finite plate aspect ratio in the analysis. We consider a rectangular deformable plate moving in a uniform flow at small amplitude such that the plate and its wake remain in the same plane at first order. The potential flow around the plate is calculated in the Fourier space and then averaged along the span. The result is a new integral equation for the vorticity distribution both inside the solid plate and in its wake. It means that the 3D effects can be taken into account by simply modifying the potential of a point-vortex (or equivalently the Green function of the Laplace’s equation).

2This work received financial support from the French ANR project DRAPEAU

10:00AM A9.00009 Symmetry breaking in gastropod locomotion through acceleration or deceleration of the pedal waves, JUAN C. DEL ALAMO, JAVIER RODRIGUEZ-RODRIGUEZ, JANICE LAI, ROBERT D. SHEPHERD, JUAN C. LASHERAS, University of California San Diego — Marine and terrestrial gastropods move by gliding over a ventral foot that is lubricated by secreted mucus (terrestrial) or simply by water (marine). The rim of the ventral foot generates suction forces that keep the animal adhered to the substrate. The central part of the foot produces a forward traction force by generating trains of pedal waves through periodic muscle contractions. Recent experiments show that, in some gastropods, these pedal waves become faster and longer as they move forward, suggesting a mechanism for breaking the symmetry in the flow between the pedal waves and the substrate. To investigate this mechanism, we have analyzed theoretically a two-dimensional lubrication layer between a train of waves of slowly varying length and speed, and a flat, rigid, impermeable surface. The inhomogeneity of the pedal waves has been modeled through multiple-scale asymptotics. We have considered a Newtonian fluid to separate the effect of this inhomogeneity from the viscoelastic symmetry breaking reported in previous works.

10:12AM A9.00010 The unsteady flow over a bat wing in mid-downstroke, FLORIAN MUJRES, CHRISTOFFER JOHANSSON, RYAN BARFIELD, MARTA WOLF, Lund University, GEOFFREY SPEDDING, University of Southern California, ANDERS HEDENSTROM, Lund University — Birds, bats and insects have provided inspiration for human-designed small-scale flying machines, and while insects have long been known to rely on unsteady separated flows for their above-average aerodynamic performance at small-scale, the details of air flows over bird and bat wings have been harder to elucidate, mainly because of the extra complexity and precautions required in live experiments. Here we report on the first experiments of the airflow around a bat wing in free (but trained) flight in a low-turbulence wind tunnel. The aerodynamics of fixed wings at these Reynolds numbers are notoriously sensitive to small disturbances of the initially laminar, attached boundary layer, but these flight experiments show that the instantaneous flow fields around the flapping wing bear almost no resemblance to an equivalent fixed-wing experiment. The circulation increment due to the presence of a strong leading-edge vortex is estimated to provide a significant fraction of the total lift. Implications for the design and control of micro-air vehicles are considered.

10:24AM A9.00011 Mechanics of Mammalian Swimming, TIMOTHY WEI, PAUL LEGAC, Rensselaer Polytechnic Institute, FRANK FISH, West Chester University, TERRIE WILLIAMS, University of California. Santa Cruz, RUSSELL MARK, USA Swimming, SEAN HUTCHISON, King Aquatics — Propulsion of large mammals (i.e. dolphins and humans) has been of great interest for both technological and athletic reasons. The fundamental question is how fast can a mammal swim? Digital Particle Image Velocimetry (DPIV) has been modified to be safely used on swimmers and dolphins. Experiments of dolphins performing various swimming behaviors were performed at the Long Marine Laboratory, University of California, Santa Cruz. Vortices generated by the dolphins’ tail motions were used to estimate thrust production. Also, a two-dimensional dynamic force balance was constructed to study and improve the mechanics of elite swimmers. Paired with an underwater video camera, the forces seen could be directly related to the motion of the swimmer. These force measurements could be correlated to time resolved DPIV measurements of flow around the swimmers. Measurements made with swimmers, Megan Jendrick (2000 Olympic gold medalist) and Ariana Kukors (4x US National Champion), as well as data from trials with two dolphins will be presented.

10:36AM A9.00012 Synchronization and hydrodynamic interactions, THOMAS POWERS, BIJAN QIAN, KENNETH BREUER, Division of Engineering, Brown University — Cilia and flagella commonly beat in a coordinated manner. Examples include the flagella that Volvox colonies use to move, the cilia that sweep foreign particles up out of the human airway, and the nodal cilia that set up the flow that determines the embryonic axis in developing vertebrate embryos. In this talk we present an experimental study of how hydrodynamic interactions can lead to coordination in a simple idealized system: two nearby paddles driven with fixed torques in a highly viscous fluid. The paddles attain a synchronized state in which they rotate together with a phase difference of 90 degrees. We discuss how synchronization depends on system parameters and present numerical calculations using the method of regularized stokeslets.
10:48 AM A9.00013 An experimental and numerical study of fluid flow generated by a single nodal cilium. XINGZHOU YANG, Center for Computational Science, Tulane University, LISA FAUCI, Department of Mathematics, Tulane University, ARSHAD KUDROLLI, Department of Physics, Clark University — A rotating nodal cilium is said to generate fluid flow in the node of a developing embryo by posterior tilt leading to the left-right asymmetry of the mammalian body. In order to develop a physical understanding of the fluid generated and the effect of the enclosing chamber, we perform scaled-up fluid-mechanics experiments and numerical simulations using the method of Regularized Stokeslets for zero Reynolds number. Important mechanical parameters, such as the geometry of the rods, dimensions of the tank, and the ratio of viscous to elastic stresses can be scaled to match typical cilia and cell. Digital imaging and tracer particle tracking techniques are used to measure the location and shape of the rods and the fluid flow. We will discuss the nature of the hydrodynamic velocity fields which are found to be more complex than anticipated by previous studies.

Monday, March 10, 2008 8:00AM - 11:00AM –
Session A10 DMP: Tunneling on Cuprate Superconductors Morial Convention Center R08

8:00AM A10.00001 Local tunneling probe of low-energy Andreev states on (110) $Y_{0.95}Ca_{0.05}Ba_2Cu_3O_{7-\delta}$ thin films in an applied magnetic field$^1$, J.H. NGAI, Department of Physics, University of Toronto, Toronto, Canada, R. BECK, G. LEIBOVITCH, G. DEUTSCHER, Department of Physics and Astronomy, Raymond and Beverly Sackler faculty of Exact Sciences, Tel Aviv University, Tel Aviv, Israel, J.Y.T. WEI, Department of Physics, University of Toronto, Toronto, Canada — Cryomagnetic scanning tunneling spectroscopy (STS) was performed on (110)-oriented $Y_{0.95}Ca_{0.05}Ba_2Cu_3O_{7-\delta}$ thin films, in order to reveal coherence-length scale information on the symmetry of the high-$T_c$ order parameter (OP) in a magnetic field. In zero-field at 4.2K, both spontaneously split and unsplit zero-bias conductance peaks (ZBCP) are seen in the STS spectrum. The two types of peak spectra exhibit increasing splitting in a field applied along the c-axis of the film. Both spontaneous and field-induced ZBCP splitting indicate a lifting in the degeneracy of the low-energy Andreev states, consistent with time-reversal symmetry breaking. These results are discussed within the context of the Doppler effect as well as intrinsic vs. field-induced complex components in the high-$T_c$ OP.

8:12AM A10.00002 Magnetic-field effect on the quasiparticle excitation observed by the tunneling spectroscopy in $Bi_2Sr_2CaCu_3O_{8+\delta}$ single crystal$^2$, YI XUAN, Texas Center for Superconductivity at the University of Houston, H.J. TAO, Z.Z. LI, B.R. ZHAO, Z.X. ZHAO, National Laboratory for Superconductivity, Institute of Physics and Center for Condensed Matter Physics, Chinese Academy of Sciences, China — In the d-wave superconductor, due to the existence of nodes of the pairing gap, the field-dependence of the quasiparticle density of state has been predicted to be essentially different from the behavior in the s-wave case $^1$. Here we report the planar junction tunneling spectra at different magnetic fields in the high-$T_c$ superconductor $Bi_2Sr_2CaCu_3O_{8+\delta}$ to study how the field modifies the quasiparticle excitation. $^1$G. E. Volovik, JETP Lett. 58, 469 (1993).

$^2$This research has been supported by the National natural Science Foundation of China under Grant No. 19974070.

8:24AM A10.00003 Role of competing orders (COs) in the low-energy pseudogap (PG) phenomena and quasiparticle (QP) excitations of hole- and electron-type cuprate superconductors$^1$. A.D. BEYER, M.S. GRINOLDS, M.L. TEAGUE, N.-C. YEH, Phys. Dept., Caltech, Pasadena, CA, S.-I. LEE, Phys. Dept., Pohang U., Korea — Our cryogenic scanning tunneling spectroscopic studies of spatially resolved QP density of states (DOS) in hole-type $YBa_2Cu_3O_7$ and electron-type $La_{2-\delta}Sr_{1.9}CuO_4$ cuprate superconductors (SC) reveal that the existence of COs in the cuprates can account for many seeming non-universal phenomena. Namely, we analyze the low-energy QP excitation spectra by using a microscopic model of coexisting SC/CO, with density-wave type COs, and find that various spectral characteristics are uniquely determined by the parameters $\Delta_{SC}$, $V_{CO}$, $Q$, and $\Gamma$ ($\Delta_{SC}$: SC gap, $V_{CO}$: CO gap, $Q$: CO wave-vector, $\eta$: strength of quantum fluctuations, $\Gamma$: line-width of QP spectral peak). For instance, $V_{CO} > \Delta_{SC}$ ($V_{CO} \leq \Delta_{SC}$) in hole- (electron-) type cuprates can account for the presence (absence) of the low-energy PG. Anomalous momentum-dependent QP properties such as the Fermi arcs and antiferromagnetic hot spots can also be explained. In finite magnetic fields, the QP DOS inside the vortex core of both types of cuprates reveal unconventional PG-like features at energies comparable to the $V_{CO}$ values derived by our analysis.

$^1$The work at Caltech was supported by NSF Grant DMR-0405088.

8:36AM A10.00004 Spatially Resolved Quasiparticle (QP) Spectra in the Vortex State of Electron-Type Cuprate Superconductor (SC) $La_{1.1}Sr_{0.9}CuO_2(La-112)$, M.L. TEAGUE, A.D. BEYER, M. GRINOLDS, N.-C. YEH, Phys Dept Caltech Pasadena, CA, S.I. LEE, Pohang U., Korea — The low-energy excitations of cuprate superconductors are unconventional and are susceptible to changes in temperature, doping and magnetic field. Our recent experiments and microscopic theoretical analysis suggest that these phenomena may be attributed to the presence of competing orders (COs) and strong quantum fluctuations. Here we present our scanning tunneling spectroscopic studies that support coexisting SC/CO in La-112, an optimally doped electron-type cuprate with $T_c=43$ K. In zero-field, the histogram of the QP spectra at 9 K over an (100x100) nm$^2$ area reveals a single set of spatially homogeneous peaks at $\Delta_{eff} = 11.8 \pm 1.5$ meV. Our analysis of the data (with two energy gaps of SC and CO, $\Delta_{SC}$ and $V_{CO}$) suggests $\Delta_{eff} = (\Delta_{SC} + V_{CO})^2/\Delta_{SC}$ and the presence of quantum fluctuations. With increasing magnetic field to 6 Tesla, $\Delta_{eff}$ shifts downward to 10.0 meV due to the overall suppression of $\Delta_{SC}$, and the spatial variation of the spectra are consistent with vortex periodicity. Moreover, pseudogap-like spectral features occur at $\Delta_{eff}$ inside the vortex cores while the spectra outside the vortex cores retain a gap value at $\Delta = \pm \Delta_{eff}$. This work was supported by NSF Grant DMR-0405088.
8:48AM A10.00005 Importance of matrix element effects in the scanning tunneling spectra of $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_8 + \delta$\textsuperscript{1}, ARUN BANSIL, Northeastern University, JOUKO NIEMINEN, TUT, Finland and Northeastern University, ROBERT MARKIEWICZ, HSIN LIN, Northeastern University — Scanning tunneling microscopy/spectroscopy (STM/STS) techniques have entered the realm of high-Tc’s impressively by offering atomic scale real space resolution and meV resolution in bias voltages. STM/STS spectra, however, represent a complex mapping of electronic states of interest related to the CuO2 planes, since the tunneling current must reach the tip after being filtered through the overlayers (e.g. SrO and BiO in Bi2212). We have developed a Green function approach for realistic modeling of STM/STS spectra of the cuprates, where the tunneling current is evaluated directly including the effect of overlayers, with all orbitals within a few eV’s of the Fermi energy $E_F$ accounted for. Our calculations show the presence of strong matrix element effects, which lead to significant differences between the d1/dv spectra and the local density of states (LDOS) of CuO2 planes. For instance, the $d_{x^2-y^2}$ signal is found to be dominated by non-vertical hopping between the CuO2 and BiO layers. A substantial electron-hole anisotropy of the tunneling spectrum, which is in accord with experiments, is naturally explained by the contribution from $d_{x^2}$ and other orbitals below $E_F$.

\textsuperscript{1}Work supported in part by the USDOE.

9:00AM A10.00006 Temperature dependent Scanning Tunneling Spectroscopy of impurities in Bi2Sr2CuO6+$\delta$ through the transition temperature, KAMALESH CHATTERJEE, DOUGLASS WISE, MICHAEL BOYER, MIT, TAKESHI KONDO, TSUNEHIRO TAKEUCHI, HIROSHI IKUTA, YAYU WANG, ERIC HUDSON, MIT — Scanning Tunneling Microscopy has been used to study detailed electronic spectrum in atomic scale defects in high temperature superconductors. We present Scanning Tunneling Spectroscopy of impurities in Bi2Sr2CuO6+$\delta$ (Bi-2201) over a wide range of temperatures. Surprisingly, native impurity resonances, similar to the ones previously observed in Bi2Sr2CaCu2O8+$\delta$ (Bi-2212), spatially coexist with the superconducting gap at low temperatures and survive almost unchanged through the superconducting transition temperature $T_c$. We shall discuss the implications of these findings on the relationship between superconducting gap and pseudogap in these materials.

9:12AM A10.00007 Visualizing Two Gaps in the High Temperature Superconductor Bi-2201, MICHAEL BOYER, W.D. WISE, KAMALESH CHATTERJEE, MIT, MING YI, Stanford U., T. KONDO, Ames, T. TAKEUCHI, H. IKUTA, Nagoya U., E.W. HUDSON, MIT — The relationship between the superconducting and pseudogap states in the cuprates has been a subject of much interest as well as debate in the HTS community. At the forefront of this debate is whether the pseudogap exists below $T_c$, and if it does, in what capacity. We present scanning tunneling microscopy measurements which provide evidence for two distinct but simultaneously coexisting gaps in the density of states of Bi2Sr2CuO6+$\delta$ (Bi-2201) below $T_c$; one identified as the superconducting gap and the other, the pseudogap. In addition, we discuss our preliminary doping dependence measurements showing that the small (superconducting) gap scales with $T_c$ while the larger (pseudogap) gap scales with $T^{*}$ indicating a consistency with their identification.

9:24AM A10.00008 Temperature and doping dependent FT-STS studies of Bi-2201, WILLIAM WISE, KAMALESH CHATTERJEE, MICHAEL BOYER, YAYU WANG, Massachusetts Institute of Technology, TAKESHI KONDO, Ames Laboratory, TSUNEHIRO TAKEUCHI, HIROSHI IKUTA, Nagoya University, ERIC HUDSON, Massachusetts Institute of Technology — We present Fourier transform scanning tunneling spectroscopy (FT-STS) results in superconducting Bi-2201. The data presented are drawn from samples at a variety of dopings, and from experiments both below and above the superconducting transition temperature $T_c$. A number of unexpected trends are revealed by this systematic study. We interpret the results in light of several theories and make comparisons to results from other crystal systems.

9:36AM A10.00009 Bogoliubov angle and visualization of particle-hole mixture in superconductors, KAZUHIRO FUJITA, Cornell University, ILYA GRIGORENKO, Los Alamos National Laboratory, JINHO LEE, MIAO WANG, Cornell University, JIAN XIN ZHU, Los Alamos National Laboratory, J.C. DAVIS, Cornell University, Brookhaven National Laboratory, HIROSHI EISAKI, AIST, Tsukuba, SHIN-ICHI UCHIDA, The University of Tokyo, ALEXANDER V. BALATSKY, Los Alamos National Laboratory — We propose a new technique to visualize particle-hole mixture in high temperature superconductor Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$, using the Spectroscopic Imaging Scanning Tunneling Microscopy (SI-STM). Depending on the polarity of bias voltage, SI-STM can sample the particle and hole content of a superconducting excitation, Bogoliubov quasi-particle. 'Bogoliubov angle' (BA) is a measure of the relative weight of particle and hole amplitude in the Bogoliubov quasiparticle, which is determined by taking ratio of the differential conductance at positive and negative biases. BA allows one to measure directly the energy and position dependent particle-hole admixture and therefore visualize robustness of superconducting state locally. We will demonstrate the power of this new technique and discuss the momentum space (q-space) electronic structure in the talk.

9:48AM A10.00010 Phase-sensitive scattering of Bogoliubov quasi-particles in (Ca,Na)$_2$CuO$_2$Cl$_2$ under magnetic field, T. HANAGURI, Y. KOHSAKA, M. ONO, RIKEN (Inst. Phys. and Chem. Research), M. MALTESEVA, P. COLEMAN, Dept. of Phys. and Astronomy, Rutgers Univ., I. YAMADA, M. AZUMA, M. TAKANO, Inst. Chem. Research, Kyoto Univ., K. OHISHI, Japan Atomic Energy Agency, H. TAKAGI, RIKEN/Univ. Tokyo — Magnetic-field effect on the quasi-particle interference (QPI) in Ca$_{1.86}$Na$_{0.14}$CuO$_2$Cl$_2$ ($T_c \sim 25$ K) has been studied using Fourier-transform spectroscopic-imaging scanning tunneling microscopy. In the absence of magnetic field, all scattering vectors expected from the octet model for QPI [1] were detected in the Fourier-transformed conductance-ratio maps [2]. We have found that magnetic field enhances (suppresses) the amplitude of the standing waves due to QPI if the signs of the d-wave superconducting order parameter in momentum space are the same (different) between initial and final states of the scattering. We interpret the results in light of several theories and make comparisons to results from other crystal systems.

10:00AM A10.00011 Evolution of the electronic excitation spectrum with strongly diminishing hole-density in superconducting Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$, J.W. ALLDREDGE, JINHO LEE, Cornell University, K. MCELROY, University of Colorado, M. WANG, K. FUJITA, Cornell University, Y. KOHSAKA, Magnetic Materials Laboratory, RIKEN, C. TAYLOR, Cornell University, H. EISAKI, NI-AIST, S. UCHIDA, University of Tokyo, P.J. HIRSCHFELD, University of Florida, J.C. DAVIS, Cornell University — We use tunneling spectroscopy to measure the $T>$0 spectrum of electronic excitations N(E) over a wide range of hole-density in superconducting Bi2212. We introduce a parameterization for N(E) based on an anisotropic d-wave energy-gap plus an effective scattering rate which varies linearly with energy. We demonstrate that this form of N(E) allows successful fitting of differential tunneling conductance spectra throughout much of the Bi2212 phase diagram. A single, particle-hole symmetric, anisotropic energy-gap, in combination with a strongly energy dependent effective scattering rate, can describe the excitations without recourse to an additional energy gap of another ordered state. However we also observe two distinct and diverging energy scales in the system: the energy-gap maximum $\Delta_1$, and a lower energy scale $\Delta_0$ separating the spatially homogeneous and heterogeneous electronic structures.
10:12AM A10.00012 Temperature Evolution of Local Pairing & Electron-Boson Coupling in Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$. KENJIRO K. GOMES, ABHAY PASUPATHY, AAKASH PUSHP, COLIN PARKER, Department of Physics, Princeton University, GENDA GU, Brookhaven National Laboratory, SHIMPEI ONO, CRIEPI, Japan, YOICHI ANDO, ISIR, Osaka University, ALI YAZDANI, Department of Physics, Princeton University — Recently, we have shown using variable temperature scanning tunneling microscopy measurements that the pairing in Y-Ba-Cu-O superconductors Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$ persists in nanoscale regions at temperatures above $T_c$. [1] Using the ability to track the same atomic location with temperature, we have examined the evolution of the electronic states from well below $T_c$ to above the temperature at which the pairs first form locally. We will present these results for an overdoped sample. Using these measurements we extract the evolution of the pairing gap with temperature and show that pairing gaps at different atomic sites close at different temperatures. Our technique also allows us to quantitatively analyze the local electron-boson coupling for different atomic sites with different pairing strengths. Our results show that there is no connection between the variation of the gap magnitude and the bosonic mode associated with the “dip-hump” feature in the spectra. [1] Gomes et al. Nature 447, 569–572 (2007).

1Work supported by NSF, DOE and PCCM-MRSEC.

10:24AM A10.00013 Electronic Origin of the Nanoscale Variation of Pairing Gaps in Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$. ABHAY PASUPATHY, KENJIRO K. GOMES, AAKASH PUSHP, COLIN PARKER, Department of Physics, Princeton University, GENDA GU, Brookhaven National Laboratory, SHIMPEI ONO, CRIEPI, Japan, YOICHI ANDO, ISIR, Osaka University, ALI YAZDANI, Department of Physics, Princeton University — The magnitude of the low-temperature superconducting gap measured in Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$ shows large nanoscale spatial variations. On raising the temperature, these superconducting gaps disappear locally at temperatures above the superconducting transition temperature $T_c$. We present the first atomically resolved measurements of the spectrum of overdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$ at temperatures where all gaps have closed. We show that the shape of this “normal” state spectrum is inhomogeneous over a length scale similar to that of the gap variation at low temperature. We then track the same lattice sites down to low temperature and observe the opening of gaps in the spectrum. We will discuss the relationship between the shape of the spectrum measured in the “normal” state at high temperature and the size of the low-temperature superconducting gap at the same atomic site.

1Work supported by NSF, DOE and PCCM-MRSEC.

10:36AM A10.00014 Temperature Evolution of the Electronic States & Multiple Gap Features in Bi$_2$Sr$_{2-y}$La$_y$CuO$_6$+$\delta$. AAKASH PUSHP, ABHAY PASUPATHY, KENJIRO K. GOMES, COLIN PARKER, Department of Physics, Princeton University, SHIMPEI ONO, CRIEPI, Japan, YOICHI ANDO, ISIR, Osaka University, ALI YAZDANI, Department of Physics, Princeton University — Like Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$, Bi$_2$Sr$_{2-y}$La$_y$CuO$_6$+$\delta$ samples show inhomogeneous gaps in the DOS at low temperature. We present atomic resolution STM spectroscopy measurements of the evolution of the DOS with temperature for optimal ($y$=0.4) and overdoped ($y$<0.4) samples and compare these measurements to Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$. In Bi$_2$Sr$_2$CaCu$_2$O$_{8+x}$+$\delta$, the low temperature ($T$< $T_c$) spectra of overdoped samples are all characterized by a single d-wave gap with sharp coherence peaks. In contrast, Bi$_2$Sr$_{2-y}$La$_y$CuO$_6$+$\delta$ shows a variety of spectra at low temperature ranging from those with gaps to ones with multiple gap features [1]. By measuring the temperature evolution of these gap features at given lattice sites for various doping levels, we estimate the local temperature at which pairing develops in these samples. [1] Boyer et al., Nat Phys 3, 802 (2007)

1Work supported by NSF, DOE and PCCM-MRSEC.

10:48AM A10.00015 Local Signatures and Spectral Inversion of Bosonic Mode Coupling in a High-Temperature Superconductor. LAILA S. MATTOS, CHRISTOPHER R. MOON, BRIAN K. FOSTER, GABRIEL ZELTZER, MARTIN GREVEN, HARI C. MANOHARAN, Stanford University — High-resolution spectroscopy and mapping of the high-temperature superconductor Bi$_2$Sr$_2$Ca$_{0.93}$Y$_{0.07}$Cu$_{2+x}$d was performed with a custom-built low-temperature scanning tunneling microscope. At optimal doping ($T_c$ ∼ 96 K), these materials exhibit unusually strong spectral sidebands characteristic of electron-boson coupling. The magnitude of these Holstein-like d-wave density of states replicas facilitates a spectral inversion procedure, from which the critical parameters of the bosonic coupling can be directly extracted. This results in electron-boson coupling $\lambda$ ∼ 0.2-0.4 and boson energy $\Omega$ ∼ 70-90 meV. Origins and implications of these excitations will be discussed.

1Supported by DOE, NSF, and ONR.

Monday, March 10, 2008 8:00AM - 11:00AM – Session A11 DMP: Focus Session: MgB2-like: Exotic Behavior in MgB2-like Materials Morial Convention Center RO9

8:00AM A11.00001 High quality MgB$_2$ thin films in clean and dirty limit realized via HPCVD. CHENGANG ZHUANG, SHENG MENG, QINGRONG FENG, ZIZHAO GAN, PKU P.R.C, HUAN YANG, YING JIA, HAIHU WEN, CAS P.R.C, XIAOXING XI, PSU USA — Pure and carbon-doped MgB$_2$ thin films are fabricated using hybrid physical-chemical vapor deposition. Excellent properties are obtained in the pure samples, including $T_c$ = 41.4K, $\rho$(42K)$\sim$0.3 $\mu$ $\Omega$ cm, which indicates that films are in the clean limit. Ultrahigh critical current density, up to $1\times10^5$A/cm$^2$ at 5K and zero fields, approaching the theoretical deparing critical of MgB$_2$, was observed in a 150nm-wide microbridge, in agreement with the results derived using a Bean Model from the magnetization measurements. Large normal state magnetoresistance before the transition, about 40% at 7T, and absence of flux jump at low temperature and low field regions in the magnetization curves strongly support that the film is very clean. To enhance upper critical field and flux pinning, carbon doping is employed and realized in a dual-heater HPCVD setup from the thermal decomposition of CH$_4$, $\mu_0$H$_{2}$(0)$\sim$54T, $J_c$(5K,6T)$\sim$3$\times$10$^5$A/cm$^2$, as well as $T_c$(0)$\sim$34K and $\rho$(42K)$\sim$47$\mu$ $\Omega$.cm are achieved in the carbon-doped films. By controlling the carbon concentration, MgB$_2$ films in dirty limit can be prepared.

8:12AM A11.00002 Superconducting properties of MoN microfibers and thin films

A. Karki, LSU Department of Physics and Astronomy, EDEM OKUDZETO, LSU Department of Chemistry, PHIL ADAMS, DAVID YOUNG, LSU Department of Physics and Astronomy — We present the superconducting transport properties measurements on polycrystalline MoN synthesized in the form of thin films and microfibers. The samples were prepared by heating Mo films and Mo-coated carbon fibers to temperatures between 850 °C and 1000 °C for different time periods in a flowing stream of ammonia (NH₃) gas under atmospheric pressure. The microfibers and thin films had a transition temperature Tc ~ 12.2 K, which is substantially higher than the first reported room temperature superconductor MoB. A high pressure furnace, using a 19 mm truncation edge length, cubic anvil capable of reaching 3.3 GPa and 2000 °C was used to grow crystals of MgB₂-O-duty coating carbon fibers grown by other methods. We also present critical current measurements on microfibers which consisted of a 50-nm thick layer of polycrystalline MoN synthesized directly onto 5 micron-diameter carbon fibers. The microfibers supported current densities in excess of 10⁷ A/cm² well below Tc. Near Tc, Jc was well described by the power law [1-(T/Tc)²]¹/².

1 NSF DMR 04-49022

8:24AM A11.00003 Theory of Raman Scattering from Leggett’s Collective Mode in a Multiple Band Superconductor: Application to MgB₂

Miles Klein, University of Illinois at Urbana-Champaign — Using an extension of BCS theory to a two-band superconductor, Leggett showed that if the relevant parameters obeyed certain conditions a collective mode would exist corresponding to the counter flow of the two condensates. I have extended earlier work on electronic Raman in superconductors to the multiple band case in order to incorporate Leggett’s theory. The following effects have been included: (a) Vertex correction in the particle/hole channel where the Raman vertex acts. (b) Realistic parameters that apply to MgB₂ yielding a counter flow mode that decays into the pair-breaking continuum associated with the lower gap π band. (c) Large finite wave-vector effects due to the relatively large Fermi velocity of the π band. (d) Integration over the wave-vector in part (c) necessitated by the exponential decay of the photon fields traveling into and out of the metallic sample. A comparison to the results of Blumberg will be given. A. J. Leggett, Progr. Theor. Phys. 36, 901 (1966). M.V. Klein and S.B. Dierker, Phys. Rev. B29, 4976 (1984). G. Blumberg et al., Phys. Rev. Lett. 99, (2007); arXiv:0710.2803.

8:36AM A11.00004 MgB₂: Novel properties due to multibands

Girsh Blumberg, Laboratory, Alcatel-Lucent — About 40 years ago A.J. Leggett proposed a new collective mode arising from cross-tunneling of Cooper pairs residing on different Fermi surfaces of a multiband superconductor: Leggett’s collective mode is caused by a counter flow of the interacting superfluids leading to small fluctuations of the relative phase of the condensates while the total electron density is locally conserved. Here we present direct spectroscopic observation of the Leggett’s excitation in the MgB₂ superconductor containing two pairs of Fermi surfaces resulting from π- and σ-bands. Electronic Raman scattering studies have revealed three distinct superconducting (SC) features: (i) a clean threshold of Raman intensity at 4.6 meV consistent with the π-band SC gap; (ii) the SC pair breaking coherence peak at 13.5 meV consistent with excitations above the superconducting (SC) features; (iii) a broad threshold at 5.5 meV consistent with the σ-band SC gap. A comparison to the results of Blumberg will be given. A. J. Leggett, Progr. Theor. Phys. 36, 901 (1966). M.V. Klein and S.B. Dierker, Phys. Rev. B29, 4976 (1984). G. Blumberg et al., Physica (Amsterdam) 456C, 75 (2007).

9:12AM A11.00005 Microwave properties of epitaxial MgB₂ films and micro-bridges

M.V. Costache, G.X. Miao, J.S. Moodera, Massachusetts Institute of Technology — The high transition temperature and simple AlB₂ structure make the MgB₂ superconductor a promising new material for application in superconducting electronic devices. In order to reach this goal, in addition to the development of MgB₂ Josephson Junctions (JJ), we have explored the superconducting properties of lithographically patterned micro sized bridges in high quality epitaxial MgB₂ films. These thin film micro size wire bridges show JJ characteristics. The current-voltage (I-V) characteristics show the expected JJ behavior as a function of temperature, magnetic field and microwave radiation including hysteresis. Large change in the hysteresis behavior is observed when the microwave power is varied. The large hysteretic I-V can have potential as a memory element. The details will be discussed.

9:24AM A11.00006 Force-Detected NMR Study of Single-Crystal MgB₂ using Ultrasonic Oscillators

Han-Jong Chia, Mark Monti, Samaresh Guhhaia, John Markert, Physics, University of Texas at Austin, JAE-Hyuk Choi, Mechanical Metrology Group, Division of Physical Metrology, KRISS, Korea, Sung-Ik Lee, Pohang University, Korea — MgB₂ is a unique superconductor with a relatively high T_c and two nearly independent electronic bands. An NMR study of ¹¹B in MgB₂ using polycrystalline samples [1] did not observe any two-band effects, nor a Hebel-Slichter coherence peak, possibly due to large H₂ anisotropy (and thus a distribution of T_c’s). Anisotropic NMR studies of MgB₂ have proven difficult due to the small size (~ 10 μm) of high-quality crystals. A large-single-crystal conventional NMR study [2] could not probe the superconducting state due to line broadening. We have set out to use the exquisite sensitivity of Nuclear Magnetic Resonance Force Microscopy (NMRFM) to probe the behavior of ¹¹B in single crystal MgB₂. We have fabricated ultrasonic mechanical oscillators using e-beam lithography to facilitate detection of the weak ¹¹B resonance; these have resonance frequencies of 1–10 kHz, spring constants of ~ 10⁹ N/m, and quality factors >3000 at 77 K. We report our initial detection of the ¹¹B nuclear resonance and our plans to study relaxation rates in single crystal MgB₂ [1] H. Kogawa et al., Phys. Rev. Lett. 87, 127001 (2001). [2] S. Strässle et al., Physica C 1046, 166 (2007). *Supported by NSF DMR-0605828 and DOE-0549147.

9:36AM A11.00007 High pressure synthesis of single crystalline MgB₂

M. Tillman, Ames Lab / Iowa State University, G. Lapertot, CEA-Grenoble, DFRMC/SPSMS/IMAPEC, R. Prozorov, C. Martin, S.L. Bud’ko, P.C. Canfield, Ames Lab / Iowa State University — We report the results of single crystal growth of MgB₂. A high pressure furnace, using a 19 mm truncation edge length, cubic anvil capable of reaching 3.3 GPa and 2000 C was used to grow crystals of MgB₂ out of the Mg-B-N ternary. Design, setup, and calibration will be discussed as well as correlations between pressure and temperature profiles and crystal size. Results of measurements of penetration depth and H₂(T) on single crystals will be shown as well as the results of initial doping studies.

3 Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.
9:48AM A11.00008 Electric-field-effect studies of atomically thin flakes of superconducting NbSe\textsubscript{2} prepared by mechanical exfoliation. NEAL STALEY, JAIN WU, PETER EKLUND, YING LIU, Pennsylvania State University, LINJUN LI, ZHUAN XIU, Zhejiang University, China — Recent years have yielded many studies on electric field modulated superconductivity. In order to achieve the high carrier density changes needed to modulate superconductivity, two main approaches have been tried, ultra thin films grown by in situ quench deposition or few-layer single crystalline films of superconductors grown by pulsed laser deposition or molecular beam epitaxy. However in both cases, difficulties have been encountered, ultra thin films are subject to large amounts of disorder, and it is difficult if not impossible to grow single layered superconductors. Using a simple micromechanical exfoliation technique, we are able to create single crystal single layered graphite, featuring a linear density of states, allowing its physical properties to be tuned by gate voltage. Using this mechanical exfoliation procedure we fabricated ultra thin single crystalline NbSe\textsubscript{2} flakes ranging from double layered to many layered as estimated using an optical technique correlated to AFM and Raman spectroscopy measurements. Using a lithography-free, “all dry” process we fabricated devices showing modulated $T_c$ with applied gate voltage as well as a superconductor insulator transition tuned by the number of layers.

10:00AM A11.00009 Low Energy Electronic Structure of an Excitonic CDW Melted Novel Superconductor\textsuperscript{1}, DONG QIAN, DAVID HSIEH, LEWIS WRAY, YUQI XIA, Physics Department, Princeton University, E. MOROSAN, R.J. CAVA, Chemistry Department, Princeton University, M.D. HASAN, Physics Department, Princeton University — A superconducting (SC) state has very recently been observed upon successful doping of the charge-density wave (CDW) ordered triangular lattice TiS\textsubscript{2} with copper. Using angle-resolved photoemission spectroscopy (ARPES) we studied the doping evolution of the electronic structure of Cu\textsubscript{x}TiS\textsubscript{2}. The momentum space locations of the doped electrons that form the Fermi sea of the parent superconductor is identified. With increasing electron doping, we observe a significant rise of chemical potential which is found to destabilize the long range CDW order. At the same time the emergence of a large density of states in the form of a narrow electron pocket near the $k$-points of the Brillouin zone favors the onset of superconductivity within the BCS-Eliashberg scenario. With doping, we find that the kinematic nesting volume increases whereas the coherence of the CDW order sharply drops. The $k$-space electron distributions highlight the unconventional interplay of CDW to SC cross-over achieved through non-magnetic copper doping.

10:12AM A11.00010 Sandwich-type MgB\textsubscript{2} tunnel junctions\textsuperscript{1}, KE CHEN, YI CUI, QI LI, XIAOXING XI\textsuperscript{2}. Department of Physics, The Pennsylvania State University, University Park, Pennsylvania, USA — Properties of superconductors, such as band gap, density of states (DOS) of quasiparticles, and effective phonon spectra, can be studied by electrical tunneling with a high energy resolution of several $\hbar\omega_{\text{ph}}$. Sandwich-type MgB\textsubscript{2} tunnel junctions with Pb or Ag as the counter-electrodes were made on Hybrid Physical-Chemical Vapor Deposition MgB\textsubscript{2} films with thermal oxide tunnel barrier. The tunnel junctions exhibit very small subgap current at 4.2 K. Fit to the BCS DOS relation, the $\sigma$-band and $\tau$-band gaps of MgB\textsubscript{2} are found to be 2.3 and 7.4 meV at 4.2 K respectively. Josephson tunneling was observed with $I_{J\text{rms}}$ product following the BCS temperature dependence relation, and the critical current showing a Fraunhofer pattern modulated by the applied magnetic field. Effective phonon modes are revealed at 42, 61, and 74 meV. These superb tunnel junctions give us deep insights into the properties of MgB\textsubscript{2}.

\textsuperscript{1}The work is supported by ONR. We appreciate helpful discussions with John Rowell and Jochen Geerk.

10:24AM A11.00011 Hybridized Abrikosov Flux-lines and Pancake Vortices in Two-band Superconductors with Mixed Dimensionality\textsuperscript{1}, K. TANAKA, Department of Physics and Engineering Physics, University of Saskatchewan, M. ESCHRICHT, Instituf fuer Theoretische Festkoerperfisik, Universitaet Karlsruhe — We study electronic structure and thermodynamic properties of a two-band superconductor, in which one band is ballistic and quasi-two dimensional (2D), and the other is diffusive and three dimensional (3D). We assume that superconductivity in the 3D diffusive band is “weak”, i.e., mostly induced, as is the case in MgB\textsubscript{2}. Hybridization with the “weak” 3D diffusive band has significant and intriguing influence on the electronic properties of the “strong” 2D ballistic band. In particular, the effects of Coulomb interactions in the diffusive band and unusual Kramer-Pesch effect are excluded. Furthermore, based on a circular-cell approximation within the quasiclassical theory of superconductivity, we explore the effects of magnetic field on vortex structure in such a two-band superconductor. We discuss hybridization of Abrikosov flux lines in the 3D diffusive band with pancake vortices in the 2D ballistic band.

\textsuperscript{1}NSERC of Canada, Canada Foundation for Innovation, Deutsche Forschungsgemeinschaft within CFN

10:36AM A11.00012 Low-temperature transport in highly disordered films of superconducting magnesium diboride . NICHOLAS BREZNAY, AHARON KAPITULNIK, Stanford University — Many features make magnesium diboride an interesting model system for understanding the behavior of two dimensional BCS superconductors, including its sensitivity to disorder and low spin-orbit coupling. We study the transport behavior of highly disordered magnesium diboride films, and will review preliminary low-temperature magnetoresistance measurements in the regime of high magnetic fields. We connect these results to recent work on multilayered films prepared using a similar process and also to similar work on other model systems, and review prospects for future study.

10:48AM A11.00013 $T_c$ vs Isotopic Mass and vs Residual Resistivity Investigation in MgB\textsubscript{2}, MARINA PUTTI, University of Genova, MATTEO TROFEO, PAOLO BROTO, CARLO FERDIGHINI, ENRICO CALLEANI, PIETRO MANFRIETTI, ANDREA PALENZONA — Almost five years after the discovery of superconductivity in MgB\textsubscript{2} the isotope effect on $T_c$ is not yet understood (M. Calandra et al, Physica C456, 38 (2007) and references therein). The isotope effect is mainly due to the B atoms reflecting the important role of B vibrations in determining $T_c$. Detailed two bands calculation leads to $\alpha(B)$ of the order of 0.4–0.45, in disagreement with experiments which evaluated $\alpha(B) = 0.30$. Anharmonicity was proposed as a possible explanation for the reduced B isotope coefficient, but recently it was emphasized that such an explanation needs to be reconsidered. On the other hand, recent investigations on the effect of disorder on $T_c$ pointed out that samples with residual resistivity ($\rho_0$) of few $\mu\Omega\text{cm}$ present $T_c$ variations comparable with the intrinsic variations due to isotopic effect. This calls for new investigations of isotopic effect in samples with controlled amount of disorder. Ultra clean Mg\textsuperscript{10}B\textsubscript{2} and Mg\textsuperscript{11}B\textsubscript{2} samples ($\rho_0 \sim 0.5 \mu\Omega\text{cm}$) were damaged respectively with annealing and neutron irradiation and $T_c$ and resistivity were measured. $T_c$ vs $\rho_0$ plot shows in both cases a linear relationship allowing us to extrapolate $T_c$ ($\rho_0=0$) for both the sample series. $\alpha(B)$ evaluated by these intrinsic $T_c$ values confirms results of previous report and the crucial role of disorder in determining $T_c$ has been proved.
8:00AM A12.00001 Local density of states in Luttinger liquids with a dynamically-generated spin gap, DIRK SCHURICHT, The Rudolf Peierls Centre for Theoretical Physics, University of Oxford, UK, AKBAR JAEFARI, University of Illinois at Urbana-Champaign, FABIAN ESSELER, The Rudolf Peierls Centre for Theoretical Physics, University of Oxford, UK, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We present a theory of STM spectroscopy in semi-infinite 1D strongly correlated electron systems with a spin-gap. We calculate the local density of states of semi-infinite Luttinger liquids with open boundary conditions and a dynamically generated spin gap at zero temperature. In order to perform this calculation, we use the boundary state formalism [1] together with a form factor expansion in the infinite system. We find explicit expressions for the local density of states as a function of the gap size and the distance from the boundary. We show how a local spectroscopic probe of this type can be used to detect the spectrum of fractionalized massive solitons and their dynamics, b) the existence of boundary states and c) charge order induced by the boundary. We will discuss the relevance of this work to STM experiments in 1D systems and in quasi-1D systems used to model stripe phases in strongly correlated systems [2]. [1] S. Ghoshal and A. Zamolodchikov, Int. J. Mod. Phys. 9, 3841(1994), ibid. 9, E4353(1994). [2] S. A. Kivelson, I. P. Bindloss, E. Fradkin, V. Oganesyan, J. Tranquada, A. Kapitulnik and C. Howald, Rev. Mod. Phys. 75, 1201(2003).

8:12AM A12.00002 Spin-Incoherent Luttinger Liquid-Superconductor Hybrid Systems, DAGIM TILAHUN, The University of Texas at Austin, GREGORY FRIEТЕ, California Institute of Technology — Strongly interacting one-dimensional systems exhibit the exotic property of spin-charge separation where a repulsive interaction suppresses the velocity of the spin degree of freedom while enhancing that of the charge. Spin-incoherent Luttinger liquids exist in the regime where the temperature is much higher than the characteristic energy of the spin sector (thermalized, random spins) but much less than that of the charge. We study a hybrid system consisting of a spin-incoherent Luttinger liquid adjoined at one or both ends to a superconductor, and find robust features that can be used as clear experimental signatures of spin-incoherence. We find the tunneling density of states diverges at low energies and exhibits an universal frequency dependence independent of the strength of the interactions in the system. We also find that in spite of exponentially decaying pair correlations with distance into the spin-incoherent Luttinger liquid, the Josephson current remains robust. Compared to the zero temperature Luttinger liquid case there is a factor of 2 reduction in the critical current and a halving of the period in the phase difference between the superconductors. Our results open the way for a new class of experiments in the spin-incoherent regime of one dimensional systems.

8:24AM A12.00003 Temperature dependence of the anomalous exponent in Li(0.9)Mo(6)O(17) that reveals Luttinger Liquid behavior, RENE MATZDORF, TATJANA NOVGORODOV, BERNARD NANSSEU, MICHAEL WAELSLCH, University of Kassel, JIAN HE, RONGYING JIN, DAVID MANDRUS, Oak Ridge National Laboratory — Scanning tunneling spectroscopy (STS) has been used to study the Luttinger-liquid behavior of the purple bronze Li(0.9)Mo(6)O(17) in the temperature range 5K ≤ T ≤ 300K. In the entire temperature range the suppression of density of states at the Fermi-energy could be fitted very well by a model describing the tunneling into a Luttinger liquid at ambient temperature. The power-law extracted from these fits reveals a significant increase above 200K. It changes from α=0.6 at low temperature to α=1.0 at room temperature.

8:36AM A12.00004 Specific heat of a one-dimensional interacting Fermi system, ANDREY CHUBUKOV, University of Wisconsin, DMITTR MASLOV, University of Florida, RONJOY SAHA, University of Oregon — We re-visit the issue of the temperature dependence of the specific heat C(T) for interacting fermions in 1D. The charge component C_{c}(T) scales linearly with T, but the spin component C_{s}(T) displays a more complex behavior with T as it depends on the backscattering amplitude which falls down under RG transformation and eventually behaves as \( g_{s}(T) \sim 1/ \log T \). We show, however, by direct perturbative calculations that C_{s}(T) is strictly linear in T to order \( g_{s}^{2} \) as it contains the renormalized backscattering amplitude not on the scale of T, but at the cutoff scale set by the momentum dependence of the interaction around 2k_{F}. The running amplitude \( g_{s}(T) \) appears only at third order and gives rise to an extra \( T \log^{3} T \) term in C_{s}(T). This agrees with the results obtained by a variety of bosonization techniques. We also show how to obtain the same expansion in \( g_{s} \) within the sine-Gordon model.

8:48AM A12.00005 Entanglement and quantum phase transition in the ground state of one-dimensional asymmetric Hubbard model, WENLING CHAN, SHI-JIAN GU, Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Hong Kong, China — We study the quantum phase transition by means of entanglement in the ground state of the one-dimensional asymmetric Hubbard model. Both the half-filling and away from half-filling cases are investigated. The local entanglement between the middle two sites with the rest of the system, and the block entanglement between the left and right portions of the system, are calculated by the DMRG method. We find that the entanglements show interesting scaling and singular behavior around the phase transition line.

9:00AM A12.00006 Is the Drude weight a thermodynamic quantity?, MARCOS RIGOL, B. SRIRAM SHASHTRY, University of California, Santa Cruz — Transport properties distinguish metals from insulators, and superconductors from ideal metals. In one dimension, they can help differentiate integrable from nonintegrable systems. The Drude weight (or charge stiffness) is found to be nonzero in integrable metals, even at very large temperature, whereas it vanishes for generic (nonintegrable) systems. In systems with periodic boundary conditions, the Drude weight can be shown to be identically zero for any finite system, regardless of its integrability. For the Drude weight to be a thermodynamically meaningful quantity, both kinds of boundary conditions should produce the same answer in the thermodynamic limit. We resolve this paradox using analytical and numerical methods.

9:12AM A12.00007 Phase diagram of hole doped two-leg Cu-O ladders, PIOTR CHUDZINSKI, MARC GABAY, Laboratoire de Physique des Solides, Bat. 510, Université Paris-Sud 11, Centre d’Orsay, 91405 Orsay Cedex, France, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva, 24 Quai Ernest-Ansermet CH-1211 Geneva, Switzerland — In the weak coupling limit, we establish the phase diagram of a two-leg ladder with a unit cell containing both Cu and O atoms, as a function of doping. We use bosonization and design a specific RG procedure to handle the additional degrees of freedom. Significant differences are found with the single orbital case; for purely repulsive interactions, a completely massless quantum critical region is obtained at intermediate carrier concentrations (well inside the bands). For some finite value of direct hopping between oxygen atoms the ground state consists of an incommensurate pattern of orbital currents plus a spin or charge density wave (DW) structure. The experimental relevance of these findings is also discussed. We have calculated the NMR properties like Knight shift and relaxation rate at each atom inside the elementary cell. We make a prediction that different temperature dependance indicates the phase of the measured system.

9:24AM A12.00008 Groundstate fidelity and the spin one chain, IAN MCCULLOCH, University of Queensland — it has been recognized quite recently that the groundstate fidelity, that is, the overlap of the groundstate wavefunctions as a function of interaction strength, can be used to obtain phase boundaries and exponents without a-priori knowledge of the order parameter. This procedure is easy to apply in a wide class of numerical algorithms based on matrix product states, of which the Density Matrix Renormalization Group (DMRG) is the most famous. I will give a brief overview of the technique, and demonstrate that the fidelity reveals all features of the bilinear-biquadratic spin one chain, while almost certainly ruling out the appearance of a (gapped or critical) nematic phase in the vicinity of \( \theta = -3\pi/4 \).
9:36AM A12.00009 Magnetism of one-dimensional Wigner lattices and its impact on charge order. MARIA DAGHOFER, Univ. of Tennessee, Knoxville, REINHARD NOACK, Philips Universitaet Marburg, PETER HORSCHE, MPI for Solid State Research, Stuttgart — We report the phase diagram of a quarter-filled Wigner lattice described by the 1D Hubbard-Wigner model with nearest and next-nearest neighbor hopping $t_1$ and $t_2$. In the $t_1$-$t_2$ plane, we find a region at negative $t_2$ with fully saturated ferromagnetic ground states due to kinetic exchange interactions, while the remaining phase diagram is controlled by antiferromagnetic exchange. We also observe a strong influence of magnetism on the charge structure factor, in contrast to the expectation that charge ordering in the Wigner lattice is well described by spinless fermions. Our results, obtained using the density-matrix renormalization group and exact diagonalization, can be transparently explained within the framework of an effective low-energy Hamiltonian.

9:48AM A12.00010 Critical lines and massive phases in quantum spin ladders with dimerization. JAVIER ALMEIDA, MIGUEL ANGELO MATIN-DELGADO, Universidad Complutense, Madrid, Spain, GERMAN SIERRA, Instituto de Fisica Teorica, C.S.I.C-U.A.M, Madrid, Spain — We study here various types of $S=1/2$ spin ladders with odd and even number of legs and intrinsically dimerized patterns. The low temperature physics of these systems is very rich and in fact their ground state at $T=0$ may undergo a quantum phase transition as we vary the microscopic parameters of the lattices. To study these many-body systems we will use the density matrix renormalization group (DMRG) algorithm, and will present accurate estimations of the critical lines found in these models as well as different measurements to characterize the nature of the ground state. We will see that the valence bond solid picture seems to be a proper description of the massive phases on each side of the phase diagram and will show evidences of this nature by means of a particular order parameter denoted generalized string order parameter.

10:00AM A12.00011 ABSTRACT WITHDRAWN —

10:12AM A12.00012 Magnetostriction and thermal expansion on 1D chain compound Azurite, FREDDERIK W. FABRIS, VIVIEN ZAPF, SONIA FRANCOUAL, MARCELO JAIME, ALEX LACERDA, National High Magnetic Field Laboratory, Los Alamos, New Mexico 87545, USA, NHMFL-LANL TEAM — Azurite is a natural mineral with a chemical structure Cu$_3$(OH)$_2$(CO$_3$)$_2$. This compound is a frustrated triangular quantum magnet consisting of Cu S=1/2 atoms arranged alternately to form infinite chains along the b axis. The magnetic behavior of this compound reflects the existence of both monomers and dimers of $S=1/2$ Cu. A magnetization plateau at 1/3 of the saturation magnetization is observed in M vs H measurements between 11 and 30 T due to saturation of the monomers. For fields above the plateau, the magnetic field energy exceeds the dimer bonding and thus the dimers cant and then align with the field. The magnetic structure and the detailed phase diagram in temperature and field are largely unknown or controversial. A recent report [1] in the specific heat behavior suggests a more complicated structure than previously thought. In addition, recent ultrasound measurements [2] indicate significant magnetoelastic coupling must be taken into account. We have acquired interesting results on magnetic torque, magnetostriction and thermal expansion. We have demonstrated that significant, anisotropic magnetostriction occurs in azurite, giving us an indication of the magnetically induced structural distortions. [1] Yasu Takeho, personal communication. [2] Lang et al, J. Phys.: Conf. Series 51, 1. (2006).

10:24AM A12.00013 Quantum Monte Carlo study of a spin-Peierls model in a magnetic field1, JEONGPIL SONG, R.T. CLAY, Mississippi State University — We present results of a quantum Monte Carlo study of a quasi one-dimensional XY spin model coupled to quantum phonons. We compare different updating techniques for the Stochastic Series Expansion method and present autocorrelation time data. We are able to reduce autocorrelation times by using loop update techniques for both spin and phonon degrees of freedom. We determine the critical phonon coupling for the spin-Peierls state, and discuss the dependence on the phonon frequency, magnetic field, and inter-chain coupling.

1Supported by the Department of Energy grant DE-FG02-06ER46315.

10:36AM A12.00014 Quantum solvation in optical lattice, YOU WENLONG1, GU SHIJIAN, LIN HAIQING, Department of Physics, The Chinese University of Hong Kong, Shatin, N. T., Hong Kong, CUHK TEAM — We have studied the ground state phase diagram of the one dimensional asymmetric t-J-2 model at various filling by different methods. The reduced dimensionality and asymmetric hopping could lead to interesting dynamics which can be conjectured to demonstrate quantum solvation process with fermion character of the quantum solvent. The system potentially can be demonstrated in optical lattice.

1Department of Physics, Peking University, Beijing 100871, China

10:48AM A12.00015 Effective model parameters for the spin-Peierls system TiOCl from first principles, YUZHONG ZHANG, ROSER VALENTI, HARALD JESCHKE, Johann Wolfgang Goethe-Universität, Institut füer Theoretische Physik — The inorganic spin-Peierls system TiOCl is studied in the frame of Density Functional Theory (DFT) by the projector augmented wave (PAW) and linearized augmented plane wave (LAPW) methods. A two-dimensional frustrated spin Peierls model is proposed to describe the system. The model parameters, such as spin exchange couplings in a, b, and c directions, are estimated by the LAPW method. With the help of the eigenvectors of the dynamical matrix, the spin-phonon couplings and the elastic constant are determined by the PAW method. The reliability of these model parameters is demonstrated by an exact diagonalization and a mean-field calculation as well as by comparison to available experiments.

Monday, March 10, 2008 8:00AM - 10:36AM –
Session A13 DCOMP GSCCM: Focus Session: Simulations of Matter at Extreme Conditions I: Hydrogen Helium, and Planetary Materials

8:00AM A13.00001 Quantum Monte Carlo Simulations of Warm Dense Hydrogen1, DAVID CEPERLEY, University of Illinois Urbana-Champaign — Quantum Monte Carlo methods are the most accurate and general methods for computing total electronic energies. However, in general, they have been limited to the temperatures or to zero temperature. In recent years, we and others have been working on methods [1] that utilize the Born Oppenheimer approximation to allow simulations coupling the correlated quantum systems and a system of ions. Using quantum Monte Carlo, one estimates the Born-Oppenheimer energy change for a movement of the ions which is then used in a Monte Carlo simulation of the ionic degrees of freedom. The quantum effects of the ionic degrees of freedom and the boundary conditions on the phase of the wavefunction can be integrated over. We have performed simulations of dense hydrogen down to temperatures of 300K. We have used this method to determine the equation of state of warm dense hydrogen, to study the cross-over from the molecular liquid to the atomic liquid [2] and for the melting temperature of solid atomic hydrogen [3].

8:36AM A13.00002 Electrical conductivity of liquid Hydrogen
1. FEI LIN, University of Illinois at Urbana-Champaign, KRIS DELANEY, University of California, Santa Barbara, MIGUEL MORALES, University of Illinois at Urbana-Champaign, CARLO PIERLEONI, University of L’Aquila, RICHARD MARTIN, DAVID CEPERLEY, University of Illinois at Urbana-Champaign — DC electrical conductivity of liquid Hydrogen under high pressure has been measured by shock-wave experiments a long time ago [Phys. Rev. Lett. 76, 1860 (1996)], however, an accurate theoretical calculation of electrical conductivity is still unavailable. Ab-initio DFT calculations seem to overestimate the DC conductivity value by about 6 times. On the other hand, coupled electron-ion—Quantum Monte Carlo (CEIMC) simulation [Phys. Rev. Lett. 97, 235702 (2006)] has predicted different high-pressure Hydrogen molecular-atomic transition than the DFT calculation. In this talk I will report our preliminary electrical conductivity results from CEIMC simulations using the Kubo formula with energies and current-current matrix elements computed with correlated quantum Monte Carlo methods.

1Supported by DE-FG52-06NA26170 and computer resources of NCSA.

8:48AM A13.00003 Properties of Hydrogen-Helium Mixtures at High Pressure and Temperature
1. SAAD KHAIRALLAH, Earth and Planetary Science Department, University of California, Berkeley, JAN VORBERGER, Centre for Fusion, Space and Astrophysics, Department of Physics, University of Warwick, Coventry CV4 7AL, United Kingdom., BURKHARD MILITZER, Earth and Planetary Science Department, University of California, Berkeley. — Most of the over 200 recently discovered extrasolar planets are giant gas planets that consist primarily of dense, hot hydrogen and helium. Using density functional molecular dynamics (DFT-MD) simulations, we study these fluids at the extreme conditions found in planet interiors. We characterize the interaction of hydrogen and helium, analyze the electronic properties, and report on structural changes in the fluid as a function of density and temperature. We further study the influence of helium concentrations on the stability of hydrogen molecules.

1NASA grant PGG04-0000-0116, NSF grant 0507321.

9:00AM A13.00004 Ultra-High-Pressure Water. MARTIN FRENCH, RONALD REDMER, Universitat Rostock, Institut fur Physik, D-18051 Rostock, Germany, THOMAS R. MATTSSON, Sandia National Laboratories, Albuquerque, NM 87185-1186, USA. — We present the first all-electron QMD simulations of water in the ultra-high-pressure regime up to conditions typical for the deep interior of Jupiter and Saturn. We calculate the equation of state and the Hugoniot curve and study the structural properties via pair correlation functions and self-diffusion coefficients. In the ultra-dense superionic phase, we find a continuous transition in the protonic structure. Water at conditions of Jupiter’s core (i.e. 20000 K, 50 Mbar, 11 g/cm^3) forms a fluid dense plasma. Supported by the DFG within SFB 652. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States DOE’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:12AM A13.00005 Ab initio Molecular Dynamics Simulations of Water Under Shock Compression: Chemistry Behind Shock Fronts. LAURENCE FRIED, NIR GOLDMAN, Lawrence Livermore National Laboratory, ALESSANDRO CURIONI, IBM Research, Zurich Research Laboratory, CHRISTOPHER MUNDY, Pacific Northwest National Laboratory, I.-F.W. KUO, EVAN REED, Lawrence Livermore National Laboratory — We report herein first principles simulations of water under shock loading of velocities from 5 - 11 km/s. Accurate description of the plateau in the ionic conductivity at high pressures and temperatures is of particular importance to models of the planetary dynamo mechanism in Neptune and Uranus. We attribute this plateau to the exceedingly short-lived molecular and ionic states that occur in water under these extreme conditions. In particular, at the intersection of the shock hugoniot and Neptune isentrope we observe transient metalization that we attribute to the formation of short-lived negatively charged species that contribute electronic states at or around the band gap.

9:24AM A13.00006 Molecular structures of CO2 and N2O under pressure1. STANIMIR A. BONEV, BRENDAN OSBERG, Department of Physics, Dalhousie University, Canada — Carbon dioxide and nitrous oxide are investigated at pressures up to 50 GPa and 1000 K using ab initio methods. In this pressure-temperature range, both materials have a number of stable molecular structures. We demonstrate that the constituent molecules in these structures do not undergo significant changes and that the proposed phases are consistent with experimental data. The differences found between the CO2 and N2O phase diagrams can be understood in terms of the polarity of the N2O molecules.

1Work supported by NSERC.

9:36AM A13.00007 Quantum Monte Carlo Computations for Equations of State, Phase Transitions, and Elasticity of Silica, R.E. COHEN, Carnegie Institution of Washington, B. MILITZER, Z. WU, University of California, Berkeley, K. DRIVER, Ohio State University, P.L. RIOS, M. TOWLER, R. NEEDS, University of Cambridge — We have performed Quantum Monte Carlo (QMC) computations for silica in the quartz, stishovite, and α-PbO2 structures as functions of compression. In spite of the great success of DFT there is still need for improvement. The local density approximation (LDA) gives excellent results for individual silica phases, but LDA predicts stishovite to be the stable ground state rather than quartz. The Generalized Gradient Approximation (GGA) does give correct energy differences, but other properties, such as the bulk moduli, are worse with the GGA than the LDA. We included thermal contributions using density functional perturbation theory with the code ABINIT. We have also computed the shear elastic constant c21-c22 in stishovite, which is associated with the phase transition to the CaCl2 structure, with QMC. We find excellent agreement with experiments. We find that the main differences found between QMC and DFT are crystalline phase dependent energy and pressure shifts. This work is supported by NSF grants EAR-0530282, EAR-0310139, and by DOE contract DE-FG02-99ER45795 to John Wilkins. Computations were performed on blueice at NCAR under a BTS grant, and on Tungsten and Abe at NCSA, and at the Carnegie Institution of Washington.

9:48AM A13.00008 The effect of temperature and anisotropic pressure on the phase transitions in α-cristobalite. ROMAN MARTONAK, Comenius University, SK., DAVIDE DONADIO, UC Davis, PAOLO RAITERI, MICHELE PARRINELLO, ETH Zurich, CH — The role of temperature and anisotropy of the pressure tensor in the pressure-induced transformations of α-cristobalite is investigated by means of first principle molecular dynamics combined with an improved version of the metadynamics algorithm for the study of solid-solid phase transitions. We reproduce for the first time the transition to α-PbO2 as found in experiment[4] and we observe that the transition paths are qualitatively different and yield different products whether the applied pressure is hydrostatic or not. While in hydrostatic conditions α-PbO2 or stishovite is obtained depending on the temperature and initial conditions, more complicated pathways with several metastable structures are followed upon non-hydrostatic compression and post-stishovite phases are obtained. Based of our simulations, we predict the metastability of a new class of high pressure polymorphs of silica obtained by non-hydrostatic compression.

The inter-vortex distance is given by \( \theta = \frac{\pi}{2 \pi l} \approx \frac{805 \text{ nm}}{8 \pi l} \), where \( l \) is the condensate diameter, and \( \phi \) is the optical wavelength. We prepare the condensate in the dressed state, whose projection onto internal states of various state-dependent Bragg momenta are well understood.

The results may bring important implications to interior models of giant planets, which may lead to a better understanding in giant planets physics.

Monday, March 10, 2008 8:00AM - 11:00AM –
Session A14 GQI DAMOP: Focus Session: Quantum Simulation of Condensed Matter Systems With Ultracold Atoms
Morial Convention Center 205

8:00AM A14.00001 Simulating Charged Particles in a Magnetic Field with Ultra-cold Atoms Using Light-induced Effective Gauge Fields, YU-JU LIN, WILLIAM PHILLIPS, JAMES PORTO, IAN SPIELMAN, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM, UNIVERSITY OF MARYLAND TEAM — We experimentally study light-induced gauge potentials in a \(^{87}\)Rb Bose-Einstein condensate. Instead of rotating the trap, we prepare the atoms in a spatially-varying optically dressed state. The atomic spin state is dressed by a spatially varying two-photon Raman coupling between the three \( F = 1 \) hyperfine ground states. The resulting effective magnetic field is equivalent to rotating the condensate (and transforming to the rotating frame), and thus generates vortices. The inter-vortex distance is given by \( \theta = \frac{\pi}{2 \pi l} \approx \frac{805 \text{ nm}}{8 \pi l} \), where \( l \) is the condensate diameter, and \( \phi \) is the optical wavelength. We prepare the condensate in the dressed state, whose projection onto internal states of various state-dependent Bragg momenta are well understood.

8:12AM A14.00002 Two-Dimensional Electron Gas with Cold Atoms in Non-Abelian Gauge Potentials, INDUBALA SATIJA, Department of Physics, George Mason University, DANIEL DAKIN, Optical Air Data Systems, J. Y. VAISHNAV, CHARLES W. CLARK, Joint Quantum Institute, National Institute of Standards and Technology — Motivated by the possibility of creating non-Abelian fields using cold atoms in optical lattices, we study two-dimensional electron gases in a lattice, subjected to such fields. In the continuum limit, the system characterized by a two-component “magnetic flux” describes a harmonic oscillator existing in two different charge states (mimicking a particle-hole pair). A key feature of the non-Abelian system is a splitting of the Landau energy levels, which broaden into bands. These Landau bands result in a coarse-grained Hofstadter “moth.” Furthermore, the bands overlap, leading to effective relativistic effects. Similar features also characterize the corresponding 2D lattice problem when at least one of the components of the magnetic flux is an irrational number. Some unique aspects of the transport properties of the non-Abelian system are the possibility of inducing localization by varying the quasimomentum, and the absence of localization of certain zero-energy states exhibiting a linear dispersion relation. Furthermore, non-Abelian systems provide an interesting localization scenario where the localization transition is accompanied by a transition from relativistic to non-relativistic theory.

8:24AM A14.00003 Observing Zitterbewegung in Ultracold Atoms, J.Y. VAISHNAV, CHARLES W. CLARK, Joint Quantum Institute, National Institute of Standards and Technology, Gaithersburg MD 20899 — We propose an optical lattice scheme which would permit the experimental observation of Zitterbewegung (ZB) with ultracold, neutral atoms. A four-level “tripod” variant of the usual setup for stimulated Raman adiabatic passage (STIRAP) has been proposed for generating non-Abelian gauge fields. [1] Dirac-like Hamiltonians, which exhibit ZB, are simple examples of such non-Abelian gauge fields; we show how a variety of them can arise, and how ZB can be observed, in a tripod system. We predict that the ZB should occur at experimentally accessible frequencies and amplitudes.

8:36AM A14.00004 Detecting the Bose glass in optical lattices, TOMMASO ROSCILDE, Max-Planck Institute for Quantum Optics — We theoretically propose a method for the unambiguous experimental detection of Bose-glass behavior in the central region of a system of bosons trapped in an optical lattice system, and to discriminate the Bose glass from more conventional Mott and band insulators. The method is based on probing the compressibility of the system in the trap center by gradually increasing the trap frequency. Straightforward measurements of the average particle density in the center of the trap and of the momentum distribution allow to detect the migration of particles from the wings into localized states in the center of the system under trap squeezing. We discuss the application of the method to simple optical lattices, and to commensurate and incommensurate optical superlattices; we moreover discuss the potential of trap squeezing techniques to probe the density of states of exotic phases realized in optical lattices.
8:48AM A14.00005 Phase Coherence and Superfluid-Insulator Transition in a Disordered Bose-Einstein Condensate. YONG P. CHEN, J. HITCHCOCK, D. DRIES, M. JUNGER, C. WELFORD, R. G. HULET, Department of Physics and Astronomy and Rice Quantum Institute, Rice University, Houston TX 77005 USA — We have studied both the transport and phase coherence properties of a Bose-Einstein condensate (BEC) of $^7$Li atoms subject to a disordered potential with tunable strength ($V_D$). The BEC is created in an elongated optical trap, while the disordered potential is produced by laser speckle. We probe transport of the disordered BEC by either slowly or abruptly offsetting the trap relative to the disordered potential. At high $V_D$, we observe pinning of the disordered BEC and suppression of its dipole excitation, consistent with the transition to an insulator. We use in-situ imaging to detect density modulation, while time-of-flight (TOF) imaging is used to probe phase coherence. At moderate $V_D$, we observe small density fluctuations in the in-situ images, and random but reproducible interference patterns in the TOF images. This interference reflects phase coherence in the disordered BEC and is interpreted as speckle for matter waves. At higher $V_D$, the TOF interference contrast diminishes while the in-situ density fluctuations increase, signifying a fragmented “granular” condensate with little phase coherence. 1Supported by NSF, ONR, NASA, Welch and Keck Foundations. 2Now at Purdue University.

9:00AM A14.00006 Effects of disorder on the interacting Fermi gases in one-dimensional optical lattices. B. TANATAR, Physics Department, Bilkent University, 06800 Ankara, Turkey, GAO XIANLONG, Physics Department, Zhejiang Normal University, Jinhua, 321004 China, M. POLINI, M. P. TOSI, NEST-CNR-INFM and Scuola Normale Superiore I-56126 Pisa, Italy — Interacting two-component Fermi gases loaded in a one-dimensional (1D) lattice and subjected to a harmonic trapping potential exhibit interesting compound phases in which fluid regions coexist with local Mott-insulator and/or band-insulator regions. Motivated by experiments on cold atoms inside disordered optical lattices, we present a theoretical study of the effects of a random potential on these ground-state phases. We employ density-functional theory within the local-density approximation to determine the density distribution of fermions in these phases. The exchange-correlation potential is obtained from the Lieb-Wu exact solution of Fermi-Hubbard model. On-site disorder and harmonic trap are treated as external potentials. We find that disorder has two main effects: it destroys the local insulating regions if it is sufficiently strong compared with the on-site atom-atom repulsion, and it induces an anomaly in the compressibility at low density from quenching of percolation.

9:12AM A14.00007 Probing non-local order parameters in highly correlated Bose insulators. EHUD ALTMAN, Department of Condensed Matter Physics, Weizmann Institute of Science — Ground states of integer spin chains are known since the late 80’s to sustain highly non-local order described by infinite string operators of the spins. Such states defy the usual Landau theory description and can be considered simple prototypes of topological order. Recently we showed that spinless Bose insulators with nearest neighbor or longer range repulsion in one dimension can exhibit similar string order in terms of the boson density [1]. The tunability of cold atomic systems would allow much more flexibility in probing the non-local order than spin systems do. For example the bosons can be tuned across a quantum phase transition between the exotic insulator, which we term Haldane insulator, and the usual Mott insulator. Investigating how the transition responds to external perturbations lends direct access to properties of the string order parameter. I will demonstrate this with several new results obtained from a field theoretic description of the phases and confirmed by numerical calculations using DMRG. Particularly revealing of the unusual character of the string order is the prediction that any external perturbation, which breaks the lattice inversion symmetry, would eliminate the distinction between the Haldane and Mott phases and allow a fully gapped adiabatic connection between them. This is remarkable given that neither phase involves spontaneous breaking of lattice inversion symmetry. We also predict that inter-chain tunneling destroys the direct phase transition between the two insulators by establishing an intermediate superfluid phase. Finally I will discuss how the new phases and phase transitions may be realized and probed in actual experiments with ultra cold atoms or polar molecules.

9:48AM A14.00008 A Hexagonal Lattice Ion Trap for Quantum Simulation of Spin Models. ZILIANG LIN, ROBERT CLARK, YUEFEI GE, ISAAC CHUANG, Massachusetts Institute of Technology. PLANAR LATTICE TRAP TEAM — Quantum simulations of one dimensional spin systems are being implemented by ions in linear Paul traps; however, a natural extension to two dimensional quantum spin simulations cannot be realized in the linear Paul trap geometry. Planar lattice traps not only offer the possibility for two dimensional simulations, but also hold two advantages over linear traps: first, neighboring ions in lattice traps have well defined and uniform spacings; second, quantum simulations with planar traps may be scaled up more easily than with linear traps. We develop a hexagonal lattice trap that allows vibrational coupling between ions due to their Coulomb repulsion, which is essential for effective spin-spin interaction. We present fabrication details, preliminary testing results, and a proposal for simulating geometrical spin frustration with three ions in a triangular configuration.

10:00AM A14.00009 Trapped-Ion Quantum Simulations of Spin Systems: From Two Qubits to Thousands. WARREN LYBARGER, Los Alamos National Laboratory, DANA BERKELAND, IARPA, JOHN CHIAVERINI, Los Alamos National Laboratory — Due to the exponential growth of a quantum system’s state-space with its size, the current technological limit for simulating the evolution of many-qubit spin systems with classical computers (CC) is 36 spin-$\frac{1}{2}$ particles. While CC’s cannot be scaled to meet the exponentially increased demand in computational resources, mapping the Hamiltonians of such problems onto that of a quantum simulator (QS) completely avoids this exponential scaling problem, allowing for efficient simulations of much larger systems. QS may be the first attainable application of quantum information processing, enabling exploration of parts of the phase space not accessible in the original system and possibly providing an exponential speedup of computations for even just a few tens of interacting qubits when compared to CC methods. Following the work of Porras and Cirac [Phys. Rev. Lett. 92. 207901-1 (2004)] we discuss the status of an experiment at Los Alamos for demonstrating a proof of principle QS of an Ising-like spin-spin interaction in a transverse magnetic field. We also discuss a novel architecture for microfabricated ion trap arrays geared toward enabling large scale QS and one-way quantum computing with potentially thousands of ions [arXiv:0711.0233].

10:12AM A14.00010 Quantitative determination of the Hubbard model phase diagram from optical lattice experiments: overcoming the singular nature of the thermodynamic limit. VIVALDO CAMPO, JR., Unidade de Brasilia, Brazil and Universidade de Sao Paulo, Brazil, KLAUS CAPELLE, Universidade de Sao Paulo, Brazil, JORGE QUIN- TANILLA, Rutherford Appleton Laboratory, U.K., CHRIS HOOLEY, University of St Andrews, U.K. — We propose an experiment to obtain the phase diagram of the fermionic Hubbard model, for any dimensionality, using cold atoms in optical lattices. It is based on measuring the total energy for a sequence of trap profiles. It combines finite-size scaling with an additional ‘finite-curvature scaling’ necessary to reach the homogeneous limit. We illustrate its viability in the 1D case, simulating experimental data in the Bethe-Ansatz local density approximation. Including experimental errors, the filling corresponding to the Mott transition can be determined with better than 3 per cent accuracy. The main obstacle that our method overcomes is the singular nature of the thermodynamic limit of atom traps. We discuss this surprising phenomenon and describe a simpler experiment that could be used to demonstrate it.
10:24AM A14.00011 The p$_{x,y}$-orbital counterpart of graphene – cold fermions in the honeycomb optical lattices, CONGJUN WU, Physics Department, UCSD, DORON BERGMAN, Physics Department, Yale, LEON BALENTS, Physics Department, UCSB, SANKAR DAS SARMA, Physics Department, Univ. of Maryland — We study the ground states of cold atoms in the tight-binding bands built from p-orbitals on a two dimensional honeycomb optical lattice. The band structure includes two completely flat bands. Exact many-body ground states with on-site repulsion can be found at low particle densities, for both fermions and bosons. We find crystalline order at $n=1/6$ with a $\sqrt{3} \times \sqrt{3}$ structure breaking a number of discrete lattice symmetries. In fermionic systems, if the repulsion is strong enough, we find the bonding strength becomes dimerized at $n=1/2$. Experimental signatures of crystalline order can be detected through the noise correlations in time of flight experiments.

10:36AM A14.00012 DMRG Studies for Strongly-Correlated Fermions on a Triangular Optical Lattice, MASAKI OKUMURA, SUSUMU YAMADA, MASAKI MACHIDA, CCSE, Japan Atomic Energy Agency and JST(CREST) — Strongly-interacting fermions in a triangular lattice attract much attention because not only the interaction but also the geometrical frustration is expected to cause non-trivial behaviors. In solids, most of materials parameters, e.g., interaction strength between electrons (fermions), fermion density, and crystalline potential are almost fixed depending on the sample and our research area are restricted. In contrast, cold atom systems enable to study it systematically because some crucial parameters are precisely controllable. Thus, we expect that the cold Fermi atoms on a triangular lattice bring us information on both strongly-correlated and frustrated systems. In this study, we examine a system described by the triangular Hubbard model by using the parallel density-matrix renormalization group (DMRG). In addition, we also investigate effects of random potential made by speckle laser in the system. We evaluate the effects of frustration, strong interaction, and randomness simultaneously.

10:48AM A14.00013 Order parameter statistics at a quantum phase transition, AUSTEN LAMACRAFT, University of Virginia, PAUL FENDLEY, University of Virginia and All Souls College, Oxford — Universality implies that at a second order phase transition the probability distribution of the order parameter takes a universal scaling form. This distribution is a natural way to characterize the quantum critical properties of ultracold atomic gases, since its histogram may be readily obtained by repeated 'single-shot' measurements. In this work we obtain the exact scaling probability distribution for the simplest quantum critical point: that of the transverse field Ising model in 1D. Using a novel identity for the Ising model correlation functions, we map the problem to a particular case of the anisotropic Kondo model.

Monday, March 10, 2008 8:00AM — 10:48AM — Convention Center 207

8:00AM A15.00001 Bias dependence of magnetic exchange coupling, PAUL HANEY, MARK STILES, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, CHRISTIAN HEILIGER, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, Maryland NanoCenter, University of Maryland, ALLAN MACDONALD, The University of Texas at Austin — An applied electrical bias can change the interlayer coupling in magnetic multilayers and magnetic tunnel junctions. The bias dependence of these changes is ultrafast; it is not clear whether the changes depend linearly or quadratically on the applied voltage. Motivated by this controversy, as well as proposals to exploit bias-dependent exchange coupling to accomplish current induced magnetic switching, we compute the bias-dependence of interlayer exchange coupling in magnetic multilayers and tunnel junctions. For simple tight-binding models, we derive expressions for this dependence, describe the special cases in which this dependence is particularly large, and derive the extent to which zero-bias expressions for interlayer coupling remain valid for biased systems. We also examine the related question of the bias-dependence of intralayer exchange interactions in a single ferromagnetic layer, and discuss experimental consequences of bias-modulated exchange stiffness, including induced changes in the Curie temperature and spin wave dispersion. This work has been supported in part by the NIST-CNST/UMD-NanoCenter Cooperative Agreement.

8:12AM A15.00002 Spin current and rectification in quantum wires, FEIFEI LI, Department of Physics, Brown University, Providence, Rhode Island 02912 USA, BERND BRAUNECKER, Department of Physics and Astronomy, University of Basel, Klingelbergstrasse 82, CH-4056 Basel, Switzerland, DIMA FELDMAN, Department of Physics, Brown University, Providence, Rhode Island 02912, USA — We study the spin and charge currents in a one-channel quantum wire with strong electron interactions in a uniform static magnetic field. We show that a dc-spin current can be generated by an ac voltage in the presence of an asymmetric potential barrier, e.g., two point scatterers of unequal strength. In an interval of voltages, the spin current increases with the decrease of the voltage bias as a negative power of the voltage. We find that the spin dc-current in units of electron charge per second can greatly exceed the charge current in units of electron charge per second. Neither spin-polarized particle injection nor time-dependent magnetic fields are required for the generation of the spin current.

3This research was supported by NSF under Grant No. DMR-0544116.

8:24AM A15.00003 Vortices and Antivortices as Harmonic Oscillators, B. KRUEGER, M. BOLTE, A. DREWS, U. MERKT, G. MEIER, D. PFANNKUHCE, University of Hamburg, Germany — In experiments the distinction between current-induced dynamics and the dynamics induced by the Oersted field of the current is still an open problem. Here we investigate the gyrosopic motion of current- and field-driven magnetic vortices/antivortices in micro- or nanostructured thin-film elements by analytical calculations and by numerical simulations. Starting from the micromagnetic equation of motion extended by the spin torque introduced by Zhang and Li, we derive an analytical expression for the current- and field-driven trajectory of the vortex/antivortex. The gyrosopic motion is well described by modeling the stray-field energy as a harmonic-oscillator potential. For small harmonic excitations the vortex/antivortex cores perform an elliptical rotation around their equilibrium positions. Our analytical model allows to calculate the amplitude and phase of the gyration. The phase of the rotation and the ratio between semi-axes are determined by the frequency and amplitudes of Oersted field and spin torque. The analytical result is compared to micromagnetic simulations with good accordance.[1] Even though the influence of weak magnetic fields on the vortex/antivortex trajectories is small, the phase of the rotation is significantly changed. Thus, the model can estimate the Oersted field’s contribution in spin-torque experiments.[1] B. Krueger et al., Phys. Rev. B 76, December (2007).

8:36AM A15.00004 Current-induced torques in magnetic textures and in antiferromagnets, REMBERT DUINE, Utrecht University — Current-induced torques on ferromagnetic nanoparticle and on domain walls in ferromagnetic nanowires are normally understood in terms of transfer of conserved spin angular momentum between spin-polarized currents and the magnetic condensate. Spin pumping is the opposite of spin transfer, namely the generation of spin currents by a time-dependent magnetization. In this talk I will discuss recent theoretical work aimed at understanding current-induced torques and spin pumping in situations that spin is not fully conserved, due to e.g., spin-orbit interactions, or when conservation of spin can not be used to infer order-parameter dynamics, as is the case in antiferromagnets.
9:12AM A15.00005 Spin transfer and the role of spin-motive-forces for spin valves and domain walls. STEWART BARNES, Physics Dept., Univ. of Miami — The interaction of magnetic domains with electrical currents has potentially far reaching applications for spintronics. The requirements of energy conservation are reflected by spin- (smf) and electro-motive-forces (emf) [1]. For spin-valves and domain walls this smf redistributes the currents between the different possible conduction channels in a manner that significantly modifies the dynamics and introduces magnetic relaxation. Our Berry phase approach to domain walls [1,2] has been extended to spin-valves. The results are consistent with the requirements of angular momentum and energy conservation but differ in a number of important ways from those obtained when the Stoner-Esaki torque transfer term is added to the Landau-Lifshitz equations with either Gilbert or Landau-Lifshitz relaxation [3].

1 A collaboration with J. Ieda and S. Maekawa.

9:24AM A15.00006 Dynamic and temperature effects in spin-transfer switching. HUY PHAM, University of New Orleans, ALEXANDRU STANCU, Iasi University, LEONARD SPINU, University of New Orleans — Recently, the current-induced spin-transfer torque has been proposed as a convenient writing process in high density magnetic random access memory. With increasing demand on the access time, the current pulse shape become important. Also, with memory area density increasing and the memory cell size further shrinking the study of thermal fluctuations in these magnetic structures becomes of extreme importance for their recording thermal stability. In this paper we have studied the dynamic switching process in spin valves and domain walls using a combination of spin-flip excitation and orbit excitation. We have observed a surprising and so far largely unexplained degeneracy in this system: when (as is often the case) there are two orbits with the same energy, even if their shapes and sizes are very different, their frequencies turn out to be the same. Although this is easy to show in the highest-symmetry (uniaxial) case, we find it is true far more generally — for any quadratic energy function with arbitrary anisotropy tensor and arbitrary external magnetic field. We have calculated the frequencies for a random selection of anisotropy tensors and magnetic fields, will show examples of asymmetrical orbits, whose frequencies are equal within numerical accuracy ($\approx 10^{-15}$).

1 Work supported by DARPA Grant No. HR0011-07-1-0031.

9:36AM A15.00007 Frequency degeneracy in spin-torque induced precession. SHUXIA WANG, PIETER VISSCHER, University of Alabama — Magnetic precession in nanometer elements, first studied by Stoner and Wohlfarth in 1948, is central to the understanding of fast switching in magnetic information storage devices. Periodic orbits have recently gained more attention because they can be stabilized (and their frequencies measured) by spin torque techniques. We have observed a surprising and so far largely unexplained degeneracy in this system: when (as is often the case) there are two orbits with the same energy, even if their shapes and sizes are very different, their frequencies turn out to be the same. Although this is easy to show in the highest-symmetry (uniaxial) case, we find it is true far more generally — for any quadratic energy function with arbitrary anisotropy tensor and arbitrary external magnetic field. We have calculated the frequencies for a random selection of anisotropy tensors and magnetic fields, will show examples of asymmetrical orbits, whose frequencies are equal within numerical accuracy ($\approx 10^{-15}$).

10:00AM A15.00009 Evaluation of Gilbert damping in transition metals using tight binding schemes. CHUNSHENG LIU, CLAUDIA K.A. MEWES, MAIRBEK CHSHIEV, TIM MEWES, WILLIAM H. BUTLER, Center for Materials for Information Technology, The University of Alabama, Tuscaloosa, AL — Recently first principle calculations of the damping in transition metals have reproduced the unusual temperature dependence observed experimentally [1, 2]. Here we present an alternative method to calculate the Gilbert damping within Kamburský’s spin torque correlation model using a combination of first principle calculations and an extended Hückel tight binding model. In our scheme we use ab initio calculations (VASP) including spin orbit coupling to obtain the band structure of the transition metal of interest. With the knowledge of the band structure we use a fitting procedure to construct an extended Hückel tight binding model which then allows the evaluation of the Gilbert damping parameter. Because of the simplicity of our Hamiltonian, we can converge the integral over the Brillouin of the spin-orbit tensor without extraordinary computational effort. We show that our results are in good agreement with the results obtained from previous calculations. [1] K. Gilmore, Y.U. Idzerda and M.D. Stiles, Phys. Rev. Lett. 99, 027204 (2007). [2] V. Kamberský, Phys. Rev. B 76, 134416 (2007).

10:12AM A15.00010 Saturation of spin-polarized current in nanometer scale aluminum grains. CHRIS MALEC, YAGUANG WEI, DRAGOMIR DAVIDOVIC, Georgia Institute of Technology — We describe measurements of spin-polarized tunnelling via discrete energy levels of single Aluminium grains. In high resistance samples ($\ll \xi_0$), spin-polarized current is carried only via the ground state and the low-lying excited states, leading to a saturation in spin polarized current with bias voltage. Both a qualitative argument based on relaxation rates, and a non-equilibrium transport model are developed and compared. In two samples, the spin-relaxation rate $T_{1}^{-1}$ for some of the low-lying excited states is comparable to the electron tunnelling rate: $T_{1}^{-1} \approx 1.5 \cdot 10^{9}$ s$^{-1}$ and $10^{7}$ s$^{-1}$, meaning the spin of an electron confined in a metallic grain is highly stable. The ratio of $T_{1}^{-1}$ to the electron-phonon relaxation rate is in quantitative agreement with the Elliot-Yafet scaling, an evidence that spin-relaxation in Al grains is driven by the spin-orbit interaction.

10:24AM A15.00011 Kondo Resonance in the Presence of Spin-Polarized Currents. YUNONG QI, University of Houston, JIAN-XIN ZHU, Los Alamos National Laboratory, SHUFENG ZHANG, University of Missouri-Columbia, CHIN-SHEN TING, University of Houston — We propose an improved method of the equation of motion approach to study the Kondo problem in spin-dependent non-equilibrium conditions. We found that the previously introduced additional renormalization for non-equilibrium Kondo effects is not required when we use a proper decoupling scheme. Our improved formulation is then applied to address the spin-split Kondo peaks when a spin current injects into a Kondo system. We believe that this work significantly advances our understanding of the non-equilibrium Kondo physics, and our predictions of the Kondo resonance are timely for the application of non-equilibrium spin-related phenomena.
10:36AM A15.00012 Resolution-dependent mechanisms for bimodal switching time distributions in simulated Fe nanopillars\(^1\), S.H. THOMPSON, G. BROWN, P.A. RIKVOLD, Florida State U., M.A. NOVOTNY, Mississippi State U. — Numerical simulations of magnetization reversals of iron nanopillars in off-axis applied fields at different lattice resolutions reveal bimodal distributions in the switching times (first-passage times through 0 of the longitudinal magnetization, \(M_z\)). We show that the mechanisms responsible for these distributions are resolution-dependent. The highest-resolution model, in which the computational cell is smaller than the exchange length, is three-dimensional. Here, the bimodal distribution results from a reversal process in which the pillar sometimes avoids a metastable free-energy well. At medium resolution, the pillar is modeled as a 1-D stack of spins. The bimodal distribution then reflects whether the reversal starts from one or both ends. Finally, for a low-resolution model in the form of a single spin with an anisotropic potential, the bimodal distribution is an artifact of the definition of a switching event: the result of the spin precessing close to \(M_z = 0\). While the zero- and one-dimensional models display bimodal switching-time distributions, the mechanisms are different for the three-dimensional model. Only the latter captures the mechanism that is most interesting from an experimental and device-application point of view.

\(^1\)Supported by NSF grant DMR-0444051.

Monday, March 10, 2008 8:00AM - 10:48AM — Session A16 DBP DPOLY: Dynamics of Nucleic Acids Morial Convention Center 208

8:00AM A16.00001 Biochemistry on a leash: A mechanism for ligand recruitment via tethered binding sites, DANIEL REEVES, KEITH CHEVERALLS, JANNE KONDEV, Brandeis University — The diffusion limited reaction rate for ligand-receptor systems is typically estimated as the rate at which the ligand stumbles upon the receptor site by three-dimensional Brownian motion. We consider a mechanism that improves upon this limiting rate by placing a binding site on a flexible polymer. The tethered binding site explores the vicinity of the receptor site via polymer diffusion. After binding the ligand, the tether directly transfers it to the receptor site. This is in contrast with existing models, which involve non-specific binding that confines the ligand to lower-dimensional diffusion. The proposed mechanism may be relevant to the biological actin capping protein formin, which increases actin polymerization rates when bound to the growing tip of actin filaments.

8:12AM A16.00002 Backtracking and error correction in DNA transcription, MARGARITIS VOLIOTIS, School of Computing and Department of Applied Mathematics, University of Leeds, NETTA COHEN, School of Computing, University of Leeds, CARMEN MOLINA-PARIS, Department of Applied Mathematics, University of Leeds, TANNIEMOLA LIVERPOOL, Department of Mathematics, University of Bristol — Genetic information is encoded in the nucleotide sequence of the DNA. This sequence contains the instruction code of the cell—determining protein structure and function, and hence cell function and fate. The viability and endurance of organisms crucially depend on the fidelity with which genetic information is transcribed/translated (during mRNA and protein production) and replicated (during DNA replication). However, thermodynamics introduces significant fluctuations which would incur massive error rates if efficient proofreading mechanisms were not in place. Here, we examine a putative mechanism for error correction during DNA transcription, which relies on backtracking of the RNA polymerase (RNAP). We develop an error correction model that incorporates RNAP translocation, backtracking pauses and mRNA cleavage. We calculate the error rate as a function of the relevant rates (translocation, cleavage, backtracking and polymerization) and show that the its theoretical limit is equivalent to that accomplished by a multiple-step kinetic proofreading mechanism.

8:24AM A16.00003 Effects of crosslinks on motor-mediated filament organization\(^1\), IGOR ARANSON, FALKO ZIEBERT, Argonne National Laboratory, LEV TSIMRING, University of California, San Diego — Crosslinks and molecular motors play an important role in the organization of cytoskeletal filament networks. Here we incorporate the effect of crosslinks into our model of polar motor-filament organization, through suppressing the relative sliding of filaments in the course of motor-mediated alignment. We show that this modification leads to a nontrivial macroscopic behavior, namely the oriented state exhibits a transverse instability in contrast to the isotropic instability that occurs without crosslinks. This transverse instability leads to the formation of dense extended bundles of oriented filaments, similar to recently observed structures in actomyosin. This model also can be applied to situations with two oppositely directed motor species or motors with different processing speeds.

\(^1\)This work was supported by the US DOE, grant DE-AC02-06CH11357.

8:36AM A16.00004 Collective alignment of polar filaments by molecular motors\(^1\), IGOR ARANSON, Argonne National Laboratory — We study the alignment of polar biofilaments, such as microtubules and actin, subject to the action of multiple molecular motors attached simultaneously to more than one filament. Focusing on a paradigm micromechanical model of only two filaments interacting with multiple motors, we were able to investigate in detail the dynamics of the filaments’ alignment. While almost no alignment occurs in the case of a single motor, we show that the filaments become perfectly aligned due to the collective action of the motors working together. Our studies revealed that the the alignment time is governed by the magnitude of the fluctuations in the motor force.

\(^1\)This work was supported by the US DOE, grant DE-AC02-06CH11357.

8:48AM A16.00005 Detecting cooperative sequences in the binding of RNA Polymerase-II, KIMBERLY GLASS, University of Maryland, JULIAN ROZENBERG, National Cancer Institute (NIH), MICHELLE GIRVAN, WOLFGANG LOSERT, ED OTT, University of Maryland, CHARLES VINSON, National Cancer Institute (NIH), UMD/NIH SYSTEMS BIOLOGY COLLABORATION COLLABORATION — Regulation of the expression level of genes is a key biological process controlled largely by the 1000 base pair (bp) sequence preceding each gene (the promoter region). Within that region transcription factor binding sites (TFBS), 5-10 bp long sequences, act individually or cooperate together in the recruitment of, and therefore subsequent gene transcription by, RNA Polymerase-II (RNAP). We have measured the binding of RNAP to promoters on a genome-wide basis using Chromatin Immunoprecipitation (ChiP-on-Chip) microarray assays. Using all 8-base pair long sequences as a test set, we have identified the DNA sequences that are enriched in promoters with high RNAP binding values. We are able to demonstrate that virtually all sequences enriched in such promoters contain a CpG dinucleotide, indicating that TFBS that contain the CpG dinucleotide are involved in RNAP binding to promoters. Further analysis shows that the presence of pairs of CpG containing sequences cooperate to enhance the binding of RNAP to the promoter.
9:00AM A16.00006 Dynamic self-assembly of nanocomposite ring structures through the interaction of thermodynamic and energy-dissipating processes. HAIQING LIU, ERIK SPOERKE, MARLENE BACHAND, STEVEN KOCH, BRUCE BUNKER, GEORGE BACHAND; Sandia National Laboratories — Self-assembly of nanostructured materials occurs in thermodynamic and energy-dissipating systems. We've described a unique self-assembly scheme in which non-equilibrium nanocomposites are formed by the interaction of energy dissipation and thermodynamics. Three distinct composite structures (mobile linear, rotating circular and immobile aggregated composites) are formed when streptavidin-coated quantum dots are introduced to biotinylated microtubules that are being transported by kinesin. The circular nanocomposites occur only in a delicately balanced regime when thermodynamic and energy-dissipating components interact cooperatively. Linear translation and axial rotation of microtubules drive the formation of non-equilibrium structures which ultimately define the structural shape and rotational direction. Disassembly of these composites occurs spontaneously, as well as induced by the addition of free biotin. Exploitation of dynamic self-assembly promises nanostructured materials with revolutionary behaviors that are unattainable through conventional self-assembly.

*Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, or the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

9:12AM A16.00007 How Large are Cooperative Effects in Hydrogen Bonded Molecular Chains? MARTIN FUCHS, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG, Berlin, Germany, JOEL IRETA, Univ. Autonoma Metropolitana Iztapalapa, Mexico — Intermolecular hydrogen bonds play an eminent role in a wide range of materials. In particular, they are critical for the secondary structure stabilization of biopolymers like proteins and nucleic acids. Arrays of hydrogen bonds (hbs), such as in chains or helices, often display a cooperative strengthening of the individual hbs. This cooperativity is crucial for understanding the stability and properties of hydrogen bonded materials. Here we investigate the hb cooperativity in model chains of HCl, HF, HCN, formamide, and 4-pyridone, i.e. molecules forming weak to strong hbs. We calculate the hb strength of infinitely long chains using density-functional theory (DFT) with the Perdew-Burke-Ernzerhof generalized gradient approximation (PBE-GGA). We show that for large intermolecular separations, the hbs in the infinite chain strengthen by 20% over the respective molecular dimers, consistent with dipolar electrostatics [1]. At the equilibrium separation, the hbs strengthen significantly further (up to 260% for HF), with additional stabilization from induced dipolar interactions. Comparing with results from higher-level calculations (MP2 and quantum Monte Carlo) we find that DFT faithfully describes the cooperativity in these systems in which the hbs are close to linear. [1] P.B. Allen, J. Chem. Phys. 120, 2951 (2004)

9:24AM A16.00008 Single stranded DNA hairpin loop kinetics: A Brownian dynamics study. MARTIN KENWARD, KEVIN DORFMAN, University of Minnesota — The dynamics of single stranded DNA (ssDNA) molecules play a role in a number of biological functions and have a found uses in several microfluidic applications. In particular, ssDNA having complementary sequences at their ends can form hairpin loops in which the complementary sections bind to one another. The appearance of these loops and fluctuations between open and closed states depend on a number of variables including: the degree of complementarity of the end sequences, the species, temperature and strength of hydrogen bonding and base stacking.

In this study, we present a Brownian dynamics model which is used to examine the kinetics of the hairpin loop formation. We present results for the melting behavior of hairpins as a function of temperature and other system parameters. We also present results for the kinetic rate constants $k_-$ and $k_+$ corresponding to the open-closed and closed-open transitions respectively.

9:36AM A16.00009 Statistical Analysis of the Chemotactic Motility Cycle of Amoeboid Cells. BALDOMERO ALONSO-LATORRE, JUAN C. DEL ALAMO1, RUEDI MEILI, RICHARD A. FIRTEL, JUAN C. LASHERAS, University of California, San Diego — Amoeboid motility results from the repetition of stereotypic steps that produce quasi-periodic oscillations of cell length and speed. We characterize the steps of the motility cycle of Dictyostelium cells crawling on elastic substrates by analyzing their traction forces. Using a high-resolution force cytomtery method for wild type and mutant cells, we find that the time evolution of the traction forces is quasi-periodic, with a period $T$ that correlates strongly with the cell speed $V$ according to a simple law $VT=L$. The constant $L$ is the distance traveled per cycle. The magnitude of the traction forces exerted by the cells does not correlate with the cell speed, suggesting that the speed of migration is determined by the ability of the cell to rapidly repeat the phases of the motility cycle. Phase average statistics allow us to combine time sequences of force maps derived from different cells to obtain a spatio-temporal representation of a canonical motility cycle divided into four steps: protrusion, contraction, retraction and relaxation. We find that myosin II-dependent contraction is present in all steps of the wild-type cycle, including protrusion.

9:48AM A16.00010 Force generated by polymerization of actin filaments. CORALINE BRANGBOURG, OLIVIA DU ROURE, EMMANUELLE HELFER, MÁRC FERMIGIER, MARIE-FRANCE CARLIER, JÉRÔME BIBETTE, JEAN BAUDRY, Laboratoire des Molécules et d’assemblage Protéique, Université Paris-Sud, CNRS, Gif-sur-Yvette, France — Actin polymerization drives protrusions at the cell surface and leads to cell motility. Using magnetic colloids, we measure how the chemical reaction of polymerization generates mechanical forces. We detail in particular the force-velocity relation of growing actin filaments; and how the scaling force is affected by the mean number of filaments between two beads.

10:00AM A16.00011 Probing Brownian Motion of an Ellipsoid with an External Force. SHAO-QING ZHANG, WU-PEI SU, Dept. of Physics, Univ. of Houston, TX 77204 — Brownian motion has translational and rotational degrees of freedom. Anisotropy in the shape of a Brownian particle leads to dissipative coupling between translational and rotational motion. However, the coupling effects, which depend on the initial orientation of an ellipsoid, cannot be detected by most typical experimental techniques. To surmount the hurdle between theoretical predictions and experimental measurements, we present a theoretical scheme for uncovering the translation-rotation coupling by applying a constant external force to an ellipsoid in a two-dimensional suspension. The geometry of the ellipsoid can be determined using only the first two cumulants. An anisotropy-isotropy alternation is found in the cumulant series. We also discuss the probability distribution function (PDF) of lab-frame displacements to gain insight into the significance of anisotropy of a Brownian particle in diverse environments.

10:12AM A16.00012 Probing Protein Conformations at the Oil-water Interface Using Single-Molecule Force Spectroscopy. AHMED TOUHAMI, MARCELA ALEXANDER, MILENA CORREDIG, JOHN DUTCHER, University of Guelph — The present work aims at a deeper understanding of the conformational changes in Beta-lactoglobulin (BLG) protein adsorbed onto the oil-in-water emulsion interfaces due to variations in pH. Mechanical unfolding of BLG by AFM-single-molecule force spectroscopy (AFM-SMFS) was performed on single oil droplets that were mechanically trapped in a polycarbonate filter. The changes in the contour length upon each unfolding event were determined by fitting the WLC model of polymer elasticity to each of the BLG peaks. Our results show clearly that at pH 2.5 BLG exists as a dimer in which each monomer is similar to two Immunoglobulin domains. At pH 6.8 BLG on the oil droplets adopts a conformation consisting of domains with a contour length of 11 nm. Furthermore, at pH 9 the interactions between the AFM tip and the BLG layer on the oil droplet surface are dominated by a huge repulsion due to the highly negatively charged BLG layer. This study demonstrates a novel application of AFM-SMFS to investigate the underlying mechanisms by which proteins can be used to stabilize food products.

Comparing with results from higher-level calculations (MP2 and quantum Monte Carlo) we find that DFT faithfully describes the cooperativity in these systems in which the hbs are close to linear. [1] P.B. Allen, J. Chem. Phys. 120, 2951 (2004)
10:24AM A16.00013 Structural motifs of biomolecules¹, HOANG TRINH, JAYANTH BANVAR, Penn State University, University Park, PA 16801, USA, AMOS MARITAN, CHIARA POLETTA, ANTONIO TROVATO, Università di Padova, 35131 Padova, Italy, JOHN MADDOCKS, Ecole Polytechnique Federale de Lausanne, CH-1015 Lausanne, Switzerland, ANDREJ STASIAK, University of Lausanne, CH-1015 Lausanne, Switzerland — Biomolecular structures are assemblies of emergent anisotropic building modules such as uniaxial helices or biaxial strands. We provide an approach to understanding a compact phase of matter that is occupied by proteins and DNA. This phase, which is in some respects analogous to the liquid crystal phase for chain molecules, stabilizes a range of shapes that can be obtained by sequence-independent interactions occurring intra- and intermolecularly between polymeric molecules. We present a singularity free self-interaction for a tube in the continuum limit and show that this results in the tube being positioned in the marginally compact phase. Our work provides a unified framework for understanding the building blocks of biomolecules.

10:36AM A16.00014 Instabilities of ordered chiral active suspensions, TAPAN ADHYAPAK, CCMT, Department of Physics, Indian Institute of Science, Bangalore 560 012 INDIA, DAVIDE MARENUZZO, The School of Physics, The University of Edinburgh, James Clerk Maxwell Building, The Kings Buildings, Mayfield Road, Edinburgh EH9 3JZ, UK, SRIRAM RAMASWAMY, CCMT, Department of Physics, Indian Institute of Science, Bangalore 560 012 INDIA — Suspensions of actively contractile or tensile filaments with simple orientational order are hydrodynamically unstable. Here we study, analytically as well as numerically, the manner in which the presence of cholesteric order competes with this instability.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A17 DCMP: Cold Fusion Morial Convention Center 209

8:00AM A17.00001 The Significance of Replication, MICHAEL C.H. MCKRUBLE, FRANCIS L. TANZELLA, SRI International, Menlo Park, CA 94025, VITTORIO VIOLANTE, ENEA, Frascati, Italy — Much has been made of an apparent lack of reproducibility in so called “cold fusion” experiments. In this paper we will demonstrate that this failure, while real, was the result of inability to meet critical threshold criteria: a thermodynamic loading, dynamic flux and disequilibrium trigger. Recent experiments, performed independently at SRI and ENEA, have successfully replicated powerful excess heat results obtained initially by Enertics in Israel. This success and high levels of experiment reproducibility are attributed to two critical factors that allow these threshold barriers to be surpassed: i) achievement and maintenance of a high level of control of the metallurgy of the bulk palladium metal host and the cathode surface morphology, guided by initial studies at ENEA and the University of Rome, ii) use of a novel non steady-state cathode current stimulus, proposed and developed by Enertics. With simultaneous high deuterium loading and high flux, excess heat effects were measured in both isoperibolic and Mass Flow calorimeters at factors several times greater than the electrical input power and several orders of magnitude larger than the sum of all conceivable chemical reactions.

8:12AM A17.00002 Public-Interest and Level-of-Evidence Considerations in Cold Fusion Public Policy, THOMAS GRINSHAW, LBJ School of Public Affairs, The University of Texas at Austin — Cold fusion (CF) protagonists and antagonists would no doubt agree that scientific processes have been challenged in the CF case. The public interest in CF turns on two questions: What are the potential benefits? What is the probability that CF is “real”? Potential benefits have been agreed on since CF announcement in 1989. The probability of CF reality may be assessed based on level of evidence (LoE): preponderance of evidence (PoE); clear and convincing evidence (CCE); and beyond a reasonable doubt (BRD). PoE, from civil law, indicates a probability of 50% or higher. BRD, from criminal law, has a probability approaching 90%. CCE, in between, thus has a 70-75% probability. CF experimental evidence, based on: 1) initial affirmations, 2) the large number of corroborations since marginalization, and 3) particularly (BRD). PoE, from civil law, indicates a probability of 50% or higher. BRD, from criminal law, has a probability approaching 90%. CCE, in between, thus has a 70-75% probability. CF experimental evidence, based on: 1) initial affirmations, 2) the large number of corroborations since marginalization, and 3) particularly 70-75% probability. CF experimental evidence, based on: 1) initial affirmations, 2) the large number of corroborations since marginalization, and 3) particularly demonstrative experiments, reasonably indicates at least a PoE level of evidence for excess heat. A case can also be made for a CCE (but probably not for a BRD) LoE. In either the PoE or CCE scenario a clear need is demonstrated for change in policy toward CR, given its potential benefits to humanity.

8:24AM A17.00003 Anomalous Radiation Produced by Glow Discharge in Deuterium Containing Oxygen, EDMUNDO STORMS, BRIAN SCANLAN, KivaLabs, LLC, 2140 Paseo Ponderosa, Santa Fe NM 87501 — Electromagnetic Radiation (EMR) and anomalous radiation (potentially produced by nuclear reactions, involving high energy particles), in a low-voltage discharge in a gas containing deuterium was measured using a Geiger counter located within the apparatus. This radiation is found to consist of energetic particles that are produced only when the voltage is above a critical value. In addition, the emission is very sensitive to the presence of oxygen in the gas. The intensity of the reaction producing the radiation could be fit by a power function when compared to the applied voltage. The effect of EMR and other sources of noise that might be attributed to the anomalous radiation are discussed.

8:36AM A17.00004 Low Energy Nuclear Reaction Products at Surfaces, DAVID J. NAGEL, The George Washington University — This paper examines the evidence for LENR occurring on or very near to the surface of materials. Several types of experimental indications for LENR surface reactions have been reported and will be reviewed. LENR result in two types of products, energy and the appearance of new elements. The level of instantaneous power production can be written as the product of four factors: (1) the total area of the surface on which the reactions can occur, (2) the fraction of the area that is active at any time, (3) the reaction rate, that is, the number of reactions per unit active area per second, and (4) the energy produced per reaction. Each of these factors, and their limits, are reviewed. A graphical means of relating these four factors over their wide variations has been devised. The instantaneous generation of atoms of new elements can also be written as the product of the first three factors and the new elemental mass produced per reaction. Again, a graphical means of presenting the factors and their results over many orders of magnitude has been developed.

8:48AM A17.00005 Evidence and Theory for Cluster Reactions in LENRs, GEORGE H. MILEY, HEINZ HORA¹, ANDREI LIPSON, PRAJAKTI JOSHI SHRESTHA, Department of Nuclear, Plasma and Radiological Engineering, University of Illinois — A distinctive array reaction products attributed to nuclear reactions was observed earlier in the "Patterson" flowing packed-bed type electrolytic cell experiments using multilayer thin films of metals on mm-size plastic beads. The swimming electron layer and a new magic number theory were proposed to explain this. More recently these theories have been expanded into a “D-Pd-D cluster” model to explain a wider range of transmutation experiments. This cluster model is consistent with certain measurements of energetic charged-particle emission during thin film electrolysis, with observations suggesting localized reactions and also with x-ray production during plasma bombardment experiments. The cluster reaction concept and supporting experimental data will be discussed in this presentation. In addition to explaining , if understood and optimized, cluster reactions could lead to an important new power source based on Low Energy Nuclear Reactions (LENRs). A conceptual power cell based on a novel electrode design that promotes cluster reactions is presented.

¹Dept. Theoretical Physics, University of NSW, Sydney 2052, Australia
9:00AM A17.00006 Compound Nucleus Reactions in LENR, Analogy to Uranium Fission , HEINRICH HORA, GEORGE MILEY1, KARL PHILBERTH2. Department of Theoretical Physics, University of New South Wales, Sydney 2052, Australia — The discovery of nuclear fission by Hahn and Strassmann was based on a very rare microanalytical result that could not initially indicate the very complicated details of this most important process. A similarity is discussed for the low energy nuclear reactions (LENRs) with analogies to the yield structure found in measurements of uranium fission. The LENR product distribution measured earlier in a reproducible way in experiments with thin film electrodes and a high density deuteron concentration in palladium has several striking similarities with the uranium fission fragment yield curve. This comparison is specifically focussed to the Maruhn-Greiner local maximum of the distribution within the large-scale minimum when the fission nuclei are excited. Implications for uranium fission are discussed in comparison with LENR relative to the identification of fission a hypothetical compound nuclear reaction via a element $^{306}_{126}$ with double magic numbers.

9:12AM A17.00007 New Mechanism for Explaining LENR and Certain forms of Technological and Natural Catastrophes , FANGIL GAREEV, Joint Institute for Nuclear Research, Dubna, Russia — We propose a new mechanism for low energy nuclear reactions (LENR): cooperative resonance processes involving the whole the system - nuclei + atoms + condensed matter can occur at a smaller threshold energies than the corresponding ones on free constitutuents. The cooperative processes can be induced and enhanced by low energy external fields. The excess heat is the emission of internal energy and transmutations at LENR are the result of a redistribution of internal energy of the whole system. The lack of financial support and ignorance by mainstream physicists has resulted in the LENR field not being accepted. We postulate that LENR can lead to catastrophes, potentially including, the runaway event involving the reactor at the Chernobyl Nuclear Power Plant, the explosion of the twin towers during the 11 September 2001 World Trade Center collapse, in New York, the explosion of transformers in Moscow, catastrophes of submarines, and other phenomena associated with a cooperative resonance synchronization mechanism.

9:24AM A17.00008 Predictability of Theory, and Collaboration with Experimentalists in CMNS, XING ZHONG LI, Department of Physics, Tsinghua University, Beijing 100084, China — Condensed Matter Nuclear Science has confirmed 2 outstanding experimental results: 144.5W of continuous “Excess Heat” in 10 minutes(ICCF-3,1992) and the nuclear transmutation induced by deuterium flux on the Pd surface (ICCF-8, 2000). Theory predicted neutron emission based on the previous beam-target experiments. It was a wrong guidance, because there was no “commensurate neutron” detected. The collaboration with experimentalists helped theorist to modify their prediction in the past 19 years. Theorists might imagine that “high loading ratio” was necessary; then, the experiments said “deuterium flux was more important.” Resonant tunneling theory imagined again “any resonance in inelastic scattering (nuclear reaction) had to be accompanied by a resonance in elastic scattering (diffusion); hence, a peak in excess heat should be correlated with a peak in deuterium flux.” The experiments seem to confirm this imagination. The next 2 predictions are: (1) Adjusting the loading rate to form a steady state for resonant tunneling;(2)Neutroin detection from this steady state to confirm its nuclear nature.

9:36AM A17.00009 Comparison of SPAWAR Co-deposition Experimental Data and Competing Condensed Matter Nuclear Science Theories, LAWRENCE P.G. FORSLEY, JWK Technologies Corporation, 7617 Little River Turnpike Suite 1050, Annandale, VA 22003, PAMELA MOSIER-BOSS, Space Warfare Systems Center, San Diego — The SPAWAR PdD co-deposition protocol has been replicated in several laboratories and shown to produce apparent nuclear tracks in solid-state CR-39 detectors. Additional spectroscoptic gamma ray measurements have been carried out using either high resolution, cryogenically cooled germanium or lower resolution sodium iodide detectors. These results are at odds with many of the competing theories in this field, suggesting the need to acquire additional temporally and spectrally resolved nuclear data.

9:48AM A17.00010 Multiple Etching of CR-39 Nuclear Track Detectors used in SPAWAR Co-Dep Experiment, PAMELA MOSIER-BOSS, Space Warfare Systems Center, San Diego, LAWRENCE P.G. FORSLEY, JWK Technologies Corporation, 7617 Little River Turnpike Suite 1050, Annandale, VA 22003 — Previously published results involving the use of the solid state track detectors, CR-39, have brought into question whether or not purported tracks are of nuclear origin. One method of determining this is to serially etch and scan these track detectors so as to determine the approximate depth of the tracks. This method, coupled with a computer code incorporating bulk and track etching rates in CR-39 for alpha particles, gives good agreement with tracks seen in SPAWAR co-deposition experiments as compared to known alpha sources.

10:00AM A17.00011 Spatial and Temporal Resolution of Three Sites Characterizing Lattice-Assisted Nuclear Reactions (LANR) , MITCHELL SWARTZ. JET Energy, Inc. Wellesley, MA 02481 — We present developing evidence that three different sites (physical locations in the solid state) are involved in lattice-assisted nuclear reactions (LANR). By expanding the equation first developed by Prof. David Nagel at ICCF-13, we correlate observations of excess heat and de novo helium-4 production to three different physical locations and to the optimal operating points (OOPs) which are now known to characterize LANR system. This observation will be shown to be consistent with our previous reports of distinct time constants which characterize the tardive thermal power regime (“heat after death”), which results after all input electrical power is terminated to an active LANR device.

1Nagel, D., “Rates for LENRs at Surfaces”, ICCF-13  
interstitial Ds. Large "cage" of CD's forms with a definite phase and zero entropy, trapping a "gas" of non-coherent Ds. In our D-Pd-D cluster theory this explains D-Pd-D cluster reactions in certain cold fusion experiments.

This compares with best plasma fusion runs of 16 MW of fusion heat for \( \leq 1s \) (\( \leq 1.6 \times 10^7 \) J). The fusion heat was less than the input energy. In 2004, Arata and Zhang pressure-loaded \( \text{ZrO}_2 + \text{nanoPd} \) with \( D_2 \) at \( 140 \, ^\circ\text{C} \) and produced an estimated steady 0.6 W of fusion heat. The ionic oxide + nanometal composites absorb abnormal amounts of hydrogen gas.

An ensemble of D atoms loaded into Pd can assume two different configurations coupled with the intrinsic EM field. A coherent state forms above critical density and temperature thresholds. This new state has lower energy than the Pd lattice. In 2004, Arata and Zhang pressure-loaded \( \text{ZrO}_2 + \text{nanoPd} \) with \( D_2 \) at \( 140 \, ^\circ\text{C} \) and produced an estimated steady 0.6 W of fusion heat. The ionic oxide + nanometal composites absorb abnormal amounts of hydrogen gas.

Cold Fusion Reactions, LINCHON WU, GEORGE MILEY, University of Illinois, NPRE Department, 103 S. Goodwin Ave — G. Preparata earlier proposed a radical new QED theory, and had just begun application to cold fusion prior to his untimely death. Cold Fusion Reactions, LINCHON WU, GEORGE MILEY, University of Illinois, NPRE Department, 103 S. Goodwin Ave — G. Preparata earlier proposed a radical new QED theory, and had just begun application to cold fusion prior to his untimely death.

8:36AM A18.00002 Microrheology of Nanospheres in Rod Suspensions, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas at Austin — Many biological processes and applications involve the motion of small (nanoscale) spherical particles through a dense (typically) semiflexible polymer matrix. While much theoretical work has characterized the motion of such particles in the limit of its size being much larger than the mesh size of the matrix, very limited understanding exists of the (more biologically relevant) crossover regime to the case where the particle size becomes comparable to the mesh size. Recently we have developed a new computer simulation method to simulate the dynamical and rheological properties of colloid suspensions of a variety of complex fluids. We first present the results of its generalization to the dynamics and linear rheological properties of dilute, semiflexible and concentrated rods suspensions in a simple fluid. Subsequently, we use this method to characterize the mobility and diffusive dynamics of nanoscale spheres in rod matrices, while paying special attention to the length scales of the fluid which characterize the hydrodynamic screening and overall viscous motion.

8:48AM A18.00003 Peptide binding to sheet silicate and metal nanoparticles: Insight from atomistic simulation, RICHARD A. VAIA, RAJESH R. NAJK, BARRY L. FARMER, Air Force Research Laboratory, WPAFB — Short peptides (8 to 12 amino acids, excluding Cys) bind selectively to nanoscale particles composed of Au, Pd, and montmorillonite depending on the sequence of amino acids, as evidenced by laboratory screening of several billion peptides. The molecular reasons for binding versus non-binding and the specificity toward a certain surface are analyzed by molecular dynamics (MD) simulations. RICHARD A. VAIA, RAJESH R. NAJK, BARRY L. FARMER, Air Force Research Laboratory, WPAFB — Using a coarse grained description, we study stability of the structure and dynamics of several peptide chains (A3, Fig, Pro10, Gly10, Pd2, Pd4) at gold surfaces on a cubic lattice. Although the structural details within the amino acid groups are ignored, the specificity of their interactions is incorporated in our computer simulation modeling of these peptide chains on a cubic lattice. Appropriate coarse-grained interactions (Lennard-Jones) among the amino acid nodes, solvent, and the gold surface with different strength are guided by the atomistic simulations and X-ray crystallographic data; the molecular weight of each amino acid groups is also considered. Peptide chains execute their stochastic motion and their proximity to the generic gold surface is monitored. Mobility of each amino acid (node), its energy, and correlations to their neighboring constituents are analyzed. Some of these results are consistent with the atomistic simulation.

9:00AM A18.00004 Adsorption-desorption of peptide chains on Au surface by a coarse-grained Monte Carlo simulation, RAS B. PANDEY, University of Southern Mississippi, HENDRIK HEINZ, University of Akron, LAWRENCE R. DRUMM, RICHARD A. VAIA, RAJESH R. NAJK, BARRY L. FARMER, Air Force Research Laboratory, WPAFB — Using a coarse grained description, we study stability of the structure and dynamics of several peptide chains (A3, Fig, Pro10, Gly10, Pd2, Pd4) at gold surfaces on a cubic lattice. Although the structural details within the amino acid groups are ignored, the specificity of their interactions is incorporated in our computer simulation modeling of these peptide chains on a cubic lattice. Appropriate coarse-grained interactions (Lennard-Jones) among the amino acid nodes, solvent, and the gold surface with different strength are guided by the atomistic simulations and X-ray crystallographic data; the molecular weight of each amino acid groups is also considered. Peptide chains execute their stochastic motion and their proximity to the generic gold surface is monitored. Mobility of each amino acid (node), its energy, and correlations to their neighboring constituents are analyzed. Some of these results are consistent with the atomistic simulation.

9:12AM A18.00005 Characterization of the translocation of polymers driven through nanopores using molecular dynamics simulations, HENDRICK DE HAAN, GARY W. SLATER, University of Ottawa — The passage of a polymer through a narrow pore (translocation) is a fundamental process with a wide range of biological applications. In particular, threading DNA through nanopores promises to have important implications for the next generation of DNA sequencing techniques. In this work, simulations of the translocation of polymers being driven through a narrow, short nanopore are conducted via the Espresso Molecular Dynamics simulation package using the Lattice-Boltzmann algorithm to include hydrodynamics. In this talk, results from simulations in which an external field is applied within the pore or to one end of the polymer are presented and compared. Characterization of the scaling of the translocation time with the number of monomers as well as details of the anomalous diffusion exhibited by the translocation coordinate will be given.

9:24AM A18.00006 Coupling of atomistic and mesoscopic scales: visualizing the translocation of biopolymers through nanopores, MARIA FYTA, Department of Physics, Harvard University, SIMONE MELCHIONNA, INF-M-SOFT, Department of Physics, Universita di Roma La Sapienza, P.le A. Moro 2, 00185 Rome, Italy, MASSIMO BERNASCHI, Istituto Applicazioni Calcolo, CNR, Viale del Policlinico 137, 00161, Roma, Italy, ETHEMIMOS KAXIRAS, Department of Physics and School of Engineering and Applied Sciences, Harvard University, Cambridge, MA, USA, SAURO SUCCI, Istituto Applicazioni Calcolo, CNR, Viale del Policlinico 137, 00161, Roma, Italy — We investigate the process of biopolymer translocation through a narrow pore using a multiscale approach, which combines Langevin Molecular-Dynamics with a mesoscopic Lattice-Boltzmann method for the solvent dynamics. We analyze the statistical features of the translocation process through extensive simulations over various polymer conformations and strengths. The translocation time obeys a power law dependence to the polymer length with an exponential factor of the order of 1.28 ± 0.01 for very good agreement with experiments of DNA translocation through solid state pores. We focus on the morphological aspects of the translocation dynamics, the folding behavior of the translocating molecule and the associated cooperation of the surrounding solvent, and report the first computational evidence of quantized current blockades.

9:36AM A18.00007 Coarse-Grained Kinetic Modeling of Polymer Networks with Non-Affine Slip-Tube Behavior and Heterogeneous Microstructure, BRIAN PASQUINI, FERNANDO ESCOBEDO, YONG LAK JOO, Department of Chemical and Biomolecular Engineering, Cornell University — Elements of existing entanglement network models have been extended to better account for non-affine slip-tube behavior and to incorporate the effect of heterogeneous spatial domains. Starting with the Density Cloud Model (DCM) framework from Terzis et al., an entanglement bond potential acting at each entanglement point is introduced. This potential mimics the non-affine tethering from network theories, and in combination with slippage accurately reproduces Non-Affine Slip-Tube behavior. This framework can easily be extended to study the effect of polymer architecture on the mechanical response of the resulting networks. Secondly, the temporary bond from the model of Terzina and Smith is combined with the DCM framework to simulate rigid domains within a matrix of soft polymer network. The modulus of the additional bonds sets the elastic properties of the rigid domain, while DCM entanglement relaxation assures that local deformation remains consistent with the bulk polymer density. The effect of rigid domain size on initial modulus is reported.

9:48AM A18.00008 Simulating thermal transport in high contrast composite media, HARSHADEWA S. GUWADARANA, KIERAN MULLEN, Homer L. Dodge Department of Physics and Astronomy, The University of Oklahoma, DIMITRIOVS P. PAPAVASSILIOU, Department of Chemical Engineering, University of Oklahoma — In dealing with transport in composites systems, high contrast materials pose a special problem for numerical simulation: the time scale or step size in the high thermal conductivity material must be much smaller than the low conductivity material. High conductivity inclusions can be treated as having an infinite conductivity, removing the need to model transport within the high conductivity inclusions. We develop a random walk algorithm to model thermal transport in composites with high conductivity. We observed the standard random walk algorithm leads to non uniform temperature distribution at the vicinity of the high conductivity inclusion violating the second law of thermodynamics. We show how a standard random walk algorithm can be altered to improve speed while still preserving the second law of thermodynamics. We demonstrate the algorithm in 1D and 3D systems.
10:00AM A18.00009 Predictive Morphology Models for Crystalline Polymers1,2 — JACOB HARVEY, ZHICHENG XIAO, YVONNE AKPALU, Department of Chemistry & Chemical Biology, Rensselaer Polytechnic Institute — Modeling of small-angle scattering data provides information on heterogeneities on sizes on the order of 10 Angstroms and larger. The typical size, shape and arrangement of the heterogeneity can be determined by applying models to the scattering intensity I(q). When there is a distribution in the size of structures present and when a system is densely packed, it is likely that models that can be used for analysis may not provide a unique description of the structure. With the recent interest developing in predicting models for molecular level control over the properties of polymers, it is desirable to determine all unique structural and morphological contributions to a scattering curve without assuming a model. However, by using a multi-scale approach (i.e. light and X-ray scattering spanning multiple size scales), it may be possible to build unique models for crystalline polymers. We will show that hybrids of statistical methods can be used to decouple scattering data into unique structural components. We will show how our approach can be used to discover analytical models and to develop a set of descriptors that can be used to predict scattering curves for several other polymers that share a similar structure or crystallization condition.

10:12AM A18.00010 Coarse-grained Molecular Dynamics Simulations and Analysis of Poly(L-lactic Acid) (PLLA) Melt — Gaurav Manik, HemanT Nanavati, Chemical Engg. Department, Indian Institute of Technology Bombay, Mumbai-400076, India, Upendra Natarajan, Chemical Engg. Department, Indian Institute of Technology Madras, Chennai-600036, India — We present coarse-grained (CG) MD simulations of the melt structure of PLLA, a very useful biodegradable polymer. Our CGMD simulations consider entire repeat unit as a one bead and use IBI scheme. The CG potentials and forces are obtained after performing atomistic MD of 52 PLLA tetramer molecules and employing the probability distributions for the corresponding CG lengths, angles, dihedrals, and the radial distribution function. The initial energy-minimized samples are equilibrated for density in NPT ensemble, followed by structural equilibration. The simulated characteristic ratio (2.13) and density (1.123g/cc) at 450K are in excellent agreement with the expt. values1 of 2.2 and 1.152g/cc at 413K. The equilibrated structures were analyzed for primitive path properties, tube diameter, , entanglement length, , etc., using Kroger’s Z-code2. This yields for longest chains (N=1000) and compare favorably with expt. values.1, 55 and 47.7Å (413K).

10:24AM A18.00011 Modeling the Thermodynamics of the Interaction of Nanoparticles with Cell Membranes1 — Valerie Ginzburg, Sudhakar BalljaPalli, The Dow Chemical Company — Interactions between nanoparticles and cell membranes may play a crucial role in determining the cytotoxicity of nanoparticles as well as their potential application as drug delivery vehicles or therapeutic agents. It has been shown that such interactions are often determined not by biochemical but by physico-chemical factors (e.g., nanoparticle size, hydrophobicity, and surface charge density). Here, we propose a mesoscale thermodynamic model describing the transitions in membrane morphology observed after exposure to various types of nanoparticles. Our simulations demonstrate under which conditions (determined by particle size and hydrophilic/hydrophobic interactions) the particles can adsorb into the membrane or compromise the membrane integrity to result in the formation of nano-sized holes. The model could be refined to include a more accurate description of various phospholipid membranes, and its results could be applied in the design of specific nanoparticles for various biomedical applications.

10:36AM A18.00012 Structure and dynamics of a model polymer nanocomposites — Monojoy Goswami, Bobby Sumpter, Oak Ridge National Laboratory — We investigate the structure and the dynamics of a model polymer nanocomposite (PNC) through molecular dynamics (MD) simulations in the canonical ensemble (NVT). Several computer experiments have been carried out at different temperatures for different Lennard-Jones well-depth and filler volume fraction. We studied the real space pair correlation functions and collective scattering structure factors of the PNC melt. This structural analysis has been compared with the previous theoretical and experimental works. The reinforcement of the nanocomposite have been investigated using stress-stress autocorrelation (σxy(t)) function for different temperatures. At lower temperatures, σxy(t) shows strong reinforcement of the nanocomposite while at higher temperatures it relaxes quite fast. Diffusion of nanoparticles in the composite has been investigated and compared with earlier works. The effect of sizes and shapes of the nanoparticles has also been investigated in this work.

10:48AM A18.00013 Strategies for design of polymeric nanoparticle — JiWu Liu, Michael Mackay, Phillip Duxbury, Michigan State University — Recently polymer nanoparticles have been synthesized using single chains as macromolecular precursors, providing unprecedented control of nanoparticle size and function. We present the results of molecular dynamics simulations which provide detailed insight into the formation kinetics of specific polymeric nanoparticles and which also predict design strategies for formation of interesting new targets. Nanoparticles are formed through chemical crosslinking which is possible when reactive species on the chain backbone are in close proximity. Since the chemical crosslinking is highly irreversible, nanoparticles formed in this way do not unfold on heating, in contrast to the familiar case of thermal denaturing of proteins. Synthesis of precursors with an alphabet of orthogonal crosslinkers provides a rich phase space for design of polymeric nanoparticles. For example, our simulations indicate that an alphabet of three orthogonal crosslinkers enables self-assembly of two-faced or Janus nanoparticles and a variety of other morphologies.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A19 DCMP: Magnetic and Superconducting Properties — Morial Convention Center 211

8:00AM A19.00001 Transport in ultrathin gold films decorated with magnetic Gd atoms — MicOl AlemAni, erIck HelCren, Addison HuGeI, frAncEs HeIlman, Physics Department, University of California, Berkeley, 366 Le Conte, Berkeley, CA, 94720 — We have performed four-probe transport measurements of ultrathin Au films decorated with Gd ad-atoms. The samples were prepared by quench condensation, i.e., sequential evaporation on a cryogenically cooled substrate under UHV conditions while monitoring the film thickness and resistance. Electrically continuous Au films at thickness of about 2 mono-layers of material are grown on an amorphous Ge wetting layer. The quench condensation method provides a sensitive control on the sample growth process, allowing us to tune the morphological and electrical configuration of the system. The ultrathin gold films develop from an insulating to a metallic state as a function of film thickness. The temperature dependence of the Au conductivity for different thickness is studied. It evolves from hopping transport for the insulating films, to a ln T dependence for thicker films. For gold films in the insulating regime we found a decreasing resistance by adding Gd. This is in agreement with a decreasing tunneling barrier height between metallic atoms. The Gd magnetic moments are randomly oriented for isolated atoms. This magnetic disorder leads to scattering of the charge carriers and a reduced conductivity compared to nonmagnetic materials.
8:12AM A19.00002 From Order to Disorder and Back: Co on Narrow Stepped Cu, NADER ZAKI, DENIS POTAPENKO, RICHARD OSGOOD, JR., Columbia University, PETER JOHNSON, Brookhaven National Lab — Bimetallic surface systems allow a ready template to explore the compositional dependence of surface phases. When these systems involve a vicinal substrate, the surface also becomes a template for nanoscale-phase formations. In this regard, we examine the bimetallic system of Co on Cu(775), due the wide-spread interest in the magnetic phenomena of the related Co/Cu(111). We present an STM imaging study of this surface to show that it is possible to observe self-assembly of reduced-dimension quantum structures. These observations show that a rich set of bimetallic phase transitions as a function of coverage – moving from wires at low coverage to step-induced ordered islands at high coverage. At coverage of less than 0.1ML, we observe growth of sharp, straight 2-atom-wide Co wires; topographic measurements suggest an interesting interpretation of recent DFT computations on such a system. Increasing coverage causes a marked change of the step spacing and causes the surface to be covered with an ordered array of 2-D islands beyond a critical deposition amount. Thus, as coverage increases, the Cu step structure evolves from straight ordered step edges to concave-shaped edges and then from disordered to ordered islands.

8:24AM A19.00003 Electron charge and spin pairing (pseudo)gaps and Nagaoka instabilities in nanoclusters, ARMEN KOCHARIAN, Department of Physics and Astronomy, California State University Los Angeles, GAYNATH FERNANDO, TUN WANG, KALUM PALANDAGE, Department of Physics, University of Connecticut, JIM DAVENPORT, Computational Science Center, Brookhaven National Laboratory — The electron pairings, phase separation and magnetism in various frustrated Hubbard clusters are studied exactly with emphasis on tetrahedron and octahedron under doping, magnetic field and temperature. Small clusters yield intriguing insight into charge spin separation and invoked thermal condensation of electron charge and spin in more than one bosonic mode. The spin saturated phase in so called Nagaoka state is found equivalent to ferromagnetic Mott-Hubbard like insulator with (negative) spin pairing gap, while non maximum spin ground state is of BCS-like metallic origin with equal charge (negative) and spin (positive) pairing gaps. The calculated phase diagrams resemble a number of inhomogeneous coherent and incoherent paired phases in high $T_c$ cuprates, fullerene molecules, Co and Nb nanoparticles.

8:36AM A19.00004 Superconductivity of Ultra-thin Pb films on Semiconductor Substrates: A Scanning Tunneling Microscopy/Spectroscopy Study, SHENGYONG QIN, JUNGDAE KIM, ALEXANDER AKO KHAJE-ToORIANS, CHIH-KANG SHIH, University of Texas at Austin — Ultra-thin Pb films on semiconductor substrates have exhibited many intriguing phenomena manifested by the quantum confinement of electronic states. Quantum confinement has been a topic of interest for many years. Recently, it was shown that quantum confinements also play an interesting role on superconductivity. Oscillations of superconductivity gap and $T_c$ as a function of film thickness have been observed in Pb/Si(111) and Pb/Ge(111) systems. Moreover, it is found that the superconductivity remains very robust even for films as thin as 5 ML. An interesting confinement also plays an interesting role on superconductivity. Oscillations of superconductivity gap and $T_c$ as a function of film thickness have been observed in Pb/Si(111) and Pb/Ge(111) systems. Moreover, it is found that the superconductivity remains very robust even for films as thin as 5 ML. An interesting question arises as to what extent the robustness of superconductivity remains in even thinner regime. By using a different surface template, namely Pb/Si(111) and Pb/Ge(111) systems. 8:48AM A19.00005 Magnetic field dependence of Interface Superconductivity in LSCO/LCO bilayers, SCOTT RIGGS, MagLab/FSU, FEDOR BALAKIREV, ALBERT MIGLIORI, MagLab/LANL, GREG BOEBINGER, MagLab/FSU, GENA LOGVENOV, ANTHONY BOLLINGER, ADRIAN GOZAR, IVAN BOZOVIC, BNL, LANL COLLABORATION, BNL COLLABORATION — Interface superconductivity (IS) with a high $T_c$ has been discovered recently in bi-layer films consisting of a thin layer of $La_1.55Sr_{0.5}CuO_4$ (overdoped and metallic but not superconducting) covered with a thin layer of $La_2CuO_4$ (undoped, insulating, and antiferromagnetic) grown by molecular beam epitaxy (MBE). Here we report on a study of magneto-transport properties in such IS systems. By measuring the magnetic-field dependence of in-plane longitudinal and Hall resistivities we find the temperature dependence of the upper critical field ($H_{c2}$). Other findings and inferences on the nature of IS and $T_c$ enhancement will be discussed as well.

9:00AM A19.00006 Separation of the strain and finite size effect on the ferromagnetic properties of $La_{0.5}Sr_{0.5}CoO_3$ thin films, CHANGKUN XIE, JOSEPH BUDNICK, BARRETT WELLS, Department of Physics, University of Connecticut, Storrs, CT 06269-3046, JOSEPH WOICIK, National Institute of Standards and Technology, Gaithersburg, Maryland 20899 — The ferromagnetic properties of epitaxial $La_{0.5}Sr_{0.5}CoO_3$ thin films have been studied. The magnetic transition is affected by both strain and finite thickness. We have used a series of films of different thickness and on different substrates in order to quantitatively determine the change in Curie temperature contributed by each effect. The phase diagram of $T_c$ versus in-plane strain suggests that the ferromagnetic transition temperature is suppressed by tensile strain and enhanced by compressive strain. The general method of separating strain and finite thickness effects should be applicable to any ordering phase transition in thin films. A leading theory for the ferromagnetism in $La_{0.5}Sr_{0.5}CoO_3$ is the double exchange mechanism. This model relies upon Co-O-Co electron hopping so that a strong dependence on bond length is expected. Our recent EXAFS results will examine whether the double exchange mechanism quantitatively predicts the strain dependence we have measured.

9:12AM A19.00007 Giant Magnetoelastic Coupling in Asymmetric Ferromagnet-Ferroelectric-Metal Trilayers: Toward Electric Control of Magnetization, TIANYI CAI, University of Texas at Austin, SHENG JU, Department of Physics, Suzhou University, Suzhou, 215006, China, JUNREN SHI, ENGE WANG, Institute of Physics and ICQS, Chinese Academy of Sciences, Beijing 100080, China, ZHENYA LI, Department of Physics, Suzhou University, Suzhou 215006, China, QIAN NIU, University of Texas at Austin — By examining electron screening at the surface of ferromagnetic metals and semiconductors, we propose an asymmetric ferromagnet-ferroelectric-metal trilayer to realize giant magnetoelastic effect. The origin is the strengthened accumulation of spin-polarized screening electrons at the ferromagnet-ferroelectric interface. Including the electrostatic energy from such spin-polarized charges in the Laudau-Devilbiss free energy for ferroelectrics, a magnetoelastic coupling term $\chi P^2M^2$ is derived, and consequently an electric control of magnetization hysteresis is observed. The dependence of $\chi$ as well as the ME effect on the choice of materials is discussed for some real ferromagnets.

9:24AM A19.00008 Room temperature ferromagnetism in as-deposited and post-annealed Co-doped ZnO films, XIAO-HONG XU, XIAO-LI LI, Shansi Normal University, China, G.A. GEHRING, University of Sheffield, UK — The Co-doped ZnO thin films were prepared on c-cut sapphire substrates by magnetron co-sputtering, and then annealed at various temperatures in vacuum. Magnetic measurements indicate that all the films are ferromagnetic at room temperature and the magnetization of the annealed $ZnO:8.8$CoO$_{12}$O films is increased about one order of magnitude in comparison with the corresponding as-deposited one. Both X-ray diffraction and TEM results show that there are not any Co and Co oxides secondary phases. Optical spectrometry indicates that Co$^{2+}$ enters the tetrahedral sites of the wurtzite structure of ZnO host and substitutes for Zn$^{2+}$.

9:36AM A19.00009 Ferromagnetic $\text{Mn}_3\text{Ga}$ On Wurtzite GaN: Initial Stages Of Growth By Molecular Beam Epitaxy, KANGKANG WANG, ABHIJIT CHINCHORE, EORDONG LU, WENZHI LIN, JEONGHIM PAK, ARTHUR R. SMITH, Nanoscience and Quantum Phenomena Institute, Department of Physics and Astronomy, Ohio University, Athens, OH 45701 — Ferromagnetic (FM) metal/wide-bandgap bilayers are of great interest due to their potential for novel spintronics applications, such as blue and ultra-violet light-emitting diodes. It has been reported that $\text{Mn}_3\text{Ga}$, a promising FM alloy, can be grown epitaxially on top of w-GaN(0001) with controllable magnetism via controlling of the Mn:Ga flux ratio. Here we report studies on the initial stages of growth of MnGa on w-GaN. Growth experiments were carried out in a UHV chamber using molecular beam epitaxy with rf (N$_2$)-plasma, on both N- and Ga-polar substrates. Reflection high-energy electron diffraction (RHEED) data suggest that at the initial stages of growth, the surface structures depend on the substrate polarity. This may be due to the structural differences between the N-polar and the Ga-polar GaN surfaces. Stoichiometry dependence of initial stages of growth is also being investigated. This work has been supported by DOE (Grant No.DE-FG02-06ER46317) and NSF (Grant No.0304314). Equipment support from ONR is also acknowledged. 9:48AM A19.00010 Molecular Beam Epitaxial Growth of Iron Nitrides on Zinc-Blende Gallium Nitride (001), JEONGHIM PAK, WENZHI LIN, ABHIJIT CHINCHORE, KANGKANG WANG, ARTHUR R. SMITH, Nanoscience and Quantum Phenomena Institute, Department of Physics & Astronomy, Ohio University, Athens, OH 45701 — Iron nitrides are attractive materials for their high magnetic moments, corrosion, and oxidation resistance. We present the successful epitaxial growth of iron nitride on zinc-blende gallium nitride (c-GaN) in order to develop a novel magnetic transition metal nitride/semiconductor system. First, GaN is grown on magnesium oxide (MgO) substrates having (001) orientation using rf N$_2$-plasma molecular beam epitaxy. Then we grow FeN at substrate temperature of $\sim$ 210 °C up to a thickness of $\sim$ 10.5 nm. In-situ reflection high-energy electron diffraction (RHEED) is used to monitor the surface during growth. Initial results suggest that the epitaxial relationship is FeN[001] $\parallel$ GaN[001] and FeN[100] $\parallel$ GaN[100]. Work in progress is to investigate the surface using in-situ scanning tunneling microscopy (STM) to reveal the surface structure at atomic scale, as well as to explore more Fe-rich magnetic phases.

10:00AM A19.00011 Synthesis of $\text{Co}_{1-x}\text{Fe}_{2x}\text{O}_4$: Towards Spin Polarized Ferrites, JARRETT MOYER, HUI-QIONG WANG, Department of Applied Physics, CRISP, Yale University, CARLOS VAZ, CRISP, Yale University, VICTOR HENRICH, Department of Applied Physics, CRISP, Yale University — Ferrites are promising materials for spintronic devices, since they are predicted to exhibit high spin polarizations [1]. Thin-film cobalt ferrite (CoFe$_2$O$_4$) has a large saturation magnetization and magnetic coercivity, but is insulating [2]. In this work, epitaxial $\text{Co}_{1-x}\text{Fe}_{2x}\text{O}_4$ thin films are grown by MBE on Fe$_3$O$_4$(001) and MgO(001), where a fraction of the Co$^{2+}$ ions are replaced with Fe$^{3+}$. LEED, RHEED and XRD confirm the crystal structure. Stoichiometry and cation valence states are ascertained by XPS, and the electronic structure near the Fermi level is determined by UPS. We show, that by varying the stoichiometry of $\text{Co}_{1-x}\text{Fe}_{2x}\text{O}_4$, we can tailor its electronic properties, which may lead to a conductive, spin polarized ferrite. [1] J. Cibert, et al., C.R. Physique 6 (2005) 977. [2] W. Huang, et al., J. Crystal Growth 300 (2007) 426.

10:12AM A19.00012 A surface-driven route to novel magnetic structures: Manganese on Si(100), PETRA REINKE, HUI LIU, CHRISTOPHER NOLPH, University of Virginia — The combination of Silicon with an element with a large magnetic moment such as Manganese is highly desirable for the development of novel spintronics devices. We present a study on the surface-driven synthesis of Mn-nanostuctures on the Si(100) (2x1) surface using STM and photoelectron spectroscopy. The Si-surface functions as a template and monatomic Mn-nanowires are formed, which always run perpendicular to the Si-dimer rows. Their length and spatial distribution is used to derive a model for the wire formation. The bonding of Mn to the Si, which is decisive for the resultant magnetic properties, are presented. The transition to a silicide is kinetically hindered and controlled by the Si-mobility. In the next step a Ge-overlayer is deposited, and analyzed with voltage dependent STM. In the low-adatom-mobility regime the Ge-growth is unperturbed by the presence of Mn, and the Mn-nanostructure is preserved and embedded.

3 The authors gratefully acknowledge the support of this work by the Nanoelectronics Research Initiative (NRI) in conjunction with NSF

10:24AM A19.00013 High-resolution ARPES studies of atomically uniform Pb films on Si(111), SHAOULONG HE, MASASHI ARITA, MASAHIRO SAWADA, Hiroshima Synchrotron Radiation Center, Hiroshima University, Higashi-Hiroshima 739-0046, Japan, SHAN QIAO, Lawrence Berkeley National Laboratory, HIROFUMI NAMATAME, MASAKI TANIGUCHI, Hiroshima Synchrotron Radiation Center, Hiroshima University, Hiroshima 739-0046, Japan. Of great interests both in basic research and in potential applications. Atomically uniform metal thin films on semiconductor substrate are the simplest quasi-2D electron systems, which demonstrate quantum confinement and form the quantum well states (QWS). Recently, atomically uniform Pb films on Si(111) have demonstrated novel properties induced by the quantum size effects. We have manufactured atomically uniform Pb films on Si(111)-7x7 surface. The dependence of the Pb films band structures on thickness has been studied by high-resolution angle-resolved photomission spectroscopy (ARPES). In addition, we have investigated the superconductivity properties in such a quasi-2D electron systems by measuring the ARPES below superconducting transition temperature.

10:36AM A19.00014 Unusual Hall effect due to carrier delocalization, XIAOHANG ZHANG, S. VON MOLNAR, P. XIONG, Florida State University, Z. FISK, University of California at Irvine — The spin polarization of EuB$_6$ crystals has been measured using Andreev reflection spectroscopy. The conductance spectra of the EuB$_6$/Pb junctions are well-described by the spin-polarized BTK model, which yields a spin polarization of about 56%. The results demonstrate that ferromagnetic EuB$_6$ is not half-metallic. Further analyses of the Hall effect and magnetoresistance indicate a semi-metallic band structure with complete spin polarization for the hole band only. The values and the spread of the measured spin polarization is quantitatively consistent with Fermi surface determined by quantum oscillation measurements and carrier densities obtained from standard two-band model fits to the low temperature magnetoresistivity and Hall resistivity. This work was supported by a FSU Research Foundation PEG, NSF DM 0710492 and 0503360 grants. 1. R. Goodrich et al., PRB 58, 14896 (1998); M. Aronson et al., PRB 59, 4720 (1999).

10:48AM A19.00015 Spin-dependent band structure of the ferromagnetic semimetal EuB$_6$, PENG XIONG, X. ZHANG, S. VON MOLNAR, Florida State University, Z. FISK, University of California at Irvine — The spin polarization of EuB$_6$ crystals has been measured using Andreev reflection spectroscopy. 8:00AM A20.00001 Phase-field modeling of solute precipitation and dissolution at solid-fluid interface. ZHUIIE XU, PAUL MEAKIN, Idaho National Laboratory — Phase phase-field methods have been developed to simulate a variety of processes in which interface dynamics play a critical role. The mathematical formulation of a phase field approach to the dynamics of liquid solid interfaces that evolve due to precipitation and/or dissolution will be presented. For the purpose of illustration, and comparison with other methods, phase field simulations have been carried out assuming first order reaction dissolution/prediction) kinetics. In contrast to solidification processes controlled by a temperature field that is continuous at the solid/liquid interface, with a discontinuous temperature gradient, precipitation/dissolution is controlled by a solute concentration field that is discontinuous at the solid/liquid interface. The sharp-interface asymptotic analysis of the phase-field equations for solidification by Karma and Rappel [Phys. Rev. E57 (1998) 4342] have been extended to demonstrate that the phase-field equations converge to the proper sharp-interface limit for the precipitation/dissolution problem. The mathematical model has been validated for a one-dimensional precipitation/dissolution problem by comparison with the analytical solutions of the free-boundary problem.

8:12AM A20.00002 Island Size Scaling and Evolution during Strained Film Epitaxy. ZHI-FENG HUANG, Department of Physics and Astronomy, Wayne State University; KEN ELDER, Department of Physics, Oakland University — Strained film growth often gives rise to the self assembly of nanostructures such as quantum dots or islands. While there has been and continues to be much interest in such behavior the fundamental mechanisms that determine the precise morphologies remain unclear. In this work the phase field crystal model, which incorporates the atomic length and diffusive time scales, and the corresponding amplitude equations are used to examine this phenomenon. Direct numerical simulations of the model and linear stability analysis of the amplitude equations are presented. The results predict that the average island size is inversely proportional to the strain. This result is consistent with recent experiments on SiGe, but inconsistent with the predictions of classic continuum elasticity theory (or the Asaro-Tiller-Grinfeld instability). Basic mechanisms identified in our study, which are associated with the crystalline nature but absent in all continuum approaches, are discussed.

8:24AM A20.00003 Optimal Capping Layer Thickness for Stacked Quantum Dots. XIAOBIN NIU, Department of Material Sciences and Engineering, UCLA, Los Angeles, CA 90095, CHRISTIAN RATSCH, Department of Mathematics/Institute for Pure and Applied Mathematics, UCLA, Los Angeles, CA 90095, YOUNG-JU LEE, Department of Mathematics, UCLA, Los Angeles, CA 90095, RUSSEL CAFLISCH, Department of Mathematics/Department of Material Sciences and Engineering, UCLA, Los Angeles, CA 90095 — We study the effect of strain on the vertical and lateral self-organization of nanoscale patterns and stacked quantum dots during epitaxial growth. The computational approach is based on the level set method in combination with an atomic strain code. Strain changes the energetics of microscopic parameters during growth, and thus determines the nucleation sites and the growth of islands and dots. Our results show that strain can lead to vertical alignment as well as lateral organization. Moreover, our simulations suggest that there is an optimal thickness of the capping layer to get the best alignment and most uniform size distribution of stacked quantum dots.

8:36AM A20.00004 Modeling the complex evolution of self-assembled quantum dots. JERRY TERSOFF, IBM T.J. Watson Research Center — In heteroepitaxy, misfit strain often leads to spontaneous formation of islands. Such islands have attracted great interest as “self-assembled quantum dots”. The growth of these quantum dots is remarkably rich, exhibiting alloy intermixing, island coarsening, trench formation, and even spontaneous lateral motion of islands. Islands also interact with topographic features on the substrate, providing a means for controlling the position of quantum dots. The diverse experimental observations provide an ideal opportunity to test and extend our theoretical understanding of growth at the nanoscale. We find that much of the complexity arises because there is a strong thermodynamic driving force for intermixing (to increase entropy and reduce strain energy) as well as for morphological evolution (to reduce strain energy); but this evolution must occur under the kinetic constraint of diffusion occurring only at the surface. Simulations of such constrained evolution directly reproduce many of the observed phenomena [Y. Tu and J. Tersoff, Phys. Phys. Lett. 98, 096103 (2007)].

3 Work done in collaboration with Yuhai Tu

9:12AM A20.00005 Effect of Elastic Inhomogeneity and Anisotropy on the Order of Epitaxial Self-Assembled Quantum Dots. CHANDAN KUMAR, LAWRENCE FRIEDMAN, Penn State University — Growth of epitaxial self-assembled semiconductor quantum dots (SAQDs) is of particular interest in the development of quantum dot based devices such as quantum computing architectures, laser diodes, and other optoelectronic devices. The ordering of these SAQDs is critical for the development of these devices. Understanding what factors the order of these SAQDs depend on, is important for guiding both experiments and simulations. Most theoretical and numerical models approximate the film substrate system as a semi-infinite solid. Although models based on such an approximation have been able to predict some general behaviour in confirmation with the experimental results, predictions about a quantitative measure would be less approximate if the models could incorporate elastic inhomogeneity. The presented linear stochastic model for SAQD growth incorporates elastic inhomogeneity and anisotropy along with stochastic surface diffusion to produce a more refined quantitative model for SAQD order formation. For the Ge/Si film-substrate system it is found that at the critical film height such an approximation could lead to an error of ~12% in the estimation of average spacing between SAQDs and an error of ~24% in the estimation of number of correlated dots for small height fluctuations.

9:24AM A20.00006 Composition Maps in Strained Alloy Quantum Dots. NIKHIL MEDHEKAR, VISH-WANATH HEGADEKATTE, VIVEK SHENOY, Brown University — Knowledge of composition profiles within self-assembled SiGe and InGaAs quantum dots is critical for applications in optoelectronic and memory devices as variations in composition at the nanoscale can substantially influence their electronic properties. Obtaining the quantitative description of composition profiles in the quantum dot is a challenging task due to the coupling between composition variations, shape of the quantum dots and long-range elastic interactions. In this talk, we present an efficient scheme that combines the finite element analysis with an optimization scheme based on a quadratic programming method to determine equilibrium profiles in strained quantum dots. Composition profiles are found to strongly depend on the shape of the quantum dots, as strain relaxation in dots with steeper sidewalls allows for segregation of the larger alloy component in the regions near the apex. Based on these observations, we have developed a phase diagram that shows the degree of segregation of the alloy components in the phase space spanned by the temperature (which governs chemical mixing) and the shape of the dot. Further, we find that the segregation of the alloy components can substantially reduce the critical dot size for the transition between the shapes with different facets.
9:36AM A20.00007 An Accelerated Molecular Dynamics Study of the GaAs (001) $\beta 2(2\times4)$ Reconstruction. MARIA MIGNOGNA, KRISTEN FICTHTHORN, Penn State University — The GaAs (001) $\beta 2(2\times4)$ reconstruction is the most commonly used substrate for growth in GaAs homoepitaxy by molecular beam epitaxy. While the atomic positions of the $\beta 2(2\times4)$ unit cell have been determined, reflection high energy electron diffraction and scanning tunneling microscopy images show long range disorder on this surface[1]. It is hypothesized that domains of anti-phase $\beta 2(2\times4)$ unit cells can be created by vacancies or As dimer shifts. Accelerated molecular dynamics (MD) allows us to examine atomic scale processes that can lead to this disorder. We have developed an adaptive accelerated MD scheme based on the bond boost method of Miron and Fichthorn[2]. The adaptive method is suitable for the rough energy landscape presented by GaAs (001). In the adaptive method, both the length thresholds for determining transition states and the magnitude of the boost are calculated on the fly. We are able to extend the physical timescale of the simulation by several orders of magnitude. We see events that lead to small domains of As dimers shifting. By simulating RHEED images of the surface, we link the disorder to experiment. [1] D.W. Pashley, J.H. Neave, B.A. Joyce, Surf. Sci., 582, 189 (2005) [2] R.A Miron, K.A. Fichthorn, J. Chem. Phys., 119, 6210 (2003)

9:48AM A20.00008 Strain and Piezoelectric Effects on the Electronic Structure of Coupled In$_{x}$Ga$_{1-x}$As/GaAs Self-Assembled Quantum Dots. USMAN MUHAMMAD, Purdue University, SHAIKH AHMED, Southern Illinois University Carbondale, GERHARD KLIMECK, Purdue University — In$_{x}$Ga$_{1-x}$As/GaAs coupled quantum dot systems have gained much attention for optical and quantum computing applications. Due to strain, originating from the assembly of lattice mismatched semiconductors, the quantum dot arrays tend to grow in the vertical direction. These vertically stacked dots are strongly coupled through the strain field, which is atomically inhomogeneous and penetrates deep into the GaAs buffer layer surrounding the dots. Crystal symmetry and atomistic details of interfaces are extremely important in such systems. Also piezoelectric fields must be taken into account to properly model the experimentally observed symmetry breaking and the introduction of a global shift in the energy spectra of the system. In this work, we present a detailed description of strain and piezoelectric potential effects on the electronic structure of closely coupled identical and non-identical quantum dot systems using spd$^{s*}$ nearest neighbor empirical tight binding model. We show that strain causes strong mixing of s- and p- electron energy levels in strongly coupled quantum dot, splits heavy hole and light hole bands and even reverses their order within dots.

10:00AM A20.00009 Structure competition in growth of In island on Si111 from first-principles calculations. CAI-ZHUANG WANG, MIN JI, J. CHEN, M. HUPALO, M.C. TRINGIDES, K.M. HO, Ames Laboratory US-DOE and Department of Physics, Iowa State University, Ames, IA 50011, USA — We have carried out first principles calculations to understand the growth of indium island on Si111 substrate which have been observed to have an interesting FCC and BCT structure competition. Our calculations show that quantum size effect (QSE) plays an important role in different island structure formation. Furthermore, the interplane energy between In and Si substrate also controls the relative stability of different island structures.

10:12AM A20.00010 Thermodynamic potentials in closed and open nanocrystalline systems: Si-Ge islands on Si(001). MARINA S. LEITE, Brazilian Synchrotron Light Source, Instituto de Fisica Gleb Wataghin - UNICAMP, ANGELO MALACHIAS, Max-Planck Institute for Solid State Research, STEFAN W. KYCIA, University of Guelph, TED I. KAMINS, R. STANLEY WILLIAMS, Hewlett-Packard Laboratories, GILBERTO MEDEIROS-RIBEIRO, Hewlett-Packard Laboratories, Brazilian Synchrotron Light Source — The driving forces for alloying in Si-Ge epitaxial nanocrystalline islands were quantified experimentally. Grazing Incidence X-Ray Diffraction (GIXRD) experiments were performed to map the composition and the strain distribution within the Si-Ge:Si(001) islands, permitting the evaluation of the relevant thermodynamic potentials for alloying. For the closed system the elastic strain energy increased, which was more than compensated by the increase in the local mixing entropy [2]. In contrast, for the open system, the elastic energy decreased and the mixing entropy increased, driven by the intermixing originated from the relevant of Si from the reservoir. For both systems, the evolution of the composition leads to a lowering of the Gibbs free energy. The results were in full agreement with a theoretical prediction of the optimum concentration for epitaxial islands. [1] M. S. Leite et al, Phys. Rev. Lett. 98, 156501 (2007). [2] G. Medeiros-Ribeiro et al, Nano Lett. 7, 223 (2007).

10:24AM A20.00011 Characterization of MBE grown PbSe Quantum Dots. NATHANIEL BECKER, DUSTN KLEIN, TIM KIDD, Univ of Northern Iowa — Lead selenide (PhSe) has been shown to be an excellent candidate for solar cell research due to its ability to allow the possibility for multiple electronic carrier production by absorption of a single photon. These quantum dots (QDs) were created using molecular beam epitaxy (MBE) to evaporate PbSe onto clean and modified silicon and germanium substrates. Control of lattice strain was achieved by the deposition of buffer layers onto clean Si(111)in ultra-high vacuum. The MBE technique allows for structural control at the atomic level. We have investigated the samples using Auger spectroscopy, scanning probe and scanning electron microscopy to determine their suitability for solar cell applications. Specifically, we examined the structural properties of the system. In this work, we present a detailed description of strain and piezoelectric potential effects on the electronic structure of closely coupled identical and non-identical quantum dot systems using spd$^{s*}$ nearest neighbor empirical tight binding model. We show that strain causes strong mixing of s- and p- electron energy levels in strongly coupled quantum dot, splits heavy hole and light hole bands and even reverses their order within dots.

10:36AM A20.00012 Self Assembling Quantum Dot Aggregates in Liquid Crystal Matrices. CHRISTOPHER FERRI, M. GALLARDO, Y. VERMA, D. KELLEY, S. GHOSH, School of Natural Sciences, University of California, Merced CA 95343 — A system of colloidal quantum dots (QDs) embedded in a matrix of highly directional and ordered liquid crystal (LC) molecules at room temperature offers the novel potential of promoting controllable aggregation of the QDs. Photoluminescence (PL) of GaSe QDs embedded in a LC matrix, studied using a confocal-microscopy setup, shows considerable red-shift in the emission spectrum of the QD-LC composite. While bare QDs in solution emit at 485 nm, mixing with LC molecules results in an emission centered at 500 nm, system suggesting their aggregation into longer structures in the matrix. A high resolution two-dimensional spatial map of the PL on the sample provided evidence of the organization of QDs into these ordered domains. Application of in-plane electric fields further enhances the aggregation effect of the QDs and emission spectrum is red-shifted to around 525 nm. Furthermore, as the aligning electric field increases the degree of ordering of the liquid crystal molecules, the polarization ($P$) of the emission of the aggregated QDs rotates in step with that of the LCs' directionality. Unlike the disc-shaped GaSe QDs, investigations on LC and CdSe QD system failed to show such dramatic aggregation effects.

8:00AM A21.00001 Self Assembly of Mixed-Valence Ionic Amphiphiles into Faceted Vesicles. MEGAN GREENFIELD, GRAZIANO VERNIZZI, LIAM PALMER, SAMUEL STUPP, MONICA OLVERA DE LA CRUZ. Northwestern University — We show that anionic and cationic amphiphiles of unequal charge can co-assemble into small faceted vesicles and we propose a theoretical model to explain the faceting behavior. The strong electrostatic interaction between the +3 and -1 head groups increases the Columbic cohesion energy of the amphiphiles and should favor the formation of a two-dimensional, flat ionic surface. The vesicle surface can form edges by breaking the ionic lattice, which can be visualized as faceted shapes. Our results demonstrate that a large charge imbalance between the cationic and anionic head groups of amphiphiles enables their coassembly into faceted vesicles. We anticipate this work to be a starting point for rationally designing new self-assembled supramolecular structures.

8:12AM A21.00002 Electrospinning Solutions of Associating Polymers – the Case of Stereocomplex PMMA. MATJIA CRNE, JUNG PARK, MOHAN SRINIVASARAO, Georgia Institute of Technology — A mixture of isotactic and syndiotactic PMMA polymers (also called a “stereocomplex PMMA”) forms a supramolecular helical structure, which is held together by non-covalent bonding. This association is thermoreversible and solvent-sensitive. If the concentration of stereocomplex PMMA is high enough, the solutions form thermoreversible physical gels. We have examined this influence through the process of electrospinning. In our work, we have used solutions of stereocomplex PMMA to study the effect of physical gelation interaction on the fiber morphology and compared it to the solutions of atactic PMMA of similar molecular weight. We have found that the stereocomplex PMMA solutions do not follow the same empirical rules that are applicable for linear polymers in solution. Instead, the concentration necessary for the production of smooth, continuous fibers is much lower. We ascribe this extraordinary behavior to the ability of these polymers to associate and form a network during the electrospinning process. The elasticity of the fluid jet thus rises and results in a more stable jet. The resulting fibers are interesting, as they have greater temperature stability than regular atactic PMMA. Therefore they have a bigger processing window for making composites with better mechanical properties.

8:24AM A21.00003 ABSTRACT WITHDRAWN

8:36AM A21.00004 Unique Properties of Reversibly Associating Polymer Networks1, MITCHELL ANTHAMATTEN, University of Rochester — Reversibly associating functional groups offer the polymer physicist with a new tool to develop stimuli-responsive polymers. Our focus has been to attach reversibly associating groups onto rubbery network polymers. Free radical copolymerization was used to synthesize a series of crosslinked poly(n-butylacrylate)s containing quadruple H-bonding ureidopyrimidinone (UPy) side-groups. Resulting elastomeric networks contain both covalent and dynamic non-covalent crosslinks, and this unique architecture is shown to affect viscoelastic behavior and mass-transport properties. Shape-memory effects are studied quantitatively using thermomechanical techniques. Experiments show how reversible interactions, such as hydrogen bonding, are capable of stabilizing mechanically strained states. Unlike conventional shape-memory polymers, these dynamic networks lack a well-defined shape recovery temperature. Instead, their shape recovery rate depends on temperature. To further study the dynamics and temperature dependence of mechanical relaxation, isothermal creep experiments and dynamic mechanical analysis were performed. Creep data, acquired at several different temperatures, are fit to a simple viscoelastic model. Fit viscosities exhibit Arrhenius-like temperature dependence with activation energies of ~90 kJ/mol, which is in rough agreement with H-bond dissociation barriers. Molecular transport through dynamic networks is studied using gravimetric sorption and dye-diffusion techniques. Diffusion depends on temperature, network architecture, solute size, and the interaction between the solute and the network. Membranes with high temperature-sensitive diffusion properties may be useful in applications such as transdermal drug delivery, microfluidics, or liquid chemical separation processes.

9:12AM A21.00005 Computer Simulations of Semi-flexible Polymer Chains. VENKAT PADMANABHAN, SANAT K. KUMAR, Columbia University, ARUN YETHIRAJ, University of Wisconsin — Monte Carlo Simulations are performed to obtain the isotropic-nematic (IN) transition in systems with semi-flexible polymer chains of different lengths. The chains are modeled as spherical beads that interact via a square-well potential. Bonded beads are connected by strings chosen so that bond length varies between 1.0σ and 1.05σ (where σ is the hard sphere diameter). The stiffness of the molecules is controlled via a potential between beads separated by two bonds; this potential restricts the distance between these beads to be between 2.0σ and 2.1σ. The vapor-liquid coexistence and isotropic-nematic (IN) coexistence curves are obtained using computer simulations. An IN transition is found for NΩ > 10. The density, at which the IN transition occurs, moves to higher values as NΩ is increased and then drops on further increase. This is analogous to the initial increase in the critical density for pure alkanes as the chain length is increased.

9:24AM A21.00006 Reversible Networks by Hydrogen Bonding of ABA Triblock Copolymers in an Ionic Liquid. TIMOTHY LODGE, University of Minnesota. ATSUSHI NORO, YUSHU MATSUSHITA, University of Nagoya — Ion gels, comprising a polymeric network solvated by an ionic liquid, are of great interest as, e.g., gate dielectrics in plastic electronics, polymer electrolytes with high ionic conductivity, actuators and artificial muscles, gas separation media, and sensors. We have explored the thermoreversible gelation of a model system containing poly(2-vinyl pyridine-b-ethyl acrylate-b-2-vinyl pyridine) (VEAV) triblocks dissolved in 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide [em][tfsi], with better mechanical properties.

9:36AM A21.00007 Examination of the Structure of Molten Hydrogen-Bonded Supramolecular Diblock Copolymers. KATHLEEN FELDMAN, MATTHEW KADE, CRAIG HAWKER, EDWARD KRAMER, UCSB — A new strategy for synthesizing low polydispersity polymers containing multiple hydrogen bonding (HBB) groups at one chain end capable of heterodimerization in both solution and the melt has been developed. Two well-known MHB systems were chosen for initial studies—2-ureido-4[1H]-pyrimidinone (UPy) and 1,8-diaminodiphenylhexidine (Nap), and ATRP initiators containing either UPy or Nap were synthesized. These initiators were shown to produce well-defined (meth)acrylic polymers with the desired HBB functionality present at the chain end. To characterize the effectiveness of the HBB interaction in the melt, blends were cast into films, annealed at various temperatures above Tg, then quenched and their structure analyzed by transmission electron microscopy (TEM) and differential scanning calorimetry (DSC). It was shown that the nature of the hydrogen bonding group(s) present in the blend has a significant effect on structure and thermal behavior, and in particular blends of UPy- and Nap-functional chains contain a significant fraction of “supramolecular diblock copolymers.”

9:48AM A21.00008 Thermoreversible bond formation in end-linking, difunctional polymer blends. RICHARD ELLIOTT, GLENN FREDRICKSON, Materials Research Laboratory, University of California, Santa Barbara — We investigate theoretically thermoreversible bond formation and phase transitions in a system composed of linear, end-linking, difunctional polymers. In this melt, two distinct species of equal-length links assemble into chains of varying sequences and polymerization depending on the affinities of binding between the blocks. Several limits, such as that of purely heterogeneous bonding which forms chains of alternating block sequences, are explored. Interactions between dissimilar segments are described with the Flory-Huggins contact potential and a mean-field approach is employed to investigate the effects of prevailing bond and the onset of meso-scale ordering.
10:00AM A21.00009 Inter- and Intra-Molecular Interactions of Associative Polymers in Solution, M. WEI, R. DAVID, JULIE KORNFIELD, Caltech — Model polymers with matched backbone length are used to examine the effects of degree of functionalization and type of interaction (self-associating or donor-acceptor) on shear and extensional rheology of associative polymer solutions. Series of polymers were prepared by functionalization of 500 and 1300 kg/mol polybutadiene chains with carboxylic acid side groups (A stickers, self-associating) and tertiary amine side groups (N stickers, forming strong hydrogen donor-acceptor interactions with A stickers). We found that stickers drive phase separation at extents of functionalization as low as 0.5 mol%. Intramolecular associations dominated the behavior of A-functionalized chains even at semi-dilute concentrations, leading to chain collapse and reduced shear and extensional viscosities. Finally, we found that intermolecular interactions were much more favorable for dilute mixtures of A-functionalized and N-functionalized chains (as evidenced by increased zero-shear viscosity and by the formation of large aggregates), but that associations still reduced solution elasticity and extensional viscosity in elongational flow.

10:12AM A21.00010 Molecular Dynamics Simulation of Polyelectrolyte Brushes: From Hemispherical Micelles to Maze-like Aggregates, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, Institute of Materials Science, University of Connecticut — We present results of the molecular dynamics simulations of the effects of solvent quality, strength of the electrostatic interactions, chain degree of polymerization and grafting density on the conformations of planar polyelectrolyte brushes in salt-free solutions. The polyelectrolyte brush could form: (1) hemispherical micelle aggregates, (2) vertically oriented cylindrical micelles, (3) maze-like aggregate structures, or (4) thin polymeric layer uniformly covering the substrate. These different brush structures appear as a result of the fine interplay between electrostatic and monomer-monomer attractive interactions. The brush thickness depends nonmonotonically on the value of the Bjerrum length. This nonmonotonic dependence is due to counterion condensing inside the brush.

10:24AM A21.00011 Effect of Hydrogen-Bonding Junctions on Microphase Separation in Block Copolymers, GREG STONE, University of California Berkeley, JIM HEDRICK, FREDRIK NEDERBERG, IBM Almaden Research Facility, NITASH BALSARA, University of California Berkeley, CPIMA COLLABORATION — The morphology of poly(styrene-block-trimethylene carbonate) (PS-PTMC) copolymers with and without thiourea groups at the junction between the blocks was studied by a combination of small angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). The thiourea groups are known to exhibit inter-molecular hydrogen bonding. We demonstrate that the presence of thiourea groups results in increased segregation between PS and PTMC blocks. We focus on symmetric systems with total molecular weights in the 5 kg/mol range. In conventional block copolymers without hydrogen bonding groups it is difficult to obtain strong segregation in low molecular weight systems because the product chi*N controls segregation (chi is the Flory-Huggins interaction parameter and N is the number of monomers per chain). The incorporation of hydrogen bonding groups may provide a route for the generation of patterns with small, sharply defined features using block copolymers.

10:36AM A21.00012 Relating Chain Structure to Physical Properties of Branched Polymers, RAMNATH RAMACHANDRAN, GREGORY BEÀUCAGE, AMIT S. KULKARNI, University of Cincinnati, VASSILIOS GAlIATsATOS, DOUGLAS C. MC-FADDIN, LyondellBasell Industries — We investigated linear and branched polyethylene (PE) using small-angle neutron scattering (SANS). The experiments were conducted on dilute solutions of PE in deuterated p-xylene. A variety of structural information such as fractal dimension (d(1)), connectivity dimension (c), minimum path dimension (d(min)), long chain branch fraction (phi_d), radius of gyration (R_g) and persistence length (l_p) were obtained. Such information presents a qualitative and quantitative assessment of branching in polymers. Theoretical models such as ‘binary contacts per pervaded volume’ model were employed to correlate the structural information of the polymer to its entanglement molecular weight (M_e). M_e was used to predict physical properties such as plateau modulus (G_0) and zero-shear viscosity (eta_0). We relate physical properties of branched polymers to their structural properties. Beaucage G. Physical Review E 70,031401 (2004) *Colby et al. Macromolecules 25, p.996 (1992)

Monday, March 10, 2008 8:00AM - 11:00AM –
Session A22 DPOLY: Focus Session: Hybrid Organic-Inorganic Nanomaterials I: Patterning and Self Assembly Morial Convention Center 214

8:00AM A22.00001 Connecting quantum dots and bionanoparticles in hybrid nanoscale ultrathin films, RAVISUBHASH TANGIRALA, YUNXIA HU, QINGLING ZHANG, JINBO HE, THOMAS RUSSELL, TODD EMRICK, University of Massachusetts, Amherst — Aldehyde-functionalized CdSe quantum dots and nanorods, and horse spleen ferritin bionanoparticles, were co-assembled at an oil-water interface. Reaction of the aldehydes with the surface-available amines on the ferritin particles enabled cross-linking at the interface, converting the assembled nanoparticles into robust ultra-thin films. The cross-linked capsules and sheets thus made by aldehyde-amine conjugation could be disrupted by addition of acid. Reductive amination chemistry could be performed to convert these degradable capsules and sheets into structures with irreversible cross-linking. Fluorescence confocal microscopy, scanning force microscopy and pendant drop tensiometry were used to characterize these hybrid nanoparticle-based materials, and transmission electron microscopy (TEM) confirmed the presence of both the synthetic and naturally derived nanoparticles.

8:12AM A22.00002 Janus Au Nanoparticle Patterning via Polymer Single Crystals, CHRISTOPHER LI, BING LI, Drexel University — Gold nanoparticles (AuNPs) possess remarkable electrical and optical properties coupled with good chemical stability. Thus, they have wide potential applications in fabrication of advanced optical and electronic devices. In order to efficiently transfer their outstanding properties from nano- to micro-scale, patterned AuNPs are desired. Here, we report a novel method using polymer single crystals as substrates to pattern AuNPs. By using thiol-terminated polyethylene oxide (HS-PEO) as the substrate, we were able to assemble AuNPs into different patterns on the PEO single crystals. Furthermore, these AuNPs are asymmetrically functionalized (Janus NPs). A variety of shapes including chains and sheets were formed, and the size and areal density of the AuNP assemblies can be controlled through the AuNP adding time and the ratio between AuNPs and polymer single crystals, respectively. Because of the asymmetrical nature of the AuNPs, the resultant chains and sheets are both asymmetric (Janus chains and Janus sheets), which could lead to a variety of interesting optic properties. We anticipate that our approach would provide a facile means to pattern AuNPs, and it could be extended to other metal and semiconductor NPs.
8:24AM A22.00003 Organic-Inorganic Nanocomposites via Directly Grafiting Conjugated Polymers onto Quantum Dots, ZHIQUN LIN, Iowa State University, JUN XU, JUN WANG, MIKE MITCHELL, PRASUN MUKHERJEE, MALIKA JEFFRIES-EL, JACOB W. PETRICH, Iowa State University — Nanocomposites of poly(3-hexylthiophene)-cadmium selenide (P3HT-Cds) were synthesized by directly grafting vinyl terminated P3HT onto [4-(bromophenyl)methyl]diocylphosphine oxide (DOPO-Br)-functionalized CdSe quantum dot (QD) surfaces via a mild palladium-catalyzed Heck coupling, thereby dispensing with the need for ligand exchange chemistry. The resulting P3HT-CdSe nanocomposites possess a well-defined interface, thus significantly promoting the dispersion of CdSe within the P3HT matrix and facilitating the electronic interaction between these two components. The photophysical properties of nanocomposites were found to differ from the conventional composites in which P3HT and CdSe QDs were physically mixed. Solid-state emission spectra of nanocomposites suggested the charge transfer from P3HT to CdSe QDs, while the energy transfer from 3.5 nm CdSe QD to P3HT was implicated in the P3HT/CdSe composites. A faster decay in lifetime further confirmed the occurrence of charge transfer in P3HT-CdSe nanocomposites.

8:36AM A22.00004 Amplification of Self-Assembled Nanopatterns: Bilayer Approach to High Aspect-Ratio Cylindrical Nanopore Arrays and Their Use for Templating Functional Materials, HO-CHEOL KIM, IBM Almaden Research Center, OUN-HO PARK, JOY CHENG, MARK HART, ROBERT MILLER, HIROSHI ITO, IBM ALMADEN RESEARCH CENTER TEAM — Thin films containing well-defined nanoscopic cylindrical pores oriented perpendicular to the surface are highly desirable for a variety of applications. Of great interest is to use the porus structures for templating a variety of functional materials into 3D nanostructures. Previous reports employ the porous oxide of anodized aluminum or thin films of block copolymers for generating high aspect-ratio nanoporous films. It is, however, still desirable to develop a generalized, simple and reliable method to fabricate nanoporous templates with controlled pore dimensions, high aspect-ratio, substrate non-selectivity and uniformity over large areas. We report a relatively simple and reproducible method for generating nanoporous templates. The approach we used in this study provides nanoporous films with controlled pore diameters (8nm – 25nm in this study) and high aspect-ratio over large areas of a variety of substrates. We also report the application of the templates for generation of nanostructured copper sulfide and titania and their functional properties.

8:48AM A22.00005 Nanoparticle Arrays via Self Assembled Peptide Templates, NIKHIL SHARMA, MATTHEW LAMM, DARRIN POCHAN, University of Delaware — The bottom up approach towards nano-scale patterning presents the possibility of creating hierarchical architectures through simple self-assembly strategies. Herein, we demonstrate the use of a peptidic template for the construction of parallel, linear arrays of inorganic nanoparticles. A 20 amino acid peptide, consisting of alternating hydrophilic (lysine) and hydrophobic (valine) residues flanking a central diproline turn sequence (VKVKVKVVKVPPTKVKVKVKV-NH₂) was employed as a nano-scale template for the organization of 2nm gold particles. This peptide self assembles into a laminated fibrillar morphology in solution and has a periodic nanostructure consisting of alternating hydrophobic and hydrophilic layers with a lateral periodicity of 2.5 nm. Negatively charged gold nanoparticles are templated into the positively charged lysine layer through electrostatic interaction and are aligned within the template that itself swells to a periodic spacing of 4.0 nm in order to accommodate the particles. These 1D nanoparticle arrays have potential applications in fields like nano-electronics, and we are currently attempting to create arrays of quantum dots and hetero-structures of metal and semiconductor particles.

9:00AM A22.00006 Study of Alkanethiol Self-Assembled Structure Grown on Silver, LIANG HU, ZISHU ZHANG, MIKHAEL YU, EFREMOV, ERIC A. OLSON, MING ZHANG, LITO DE LA RAMA, LESLIE H. ALLEN, Department of Materials Science and Engineering, University of Illinois at Urbana-Champaign — Alkanethiol self-assembled structures grown on surface-supported Ag clusters (3D) are studied by measuring heat capacity with nanocalorimeter at high scanning rate (40,000 K/s), and compared with the self-assembled monolayer (SAMs) grown on planar Ag surface (2D). There is more amount of alkanethiol assembled on 3D Ag clusters compared with 2D SAMs, and the melting transition occurs at a higher temperature with sharper melting peak. This is due to the formation of layered Ag-alkanethiolate structure demonstrated by X-ray diffraction. IR spectrum indicates this self-assembled structure has a high degree of conformational order.

9:12AM A22.00007 Ordered Inorganic/Organic Composites via Novel Templates and Techniques, JAMES WATKINS, University of Massachusetts — The fabrication of well ordered nanocomposite materials offers new opportunities for device applications. Recently we reported that nanostructured templates with sub-10 nm domains can be easily obtained through the blending of disordered polymer surfactants containing poly(ethylene oxide) as the hydrophilic block with homopolymers including poly (acrylic acid), poly (4-vinyl phenol) and poly (stylene sulfonate) that selectively associate with the PEO block through hydrogen bonding. These inexpensive blends are strongly segregated, yielding well ordered domains. Moreover, the functionalities imparted by the homopolymers provide convenient handles for binding active materials such as nanoparticles and for promoting in situ, phase selective reactions to produce hierarchical metal oxide polymer composites. The behavior of the template systems and their use for the fabrication of well ordered polymer/nanoparticle, metal/oxide polymer, and metal oxide/polymer/nanoparticle composites using aqueous routes or via the 3-D replication of the template structure in supercritical fluids will be discussed.

9:48AM A22.00008 Two-Dimensional Confinement of Nanorods in Block Copolymer Domains, YU LIU, RANJAN DESHMIKH, RUSSELL COMPOSTO, University of Pennsylvania, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING TEAM — To control their unique electrical and optical properties, one-dimensional metallic-semiconductor nanoparticles need to be aligned and assembled within a host material. In our research, we investigated the assembly of gold nanorods (NRs) in films of a symmetric diblock copolymer, poly(styrene-b-methyl methacrylate), PS-b-PMMA (211kg/mol). The NR length and diameter was 42nm and 13nm, respectively. The NRs were grafted with a short PEG-brush (5kg/mol). During solvent annealing, the NRs become oriented as the PS-b-PMMA chains assemble into a parallel lamellar morphology. The NRs are selectively sequenced and confined in the PMMA domains, which are narrower than the NR length, due to the favorable interaction between the PEG brush and PMMA block. This confinement orients 71% of NRs within ± 5° of the lamella plane. This route to produce alternating layers containing conducting NRs separated by dielectric domains has the potential for fabricating self-assembled nanodevices. The thermal stability of the NRs in PS-b-PMMA and homo PMMA films will also be discussed.

10:00AM A22.00009 Surfactant Directed Assembly of ZnS Nanocrystals, YOU LI, CYRUS SAFINYA, JACOB ISRAELACHVILI, University of California Santa Barbara, NATALY BELMAN, YUVAL GOLAN, Ben Gurion University of the Negev, Israel — Post-synthesis assembly of nanocrystals into ordered two- and three-dimensional super-structures is an important step in many technological applications. A method was developed to use chain-crystalline surfactants to link nanocrystals into 2D and 3D assemblies with precise control of inter-particle distances as well as crystallographic orientation of the nanocrystals. X-ray diffraction and transmission electron microscopy data revealed that ZnS nanocrystals synthesized in octadecylamine (ODA) self-assemble into a highly ordered structure composed of stacked sheets with in-plane 2D-crystalline order. The unit cell of the nanocrystal superlattice (including type and dimensions) is directly related to the crystal structure of the pure surfactant, and thus can be tuned predictably by varying the surfactant chain length. This method can be used to assemble a broad range of nanocrystals and particles (Work supported by ONR N00014-05-1-0540, DOE DE-FG02-00ER46314, NSF DMR-0619171 and BSF 2002059).
10:12AM A22.00010 End-functionalized triblock copolymers as a robust template for assembly of nanoparticles1, RASTKO SKNEPNEK, JOSHUA ANDERSON, MONICA LAMM, JOERG SCHMALIAN, ALEX TRAVESSET, Iowa State University and Ames Lab — Polymers with attached end groups with specific affinity for nanoparticles, i.e., functionalized polymers, are shown to provide a robust templating strategy, where the aggregated nanoparticles follow the mesoscopic order imposed by the polymeric matrix. In this talk, we will present a detailed investigation of triblock polymer templating as a function of both nanoparticle size and concentration. Next to phases such as hexagons or gyroids, regularly observed in copolymer solutions and melts, we find a novel square columnar phase of two interpenetrating line-lattices of micellar cylinders and aligned nanoparticles. We argue that this phase is a realization of the packing problem of binary mixtures of disks. Our study suggests that nanoparticle templating with functionalized block copolymers can provide a simple and efficient tool for assembling novel materials with nanometer scale resolution.

10:24AM A22.00011 Nanoparticle Ordering in Diblock Copolymer-based Supramolecular Systems, THOMAS SCHILLING, UC Berkeley, MSE, TING XU, UC Berkeley, MSE & Chemistry, SHIH-HUANG TUNG, UC Berkeley, MSE, YUE WU, UC Berkeley, Chemistry — A well-controlled nanoparticle dispersion within a polymer matrix can have a significant impact on a wide range of material properties. A simple, efficient strategy to direct nanoparticle assembly within nanoscopic domains has been developed. Cadmium selenide (CdSe) nanoparticles were directly blended with diblock copolymer-based supramolecules wherein small molecules were attached to the side chain of one block via hydrogen-bonding. Co-assembly of nanoparticle and supramolecule were examined using SAXS and TEM, confirming fine orderning of the nanoparticles. The influence of nanoparticle concentration on supramolecule microphase separation and nanoparticle ordering was studied. Various functionalities should be readily incorportable into these systems by simply varying the nanoparticle type. The hierarchical assembly of supramolecule and nanoparticles presents many new opportunities for the fabrication of functional nanodevices.

10:36AM A22.00012 The metal insulator transition in self-assembled gold nanoparticle wires, M. E. REEVES, JIANWEI SUN, George Washington University, J. A. HOFFMANN, Applied Physics Laboratory, JASPER NIJDAM, George Washington University, QUEBRE TESSEMA, National Science Foundation, GWU/NP COLLABORATION — We report the temperature dependence of wires assembled from spherical nanoparticles by a relatively new technique, vertical colloidal deposition. This is a simple, one-step method for assembling spherical nanoparticles into wires without the need for lithographic templating. It is effective for a variety of conducting and nonconducting nanoparticles and substrates, and the only material requirement is that the nanoparticles be placed in a colloidal suspension that is wettable on the desired substrate. The shape of the meniscus defines the wire’s geometry, and we report the synthesis and physical properties of wires several millimeters long by a few micrometers wide. When wires are formed from 12 nm gold nanoparticles, they exhibit a weak metallic temperature dependence. Those assembled from 6 nm nanoparticles show activated behavior. Post-processing also affects the conductivity of the nanoparticle wires, such as when they are intercalated with proteins or other short organic molecules. Evidence for the metal insulator transition in these materials will be presented and discussed.

10:48AM A22.00013 Effects of Electric-Magnetic Fields on Hybrid Excitons in a Semiconductor Quantum Dot Coated by an Organic Shell, QUE HUONG NGUYEN, Marshall University, One John Marshall Drive, Huntington WV 25701 — The effect of electric and magnetic fields on the hybrid exciton of an organic-coated semiconductor spherical quantum dot is considered. Due to dipole-dipole interaction at the semiconductor dot-organic shell interface, a strong mixing of the Wannier-Mott exciton in the quantum dot and the Frenkel exciton of the organic medium occurs, resulting in a new hybrid exciton having priorities of both kinds of excitons as large exciton radius and large oscillator strength. The hybrid excitons are as sensitive to external perturbation as Wannier-Mott excitons. We investigate the effect of mutual presence of electric and magnetic fields on the hybrid exciton of the isolated semiconductor quantum dot such as CdSe (core) clothed by an organic or glass coating for two configuration of fields when the electric and magnetic fields are parallel and orthogonal. The fields affect the eigenfunctions (by a Stark -effect distortion and by the magnetic field-induced distortion) and the Frenkel-Wannier coupling term. Upon the application of the magnetic and electric fields the coupling term between the two kinds of excitons increases. The most important feature of this system is by adjusting the magnetic field and electric field, one can tune the resonance between the two kinds of excitons to get different regions of mixing to obtain the expected high non-linearity.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A23 DMP GMAG: Focus Session: Manganites

8:00AM A23.00001 Sliding charge density wave in manganites, SUSAN COX, NHMFL, Los Alamos National Laboratory — Stripe and checkerboard phases appear in many metal oxide compounds, and are thought to be linked to exotic behaviour such as high temperature superconductivity and colossal magnetoresistance. It is therefore extremely important to understand the fundamental nature of such phases. The so-called stripe phase of the manganites has long been interpreted as the localisation of charge at atomic sites. Here, we present resistance measurements on La0.50Ca0.50MnO3 which strongly suggest that this state is in fact a prototypical charge density wave (CDW) which undergoes collective transport. Dramatic resistance hysteresis effects and broadband noise properties are observed, both of which are typical of sliding CDW systems. Moreover, the high levels of disorder typical of manganites result in behaviour similar to that of well-known disordered CDW materials. The CDW-type behaviour of the manganite superstructure suggests that unusual transport and structural properties do not require exotic physics, but could emerge when a well-understood phase (the CDW) coexists with disorder.

8:36AM A23.00002 Polaron dynamics in La0.7Ba0.3MnO3 and La0.7Sr0.3MnO3, Y. CHEN, University of Maryland and NCNR, B. G. UELAND, J. W. LYNN, NCNR, S. BARILO, Institute of Solid State and Semiconductor Physics, Belarus, Y. MUKOVSKI, R. PRIVEZENTSEV, Moscow Institute of Steel and Alloys, Russia — In the perovskite manganites La1−xAxBi0.5MnO3 (A = Sr and Ba), the spin, lattice, charge and orbital degrees of freedom are intimately coupled, leading to a rich phase diagram. La0.7Ca0.3MnO3 (LCMO) is a metallic ferromagnet at temperatures below Tc ~ 257 K and colossal magnetoresistivity is observed and associated with the formation of nanoscale polarons that develop at elevated temperatures with an ordering wave vector of ~ (1/4,1/4,0). As the paramagnetic-insulating state is entered, a purely elastic component to the structural polaron scattering signals the development of the correlated polaron glass phase in LCMO. We investigated the structure and dynamics of these polarons through and above the ferromagnetic-paramagnetic-insulating transition by neutron scattering on single crystals of La0.7Ba0.3MnO3 and La0.7Sr0.3MnO3. In contrast to LCMO, no static polaron correlations are observed, however, we find that dynamic polaron correlations exist. We have measured the energy and temperature dependence of the dynamic polaron correlations. The formation of the dynamic polarons is not directly related to Tc.

This research was supported by the U.S. Department of Energy-Basic Energy Science under contract no. DE-AC02-07CH11358.
8:48AM A23.00003 Composition Dependence of Polaron Formation and Dynamics in La$_{1-x}$Ca$_x$MnO$_3$.

B.G. UELAND, Y. CHEN, J.W. LYNN, NIST Center for Neutron Research, Gaithersburg MD 20899, Y.M. MUKOVSKII, R. PRIVEZENTSEV, Moscow Institute of Steel and Alloys, Moscow 117936, Russia — The colossal magneto resistive perovskites La$_{1-x}$Ca$_x$MnO$_3$ have generated much interest due to the intimate correlation between their magnetic and transport properties. It is well known that for the doping range 0.22<x<0.47 a transition from a paramagnetic insulating to a ferromagnetic metallic state occurs upon cooling below T$_C$~150-250 K, and experiments have shown that the transition between these states is closely tied to the formation of lattice polarons. Recent neutron scattering experiments have directly observed that these polarons freeze into a glassy state at T=T$_M$, which is responsible for the first order phase transition at this level of doping. While it has been proposed that this glass state occurs at x=0, its dependence on doping and temperature has yet to be fully mapped out. Here we present results from elastic and inelastic neutron scattering experiments performed on single crystal samples of these materials for x=0.15, 0.2, and 0.25, which have been undertaken to determine the influence of the boundary for the glass phase evolves with x. Preliminary results indicate that in the insulating state (x<0.22), no static polaron scattering is observed (in zero field), in contrast to the results for the metallic regime.

9:00AM A23.00004 Current-induced persistent ferromagnetic metallic state in an Fe-doped manganite. HIDEAKI SAKAI, YOSHINORI TOKURA, Department of Applied Physics, University of Tokyo — A persistent ferromagnetic metallic state has been observed to be induced by excitation of an electric current for a single crystal of 7% Fe-doped (La$_{0.5}$Pr$_{0.3}$)$_x$Ca$_{0.2}$MnO$_y$, a typical "relaxor ferromagnet" [1] with coexisting clusters of the ferromagnetic metal and charge-orbital-ordered insulator. According to the simultaneous measurement of the resistance and magnetization, the induced ferromagnetic state is likely to form a filamentary pathway, where the increase in magnetization is estimated to be ∼0.4 μ$_B$/Mn. Distinguishing the current heating effect, which tends to conversely decrease the ferromagnetic fraction, from the intrinsic effect, we have successfully demonstrated the reproducible switching of both the resistance and magnetization by changing the magnitudes of the applied voltages.

9:12AM A23.00005 Terahertz time domain spectroscopy of ordered and disordered half-doped manganites. K.R. MAVANI, M. NAGAI, H. YADA, K. TANAKA, D.S. RANA, I. KAWAYAMA, M. TONOUCHI, DEPARTMENT OF PHYSICS, KYOTO UNIVERSITY, JAPAN TEAM, INSTITUTE OF LASER ENGINEERING, OSAKA UNIVERSITY, JAPAN COLLABORATION — Terahertz (THz) time domain spectroscopic studies were carried out on Nd$_{0.5}$Ca$_{0.5}$MnO$_3$ and Nd$_{0.5}$Ca$_{0.48}$Ba$_{0.02}$MnO$_3$ (NCBMO) charge-ordered (CO) manganite thin films. Temperature dependent complex optical conductivity (σ = σ$_1 + i$σ$_2$) was studied to probe the cation disorder effects on low energy charge dynamics. The frequency dependent σ$_1$ suggests formation of charge-density-waves in these manganites. A induced doping induced disorder, as in the case of NCBMO, weakens the CO state. However, at THz frequency, there are subtle effects of disorder on low frequency charge density wave critical temperature (T$_C$) and superexchange coupling is studied using Monte Carlo simulations. In the absence of on-site disorder, the model has a second order phase transition from a paramagnetic insulating phase to a ferromagnetic metallic phase in the CMR regime. The CMR effect is found to be associated with short-range charge and spin correlations in the insulating phase. This clearly shows that the CMR effect arises from the competition between the ferromagnetic (ferromagnetic) and insulating (paramagnetic) phases. In addition, our magnetic and transport data appear to imply that the paramagnetic-ferromagnetic (which gives rise to the CMR) occurs at a somewhat higher temperature, suggesting that it does not correspond to a threshhold of percolation between metallic and insulating states. The σ$_1$ and σ$_2$, both increase with temperature and show a scaling relationship, σ$_1$<σ$_2$, that is consistent with similar result observed for (PrCaSr)MnO$_3$ manganite. 2 Mavani et al., Europhys. Lett. (in print). 3 Pimenove et al., Phys. Rev. B 73, 220407(R).

This work is supported by JSPS through 'Grant-in-Aid for Creative Scientific Research' and 'Grant-in-Aid for Young Scientists (start-up)'.

9:24AM A23.00006 High Magnetic Field Time-resolved Optical Study of Manganites. PAULA SAHANGAMU, SANHITA GHOSH, STEPHÉN MCGILL, National High Magnetic Field Laboratory, Florida State University, HAIDONG ZHOU, BEN CONNER, CHRISTOPHER WIEBE, Department of Physics and NHMFL, Florida State University — We study the effects of applied electric fields and large magnetic fields on the optical properties of La$_{1-x}$Ca$_x$MnO$_3$ (x=0.18) (LCMO) and Pr$_{1-x}$Ca$_x$MnO$_3$ (x=0.5) (PCMO) using time-resolved techniques. Our measurements are performed from 4 K to room temperature and in magnetic fields up to 31 T. The conductivity of the low-temperature ferromagnetic state in LCMO is altered by the application of an electric field and these electrically-induced changes are further modified in the presence of an applied magnetic field. We demonstrate that time-resolved optical methods are capable of capturing these mixed electronic and magnetic effects. In addition, we performed time-resolved Kerr effect measurements in PCMO in an attempt to gain further insight into the loss of strong charge/orbital ordering in the presence of large applied magnetic fields.

This work is supported by the NHMFL through an IHRP grant.

9:36AM A23.00007 Properties of Doped Magnesio Oxide and the Origin of Colossal Magneto-resistance. I. FELNER, I. NOWIK, D. ORGAD, M. I. TSINDLEKHT, Hebrew Univ, Israel, A. FRYDMAN, D. I. GOLOSOV, N. OSSI, Bar-Ilan Univ, Israel, Y. M. MUKOVSKII, Moscow State Steel and Alloys Inst, Russia — We report a series of magnetic and transport measurements on high-quality single crystal manganate samples in the colossal magnetoresistive (CMR) regime. A small iron doping allows also for a Mössbauer spectroscopy study, showing both an unusual line broadening within the ferromagnetic phase and a coexistance of ferro- and paramagnetic contributions in the critical region. The resistance peak (which gives rise to the CMR) occurs at a somewhat higher resistivity than the CMR regime, suggesting that it does not correspond to a threshold of percolation between metallic (ferromagnetic) and insulating (paramagnetic) phases. In addition, our magnetic and transport data appear to imply that the paramagnetic-ferromagnetic (Curie) transition and the metal-insulator transition (the resistivity maximum) are two distinct phenomena on their own right, with distinct (although probably interrelated) physical origins. We speculate that these results can be understood phenomenologically within the framework of a two-fluid model.

9:48AM A23.00008 Monte Carlo study of the one-orbital model for manganites in the CMR regime. RONG YU, Department of Physics, University of Tennessee, CENGIZ SEN, GONZALO ALVAREZ, ORNL, ELBIO DAGOTTO, Department of Physics, University of Tennessee and Condensed Matter Sciences Division, ORNL — The thermal phase transition in the one-orbital model for manganites with cooperative phonons and superexchange coupling is studied using Monte Carlo simulations. In the absence of on-site disorder, the model has a second order phase transition from a paramagnetic insulating phase to a ferromagnetic metallic phase in the CMR regime. The CMR effect is found to be associated with short-range charge and spin correlations in the insulating phase. This clearly shows that the CMR effect arises from the competition between the ferromagnetic and a charge-ordered competing states. Motivated by a recent STM experiment, we also studied the local density of states in this one-orbital model. We show how the experimental results can be understood within our model.

10:00AM A23.00009 A New Correlated Model of Colossal Magneto resistive Manganese Oxides. D.I. GOLOSOV, Bar-Ilan University, Israel — A new minimal model is proposed for the doped manganese oxides which exhibit colossal magnetoresistance (CMR), involving (in addition to the ionics) a broad spin-majority conduction band as well as nearly localised-spin-minority electron states. We outline the reasons to introduce this model, and discuss some of its properties. In particular, a mean field analysis yields an interaction-induced enhancement of the interband hybridisation and implies an emergence of a small energy scale, linked to the longitudinal spin dynamics, charge fluctuations, and presumably also to the carrier transport. We suggest that these conclusions merit further theoretical and experimental investigation in the context of the CMR manganates.
10:12 AM A23.00010 Combined Effect of Bond- and Potential-Disorder in Half-Doped Manganites, SANJEEV KUMAR, University of Twente and Leiden University, ARNO KAMPF, University of Augsburg — We analyze the effects of both bond- and potential-disorder in the vicinity of a first-order metal insulator transition in a two-band model for manganites using a real-space Monte Carlo method. Our results reveal a novel charge-ordered state coexisting with spin-glass behavior. We provide the basis for understanding the phase diagrams of half-doped manganites, and contrast the effects of bond- and potential-disorder and the combination of both.

10:24 AM A23.00011 Nanoscale ferromagnetism and doping effect in manganites, S. M. YOSHIDOME, Osaka Prefecture University, Y. HORIBE, Rutgers University, T. ASA K, Y. MATSUI, NIMS, K. TAKENAKA, Nagoya University — We investigated temperature variation of ferromagnetic (FM) microstructures in La$_{1-x}$Sr$_x$MnO$_3$ ($x=0.175$) by low-temperature Lorentz microscopy. Also, changes of the FM domain structures by substituting non-magnetic Al$^{3+}$ ion for Mn one were examined. We succeeded in observing changes of magnetic domain structures from large FM domains with the average width of 1μm to stripe-shaped FM ones with the 100nm width in the metallic phase. On the other hand, the insulator phase was found in La$_{1-x}$Sr$_x$Mn$_{1-y}$Al$_y$O$_3$ ($x=0.175$, $y=0.02$). We found that the insulating phase exhibits a characteristic bi-modal distribution of the FM domains, which is characterized as the coexisting state of distinct types of the FM domains; one is the stripe-shaped FM domains and the other is the plate-shaped one. This mixture of distinct types of the FM domains breaks the coexistence of the conductivity and results in the insulating character in La$_{1-x}$Sr$_x$Mn$_1$-$x$$_y$Al$_y$O$_3$ ($x=0.175$, $y=0.04$).

10:36 AM A23.00012 Multiple Metal-Insulator Transitions in LPCMO Wires, T.Z. WARD, S.H. LIANG, K. FUCHIGAMI, University of Tennessee and Oak Ridge National Laboratory, L.F. YIN, Oak Ridge National Laboratory, E. DAGGOTTO, E.W. PLUMMER, J. SENH, University of Tennessee and Oak Ridge National Laboratory — The two hottest areas of research in condensed matter physics are complexity and nanoscale physics. Interestingly, these two areas have little overlap as most of the nanophysics research work is conducted using “simple” materials of metals or semiconductors instead of complex materials such as transition metal oxides (TMOs). However, due to the strong electronic correlation, it is exactly the transition metal oxides that will most likely lead to observations of new phenomena under spatial confinement. In this work, spatially confined La$_{325}$Pr$_{233}$Ca$_{375}$Mn$_3$O$_7$ (LPCMO) is shown to exhibit never before seen transport properties which reveal a double metal-insulator transition. These findings shine new light on the processes at play in LPCMO, as we use this novel technique to probe the material.

1Research sponsored by the U. S. Department of Energy under contract DE-AC05-000R22725 with the Oak Ridge National Laboratory, managed by UT-Battelle, LLC

10:48 AM A23.00013 Ferromagnetic tendencies at the surface of AF/CO bulk manganites, SHuai DONG, Rong YU, Seiji YUNOKI, Elbio DAGGOTTO, Department of Physics and Astronomy, University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory — Previous investigations have shown that the surface of a ferromagnetic (FM) manganite has antiferromagnetic (AFM) tendencies. However, the development of ferromagnetism has been observed experimentally in some AFM charge-ordered (CO) manganites by reducing the grain size down to the nanoscale. Similar phenomena was also found in other nanosized CO oxides, such as La$_{1/3}$Sr$_{1/3}$FeO$_3$. To clarify these puzzling observations, using Monte Carlo techniques we studied the FM Kondo model, using open boundary conditions to simulate a surface. For some values of the couplings, the previously known tendency to an AFM outer shell was found for the case of a bulk FM state. But for other couplings, the opposite effect was observed: the existence of a FM layer at the surface of a AFM/CO material. Details will be provided in this presentation.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A24 DMP: Focus Session: Transport in Nanostructures I: STM and Atomic Control

8:00 AM A24.00001 Single electron tunneling measurements of Titanium Silicide islands on Si(100). J.L. TEDESCO, J.E. ROWE, North Carolina State University, R.J. NEMANICH, Arizona State University — Titanium silicide (TiSi$_2$) islands have been formed by the ultrahigh vacuum (UHV) deposition of thin films of titanium (< 1 nm) on clean Si(100) surfaces followed by annealing to ~800°C. Scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) have been performed on these islands to demonstrate single electron tunneling (SET). Evidence of Coulomb staircase peaks corresponding to SET has been identified in current-voltage (I-V) curves recorded from islands at room temperature. Predictions of the orthodox model were found to agree with our data, except for slight discrepancies of the shape of the I-V curves at current steps. Many islands that were expected to exhibit SET did not do so. Potential reasons for the absence of SET include Schottky barrier lowering due to Fermi level pinning, and interfacial faceting which was identified as the most likely reason for the absence of observable SET. The positive SET results establish that a Schottky barrier can be used as an effective tunnel junction in a future double barrier tunnel junction (DBTJ) device. Possible approaches to improve the reliability based on control and engineering of surface and interface electronic bands will be discussed.

8:12 AM A24.00002 Tunneling Spectroscopy of Ultrathin Insulating Films: CuN on Cu(100), Charles D. RUGGIERO, TaeYoung Choi, Jay A. GUPTA, The Ohio State University — Insulating films comprising only a few atomic layers offer insight into the evolution of electronic structure at the nanoscale and are useful for controlling electronic coupling of adsorbates. We have studied the electronic structure of one monolayer thick CuN islands grown on Cu(100) with a low temperature (5K), ultrahigh vacuum scanning tunneling microscope. We find that CuN acts as an insulator, with a band gap that exceeds 4 eV. Measurements of the tunneling barrier height and image potential states indicate that the CuN work function is ~0.9 eV larger than bare Cu. This suggests a significant surface dipole, consistent with charge transfer predicted by theory. We find no significant dependence of these results on CuN coverage, from small islands (~ 10 nm$^2$) to complete films. This suggests that collective electronic structure is already established in the smallest islands. We use the CuN films to decouple metal nanoclusters from the Cu surface electron density. Tunneling spectra of few-atom Nb clusters on CuN reveal an atomic resonance that is not observed for clusters on Cu. http://www.physics.ohio-state.edu/~jagupta

8:24AM A24.00003 STM studies of transport through single azobenzene molecules1. TAELYOUNG CHOI, JAY A. GUPTA, Department of Physics, Ohio State University — A microscopic understanding of electrical contact to molecules is needed to improve the performance and reproducibility of devices based on organic materials. We use a low-temperature scanning tunneling microscope to study current flow through single molecules where the contacts and local environment are characterized with atomic resolution. Azobenzene was adsorbed on a Cu(100) surface partially covered with one-monolayer thick islands of CuN, an insulator with a bandgap exceeding 4 eV. Peaks in tunneling spectra attributed to molecular orbitals are observed for molecules on CuN, but not on Cu. This is consistent with the decrease in hybridization expected for adsorbates on insulating films. Current flow through azobenzene molecules which bridge Cu and CuN regions is highly asymmetric with bias voltage, suggestive of rectifying behavior. Atomically precise contacts can be made to the molecules by using the STM tip to manipulate nearby metal atoms. Spectroscopic imaging is used to monitor changes in molecular orbitals due to charge transfer to molecule and contacts.

1Supported by NSF CAREER (DMR-0645451)

8:36AM A24.00004 An atomic switch of electron propagation on Ge (001) by tunneling carrier injection. FUMIO KOMORI, Institute for Solid State Physics, The University of Tokyo — Reversible switching of electronic conduction through atom manipulation is one of the important subjects of nanoscience. However, different conducting pathways were not clearly observed with atomic resolution. We have demonstrated the correlation between the change of surface atomic position by tunneling carrier injection and that of the reflection of one-dimensional (1D) surface-state electrons on the Ge (001) surface with a low density of atomic Sn-Ge dimers.

[1] On the clean Ge(001) surface, two adjacent atoms form a buckled dimer, and the buckling orientation of the Ge dimer can be locally and reversibly controlled by carrier injection to the surface from the STM tip.

[2] The unoccupied surface π*-electron behaves like a 1D free electron along the Ge dimer row. When Sn atoms are deposited on the clean Ge(001) surface at room temperature, buckled dimers originating from the Sn atoms are formed at the Ge dimer position in the surface. [3] An atomic switch is realized for the π*-electrons in the Ge dimer row direction by injection carriers to reversibly flip the buckling orientation of a single Sn-Ge dimer in the dimer row. When the Sn atom of the heterogeneous dimer is at the lower position, the 1D electrons are reflected and a standing wave of this state is observed. Whereas, when it is at the upper position, the 1D electrons pass through the heterogeneous dimer, and no standing wave is observed. In this state, the lower atom of the dimer is Ge, and the π* state at the dimer is little different from that of the Ge-Ge dimers.

9:12AM A24.00005 Quantum Channels and Conductance Oscillations in TiOx Nano-switches. FENG MIAO, Department of Physics and Astronomy, University of California, Riverside; J. JOSHUA YANG, DUNCAN R. STEWART, R. STANLEY WILLIAMS, HP labs, Palo Alto, CHUN NING LAU, Department of Physics and Astronomy, University of California, Riverside — We investigate conductance switching in Pt/TiOx/Pt devices by pressure-modulated conductance microscopy. For devices with conductance G > GQ, and G < GQ, where GQ is the conductance quantum, localized pressure-induced conductance peaks are observed, indicating formation of nanoscale conductance pathways on the electrodes. We postulate that these nano-conducting channels are related to the drift of oxygen vacancies under electrical field. For devices with G > 1-2 GQ, in addition of conductance peaks, we also observed conductance dips and oscillations in response to localized pressure. These results suggest formation of quantum conductance channels in our devices, and can be modeled by considering interfering electron waves between two partially transmitting electrodes. Our findings suggest the possible use of these devices as atomic-scale switches.

9:24AM A24.00006 Electronic switching in nanoscale titanium oxide devices, DUNCAN STEWART, Hewlett-Packard Laboratories, Palo Alto, CA USA, J. JOSHUA YANG, JULIEN BORGHETTI, DOUGLAS OHLBERG, MATTHEW PICKETT, FENG MIAO, R. STANLEY WILLIAMS — Titanium metal is widely used as a top metal contact for nanoscale molecular electronic devices, where it has been assumed to form a few-atom-thick Ti carbide overlayer. Using a vacuum delamination technique we expose and analyze chemically pristine buried titanium/organic monolayer interfaces from devices that have displayed ‘molecular electronic switching’. We establish that under many conditions the titanium instead forms a few-nanometer-thick Ti carbide overlayer. Using a vacuum delamination technique we expose and analyze chemically pristine buried titanium/organic monolayer interfaces from devices that have displayed ‘molecular electronic switching’. We establish that under many conditions the titanium instead forms a few-nanometer-thick Ti carbide overlayer.

9:36AM A24.00007 Electron transport simulations through organic adlayers on metal surfaces1, MANUEL COBIAN, ICMAB - CSIC, NICOLAS LORENTE, PABLO ORDEJON, CIN2 - CSIC — Molecular entities at the interface with an inorganic surface are the basis for new hybrid functional materials for microelectronics. In most cases, strong bonding of molecules to metal surfaces perturbs the discrete molecular energy levels leading to a broadening of the molecular density of states. Deposition of C60 on a Au(111) surface previously exposed to tetraphenyladamantane give rises to a nanostructured organic layer where the electronic coupling between the C60 and the Au(111) surface is significantly reduced compared to C60 on a clean Au(111) surface. Calculations based on Density Functional Theory reveal that intermolecular interactions lock C60 into a particular orientation in agreement with Scanning Tunneling Microscopy experiments. This system exhibits the presence of negative differential resistance which can be understood by simulations of the transport properties at the ab-initio level using TRANSIESTA.

9:48AM A24.00008 Scanning tunneling spectroscopy (STS) of DNA and G4-DNA molecules1, DANNY PORATH, Physical Chemistry Department and Center for Nanoscience and Nanotechnology, The Hebrew University, Jerusalem 91904, Israel, ERREZ SHAPIR, HEZY COHEN, Hebrew University, Israel, ALEXANDER KOTLYAR, Tel Aviv University, Israel, ROSA DI FELICE, INFM-CNR, Modena, Italy — Attempts to resolve the energy level structure of single DNA molecules by STS span over the last two decades, thanks to this technique ability to probe the local density of states of objects deposited on a surface. Success was hindered by extreme technical difficulties in stable deposition and reproducibility. By using STS at 78 °K, for the first time we disclose the energy spectrum of poly(G)-poly(C) DNA molecules deposited on gold. The tunneling current-voltage characteristics and their derivative curves exhibit a clear gap and a peak structure around the gap. By means of ab initio Density Functional Theory calculations the character of the observed peaks is consistent to orbitals originating from the different molecular components. Limited fluctuations in the I-V curves are observed and statistically characterized.

1Funding was provided by the EC through contracts IST-2001-38951 (“DNA-Based Nanowires”) and FP6-029192 (“DNA-Based Nanodevices”).
10:00AM A24.00009 Microscopic Characterization of Organic/Metal Interfaces: a Combined DFT and Many-Body Perturbation Theory Study , YAN LI, DEYU LU, GIULIA GALLI, University of California, Davis — Aromatic molecules and molecular assemblies have received widespread attention as possible components of molecular electronic devices. An essential prerequisite to understand their stability and transport properties is the microscopic characterization of the interface formed with metallic leads. We present a comprehensive, first-principles study of the interface of Au(111) and a representative aromatic isocyanide molecular SAM (phenylenediisocyanide). We provide predictions about the binding geometries, coverage and stability properties, which are in good agreement with experimental measurements. We also discuss the electronic properties of the organic/metal interface by including self-energy corrections through many-body perturbation theory (GWA), and surface polarization effects. Our results indicate that electronic structure calculations beyond DFT are required to make an accurate assessment of energy level alignments between SAMs and the metallic leads.

10:12AM A24.00010 Scanning tunneling spectroscopy of mass selected Ag clusters on C_{60} functionalized surfaces1 , HEINZ HÖVEL, STEFANIE DUFFE, LUKAS PATRYARCHA, Technische Universität Dortmund, Experimentelle Physik I, Germany, CHUNRONG YIN, BERND VON ISSENDORFF, Universität Freiburg, Fakultät fuer Physik, Germany, MICHAEL MOSELER, Fraunhofer-Institut fuer Werkstoffmechanik IWM, Freiburg, Germany — Scanning tunneling spectroscopy (STS), which can be used to study the electronic properties of individual clusters on surfaces [1] is combined with the deposition of mass selected Ag clusters (from Ag_{95}^{+} to Ag_{56}^{+}). A functionalization of the substrate with C_{60} layers proved to be very useful to ensure the soft landing of the clusters and to bind them to fixed positions on the surface [2]. The knowledge of the exact cluster size shows that one has to interpret the STS derived cluster height carefully, considering details of the STM imaging process. For the soft landed clusters we measured identical spectral features for individual clusters with the same selected size using STS at 5 K.

1Work supported by the Deutsche Forschungsgemeinschaft (SPP 1153)

10:24AM A24.00011 Rectification in Porphyrin/Fullerene Dyads on Au(111)*, DOMINIC BRITTI, RAY PHANEUF, University of Maryland, FRANCESCA MATINO, VALENTINA ARIMA, MANUEL PIAZENZA, FABIO DELLA SALA, GIUSEPPE MARUCCIO, NNL Lecce, Italy, ROBERTA DEL SOLE1, GIUSEPPE MELE, GIUSEPPE VASAPOLLO, Universita del Salento, Italy, ROBERTO CINGOLANI, ROSS RINALDI, NNL Lecce, Italy — We present an ultrahigh vacuum scanning tunneling microscopy (UHV-STM) and scanning tunneling spectroscopy study of ex-situ self assembled supramolecular dyads, consisting of fulleropyrrolidines (PyC_{2}C_{60}) axially ligated to zinc(II) tetraphenylporphyrin (ZnTPP), self organized by axial ligation to a 4-aminophenol (4-ATP), self assembled monolayer on gold (111). By highly diluting the PyC_{2}C_{60} solution, and subsequently annealing in vacuum, isolated dyads are obtained; these show both bias polarity-dependent apparent height in STM images, and highly rectifying behaviour in tunneling spectroscopy. First principles density functional theory calculations clarify the conformational and the electronic properties of the 4-ATP/ZnTPP/PyC_{2}C_{60} system. The rectifying behavior is explained using a model based on the Aviram-Ratner mechanism. * Work supported by the CNR-INFM, by a NSF US-Italy Cooperative Research Program #OISE-0242579, by the SpiDME European project and by MIUR FIRB 2003 ‘SYNERGY’ grant. 10:36AM A24.00012 Electron transport study of surface-supported nanostructures with a quadruprobe scanning tunneling microscope1 , TAE-HWAN KIM, JOHN WENDELKEN, AN-PING LI, Oak Ridge National Laboratory — We report the study of the electron transport and structural properties of nanostructured materials with a low temperature quadruprobe scanning tunneling microscope (STM) system. Self-assembled nanostructures including epitaxially grown nanowires and atomic chains have been fabricated by doping with small amounts of metal atoms (Au, Gd, Y, Ag) on a Si surface. The local electronic states and transport properties have been characterized in situ. This research took the advantage of our recent development of the quadruprobe STM system. As a "nano" version of a four-probe station, the quadruprobe STM system provides an integrated research platform with a low temperature four-probe STM, a molecular-beam epitaxy growth chamber, a high resolution scanning tunneling microscope, and a scanning Auger microscope. The four STM probes can be driven independently with sub-nanometer precision, enabling conventional STM imaging and four-point electrical transport study of surface electronic systems and nanostructured materials at temperatures down to 10 K.

surface of the film. The surface tension obtained from static grazing incidence scattering data shows that a PDMS layer segregates to the free angle, the surface dynamics and the micelle dynamics were selectively measured. The obtained viscosity will be compared with the value from the mechanical copolymers films used in this study have an internal structure of spherical micelles. This ought to have a strong influence on the physical properties of the
ZHANG JIANG, SUNIL K. SINHA, Dept. of Physics, University of California San Diego, A. RUEHM, Max Planck Institute for Metals Research, Stuttgart, HEEJU LEE, YOUNG JOO LEE, SANGHOON SONG, Dept. of Physics & Interdisciplinary Program of Intergrated Biotechnology, Sogang University, Korea, consider an ideal two-dimensional system, the creation of various structures using laser lithography provides an excellent probe for studying instabilities in two instability, which results in the breaking up of an extended cylinder into an arrangement of smaller, evenly spaced droplets. Since our diblock system can be films allows us to produce structures far smaller than those imposed by the resolution of the laser patterning procedure. An example of this is the Plateau-Rayleigh Brockhouse Institute for Materials Research, McMaster University — We have developed a novel surface tension-driven laser lithography technique that enables 8:00AM A25.00001 Control of P(S-b-PMMA) Orientation on Organosilicate Substrates by Thermal Treatment, KOOKHEON CHAR, HYOSEON SUH, Seoul National University — One of most important factors to control the orientation of microdomains in block copolymer films is the wetting behavior of a block copolymer at an interface. From this perspective, we studied the wetting behavior of P(S-b- MMA) block copolymer (BCP) thin films on silesquioxane-based organosilicate (OS) substrates, which have potential applications as interlayer dielectrics (ILDs) for next generation semiconductor devices. We controlled the surface energy of OS substrates by changing the treatment temperature. As the treatment temperature was increased, the wetting behavior of a P(S-b-MMA) film on OS substrates changed from the asymmetric to the symmetric wetting, which allowed us to find the optimum treatment temperature for the neutral wetting behavior. Changes in the orientation of BCP microdomains on OS substrates were analyzed by AFM, FE-SEM, and GI-SAXS. These results show the potential that the OS ILDs prepared in this study do not require any additional surface modifications such as random copolymer brushes or SAMs for BCP microdomains to orient perpendicular to the substrate, which could ultimately be applied to BCP lithography.

8:12AM A25.00002 Functionalization of PEO Nanocylinder Array Structure in Block Copolymer Thin Film, KAORI KAMATA, JST-PRESTO, TOMOKAZU IYODA, Tokyo Institute of Technology — Phase-separated nanostructure of block copolymer has been intensively studied as one of the most promising candidates for many important nanotechnological applications, because the feature size of domain structure generated by block copolymers is ranging to a level of several nanometers. We have studied the nanostructures of block copolymers, which are based on the use of amphiphilic block copolymer, PEO-b-PMA(Az), to establish the long range orderness onto the substrate. Here, we describe the nanotemplating process with domain selective doping of PEO cylindrical domains, using various kinds of metal cation sources, such as Fe or Pb ions. Furthermore, the ionic liquid also hybridized into the PEO nanocylinders to form liquid nanochannels perpendicular to the substrate. A wide variety of cations were successfully incorporated through the coordination bonding with the oxygen in PEO chain. The resulting metal cation hybrid films could offer the metallic nanopillar arrays, with the nanostructure-specific electrochemical, electric or magnetic properties.

8:24AM A25.00003 Block copolymer mask with cylindrical nanochannels for wet nanopatterning on silicon wafer, RYOKO WATANABE, KAORI KAMATA, TOMOKAZU IYODA, Division of Integrated Molecular Engineering, Chem. Res. Lab., Tokyo Institute of Technology — Microphase-separated structure of block copolymer (BC) thin films has been considered as a mass-productive nanomask, in which the periodicity of the pattern can be tuned by molecular weight. We have developed a series of amphiphilic BC, PEO<sub>n</sub>-b-PMA(Az)<sub>m</sub>, consisting of hydrophilic, ion-conductive poly(ethylene oxide) (PEO) and hydrophobic poly(methacrylate) with azobenzene in its side chain. This BC forms hexagonally arranged PEO cylinders which span across the thickness of the film after thermal annealing. In this study, PEO cylinders were blended with poly(ethylene glycol) monomethylether to provide effective nanochannel that can perpendicularly diffuse etching species for wet etching of silicon wafer. As a quick and total wet nanopatterning process, a silicon wafer covered by the BC mask was annealed at 140 degrees C for 1 h and immersed into 33 wt.% NH<sub>4</sub>F aqueous solution for 3 min. AFM observation of the resulting silicon wafer surface revealed a hexagonally arranged nanohole array with 24 nm of center-to-center distance and 10 nm of diameter was fabricated.

8:36AM A25.00004 Is a short fluorinated segment sufficient to induce interfacial rearrangements in diblock co-polymers?, UMESH SHRESTHA, DVORA PERAHIA, Clemson University, STEPHAN CLARSON, University of Cincinnati — The interfacial structure of thin diblock co-polymer films is a result of internal segregation between the blocks and their affinity to the interfaces. Introducing a fluorinated group affects significantly the segregation of the fluorinated block to the interface. The interfacial structure and dynamics of thin layers of a diblock co-polymer Polytetrafluoro propyl methyl siloxane-polystyrene (PTEPMS-PS) with the fraction of the fluorinated block ranging from 0.03 to 0.5 was studied by neutron reflectivity. The uniqueness of this diblock lies in the presence siloxane group and a fluorinated group intercalated into one of the where the siloxane offers flexibility and the fluorine exhibits low interfacial energies. While the air interface is dominated by fluorinated segments for all volume fractions, layering is observed even for the shortest fluorinated segments. The rate of rearrangement upon annealing varies with the size of the fluorinated block.

8:48AM A25.00005 Multi-block copolymers in thin films, PANAGIOTIS MANIADIS, EDWARD KOBER, TURAB LOOKMAN, Los Alamos National Laboratory, Los Alamos NM — We study the behavior of an {AB}, multi-block copolymer confined to a thin film, using self consistent field theory (SCFT) methods. Due to the breaking of symmetry in the direction of confinement, the propagators do not obey the usual diffusion equation. We derive the diffusion equation which correctly describes the confined polymer system and find that it differs from the original in an area which is approximately 3 times the Kuhn length of the polymer, close to the surface of the film. We use the modified diffusion equation to study the structure of the confined polymer.

9:00AM A25.00006 Two-Dimensional Instabilities in Patterned Diblock Copolymer Films, JOSEPH PARETE, Department of Engineering Physics and the Brockhouse Institute for Materials Research, McMaster University, ANDREW B. CROLL, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, JOHN S. PRESTON, Department of Engineering Physics and the Brockhouse Institute for Materials Research, McMaster University, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — We have developed a novel surface tension-driven laser lithography technique that enables the effective generation of microstructures in polymer systems. Combining this approach with naturally occurring instabilities in symmetric diblock copolymer films allows us to produce structures far smaller than those imposed by the resolution of the laser patterning procedure. An example of this is the Plateau-Rayleigh instability, which results in the breaking up of an extended cylinder into an arrangement of smaller, evenly spaced droplets. Since our diblock system can be considered an ideal two-dimensional system, the creation of various structures using laser lithography provides an excellent probe for studying instabilities in two dimensions. Optical and atomic force microscope measurements are presented and discussed in terms of a linear stability analysis.

9:12AM A25.00007 Structure and dynamics of block copolymer films by XPCS, HYUNJUNG KIM, HEEJU LEE, YOUNG JOO LEE, SANGHOON SONG, Dept. of Physics & Interdisciplinary Program of Intergrated Biotechnology, Sogang University, Korea, ZHANG JIANG, SUNIL K. SINHA, Dept. of Physics, University of California San Diego, A. RUEHM, Max Planck Institute for Metals Research, Stuttgart, Germany — We have measured the structure and the dynamics of block copolymer films in the melt using X-ray Photon Correlation Spectroscopy. Block-copolymers films used in this study have an internal structure of spherical micelles. This ought to have a strong influence on the physical properties of the thin films. The results from the surface dynamics are compared with the theory of overdamped thermal capillary waves on thin films. By changing the incident angle, the surface dynamics and the micelle dynamics were selectively measured. The obtained viscosity will be compared with the value from the mechanical measurement of the bulk material. The surface tension obtained from static grazing incidence scattering data shows that a PDMS layer segregates to the free surface of the film.

9:24AM A25.00008 Sphere-Forming and Cylinder-Forming Block Copolymer Thin Films Aligned Under Double Shear. ANDREW MARENIC, RICHARD REGISTER, Princeton University, PAUL CHAIKIN, New York University — Studies have shown that stress transmitted through a viscous layer to a sphere- or cylinder-forming block copolymer thin film can orient the microdomains in the direction of the imposed shear. For the creation of complex patterns, reorientation of these unidirectionally oriented films is necessary. Here we demonstrate the ability of shear to realign the microdomains along a second direction, as imaged by atomic-force microscopy. The results are in qualitative agreement with our previously proposed phenomenological model; however, the stress required for realignment is larger (factor of 2.7 for sphere-formers and factor of 1.2 for cylinder-formers) than the stress required to orient a film from the polycrystalline state. We also observed grain boundary generation within the transition region between alignment with the first shear direction and alignment with the second shear direction. No noticeable change in the dislocation density or its angular distribution was observed in the sphere-forming block copolymer thin films following the second shear.

9:36AM A25.00009 Rapid Directed Assembly of Block Copolymer Films on chemically patterned surfaces at Elevated Temperatures. ADAM WELANDER, PAUL NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin, Madison — We report on the rapid directed assembly of poly(styrene-b-methyl methacrylate) (PS-b-PMMA) block copolymer thin films at elevated temperatures well above the glass transition temperature ($T_g$) on chemically patterned surfaces. The time needed for defect free assembly, where the chemical pattern ($L_S$) closely matches the natural length of the block copolymer ($L_0$), is strongly dependent on the annealing temperature. Annealing times range from 150 minutes at 180 °C to 3 minutes at 230 °C. This system behavior is well described as a simple thermally activated process with an apparent activation energy ($\Delta E_a$) of 182 kJ/mol and a polymer diffusion coefficient of 7.5E-15 cm²/s⁻¹ at 190 °C. Modeling this behavior predicts annealing times of 13.5 seconds at 250 °C and 1.9 seconds at 280 °C. While these times are difficult to investigate experimentally, a one minute anneal at these elevated temperatures not only shows perfect assembly where $L_S = L_0$, but also where $L_S < L_0$.

9:48AM A25.00010 Precise Control of 3-dimensional Block Copolymer Assembly using 2-dimensional Chemical Templates. SANGCHEOL KIM, Polymers Division, NIST/Dept. of Materials Science and Engineering, University of Maryland, HAE-JEONG LEE, RONALD L. JONES, ALAMGIR KARIM, Polymers Division, NIST, R.M. BRIBER, Dept. of Materials Science and Engineering, University of Maryland, HQ-CHEML KIM, Almaden Research Center, IBM — Chemically heterogeneous substrates, where the periodicities of the chemical pattern are close to those of lamellae microdomains of block copolymers, have been used as an effective route to align the microdomains with a low number density of defects. Macroscopic chemical heterogeneity is, however, still valuable for providing insights on ordering behavior of block copolymers. Using a series of chemical patterns with micrometers length scales, we studied the wetting and self-assembly behavior of poly(styrene-b-methyl methacrylate) (PS-b-PMMA). We found that the variation in morphology and orientation of microdomains are governed by the degree of chemical contrast and the size of the underlying chemical patterns. The two-dimensional chemical template is shown to precisely control the three dimensional assembly of the block copolymer film.

10:00AM A25.00011 Novel Complex Nanostructures from Directed Assembly of Block Copolymers on Incommensurate Surface Patterns. SANG OK KIM, BONG HOON KIM, Materials Science and Engineering, KAIST, South Korea, HARUN H. SOLAK, Paul Scherrer Institute, Switzerland, DONG MENG, QIANG WANG, Chemical and Biological Engineering, Colorado State University, USA — Self-assembled nanostructures of block copolymer thin films have attracted enormous attention as useful templates for nanofabrication. We present that a chemically nanopatterned surface prepared by photolithography is able to direct the assembly of a block copolymer thin film to form a novel complex nanostructure. When a cylindrical block copolymer was assembled on a stripe pattern, whose pattern period was twice as large as a natural lattice size of the bulk nanostructure, a new structure was produced, where cylinders were alternately oriented parallel and perpendicular to the surface. Self-consistent field calculations supported the emergence of the new structure, providing insight into the detailed structure and formation mechanism. Our work suggests that the combining top-down and bottom-up approaches may provide a versatile pathway for fabricating well-registered complex nanostructures, potentially useful in diverse advanced applications. 10:12AM A25.00012 Templated Self-Assembly of Asymmetric Ternary Blends of Block Copolymers and Homopolymers1. KARL STUEN, FRANCOIS DETCHEVERRY, CARLA THOMAS, Univ. of Wisc. - Madison Dept. of Chem. and Biol. Eng., RICHARD FARRELL, CRANN, Dept. Chem. Univ. Coll. Cork, Tyndall Nat. Inst., IRELAND, MICHAEL MORRIS, CRANN, Dept. Chem. Univ. Coll. Cork, Ireland, JUAN DE PAULO, PAUL NEALEY, Univ. of Wisc. Madison Dept. of Chem. and Biol. Eng. — Template assembly of ternary blends of cylinder-forming PS-block-PMMA and homopolymers of PS and PMMA was investigated experimentally and with Monte Carlo simulations of a coarse-grained model. The blends were deposited into trench features coated with a neutral brush to induce cylinder orientation perpendicular to the substrate. The ternary blends were used to systematically control the commensurability between the blend and trenches of constant width. Important patterning parameters such as the degree of perfection, the domain spacing perpendicular and parallel to the confining template, the domain uniformity, and shape of the unit cell were quantified as a function of blend composition. The cylindrical nanostructures appear to have improved uniformity across the trench width compared with spherical systems.

10:24AM A25.00013 Directed Assembly of Asymmetric Ternary Block Copolymer-Homopolymer Blends Thin Films on Checkerboard Trimming Chemical Pattern. HUIMAN KANG, PAUL F. NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin, Madison, WI 53706 USA — Typical 2-dimensional projections of ordered block copolymer morphologies in thin films include periodic lines or hexagonal arrays of spots and therefore may not be suitable for patterning even strictly periodic device-oriented arrays, such as checkerboard trimming patterns (alternating lines and dashed lines) used in the fabrication of dynamic random access memory (DRAM). Here we direct the assembly of asymmetric ternary polystyrene-block-poly(methylmethacrylate) (PS-b-PMMA)/homopolymer PS/homopolymer PMMA blends on checkerboard trimming chemical patterns. The degree of perfection and domain uniformity of the assembled films was quantified as a function of overall composition of PS or PMMA and total homopolymer fraction in the blends. By matching polymer volume fractions and pattern area fractions, blends composed of lamellae-forming block copolymer and substantially asymmetric fractions of the two homopolymers could be assembled into equilibrated line and dash morphologies.
10:36AM A25.00014 Influence of added copolymers on thin film polymer blends studied by atomic force microscopy: surface morphology and dewetting. DEAN WALDOW, JENIFER HOFFERT, KRIS PETERSON, Pacific Lutheran University — Atomic force microscopy (AFM) was used to study thin film polymer blends of polystyrene (PS) and polybutadiene (PB). These blends were studied with increasing concentration of block, random, and graft copolymers. Thin films were prepared by spin coating from a good solvent, which resulted in film thicknesses of approximately 65 nm. The AFM data were collected in AC mode and included both topographic and phase data. The topography data were analyzed using lateral Fourier Transform analysis as well as real space techniques both lateral and normal to the surface. The results suggest that lateral phase separated domain size decreases with increasing copolymer concentration for each of additives studied and for all concentrations.

10:48AM A25.00015 Controlled Dimensions of Nanostructures in Asymmetric Ternary Blends of Block Copolymers and Homopolymers in Thin Films. CARLA THOMAS, KARL STUEN, - Madison Dept. of Chem. and Biol. Eng., NICOLÁF FERRIER, Univ. of Wisc. - Madison Dept. of Mech. Eng., PAUL NEALEY, Univ. of Wisc. - Madison Dept. of Chem. and Biol. Eng. — Ternary blends of cylinder-forming PS-block-PMMA and homopolymers of PS and PMMA were investigated in thin films on a neutral brush with the domains oriented perpendicular to the substrate. Five blends with homopolymers having different degrees of polymerization (N) were studied to quantify the dimensional scaling of the domains and suitability for patterning. In the dry brush regime, the best pattern uniformity and fewest defects were found when N of the homopolymers matched N of the corresponding block of the block copolymer. The lattice spacing of the cylindrical array, D, and cylinder diameter uniformity changed with φPS, the homopolymer volume fraction in the film, and N of the homopolymers. With the ternary blends, D could be increased up to 200 percent relative to the neat block copolymer; the ternary blends allow φPS greater than 0.4 without inducing a phase change.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A26 DCP: Focus Session: Photophysics of Cold Molecules I Morial Convention Center 218

8:00AM A26.00001 Isolation of Molecules in Helium Nanodroplets: Spectroscopy and Dynamics at Ultra-cold Temperatures , FRANK STIENKEMEIER, University of Freiburg — The isolation of atoms, molecules, clusters or nano-sized complexes in helium nanodroplets allows detailed spectroscopic studies at temperatures in the millikelvin range. Moreover, femtosecond real-time spectroscopy has been introduced to study dynamical processes in the ultracold helium environment. On the one hand, wave packet propagation opens a window to dynamical processes, allowing even a view to superfluid properties at the nanoscale. This is exemplified at decoherence effects in the wave packet propagation of small molecules attached to the droplets. On the other hand, high-resolution mass spectra using both femtosecond photoionisation (PI) as well as electron impact ionization enable us to characterize reactive processes at temperatures in the millikelvin range. As an example, alkali cluster – water complexes are formed in helium droplets. By recording multi-photon PI spectra we can distinguish between reactive processes of the neutral clusters and ionic reactions occurring after ionisation of the alkali cluster component. These studies pave the way to time-resolved reaction dynamics at very low temperatures.

8:36AM A26.00002 Nonequilibrium magnesium complexes formed in helium nanodroplets. JOSEF TIGGESBAUMKER, ANDREAS PRZYSTAWIK, SEBASTIAN GODE, KARL-HEINZ MEIWES-BROER, Institute of Physics, University of Rostock, 18051 Rostock, Germany — Doping helium droplets with alkaline earth atoms is an interesting tool to investigate the interaction with the superfluid helium. Magnesium is a corner case regarding the degree of solvation in helium [1,2] which may enable the detection of quantized vortices in helium droplets. In this contribution we add another facet to the discussion. The absorption of helium droplets doped with magnesium atoms is measured with resonant two-photon ionization at different concentrations of droplet size and the number of doped Mg atoms. This enables the unambiguous identification of the absorption of an isolated atom inside the droplet centered around 279 nm. When increasing the Mg content of the droplet we find evidence for the formation of metastable, weakly bound Mg complexes. After excitation of such a complex it collapses to a Mg cluster on a timescale of 20 ps.

8:48AM A26.00003 Superfluid ⁴He density functional theory in 2-D cylindrical coordinates. JUSSI ELORANTA, SEAN FRENCH, Department of Chemistry and Biochemistry, California State University at Northridge, STEVEN FIEDLER, Department of Chemical Engineering, The University of Michigan — Bosonic density functional theory describing superfluid ⁴He is formulated in 2-D cylindrical coordinates and a numerical implementation of the model using a regular spatial grid basis is presented. The 2-D formulation has many important applications as the 1-D treatment cannot, for example, describe translational motion of atoms and molecules solvated in the liquid and the 3-D theory is usually computationally too expensive, especially when describing dynamics in bulk superfluid ⁴He. The theory is implemented in both real and imaginary time forms for allowing solution of both time-dependent and time-independent problems. Two test cases for the developed method are presented and the results are compared against the previously published results. Finally, the method is applied to describe solvation of single wall carbon nanotubes in superfluid ⁴He at 0 K and the implications of the results to dynamic liquid response are discussed.

9:00AM A26.00004 Photo-induced isomerization and chemical reaction dynamics in superfluid helium droplets. JEREMY MERRITT, GARY DOUBERLY, ROGER MILLER, University of North Carolina-Chapel Hill — Near threshold photo-induced isomerization and photo-induced chemical reactions have long been sought after as sensitive probes of the underlying potential energy surface. One of the most important questions asked is how the initially bright quantum state couples to the reaction coordinate, and thus relates to energy transfer in general. Helium droplets have now allowed us to stabilize entrance channel clusters behind very small reaction barriers such that vibrational excitation may result in reaction. Through two examples, namely the isomerization of the 2 binary complexes of HF-HCN {Douberty et al. PCCP 2005, 7, 4633}, and the induced reaction of the gallium-HCN complex {Merritt et al. JPCA 2007, DOI:10.1021/jp074981e} we will show how the branching ratios for reaction and predissociation can be determined and the influence of the superfluid He solvent.
9:12AM A26.00005 Rydberg States of Na-doped Helium Nanodroplets, MARCEL DRABBELS — The dynamics of excited states of Na atoms deposited on the surface of helium nanodroplets has been investigated with velocity map ion imaging, photoelectron spectroscopy and time-of-flight mass-spectroscopy. For the first time, the excitation spectra of Na-doped helium nanodroplets corresponding to Rydberg states of Na atoms have been measured from the lowest excited 3p state up to the ionization threshold. All lines in the excitation spectra are shifted and broadened with respect to the corresponding atomic lines. In addition to bare Na* atoms also NaNaHe (N = 1-6) exciplexes are detected upon excitation. Photoelectron spectroscopy reveals the desorption of Na* not only in the initially excited states but also in lower lying states, indicating that relaxation plays an important role. The recorded velocity distributions show interesting characteristics: for the lowest states the mean kinetic energy of Na* increases linearly with excitation energy. The velocity distributions of NaNaHe exciplexes do not manifest such remarkable properties. The observations can be largely explained by assuming that the interaction of Na* with the helium nanodroplet can be described by the sum of Na*He pair potentials.

9:24AM A26.00006 Photoelectron imaging of doped helium nanodroplets, DANIEL NEUMARK, University of California, Berkeley — Photoelectron images of helium nanodroplets doped with Kr and Ne atoms are reported. The images and resulting photoelectron spectra were obtained using tunable synchrotron radiation to ionize the droplets. Droplets were excited at 21.6 eV, corresponding to a strong droplet electronic excitation. The rare gas dopant is then ionized via a Penning excitation transfer process. The electron kinetic energy distributions reflect complex ionization and electron escape dynamics.

9:36AM A26.00007 High Resolution Fluorescence Excitation and Dispersed Emission Spectra of Organic Molecules in Superfluid Helium Nanodroplets1, MARCEL DRABBELS — We present a theoretical study on the effect of a helium nanodroplet environment on the fragmentation dynamics of embedded rare gas cluster ions. As a complement to the fluorescence excitation spectrum the emission spectra provide important details on dynamic processes of intramolecular as well as intermolecular nature. This will be demonstrated for various examples such as intramolecular proton tunnelling, isomeric van der Waals complexes, tautomerization and microsolvation.

1A Humboldt fellowship for A.V. is gratefully acknowledged

9:48AM A26.00008 Coherent boson dynamics in strongly localized potentials - helium excitations at planar aromatic molecules and trapped cold atoms, K. BIRGITTA WHALEY, University of California, Berkeley — Planar aromatic molecules provide strongly localizing potentials for helium that considerably modify the local superfluid properties of a solvating helium environment. I shall describe some of the effects of these interactions on the solvation structure and spectroscopy of tetracene and phthalocyanine in helium droplets, comparing results of zero and finite temperature quantum Monte Carlo simulations with experimental data. The helium atoms closest to the molecule are seen to show similarities to trapped cold atoms in multi-well potentials. Studies of cold bosons with attractive and repulsive interactions in double well potentials will also be presented, showing formation of squeezed and quantum superposition states of cold atoms.

10:24AM A26.00009 Fragmentation dynamics inside helium nanodroplets: new theoretical results, NADINE HALBERSTADT1, LCAR-IRSAMC, CNRS and Universite Toulouse, DAVID BONHOMMEAU2, University of Minnesota, MARIUS LEWINERZ3, Universite Paris Est, Laboratoire de Chimie Theorique — We present a theoretical study on the effect of a helium nanodroplet environment on the fragmentation dynamics of embedded rare gas cluster ions. The helium atoms are treated explicitly, with zero-point effects taken into account through an effective helium-liquid interaction potential. All the nonadiabatic effects between electronic states of the ionized gas cluster are taken into account. Our results reveal new mechanisms for the cooling by helium, and show that the dopant can be ejected from the helium droplet. These results will be presented and discussed.

10:36AM A26.00010 Suppressing the fragmentation of fragile molecules in helium nanodroplets by co-embedding with water: Possible role of the electric dipole moment, YANFEI REN, VITALY KRESIN, University of California, Berkeley — When fragile molecules are embedded in liquid helium nanodroplets, electron-impact ionization usually leads to fragmentation which is as extensive as for isolated gas-phase molecules. This occurs because of the energy release accompanying charge transfer from the impurity to the He+ hole created by electron bombardment. However, in experiments with glycin, polyglycine peptide chains, and alkan hydrocarbon chains we found that if a few molecules of water are co-embedded with these molecules, the fragmentation of the latter is drastically reduced or completely eliminated. On the other hand, the fragmentation of alkanethiols remains unaffected. On the basis of these observations, it is proposed that the fragmentation “buffering” effect may correlate with the magnitude of the impurity’s electric field and the ionization of the He+ hole through the droplet.

10:48AM A26.00011 Path integral investigation of the electronic spectra of He-tetracene clusters, HEATHER D. WHITLEY1, Lawrence Livermore National Laboratory, Livermore, CA 94551, K. BIRGITTA WHALEY, Department of Chemistry and Kenneth S. Pitzer Center for Theoretical Chemistry, University of California, Berkeley, CA 94720 — Planar aromatic molecules (PAMs) are nanoscale precursors to bulk graphite. Their electronic spectra have been extensively studied in He nanodroplets and show a number of unusual spectroscopic features. We have conducted many-body quantum simulations of tetracene in He nanodroplets to probe the 1.1 cm−1 spectral splitting of the electronic origin seen for this PAM. We calculate spectral shifts and He density profiles via path integral quantum Monte Carlo simulations. The spectral splitting is examined using a path integral correlation function approach to determine the lowest-lying vibrational excitation frequencies for small HeN−tetracene clusters. Simulations in the $S_1$ state of tetracene utilize a semi-empirical perturbative interaction potential for a He atom with a PAM. Results for the splitting of the electronic origin and the spectral shifts are in good agreement with experiment. Prepared by LLNL under Contract DE-AC52-07NA27344.

8:00AM A27.00001 Low temperature spin dynamics and high pressure effects in frustrated pyrochlores, ISABELLE MIREBEAU, Laboratoire Léon Brillouin CEA/CNRS, CE-Saclay, 91919 Gif sur Yvette France — Frustrated pyrochlores R2MoO7, where R is a rare earth and M+4 a transition or sp metal ion, show a large variety of exotic magnetic states due to the geometrical frustration of the pyrochlore lattice, consisting of corner sharing tetrahedra for both R and M ions. Neutron scattering allows one to measure their magnetic ground state as well as the spin fluctuations, in a microscopic way. An applied pressure may change the subtle energy balance between magnetic interactions, inducing new magnetic states. In this talk, I will review recent neutron results on Terbium pyrochlores, investigated by high pressure neutron diffraction and inelastic neutron scattering.

8:36AM A27.00002 Spin Structure of Three Dimensional Frustrated Magnetic System of Tb2Mo2O7 — DEEPAK SINGH, JOEL HELTON, Massachusetts Institute of Technology, JEFFREY LYNN, NCNR, National Institute of Standard and Technology. YOUNG LEE, Massachusetts Institute of Technology, YOUNG LEE TEAM, JEFFREY LYNN COLLABORATION — The pyrochlore compound Tb2Mo2O7 has been of interest since it exhibits spin-glass behavior despite the apparent lack of chemical disorder. This compound crystallizes in a cubic space group in which both the Tb and Mo atoms form three-dimensional networks of corner-sharing tetrahedra. Thus, each magnetic ion resides on a highly frustrated pyrochlore lattice. To clarify the nature of the spin correlations in the spin-glass state of Tb2Mo2O7, we have succeeded in growing single crystal samples. Magnetic susceptibility (zero field cooled and field cooled) measurements confirm the spin-glass behavior, similar to that observed in previous powder samples. Recently we performed elastic neutron scattering measurements on a single crystal sample and identified the Q-vectors associated with the short-range diffuse scattering. The spin structure for this compound, consistent with elastic scattering, will be discussed. In addition, recent inelastic neutron scattering measurements will be discussed.

8:48AM A27.00003 Field driven phases in the geometrically frustrated dipolar Heisenberg pyrochlore antiferromagnet Gd4Ti2O7, MATTHEW ENJALRAN, Department of Physics, Southern CT State University, New Haven, CT, ADRIAN DEL MAESTRO, Department of Physics, Harvard University, Cambridge, MA, MICHEL J.P. GINGRAS, Department of Physics and Astronomy, University of Waterloo, Waterloo, ON, Canada; Canadian Institute for Advanced Research, Toronto, ON, Canada — The rare-earth pyrochlore gadolinium titanate, Gd4Ti2O7, represents an excellent experimental realization of a Heisenberg antiferromagnet (AFM) in a frustrated geometry with weak long-range dipole-dipole interactions (approximately 20% of nearest neighbor AFM exchange). Experiments on Gd4Ti2O7 in a magnetic field reveal a complex phase diagram associated with the breaking of spatial symmetries of the pyrochlore lattice as the field is applied along select symmetry directions. We study a model of classical Heisenberg spins (O(3) symmetry) on a pyrochlore lattice with exchange and dipolar interactions within mean-field theory. We report recent single crystal neutron scattering measurements of the XY pyrochlore antiferromagnet Er3Ti2O7 in zero and non-zero magnetic field applied along the (110) direction. Previous results show a magnetically-ordered ground state which is suggested to be stabilized by an unusual order-by-disorder mechanism driven by quantum fluctuations [1]. We present measurements of the low-lying spin excitations of this system, revealing Goldstone modes previously thought to be absent. [1] J.D.M. Champion et al. “Er3Ti2O7: Evidence of quantum order by disorder in a frustrated antiferromagnet” PRB 68 (2003)
HEINZ, Columbia University — Single-walled carbon nanotubes (SWCNTs) constitute a fascinating class of 1-dimensional materials. While the electrical, thermal, and mechanical properties of SWCNTs have been studied in depth for some time, only recently have their optical properties emerged as a major topic of research. This interest reflects several factors: The importance of nanotube optical properties for analysis of their structure, quality, and growth; the potential to use their optical properties to control and integrate electronic and optical functions; and the unique properties of optical excitations such as the hundreds of electronic states available in each nanotube. 

We will present an overview of our current understanding of excited electronic states in nanotubes and of the methods and applications of single-molecule optical spectroscopy of carbon nanotubes. We will present recent results on optical spectroscopy of single carbon nanotubes, and compare these results with theoretical predictions. These results will be presented and compared with relevant theoretical studies.

weakly-dispersive low-energy (quasi-1D absorbing bodies [1]. We show that these interactions result in the exciton-plasmon coupling that is significant in its strength due to the presence of modes of a single-walled carbon nanotube. We use our previously developed Green's function formalism to quantize an electromagnetic field in the presence of University, KEVIN TATUR, LILIA WOODS, University of South Florida — We study theoretically the interactions of excitonic states with surface electromagnetic

9:12AM A28.00003 Effective One-Dimensional Electron-Hole Interaction in Single-Walled Carbon Nanotubes1, JACK DESLIPPE, MARIO DIPOPPA, UC Berkeley and LBNL, DAVID PRENDERGAST, Molecular Foundry, LBNL, RODRIGO CAPAZ, Universidade Federal do Rio de Janeiro, STEVEN LOUIE, UC Berkeley and LBNL — Using the results of ab initio GW-Bethe-Salpeter-Equation (GW-BSE) calculations on the excitonic effects in single-walled carbon nanotubes (SWCNTs), we derive a 1D quantum model for the electron-hole interaction in both semiconducting and metallic SWCNTs. The model includes the important effects of spatial dependent screening and reproduces the exciton binding energies and envelope wave functions of the complete GW-BSE solution of the electron-hole excited states. The inclusion of the spatial dependence in the dielectric function arises from the effects of the surrounding tube on the density of states. The model captures the positioning of the exciton states in the spectrum whose calculated energies differ dramatically from those obtained using previous models based on constant dielectric screening. The present effective interaction can be used to calculate the binding energies of exciton states in a range of SWCNTs, which would be impractical by ab initio study.

9:24AM A28.00004 Environmental effect for exciton transition energy of single carbon nanotubes1, RICHIRO SAITO, KENTARO SATO, PARK JINSUNG, Tohoku University, YUHEI MIYAUCHI, SHIGEO MARUYAMA, The University of Tokyo, MILDRED DRESSELHAUS, GENE DRESSELHAUS, MIT — The exciton transition energies of nanotube samples which are observed in resonance Raman, photo-absorption, and photoluminescence spectroscopies, depend on the surrounding materials (environmental effect). The environmental effect can be explained by screening of the excitonic states by the dielectric materials. We calculate the transition energies for many different (n,m) carbon nanotubes up to 4eV and to 3nm in diameter. The calculated results are compare with many experimental data with different conditions for samples. The energy shift for the exciton transition energies can be explained by using a fitting parameter of static dielectric constants of surrounding materials. However we will show that the effective dielectric constant has a unique, type, metallicity, diameter, and energy dependence of the dielectric constants in order to reproduce the exciton energies for the wide range of diameter and excitation energies. By analyzing the data, we will give a simple formula for the dielectric constants for carbon nanotubes themselves and the surrounding materials as a function of chirality and diameter of single wall carbon nanotubes.

9:36AM A28.00005 Surface Exciton-Plasmons in Carbon Nanotubes1, IGOR BONDAREV, NC Central University, KEVIN TATUR, LILIA WOODS, University of South Florida — We study theoretically the interactions of excitonic states with surface electromagnetic modes of a single-walled carbon nanotube. We use our previously developed Green’s function formalism to quantize an electromagnetic field in the presence of quasi-1D absorbing bodies [1]. We show that these interactions exhibit a new plasmon coupled exciton bands that is sensitive to the presence of weakly-dispersive low-energy (~0.5-2eV) interband surface plasmon modes [2] and large exciton excitation energies ~1eV in small-diameter nanotubes [3]. We estimate the exciton-plasmon Rabi splitting to be ~0.01-0.1eV which is close to that observed in organic semiconductors [4] and much larger than that reported for hybrid semiconductor-metal nanoparticle molecules [5]. We calculate the exciton absorption line shape and demonstrate a clear line splitting effect as the exciton energy is tuned to the closest interband surface plasmon resonance.

9:48AM A28.00006 Cross-polarized optical absorption of single-walled carbon nanotubes probed by photoluminescence excitation spectroscopy, UV-Vis-IR and polarized Raman Scatterings , SHIGEO MARUYAMA, The University of Tokyo — Because of the depolarization effect, or so-called antenna effect, optical absorption of single-walled carbon nanotubes (SWNTs) is weak when excited by light polarized perpendicular to the nanotube axis. However, in photoluminescence (PL) excitation spectra of isolated SWNTs, PL peaks due to cross-polarized excitation can be clearly identified. By decomposing the cross-polarized component, the optical transition energy of E12 or E21 can be experimentally measured, and the smaller exciton binding energy for perpendicular excitations is concluded [1]. Cross-polarized absorption is dominant in the absorption of a vertically aligned film of SWNTs [2] when excited from the top of the film. In our previous study, a p-plasmon absorption at 5.25 eV was revealed in contrast to 4.5 eV for parallel excitation [3]. Resonant Raman scattering from such a film is also influenced by the cross-polarized excitation [4]. Even though a Kataura plot for the E33 and E44 range has been proposed by using such a vertically aligned film [5], polarized Raman scattering excitation energy is tuned to the closest interband surface plasmon resonance.

10:24AM A28.00007 Carbon nanotube excited states: the role of the environment , PHAEDON AVOURIS, IBM T.J. Watson Research Center — The nature of the excited states and the radiative and non-radiative decay of isolated CNTs will be briefly reviewed. I will then focus on the role of the environment, external fields and photon confinement on these properties. I will discuss the use of photovoltage microscopy as a means of imaging environment-induced potential fluctuations in CNTs, presence and size of Schottky barriers at contacts and the extent of band-bending. Scanning resonant micro-Raman scattering will be used to evaluate the CNT excited state shifts induced by the substrate, and, also, the phonon frequency and linewidth changes due to the effects of trapped substrate charges, and charge-transfer effects. Variations in local charge density will be determined by making use of the dependence of electron-phonon coupling on the local charge density. The non-radiative decay of free and localized excitons will then be examined and it will be shown that a phonon-assisted electronic decay mechanism made possible by interaction with the environment can dominate the lifetime of excited CNTs. Finally, results on the modification of the radiative properties of CNTs by changing the photon field mode density for CNTs enclosed in micro-cavities will be presented.

Session A29 DMP: Focus Session: Carbon Nanotubes and Related Materials I: Graphene Transport
Morial Convention Center 221

8:00AM A29.00001 Thermopower of Few-Layer Graphene Devices , PENG WEI, WENZHONG BAO, YONG PU, CHUN NING LAU, JING SHI — We report thermopower measurements of few-layer graphene (FLG) devices at low temperatures. FLG flakes are separated by mechanical exfoliation and then connected to form devices using electron beam lithography. FLG devices are fabricated on a 300 nm-thick SiO2 layer which separates from the heavily-doped silicon substrate used as a gate. As the gate voltage is swept from -55 V to 55 V, the electrical conductivity of FLG devices undergoes a minimum. In the meantime, the Seebeck coefficient changes the sign near the conductivity minimum, marking the transition from p- to n-type in graphene. By directly comparing the derivative of the logarithmic conductivity with the measured Seebeck coefficient, we have experimentally validated the Mott relation. We also have measured the Seebeck coefficient and electrical conductivity under magnetic fields up to 8T. Detailed analysis of the experimental data will be presented.

8:12AM A29.00002 Measurement of the Thermal Conductance at the Graphene-Quartz Interface by Optical Pump-Probe Spectroscopy , CHUN HUNG LUI, KIN FAI MAK, YANG WU, TONY HEINZ, Columbia University — We have determined the interfacial thermal conductance of single and multi-layer graphene samples prepared on quartz substrates by mechanical exfoliation of graphite. The measurements were performed by suddenly heating the graphene sample with a femtosecond optical laser pulse and then monitoring the sample’s subsequent temperature evolution through the slight changes in reflectivity experienced by a time-delayed optical probe pulse. For the study of thermal transport, the transient response occurring on a time scale of tens of picoseconds was relevant. A faster transient related to non-equilibrium electronic excitation was also observed at early delay times. By studying the dependence of the slow decay component on the number of graphene layers in the sample, we could identify interfacial heat flow as the relaxation mechanism. An interfacial conductance in excess of 5,000W/cm × K on the surface of graphene based-devices which are otherwise devoid of any surface adsorbates [2] in ultra high vacuum environment. Adsorbed potassium decreases the charge carrier mobility, renders the gate-dependent conductivity linear, shifts the minimum conductivity point in gate voltage, broadens the width of minimum conductivity region, and lowers the minimum conductivity. Our results are in qualitative agreement with a recent Boltzmann transport calculation [3]. New features, such as asymmetric response of electron-hole mobility and the observation of a “residual” conductivity (the extrapolation of the linear gate-voltage dependent conductivity to the minimum conductivity point) near 2 e2/h, indicate transport properties beyond the simple Boltzmann picture. [1] J.H.Chen et al., http://xxx.lanl.gov/abs/0708.2408. [2] M.Ishigami et al., Nano Letters, 7, 1643 (2007). [3] S. Adam et al., PNAS 104, 18392 (2007).

8:24AM A29.00003 A graphene-based atomic-scale switch , BRIAN STANDLEY, MARC BOCKRATH, California Institute of Technology — Graphene’s remarkable mechanical and electrical properties combined with its compatibility with existing planar CMOS technology make it an attractive material for novel computing devices. Thus far work has focused primarily on realizing transistor functionality. To complement this effort, we have developed a graphene-based switch that realizes a non-volatile memory element. Our devices have demonstrated tens of thousands of writing cycles and long retention times. Additionally, the devices’ atomic-scale dimensions correspond to bit densities far greater than present-day memory technologies. We will present the fabrication process, switching behavior, and further performance characterization.

8:36AM A29.00004 Electronic properties of graphene , KOSTYA NOVOSELOV, University of Manchester — Graphene is a first two-dimensional atomic crystal. In my talk I’ll overview our latest results on the electronic properties of this material.

9:12AM A29.00005 Charged Impurity Scattering in Graphene , MASA ISHIGAMI, JIANHAO CHEN, C. JANG, E.D. WILLIAMS, M.S. FUHRER, Physics Department, Materials Research and Engineering Center, and Center for Nanophysics and Advanced Materials, University of Maryland, College Park — We have measured the impact of charged impurity scattering on the transport properties of graphene sheets [1]. We vary the density of adsorbed potassium atoms in our experiment up to 5 × 1012 K/cm2 on the surface of graphene based-devices which are otherwise devoid of any surface adsorbates [2] in ultra high vacuum environment. Adsorbed potassium decreases the charge carrier mobility, renders the gate-dependent conductivity linear, shifts the minimum conductivity point in gate voltage, broadens the width of minimum conductivity region, and lowers the minimum conductivity. Our results are in qualitative agreement with a recent Boltzmann transport calculation [3]. New features, such as asymmetric response of electron-hole mobility and the observation of a “residual” conductivity (the extrapolation of the linear gate-voltage dependent conductivity to the minimum conductivity point) near 2 e2/h, indicate transport properties beyond the simple Boltzmann picture. [1] J.H.Chen et al., http://xxx.lanl.gov/abs/0708.2408. [2] M.Ishigami et al., Nano Letters, 7, 1643 (2007). [3] S. Adam et al., PNAS 104, 18392 (2007).

9:42AM A29.00006 Conductivity and Fano factor in disordered graphene , EDUARDO R. MUCCIOLI, Department of Physics, University of Central Florida, MI presente Department of Physics, University of Central Florida.

9:42AM A29.00007 The conductivity of pure graphene , SUBIR SACHDEV, LARS FRITZ, Harvard University, JOERG SCHMIALAN, Iowa State University — Pure graphene, in the absence of impurities or bias voltage, is described by a theory of Dirac fermions with Coulomb interactions. We argue that this theory has a finite conductivity, σ, and show that at frequencies ω ≪ k_B T/h (where T is absolute temperature) σ = Ξ(2e^2/h)/(ln(W/T))^2, where W is the bandwidth, and ξ is a universal number. We compute Ξ by the solution of a quantum Boltzmann equation. The influence of a dilute concentration of impurities and finite bias voltage is also discussed.
9:48AM A29.00008 Theoretical study of graphene transport regimes, SHAFFIQUE ADAM, S. DAS SARMA, Condensed Matter Theory Center, University of Maryland, College Park, MD 20742-4111, USA — In recent work [Adam et al. Proc. Natl. Acad. Sci. 104, 18392 (2007); Y.-W. Tan et al. arXiv:0707.1807, Phys. Rev. Lett., in press (2007)], we argued that the transport properties of currently available experimental graphene samples are dominated by diffusive carriers scattering off Coulomb impurity centers typically located in the substrate. In the current paper we study graphene monolayers, bilayers and nanoribbons and show theoretically that by tuning external parameters, one can access several different transport regimes ranging from the aforementioned diffusive Boltzmann transport to phase-coherent ballistic transport to classical percolation through puddles of electrons and holes. This work is supported by U.S. ONR and NRI-NSF.

10:00AM A29.00009 Impact of physisorbed species on transport properties of graphene, CHAUN JANG, JIANHAO CHEN, SHUDONG XIAO, Department of Physics and Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742, MASA ISHIHIGAMI, ELLEN WILLIAMS, Department of Physics and Materials Research Science and Engineering Center, University of Maryland, College Park, MD 20742, MICHAEL FUHRER, Department of Physics and Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD 20742 — We have measured the impact of physisorbed species, including Argon, Krypton, Nitrogen, water and Benzene, on the transport properties of mechanically-exfoliated graphene sheets on SiO$_2$/Si in an ultra-high vacuum environment at temperatures near 30 K. We controlled the gas dosage down to the sub-monolayer level and found species-specific effects on the field-effect mobility of graphene. We observed the influence of different molecular sizes, molecular dipole moment, and intermolecular interactions. We will discuss our results in the context of recent theoretical calculations within the Boltzmann transport framework.

10:12AM A29.00010 Stress-induced Controlled Fabrication of Graphene Nano Ribbons and Carbon Nanotubes via Electrostatic force and electrical transport properties of freely suspended graphene monolayers and bi-layers, ANTON SIDOROV, DAVID MUDD, VLADIMIR DOBROKHOTOV, C.S. JAYANTHI, SHI-YU WU, GAMINI SUMANASEKERA — A simple electrostatic force to transfer loosely bound graphene sheets from a freshly cleaved highly oriented pyrolytic graphite (HOPG) to a desired substrate has been recently reported (Sidorov et al., Nanotechnology, 2007). Here we demonstrate that this technique can be further extended to roll/scroll graphene sheets in a controllable manner by changing the environment during this electrostatic deposition. Deposition under high vacuum (10$^{-7}$ Torr) is observed to deposit extremely flat graphene monolayers on a substrate. In contrast, high density of completely scrolled graphene layers are observed in hydrogen atmosphere and in the presence of an electrostatic field. No scrolling was seen in He atmosphere; but partial scrolling is seen in nitrogen atmosphere under the influence of an electrostatic field. It is believed that in addition to the stress induced due to the adsorption of hydrogen, an additional electrostatic field is necessary to scroll the graphene layers loosely bound to HOPG. Also electrical transport properties of monolayers and bi-layers of graphene layers freely suspended between two electrodes and deposited between trenches on a substrate will be presented and compared.

10:24AM A29.00011 Interaction of Si atoms and Si-based radicals with carbon nanotubes and graphene monolayers, KISEOK CHANG, SAVAS BERBER, DAVID TOMÁNEK, Michigan State University — We use ab initio density functional calculations to study the interaction of Si atoms and Si-based radicals, such as SiH$_3$, with single-wall carbon nanotubes and graphene monolayers. We find that both Si atoms and radicals form a strong chemisorption bond, accompanied by a small relaxation and a locally increased sp$^3$ bond character of the graphitic nanostructure. We identify the optimum adsorption geometries at different adsorbate coverages and adsorbate-related changes in the electronic structure and vibration spectra of the systems. We propose that successful functionalization of carbon nanotubes or graphene by Si atoms or Si-based radicals can be verified by studying changes in the radial breathing mode of nanotubes and the G-band of graphitic nanocarbons using Raman spectroscopy.

1 Supported by NSF NSEC Grant No. 425826.

10:36AM A29.00012 First-principles Studies of Metal Adsorption on Graphene, KEVIN T. CHAN, Department of Physics, University of California, Berkeley, J. B. NEATON, The Molecular Foundry, Lawrence Berkeley National Laboratory, MARVIN L. COHEN, Department of Physics, University of California, Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — Quantitative first-principles theory can aid in understanding many experimental phenomena involving metal adsorption on graphene and carbon nanotubes, including adatom mass transport, modification of electronic, mechanical, and magnetic properties, and adhesion and efficacy of electrical contacts. In this work, the binding energy and geometry, charge transfer, work function, and electronic structure of adatom-graphene systems are calculated using first-principles density functional theory for a variety of metal elements. Trends in these calculated data are analyzed, and their implications for graphene-based devices are discussed.

1 This work was supported by National Science Foundation Grant No. DMR07-05941 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources were provided by Indiana University, SDSC, NERSC, and the Molecular Foundry.

10:48AM A29.00013 Carbon-based ion and molecular channels, KYAW SINT, BOYANG WANG, PETR KRAL, University of Illinois at Chicago, PROF. KRAL'S RESEARCH GROUP TEAM — We design ion and molecular channels based on layered carboneous materials, with chemically-functionlialized pore entrances. Our molecular dynamics simulations demonstrate that these ultra-narrow pores, with diameters around 1 nm, are highly selective to the charges and sizes of the passing (Na$^+$ and Cl$^-$) ions and short alkanes. We demonstrate that the molecular flows through these pores can be easily controlled by electrical and mechanical means. These artificial pores could be integrated in fluidic nanodevices and lab-on-a-chip techniques with numerous potential applications.

8:00AM A30.00001 First-principles calculations of zigzag-edge graphene nanostrips with different edge species, JOHN W. MINTMIRE, Oklahoma State University, DANIEL GUNLYCKE, Naval Research Laboratory, JUNWEN LI, Oklahoma State University, CARTER T. WHITE, Naval Research Laboratory — First-principles calculations have suggested that zigzag-edge graphene nanostrips terminated with hydrogen atoms have edge states which exhibit magnetic behavior. However, it is not clear that zigzag-edge graphene nanostrips terminated with other atoms or functional groups also show similar magnetic behavior. Our local-spin-density calculations suggest that some zigzag-edge nanostrips, including oxygen-terminated nanostrips, have no magnetic edges. One reason could be that there is charge transfer at the edges which effectively dopes the p-orbital network, causing the spin polarization to collapse.

1 This work was supported by the NRC and ONR through NRL, and at OSU by the DOE EPSCoR program.
8:12AM A30.00002 Hydrogenation of graphitic nanocarbons1, SAVAS BERBER, DAVID TOMAÑEK, Michigan State University, EUNJA KIM, PHILIPPE F. WÆCK, University of Nevada Las Vegas, GLEN P. MILLER, University of New Hampshire — We apply ab initio density functional calculations to study the hydrogenation of graphitic nanocarbons including fullerenes, onions and nanotubes using diethylenetriamine (DETA) as hydrogenation reagent. Our results indicate that transfer of atomic hydrogen from the amine end-group of chemisorbed DETA molecules to nanocarbons is an exothermic reaction. We explore the optimum pathway for the hydrogenation reaction and find the activation energy associated with sigmatropic rearrangement of chemisorbed hydrogen atoms to lie near 1 eV, thus facilitating formation of energetically favorable adsorbate structures by surface diffusion. Chemisorbed hydrogen assists in a local sp² to sp³ bonding conversion of the graphitic nanocarbons, causing large-scale structural changes ranging from local relaxations in nanotubes to shell opening in multi-wall onions.

1Supported by NSF NSEC Grant No. 425826.

8:24AM A30.00003 Electronic Structure Study of Edge Saturated Graphene Nanoribbons, YIMING ZHANG, PHILIP SHEMELLA, Rensselaer Polytechnic Institute, P.M. AJAYAN, Rice University, SAROJ NAYAK, Rensselaer Polytechnic Institute, RENSESLEAER POLYTECHNIC INSTITUTE TEAM — Using density functional theory and GW method, we have studied how the electronic structures of graphene nanoribbons responds to the edge saturation. The energy gaps and effective mass of the nanoribbons are highly sensitive to the edge states, as well as the nanoribbon width. This suggests a new approach to modify the electronic structure of graphene nanoribbons by tweaking the edge saturation.

8:36AM A30.00004 Imaging massless Dirac fermion flow in graphene nanoribbons, LIVIU P. ZĂRBO, Texas A&M University, BRANISLAV K. NIKOLIC, University of Delaware — Since its recent experimental discovery, graphene has been the focus of intense theoretical and experimental research. Its unconventional electronic structure characterized by the linear momentum dispersion of electrons which behave as massless Dirac particles at half-filling makes graphene an ideal candidate not only for investigating fundamental physics questions, but also for constructing new nanoscale devices. Despite its importance for device applications, there are very few studies of local features of electronic transport in graphene nanoribbons (GNRs). Moreover, the application of recently advanced scanning probe techniques to imaging electronic flow in graphene is expected to lead to many interesting discoveries. Therefore, we investigate the local features of charge transport through GNRs, by employing our bond current formalism which expresses the local current fluxes flowing between neighboring sites of the hexagonal lattice in terms of nonequilibrium Green functions. We show that, while the charge density profiles for clean zigzag graphene nanoribbons (ZGNRs) close to Dirac point peak at the edges due to the zero-energy edge states, the current densities concentrate towards the nanoribbon center. The analysis of local charge current flow explains unusual transport properties of ZGNRs such as low sensitivity of current flow to edge vacancies or long-range impurities. Journal Ref: EPL 80, 47001 (2007).

8:48AM A30.00005 First principles study of graphene nanoribbons and nanorectangles, PHILIP SHEMELLA, LI CHEN, YU ZHOU, YIMING ZHANG, SREEKALA SUBBULAKSHMI, PULICKEL AJAYAN, SAROJ NAYAK, Rensselaer Polytechnic Institute — We have studied the finite size effect on the electronic structure of graphene nanoribbons (GNRs) using first principles density functional techniques. In particular, we have computed the energy gap dependence on the width and length for zero-dimensional nanoribbons for both the armchair and zigzag ribbons; and compared to the one-dimensional (infinite length) cases. One-dimensional armchair ribbons are expected to be metallic if the number of carbon atoms across the ribbon is N = 3M-1, and non-metallic N ≠ 3M-1, where M is an integer. In addition to quantum confinement along the width of the ribbon for metallic widths, an additional finite size effect emerges along the length of ribbons only for non-metallic armchair ribbons. The origin of additional quantum confinement in these structures is explained based on the energy states near the Fermi energy. The differences between zero- and one-dimensional electronic structure properties are considered with the addition of passivating groups and their effect on the electronic properties of graphene and their impact on nanoelectronics devices are discussed.

9:00AM A30.00006 Band gaps in armchair-edge graphene nanostraps1, CARTER T. WHITE, DANIEL GUNLYCKE, Naval Research Laboratory, JOHN W. MINTMIRE, Oklahoma State University — First-principles calculations have shown that all graphene nanostraps terminated with hydrogen atoms exhibit band gaps at the Fermi level. In the case of armchair-edge nanostraps, the calculations contradict a first-nearest-neighbor tight-binding prediction that one third of these nanostraps should be metallic. At the one-electron level, at least two independent causes for the band gaps in these nanostraps have been suggested, namely lattice distortion and long-range interactions. In this presentation, we present theoretical calculations of arbitrary armchair-edge nanostraps. The model, which includes distortion of edge atoms and third-nearest-neighbor interactions, leads to band gaps and band structures which are in good agreement with those obtained from our first-principles calculations.

9:12AM A30.00007 Study of partial oxidation of zigzag graphene 1-d ribbons, S. SREEKALA, Y. ZHANG, P.M. AJAYAN, S.K. NAYAK, Rensselaer Polytechnic Institute — We study the effect of partial oxidation of graphene 1-d ribbons using the first principle- density functional theory. We have considered zigzag graphene, n=8 with four dangling carbon on each edge. The zigzag graphene 1-d ribbon is a zero bandgap material, when it is functionlialized completely with hydrogen atoms. However, when two of these hydrogen atoms are replaced by oxygen, the band gap opens. This is due to the fact that the oxygen forms double bond with the carbon and hence disrupts the delocalization of the π and π* bond. This functionalization does not induce magnetization. On further increase of oxygen, the band decreases. When oxidation is more than 75% on one side of the graphene ribbon or on either sides, the lone pair of electrons of the oxygen induces magnetization to some of the carbon atoms. Also some configurations of partially oxidized graphene show that antiferromagnetic order is the stable ordering in these systems.

9:24AM A30.00008 Graphene Nanoribbon(GNR) based Nanoelectronics for Interconnect Applications and Logic Devices using First Principles Calculations1, YU ZHOU, SUBBULAKSHMI SREEKALA, YIMING ZHANG, PHILIP SHEMELLA, Rensselaer Polytechnic Institute, PULICKEL AJAYAN, Rice University, SAROJ NAYAK, Rensselaer Polytechnic Institute, RPI TEAM — We have studied electronic structures of graphene ribbon based nanoelectronics using first principles density functional techniques for interconnect applications as well as for logic devices. The conductance behaviors of them are computed based on Non-equilibrium Green’s Function. For example, we have calculated the energy gap and I-V curve of Schottky diode built by connecting two zig-zag GNRs with different passivations. All new configurations will show nonlinear I-V behavior and explicit step feature is observed in the I-V plot as well. There is also a small charge transfer at the junction area for this new configuration which is more like a traditional diode, which leads to different phenomena during the negative biasing.

1Interconnect Focus Center
Studies on such interfaces. It is not completely clear yet to what extent they are decisive for some of these properties. In this talk I will discuss recent experimental and theoretical results. They can become conducting, remain insulating, show magnetic activity and even become superconducting. An important aspect concerns the role of oxygen vacancy effects. In the case of voids in semiconductor ribbons, we study the magnetism associated to a single void and the magnetic interactions developed between them.[2] [1] J. Fernández-Rossier, J. J. Palacios, Phys. Rev. Lett. 95, 226801 (2005). [2] M. Zarea and N. Sandler, Phys. Rev. Lett. Dec (2007)

Ab-initio calculation of bonding, charge redistribution and transfer of graphene on amorphous silica, NING SHEN, JORGE SOFO, Department of Physics, Penn State University — We study the effects of an amorphous silica substrate on the electronic structure and electron density of graphene using Density Functional Theory. We observe that the silica substrate transfers charge to the graphene layer and the workfunction of the combined system is lower than that of an isolated graphene sheet. The inhomogeneous charge distribution of the substrate induces an inhomogeneous charge redistribution on the graphene layer, which is experimentally observed as electron and hole puddles. The binding energy between one graphene layer and the substrate is weak and reveals no sign of chemical bonding. This can also be inferred from a rigid band shift observed in the system.

Electron states of mono- and bilayer graphene on SiC probed by STM, FRANÇOIS VARCHON, PIERRE MALLET, CÉCILE NAUD, Institut NEEL CNRS/UJF, 25 rue des Martyrs BP166, 38042 Grenoble, CLAIRE BERGER, The Georgia Institute of Technology, Atlanta, Georgia 30332-0430; Institut NEEL CNRS/UJF, 25 rue des Martyrs BP166, 38042 Grenoble, LAURENCE MAGAUD, JEAN-YVES VEUILLEN, Institut NEEL CNRS/UJF, 25 rue des Martyrs BP166, 38042 Grenoble — We present a scanning-tunneling microscopy (STM) study of a gently graphitized 6H-SiC(0001) surface in ultrahigh vacuum [1]. From an analysis of atomic scale images, we identify two different kinds of atomic scale contrasts, which we attribute to mono- and bilayer (or trilayer) graphene capping a C-rich interface. At any temperature, both terraces show quantum interference effects generated by point defects. Such interferences are a fingerprint of π-like states close to the Fermi level. We conclude that the metallic states of the first graphene layer are almost unperturbed by the underlying interface, in agreement with recent ab initio studies [2] and photoemission experiments [3]. However, a significant density of interface states is detected close to the Fermi level in the C-rich interface. [1] P. Mallet et al., Phys. Rev. B 76, 041403(R) (2007) [2] F. Varchon et al., Phys. Rev. Lett. 99, 126805 (2007) [3] A. Bostwick et al., Nat. Phys. 3, 36 (2007)

Magnetism in graphene nanoislands and nanovoids, JUAN JOSE PALACIOS, JOAQUIN FERNANDEZ-ROSSIER, Universidad de Alicante, LUIS BREY, ICM-M-CSC — The rules to predict the magnetic state of both graphene nanoislands and nanovoids in otherwise perfect graphene systems are presented. We discuss how the shape of the island or void, the associated imbalance in the number of atoms belonging to the two graphene sublattices, the existence of zero-energy states, and the total and local magnetic moment are intimately related. We consider electronic interactions both in a mean-field approximation of the one-orbital Hubbard model and with density functional calculations. The magnetic properties of nanometer-sized graphene structures with triangular and hexagonal shapes terminated by zigzag edges happen to be drastically different[1]. In the case of voids in semiconductor ribbons, we study the magnetism associated to a single void and the magnetic interactions developed between them[2]. [1] J. Fernández-Rossier and J. J. Palacios, Phys. Rev. Lett. 99, 177204 (2007). [2] J. J. Palacios,J. Fernández-Rossier, L. Brey, in preparation.

The electronic structure of graphene layers on SiO2 substrate, YONG-JU KANG, JOONGOOK KANG, KEE JOO CHANG, Korea Advanced Institute of Science and Technology — Graphene is a single layer of carbon atoms packed in a honeycomb lattice, and its quasiparticles behave like massless Dirac fermions. Since graphene is usually supported and deposited on dielectric materials such as SiO2 and SiC, interactions between graphene and substrate atoms can modify the electronic structure of graphene. In this work we study the structural and electronic properties of a few graphene layers on SiO2 surfaces through first-principles calculations within the local-density-functional approximation. We examine interactions between graphene layers and Si- and O- terminated surfaces of α-quartz and the substrate-induced doping effect. For a single graphene layer, we find that graphene strongly interacts with the O-terminated surface. A charge transfer occurs from the graphene to the surface O atoms, leading to the p-type doping. For a bilayer graphene in AB stacking, the charge transfer mostly occurs for the graphene layer right on the substrate, resulting in an asymmetric distribution of electron charges between two graphene layers and thus a gap opening at the Dirac point.

Pair condensation in electron-hole graphene bi-layer, RAFI BISTRITZER, HONGKI MIN, JUNG-JUNG SU, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin — Using self consistent Hartree Fock calculations we show that an electron-hole graphene bi-layer exhibits spontaneous interlayer coherence when the distance between layers is sufficiently small. We describe the unique transport properties of the emergent dipolar superfluid and relate them to the nature of the underlying massless Dirac particles.
8:36AM A31.00002 Magnetic anisotropy modulation in Fe$_3$O$_4$/BaTiO$_3$(100) epitaxial structures, C.A.F. VAZ, J. HOFFMAN, A. POSADAS, C.H. AHN, Department of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University, New Haven, CT 06520 — Renewed interest in ‘classical’ ferroic materials has been accompanied by the study of a new class of multiferroic composite materials, based on magnetic and dielectric multilayer structures. One motivation is the search for materials that allow independent control of both the magnetic and electric properties. In this context, we investigate the modulation of the magnetic anisotropy of a 10 nm magnetite (Fe$_3$O$_4$) film grown epitaxially by off-axis magnetron sputtering on (001)BaTiO$_3$ (BTO). SQUID and magnetoresistance measurements as a function of temperature show a series of discontinuities that are attributed to changes in the strain of the magnetite film via elastic coupling with the substrate, as the latter undergoes a series of structural phase transitions. Magnetic hysteresis loops carried out at temperatures above and below each transformation in the BTO elucidate the variation of the effective anisotropy of the Fe$_3$O$_4$ film. The possibility of using the piezoelectric response of BTO to modulate the magnetic anisotropy of magnetite films is discussed.

8:48AM A31.00003 Epitaxial strain-mediated spin-state transitions: can we switch off magnetism?, JAMES RONDINELLI, NICOLA SPALDIN, Materials Dept., UC Santa Barbara, MATERIALS RESEARCH LABORATORY COLLABORATION — We use first-principles density functional theory calculations to explore spin-state transitions in epitaxially strained LaCoO$_3$. While high-spin to low-spin state transitions in minerals are common in geophysics, where pressures can reach over 200 GPa, we explore whether heteroepitaxial strain can achieve similar transitions with moderate strain in thin films. LaCoO$_3$ is known to undergo a low-spin ($S=0$, $t^6_2g^0$) to intermediate-spin ($S=1$, $t^5_2g^1$) or high-spin ($S=2$, $t^4_2g^2$) state transition with increasing temperature, and thus makes it a promising candidate material for strain-mediated spin transitions. Here we discuss the physics of the low-spin transition and changes in the electronic structure of LaCoO$_3$, most notably, the metal-insulator transition that accompanies the spin-state transitions with epitaxial strain. As thin film growth techniques continue to reach atomic-level precision, we suggest this is another approach for controlling magnetism in complex oxide heterostructures.

9:00AM A31.00004 Density functional study of ferromagnetic ferroelectric LaMnO$_3$/BaTiO$_3$ superlattice, LEONARD KLEINMAN, BHAGAWAN SAHU, ADRIAN CIUCIVARA, University of Texas at Austin — Using the GGA + U density functional, we have calculated the lattice constants, atomic positions, magnetization, and ferroelectric polarization of a (LaMnO$_3$)$_n$(BaTiO$_3$)$_m$ superlattice containing five LaO and TiO$_2$ planes and four MnO$_2$ and BaO planes. Although LaMnO$_3$ is antiferromagnetic, it is ferromagnetic in the superlattice. An approximation to the ferroelectric polarization, obtained from a comparison of superlattice and bulk crystal atomic displacements and unit cell volumes, is found to agree reasonably well with the polarization obtained from a Berry phase calculation. The electric polarization points along the longer in-plane lattice vector, while the atomic spins, after the spin-orbit interaction and spin noncollinearity are included, are all in directions close to that lattice vector.

9:12AM A31.00005 Electron Localization and Interface Magnetism in CaRuO$_3$/CaMnO$_3$ Superlattices, J.W. FREELAND, Advanced Photon Source, Argonne National Lab., J. CHAKHALIAN, University of Arkansas, Fayetteville, J.J. KAVICH, Advanced Photon Source, Argonne National Lab., B. KEIMER, Max Planck Institute for Solid State Research, H.N. LEE, Oak Ridge National Lab. — We present a study of interface physics in superlattices composed of a G type anti-ferromagnetic insulator (CaMnO$_3$) and a paramagnetic metal (CaRuO$_3$). Using laser MBE, ultra-thin superlattices were grown with the structure [CaRuO$_3$ (N u.c.)/CaMnO$_3$ (10 u.c.)]$_6$ on LaAlO$_3$(100) substrates. Polarized x-ray probes clearly show a large Mn magnetic moment, which is attributed to a canted anti-ferromagnetic state at the interface. The electronic state of the system was probed by current-in-plane transport measurements. Due to the large resistivity of CaMnO$_3$, magneto-transport measurements probe primarily the behavior of the carriers in the CRO layer, which show a non-bulk like insulating behavior that is attributed to disorder induced localization from interface scattering. Field dependence shows a large negative magneto-resistance (MR), which results from strong scattering of the carriers by Mn spins at the interface since the MR drops with increasing CRO layer thickness. Work at Argonne is supported by the U.S. Department of Energy, Office of Science, under Contract No. DE-AC02-06CH11357. JC is funded by U.S. DOD-ARO under Contract No. 0402-17291.

9:24AM A31.00006 Exploring artificial layered heterostructures of LaM’O’3/LaM”O’3 (M’M” = NiCr, FeCr and NiV), J. LII, M. KAREEV, University of Arkansas, Fayetteville, J.W. FREELAND, Advanced Photon Source, Argonne National Lab., A. KAREEV, University of Arkansas, H.W. LEE, Oak Ridge National Lab. — Digital synthesis of atomically sharp interfaces between strongly correlated electron systems can provide a template to build completely new materials. Here we present our results on magnetism and electronic structure in LaM’O’3/LaM”O’3 (M’M” = NiCr, FeCr and NiV) superlattices by using polarized X-ray spectroscopies. Using laser MBE, the (111) and (100) oriented ultrathin superlattices were grown with alternating layer thicknesses of 1 unit cell. In the bulk, LaM03 (M=Cr,Fe,V) are antiferromagnetic insulators while LaNiO3 is a paramagnetic metal. The evolution of element specific magnetism and charge at the interface containing five LaO and TiO$_2$ planes and four MnO$_2$ and BaO planes. Although LaMnO$_3$ is antiferromagnetic, it is ferromagnetic in the superlattice. An approximation to the ferroelectric polarization, obtained from a comparison of superlattice and bulk crystal atomic displacements and unit cell volumes, is found to agree reasonably well with the polarization obtained from a Berry phase calculation. The electric polarization points along the longer in-plane lattice vector, while the atomic spins, after the spin-orbit interaction and spin noncollinearity are included, all point in directions close to that lattice vector.

9:36AM A31.00007 Strain effect on Magnetism at the Manganite Interfaces: SrMnO$_3$/LaMnO$_3$, BIRBARAB NANDA, SASHI SATPATHY, University of Missouri, Columbia — Recently it has been shown that new magnetic and electronic phases can be produced by varying the strain condition at the manganese interfaces[1]. From the density-functional studies of the electronic structure at the interface of SrMnO$_3$ and LaMnO$_3$ we show that the epitaxial strain, which enforces a tetragonal distortion, splits the itinerant interface Mn-$e_g$ states to $x^2-y^2$ and $3z^2-R_1$ states. If the strain is tensile in the plane the $x^2-y^2$ orbital becomes more occupied, enhancing thereby the ferromagnetic double exchange which overcomes the antiferromagnetic super exchange between the core $t_{2g}$ states to produce a net in-plane ferromagnetic interaction. Due to the lower occupancy of the $3z^2-R_1$ orbitals, the super exchange supercedes the double exchange to produce out-plane antiferromagnetic ordering. For in-plane compressive strain higher occupancy of $3z^2-R_1$ orbital results in the out-of-plane ferromagnetic ordering while in-plane ordering remains antiferromagnetic. Without any epitaxial strain, the itinerant $x^2-y^2$ and $3z^2-R_1$ states are more or less equally occupied and ferromagnetic ordering prevails both in-plane and out-of-plane. While for the tensile strain we find the heterostructure to be metallic, for the compressive strain an insulating phase is obtained if the strain is sufficiently large. This work was supported by DOE-DE-FG02-00ER45818.

9:48AM A31.00008 Asymmetric and modulated magnetic profiles in (LaMnO$_3$)$_{2n}$/SrMnO$_3$ superlattices$^1$. S.J. MAY, S.G.E. TE VELTHUIS, MSD, Argonne National Laboratory, M.R. FITZSIMMONS, Los Alamos National Laboratory, A.B. SHAH, J.M. ZUO, X. ZHAI, J.N. ECKSTEIN, University of Illinois, Urbana-Champaign, S.D. BADER, A. BHATTACHARYA, MSD and CNM, Argonne National Laboratory — We have determined the magnetic depth profile of MBE-grown ferromagnetic (LaMnO$_3$)$_{2n}$/SrMnO$_3$ superlattices, where $n$ is nominally equal to 3 and 5. Polarized neutron reflectivity measurements reveal the existence of a modulated magnetic structure that repeats with the superperiod in both samples. For $n=5$, a moment of $\sim -2.6 \mu_B$/Mn is measured in the LaMnO$_3$ (LMO) layer, while the moment in the middle of the SrMnO$_3$ (SMO) layer is negligible. The magnetization at the interfaces is found to be asymmetric with an enhanced moment residing at the LMO/SMO interfaces but not at the SMO/LMO interfaces. The origin of the magnetic asymmetry at the interfaces is elucidated from comparison with the structural properties determined by x-ray reflectivity and transmission electron microscopy.

10:00AM A31.00009 Complex oxide F/S/F trilayers. C. VISANI, Z. SEFRIOU, C. LEON, J. SANTAMARIA, Universidad Complutense de Madrid, Spain, S.G.E. TE VELTHUIS, A. HOFFMANN, Argonne National Laboratory, NORBERT M. NEMES, M. GARCIA-HERNANDEZ, Instituto de Ciencia de Materiales de Madrid, Spain, M.R. FITZSIMMONS, B.J. KIRBY, Los Alamos National Laboratory — The origin of the large magnetoresistance in epitaxial F/S/F trilayers composed of highly spin polarized ferromagnetic La$_{1-x}$Ca$_x$MnO$_3$ and high-$T_c$ superconducting YBa$_2$Cu$_3$O$_{7-x}$ (YBCO) is investigated by characterizing the magnetic structure. Polarized neutron reflectometry experiments have determined the detailed magnetization profiles in trilayers with varying YBCO layer thicknesses. In addition to inhomogeneous magnetization profiles, rotation of the magnetization during the magnetization reversal for the films with thick ($\geq 17.7$ nm) YBCO layers has been observed. The results are consistent with the presence of an (in plane) easy-axis tilted away from the (100) direction.

10:12AM A31.00010 Origins of Anomalous Ferromagnetism in F/AF LCMO Multilayers. B. J. KIRBY, S. M. WATSON, National Institute of Standards and Technology, M. KAREEV, J. CHAKHALIAN, University of Arkansas — Unexpected behavior can emerge from magneto-electronic interactions at the interface between two different strongly correlated electron systems. Exchange bias - giving a ferromagnet (F) a preferred direction via coupling with an antiferromagnet (AF) - is a phenomenon of great fundamental and applied research interest. Both topics are pertinent in the case of the interface between F and AF La$_1-x$Ca$_x$MnO$_3$ (LCMO) layers. Depending on $x$, LCMO can be F ($x = 1/3$ Ca) or AF ($x = 2/3$ Ca), and exchange bias has been reported in superlattices consisting of such layers. Surprisingly SQUID magnetometry has shown that the saturation moment of such a structure increases as the nominally AF layer thickness is increased [1]. This has been attributed to electronic effects that cause F order to extend into the nominally AF layer. However, the location of the extra moment cannot be determined with bulk magnetometry techniques. Thus, we have used polarized neutron and x-ray reflectometry to measure the magnetic and structural depth profiles in an exchange biased $x=1/3$ LCMO / $x=2/3$ LCMO bilayer. Our results suggest that the magnetic profile extends beyond the $x = 1/3$ layer, implying that some F order indeed exists in the nominally AF $x = 2/3$ layer. [1] G. Campillo, et al., J. Appl. Phys. 97, 10K104 (2005).

10:24AM A31.00011 Ferroelectric field effect modulation of the magnetic properties of colossal magnetoresistive La$_{1-x}$Sr$_x$MnO$_3$. JASON HOFFMAN, Department of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University, HAIJUO MOLEGRAAF, DPMC, University of Geneva, CHANG HONG, Department of Materials, Pennsylvania State University, JEAN-MARC TRISCONE, DPMC, University of Geneva, C.H. AHN, Department of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University — In this work, we have tuned the magnetic properties of the colossal magnetoresistive oxide La$_{1-x}$Sr$_x$MnO$_3$ (LSMO) using a ferroelectric field effect approach. Epitaxial LSMO thin films and ferroelectric Pb(Zr,Ti)O$_3$ (PZT) / LSMO heterostructures were fabricated using off-axis RF magnetron sputtering. LSMO films with high crystalline quality and atomically smooth surfaces have been achieved. Using the magneto-optical Kerr effect (MOKE), we measured a shift in the Curie temperature ($T_c$) of LSMO upon switching the polarization direction of PZT, in agreement with the modulation of $T_c$ found from magnetotransport measurements. Unlike the traditional chemical doping approach, the ferroelectric field effect approach allows one to control the magnetism in the system reversibly, without introducing additional lattice disorder/distortion.

10:36AM A31.00012 Structure and properties of CaMnO$_3$/SrMnO$_3$/BaMnO$_3$ superlattices from first principles. SHEN LI, SEONGSHIK OH, KARIN RABE, Department of Physics and Astronomy, Rutgers the State University of New Jersey, Piscataway, 08854, USA — Previous theoretical and experimental studies have shown that three-component, or “tri-color” superlattices can exhibit intrinsic electric polarization due to inversion-symmetry breaking in the layer sequence. In ferromagnetic inversion-symmetry-breaking superlattices, controlled rotation of the magnetization during the magnetization reversal for the films with thick ($\geq 17.7$ nm) YBCO layers has been observed. The results are consistent with the presence of an (in plane) easy-axis tilted away from the (100) direction.

10:48AM A31.00013 Phase separation at the La$_{1-x}$Sr$_x$CoO$_3$ / SrTiO$_3$ (001) interface from thickness and doping dependent magnetotransport$^1$. M.A. TORIJA, M. SHARMA, C. LEIGHTON, University of Minnesota — Bulk La$_{1-x}$Sr$_x$CoO$_3$ (LSCO) has received considerable attention with regard to nanoscale magnetic phase separation. Fabrication of epitaxial films provides a means to study this phase separation under dimensional confinement and at interfaces. Moreover, the characteristic intercluster “GMR” effect observed in the phase-separated state of this material provides a simple means to probe phase separation even in very thin films. We have found that even at $x = 0.5$ (a homogeneous ferromagnetic metal in bulk), sufficiently thin films ($< 60$ Å) grown on SrTiO$_3$ (001) show a crossover to a reduced moment insulating phase, with the characteristic intercluster MR effect. i.e. phase separation occurs. By measuring the thickness dependence of the magnetotransport as a function of doping we have assembled a three-dimensional phase diagram in temperature-doping-thickness space. The interfacial phase-separated region increases dramatically as $x$ is decreased (to over 250 Å at $x = 0.2$) and the non-ferromagnetic phase boundary is approached. The increased prominence of phase separation as proximity to the non-ferromagnetic phase is increased provides a strong hint to the origin of this interfacial phase separation.

$^1$Work supported by NSF DMR.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A32 GMAG: Disordered Magnetic Materials Morial Convention Center 225
8:00AM A32.00001 Transport in strongly disordered classical spin chains, VADIM OGANESYAN, Yale University, ARUJET PAL, DAVID HUSE, Princeton University — We present a numerical study of diffusion of energy at high temperature through strongly disordered arrays of interacting classical spins with Hamiltonian dynamics. We find that quenched randomness strongly supresses transport, with diffusion constant apparently becoming smaller than any power of spin-spin interaction rescaled by randomness. We have looked for but not found signs of a classical many-body localization transition at any finite strength of disorder.

8:12AM A32.00002 Ferromagnetism in Melt-spun Gd\textsubscript{0.946}Fe\textsubscript{0.054}, PAUL SHAND, NICHOLAS JENSEN, JUSTIN BOHNET, University of Northern Iowa, JARED GÖERTZEN, JEFFREY SHIELD, University of Nebraska-Lincoln, DAVID SCHMITTER, Providence College, GEOFFREY SHELBURNE, DIANDRA LESLIE-PELECKY, University of Nebraska-Lincoln — The ac susceptibility and dc magnetization at various temperatures were measured for a melt-spin Gd\textsubscript{0.946}Fe\textsubscript{0.054} alloy. The grain size was \( \approx 100 \) nm. A sharp paramagnetic-to-ferromagnetic transition was observed at a temperature close to that of pure Gd. Effective exponents of the critical temperature and the critical temperature \( T_C \) were extracted by using modified Arrrott plots and Kouvel-Fisher analysis. The values obtained were \( \beta_{eff} = 0.398 \pm 0.004 \), \( \gamma_{eff} = 1.24 \pm 0.02 \), \( \delta_{eff} = 3.83 \pm 0.05 \), and \( T_C = 290.25 \pm 0.17 \) K. These exponent values do not satisfy the Widom scaling relation \( \delta = (3-\gamma_{eff})/\beta_{eff} \). The \( \beta_{eff} \) and \( \gamma_{eff} \) values for ms-Gd\textsubscript{0.946}Fe\textsubscript{0.054} are similar to those obtained for pure Gd in the same temperature interval around \( T_C \). This is in consonance with x-ray microanalysis measurements indicating that the grains are nearly pure Gd. The lower-than-expected value of \( \delta_{eff} \) may be due to the effect of increased anisotropy due to the presence of Fe in the grain-boundary regions.

8:24AM A32.00003 Observation of spin-wave mediated Altshuler-Aronov and weak localization corrections to the conductivity in thin films of gadolinium, RAJIV MISRA, ARTHUR F. HEBARD, KHANDKER MUTTALIB, University of Florida, Gainesville, FL, USA, PETER WOELFLE, IJKM, Universität Karlsruhe, Germany — We present a study of quantum corrections to the conductivity tensor of thin ferromagnetic gadolinium films. Using the sheet resistance as a measure of disorder, in situ magnetotransport studies were performed on a series of gadolinium films deposited onto sapphire substrates having sheet resistance \( R_0 = R_{xx} (5K) \) varying over the range 428 \( \Omega \) (\( \approx 135\)Å) to 4011 \( \Omega \) (\( \approx 35 \) Å). For temperatures \( T < 30 \) K and \( R_0 < 4011 \) \( \Omega \), we observe the simultaneous presence of two types of quantum correction to the Drude conductivity, \( \sigma = \sigma_{Drude} + \Delta \sigma_{SpinWaveMediated} + \Delta \sigma_{WL} \). The characteristic feature of the first correction is an approximately linear increase with temperature of conductivity, and we attribute this as a spin-wave mediated Altshuler-Aronov correction to conductivity. The second correction to the Drude conductivity comes from weak localization, with a characteristic logarithmic temperature dependence of conductivity with a prefactor \( e^2/2\pi^2 h \) in 2D. We observe a breakdown of this behavior at a sheet resistance \( R_0 = 4011 \Omega \), which is very close to the quantum of resistance, \( h/e^2 \approx 41000 \).

8:36AM A32.00004 Monte Carlo study of the three-dimensional Coulomb glass, BRIGITTE SURER, HELMUT G. KATZGRABER, Theoretische Physik, ETH Zurich, CH-8093 Zurich, Switzerland, GERGELY T. ZIMANYI, Department of Physics, University of California, Davis, California 95616, USA, BRANDON A. ALLGOOD, Numerate Inc., 1150 Bayhill Drive, San Bruno, CA 94066, USA — The memory and hysteretic effects found in strongly-disordered electron systems can be explained by the existence of a glassy phase, the Coulomb glass. Efros and Shklovskii have predicted the emergence of a soft Coulomb gap, resulting from the long-range interactions between the localized electrons. However, the relationship between the soft Coulomb gap in the density of states and the electron's glassy behavior has been a long-standing unresolved question. Only recently has it been surmised within the framework of a mean field theory that the disordered electron system undergoes a replica symmetry breaking transition at a finite temperature, similar to the Sherrington-Kirkpatrick model of spin glasses. Because it is not clear, however, whether the transition persists beyond the mean-field approximation, we study in detail the critical behavior and the shape of the Coulomb glass in three space dimensions using Monte Carlo methods. Furthermore, we compare our results for the (random-energy) Coulomb glass model to previous results on a random lattice version of the model. Since these models possess different symmetries, the equivalence of the phase diagrams is far from obvious, contrary to previous claims.

8:48AM A32.00005 Reentrant spin-glass behavior and enhanced Curie temperature in epitaxial MnSi, ERIC KARHU, SAMER KAHWAJI, TED MONCHESKY, Dalhousie University, KRISTA RAFFEL, MICHAEL ROBERTSON, Acadia University, CHRISTIAN MAUNDERS, McQuaid-Stewart, Buchan, Canada — We grew single crystal MnSi(111) thin films on Si(111) substrates by molecular beam epitaxy. The 3\% lattice mismatch created an in-plane tensile strain of \( \epsilon_l = 0.005 \pm 0.001 \), as measured by transmission electron microscopy, and induced an out-of-plane compressive strain \( \epsilon_z = -0.0033 \pm 0.0001 \), as determined by x-ray diffraction. The MnSi(111) films displayed two magnetic phases. The first transition from a paramagnetic phase to a phase with long range magnetic order occurs with an enhanced Curie temperature \( T_C = 40 \) K as compared to bulk MnSi, which develops helical magnetic structure below \( T_C = 29.5 \) K. This increase in \( T_C \) can be explained by an in-plane strain. A second phase transition to spin glass, below \( T_f = 35 \) K, maybe due to geometric frustration created by the compressive out-of-plane strain. We propose a relationship between the reentrant spin-glass behavior and the partial magnetic order reported for bulk MnSi under pressure.

The authors gratefully acknowledge the support received from NSERC and Dr. G. Bolton and the Canadian Centre for Electron Microscopy.

9:00AM A32.00006 Dynamical behavior of spin clusters in La\textsubscript{1-x}Sr\textsubscript{x}CoO\textsubscript{3}, ROBERT SMITH, MICHAEL HOCH, WILLIAM MOULTON, PHILLIP KUHNS, GREGORY BOEBINGER, ARNEIL REYES, National High Magnetic Field Lab, JOHN MITCHELL, Argonne National Lab — Previous work has provided evidence for magnetic glassing behavior in the hole-doped cobaltite system La\textsubscript{1-x}Sr\textsubscript{x}CoO\textsubscript{3}(LSCO). Models proposed to describe the interesting and unusual magneto-transport properties of LSCO involve hole-rich clusters in a hole-poor matrix. The glassy properties, which are not well understood, have variously been interpreted in terms of spin glass and cluster glass components. The present 1\textsuperscript{39}La NMR spectral line shapes on single crystal LSCO, that map the hyperfine field distribution in the \( x-T \) plane, confirm the presence of magnetic clusters, identified as spin polaron, and provide a phase inhomogeneity diagram. NMR relaxation rates have been used to probe the dynamical behavior of the system at the nanoscale level in macroscopically insulating and metallic samples as a function of temperature in the range 4-280 K. For \( x \) less than the metal-insulator critical concentration \( x_{C} = 0.17 \) value has been obtained for two classes of glassy component with different characteristic correlation time distributions and freezing temperatures. The magnetic glass properties persist above \( x_{C} \). A spin polaron model is used to explain the results.

9:12AM A32.00007 Local field distributions in spin glasses, DAVID SHERRINGTON, University of Oxford, HELMUT G. KATZGRABER, ETH Zurich, STEFAN BOETTCHER, Emory University — Numerical results for the local field distributions of a family of Ising spin-glass models are presented. In particular, the Edwards-Anderson model in dimensions two, three, and four is considered, as well as spin glasses with long-range power-law-modulated interactions that interpolate between a nearest-neighbor Edwards-Anderson system in one dimension and the infinite-range Sherrington-Kirkpatrick model. Remarkably, the local field distributions only depend weakly on the range of the interactions and the dimensionality and show strong similarities except for near zero local field.

9:24AM A32.00008 ABSTRACT WITHDRAWN —
9:36AM A32.00009 The Antiferromagnetic SO(3) Heisenberg Quantum Spin-Glass with Short Range Interaction, EDUARDO MARINO, Princeton University, CARLOS CONCEICAO, UFRJ — We study the quenched disordered magnetic system which is obtained from the 2D SO(3) Heisenberg model, with nearest neighbors interaction, by taking the random values of the exchange couplings as given by a Gaussian probability distribution centered in a value of the coupling that corresponds to anti-ferromagnetic order. Using coherent states, we map this system onto a generalization of the SO(3) nonlinear sigma model, containing different flavors, which correspond to the replicas and a quartic interaction. We then integrate over the transverse components and perform a mean-field calculation of the free energy density in the limit of zero replicas. The phase diagram of the system is then obtained and shows a critical curve, starting at a quantum critical point at $T=0$ separating a paramagnetic from a spin-glass phase. The stability of the phases is demonstrated by an analysis of the Hessian matrix of the free energy.

9:48AM A32.00010 On the ordering of Ising spin glasses in a field, HELMUT G. KATZGRABER, Theoretische Physik, ETH Zurich, CH-8093 Zurich, Switzerland, THOMAS JÖRG, LPTMS, UMR 8626 CNRS et Univ. Paris-Sud, 91405 Orsay CEDEX, France, FLORENT KRZAKALA, Laboratoire PCT, UMR Gulliver CNRS-ESPCI 7083, 10 rue Vauquelin, 75231 Paris CED — We study the existence of a spin-glass phase in a magnetic field in three space dimensions using a novel approach where the Monte Carlo simulations are performed along a nontrivial path in the magnetic field–temperature plane which must cross any putative de Almeida-Thouless line. The method is first tested on the mean-field version of the Edwards-Anderson Ising spin glass on a Bethe lattice where we compute analytically the instability line that separates the spin glass from the paramagnetic state. While the de Almeida-Thouless line is clearly reproduced by our simulations on the mean-field Bethe lattice, no such instability line can be found numerically for the short-range three-dimensional model. We thus conclude that there is no such instability line for three-dimensional short-range Ising spin glasses.

10:00AM A32.00011 Spin glass of a diluted Ising dipolar system, KA-MING TAM, MICHEL GINGRAS, University of Waterloo — The diluted dipolar Ising system has been regarded as a standard example which exhibits spin glass properties. Recent studies have challenged the existence of spin glass phase transition in one of the materials in this category, $\text{LiHo}_x\text{Y}_{1-x}F_4$. Using Monte Carlo simulations, we calculate various quantities to address the current controversy of a possible spin glass phase transition in this material. Beside the conventional method to locate the spin glass transition by observing the crossing of Binder ratios of magnetization moments, another crucial probe for the nature of spin glass, order parameter fluctuations, is studied via the so-called fluctuation sensitive parameters. Crossing is observed in the Binder ratio of overlap order parameter, and non-trivial structures of overlap order parameter are obtained at low temperature.

10:12AM A32.00012 Nonlinear and ac Susceptibility of the Dilute Ising Magnet $\text{LiHo}_x\text{Y}_{1-x}F_4$, JEFFREY QUILLIAM, SHUCHAO MENG, CHAS MUGFORD, JAN KYCIA, Department of Physics and Astronomy, University of Waterloo — Recent work has called into question the existence of a spin glass phase transition in the dilute dipolar Ising magnet $\text{LiHo}_x\text{Y}_{1-x}F_4$. Other work has suggested that there is an exotic spin liquid phase found at a Ho concentration of $x = 0.045$ [2]. In order to carefully study the dynamics of this system, we have put together a SQUID magnetometer which allows for measurements of ac susceptibility and nonlinear susceptibility over a large frequency range. We present results from measurements on single crystals of $\text{LiHo}_x\text{Y}_{1-x}F_4$, particularly on an $x = 0.045$ sample, in an attempt to either reproduce the exotic “anti-glass” physics that was previously observed or to detect a spin glass transition. 10:24AM A32.00013 Low-temperature properties of the dilute dipolar magnet $\text{LiHo}_x\text{Y}_{1-x}F_4$, ANDERS BILTMO, PATRIK HENELIUS, KTH, Stockholm — The phase diagram of the rare-earth compound $\text{LiHo}_x\text{Y}_{1-x}F_4$ is considered as a function of dilution as given by a Gaussian probability distribution centered in a value of the coupling that corresponds to anti-ferromagnetic order. Using coherent states, the ground state of the system is ferromagnetic and as $x$ decreases a disordered ground state with glassy properties arises. If $x$ is decreased further, the system enters a phase sometimes referred to as “antiglass”. Both the non-canonical glassy state and the not yet understood “antiglass”, have never been systematically studied using a microscopic probe. We performed muon spin relaxation measurements in five samples ($x=0.018$, 0.045, 0.08, 0.12 and 0.25) which span these disordered phases. In this talk we will show from the microscopic point of view, how does the glassy state manifests itself as well as how does the evolution from the glass to the “antiglass” occurs.

Monday, March 10, 2008 8:00AM - 10:36AM — Session A33 DMP GMAG FIAP: Focus Session: Spin Dependent Phenomena in Semiconductors: — Morial Convention Center 224
8:00AM A33.00001 Cross-sectional scanning tunneling microscopy of Ga_{1-x}Mn_xAs/GaAs Heterostructures

PEDRAM ROUSHAN, ANTHONY RICHARDELLA, Department of Physics, Princeton University, SHAWN MACK, DAVID AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, ALI YAZDANI, Department of Physics, Princeton University — We have used a cryogenic scanning tunneling microscope (STM) to perform cross-sectional imaging studies of GaMnAs heterostructures. The heterostructures, consisting of a p-type buffer followed by a 3% Mn doped layer, were grown on a n-type GaAs substrate by molecular-beam epitaxy and cleaved in situ for STM measurements. The topographic measurements on the GaMnAs layer showed a variety of long range electronic structure modulations on the order of a few nm due to high level of disorder and compensation. Combining bias-dependent imaging and spectroscopy, we have used the STM to identify electronic features due to Mn dopants and other defects. In particular, we find that Mn dopants on the top most layer act as deep acceptors and exhibit both topographic and spectroscopic features as our previous work [1] on Mn adatoms substituted into GaAs using STM manipulation techniques. [1] D. Kitchen, A. Richarrella, J-M. Tang, M. Flate, A. Yazdani, Nature 442, 436–439 (2006)

8:12AM A33.00002 Spectroscopic Mapping of Electronic States near Fermi Energy in GaMnAs

ANTHONY RICHARDELLA, PEDRAM ROUSHAN, Department of Physics, Princeton University, SHAWN MACK, DAVID AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, ALI YAZDANI, Department of Physics, Princeton University — We have used atomic resolved spectroscopic mapping with the scanning tunneling microscope (STM) to probe the spatial structure of electronic states in GaMnAs/GaAs heterostructures. Mapping the electronic states over a wide range of energies across the heterostructure, we find significant differences from the p-type buffer layer to the Mn-doped layer. The features include gap narrowing and in gap resonances, some of which are due to the bulk electronic structure of GaMnAs. We focus on these bulk states, in particular a broad state that is observed near the valance band above the Fermi energy. We analyze the spatial distribution of these states in conjunction with our observations of disorder in the sample and variations in the electrostatic potential landscape due to compensation. Finally, we discuss the implications of our results to the questions of localization, band tails and whether highly doped GaMnAs has an impurity band separated from or merged with the host valance band.

This work was supported by ARO and ONR, NSF and ASEE.

8:24AM A33.00003 STM studies of spin-spin interactions between Mn acceptors in p-type GaAs

DONGHUN LEE, DAVID R. DAUGHTON, JAY A. GUPTA, The Ohio State University, Department of Physics — We use a custom STM operating in a cryogenic, ultrahigh vacuum environment to study spin-spin interactions in semiconductors at the single-impurity level. By applying a voltage pulse with the STM tip, single magnetic impurities (e.g. Mn) can be substituted for Ga atoms in the first layer of the GaAs(110) surface. It was previously found that pairs of Mn acceptors exhibit an exchange splitting which depends on their separation and crystal orientation [2]. We are developing a capability for spin-polarized STM to better study long range magnetic ordering between pairs and larger clusters of Mn acceptors. To characterize the magnetic orientation of our STM tips, we have prepared samples such as Co/Cu(111) which exhibits out-of-plane magnetization, and Cr(001), which is an antiferromagnet with in-plane magnetic contrast between alternating terraces. http://www.physics.ohio-state.edu/~jugupta [2] D. Kitchen et al., Nature 442, 436-439 (2006)

8:36AM A33.00004 Magnetic Memory Effects in Coherent Magnetization Dynamics of GaMnAs: From Non-equilibrium to Thermal Regime

INGRID COTOROS, University of California at Berkeley, California, JIGANG WANG, Lawrence Berkeley National Laboratory, California, XINYU LIU, JACEK FURDYNA, University of Notre Dame, Indiana, JAROSLAV CHOVAN, ILIAS PERAKIS, University of Crete, Heraklion, Greece, DANIEL CHEMLA, University of California at Berkeley, California — III-Mn-V heterostructures exhibit rich spin memory effects and their magnetic properties show strong responses to external stimuli (light, electrical gate and current) via carrier density tuning. Here we report on the coherent magnetization dynamics due to laser excitation of transient carriers in GaMnAs, distinctly depending on the initial magnetic state the system is prepared in. We identify two distinct temporal regimes that reveal a complex scenario of spin reorientation, marked by the transition from a highly non-equilibrium, non-thermal, transient carrier-mediated regime (< 300 femtosecond), to a thermal, lattice-heating regime (on the picosecond time scale). The ultrafast, sub-picosecond response can be used as footing for ultrafast optical detection of magnetic memory states. This observed femtosecond cooperative magnetic phenomenon may represent an as-yet-undiscovered universal principle in all carrier-mediated ferromagnetic materials, offering potential perspectives for terahertz (10^{12} Hz) speed “spintronic” devices and functional systems.

8:48AM A33.00005 Epitaxial engineering of ferromagnetism in (GaAs)/(Ga,Mn)As digital superlattices

M.J. WILSON, G. XIANG, B.L. SHEU, P. SCHIFFER, N. SAMARTH, Penn State University — Recent theory predicts novel pathways for the epitaxial engineering of ferromagnetism in GaAs/MnAs digital superlattices grown along different crystalline directions [Francosetti et al., PRL 97, 047202 (2006)]. This has motivated us to systematically study GaAs/(Ga,Mn)As digital superlattices grown along the [001], [110], [210] and [311] directions. We have characterized these samples using SQUID magnetometry, magnetotransport, TEM and SIMS. We observe clear trends in the Curie temperature that are correlated with the epitaxy direction and the GaAs spacer layer thickness. Our results suggest that – for a given Mn concentration – the Curie temperature of (Ga,Mn)As may depend on the geometrical arrangement of the Mn ions. We also explore alternative explanations, such as an orientation dependence of the Mn incorporation rate and defect formation energies.

Work supported by the DARPA PROM program

9:00AM A33.00006 Stoichiometric growth of high Curie temperature heavily-alloyed GaMnAs

S. MACK, R.C. MYERS, J.T. HERON, A.C. GOSSARD, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Previous work indicates that single-phase, high-Mn incorporation (>9%) in GaAs can be obtained via MBE at very low substrate temperatures with film thicknesses on the order of a few nanometers. Here we present the properties of smooth, single-crystalline GaMnAs samples with Mn densities between 9 and 18% and continuously tuned arsenic stoichiometry using a combinatorial, non-rotated growth method. [1] Systematic, reproducible thick films (100 nm) display optimal magnetic, electronic, and structural properties in a narrow band of As:Ga flux ratios at the stoichiometric condition, where the Curie temperature is maximum. Post-growth annealing increases the Curie temperature while lowering the lattice constant, indicating that Mn interstitials are the dominant compensating defect in high-Mn containing GaMnAs. Curie temperatures from many samples grown with varying conditions all reach a maximum near the previously reported maximum (~165K).

9:24AM A33.00008 Magnetic domain structure study of a ferromagnetic semiconductor using a home-made low temperature scanning Hall probe microscope\textsuperscript{1}, SEONGSOO KWEEON, Materials Science and Engineering, ALEX DE LOZANNE, Department of Physics, U Texas at Austin, NITIN SAMARTH, Physics Department, Penn State U,University Park, PA — GaMnAs is a ferromagnetic semiconductor actively studied for basic research and for the possibility of application to spintronic devices. To study the local magnetic properties of this material the magnetic force microscope (MFM) is too invasive (by affecting the domains in the sample) or not sensitive enough (due to the weak magnetization of the GaMnAs). We have therefore developed a scanning Hall probe microscope (SHPM) to complement our MFM studies. We use a lock-in technique to supply a bias current of 1-10\textmu A and to measure the Hall voltage. We have used this home-made SHPM in conjunction with a computer hard disk sample. Comparing images of this sample obtained with MFM and SHPM we show that our home-made SHPM is operating well. We observed the domain structure of 30-nm thick Ga\textsubscript{0.99}Mn\textsubscript{0.01}As epilayer grown on a 700nm-thick In\textsubscript{0.13}Ga\textsubscript{0.87}As buffer covering a GaAs substrate. We will study the magnetic domain structure as a function of temperature with varying external magnetic fields.

9:36AM A33.00009 Si co-doping of GaMnAs: a solution for removing As antisites , Y.J. CHO, X. LIU, J.K. FURDYNA, University of Notre Dame — The primary defects that degrade the ferromagnetism of GaMnAs are believed to be Mn interstitials and As antisites. The former can be reduced by low temperature annealing after growth. However, so far no solution for removing As antisites in GaMnAs has been developed. In this connection we report the effect of Si co-doping on Ga\textsubscript{1-x}Mn\textsubscript{x}As films. For x < 0.05, Si co-doping decreases the Curie temperature compared to undoped GaMnAs. However, at higher Mn concentration Si co-doping has the desirable effect of improving both ferromagnetic and structural properties of GaMnAs. To achieve a high Mn concentration in GaMnAs the growth temperature has to be sufficiently low to prevent the formation of MnAs clusters, but this introduces a high density of As antisites in GaMnAs, thus degrading its structural and ferromagnetic properties. However, when such growth of GaMnAs is accompanied by Si co-doping, x-ray diffraction results show that such co-doping removes almost all As antisites in GaMnAs with high Mn concentration. Furthermore, magneto-transport and magnetization measurements show that the ferromagnetic properties of thick Si co-doped Ga\textsubscript{1-x}Mn\textsubscript{x}As (x > 0.1) films are greatly improved compared to samples without Si. This suggests that Si co-doping provides an effective solution for removing As antisites in GaMnAs at high Mn concentrations.

9:48AM A33.00010 Ferromagnetism in epitaxial InMnSb films , NIDHI PARASHAR, BRUCE WESSELS, Northwestern University — The structure and ferromagnetic properties of epitaxial In\textsubscript{1-x}Mn\textsubscript{x}Sb semiconductor films deposited using metal-organic vapor phase epitaxy were investigated. Films were single phase as determined by x-ray diffraction for x = 0.01 to 0.05. A rocking curve width of 0.3 degrees was measured in 2\textTheta-x-ray scans. XRD data is consistent with the formation of self-assembled Mn-rich nanocolumns. These nanocolumns are observed in a wide range of growth temperatures (80°C to 180°C) and Mn concentrations (1% to 11%). However the deposition rate is kept very low in order to favor the 2D spinodal decomposition which promotes the growth of nanocolumns. In this talk, we first present a complete phase diagram of nanocolumns as a function of growth temperature and Mn concentration focusing on their size, density, crystalline structure and magnetic properties. In particular, we could demonstrate that at low growth temperature it is possible to tune the columns density and at higher growth temperatures their size distribution. Moreover vertical self-organization of nanocolumns in (GeMn/Ge) superlattices could be achieved. At low growth temperatures, nanocolumns exhibit the diamond structure of Ge and contain up to 30 % of Mn. By combining ab-initio calculations and EXAFS measurements, we could suggest a realistic building block of the nanocolumns. In parallel we have studied the crystalline structure of nanocolumns using grazing incidence x-ray diffraction on synchrotron radiation facilities. We then correlated the magnetic properties like magnetic anisotropy of nanocolumns to their structure by combining SQUID and EPR measurements in a three-dimensional geometry. Finally magneto-transport measurements were performed to evidence the coupling between carriers and the magnetic nanocolumns. CIP measurements mostly give information on the Ge matrix electronic properties and CPP measurements on the nanocolumns. We show the first CPP measurements on a single nanocolumn using nanointerfaces.

Monday, March 10, 2008 8:00AM - 10:48AM — Session A35 FIAP: Focus Session: Negative Index Materials I Morial Convention Center 227

8:00AM A35.00001 Discrete Breathers in magnetic metamaterials in one and two dimensions, GIORGOS TSIRONIS, MARIA ELEFTHERIOU, NIKOS LAZARIDES, Physics Department, University of Crete, and IESL, Foundation of Research and Technology, P. O. Box 2208, 71003, Heraklion, Greece — We study the formation, stability as well as mobility of discrete breathers (DBs) in magnetic metamaterials in one and two dimensions. Magnetic metamaterials consists of split ring resonators (SRRs) exhibit large magnetic response at Terahertz and optical frequencies. We use nonlinear arrays of SRRs where DBs arise as a result of the nonlinearity and discreteness. We consider different geometries of SRRs in both dimensions and find several different types of Hamiltonian nonlinear excitations such as dark, single-site and multibreathers. We also consider the dissipative version of the problem where DBs are formed as well. In the latter case, DBs locally alter the paramagnetic character of MMs to a diamagnetic.
8:12AM A35.00002 Negative response and intrinsic localization in rf SQUID metamaterials.

GEORGE TSIRONIS, NIKOLAOS LAZARIDES, MARIA ELEFFTERIOU, University of Crete, and Institute of Electronic Structure and Laser, Foundation for Research and Technology-Hellas — A periodic array of rf SQUIDs in an alternating magnetic field acts as an inherently nonlinear magnetic metamaterial, due to the nonlinearity of the Josephson element and the resonant properties of the SQUIDs themselves. Neighboring SQUIDs are weakly coupled due to magnetic dipole-dipole interaction through their mutual inductances, allowing an effective medium description if the wavelength of the applied field is much larger than the array period. We found that SQUID arrays can provide negative magnetic response, and thus negative permeability, above the resonance frequency of the individual SQUIDs. Moreover, that response can be tuned by the applied flux. Dissipative SQUID arrays, modeled as discrete networks, support nonlinear excitations in the form of intrinsic localized modes (discrete breathers). We found that dissipative discrete breathers exist in both one- and two-dimensional SQUID arrays. Furthermore, those breathers alter locally the magnetic response of an array from paramagnetic to diamagnetic or vice versa.

8:24AM A35.00003 Hybrid metamaterials for dynamic tuning

TOM DRISCOll, University of California San Diego, SABARNI PALIT, Duke University, MUMTAZ QAZILBASH, University of California San Diego, MARCUS BREHM, F. KEILMANN, Max-Planck-Institut, B. CHAE, H. KIM, IT Convergence & Components Lab, DIMITRI BASOV, University of California San Diego, NAN MARIE-JOKERST, DAVID SMITH, Duke University — Advances in the field of metamaterials have created many new and exciting devices, but the performance and applicability of these devices to date have been hindered by the reliance on a dispersive resonance. In this talk we present a metamaterial device with the ability to dynamically tune the center frequency of its far-infrared resonance in real-time, alleviating many of the limitations of dispersion. Our device combines the familiar Split Ring Resonator (SRR) element with a thin film of rare earth oxide possessing a metal-to-insulator phase transition that occurs just above room temperature. During this phase transition, the electromagnetic responses of the oxide-film and SRR become intertwined, creating a sort of hybrid metamaterial. This interaction allows us to manipulate the resonance of the SRR via the oxide-film material properties. The device exhibits a dynamically tunable resonance — shifting center frequency of the magnetically active SRR mode by as much as 20% within 2 degrees Kelvin of temperature control.

8:36AM A35.00004 Tunable plasmonic nanostructures and nanolenses in optical domain

A.M. BRATKOVSKY, Hewlett-Packard Laboratories — We have designed and studied various periodic metamaterials with the resonant response in the IR and optical range. In particular, the stacks of metallic films with periodic hole arrays separated by dielectric layers (fishnet, FN) have been demonstrated to have a negative index at IR frequencies. We were able to control the index of refraction of a fishnet with an amorphous semiconductor spacer layer in a pump-probe experiment [1]. This opens up ways for modulating the light at the nanoscale. We have also observed strong second- and third- harmonic generation with this metamaterial. We discuss various uses of a gain material to compensate the losses. Arrays of metallic nanoparticles or holes support individual and collective plasmonic excitations that contribute to surface enhanced Raman scattering (SERS) with thousand-fold field enhancement factor that can be used for single-molecule detection and other applications of the “light at the nanoscale.”

9:12AM A35.00005 Negative Refraction Index in Magnetic Semiconductors

ADIL-GERAI KUSSOW, University of Massachusetts Lowell, Department of Physics, ALKIM AKYURTLU, University of Massachusetts Lowell, Electrical and Computer Engineering Department — A novel principally homogeneous, non-composite magnetic semiconductor, or Chromium doped Indium Oxide, with the Curie temperature well above room temperature with natural negative refraction index in the THz range will be presented. The negative refraction index arises due to the overlapping of the negative permittivity in the plasmon subsystem and the negative permeability in the spin wave (magnon) subsystem within the same frequency domain. Since the losses in the magnetic mode are almost negligible, and the additional scattering losses due to the inhomogeneities are not present in our homogeneous medium, the total losses are exclusively due to the plasmon decay. Consequently, the negative refraction index wave has losses approximately 5 times smaller than losses in any of the currently known inhomogeneous designs. The parameters of both plasmon and magnon subsystems are calculated from the extended Band Theory, and first principles, respectively, and validated with available experimental data. Analytical expressions which describe the negative refraction index band are also presented.

9:24AM A35.00006 Negative refraction and an optical analogue of a directional spin valve in multiferroic materials

KEI SAWADA, RIKEN, SHUICHI MURAKAMI, Tokyo Institute of Technology, NAOITO NAGAOSA, CREST, The University of Tokyo — We present a new mechanism for negative refraction caused by a magnetoelectric (ME) effect. The ME effect appears in multiferroic materials in which spatial inversion and time-reversal symmetries are simultaneously broken. Such symmetry breakings allow us to control the spontaneous electric polarization by a magnetic field. We study polaronic states in multiferroics and show that an asymmetric dispersion relation due to the ME effect gives rise to an optical analogue of a directional spin valve and a one-way waveguide as well as the negative refraction. We also estimate a realistic size of the effect.

9:36AM A35.00007 Infrared Properties of NiO-SrTiO3 Composites

I.D. VUGMEYSTER, K. KASTELLA, C. KNILL, R. MERLIN, J.F. WHITAKER, J.A. AZURDIA, S.N. KARLSDOTTIR, V. VOMECKOVA, C. TORRES-GARIBAY, J.W. HALLORAN, U. Michigan, G.O. ANDREEV, D.N. BASOV, U. California San Diego — Magnetic-dielectric composites with overlapping magnetic- and electric-dipole resonances are promising candidates in the search for artificial systems with negative refractive index [1]. Here we report on the fabrication and infrared characterisation of NiO-SrTiO3 ceramics. Transmission and reflection data were obtained in the 10-700 cm−1 range using both a THz time-domain and a FTIR spectrometer. The spectra show features associated with the bulk antiferromagnetic resonance of NiO and the soft mode of SrTiO3, as well as new collective modes of the aggregate. The results are in qualitative agreement with effective medium theories.

9:48AM A35.00008 Measurements of the electric susceptibilities of Au nanorods at optical frequencies

JAKE FONTANA, PETER PALFFY-MUHORAY, Liquid Crystal Institute, KSU, NICHOLAS KOTOV, ASHISH AGARWAL, University of Michigan — Accurate knowledge of the electric susceptibilities of nanoparticles is of key importance in the design of optical metamaterials. We have determined the principal values of the susceptibility tensor of Au nanorods by measuring the real and imaginary phase shift of light transmitted by Au nanorod suspensions in organic solvents. The nanorods were aligned by an externally applied low frequency electric field. The real and imaginary parts of the phase shift were determined using a conoscopic Mach-Zehnder interferometer with a dye laser and a spectrophotometer, respectively. We discuss our procedure of extracting the principal values of the susceptibility tensor as function of wavelength from the experimental data. We consider the implications of our results for the construction of optical negative index metamaterials.

1This work was supported by the AFOSR under MURI grant FA9550-06-1-0337.
10:00AM A35.00009 Tuned permeability in terahertz split-ring resonators for devices and sensors, GREG ANDREEV, TOM DRISCOLL, DIMITRI BASOV, MASSIMILIANO DIVENTRA, University of California at San Diego, SABARNI PALIT, SANG YEON CHO, NAM MARIE JOKERST, DAVID SMITH, Duke University — A process is demonstrated for tuning the magnetic resonance frequency of a fixed split-ring resonator array, by way of adding material near the split-ring elements. Applying drops of a silicon-nanospheres/ethanol solution to the surface of the sample decreases the magnetic resonance frequency of the split-ring array in incremental steps of 0.03 THz. This fine tuning is done post fabrication and is demonstrated to be reversible. The exhibited sensitivity of the split-ring resonance frequency to the presence of silicon nanospheres also suggests further application possibilities as a sensor device.

10:12AM A35.00010 Double Negative Index of Refraction Observed in a Single Layer of Closed Ring Resonators, ZHAO HAO, MICHAEL MARTIN, Advanced Light Source, Lawrence Berkeley National Laboratory, BRUCE HARTENECK, STEFANO CABRINI, Molecular Foundry, Lawrence Berkeley National Laboratory, ERIK ANDERSON, Center of X-Ray Optics, Lawrence Berkeley National Laboratory — We report the results of a spectroscopic study of a single layer of nanoscale metallic single closed ring resonators on a free- standing thin membrane at near-normal and grazing angles of incidence. When the magnetic component of the light is perpendicular to the ring plane, we observe a so-called “double” negative index of refraction at near-infrared frequencies attributed to a strong magnetic dipolar resonance and a broad electric resonance in this metamaterial. We experimentally identify the different resonance modes and the spectral component of the region of negative refractive index on a series of samples with different feature and lattice sizes, using multiplexing and comparing to electromagnetic simulations.

1This work was supported by the LDARD Program and at M. F. by the Office of Science, Office of Basic Energy Sciences, of Lawrence Berkeley National Laboratory under the DOE Contract No. DE-AC02-05CH11231.

10:24AM A35.00011 Z-scan measurement of oriented Au nanoparticle suspensions, PIOTR LESIAK, Warsaw University of Technology, MICHELE MOREIRA, PETER PAlFFY-MUHORAY, Liquid Crystal Institute, KSU, NICKOLAS KOTOV, ASHISH AGARWAL, University of Michigan — The Z-scan technique, developed by the CREOL group, is a simple and effective method for measuring intensity dependent optical nonlinearities of materials. We have carried out Z-scan measurements of gold nanorods suspended in organic solvents using a CW laser. A low frequency external electric field was used to orient the nanoparticles. We present our experimental results for the real and imaginary parts of the nonlinear phase shift as function of the applied aligning electric field. We consider a variety of possible contributing physical mechanisms, and compare their expected contributions with experimental observations. [1] M. Sheik, A.A. Said, and E.W. Van Stryland, Opt. Lett. 14, 955 (1989). [2] J. Fontana, and P. Palffy-Muhoray, APS March meeting 2008, New Orleans, LA (2008).

10:36AM A35.00012 Numerical simulation of the non-local optical response of nanoparticles, JEREMY NEAL, PETER PAlFFY-MUHORAY, Liquid Crystal Institute, KSU — The interaction of nanoparticles with light is a primary focus of research in negative index materials. When the wavelength of light is comparable to the particle size, significant non-local effects are expected in the electric and magnetic response of the nanoparticles. It has been suggested that the spatially non-local response may be taken into account via the bianisotropic formalism for the constitutive equations. We have carried out numerical simulations of the optical response of nanoparticles using both the discrete dipole approximation and the finite integration technique to determine the effectiveness of these bianisotropic constitutive equations. We present our results, which indicate that the approach of Agranovich et al.[1] provides a better description of the non-local optical response than the bianisotropic formalism.

8:00AM A36.00001 , WENBING YUN, XRadia Corp. — No abstract available.

8:36AM A36.00002 Optimal conditions for combining a transmission x-ray microscope with a grating interferometer, XIANGHUI XIAO, QUN SHEN. Argonne National Laboratory, X-RAY MICROSCOPY & IMAGING GROUP TEAM — Transmission x-ray microscope (TXM) is a powerful imaging tool that can provide resolution down to 15~20 nm. Grating interferometer (GI) is a recently established imaging technique with which both phase and attenuation information of an arbitrary specimen can be extracted in a straightforward way. The achievable resolution of a GI is limited by either the grating analyzer period or the detector pixel size, which is currently at about micron level. It is natural to imagine that combing a TXM with a GI (TXMGI) will give ability to image a weak-absorbing specimen with high resolution. However, it is not trivial to obtain reliable structure information from a TXMGI. In this presentation, we will discuss the dependence of the interferogram on three key parameters in a TXMGI, i.e. the coherence of the illumination beam, the numerical aperture of the TXM, and the grating period. Based on that result, the optimal conditions and the limits on the achievable resolution are obtained.

3Use of the Advanced Photon Source was supported by the U. S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

8:48AM A36.00003 Consideration in the Reconstruction of 3D atomic Structure from X-Ray, YUHAO WANG, NEW JERSEY INSTITUTE OF TECHNOLOGY, J. BAI, UNIVERSITY OF TENNESSEE, T.A. TYSON, NEW JERSEY INSTITUTE OF TECHNOLOGY, P. SIDDONS, G. DE GERONIMO, BROOKHAVEN NATIONAL LABORATORY — X-Ray Holography is a promising technique for recovery of the three dimensional structure of materials. With the advent of high flux sources and fast x-ray detectors this method is under serious consideration as main stream technique. Simulations based on spherical atomic scattering factors method are performed to estimate the effects of wave front curvature by application to specific systems. An assessment is made of the distortions which arise if artifacts such as errors in the position of the origin exists. Simulations are performed to determine the influence of counting rates on the image reconstruction.

3This work is supported by NSF MRI-0722730.
9:00AM A36.00004 Synchrotron topographic studies of stacking faults in type-IIa diamond crystals.  XIANRONG HUANG, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439; Brookhaven National Laboratory, Upton, NY 11973, ALBERT MACRANDEL, JOZEF MAJ, Advanced Photon Source, Argonne National Laboratory, Argonne, IL 60439 — High-quality diamond is an ideal material for various synchrotron x-ray optical applications. However, diamond crystals generally contain various defects, among which stacking faults (SFs) are more detrimental since they are planar defects extended up to square centimeters. In this presentation, we will introduce monochromatic synchrotron topographic studies of SFs (as well as other defects) in type-IIa diamond crystals. SFs show strong contrast at the tails of the rocking curve, thus broadening the rocking curve width. The outcrops of SFs on the crystal surface still show sharp white-line contrast at the Bragg peak, indicating strong strains or lattice misorientations near the outcrops. From the variation of SF contrast with the rocking angle, we obtain a detailed picture how the extended SFs influence the diffraction performance of diamond crystals. A straightforward diffraction contrast mechanism of SFs will also be presented in addition to the dynamical theory description.

9:12AM A36.00005 Design, nanofabrication and testing of silicon and diamond hard X-ray optics.  A.F. ISAKOVIC, NSLS-Brookhaven National Laboratory, A. STEIN, J.B. WARREN, K. EVANS-LUTTERODT, Brookhaven National Laboratory, S. NARAYANAN, Argonne National Laboratory, M. SPRUNG, A. SANDY, Argonne National Laboratory — We have designed, fabricated and tested silicon (Si) and diamond based X-ray kinoform lenses. In design and nanofabrication of such X-ray optics elements, surface roughness and wall verticality are among the tasks of critical importance for achieving as-designed performance. Our cyclic cryogenic RIE method [1], developed to deal with such stringent nanofabrication requirements, is comparable in performance to licensed Bosch process, as established in measurements of the surface roughness, and the etch rate (>2 microns/min for Si; ~100 nm/min for diamond) and verticality (<1deg over 100 microns) parameters. We compare nanofabrication procedures for Si and diamond lenses, and discuss relative merits of Si and diamond as materials for X-ray lenses. We also show sub-100 nm spot size tests of kinoform Si-based X-ray focusing optics, determined via knife edge measurements at APS 8-ID, and a preliminary results of tests of diamond-based kinoform lens at NSLS, performed at X13B and APS 8-ID. [1] A. F. Isakovic et al., submitted for publication.

9:24AM A36.00006 X-ray Reflectivity and Power Spectral Density of Smoothly Polished Silicon.  LAHSEN ASSOUFID, ALBERT MACRANDEL, SURESH NARAYANAN, RUBEN KHachatRyAN, Argonne, SUNIL SINHA, UCSD — Silicon polished by means of chemical-mechanical-polishing has been studied. A finely crevaced top surface was seen in the AFM data. The power-spectral-density was measured by means of interferometry and by atomic force microscopy, and a roughness value of 0.21 - 0.23 nm rms was found by integration. X-ray reflectivity data for 10 keV x-rays were obtained at the Advanced Photon Source, and a roughness of 0.22 - 0.30 nm was found to be roughly consistent with these data. A surface layer with a slightly higher density than that of crystalline silicon was needed to model the x-ray reflectivety. Crevaces 3.6 nm deep and resulting in land areas having 85% coverage were invoked for the modeling. A total layer thickness of 7.4 nm was invoked for the modeling. That is, the crevaces penetrated roughly half way through the total layer thickness. Due to the overall agreement between the two very different techniques for measuring roughness, namely, PSD and x-ray reflectivity data, we consider these results to accurately quantify roughnesses for a silicon surface that is near the state-of-art for smoothness.

9:36AM A36.00007 Wide-angle incidence x-ray waveguides prepared by micro-/nano-technology using crystal surface diffraction.  SUNG-YU CHEN, National Tsing Hua University, YU-CHI SHEN, MAU-SEN CHIU, CHIA-HUNG CHU, National Tsing Hua University, YURIY P. STETSKO, BO-YUAN SHEW, Nat’l Synchrotron Radiation Research Center, SHIH-LIN CHANG, National Tsing Hua University — Grazing incidence x-ray waveguides have been most studied because of its simple geometry and its applicability for all photon energies. However, wide-angle incidence waveguides are also essential for modern x-ray optics, as far as coupling/guiding x-ray beams into given directions are concerned. To investigate this possibility we have prepared waveguides on silicon wafers by x-ray lithographic technique. The waveguides are 100μm high and 1cm long with different widths and the distance between the adjacent waveguides is 2.5 mm. Both the top and bottom surface of a waveguide are plated with gold. With this type of waveguides we have actually observed the effects of guiding x-rays in both lateral and vertical directions using (113) surface diffraction in Au/Si waveguide systems.

9:48AM A36.00008 Fluctuation electron microscopy studies of complex structured materials.  GONGPU ZHAO, School of Earth and Space Exploration and Department of Chemistry/Biochemistry, Arizona State University, Tempe, AZ, 85287, ANNICK ROUGÉE, Department of Physics, Arizona State University, Tempe, AZ, 85287, PETER BUSECK, School of Earth and Space Exploration and Department of Chemistry/Biochemistry, Arizona State University, Tempe, AZ, 85287, MICHAEL TREACY, Department of Physics, Arizona State University, Tempe, AZ, 85287 — Fluctuation electron microscopy (FEM) is a hybrid imaging-diffraction technique. This technique is particularly sensitive to paracrystalline structures of dimension 0.5-2 nm, which are difficult to detect by either imaging or diffraction techniques alone. It has been successfully deployed to study paracrystalline structures in amorphous silicides, glass, and oxide glasses. This technique has also been used to study metallic glasses and oxide glasses. Until now, FEM has not been used to study disordered geological materials. In this talk we present our FEM studies of shungite, a naturally occurring disordered carbonaceous material, reveal that trace quantities of tightly curved graphene structures such as C60, or fragments of C60, is present in shungite. We also present results from our study of metamict zircon, whose crystal structure is destroyed by self-radiation during naturally occurring α decay events. Work is in progress to study the structural evolution during the metamictization process.

10:00AM A36.00009 Holography with Low Energy Electrons - a New Tool for Structural Biology.  TATIANA LATYCHEVSKAIA, HANS-WERNER FINK, University of Zurich — Holography is widely used for three-dimensional imaging of macroscopic objects using visible light. The same principle can also be applied for imaging of individual molecules like DNA or larger objects, for instance viruses. The holograms are recorded with coherent low energy electrons with wavelength, and thus potential resolution, in the sub-nanometer regime. The experimental setup together with holograms of individual biological molecules and their numerical reconstructions shall be presented. Current experimental and theoretical challenges of holography with low energy electrons will also be addressed. Strong forward scattering of electron waves has been taken into account for the reconstruction process. Since most biological molecules exhibit phase shifting rather than absorbing properties, the retrieval of the phase parallel to the absorbing properties of an object has been realized. On the experimental side, a method towards a significantly improved signal to noise ratio in holograms has been established by acquiring several hundred short pulsed holograms followed by a cross correlation alignment. Finally, the solution to the twin image problem in holography will be presented and reconstructed twin-image free experimental holograms will be shown.

1Supported by the European project SIBMAR.
10:12AM A36.00010 Theory of ultrafast electron diffraction: the role of the pulse properties.1, JOHN SIPE, ANIA MICHALIK, EUGENE SHERMAN, Department of Physics and Institute of Optical Sciences, University of Toronto — We present a general formalism for scattering of electron bunches used in ultrafast electron diffraction (UED) experiments that incorporates characteristic parameters of the incident electron bunch. To perform the scattering calculation, we associate the classical distribution function, which describes the electron bunch just before scattering, with the asymptotic-in Wigner distribution. Using single-scattering and far-field approximations appropriate for typical UED experimental conditions, and considering the effects of the bunch parameters on the scattered signal, we derive two diffraction expressions. We derive a Fraunhofer type expression suitable for scattering from small samples, such as molecules, and a Fresnel type expression appropriate for scattering from large targets such as thin films. In our analysis we also identify the coherence length of an electron bunch. We present sample numerical calculation for scattering by nanosize particles based on our model, and discuss the effects of bunch and scattering target parameters on the diffraction signal.

3We are grateful to the NSERC (Canada) for support.

10:24AM A36.00011 Determination of Adsorbed C_{60} Nanostructures by Low-Energy Electron Diffraction1, M.A. VAN HOVE, G.M. GAVAZA, Z.X. YU, G. XU, S.Y. TONG, City University of Hong Kong, W.W. PAI, C.H. LIN, Center for Condensed Matter Sciences, National Taiwan University — We have recently extended to nanostructures the basic theoretical capabilities of surface structure determination by Low Energy Electron Diffraction (LEED), by adopting a non-periodic cluster approach and substantially accelerating the computation time for complex structures. In this contribution, we describe two further theoretical enhancements and their application to experimental data for buckyballs adsorbed on a Cu(111) surface. One enhancement addresses occasional situations where strong multiple scattering causes poor convergence: this is solved by treating all scattering within subclusters of a few atoms with accurate matrix inversion. Secondly, for the structure determination of complex nanostructures, an efficient search method is essential: for that purpose a modified version of tensor LEED is adapted to nanostructures, called NanoTensorLEED. We exhibit the resulting ability to analyze detailed nanostructures with the case of buckyballs adsorbed on a Cu(111) surface.

1Funded in part by RGC Grant No. CityU1/02C and CityU Grant No. 9610059.

10:36AM A36.00012 RHEED-TRAXS as a tool for in-situ stoichiometry control.1, SANDEEP CHANDRIL, CAMERON KEENAN, THOMAS MYERS, DAVID LEDERMAN, West Virginia University — RHEED-total reflection x-ray spectroscopy (TRAXS) is an in-situ chemical and structural characterization technique which is highly surface sensitive. This consists of a grazing-angle electron beam from which characteristic x-rays from the sample are measured also at grazing angles. We have demonstrated that monolayer sensitivity in Y and Mn films on GaN can be achieved. We have also developed a theoretical model for the angular dependence of the x-ray Kα peaks for the thin films, based on Parratt’s formalism for x-ray reflectivity and the electron trajectory simulation software CASINO, to correct for grazing angle electron beam as a source for x-rays. As the angular dependence is highly dependent upon the film thickness and the smoothness of the film, it can be used to determine the deposition rate of individual elements as well as the interface chemical roughness.

1This work was funded by ONR (Grant N00014-02-1-0974), the AFOSR (MURI grant F49620-03-1-0330), and NSF (CIAM-DMR grant 0502825).

10:48AM A36.00013 First background free measurement of the inelastic tail of the Auger electron spectrum down to 0 eV1, A. H. WEISS, S. MUKHERJEE, M.P. NADESALINGAM, N. G. FAZLEEV, U. Texas at Arlington — Background free measurements of the inelastic tail of the Auger electron energy spectrum were performed by using very low energy positrons to excite Auger transitions in Au and Cu via positron-electron annihilation. The kinetic energy of the incident positrons (1.5eV) was set below the energy threshold required to excite secondary electrons resulting in a Auger spectra that was completely free of collision induced secondary electrons. The measured spectra contain contributions solely from either annihilation induced Auger electrons or annihilation induced Auger electrons that have lost energy on the way out. By using the time of flight technique it was possible to measure the inelastic tail of the Auger electron energy spectrum down to 0 eV.

Session A37 FLAP: Semiconductors I: Growth and Processing Morial Convention Center 229

8:00AM A37.00001 Single phase In_xGa_{1−x}N (0.25 ≤ x ≤ 0.63) alloys synthesized by MOCVD. , BED PANTHA, LI JING, JINGYU LIN, HONGXING JIANG, Kansas State University. KANSAS STATE UNIVERSITY TEAM — In_xGa_{1−x}N alloys have received much attention due to their applications in optoelectronic devices operating in the near infrared region to the near UV region as the band gap of In_xGa_{1−x}N can be continuously tuned from ∼ 0.7 eV (InN) to 3.4 eV (GaN). Recently, it has been suggested that high quality In-rich InGaN alloys offer great potential applications in many important areas as follows: (1) high efficiency multijunction solar cell, (2) high efficiency photoelectrochemical (PEC) cell, and (3) thermoelectric (TE) devices. Our recent experimental results show that In-rich InGaN alloys could be as good as SiGe alloys in terms of figure of merit (ZT) for TE applications. However many experimental techniques have proven that growth of In-rich InGaN alloys is extremely challenging due to the solid phase miscibility gap between InN and GaN. Here we present the growth of single phase InGaN alloys with high In-contents by metal organic chemical vapor deposition on AlN/Al_{2}O_{3} and/or GaN/Al_{2}O_{3} templates. X-ray diffraction was employed to determine indium content. Single peak of wide range theta-2theta scan of (002) plane confirmed that there is no evidence of phase separation. Optical and electrical properties and surface morphology were also studied by photoluminescence, Hall-effect and atomic force microscopy measurements, respectively.

8:12AM A37.00002 High Mobility InN epilayers grown on AlN templates by MOCVD. NEELEM KHAN, ASHOK SEDHAINE, JING LI, JINGYU LIN, HONGXING JIANG, Department of Physics, Kansas State University, Manhattan, KS 66506-2601. — Among III-nitrides, InN has the smallest electron effective mass, the largest mobility and smallest direct band gap. These distinguished properties make InN an interesting material for applications in high speed electronic devices and full color displays. However, obtaining InN and In-rich InGaN epilayers with controllable conductivity is still a challenging task. We report here on the growth and transport property studies of InN epilayers on AlN templates, as compared to GaN templates. Significant improvements in the electrical and optical properties of InN epilayers were observed on AlN templates. A Hall mobility of 1390 cm^2/Vs with a carrier concentration of 1x10^{19}cm^{-3} at room temperature was observed, which is highest value reported for MOCVD grown InN epilayers. The photoluminescence emission spectra revealed band to band emission peak at ∼0.75 eV. The effects of post growth annealing on transport, structural and optical properties of undoped and Mg-doped InN epilayers will also be presented.
Si nanomembranes with mixed crystal orientations

SHELLEY SCOTT, DEBORAH COTTRELL, DONALD SAVAGE, MAX LAGALLY, University of Wisconsin-Madison — Higher-carrier-mobility CMOS devices enhance processor speed. The large mobilities that have a form of the lognormal type. The resulting expression is used to discuss the grain size distribution of solid phase crystallized Si-films.

time development of grain size distribution in random nucleation and growth processes. The solution of this equation provides an analytical derivation of size distributions that has a form of the lognormal type. The logarithmic-normal (lognormal) distribution is one of the most frequently observed distributions in nature and describes a large number of physical, biological, and technological processes. The lognormal distribution is often used in modeling phenomena where the logarithm of the variable follows a normal distribution.

BERGMANN, Robert Bosch GmbH, Automotive Electronics, Quality Management Suppliers, Physical Analysis, P.O.Box 1342, 72703 Reutlingen, Germany — The need to develop reliable and cost-effective alternatives to solid-state devices is rapidly growing. Solar light is among the most important and promising, therefore new materials are searched for to effectively overlap and harvest the solar spectrum. Here we describe the preparation of titanium oxide nano-clusters utilizing amorphous solid water (ASW) as a reactive buffer layer to assist the growth of titanium oxide clusters. These clusters were grown in-vacuum on top of ASW layers at 120K. Upon evaporation of the water layer, seed Ti(OH)$_n$ clusters polymerize via a solid-state "Sol-Gel-like" mechanism. Self-termination process, dictated by the evaporated water vapor, results in hemispherical clusters 5-7 nm in diameter. The clusters were analyzed by XPS at 300K. The clusters grown this way were studied by employing 4K photoluminescence spectroscopy, revealing a typical diode-like I-V profile. An apparent band gap of 2.3-2.5 eV was obtained, significantly narrower than the bulk value of TiO$_2$ crystal (3.2 eV). Thermal stability of these defect rich clusters need to be studied, since this may prove important for photocatalysis and photovoltaic applications.

8:24AM A37.00003 Growth of the BN – nanostructured materials using borazine decomposition by Laser Chemical Vapor Synthesis, ARTURO HIDALGO, VLADIMIR MAKAROV, DACHUN HUANG, GERARDO MORELL, BRAD WEINER — We describe BN nanostructured materials growth by Laser Chemical Vapor Synthesis (LCVS) using the precursor borazine B$_3$N$_6$H$_6$. As a result due to laser induced creation of the active chemical intermediates in the bulk volume, and further development of the "dark" chain processes in the borazine vapor with formation of the BN nano-tubes and hydrogen gas. The phenomenological model qualitatively describing the observed phenomenon was developed and applied to explanation of the studied effects. The variation of radiation density (J/cm$^2$) for both harmonics and pressure is used for optimized the amount obtained.

8:36AM A37.00004 Anomalous Coherent Bragg Rod Analysis Studies of GaAs/InGaAs. DIVINE KUMAH, NAJI HUSSENI, CODRIN CIONCA, ALEX RIPOSAN, Applied Physics Dept. University of Michigan, JOANNA MIRECKI MILLUNICH, Department of Materials Science and Engineering, University of Michigan, PHIL WILLMOTT, ROY CLARKE, Swiss Light Source, YIZHAK YACOBY, Racah Institute of Physics, Hebrew University — A considerable amount of work has been carried out recently in correlating growth conditions with electronically observed properties of Group III-V systems using a variety of characterization techniques. Ambiguity in interpretation of most characterization techniques arises due to difficulties in separating roughness effects from segregation and inter-diffusion of atomic species. We apply x-ray resonant techniques to the Coherent Bragg Rod Analysis (COBRA) phase retrieval procedure to produce high resolution electron density maps from bragg rod scans to determine with a high degree of accuracy, the relative concentrations of In and Ga in a system comprising of 1ML of GaAs on InGaAs.

8:48AM A37.00005 Growth and Characterization of Non-Polar, A-Plane ZnO Thin Films, PRIYA V. CHINTA, O. LOZANO, P. WADEKAR, L.H. CHU, Q.Y. CHEN*, W.K. CHU, Texas Center for Superconductivity and Dept. of Physics, University of Houston, TX, H.W. SEO, Department of Physics, University of Arkansas, AR, L.W. TU, N.J. HO, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, NSYSU, Taiwan. — The growth and characterizations of non-polar a-axis-oriented epitaxial films of ZnO deposited by magnetron sputtering were investigated in comparison with the polar c-axis-oriented counterparts. The single-phase a-axis-oriented films were obtained at 700-degree C substrate temperature, whereas both a- and c-axis orientations were observed when deposited at lower temperatures ranging from 400 degree C to 600 degree C. The structural, morphological and temperature effects on photoluminescence behaviors have been studied. X-ray rocking curves show that the FWHM of (11-20) peak increases with temperature up to 600 degree C but start to decreases beyond 700C. Atomic force microscopy reveals significant changes in surface morphology as the growth temperature varies. Optical properties of the differently oriented films will be presented. PL emission in UV range was observed for the a-plane ZnO films which has been attributed to neutral donor bound exciton. The effect of Al-doping will also be discussed. *Also with NSYSU.

9:00AM A37.00006 Pinpoint Growth Mechanism Of ZnO Nanoparticles, DA-JUN SHU, XIANG XIONG, MU WANG, National Laboratory of Solid State Microstructures and Department of PhysicsUniversity, Nanjing University, Nanjing 210093, China, NATIONAL LABORATORY OF SOLID STATE MICROSTRUCTURES AND DEPARTMENT OF PHYSICSUNIVERSITY COLLABORATION — We investigate the growth mechanism of ZnO nanoparticles synthesized by thermal evaporation method. Temperature is tuned to control the growth driving force while other conditions are fixed. Classical nucleation theory and growth dynamics are used to analyze the competition between growth in lateral and vertical directions. Interfacial diffusion properties, step edge diffusion barrier and several other factors affecting the growth of nanostructures are taken into account. Based on these considerations we have established a model which suggests a quantitative relation between temperature and the size of nanoparticles. Programmed cooling processes are introduced into the thermal evaporation to verify the theoretical expectations. It is also demonstrated that a morphology-controllable hierarchical prisms, which is expected from our theoretical model, can be easily achieved by tuning the temperature. The authors acknowledge the financial support from the Ministry of Science and Technology of China (Grants No.2004CB119005 and No.2006CB801004).

9:12AM A37.00007 Titanium oxide nano-clusters prepared via amorphous solid water: Improved overlap with solar spectrum, MICHA ASCHSER, The Hebrew University of Jerusalem — The need to develop reliable and cost-effective alternative energy sources is rapidly growing. Solar light is among the most important and promising, therefore new materials are searched for to effectively overlap and harvest the solar spectrum. Here we describe the preparation of titanium oxide nano-clusters utilizing amorphous solid water (ASW) as a reactive buffer layer to assist the growth of titanium oxide clusters. These clusters were grown in-vacuum on top of ASW layers at 120K. Upon evaporation of the water layer, seed Ti(OH)$_n$ clusters polymerize via a solid-state "Sol-Gel-like" mechanism. Self-termination process, dictated by the evaporated water vapor, results in hemispherical clusters 5-7 nm in diameter. The clusters were analyzed by XPS at 300K. The clusters grown this way were studied by employing 4K scanning tunneling spectroscopy, revealing a typical diode-like I-V profile. An apparent band gap of 2.3-2.5 eV was obtained, significantly narrower than the bulk value of TiO$_2$ crystal (3.2 eV). Thermal stability of these defect rich clusters need to be studied, since this may prove important for photocatalysis and photovoltaic applications.

9:24AM A37.00008 On the logarithmic-normal distribution in nucleation and growth processes, ANDREAS BILL, ANTHONY TERAN, California State University Long Beach, Dept. of Physics & Astronomy, Long Beach, CA 90840-3901, RALF B. BERGMANN, Robert Bosch GmbH, Automotive Electronics, Quality Management Suppliers, Physical Analysis, P.O.Box 1342, 72703 Reutlingen, Germany — The logarithmic-normal (lognormal) distribution is one of the most frequently observed distributions in nature and describes a large number of physical, biological and even societal phenomena. However, a deviation of this distribution from first principles is lacking. We propose a differential equation governing the time development of the size distribution in random nucleation and growth processes. The solution of this equation provides an analytical derivation of size distributions that has a form of the lognormal type. The resulting expression is used to discuss the grain size distribution of solid phase crystallized Si-films.

9:36AM A37.00009 Si nanomembranes with mixed crystal orientations, SHELLEY SCOTT, DEBORAH COTTRELL, DONALD SAVAGE, MAX LAGALLY, University of Wisconsin-Madison — Higher-carrier-mobility CMOS devices enhance processor speed. Carrier mobility can be optimized by fabricating mixed regions of Si(110) (high hole mobility) and Si(001) (high electron mobility) on a single substrate, so-called hybrid-orientation technology (HOT). We fabricate a mixed-crystal-orientation material using Si nanomembrane (SiNM) transfer and overgrowth. The top Si layer of SOI(110) is patterned with an array of holes and removed from its handle substrate, creating a Si(110)NM, which is then bonded to Si(001). We deposit Si over the structure with CVD, which is much faster on Si(001) than on Si(110), allowing planarization of the surface (i.e., hole filling), to produce a flat mesh of Si(001) and Si(110) regions. We characterize the mesh with XRD, SEM, and AFM. We can fabricate HOT membranes for transfer to various (including flexible) substrates, and can incorporate strain to tune mobilities. With strained Si(110)NMs, we expect a hole mobility enhancement of ~70% over Si(001) while maintaining the high electron mobility of Si(001), thereby dramatically reducing the mobility imbalance between n- and p-type devices. Supported by DOE and NZFRST.
9:48AM A37.00010 Strain Relaxation in Elastically Strain-Sharing Silicon (110) Nanomembranes1, DEBORAH COTTRILL, SHELLEY SCOTT, DONALD SAVAGE, MAX LAGALLY, University of Wisconsin-Madison. — TEAM — Tensely strained Si(110) has potential for advanced CMOS and p-MOS devices because, depending on strain and current direction, hole mobility can be increased to 150% of that of unstrained Si(110) and an electron mobility nearly equal. Previous efforts to strain Si(110) tensely have relied on the formation of partial dislocations for strain relaxation, resulting in large asymmetric components of the in-plane strain and high threading dislocation densities, which alter device performance. We use thin multi-layer heterostructures of Si/SiGe/Si(110) grown with MBE on Si(110)-on-insulator that elastically strain share when released from the handling substrate. Besides their very high flexibility, these nanomembranes (NMs) are virtually dislocation free and exhibit a lower degree of asymmetric in-plane strain relaxation than achieved with threading dislocation relaxation; the NMs rely on elastic strain transfer rather than partial dislocation propagation. We use AFM, XRD, and Raman to characterize growth, strain transfer, and strain anisotropy.

1Supported by AFOSR DOE, NDSEG Fellowship (DMC), and NZFRST Fellowship (SAS).

10:00AM A37.00011 A Novel Route for the Synthesis of Graphene by Microwave Plasma Enhanced Chemical Vapor Deposition, ALEXANDER MALESEVIC, MANISH PAL CHOWDHURY, LIANG ZHANG, ANNIK VAN-HULSEL, CHRIS VAN HAESENDONCK — A novel route for the synthesis of graphene by means of microwave plasma enhanced chemical vapor deposition is presented. This technique outclasses its competitors in many ways since it is less elaborate and better reproducible than micromechanical cleavage of graphite and less expensive than thermal decomposition of silicon carbide wafers. Methane diluted with hydrogen is decomposed in a high power microwave plasma and the resulting carbon radicals recombine on the surface of any substrate that withstands temperatures up to 700 °C. A broad range of substrates were successfully tested including silicon, quartz, stainless steel and many metals. The resulting carbon nanostructures are freestanding graphene flakes, only four to six atomic layers thick but up to several micrometers wide and high. The flakes are perpendicular aligned to the substrate surface. Thorough qualitative analysis lead to the conclusion that the flakes are highly crystalline sp2 carbon nanostructures with few defects or impurities. A possible growth scheme is proposed and field emission measurements of as grown flakes reveal a low turn on voltage of only 3V/µm which is a promising value for possible future applications.

10:12AM A37.00012 Structure of Iron Silicon Germanide and Osmium Silicide Epitaxial Films Measured by X-Ray Absorption Spectroscopy1, NADER ELMARHOUMI, R. COTTIER, F. AMIR, Univ. of North Texas, G. MERCCHAN, A. ROY, CAMD/LSU, H. GEISLER, C. A. VENTRICE JR., T. D. GOLDING, Texas State Univ. — Some of the iron- and osmium-based metal silicide and germinide phases have been proposed to be direct band gap semiconductors. We have used synchrotron-based x-ray absorption spectroscopy to study the structure of iron silicon germanide and osmium silicon silicide films grown by molecular beam epitaxy. Osmium silicide films which are primarily in the Os5Si3 phase and a series of Fe(Si1−xGex)2 films with a nominal Ge concentration of up to x = 0.04 have been grown. X-ray absorption near edge structure (XANES) measurements on both the iron silicon germinide and osmium silicide films have been performed. An absorption edge shift of 0.9 eV is observed for the osmium silicide films; however, no shift was observed for the iron silicon germinide films. Extended x-ray absorption fine structure (EXAFS) measurements have also been performed on the iron silicon germinide films. The nearest neighbor coordination corresponding to the β-FeSi phase of iron silicide provides the best fit with the EXAFS data.

1This work was supported in part by ONR.

10:24AM A37.00013 Studies of the Ge(100) Surface Using a Low Energy Positron Beam: The Effects of Surface Reconstructions on Positron Trapping and Annihilation Characteristics, N. G. FAZLEEAA, A. H. WEISS, Department of Physics, University of Texas at Arlington — Positron annihilation induced Auger electron spectroscopy (PAES) has been applied to study the Ge(100) surface. The PAES spectrum from the Ge(100) surface displays several strong Auger peaks corresponding to M4.5N1N2,3, M2.3M4.5M4.5, M2.3M4.5V, and M1M4.5M4.5 Auger transitions. The integrated peak intensities of Auger transitions are used to obtain experimental annihilation probabilities for the Ge 3d and 3p core level electrons. The experimental results are analyzed by performing calculations of positron surface states and annihilation characteristics of surface trapped positrons with relevant Ge core-level electrons for the reconstructed Ge(100)-p(2x1), Ge(100)-p(2x2), and Ge(100)-c(4x2) surfaces. The PAES spectrum from the Ge(100) surface displays several strong Auger peaks corresponding to M4.5N1N2,3, M2.3M4.5M4.5, M2.3M4.5V, and M1M4.5M4.5 Auger transitions. The integrated peak intensities of Auger transitions are used to obtain experimental annihilation probabilities for the Ge 3d and 3p core level electrons. The experimental results are analyzed by performing calculations of positron surface states and annihilation characteristics of surface trapped positrons with relevant Ge core-level electrons for the reconstructed Ge(100)-p(2x1), Ge(100)-p(2x2), and Ge(100)-c(4x2) surfaces. Estimates of positron binding energy, work function, and annihilation characteristics reveal their sensitivity to surface reconstruction of the topmost layers of clean Ge(100). These results are compared to the ones obtained for the reconstructed Si(100)-(2x1) and Si(100)-(2x2) surfaces. A comparison with PAES data reveals an agreement with theoretical core annihilation probabilities for the Auger transitions considered.

10:36AM A37.00014 X-ray Photoelectron Spectroscopic Investigation of Oxidation of Hafnium1, JOHN HICKMAN, STEVEN MCDONOUGH, R.L. MILLER, M.A. SEABOLT, G.A. NIXON, A.R. CHOURASIA, Department of Physics, Texas A&M University-Commerce — X-ray photoelectron spectroscopy has been employed to investigate the oxidation of hafnium. Thin films (20 Å) of elemental hafnium were deposited on silicon substrates using e-beam technique. Two types of samples were investigated. In one type, the substrate was annealed at the desired temperature after the deposition. In the other type, the substrate was kept at the desired temperature during the deposition. The substrate temperatures were kept at 100, 200, 300, 400, 500, and 600 °C. Hafnium is observed to get deposited mostly as hafnium dioxide with some suboxide. The amount of the suboxide is found to vary with the processing conditions. The concentration of the dioxide and the suboxide were determined by curve fitting the spectra. The fitting was performed using the parameters determined from fitting pure elemental hafnium spectrum and pure hafnium dioxide spectrum.

1Supported by Research Corporation and Organized Research, TAMU-Commerce.

Monday, March 10, 2008 8:00AM - 10:24AM — Session A38 DBP DMP: Focus Session: Biocompatibility Morial Convention Center 230
8:00AM A38.00001 The quantification of biocompatibility: toward a new definition, BUDDY RATNER, University of Washington — Implantable medical devices, and the biomaterials that comprise them, form a $100B business worldwide. Medical devices save lives and/or improve the quality of life for millions. Tissue engineering also makes extensive use of biomaterials—biomaterials are an enabling technology for tissue engineering. A central word to understanding the effectiveness of such materials and devices is biocompatibility. The word “biocompatible” is widely used in reference to biomaterials and medical devices and most everyone has some value understanding of its meaning. Many formal definitions have been proposed for this word, but it is still largely used in an imprecise manner. Four descriptions or definitions of biocompatibility will be reviewed: a widely adopted definition from a consensus conference, a surgeon’s perspective on this word, the regulatory agency view, and the factors that clearly influence biocompatibility. In this talk, the classical definition of biocompatibility will be contrasted to a newer definition embracing molecular concepts and the understanding of normal wound healing. The biological data on the in vivo healing responses of mammals to implants will be described. A strategy to improve the healing of biomaterials will be presented. It is based upon surface molecular engineering. First, non-specific protein adsorption must be inhibited. Strategies to achieve this design parameter will be presented. Then methods to deliver the specific protein signals will be addressed. Matricellular proteins such as osteopontin, thrombospondin 2 and SPARC will be introduced with an emphasis on exploiting the special reactivity of such proteins. A discussion of the influence of surface textures and porosities will also be presented. Finally a new scheme based upon macrophage phenotypic pathways will be proposed that may allow a quantitative measure of extent of biocompatibility.

8:36AM A38.00002 Biocompatibility of implantable biomedical devices, SUPING LU, Medtronic Inc — Biomedical devices have been broadly used to treat human disease, especially chronic diseases where pharmaceuticals are less effective. Heart valve and artificial joint are examples. Biomedical devices perform by delivering therapies such as electric stimulations, mechanical supports and biological actions. While the uses of biomedical devices are highly successful they can trigger adverse biological reactions as well. The property that medical devices perform with intended functions but not causing unacceptable adverse effects was called biocompatibility in the early time. As our understanding of biomaterial-biological interactions getting broader, biocompatibility has more meanings. In this talk, I will present some adverse biological reactions observed with implantable biomedical devices. Among them are surface fouling of implantable sensors, calcification with vascular devices, restenosis with stents, foreign particle migration and mechanical fractures of devices due to inflammation reactions. While these effects are repeatable, there are very few quantitative data and theories to define them. The purpose of this presentation is to introduce this biocompatibility concept to biophysicists to stimulate research interests at different angles. An open question is how to quantitatively understand the biocompatibility that, like many other biological processes, has not been quantified experimentally.

9:12AM A38.00003 A Gaussian theory of the response of heart frequency to ventilator, YAN LU, MICHAEL DEEM, Rice University, ANTON BURYKIN, TIMOTHY BUCHMAN, Washington University School of Medicine, RICE UNIVERSITY TEAM, WASHINGTON UNIVERSITY SCHOOL OF MEDICINE TEAM — Extensive studies suggest that there exists a coupling between the human heart and respiration. We studied changes in cardio-respiratory synchrony and dynamics of cardiovascular system during transition from mechanical ventilation to spontaneous respiration in critically ill patients. This observational study exploits a standard clinical practice—the spontaneous breathing trial (SBT). The SBT consists of a period of mechanical ventilation, followed by a period of spontaneous breathing, followed by resumption of mechanical ventilation. We collected continuous respiratory, cardiac (EKG), and blood pressure signals of mechanically ventilated patients before, during and after SBT. The data were analyzed by means of spectral analysis, phase dynamics, and entropy measures. Mechanical ventilation appears to affect not only the lungs but also the cardiac and vascular systems. Spontaneous cardiovascular rhythms are entrained by the mechanical ventilator and are drawn into synchrony. Sudden interruption of mechanical ventilation causes gross desynchronization, which is restored by reinitiation of mechanical ventilation. The data suggest (1) therapies intended to support one organ system may propagate unanticipated effects to other organ systems and (2) sustained therapies may adversely affect recovery of normal organ system interactions.

9:24AM A38.00004 Synchronization of Cardio-Respiratory Dynamics in Critically Ill Patients, ANTON BURYKIN, TIMOTHY BUCHMAN, Washington University in St. Louis — We studied changes in cardio-respiratory synchrony and dynamics of cardiovascular system during transition from mechanical ventilation to spontaneous respiration in critically ill patients. This observational study exploits a standard clinical practice—the spontaneous breathing trial (SBT). The SBT consists of a period of mechanical ventilation, followed by a period of spontaneous breathing, followed by resumption of mechanical ventilation. We collected continuous respiratory, cardiac (EKG), and blood pressure signals of mechanically ventilated patients before, during and after SBT. The data were analyzed by means of spectral analysis, phase dynamics, and entropy measures. Mechanical ventilation appears to affect not only the lungs but also the cardiac and vascular systems. Spontaneous cardiovascular rhythms are entrained by the mechanical ventilator and are drawn into synchrony. Sudden interruption of mechanical ventilation causes gross desynchronization, which is restored by reinitiation of mechanical ventilation. The data suggest (1) therapies intended to support one organ system may propagate unanticipated effects to other organ systems and (2) sustained therapies may adversely affect recovery of normal organ system interactions.

9:36AM A38.00005 Crystal Structure Properties of Human Teeth as a Function of Age, TH. LEVENTOURI, A. KYRIACOU, R. VENTURELLI, A. ANTONAKOS, E. LIAROKAPIS, V. PERDIKATSIS, Florida Atlantic University — We report on crystal structure studies of human teeth as a function of age in the range of 5-87 years. The crystallinity of the hydroxyapatite, which is the main dental mineral phase in teeth, decreases with age in a systematic way starting at ~40 years old teeth. The average crystallite size decreases from ~40 nm to ~12 nm in the age range 30 to 60 years old and then it remains practically constant. The a-lattice constant decreases in a similar systematic way and it is associated with the carbonate content of the tooth. Development of the secondary phases with the tooth-age questions the crystallographic structure of the dental apatite. FTIR spectroscopy reveals both types of carbonate substitution, but B-type substitution is greater by a factor of 4 than the A-type. An increase of the carbonate content with the tooth age is also deduced from the ratio of the V2 CO3 to the V1 PO4 IR modes from 17 to 70 years of age. TGA measurements confirm the results of both experimental methods.

1Support from the Cancer Institute at the FAU Research Park is acknowledged.

9:48AM A38.00006 Procedure to Measure Effect of Excess Body Mass on Musculoskeletal: II. Implementation, SAAMI J. SHAIBANI, Independent Modeling, Algorithms & Analytical Studies (IMAAS) — There are a number of ways in which the musculoskeletal system can be affected by excess body mass. One representative quantity for these is the torque exerted on the spinal column about a horizontal lateral axis; hence, its use as an illustrative mechanical indicator in the research reported here. Values of the torque are determined for all subjects in an exceptionally broad adult population that was developed during a companion study. Increases in body mass index caused nearly uniform increases in torque for all height percentiles in both sexes. Overweight individuals had torques that were 35 and 30 percent greater (females and males, respectively) than those for healthy individuals of the same height. Corresponding increases for obese individuals occurred at the much higher levels of 75 and 66 percent. Any resulting musculoskeletal damage from this is in addition to other problems arising from obesity, such as heart disease, diabetes, and high blood pressure. However, whereas the latter can be treated or managed with medication, some facets of the former might be irreversible and/or irremediable.
10:00AM A38.00007 Extremely high paw accelerations during paw shake in the cat: A mechanism revealed by computer simulations. ALEXANDER KLISHKO, Georgia Tech USA; Inst of Math Problems of Biol Puschino Russia. DAVID COFER, DONALD EDWARDS, Georgia State University; BORIS PRILUTSKY, Georgia Tech, GEORGIA TECH TEAM, GEORGIA STATE UNIVERSITY COLLABORATION — Paw shake response is a reflex aimed at removing an offending stimulus from the paw by imparting to it high periodic accelerations (≥10 g). These values seem too high to be produced by distal muscles exclusively. According to Prilutsky et al. (2005), resultant hip moments during paw shake are much greater than distal joint moments, whereas distal joint velocities and accelerations exceed those of the proximal joints. The goal of this study was to examine how proximal hip muscles could contribute to high paw accelerations. Using software AnimatLab, we developed a 2D model of the cat hindlimb consisting of 5 rigid segments with 4 hinge joints and 11 muscles spanning all joints. The muscles were assumed passive except for those crossing the hip. When in simulations the hip muscles were reciprocally activated to periodically flex and extend the hip joint with a typical paw shake frequency of 10 Hz, the hindlimb segments demonstrated motion resembling experimental observations: linear and angular velocities and accelerations of the distal segments exceeded several fold the values of the proximal segments. Simulated paw shake revealed features of a whip-like motion.

Monday, March 10, 2008 8:00AM - 11:00AM — Session A39 GSNP: Focus Session: Elasticity and Geometry of Thin Objects Morial Convention Center 231

8:00AM A39.00001 Delamination of thin elastic sheets from soft, sticky substrates. DOMINIC VELLA, LPS ENS, PEDRO REIS, Department of Mathematics, MIT; DENIS BARTOLO, JOSE BICO, PMMH, ESPCI; ALEXZK BOUDAOU, LPS ENS, BENOIT ROMAN, PMMH, ESPCI — We study the compression of a soft elastic substrate with a thin sheet adhered to its surface. In this situation, it is energetically expensive for the thin sheet to alter its length. Instead, it accommodates its excess length by delamination from the substrate, allowing it to bend out of the plane. Rather than forming a single ‘blister’, however, we observe the formation of several blisters with a characteristic size. Here, we investigate the dependence of this characteristic blister size on the material properties of the system using a combination of experimental and theoretical analyses.

8:12AM A39.00002 The frustrating tearing of adhesive tape. BENOIT ROMAN, PMMH UMR7636 CNRS/ESPCI; Paris6, Paris 7, EUGENIO HAMM, Departamento de Fisica, Universidad de Santiago de Chile. PEDRO M. REIS, Department of Mathematics, M.I.T.; M. LEBLANC, University of Chicago, ENRIQUE CERDA, Departamento de Fisica, Universidad de Santiago de Chile — When trying to remove an adhesive tape, one often only manages to peel off a useless pointy strip: the fracture tips on both sides of the pulled strip seem to attract each other, and merge in a finite distance. Why don’t they repel each other and lead to a continually increasing width of the strip, as one would like to? We will present an experimental and theoretical study of this pinch-off phenomenon in the rupture of peeled adhesive sheets. The cut shapes are very reproducible, and we will show that the geometry of the peeling field, where elastic energy is concentrated, plays a major role here.

8:24AM A39.00003 Instability of an elastic knot under twist. BASILE AUDOLY, CNRS / University Paris 6, NICOLAS CLAUVELIN, Universite Paris 6, SEBASTIEN NEUKIRCH, CNRS / University Paris 6, INSTITUT DE MECANIQUE D’ALEMBERT TEAM — In a recent paper, we derived a solution to the Kirchhoff equations representing a knotted elastic rod held by a tensile force applied at its ends. This problem has been formulated as the minimization of a curvature energy in the presence of a topological constraint. We extend this analysis to the case of a knot subjected to both a tensile force and a twisting moment. We unveil a striking instability that can be easily reproduced with a piece of computer cord: a simple knot, initially comprising a loop merging with a localized brad, can be unfolded under applied twist into a symmetric shape resembling the figure of eight. Doing so, it becomes much easier to untie.

8:36AM A39.00004 On the statistical physics of folding and crumpling. AREZK BOUDAOU, LPS CNRS/Ecole Normale Superieure — Unfolding a ball of crumpled paper reveals numerous ridges with a wide distribution of sizes. How can we describe the statistics of sizes and energies? Can we understand this system using the tools of statistical physics? During my talk, I will review the various experimental and theoretical approaches that we used to tackle these questions, which are typical of glasses and granular media.

9:12AM A39.00005 The Shape of the Optimal Javelin. YOSSI FARJOUN, MIT, JOHN NEU, UC Berkeley — To find the shape of a javelin whose vibrations dampen the fastest, we seek to maximize the eigenvalue of the first eigen-mode of a vibrating rod. The problem is related to (and is inspired by) the classical problems of finding the tallest and strongest columns solved by J. B. Keller [1], and J. B. Keller and F. I. Norisron [2]. A 4th order ODE for the maximizing eigen-mode is readily solved, however it is ill-conditioned at the boundaries, and standard numerical methods fails. Using a similarity solution, we “peel away” the singularity, and solve the remaining part “backwards”. The resulting shape has a frequency of vibration 5 times larger than that of the uniform-diameter rod. The method of solution is applicable to other similar problems. For example, we confirm the shape of the tallest column with it. [1] The Strongest Column / J. B. Keller ; Arch. Rat. Mech. Anal. 1960 (5), pp. 275–285

9:24AM A39.00006 Impacts on thin elastic sheets. ROMAIN VERMOREL, NICOLAS VANDENBERGHE, EMMANUEL VILLERMUAY, IRPHE - Aix Marseille Université, FRAGMENTATION AND MIXING TEAM TEAM — The radial cracks developing from the impact point of a projectile on a windscreen are of common experience. We investigate the origin of this phenomenon using thin elastic sheets as an experimental model. A projectile launched at controlled speed impacts a free membrane at rest. A tensile front set off from the point of impact and propagates radially at the speed of sound. Flexural waves can propagate in the extended area. Specifically, the interaction between the rigid body and the elastic sheet gives birth to a conical flexural wave whose base expands radially at a well defined velocity. During the propagation of both the tensile and flexural fronts, the radial tensile stress field results in a compressive stress in the azimuthal direction, which triggers a buckling instability. That instability is responsible for the formation of radial folds, with a well defined azimuthal wave number. Based on detailed experimental observations and measurements, we propose a model to understand the wave motion and stress field consequent to the impact; in addition, we provide a prediction for the number of folds selected during the buckling instability as a function of the relevant parameters, including impact velocity.

9:36AM A39.00007 Spiraling Cracks in Thin Sheets¹, VICTOR ROMERO², BENOIT ROMAN, PMMH CNRS, ENRIQUE CERDA, Universidad de Santiago de Chile — A wide kind of everyday-life industrial products come in a thin package that needs to be torn open by the user, and the opening is not always easy. We built a simple setup to study crack propagation in thin sheets coupled with large out-of-plane displacement: A cylindrical tool is inserted in a straight incision in a thin sheet, and is pushed against the sheet perpendicularly to that incision, eventually propagating a crack. When the blunt tool is continually pushed against the lip, we found that the crack follows a very robust spiraling path. Experiments may be interpreted in terms of “Spira Mirabilis” (logarithmic spiral). Starting with crack theory argument, we will show that the early behavior of the cut path follows a portion of a logarithmic spiral, and that the path tends to another spiral with a different pitch as the crack adds more turns. Our crack experiment illustrates the fact that thin sheets mechanics is deeply connected to geometry, and finally spirals characteristics allow us to measure material crack properties of the thin layer used.

9:48AM A39.00008 Interaction Between Two Localized Wrinkle Patterns, JIANGSHUI HUANG, WIM H. DE JEU, NARAYANAN MENON, THOMAS P. RUSSELL, Department of Physics, Polymer Science and Engineering, University of Massachusetts Amherst — A drop of water placed on the surface of a freely floating ultrathin polymer film produces a radial wrinkling pattern due to the capillary force it exerts on the film. We have previously characterized the number N and length L of the wrinkles. We now study the interaction between two such localized wrinkling patterns each induced by one drop of water. The patterns distort, and radial symmetry about each drop is lost, with the wrinkles extending further along the line between the drops. When the drops are brought closer, a single long wrinkle forms along this axis. We use the distance at which this connecting wrinkle appears to quantify the range of the interaction between the wrinkles. We will present data for this interaction length as a function of other length scales in the experiment. 1. Full reference here. Science 317, 650(2007)

10:00AM A39.00009 Pattern transformation triggered by deformation,¹ TOM MULLIN, University of Manchester — Periodic elastomeric cellular solids are subjected to uniaxial compression and novel transformations of the patterned structures are found upon reaching a critical value of applied load. The results of a numerical investigation reveal that the pattern switch is triggered by a reversible elastic instability. Excellent quantitative agreement between numerical and experimental results is found and the transformations are found to be remarkably uniform across the samples. Moreover the phenomenon is found to be robust for a range of soft solids including rubber and jelly. *Joint work with M.C. Boyce, K. Bertoldi and S. Deschanel, MIT.

¹EPSRC

10:12AM A39.00010 Granular Silo collapse: an experimental study,¹ ERIC CLEMENT, ESPCI-Universite Paris 6, GUSTAVO GUTIERRIEZ, Departamento de Fisica, Universidad Simon Bolivar, Caracas, Venezuela, PHILIPPE BOLTENHAGEN, boltenhagen@pmmh.espci.fr, JOSE LANUZA, ESPCI-Universite Paris 6 — We present an experimental work that develop some basic insight into the pre-buckling behavior and the buckling transition toward plastic collapse of a granular silo. We study different patterns of deformation generated on thin paper cylindrical shells during granular discharge. We study the collapse threshold for different bed height, flow rates and grain sizes. We compare the patterns that appear during the discharge of spherical beads, with those obtained in the axially compressed cylindrical shells. When the height of the granular column is close to the collapse threshold, we describe a ladder like pattern that rises around the cylinder surface in a spiral path of diamond shaped localizations, and develops into a plastic collapsing fold that grows around the collapsing silo.

¹Progran PCP-France-Venezuela

10:24AM A39.00011 Sudden ridge collapse in the stress relaxation of thin crumpled polymer films, INGO DIERKING, PAUL ARCHER, University of Manchester — Uniform compression of thin crumpled sheets subjected to a constant weight has been shown to exhibit a remarkably wide range of scaling behaviour, covering up to five orders of magnitude [1], i.e. time scales from seconds to weeks. We demonstrate that this scaling behaviour is not smooth, but rather interrupted by sudden changes in height of the uniformly compressed crumple, which we attribute to sudden ridge collapses. The height of the discontinuous jumps due to sudden ridge collapse during the compression process increases with increasing thickness of the polymer film. This is attributed to the fact that thick films exhibit a smaller defect density, but increased defect length. Interestingly, when plotting the time laps between successive ridge collapses as a function of time, the data collapses to a single line for all film thicknesses, with a slope of $d\Delta t/dt=1$ over a scaling regime of four orders of magnitude. Possible explanations will be discussed. [1] K. Matan, R.B. Williams, T.A. Witten, S.R. Nagel, Phys. Rev. Lett., 88, (2002), 076101.

10:36AM A39.00012 Geometry, mechanics and statistical physics in crumpled structures, LAURENT BOUE, AREZKI BOUDAOU, MOKHTAR ADDA-BEDIA, STÉPHANIE DEBOEUF, EYTAN KATZAV, Laboratoire de Physique Statistique, ENS Paris — There’s been a recent surge of interest in the study of low-dimensional packed elastic manifolds. In fact, the simple act of crumpling a piece of paper does require the simultaneous interaction of many fascinating mechanisms. These include energy condensation from large length scales to small singular topological self-avoidance and complex phase space landscapes reminiscent of frustration in the context of glassy systems. We will present a numerical experiment modeling the folding of an elastic rod (1D) restricted to a shrinking 2D space. The confinement is obtained by preparing an initially disordered elastic line embedded in a quadratic potential. Varying the strength of this confining potential shows that many metastable states can be observed. We are reaching a critical value of applied load. The results of a numerical investigation reveal that the pattern switch is triggered by a reversible elastic instability. Excellent quantitative agreement between numerical and experimental results is found and the transformations are found to be remarkably uniform across the samples. Moreover the phenomenon is found to be robust for a range of soft solids including rubber and jelly. *Joint work with M.C. Boyce, K. Bertoldi and S. Deschanel, MIT.

10:48AM A39.00013 Inside a Ball of Crumpled Aluminum Foil,¹ ANNE DOMINIQUE CAMBOU, NARAYANAN MENON, UMass Amherst — We have studied the three-dimensional geometry of a crumpled sheet via x-ray CT scans. We crumple circular sheets of aluminum with thicknesses of 30-50µm and diameter 100000µm into spherical balls of diameter 15000-20000µm. We then perform CT scans with a resolution of 6µm³/voxel. This allows us to fully resolve the conformation of the sheet. We use the reconstructed CT images to determine the mass distribution inside the crumpled ball. We also report on a box-counting analysis to assess the fractal nature of the mass distribution.

Monday, March 10, 2008 8:00AM - 11:00AM – Session A40 DCMP: Phase Stability and Phase Transitions Morial Convention Center 232
8:00AM A40.00001 First-principles solution to the problem of Mo lattice stability. IGOR ABRIKOSOV, CHRISTIAN ASKER, ARKADY MIKHAYLYUSHKIN, Department of Physics, Chemistry and Biology, Linköping University, Sweden — The energy differences between the ground state body-centred structure (bcc) and closed-packed face-centred structure (fcc) structures for transition metals in the middle of the series show unusually large disagreements when they are obtained by the thermochemical approach based on the analysis of experimental data or by first-principles electronic structure calculations. Considering a typical example, the lattice stability of Mo, we present a solution to this long-standing problem. In contrast to conventional total energy calculations within Density Functional Theory framework, we carry out ab initio molecular dynamics simulations for the two phases at high temperature. We show that at these conditions the fcc structures of Mo are dynamically stable, and the difference in their configurational energies decreases dramatically as compared to the zero temperature result, approaching the value derived by means of the thermochemical approach. We show that the main contribution to the effect comes from the modification of the canonical band structure for bcc and fcc phases due to lattice vibrations at high temperature, and discuss consequences of our finding for future first-principles simulations of phase stability.

8:12AM A40.00002 Link between structural and mechanical stability of fcc- and bcc-based ordered Mg-Li alloys. MAJE PHASHA, Materials Science and Manufacturing, CSIR, Pretoria, SA, PHUTI NGOEPE, Materials Modeling Centre, University of Limpopo, SOVENGA, SA, HASANI CHAUKE, Materials Modeling Centre, University of Limpopo, SOVENGA, SA, DUC NGUYEN-MANH, UKEA, Culham Science Centre, Oxfordshire, UK, DAVID PETTIFOR, Materials Modeling Laboratory, Department of Materials, University of Oxford, Oxford, UK — The first principles pseudopotential calculations based on the Perdew-Burke-Ernzerhof (PBE) form of generalized gradient approximation (GGA) within density functional theory (DFT) have been used to successfully investigate the electronic and elastic properties of cubic-based Mg-Li alloys. The heats of formation, Jones-type analysis and mechanical elasticity were utilized in predicting structural stability profile, and their results consistent with each other. An interesting correlation between shear modulus (C11) and the predicted energy differences of corresponding bcc and fcc ordered compounds relative to hcp Mg and Li lattices is observed.

8:24AM A40.00003 Density-Functional and CALPHAD Studies of U-Zr Alloys. ALEXANDER LANDA, PER SODERLING, PATRICE TURCHI, Lawrence Livermore National Laboratory, Livermore, CA 94551, USA, LEVENTE VITOS, ANDREI RUBAN, Royal Institute of Technology, Stockholm, SE-10044, Sweden — The U-Zr alloy alloys have been recognized as a fuel for liquid-metal fast breeder reactors. First-principles methods are employed to study ground-state properties of U-Zr alloys for the most important phases observed experimentally, namely γ (bcc) and δ (C32). Effective interatomic interactions obtained from the screened GPM, incorporating KKR-ASA-CPA, have been applied in MC simulations to derive the γ-δ miscibility gap. EMTO-CPA method has been applied to study properties of the open κ-phase. Results of ab initio calculations are compared with experimental data and CALPHAD assessment. Then, the CALPHAD assessed U-Zr phase diagram is contrasted with the one predicted with the input from ab initio. This work shows that an overall validity of a combined ab initio—CALPHAD approach to thermodynamic properties exists, and that the knowledge and quantitative output gained from quantum mechanics on phase stability and its relation to f-bonding, can be used to explore other actinide-based systems, for which experimental data are sparse or lacking. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

8:36AM A40.00004 Phase Stability Studies of Ni3Al and Pt3Al Structures. HASANI CHAUKE, Materials Modeling Centre, University of Limpopo, SOVENGA, SA, RALF DRAUTZ, Materials Modeling Laboratory, Department of Materials, University of Oxford, Oxford, UK, BENOIT MINISINI, ISMANS, 44 Avenue Bartholdi, 72000 Le Mans, FRANCE, PHUTI NGOEPE, Materials Modeling Centre, University of Limpopo, SOVENGA, SA, DAVID PETTIFOR, Materials Modeling Laboratory, Department of Materials, University of Oxford, Oxford, UK — The structural instability of cubic L12 against the non-cubic DO′C and tP16 Pt3Al have been investigated in direct comparison with Ni3Al, using plane-wave pseudopotential methods within the local density approximation. We predict that the deleterious DO′C is more stable than cubic ductile L12 Pt3Al, in agreement with the experimental observation of the LT DO′C phase and HT L12 phase. In contrast to the Pt-Al, the L12 Ni3Al is ground state and is consistent with the experimental phase diagram. The transformation from L12 into DO′C has been investigated more explicitly, where the transformation path along DO′C leads to a stable phase at displacement parameter u=0.0417. However the Ni3Al phase, is stable at u=0.0 corresponding to the cubic L12 phase, as expected. The phonon dispersion spectra have been used to confirm the relative structural trend where a soft mode was detected for L12 and DO′C which is not found in tP16 Pt3Al.

8:48AM A40.00005 Where are Nature’s missing structures1. GUS L.W. HART, Brigham Young University — Our society’s environmental and economic progress depends on the development of high-performance materials such as lightweight alloys, high-energy-density battery materials, recyclable motor vehicle and building components, and energy-efficient lighting. Meeting these needs requires us to understand the central role of crystal structure in a material’s properties. Despite more than 50 years of progress in first-principles calculations, it is still impossible in most materials to infer ground-state properties purely from a knowledge of their atomic components—a situation described as ‘scandalous’ in the well-known essay by Maddox. Although the key to the generic nature of the approach is energy minimization, the extrema are found in a chemistry-independent way.

1Supported by NSF DMR-0650406.

9:00AM A40.00006 Fully ab initio melting curve of aluminium up to 350 GPa. JOHANN BOUCHET, FRANCOIS BOTTIN, GERALD JOMARD, Commissariat à l’Energie Atomique — We performed ab initio molecular dynamics simulations to compute the melting curve of aluminium. Both the two-phase (TP) and heat-until melt (HUM) methods have been considered. The former describes an heterogeneous mechanism with a well-defined melting temperature Tm. On the other hand, in the HUM the crystal melts homogeneously and can be overheated above Tm. The limit of superheating is the critical temperature Te. Calculations are carried out in the NVT ensemble up to 350 GPa with supercells of different sizes. For each method, we present the convergence of the melting curves as a function of the number of atoms, and compare our results with previous calculations and experiments. We also discuss the evolution of the degree of overheating with respect to the pressure. At last, by means of NPT simulations we also compute volume change on melting, which is in good agreement with previous free energy calculations.

9:12AM A40.00007 Free energies from ab initio calculations for liquid Mg. RAQUEL LIZARRAGA, Universidad Austral de Chile, CARL GREEFF, Los Alamos National Laboratory — We performed free energy calculations for liquid metals from ab initio potential surfaces by means of Monte Carlo methods that involve sampling on the potential surface defined by a reference system. This allows for large gains in efficiency because the random walk is carried out on the much faster reference potential, and the ab initio potential is only evaluated on a small subset of uncorrelated configurations. This is highly desirable since direct free energy calculations for liquid metals from ab initio potential surfaces are very computationally intensive. Our calculations on liquid magnesium show that we can obtain free energies accurate at the meV/atom level with only 100 evaluations of the ab initio total energies.
9:24AM A40.00008 Ultrafast melting and solidification of Ag studied by time-resolved third harmonic generation, WAI LUN CHAN, VIRGINIA MCCREARY, ALEXIE LAGOUTCHEV, University of Illinois, Urbana-Champaign, YINON ASHKENAZY, The Hebrew University of Jerusalem, KWANGU KANG, DAVID CAHILL, ROBERT AVERBACK, University of Illinois, Urbana-Champaign. — We study the transformation of Ag between the solid and liquid phases using pump-probe femtosecond laser experiments. A pump with fluences of 100-500 mJ cm⁻² is used to heat the sample while third harmonic generation of light from a time-delayed probe is used to determine the structure as a function of time. For the melting experiment, we find that the solid begins to melt before the phonons are thermalized by the electrons, according to the two-temperature model. In addition, we find by using Ag thin films with different thicknesses, that the depth of heat deposition is less than 100nm. Both observations suggest that the established two-temperature model is insufficient to explain the melting kinetics in Ag by the femto-second laser. For the solidification experiment, we are able to determine the solidification velocity as a function of undercooling down to half of the melting temperature. The results are compared to predictions from molecular dynamics simulations.

9:36AM A40.00009 Revisiting the segregation driving forces rule: the Coupled Three Effects Model, JÉRÔME CREUZE, ISABELLE BRAEMS, FABIENNE BERTHIER, LEMHE/ICMMO, UMR 8182, Universite Paris Sud-XI, Bat. 410, F91405 Orsay cedex, France., CHRISTINE MOTTET, GUY TRÉGLIA, CRMCN-CNRS, Campus de Luminy, Case 913, 13288 Marseille cedex 9, France., BERNARD LEGRAND, SRMP-DIMN, CEA Saclay, F91911 Gil-sur-Yvette cedex, France. — Separating the surface segregation enthalpy into three elementary contributions (cohesive, alloy and size) has been proposed by many authors, but rarely tested quantitatively. Such a separation rule, derived from a tight-binding Hamiltonian years ago, has yielded very satisfying results for various environments (surfaces, grain boundaries and clusters) for the Cu-Ag system and for many other alloys, but recently stumbled over the Co-Pt system. We propose a new approach based on a systematic study of the permutation enthalpies, both in the bulk and in the surface, as a function of the mixed interaction involved in the N-body interatomic potentials derived from the electronic structure. We then show that both the disagreement observed for Co-Pt and the agreement mentioned for Cu-Ag can be explained by the variation of the effective pair interactions in the surface and by the existence of coupling coefficients between the three effects. Finally, we introduce a new decomposition, the Coupled Three Effects Model (CTEM), that is valid for systems with both size and cohesive effects.

9:48AM A40.00010 Ambient-temperature Conditioning as a Probe of Double-C Transformation Mechanisms in Pu-2 at. % Ga.¹ JASON R. JEFFRIES, K.J.M. BLOBAUM, M.A. WALL, A.J. SCHWARTZ, Lawrence Livermore National Laboratory — The gallium-stabilized Pu-2.0 at. % Ga alloy undergoes a partial or incomplete low-temperature martensitic transformation from the metastable delta phase to the monoclinic alpha-prime phase near -120 °C. This transformation has been shown to occur isothermally and it displays anomalous double-C kinetics in a time-temperature-transformation diagram. While the underlying mechanisms responsible for the double-C behavior are currently unresolved, recent experiments suggest that a conditioning treatment influences the upper-C. As such, the effects of the conditioning treatment can provide valuable insight into the mechanisms dominating the phase transition. A differential scanning calorimeter (DSC) is used to investigate the effects of conditioning temperature and time upon the delta/alpha-prime transition. The results will be discussed as they pertain to radiation damage, nucleation, embryo formation, or phase-field stability.

¹This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

10:00AM A40.00011 New Transformation Path of Shape Memory NiTi¹, N. HATCHER, O. YU. KONTSEVOI, A.J. FREEMAN, Northwestern University — The detailed mechanism of structural evolution during the martensitic transformation in NiTi is not fully understood. To fully characterize the transformation path and to precisely determine the structure of its martensitic phase, we employ the highly-precise all-electron full-potential linearized augmented plane wave (FLAPW) method² and identify the governing processes of the martensitic transformations between the B2, B19, R, B19' and recently proposed B33 and BCO phases. Several precursor phenomena for displacive phase transformations in the B2, B19, and R phases are identified, i.e. soft C_{14} and C' elastic constants, regions of Fermi surface nesting, and instabilities towards electronic topological transitions. By means of generalized stacking fault calculations, we find that the B2 phase has a low resistance to (100)⟨110⟩ shear. A new, barrierless transformation path from B2 to B19' is established by calculating a bilayer (100)⟨110⟩ shear with full structural optimization which leads to a monoclinic intermediate phase at 1/2a displacement; a relaxation of this structure's monoclinic angle results in the B19' phase.

10:12AM A40.00012 Magneto-Resistance at the Pre-Martensite Transition in Ni₅MnGa, C. P. OPEIL, Boston College, J. C. LASHLEY, J. L. SMITH, Los Alamos National Laboratory — A magneto-resistance and angle resolved photoemission (ARPES) study of the pre-martensite phase of the ferromagnetic shape memory alloy single crystal Ni₅MnGa, reveals a temperature (235 > T > 190 K) and field dependent (0 – 1 T) positive/negative magneto-resistance slope. Previous inelastic neutron scattering experiments (Zheludev et al., PRB 51, 1995) on this Heusler alloy indicate a phonon branch [110]-TA₂ softening in the pre-martensite phase along q = (1/3, 1/3, 0). This phonon softening combine with our ARPES data that show significant depletion of states (pseudo gap) occur at the premartensitic transition temperature. Recent results (Shapiro et al., EPL 77, 2007) reveal phases associated with the charge density wave (CDW) resulting from Fermi surface (FS) nesting. Our experimental results will be discussed in light of electron-phonon coupling.

10:24AM A40.00013 Optical properties of ErH₂₊ₓ: First principles calculations and experimental measurements, CLARK SNOW, THOMAS MATTSSON, Sandia National Laboratories — Rare earth and transition metal hydrides exhibit many interesting physical phenomena, from metal-semiconductor transitions to transparency changes at RT as a function of hydrogen content. Electrical resistivity measurements by P. Vajda (1) indicate that ErH₂₊ₓ undergoes a metal-semiconductor transition between 240-290K and an antiferromagnetic transition between 1.75-2.3K depending on hydrogen content. These same transitions should also cause profound changes in the optical properties. This work will present first principles calculations of the optical properties of ErH₂₊ₓ from 300-600K where x ranges from -0.2 to 0.2. The calculations will be compared to experimental results on thin films of ErH₂₊ₓ which were obtained as a function of temperature from 10-600K and hydrogen content.

¹Sandia is a multi-program laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04-94AL85000.
10:36 AM A40.00014 Role of defects and impurities on the thermal stability of transition-metal nitrides and carbides, L. TSETSERIS, N. KALFAGIANNIS, S. LOGOTHEITIDIS, Aristotle University of Thessaloniki, Thessaloniki, Greece, S. T. PANTELIDES, Vanderbilt University, Nashville, TN — Transition-metal nitrides and carbides are used in a variety of applications because of their renowned hardness and stability. Here, we present the results of first-principles calculations on point defects and impurities in the prototype systems of TiN and TiC, and in HfN and ZrN. We find features which are common to all systems, while we unravel also key differences. In cases, for example Ni interstitials in TiN, the interaction between defects is attractive and it favors the formation of defect complexes. Moreover, we show that the atomic-scale mechanisms of interaction and migration of point defects and their complexes can account for various changes of transition metal nitrides and carbides after annealing at widely different temperatures. Finally, we discuss the fundamentals of trapping and release of the most common impurities in TiN. The work was supported in part by the McMinn Endowment at Vanderbilt University, AFOSR MURI Grant FA9550-05-1-0306, and GSR-PTENED-03ED613.

10:48 AM A40.00015 Atom Transport in Random Close Packed Metal Alloys under Thermal Forcing, YONG W. KIM, Lehigh University — Alloy making entails disparate pyro-metallurgical pathways, contributing to variability in elemental composition profiles. Surface segregation by constituent elements is a long-standing example. Thermal cycling and exposures to intense fluxes of energetic particles and photons, as in fission and fusion reactors, force the movement of composition profiles. Transport properties thus become dependent of materials’ history. We note that a non-crystalline alloy specimen is a randomly close packed assembly of atoms, and, as such, contains a distribution of residual nano-crystallites. The primary effect of varied forcing mechanisms is to convert atoms bound in nano-crystallites into those of glassy configurations. Spatial fluctuation is increased, specific to elemental species. In this paper we present a modeling of thermal conversion of crystallite atoms into a glassy state. The distribution function of nano-crystallites by size at room temperature is modeled by the distribution of nano-clusters formed from an atomic vapor plume. [Kim, Lee, Belony, Rev. Sci. Instr. 17, 10F115 (2006)] At a given temperature, equilibrium dissociation of a nano-crystallite into ‘glassy’ atoms is treated by the law of mass action. The equation of state is fashioned after the thermal expansion of the specimen volume with respect to a reference. A large set of simultaneous dissociation equations is solved iteratively. Work supported in part by NSF-DMR(Metals).

Monday, March 10, 2008 11:15AM - 2:15PM – Session B1 DCMP: Strongly Correlated Electrons in One Dimension Morial Convention Center LaLouisiane AB

11:15AM B1.00001 Narrow-gap Luttinger liquid in carbon nanotubes, LEONID LEVITOV, MIT — Single-walled carbon nanotubes are the thinnest and the cleanest among the currently available nanoscale quantum wires. Transport properties of nanotubes depend on the presence of a gap in electron spectrum, defining two main nanotube types, metallic and semiconducting. Semiconducting tubes attract interest in particular because of the sensitivity of their properties to external fields and doping. Among semiconducting tubes there is an interesting class of narrow-gap tubes, or so-called chiral metallic tubes, which exhibit a narrow semiconducting gap arising due to curvature [1]. The Luttinger liquid effects, which are strong in all nanotubes, are particularly interesting in the narrow-gap tubes. Interaction strongly affects the energy gap, reinforcing it and making it sensitive to the long-wavelength charge mode dynamics [2]. We discuss new types of charge carriers possible in the gapped states and their relation to recent experimental work [3].

11:51AM B1.00002 Observation of spin-charge separation and localization in one-dimensional quantum wires1, OPHIR AUSLAENDER2, Stanford University — We have been able to measure hallmark properties of electrons confined to one-dimensional (1D) wires. Profoundly affected by interactions, the 1D electron liquid is a Luttinger-liquid. Single particle elementary excitations, which survive in spite of interactions in higher dimensions, completely lose their integrity in a Luttinger-liquid. Instead, the elementary excitations of the 1D electron liquid are all collective, with long range correlations and are spin-charge separated. In spite of the drastic influence of electron-electron interactions on the many-body states, the observation of these effects in experiment has been elusive. Our wires were fabricated from a GaAs/AlGaAs heterostructure using cleaved edge overgrowth. The sample I shall discuss contained two parallel wires, 20nm and 30nm thick, which were separated by a 6nm insulating AlGaAs barrier. A series of top gates allowed us to contact each wire separately, and thus allowed us to control both the energy and the momentum of the electrons tunneling between the wires. The resulting tunneling conductance was a direct measure of the spectral function in each of the wires, and thus enabled us to map the dispersions of the 1D many-body elementary excitations. Pushing the wires to low density allowed us to probe the regime where interactions dominate over kinetic energy. In this regime we clearly observed two spin modes and one charge mode of the coupled wires. Mapping the dispersion velocities as a function of decreasing density, we found good agreement between the data and theoretical calculations of the velocity of the antisymmetric charge mode of the coupled wires. The theory also predicted an additional symmetric charge mode, that was not observed. The spin velocities were found, within experimental precision, to be smaller than theoretically predicted. Reducing the density of electrons even further, we found an abrupt transition in the extent of the 1D states along the wires: At high densities they were extended and had well defined momenta, while at low densities they localized as a result of interactions and exhibited Coulomb blockade physics. A simultaneous measurement of the two-terminal conductance, which displayed the typical stepwise drop with decreasing density, showed that a localization transition was concurrent with each conductance drop.

12:27PM B1.00003 The One-Dimensional Wigner Crystal in Carbon Nanotubes1, VIKRAM DESHPANDE, Applied Physics, Caltech — Electron-electron interactions strongly affect the behavior of low-dimensional systems. In one dimension (1D), arbitrarily weak interactions qualitatively alter the ground state producing a Luttinger liquid (LL) which has now been observed in a number of experimental systems. Interactions are even more important at low carrier density, and in the limit when the long-ranged Coulomb potential is the dominant energy scale, the electron liquid is expected to become a periodically ordered solid known as the Wigner crystal. In 1D, the Wigner crystal has been predicted to exhibit novel spin and magnetic properties not present in an ordinary LL. However, despite recent progress in coupled quantum wires, unambiguous experimental demonstration of this state has not been possible due to the role of disorder. We propose using low-temperature single-electron transport spectroscopy that a hole gas in low-disorder carbon nanotubes with a band gap is a realization of the 1D Wigner crystal [1]. We observe for the first time three distinct regimes as a function of carrier density and axial magnetic field: (I) a completely spin and isospin polarized state, (II) an isospin polarized, spin antiferromagnetic state, and (III) an unpolarized state with a four-fold addition energy period. The transitions among these regimes can be quantitatively and intuitively explained using a Wigner crystal picture based on a gapped LL model [2] with the carriers represented by spatially localized solitons. Our observation provides a clean platform for testing theories of interacting electrons in 1D and also indicates the possibility of using this many-body state for solid-state quantum information processing. [1] V. V. Deshpande and M. Bockrath, arXiv:0710.0683
[1] With Prof. Marc Bockrath (Applied Physics, Caltech)
1:03PM B1.00004 Fermi-Edge Singularity in a Spin-Incoherent Luttinger Liquid, GREGORY A. FIETE, University of Texas at Austin — In recent years the spin-incoherent Luttinger liquid, obtained in the energy window \( E_{\text{pin}} \ll k_B T \ll E_{\text{charge}} \), has attracted much attention because of its qualitatively distinct properties relative to the more familiar Luttinger liquid \[1\]. Some of the most remarkable effects appear in correlations in which the number of particles is abruptly changed, such as single particle Green’s function \[2\] or in the Fermi-edge singularity when a particle-hole pair is photo-excited \[3\]. In this talk, I draw on the methods developed in Ref.\[2\] to study the Fermi-edge singularity in the spin-incoherent Luttinger liquid \[3\]. Both cases of finite and infinite core hole are explored, as well as the effect of a static external magnetic field of arbitrary strength.

For a finite mass core hole the absorption edge behaves as \( (\omega - \omega_{\text{th}})^{3/2} / \sqrt{\ln(\omega - \omega_{\text{th}})} \) for frequencies \( \omega \) just above the threshold frequency \( \omega_{\text{th}} \). The exponent \( \alpha \) depends on the interaction parameter \( K_c \) of the excited one dimensional system, the electron-hole coupling, and is independent of the magnetic field strength, the momentum, and the mass of the excited core hole (in contrast to the spin-coherent case). In the infinite mass limit, the spin-incoherent problem can be mapped onto an equivalent problem in a spinless Luttinger liquid for which the logarithmic factor is absent, and backscattering from the core hole leads to a universal contribution to the exponent \( \alpha \).

1:39PM B1.00005 Transition from a one-dimensional to a quasi-one-dimensional state in interacting quantum wires\[1\], KONSTANTIN MATVEEV, Argonne National Laboratory — At low density, all electrons in a quantum wire occupy the lowest state of transverse quantization, and it is natural to view the system as one-dimensional. As the density is increased, the electrons start to populate the second subband, resulting in a transition to a quasi-one-dimensional state. I will discuss this transition in the presence of electron-electron interactions in a model that neglects electron spins. Clearly, in the non-interacting case the transition is accompanied by the emergence of a second gapless excitation mode. On the other hand, at very strong interactions, the one-dimensional electrons form a Wigner crystal, and the transition corresponds to it splitting into two chains. Unlike the non-interacting electrons, this two-row (zigzag) crystal still has only one acoustic excitation branch. This raises the question of how the nature of the transition to a quasi-one-dimensional state changes with interaction strength. We can show that in the vicinity of the transition already arbitrarily weak interactions open a gap in the second excitation mode. We then argue that only one gapless mode exists near the transition at any interaction strength.

Monday, March 10, 2008 11:15AM - 1:39PM –
Session B2 GMAG: Magnetism in Semiconductors: New Frontiers
Morial Convention Center LaLouisiane C

11:15AM B2.00001 Optical Properties of III-Mn-V Ferromagnetic Semiconductors, KENNETH BURCH, Los Alamos National Laboratory — We discuss the important role optical studies have played in our understanding of the electronic structure of III-Mn-V ferromagnetic semiconductors. These extensive studies have established the electronic structure is strongly affected by the strength of the exchange between the Mn local moments and the holes they introduce. Particular focus is given to Ga\textsubscript{1-x}Mn\textsubscript{x}As, where spectroscopic studies suggest the metallic state is unconventional. Finally, we will detail our recent experiments into the ultrafast manipulation of magnetism on the nanoscale. This work is in collaboration with D.B. Shrekenhamer, E.J. Singley, D.N. Basov (University of California, San Diego) J. Stephens, S. Mack, R.K. Wakamaki, D.D. Awschalom(University of California, Santa Barbara), B.L. Sheu, N. Samarth (Pennsylvania State University), F. Chen, A. Azad, J. O’Hara, A.M. Dattelbaum, G. Montano, S. Crooker, and A.J. Taylor (Los Alamos National Laboratory).

11:51AM B2.00002 Spin Transport in Ferromagnet-Semiconductor Heterostructures\[1\], PAUL CROWELL, University of Minnesota — Over the last two years, there has been significant progress in the integration of metallic ferromagnets with semiconductors, resulting in devices in which spin-polarized carriers are injected and detected electronically. I will discuss experiments on epitaxial Fe/GaAs Schottky tunnel barrier heterostructures patterned into lateral devices in which the ferromagnetic injection and detection contacts are separated by several microns.\[1\] The Schottky barrier consists of a highly-doped n\textsuperscript{+} region \( (n^+ \approx 5 \times 10^{18} \text{ cm}^{-3}) \) and the channel of the device is n-doped GaAs \( (n \approx 2 \times 10^{16} \text{ cm}^{-3}) \). A non-equilibrium spin polarization generated by electrical injection is detected potentiometrically using the non-local transport technique applied originally to metallic systems. An important aspect of this approach is the observation of spin precession and dephasing in the semiconductor channel (the Hanle effect), allowing for electrical measurements of the spin lifetime and diffusion length. We find a strong non-linear dependence of the spin polarization on the injection voltage, which we have investigated by preparing samples with different thicknesses of the channel of the device and varying the tunnel barrier profile. We find a systematic change in the spin accumulation observed under forward and reverse bias currents as the thickness of the n\textsuperscript{+} region increases. Other aspects of these devices have also been explored. For GaAs channels that are doped near the metal-insulator transition, the non-equilibrium electron spin polarization leads to dynamic nuclear polarization, which has a profound impact on the electron spin dynamics at low temperatures. Finally, I will discuss some important considerations for applications in which a bias current flows in the detector. [1] X. Lou et al., Nature Physics 3, 197 (2007)

\[1\] In collaboration with X. Lou, C. Adelmann, E.S. Garlid, Q. Hu, T. Kondo, J. Zhang, S.D. Flexner, K.S.M. Reddy, S.A. Crooker, and C.J. Palmstrom and supported by ONR, the NSF MRSEC, NNI, and IGERT programs, and the Los Alamos LDRD program.

12:27PM B2.00003 Ultrafast Photoinduced Non-thermal Phenomena in (III, Mn)V Ferromagnetic Semiconductors, JIGANG WANG, Materials Sciences Division, Lawrence Berkeley National Laboratory — Magnetic materials display carrier-mediated exchange interaction are ideal for non-thermal, potentially fast spin manipulation and detection. Prominent examples of such materials are Mn doped III-V semiconductors such as GaMnAs, in which the strong interaction of carriers (holes) and Mn ions results in high transition temperature ferromagnetism. The steady-state magneto-optical/transport measurements reveal rich magnetic memory effects and strong enhancement of ferromagnetism via external stimuli (i.e., light, electrical field or current). However, no time-resolved experiments in (III,Mn)V semiconductors have shown these collective magnetic phenomena, and hence their time scales are completely unknown. In this talk, I will present our recent observations in GaMnAs of: (1) ultrafast enhancement of ferromagnetism via photoexcited transient holes on a 100 ps time scale and (2) femtosecond detection of magnetic memory states. Our measurements reveal new fundamental collective magnetic processes at ultrafast time scales, and identify the critical roles of the Mn-hole correlation in these photo-induced cooperative behaviors. These results constitute the first evidence for ultrafast, non-thermal manipulation of the spin order in (III,Mn)Vs, which may represent as-yet-undiscovered universal features in all carrier-mediated ferromagnetic materials.
1:03PM B2.00004 Ferromagnetism and localization in Ga$_{1-x}$Mn$_x$As, Ga$_{1-x}$Mn$_x$P, and in between$^1$, OSCAR DUBON, U.C. Berkeley and Lawrence Berkeley National Laboratory — Because of their potential as both injectors and filters of spin-polarized carriers, ferromagnetic semiconductors may play an important role in spin-based electronics, or spintronic devices. Ferromagnetic semiconductors are formed by the substitution of a relatively small fraction of host atoms with a magnetic species. Ga$_{1-x}$Mn$_x$As has been the most thoroughly studied material among these, and ferromagnetism in it arises from hole-mediated inter-Mn exchange. The Curie temperature $T_C$ in Ga$_{1-x}$Mn$_x$As has been shown to increase with increasing concentration of substitutional Mn acceptors. However, room temperature ferromagnetism in this canonical system has been elusive due to challenges in materials synthesis—namely, raising $x$ while avoiding the formation of second phases or compensating defects. Increasing $p-d$ exchange by modifying the host semiconductor via anion substitution (e.g., replacing As with P) is a significantly less explored route by which $T_C$ may be raised. We are investigating the effect of anion substitution in ferromagnetic Ga$_{1-x}$Mn$_x$As$_1-y$P$_y$ formed by ion implantation followed by pulsed-laser melting. In the endpoint compound Ga$_{1-x}$Mn$_x$P $T_C$ is found to vary linearly with $x$, and non-metallic transport is observed for $x$ up to $\sim$4.2%, corresponding to a $T_C$ of $\sim$62 K compared to $\sim$112 K for Ga$_{1-x}$Mn$_x$As with a similar $x$. Dilution of the endpoint compound Ga$_{1-x}$Mn$_x$As with P results in a precipitous decrease in $T_C$ to below 60 K for $y=2.8\%$. Remarkably, Ga$_{1-x}$Mn$_x$As$_1-y$P$_y$ films undergo a metal-insulator transition between $y=1.5\%$ and 2.3% even as $x$ is held approximately constant indicating that alloy disorder in the anion sublattice induces hole localization, which in turn may be responsible for a strong suppression of $T_C$. Thus, while anion substitution may enhance $p-d$ exchange, localization effects must be considered when developing a suitable picture for ferromagnetism in these materials.

$^1$Supported by the Director, Office of Science, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231

Monday, March 10, 2008 11:15AM - 2:15PM – Session B3 FIAP: Silicon Photonics Morial Convention Center RO2 - RO3

11:15AM B3.00001 Silicon lasers, integration, interconnect, etc. at Intel , MARIO PANICCIA, Director Photonics Technology Lab, Intel Corporation — In this talk, we discuss integrated silicon photonics technologies that enable Tbit/s optical link for future VLSI interconnect applications. We also review the recent advances in various fundamental building blocks, including high-speed silicon optical modulator, SiGe detector, and hybrid silicon laser.

11:51AM B3.00002 Ultrafast Silicon Photonics Modulators , MICHAL LIPSON, Cornell University — No abstract available.

12:27PM B3.00003 Silicon integrated nanophotonics for on-chip interconnects$^1$, YURI VLASOV, IBM — Current trend in microelectronics industry is to increase the parallelism in computation by multi-threading, by building large scale multi-chip systems and, more recently, by increasing the number of cores on a single chip. With such increase of parallelization the interconnect bandwidth between the racks, chips or different cores is becoming a limiting factor for the design of high performance computer systems. The on-chip ultrahigh-bandwidth silicon-based photonic network might provide an attractive solution to this bandwidth bottleneck. We will review recent results on silicon nanophotonic circuits based on photonic wires and photonic crystals. Strong light confinement at the diffraction limit enables dramatic scaling of the device area and allows unprecedented control over optical signals. Silicon nanophotonic devices have immense capacity for low-loss, high-bandwidth data processing that might enable the design of ultra-compact on-chip optical networks. In particular we will show recent results on design and characterization of various ultra-compact (<0.03mm$^2$) silicon nanophotonic circuits as optical delay lines, electro-optic modulators, broadband optical switches, wavelength filters, etc.

$^1$Yuriy A. Vlasov, Fengnian Xia, William Green, Solomon Assefa

1:03PM B3.00004 Silicon Detectors, Sensors and Ultrafast Interconnect. , MEHDI ASGHARI, Kotura — No abstract available.

1:39PM B3.00005 Monolithic Integration of Photonic and Electronic Circuits in a CMOS Process , ATTILA MEKIS, Luxtera — We present our approach to a low-cost, highly scalable opto-electronic integration platform in silicon. We have developed a process in a commercial CMOS foundry that enables tightly integrated photonic devices and electronic circuits. The device library includes optical and opto-electronic components as well as electronic circuits. In this talk, we detail the performance of the building blocks and highlight the performance trade-offs encountered in integrating different functions on the same chip. We describe an opto-electronic circuit design toolkit, which is modeled after the standard electronic design flow and builds on commercial circuit design tools. The design flow includes automated design rule checking and layout-versus-schematic checks covering all types of circuit elements. As an example, we detail the design of a multi-channel transceiver chip with 10 Gbps/channel optical data transmission speed and report on its performance.

11:15AM B4.00001 Stimuli Responsive Vesicles, Micelles and Rods from Polypeptide-based Block Copolymers , DANIEL SAVIN, University of Vermont — The self-assembly of amphiphilic block copolymers is dictated primarily by the balance between the hydrophobic core volume and the hydrophilic corona. In these studies, amphiphilic block copolymers containing poly(lysinine) (P(Lys)) blocks were synthesized and their solution properties studied using dynamic light scattering, circular dichroism spectroscopy and transmission electron microscopy. The hydrophobic block used was either poly(2-butene) or a statistical copolymer of propylene oxide and ethylene oxide. The latter polymer exhibits a tunable critical point, below which the block copolymer is in the “double hydrophilic” limit. In these multiply-responsive materials, we exploit secondary structure changes that occur within the P(Lys) chain to observe changes in solution morphology as a function of solution conditions. At high pH, the P(Lys) chain assumes either an $\alpha$-helical or $\beta$-sheet conformation depending on temperature, while at lower pH the side chains become protonated, resulting in an expanded coil configuration. The effect of morphology changes due to these structural transitions will be discussed in the context of the interfacial curvature changes with $\text{pH}$ and temperature. These dynamic materials have potential applications as viscosity modifiers, liquid crystals and gels.
11:51AM B4.00002 Templated Self Assembly of Block Copolymer Thin Films, ALAMGIR KARIM. PPARC/NERC, University of Manchester and University of Essex — We study the shearinduced assembly of block copolymers in the early stages of development, providing insights into the fundamental behavior of these materials. The process involves the self-assembly of well-ordered periodic structures at a length scale of 10-100 nm. We explore the generality of this curvature cancellation phenomenon.

12:27PM B4.00003 Single Molecules and Surface Induced Nanopattern in Ultrathin Block-copolymer Films - Scanning Force Microscopy, MARA IOS, University of Manchester and University of Essex — We study the self-assembly of block copolymers in the early stages of development, providing insights into the fundamental behavior of these materials. The process involves the self-assembly of well-ordered periodic structures at a length scale of 10-100 nm. We explore the generality of this curvature cancellation phenomenon.

1:03PM B4.00004 Using block copolymer assembly to tailor surface properties, CHRISTOPHER OBER, The University of Texas at Austin — We study the self-assembly of block copolymers in the early stages of development, providing insights into the fundamental behavior of these materials. The process involves the self-assembly of well-ordered periodic structures at a length scale of 10-100 nm. We explore the generality of this curvature cancellation phenomenon.

1:39PM B4.00005 Integration of block copolymers into lithographic processes, PAUL NEALEY, University of Wisconsin — We study the self-assembly of block copolymers in the early stages of development, providing insights into the fundamental behavior of these materials. The process involves the self-assembly of well-ordered periodic structures at a length scale of 10-100 nm. We explore the generality of this curvature cancellation phenomenon.

Monday, March 10, 2008 11:15AM - 2:15PM — Session B5 DCMP: Geometry and Elasticity, Morial Convention Center R01

11:15AM B5.00001 Generalized Crumpling: induced singularities in gently deformed elastic sheets, THOMAS WITTMAN, University of Chicago — If a thin disk of elastic material is confined in a shrinking sphere, the deformation of the disk is not smooth but nearly singular when its radius becomes larger than that of the sphere: the curvature at a point diverges as the thickness goes to zero. This talk considers induced singularities that arise from the interaction of these "vertex" singularities with their environment. For example, if two vertices are present, the curvature on the line joining them also diverges, forming the familiar ridge singularity [1]. Other induced singularities are coming to light. Here we consider two such singularities. The first is the induced vertex at the boundary [2] of a disk that has been compressed until it contains two interior vertices. Asymptotically, the triangular region bounded by the three vertices becomes arbitrarily flat as the sheet thickness goes to zero, while the curvature outside approaches a nonzero limit. The second singularity appears when a vertex is formed by forcing a flat sheet into a circular ring so that the sheet buckles. Then the ring force induces a singular radial curvature in the sheet. Remarkably this curvature just sufficient to make the mean curvature vanish where the ring contacts the sheet [3].

We explore the generality of this curvature cancellation phenomenon.

1 T. A. Witten, Rev. Mod. Phys. 79 643 (2007)

11:51AM B5.00002 Columnar and crystalline monolayers on curved substrates, VINCENZO VITELLI, University of Pennsylvania — We study thin self-assembled columns constrained to lie on a curved, rigid substrate. The curvature presents no local obstruction to equally spaced columns in contrast to curved crystals for which the crystalline bonds are frustrated. Instead, the vanishing compressional strain of the columns implies that their normals lie on geodesics which converge (diverge) in regions of positive (negative) Gaussian curvature, in analogy to the focussing of light rays by a lens. The bending of the layers generates a pre-stress of geometric frustration in the ground state that exists prior to the inclusion of defects. This simple observation is the basis for a versatile analytical approach to calculate the geometrical forces between dislocations and Gaussian curvature in columnar as well as in crystalline monolayers. The resulting forces play an important role in stress relaxation dynamics, elastic instabilities, and melting.

1We gratefully acknowledge the NSF/UW NSEC and the Semiconductor Research Corporation for funding.

1Penn MRSEC Grant DMR-0520020
12:27PM B5.00003 The shape, stability and dynamics of elastic surfaces. L. MAHADEVAN, Harvard University — Bending a thin sheet is easier than stretching it, an observation which has its roots in geometry. We will use this fact to explain some unusual problems in biology, physics and geology. At the everyday scale, I will discuss the morphology of avascular algal blades, the dynamics of defects in an elastic ribbon, and the dynamics of prey capture by certain carnivorous plants. At the geological scale, I will try to explain the shape of island arcs on our planet. Finally, time permitting, I will discuss how we might extend these ideas to the macromolecular scale, to derive a mechanical model for the dynamic instability of a growing microtubule.

1:03PM B5.00004 Elasticity and capillarity: wet hairs and origami. BENOIT ROMAN1, PMMH - Paris — Capillary forces are responsible for a large range of everyday observations: the shape of rain droplets, the imbibition of a sponge, the clumping of wet hair into bundles. Although they are often negligible on macroscopic structures, surface capillary forces may overcome volume forces at small scales and deform compliant micro-structures. Capillary-induced sticking can indeed prevent the actuation of mobile elements in micro-electro-mechanical systems (MEMS), or even cause their collapse. Capillary forces also have important consequences in biology such as the buckling of the airway lumen induced by surface tension, which can eventually cause the lethal closure of lung airways (known as neonatal respiratory distress syndrome). We will review a few experimental situations where capillary forces are able to deform two types of objects: rods, and thin sheets. For instance, the nanotubes of a “carbon nanotube carpet” self-assemble into conical “teepee” structures after the evaporation of a solvent and can produce intriguing cellular patterns. Similarly, macroscopic wet hairs tend to assemble into bundles through a cascade of successive pairings. Comparing attracting capillary forces to bending elasticity, leads to a characteristic “elasto-capillary” length. The case of thin sheets is challenging because of geometrical constraints, which generally leads to singularities. Can a thin sheet spontaneously wrap around droplet? We will describe in detail this “capillary origami” experiment.

1:39PM B5.00005 Folding and swirling instabilities of viscous fluid threads in microchannels. THOMAS MASON1, Depts. of Physics and Chemistry, University of California-Los Angeles — We study the behavior of viscous fluid threads formed by hydrodynamic focusing as they are swept along by the flow of a different outer fluid in hard microfluidic channels. By examining pairs of miscible liquids for which interfacial tension is essentially absent, such as silicone oils having different molecular weights, we reveal a rich variety of fluid instabilities that occur at low Reynolds numbers. When a single thread that propagates stably in the center of a straight channel encounters a divergence in the channel’s width, the thread simply dilates if its viscosity is similar to that of the outer fluid. However, due to the extensional flow and deceleration in the diverging channel, a thread that is sufficiently viscous becomes unstable and reduces energy dissipation by performing sinusous bending oscillations, or ‘folding’, rather than dilating. By tuning the flow rates, we reveal a novel period-doubling route to chaotic folding. The folding and stretching of a thread in a diverging channel provides a simple means of mixing viscous liquids and creating controlled viscosity gradients. Moreover, using a sequence of two cross-channels, we make a pair of viscous threads that become unstable when swept along near the walls of a straight channel as a result of the viscous torque induced by the velocity gradient. The amplification of lateral undulations ultimately causes the threads to break up and form an array of viscous swirls, the miscible counterpart of droplets. This swirling instability provides a means for producing discrete and uniform ephemeral swirls, the miscible counterpart of droplets. By injecting three different miscible liquids into a dual cross-channel geometry, we examine the complex patterns that form when several fluid instabilities interact and compete. Overall, we anticipate that these measurements will provide important insight into the behavior of flowing threads in which interfacial tension plays a more substantial role.

Monday, March 10, 2008 11:15AM - 2:15PM
Session B6 GQI DAMOP: Quantum Simulation and Quantum Information Theory in Cold Atoms Morial Convention Center R04

11:15AM B6.00001 Cold atoms in 1D. ULRICH SCHOLLWOECK, RWTH Aachen — Ultracold atoms in optical lattices present a wealth of phenomena in one-dimensional geometries. In this talk, I will focus on specifically one-dimensional phenomena such as spin-charge separation in fermionic systems and the bosonic counterpart, as well as models of collective magnetism realized in ultracold atom systems. Special emphasis will be given to the observation of coherent quantum dynamics far from equilibrium which we can now simulate using the time-dependent density-matrix renormalization group method, in order to use cold atoms to address questions of relaxation to steady states in interacting quantum systems.

11:51AM B6.00002 Probing Phase Transitions in Cold Atoms1. ANATOLI POLKOVNIKOV, Boston University — In this talk I will describe various interferometric probes, which can be used to study correlation functions of low-dimensional cold atom systems. These probes allow one to analyze both properties of phases with long or quasi-long range order and phase transitions. I will suggest the way of detecting fermionic superfluidity and the symmetry of the pairing gap. I will also discuss connections between interferometry in 1D bosonic systems with partition functions of some condensed matter models and with extreme value statistics. Finally I will describe the shot noise and argue how one can suppress it both for bosons and fermions using optical lattices.

1Supported by AFSOR YIP

12:27PM B6.00003 Quantum Control with Ultracold Atoms1. IVAN DEUTSCH, University of New Mexico — Ultracold atoms have long been considered as a platform for quantum information processing. Of critical importance is the ability to coherently control both internal degrees of freedom such as spin and also interactions between atoms that depend on “external” motional degrees of freedom. In this talk I will review a variety of advances, including the ability to perform qudit operations such as state preparation and unitary gates, quantum-state reconstruction via continuous measurement, and cooling of atomic motion without decohering spin qubits. Two different platforms will be presented — alkali atoms transported in a lattice with microwave-induced spin-flips, and alkaline-earth atoms in which quantum information is stored in nuclear spins. Microwave-induced spin flips provide a robust mechanism for inducing cold collisions between atoms that can form the basis of a quantum logic gate. As an alternative, cold alkaline-earth atoms are attractive since the ground state is a closed shell, with zero electron angular momentum. The nuclear spin is thus decoupled from the system and can acts as robust decoherence-free qubit.

1Supported by NSF, ONR, DTO.
1:03PM B6.00004 Imaging single atoms in a three dimensional array1. DAVID WEISS, Penn State — We have demonstrated trapping and imaging of 250 single atoms in a 3D optical lattice. The 5 micron lattice spacing is large enough that individual atoms can be addressed using lasers and microwaves in a way that does not affect the quantum coherence of other atoms. Our goal is to use these trapped atoms as qubits. So far, we fill a random half of the lattice sites, but a combination of site-selective state changes and state-selective lattice translations should allow us to verifiably fill all vacancies. We will describe our experiments to date and our plans for entangling atoms and implementing a neutral atom quantum computer. Our lattice can readily be scaled to include thousands of trapped atoms. This work was performed in collaboration with Karl Nelson and Xiao Li.

1:39PM B6.00005 Atomtronics. MURRAY HOLLAND, University of Colorado at Boulder — We explore the analogy between ultracold atoms in optical lattices and electrons in crystal lattices. Of particular interest is atomtronics, where the analogy is extended to include electrical circuits and doped semiconductor materials. Lattice “defects” achieve behaviors similar to P-type and N-type semiconductor materials. Naturally the interest is to adjoin P-type and N-type atoms lattices to produce an atom diode, and then an NPN or PNP lattice “sandwich” to achieve bipolar transistor-like behavior for ultracold atoms.

Monday, March 10, 2008 11:15AM - 2:15PM — Session B7 DBP GSNP: Gene Regulation Morial Convention Center R05

11:15AM B7.00001 Max Delbruck Biological Physics Prize Talk: The Biophysics of Gene Regulation, Studied One Molecule at a Time1. STEVEN BLOCK2, Stanford University — Advances have led to a new field, dubbed single molecule biophysics. Prominent among the new technologies is the optical trap, or ‘optical tweezers.’ Sensitive systems for measuring force and displacement in optical traps permit the nanomechanical properties of individual macromolecules to be explored with unprecedented precision, revealing behaviors heretofore obscured by ensemble-based approaches. This talk will focus on some of our current work with single-molecule systems, including transcription by RNA polymerase and structural transitions in nucleic acids. We developed high-resolution instrumentation that has broken the nanometer barrier and is thereby able to detect displacements down to the atomic level, in aqueous buffer at room temperature. Consequently, we can monitor the motions of RNA polymerase molecules in real time as these step from base to base along DNA. On the practical side, base-pair resolution makes it possible to sequence DNA in a new way, based on enzyme motions, and points to new directions in nanoscience. The improved stability afforded by the current generation of optical trapping apparatus has allowed us to reconstruct the complete energy landscapes for folding transitions in nucleic-acid hairpins. Recently, we have turned our attention to the problem of co-transcriptional folding, aptamers, and riboswitches formed in nascent mRNAs, and to the DNA or RNA sequence elements that regulate expression.

11:51AM B7.00002 Using DNA mechanics to predict intrinsic and extrinsic nucleosome positioning signals1. ALEXANDRE MOROZOV, Rutgers University — In eukaryotic genomes, nucleosomes function to compact DNA and to regulate access to it both by simple physical occlusion and by providing the substrate for numerous covalent epigenetic tags. While nucleosome positions in vitro are determined by sequence alone, in vivo competition with other DNA-binding factors and action of chromatin remodeling enzymes play a role that needs to be quantified. We developed a biophysical, DNA mechanics-based model for the sequence dependence of DNA binding energies, and validated it against a collection of in vitro free energies of nucleosome formation and a nucleosome crystal structure; we also successfully designed both strong and poor histone binding sequences ab initio. For in vivo data from S.cerevisiae, the strongest positioning signal came from the competition with other factors rather than intrinsic nucleosome sequence preferences. Based on sequence alone, our model predicts that functional transcription factor binding sites tend to be covered by nucleosomes, yet are uncovered in vivo because functional sites cluster within a single nucleosome footprint and thus make transcription factors bind cooperatively. Similarly a weak enhancement of nucleosome binding in the TATA region becomes a strong depletion when the TATA-binding protein is included, in quantitative agreement with experiment. Our model distinguishes multiple ways in which genomice sequence influences nucleosome positions, and thus provides alternative explanations for several genome-wide experimental findings. In the future our approach will be used to rationally alter gene expression levels in model systems through redesign of nucleosome occupancy profiles.

12:27PM B7.00003 Towards a Quantitative Understanding of Single-Gene Transcription. DÁIBHID Ó MAOLÉIDIGH1. Max-Planck-Institut für Physik komplexer Systeme, Dresden, Germany — The transcription of the genetic information in DNA into RNA is the first step in protein synthesis. This process is highly regulated and is carried out by RNA polymerase (RNAP), a complex molecular motor. Here we discuss some of the consequences of a Brownian ratchet model of transcription, which incorporates internal structural degrees of freedom of RNAP and kinetic barriers to backtracking of RNAP resulting from steric clashes with co-transcriptionally folded RNA. This approach was previously used (a) to successfully predict sequence dependent positions of pauses during the elongation process [1,2]; (b) to study the behavior of a number of mutants of RNAP, with different elongation behaviors, believed to involve different internal motions of the enzyme [3]; and (c) to gain insight into the interpretation of single-molecule transcription elongation experiments [2]. The same model can be used to characterize the stability of the elongation complex at specific termination sequences, places along DNA where, with high probability, RNAP releases the RNA transcript and disengages from the template. Recent experimental results on termination reinforce a picture of the elongation complex as a flexible structure, not a rigid body [4]. In more general terms, some of the modeling to be presented raises fundamental issues related to “model comparison” and “model selection,” the problem of identifying and characterizing quantitative models on the basis of limited sets of experimental data [5].

1:03PM B7.00004 Information flow and optimization in transcriptional regulation. GASPER TKACIK, Princeton University — In the simplest view of transcriptional regulation, the expression of a gene is turned on or off by the changes in the concentration of a transcription factor (TF). Here we analyze transcriptional regulatory elements with the tools of information theory. Recent data on noise levels in gene expression are used to show that it should be possible to transmit much more than just one regulatory bit. Realizing this optimal information capacity would require that the dynamic range of TF concentrations used by the cell, the input/output relation of the regulatory module, and the noise levels of binding and transcription satisfy certain matching relations. This parameter-free prediction is in good agreement with recent experiments on the Bicoid/Hunchback system in the early Drosophila embryo, and this system achieves around 90% of its theoretical maximum information transmission. The dependence of information capacity on parameters that govern gene expression for simple, single-input / single-output, genetic regulatory elements is systematically examined and the extensions of the work to genetic circuits consisting of several interacting elements are presented.

1:39PM B7.00005 The Genomic Code for Nucleosome Positioning, JONATHAN WIDOM, Dept. of Biochemistry, Molecular Biology and Cell Biology, and Dept. of Chemistry, Northwestern University — Eukaryotic genomes encode an additional layer of genetic information, superimposed on top of the regulatory and coding information, that controls the organization of the genomic DNA into arrays of nucleosomes. We have developed a partial ability to read this nucleosome positioning code and predict the in vivo locations of nucleosomes. Our results suggest that genomes utilize the nucleosome positioning code to facilitate specific chromosome functions including to delineate functional versus nonfunctional binding sites for key gene regulatory proteins, and to define the next higher level of chromosome structure itself.

Monday, March 10, 2008 11:15AM - 2:15PM – Session B8 DFD: Colloidal Self-Assembly II Morial Convention Center R06

11:15AM B8.00001 Orthogonal Tracking Microscopy for Nanofabrication Research. MATTHEW MCMAHON, ANDREW BERGLUND, PETER CARMICHAEL, JABEZ MCCLELLAND, J. ALEXANDER LIDDLE, National Institute of Standards and Technology — Constructing two-dimensional lateral particle trajectories from digital video sequences of nanoparticle motion in a liquid is straightforward and fairly common, requiring only the use of centroid-finding algorithms. On the other hand, extracting particle trajectories in the third (out-of-plane) dimension has been more difficult, requiring detailed calibration of the radius of the defocused diffraction rings which result from vertical fluctuations of particle position. We introduce a new technique, termed orthogonal tracking microscopy or orthogonal projection microscopy, in which integrated micromirrors produce one or more reflected images of a particle within the same field of view as the direct image. The reflected images project vertical motion into lateral motion. Thus, we are able to construct a fully 3D particle trajectory from 2D digital video using only centroid-finding algorithms. We use this technique to study particle-surface interactions relevant to directed assembly of nanoparticles.

11:27AM B8.00002 Self-Assembly of Colloidal Membranes, EDWARD BARRY, ZVONIMIR DOGIC, Brandeis University — Symmetric monolayer membranes are observed to self-assemble in a colloidal suspension of hard rods with soft attractions. This attractive component to the interaction is enough to drive the self-assembly of stable two dimensional fluid-like surfaces of rods. Simultaneous measurements are made at both the molecular, via direct imaging of individual fluorescently labeled particles, and the continuum length scales. At the continuum scale, the elastic Hamiltonian for a two dimensional fluid-like surface is verified for a symmetric monolayer, and measured material constants such as the bending modulus and the area compression modulus are demonstrated to obey a simple elastic relationship.

11:39AM B8.00003 Self-Assembled 3D Ordered Macroporous Structures for Tissue Engineering Scaffolds, WEN-TAU JUAN, KUO-YUAN CHUNG, Institute of Physics, Academia Sinica, Taipei, Taiwan, NARAYAN MISHRA, Dept. of Paper Technology, Indian Institute of Technology, Roorkee, KENG-HUI LIN, Institute of Physics, Academia Sinica, Taipei, Taiwan — A simple, inexpensive and fast microfluidic method to fabricate three-dimensional ordered macroporous gel is demonstrated using alginate as the scaffold material. The microfluidic device consists of two concentric micropipettes where one is nested inside the other. Nitrogen gas and aqueous alginate solution with Pluronic F127 are pumped through the inner and the outer channel respectively. Under appropriate conditions, bubbles of a uniform size are generated within the device at few thousand Hz. We show the control over bubble size by the gas pressure and quantitatively predict the size dependence from the geometry of fluidic device. Monodisperse bubbles are collected and self-assemble into crystal structures as wet foam. The alginate solution between bubbles is crosslinked by divalent calcium ions and turns into 3D ordered macroporous gel where the pores are highly interconnected. The pore size can be directly controlled by the bubble size which ranges from few tens microns to few millimeters. This technique promises a versatile and robust way to make 3D ordered tissue engineering scaffolds.

11:51AM B8.00004 Five-fold attractor in two-dimensional diffusion processes, GUILERMO RAMIREZ-SANTIAGO, Instituto de Física, UNAM, CARLOS I. MENDOZA, Instituto de Investigaciones en Materiales, UNAM — We introduce an algorithm to generate two-dimensional diffusion-limited star-branched polymers (DLSP) attaching monomers successively to a central colloidal particle with any desired number of reactive sites. The proposed algorithm produces star-shaped aggregates whose final structure at relatively large distances from the central colloid has five-fold symmetry independently of the initial number of reactive sites. Therefore, the final morphology can be considered as a universal attracting distribution for this irreversible diffusion-limited aggregation process.

1:03PM B8.00005 Template-Guided Langmuir-Blodgett Deposition of Colloidal Particles, JAEHYUN HUR, YOU-YEON WON, Purdue University — We present a new method of fabricating highly-ordered two-dimensional (2D) colloidal crystals with non-closed-packed symmetries. In this method, using the Langmuir-Blodgett (LB) monolayer deposition technique, we transfer a Langmuir monolayer of colloidal particles constructed at the air-water interface onto a substrate which contains micro-fabricated topological patterns. We demonstrate that by using this template-guided LB deposition method, a perfect single 2D colloidal crystal structure that is homogeneous throughout the entire area of the patterned substrate can be economically fabricated under appropriate LB processing conditions. We investigate the effects of various control parameters (such as the initial particle density at the air-water interface, the substrate lifting speed, and the humidity condition during the LB monolayer deposition) on the structural properties of the resultant LB colloidal monolayer. As the compression area or the lifting speed is increased, the average density of the deposited particles in the resultant LB colloidal monolayer becomes reduced. The evaporation of water causes an undulation in the deposited particle density profile along the substrate lifting direction. We present a theoretical model which can quantitatively explain all these experimental observations.

We acknowledge partial financial support by DGAPA-UNAM project IN-107607 and CONACYT 43596-F.

12:03PM B8.00006 Template-Guided Langmuir-Blodgett Deposition of Colloidal Particles, JAEHYUN HUR, YOU-YEON WON, Purdue University — We present a new method of fabricating highly-ordered two-dimensional (2D) colloidal crystals with non-closed-packed symmetries. In this method, using the Langmuir-Blodgett (LB) monolayer deposition technique, we transfer a Langmuir monolayer of colloidal particles constructed at the air-water interface onto a substrate which contains micro-fabricated topological patterns. We demonstrate that by using this template-guided LB deposition method, a perfect single 2D colloidal crystal structure that is homogeneous throughout the entire area of the patterned substrate can be economically fabricated under appropriate LB processing conditions. We investigate the effects of various control parameters (such as the initial particle density at the air-water interface, the substrate lifting speed, and the humidity condition during the LB monolayer deposition) on the structural properties of the resultant LB colloidal monolayer. As the compression area or the lifting speed is increased, the average density of the deposited particles in the resultant LB colloidal monolayer becomes reduced. The evaporation of water causes an undulation in the deposited particle density profile along the substrate lifting direction. We present a theoretical model which can quantitatively explain all these experimental observations.
12:15PM B8.00006 Clustering in Hard Core/Soft Shoulder Lattice Gas Models. Paul D. Beale, University of Colorado at Boulder. Charles A. Sievers, Matthew A. Glaser — Isotropic hard core/soft shoulder interacting particle models have been shown to display a wide variety of thermodynamic phases: structured liquids, micellar solids, layered and columnar liquid crystals, and a variety of modulated solid phases. We have explored the phase diagram of a class of lattice gas models that are designed to approximate continuum models. We use generalizations of Baxter’s hard hexagon model on a two-dimensional hexagonal lattice to model the hard core repulsions. The longer-ranged repulsive soft shoulder is included to induce a Klein/Likos clustering instability. The clustering instability creates softly interacting fluidic micelles, as well as several type of modulated solid phases. The lattice model allows the observation of two different solid phase models, typically only display liquid phases with short-range order and solids with long-range order that is commensurate with the underlying lattice. Preliminary results indicate the model exhibits soft solid phases composed of fluidic micelles that form a quasi-long ranged solid phase characteristic of continuum solid phases in two dimensions. We will also present a mean field theory analysis of the initial clustering instability.

12:27PM B8.00007 Elastic Theory of Defects in Toroidal Crystals. Luca Giomi, Mark Bowick, Syracuse University — Crystalline assemblages of identical sub-units packed together and elastically bent in the form of a torus have been found in the past ten years in a variety of systems of surprisingly different nature, such as viral capsids, self-assembled monolayers and carbon nanomaterials. We investigate the structural properties of toroidal crystals and we provide a unified description based on the elastic theory of defects in curved geometries.

12:39PM B8.00008 Two-dimensional hopping of aqueous colloidal clusters on commensurate surface wells. Minsu Kim, Physics, UIUC, Stephen Anthony, Chemistry, UIUC, Steve Granick, Material Science and Engineering, UIUC — Hopping of colloidal clusters in various shapes and sizes that are mainly confined within commensurate surface wells except for diffusing between them by Brownian motion is studied. The mobility of clusters decreases nonmonotonically with increasing cluster size. The mobility proceeds, depending on cluster shape, by different jumping mechanisms such as zigzagging or translation without rotation; this produces nonmonotonic changes of mobility when, at fixed cluster size, cluster shape varies. Unlike atomic clusters that change configuration and dissociate easily, these colloidal clusters are very stable and each type of jump can be identified separately. Hopping rate, diffusion and different jumping mechanisms that are associated with them will be discussed for various sizes and shapes of clusters.

12:51PM B8.00009 Complexity from Specificity: Light Scattering and Colloidal Studies of Dscam Self-Association. Jesse Collins, Harvard School of Engineering and Applied Science (SEAS), Natalie Arkus, Harvard SEAS, Guanganmeng, Harvard Physics, Michael Brenner, Harvard SEAS, Dietmar Schmucker, Dana Farber Cancer Institute, Vinothan Manoharan, Harvard SEAS and Department of Physics — The self-assembly of complex structures from nanometer-sized building blocks is of great technological importance (i.e., for the development of tissue scaffolds and photonic crystals) and is of significant basic scientific interest. Here I present light scattering and colloidal aggregation studies of Dscam, a protein with over 18,000 splice variants which all (or almost all) exhibit exclusively homophilic binding, and which is necessary for the generation of structural complexity in the brain of insects. Static and dynamic light scattering data reveal the statistical mechanical properties of Dscam self-association, including the free energy, second virial coefficient, and oligomer molecular weight. Finally, I demonstrate how to exploit Dscam’s unprecedented level of molecular diversity and specificity for the self-assembly of custom nano- and micro-structures out of Dscam-conjugated colloids.

1:03PM B8.00010 Non-spherical Depletants in Colloidal Suspensions. Stephen Barr, Erik Luijtjen, University of Illinois at Urbana-Champaign — We investigate the effective interactions between spherical colloids induced by rigid rod-like depletants. The size disparity between the colloids and the rods makes conventional simulation methods inefficient. We overcome this by extending the generalized geometric cluster algorithm for colloidal suspensions (J. Liu and E. Luijtjen, Phys. Rev. Lett. 92, 035504 (2004)) to systems of non-spherical particles. We investigate both uncharged and charged colloids and rods, where the electrostatic potential is modeled through a screened interaction. The dependence of the induced depletion potential on both the strength and the range of the electrostatic interactions is quantified. In case of a rod-shape depletion, the depletion attraction between the colloids is enhanced as the screening length becomes larger, owing to the increased effective size of the rods. Systems with a rod-shape attraction are also explored.

This work is supported by the National Science Foundation through Grant No. DMR-0346914.

1:15PM B8.00011 Magnetically assembled “ring-shaped” colloidal particle structures. Hui Son, Randall Erb, Duke University, Mechanical Engineering and Material Science, Bapappidya Samanta, Vincent Rotello, University of Massachusetts, Amherst, Chemistry, Benjamin Yellen, Duke University, Mechanical Engineering and Material Science — We demonstrate a convenient method for assembling ring-shaped colloidal structures by applying uniform magnetic field to a mixture of 2.7-μm paramagnetic beads, 1-μm non-magnetic polystyrene beads, and a fluid dispersion of 10-nm iron oxide nanoparticles (i.e., ferrofluid). The ferrofluid serves as a magnetic contrast medium and induces dipole moments in both the paramagnetic and non-magnetic beads when an external magnetic field is applied. We discovered that for certain volume fractions of ferrofluid, the attractive forces generated between the smaller non-magnetic beads and the larger magnetic beads induce the non-magnetic particles to form a ring structure around the circumference of the paramagnetic beads. This method differs from similar self-assembly techniques in that the ring structures form solely through magnetic force, rather than depending on random motion and patterned bonding.

1:27PM B8.00012 Effects of surface biotin density on lipid monolayer-assisted 2D crystallization of streptavidin at the aqueous solution-vapor interface. MasaFumi Fukuto, Matthew Loehr, Suntao Wang, Sumit KevalRamani, Lin Yang, Brookhaven National Laboratory — Adsorption and two-dimensional (2D) crystallization of soluble protein streptavidin on a biotinylated lipid monolayer at an aqueous solution-vapor interface have been studied extensively since the 1990s. These previous studies, largely based on fluorescence microscopy and ex-situ electron microscopy measurements, revealed the effects of protein modifications and aqueous buffer conditions, such as pH and ionic strength. We have examined the dependence of 2D streptavidin crystallization on the areal biotin density in the lipid monolayer template, using Brewster-angle microscopy (BAM) and in-situ x-ray reflectivity and grazing-incidence x-ray diffraction (GID). The lipid monolayer consisted of a binary mixture of DMPC and DPPE-x-biotin, and the biotin density was controlled by varying the lipid composition while keeping the area per lipid fixed. Both BAM and GID results demonstrate that in order for 2D crystallization of streptavidin to occur, the surface biotin density must exceed a threshold, corresponding to approximately two biotins per protein. The results highlight the importance of well-defined molecular orientations to the 2D crystallization of proteins.
Lipid Monolayers, Suntao Wang, Antonio Checco, Brookhaven National Laboratory, Zhongwei Niu, Qian Wang, University of South Carolina, Masafumi Fukuto, Lin Yang, Brookhaven National Laboratory — Bio-nanoparticles (large proteins, viruses) are ideal building blocks for creating ordered two-dimensional (2D) arrays. These 2D protein crystals or ordered arrays are of great scientific and technological interest. Here, we demonstrate the use of in-situ x-ray scattering and Brewster angle microscopy (BAM) to monitor the formation of self-assembled, 2D ordered arrays by tobacco mosaic viruses (TMVs) on a lipid layer that was either supported by a solid substrate or formed at the liquid-vapor interface. The lipid monolayer not only confines the viral particles within a plane, but also provided the lateral mobility that is crucial for developing structural order. In-situ X-ray scattering was used to provide real-time information on the structure of the virus array and guide optimizations of the surrounding chemical environment to improve in-plane structural order. The presence of Ca\(^{2+}\) ions is also essential to the formation of well-ordered, closely packed 2D arrays of TMV. Atomic Force Microscopy was also used to directly image the final structure to provide real space confirmation of developed structural order.

Non-equilibrium dynamics of virus capsid assembly, Artem Levandovsky, University of California Riverside — The process of self-assembly of nano-structures under non-equilibrium conditions has recently received a lot of attention in various fields. A viral shell (capsid) is, for one, one of the most interesting biological structures that can spontaneously form (from statistical mechanics point of view) at the right pH and ionic strength. While the viral capsids are by far less complex than most other biological objects, the process of virus assembly remains poorly understood. Viruses are found to adopt many different shapes. The mechanisms involved in the self-assembly of capsids into a particular shape as well as the transitions from spherical to non-spherical shells are the subject of this presentation. We show that the kinetic formation of the protein building blocks into the intermediate states (dimers, trimmers, pentamers and hexamers) can lead to the construction of shells with different morphologies.

Transportal thermal transport in colloidal silica system: effect of particle size and aggregation, Gang Chen, Fan Jiang, Department of Physics and Astronomy, Ohio University, Wenhua Yu, Jules Routbort, Energy Systems Division, Argonne National Laboratory, Department of Physics and Astronomy, Ohio University Team, Energy Systems Division, Argonne National Laboratory Collaboration — Knowledge of distribution of nanoparticles in solution is critical to understanding the observed enhancements of thermal conductivity in colloidal systems. We have applied small-angle x-ray scattering (SAXS) to study particle size and distribution of monodispersed and aggregated silica colloids. A hot-wire method has been used to measure thermal conductivity of the colloidal system. The results indicate that the thermal conductivity depends not only on the particle concentration, but also on the particle size and distribution. The experimental data contradict thermal transport models based on fluid interfacial layers or Brownian motion but shed light on the detrimental role of liquid-particle interface on the thermal transport properties.

Thermal conductivity in colloidal silica system: effect of particle size and aggregation, Gang Chen, Department of Physics and Astronomy, Ohio University, Wenhua Yu, Jules Routbort, Energy Systems Division, Argonne National Laboratory, Department of Physics and Astronomy, Ohio University Team, Energy Systems Division, Argonne National Laboratory Collaboration — Knowledge of the size and distribution of nanoparticles in solution is critical to understanding the observed enhancements of thermal conductivity in colloidal systems. We have applied small-angle x-ray scattering (SAXS) to study particle size and distribution of monodispersed and aggregated silica colloids. A hot-wire method has been used to measure thermal conductivity of the colloidal system. The results indicate that the thermal conductivity depends not only on the particle concentration, but also on the particle size and distribution. The experimental data contradict thermal transport models based on fluid interfacial layers or Brownian motion but shed light on the detrimental role of liquid-particle interface on the thermal transport properties.

Monday, March 10, 2008 11:15AM - 2:03PM — Session B9 GSNP: Pattern Formation and Nonlinear Dynamics Morial Convention Center R07

11:15AM B9.00001 Intermediate State in Type-I Superconducting Strip with Current1, Jacob Hoberg, Rulshan Prozorov, Iowa State University — The dynamic structure of the intermediate state was studied in pinning-free Pb strips using real-time magneto-optical visualization. It is found that topological hysteresis can be lifted by applying sufficiently large current. Namely, laminar structure that appears on flux exit in a static case is turned into tubular when the current is present. Temperature, magnetic field and current phase diagram is discussed.

1Supported by the DOE-BES contract No. DE-AC02-07CH11358, NSF grant No. DMR-05-53285 and Alfred P. Sloan Foundation.

11:27AM B9.00002 Generation of dynamic self-propelled structures by symmetry breaking mechanism in driven magnetic layers on the surface of liquid, Alexey Snezhko, Maxim Belkin, Igor Aranson, Argonne National Laboratory — Magnetic particles suspended over the surface of a liquid and energized by a vertical alternating magnetic field give rise to remarkable dynamic multi-segment magnetic structures (‘snakes’). These structures (dynamic by nature) are directly related to wave surfaces in the liquid generated by the collective response of magnetic microparticles to the alternating magnetic field. The self-assembly process and existence of the magnetic snakes is accompanied by a generation of strong surface flows in the liquid. Properties of the snake and corresponding surface flows could be tuned by the parameters of the external magnetic driving. We demonstrate that above some critical frequency threshold magnetic snakes lose their stability and start to swim in the container. The effect is attributed to the development of symmetry breaking instability of the structure with respect to self-generated surface flows in the liquid. Parameters of the driving magnetic field are effectively used to control rich behavior of the dynamic magnetic swimmers.

11:39AM B9.00003 Collective dynamics and pattern formation in 2D regular arrays of spherical particles in Stokes flow between two parallel walls1, Jerzy Blawzdziewicz, Yale University, Eligiusz Wajnryb, IPPT Warsaw, Poland, Matthew Baron, Nidhi Khurana, Yale University — We present results of our numerical and theoretical investigations of collective dynamics of linear trains and regular square arrays of spherical particles suspended in a fluid bounded by two parallel walls. The simulations reveal propagation of particle-displacement waves, deformation and rearrangements of a particle lattice, propagation of dislocation-like defects in ordered arrays, and transitions between ordered and disordered regions that can coexist for a long time. We argue that ordered motion of the arrays is associated with the dipolar form of the external magnetic driving. We demonstrate that above some critical frequency threshold magnetic snakes lose their stability and start to swim in the container. The effect is attributed to the development of symmetry breaking instability of the structure with respect to self-generated surface flows in the liquid. Parameters of the driving magnetic field are effectively used to control rich behavior of the dynamic magnetic swimmers.

11:51AM B9.00004 Theory of slope-dependent disjoining pressure with application to Lennard-Jones liquid films, Taeil Yi, Harris Wong, Louisiana State University — A liquid film of thickness h < 100 nm is subject to additional intermolecular forces, which are collectively called disjoining pressure P. Since dominates at small film thicknesses, it determines the stability and wettability of thin films. Current theory derived for uniform films gives P=P(h). This solution has been applied recently to non-uniform films and becomes unbounded near a contact line as h→0. Consequently, many different effects have been considered to eliminate or circumvent this singularity. We present a mean-field theory of that depends on the slope as well as the height h of the film.[1] When this theory is implemented for Lennard-Jones liquid films, the new P=P(h,hu) is bounded near a contact line as h→0. Thus, the singularity in P(h) is artificial because it results from extending a theory beyond its range of validity. We also show that the new can capture all three regimes of drop behavior (complete wetting, partial wetting, and pseudo partial wetting) without altering the signs of the long and short-range interactions. We find that a drop with an unbounded precursor film is linearly stable.[1] Wu & Wong, J. Fluid Mech, 506, 157 (2004)2 Yi & Wong, J. Colloid Inter. Sci. 313, 579 (2007)
12:03PM B9.00005 The effects of chaotic mixing on patterns and fronts in an advection-reaction-diffusion system\footnote{Supported by NSF Grants DMR-0404961, DMR-0703635 and PHY-0552790.}, TOM SOLOMON, JEFFREY BOEHMER, Bucknell University — We present experimental studies of the effects of fluid flows on reaction fronts and spatial patterns in the excitable Belousov-Zhabotinsky reaction. The flow is a square array of vortices, generated using magnetohydrodynamic techniques. Time-dependent forcing of the flow is achieved by displacing the fluid periodically in a circular manner relative to the vortex flow. Mixing of passive impurities in this flow is chaotic, with long-range transport that is typically diffusive (enhanced), although superdiffusion with Lévy flights is also possible. Reaction fronts in this flow show small-scale patterns that reflect the stable and unstable manifolds that characterize chaotic mixing in this flow. Even on a larger scale, front structure reflects the underlying anisotropy of the vortex lattice. In many cases, the front mode-locks to the external forcing, lining up with the vortex array in a self-extracting manner. Self-generating trigger waves are also found in this system, producing both spiral and target patterns similar to those found in reaction-diffusion systems.

12:15PM B9.00006 Spatial Forcing in Thermal Convection, GABRIEL SEIDEN, STEPHAN WEISS, EBERHARD BODENSCHATZ, Max Planck Institute for Dynamics and Self-Organization — An intrinsic characteristic of thermal convection is the preference of a particular wavenumber at onset. This fact renders experimental investigations of different important aspects, such as the exploration of phase space, difficult. The main tool employed to overcome this difficulty is spatial forcing, whereby, using external means, one forces a desired pattern and observes the evolution of the system thereafter. We present results on topologically and optically induced modulations of large aspect ratio isotropic (horizontal) and anisotropic (inclined layer) Rayleigh-Bénard convection. These include detailed bifurcation curves and phase diagrams for different forcing scenarios.

12:27PM B9.00007 Renormalization group method for predicting frequency clusters in a chain of nearest-neighbor Kuramoto oscillators, OLEG KOGAN, GIL REFAEL, MICHAEL CROSS, Caltech, JEFFREY ROGERS, Caltech, HRL, CALTECH CONDENSED MATTER TEAM — We develop a renormalization group (RG) method to predict frequency clusters and their statistical properties in a 1-dimensional chain of nearest-neighbor coupled Kuramoto oscillators. The intrinsic frequencies and couplings are random numbers chosen from a distribution. The method is designed to work in the regime of strong randomness, where the distribution of intrinsic frequencies and couplings has long tails. Two types of decimation steps are possible: elimination of oscillators with exceptionally large frequency and renormalization of two oscillators bonded by a very large coupling into a single one. Based on these steps, we perform a numerical RG calculation. The oscillators in the renormalized chain correspond to frequency clusters. We compare the RG results with those obtained directly from the numerical solution of the chain’s equations of motion.

12:39PM B9.00008 Pattern morphology and dynamical scaling in the Cahn Hilliard model\footnote{The authors thank the Ohio Supercomputer Center, Kenyon College, the Liquid Crystal Institute at Kent State University, and the NSF (grant DMS0440299) for their support.}, TIMOTHY SULLIVAN, PUSHKAR DAHAL, Department of Physics, Kenyon College, PETER PALFY-MUHORAY, Liquid Crystal Institute, Kent State University — Numerical simulations were carried out in two-dimensions of the dimensionless Cahn-Hilliard equation. Simulations were run for a factor of ten in time beyond previously reported results. The simulations also covered a broad range of values of the mean composition, $\langle \psi \rangle_0$. To determine the dynamical scaling exponent, $b$, an equation of the form $R_2(t) = at^b + c$ was fit to a measure of average domain size. In contrast to previous results, we found that $b$ varied substantially with $\langle \psi \rangle_0$. The largest deviation from the Lifshitz-Slyozov value of 1/3 occurred at $\langle \psi \rangle_0 = 0.15$, where $b = 0.221 \pm 0.04$. We used a measure of the non-uniformity of minority domains to show that for $\langle \psi \rangle_0 \leq 0.20$ the domain shapes are not scale invariant for times exceeding our simulation times. We also point out the possible existence of a phase boundary $\langle \psi \rangle_{0,c}$ that separates a phase with circular domains of minority component from a phase with non-circular minority component domains.

12:51PM B9.00009 Experimental Evidence for Mixed Reality States\footnote{This work is supported in part by the NSF grant DMS 03-25939 ITR.}, VADAS GINTAUTAS, ALFRED HUBLER, Center for Complex Systems Research, Department of Physics, University of Illinois at Urbana-Champaign — We present experimental data on the limiting behavior of an inter-reality system: a virtual pendulum with a bi-directional instantaneous coupling to its real-world counterpart [Gintautas & Hubler, Phys.Rev.E 75, 057201 (2007)]. The data show that if the physical parameters of the simplified virtual system are close to the parameters of the real system, there is a phase transition from an uncorrelated dual reality state to a mixed reality state in which the motion of the two pendulums is highly correlated. As virtual systems better approximate real ones, even weak couplings in inter-reality systems may induce sudden transitions to mixed reality states. This phenomenon may be typical for systems with instantaneous coupling and was recently featured on the tip sheet of the American Physical Society [http://www.aps.org/about/tipsheets/tip68.cfm]. We show that mixed reality states in physical systems are related to out-of-body experiences of humans in 3D-video feedback systems [H. H. Ehrsson, The Experimental Induction of Out-of-Body Experiences. Science 317, 1048 (2007)].

1:03PM B9.00010 Classical dynamics simulations with pattern formation by metallic spheres with induced electrostatic interactions, PETER FLECK, ALFRED HUBLER, Center for Complex Systems Research, University of Illinois at Urbana-Champaign — We study classical dynamics simulations of metallic spheres immersed in a highly viscous, but weakly conducting medium while exposed to the electrostatic field of external electrodes of various geometries. We represent the system’s charge dynamics by the spheres’ multipole moments and determine the phase boundaries of this line formation behavior in the sphere dynamics simulations. We find the phase diagram to be in good agreement with analytical predictions.

1:15PM B9.00011 Hopping Conduction and Bacteria: Transport Properties of Disordered Reaction-Diffusion Systems, ANDREW MISSEL, KARIN DAHMEN, University of Illinois, Urbana-Champaign — Reaction-diffusion (RD) systems are used to model everything from the formation of animal coat patterns to the spread of genes in a population to the seasonal variation of plankton density in the ocean. In all of these problems, disorder plays a large role, but determining its effects on transport properties in RD systems has been a challenge. We present here both analytical and numerical studies of a particular disordered RD system consisting of particles which are allowed to diffuse and compete for resources ($\lambda \rightarrow A$) with spatially homogeneous rates, reproduce ($A \rightarrow 2A$) in certain areas (“oases”), and die ($A \rightarrow 0$) everywhere else (the “desert”). In the low oasis density regime, transport is mediated through rare “hopping events” in which a small number of particles diffuse through the desert from one oasis to another; the situation is mathematically analogous to hopping conduction in doped semiconductors, and this analogy, along with some ideas from first passage percolation theory, allows us to make some quantitative predictions about the transport properties of the system on a large scale.
in the role lattice strain plays between the copper oxide planes. We have examined Bi$_2$EISAKI, ALESSANDRA LANZARA — Towards understanding the physics of the high-temperature superconducting cuprates, there has been growing interest if not impossible, to observe in material plasma.

plasma. Using wave-kinetic theory and Wigner formalism, we interpret the speckles of statistical light as quasi-particles which can interact via the nonlinearity.

FLEISCHER, Princeton University, Princeton, NJ 08544, USA — We consider the nonlinear propagation of partially-spatially-incoherent light as a photonic interaction. The simulations were done for a chosen value of electric dipole moment and for a set of temperatures. Chain formation is observed when the potential is dipolar as well as when both terms are included. However, our simulation shows some differences in the pattern formation of the chains.

Monday, March 10, 2008 11:15AM - 2:15PM –

11:15AM B10.00001 Revealing pseudogap physics using lanthanide substituted Bi$_2$Sr$_{1.6}$Ln$_0$_0.4CuO$_{6+δ}$, DANIEL GARCIA, University of California, Berkeley. JEFF GRAF, CHRIS JOZWIAK, SHUYUN ZHOU, HIROSHI EISAKI, ALESSANDRA LANZARA — Towards understanding the physics of the high-temperature superconducting cuprates, there has been growing interest in the role lattice strain plays between the copper oxide planes. We have examined Bi$_2$Sr$_{1.6}$Ln$_0$_0.4CuO$_{6+δ}$ (Ln=La, Nd, Eu, Bi) near optimal doping using angle resolved photoemission spectroscopy. The increasing radius mismatch of the substituted lanthanide, which monotonically decreases the superconducting $T_c$, appears to also affect the electronic properties of these system. The effect of strain on Fermi arcs, superconducting gap and pseudogap physics will be discussed.

11:27AM B10.00002 A Laser Based ARPES Study of the Nodal Region of the Cuprates1, J.D. RAMEAU, CMPMSD, Brookhaven National Laboratory / Stonybrook University, H.-B. YANG, G.D. GU, P.D. JOHNSON, CMPMSD, Brookhaven National Laboratory — A new laser based facility has been constructed at the NSLS for studies of strongly correlated electron systems. While recent studies of the nodal and near-nodal spectrum of the cuprates with low energy lasers appear to show good agreement with correlated energy, synchrotron based ARPES, several adverse effects of performing ARPES with lasers remain to be explored. Using the new facility we show that the combination of high emission angles and low energy laser kinetic energies has many implications for the accurate measurement of any linewidth or band dispersion. We show that this is particularly so for the nodal and near-nodal single particle spectrum of the cuprates. The results and implications of our studies for future laser based ARPES are analyzed and discussed.

11:39AM B10.00003 Evidence for pairing above $T_c$ from the electronic dispersion in the pseudogap phase of cuprates, A. KANIGEL, Technion, Haifa 32000, Israel, U. CHATTERJEE, University of Illinois at Chicago, Chicago, IL 60607, M. RANDERIA, The Ohio State University, Columbus, OH 43210, M.R. NORMAN, Argonne National Laboratory, Argonne, IL 60439, J.C. CAM-PUZANO, University of Illinois at Chicago, Chicago, IL 60607 — In the BCS paradigm for the superconducting state, electrons close to the Fermi level $E_F$ form Cooper pairs which condense into a zero center of mass momentum state. This results in a gap in the electronic excitation spectrum which is symmetrically centered about $E_F$. Above $T_c$, where the condensate is lost, the pairs dissociate, the energy gap collapses, and the the normal state Fermi surface appears. On the other hand, in the underdoped high temperature superconductors, instead of a complete Fermi surface above $T_c$, only disconnected Fermi arcs appear, separated by regions that still exhibit an energy (pseudogap). We show that in this pseudogap phase, the energy-momentum relation of electronic excitations near $E_F$ behaves like the dispersion of a normal metal on the Fermi arcs, but like that of a superconductor in the gapped regions. We argue that this dichotomy in the dispersion is hard to reconcile with a competing order parameter, but is consistent with pairing without condensation. Below $T_c$ the pairs condense and the electronic excitations, that were short-lived above $T_c$, become long-lived and exhibit a d-wave energy gap.

11:51AM B10.00004 Possible Explanation of the Fermi Arcs in Cuprates, based on a clustered superconducting state above $T_c$1, GONZALO ALVAREZ, Oak Ridge National Laboratory, ELBIO DAGOTTO, University of Tennessee and ORNL — A previously introduced Landau-Ginzburg model [1] to describe the competition between antiferromagnetism and d-wave superconductivity in the cuprates is here further investigated. The state above the critical temperature $T_c$ is made of superconducting (SC) clusters, with a nonzero amplitude of the SC order parameter but random phase factors, coexisting with antiferromagnetic(AF) regions. This state disappears above a higher temperature scale $T^*$. The LDOS of this state is in good agreement with recent STM experiments [2]. Our main result is that the angle-resolved photoemission spectrum of this SC-AF clustered state contains Fermi surface arcs in the region $T < T_c < T^*$, very similar to those observed experimentally [3]. Low energy states created at the interface between clusters are responsible for the arcs. [1] G. Alvarez et al., Phys. Rev. B 71, 014514 (2005). [2] K. K. Gomes et al., Nature 447, 569 (2007). [3] A. Kanigel et al., cond-mat/0708.4099 (2007).

11:39AM B10.00003 Evidence for pairing above $T_c$ from the electronic dispersion in the pseudogap phase of cuprates. A. KANIGEL, Technion, Haifa 32000, Israel, U. 12:03PM B10.00005 Understanding the Protected Nodes and the Fermi Arcs in the Cuprate Superconductors. QUIN CHEN, K. LEVIN, University of Chicago — We address a recent analysis of photoemission data which elucidates the superconducting phase of the underdoped cuprates. We first present a simple phenomenological approach to the spectral function which shows how the $d$-wave order parameter symmetry results in protected nodes, which, above $T_c$, broaden into Fermi arcs; this “protection” is associated with superconducting coherence rather than reduced thermal broadening. A microscopic theory, consistent with this phenomenology, is presented. It reconciles the observations that the excitation gap below $T_c$ is temperature independent while the superfluid density necessarily vanishes at $T_c$. Reference: Q.J. Chen, K. Levin, and I. Kosztin, Phys. Rev. B 63, 164519 (2001).

This work was supported by NSF Grants No. PHY-0555325 and No. MRSEC DMR-0213745.

12:15PM B10.00006 Pseudogap correlations inside the superconducting dome. ELENA BASCONES, BELEN VALENZUELA, Instituto de Ciencias Materiales de Madrid (CSIC) — Recent experiments[1,2] have uncovered, two energy scales, an antinodal energy $g_{an}$ and a nodal one in the superconducting phase of underdoped hole doped cuprates. This finding reminds the nodal-antinodal dichotomy seen in the pseudogap state. The competing Yang-Rice-Zhang[3] scenario for the pseudogap has shown to be useful to understand these experiments[4]. Here we explore the effect of the competition between pseudogap and superconductivity on the condensation energy and superfluid density which show deviations from the standard BCS behavior. We compare the theoretical results with experiments.

12:27PM B10.00007 Pseudogap and Superconducting Gap - Same or Different? W.S. LEE, J.M. VISHIK, K. TANAKA, R. MOORE, D.H. LU, T. SASAGAWA, Stanford University, N. NAGAOSA, T.P. DEVEREAUX, University of Waterloo, Z. HUSSAIN, ALS, National Lawrence Berkeley Lab, Z.X. SHEN, Stanford University — The pseudogap state in underdoped cuprates has been one of the central questions in high-$T_c$ research. Recently, whether pseudogap and superconducting gap are same energy gap or two different energy scales is strongly debated in data interpretation of single-particle spectrum, such as ARPES and STM. To gain further insight into this issue, detailed doping dependence and temperature dependence of the gap were studied using ARPES. In contrast to the behavior of the well-known pseudogap in the antinodal region, we found that the behavior of the gap is qualitatively different near the nodal region, a momentum space region overlooked in the previous measurements. This gap seems closely related to the superconductivity; it opens up at $T_c$ and reduces with decreasing doping in the deeply underdoped region following the trend of the superconducting dome in the heavily underdoped region of the phase diagram. The emerging two-gap phenomenon points to a picture of richer quantum configurations in high-$T_c$ superconductors.

12:39PM B10.00008 Different temperature evolution of electronic states in superconducting state and normal state in underdoped Bi2212 high-Tc superconductor , KIYOSHISA TANAKA, W.S. LEE, Stanford University, D.H. LU, Stanford Synchrotron Radiation Laboratory, R. MOORE, T. SASAGAWA, Stanford University, Z. HUSSAIN, Lawrence Berkeley National Laboratory, Z.X. SHEN, Stanford University — One of the most mysterious issues in high-Tc superconductor is an energy gap called “pseudogap”, well above $T_c$, which exists over a wide region of compositions and temperatures. The origin of this pseudogap and its relation to the superconducting gap are believed to hold the key for understanding the mechanism of high-Tc superconductivity. Recent angle-resolved photoemission spectroscopy (ARPES) revealed the coexistence of two distinct energy gaps in heavily underdoped samples which have opposite doping dependence [1]. One gap can be assigned as pseudogap and the other gap as superconducting gap because of the positive correlation between the gap magnitude and $T_c$. This result suggests that pseudogap arises from another mechanism and gives profound implications on the mechanism of high-Tc superconductivity. More recently, this two gap feature has been observed in the temperature dependence even in near optimally doped samples [2]. Detailed temperature dependence of ARPES spectra will be shown and the special character of pseudogap state will be discussed. [1] K. Tanaka et al., Science, 314, 1910 (2006). [2] W.S. Lee et al., Nature, 450, 81 (2007).

12:51PM B10.00009 Temperature and doping dependent ARPES study of the gaps in Bi2212. H.-B. YANG, CMPMSD, Brookhaven National Laboratory, J.D. RAMEAU, CMPMSD, Brookhaven National Laboratory / Stonybrook University, P.D. JOHNSON, T. VALLA, G.D. GU, A.T. TSVELIK, CMPMSD, Brookhaven National Laboratory, CMPMSD, BROOKHAVEN NATIONAL LABORATORY TEAM — High-resolution angle-resolved photoemission (ARPES) is used to probe the development of the gaps around the Fermi surface in Bi2212. A new method of data analysis is presented to remove the complications associated with the experimental resolution. Normalizing by the Fermi function then allows the observation of both the occupied and unoccupied states. The results on the temperature and doping dependence of the gap show that the underdoped system in the normal state behaves differently from all region of the phase diagram in the superconducting state, and point to potentially different origins for the pseudogap.

1:03PM B10.00010 Fermi arcs and phase diagram of the high- $T_c$ cuprates: Insights from Raman and angle resolved photoemission spectroscopies. JAMES STOREY, Victoria University of Wellington, JEFFERY TALLON, GRANT WILLIAMS, MacDiarmid Institute for Advanced Materials and Nanotechnology — We calculate the $B_{1g}$ and $B_{2g}$ Raman responses of Bi2212 from an ARPES-derived energy momentum dispersion and a model for the normal-state pseudogap. In light of these calculations, the Raman data demonstrates that the Fermi arc length remains finite in the pseudogap ground state. A re-examination of recent ARPES results is found to confirm this result. In addition, the presence of a van Hove singularity in the overdoped regime, as revealed by ARPES, allows us to propose a universal pairing potential that reproduces both the doping dependence of $T_c$ as well as the variation in $T_{c,\text{max}}$ between different species of cuprate superconductors.

1:15PM B10.00011 Hall Effect Signature of Fermi Surface Reconstruction in High- $T_c$ Superconductors. F.F. BALAKIREV, J.B. BETTS, A. MIGLIORI, Los Alamos National Laboratory, I. TSUKADA, Central Research Institute of Electric Power Industry, Japan, YOICHI ANDO, Osaka University, Japan, G.S. BOEBINGER, National High Magnetic Field Laboratory and Florida State University — The doping dependence of the Hall number in the normal state of two different HTS systems, La$_{2-x}$Sr$_x$CuO$_4$ and Bi$_{2-x}$Sr$_2$La$_x$CuO$_{6+\delta}$, exhibits an anomalous peak at optimum doping that emerges only at low temperatures. With increasing hole doping, as the pseudogap energy scale decreases, the peak onset is ascribed to the emergence of electron-like Fermi pockets in the Brillouin zone. The destruction of the peak beyond optimum doping suggests the destruction of the electron pockets and emergence of a large hole pocket, two phenomena that would result simultaneously with the loss of the Brillouin zone folding associated with the pseudogap state. The low temperature Hall resistance thus elucidates the Fermi surface evolution in the HTS cuprates, characterized by a zero temperature phase transition upon collapse of the pseudogap near optimum doping.

1:27PM B10.00012 Energy gaps in failed superconductor \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) - R.-H. HE. Dept of Phys, Appl Phys, SSRL, Stanford Univ., K. TANAKA, SSRL, Stanford and ALS, LBNL, S.-K. MO, SSRL, Stanford and ALS, Berkeley, T. SAGAWA, SSRL, Stanford and Mat. and Struct. Lab, TIT, Japan, M. FUJITA, Inst. of Mat. Res., Tohoku Univ, Japan, N. MANIELLA, SSRL, Stanford and ALS, Berkeley; K. YAMADA, Tohoku, Japan, Z. HUSSAIN, ALS, Berkeley, Z. SHEN. SSRU, Stanford — By angle-resolved photoemission spectroscopy with improved energy and momentum resolution, we find in the normal state of \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \times = 1/8 \) a strong existence of the nodal quasi-particle together with a \( d \)-wave energy gap along the underlying Fermi surface extending over a significant range in the momentum space before an abrupt take-off of the gap close to the antinodal region. This suggests the presence of a novel nodal metal state, which is different from the one proposed that assumes a single \( d \)-wave extension of the pseudogap from the antinode toward the node along the whole underlying Fermi surface. This state is compatible with the static stripe ordering but only involves a precursor pairing of the electrons away from the antinodal region. We argue that the traditional pseudogap defined exclusively for the antinodal states has a distinct origin than its new nodal counterpart, i.e., a \( c \)-wave gap above \( T_c \). Moreover, this normal state gap function is found to be quantitatively very similar with those of \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \times = 1/8 \) (\( T_c < 4K \)) in the superconducting state, pointing to a universal doping dependence of the pairing strength for \( \text{La}_x\text{CuO}_4 \)-based cuprates, which also highlights the inherent lack of a global phase coherence in \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \times = 1/8 \) that makes it a failed superconductor.

1:39PM B10.00013 Quantum Oscillations in the mixed state of \( d \)-wave superconductors1, ASHOT MELIKIAN, Argonne National Laboratory. OSKAR VAFEK, National High Magnetic Field Lab and Florida State University — We show that the low-energy density of quasi-particle states in the mixed state of ultra-clean \( d \)-wave superconductors is characterized by pronounced quantum oscillations in the regime where the cyclotron frequency \( \hbar \omega_c \ll \Delta_0 \), the \( d \)-wave pairing gap. Such oscillations as a function of magnetic field \( B \) are argued to be due to the internodal scattering of the \( d \)-wave quasiparticles near wavevectors \( \pm k_D, \pm k_D' \) by the vortex lattice as well as their Zeeman coupling. The periodicity of the oscillations is set by the condition \( k_D \pm k_D' / \hbar c (eB)^{1/2} \ll \hbar c k_D / \hbar c (eB')^{1/2} \) (mod 2\( \pi \)). We find that there is additional structure within each period which grows in complexity as the Dirac node anisotropy increases.

1A. M. was supported by the U.S. Dept. of Energy, Office of Science, under Contract No. DE-AC02-06CH11357. O.V. was supported in part by the NSF grant DMR-00-84173.

1:51PM B10.00014 Quantum Oscillations in the Underdoped Cuprate \( \text{YBa}_2\text{Cu}_3\text{O}_4 \) - EDWARD YELLAND, University of St Andrews, UK. JOHN SINGLETON, CHUCK MIELKE, NEIL HARRISON, FEDOR BALAKIREV, LANL, BOGDAN DABROWSKI, Northern Illinois University, MARCIN MATUSIAK, JOHN COOPER, University of Cambridge — The quantum oscillations (QOs) seen in the underdoped cuprate superconductor \( \text{YBa}_2\text{Cu}_3\text{O}_4 \) (\( T_c = 124K \)) in magnetic fields up to \( B = 85T \) [1] are strong evidence for a well-defined Fermi surface (FS) in \( T = 124K \) at low temperature \( T \) and high \( B \). The QO frequency \( F \approx 660 \pm 15T \), implies a FS pocket with 2.4% of the full Brillouin zone (BZ) area. Taken with earlier work [2], our data suggest FS pockets are generic to underdoped \( \text{Cu}_2\text{O}_2 \) planes and give the first hint of doping dependence of the FS. We discuss the carrier concentration implied by the QOs within various models. Comparison of the T-linear specific heat \( \gamma \) (from QO quasi-particle mass \( m^* \)) to \( \gamma \) estimated from zero-field specific heat measurements constrains the number of FS pockets present in the BZ and supports a reduced BZ due e.g. to a charge/spin density wave or ordered orbital currents. [1] E. A. Yelland et al, arXiv:0707.0057. [2] N. Doiron-Leyraud et al, Nature 446, 565 (2007)

203PM B10.00015 Fermi surface pockets in the underdoped cuprate \( \text{YBa}_2\text{Cu}_3\text{O}_4 \), are they present in low magnetic fields? , J. R. COOPER, M. MATUSIAK, J. W. LORAM, Department of Physics, University of Cambridge, E. A. YELLAND, School of Physics and Astronomy, University of St. Andrews, B. DABROWSKI, Department of Physics, Northern Illinois University — The observations of quantum oscillations in the underdoped cuprate superconductors, ortho-II \( \text{YBa}_2\text{Cu}_3\text{O}_4 \) [1] and \( \text{YBa}_2\text{Cu}_3\text{O}_4 \) (\( T_c = 124K \)) [2] at very high magnetic fields and low temperatures could lead to improved understanding of cuprate superconductivity. This will be especially true if the small Fermi surface (FS) pockets are still present at higher temperatures and lower magnetic fields. As pointed out in ref. [2] the pockets appear to have low Fermi energies \( T \approx 300 \), and could therefore give rise to T-dependent magnetic anisotropy in the normal state associated with Landau-Peierls diamagnetism. We report susceptibility measurements constrains the number of FS pockets present in the BZ and supports a reduced BZ due e.g. to a charge/spin density wave or ordered orbital currents. [1] E. A. Yelland et al, arXiv:cond-mat/07070057.

Monday, March 10, 2008 11:15AM - 1:51PM Session B11 DCMP: Magnetic Properties of Cuprate Superconductors Morial Convention Center RO9

11:15AM B11.00001 Disappearance of antiferromagnetic spin excitations in overdoped \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) — JOHN TRANQUADA1, Brookhaven National Lab, S. WAKIMOTO, Japan Atomic Energy Agency, K. YAMADA, IMR, Tohoku Univ., C.D. FROST, ISIS Facility, RAL, R.J. BIRGENEAU, UC Berkeley, H. ZHANG, Univ. of Toronto — We have used time-of-flight neutron spectroscopy to study magnetic excitations, for energies up to \( \sim 100 \text{ meV} \), in overdoped \( \text{La}_{2-x}\text{Sr}_x\text{CuO}_4 \) with \( x = 0.25 \) and 0.30 [1]. Comparison of spectra integrated over the width of an antiferromagnetic Brillouin zone demonstrates that the magnetic scattering at intermediate energies, 20 < \( \omega < 100 \text{ meV} \), progressively decreases with overdoping. Previous work has shown that the low-energy magnetic excitations also disappear with overdoping [2]. This strongly suggests that the magnetism is a vestige of the parent antiferromagnet; spatial segregation of the doped holes, as in the stripe picture, provides a natural way for this to occur. Both the magnetism and superconductivity disappear as the system becomes a homogeneous metal. [1] S. Wakimoto et al., Phys. Rev. Lett. 98, 247003 (2007). [2] S. Wakimoto et al., Phys. Rev. Lett. 92, 217004 (2007).

11:27AM B11.00002 Spin Susceptibility of Underdoped Cuprates: Insight from Stripe-Ordered \( \text{La}_{1.875}\text{Ba}_{0.125}\text{CuO}_4 \) - MARKUS HÜCKER, GEN D. GU, JOHN M. TRANQUADA, Brookhaven National Laboratory — The low-temperature decrease of the bulk magnetic susceptibility in underdoped high-temperature superconductors has commonly been cited as evidence for a pseudogap; however, the interpretations range from a Fermi-liquid perspective, with the susceptibility being proportional to the density of free carriers, to strong coupling pictures, with the susceptibility resulting from antiferromagnetic correlations among local moments. Analysis of the susceptibility of a particular cuprate, the stripe ordered \( \text{La}_{1.875}\text{Ba}_{0.125}\text{CuO}_4 \), sheds new light on this remarkable system and puts tight constraints on possible interpretations. The recently discovered magnetic transition in high magnetic fields will also be discussed.

11:39AM B11.00003 Magnetic correlations on full chains of ortho-II YBCO6.5, WEI CHEN, PETER J. HIRSCHFELD, Department of Physics, University of Florida — We propose that the $^{63}$Cu NMR line shape of chain Cu in YBCO6.5 ortho-II samples may be explained by assuming induced magnetization due to oxygen vacancies and strong correlations in the chain. The model consists of CuO chains coupled to CuO2 plane with Hubbard correlations treated in unrestricted Hartree-Fock approximation, which induce magnetic moments around oxygen chain vacancies. The broadening and shift of Pr0.5La0.5Sr2CuO4 (Pr0.5La0.5Sr2CuO4) Pr0.5La0.5Sr2CuO4 main line is consistent with increased chain magnetization at low temperature. Tunnelling between chains and the plane induces magnetization on the planar copper as well, which gives rise to quasi-1D like spin correlations in the plane.

11:51AM B11.00004 Normal state magnetic susceptibility measurements in overdoped YBa2Cu3O7−δ, BRIGITTE LERIDON, PHILIPPE MONOD, LPEM - CNRS/ESPCI - 10 rue Vauquelin -75231 Paris cedex 05 - France, DOROTHÉE COLSON, Service de Physique de l’Etat Condensé - DSM/DREAMC - CEA Saclay - 91191 Gif-Sur-Yvette Cedex - France — Motivated by the observation of staggered magnetic moments by Faquè et al. [Phys. Rev. Letters 96, 197001 (2006)] using neutron diffraction in overdoped YBa2Cu3O7−δ, we have measured the magnetization of fourteen overdoped YBa2Cu3O7−δ samples under 1 T from $T_c$ to 400 K. The oxygen contents are ranging from 6.43 to 7.00, and the critical temperatures $T_c$ from about 30 K to 91 K. We present here high resolution susceptibility data corresponding to a sensitivity of $10^{-8}$ μemu per Cu atom. We separate the different contributions to the magnetization. We find: i) a small ferromagnetic contribution, visible at all temperatures within our range of measurement and consistent with a few ppm of $F_{c2}(T)$, ii) A “1/T” paramagnetic contribution attributed to a few percent of free Cu ions, iii) The contribution of the “pseudogap” which gives a susceptibility increasing with temperature excepted in the optimally doped samples where the susceptibility is flat as expected for Pauli paramagnetism. We discuss the physical implications of this contribution in light of experiments from Faquè et al.

12:03PM B11.00005 The Persistence of High-Frequency Spin Fluctuations in Overdoped Superconducting La2−xSrxCuO4 ($x=0.22$), O.J. LIPSCOMBE, B. VIGNOLLE, S.M. HAYDEN, H.H Wills Physics Laboratory, Tyndall Avenue, Bristol, BS8 1TL, UK, D.F. MCMORROW, London Centre for Nanotechnology and Department of Physics and Astronomy, University College London, London WC1E 6BT, UK, T.G. PERRING, ISIS Facility, Rutherford Appleton Laboratory, Chilton, Didcot OX11 0QX, UK — The wavevector and energy dependence of the spin fluctuations in overdoped superconducting La2−xSrxCuO4 ($T_c$=26 K) were investigated up to high energy (160 meV) by inelastic neutron scattering. Overdoping was found to suppress the strong magnetic response $\chi(q,ω)$ present in optimally doped La2−xSrxCuO4 which is peaked near 50 meV. The magnetic excitations were less dispersive than in the optimal compound and incommensurate at all energies investigated. Overdoping did not appear to weaken the high-frequency $E \geq 100$ meV response, suggesting that significant antiferromagnetic exchange couplings persist well into the overdoped part of the cuprate phase diagram.

12:15PM B11.00006 Conditions for magnetically induced singlet d-wave superconductivity on the square lattice1, S.R. HASSAN, B. DAVOUDI, B. KYUNG, A.-M.S. TREMBLAY, Universite de Sherbrooke — It is expected that at weak to intermediate coupling, d-wave superconductivity can be induced by antiferromagnetic fluctuations. However, one needs to clarify the role of Fermi surface topology, density of states, pseudogap, and wave vector of the magnetic fluctuations on the nature and strength of the induced d-wave state. To this end, we study the generalized phase diagram of the two-dimensional half-filled Hubbard model as a function of interaction strength $U/t$, frustration induced by second-order hopping $t''/t$, and temperature $T/t$. In experiment, $U/t$ and $t''/t$ can be controlled by pressure. We use the two-particle self-consistent approach (TPSC), valid from weak to intermediate coupling. D-wave superconductivity can be induced by magnetic fluctuations but only if they are near commensurate wave vectors and not too close to perfect nesting conditions where the pseudogap becomes detrimental to superconductivity. For given $U/t$ there is an optimal value of frustration $t''/t$ where the superconducting $T_c$ is maximum. The symmetry $d_{x^2−y^2}$ vs $d_{xy}$ of the superconducting order parameter depends on the wave vector of the underlying magnetic fluctuations in a way that can be understood qualitatively from simple arguments.

1Supported by NSERC, CRC program, CFI, MEQ, CIFAR, FQRNT.

12:27PM B11.00007 Finite size effects in NMR $T_2$ relaxation by vortex vibrations1, RACHEL WORTIS, Trent University, ERIC BROWN, SINAN BULUT — Nuclear magnetic resonance measurements are a powerful probe of electronic behavior in superconductors, but a precise understanding of all relaxation mechanisms is required to draw accurate conclusions. A previous calculation of the rate of transverse relaxation $T_2(\mathbf{r})$ present in optimally doped La2−xSrxCuO4 which is peaked near 50 meV. The magnetic excitations were less dispersive than in the optimal compound and incommensurate at all energies investigated. Overdoping did not appear to weaken the high-frequency $E \geq 100$ meV response, suggesting that significant antiferromagnetic exchange couplings persist well into the overdoped part of the cuprate phase diagram.

1Supported by NSERC of Canada, SHARCNET and Trent University.

12:39PM B11.00008 Evolution of the spin dynamics in electron-doped high-temperature superconductor Pr0.88LaCe0.12CuO4−δ ($T_c=24K$, 27K), JUN ZHAO, Department of Physics, University of Tennessee, Knoxville, TN, PENGCHENG DAI, Department of Physics, University of Tennessee, Oak Ridge National Lab, SHILIANG LI, Department of Physics, University of Tennessee, Knoxville, TN, HYE JUNG KANG, Center for Neutron Research, National Institute of Standards and Technology,Gaithersburg, MD, LOUIS-PIERRE REGNAULT, Laboratoire de Magnétisme et Diffraction Neutronique, Service de Physique Statistique, Magnétisme et Supraconductivité, PAUL STEPPENS, Institut Laue-Langevin, Grenoble, France, ARNO HIESS, instut Laue-Langevin, Grenoble, France, STEPHEN WILSON, Department of Physics, University of Tennessee, Knoxville, TN — We use both polarized and unpolarized neutron scattering to study spin excitations in electron doped cuprates Pr0.88LaCe0.12CuO4−δ($T_c=24K$, 27K). We determine the dynamic susceptibility and its temperature dependence for energies between 0.5meV to 30meV in these samples. Our results show that the spectral weight of optimal doped PLCCO (27K) around resonance energy region (~10meV) is much stronger than that of the slightly underdoped 24K PLCCO. We also demonstrate that using polarized neutrons are necessary to isolate magnetic scattering from nonmagnetic processes. A determination of the evolution of spin excitations in PLCCO as the system is tuned from nonsuperconducting to superconducting states is important to our understanding of the role of magnetism in high-Tc superconductivity.
12:51PM B11.00009 Incompatibility of Checkerboard Patterns with the Resonance Peak in Cuprate Superconductors\textsuperscript{1}. ERICA CARLSON, DAOXIN YAO, Purdue University — Checkerboard patterns have been proposed to explain STM experiments on the cuprates BSCCO and Na-COCO. However, simple checkerboard patterns are inconsistent with neutron scattering data, since they have low energy incommensurate spin peaks rotated 45° from the direction of the charge peaks.\textsuperscript{[1]} Recently, more complicated checkerboard patterns have been proposed in order to reconcile this conflict. In this work, we have studied modulated checkerboards by using spin wave theory and analyzed noncollinear checkerboards as well. We find that the high energy response of the modulated checkerboards is inconsistent with neutron scattering results, since they fail to exhibit a resonance peak at $(\pi, \pi)$ which has recently been shown to be a universal feature of cuprate superconductors. Furthermore, noncollinear checkerboards also lack a resonance peak.\textsuperscript{[2]} However, stripe patterns naturally exhibit a resonance peak consistent with neutron scattering data. References: [1] D. X. Yao, E. W. Carlson, and D. K. Campbell, Phys. Rev. B 73, 224525 (2006) [2] D. X. Yao and E. W. Carlson, arXiv:0708.1966

1:03PM B11.00010 High field, low temperature 17O Knight shift in an underdoped High-Tc cuprate: La(2-x)Sr(x)CuO(4) for $x = 0.115, 0.15$. GREG BOEBINGER, ROBERT SMITH, PHILIP KUHNS, ARNEIL REYES, National High Magnetic Field Lab, TAKASHI IMAI, McMaster University — We use high magnetic fields (>30T) to suppress the superconducting Tc in order to investigate the normal state NMR properties of La(2-x)Sr(x)CuO(4) (LSCO) at low temperatures. Recent studies have shown glassy behavior and incommensurate spin-waves in LSCO, which has been discussed as evidencing a stripe ordered phase at low temperatures in the under-doped regime. We use 17O NMR as a local probe of the electron density on the planar oxygens. 17O Knight shift and linewidth were obtained over a wide temperature range in the normal state for under-doped ($x=0.115$) and optimally doped ($x=0.15$) LSCO.

1:15PM B11.00011 Static Magnetic Order in Underdoped HgBa$_2$CuO$_{4+\delta}$. YUAN LI, Stanford Univ., VICTOR BALENTED, LLB, France, NEVEN BARISTIC, Universitat Stuttgart, Germany, PHILIPPE BOURGES, LLB, France, YONGCHAN CHO, Pusan National Univ., Korea, BENOIT FAUQU, YUAN SIDIS, LLB, France, GIUCHUAN YU, Stanford Univ., XUDONG ZHAO, Jilin Univ., P. R. China, MARTIN GREVEN, Stanford Univ. — It is believed by many that understanding the pseudogap phase is essential to understanding the mechanism of high-transition-temperature superconductivity. Here we present the first experimental identification, by polarized neutron diffraction, of an exotic magnetic order in the HgO$_2$Cu$_4$ (Hg1201), which is considered the model high-Tc material with (i) simple tetragonal structure, (ii) large spacing between the CuO$_2$ planes, and (iii) the highest Tc among all single-layer compounds [1]. The parameter $\delta$ develops below a characteristic temperature $T_{\text{mag}}$ that nicely agrees with the pseudogap temperature $T^*$ determined by DC transport. Our result is highly consistent with the previous work by B. Fauque et al. on the bi-layer compound YBCO [2], and can be interpreted within an orbital-current picture that breaks time-reversal symmetry but preserves discrete translational symmetry. The magnitude and the orientation of the magnetic moments of the current loops are experimentally investigated. 1. X. Zhao et al., Adv. Mat. 18, 3243 (2006). 2. B. Fauque et al., PRL 96, 197001 (2006).

1:27PM B11.00012 Quantum Spin Excitations through the metal-to-insulator crossover in YBa$_2$Cu$_3$O$_{y+y'}$. SHILIANG LI, University of Tennessee, ZAHRA YAMANI, Chalk River Laboratories, Canada, HYE-JUNG KANG, NIST and University of Maryland, KOJI SEGAWA, YOICHI ANDO, Osaka University, Japan, XIN YAO, Shanghai Jiaotong University, China, H.A. MOOK, ORNL, PENGCHENG DAI, University of Tennessee and ORNL. — We use inelastic neutron scattering to study the temperature dependence of the spin excitations of a detwinned superconducting YBa$_2$Cu$_3$O$_{6.45}$ ($T_c = 48$K). In contrast to earlier work on YBa$_2$Cu$_3$O$_{6.5}$ ($T_c = 58$K), where the prominent features in the magnetic spectra consist of a sharp collective magnetic excitation termed “resonance” and a large ($h\omega \approx 15$ meV) superconducting spin gap, we find that the spin excitations in YBa$_2$Cu$_3$O$_{6.45}$ are gapless and have a much broader resonance. Our detailed mapping of the spin excitations along the $\gamma$-axis direction reveals a dispersion consistent with the “hourglass” like dispersion near the resonance, but the spin excitations are isotropic at lower energies. Since a fundamental change in the low-temperature normal state of YBa$_2$Cu$_3$O$_{6+y}$ when superconductivity is suppressed takes place at $y \approx 0.5$ with a metal-to-insulator crossover (MIC), where the ground state transforms from a metallic to an insulating-like phase, our results suggest a clear connection between the large change in spin excitations and the MIC.

1:39PM B11.00013 Magnetic excitations in the high-temperature superconductors HgBa$_2$CuO$_{4+\delta}$ and Nd$_{1.84}$Ce$_{0.155}$CuO$_4$. GIUCHUAN YU, YUAN LI, EUGENE MOTOYAMA, Stanford University, PHILIPPE BOURGES, Laboratoire Léon Brillouin, KLAUDIA HRADIL, RICHARD MOLE, Forschungszentrum Jülich, Heinz Maier-Leibnitz, MARTIN GREVEN, Stanford University — We report inelastic neutron scattering results for the magnetic excitations in hole-doped HgBa$_2$CuO$_{4+\delta}$ (Hg1201) and electron-doped Nd$_{2-x}$Ce$_x$CuO$_{4+\delta}$ (NCCO). The magnetic resonance mode has been observed previously in the superconducting state of several hole-doped systems. Recently, this mode has also been claimed to be present in the electron-doped compounds. We found in underdoped Hg1201 ($T_c \approx 95$K) the resonance-like feature appearing at rather high energy of 57(2)meV. Surprisingly, the dynamic susceptibility enhancement appears below the pseudogap temperature $T^*$ and shows no anomaly at $T_c$. Unlike recent reports for optimally-doped NCCO and (PrLaCe)$_2$CuO$_{4+\delta}$, we found no evidence for a resonance mode in NCCO ($x=0.155$) in the 7-12 meV range. Instead, we identify two lower-energy features. One is associated with spectral weight redistribution below $T_c$ due to the electronic gap $2\Delta$, the other already present in normal state is likely associated with the significant spin correlations in the electron-doped cuprates.

Monday, March 10, 2008 11:15AM - 2:03PM –
Session B12 DCMP: Organic Conductors and Strongly Correlated 2D Systems Morial Convention Center 203

11:15AM B12.00001 The metal insulator transition in correlated quasi-one-dimensional organic conductors\textsuperscript{1}. CLAUDE BOURBONNAIS, ABDELOUAHAB SEDEKI, Departement de Physique, Universite de Sherbrooke, Sherbrooke (QC), Canada J1K-2R1 — We use a two-loop functional renormalization group approach to calculate the quasi- particle weight along the Fermi surface in the framework of the quasi-one- dimensional electron gas model which includes weak Umklapp scattering at half-filling. The location and evolution of cold and hot spots for electron-electron scattering is described and the Fermi surface reconstruction is clarified as a function of the amplitude of Umklapp scattering. The results are applied to the Mott transition in the Fabre salts series (TMTTF)$_2$X where the emergence of a Fermi surface is found as a consequence of electronic deconfinement under the application of hydrostatic pressure.

\textsuperscript{1}Supported by NSERC and the Canadian Institute of Advanced Research.
11:27AM B12.00002 Numerical Study of Finite-Temperature Phase Transitions in Quasi-One-Dimensional Molecular Conductors, YUCHI OTSUKA, CREST-JST, JAE/A/SPRING-8, HITOSHI SEO, JAE/A/SPRING-8, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo, TAKEO KATO, Institute for Solid State Physics, University of Tokyo — We have theoretically investigated the charge ordering, the dimer Mott, and the spin-Peierls phase transitions in quarter-filled quasi-one-dimensional organic conductors, such as DCNQI$_2$X and TMTTF$_2$X, by considering the extended Hubbard model with electron-lattice couplings and inter-chain Coulomb interaction. We apply the stochastic-series-expansion quantum Monte Carlo method to the effective one-dimensional model obtained by the adiabatic and inter-chain mean-field approximation. We discuss the competition of the order parameters and the susceptibilities are calculated for the charge ordering, the dimer Mott, and the spin-Peierls transitions. The results show a competition between the charge-ordered and dimer Mott insulating states, consistent with our previous work [1], and both of them undergo the spin-Peierls transition at low temperatures. There, two types of spin-Peierls phases with spin gap appear in competition with showing different orderings of period four in lattice distortion and charge disproportionation. [1] H. Seo, Y. Motome, and T. Kato, J. Phys. Soc. Jpn. 76, 013707 (2007).

11:39AM B12.00003 High field ESR on tau phase conductor —from GHz to THz—, TAKAHIRO TOKUMOTO, J. VAN TOL, L.-C. BRUNEL, D. GRAF, J.S. BROOKS, FSU/NHMFL, Y. OSHIMA, IMR, Tohoku Univ., G. PAPAVASSILIOU, NSW, Greece — Organic conductors have exotic electronic and magnetic properties ranging from the possibility of unconventional, anisotropic superconductivity, to the observation of a variety of ground states such as charge-density waves, spin-density waves, field-induced spin density waves, and the observation of quantum Hall effect, or a spin-Peierls state. One example is tau - [P-(S,S) - DMEDT-TTF)(AuBr2)]$_1$ y (-0.75). The crystal structure of this quasi two dimensional organic compound is tetragonal with unit cell dimensions: a = 7.3546 A and c = 67.977 A. Even though there are no magnetic ions in the system, several measurements indicate magnetic ordering at low temperature and under magnetic fields. Furthermore, this compound exhibits field induced hysteretic MI transition above 38T with an inking of weak ferromagnetism. We investigate the origin of the magnetic behavior by conducting a CW ESR study from 90GHz to 1.2 THz. Results and analysis will be presented.

12:03PM B12.00005 Charge frustration and novel electron-lattice coupled phase transition in organic conductor DI-DCNQI$_2$Ag, HITOSHI SEO, JAE/A/SPRING-8, YUKITOSHI MOTOME, Department of Applied Physics, University of Tokyo — We have theoretically investigated the phase transition accompanying charge ordering in 1/4-filled quasi-one-dimensional organic conductor DI-DCNQI$_2$Ag. The nature of this phase transition at 220 K has been under debate since the first direct observation of charge ordering among organic quasi-one-dimensional systems by Hiraki and Kanoda[1]. In this study, motivated by a recent synchrotron radiation x-ray study by Kakiuchi et al.[2], we investigate a three-dimensional interacting spinless fermion model coupled to the lattice degree of freedom. We have found that the peculiar “spiral frustration” existing in the interchain Coulomb interaction destabilizes simple Wigner crystal-type charge order and gives rise to a novel state where different chains show different orders and align periodically: charge order, lattice dimerization, and a co-existence of them. The co-existence of these two orders was in fact predicted in our previous study for the non-frustrated case[3], which was stabilized as a result of competing interactions. In contrast, the co-existence in the present study is obtained by compromising the frustration in charge sector. [1] K. Hiraki and K. Kanoda, Phys. Rev. Lett. 80 (1998) 4737. [2] T. Kakiuchi et al., Phys. Rev. Lett. 98 (2007) 066402. [3] H. Seo, Y. Motome, and T. Kato, J. Phys. Soc. Jpn. 76 (2007) 013707.

12:15PM B12.00006 Finite size effects in micro- and nanocrystals of (TMTSF)$_2$ClO$_4$, P. DHAKAL, J.I. OH, M.J. NAUGHTON, Boston College — We report transport measurements in micro- and nano-sized crystals of the molecular organic (super)conductor (TMTSF)$_2$ClO$_4$. Synthesized using the standard electrocrystallization process, various techniques such as focus ion beam-induced metallization, photo lithography, and atomic layer deposition were then employed to successfully make micro- and nano-electrodes contacting these samples. In addition, FIB sculpting was used to reshape crystals to reduce their sizes. We have successfully measured crystals with dimensions as small as 300 nm. We have observed that electrical transport behaviors of these finite sized crystals are very different from those of their parent bulk crystals. We will discuss our observations in terms of various origins such as finite size effects, fabrication-induced defects, and combinations thereof.

12:27PM B12.00007 Pulsed-field study of the interference commensurate effect in quasi-one-dimensional organic conductors, J. ROY, J.I. OH, H. YOSHINO, P. DHAKAL, M.J. NAUGHTON, Boston College — We report angle-dependent magnetoresistance oscillations for fields up to 43 T oriented mainly in the most conducting x-y plane, with small field component along the least conducting z axis, in the q1d compounds (TMTSF)$_2$ClO$_4$ and (DMET)$_2$I$_3$ at 1.5 K. A hybrid plastic-metal cryoprobe system with pseudo dual-axis rotation has been built for these pulsed-field measurements. Due to the interference commensurate effect, (aka Lee-Naughton oscillations) [1-3], we have observed rich magnetoresistance oscillations, resulting from an interference effect of commensurate electron trajectories in the extended Brillouin zone. Also, we have found that, as theoretically expected [2], field-dependent magnetoresistence shows 1D and 2D transport behavior at local resistance maxima and minima (versus field angle), respectively. Temperature dependences of the order parameters and the susceptibilities are calculated for the charge ordering, the dimer Mott, and the spin-Peierls transitions. The results show a competition between the charge-ordered and dimer Mott insulating states, consistent with our previous work [1], and both of them undergo the spin-Peierls transition at low temperatures. There, two types of spin-Peierls phases with spin gap appear in competition with showing different orderings of period four in lattice distortion and charge disproportionation. [1] J.J. Lee and M.J. Naughton, Phys. Rev. B 57, 7423 (1998). [2] A.G. Lebed, et al., Phys. Rev. Lett. 91, 187003 (2003). [3] H.I. Ha, et al., Phys. Rev. B 73, 033107 (2006).

12:39PM B12.00008 Acoustic properties of quasi-one-dimensional organic conductor (TMTSF)$_2$ClO$_4$ in the relaxed state: Superconductivity and FISDW anomalies. ALEXANDRE LANGLOIS, MARIO POIRIER, CLAUDE BOURBONNAIS, Universite de Sherbrooke, KLAUS BECHGAARD, Risoe National Laboratory — Through competing electronic instabilities, the anion sublattice plays an important role in the nematic phase diagram of the Bechgaard salts. In the quasi-one-dimensional organic conductor (TMTSF)$_2$ClO$_4$, anion ordering at 24 K affects the nesting properties of the Fermi surface and controls the stability of the superconducting phase below 1.2 K at ambient pressure. Moreover, the field induced spin density wave phases FISDW, one of the several features induced by a magnetic field in this compound, are also sensitive to the symmetry of the anions. In order to address the coupling issue between the lattice and these electronic instabilities, we have performed the first ultrasonic measurements on (TMTSF)$_2$ClO$_4$ in the relaxed state below 4 K using longitudinal and transverses waves (30-500 MHz). If low-frequency vibrating reed experiments have revealed magneto-elastic anomalies in the FISDW phases [1], the superconducting one was never investigated by similar techniques. We report anomalies in the ultrasonic velocity and attenuation for the superconducting and the FISDW phases. The coupling of these phases to the lattice is discussed in relation with the known T-B phase diagram. [1] X.D. Shi et al., Phys. Rev. B. 50, 1984 (1994).

12:51PM B12.00009 Spin dynamics of the field-induced spin density wave phases in (TMTSF)$_2$ClO$_4$ in tilted magnetic fields. L.L. LUMATA, J.S. BROOKS, A.P. REYES, P.L. KUHNS, Department of Physics and National High Magnetic Field Laboratory, Florida State University, S.E. BROWN, Department of Physics, UCLA, H.B. CUI, Department of Physics and National High Magnetic Field Laboratory, Florida State University, J.-I. TAMADA, Department of Material Science, University of Hyogo — The spin dynamics of the different subphases of the field-induced spin density wave (FISDW) ground state in (TMTSF)$_2$ClO$_4$ was investigated using simultaneous $^{77}$Se nuclear magnetic resonance (NMR) and electrical transport. The metallic and FISDW phases were accessed by rotating the sample along its most conducting axis in a constant magnetic field $H$ and constant temperature. At a fixed field of 30 T and constant temperature 1.47K, we report observation of divergence in the spin-lattice relaxation rate $1/T_1$ at angles corresponding to $H_z = H \cos(\theta) \sim 6.4T, 15.9T,$ and 26T phase transitions. There is a gradual increase in $1/T_1$ in the 2nd-order/FISDW cascade region and a nearly metallic-like behavior deep in the final reentrant SDW phase is observed. rf enhancements in the metallic and FISDW phases were also measured. The details will be discussed.

1:03PM B12.00010 Interlayer Cooperon correction to angular-dependent magnetoresistance in layered metals. MALCOLM KENNEDIT, Simon Fraser University, ROSS MCKENZIE, University of Queensld — Studies of angle-dependent magneto-resistance oscillations (AMRO) in the interlayer conductivity of layered metals have generally considered semi-classical electron transport. We consider a quantum correction to the semi-classical conductivity which arises from what can be described as an interlayer Cooperon. This depends on both the disorder potential within a layer and the correlations of the disorder potential between layers. We compare our results with existing experimental data on organic charge transfer salts that is not explained within the standard semi-classical transport picture. In particular, our results may be relevant for weak localization-like effects that have been seen when the applied magnetic field is close to parallel to the conducting layers.

1:15PM B12.00011 Coulomb drag at zero temperature. ALEX LEVCHENKO, ALEX KAMENEV, University of Minnesota — We show that the Coulomb drag effect exhibits saturation at small temperatures, when calculated to the third order in the interlayer interactions. The zero-temperature transresistance is inversely proportional to the third power of the dimensionless sheet conductance. The effect is therefore the strongest in low mobility samples. This behavior should be contrasted with the conventional (second order) prediction that the transresistance scales as a certain power of temperature and is almost mobility-independent. The result demonstrates that the zero-temperature drag is not an unambiguous signature of a strongly-coupled state in double-layer systems.

1:27PM B12.00012 Collective modes in quantum electron glasses and electron-assisted hopping. MARKUS MUELLER, Harvard University, LEV IOFFE, Rutgers University — We study electronic transport in Anderson insulators with strong Coulomb interactions in dimensions $d \geq 2$. Close to the metal insulator transition where the single particle localization length is much larger than interparticle-distance, the interactions lead to a strongly correlated quantum glass phase. Even though single particle excitations are localized and the system is insulating, there are collective electronic modes which remain delocalized down to parametrically small energies. These collective excitations serve as a continuous bath which can provide the activation energy for variable range hopping transport. This circumvents the energy conservation problem arising when only discrete particle-hole excitations are present. In contrast to the weak and material-dependent phonon-assisted hopping mechanism, the activation by an electronic bath leads to a nearly universal prefactor $e^2/h$ of the Efros-Shklovskii conductance, as is observed in many recent experiments.

1:39PM B12.00013 Hall effect on the triangular lattice. GLADYS LEON, CHRISTOPHE BERTHOD, THIERRY GIAMARCHI, DPMC-MaNEP, University of Geneva, 24 quai Ernest-Abnsermet, 1211 Geneva 4, Switzerland., ANDREW MILLIS, Department of Physics, Columbia University, 538 West, 120th Street, New York, NY 10027, USA — We investigate the Hall effect on the two-dimensional triangular lattice. We calculate the high frequency Hall constant $R_H$ and its temperature dependence for three regimes of the Hubbard interaction $U$. In the non-interacting case $U=0$ we find that $R_H$ behaves at temperature $T=0$ like the classical dc Hall constant, $R_H \sim 1/\pi e$. At high $T$ we find a positive $R_H$ increasing linearly with temperature, with a slope depending on the electron density. For small to moderate values of $U$, we study the effect of interactions on $R_H$ within second-order perturbation theory, and we find these effects to be small. The perturbation theory also shows that the electron self-energy is almost local ($k$-independent), suggesting the use of a local approximation as the Dynamical Mean Field Theory (DMFT) method to treat higher values of $U$. We therefore evaluate $R_H$ at large $U$ using both DMFT and the atomic limit of the self-energy, and we compare the results with those obtained at small $U$. Finally, we discuss the relevance of our calculations for the interpretation of recent Hall measurements in cobaltates.

1:51PM B12.00014 Quantum Phase Transition in a Cold Atomic Spin-Boson Mixture. PETER P. ORTH, IVAN STANIC, KARYN LE HUR, Yale University — We theoretically implement a spin array in a tunable bosonic environment using cold bosonic atoms with two (hyperfine) ground states, trapped by different potentials [1]. The first specie lies in a deep optical lattice with tightly confining wells and the second specie forms a superfluid reservoir. Different species are coupled coherently via laser transitions and collisions. Whereas the laser coupling mimics a transverse field for the spins, the coupling to the reservoir phonons (sound modes) induces a ferromagnetic (Ising) coupling as well as dissipation. This results in a peculiar ferro-paramagnetic quantum phase transition where the effect of dissipation can be studied in a controllable manner.

Session B13 DCOMP GSCCM: Focus Session: Simulations of Matter at Extreme Conditions
II: Beryllium, Carbon, and Metals
Morial Convention Center 204

11:15AM B13.00001 The Role of Anharmonicity in the Beryllium Equation of State, LORIN X. BENEDICT, ANDREA TRAVE, CHRISTINE WU, TADASHI OGITSU, PHIL STERNE, ERIC SCHWEGLER, Lawrence Livermore National Lab, H-DIV COLLABORATION — We discuss the construction of a multi-phase equation of state for Be from first principles, aimed at understanding the material’s properties at extreme conditions. In addition to the usual computation of cold, quasiharmonic ion-thermal, and (negligible here) electron-thermal contributions, we consider the effects of strong anharmonicity in the bcc phase, and argue that the inclusion of such effects may greatly perturb the picture (in particular, the phase diagram) derived from assuming quasi-harmonic lattice dynamics. Our analysis involves studying the mean displacement from equilibrium of Be atoms in the lattice by DFT-molecular dynamics methods and comparing the results to those of the quasiharmonic theory.

11:27AM B13.00002 Quantum molecular dynamics simulations of beryllium at high pressures1, MICHAEL DESJARLAIS, MARCUS KNUDSON, Sandia National Laboratories — The phase boundaries and high pressure melt properties of beryllium have been the subject of several recent experimental and theoretical studies. The interest is motivated in part by the use of beryllium as an ablative material in inertial confinement fusion capsule designs. In this work, the high pressure melt curve, Hugoniot crossings, sound speeds, and phase boundaries of beryllium are explored with DFT based quantum molecular dynamics calculations. The entropy differences between the various phases of beryllium are extracted in the vicinity of the melt curve and agree favorably with earlier theoretical work on normal melting. High velocity flyer plate experiments with beryllium targets on Sandia’s Z machine have generated high quality data for the Hugoniot, bulk sound speeds, and longitudinal sound speeds. This data provides a tight constraint on the pressure for the onset of shock melting of beryllium and intriguing information on the solid phase prior to melt. The results of the QMD calculations and the experimental results will be compared, and implications for the HCP and BCC phase boundaries of beryllium will be presented.

1Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the US DOE’s NNSA under Contract No. DE-AC04-94AL85000.

11:39AM B13.00003 Equation of state of beryllium from first-principles calculations, ANDREA TRAVE, LORIN BENEDICT, TADASHI OGITSU, CHRISTINE J. WU, PHILIP A. STERNE, ERIC SCHWEGLER, Lawrence Livermore National Lab — The design of experiments of materials at extreme conditions of pressure and temperature is often based on hydrodynamic simulations, which make use of equation of state (EOS) models for the description of the systems under study. The validity of these models is extremely critical, and first-principles calculations can provide consistent and accurate parameters for the determination of the EOS in a wide range of thermodynamic conditions. Extensive density functional theory calculations at zero temperature have been performed for beryllium in various solid structures, in order to obtain accurate predictions for their compression curves, and phonon and electronic densities of states. Finite-temperature simulations have been used to further improve the models to include anharmonic effects. The melting line of beryllium has been obtained with first-principles two-phase simulations, which enables the construction of a multi-phase EOS for both liquid and solid beryllium. The results of these simulations provide useful indications on the relative stability of the various solid and liquid phases of beryllium in a region of the phase diagram lacking any experimental study so far. Prepared by LLNL in part under Contract W-7405-Eng-48 and in part under Contract DE-AC52-07NA27344.

11:51AM B13.00004 Construction of a multi-phase equation of state for carbon at extreme pressures1, ALFREDO A. CORREA, University of California at Berkeley and Lawrence Livermore National Laboratory, LORIN X. BENEDICT, Lawrence Livermore National Laboratory, STANIMIR A. BONEV, Dalhousie University, Halifax, Canada, DAVID A. YOUNG, Lawrence Livermore National Laboratory, ERIC SCHWEGLER, Livermore National Laboratory — We describe the construction of a multi-phase equation of state for carbon at extreme pressures that is based on the results of first principles electronic structure calculations. Two solid phases (diamond, B6) and the liquid are considered. Solid-phase free energies are built from a knowledge of cold curve and phonon calculations, together with first principles molecular dynamics calculations of the equation of state itself to extract anharmonic terms. The liquid free energy is constructed from a combination of molecular dynamics calculations and constraints determined from previously calculated melt curves, assuming a simple solid-like free energy model. The resulting equation of state is extended to more extreme densities and temperatures with a plasma-based free energy model. Comparisons to available experimental results are discussed.

1Prepared by LLNL under Contract DE-AC52-07NA27344.

12:03PM B13.00005 Clustering in dense molten lithium, ISAAC TAMBLYN, Dalhousie University, JEAN-YVES RATY, University of Liege, STANIMIR A. BONEV, Dalhousie University — Molten lithium is investigated from zero to over nine-fold compression using first principles theory. Over this pressure range, we observe several electronic and structural transitions. The changes that lithium undergoes with increasing pressure are initially analogous to those predicted for liquid sodium [1]. However, upon further compression, effects due to increased core overlap lead to a new liquid phase composed of weakly bound lithium clusters. The properties of the proposed new liquid phases, the melting curve of lithium, and the implications of our findings for the stability of low-symmetry lithium solids will be discussed. [1] J.-Y. Raty, E.R. Schwegler, S.A. Bonev, Nature, 449, 448-451 (2007)

12:15PM B13.00006 Lithium at ultra-high pressures, ANDRE KIETZMANN, RONALD REDMER, Univeritat Rostock, Institut fur Physik, D-18051 Rostock, Germany, MICHAEL P. DESJARLAIS, THOMAS R. MATTSION, Sandia National Laboratories, Albuquerque, NM 87185-1186, USA — Lithium is a prototypical simple metal at standard conditions. However, by changing the density towards expanded or compressed states, the electrical conductivity shows strong variations. We have performed quantum molecular dynamics simulations for fluid lithium covering a wide range of densities and temperatures in order to derive the equation of state, the electrical conductivity, and information about structural and electronic changes along the expansion or compression. The electrical conductivity changes from the nonmetallic expanded fluid via the fluid metal region up to the degenerate electron liquid at high densities. We find a largely ordered ion structure at ultra-high densities reflecting a multi-centered ion situation in the liquid as predicted earlier for solid lithium. Supported by the DFG within SFB 652. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States DOE’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

12:27PM B13.00007 ABSTRACT WITHDRAWN –
12:39PM B13.00008 Optical Properties of LiH From Mixing Rules. DANIEL HORNER, JOEL KRESS, LEE COLLINS, Theoretical Division, Los Alamos National Laboratory — We investigate the use of pressure and density matching mixing rules for predicting the optical properties and equation-of-state (EOS) of lithium hydride for densities from half to twice solid [0.78 g/cc] and temperatures from 0.5 to 3.0 eV. The mixing rules allow us to perform simulations of lithium and hydrogen separately and, from them, calculate properties of the mixture. Using the VASP code, we performed constant (N, V, T) quantum molecular dynamics simulations for H, Li, and LiH with the results for the mixture (LiH) as a benchmark of the mixing procedures. A finite-temperature density functional theory formulation produces the electronic wave function at each time step within the generalized gradient approximation with projector augmented wave pseudopotentials. Optical properties were determined using the electronic wave function in a Kubo-Greenwood formula. We compare the frequency-dependent absorption coefficient, Rosseland Mean Opacity, and EOS computed via the mixing rules and those from a full LiH simulation.

12:51PM B13.00009 First principles investigation of the dielectric function of gold under ultrafast laser excitation¹, TADASHI OGITSU, LLNL, DAVID PRENDERGAST, LBL, ERIC SCHWEGLER, YUAN PING, ANDREW NG, LLNL — Recently, a quasi-steady state in ultrathin, ~30 nm gold foils exposed to an ultrafast laser pulse has been observed, which includes an enhanced interband transition peak at 2.6 eV in the imaginary part of the dielectric function [1]. Simulations of this system assuming a two-temperature model for the electronic and ionic degrees of freedom do not provide this enhancement in optical absorption, possibly indicating that both of these degrees of freedom are not in equilibrium. Our approach is to treat this as an inverse problem: to reproduce experiment by sampling various states of electrons and ions. We employ an efficient first principles technique to quickly estimate the dielectric function of this fcc metal for various finite temperature and non-equilibrium model distributions. Converged Brillouin zone sampling is achieved using a compact k-dependent Hamiltonian derived from first principles calculations [2]. [1] Y. Ping et al., Phys Rev Lett 96, 25503 (2006). [2] E. L. Shirley, Phys Rev B 54, 16464 (1996).

1:03PM B13.00010 High pressure lattice dynamics and elasticity of transition metals. DANIEL ORLIKOWSKI, LORIN BENEDICT, JOHN KLEPEIS, Lawrence Livermore National Laboratory — For continuum-level description of transition metals using equation of state and strength models, a high-pressure lattice dynamics effort is required. We present here a subset of that work to provide Debye temperatures and elastic moduli for the equation of state (EOS) and strength models. DFT calculations for the phonons are performed to obtain the Debye temperature over the pressure range required by the EOS model. For the strength model, we have combined several sets of quantum-based, atomistic calculations with density functional theory (DFT) to develop elastic moduli over a wide range of temperatures (12,000 K) and pressures (4 Mbar). Our focus is upon vanadium but other transition metals will be presented tantalum and molybdenum. Our results are comparable to available experimental data. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

1:15PM B13.00011 A new wide-range equation of state for tungsten. JOHN H. CARPENTER, Sandia National Laboratories, MICHAEL P. DESJARLAIS, ANN E. MATTSSON, KYLE R. COCHRANE — A new wide-range equation of state for tungsten is described. Quantum molecular dynamics calculations in the warm dense matter region are combined with other experimental and theoretical calculations, providing a set of information on which to tune a model of the free energy landscape. The resulting model, describing the liquid, gas, and bcc solid phases, provides a good description of the liquid-vapor critical point, melt curve, static compression data, isobaric expansion data, and the Hugoniot. Finally, improvements in table generation greatly improve the resolution of phase boundaries.

1:27PM B13.00012 ABSTRACT WITHDRAWN —

1:39PM B13.00013 Pressure Induced Solidification of Ta and Cu: A Comparison. DAVID RICHARDS, JAMES GLOSILI, FREDERICK STREITZ, Lawrence Livermore Natl Lab — Using powerful computers such as Blue Gene/L it is now possible to use classical molecular dynamics to simulate pressure induced solidification at size scales that are free of finite size effects. We present a comparison of the nucleation, growth, and coalescence of clusters during pressure induced solidification in large scale MD simulations of liquid Ta and Cu. We extract growth and nucleation rates from our simulations, as well as cluster size distributions that can be compared against the predictions of simple models. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

1:51PM B13.00014 New Phase Diagram of Ta: Bridging Laser Heated Diamond-Anvil Cell and Shock Melting³, CHRISTINE J. WU, PER A. SÖDERLIND, JAMES N. GLOSILI, JOHN E. KLEPEIS, Lawrence Livermore National Laboratory — Determination of the melt line of materials under high pressures is essential for establishing its phase diagrams and has important implications for geophysics, material science, and high-pressure physics. So far, melting temperatures at high pressure are primarily measured by in situ laser-heated diamond-anvil cell (DAC) or shock wave experiments. Often, these two methods yield significantly different results, particularly for non close-packed metals, such as bcc metals. For instance, anomalously flat melting slopes were reported for numerous bcc metals by laser-heated DAC. The flatness of the melting slope is in sharp contrast to the classical Lindemann behavior which shock-melting temperatures follow closely. In this presentation, we will report a novel phase diagram of Ta obtained from ab initio methods, and molecular dynamics (MD) simulations, which resolves the long-standing controversy, and has significant impact on our understanding of phase diagrams of bcc metals.

³This work preformed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Monday, March 10, 2008 11:15AM - 2:03PM —
Session B14 DAMOP: Casimir Forces, Collisions and Atomic Structure  Morial Convention Center 205
Numerically calculate the Casimir force on a piston in a periodically driven micromachined torsional oscillator, yielding a highly sensitive measurement of the force gradient for separations between 80nm and 500nm.

In our experiment, the force gradient is measured by the frequency shifts caused by Casimir force in the response of the crystal surfaces versus the case in which they are parallel to the surfaces. We compute the force numerically for cases of experimental interest, and discuss the orientation of the optical axes. For strongly anisotropic crystals, the Casimir force can be substantially different when the optical axes are perpendicular to the crystal surfaces versus the case in which they are parallel to the surfaces. We compute the force numerically for cases of experimental interest, and discuss the prospects for observing this effect.

We present measurements of the Casimir force gradient between a gold-coated sphere and a highly doped silicon plate with an array of nanoscale, high-aspect-ratio trenches. The Casimir force arises from quantum fluctuation of electromagnetic fields in vacuum and is strongly dependent on the boundary condition. While the majority of the precise measurements have been performed on simple arrangements of plate-shaped objects, few experiments have been done in geometries with interactions that deviate significantly from the pair-wise summation of two-body potentials. We choose one of the interacting surfaces to be an array of trenches with widths ranging from 200 nm to 500 nm and depth of 1μm. Theoretical analysis predict that for perfectly conducting surfaces with such geometry, the Casimir force differs by up to 70% from the pair-wise summation of two-body potentials. We show that large corrections to these approximations could be measured using present-day technology with a BEC used as a vacuum field sensor. For details, see D.A.R. Dalvit et al, arXiv:0710.5249, 0709:2095.

We present measurements of the Casimir force gradient between a metal and a dielectric in fluid. The boundary conditions on these fields are dependent upon the electromagnetic properties of the interacting materials and affect both the magnitude and sign of the resulting force. We will discuss our experiments for measuring the Casimir-Lifshitz force between a metal and a dielectric immersed within a fluid and will describe situations which can give rise to a repulsive interaction.

On the repulsive Casimir force using metamaterials. We discuss as realistically as possible the role that metamaterials play in the Casimir force and bring to the surface some aspects of this issue that were previously rarely mentioned, such as the typical anisotropy of metamaterials and the presence of a Drude background in its electric permittivity. We also study the Casimir and Polder force between an atom and a metamaterial, since this setup may be more suitable to the detection of repulsion forces.
Spin depolarisation of $\text{N}_2^+$ ($^2\Sigma^+$) in collisions with $^3\text{He}$ and $^4\text{He}$ in a magnetic field. TIERRY STOECKLIN, GRÉGOIRE GUILLOIN, ANATOLI VORONIN — The possibility of tuning the interactions between atoms and molecules using a magnetic field has open new possibilities of controlling collisional energy transfer at very low temperature. In a first study dedicated to $\text{He}-\text{N}_2$ inelastic collisions we found that spin free collisions of $\text{N}_2^+$ with $^3\text{He}$ and $^4\text{He}$ exhibit a strong isotope effect in the ultra cold regime, and recently found a similar effect for another ionic system: the He-CH$^+$ collision. In the present work, we compare first in the absence of an applied magnetic field the cross sections for the transitions changing the projection of the total angular momentum of $\text{N}_2^+$ ($^2\Sigma$) in collisions with $^3\text{He}$ and $^4\text{He}$ at very low collision energy. In the second part of this contribution we investigate the effect of an applied magnetic field and compare the results obtained for the fundamental states of the two nuclear spin isomers of $\text{N}_2^+$. As a result of the different mechanisms of action of the spin rotation interaction for these two rotational levels we find a great difference of sensitivity to the applied magnetic field. Whereas even moderate values of the applied magnetic field (10 Gauss) completely modify the very low collision energy behaviour of the spin depolarisation cross section of the fundamental ortho level, we find that one has to apply magnetic fields two orders of magnitude larger to obtain similar effects for the fundamental para level.

III-3PM B14.00010 Observation of the (n$^3\text{He},t)p$ Reaction by Detection of Far-Ultraviolet Radiation. CHARLES W. CLARK, Joint Quantum Institute, NIST and the University of Maryland, ALAN K. THOMPSON, National Institute of Standards and Technology, MICHAEL A. COPLAN, JOHN W. COOPER, Institute for Physical Science and Technology, University of Maryland, PATRICK HUGHES, Department of Physics, University of Maryland, ROBERT E. VEST, Electron and Optical Physics Division, National Institute of Standards and Technology — We have detected Lyman alpha radiation as a product of the n($^3\text{He},t)p$ nuclear reaction, induced in a $^3\text{He}$ gas cell irradiated by a cold neutron beam at the NIST Center for Neutron Research. The predominant source of this radiation appears to be decay of the 2p state of tritium produced by charge transfer and excitation collisions with the background $^3\text{He}$ gas. For atmospheric pressure and room temperature in the $^3\text{He}$ cell, we find yields of tens of Lyman alpha photons for every neutron reaction. These results suggest a method of cold neutron detection that is complementary to existing technologies that use proportional counters. In particular, this approach may provide single neutron sensitivity with wide dynamic range capability, and a class of neutron detectors that are compact and operate at relatively low voltages.

Photo-Fragmentation of Lithium Atoms in FEL Radiation Fields, MATTHEW FOSTER, J. COLGAN, Los Alamos National Laboratory, Theoretical Division, M.S. PINDZOLA, Auburn University, ALEXANDER DORN, Max-Planck-Institut für Kernphysik — Multi-electron ejection from lithium induced by absorption of a single photon is a fundamental few-body reaction that tests the correlated interaction dynamics between atomic constituents. Experiments have been proposed using intense FEL radiation at FLASH in combination with reaction microscopes to measure four-body dynamics. These proposed experiments will first measure the double ionization dynamics from both the even parity Li ground state and the laser excited odd parity Li(2p$^2P^o$) state. We will present theoretical calculations using the time-dependent close-coupling method (TDCC) to assist in the experimental search for interesting correlation effects for both double and triple ionization of lithium.

Long range anions: diatomic, triatomic and polyatomic molecules. EDWARD C. CHEN, The Wentworth Foundation, EDWARD S. CHEN, Baylor College of Medicine — The observation of both long range and valence anions of O$_2$, NO, CS$_2$, NO$_2$, O$_3$, SF$_6$, C$_2$F$_6$, CH$_3$NO$_2$, tetracene, anthracene, acridine, perylene, pyrene, naphthalene and the nucleobases is reported in negative ion mass spectrometry, photoionization, electron impact in nanodroplets, electron swarm experiments at low temperature and alkali metal beam studies. New polarization or quadrupole bound electron affinities less than 0.1 eV are reported for the aromatic hydrocarbons, O$_2$, SF$_6$, CS$_2$, C$_2$F$_6$ while dipole bound values less than 0.15 eV are reported for the nucleobases, NO$_2$ and NO. The long range states act as gateways to valence states. This relationship is illustrated by Morse potential energy curves in single bond dissociations and in reaction coordinates analogous to Marcus parabolas. New adiabatic electron affinities values less than 0.15 eV are reported for the nucleobases, N$_2$, O$_2$, and NO. The long range states act as gateways to valence states. This relationship is illustrated by Morse potential energy curves in single bond dissociations and in reaction coordinates analogous to Marcus parabolas. New adiabatic electron affinities are reported for some of these molecules, including (in eV) guanine, 1.64(2) adenine, 1.09(2); C$_2$F$_6$, 1.26(5); acridine, 1.09(2); perylene, 1.09(2); tetracene, 1.10(2); naphthalene, 0.19(2) eV.

The Wentworth Foundation.

The Effect of Birth Location in an Intense Laser Focus on the Non-Sequential Double Ionization Yield. JAY PAQUETTE, JAN CHALoupKA, College of William and Mary — Atoms in an intense laser field can become doubly ionized through a direct process known as rescattering, where a single electron is liberated through tunnel ionization and is driven back to the ion core by the laser field, leading to impact ionization and release of a second electron. In this quasi-classical description, the trajectory of the first electron will have a strong influence on the probability of release of a second electron, as evidenced by the reduction in yield with elliptical laser polarization. Even with linear polarization, the first electron can avoid a reencounter with the ion due to the v x B term or the longitudinal electric field component (E$_z$) in the laser focus. Since the E$_z$ term is given from the requirement of zero divergence of the electric field, its magnitude will vary as a function of position within the laser focus. Using completely classical 3-D simulations, we demonstrate how longitudinal electric field variations affect electron trajectories, how the ion yields from various regions within the focus are affected, and the likelihood of observing this effect experimentally.
Austrian Academy of Sciences, ANTON ZEILINGER, IQOQI; Faculty of Physics, University of Vienna — We successfully transmitted both photons of various link key distribution involving phase reference beams. Based on coherent states and homodyne detection is used to illustrate the method. A possible test for the quantum nature of memories using two non-orthogonal values in conjunction with the partial transposition map. Our method is designed to reduce the resources for entanglement verification. A particular protocol quantum behavior can be phrased as the verification of effective entanglement. Necessary separability criteria are formulated in terms of a matrix of expectation of quantum information processing devices, such as quantum memories, teleportation devices, channels and quantum key distribution protocols. The test of FOR QUANTUM COMPUTING COLLABORATION, UNIVERSITY OF ERLANGEN COLLABORATION — We present a method to test quantum behavior, HAUKE HASELER, TOBIAS MORODER, NORBERT LUTKENHAUS, Institute for Quantum Computing, INSTITUTE OF QUANTUM COMPUTING COLLABORATION, UNIVERSITY OF ERLANGEN COLLABORATION — We present a method to test quantum behavior of quantum information processing devices, such as quantum memories, teleportation devices, channels and quantum key distribution protocols. The test of quantum behavior can be phrased as the verification of effective entanglement. Necessary separability criteria are formulated in terms of a matrix of expectation values in conjunction with the partial transposition map. Our method is designed to reduce the resources for entanglement verification. A particular protocol based on coherent states and homodyne detection is used to illustrate the method. A possible test for the quantum nature of memories using two non-orthogonal signal states arises naturally. Furthermore, closer inspection of the measurement process in terms of the Stokes operators reveals a security threat for quantum key distribution involving phase reference beams.

11:27AM B15.00002 Testing Quantum Devices: Practical Entanglement Verification in Bipartite Optical Systems, HAUKE HASELER, TOBIAS MORODER, NORBERT LUTKENHAUS, Institute for Quantum Computing. INSTITUTE OF QUANTUM COMPUTING COLLABORATION, UNIVERSITY OF ERLANGEN COLLABORATION — We present a method to test quantum behavior of quantum information processing devices, such as quantum memories, teleportation devices, channels and quantum key distribution protocols. The test of quantum behavior can be phrased as the verification of effective entanglement. Necessary separability criteria are formulated in terms of a matrix of expectation values in conjunction with the partial transposition map. Our method is designed to reduce the resources for entanglement verification. A particular protocol based on coherent states and homodyne detection is used to illustrate the method. A possible test for the quantum nature of memories using two non-orthogonal signal states arises naturally. Furthermore, closer inspection of the measurement process in terms of the Stokes operators reveals a security threat for quantum key distribution involving phase reference beams.

11:39AM B15.00003 Transmission of photonic Bell states over a 2x32dB, 144km free-space link1, ALESSANDRO FEDRIZZI, R. URSIN, T. HERBST, M. NESPOLI, R. PREVEDEL, T. SCHEIDL, F. TIEFENBACHER, T. JENNENWEIN, IQOQI, Austrian Academy of Sciences, ANTON ZEILINGER, IQOQI; Faculty of Physics, University of Vienna — We successfully transmitted both photons of various Bell states over a 144 km free-space link between the islands of Tenerife and La Palma. Creating and transmitting more than $6 \times 10^9$ highly entangled photon pairs/s over the $2 \times 32$ dB channel we received 0.07 pairs/s at the receiver. We were able to distinguish between $|\psi^+\rangle$ and $|\psi^-\rangle$ states and verified the presence of entanglement by violating a CHSH Bell inequality to $S = 2.61 \pm 0.11$, 5 standard deviations above the classical limit of 2. Using a small and compact photon source, we effectively emulate quantum communication in a loss regime comparable to a two-link satellite communication scenario. Furthermore, we convincingly demonstrate the feasibility of 2-photon quantum communication protocols like dense coding, teleportation or quantum cryptography without reference frame over long distance. Finally, with a flight time of 0.5 ms the transmitted Bell states are the longest lived photonic Bell states ever reported.

11:51AM B15.00004 Correlated photon generation via four-wave mixing in a birefringent semiconductor waveguide, DANIEL ROGERS, Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology, JULIUS GOLDHAR, University of Maryland, CHRISTOPHER RICHARDSON, Laboratory for Physical Sciences, University of Maryland, ALESSANDRO RESTELLI, JOSHUA BIENFANG, CHARLES CLARK, Joint Quantum Institute, University of Maryland and National Institute of Standards and Technology — The next generation of quantum cryptography will benefit from a fast and practical source of entangled photon pairs. Current methods of generating entanglement, whether in bulk nonlinear crystals or microstructure optical fibers, pose significant challenges to integration into fieldable quantum communications systems. In order to meet the demands of speed and practicality, we investigate third-order nonlinearity in a semiconductor waveguide as a source of correlated and ultimately entangled photon pairs. This device offers an advantage over existing sources due to the relative ease of coupling to standard optical fibers. It is potentially useful for free-space and fiber-optic quantum key distribution as well as a host of other applications such as correlated photon metrology and two-photon interferometry. We show the feasibility of using phase-matched four-wave mixing in a birefringent AlGaAs waveguide to generate correlated photon pairs at wavelengths compatible with silicon detectors. We demonstrate the operation of such a device, consider the effects of loss and two-photon absorption, and evaluate the implications of birefringent phase matching.

12:03PM B15.00005 Macroscopic quantum memories get entangled from far away1, ZHEN-SHENG YUAN, YU-AO CHEN, SHUAI CHEN, JÖRG SCHMIEDMAYER, JIAN-WEI PAN, PHYSIKALISCHES INSTITUT, RUPEZRECHT-KARLS-UNIVERSITÄT HEIDELBERG, GERMANY TEAM, HEFEI NATIONAL LABORATORY FOR PHYSICAL SCIENCES, ATOMIC INSTITUT DER ÖSTERREICHISCHEN UNIVERSITÄTEN, TU-WIEN, AUSTRIA TEAM — We report an experimental implementation of a fundamental unit for long-distance quantum communication. By means of entanglement swapping, entanglement is generated between two remote atomic ensembles connected with either 6 m or 300 m fiber-based optical channel, where the flying qubits–two emitted photons from the atomic ensembles are sent to an intermediate station for a joint Bell-state measurement. Afterwards, the measurement induced entanglement between the atomic ensembles are verified by the violation of Bell’s inequality or by an entanglement witness. The striking features, phase-error insensitiveness and scalable flexibility, promise the present setup as a fundamental unit for future quantum information processing.

12:15PM B15.00006 Long-distance atom-photon entanglement and its coherence properties. H. WEINFURTER, M. WEBER, J. VOLZ, W. ROSENFELD, M. KRUG, F. HOCKE, F. HENKEL, (1) SEKTION PHYSIK, LUDWIG-MAXIMILIANS-UNIVERSITY, D-80799 MUNICH, GERMANY COLLABORATION, (2) MAX-PLANCK-INSTITUTE FOR QUANTUM OPTICS, D-85748 GARCHING, GERMANY COLLABORATION — The distribution of entanglement between quantum memories at remote locations is one major challenge for the first demonstration of a quantum repeater. Entanglement between matter and light [1] is crucial for achieving this task. Here we report the observation of entanglement between a single trapped atom and a single photon, separated 300 m via an optical fiber. The entanglement is verified by appropriate correlation measurements of the atom-photon pair after communicating the photon through the fiber. In addition, we measure the temporal evolution of the atomic density matrix after projecting the atom-photon pair via a state measurement of the photon onto a well defined atomic spin state. We find that the atomic Zeeman qubit decoheres after 100 µs. Our results represent important steps towards the realization of entanglement between single neutral atoms at distances of several 100 m. [1] J. Volz, M. Weber, D. Schlenk et al., Phys. Rev. Lett. 96, 030404 (2006).

12:17PM B15.00007 Entanglement dynamics in a qubit-nanomechanical resonator system. DIAN WAHYU UTAMI, AASHISH CLERK, Physics Department, McGill University, Montreal — Over the recent years, finding signatures of entanglement in macroscopic systems has been a central goal in many aspects of mesoscopic physics. Here we present our study of non-equilibrium entanglement dynamics between a qubit and a nanomechanical resonator that is coupled to a phonon bath. Unlike previous studies, we specifically look at disspersive coupled qubit-oscillator system which has been realized in many different experiments. Using master equation expressed in gaussian wigner functions, we obtained an elegant and intuitive expression for the entanglement. Two ways of generating entanglement were found; entanglement of the qubit to the amplitude of the driven oscillator and to the phase of the oscillator. A full analytical result within the zero temperature limit of the two cases were derived. We also investigate the effect of finite temperature to the entanglement dynamics and found the phase entanglement to be more robust against temperature. The result indicates that an indirect method to measure the presence of entanglement in the system is possible.

12:19PM B15.00008 Generation of Entanglement Outside of the Light Cone. JAMES FRANSON, University of Maryland, Baltimore County — The probability amplitude to emit a photon at one location and then annihilate it at another location is proportional to the Feynman propagator, which has nonzero values outside of the forward light cone. This does not allow messages to be transmitted faster than light, but it does allow correlations, and mutual information to be generated outside the light cone. These effects are illustrated by considering two distant atoms, one of which is initially in its excited state and the other in its ground state. The probability amplitude for the two atoms to exchange a photon and make a transition to the other state is calculated using perturbation theory and commutator techniques, which gives a result proportional to the Feynman propagator. These effects can be interpreted as being due to the propagation of virtual photons outside of the light cone or as a transfer of pre-existing entanglement from the quantum vacuum.

12:21PM B15.00009 Towards single time-bin entangled photons from a quantum dot. CHRISTOPHE COUTEAU, GREGOR WEIHS, University of Waterloo — We present our results on photon statistics of quantum dots. We show evidence for photon antibunching and cross-correlation measurements within the biexciton-exciton cascade. We also discuss directions towards a demonstration of time-bin entangled photons from a dot. Recently, it has been showed theoretically that a quantum dot could provide pairs of time-bin entangled photons. The temporal entanglement is due to the fact that we know the twin photons will come in pairs but we don’t know when: either both the photons are really or both are late. Under the right conditions and using a double excitation of the dot corresponding to the two time bins, Simon and Poizat showed that one could get deterministic emission of pairs for time-bin entanglement using a single quantum dot. We present our latest results on photon statistics and our demonstration of photon antibunching as well as cross-correlations within the biexciton-exciton cascade using an original new set-up. Based on these measurements we are confident that we will be able to demonstrate time-bin entangled photons in the near future.

1:03PM B15.00010 Teleportation and Broadcasting of continuous variable entanglement. ARCHAN S. MAJUMDAR, SATYABRATA ADHIKARI, N. NAYAK, S. N. Bose National Centre for Basic Sciences — We present the first example for broadcasting of the entanglement of a two-mode squeezed state of the electromagnetic field shared by two distant parties into two nonlocal bipartite entangled states. Using the technique of covariance matrices we demonstrate the entanglement between the nonlocal output modes and the separability of the local output modes. We find the range of values for the squeezing parameter and the amplifier phase for which broadcasting of continuous variable entanglement can be implemented for physical states. We next present a scheme for teleporting two-mode entangled states of continuous variables from Alice to Bob. Our protocol is operationalized through the creation of a four-mode entangled state shared by Alice and Bob using linear amplifiers and beam splitters. Teleportation of the entangled state proceeds with local operations and the classical communication of four bits. We compute the fidelity of teleportation and find that it exhibits a trade-off with the magnitude of entanglement of the resultant teleported state. [arXiv:0708.1869; arXiv:0710.2777]

1:15PM B15.00011 Entanglement structure of two-mode squeezed states in absorbing and amplifying environment. PHOENIX S.Y. POON, C.K. LAW, Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Shatin, Hong Kong SAR, China — We examine the structure of entanglement for two-mode squeezed states interacting with symmetric linear baths [1]. In Fock space, $\rho^{TA}$ is observed to be maintaining a block diagonal form as the system evolves. We explicitly obtain the eigenvalues and eigenvectors of $\rho^{TA}$ (the partial transposition of density matrix $\rho$) as a function of time. The decoherence induced by the baths are shown to destroy the degeneracy of $\rho^{TA}$, leading to a set of eigenvectors for the construction of entanglement witness operators. We prove that the eigenvectors are time-independent, which is an indicator for the robustness of entanglement of two-mode squeezed states in the presence of noise. [1] Phoenix S. Y. Poon and C. K. Law, Phys. Rev. A 76, 012333 (2007).

1:27PM B15.00012 Quantum Second Law with Entanglement1. LADISLAV ANDREY, Academy of Sciences, Prague — It is proved rigorously that every quantum operation generating quantum entanglement states in the multipartite quantum system of qubits leads to the reduction of quantum entropy of whole system. By other words the quantum entanglement can be the source of quantum information. As the consequence the novel formulation of quantum second law is presented with possible applications to progressively developing quantum information science and quantum communications.

1:39PM B15.00013 Entanglement and Standard Thermodynamic Relations. INTI SODEMANN, University of South Carolina, ALONSO BOTERO, Universidad de Los Andes and University of South Carolina — We re-examine thermal properties of the standard (Boltzmann) canonical ensemble from the point of view of canonical typicality. In this approach, the thermodynamic system is described by the reduced density matrix of a correlated state from an energy-constrained total Hilbert space for the system and environment, with the entanglement entropy playing the role of thermodynamic entropy. We examine the average and variance of the entanglement entropy over all pure states of the restricted total Hilbert space, and show correspondence with the expected results of standard statistical mechanics in the limit of a large environment. We study the correlation between energy and entropy fluctuations, and show that the temperature can also be defined from a variational principle minimizing deviations from a microscopic version of the first law of thermodynamics, involving energy and entropy fluctuations.

This work was partly supported by the grant 1ET30010043 of GAAV and AVOZ 10300504.
Quantitative universality and non-local interactions in neural pattern formation. MATTHIAS KASCHUBE, Princeton University, MICHAEL SCHNABEL, MPI-DS, SIEGRID LOEWEL, University of Jena, DAVID COPPOLA, Randolph-Macon College, LEONARD WHITE, Duke University, FRED WOLF, MPI-DS — The occurrence of universal quantitative laws in a strongly interacting multi-component system indicates that its behavior can be elucidated through the identification of general mathematical principles rather than by the detailed characterization of its individual components. Here we demonstrate that universal quantitative laws govern the spatial layout of orientation selective neurons in the visual cortex in three mammalian species separated in evolution by more than 50 million years. Most suggestive of a mathematical structure underlying this universality, the average number of pinwheel centers per orientation hyper-column in all three species is statistically indistinguishable from the constant $\pi$. Mathematical models of neural pattern formation can reproduce all observed universal quantitative laws if non-local interactions are dominant, indicating that non-local interactions are constitutive in visual cortical development. The spatial layout adheres to these laws even if visual cortical organization exhibiting marked overall inhomogeneities and when neuronal response properties are experimentally altered. These results demonstrate that mathematical principles can shape the organization of the brain as powerfully as an organism's genetic make-up.

Spike-timing dependent plasticity in integrate-and-fire networks. CHUNG CHEN, DAVID JASON, University of Pittsburgh — We study plastic integrate-and-fire networks with spike-timing dependent plasticity. Following recent experiments, the long-term potentiation (depression) for causal (anti-causal) spike pairs is assumed to be additive (multiplicative) with reference to the existing synaptic strength. Assuming realistic physiological parameters, for time scales of minutes, the synaptic strength can be assumed fixed while neural activities equilibrate. A mean-field analysis in this regime predicts a first order phase transition for the neural activity. As the constant synaptic strength is increased, the network goes from a quiescent phase with only noise triggered activities, to a phase of persistent activity. The number of synapses per neuron controls the transition point in the synaptic strength. However, the activity level of the network just above the transition point is insensitive to the synapse number and represents a neural firing rate of about 20 to 30 Hz for the set of physiological parameters we considered. Simulations on random networks with fixed connectivities agree well with the mean-field predictions for a per-neuron synapse number of 10 or larger. Applying the plasticity rules and performing simulations covering physical times of days, at fixed depression factor for anti-causal spike pairs, the networks develop a unimodal distribution of synaptic strengths at small potentiation values for causal pairs, while run-away synaptic strengths are observed at large values.

A Maximum Entropy Model Applied to Temporal Correlations in Cortical Networks. WEI CHEN, AONAN TANG, JON HOBBS, JODI L. SMITH, HEMA PATEL, ANITA PRIETO, JOHN BEGGS, Indiana University, DAVID JACKSON, Brown University, DUMITRU PETRUSCA, MATTHEW I. GRIVICH, ALEXANDER SHER, ALAN M. LITKE, University of California, Santa Cruz — Multi-neuron firing states are often observed, yet are predicted to be rare by models that assume independent firing. To predict these states, two groups recently applied a second-order maximum entropy model that used only observed firing rates and pairwise interactions as parameters (Schneidman et al., 2006; Shin et al., 2006). Interestingly, these models predicted 90-99% of network correlations. If generally applicable, this approach could vastly simplify analyses of complex networks. However, this work did not address the temporal evolution of correlated states. We applied the model to multielectrode data from cortical slices and cultures. In 8/13 preparations the observed sequences of correlated states were significantly longer than predicted by concatenating states from the model. We found a significant relationship between strong pairwise temporal correlations and observed sequence length, suggesting that pairwise temporal correlations may allow the model to be extended into the temporal domain.

Effective connectivity in a network of spiking cortical neurons. AONAN TANG, JON HOBBS, WEI CHEN, Indiana University, DUMITRU PETRUSCA, MATTHEW GRIVICH, ALEXANDER SHER, ALAN LITKE, University of California, Santa Cruz, JOHN BEGGS, Indiana University — The average cortical neuron makes and receives about 1,000 synaptic contacts. This anatomical information suggests that local cortical networks are connected in a fairly democratic manner, with all nodes having about the same degree. But the physical connections found in the brain do not necessarily reveal how information flows through the network. We used transfer entropy (Schreiber, 2000) to assess effective connectivity in cortical slice cultures placed on a 512 electrode array system (in collaboration with Alan Litke of UC Santa Cruz). These cultures ($n = 6$) were active for periods exceeding 1 hr, allowing us to collect long data sets for entropy statistics. Data were binned at 1 ms to match the width of a single neural spike. Analysis revealed widespread differences in node degrees, but did not clearly point to a small-world or a scale-free structure.

Inhibition is Needed to Learn Precise Multimodal Integration$^1$. J. LEO VAN HEMMEN, Physik Department, TU Munich — Multimodal neuronal maps, combining input from two or more sensory systems, e.g., vision and audition, play a key role in processing and transforming sensory to motor information. For such maps to be of any use, the input from all participating modalities must be calibrated so that a stimulus at a specific spatial location is represented at an unambiguous position in the multimodal map. Here we discuss a method based on supervised spike-timing-dependent plasticity (STDP) to gauge input from different sensory modalities so as to ensure proper map alignment. We therefore analyze excitation- and inhibition-mediated learning in conjunction with the problem of how perfect a teacher should be. Analytical calculations and numerical simulations show on the one hand that inhibitory teacher input is essential if high-quality multimodal integration must be learnt rapidly. On the other hand, the quality of the resulting map is not limited by the quality of the teacher signal alone but rather by the accuracy of the input from other sensory modalities.

Distinguishing Similar Odor Stimuli in Nonlinear Recurrent Networks. STUART WICK, Northwestern U, MARTIN WIECHERT, RAINER FRIEDRICH, Friedrich Miescher Inst., Basel, HERMANN RIECKE, Northwestern U — The olfactory bulb (OB) is the first processing stage for olfactory information and receives input in the form of activity patterns across an array of discrete input channels (glomeruli). Experiments show that the OB decorrelates similar olfactory inputs: the output patterns are more distinct than the input patterns, which is likely to be important for downstream computations. The high dimensionality of odor space implies a fractured representation of odors on the two-dimensional array of glomeruli. The neural circuits achieving the decorrelation must therefore be non-trivial; their connectivity is, however, poorly known. We investigate what connectivities are optimally suited for this task. For neural networks with linear dynamics the connectivity can be given explicitly. Experiments indicate, however, that the bulbar dynamics are strongly nonlinear and must be minimally modeled by a piece-wise linear rectifier. We investigate the impact of the rectifier on two types of connectivities which are optimal for linear networks, but only one of which accomodates the rectifier. We test the performance of both types of networks by adapting them to an ensemble of odors and assessing their ability to decorrelate these and related odors at the same and other concentrations.
12:27PM B16.00007 A low dimensional description of globally coupled heterogeneous neural networks of excitatory and inhibitory neurons. ROXANA A. STEFANESCU, Florida Atlantic University, VIKTOR K. JIRSA, CNRS and Florida Atlantic University — Neural networks consisting of globally coupled excitatory and inhibitory non-identical neurons may exhibit a complex dynamic behavior including synchronization, multi-clustered solutions in phase space and oscillator death. We investigate the conditions under which these behaviors occur in a multidimensional parametric space defined by the connectivity strengths and dispersion of the neuronal membrane excitability. Using mode decomposition techniques, we further derive analytically a low dimensional description of the neural population dynamics and show that the dynamics of the entire network can be very well reproduced by this reduced system. Examples of networks of FitzHugh-Nagumo and Hindmarsh-Rose neurons are discussed in detail.

12:39PM B16.00008 A Neuron-Based Model of Sleep-Wake Cycles. SVETLANA POSTNOVA, University of Marburg, ACHIM PETERS, University of Luebeck, HANS BRAUN, University of Marburg — In recent years it was discovered that a neuropeptide orexin/hypocretin plays a main role in sleep processes. This peptide is produced by the neurons in the lateral hypothalamus, which project to almost all brain areas. We present a computational model of sleep-wake cycles, which is based on the Hodgkin-Huxley type neurons and considers reciprocal glutameric projections between the lateral hypothalamus and the prefrontal cortex. Orexin is released as a neuromodulator and is required to keep the neurons firing, which corresponds to the wake state. When orexin is depleted the neurons are getting silent as observed in the sleep state. They can be reactivated by the circadian signal from the suprachiasmatic nucleus and/or external stimuli (alarm clock). Orexin projections to the thalamocortical neurons also can account for their transition from tonic firing activity during wakefulness to synchronized burst discharges during sleep.

12:51PM B16.00009 Interdependencies of Neural Impulse Pattern and Synchronization. HANS BRAUN, SVETLANA POSTNOVA, HORST SCHNEIDER, University of Marburg — Neuronal synchronization plays a crucial role in many physiological functions such as information binding and wake-sleep transitions as well as in pathophysiological processes like Parkinson’s disease and epileptic seizures. The occurrence of synchronized activity is often associated with significant alterations of the neuronal impulse pattern, mostly with a transition from tonic firing to burst discharges. We have used Hodgkin-Huxley type simulations to study how alterations of individual neurons’ dynamics influence the synchronization in electrotonically coupled networks. The individual neurons have been tuned from tonic firing to bursting with chaotic dynamics in between. Our results demonstrate that these transitions have significant impact on the neurons’ synchronization. Vice versa, the synchronization state can essentially modify the impulse pattern. The most remarkably effects appear when the individual neurons operate in a periodically tonic firing regime close to the transition to chaos.

1:03PM B16.00010 Mosaics of retinal cells that transmit maximal information. TATYANA SHARPEE. The Salk Institute for Biological Studies — In the nervous system, visual signals are encoded by retinal ganglion cells into sequences of discrete electrical pulses termed spikes. Response properties of different ganglion cell types are encoded visual field and are arranged on approximately hexagonal lattice. Here we consider the optimal arrangement of response regions that would collectively allow for maximal information transmitted about the location of a point light source. We find that maximal information can be transmitted when at most three neighboring regions overlap and the average radius of response field is ~0.67 of the distance between response field centers. This finding was obtained with no adjustable parameters and agrees with experimental measurements of retinal mosaics [1, 2].

1:15PM B16.00011 Phase synchronization analysis of voltage-sensitive dye imaging during drug-induced epileptic seizures. DAISUKE TAKESHITA, VASSILY TSYTSAREV, SONYA BAHAR, Dept. of Physics and Astronomy and Center for Neurodynamics, University of Missouri-St. Louis — Epileptic seizures are generally held to result from excess and synchronized neural activity. However, recent studies have suggested that this is not necessarily the case. We investigate how the spatiotemporal pattern of synchronization changes during drug-induced in vivo neocortical seizures in rats. Epileptic seizures are caused by the potassium channel blocker 4-aminopyridine, which is often used in experiments to induce epileptic seizures. In our experiments, the neocortex is stained with the voltage-sensitive dye RH-1091. The intensity changes in dye fluorescence are measured by a CCD camera and are consistent with the signal from local field potential recording. We apply phase synchronization analysis to the voltage-sensitive dye signals from pairs of pixels in order to investigate the degree to which synchronization occurs, and how spatial patterns of synchrony may change, during the course of the seizure. Our preliminary results show that two distant pixels are well synchronized during a seizure event.

1:27PM B16.00012 Information transfer in ampullary electroreceptors. ALEXANDER NEIMAN, Ohio University, TATIANA ENGEL, Max Planck Institute of Colloids and Interfaces — Many neurons in central nervous system and in sensory periphery are characterized by significant correlations between consequent interspike intervals of their stochastic spontaneous activity. Such non-renewal stochastic dynamics can result from internal properties of a neuron, such as spike-frequency adaptation, as well as from external perturbations or both. We consider one example of such system, peripheral ampullary electroreceptors in paddlefish. Spontaneous dynamics of electroreceptors is characterized by extended serial correlations of interspike intervals resulting from nonlinear interaction of two stochastic oscillators embedded into the system. Using computational modeling and approaches from information theory we show that these correlations significantly improve information transfer of weak external stimuli.

1:39PM B16.00013 Spike-time-variability in stochastic Hodgkin-Huxley type neural models. PETER ROWAT, University of California San Diego — When the classical Hodgkin-Huxley equations are simulated with Na- and K-channel noise and fixed applied current, the distribution of inter-spike intervals is bi-modal: one part is an exponential tail, as often assumed, while the other is a narrow gaussian peak centered at a short ISI value. The gaussian arises from bursts of spikes in the gamma-frequency range, the tail from the inter-burst-intervals, giving overall a very high coefficient of variation: up to 2.5 for 180,000 Na-channels. Since neurons with a bimodal inter-spike interval distribution are common, it may be a useful model for any neuron with class 2 firing. The underlying mechanism is due to a sub-critical Hopf bifurcation together with a switching region in phase-space where a fixed point is very close to a system limit cycle. This mechanism may contribute to highly irregular spike times in cortex. Other mechanisms underlying neural variability will also be presented.
activity with increased/decreased number of spikes per burst. The neural bursts and Ca\(^{2+}\) connection strengths. In the neural networks with "all-with-all" connections and AMPA/GABA synapses an increase in average synaptic strength yielded bursting activity with increased/decreased number of spikes per burst. The neural bursts and Ca\(^{2+}\) transients were synchronous at relatively large connection strengths despite random connection strengths. Simulations of the neural networks with 20 connections per neuron and with only AMPA synapses showed synchronous oscillations, while the neural networks with GABA or hybrid synapses generated propagating waves of membrane potential and Ca\(^{2+}\) transients.

1:27AM B17.00002 Adhesion induces and localizes phase separation in lipid membranes. MARKUS DESERNO, Carnegie Mellon University, VERNITA GORDON, University of Illinois, Urbana-Champaign, CAROLINE ANDREW, University of Edinburgh — We study the evolution of GUVs from spherical to pearl-like and to tube-like shapes, and back again reversibly.

1:39AM B17.00003 Cholesterol Effect on Phase Behavior in Ternary Lipid Membrane—X-ray Diffraction and AFM. JING YUAN, ALEX KISS, YOHANES PRAMUDYA, LAM NGUYEN, LINDA HIRST — There is growing evidence that lipid membranes are not uniform, but contain lipid microdomains or "rafts", which are enriched in cholesterol, saturated long-chained lipids, and particular proteins. The effects of cholesterol on lipid ordering and phase separation in lipid-rafts-contained model membrane systems have been investigated by Synchrotron X-ray Diffraction and Atomic Force Microscope (AFM). We have measured bilayer d-spacings in two ternary lipid mixtures: DOPC/eSM/Cholesterol and DOPC/DPPC/Cholesterol, as cholesterol content is varied. Mixtures containing intermediate amounts of cholesterol exhibited two phases, and for DOPC/eSM/Cholesterol with 10% and 12% cholesterol, three d-spacings were observed, indicating the possible coexistence of three different phases: liquid disordered (ld) phase, liquid ordered (lo) phase, and gel phase. AFM images of supported lipid bilayers on mica substrates contained clearly visible raft-like micro-domains in the similar cholesterol amount range.

11:51AM B17.00004 Thermodynamic properties of planar membranes: applications to stripped phases. FRANCISCO J. SOLIS, Integrated Natural Sciences, Arizona State University, CHLOE FUNKHAUSER, KATSUYO THORNTON, Materials Science and Engineering, University of Michigan — Multicomponent membranes can have shapes that are planar at large length scales while retaining complex morphologies at smaller scales. We explore the properties of these membranes that arise from the planarity condition. We show that planarity requires that the average stress tensor of the membrane be parallel to the planar directions. We apply this description of planar membranes to the case of lipid bilayers.

12:03PM B17.00005 Phospholipid Membranes Restructure Locally Where Nanoparticles Bind, BO WANG, YAN YU, STEPHEN ANTHONY, SUNG CHUL BAE, STEVE GRANICK, University of Illinois — In the field of surface science, it is known that metal and semiconductor surfaces may respond to their environment by restructuring. Similar issues are more significant in nanoscience, since large populations of the atoms/molecules reside on the surfaces. It is natural to inquire whether analogous restructuring might also be characteristic of phospholipid membranes, bearing mind that no bulk exists at all in this case. We show here that the two categories of reconstructions, phase state and local curvature, of unicomponent lipid bilayers can occur through non-specific interactions when charged nanoparticles adsorb. This coupling not only modulates the short-range molecular orientation and packing, but also is believed to be responsible for long-range interaction and transportation on fluctuating membranes.

12:15PM B17.00006 Multiscale Modeling of supported lipid bilayers, ROLAND FALLER, CHENYUE XING, MATTHEW HOOPES, UC Davis — The study of lipid structure and phase behavior at the nano scale length is of importance due to implications in understanding the role of the lipids in biochemical membrane processes. We performed a variety of simulations in homogeneous and heterogeneous membrane systems to elucidate such behaviors. Our simulations demonstrate that various coarse grained simulation models can predict different aspects of lipid phase separation and describe the change of the system under the influence of a support. The simulations are performed using models at different length scales ranging from the atom scale to a scale where lipids are modeled by only three interaction sites. We are able to follow transformations, such as lipid phase transitions. These phase transitions are determined by analyzing parameters like area per lipid head group, the deuterium order parameter and dynamic properties. Additionally, we characterize individual lipid molecules using rotational correlation functions to classify different dynamic populations and we study the stability of artificially designed patterns. We discuss the changes of the system phase behavior as well as differences between the two leaflets as induced by the support.
12:27PM B17.00007 Synergy of Membrane Curvature-Stabilization and Electrostatic Interaction leads to Formation of Block Liposomes by Colossal Charged Lipids, ALEXANDRA ZIDOVSKA, KAI K. EWERT, CYRUS R. SAFINAYA, Materials, Physics, and Molecular, Cellular and Developmental Biology Departments, University of California, Santa Barbara, JOEL QUISPE, BRIDGET CARRAGHER, CLINTON S. POTTER, National Resource for Automated Molecular Microscopy, The Scripps Research Institute, La Jolla — Recently, we have reported block liposomes (BLs), a new vesicle phase formed in mixtures of MVLB2G, DOPC and water (A. Zidovska et al., Submitted, 2007), where MVLB2G is a newly synthesized highly charged (16+) lipid (K. Ewert et al., JACS, 2006) with giant dendrimer-like headgroup. BLs are liposomes consisting of distinctly shaped nanoscale spheres, pears, tubes, or rods connected into blocks. In this work we investigate the contribution of spontaneous curvature and membrane charge density to the formation of BLs. By comparing with a system of matching membrane charge density but zero spontaneous curvature and by screening the charge of MVLB2G but keeping the curvature constant, we were able to identify both, spontaneous curvature and membrane charge, as critical parameters for BLs-formation. The effect of salt and pH on the shape evolution of the BLs was also carefully studied. Funding provided by DOE DE-FG-02-06ER46314, NIH GM-59288, NSF DMR-0503347.

12:39PM B17.00008 Photo-induced Phase Separation Phenomena in Lipid Tubules, LINDA HIRST, JING YUAN, Florida State University — The self-assembly of biological amphiphiles has proved a fascinating topic in recent years, the hollow cylindrical lipid tubule morphology being of particular interest due to its potential relevance to intercellular transporting channels and applicability to controlled-release systems, chemical micro-reactors and nano-conductors. Co-existence of the liquid-ordered and liquid-disordered phases in the lipid bilayer has recently been observed in biologically-relevant three-component giant unilamellar vesicles. We have generated stable, photo-induced micron-scale phase separation in lipid tubules formed from ternary lipid mixtures, inducing a new bilayer disc structure. This investigation not only aids in our understanding of lipid sorting phenomena in cell membranes (suggesting a mechanism for bilayer disc formation in retinal rod-cells), but is also a fascinating route to the generation of new, functional structures. This work is supported by the MARTECH and the Institute of Molecular Biophysics, both at Florida State University.

12:51PM B17.00009 Dynamics of Multi-Component Model Membranes Studied via Light and X-Ray Scattering, KEVIN JOHNSON, MAIKEL RHEINSTÄDTGER, University of Missouri — We study the dynamics of multicomponent biological model membranes (phospholipid, ethanol, cholesterol systems) via X-ray and light scattering to probe the dynamics of such membranes in solid supported and freestanding configurations. Collective molecular motions may play a significant role in different biological functions such as transmembrane transport and pore opening processes. Our main research objective is to quantify collective molecular motions in membranes and establish relationships to key physiological and biological functions of the bilayers. The phase diagram of this system with varying cholesterol and ethanol concentrations at set temperatures is determined using X-ray diffraction techniques and the mesoscopic membrane dynamics is then measured using time correlation light scattering techniques. The results can be compared to molecular dynamics simulations in a coarse grained membrane model. The dynamics shows propagating and relaxing processes, which allow to determine, e.g. the elasticity parameters of the bilayers. By understanding the mesoscopic properties of membranes with selected composition, membranes with specific properties can be designed.

1:03PM B17.00010 The Impact of Collective Molecular Dynamics on Physiological and Biological Functionalities of Artificial and Biological Membranes, MAIKEL RHEINSTÄDTGER, University of Missouri-Columbia — We use neutron, X-ray and light scattering techniques to determine dynamical and structural properties of artificial and biological membranes. The combination of various techniques enlarges the window to length scales from the nearest-neighbor distances of lipid molecules to more than 10^{-6} m, covering time scales from about 0.1 ps to 1 s. The main research objective is to quantify collective molecular fluctuations in these systems and to establish relationships to physiological and biological functions of the bilayers, such as transmembrane transport. The motivation for this project is twofold: 1) By understanding fundamental properties of bilayers at the microscopic and mesoscopic level, we aim to tailor membranes with specific properties such as permeability and elasticity. 2) By relating dynamical fluctuations to physiological and biological functions, we can gain a deeper understanding of the bilayers on a molecular scale that may help optimizing the transmembrane transport of certain drugs. We show how bilayer permeability, elasticity and inter protein excitations can be determined from the experiments. M.C. Rheinstädter et al., Phys. Rev. Lett. 93, 108107 (2004); Phys. Rev. Lett. 97, 048103 (2006); Phys. Rev. E 75, 011907 (2007); J. Vac. Soc. Technol. A 24, 1191 (2006).

1:15PM B17.00011 ABSTRACT WITHDRAWN —

1:27PM B17.00012 Effect of anesthetics on bending elasticity of lipid membranes, ZHENG YI, Indiana University, NAGAO MICHIIHO, NIST/Indiana University, DOBRIN BOSSEV, Indiana University — Change in physical and chemical properties of bio-membranes is of great interest for understanding the mechanism of anesthetic action on membranes. Hypothetically the anesthetic alters the lipid membrane structure (promoting pore formation across membranes or at least switching transmembrane channels) and therefore the biophysical properties of the membrane. We have used neutron spin echo (NSE) spectroscopy to study the effect of anesthetic molecule, lidocaine, on the bending elasticity (BE) of lipid membranes. BE of lipid bilayers made of (1,2-Dimyristoyl-sn-Glycero-3-Phosphocholine) DMPC and 1,2-Dipalmitoyl-sn-Glycero-3-Phosphocholine (DPPC) have been measured at different temperatures and different in the fluid (L_{alpha}) phase. Using Zilman-Granek theory the BE were obtained from the decay of the NSE intermediate scattering function. We have found that in the presence of lidocaine the BE of DMPC and DPPC bilayers increases. The results were correlated with those from differential scanning calorimetry. Increase in the lidocaine concentration leads to decrease in the liquid/crystalline transition temperature.

1:39PM B17.00013 Interactions between non-steroidal anti-inflammatory drugs and lipid membranes, MOHAN BOGGARA, RAMANAN KRISHNAMOORTI, Dept of Chemical and Biomolecular Enng, Univ of Houston — Chronic usage of Non-steroidal anti-inflammatory drugs(NSAIDs) leads to gastrointestinal toxicity and clinical evidences point the cause to direct interactions between NSAIDs and phospholipid membranes. Also, NSAIDs pre-associated with phospholipid vesicles are shown to be safer and therapeutically more effective than unmodified ones. Our initial experiments and simulations on the partitioning of Aspirin and Ibufrofen clearly indicate role played by the drug structure in drug-membrane interactions. Those results motivated systematic molecular dynamics simulations of membranes with NSAIDs of different size, structure and pKa values. Our results suggest high partition coefficients for these NSAIDs in the membrane compared to water and thinning effect on the bilayer. Our small angle neutron scattering and reflectivity studies on DMPC-Ibufrofen systems indicate that the drug affects both ~5 nm thick bilayer and overall ~100 nm diameter vesicle, indicating that NSAIDs affect vesicles on various length scales. We will discuss the structural perturbations to membranes due to NSAIDs at clinically relevant molar ratios and their implications on the use of vesicles as delivery vehicles for NSAIDs.1

1:51PM B17.00014 Calorimetric and Optical Studies of Cholesterol-Rich Filamentous, Helical Ribbon, and Crystal Microstructures, KLaida Kashuri, Germano S. Iannacchione, Worcester Polytechnic Institute (WPI), Yekaterina A. Miroshnikova, Yevgeniya V. Zastavker, Franklin W. Olin College of Engineering, Worcester Polytechnic Institute (WPI) Team, Franklin W. Olin College of Engineering Team — Calorimetry (differential-scanning and modulation) and optical phase contrast microscopy studies have been performed on the filamentous, helical ribbon, and crystal microstructures formed in Chemically Defined Lipid Concentrate (CDLC). CDLC is a quaternary sterol system consisting of a cholesterol, bilayer-forming amphiphiles, micelle-forming amphiphiles, and water. Phase contrast microscopy confirms the presence of the three microstructure types in all samples studied. Sample size and temperature scan rate were varied on samples ranging from 1 to 20 mg and rates from 0:017 to 1 degree C/min, respectively. Thermal profiles are strongly dependent on sample size, scan rate, and thermal history. These scans also reveal numerous “transition” features, likely due to melting of various microstructures in CDLC, that generally shift to higher temperatures with increasing sample size. These results indicate that the filamentous, helical ribbon, and crystal microstructures formed in CDLC may be coexisting in a meta-stable chemical equilibrium with each other and the solvent environment from which they grow.

2:03PM B17.00015 Structural and dynamical properties of water at the bilayer DPPC membrane interface, Jianping Gao, Charles Cleveland, Uzi Landman, School of Physics, Georgia Institute of Technology — The properties of interfacial water near the DPPC lipid bilayer surface are probed by a nano-size quartz tip through large scale atomistic molecular dynamics simulations. The water films confined between the bilayer membrane surface and a crystalline wetting quartz surface are kept in contact with a water reservoir at 293K. The distance between the solid tip and the gel phase membrane is varied between 0.5 to 2 nanometers. Layering of the confined water film is found near the solid tip while the water at the membrane surface remains unlayered. Some water is trapped in the cavities between the head groups of the lipid molecules. The recorded solvation force does not show oscillations due to the rough nature of the membrane surface.

11:15AM B18.00001 High Strain Deformation and Fracture of Self-Assembled Polymer Gels, Kenneth Shull, Northwestern University — Triblock copolymers with poly(methyl methacrylate) (PMMA) endblocks and a poly(n-butyl acrylate) (PNBA) midblock form thermoreversible gels in a variety of alcohols. The mechanical response of the gels is determined by the nature of the PMMA aggregates that are bridged by PNBA midblocks. The close proximity of the ordering temperature to the glass transition of the PMMA aggregates gives rise to a remarkably strong temperature dependence of the relaxation time for the polymer gels. At low temperatures, where the relaxation times are very large, the gels can be deformed to very large strains prior to solid-like fracture. At intermediate temperatures the materials flow, but strain localization leads to a melt fracture phenomenon, and at higher temperatures the materials behave as viscous polymer solutions. We have used these gels as a model material for studying rate effects in the high strain deformation and fracture of soft solids.

11:51AM B18.00002 Reinforcement of Epoxies Using Single Walled Carbon Nanotubes, Ramanan Krishnamoorti, Jitendra Sharma, Tirtha Chatterjee, University of Houston — The reinforcement of bisphenol-A and bisphenol-F epoxies using single walled carbon nanotubes has been approached experimentally by understanding the nature of interactions between the matrices and nanotubes. Unassisted dispersions of single walled carbon nanotubes in epoxies were studied by a combination of radiation scattering (elastic small angle scattering and inelastic scattering), DSC based glass transition determination, melt rheology and solid-state mechanical testing in order to understand and correlate changes in local and global dynamics to the tailoring of composite mechanical properties. Significant changes in the glass transition temperature of the matrix can successfully account for changes in the viscoelastic properties of the epoxy dispersions for concentrations below the percolation threshold, while above the percolation threshold the network superstructure formed by the nanotubes controls the viscoelastic properties.

12:03PM B18.00003 Mechanical and Electrical Properties of Organogels with Multiwall Carbon Nanotubes, Mohammad Moniruzzaman, Karen Winey, University of Pennsylvania — Organogels are fascinating thermally reversible viscoelastic materials that are composed of an organic liquid and low concentrations (typically <2 wt %) of low molecular mass organic gelators. We have fabricated the first organogel/carbon nanotube composites using 12-hydroxystearic acid (HSA) as the gelator molecule and pristine and carboxylated multi-wall carbon nanotubes as the nanofillers and 1,2-dichlorobenzene as the organic solvent. We have achieved significant improvements in the mechanical and electrical properties of organogels by incorporating these carbon nanotubes. For example, the linear viscoelastic regime of the HSA organogel, an indicator of the strength of the gel, extends by a factor of 4 with the incorporation of 0.2 wt% of the carboxylated nanotubes. Also, the carbon nanotubes (specially the pristine tubes) improve the electrical conductivity of the organogels, e.g. six orders of magnitude enhancement in electrical conductivity with 0.2 wt% of pristine tubes. Differential scanning calorimetry experiments indicate that the nanotubes do not affect the thermoreversibility of the organogels.

12:15PM B18.00004 Identification of key deformation mechanisms of polyethylene materials via in-situ x-ray scattering, Theresa Hermel-Davidock, Brian Landes, Mehmet Demirors, The Dow Chemical Company — Changes in the microstructure of ethylene based copolymers can be used to modify and enhance their mechanical performance. In this study, the effects of comonomer content, molecular weight, and molecular weight distribution on the mechanical performance of select polyethylene polymers were examined. Two key performance parameters for commercial polymer materials, especially in the area of blown film applications, are tear resistance and puncture resistance. However, polyethylene films which exhibit very similar morphology often exhibit very different Dart and Elmendorf tear values which cannot be differentiated by standard tensile test methods. Alternative methods to link morphology and mechanical response need to be found. Wide-angle and small-angle x-ray scattering was collected during in-situ tensile testing to understand how compositional and structural differences affect the mechanical response of semicrystalline polyethylene polymers. Microstructural changes observed during the in-situ deformation process are correlated to Elmendorf tear performance for both intrinsic and blown film samples.
12:27PM B18.00005 Brittle-tough transitions during crack growth in toughened adhesives
MICHAEL THOULES, University of Michigan — The use of structural adhesives in automotive applications relies on an effective understanding of their performance under crash conditions. In particular, there is considerable potential for mechanics-based modeling of the interaction between an adhesive layer and the adherends, to replace current empirical approaches to design. Since energy dissipation during a crash, mediated by plastic deformation of the structure, is a primary consideration for automotive applications, traditional approaches of fracture mechanics are not appropriate. Cohesive-zone models that use two fracture parameters - cohesive strength and toughness - have been shown to provide a method for quantitative mechanics analysis. Combined numerical and experimental techniques have been developed to deduce the toughness and strength parameters of adhesive layers, allowing qualitative modeling of the performance of adhesive joints. These techniques have been used to study the failure of joints, formed from a toughened adhesive and sheet metal, over a wide range of loading rates. Two fracture modes are observed: quasi-static crack growth and dynamic crack growth. The quasi-static crack growth is associated with a toughness of the adhesive. Generic, the work done by the applied force on the fracture opening area per unit crack extension length is proportional to the energy dissipated. The results of the experiments indicate that the fracture parameters for quasi-static crack growth in this toughened system are essentially rate independent, and that quasi-static crack growth can occur even at the highest crack velocities. Effects of rate appear to be limited to the ease with which a transition to dynamic fracture could be triggered. This transition appears to be stochastic in nature, and it does not appear to be associated with the attainment of any critical value for crack velocity or loading rate. Fracture mechanics failures do exist in the literature for brittle-ductile transitions in rate-dependent polymers, which rely on rate dependent values of toughness with unstable branches. The present observations do not appear to follow the type of behavior that would be expected from these models, but are consistent with prior observations of fracture instabilities in bulk polymer rubber-toughened epoxies. Some alternative models for the transitions in fracture mode will be discussed.

1:03PM B18.00006 Controlling polymer adhesion with surface wrinkles, EDWIN CHAN, Massachusetts Institute of Technology, ERICA SMITH, Trinity College, RYAN HAYWARD, ALFRED CROSBY, University of Massachusetts Amherst — One of nature’s solutions in controlling adhesion is through the intelligent design of patterned interfaces. For example, the feet of geckos and some insects are decorated with fibrillar structures designed specifically for locomotion, i.e. enhanced control of adhesion and release. Recently, there have been significant efforts in mimicking these materials to develop synthetic analogs to tailor polymer adhesion. However, challenges such as reusability and fabrication scalability limit the successful applications of these materials. In this work, we present an alternative approach to the design of a patterned adhesive that utilizes surface wrinkles to control the adhesion of a polymer (n-butyl acrylate) (PnBA) elastomer. Using a probe-type contact adhesion test, we experimentally show that surface wrinkles enhance adhesion of the PnBA elastomer based on a mechanism termed contact line splitting. We demonstrate that the efficiency of this contact line splitting mechanism is coupled with the wavelength of the wrinkles. Furthermore, the geometry of the surface wrinkles facilitates a repeatable interfacial response necessary to function as a reusable adhesive. Our approach provides a simple and scalable strategy to the design of patterned adhesives that is amenable to a variety of polymeric materials while facilitating enhanced control of interfacial response.

1:15PM B18.00007 Soft-soft nanocomposite adhesives made from colloidal particles, COSTANTINO CRETON, FANNY DEPLACE, ESPCI, MICHAEL RABJOHNS, ANDREW FOSTER, PETER LOVELL, University of Manchester, CHUNGHONG LEI, JOSEPH KEOUIE, University of Sheffield, SERGEY PANYUKOV, P.N. Lebedev Physics Institute, Russian Academy of Sciences, Moscow, Russian Federation, MICHAEL LANG, Leibniz-Institute for Polymer Research, Hohe Str, 6, 01069 Dresden, Germany — We investigate ideal Gaussian networks both analytically and with computer simulations using the Bond Fluctuation model with and without excluded volume interactions. The focus of this study is on fluctuations and the collapse of networks with different connectivity and dimensionality. We show that the size of a perfect square 2D network made from $N^2$ Gaussian chains with $N$ monomers each is $R_g \sim N^{1/2} \log(n)$. Thus fluctuations in two-dimensional networks diverge logarithmically with the size of these films while fluctuations of three-dimensional networks $\sim N^{3/2}$ and do not increase with their size. We study the cross-over between two and three-dimensional networks by following the dependence of junction fluctuations on the thickness of films. The results of model systems are compared with more realistic networks in order to understand the effect of disorder on the properties of the network and fluctuations of network junctions.

1:27PM B18.00008 Dangling chain effect on the modulus of polyurethane networks, BRUNO FAYOLLE, JULIE DIANI, PIERRE GILORMINI, Arts et Métiers ParisTech — While the theory of elasticity has been well verified for the non ideal structures accounting for contribution of entanglements, some effort is needed to investigate the contribution of dangling chains. In order to establish a quantitative contribution of dangling chains, networks with a controlled architecture, i.e. where architecture is determined by synthesis of well-characterized reactants, are required. In this work, polyurethane networks based on (poly(propylether) and poly(tetramethyl adipate) crosslinked by triisocyanate were prepared and studied. Different polyether molar masses are chosen from 430 g/mol up to 4000 g/mol. By varying the stoechiometric ratio $r = [\text{NCO}] / [\text{OH}]$ between 0.4 and 1, dangling chains are introduced, provided that the reaction between NCO groups is negligible. After synthesis, the Young’s modulus (E) of the networks has been measured from tensile tests according to the neo-Hookean law. The molar mass of elastically active network chains (ENAC) is determined from E. Since this molar mass is close to the molar mass of each diol used for synthesis at $r=1$ ("ideal" network), a correction taking into account the number of dangling chains (b) calculated from r is proposed.

1:39PM B18.00009 Morphological Determinants of Yield Stress for Semicrystalline Ethylene / Methacrylic Acid Copolymers, ROBERT SCOGNA, RICHARD REGISTER, Princeton University — Reducing the crystal thickness of ethylene/α-olefin copolymers typically results in a decrease in the measured yield stress. However, statistical incorporation of methacrylic acid, also a noncrystallizable comonomer, actually increases the yield stress at room temperature. The yield stress for ethylene/methacrylic acid (E/MAA) copolymers as a function of temperature and test rate is described using a model which accounts for polyethylene crystal plasticity through thermal nucleation of screw dislocations. The effects of temperature and test rate employed in the morphological model are both effective in increasing the yield stress. The model requires a small number of physically reasonable best-fit parameters. Yield stress master curves can be constructed for any material that obeys the model; such curves have been constructed for a low-density polyethylene and five copolymers of varying MAA content from data taken at various strain rates and temperatures. The master curves clearly show that this unusual behavior of the yield stress is caused by the increase in β relaxation temperature with increasing MAA content, as seen via dynamic mechanical testing.

1:51PM B18.00010 On the statistics of Gaussian two and three-dimensional networks: Fluctuations of junctions and collapse driven by structure, MICHAEL LANG, Leibniz-Institute for Polymer Research, Hohe Str. 6, 01069 Dresden, Germany — We investigate ideal Gaussian networks both analytically and with computer simulations using the Bond Fluctuation model with and without excluded volume interactions. The focus of this study is on fluctuations and the collapse of networks with different connectivity and dimensionality. We show that the size of a perfect square 2D network made from $N^2$ Gaussian chains with $N$ monomers each is $R_g \sim N^{3/2} \log(n)$. Thus fluctuations in two-dimensional networks diverge logarithmically with the size of these films while fluctuations of three-dimensional networks $\sim N^{3/2}$ and do not increase with their size. We study the cross-over between two and three-dimensional networks by following the dependence of junction fluctuations on the thickness of films. The results of model systems are compared with more realistic networks in order to understand the effect of disorder on the properties of the network and fluctuations of network junctions.
may be useful for the nano-scale imaging of the soft material. ×

peaks can reveal the contrasts of the interface structure on Ag/Si(111)7 surfaces. It is shown that the spectral intensity of the Gundlach oscillation peaks can vary with observed locations. The spatial mappings of spectral intensities at of samples: bare multilayers of Si/Mo and epitaxial SrTiO3 chemical species and their magnetic properties. We have applied this method, using both rocking curves and sample scans over a wedge profile, to several types by reflection from a multilayer mirror substrate. Combining experiment with x-ray optical simulations can provide information on depth profiles of different

characteristic of Gundlach oscillation can always appear in the tunneling spectrum. We use STS to study Gundlach oscillation on Ag/Si(111)7 × is a phenomenon of field-emission resonance through standing-wave states in the tip-sample gap. No matter if the sample is the thin film or the bulk, peak

oscillations on Ag/Au(111), Ag/Cu(111) and Co/Cu(111) systems, we demonstrate that the work function difference is not the energy shift of the lowest order manifesting in the tunneling spectrum acquired from a metal surface using scanning tunneling spectroscopy. Previous studies relate the energy shift between tuning by gradually approaching the diffusion temperature of the multilayer, which lead to intermixing. We show that core-level spectroscopy directly reflects model system, we demonstrate that this technique is a sensitive tool to characterize the sharpness of a buried interface. We performed controlled interface propulsion nondestructive technique based on atomic core-level shifts to characterize the interface quality of thin film nanomaterials. Our method uses the changes in the electronic structure of the buried interfaces, which ultimately determines the functionality of the nanosized material.

The results showed that the Van der Waals interactions control the bulk modulus below the glass transition. Above the glass transition the internal energy contribution to the bulk modulus is driven by the Van der Waals interaction but a non negligible entropic contribution appeared which at a first order may be considered as independent on the temperature.

Monday, March 10, 2008 11:15AM - 2:15PM — Morial Convention Center 211

11:15AM B19.00001 Spectromicroscopic characterization of Ag surfaces by energy-filtered LEEM Y. FUJIKAWA, T. SAKURAI, Institute for Materials Research, Tohoku University, R.M. TROMP, IBM Research Division, T.J. Watson Research Center — Low energy electrons have been applied successfully for both structural and spectroscopic studies since the early days of modern surface science. While the reciprocal space analysis has been combined with both microscopic and spectroscopic studies, there is still very limited availability of spectromicroscopic analysis because it is not easy to achieve both high spatial and spectroscopic resolution at low energies. We present spectromicroscopic characterization of Ag islands on Si substrates using a newly developed energy-filtered Low Energy Electron / Photo-Electron Emission Microscope capable of 5D (2D spatial + 2D reciprocal + energy) surface analysis. The electron energy loss signal from Ag surface plasmons (SP) was imaged in real space with a resolution of 35 nm or less, while the SP energy dispersion was obtained from a 6 µm diameter area on Ag(111) within ~1 second. Hel photoemission spectra were obtained from a complex Ag island, selecting Ag(111) and Ag(100) areas with a 0.5 µm aperture during PEEM observation. Full dispersion data covering the full reciprocal-energy space were obtained from both surfaces, reflecting their respective symmetries. The ability to perform detailed spectromicroscopic experiments in a standard lab environment is of key importance for nanoscale analysis of novel structures and materials.

11:27AM B19.00002 Enhanced depth-resolution in multilayer nanostructures from standing-wave excited photomission SVEN DOERING, DELTA, TU Dortmund, Germany, MIHAELA GORGOI, RUSLAN OVSYANNIKOV, BESSY, Berlin, Germany, SEE-HUN YANG, IBM Almaden, USA, MARK HJULIBEN, LBNL, Berkeley, USA, FRANZ SCHEAFFER, BESSY, Berlin, Germany, DANIEL BUERGLER, CLAUS SCHNEIDER, Forschungszentrum Juelich, Germany, CHARLES S. FADLEY, LBNL, Berkeley, USA; University of California, Davis, USA; Forschungszentrum Juelich, Germany, WALTER BRAUN, BESSY, Berlin, Germany, CARSTEN WESTPHAL, DELTA, TU Dortmund, Germany — The depth resolution for studying buried layers and interfaces in multilayers with photoemission can be enhanced by exciting with a standing-wave field created by reflection from a multilayer mirror substrate. Combining theoretical analysis of the tunneling differential cross section and experimental measurements of different chemical species and their magnetic properties. We have applied this method, using both rocking curves and sample scans over a wedge profile, to several types of samples: bare multilayers of Si/Mo and epitaxial SrTiO3/La0.7Sr0.3MnO3, and epitaxial MgO on a Fe of top on Au of GaAs/AIAs multilayer. Both soft x-ray excitation at the TU Dortmund DELTA facility and hard x-ray excitation at BESSY II in Berlin have been utilized, with the hard x-rays for the first time permitting the study of deeper layers and interfaces.

11:39AM B19.00003 Interface characterization using atomic core-level shifts, ERIK HOLMSTROM, Universidad Austral de Chile, WEINE OLOVSSON, Kyoto University, IGOR ABRIKOSOV, Linkping University, ANDRES NIKLASSON, Los Alamos National Laboratory, M. F. KOHL, BESSY, Berlin, Germany, OLIVIA KARIS, SVANTE SVENSSON, Uppsala University, SWANTE SVENSSON, Uppsala University, W. BRAUN, BESSY, Berlin, Germany, G. OHRWALL, G. ANDERSSON, B. JOHANSSON, M. MARCELLINI, Uppsala University, W. EBERHARDT, BESSY, Berlin, Germany — We propose a nondestructive technique based on atomic core-level shifts to characterize the interface quality of thin film nanomaterials. Our method uses the inherent sensitivity of the atomic core-level binding energies to their local surroundings in order to probe the layer-resolved binary alloy composition profiles at deeply embedded interfaces. From an analysis based upon high energy x-ray photoemission spectroscopy and density functional theory of a Ni/Cu fcc (100) model system, we demonstrate that this technique is a powerful way to characterize the sharpness of a buried interface. We performed controlled interface tuning by gradually approaching the diffusion temperature of the multilayer, which lead to intermixing. We show that core-level spectroscopy directly reflects the changes in the electronic structure of the buried interfaces, which ultimately determines the functionality of the nanosized material.

1Support from FONDECYT grant: 11070115.

11:51AM B19.00004 Manifestation of Work Function Difference in High Order Gundlach Oscillation, CHUN-LIANG LIN, SHIN-MING LU, WEI-BIN SU, HWA-TE SHIH, BI-FEN WU, YEONG-DER YAO, CHIA-SENG CHANG, TIEN-TZOU TSONG, Institute of Physics, Academia Sinica, Nankang, Taipei 11529, Taiwan — Gundlach oscillation (or standing-wave state) is a general phenomenon manifesting in the tunneling spectrum acquired from a metal surface using scanning tunneling spectroscopy. Previous studies relate the energy shift between peaks of the lowest-order Gundlach oscillation observed on the thin film and the metal substrate to the difference in their work functions. By observing Gundlach oscillations on Au(111), Ag/Cu(111) and Co/Cu(111) systems, we demonstrate that the work function difference is not the energy shift of the lowest order but the ones of higher order where a constant energy shift exhibits. Higher order Gundlach oscillations can thus be applied to determine the work function of thin metal films precisely.

12:03PM B19.00005 Application of Gundlach Oscillation in Scanning Tunneling Spectroscopy on Nano-Scale Imaging, SHIN-MING LU, Academia Sinica Taiwan — Gundlach oscillation observed with scanning tunneling spectroscopy (STS) is a phenomenon of field-emission resonance through standing-wave states in the tip-sample gap. No matter if the sample is the thin film or the bulk, peak characteristic of Gundlach oscillation can always appear in the tunneling spectrum. We use STS to study Gundlach oscillation on Ag/Si(111)/7×7 and Au(111) surfaces. It is shown that the spectral intensity of the Gundlach oscillation peaks can vary with observed locations. The spatial mappings of spectral intensities at peaks can reveal the contrasts of the interface structure on Ag/Si(111)/7×7 and herringbone reconstruction on Au(111) surfaces. The contrast can be attributed to the local variation of the electron transmision which affects the transmission background superposing with Gundlach oscillation in the tunneling spectrum. In our observation, the spatial resolution of the mapping is 1 nm and can be preserved even the tip is away from the sample by 60 angstrom. Gundlach oscillation may be useful for the nano-scale imaging of the soft material.
**12:15PM B19.00006 Standing Friedel waves**

JUN-QIANG LU, CNMS, Oak Ridge National Laboratory, Oak Ridge, TN 37831, X.-G. ZHANG, CNMS & CSMD, Oak Ridge National Laboratory, Oak Ridge, TN 37831, SOKRATEST. PANTELIDES, Department of Physics and Astronomy, Vanderbilt University, Nashville, TN 37235, and MSTD, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — The electron density around defects in a metal is known to exhibit Friedel oscillations. Here, we report simulations that demonstrate a dynamic analogue of the static Friedel oscillation in nanoscale devices. We use a spot gate capacitively coupled to a nanowire or a two-dimensional electron gas, a setup that can be implemented with a sharp STM tip. The application of an AC voltage generates a dynamic standing Friedel wave (SFW), near the spot gate and edges and boundaries. The SFW wave length is controlled by the AC frequency and the device’s Fermi velocity, whereby the latter can be measured. The SFW amplitude exhibits resonant behavior at AC frequencies that are related to eigenenergy spacings in the device, allowing their direct measurement. Spin-polarized SFW may be generated in a graphene nanoribbon.

**12:27PM B19.00007 Molecular Etching of Pure and Mn Intercalated TiSe₂ using an STM**

TIM KIDD, BRETT GAMBL, POLINA SKIRTACHENKO, LAURA STRAUSS, University of Northern Iowa — STM is normally a non-destructive technique. However, some materials, such as the transition metal dichalcogenides (TMDCs), are so weakly bonded that STM measurements performed in air can change the surface topology. We performed STM measurements on single crystals of TiSe₂ and Mn₀.₀₅TiSe₂ in air. Under normal scanning conditions, the surface of both TiSe₂ and Mn₀.₀₅TiSe₂ would spontaneously etch, removing single and double molecular layers. In pure TiSe₂, step edges were unusually rounded and the etching predominately occurred along the scanning direction. In Mn₀.₀₅TiSe₂, the etching occurred even more readily. However, step edges in these samples were much straighter, reflecting the crystal symmetry. The symmetry was also seen in the etching of these samples, as triangular pits were often formed along with the usual etching along the scanning direction. The differences seen in the etching of Mn₀.₀₅TiSe₂ samples indicate intercalated ions can affect both intra- and inter-layer bond strengths. The etched material disappeared completely from the sample, suggesting that TiSe₂ molecules are energized sufficiently to sublime from the sample. This research indicates that the etching process can be controlled to induce complex nanostructures in the surface of TMDCs.

**12:39PM B19.00008 Effect of Surface Stress on the Stiffness of Cantilever Plates**

JOHN SADER, MICHAEL LACHUT, Department of Mathematics and Statistics, University of Melbourne — Measurements over the past 30 years have indicated that surface stress can significantly affect the stiffness of microcantilever plates. Several one-dimensional models based on beam theory have been proposed to explain this phenomenon, but are found to be in violation of Newton’s third law, in spite of their good agreement with measurements. In this talk, we shall review this work and rigorously examine the effect of surface stress on the stiffness of cantilever plates using a full three-dimensional model. This study establishes the relationship between surface stress and cantilever stiffness, and in so doing elucidates its scaling behavior with cantilever dimensions. Use of short nanoscale cantilevers thus presents the most promising avenue for future investigations.

**12:51PM B19.00009 Direct determination of transient heating in a nanoconfined environment by ultrafast electron diffraction**

RYAN A. MURDICK, RAMANI K. RAMAN, YOSHIE MUROOKA, RICHARD J. WORHATCH, CHONG-YU RUAN, Michigan State University — Temperature is generally ill-defined at the statistical limit, as such on the ultrashort time scale and in mesoscopic systems. Understanding the thermal energy relaxation and transport at such limits is key to nanoelectronics and energy research. We report on the development of local temperature determination on the atomic scale using the technique of ultrafast electron diffraction. Lattice heating characteristics are elucidated by determining the dynamical Debye-Waller factor and local bond stretches, allowing the time scale of electron-phonon coupling and local heating at different length scales to be detailed. We compare these measured temperatures with predictions from two-temperature model (2TM) and determine that strongly coupled ‘hot’ phonons dominate lattice heating at short times (10 ps), and cannot explained by 2TMs. Models beyond the 2TM are developed to explain our data. We also discuss other novel heating scenarios at the statistical limits.

1:03PM B19.00010 Surface Femtochemistry with Hyperthermal Energy Ion Beams**

M.P. RAY, R.E. LAKE, C.E. SOSOLIK, Clemson University — We are investigating the interactions of hyperthermal energy ions with ultrathin film Schottky diode devices. Specifically, we apply a bias voltage across the device in order to alter the charge transfer dynamics between an incident ion and the metal surface of the Schottky diode. This is an extension of previous work where thermal energy atoms were used to excite electrons-hole pairs and ballistically transport electrons through an ultrathin metal film [1]. In our experiment, we modify the surface electron energy distribution by ballistically transporting electrons to the surface of the thin film. This allows us to tailor the energy level crossings between the incident ion and the metal film and to change the neutralization probability of the scattered beam. Varying the bias voltage will open the possibility for tunable chemical reactions. Preliminary results are presented and discussed in the context of basic ion-surface interactions. [1] H. Nienhaus, H.S. Bergh, B. Gergen, A. Majumdar, W.H. Weinburg and W. McFarland, Physical Review Letters 82, 446 (1999).

1:15PM B19.00011 Hyperthermal Energy Ion Scattering as a Time Resolved Probe of Pico- to Femtosecond Surface Excitations**

R.E. LAKE, M.P. RAY, C.E. SOSOLIK, Clemson University — Trajectories of hyperthermal energy alkali ions scattered from single crystal metal surfaces are well described by binary classical collisions with a strong dependence on the atom-surface mass ratio. Such simple events allow hyperthermal ion scattering to be used as a time resolved probe for studying novel surface effects such as femtosecond scale electron transport and ballistic electron excitations. In this talk, three ion scattering cases from the 1-1000 eV energy regime are discussed. K⁺ scattered from Ag(100) is compared to Na⁺ scattered from Cu(100) in terms of interaction potential, image charge effects and neutralization probability. Secondly the heavy atom Cs⁺-Ag(100) system will be presented including a discussion of an anomalous high energy peak possibly attributable to a collective surface response. Finally a method for probing hot electron excitations by an alkali beam scattered from a biased atomically ordered ultrathin film device will be discussed including charge transfer predictions based on rate equations and quantum mechanical I/N and dynamic matrix renormalization group codes.

1:27PM B19.00012 An Investigation of Nitride Formation on InP Surface After Nitrogen Ion implantation**

MOHAMMAD REZA HANTEHZADEH, Azad University — The effect of nitrogen ion implantation and change in physical characteristics of InP [100] surface after nitrogen ion implantation is investigated. The energetic 30 keV nitrogen ions with different doses were implanted into [100] InP surface at about 500-700 k. The formation of different phases of indium nitride and change in surface morphology after the implantation is studied. The annealing effect on change in nitride phase in a nitrogen environment at temperatures above 900 k is observed. The morphology and phases of the surface after ion implantation is characterized using AFM and XRD.
1:39PM B19.00013 Sputter Deposition System for High Throughput Fabrication of Composition Spread Thin Films

JOHN GREGOIRE, FRANK DISALVO, HECTOR ABRUNA, ROBERT BRUCE VAN DOVER, Cornell University — We describe a custom built sputtering system that can deposit composition spreads in an effectively UVH environment but which does not require the high-throughput paradigm to be compromised by a long pumpdown each time a target is changed. The system employs four magnetron sputter guns in a cryoshroud (getter sputtering) which allows elements such as Ti and Zr to be deposited with minimal contamination by oxygen or other reactive background gases. Other features of the deposition system will be presented, most notably the ability to quickly measure deposition profiles from individual deposition sources. We discuss the possibility of calculating codeposited film composition from these profiles, noting that codeposition affords resputtering phenomena which are absent in single-source deposition. To demonstrate the efficacy of this system, we describe our study of combinatorial libraries of electrocatalyst materials for fuel cell applications. This study includes a high-throughput parallel screening of composition spreads using a fluorescence indicator.

1:51PM B19.00014 Discharging Optics in Vacuum

MARK GIRARD, DENNIS UGOLINI, Trinity University — We have studied using UV illumination to remove excess surface charge from fused silica optics. We commissioned and calibrated a commercial Kelvin probe to measure the surface potential of charged optics in vacuum. Using a Xenon light source and a monochromator, we directed UV light at the sample and were able to remove the excess charge. We determined that the discharging rate scaled linearly with the intensity of the light and the charge density on the surface. By varying the wavelength of the light, we saw a peak discharge rate at 215nm in both uncoated and coated optics. The Kelvin probe also allows us to study the sign of the charge carriers and other techniques for charge removal.

2:03PM B19.00015 Ordering process in metallic thin films investigated with angle-resolved photoelectron spectroscopy

DAH-AN LUH, National Central University, CHENG-MAW CHENG, National Synchrotron Radiation Research Center, CHI-TING TSAI, National Central University, KU-DING TSUEI, National Synchrotron Radiation Research Center, JIAN-MING TANG, University of New Hampshire — We report the observation of the ordering process in real time of a Ag thin film on a Au(111) surface by measuring the in-plane dispersion of quantum well states using temperature-dependent angle-resolved photoelectron spectroscopy. Low-temperature deposited Ag films on a Au(111) substrate were annealed to yield atomically flat films, and the in-plane dispersion of quantum well states was measured in real time during annealing. Our results revealed that isolated ordered patches, fully crystallized along the surface normal, are formed as an intermediate step in the process of film crystallization. We observed the transition from localized states in a partially ordered film to free-electron-like states in a fully ordered film. This process may be general in many other systems of metal thin films.

11:15AM B20.00001 Growth instabilities and adsorbed impurities: Nanostructuring of vicinal surfaces controlled by adsorbates

AJMI BHADJ HAMOUDA, T.L. EINSTEIN, U. of Maryland, College Park, P.E. HOGGAN, A. PIMPINELLI, LASMEA, U. Blaise-Pascal, Clermont-2 — A kinetic Monte Carlo study of the meandering instability of a vicinal surface growing by step flow is performed. Impurities are co-deposited during growth, and they are shown to be responsible for quantitative and qualitative modifications of the surface morphology. In particular, impurities make adatom diffusion less dependent on the deposition rate, affecting thus the wavelength of the meandering. Impurities also act as nucleation centres, causing small stepped pyramids to appear on the surface. Comparison with step-flow experiments on vicinal Cu(100) make plausible the hypothesis that many previously unexplained features of the meandering instability in this system are due to impurities. The density of nano-pyramids can be tuned by varying the impurity concentration. Our results show also that the step bunching instability is strongly affected by adsorbed impurities having lower diffusion rate than adatoms. Such impurities slow the adatoms diffusion and weakens the instability, even removing it at large impurities concentration.

11:27AM B20.00002 Effects of deposition angle in metal(100) epitaxial growth

JACQUES G. AMAR, VALERY BOROVIKOV, YUNCIS SHIM, University of Toledo — The effects of oblique incidence on the surface roughness and morphology in Cu/Cu(100) epitaxial growth are investigated via multiscale kinetic Monte Carlo simulations in which the effects of shadowing and short-range (SR) and long-range (LR) attraction during deposition are taken into account via molecular dynamics simulations. Somewhat surprisingly, while the effects of deposition angle are found to depend strongly on deposition angle even for moderate deposition angles. These results resolve a long-standing puzzle regarding the growth behavior of Cu/Cu(100) over this temperature range. We also find that while the effects of shadowing and SR attraction play important roles, for moderate deposition angle the effects of LR attraction are relatively weak. Our results also demonstrate that, in general, the effects of deposition angle must be considered in low-temperature growth even for moderate deposition angles. Results for the surface morphology and roughness at higher temperatures and for very large deposition angles are also presented and compared with experiments.

11:39AM B20.00003 Shape fluctuations of small Pb(111) islands at low temperatures

M. HUPALO, M.C. TRINGIDES, Iowa State University and Ames Laboratory of US-DOE — With STM we have measured shape fluctuations of monolayer Pb(111) islands grown on top of Pb mesas of controllable height to determine their step energy. Islands as small as 10nm in diameter were used to test the limit of the thermodynamic analysis. It found that the mean square deviations of the fluctuations obey a linear relation on RT where R is the island radius and T the temperature in agreement with the standard analysis. The extracted step energy 140eV/atom is in good agreement with the one obtained in the literature on islands of much larger sizes. Fluctuation magnitude of bilayer island grown on top of 5-layer island (which corresponds to a magic 7-layer height) are much lower and the corresponding step free energy is three times higher than for monatomic steps.

11:51AM B20.00004 Connector Model for Many-Body Interactions at Surfaces from First Principles, YOGESH TWIARY, KRISTEN FICHTHORN, The Pennsylvania State University — First-principles calculations based on DFT indicate that pair, trio, four- and five-body atomic interactions are significant in Al clusters on Al(110). These many-body interactions are a signature of “elastic screening” of long-ranged, substrate-mediated, elastic interactions between atoms in dilute adlayers by direct bonding and short-ranged substrate relaxation in dense clusters. As a consequence of this screening, we developed the Connector Model to effectively describe the energies of compact clusters. Adsorbate structures and interactions are described in terms of single-atom, many-body connector units, which link to one another to form the structures that can occur in thin-film and crystal growth. The additive connector energies can be effectively incorporated into a lattice-based Hamiltonian to study thermodynamics and kinetics at surfaces. The Connector Model is considerably more efficient than lattice-gas Hamiltonian approaches, which would require a large number of terms to accurately capture many-body effects. Details of the connector model and its application to predicting the shapes of compact clusters on Al(110) including the chain-to-island transition will be discussed. This model can be extended to other crystalline surfaces.

12:03PM B20.00005 Double-layer island decay on Ag(111): A molecular dynamic simulation, BERK ONAT, Informatics Institute, Istanbul Technical University, Maslak, 34469, Istanbul, Turkey, SONDAN DURUKANOGLU, Department of Physics, Istanbul Technical University, Maslak, 34469, Istanbul, Turkey — We have performed molecular dynamic simulations to investigate double-layer island decays on Ag(111) using the interaction potentials based on the embedded atom method with a specific aim to observe the effect of varying island size and temperature on interlayer mass transport between two layers of the adatom islands. Our preliminary results indicate that decay rates of adatom islands show different characteristics with varying adatom island size. From an analysis of MD simulations, we further examine how the activation barriers for several diffusion processes taking place during adatom island decay change with respect to varying temperature and island size.

This work was partially supported by TUBITAK under Grant No. TBAG-105E067 and TBAG-106T567. B. Onat acknowledges the graduate student fellowships by Advanced Technologies program of Turkish State Planning Organization.

12:15PM B20.00006 Kinetics of Facile Bilayer Island Formation for Ag on NiAl(110), J.W. EVANS, YONG HAN, D.-J. LIU, BARIS UNAL, F. QIN, D. JIN, C.J. JENKS, P.A. THIEL, Iowa State University — STM studies reveal that deposition of Ag on NiAl(110) at 27 K and above leads to bilayer-by-bilayer growth of a nearly-strain-free film with Ag(110) structure [1]. This growth mode is attributed to Quantum Size Effects (QSE) associated with electron confinement in the Ag film. Our focus here is on analysis the initial nucleation and growth of bilayer Ag(n) islands on NiAl(110) which is facile even at 127K despite requiring uphill transport of Ag. DFT analysis for supported Ag films determines adatom adsorption energies (which display QSE), interaction energies, and various relevant diffusion barriers. Kinetic Monte Carlo simulation of an atomistic lattice-gas model incorporating these energies highlights the role of strongly anisotropic interactions in facilitating bilayer island formation.

12:27PM B20.00007 Self-organization and pattern selection under nanosecond pulsed laser-induced melting of ultrathin metal films, RAMKI KALYANARAMAN, CHRISTOPHER FAVAZZA, JUSTIN TRICE, Dept. of Physics, Washington University in St. Louis, RADHAKRISHNA SURESHKUMAR, Energy, Environmental and Chemical Engineering, Washington University in St. Louis — When an ultrathin metal film is rapidly melted by nanosecond (ns) laser pulses, ensuing hydrodynamic instabilities and/or fluid flow due to surface tension gradients lead to self-organizing patterns of ordered nanostructures. The extremely fast heating O(100 K/ns) and resolidification (O(10 K/ns) in such ns melting experiments permits quenching in of the morphology. Thus, multiple pulses of such fast melting/resolidification cycles in the film allow different stages of the patterning process to be identified and studied. We show that pattern formation via a thin film hydrodynamic dewetting instability and thermocapillary flow can compete and the dominating mechanism is one which has shorter time scale. We have explored this behavior for a large variety of metals, including Ti, V, Mn, Fe, Co, Ni, Cu, and Ag. This ns melting approach permits the robust self-organization of a wide variety of nanoscale structures, including nanoholes, nanostars, nanoparticles and nanowires.

12:39PM B20.00008 Quantum engineering of apparent tunneling height in ultra thin Pb films, JUNGDAE KIM, SHENGYONG QIN, CHIH-KANG KEN SHIH, Department of Physics, University of Texas at Austin — The thickness dependence of tunneling decay constant (κ) for ultra thin Pb films is studied with various sample biases by using low temperature STM. It is found that quantum well states (QWS) have a strong influence on the tunneling decay constant κ. While the decay constant versus layer thickness (κ vs. L) clearly shows bilayer oscillations, we found that the apparent contrast in κ vs. L also show strong bias dependence. Depending on the bias voltage, contrast reversal in the apparent oscillation of κ vs. L can be precisely tuned when the tunneling into the sample empty states. This result also shows that κ-oscillation does not necessarily imply the work function oscillation. We further show that in this case, the parallel component of crystal momentum plays a critical role in tunneling process and is largely responsible for the observed phenomena. On the other hand, at negative sample bias, we show that the measured decay constants well reflect the variation of surface work function. In this case, the layer-dependent surface work functions indeed show bi-layer oscillations and the signature of phase slip due to non-perfect phase matching between Fermi wavelength and the vertical lattice constant.

12:51PM B20.00009 Why Is The Size Dependence Of the Scanning Tunneling Microscopy Workfunction Order Of Magnitude Larger Than That Of Photoemission?, WEI-XUE LI, XIN LIU, Dalian Institute Of Chemical Physics, CAS, Dalian, China, S.B. ZHANG, National Renewable Energy Laboratory, Golden, CO, U.S.A. — Quantum size effect (QSE) has been studied extensively, as a primary driving force for nano technology. Recent scanning tunneling microscopy workfunction of ultrathin Pb(111) film found however order of magnitude larger of QSE than that of photoemission. By first-principles calculations, we show that the QSE is not merely a size effect but symmetry driven: being maximal at the Σ point (i.e., the center of the surface Brillouin zone) derived from interlayer coupling of p_x orbital, but could be vanishingly small at other symmetry points from in-plane p_{x,y} orbital. The Σ valley states have the slowest decay. Thus they are the ones being picked up by near-field techniques such as the scanning tunneling spectroscopy. While whole surface Brillouin zone contributes equally to photoemission, and only marginal QSE effect occurs. For this reason, symmetry could be essential for all near-field physics and chemistry.
1:03PM B20.00010 Tuning Surface Energy Landscapes in Metallic Quantum Films using Alkali Adsorbates 1. ALEXANDER KHAJE TO RIAN, SHENGYO QIN, Dept Physics; U. Texas Austin, WENGUANG ZHU, U. Tennesse-Knoxville; Oak Ridge National Laboratory, HOLGER EISELE, TU-Berlin, ZHENYU ZHANG, U. Tennesse-Knoxville; Oak Ridge National Laboratory, CHIH-KANG SHIH, Dept Physics; U. Texas Austin — Quantum confinement shows a strong interplay with growth and kinetics in thin metal systems where the Fermi wavelength has a special relationship to the surface normal lattice constant. In the case of Pb/Si(111) systems, this relationship reveals an interesting thickness-dependent bilayer oscillation in the density of states and surface energy up to a phase. In this paper, we report on a novel effect: tuning of the energy landscape of a flat-top quantum Pb mesa using Cs adsorbates. Using STM/STS, we show that depositing Cs adsorbates on a thin Pb mesa promotes quantum stable Pb islands on preferentially unstable thicknesses. Thickness-dependent nanoisland densities show a strong bilayer oscillation correlating with quantum stability. By modifying the Cs coverage on the mesa surface, we can tune the lateral size distribution of the nanoislands and the overall amplitude of the island density oscillation. Nanoisland formation is linked to a step decoration of Cs adatoms along the step edge of the nanoisland.

1:15PM B20.00011 Super-oscillations in the Interlayer Lattice Relaxation of Quantum Pb Films. 1. YU JIA, Zhengzhou University, China, BIAO WU, Institute of Physics, CAS, China, T.L. EINSTEIN, University of Maryland, H.H. WEITERING, The University of Tennessee & ORNL, ZHENYU ZHANG, ORNL & The University of Tennessee — Using first-principles total energy calculations, we study the interlayer relaxation in lead films and observe oscillations of the interlayer lattice relaxation with layer number (distance from vacuum) and with film thickness. By analyzing the charge distribution along the direction perpendicular to the film, we show that the former oscillations of lattice relaxation are induced by Friedel interlayer relaxation in lead films and observe oscillations of the interlayer lattice relaxation with layer number (distance from vacuum) and with film thickness.

1:27PM B20.00012 Modifying the Adsorption of Molecules at Metal Surfaces by Quantum Confinement of Electrons, LEVAN TSKIPURI, ROBERT BARTYNSKI, Rutgers University — We have studied the bonding of CO on several ultrathin Cu and Co films that exhibit metallic quantum well (MQW) states, whose energies change as a function of overlayer thickness, using inverse photoemission (IPE), reflection-absorption infrared spectroscopy (RAIRS) and temperature programmed desorption (TPD). For Co system, which has unoccupied MQW states that do not cross the Fermi level, a CO 2r-induced feature is observed in IPE at 3.8 eV above E_F. CO desorbs at 375 K (30 K lower than for hcp Co surfaces) and a second TPD feature at 230 K appears upon low temperature (∼100K) dosing. These TPD peak temperatures change as a function of film thickness and are correlated with two different C-O stretch vibrational frequencies observed in the IR spectra. The intensity of the C-O stretch feature in IRAS spectra, and the peak CO desorption temperature in TPD from CO on Cu MQWs both show modulations that are correlated with MQW states crossing the EF. We have also studied the influence of MQW states on the adsorption properties of the dimethyl disulfide (thiol) molecule (CH_3S_2), which forms a self-assembled monolayer when adsorbed on the Cu(100) surface.

1:39PM B20.00013 Crystal structure and height selection for Indium growth on Si(111) interfaces 1. J. CHEN, M. HUPALO, M. JI, C.Z. WANG, K.M. HO, M.C. TRINGIDES, Iowa State University and Ames Laboratory of US-DOE — The growth of In/Si(111) has been studied with SPA-LEED and STM to identify whether QSE-driven height selection with mono-disperse distribution is possible. The motivation is to discover other metals besides Pb/Si(111) with high degree of self-organization. Indium growth only on one substrate (Si(111)- Pb-α < 3x√3/3) has resulted in uniform height In(111) 4-layer flat top islands (with the fcc(111) orientation different from the bct In bulk structure). This allotropic transition is observed at low temperatures T<250K and coverages θ<0.1ML. Otherwise bct(110) oriented In islands are observed with continuously increasing height/size aspect ratios. These results suggest two stabilizing energetic effects for the fcc In(111) height selection i.e. Quantum Size Effects (QSE) stabilize uniform height and orientation dependent surface energy favours the different crystallography. The contribution of each effect was studied with first principles calculations and both the height selection and the allotropic transition can be quantitatively explained. -/a

1:51PM B20.00014 Non-classical scaling in the Pb/Si(111) coarsening at low temperature 1. MYRON HUPALO, Iowa State University Ames Lab-USDOE, R. FENG, E.H. CONRAD, C.A. JEFFREY, P. F. MICIELI, S. HAYDEN, M. GRAMLICH, P. J. RYAN, C. KIM, MUCAT, Advanced Photon Source, Argonne National Laboratory, M.C. TRINGIDES, Iowa State University Ames Lab-USDOE — Recent coarsening experiments monitoring the evolution of a mixture of stable and unstable islands in Pb/Si(111) towards a mono-disperse T-layer height distribution have revealed novel features that extend the classical curvature driven growth. Two complementary techniques are used, X-ray scattering and STM. In particular the coverage θ, temperature T and flux F dependence are the opposite of what is expected from the classical analysis. The coarsening time τ increases with increasing temperature T, coverage θ and decreases with increasing flux rate F according to the scaling relation τ F^c. These paradoxical results can be understood from the island stability dependence on lateral size L in addition to the QSE-driven well-analyzed height dependence. The decay constant of an unstable island is an increasing function of its lateral size and for sizes larger than L≃50nm the unstable states do not decay but grow in the next stable height. Since the lateral size increases with T, θ and decreases with F this can account for the novel coarsening results.

2:03PM B20.00015 Surface, quantum well, and bulk states in Ag films, NATHAN SPEER, UIUC, CHING WEI, Academia Sinica, TOM MILLER, TAI CHIANG, UIUC — Atomically uniform Ag films grown on Si(111) substrates show, in addition to the usual Shockley Surface state, multiple surface states in pockets within the d-band manifold as observed by angle-resolved photoemission spectroscopy. At low coverages, quantum well states are resolved. As the film thickness increases, quantum well states evolve into the bulk band continuum plus separate surface states. The results are compared to a density functional theory calculation.

Session B21 DCP: Focus Session: Clusters, Cluster Assemblies, Nanoscale Materials I
Morial Convention Center 213
We have also shown that all transition metals including the f-block elements can be doped inside Sn cages, confirming their structural robustness, as well as demonstrating chemical tuning of their electronic, magnetic, and catalytic properties.

$n = 16-18$ possess unprecedented hollow cage structures. We have been able to successfully dope a variety of transition-metal atoms into the empty spaces.

-PES with theoretical calculations has become an effective approach to obtain structural information for small and medium-sized clusters. We present a synergistic effort combining PES with theoretical calculations to examine the geometries, stability, vibrational frequencies and optical properties of Si clusters. It is proposed that the oxygen enrichment needed to form silicates in interstellar space, starting from SiO molecules can occur via two processes: (1) Chemically driven compositional separation in [SiO] motifs resulting in oxygen rich and oxygen poor regions, and (2) reaction between SiO$_m$ clusters leading to oxygen richer and poorer fragments. Theoretically calculated optical and infrared spectra of SiO$_m$ clusters exhibit features observed in the extended red emissions and blue luminescence from interstellar medium indicating that the SiO$_m$ fragments could be contributing to these spectra.

Supported by the National Science Foundation.

Recent ab initio studies have predicted large electric dipole moments in neutral Na clusters. We performed an electric deflection experiment on these clusters at 20 K and have found upper bounds on their dipole moments that are orders of magnitude smaller than predicted, and consistent with zero.

Supported by the National Science Foundation.

Theoretical studies on the geometry, electronic structure and spin multiplicity of Sc, Ti and V doped Na$_n$ clusters have been carried out within a gradient corrected density functional approach. Two complementary approaches including all-electron calculations on free clusters, and supercell calculations using planewave pseudopotential and projector augmented wave formalisms have been carried out. It is shown that spin magnetic moments of the transition metal atoms, the magnitude of host polarization, and the sign of the host polarization all change with the number of alkali atoms. In particular the transition metal atoms are shown to attain spin moments that are higher than their atomic values. The role of hybridization between the transition atom d-states and the alkali sp-states is highlighted to account for the evolutions in the spin moments and host polarization.

Cooperative effect between electronic and geometric structures in binary clusters of superatoms, ATSUHIKO NAKAJIMA, Keio University & JST-CREST — The fabrication of cluster-assembled materials is dependent upon finding a suitable building block for a cluster that is chemically stable and that interacts weakly with other clusters of the same material. For designing the characteristics of clusters, binary systems are very important to create functionality of materials, and application of hetero-atom encapsulated clusters were examined experimentally. For aluminum-based binary superatoms of Al12X, both experimental and theoretical results show that Al12Si has high ionization energy and low electron affinity, and Al12P has low ionization energy, both with the icosahedral structure having a central Si or P atom, revealing that Al12Si and Al12P exhibit rare-gas-like and alkalai superatoms, respectively. Experiments confirmed the possibility that the change in the total number of valence electrons on substraction could produce ionically bound binary superatom complexes; the binary cluster salts (Al12P)· F− and (Al12B)· CS−. For silicon-based binary superatoms of MnOSi6, on the other hand, results obtained by mass spectrometry, anion photoelectron spectroscopy, and adsorption reactivity towards H2O show that the neutral cluster doped with a group-4 atom exhibits a nuclear and an electronic geometric closing at n=6. The MnSi6 cluster with a group-4 atom undergoes an electronic change in (i) the number of valence electrons when the metal atom is substituted by the neighboring metals with a group-3 or -5 atom, and in (ii) atomic radii with the substitution of the same group element of Zr and Hf. The reactivity of a halogen atom with the MnSi6 clusters reveals that VSi12F forms a superatom complex with ionic bonding.

Stability and Magnetic Coupling between Mn doped Stannaspherenes, ANIL KANDALAM, GANG CHEN, PURU JENA, Virginia Commonwealth University — The discovery of carbon fullerenes has stimulated considerable interest in the search of cage clusters involving not only group IV elements but also metallic systems. The recent discovery of stannasphene, a highly stable Sn12 0 hollow cage cluster with a reported diameter of 6.1 Å has triggered a renewed interest in the search for stable endohedral cage complexes with 3d transition metal atomic dopants. It is anticipated that these complexes may carry large magnetic moments and can be used as building blocks for novel magnetic materials. We report the first density functional theory based study of the interaction between two Mn doped stannaspherenes (Mn@Sn12) and show that Mn@Sn12 is not only highly stable and carry a magnetic moment of 5µB, but the clusters retain their structural identity even when they interact with each other. Equally important, the magnetic coupling depends strongly on the orientation of the clusters. We believe that these new results would encourage the scientific community to explore the possibility of synthesizing novel magnetic materials with magnetic element doped Sn12 clusters as building blocks.

11:15AM B22.00001 In-crystal carriers in organic single crystal transistors, JUN TAKEYA, Y. TOMINARI, M. YAMAGISHI, Y. IWASAKI, Osaka University, OSAKA UNIVERSITY TEAM — The intrinsic semiconductor character of organic semiconductors, consisting of one molecular species, causes peculiar features different from those of doped inorganic semiconductors, when they are built in field-effect transistors (FETs). The effect can be most drastic with purified organic single crystal devices because of their minimized impurity (defect) concentrations of ~ 10^14 cm^-3, resulting in relatively long length scale (more than 1 µm) of band bending and carrier distribution in the direction of the crystalline thickness. In this presentation, we report effects of the in-crystal carriers in two FET structures of clean rubrene single-crystals with the thickness comparable to the length scale of the distribution. With a double-gate device incorporating two transistor structures on the both sides of the crystal, we found that each transistor cross-talks with each other, inducing high-mobility (higher than 30 cm^2/Vs) carriers inside the crystal. The similar cross-talking events are observed also for a device with an acceptor layer of F3-TCNQ on one side of the rubrene crystal.

11:27AM B22.00002 Defect healing at room temperature in pentacene thin films and improved transistor performance, WOLFGANG KALB, FABIAN MEIER, KURT MATTENBERGER, BERTRAM BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — We observed a healing of defects at room temperature in the prototypical organic semiconductor pentacene. Pentacene thin-film transistors were fabricated and characterized by in situ gated four-terminal measurements. Under high vacuum conditions (base pressure of order 10^-10 mbar), the device performance is found to improve with time. The effective field-effect mobility increases by as much as a factor of two and the contact resistance decreases by more than an order of magnitude. Oxygen/nitrogen exposure and annealing experiments show the improvement of the electronic parameters to be due to a reduction in the density of shallow traps, while the energetic deeper traps are essentially unaffected. This peculiar effect is a direct consequence of the weak intermolecular interaction which is characteristic of organic semiconductors.

11:39AM B22.00003 Impurities and carrier trap formation in rubrene, LEONIDAS TSETSERIS, Aristotle University of Thessaloniki, Greece, and Vanderbilt University, SOKRATES PANTELIDES, Vanderbilt University and Oak Ridge National Laboratory — Rubrene has emerged recently as a very promising system for applications in organic electronics. In particular, measured carrier mobilities of rubrene films have been among the highest values reported for organic semiconductors. Here we present the results of first-principles calculations on impurities in rubrene crystals. We find that the most stable atomic H defect induces deep traps in the energy band gap of this prototype organic semiconductor, but we further show that the formation of a stable pair of vicinal H impurities eliminates these traps. We thus establish a dual role of hydrogen in carrier trap formation in rubrene devices. We also find that the incorporation of oxygen and water-related impurities is energetically favorable, and we address their possible role in the appearance of energy levels in the band gap of rubrene. Finally, we discuss the relevance of our findings for the development and operation of rubrene-based devices. This work was supported in part by DOE Grant DEFG0203ER46096.
11:51AM B22.00004 Organic Field Effect Transistors Based on Micro and Nano-sized Single Crystalline Semiconductors. ZHENAN BAO — Organic single crystals are of interest for fundamental charge transport studies. Recently, we have shown that organic semiconductor single crystals can be patterned over a large area using vapor phase growth method. This opens up new possibilities of using organic single crystals for high performance devices. In this talk, I will present our recent work in solution deposition of single crystals by various methods and their device performance.

12:27PM B22.00005 Field-effect modulated Seebeck coefficient in pentacene and rubrene. K.P. PERNSTICH, B. ROESSNER, B. BATLOGG, Laboratory for Solid State Physics, ETH Zurich, 8093 Zurich, Switzerland — We report on the first study of the charge carrier concentration and the temperature dependence of the Seebeck coefficient $S$ for two prototypical organic semiconductors measured in a field-effect transistor (FET) structure. As a basic transport property of solids, the Seebeck coefficient provides deep insights into the nature and dynamics of charge carriers. Using a FET structure enables the variation of the Fermi-level position in the active semiconductor region while measuring $S$, which is essential for determining individual contributions to the thermopower. The sign of the measured Seebeck coefficient is consistent with hole transport, and $S$ is in the range of 0.3-1 mV/K, it is independent of temperature between 295 K and 200 K, and interestingly it decreases for both semiconductors as $S \propto |V_a|$. The measured $S$ is quantitatively described by $S = (k/e)(E(V_a)/kT + A)$. The Fermi-level position $E(V_a)$ is obtained from analyzing the transistor's characteristic which then allows to calculate the parameter $A$. For both semiconductors we find that $A$ is in the range of 1.7-3.6, just as in conventional semiconductors. The results are well described by solely considering a realistic density of in-gap trap states and band-like transport of quasiparticles that are subjected to scattering. There is no need to invoke self-trapping of massive charge carriers.

12:39PM B22.00006 Contact-correlated bias stress instability in pentacene thin film transistors. K. TSUKAGOSHI, S.D. WANG, T. MINARI, T. MIYADERA, Y. AYOAGI, RIKEN, Saitama 351-0198 and CREST-JST, Saitama 332-0012. Japan — The bias stress effect and large contact resistance are the remaining problems for practical applications of organic thin film transistors (OTFTs). The bias stress effect in top-contact pentacene TFTs was observed to be correlated with the metal/organic contact. The drain current decay under the bias stress condition results from the combination of the contact resistance change and the channel resistance change arising from the threshold voltage shift in the channel. The transistors with the different contacts (gold and copper) show the very similar channel properties. On the other hand, the bias-stress-induced contact resistance change in the gold transistor is much larger than the corresponding channel resistance change, so that the bias stress effect can be even dominated by the gold contact. In contrast, the copper contact is more stable, showing the small contact resistance change. The temperature variance measurements on contact resistance indicate that, the gold contact has a wider trap distribution compared with the copper contact, that is, there are much more deep trap states at the gold contact. Therefore, the time-dependent charge trapping in the deep traps is proposed to be the mechanism of the bias stress effect in OTFTs.

12:51PM B22.00007 Negative Magnetoresistnace of Organic Field Effect Transistors. MASAYA NISHIOKA, YEONBAAE LEE, ALLEN GOLDMAN, School of Physics and Astronomy, University of Minnesota, YU XIA, DANIEL FRISBIE, Department of Chemical Engineering and Materials Science, University of Minnesota — The magnetoresistance (MR) of organic field effect transistors has been studied. Both pentacene films and tetracene single crystal and rubrene single crystal devices exhibit negative MRs of up to 1.2 % at 9 T. This has been demonstrated to not be contact related. The effect has been found to increase with decreasing temperature between 150 and 300 K. On the other hand, this effect is not strongly affected by the magnetic field direction. The phenomenon may result from the action of the magnetic field on the hopping transport of carriers. However, the possibility of a magnetocapacitance effect that would increase the number of carriers cannot be ruled out.

1:03PM B22.00008 Pentacene Thin-Film Transistors With Organophosphonate Self-Assembled Monolayer Modified Gate Dielectrics. IAN HILL, MATTHEW MCDOWELL, Dalhousie University, JOSEPH MCDERMOTT, JEFFREY SCHWARTZ, STEVEN BERNASEK, JAEHYUNG HWANG, ANTOINE KAHN, Princeton University — Organophosphonate-based self-assembled monolayers synthesized from aliphatic, aromatic, and heterocyclic moieties were used to modify silicon dioxide gate dielectric in pentacene organic thin-film transistors. Striking improvements in the subthreshold performance of these devices is noted, with a dependence on the molecular species used in fabricating the monolayer. All modified gate dielectrics outperform the untreated surface. As determined by parameters such as the subthreshold slope, threshold voltage magnitude and uniformity, and the on/off ratio, the aromatic species outperform the heterocyclic species, which outperform the aliphatic species. Origins of the improvement, based on energetic alignment of the molecular levels of the SAM and the pentacene, and charge trap densities will be discussed.

1:15PM B22.00009 Percolative Effects on Noise in Pentacene Transistors. BRAD CONRAD, WILLIAM CULLEN, WINSTON YAN, ELLEN WILLIAMS, University of Maryland - College Park — Noise in pentacene thin film transistors has been measured as a function of device thickness from well above the effective conduction channel thickness to only two conducting layers. Over the entire thickness range, the spectral noise level is 1/f, and the noise parameter varies inversely with gate voltage, confirming that the noise is due to mobility fluctuations, even in the thinnest films. Hooge's parameter varies as an inverse power-law with conductivity for all film thicknesses. The magnitude and transport characteristics of the spectral noise are well explained in terms of percolative effects arising from the grain boundary structure. http://arxiv.org/abs/0710.2700v2

1:27PM B22.00010 Surface-Treatment Effects on the Pentacene-Based Organic Field-Effect Transistors with Anodized Gate Dielectrics. YEON TAEK JEONG, CHRISTOPHER LOMBARDO, DAVIANNE DUARTE, ANANTH DODABALAPUR, The University of Texas at Austin — The realization of low operating voltage organic field-effect transistors (OFETs) is technologically important with many methods having been proposed to achieve this goal. The use of anodized high-k dielectrics is very promising in that the approach is applicable to obtaining gate dielectrics at low temperature. We report on the device characteristics and proper surface-treatment effects on low voltage OFETs with anodized Ta2O5 and SiO2 gate dielectrics. Pentacene-based OFETs with anodized Ta2O5 gate dielectric obtained from an e-beam-evaporated and a sputtered Ta thin film exhibited the saturation mobility of 0.52 cm2/Vs and 0.45 cm2/Vs at Vds = -10V, respectively. Moreover, a hexamethyldisilazane (HMDS) and a mono-dodecyl phosphate surface treatment resulted in enhanced mobility and significantly reduced gate leakage current. In the case of anodized SiO2 devices, an octadecyltrichlorosilane (OTS) treatment increased the saturation mobility from 0.38 cm2/Vs to 0.88 cm2/Vs at Vds = -10V. The OTS treatment also proved to reduce gate leakage current by more than 90%. In related work, we will discuss the fabrication of all-organic dual-channel devices. These devices are promising because of their probable applications to organic sensing and CMOS transmission gates.

3This work was supported by NIST under contract #70NANB6H6138, by the LPS, and by the UMD NSF-MRSEC under grant DMR 05-20471. We are grateful to M. Ishigami and D. Dougherty for setting up the noise measurements and for extremely insightful discussions.
1:39PM B22.00011 Drift mobility and frequency response of diode connected organic field effect transistors, BRIAN COBB, ANANTH DODABALAPUR, University of Texas at Austin — Common methods of estimating the mobility of carriers in organic field effect transistors (OFETs) include extraction from output or transfer characteristics. Mobilities extracted from transfer curves are realistic only in certain steady-state regimes. Optical time-of-flight methods measure charge mobility in directions perpendicular to the semiconductor-dielectric interface, perpendicular to the direction of transport in a functioning OFET. We have developed a method that allows the extraction of the drift mobility of charges through an active channel in an OFET by measuring the frequency response of a diode connected device. An AC signal of varying frequency was applied to both the Gate and Drain nodes, while the rectified output voltage was measured at the Source node using an oscilloscope. This rectified voltage remains relatively steady at lower frequencies, then displays a marked fall. This pole was found to correspond to the transit time of the carriers through the channel. The fabrication of the OFETs, calculation of drift mobility from the frequency of the pole, and the effects of varying channel length will be reported.

1:51PM B22.00012 Field-induced polymorphous disorder and bias-stress instability of pentacene organic thin-film transistors, MASAHIKO ANDO, Hitachi Cambridge Laboratory, CLAUDIA DUFFY, JESSICA WINFIELD, Cavendish Laboratory, TAKASHI MINAKATA, Asahi Kasei R&D Center, HENNING SIRRINGHAUS, Cavendish Laboratory — We propose a field-induced polymorphous disorder model to explain bias-stress instability in organic pentacene-thin film transistors Field-effect mobility at 0.7 cm²/Vs and threshold voltage, Vth, at 0 V were obtained by using highly crystalline zone-cast pentacene semiconductor on benzyoclobutene insulator. Vth shifted up to +25V with positive gate bias-stress at +40 V for 15 hours and recovered after gate bias removal. Vth recovery was drastically accelerated by direct photo-excitation of pentacene and it indicated electrons were trapped in pentacene and not in BCB. After annealing at 130 °C in N₂, the initial electrical performance were recovered. Micro-Raman spectroscopy of pentacene at the channel revealed that shape of the C-H vibrational peaks at around 1160 cm⁻¹ changed reversibly in accordance with the positive shift and recovery of Vth. Our pentacene films with average d-spacing at 14.3 A were considered to be composed of a mixture (mosaic) of two kind of polymorphs with d-spacing at 14.1 A and 14.5 A. The polymorphous mixture should be disordered by electric field to create electron traps and induce Vth shift.

2:03PM B22.00013 Prediction of the absolute charge mobility of molecular crystals, ALESSANDRO TROISI, University of Warwick — I propose a computational protocol to predict the absolute mobility of molecular semiconductors without adjustable parameters. The system dependent parameters are computed using a combination of classical molecular dynamics simulations and quantum chemical methods. The model used to connect these intractable quantities are the observable temperature dependent mobilities. The model is validated by the accurate prediction of the temperature dependence of the inorganic molecular mobility, and the fluctuation of the transfer integral due to thermal motions. The absolute value of the hole mobility, computed for the case of rubrene, is in excellent agreement with the experiments. The possibility of using computational chemistry methods to improve the theoretical models of charge transfer will be discussed in some detail. The predictive capabilities of the model presented in this work will be further validated considering the recent THz spectroscopy measurements performed by R. van Laarhoven in Eindhoven and the results in literature on temperature dependent band structure and density of state tails.

11:15AM B23.00001 Direct Electron Spectroscopy Investigation of the Spin State of LaCoO₃, J. STANLEY, J. HINTON, N. SUNDARAM, University of California, Santa Cruz, B. S. MUN, A. BOSTWICK, E. ROTENBERG, Lawrence Berkeley National Laboratory, D. P. BELANGER, G.-H. GWEON, University of California, Santa Cruz — The spin state of LaCoO₃ and related properties have been a topic of high interest lately. Here we investigate the electronic structure of LaCoO₃ using core level and valence band photo-electron spectroscopy. We compare the competing spin models in the literature by using our data obtained as a function of incident photon energy and temperature. We are able to make an interesting contribution to the discussion of the spin state of this material.

11:27AM B23.00002 Field Effect on Spin Correlations in La₁₋ₓSrₓCoO₃, DANIEL PHELAN, National Institute of Standards and Technology, DESPINA LOUCA, SEUNGHUN LEE, University of Virginia, STINE ANCONA, STEPHAN ROSENKRANZ, JOHN MITCHELL, Argonne National Laboratory — La₁₋ₓSrₓCoO₃ evolves from a non-magnetic, insulating ground state in the parent compound (x=0) into a metallic, ferromagnetic cluster-glass (x=0.18). For intermediate concentrations, the ground state is characterized by a competition between ferromagnetic and incommensurate spin correlations, which leads to short-range clustering. The field effect on these competing spin correlations has been investigated by neutron diffraction from a single crystal of La₈₅Sr₁₅CoO₃ under an externally applied vertical magnetic field ranging from 0 to 7 T. The intensity of the incommensurate reflections is significantly reduced under 7 T. On the other hand, the ferromagnetic signal is enhanced by more than an order of magnitude under 7 T, while simultaneously narrowing in reciprocal space, implying an increase in the correlation length, which cannot be understood simply by a reorientation of ferromagnetic clusters along the direction of the applied field. Instead, the data is interpreted in a phase-separated scenario in which the applied field polarizes regions which are initially not ferromagnetic in zero field.

11:39AM B23.00003 Ionic Size Effects and Magnetic Incommensurability in Cobaltite, JUAN YU, DESPINA LOUCA, Physics Department, UVA, DANIEL PHELAN, NIST, K. YAMADA, Institute of Materials Research, Tohoku University — LaCoO₃ in which Co⁺⁺ has nearly degenerate spin states shows unusual magnetic behavior attributed to the fact that the different states can co-exist. The cobalt ions interact with each other via complex magnetic coupling, that is further complicated by the addition of Co⁴⁺ ions with hole doping. In the case of hole doped La₁₋₋ₓSrₓCoO₃ (LSCO), we found that the system exhibits a rich phase diagram, dominated by two competing magnetic phases, one that is ferromagnetic and metallic and another that is metallic and incommensurate. Our recent elastic neutron scattering measurements on single crystals of La₁₋₋ₓSrₓBa₂CoO₇ (LBCO) with x = 0.03, 0.06, 0.10 and 0.15) also identified the coexistence of these two phases. Compared to LSCO, the LBCO series shows different incommensurability, but has a similar trend in the progression of intensity with increasing x. However, the LBCO series shows a much longer correlation length particularly in the direction perpendicular to (111), and a significantly stronger incommensurate peak than in LSCO. The incommensurate and ferromagnetic-like intensities exhibit identical temperature dependence in LBCO unlike in LSCO, in which ferromagnetic scattering had a higher onset temperature than the incommensurate phase at identical compositions.

11:51AM B23.00004 Electronic structure of La₁₋₋ₓSrₓCoO₃ investigated from doping evolution of its soft x-ray spectra, YINWAN LI, DAVID EDERER, Tulane University, THOMAS CALLCOTT, University of Tennessee, J. W. FREELAND, Argonne National Laboratory — Pentacite cobalt oxide LaCoO₃ attracted a lot of attention because of its spin state transition around 90K, the interpretation of which is still under debate. We performed soft X-ray absorption and emission experiments on La₁₋₋ₓSrₓCoO₃ at O K-edge and Co L-edge with various doping from x = 0 to x = 30. The doping evolution of the spectra can be understood as a result of introduction of holes at the top of valence band accompanied with a lowering of the Fermi level. The significant change of oxygen K edge spectra with doping indicates that the top of the valence band is largely of oxygen character, indicating strong Co 3d – O 2p hybridization. The bottom of unoccupied band has a double peak feature indicating a splitting e_g band. This split is the largest in the undoped sample and becomes smaller with doping. A gap of less than 1eV is observed from the excitation feature in the emission spectra and its change with doping again indicates a lower Fermi level in doped samples.
12:03PM B23.00005  Thickness dependent magnetotransport properties of epitaxial La$_{0.5}$Sr$_{0.5}$CoO$_3$ (001) films\textsuperscript{1}, M. SHARMA, M. TORJIA, C. LEIGHTON, University of Minnesota, M. VARELA, Oak Ridge National Lab

Thin films of the doped perovskite cobaltite La$_{1-x}$Sr$_x$CoO$_3$ offer an ideal system to study the effect of dimensional confinement on spin state transitions and magnetoelectronic phase separation, and have application possibilities as electrodes in ferroelectric memory and solid oxide fuel cells. In this work we present the magnetotransport properties of epitaxial La$_{0.5}$Sr$_{0.5}$CoO$_3$ (001) thin films deposited on SrTiO$_3$ (001) by high pressure reactive sputtering. The films were structurally characterized by high-resolution x-ray diffraction, scanning probe microscopy, and STEM. Films with thickness > 100 Å exhibit bulk-like ferromagnetic metallic characteristics with the conventional negative MR in the vicinity of T$_C$ and a large AMR at low T. In stark contrast, films with thickness below 60 Å exhibit reduced magnetization and a crossover to an insulating-like temperature dependence of the resistivity. This crossover is accompanied by a large negative MR at low T which bears a striking resemblance to that seen in bulk at x < 0.17, which is known to be due to an intercluster "GMR" effect.

In essence, x = 0.5 films on STO, when sufficiently thin, behave much like x < 0.17 bulk samples, i.e. phase separation is evidenced at the LSCO/STO interface.

12:15PM B23.00006  Heat capacity investigation of phase separation and spin-state transitions in La$_{1-x}$Sr$_x$CoO$_3$\textsuperscript{\*}, CHUNYONG HE, University of Minnesota, HENG ZHENG, JOHN MITCHELL, Argonne National Laboratory, C. LEIGHTON, University of Minnesota — We present a heat capacity study (to 0.3 K) on La$_{1-x}$Sr$_x$CoO$_3$ single crystals (0.00 < x < 0.30). In doped samples we observe three contributions at low T; a lattice term (∝ T$^2$), an electronic term (∝ T), and a third term proportional to T$^0$. Remarkably, the x dependence of the electronic and T$^2$ contributions reflects very clearly the known magnetic phase separation, indicating that the T$^2$ term is a signature of the non-F matrix. Possible origins related to AF fluctuations will be discussed. At the lowest T the nuclear hyperfine contribution provides a further probe of magnetic order. The electronic contribution also gives the density of states at the Fermi level which, in combination with the hole density from Hall effect, suggests a large effective mass indicative of strong correlations. Finally, the end-member LaCoO$_3$ shows a striking Schottky anomaly providing new information on the controversial spin-state transition. In particular, we find further evidence of the around 0.5 meV excitation recently observed by inelastic neutron scattering.

\textsuperscript{1}Work supported by DoE and NSF.

12:27PM B23.00007  Phase separation and inhomogeneity in La$_{1-x}$Sr$_x$CoO$_3$ single crystals, W.G. MOULTON, ROBERT SMITH, MICHAEL HOCH, PHILLIP KUHNS, ARNEIL REYES, GREGORY BOBINGER, National High Magnetic Field Laboratory 32310, JOHN MITCHELL, Materials Science Division, Argonne National Laboratory, Argonne, IL, CHRIS LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota, Minneapolis, MN 55455 — Nanoscale inhomogeneity in La$_{1-x}$Sr$_x$CoO$_3$ has been studied in single crystal samples for 0.05 ≤ x ≤ 0.3 using \textsuperscript{139}La NMR as a probe of the internal magnetic field distribution. The results show that phase separation occurs for x near the metal-insulator critical concentration x$_c$=0.17. The phase separation is confined to a much smaller range of x than that previously found in polycrystalline samples even though the bulk magnetic properties are similar. In single crystals with increasing x large, spin polarized (FM) regions merge into networks while smaller regions, identified as spin polarons, coexist with the larger regions. Insight into phase separation has been obtained by simulating the spectra with statistical model A phase diagram summarizing the evolution of the inhomogeneous internal field distribution with x and T will be presented.

12:39PM B23.00008  Strongly Inhomogeneous Conduction in Cobaltite Films\textsuperscript{1}, VLADIMIR ORLYANCHIK, MICHAEL WEISSMAN, UIUC, MÁRIA TORIJA, MANISH SHARMA, CHRIS LEIGHTON, UMN — The prototypical doped perovskite cobaltite, La$_{0.5}$Sr$_{0.5}$CoO$_3$, has received considerable attention in bulk form. It shows a striking Schottky anomaly providing new information on the controversial spin-state transition. It has a ferromagnetic transition at 230 K and an anomalous magnetic transition at 120 K which is manifested in steps in the temperature dependent magnetization and coercivity. The origin of this transition is still under investigation and recent experiments have suggested a change in magnetic anisotropy associated with this anomalous transition. In this work, we report systematic investigations of the magnetic anisotropy and switching fields across the 120 K transition in polycrystalline Pr$_{0.5}$Sr$_{0.5}$CoO$_3$ using a very sensitive RF transverse susceptibility method based on a tunnel diode oscillator resonant at 12 MHz. Our experiments reveal evidence for a sharp change in the anisotropy at 120 K with the anisotropy field (H$^\text{meas}$) dropping from around 1.8 kOe to 750 Oe on cooling. By tracing the evolution of the anisotropy and switching peaks, we are able to discern behavior associated with separate ferromagnetic phases with 120 K signaling the transition between the two.

\textsuperscript{1}This work was funded by NSF DMR 06-05726

12:51PM B23.00009  The spin state issue in the \textit{RBaCo}_2O_5$_{5ь}$ cobaltates, HUA WU, Z. HU, T. BURNUS, D. I. KHOMSKII, L. H. TJENG, Institute of Physics II, University of Cologne, Germany — The double perovskites NbBa$_2$Co$_2$O$_{5ь}$ ($R$=rare earth, 0≤ ν ≤ 1) display intriguing phenomena such as charge and orbital ordering, as well as antiferromagnetic to ferromagnetic transition, depending on the oxygen concentration. In particular, the $\delta$=0.5 system shows a giant magnetoresistance effect, and its metal-insulator transition has been often interpreted in terms of a spin-state transition [1,2], which, however, is fiercely debated [3,4]. To address the spin-state issue, we performed density-functional theory calculations which include a \textit{\emph{\textsuperscript{\*}}}$\delta$-inhomogeneous conductivity may account for the unusual geometry dependent conductance.

1:03PM B23.00010  Magnetic anisotropy and switching in Pr$_{0.5}$Sr$_{0.5}$CoO$_3$ using RF transverse susceptibility\textsuperscript{1}, N.A. FREY, H. SRIKANTH, Physics Department, University of South Florida, D.D. STAUFFER, C. LEIGHTON, Department of Chemical Engineering and Materials Science, University of Minnesota — Pr$_{0.5}$Sr$_{0.5}$CoO$_3$ has been a system of current interest that appears very different from manganites or even other cobaltites. It has a ferromagnetic transition at 230 K and an anomalous magnetic transition at 120 K which is manifested in steps in temperature dependent magnetization and coercivity. The origin of this transition is still under investigation and recent experiments have suggested a change in magnetic anisotropy associated with this anomalous transition. In this work, we report systematic investigations of the magnetic anisotropy and switching fields across the 120 K transition in polycrystalline Pr$_{0.5}$Sr$_{0.5}$CoO$_3$ using a very sensitive RF transverse susceptibility method based on a tunnel diode oscillator resonant at 12 MHz. Our experiments revealed a sharp change in the anisotropy at 120 K with the anisotropy field (H$^\text{meas}$) dropping from around 1.8 kOe to 750 Oe on cooling. By tracing the evolution of the anisotropy and switching peaks, we are able to discern behavior associated with separate ferromagnetic phases with 120 K signaling the transition between the two.

1:15PM B23.00011 Influence of cation and oxygen vacancy ordering on magnetic properties of RE$_{1-x}$Sr$_x$CoO$_{2-\delta}$ (RE=Ho, La) — S. KOLESNIK, B. DABROWSKI, O. CHMAISSEM, J. MAIS, Department of Physics, Northern Illinois University, DeKalb, IL 60115, Materials Science Division, Argonne National Laboratory, Argonne, IL 60439, A. BASZCZUK, Institute of Materials Science and Applied Mechanics, Wroclaw University of Technology, 50-370 Wroclaw, Poland — The attractive physical properties of RE$_{1-x}$Sr$_x$CoO$_{2-\delta}$ (RE - rare earth and Y) are strongly dependent upon overall oxygen content $\delta$ and the ordering of oxygen and RE/Sr, as well as charge and spin ordering on the Co$^{3+}$/Co$^{4+}$ sites. Structural, magnetic and thermoelectric properties of Ho$_{1-x}$Sr$_x$CoO$_y$ have been studied within the oxygen content range 2.67<$\delta$<2.80. The studied samples demonstrate antiferromagnetic order (G-type) and semiconductive behavior. No ferromagnetic ordering has been observed and compared with A. Maignan et al. on a closely related Sr$_2$/Y$_{1.5}$/CoO$_5$ with similar $\delta$. We have observed that a the same high degree of oxygen ordering and antiferromagnetic structure exists for both cation disordered (La) and ordered (Y,Ho) materials. We conclude that the high degree of oxygen vacancy ordering determines the observed properties via strong localization of Co$^{3+}$ electrons. Work at NIU was supported by the NSF-DMR-0302617 and at ANL by the U.S. DOE under contract No. DE-AC02-06CH11357.

1:27PM B23.00012 Orbital Ordering in Room Temperature Ferromagnet Sr$_3$YCo$_4$O$_{10.5}$ Studied by a Resonant X-ray Scattering — HIRONORI NAKAO, TETSUYA MURATA, DAISUKE BIZEN, YOUICHI MURAKAMI, Tohoku Univ., SHINTARO ISHIWATA, JST-ERATO, WATARU KOBAYASHI, ICHIRO TERASAKI, Waseda Univ. — Sr$_3$YCo$_4$O$_{10.5}$ has been found recently as a room temperature ferromagnet with $T_C$ ~ 340 K, which is the highest $T_C$ among perovskite Co oxides. The crystal structure is formed with the CoO$_6$ octahedral layers and the CoO$_{12.5}$ layers, which stack along c axis alternatively. By powder x-ray diffraction, the orbital state of Co$^{3+}$ (3d$^6$) was evaluated from the anisotropy of the CoO$_6$ octahedron in the ferromagnetic phase, and the $e_g$ orbital ordering of intermediate spin was proposed as an origin of the ferromagnetism. [1] Therefore, the orbital ordering of Co ion has been investigated using a resonant x-ray scattering technique, and a signal resonating near Co K-edge was found clearly. We present an antiferro-orbital and spin-state ordering, and the physical properties can be explained by the ordering model. [1] S. Ishiwata et al., Phys. Rev. B 75 (2007) 220406.

Monday, March 10, 2008 11:15AM - 2:15PM — Session B24 DMP: Focus Session: Transport in Nanostructures II: Strong Correlations Morial Convention Center 216

11:15AM B24.00001 Symmetries and interaction effects in carbon nanotube quantum dots$^1$. GLEB FINKELSTEIN, Duke University — By controlling the contact transparency within the same nanotube quantum dot, we observe the conductance evolving from the well-developed Coulomb blockade through the Kondo regime to the mixed valence regime. We work with high quality nanotubes, where energy subbands are doubly-degenerate, resulting in the SU(4) Kondo effect for one, two, and three electrons filling two degenerate orbitals. As the contacts are made more transparent, the sample enters the mixed valence regime, where different charge states within a pair of orbitals are hybridized. The hallmark of this regime in nanotube conductance is washing out of single-electron features at low temperature. In our measurement the level broadening is close to the charging energy and level spacing (both $\sim$ 10 meV). Nevertheless, the low temperature regime is established only at temperatures of the order or less than 0.5 meV. The same low energy scale is also apparent from the width of the zero-bias peak in the tunneling density of states.

11:51AM B24.00002 SU(4) Kondo effect in coupled quantum dots in parallel: Evidence of marginal fixed point$^2$. MIKIO ETO, Keio University — We theoretically study the Kondo effect in coupled quantum dots in parallel, using the scaling and NRG methods. The double quantum dots are capacitively coupled to each other, whereas they are attached to separate leads$^2$. The SU(4) Kondo effect is realized when the energy levels are matched between the quantum dots. We show that (i) the Kondo temperature $T_K$ decreases with increasing $|\Delta|$, where $\Delta$ is the level separation between the dots, obeying a power law [crossover from SU(4) to SU(2) Kondo effect]. (ii) The exponent of the power law is not a universal value in general. This is an evidence of the marginal fixed point of SU(4) Kondo effect$^3$. (iii) The conductance through one of the quantum dots may show a non-monotonic behavior as a function of temperature $T$ although the total conductance is a universal function of $T/T_K$.

12:03PM B24.00003 Exact-diagonalization treatment of the non-universal transport regime in few-electron quantum dots$^1$. LESLIE O. BAKSMATY$^2$, CONSTANTINE YANNOULEAS, UZI LANDMAN, School of Physics, Georgia Institute of Technology — Recently, experimental studies$^3$ have revealed a second transport regime in the behavior of transmission phases obtained via Aharonov-Bohm interferometry using small quantum dots (QDs); namely, a non-universal regime for QDs with $N$ < 10 electrons, in addition to the earlier known universal one for larger QDs with $N$ > 14. Sophisticated (beyond-the-mean-field) many-body methods are needed for describing this non-universal regime. Here, we study the transport properties of small QDs using exact-diagonalization (EXD) calculations in conjunction with Bardeen’s theory of quasiparticle mediated conductance$^4$. We will present EXD calculations$^5$ for anisotropic QDs, and for a wide range of anisotropies and strengths of inter-electron repulsion.

12:15PM B24.00004 Quantum dot in a Aharonov-Bohm interferometer: magnetic flux-dependent pseudogap in the Kondo regime. — PASCAL SIMON, CNRS and Universite Joseph Fourier, Grenoble, France, LUIS DIAS DA SILVA, Oak Ridge Natl. Lab. and U. of Tennessee, NANCY SANDLER, Ohio University, SERGIO ULLOA, Oak Ridge Natl. Lab. — We study a quantum dot embedded in one of the arms of a Aharonov-Bohm interferometer threaded by a magnetic flux $\Phi$. In the regime where a single resonant mode propagates in the interferometer’s “free arm”, the system can be described by an effective one-channel Anderson impurity model coupled to a non-constant, flux-dependent density of states (DoS). We present numerical renormalization-group results for the Kondo temperature $T_K$, phase shift and finite-temperature linear conductance. For $\Phi \neq 0$, the ground state of the system is Kondo-like, with a renormalized $T_K$. For $\Phi = 0$, the effective DoS vanishes at the Fermi energy and the system maps into the single-particle Anderson model, which displays a quantum critical transition between Kondo and non-Kondo phases [1]. Signatures of these effects appear in the conductance and transmission phase-shifts across the system. This setup constitutes an experimental realization of a tunable pseudogap Anderson Hamiltonian, allowing for an experimental probe into the non-trivial properties of such a model. [1] L.G.G.V. Dias da Silva et al., PRL 97, 096603 (2006).

12:27PM B24.00005 Two-particle processes in quantum dots — ERAN SELA, University of British Colombia — Inelastic two-electron processes in transport through quantum dots can lead to unexpected effects. At the low temperature Kondo regime, transport is described by an effective low-temperature theory in terms of weakly interacting quasiparticles. Despite the weakness of the interaction, we find that the backscattering current and hence the shot noise are dominated by two-quasiparticle scattering. We show that the simultaneous presence of one- and two- quasiparticle scattering results in a universal average charge $5/3e$ as measured by shot-noise experiments. As will be presented, recent experimental data measured in the vicinity of the Kondo limit supports our findings. Furthermore, this experiment suggests that many-body effects are not restricted to the low temperature regime only. Extending our study to the high temperature regime, we found under general conditions in Coulomb blocked quantum dots, signatures of transfer of electron pairs. Those results on many-body corrections to the cotunneling current will be discussed in a related talk by M.E. Raikh.

1:03PM B24.00006 ABSTRACT WITHDRAWN

1:15PM B24.00007 Finite-temperature conductance signatures of a quantum-critical transition in a double quantum-dot device — NANCY SANDLER, Ohio University, LUIS DIAS DA SILVA, Oak Ridge Natl. Lab. and U. of Tennessee, KEVIN INGERSENT, U. of Florida, SERGIO ULLOA, Ohio University — We present conductance results for a quantum-dot system containing one dot in the Kondo regime coupled to two leads in parallel with a noninteracting resonant level. The system can be mapped onto a single-impurity Anderson model with a pseudogapped effective density of states [1]. The finite-temperature linear conductance $G(T)$ of this double-dot device is obtained via numerical renormalization-group calculations. The position of the single-particle levels can be controlled with gate voltages so that the effective density of states vanishes in power-law fashion at the Fermi energy of the leads; within this regime, further tuning can drive the system through a quantum critical point separating Kondo and unscreened phases. Signatures of both effects appear in $G(T)$, with a prominent feature at the scale $T^*$ marking the crossover from the high-temperature quantum-critical regime to a low-temperature Fermi liquid. These results open the way for experimental verification of the effect, and in principle allow access to a quantum critical point in a unique tunable system. [1] L.G.G.V. Dias da Silva et al., PRL 97, 096603 (2006).

1:27PM B24.00008 Conductance signatures of quantum phase transitions in asymmetric double quantum dots — W. BRIAN LANE, Jacksonville U. and U. of Florida, KEVIN INGERSENT, U. of Florida, LUIS DIAS DA SILVA, Oak Ridge Natl. Lab. and U. of Tennessee, NANCY SANDLER, SERGIO ULLOA, Ohio U. — Double quantum dots (DQDs) are currently of great theoretical and experimental interest. A DQD device in which dot 1 is in the Kondo regime and dot 2 acts as a noninteracting resonant level can be tuned to access a pair of quantum phase transitions separating Kondo-screened and local-moment phases [1]. This talk focuses on the effects of introducing a nonzero Coulomb interaction $U_2$ on the second dot. For small $U_2$, the system continues to exhibit two quantum phase transitions, although their nature is markedly different than for $U_2 = 0$. However, stronger interactions $U_2 > U_1$ suppress the local-moment phase and destroy the quantum phase transitions. We use numerical renormalization-group techniques to identify signatures of these behaviors in the linear conductance of the DQD device. [1] L. G. V. Dias da Silva, N. P. Sandler, K. Ingersent, and S. E. Ulloa, Phys. Rev. Lett. 97, 096603 (2006).

1:39PM B24.00009 Symmetries and conductance in Kondo quantum dots — EDSON VERNEK, CARLOS BÜSSER, Ohio University, ENRIQUE V. ANDA, PUC-Rio, Brasil, NANCY SANDLER, SERGIO E. ULLOA, Ohio University — The role of symmetries on nanoscale structures is essential for the physical behavior exhibited in these systems while its understanding offers deeper insights into the observed properties. The ability to fabricate structures such as quantum dot arrays with tailored symmetries provides further motivation to understand the interplay of geometrical and orbital symmetries in interacting systems at low temperatures, where quantum coherence and Kondo correlations determine the electronic properties. In this work we study the transport properties of three interconnected quantum dots coupled to different leads in a triangular geometry. Conductance calculations carried out in a finite-U slave-boson mean field approximation show excellent agreement with results from the embedded cluster approximation (ECA), highlighting the rich features of the various physical regimes. We focus on and compare two important geometries with: equilateral (all couplings and leads identical) and isoceles (one lead and respective couplings different from the others) symmetries. In the first case, we show that only two degenerate orbitals contribute to the Kondo state conductance. Further, we show that the presence of an open third lead in all cases introduces dephasing which affects differently the various features of the conductance.

1:51PM B24.00010 Kondo correlations and transport in single and triple quantum dots with damped lead hoppings: a tDMRG study — LUIS DIAS DA SILVA, Oak Ridge Natl. Lab. and U. of Tennessee, FABIAN HEIDRICH-MEISNER, Inst. for Theoretical Physics C, RWTH Aachen, Germany, ADRIAN FEIGUIN, Microsoft Project Q, U. of California at Santa Barbara, ELBIO DAGOTTO, Oak Ridge Natl. Lab. and U. of Tennessee — We study the transport properties of one and three quantum dot systems with the time-dependent Density Matrix Renormalization-Group method (tDMRG). As previously noted [1,2], fine-size effects make the tDMRG description of the strongly interacting Kondo regime a numerically demanding task. We address this issue by introducing an exponential decay in the hopping terms in the leads ($t_{ij} \propto \lambda^{-n/2}$), recently introduced in cluster embedding methods [3]. For a given size system, results for $\lambda > 1$ show several improvements over the undamped ($\lambda = 1$)[1,2] case: the Kondo plateau in the differential conductance is correctly obtained deeper in the strongly interacting regime; steady-state current plateaus remain well defined for longer time scales. These results show that, with the proposed modification, the characterization of Kondo correlations in the transport properties can be substantially improved, at less computational cost. [1] K. A. Al-Hassanieh et al. PRB, 73, 195304 (2006). [2] F. Heidrich-Meisner et al. arxiv:0705.1801 (2007). [3] E. Anda et al., pre-print (Nov. 2007).

NB controlled not only by the degree of polymerization of the surrounding linear chains, but also by the degree of polymerization of the brush's side chains, \( \chi(T) \). In simulations of simple models, a useful independent definition of \( \chi(T) \) may be obtained from a thermodynamic perturbation theory in which the difference between AB and AA interactions is treated as a perturbation of a one-component melt. For lattice models, this yields a value that, in the limit of long chains, is related to the Flory-Huggins value by replacing the coordination number \( z \) by an effective coordination number given by the average number of inter-molecular contacts per monomer, as proposed previously by M. Mueller. Generalizations of the idea are provided for continuum models, and for shorter chains. An analytic theory is presented that quantitatively predicts the N-dependence of the effective coordination number found in lattice simulations. The approach provides a clean way to separate RPA from non-RPA effects in the analysis of simulations.

**Monday, March 10, 2008 11:15AM - 2:03PM**

**Session B25 DPOLY: Polymer Blends** Marriot Convention Center 217

**11:15AM B25.00001 Effective Coordination Number and Interaction Parameter In Simple Models of Polymer Blends** DAVID MORSE, University of Minnesota — One challenge faced when trying to quantify corrections to the RPA in either simulations or experimental measurements of correlations in polymer blends is the need to estimate the temperature or parameter dependence of a self-consistent field interaction parameter \( \chi(T) \). In simulations of simple models, a useful independent definition of \( \chi(T) \) may be obtained from a thermodynamic perturbation theory in which the difference between AB and AA interactions is treated as a perturbation of a one-component melt. For lattice models, this yields a value that, in the limit of long chains, is related to the Flory-Huggins value by replacing the coordination number \( z \) by an effective coordination number given by the average number of inter-molecular contacts per monomer, as proposed previously by M. Mueller. Generalizations of the idea are provided for continuum models, and for shorter chains. An analytic theory is presented that quantitatively predicts the N-dependence of the effective coordination number found in lattice simulations. The approach provides a clean way to separate RPA from non-RPA effects in the analysis of simulations.

**11:27AM B25.00002 Nucleation in Polymer Blends** EDWARD FENG, NITASH BALSARA, University of California, Berkeley — Balsara and co-workers used small angle neutron scattering experiments on binary homopolymers blends to determine the size of the critical nucleus during phase separation. This suggests measuring the size of a single critical nucleus through a measurement of total density fluctuations. We carefully analyze this idea through kinetic Monte Carlo simulations of the Ising model, performing simulations of phase separation that conserve and do not conserve the magnetization. Calculations of the structure factor and spin-spin correlation function reveal clear differences in the nucleation mechanism for these two dynamics. Simulations that conserve the magnetization qualitatively agree with the experimental results on binary blends. Moreover, we calculate the cluster distribution during nucleation to determine the critical nucleus size of the Ising model. Comparing this result with the value determined from the structure factor shows qualitative agreement with increasing supersaturation.

**11:39AM B25.00003 Molecular dynamics simulations of constraint release effects in entangled binary blends of linear polymers** ZUOWEI WANG, RONALD G. LARSON, Department of Chemical Engineering, University of Michigan, Ann Arbor, MI 48109-2136 — We present extensive molecular dynamics simulations of the dynamics of entangled binary blends consisting of long test chains diluted in shorter chain matrix. The ratio between the long and short chain lengths is varied by a factor of ten covering the crossover from the chain reptation regime to the tube Rouse relaxation regime. Consistent with Neutron Spin Echo experiments, the dynamic structure factor of the long chains is found to decay faster in the matrix with shorter chain lengths, owing to the stronger constraint release effect. Correspondingly the monomers and centers of mass of the long chains show a faster time-dependent diffusivity than that expected from pure reptation. The simulation results for the diffusion properties agree qualitatively with the predictions based on constraint release Rouse motion model at long time scales, but show deviations from the theoretical predictions in the intermediate time regime. Our preliminary analysis of diffusion of the matrix chains in the tube-region of the long chains indicates that this discrepancy results from neglect of the broad distribution of the lifetimes of constraint release events in the theoretical treatment.

**11:51AM B25.00004 Flory Theorem for Structurally Asymmetric Mixtures** ANDREY DOBRYNIN, Institute of Materials Science, University of Connecticut, FRANK SUN, DAVID SHIRVANYANTS, GREGORY RUBINSTEIN, MICHAEL RUBINSTEIN, SEUNG-JUN HEO, Department of Chemistry, University of North Carolina at Chapel Hill, HYUNG-IL LEE, KRZYSZTOF MATYJASZEWSKI, Department of Chemistry, Carnegie Mellon University — The generalization of the Flory theorem for structurally asymmetric mixtures was derived and tested by direct visualization of conformational transformations of brushlike macromolecules embedded in a melt of linear chains. Swelling of a brush molecule was shown to be controlled not only by the degree of polymerization of the surrounding linear chains, \( NB \), but also by the degree of polymerization of the brush’s side chains, \( N \), which determines the structural asymmetry of the mixed species. The boundaries of the swelling region were established by scaling analysis as \( N^{2/3} < NB < NA/N \), where \( NA \) is the degree of polymerization of the brush backbone. Experiment and theory demonstrated good agreement.

**12:03PM B25.00005 The Molecular Weight and Composition Dependence of Measured Flory-Huggins Interaction Parameters for Blends of Model Polyolefins** ALISYN NEDOMA, Univ. of California, Berkeley, MEGAN ROBERTSON, Univ. of Minnesota, NISITA WANAKULE, NITASH BALSARA, Univ. of California, Berkeley — The thermodynamics of binary blends of model polyolefins (deuterated polybutadiene and polysisobutylene) was studied using small angle neutron scattering (SANS) and small angle light scattering (SALS). SANS experiments on single phase blends reveal that the Flory-Huggins interaction parameter, \( \chi_i \), for this system depends on both blend composition and component molecular weights. This is in contrast to numerous previous studies on thermodynamics of polymer blends where \( \chi_i \) is reported to be independent of molecular weight. The phase separation temperatures of our blends, determined by SALS and SANS, will be compared to predictions based on the measured \( \chi_i \) parameters.

We acknowledge the support of the National Institute of Standards and Technology, U.S. Department of Commerce, in providing the neutron research facilities used in this work.

**12:15PM B25.00006 Porod SAXS Studies of Shear-Induced Droplet Deformation in a Concentrated Immiscible Polymer Blend** WESLEY BURGHARDT, KRISTIN BRINKER, Northwestern University — Droplet deformation, break-up and coalescence of immiscible polymer blends under flow is fundamental to understanding the effect of processing on ultimate blend properties, as well as the excess rheological properties associated with deformation of the multiphase structure. Both optical methods have frequently been employed to gain insight into these processes, but in most cases, optical methods are restricted to quite dilute concentrations, owing to concerns of high turbidity and multiple scattering. Here we explore used of time-resolved synchrotron small-angle x-ray scattering as an alternative method to study multiphase materials under shear. Typical blend droplet sizes of ~1 micron are large relative to length scales typically probed by SAXS; however, the wide-angle limit of small-angle scattering (i.e. the Porod regime) is directly sensitive to interfacial structure of multiphase materials and, when rendered anisotropic by shear flow, provides direct insights into the deformation and orientation of interface. We report scattering studies in the flow-gradient plane of a polystyrene/polymethyl methacrylate) blend, which is approximately viscosity matched, to step-strain deformations. Postulating that each droplet is deformed to a geometrically similar shape, data are analyzed in the context of a model of Porod scattering from ellipsoids.
12:27PM B25.00007 Measurements of the Onsager coefficient in a phase-separating polymer blend, AMISH PATEL, NITASH BALSARA, U. C. Berkeley — Phase separation in a polymer blend of critical concentration was studied using time-resolved Small Angle Neutron Scattering (SANS). To start off, the blend was homogenized by taking it well into the 1-phase region of the phase diagram. It was then quenched into the 2-phase region by using a rapid change in pressure. Since, the sample enters the two-phase region at the critical point, it is expected to phase separate by spinodal decomposition. Hence, the time dependent SANS intensity was fit to the Cahn-Hilliard-Cook equation for systems undergoing spinodal decomposition. The fit parameters were then used to calculate the non-local Onsager coefficient at several different pressures. The functional form of the Onsager coefficient, as a function of the wave-vector, was compared to that predicted by theory. Finally, the molecular parameters that go into the theory were extracted.

12:39PM B25.00008 Structure And Dynamics Of Semi-crystalline Polyethylene Oxide / Polyvinyl Acetate Blends 1, JAMES RUNT, DANIEL FRAGIADAKIS, Penn State University — The structure and dynamics of semi-crystalline, melt-miscible polyethylene oxide / polyvinyl acetate (PEO/PVAc) blends were investigated using small-angle X-ray scattering and dielectric relaxation spectroscopy. PEO/PVAc blends with selected compositions were crystallized at various temperatures. Small-angle X-ray scattering was used to quantitatively determine the semi-crystalline microstructure, including the location(s) of the non-crystallizable PVAc in the structure. Segmental and local dynamics were studied using broadband dielectric relaxation spectroscopy. We attempt to clarify the origin of an additional relaxation, located at intermediate frequencies between the segmental and local processes, which has been proposed to be related to initial stages of crystallization even in blends lacking macroscopic crystallinity.

12:51PM B25.00009 The Structure and Thermodynamics of Cellulose Acetates, MARK DADMUN, RUJUL MEHTA, University of Tennessee, GARY LYNN, Oak Ridge National Laboratory — Cellulose acetate (CA) polymers having different degrees of substitution (DS) vary widely in their properties, such as glass transition, miscibility, chemical resistance, and gas permeation. These variations hint at differences in their molecular structure. We have systematically studied the variation in the molecular structure of CA with DS, utilizing small angle neutron scattering (SANS). SANS measurements were carried out in 1% (w/v) solutions in DMSO (which is sufficiently dilute to avoid intermolecular scattering). The polymer chains display rigidity along their main chain and have persistence lengths in the range of 12 to 14 nm. The effect of DS on the extent of miscibility is explained on the basis of available intra-molecular hydrogen bonding sites along the polymer chain. SANS measurements were also carried out on 50-50(w/w) miscible blends of two sets of CA, where the difference in the DS between the polymers varied from 0.05 to 0.25. Random phase approximation analysis provides an estimate of the Flory-Huggins interaction parameter between the two polymers in the blend. The influence of both the amount of substitution and hydrogen bonding on the polymer miscibility will be discussed.

1:03PM B25.00010 Effect of solvent evaporation and coagulation on morphology development of asymmetric membranes, NEELAKANDAN CHANDRASEKARAN, THEIN KYU, The University of Akron — Miscibility behavior of blends of amorphous polycarbonate (PA) and polyvinylpyrrolidone (PVP) was studied in relation to membrane formation. Dimethylsulfoxide (DMSO) and water were used as solvent and non-solvent, respectively. Differential scanning calorimetry and cloud point measurements revealed that the binary PA/PVP blends as well as the ternary PA/PVP/DMSO system were completely miscible at all compositions. However, the addition of non-solvent (water) to this ternary system has led to phase separation. Visual turbidity study was used to establish a ternary liquid-liquid phase diagram of the PA-PVP/DMSO/water system. Scanning Electron Microscopy (SEM) showed the development of finger-like and sponge-like cross sectional morphologies during coagulation. Effects of polymer concentration, PA/PVP blend ratio, solvent/non-solvent quality, and evaporation time on the resulting membrane morphology will be discussed.

1:15PM B25.00011 The Glass Transition and Dynamics in Athermal Poly(a-Methyl Styrene)/Oligomer Blends, WEI ZHENG, SINDEE SIMON, Texas Tech University — The glass transition and dynamics in athermal blends of poly(a-methyl styrene) (PMS) and its short chain oligomers are investigated using differential scanning calorimetry (DSC). A methodology is described to partition the calorimetric transition in order to obtain effective Tgs for each component of the blend. The dependences of these effective Tgs on overall blend composition are described by the Lodge-McLeish model although the self-concentration effect is less than expected based on the Kuhn length. The kinetics associated with the glass transition, Tg, are examined by studying the cooling rate dependence of Tg for the pure components and the blends, as well as by examining the enthalpy overshoots in the heating DSC scans. Extension of Colmenero’s model to describe the dynamics in these materials will be discussed.

1:27PM B25.00012 Effect of compositional heterogeneity on the phase structure and crystallization behavior of polypropylene in-reactor alloys, DUJIN WANG, HAIJIN ZHU, BENJAMIN MONRABAL, CHARLES C. HAN — Although the compositional heterogeneity and chain structure of PP/EPR in-situ blends have been extensively investigated, little is known about the conclusive relationship among the molecular/phase structure and the ultimate mechanical properties due to its complex compositions in such systems. A systematic study was conducted on the compositional heterogeneity, phase structure, the crystallization and subsequent melting behavior of two in-reactor alloys EB-P and EP-P. The composition of the alloys and the chain structure of each component were characterized by preparative TREF and 13C-NMR technique. The results showed that the excellent balance between toughness and rigidity of EB-P primarily benefits from the polyethylene homopolymer (HE) phase and the ethylene-o-cycloolefin copolymer (EC) component, which is enriched at the interface between the dispersed phase (HPP) and the matrix (HE). As for EP-P, the amorphous EC and the interpenetrating phase are mainly responsible for the outstanding low temperature impact toughness.

1Financial support from Ministry of Science and Technology is greatly acknowledged.

1:39PM B25.00013 Mesoscopic drop dynamics and rheological modeling for polymer blends, YUANZE XU, Fudan University, WEI YU, Shanghai Jiao Tong University, JIANMAO YANG, Fudan University — Fundamental challenge to rheology for polyblends originates from the dynamic coupling between interfacial morphology and viscoelastic flow. This work will outline our approaches. The framework of irreversible thermodynamics was employed to model immiscible viscoelastic blends considering the chain conformation, the drop deformation, drop break-up and collapse and the hydrodynamic interaction of drops in concentrated blends. The theoretical predictions were proved by measuring the drop dynamics in a four-roll mill rheometer with success. Great challenge to the model exists in systems where the drop dynamics severely deviating from emulsions of Newtonian droplets. A new type of drop merging by a string pulling two beads together (BSB) was observed and analyzed. The relevant material and process conditions causing BSB or beads-on-string are discussed elucidating its origin of non-linear viscoelasticity of polymers.

1:51PM B25.00014 Self Similar Growth of Polyolefin Blends On a Micro-Nano Granule Reactor

CHARLES HAN, JIANG DU, KUN MENG, XIA DONG, JIN-YONG DONG,1 DUSJIN WANG, State Key Laboratory of Polymer Physics and Chemistry, Joint Laboratory of Polymer Science and Materials, ICCAS, Beijing, China — A Ziegler-Natta/metalocene hybrid catalyst was used in this MRGT (Multi-catalyst Reactor Granule Technology) synthesis. Isotactic polypropylene/polyethylene-co-octene (iPP/PEO) polymer blends were prepared on the micro-nano granule reactors. A self-similar growth mechanism has been observed and deciphered. The self-similar structure is extended and observed at least for 5 decades in a combined real and reciprocal spatial range. With thermal treatment, structure growth and crystallization kinetics has been studied on these single reactor granules.

Morial Convention Center 218

11:15AM B26.00001 Molecular collision studies with Stark-decelerated beams, GERARD MEIJER, Fritz-Haber Institute of the Max Planck Society, Faradayweg 4-6, D-14195 Berlin, Germany — Molecular scattering behaviour has generally proven difficult to study at low collision energies. We formed a molecular beam of OH radicals with a narrow velocity distribution and a tunable velocity by passing the beam through a Stark decelerator [1]. The transition probabilities for inelastic scattering of the OH radicals with Xe atoms were measured as a function of the collision energy in the range of 50 to 400 wavenumbers. The behaviour of the cross-sections for inelastic scattering near the energetic thresholds was accurately measured, and excellent agreement was obtained with cross-sections derived from coupled-channel calculations on ab initio computed potential energy surfaces [2]. For collision studies at lower energies, the decelerated beams of molecules can be loaded into a variety of traps. In these traps, electric fields are used to keep the molecules confined in a region of space where they can be studied in complete isolation from the (hot) environment. Typically, 107 state-selected molecules can be trapped for times up to several seconds at a density of 107 mol/cm3 and at a temperature of several tens of mK [3]. The long interaction time afforded by the trap has been exploited to measure the infrared radiative lifetime of vibrationally excited OH radicals, for instance, as well as to study the far-infrared optical pumping of these polar molecules due to blackbody radiation [4]. As an alternative to these traps, we have demonstrated an electrostatic storage ring for neutral molecules. In its simplest form, a storage ring is a trap in which the molecules - rather than having a minimum potential energy at a single location in space - have a minimum potential energy on a circle. To fully exploit the possibilities offered by a ring structure, it is imperative that the molecules remain in a bunch as they revolve around the ring. This ensures a high density of stored molecules, moreover, this makes it possible to inject multiple - either co-linear or counter propagating - packets into the ring without affecting the packet(s) already stored. We have recently demonstrated a prototype molecular synchrotron, which will be used as a low-energy collider for neutral molecules in the future [5].

11:51AM B26.00002 Magnetoelectrostatic trapping of neutral OH molecules1, BRIAN SAWYER, BENJAMIN STUHL, JILA/University of Colorado, BENJAMIN LEV, University of Illinois, Urbana-Champaign, MARK YEO, JILA/University of Colorado, D AJUN WANG, JUN YE, JILA/NIST/University of Colorado — Advances in cold molecule production promise to profoundly impact research on precision measurement, quantum information, and controlled chemistry. To this end, we employ a Stark decelerator to remove 99.5% of the center-of-mass kinetic energy of a super-bunch as they revolve around the ring. This ensures a high density of stored molecules, moreover, this makes it possible to inject multiple - either co-linear or counter propagating - packets into the ring without affecting the packet(s) already stored. We have recently demonstrated a prototype molecular synchrotron, which will be used as a low-energy collider for neutral molecules in the future [5].

12:03PM B26.00003 Photodissociation of SO2 as a way to cold atoms and molecules, LISDAT CHRISTIAN, Physikalisches-Technische Bundesanstalt, Braunschweig, Germany, OLEG BUCICOV, MARCIN NOWAK, SEBASTIAN JUNG1, EBERHARD TIE-MANN, Institute of Quantum Optics, Leibniz University Hannover, Germany — We discuss the possibility of using the photodissociation of cold SO2 molecules to produce internally and translationally cold photofragments SO and O. It is expected from our measurements of the molecular Stark effect [1] that the dissociation pathways and excess energies of the fragments are tunable by electric fields [2]. Cold SO2 molecules are produced by Stark deceleration. We have realized a Stark decelerator that is able to slow down packages SO2 in weak-field seeking levels to a few 10 m/s center of mass velocity. A Stark decelerator with 326 stages is required for this purpose, since the ratio of Stark shift to initial kinetic energy is small for SO2. The photofragments SO and O have triplet ground states, while the ground state of SO2 is diamagnetic. In combination with the photodissociation at the threshold we want to employ this constellation to accumulate fragments in a magnetic trap by dissociating SO2 as it is stopped by electric fields in the center of the trap.

1present address: Atomic Physics Division, NIST Gaithersburg

12:15PM B26.00004 Alternating gradient focusing and deceleration of large molecules, KIRSTIN WOHLFART, FABIAN GRÄTZ, FRANK FILSINGER, GERARD MEIJER, JOCHEN KÜPPER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195 Berlin, Germany — During the last decade, fascinating progress has been made in the spectroscopy of the “molecular building blocks of life”. Meanwhile, our group has been developing methods to decelerate neutral, polar molecules using time varying inhomogeneous electric fields. Extending these techniques to bio-molecules would allow, for instance, to increase observation times for precision spectroscopy or to separate different conformers. However, for such large molecules all states are practically high-field seeking. Therefore, alternating gradient focusing has to be applied. Here, we demonstrate the focusing and deceleration of benzonitrile (C6H5N) from a molecular beam. Benzonitrile is prototypical for large asymmetric top molecules that exhibits rich rotational structure and a high density of states. It is decelerated in its absolute ground state from 320 m/s to 289 m/s, and similar velocity changes are obtained for excited rotational states. We are setting up a longer alternating gradient decelerator, which will enable us to decelerate benzonitrile or larger molecules to much lower velocities and to thereby completely separate the decelerated packet from the rest of the beam pulse.
1:15PM B26.00007 Kinetics of Cold Molecule Production in “Kinematic” Cooling , JEFFREY KAY, KEVIN STRECKER, DAVID CHANDLER, Sandia National Laboratories — “Kinematic” cooling is a general technique by which a vast array of molecules can be translationally cooled using crossed atomic and molecular beams. The success of the technique relies primarily on the existence of an approximate mass degeneracy between the molecule to be cooled and its atomic or molecular collision partner. Here, we discuss factors that affect the efficiency of cold molecule production by this method, as well as schemes that may allow tunability of the velocity and temperature of the cold molecules on a fine scale.

1:27PM B26.00008 A new source for quantum optics with biomolecules and biomolecular clusters , MARKUS MARKSTEINER, PHILIPP HASLINGER, HENDRIK ULBRICH, MARKUS ARNDT, Faculty of Physics, University Vienna — We present recent progress towards matter wave experiments with amino acids, polypeptides and large biomolecular clusters. All successful experiments on macromolecule interferometry so far, with fullerenes, fullerene derivatives and large perfluoroalkyl-functionalized azobenzenes used effusive beam sources. The combination of Stark deflection with quantum interferometry also allowed us to create a new device for precisely measuring electric susceptibilities of large molecules in the gas phase. In order to apply quantum interference to molecules of biological interest, we have now implemented a pulsed laser desorption source. The combination of UV laser desorption into an intense noble gas jet and single-photon ionization by a VUV excimer laser (157nm) allows us to observe intense neutral jets of amino acids (e.g. Tryptophan), nucleotides (e.g. Guanin) and polypeptides ranging from tri-peptides to Gramicidin. Remarkably, we also found a new method for producing large neutral amino acid clusters, such as for instance Trp$_{30}$, with masses exceeding 6000 amu: the addition of alkaline Earth salts in the desorption process leads to the inclusion of at least one metal atom per complex and is sufficient to catalyze the cluster formation process.

1:39PM B26.00009 Collisions of ultracold molecules , HANNS-CHRISTOPH NAEGERL, University of Innsbruck — In our experiments we routinely produce ultracold trapped samples of dimer molecules out of a Cs atomic gas by exploiting the atom-dimer coupling near Feshbach resonances. We explore the rich molecular structure for the Cs dimers near the atomic threshold by consecutive state transfer after initial dimer production and produce atom-dimer mixtures for which we measure the atom-dimer collisional rate as a function of kinetic energy at temperatures down to 40 nK. We find resonant enhancement of this rate for sufficiently small dimer binding energies for which coupling to an Efimov trimer state is possible. We also produce pure dimer samples for which we measure the collisional loss rate. For a weakly bound molecular s-state this rate depends strongly on temperature and on the applied magnetic field. We will also discuss first results from our experiment on producing ultracold ro-vibrational ground state molecules for the case of Cs dimers and RbCs starting from weakly bound molecules which initially are produced on a Feshbach resonance.

Monday, March 10, 2008 11:15AM - 2:15PM — Session B27 GMAG: Focus Session: Molecular Magnets I Morial Convention Center 219

11:15AM B27.00001 Self-Assembled Growth and Magnetism of Ordered Cluster Arrays , AXEL ENDERS, University of Nebraska - Lincoln — It is generally recognized that the fabrication of magnetic storage media with bit densities of Gigabytes per square inch and more is out of reach of currently available thin film technologies. Patterned media may therefore set off to challenge thin film media as they allow in principle for bit densities several orders of magnitude larger than what is currently feasible. In this talk I will show how nanoclusters can be fabricated on substrates directly by self-assembled growth, and how their magnetism and their lateral arrangement on the substrate can be controlled. Buffer layer assisted growth is used to form clusters of controlled density and size, in the range between a few atoms to several nanometers diameter. The clusters are randomly distributed over the bare substrate surface. The cluster nucleation on the buffer layer and their growth after making contact with the substrate was studied with variable temperature scanning tunneling microscopy, and will be discussed in the talk. The investigation of the cluster magnetism with X-ray magnetic circular dichroism revealed size and strain effects as well as mutual dipolar and cluster-substrate interactions. We found a pronounced dependence of the magnetic anisotropy on the substrate material. On Pt, for instance, the preferential magnetization direction is out-of-plane, while it is in-plane on Ag. The application of self-assembled clusters as individually addressable magnetic units requires their controlled arrangement into well-defined ordered arrays. We are therefore guiding the clusters with energetic sinks provided by periodic network structures prefabricated on the substrate. We use mechanically extremely stable, electronically insulating boron nitride nanomesh monolayers as template surfaces. Repeated cluster deposition cycles increase the cluster density on the nanomesh, eventually resulting in an densely packed, ordered cluster array with a cluster-cluster distance corresponding to the BN nanomesh periodicity of 3.2 nm. These cluster layers offer densities of magnetic elements as high as 80 x 10$^{12}$ clusters per square inch.

11:51AM B27.00002 Transition linewidth of Mn12-Acetate$^1$, BETH PARKS, KURT ANDRESEN, Colgate University, CHRISTOPHER BEEDLE, DAVID HENDRICKSON, UC San Diego — The single-molecule magnet Mn$_{12}$-acetate forms macroscopic crystals in which quantum tunneling of the magnetic moment can be observed. This quantum tunneling is governed to a large extent by defects in the crystal structure. These same defects are thought to be responsible for the broadening of the transition linewidth between adjacent levels, such as $m_s = 10$ to $m_s = 9$. It is possible to test this understanding by observing the linewidth of the transition during the tunneling process. If the same defects are responsible for both effects, then as tunneling progresses, the linewidth should change. Results of this measurement of the linewidth obtained using terahertz time-domain spectroscopy will be presented.

12:03PM B27.00003 Low temperature relaxation crossover in one dimensional chain-like molecular magnet \([\text{Fe}^\text{II}(\Delta)\text{Fe}^\text{II}(\Lambda)\text{(ox)}_2(\text{phen})_2]_n\) , J.L. HER, C.P. SUN, S. TARAN, C.C. CHOU, C.L. CHAN, C.C. LIN, Department of Physics, Center of Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung 804, Taiwan, L.L. LI, K.J. LIN, Department of Chemistry, Center of Nanoscience and Nanotechnology, National Chung-Hsing University, Taichung 402, Taiwan, H.D. YANG, Department of Physics, Center of Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — The frequency-dependent ac susceptibility, theromromagnetization magnetization relaxation (TRM) and magnetic field dependent magnetization have performed on a hand-aligned partially orientated molecular magnet compound \([\text{Fe}^\text{II}(\Delta)\text{Fe}^\text{II}(\Lambda)(\text{ox})_2(\text{phen})_2]_n[\text{I}]\) which exhibits one dimension chain like structure. The ac susceptibility shows spin glass-like relaxation at temperatures between 7.8 and 8.2 K. In addition, the TRM results show various relaxation behaviors below \(T_m \sim 8.6\) K, indicating that there is a remnant instability at low temperature. It might be caused by the complex interaction within and/or between the chains and the stacked layers. With slowly sweeping the magnetic field, a step-like behavior in the magnetic hysteresis loop was observed below \(T_m\). The possible origins for these properties are discussed. [1] L. L. Li, K. J. Lin, C. J. Ho, C. P. Sun, and H. D. Yang, Chem. Commun. 12, 1286 (2006).

12:15PM B27.00004 A novel experiment using rotating magnetic fields to study the pumping spin states in molecular magnets , ALBERTO HERNANDEZ-MINGUEZ, FERRAN MACIA, JOAN MANEL HERNANDEZ, CARLA CARBONELL, ROGER AMIGÓ, JAVIER TEJADA, Universitat de Barcelona — We report here a new experimental technique to monitor spin population dynamics in molecular magnets. This deals with a huge rotating magnetic field initially applied along the easy magnetization direction, \(z\)-axis, that rotates with components parallel and perpendicular to the \(z\) axis. This technique allows us to probe spin relaxation on reasonably fast time scales detecting the inversion of the whole spin states. The population of spin levels depends on the frequency of the rotating magnetic field. This very new technique could help to carry out new experiments in a number of different fields, broadening substantially the scope of their use until now. A Hernández-Minguez et al., Appl. Phys. Lett. 91, 202502 (2007).

12:27PM B27.00005 Anomalous magnetic relaxation in 2D layered organic-based magnet \([\text{Fe(TCNE)(NCMe)}_2][\text{FeCl}_4]\) , JUNG-WOO YOO, V. N. PRIGODIN, Department of Physics, The Ohio State University, K. I. POKHOD-NYA, JOEL S. MILLER, Department of Chemistry, University of Utah, A. J. EPSTEIN, Department of Physics and Chemistry, The Ohio State University — The magnetic relaxation of the 2D organic-based magnet \([\text{Fe(TCNE)(NCMe)}_2][\text{FeCl}_4]\) was explored using both static and dynamic measurements. Static \(M(H,T)\) studies showed that the ferrimagnetic order between the spins in \(\text{Fe}^\text{II}\) \((S = 2)\) and the spin in \((\text{TCNE})^-\) \((S = 1/2)\) occurs principally within the plane of \([\text{Fe(TCNE)(NCMe)}_2]\) layers, with no magnetic coupling to the \(S = 5/2\) of the \([\text{FeCl}_4]^-\), which is located between layers [1]. The DC magnetic relaxation in ZFC states shows the memory effects similar to that observed in superparamagnetic systems. This reflects the weak magnetic coupling between the layers enabling the bistable nature between FC and ZFC states [1]. The memory effects disappear when the system is cooled in field supporting bistable nature of interlayer coupling. The dynamic susceptibility near the critical \(T\) shows two relaxation processes the possible origins of which will be discussed. [1] K. I. Pokhodnya, et al. J. Am. Chem. Soc., 118, 12844 (2006).

12:39PM B27.00006 Ferromagnetic resonance (FMR) of a room temperature organic based mixed valent Vanadium Hexacyanochromate magnet \(K_{1.54}\text{V}^{\text{III}}\text{V}^{\text{II}}\text{V}^{\text{III}}\text{Cr}^{\text{III}}\text{(CN)}_6\text{(SO}_4\text{)}_{0.16}\text{3.1H}_2\text{O}\) , N.P. RAJU, J.W. YOO, Dept. of Physics, The Ohio State University, AMBER C. MCCONNELL, WILLIAM W. SHUM, KENDRIC J. NELSON, Dept. of Chemistry, University of Utah, JOEL S. MILLER, Dept. of Chemistry, A.J. EPSTEIN, Deps. of Physics and Chemistry, The Ohio State University — Recently, organic materials both magnetic and non-magnetic have been receiving significant attention for their potential applicability in spintronics devices such as spin-valves, memory devices, spin-transistors etc. Here we report magnetic and X-band FMR studies of an organic based mixed valent Vanadium Hexacyanochromate magnet \(K_{1.54}\text{V}^{\text{III}}\text{V}^{\text{II}}\text{V}^{\text{III}}\text{Cr}^{\text{III}}\text{(CN)}_6\text{(SO}_4\text{)}_{0.16}\text{3.1H}_2\text{O}\) with an ordering temperature well above room temperature (>300K). Temperature dependencies of FMR parameters including intensity, linewidth, resonance field will be discussed in terms of the coexistence of long-range magnetic ordering and spin-glass-like behavior in this material. [1] Øyvind Hatlevik et. al. Adv. Mater. 11, 914 (1999).

12:51PM B27.00007 Origin of edge magnetism in zig-zag graphene nanoribbons , JIEL JUNG, ALLAN MACDONALD, University of Texas at Austin — We explore the physical origins of edge magnetism in zig-zag terminated graphene nanoribbons addressing the role of exchange effects and the band structure in the ferromagnetic alignment of the spins along the edge, the preference of anti-ferromagnetic inter-edge ground state to the ferromagnetic one, and the microscopic physics of the spin stiffness along an edge. Our analysis of the qualitative physics will rest largely on unrestricted Hartree-Fock theory calculations for \(\pi\)-band model Hamiltonian with long-range Coulomb interactions. Unlike Hubbard models, or ab initio LDA calculations, this type of theory can consistently account for non-local exchange effects.

1:03PM B27.00008 Magnetic Properties and Inelastic Neutron Scattering for a Spin Hexamer: Application to the \(V_6\) Molecular Magnets , J. T. HARALDSEN, University of Tennessee, T. BARNES, University of Tennessee/Oak Ridge National Laboratory, J. SINCLAIR, University of Tennessee, J. THOMPSON, University of Tennessee/Oak Ridge National Laboratory, R. SACCI, University of Tennessee, J. TURNER, University of Sussex, UK — We present the study of the magnetic susceptibility and inelastic neutron scattering energies and intensities for a spin hexamer formed by two interacting spin \(S\) and \(S'\) trimers. Using an isotropic Heisenberg Hamiltonian, we conclude that, regardless of spin, the structure factors for the magnetic excitations will have a specific function form which is dependent on the symmetric parts of the hexamer being excited. This work is then compared to previous work performed on two vanadium compounds \((\text{CN})_2\text{H}_2\text{O}_2\text{Na}_2\text{H}_2\text{V}_2\text{O}_7\text{(PO}_4\text{)}_3\text{(OCH}_3\text{)}_2\text{OH}_2\text{O})_2\text{1H}_2\text{O}\) and \(\text{Na}_2\text{H}_2\text{V}_2\text{(SO}_4\text{)}_3\text{(OCH}_3\text{)}_2\text{OH}_2\text{O})_2\text{1H}_2\text{O}\), which are thought to be magnetically well described as trimers of \(S=1/2\) \(V^{4+}\) ions. We show that it is possible to that a very weak inter-trimer interaction exists and we predict the energy and momentum transfer dependence for these compounds that may be observable with inelastic neutron scattering.
Can large magnetic anisotropy and high spin really coexist? ClAUDIA LOOSE, Institute for theoretical Physics, TU Bergakademie Freiberg, Leipziger Str. 23, D-09599 Freiberg, Germany, ELISEO RUIZ, JORDI CIRERA, JOAN CANO, SANTIAGO ALVAREZ, Departament de Quimica Inorganica and Institut de Recerca de Quimica Teorica i Computacional, Universitat de Barcelona, Diagonal 647,08028, JENS KORTUS, Institute for theoretical Physics, TU Bergakademie Freiberg, Leipziger Str. 23, D-09599 Freiberg, Germany — This theoretical study discusses the interplay of the magnetic anisotropy and magnetic exchange interaction of two Mn$_{12}$ complexes. Our results for two polynuclear Mn$_{12}$ complexes show a very strong dependence of the D value on the spin of the ground state while the energy barriers are practically constant. Thus, complex 2 with a large spin (S = 12) favoured by ferromagnetic interactions has a small D value, while the lower spin complex 1 (S = 4) has a large D value. Therefore we suggest, that a large magnetic anisotropy is not favoured by a high spin state of the ground state.

1:51PM B27.00009 Time Evolution of Electric Properties of Mn$_{12}$-Acetate Film Measured with Self-assembled Tunneling Junction, LIANXI MA, Dept. of Physics, Texas A&M University, CHI CHEN, GLENN AGNOLET, Texas A&M University — we report the results of tunneling measurement of Mn$_{12}$-Ac thin film (~2 monolayer) at the time right after the film is made and after 6 months. We found that for the fresh film the differential conductance can change suddenly at bias voltage about -0.1 V and staircase form of $I$ − $V$ curves are observed. At about 0 V bias voltage, we see the conductance changes from minimum to maximum as the initial resistance decreases. For the film stored for 6 months, however, all of these properties have been lost and high frequency oscillation on conductance is frequently observed. Also for the stored sample, clean $I$ − $V$ curves are rarely seen. All of these results indicate that deterioration of the molecules after 6 months.

2:03PM B27.00013 Order from disorder in the molecular-based spin ladder Cu(Qnx)Br$_2$, CHRISTOPHER LANDEE, CHRIS SATALINE, BRIAN KEITH, IGOR PARTOLA, MARK TURNBULL, Clark University — Copper quinoxaline dibromide is a molecular-based antiferromagnetic spin ladder in which Cu$_2$Br$_4$ dimers are linked into ladders by the quinoxaline molecules. The rung exchange occurs through the bridging bromide ions while the rail exchange occurs through the organic molecules [1]. It is possible to introduce randomness into this ladder by replacing bromide ions by chlorides, by replacing the quinoxaline molecules by the structurally equivalent 2,3-dimethylpyrazine, or by substituting diamagnetic cadmium ions into the copper sites. In all cases, order occurs at low temperatures (4 to 6 K) as evidenced by FC/ZFC studies, hysteresis and remnant magnetizations, as well as sharp anomalies in the susceptibility. [1] C. P. Landee et al, Polyhedron 22, 2325-2329 (2003).

Monday, March 10, 2008 11:15AM - 1:51PM – Session B28 DMP: Focus Session: Optical Properties of Nanostructures II: Graphene, Graphite and Related Materials Morial Convention Center 220

11:15AM B28.00001 Optical studies of multilayer graphene in magnetic fields, HSIANG-LIN LIU, Department of Physics, National Taiwan Normal University, G. L. CARR, Brookhaven National Laboratory, National Synchrotron Light Source, K. A. WORSLEY, M. E. ITKIS, E. BEKYAROVA, R. C. HADDON, Department of Chemistry, University of California-Riverside, A. N. CARUSO, Center for Nanoscale Science and Engineering, North Dakota State University — We report the optical properties of multilayer graphene thin films grown on silicon substrate. The room-temperature reflectance and transmittance of the samples were measured over the energy range from the far-infrared to near-infrared. To extract the optical constants of the films, we analyzed all of the layers of this thin-film structure using a Drude-Lorentz model. From the parameters obtained, we compute the optical constants. With decreasing temperature, the far-infrared transmittance of the samples is increasing up to 4 % down to 2 K. Interestingly, in an applied magnetic field of up to 10 Tesla, the giant positive magneto-optical effects over 20 % are observed in the far-infrared region from 2 K to 300 K. Possible origin of these will be discussed.

Research at the NSLS is supported by the Department of Energy under contract DE-AC02-98CH10886
11:27AM B28.00002 Edge states and optical transition energies in carbon nanoribbons\(^1\) JIE JIANG, WENCHANG LU, JERRY BERNHOLC, Center for High Performance Simulation and Department of Physics, North Carolina State University, Raleigh, NC 27695-7518 — The local density of states (LDOS) of edge states and optical transition energies in carbon nanoribbons are investigated with density-functional calculations. The LDOS in either magnetic or non-magnetic phases show peaks both below and above the Fermi level. The peaks in the two phases are localized in different energy ranges. Moreover, the LDOS in the two phases have the same decay shapes. The defects at zigzag edges are found to destroy spin-polarization in edge states. They also tend to increase the decay length in edge states by mixing defect and edge states. Thus, the LDOS measured by scanning tunneling spectroscopy shows different features depending on the edge quality. We also find that the optical transition energies \( E_{\text{opt}} \) are not affected by the spin-polarization. However, edge effects tend to increase \( E_{\text{opt}} \) values by 1.25/W, where \( W \) is the ribbon width. Therefore, the ratios of \( E_{\text{opt}} \) in nanoribbons for different \( i \) are changed from those observed in single-wall carbon nanotubes.

\(^1\)We gratefully acknowledge support by DOE, DOD and ONR.

11:39AM B28.00003 Raman Studies of Electron-Phonon Coupling in Graphene and Graphite Intercalated Compounds\(^1\) J. CAMACHO, M. Y. SFEIR, A. T. BOLLINGER, Brookhaven National Laboratory, A. C. WALTERS, C. A. HOWARD, M. ELLERBY, University College London, J. A. MISEWICH, T. VALLA, Brookhaven National Laboratory — Effects of the electron-phonon interaction in carbon-based materials can be seen in many physical properties, ranging from relatively high-Tc superconductivity in doped fullerenes and graphite intercalated compounds to being a limiting factor on the mobility of carriers in carbon nano-tubes. Despite the intensive research, these effects are not completely understood. Here we present Raman scattering studies of several long wavelength optical phonons in different graphite-based materials. We find that the frequency and line-width of some modes are very sensitive to electric field doping and to chemical doping of graphene sheets, reflecting the changes in interactions of these modes with charge carriers in the system.

11:51AM B28.00004 Optical Selection Rule from Inversion Symmetry Breaking and Valley Optoelectronics in Graphene, WANG YAO, DI XIAO, QIAN NIU, The University of Texas at Austin — Inversion symmetry breaking allows contrasted circular dichroism in different \( k \)-space regions, which takes the extreme form of optical selection rules for interband transitions at high symmetry points. In graphene systems with broken inversion symmetry, this enables valley dependent interplay of electrons with light of different circular polarizations, in analogy to spin dependent optical activities in semiconductors. We discuss graphene based valley optoelectronics applications where light polarization information can be interconverted with electronic information.

12:03PM B28.00005 Gate-Variable Optical Transitions in Graphene, FENG WANG, UC Berkeley, YUANBO ZHANG, CHUANSHAN TIAN, CAGLAR GIRIT, ALEX ZETTL, MICHAEL CROMMIE, Y. RON SHEN — Two-dimensional graphene monolayers and bilayers exhibit fascinating electrical transport behaviors. Using infrared spectroscopy we find that they also have strong interband transitions and, remarkably, their optical transitions can be significantly modified through electrical gating. This unique gate-dependence of interband transitions adds a valuable dimension for optically probing graphene bandstructure. For a graphene monolayer, it yields directly the linear band dispersion of Dirac fermions, while in a bilayer it reveals a dominating van-Hove singularity arising from interlayer coupling.

12:15PM B28.00006 Filling-Factor-Dependent Magnetophonon Resonance in Graphene, KOSTYANTYN KECHEDZHI, Physics Department, Lancaster University, Lancaster, LA1 4YB, UK, MARK GOERBIG, JEAN-NOEL FUCHS, Laboratoire de Physique des Solides, Univ. Paris-Sud, CNRS UMR 8502, F-91405 Orsay, France, VLADIMIR FALKO, Department of Physics, Lancaster University, Lancaster, LA1 4YB, UK — We describe a peculiar fine structure acquired by the in-plane optical phonon at the \( \Gamma \)-point in graphene when it is brought into resonance with one of the inter-Landau-level transitions in the material. The effect is most pronounced when this lattice mode is in resonance with inter-Landau-level transitions \( \nu \equiv 0 - \nu_0 \equiv 1 \) at a magnetic field \( B_0 \approx 30 \) T. The predicted mode splitting may be used to measure directly the strength of the electron-phonon coupling, and also to distinguish between circularly (left- and right-hand) polarized lattice modes. A similar effect is predicted in bilayer graphene in lower magnetic fields.

12:27PM B28.00007 Raman Spectrum of Strained Single Layer Graphene\(^1\), MINSHENG WANG, SONG HAN, KANG L. WANG, UCLA — Two-dimensional single layer graphene (SLG) films are very attractive due to their unique electrical and optical properties. In this work, silicon nitride, silicon oxide and polyimide are used to induce strain in SLG sheets. Micro-Raman spectra reveal the evolution of graphene feature peaks under various stress conditions. Different peak position, width and shape are observed due to different stress type, level and direction. Changes of the second order D peaks show that strain affects not only the phonon spectrum but also the electron band through a double resonant Raman process. Relative intensity changes between D and G bands indicate that defects are introduced into graphene during some of the deposition processes, which usually are not observed in spin-coated SLG samples. Strain effects also can be utilized to further modify the electron band structure of graphene.

\(^1\)This work was in part supported by FCRP-FENA (Functional Engineered Nano Architectures).

12:39PM B28.00008 Infrared probe of charge dynamics in graphene transistors, ZHIQIANG LI, University of California, San Diego, ERIK HENRIKSEN, Columbia University, ZHIGANG JIANG, Columbia University/NHMFL, ZHAO HAO, MICHAEL MARTIN, Lawrence Berkeley National Laboratory, PHILIP KIM, Columbia University, HORST STORMER, Columbia University/Bell Labs, DIMITRI BASOV, University of California, San Diego — We report on infrared (IR) spectroscopy of charge dynamics in monolayer graphene. IR reflectance and transmission measurements were performed on graphene transistors as a function of gate voltage. From these data, we obtained the optical conductivity of graphene at various carrier densities. The dominant feature of the optical conductivity is an interband transition with the onset at twice the Fermi energy, which evolves systematically with gate voltage. Similar behavior was observed with the Fermi level on either side of the Dirac point. We will compare these results with theoretical predictions and discuss several new aspects of the charge dynamics in graphene uncovered by this work.

12:51PM B28.00009 The G-band phonon frequency in single layer graphene, HYUNGBIN SON, ALFONSO REINA, MILDRED DRESSELHAUS, JING KONG, Massachusetts Institute of Technology — Recent experimental studies on the high-frequency phonon modes of as-deposited \( n \)-graphene layer (nGL) films report that the frequency of the G-band in single graphene layer is generally higher than that in nGL films (n\( \equiv 2 \)) and highly ordered pyrolytic graphite (HOPG). However, our results show that the frequency of the G-band in single graphene layer approaches that in HOPG when the single graphene layer transferred to different substrate, sonicated, or exposed to \( \text{NaOH} \). These results suggest that the difference in the frequency of the G-band in single graphene layer and HOPG is due to the strain generated in the deposition process.
1:03PM B28.00010 Spatially resolved and polarized Raman spectroscopy of graphene. 
DUHEE YOO, HYERIM MOON, HYEONSOOK CHEONG, Sogang University — Graphene samples were prepared by micromechanical cleavage of graphite flakes on silicon wafer, which was covered with a 300-nm silicon oxide layer. Raman spectra of a single-layer graphene were clearly differentiated from those of a few layers of graphene sheets. We compared the spatially resolved micro-Raman spectra with atomic force microscopy to determine the number of layers for each sample, and variations of Raman spectra, which intensity and shift of Raman peak, were observed through the Raman image. The Raman G peak, corresponding to Raman active mode \(E_2g\), was observed at \(\sim -1590\) cm\(^{-1}\), and \(G^*\) peak due to double resonance Raman scattering was observed at \(\sim -2700\) cm\(^{-1}\). We performed polarized Raman spectroscopy of a single-layer graphene. The intensity of G peak was independent of polarization, in agreement with Raman tensor calculation. The variation of Raman intensity of \(G^*\) peak was measured as a function of the analyzer angle. The intensity was maximum for parallel polarization and was minimum for perpendicular polarization. The depolarization ratio was 1/3.

1:15PM B28.00011 Probing Edge defects in \(n = 1, 2, \ldots\) Graphene Layer system via Raman Scattering. 
HUMBERTO GUTIERREZ, AWNISH GUPTA, PETER EKLUND, Pennsylvania State University — Results of a micro-Raman study (spot size \(\sim 0.7\) microns; 514.5 nm excitation) of an edge (or boundary) of \(n\)-layer graphene films is presented. Graphene \((n=1\text{ layer})\) exhibits a very narrow Lorentzian D-band at \(\sim 1344\) cm\(^{-1}\) with FWHM \(\sim 15\) cm\(^{-1}\). For \(2<n<5\), this narrow peak is found to split into four bands. Interestingly, the D band intensity of the edge is quite strong (1/4 of the G-band). If the defects are truly localized on the edge, this implies a better resonance than found for defects at the interior, or, on the other hand, the range of the defects may extend a long distance into the interior of the films and involve many sites. Polarized Raman studies on this D band were made with the incident field at an angle \(\theta\) with respect to the average direction of the edge. The scattered light was collected either parallel (H) or perpendicular (V) to the edge. The polar intensity plots \(I_H(\theta)\) and \(I_V(\theta)\) were found to exhibit a quadrupolar and dipolar pattern, respectively.

1:27PM B28.00012 X-ray absorption spectroscopy of graphite oxides. 
HAE-KYUNG JEONG, BK21 Physics Division, Center for Nanotubes and Nanostructured Composites, Sungkyunkwan University; LEYLA COLAKEROL, Department of Physics, Boston University, Boston, MA 02215, USA; HAN-JIN NOH, Department of Physics, Chonnam National University, Gwangju 500-757, Korea; YUN PYO LEE, MEI HUA JIN, BK21 Physics Division, Center for Nanotubes and Nanostructured Composites, Sungkyunkwan University, PER-ANDERS GLANS, Department of Physics, Boston University, Boston, MA 02215, USA, JAE-YOUNG KIM, Pohang Accelerator Laboratory & Department of Physics, POSTECH, KEVIN E. SMITH, Department of Physics, Boston University, Boston, MA 02215, USA, CHONG YUN PARK, YOUNG HEE LEE, BK21 Physics Division, Center for Nanotubes and Nanostructured Composites, Sungkyunkwan University — We have investigated electronic structures of graphite oxide using x-ray absorption spectroscopy, and variations of Raman spectra, which intensity and shift of Raman peak, were observed through the Raman image. The polar intensity plots \(I_H(\theta)\) and \(I_V(\theta)\) were found to exhibit a quadrupolar and dipolar pattern, respectively.

1:39PM B28.00013 Symmetry breaking in epitaxial graphene probed by ARPES. 
AARON BOSTWICK, TAISUKE OHTA, JESSICA MCCHESNEY, Lawrence Berkeley National Lab, K. V. EMTSEV, TH. SEYLLER, University of Erlangen, KARSTEN HORN, Fritz Haber Institute, ELI ROTENBERG, Lawrence Berkeley National Lab — The energy bands of n-doped graphene on SiC(0001) have been observed to deviate significantly from the expected conical shape near the Dirac crossing[Bostwick et al 2007, Zhou et al 2007]. Two scenarios have been proposed to explain these deviations, either as originated from the real part of the electronic self-energy due to many-body interactions[Bostwick et al], or from “A–B” symmetry-breaking due to chemical interactions between the graphene and the underlying layer[Zhou et al]. In this talk we present a number of arguments against the A–B symmetry breaking scenario, among which is the observed k-dependent intensity of the Fermi surface as measured by ARPES. We show that the observed intensity distribution is directly sensitive to the degree of A–B symmetry breaking and show that the upper limit for an energy gap in graphene on SiC is much smaller than the observed deviations in the band structure.

11:15AM B29.00001 Intrinsic and Extrinsic Limits of Mobility in Graphene. 
MICHAEL S. FUHRER, Department of Physics and Center for Nanophysics and Advanced Materials, University of Maryland — Graphene is an exciting new condensed matter system, both for the opportunity to observe the physics associated with massless Dirac Fermions in the laboratory, and because of materials parameters which make it attractive for technological applications. However, in the few years since the experimental realization of graphene, progress toward cleaner (higher mobility) samples has largely stalled. I will discuss experiments performed on atomically-clean graphene on SiO\(_2\)[1] in ultra-high vacuum to determine the intrinsic and extrinsic limits of mobility in graphene[2,3], which point out both the promise of the material as well as the technological challenges that lie ahead in realizing better graphene samples. Intrinsic scattering by the acoustic phonons of graphene[3] limits the room-temperature mobility to \(2 \times 10^5\) cm\(^2\)V\(\cdot\)s\(^{-1}\) at a carrier density of 10\(^{12}\) cm\(^{-2}\), higher than any known material. However, extrinsic scattering due to charges in the substrate[2] and substrate polar optical phonons[3] currently impose much more severe limits on the mobility, pointing out the importance of substrate choice for graphene devices[4].

12:03PM B29.00003 Single-particle relaxation time versus scattering time in 2D graphene layers

EUYHEON HWANG, SANKAR DAS SARMA, University of Maryland, College Park — We calculate the transport scattering time ($\tau_s$) and the single particle relaxation time ($\tau_r$) for disordered graphene in the lowest order of the electron-impurity interaction (Born approximation). We find that the ratio of $\tau_r$ to $\tau_s$ is always greater (less) than two for charged Coulomb (short-ranged neutral) scatterers. Thus, the calculated scattering time ratio can be a good criterion of directly selecting the dominating scattering mechanism in graphene. As a direct consequence of the simple form of our results we calculate graphene mobility, damping rate, and density of states of single particle state.

1This work was supported by U.S. ONR, LPS-NSA, and SWAN-NSF-NRI.

12:15PM B29.00004 The Coulomb Impurity Problem in Graphene

VITOR PEREIRA, JOHAN NILSSON, ANTONIO CASTO NETO, Boston University — We address the problem of an unscreened Coulomb charge in graphene and calculate the local density of states and displaced charge as a function of energy and distance from the impurity. This is done nonperturbatively in two different ways: (1) solving the problem exactly by studying numerically the tight-binding model on the lattice and (2) using the continuum description in terms of the 2D Dirac equation. We show that the Dirac equation, when properly regularized, provides a qualitative and quantitative low energy description of the problem. The lattice solution shows extra features that cannot be described by the Dirac equation: namely, bound state formation and strong renormalization of the van Hove singularities.

12:27PM B29.00005 Coulomb Impurity Screening in Graphene

VALERI KOTOV, Boston University — I will discuss the vacuum polarization charge density around a Coulomb impurity with charge $Ze$. Perturbation theory in powers of $Ze$ is the effective coupling constant in graphene), shows that the polarization charge is localized at the impurity site. An exact calculation, based on the Green’s function in a Coulomb field, leads to a non-perturbative result, valid to all orders in $Ze$ [1]. Taking into account also electron-electron interactions in the Hartree approximation, we solve the problem self-consistently in the subcritical regime, where the impurity has an effective charge $Z_{\text{eff}}$, determined by the localized induced charge. We find that an impurity with bare charge $Z = 1$ remains subcritical, $Z_{\text{eff}} < 1/2$, for any $\alpha$, while impurities with $Z = 2, 3$ and higher can become supercritical at certain values of $\alpha$.

LUIS BREY, ICMM-CSIC (Spain), HERBERT FERTIG, Indiana University — In this work we present a detailed study of the conductive properties of wide graphene strips, with two different models for the source and drain leads. We reconfirmed that for undoped graphene, the system can be described by a conductivity in the $L \rightarrow \infty$ limit even when defects are absent from the system, and examined this behavior with respect to a broad range of lead parameters. Our results indicate that the conductance is relatively insensitive to the electronic structure of the leads. We then compute the conductivity of a simple three stripe spin-valve device with graphene acting as the non-magnetic material between the ferromagnetic leads. Two types of ferromagnetic lead systems were considered: one with a single ($s$) orbital for each spin state, with band centers separated in energy to induce spin polarization, and another with a narrow d band which was taken to be spin-polarized. We find that the conductivity depends only weakly on the relative spin orientations of the leads, and therefore the magnetoresistance is rather small for most circumstances, largely due to the insensitivity of the conductivity with respect to conditions in the leads. Our results indicate that, although graphene has properties that make it attractive for spintronic devices, the performance of a graphene-based spin-valve is likely to be poor.

12:51PM B29.00007 Spin transport in graphene strongly coupled to ferromagnetic leads

JELENA TRBOVIC, HAGEN AURICH, GUNNAR GUNNARSSON, CHRISTIAN SCHONENBERGER, University of Basel — We study low temperature spin transport in graphene layers by using NiPd alloy as ferromagnetic contacts. This type of contacts has been successfully used in realizing carbon nanotube-based spin devices. The measurements are done in the temperature range between 240 mK and 1.6 K with average electrode separation of 0.7 µm. We find a clear two-terminal spin-valve signal while sweeping the magnetic field in plane of the device, with about 3% effect. However, the signal rapidly decays with increasing temperature and vanishes above 1.6 K. We believe that the observed rapid dephasing is due to the strong coupling of PdNi contacts to the graphene layer. In addition, three-terminal measurements (quasi non-local) have been done in the same temperature range in order to study the influence of a single NiPd electrode on the observed spin transport.

1:03PM B29.00008 Interference of Electron Waves in a Ballistic Graphene Transistor

SUNGJAE CHO, MICHAEL FUHRER — We have prepared single- and few-layer graphene samples by mechanical exfoliation of Kish graphite on SiO$_2$/Si substrates. We have fabricated graphene field-effect transistors by electron beam lithography followed by thermal evaporation of Cr/Au or Permalign source and drain electrodes; the conducting silicon underneath 300 nm silicon dioxide serves as a back gate electrode. We find that at low temperatures that the two-dimensional plot of conductance as a function of gate voltage and drain voltage shows an interference pattern of maxima and minima which occur along diagonal lines. We analyze the pattern in terms of interference of electron waves reflected between source and drain electrodes. The slope of the lines measures the compressibility of the two-dimensional electron system, and has strikingly different dependence on carrier density (gate voltage) for single- and few-layer graphene samples, as expected theoretically.

1Interference of Electron Waves in a Ballistic Graphene Transistor
1:15PM B29.00009 Local Gating of Graphene Devices via Contactless Top Gates, JAIRO VELASCO JR., GANG LIU, CHUN NING LAU, Department of Physics and Astronomy, University of California at Riverside — Graphene devices with local electrostatic gates are promising candidates for investigation of novel phenomena such as Klein tunneling and the veselago lensing effect. However, it is experimentally challenging to fabricate local gates without inadvertent introduction of dopants or defects. We have developed a novel lithography process that enables fabrication of contactless, suspended top gates above single and bi-layer graphene devices. Using this technique, we have demonstrated graphene p-n junctions. We will discuss latest progress towards electrical transport of such devices in the zero-magnetic field regime, as well as in the quantum Hall regime.

1:27PM B29.00010 Current-Voltage Characteristics of Electrolyte-Gated Graphene Field-Effect Transistors$^1$, INANC MERIC, SEBASTIAN SORGENFREI, MELINDA HAN, BARBAROS OZEYILMAZ, PHILIP KIM, KENNETH SHEPARD, Columbia University — We investigate the current-voltage characteristics of graphene field-effect transistors (FET) with ionic-solution gating. Single-layer graphene FETs are fabricated with different device dimensions and electrolytically gated with a potentialistat in which a Pt counter electrode and an Ag/AgCl reference electrode in a feedback configuration hold the solution at a desired potential. This setup enables the gating of graphene with high efficiency due to the short Debye length and high dielectric constant in ionic solutions, leading to enhanced measured transconductances. Electrolytic gating has direct applicability to field-effect sensor applications of graphene devices.

1:39PM B29.00011 Fabrication of gated suspended graphene devices, KIRILL BOLOTIN, MARTIN KLIMA, KENNETH SIKES, GEOFF FUDENBERG, JAMES HONE, PHILIP KIM, HORST STORMER, Columbia University — We find that graphene acts as a catalyst for the vapor-phase etch of silicon dioxide: silicon dioxide under graphene is etched much faster compared to the bare surface. This is consistent with the presence of a trapped water layer between graphene and the silicon dioxide substrate which accelerates etching of the substrate. This unusual property allows us to fabricate devices where a large-area graphene flake is suspended over a micron-sized trench with the unetched silicon substrate serving as a gate electrode. Electronic transport in the resulting devices suggests enhanced sample mobilities near the Dirac point.

1:51PM B29.00012 High resolution, temperature dependent Raman spectroscopy of graphene, SEBASTIAN RÉMI, CONSTANZE METZGER, BILLY HUBBARD, CLAIRE THOMAS, BENNETT B. GOLDBERG, Boston University, Department of Physics, ANNA SWAN, Boston University, ECE — Single and bi-layer graphene are studied with high resolution, temperature dependent Raman scattering. The electron-phonon coupling in graphene depends sensitively on both the concentration of charge carriers and the temperature. Raman spectroscopy directly probes electron-phonon coupling, and has been used to examine the stiffening of the G-band, phonon damping [1] and spatial inhomogeneities in the carrier density [2]. Our measurements are performed between room temperature and 4K in a confocal scanning Raman system. The samples are back-gated, allowing us to tune the carrier density and spectroscopically map the Raman response. We will discuss our recent measurements. [1] J. Yan, Y. Zhang, P. Kim, and A. Pinczuk, Phys. Rev. Lett. 98, 166802 (2007) [2] C. Stampfer, et al. Arxiv, cond-mat 0709.4156v1.

2:03PM B29.00013 Studies of limitations on the mobility and mean free paths in graphene devices.$^1$, XU DU, IVAN SKACHKO, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — The Dirac Fermion nature of the quasiparticles in graphene has led to many predictions for novel phenomena such as specular Andreev reflections at graphene-superconductor interfaces and a negative index of refraction for transmission of charge across graphene p-n junctions. These predictions presuppose ballistic transport, which requires long mean free paths compared to the distance between leads. However, within current fabrication techniques, the mean free paths of charge carriers in graphene devices are often too short for ballistic transport. The reduced mean free path is primarily due to excess scattering introduced by extrinsic factors such as material imperfections, substrate contamination, e-beam resist residue, chemical doping, contact potential and contact geometry. We will discuss the results of systematic studies of extrinsic factors, highlighting the case of graphene SNS weak links, and will propose strategies to increase the mean free path.

Monday, March 10, 2008 11:15AM - 2:15PM
Session B30 DMP: Focus Session: Carbon Nanotubes and Related Materials III: Synthesis
Morial Convention Center 222

11:15AM B30.00001 Novel Functions in Double Walled Carbon Nanotubes, MORINOBU ENDO, Shinsu University — Nano-sized carbon nanotubes with hollow core were observed when hydrocarbons were catalytically decomposed in the existence of nano-sized catalyst such as iron at higher temperature. Up to now, this catalytic chemical vapor deposition (CCVD) method has been utilized as the most powerful technique for the selective and large-scale production of carbon nanotubes. Since large amount of multi-walled carbon nanotubes (up to 250 ton/year) are available, much efforts has intensified on the development of their industrial usages. A recent hot topic has focused on the synthesis of double walled carbon nanotubes (DWNTs) because these tubes are more thermally and chemically stable when compared to single wall carbon nanotubes (SWNTs); they also exhibiting the 1D character of a quantum wire. In addition, DWNTs could also be used in the fabrication of electron field emitter and nano-composites. Very recently, we have successfully prepared highly pure and crystalline DWNTs by the combination of the CCVD and the subsequent oxidative purification process. In this talk, I will describe the preferential growth of DWNTs over SWNT or MWNTs, their structural characterizations using variuos analytis techniques and their possible applications. We found that these coaxial tubes consist of two relatively round, small and homogeneous-sized (below 2 nm in the outer shell) concentric tubes and are packed in a hexagonal array. Then, I will discuss a novel and stable structure consisting of flattened tubes consisting two SchwNTs via the coalescence of two adjacent tubes, chemical doping effect as a tunable way of electronic structure of DWNTs, and formation of atomic scale metal wires in the hollow core of DWNTs. Finally, I will report their transport properties as well as their performance in field effect transistors as compared with those of SWNTs. Therefore, in the near future, it may be possible that DWNTs replace SWNTs in specific carbon nanotube devices used today.

11:51AM B30.00002 Electron Spin Resonance in Single-Walled Carbon Nanotubes$^1$, W. D. RICE, J. KONO, Rice University — We have performed electron spin resonance (ESR) measurements on various types of single-walled carbon nanotube (SWNT) samples. As catalyst particles were chemically removed from the SWNTs, the linewidth of the conduction electron spin resonance (CESR) signal became smaller, reaching 43 G at 5 K for acid-purified HiPco SWNTs. For every type of SWNT tested, a ferromagnetic resonance (FMR) signal was observed; we show that this is attributed to catalyst particles. The g-factor for the CESR signal was slightly shifted from the free electron value; as purity increased, the resonance moved closer to $g = 2.003$. The conduction electron signal increased as the temperature was decreased, indicating that we are observing both Pauli and Curie paramagnetism. No spin gap for either laser-oven acid-purified or HiPco acid-purified SWNTs was seen when the temperature was taken from 295 K to 5 K. In addition, the FMR signal decreased as the temperature was decreased. SWNTs suspended in aqueous surfactant solutions were also measured. As a function of purity, the FMR signal was substantially decreased. We show that as a function of metal catalyst content, the ESR lineshape of SWNTs changes significantly.

12:03PM B30.00003 IPS verification of the integrity of CNTs walls after purification. PATRICIO HABERLE, SAMUEL HEVIA, RODRIGO SEGURA, UTFSM, MANISH CHHOWALLA, Rutgers University — We report results from measurements by inverse photoemission spectroscopy (IPS) from single wall carbon nanotubes (SWCNTs). We have used this technique to verify the influence of strong purification procedures on the integrity of the tube walls. The purification included an HNO$_3$ immersion in a solution for 3 hours, before a 400 °C annealing. Even though the thin layers of CNTs present a high conductivity, the treated tubes trap the electronic charges from the IPS electron beam. A possible explanation for this apparent inconsistency is that the acid treatment induces the formation of charge traps in the outside tubes of the bundles. RAMAN spectroscopy from the same samples, with and without the acid treatment, show almost no variations. The IPS signal is extremely sensitive to the conditions of the tube’s external wall, while Raman spectroscopy can detect signals from inner tubes. Using IPS may then prove useful to determine electronic quality of CNTs arrays.

12:27PM B30.00005 Controlled Fabrication of Single Electron Transistors from Single-Walled Carbon Nanotubes. PAUL STOKES, SAIFUL I. KHONDAKER, NANOSCIENCE TECHNOLOGY CENTER AND DEPARTMENT OF PHYSICS, UNIVERSITY OF CENTRAL FLORIDA TEAM — Single-walled carbon nanotubes (SWNTs) are considered to be an ideal material for quantum electronic applications such as single electron transistors (SETs). However, fabrication of SET based devices is still in its infancy. Controlled fabrication of SWNT-SETs has been demonstrated by introducing kinks using AFM. However, AFM manipulation is time consuming and reproducibility can be extremely challenging. Here, we show a novel approach to fabricate controllable and reproducible SETs using SWNT. SWNTs were placed on 100 nm wide local Al/Al$_2$O$_3$ bottom gates and then contacted with Pd source and drain electrodes with 1 um spacing on Si/SiO$_2$ substrates. The Al gate serves two purposes: (i) it defines tunnel barriers at the edges of the gate electrodes by introducing buckles, and (ii) it acts as a local gate to tune the number of carriers in the central island. Low temperature electronic transport measurements show coulomb oscillations up to 125 K. The stability diagram shows a charging energy of $\sim 13$ meV and energy level spacing of $\sim 5$ meV. These energies are consistent with a quantum dot size of $\sim 100$ nm, thus verifying the dot is defined and controlled by the 100 nm wide aluminum oxide gate.

12:51PM B30.00007 Structural and Electronic Properties of Single-Walled Carbon Nanotube Heterojunctions$^1$. JOYDEEP BHATTACHARJEE, Molecular Foundry, LBNL., YOUNG WOO SON, Dept. of Physics, Konkuk Univ., Seoul, Korea., BHUPESH CHANDRA, JAMES HONE, Dept. of Mech. Eng., Columbia Univ., JEFFREY B. NEATON, Molecular Foundry, LBNL. — Inspired by recent experiments$^1$, we present a systematic approach to construct structural models of mostly linear single walled carbon nanotube (SWCNT) heterojunctions. A minimum number of 5-7 defects is found to be required to join two SWCNTs of differing chiralities. Using nearest-neighbor tight-binding and first-principles density functional theory, we explore the sensitivity of the heterojunction electronic structure and transport properties to different arrangements of the interfacial 5-7 defects, and discuss their implications for future experiments and nanoelectronic applications.

1:03PM B30.00008 Synthesis and Structure of Carbon Nanotube Junctions and Co$_8$S$_8$ Nanowire-filled Carbon Nanotubes$^1$. WENZHI LI, GAOHUI DU, Florida International University, NANOPHYSICS TEAM — We describe the synthesis of carbon nanotube junctions and Co$_8$S$_8$ nanowire-filled carbon nanotubes by pyrolysis of thiophene on cobalt catalyst in chemical vapor decomposition. The formation of these nanostructures is strongly dependent on the thiophene vapor concentration during the material synthesis. The carbon nanotube junctions have hollow channels while the filled carbon nanotubes have solid Co$_8$S$_8$ cores. The encapsulated Co$_8$S$_8$ nanowires are single crystals, and their lengths are about 10 $\mu$m with their [110] direction parallel to the axis of the carbon nanotubes. It is postulated that the filling of the Co$_8$S$_8$ nanowires results from the volume increase of the catalyst induced by a phase transition from cobalt to cobalt sulfide and the spatial confinement of the carbon nanotubes as nano-molds.

1:15PM B30.00009 Adsorption of Alcohols and Alkanes on Single-Walled Carbon Nanotubes  

ERIK ALLDRIDGE, STEFAN BADESCU, THOMAS REINECKE, NADEEP BAJWA, F. KEITH PERKINS, ERIC SNOW, Naval Research Laboratory  
Recent experiments with arrays of carbon nanotubes (CNTs) reveal a strong electrical response during exposure to polar alkane derivatives such as linear alcohols \( C_nH_{2n+1}OH \), which is in contrast with the weak response to linear alkanes \( C_nH_{2n+2} \). To develop an understanding of the microscopic mechanisms involved, we perform detailed \textit{ab initio} calculations of adsorption geometries and charge configurations for the size parameter \( n \) from 1 to 8 on pristine zig-zag and armchair CNTs. We use Density Functional Theory with localized orbitals in a cluster approach, along with the Möller-Plesset functional appropriate for the weak interactions of physisorption for these systems. We find that adsorption energies are larger for alcohols than for alkanes and increase linearly in energy with length of the molecule \( n \) for both alcohols and alkanes (at 35 meV and 40 meV per additional \( CH_2 \), respectively). This is found to be in good agreement with the binding energy per additional \( CH_2 \) estimated from the fast conductance response measurements for both alcohols and alkanes using a simple kinetic theory model. We estimate small charge transfers for all molecules, which suggest that the electric response is dominated by the scattering from the dipole moments of the adsorbates. [This work is supported by the Office of Naval Research.]

1:27PM B30.00010 Adsorption of neon and tetrafluoromethane on carbon nanohorn aggregates: differences in specific surface area values  

VAIVA KRUNGLEVICIUTE, Southern Illinois University Carbondale, MASAKO YUDASAKA, SUMIO IJIMA, Japan Science and Technology Corporation, c/o NEC Corporation, ALDO MIGONE, Southern Illinois University Carbondale  
We have measured adsorption isotherms for two different adsorbates, neon and tetrafluoromethane, on dahlia-like carbon nanohorn aggregates. The experiments were performed at similar relative temperatures for both gases. The measurements were conducted to explore the effect of adsorbate diameter on the behavior of the resulting adsorbed systems. We measured the effective specific surface area value of the nanohorn sample using both gases, and we found that this quantity was about 22% smaller when we determined this quantity using tetrafluoromethane, the larger molecule. Isothermic heat and binding energy values were also determined from our measurements. We will compare our experimental results with those from a computer simulation study performed by Prof. M. Calib. The simulations help us understand the source of the observed differences in the measured specific surface values, as well as the coverage dependence of the isosteric heat of adsorption for both gases.

1:39PM B30.00011 Application of nanohorns to anti-cancer drug carriers  

MASAKO YUDASAKA, JST, NEC, MINFANG ZHANG, KUMIKO AJIMA, JIN MIYAWAKI, JST, TATSUMI MURAKAMI, KUNIHIRO TSUCHIDA, Fujita Health Univ., SUMIO IJIMA, JST, NEC, Meijo Univ — Potential applications of single-wall carbon nanohorns (SWNH) that have shown no acute toxicity in various tailored animal experiments, to the drug delivery system have been studied. We previously reported that the drugs were able to be incorporated inside SWNH at room temperature through liquid phase, and chemical modifications with hydrophobic molecules enhanced dispersion of SWNHs in aqueous solutions. The modifications with the tumor-targeting molecules were also possible. The contrast agent attachments enabled the in vivo visualization of SWNHs by magnetic resonance imaging. We show in this report how the effects of anti-cancer drugs can be influenced by being incorporated inside SWNHs, and discuss its reasons.

1:51PM B30.00012 Building Physical Carbon Nanoparticles from Small-World Networks: Density Functional Theory Calculations  

JEREMY A. YANCEY, M.A. NOVOTNY, Mississippi State University Dept of Physics and Astronomy, HPCC Center for Computational Sciences, STEVEN R. GWALTNEY, Mississippi State University Dept of Chemistry, HPCC Center for Computational Sciences — We have performed B3LYP/6-31G* Density Functional Theory calculations on carbon cluster nanoparticles built with (pseudo) small-world network topologies to determine whether they are stable and can exist in nature. Such particles may have novel material properties due to their (pseudo) small-world nature [1]. We have embedded a ring of carbons with one or more small-world connections made with and without additional carbon atoms. No carbon is allowed to make more than four bonds. The energy per atom of these (pseudo) small-world carbon systems is compared with benchmark carbon clusters including monocyclic rings, linear rods, graphene fragments, and various fullerences from \( C_{60} \) to \( C_{60} \). The energy per atom and vibrational frequency calculations results for these materials indicate that there are pure-carbon small-world nanomaterials that are reasonable for real world synthesis. We present both NMR and IR spectra for these nanoparticles. [1] M.A. Novotny, et al, J. Appl. Phys, 97, 10B309 (2005).

2:03PM B30.00013 First-Principles Study of Carbon Nanoframeworks Tailored for Hydrogen Storage  

EUNJIA KIM, PHILIPPE WIECK, BALAKRISHNAN NADUVALATH, University of Nevada, Las Vegas, HANSONG CHENG, Air Products and Chemicals, Inc., BORIS YAKOBSON, Rice University — Based on first-principles calculations, we propose a novel class of 3-D materials consisting of small diameter single-walled carbon nanotubes (SWCNTs) functionalized by organic ligands as potential hydrogen storage media. Specifically, we have carried out density functional theory calculations to determine the stable structures and properties of nanoframeworks consisting of \( 5,0 \) and \( 3,3 \) SWCNTs constrained by phenyl spacers. Valence and conduction properties, as well as normal modes, of pristine nanotubes are found to change significantly upon functionalization, in a way that can serve as experimental diagnostics of the successful synthesis of the proposed framework structures. Ab initio molecular dynamics simulations indicate that such systems are thermodynamically stable for on-board hydrogen storage. In order to increase the hydrogen uptake in the interstitial cavity of such nanoframeworks, we are currently investigating the possibility of Li deposition on these nanostructures.

---

11:15AM B31.00001 Optical Properties of Free and Embedded Small Nanoparticles  

JUAN IDROBO, Vanderbilt University and Oak Ridge National Laboratory — It is well known that the absorption spectra, as well as the effective dielectric function, of nanoparticles in vacuum or surrounded by a dielectric medium can be obtained by classical Mie and Maxwell-Garnett theories. A limit as to how the particles can be for the theory to apply has not been established. Here I present theoretical results on the optical properties of small Ag, Au, and Si and Ge nanoparticles with tens of atoms in vacuum and in an embedded dielectric medium obtained from first-principles density-functional calculations. In particular, I will discuss the role that d-electron play on the optical properties of Ag and Au nanoparticles, and the cases when classical Mie and Maxwell-Garnett theories can be applied for nanoparticles of just few atoms in size and whose atoms are in bulk-like and not bulk-like positions. Comparison will be made for nanoparticles in vacuum and in an alumina matrix. The quantum-mechanical results indicate that small nanoparticles in alumina can have an imprint on the effective dielectric function that is several times larger than what is expected from Maxwell-Garnett theory for same-size particles. This work was supported by a GOALI NSF grant, DOE, the Office of Basic Energy Sciences, Division of Materials Sciences and Engineering, and Alcoa Inc. Collaborators: S. Ögüt, K. Jackson, J. Jellinek, A. Halabica, R. F. Haglund, R. Magruder, S.J. Pennycook and S.T. Panteleides.
The results show previous tight-binding calculations greatly exaggerate the electronic response of large fullerenes. Within linear response theory, the SOS polarizabilities are within 1-3% of the finite-field polarizabilities. The polarizability per carbon atom increases from 1.34 in this series, namely C_{240}, to 4 in C_{2160}. This increase is characterized by determining their static dipole polarizabilities by all-electron density-functional theory. We first determine the dipole polarizabilities of C_{2160} and DE-FG02-06ER46286. Computers and mathematics. The electronic response of C_{2160} and DE-FG02-06ER46286. Computers and mathematics.

The fluctuations in the vibrational free energy depend on the elemental environment which is more pronounced in the case of copper atoms. Correlations between Cu atoms in the Cu-core/Ag-shell structure, with coordination 6 show a bi-modal feature with 2 distinct ranges of bond lengths. A global analysis shows that the d band characteristics with coordination/bond length and environment will also be discussed. In addition, correlations between the fluctuations in the vibrational free energy depend on the elemental environment which is more pronounced in the case of copper atoms.

Overall, our theoretical results exhibit quite good agreement with spectra obtained for Ag clusters trapped in rare-gas matrices. We show that the classical predictions from Mie-Gans theory using the bulk dielectric function of Ag are in rather good agreement with experimental results and TDDFT spectra for the ground state and low-energy isomers of Ag_{n} (n = 10 - 20) are presented. The fluctuation in the vibrational free energy depend on the elemental environment which is more pronounced in the case of copper atoms. Correlations between the d band characteristics with coordination/bond length and environment will also be discussed.

Work was supported in part by NSF-ITR 0428826 and DOE grant DE-FG02-03ER46354.

12:39PM B31.00006 Trends in the Electronic Structure and Vibrational Dynamics of 34 atom Ag-Cu Nanoalloy (Ag_{n}-Cu_{34-n})

1, H. YILDIRIM, A. KARA, T.S. RAHMAN, Department of Physics, University of Central Florida — We report results of a systematic study of the electronic and geometric structures as well as vibrational and thermodynamical properties of Ag_{n}-Cu_{34-n}, using density functional theory and model interaction potentials. A detailed analysis of the effect of coordination and atomic environment shows the limitation of coordination to solely explain the changes in the structural and vibrational characteristics. On the other hand, a combination of coordination and environment, as expressed in the elemental characteristics of the neighbors, shows systematic trends in the bond length and vibrational free energy distribution. In addition, Cu atoms in the Cu-core/Ag-shell structure, with coordination 6 show a bi-modal feature with 2 distinct ranges of bond lengths. A global analysis shows that the fluctuations in the vibrational free energy depend on the elemental environment which is more pronounced in the case of copper atoms. Correlations between the d band characteristics with coordination/bond length and environment will also be discussed.

1Work was supported in part by NSF-ITR 0428826 and DOE grant DE-FG02-03ER46354.

12:03PM B31.00003 Bethe-Salpeter and Quantum Monte Carlo Calculations of the Optical Properties of Carbon Fullerenes

P.R.C. KENT, M.L. TIAVO, F.A. REBOREDO, Oak Ridge National Laboratory, RANDOLPH Q. HOOD, Lawrence Livermore National Laboratory — We have calculated the low energy optical excitations of the carbon fullerenes C_{20}, C_{24}, C_{50}, C_{60}, C_{70}, and C_{80}. Properties are calculated via the GW-Bethe-Salpeter Equation (GW-BSE) and diffusion Quantum Monte Carlo (QMC) methods. We compare these approaches with time-dependent density functional results and with experiment. GW-BSE and QMC have previously shown good agreement for small molecules, but this is the first study of these methods for these larger yet prototypical nanostructures. The first ionization potentials are consistently well reproduced and are similar for all the fullerenes and methods studied. However, electron affinities and first triplet exciton show substantial method and geometry dependence. GW-BSE yields triplet energies around 1 eV below the QMC results. We discuss the possible reasons for these differences. Research at Oak Ridge National Laboratory performed at the Materials Science and Technology Division, sponsored by the Division of Materials Sciences, and at the Center for Nanophase Materials Sciences, sponsored by the Division of Scientific User Facilities, U.S. Department of Energy. Research at Lawrence Livermore National Laboratory was performed under Contract DE-AC52-07NA27344.
**1:03PM B31.00008 Heusler clusters**1. ALEXEY ZAYAK, University of Texas at Austin, SCOTT BECKMAN, Rutgers University, MURILIO TIAGO, Oak Ridge Natl. Laboratory, PETER ENTEL, University of Duisburg-Essen, JAMES CHELIKOWSKY. University of Texas at Austin — Real space pseudopotential calculations are used in order to investigate the properties of Heusler clusters. Bulk-like clusters with various Ni-Mn-Ga compositions have been examined in the size range from 15 up to 169 atoms. Among these compositions the closest to the stoichiometric Ni$_2$MnGa are the most stable. These clusters retain tendency for tetragonal distortion, which is inherited from the bulk properties. Although, the surface effects dominate suppressing the tetragonal structure in the smaller clusters, the bigger clusters develop a bulk-like tetragonal distortion. We predict the existence of switchable Ni-Mn-Ga clusters, which might be of great interest for the nano-Magnetic-Shape-Memory technology.

1This work was supported by the National Science Foundation under Contract No. DMR-0551195, by the U.S. Dept. of Energy under Grants No. DE-FG02-06ER46286 and DE-FG02-06ER15760, by the Computational Material Science Network of the U.S. Dept. of Energy.

**1:15PM B31.00009 Tangential Ligand-Induced Strain in Icosahedral Au13**. LEEROY KRONIK, OLGA GULIAMOV, Weizmann Institute of Science, ANATOLY FRENKEL, Yeshiva University, LAURENT MENARD, RALPH NUZZO, University of Illinois — A quantitative comparison of first principles calculations with extended x-ray absorption fine structure and transmission electron microscopy measurements provides strong evidence that Au$_{13}$ nanocrystals are stabilized in a slightly distorted icosahedral structure by on-top phosphine ligands and a combination of on-top and bridging thiol ligands. Importantly, the ligands change the icosahedral strain (i.e. the radial-tangential bond length ratio) significantly, with the tangential bonds within the Au core exhibiting much more disorder than the radial ones.

**1:27PM B31.00010 Structural Properties and Phase Transitions in Small Gold Nanoclusters**. YANTING WANG, SERGEY RASHKEEV, Idaho National Laboratory — Small gold nanoclusters (below 5 nm in diameter) exhibit good catalytic activity. Molecular dynamics simulations combined with the parallel tempering method have been used to investigate the bulk and surface structural properties and phase behavior of small gold nanoclusters ($10^3$-$10^4$ atoms). For small clusters, the transition from solid to liquid does not occur at a definite temperature. Instead, one gets a temperature range within which the transition state from solid to liquid is observed, and this range become broader for nanoclusters with smaller number of atoms. In this work, we perform an analysis of structural and dynamic properties of gold nanoparticles of different sizes and show that the nature of the solid-liquid phase transition in very small nanoparticles (with tens of atoms) is radically different from that of the mid-sized ones ($10^2$-$10^3$ atoms). The surface characteristics of the particle (the presence of low-coordinated atoms at the surface and the dynamic fluxionality, i.e., an ability of the surface to reconstruct) that define its catalytic behavior are also investigated and analyzed.

**1:39PM B31.00011 The peculiar distribution pattern of Pd on the PdAu bimetallic nanoclusters**1. DINGWANG YUAN, University of California, Irvine, XINGAO GONG, Fudan University, RUQIAN WU, University of California, Irvine — Through systematic density functional calculations, we found that Pd atoms in PdAu nanoclusters may only take the (111) facets while leave the (001) facets with pure Au. This is promoted by the tendency that Pd prefers to form bonds with Au, rather than with Pd. The segregation from the (001) facet to the (111) facet appears to occur easily. The local activity of Pd somewhat depends on the size of cluster and site of substitution. The peculiar distribution pattern of the active constituent should strongly alter the chemical properties of bimetallic nanoclusters toward catalyzing reactions.

1Work was supported by the DOE-BES (grant No: DE-FG02-04ER15611). Calculations are performed on supercomputers in the NERSC.

**1:51PM B31.00012 Computational model for the production of monodisperse silver spheres in solution**1. DANIEL ROBB, IONEL HALACIUGA, VLADIMIR PRIVMAN, DAN GOIA, Clarkson University — We report the results of computational modeling of the production of monodisperse, spherical silver particles through the rapid mixing of reducing agent and silver-amine complex solutions, in the absence of a protective colloid. We find that the process can be modeled effectively by a two-stage reaction mechanism used previously to model the production of gold particles [1]. Here, we treat both the equilibrium concentration of silver atoms and the surface tension of silver particles as free parameters in our simulation, finding that the reaction time scale is fit by a narrow region of this parameter space. As in the previous work on gold particles, a kinetic ‘dimer suppression factor’ is required to limit the number of final particles produced. In addition, we consider an extension of the two-stage reaction model which incorporates the effect of the silver-amine complexation reaction on the availability of Ag monomers. [1] J. Park, V. Privman, and E. Matijevic, J. Phys. Chem. B 105, 11630 (2001).

Session B32 GMAG DMP: Focus Session: Nanocontacts and Inhomogeneous Magnetic States

**11:15AM B32.00001 Theory of magnetic interactions and transport in tunnel junctions and point contacts**. EVGENY TSYMBAL, University of Nebraska-Lincoln — No abstract available.

**11:51AM B32.00002 Fabrication of point contacts by FIB patterning**1. B. O’GORMAN, M. TSOI, University of Texas at Austin, Austin, TX — Nanoscale electrical contacts currently receive an increased amount of attention due to their capability to produce extremely high current densities needed, e.g., in experiments on current-driven precession and reversal of magnetization. Here we describe a new technique for the fabrication of such point contacts using a focused ion beam (FIB) patterning. FIB-fabricated point contacts combine the robustness and size-control of other lithographical methods with the flexibility of mechanical techniques to produce contacts to samples of arbitrary shape and composition. After sample coverage with a thin insulating layer (SiO$_2$), an FIB is used to mill a 100-nm-diameter hole through the insulator. Electrical contact to the sample is then made in-situ by filling the hole with a metal (Pt) using the ion beam assisted chemical vapor deposition capability of our FIB system. We have demonstrated the use of two such contacts (as an emitter and collector) in a transverse electron focusing (TEF) experiment. The contacts were made to a single crystal of bismuth, ballistic electrons were injected into the crystal through the emitter, and then focused onto the collector by a magnetic field. We see the expected voltage peaks at the collector as a function of the applied magnetic field.

12:03PM B32.00003 Electronic excitations in four structurally similar but magnetically different nickel chain compounds. V.C. LONG, Y.H. CHOU, J.A. CROSS, A.C. KOZEN, L.A. LAVOLET, C.A. MILLER-SHELLEY, J.R. MONTAGUE, E.P. PLUMB, Colby College, S.A. MCGILL, X. WEI, National High Magnetic Field Lab, B.R. LANDRY, K.R. MAXCY-PEARSON, M.M. TURNBULL, C.P. LANDEE, Clark University, R.D. WILLET, Washington State University — We report the low temperature zero-field and magnetic-field-dependent optical spectra of four Ni$^{2+}$ chain compounds: NENP (Ni[en]$^2$NO$_2$ClO$_4$), NENB (Ni[en]$^2$NO$_2$BF$_4$), NTNB (Ni[tn]$^2$NO$_2$BF$_4$), and NINO (Ni[tn]$^2$NO$_2$ClO$_4$). The four differ in the counterions isolating the chains and the rings coordinated to the Ni$^{2+}$ ions. Despite the structural similarities, only three of the compounds exhibit the Haldane gap typical of a spin-1 chain; the fourth, NTNB, behaves like spin glass, likely due to finite chain effects. We focus on the near infrared spin-forbidden (SF) electronic $d - d$ transitions and the visible Ni$^{2+}$-to-NO$_2^-$ charge transfer (CT) band. The zero-field absorption spectra differ in the en and tn ring compounds but are nearly identical in compounds with identical rings. The SF and CT band absorption intensities depend on field in a way that reflects the magnetic ground state. In the Haldane compounds, the onset of intensity changes occurs above the crossover field, whereas in NTNB the field-dependent absorption intensities respond to any finite field.

12:15PM B32.00004 Theory and application for chain formation in break junctions. YURIY MOKROUSOV, ALEXANDER THIESS, Institute of Applied Physics, University of Hamburg, Jungiusstrasse 11, 20355 Hamburg, Germany, STEFAN BLUGEL, Institut fuer Festkoerperforschung, Forschungszentrum Juelich, 52425 Juelich, Germany, STEFAN HEINZE, Institute of Applied Physics, University of Hamburg, Jungiusstrasse 11, 20355 Hamburg, Germany — We introduce a generic model for chain formation in break junctions by formulating separate criteria for the stability and producibility of suspended monoatomic chains based on total energy arguments. Using first-principles calculations [1], we apply our model to break junctions of 1d and 2d transition-metals (TMs), as well as Ag and Au, including the effects of spin-polarization and spin-orbit coupling. Thereby, we can explain the physical origin of the experimentally observed trend of increasing probability for the creation of long suspended chains in break junctions for 1d-TMs at the end of the series [2] and suppressed chain elongation for 2d elements. Moreover, we clarify why the probability of chain elongation is greatly enhanced by the presence of oxygen in experiments with Au and Ag. Our model also allows us to make predictions on the ballistic transport properties of suspended chains. [1] Y.Mokrousov et al., Phys. Rev. B 72, 045402 (2005). [2] R.H.M.Smit et al., Phys. Rev. Lett. 87, 266102 (2001).

12:27PM B32.00005 Anderson model of local magnetism at a break junction nanocontact. PAOLA GENTILE, SISSA, Democritos, Trieste, Italy, MICHELE FABRIZIO, GIUSEPPE E. SANTORO, EROS TOSATTI, SISSA, Democritos, ICTP, Trieste, Italy — Atoms at break junction nanocontacts in nearly magnetic heavy transition metals such as Pt and Pd may develop a nonzero magnetization. Since here the nanocontact is strongly electronically tied to the two bulk leads, it is not automatically clear what the correct physical picture of the system should be, and in particular whether the nanocontact should or should not become analogous to a Kondo impurity in quantum dot devices. To clarify this, we consider one (or more) impurity sites inserted into a linear chain (representing the nonmagnetic leads), every site endowed with orthogonally degenerate orbitals, large spin orbit coupling, and Hund’s rule exchange; neighboring sites connected by electron hopping and by intersite ferromagnetic exchange. The mean-field solution when the impurity site (where Hund’s rule exchange is made stronger) is locally magnetic shows a ferromagnetic polarization around it, in agreement with realistic density functional calculations for nanocomposites consisting of monatomic chain segments. Our results suggest that this type of nanocontact, regarded as an Anderson impurity, is ferromagnetically coupled to the leads, and hence that Kondo screening does not occur in this case. The physical consequences for the conductance through the chain are discussed.

12:39PM B32.00006 Dynamics of a pinned magnetic vortex. ROBERT COMPTON, University of Minnesota — Disks patterned from soft ferromagnetic films typically form a single magnetic vortex for diameters on the order of a few microns or less. The vortex dynamics include both ordinary spin waves and a gyroscopic mode, in which the vortex core undergoes circular motion about its equilibrium position [1, 2]. This mode has sub-GHz frequencies which ideally depend on the aspect ratio (diameter over thickness) of the disk [2, 3]. We have used time-resolved Kerr microscopy to investigate the gyroscopic mode as a function of the equilibrium position of the core, which can be tuned by an applied field with a sensitivity of ~ 1 nm/Oe. In the limit of high excitation amplitude, the gyrotropic frequency $f_G$ is independent of the vortex core position, as previously predicted and observed [1, 3]. For small amplitudes, however, we observe unexpected fluctuations in $f_G$ as a function of the applied field. The average core displacement between consecutive frequency peaks, as well as the average frequency shift, is observed to be independent of disk diameter. These observations indicate that the fluctuations are due to a distribution of nanoscale defects that pin the vortex core by lowering its energy [4]. Furthermore, they are consistent with a model in which the frequency shift for a particular fluctuation is a direct measure of the interaction energy of the vortex core with one defect. By mapping $f_G$ as a function of orthogonal in-plane static fields, we image the 2D spatial distribution of defects with nanoscale resolution.

1:15PM B32.00007 Angular Dependence of Vortex Annihilation Field in Asymmetric Co Nanodots. RANDY DUMAS, KAI LIU, Physics Department, UC Davis, THOMAS GREDIG, CHANG-PENG LI, IVAN K. SCHULLER, Physics Department, UC San Diego — Magnetization reversal via a vortex state is a common occurrence in sub-micron magnetic nanodots. We have investigated arrays of 500 nm polycrystalline Co dots prepared by e-beam lithography. The circular symmetry of the dots has been broken by introducing a flat edge to the dots. Magneto-optical Kerr effect (MOKE) measurements and micromagnetic simulations confirm the reversal mechanism of the dots is via the nucleation, propagation, and annihilation of a vortex core. The asymmetric dot shape favors vortex nucleation from the flat edge and therefore allows for control over the vortex chirality. Additionally, by modifying the applied field sweep, we can control which side of the dot the vortex annihilates from. We have studied the vortex annihilation field as a function of the angle between the applied field and the flat edge of the dot. At small angles, the annihilation field depends on the chirality of the vortex and annihilation is easier from the flat edge of the dot. The difference in annihilation fields for the two chiralities is strongly dependent on the angle of the applied magnetic field. This behavior is due to the complex motion of the vortex core across an asymmetric dot during reversal. This work supported by ACS-PRF, AFOSR-MURI, and the Alfred P. Sloan Foundation.

1:15PM B32.00007 Angular Dependence of Vortex Annihilation Field in Asymmetric Co Nanodots. RANDY DUMAS, KAI LIU, Physics Department, UC Davis, THOMAS GREDIG, CHANG-PENG LI, IVAN K. SCHULLER, Physics Department, UC San Diego — Magnetization reversal via a vortex state is a common occurrence in sub-micron magnetic nanodots. We have investigated arrays of 500 nm polycrystalline Co dots prepared by e-beam lithography. The circular symmetry of the dots has been broken by introducing a flat edge to the dots. Magneto-optical Kerr effect (MOKE) measurements and micromagnetic simulations confirm the reversal mechanism of the dots is via the nucleation, propagation, and annihilation of a vortex core. The asymmetric dot shape favors vortex nucleation from the flat edge and therefore allows for control over the vortex chirality. Additionally, by modifying the applied field sweep, we can control which side of the dot the vortex annihilates from. We have studied the vortex annihilation field as a function of the angle between the applied field and the flat edge of the dot. At small angles, the annihilation field depends on the chirality of the vortex and annihilation is easier from the flat edge of the dot. The difference in annihilation fields for the two chiralities is strongly dependent on the angle of the applied magnetic field. This behavior is due to the complex motion of the vortex core across an asymmetric dot during reversal. This work supported by ACS-PRF, AFOSR-MURI, and the Alfred P. Sloan Foundation.
1:27PM B32.00008 Influence of excitation fields on vortex core dynamics in micron-sized magnetic disks\textsuperscript{1}. XIUEMEI CHENG, DAVID KEAVNEY, KRISTEN BUCHANAN, RALU DIVAN, Argonne National Laboratory — Magnetization vortices in micron-sized magnetic disks have been of great interest because of potential applications in memory devices. Theory predicts a rich spectrum of excitations including the fundamental or gyrotropic mode. Experimentally the gyrotropic mode is observed in some experiments while in others a linear or elliptical trajectory is seen. We have imaged free vortex core motion in permalloy disks of $6 \mu m$ diameter using time-resolved x-ray photoemission electron microscopy at beamline 4-ID-C of the Advanced Photon Source with 90 ps temporal resolution. We demonstrate that the vortex core motion trajectory depends on the magnitude of the excitation field. The vortex core exhibits a gyrotropic trajectory under low excitation fields, while under high excitation fields the core shows a more linear trajectory. We find that if the initial displacement of the core is greater than 20\% of the disk radius, transient magnetic domains appear in the first 1 ns after removal of field. These domain states then profoundly influence the subsequent motion. The core oscillation frequencies are consistent with theoretical predictions, regardless of the excitation amplitude.

1:39PM B32.00009 Direct Observation of Magnetic Vortex Cores using Scanning Electron Microscopy with Polarization Analysis (SEMPA), SEOK-HWAN CHUNG, CNST, NIST, Gaithersburg, MD 20899 / Maryland NanoCenter, University of Maryland, College Park, MD 20742, DANIEL PIERCE, JOHN UNGURIS, CNST, NIST, Gaithersburg, MD 20899 — Magnetic singularities associated with magnetic vortex cores are a common feature in patterned magnetic nanostructures. Their small size, on the order of 10 nm, makes them technologically interesting, but also difficult to measure or image directly. We used Scanning Electron Microscopy with Polarization Analysis (SEMPA) to image magnetic vortices in a wide variety of patterned nanostructures. Since SEMPA can measure both the in-plane and the out-of-plane component of the surface magnetization, SEMPA can potentially determine both the chirality and the polarity of the vortex core, simultaneously. Samples consisted of NiFe (25nm) / Ta (3nm), and other soft magnetic films, patterned by electron beam lithography and lift-off into disks with various diameters. The films were grown on 85nm thick SiN membranes to reduce image degradation from backscattered electrons. The experimental results were compared to micromagnetic simulations and the vortex core profile showed a good correspondence with theoretical predictions, which considers only the exchange and magnetostatic energy. This work has been supported in part by the NIST-CNST/UMD-NanoCenter Cooperative Agreement.

1:51PM B32.00010 Transition states of magnetization reversal in ferromagnetic nanorings, GABRIEL CHAVES-O'FLYNN, ANDREW KENT, DANIEL STEIN, New York University — Thin ferromagnetic rings are of interest for fundamental studies of magnetization reversal, in part, because they are a rare example of a geometry for which an analytical solution for the rate of thermally induced switching has been determined [1]. The theoretical model predicts the transition state to be either a global magnetization rotation of constant azimuthal angle or a localized fluctuation, denoted the instanton saddle. Numerically we have confirmed that for a range of values of external magnetic field and ring size the instanton saddle is energetically favored [2]. The model takes the annular width to be small compared to the mean radius of the annulus; in which case the main contribution to the magnetization energy comes from the surface magnetostatic energy. We present numerical micromagnetic calculations of the activation energy for thermally induced magnetization reversal for the two different transition states for the case when the annular width is equal in magnitude to the mean radius of the ring. Results of the total and surface magnetostatic energies are compared for different ring sizes. [1] K. Martens, D.L. Stein, A.D. Kent, PRB 73, 054413 (2006) [2] G.D. Chaves-O'Flynn, K. Xiao, D.L. Stein, A. D. Kent, arXiv:0710.2546 (2007)

2:03PM B32.00011 Probing a SET nanomagnet with shot noise, L.D. CONTRERAS-PULIDO, Instituto de Ciencia de Materiales de Madrid, CSIC, Spain., J. FERNANDEZ-ROSSISSERT, Universidad de Alicante, Spain., R. AGUADO, Instituto de Ciencia de Materiales de Madrid, CSIC, Spain. — Although recent experiments show that single atomic spins [1] and molecular magnets [2] can be probed via transport measurements, their magnetic properties can hardly be tuned once they are fabricated. In a recent Letter [3], we have shown that a single-electron transistor (SET) based upon a 11-ML semiconductor quantum dot and doped with a single Mn ion behaves like a quantum nanomagnet with magnetic properties which can be controlled electrically. Conversely, the electrical properties of this SET depend on the quantum state of the Mn spin. Here, we extend these previous ideas and study the shot noise of this kind of nanomagnets. Our results reveal that shot noise contains much more information that the one contained in the average current. Interestingly, important quantities of the nanomagnet like the spin relaxation time and information about current-induced spin precession can be directly extracted from shot noise measurements. Monday, March 10, 2008 11:15AM - 2:03PM — Session B33 DMP GMAG FIAP: Focus Session: Spin Dependent Phenomena in Semiconductors: II Morial Convention Center 224

11:15AM B33.00001 Imaging Drift and Diffusion of Accumulation from the Spin Hall Effect\textsuperscript{1}. N.P. STERN, D.W. STEUERMAN, S. MACK, A.C. GOSSARD, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — The spontaneous generation of spin polarization near sample edges by the spin Hall effect when electron currents flow in a metal or semiconductor with spin-orbit coupling has attracted recent attention due to the elegant and complex spin-orbit physics as well as the potential for all-electrical spin generation in spintronics devices. Optical techniques in semiconductors allow for spatial resolution of the electrically generated spin accumulation, a feature not present in all-electrical measurements. We use Kerr rotation microscopy to image the spatial and temporal evolution of spin accumulation produced by the extrinsic spin Hall effect in n-GaAs devices. Measurements in a variety of device geometries, including arms transverse to a channel, reveal the unambiguous contribution of longitudinal spin drift in accumulation profile.\textsuperscript{2} We develop one- and two-dimensional drift-diffusion modeling to explain the observed features, providing a more complete understanding of observations of spin accumulation and the spin Hall effect.

11:27AM B33.00002 ABSTRACT WITHDRAWN

11:39AM B33.00003 Fractional Charge and Topological Pumping in the Quantum Spin Hall Insulators, TAYLOR HUGHES, XIAO-LIANG QI, SHOUCHENG ZHANG, Stanford University — We study the physics at the edge of a 2d topological (quantum spin Hall) insulator. This system is known to be topologically non-trivial and a profound manifestation of topologically non-trivial states of matter is the occurrence of fractional charge. In this work, we show that a magnetic domain wall at the edge of the quantum spin Hall insulator carries one half of the unit of electron charge, and we propose an experiment to directly measure this fractional charge on an individual basis. As an additional consequence, a rotating magnetic field can induce a topologically pumped dc electric current, and vice versa. Finally, we discuss an interacting version of this model in which the fractional charge is carried by the fundamental excitations. These physical phenomena can be derived from a generic topological effective action for topological insulators and are directly related to the physics of the second Chern number as will be described in another talk.
that the Anderson localization-delocalization transition between the metallic and insulating phases belong to the conventional symplectic universality class $Z_2$. Extensive numerical calculations indicate that the two models have exactly the same universal QSHE conductance fluctuation value $\pi/2$. This is confirmed by the analytical solution for a hard-wall boundary, which also yields the detailed distribution of the local spin polarization. The latter shows a universal distribution rather than a Gaussian distribution. Our results strongly suggest that the quantized spin-Hall conductance fluctuation belongs to a new universality class.

in the spectral distribution of the local spin density. Fast (Friedel) oscillations with the spin-orbit coupling entering via the period of slow beatings only. Long-wavelength contributions of evanescent and normal modes exactly cancel each other in the spectral distribution of the local spin density. The result is confirmed by the analytical solution for a hard-wall boundary, which also yields the detailed distribution of the local spin polarization. The latter shows a universal distribution rather than a Gaussian distribution. Our results strongly suggest that the quantized spin-Hall conductance fluctuation belongs to a new universality class.

1:03PM B33.00010 Network Model for $Z_2$ Quantum Spin-Hall Effects with Disorder, HIDEAKI OBUSE, AKIRA FURUSAKI, RIKEN, Japan, SHINSEI RYU, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, CHRISTOPHER MUDRY, Paul Scherrer Institute, Switzerland — We study the effects of static disorder on the $Z_2$ quantum spin-Hall effect for noninteracting electrons on the propagation of noninteracting electrons subjected to spin-orbit couplings with the time-reversal symmetry. This network model is different from past network models belonging to the symplectic symmetry class in that the propagating modes along the links of the network has a single Kramers doublet. By investigating this network model numerically, it is found that a two-dimensional metallic phase of finite extent is embedded in insulating phases. We also find that the Anderson localization-delocalization transition between the metallic and $Z_2$ insulating phases belong to the conventional symplectic universality class in two dimensions.
and challenges of UNCD-electronics, which will be discussed, are (a) the possibility of controlled doping of these films, (b) the influence of doping on chemical and ferromagnetic ring nanodevices. A brief discussion and

1:15PM B33.00011 Intrinsic spin-Hall effect in the presence of an in-plane magnetic field\(^1\), LUYAO WANG, CHONSAAR CHU, National Chiao Tung University, ANATOLY MALSHUKOV, Russian Academy of Sciences, Institute of Spectroscopy — The intrinsic spin-Hall effect (SHE) induced by a driving electric field \(E_x\) in the presence of an in-plane magnetic field \(\vec{B}\) in a 2D semiconductor strip is studied. In the diffusive regime, the spatial distribution of spin densities \(S_i(x=\pm x_0, y)\) is calculated from a spin diffusion equation derived from nonequilibrium Green’s function. For the case of Rashba spin-orbit interaction (SOI), we find that the spin polarization \(S_x\) normal to the 2D strip remains zero with or without the in-plane magnetic field. For the case of Dresselhaus SOI, where cubic term is included, the symmetry of \(S_x\) with respect to the in-plane magnetic field depends on the orientation of the \(\vec{B}\) field. With \(\vec{B}\) along \(x\), \(S_x\) exhibits symmetric dependence on \(B_z\). However, with a transverse in-plane magnetic field, along \(y\), at the edge of the strip exhibits asymmetric dependence on \(B_y\). These results lead to a possible diagnostic tool for the identification of the SOI in the system.

\(^1\)National Science Council of ROC, NSC95-2112-M-009-004.

1:27PM B33.00012 Phase transition between quantum spin Hall and ordinary insulating phases, SHUCHI MURAKAMI, Tokyo Institute of Technology and PRESTO, JST, SATOSHI ISO, KEK, YSHAI AVISHAI, Ben-Gurion University and RTRA project, LPS and CEA, MASARU ONODA, CERC, AIST and CREST, JST, NAOOTO NAGAOCHA, University of Tokyo, CREST, JST, and CERC, AIST — We theoretically study the phase transition between the quantum spin Hall (QSH) and insulator phases, which involves a change of the \(Z_2\) topological number. We deal with 2D and 3D systems without impurity and interaction. We introduce a parameter \(m\) controlling the phase transition, and we study whether the gap closes or not by one-parameter tuning. In general, level repulsion prevents the gap from closing. In fact, the physics of the \(Z_2\) topological number is encoded in the problem whether the gap closes by tuning a single parameter. In 2D \([1]\), as well as in the 3D inversion-symmetric systems \([2]\), the gap closes at one point, \(m = n_0\), whereas in 3D inversion-asymmetric systems \([2]\), there appears a finite regime for \(m (n_1 < m < n_2)\) showing a gapless phase between the QSH and insulator phases. In the gapless phase the monopoles and antimonopoles exist in the \(k\)-space, and they annihilate in pair at the gap opening. Implications of the present results to real materials \([3]\) are discussed. \([1]\) S. Murakami et al., Phys. Rev. B76, 205304 (2007). \([2]\) S. Murakami, New J. Phys. 9, 356 (2007). \([3]\) S. Murakami, Phys. Rev. Lett. 97, 236805 (2006).

1:39PM B33.00013 A voltage probe of the spin Hall effect\(^1\), YURIY PERSHYN, MASSIMILIANO DI VENTRA, Department of Physics, University of California, Santa Barbara, California 93106, USA — The spin Hall effect does not generally result in a transverse voltage. We predict that in systems with inhomogeneous electron density in the direction perpendicular to the main current flow, the spin Hall effect is instead accompanied by a transverse voltage. We find that, unlike the ordinary Hall effect, this voltage is quadratic in the longitudinal electric field for a wide range of parameters accessible experimentally. We also predict spin accumulation in the bulk and sharp peaks of spin Hall induced charge accumulation near the edges. Our results can be readily tested experimentally, and would allow the electrical measurement of the spin Hall effect in non-magnetic systems and without injection of spin-polarized electrons.

\(^1\)This work is partially supported by NSF Grant No. DMR-0133075.

1:51PM B33.00014 Spin-charge Separated Excitations in a Topological Insulator, DUNG-HAI LEE, YING RAN, ASHVIN VISHWANATH, University of California, Berkeley — We construct a simple, controllable, two dimensional model based on a topological band insulator. It has many attractive properties. The main conclusions are: (1) The quasiparticles exhibit spin-charge separation. (2) It suggests an alternative way to classify \(Z_2\) topological insulator without resorting to the sample boundary. (3) The quasiparticle condensation triggers a phase transition from a spin liquid to an insulating easy-plane ferromagnet.

Monday, March 10, 2008 11:15AM - 1:39PM — Session B35 FLAP: Focus Session: Emerging Materials and Devices I Morial Convention Center

11:15AM B35.00001 The Nanoelectronics Research Initiative and Beyond CMOS Research Activities in the US, GEORGE I. BOURIANOFF, Intel — The six leading Semiconductor Companies in the US have joined forces with Federal and State government to form the Nanoelectronics Research Initiative in 2005. The goal is to find new information processing paradigms, systems and devices which will extend Moore’s Law functional scaling into the indefinite future. The research activities are guided by 5 central research vectors which define the scope and content of the program and are listed below.

1. Computational state variables other than electronic charge
2. Non-equilibrium systems out of equilibrium with the thermal environment
3. Novel information transport mechanisms
4. Nanoscale thermal management
5. Directed self assembly of complex heterostructures

The current NRI research effort consists of 56 projects at 25 universities and 3 research centers in a coherent program where each project is aligned with one or more of the research vectors. During the past two years, significant progress has been made in a number of areas including spin wave, generation, detection and characterization, room temperature DMS materials, femtosecond magnetic domain switching characterization, improved MQCA structures, multiferroic and, magnetoelectric materials and devices, non-conformational metal insulator phase transitions in \(\mathrm{ VO}_2\) and ferromagnetic ring nanodevices. A brief discussion and references will be provided.

11:51AM B35.00002 Diamond Nanoelectronics\(^1\), IGOR ALTFEDER, Air Force Research Laboratory, JACQUELINE KRIM, North Carolina State University, ANDREY VOEVODIN, Air Force Research Laboratory — Thin films of ultra-nanocrystalline diamond (UNCD) represent an extremely promising nanoelectronic material. The electronic devices based on UNCD can operate at temperatures exceeding by an order of magnitude the working temperature of silicon-based devices. This talk will describe the recent STM/AFM study of CVD-grown UNCD films. The most important advances and challenges of UNCD-electronics, which will be discussed, are (a) the possibility of controlled doping of these films, (b) the influence of doping on chemical structure of UNCD surfaces and interfaces, and (c) exploring extremely low surface adhesion/friction of UNCD for design of MEMS.

\(^1\)Research supported by AFOSR/MURI.
12:03PM B35.00003 Low frequency Noise in Top-Gated Ambipolar Carbon Nanotube Field Effect Transistors. GUANGYU XU, Department of Electrical Engineering, University of California at Los Angeles (UCLA), FEI LIU, IBM T. J. Watson Research Centers (IBM), SONG HAN, UCLA, KOUNGMIN RYU, Department of Electrical Engineering, University of Southern California (USC), ALEXANDER BADMAEV, CHONGWU ZHOU, USC, KANG L. WANG, UCLA, UCLA TEAM, IBM TEAM, USC TEAM — Low-frequency noise of top-gated ambipolar carbon nanotube field effect transistors (CNT-FET) with aligned CNT growth onto the quartz substrate is presented. The noise of top-gated CNT-FETs in air is lower than that of back-gated devices, and is comparable with that of back-gated devices in vacuum. This shows that molecules in air act as additional scattering sources, which contribute to the noise. Different noise amplitudes in the electron-conduction region and hole-conduction region are due to both the Schottky barriers (SB) with respect to the conduction band and valance band and the scattering in the channel. The SB contact determines the sample conductance, and thus the noise; the channel scattering also determines the noise. The impact of channel length to the noise amplitude is discussed. This device offers a potential low noise CNT-FET structure.

3Work supported by DARPA and AFOSR.

12:15PM B35.00004 Nanopositioning of Individual Vertical Aligned Carbon Nanotubes on Interconnects. REGINALD C. FARROW, AMIT GOYAL, SHENG LIU, ZAFAR IQBAL, GORDON A. THOMAS, New Jersey Institute of Technology, LINUS A. FETTER, Bell Laboratories — Electrophoresis has been used to deposit single wall carbon nanotubes in arrays of sub-100 nm windows in insulating thin films over metal interconnects. The number of nanotubes that are deposited depends on the electric field and the geometry of the windows and nanotubes. Surface charge on the insulator causes the windows to become nanoscopic electrostatic lenses. Under certain readily achievable conditions only one nanotube will be deposited at the base of a window since each deposited nanotube modifies the electric field. This discovery enables the process integration of vertical aligned carbon-based electronics with more traditional technologies such as complementary metal oxide semiconductor (CMOS) using the current generation of lithography and process technology. Devices such as vertical field effect transistors and interconnected nanopore arrays may now be fabricated in the metal levels of CMOS integrated circuits to facilitate three-dimensional polyhilitic circuit architectures.

3Work supported by DARPA and AFOSR.

12:27PM B35.00005 Impact Ionization in Photocurrent Measurements of Carbon Nanotube p-n Junctions. NATHANIEL GABOR, Lab of Atomic and Solid State Physics, Cornell University, Z. ZHONG, LASSP, Cornell U., K. BOSNICK, Natl Inst for Nanotech, Natl Research Council of Canada, J. PARK, Chem. and Chem. Biology, Cornell U., P.L. MCEUEN, LASSP, Cornell U. — We investigate the photocurrent response at a nanotube gated p-n junction using a focused laser illumination source. Scanned photocurrent imaging demonstrates that photocurrent response occurs primarily in the p-n junction. Measurements in an optical cryostat down to 4K reveal large photoresponse and unusual step-like structure in the reverse bias photocurrent. We relate the intersection point of the forward bias photocurrent to the flat band condition in the device and infer the band gap, which is in excellent agreement with the band gap determined by thermal activation and diameter measurements. The striking photocurrent steps in reverse bias occur at intervals roughly equal to the band gap. We attribute these steps to impact ionization and carrier multiplication in the junction region of the device. By measuring the photon energy dependence of the impact ionization process, we determine that ionization occurs with high probability for carriers in the second and higher subbands of carbon nanotubes. These results show that nanotube p-n junctions provide an ideal system for probing carrier dynamics and interactions of electrons and holes in nanotubes.

12:39PM B35.00006 High Performance Silicon Nanowire Field Effect Transistor. QILIANG LI, Professor of Electrical Engineering, George Mason University, XIAOXIAO ZHU, YANG YANG, DIMITRIS IOANNOU, JOHN SUEHLE, CURT RICHTER — We report the fabrication and characterization of double-gated Si nanowire field effect transistors with excellent electrical characteristics and a small subthreshold slope: ~ 85 mV/dec. The Si nanowires were grown by chemical vapor deposition at pre-defined location on a 50 nm thermal SiO$_2$ (bottom gate oxide). The source/drain electrodes (Al) were formed by using photolithographic alignment and metal lift-off processes. A thin layer of SiO$_2$ was deposited on the HfO$_2$ as a buffer layer before the top gate electrode formation (Al, using photolithographic and lift-off processes). This self-aligned process enables the integration of a large number of high-quality nanowire transistors for electronic circuitry. We have investigated the effect of device structure and annealing conditions on the final device performance, and developed theoretical models to assist the device optimization.

1We acknowledge the support of the NIST Office of Microelectronics Programs and Semiconductor Electronics Division.

12:51PM B35.00007 Effects of Non-Ideal Edges in Graphene Nanoribbons. D. BASU, M.J. GILBERT, L.F. REGISTER, S.K. BANERJEE, Microelectronics Research Center, The University of Texas at Austin, A.H. MACDONALD, Department of Physics, The University of Texas at Austin — We report quantum mechanical transport simulations of the edge effects of nanoribbons of two-dimensional (2D) graphite sheets or graphene. Semiconducting graphene nanoribbons have the potential to augment Si technology because of their excellent electronic properties. In practice we find that scattering from the vacant sites in an otherwise perfect armchair edge of graphene reduces its transmission characteristics drastically. These effects decrease as the widths of the ribbons increase and as the number of steps along the edges decrease. However, band gap of these semiconducting graphene decreases as the width increases, leading to an increase in the band-to-band leakage current. We conclude that without atomic precision to define perfect edges, it may not be practical to use very narrow graphene layers as a semiconducting material for field effect transistors (FETs). Our tight-binding treatment of vacancies allows us to study not only FET-like devices, but also the effect of disorder that breaks symmetry in the graphene sheet for more exotic applications such as pseudospin-type devices.

1:03PM B35.00008 Determination of Non-Accumulative Effects in PCMO Resistive Switches. STEPHEN TSUI, NILANJAN DAS, Y.Q. WANG, Y.Y. XUE, Texas Center for Superconductivity at the University of Houston, C.W. CHU, Hong Kong University of Science and Technology, Technology Center for Superconductivity at the University of Houston, Lawrence Berkeley National Laboratory — In recent years, the observation of electric field induced resistive switching occurring at the interface between a Ag electrode and Pr$_{0.7}$Ca$_{0.3}$MnO$_3$ (PCMO) thin film has stirred a great deal of activity. The controllable switching, depending on the applied voltage polarity, associated with this and other perovskite oxide systems may very well be a means to develop new nonvolatile memory devices. However, a consensus has not yet been reached on the origins of the physical mechanism, be it lattice rearrangement, electromigration, charge trapping, or carrier doping. An important issue is whether the switching behaves in an accumulative fashion, e.g. driven by a change in oxygen stoichiometry through ion-migration. We explore the situation through transport properties, switching characters and the size dependence of the switching area. Our results indicate that a large scale accumulation driven mechanism is not likely for the switching and that a local structural rearrangement may be a more reasonable physical process.
1:15PM B35.00009 A Physical Model for Resistive Switching In Metal-Oxide Interface, NILANJAN DAS, STEPHEN TSUI, YURI WANG, YUJU XUE, Department of Physics, University of Houston and TCSUH, CHING-WU CHU, Department of Physics, University of Houston, TCSUH, LBNL, California and HKUST, Hong Kong — Resistive switching in metal-oxide interfaces has been studied extensively and different models have been proposed. We have investigated the switch in metal-PMO (Pr$_{0.7}$Ca$_{0.3}$MnO$_3$) sample. Interface R and C, both have been found to be frequency independent almost up to 10 MHz. Also the activation energy for both the states (High and Low) are almost the same with bulk as found in R(T) plot. The physical picture will be very shallow potential wells, which may not be enough for retention observed. A pure electronic process (trapping and de-trapping in defects) of carrier only, as suggested earlier, will not be correct answer.

1:27PM B35.00010 Percollative model for resistance switching, S. H. CHANG, S. C. CHAE, J. S. LEE, S. B. LEE, Seoul National University, D.-W. KIM, Hanyang University, B. KHANG, T. W. NOH, Seoul National University — There have been research efforts on resistive switching in numerous insulating oxide films for the next nonvolatile memory device. Recently percolation has been considered as a key concept to explain unipolar memory switching [1]. The rupture process of conducting path is closely related to thermal heat budget induced by Joule-heating effect. In this process, the thermal heat dissipation during rupture could play important role in details of unipolar memory switching. In this study, we investigated correlation between the resistance switching behaviors of Pt/NiO/Pt capacitor structures and thermal heat dissipation as a function of the bottom electrode and temperature. Our modified percolative simulation and finite element analysis demonstrated these phenomena. [1] S. C. Chae et al., Adv. Mat., to be published (2007).

Monday, March 10, 2008 11:15AM - 1:39PM —
Session B36 GIMS: Focus Session: Advances in Scanned Probe Microscopy I: Low Temperatures
Morial Convention Center 228

11:15AM B36.00001 Subkelvin spin polarized STM: measuring magnetization curves of individual adatoms, JENS WIEBE, Institute of Applied Physics, University of Hamburg — Magnetic nanostructures consisting of a few atoms on non-magnetic substrates are explored as model systems for miniaturized data storage devices and for the implementation of novel spin-based computation techniques. Since these nanostructures are well defined and controllable on the atomic scale, they are ideally suited to study the fundamentals of magnetic interactions. We used spin polarized scanning tunneling spectroscopy at subkelvin temperatures to image the magnetization of individual adatoms as a function of an external magnetic field. This allows to directly measure their magnetic interactions at very low energy scale. We will present the design of the 300mK STM [1] and then focus on the results. Interestingly, Co atoms on Pt(111) behave paramagnetic even at very low temperatures. 300 times smaller than the previously reported giant barrier between up and down spin [2]. A peculiar variation in the saturation flux density, which is measured for each atom, is found. This is attributed to their mutual indirect exchange via the substrate electrons. Indeed, we observe an interaction between the adatom and a Co monolayer stripe oscillating with distance between ferromagnetic and antiferromagnetic coupling on the scale of the Fermi wavelength.

11:51AM B36.00002 Investigation of Acceptor States and Landau Levels in (In,Mn)As by Scanning Tunneling Spectroscopy, YOUNG JAE SONG, NIST-CNST/UMD-NanoCenter, NIKOLAI ZHITENEV, JOSEPH STROSCIO, Center for Nanoscience and Technology, NIST, Gaithersburg, MD, GREGORY RUTTER, PHILLIP FIRST, Georgia Tech., Atlanta, GA — Increased interest in spin-based electronics as a replacement for charge-based electronics has led to significant scientific attention on dilute magnetic semiconductors (DMS). Magnetically doped III-V semiconductors are a strong research focus, with the aim of achieving higher Curie temperatures by understanding the microscopic nature of ferromagnetism in these DMS materials. In this presentation, we discuss our recent study of single Mn acceptor states in InAs(110). Mn impurities deposited at low temperature are substituted by using STM atom manipulation techniques to exchange a Mn atom with a surface In atom [1]. Voltage-dependent imaging and scanning tunneling spectroscopy (STS) reveal a number of electronic states associated with the Mn acceptor state and the Landau levels in the 2D subbands of an accumulation layer as a function of applied magnetic field. This work has been supported in part by the NIST-CNST/UMD-NanoCenter Cooperative Agreement, NSF grant ECS-0404084, and Dept. of Commerce/NIST grant 60NANB7D6166. [1] Dale Kitchen et al, Nature 442, 436 (2006).

12:03PM B36.00003 Atomic manipulation and tunneling spectroscopy on vacancy of Ag(111) surface studied with LT-STM, DANDA P. ACHARYA, KAI F. BRAUN, SAW W. HLA, Ohio University — The evolution of the surface state and the effect of vacancies on the Ag(111) surface are investigated at an atomic scale by combining scanning tunneling microscopy and spectroscopy and atom manipulation at 5 K. Various vacancy sizes, from one atom to hundreds of atoms, on Ag(111) are first created by tip-sample contact in a controlled manner. Using lateral manipulation, a vacancy is filled one at a time and the corresponding differential conductance spectra are recorded. Small energy shifts in the onset of surface state are observed. The shift is more pronounced for small size vacancy and becomes less and less pronounced for larger size vacancies. The observed dI/dV intensities at different size of vacancies clearly reveals that the surface state onset on Ag(111) disappears after reaching towards the 6th layers.

12:15PM B36.00004 Direct detection of force gradient using atomic force microscopy with very small oscillation amplitude, TOSHU AN, ATSUSHI NOMURA, TAKAHIRO NISHIO, TOYOAKI EGUCHI, KOTONE AKIYAMA, YUKIO HASEGAWA, The Institute for Solid State Physics, The University of Tokyo — Using a quartz, which has a self-sensing capability, simple configuration of atomic force microscopy (AFM) is realized, and because of its high stiffness frequency-modulation (FM) operations with a small oscillation amplitude below 100 pm is possible. The small amplitude AFM operation enhances sensitivity of short range forces. Moreover, a force gradient can be directly detected from force vs. distance measurements. We carried out FM-AFM at low temperature (LT) in ultra-high vacuum using a quartz length-extension resonator with a tungsten tip (Spring constant and resonant frequency of the resonator are 540 000 N/m and 1 MHz, respectively) (An et al., APL 76, 133114 ’05). The system was simply made by attaching an extra electrode to the tip-holder of our LT scanning tunneling microscope cooled by He (APL 88, 113115 ’06). Direct detection of the force gradient was performed on the Si(111) 7X7 surface using very small oscillation amplitude of 70 pm at 2.4 K.

2:present address, Institute for Materials Research, Tohoku Univ.
12:27PM B36.00005 Low-Temperature Nanotribology of Au and Pb using a Quartz Tuning-Fork. CARLOS UNTIEDT, GIOVANNI SAENZ-ARCE, Depto. Fisica Aplicada. Universidad de Alicante. — Quartz Tuning-Fork (TF) has been in recent years successfully implemented in force detection schemes for scanning probe microscopy (SPM) applications. Here we report its use as a nanotribometer for measuring friction in atomic size areas. The idea behind such a friction detector, is to take advantage of the large Q-factor of a TF ($Q_{air} \sim 6000$, $Q_{vac} \sim 20000$ at room temperature) which in our set-up depends of the SPM tip-sample dissipative forces. We have measured the Q-factor and the resonance frequency for various TFs. As a first step in the use of a TF as a nanotribometer, we studied the reactive forces that are associated with the combined local elastic properties of the sample and tip and calculated the damping rate associate with changes of the tip-sample distance. Finally, we show the variation of the measured damping rate and local spring constants with tip-sample distances for Au and Pb. For the measurement we have used our TF-nanotribometer at different temperatures ranging from 1.5K to room temperature in high vacuum.

12:39PM B36.00006 A Nano-Scale Scanning SQUID Susceptometer for the Measurement of Isolated Magnetic Moments. NICHOLAS C. KOSHNICK, Stanford University, MARTIN E. HUBER, University of Colorado Denver, JULIE BERT, HENDRIK BLUMH, Stanford University, JEFFREY LARGE, HAL EDWARDS, Texas Instruments, KATHRYN A. MOLER, Stanford University — Superconducting Quantum Interference Devices (SQUIDs) are well known as excellent magnetic field sensors. We present a scanning DC SQUID susceptometer that is designed to couple well to nanometer-sized objects. Its gradiometric design and local field coils allow for cancellation of the applied field so that dynamic range issues do not limit the SQUID’s sensitivity. Integrated modulation coils linearize the signal and allow for optimal performance at all applied fields. Planar coaxial shielding, enabled by a multi-layer niobium process, results in a low inductance (100 pH) millimeter scale design where the pickup loops can be optimized independently from the junction and shunt resistor parameters. The sensor loop is on a terraced structure so that it can be scanned approximately 100 nm from the sample surface. Focused Ion Beam milling is used to fabricate pickup loops with inner diameters between 250 nm and 2 microns with line widths of approximately 200 nm. A white noise sensitivity of 0.8 $\mu$V/$\sqrt{Hz}$ gives an estimated spin sensitivity of 80 $\mu$G/$\sqrt{Hz}$ at 4 Kelvin. We will also report on on-going scanning susceptometry measurements, and on the spin sensitivity at low temperatures.

12:51PM B36.00007 Absolute in-situ calibration piezoelectric quartz tuning fork force Sensors. SANJAY BIDASARIA, Georgia Tech, ALEXEI MARCHENKOV, Georgia Tech, MARCHENKOV GROUP TEAM — A method has been developed for absolute calibration of piezoelectric quartz tuning forks for use as force sensors with nano-newton resolution. The performance of the forks in a cryogenic environment is investigated. The mechanical properties of the forks are extracted from the frequency dependent admittance and compared to the exact model of a vibrating cantilever in a helium atmosphere. The method is verified by simple application of calibrated point loads to the cantilever in vacuum.

1:03PM B36.00008 A UHV-LT-STM System for Optical Experiments1. DAVID R. DAUGHTON, DONGHUN LEE, JAY A. GUPTA, The Ohio State University — The combination of optical techniques and scanning tunneling microscopy (STM) provides insight into a diverse set of physical processes including surface chemistry, surface-photon interactions, and spin scattering in semiconductors. We present a novel cryogenic setup, ultrahigh vacuum STM which incorporates a manipulable, high numeric aperture lens, with sub-5 micron spot size, in proximity to the tunnel junction. Modifications to our microscope have been made to improve upon the 12.5 K base temperature and 10 pm tip stability. Our initial efforts are focused on studies of photo-chemical reactions and chemical identification by tip-enhanced Raman spectroscopy (TERS). UHV deposition techniques have been developed for a variety of molecules well suited for TERS studies including azulene, azobenzene, methylene blue, and C60. Electrochemically and chemically-etched Au and Ag are optimized for field enhancement with characterization by scanning electron microscopy and collection of the plasmon emission from the tip. Raman spectra have been collected from molecule-coated tips in vacuum to test the optical setup for TERS.

1:15PM B36.00009 Photon-induced Molecular Motion Probed by STM. JUN ZHANG, KEVIN KELLY, Rice University, TAKASHI SASAKI COLLABORATION, JAMES TOUR COLLABORATION — To understand the mechanisms of nanoscale motion and manipulation in true molecular machines, we have investigated fullerenes and fullerene-based derivatives with an eye towards the molecular rolling motion on surfaces. Assisted by scanning tunneling microscopy (STM), we have successfully observed several bi-functional reactions between the chemically stable recording layer and the external photonics and tunneling electron excitations. In particular, we investigated a fullerene dimer structure which included an azo-based linkage. This system demonstrated a mechanical switching by incident irradiation, due to the azo transformation between the "cis" and "trans" states. This is particularly exciting in true molecular machines, we have investigated fullerenes and fullerene-based derivatives with an eye towards the molecular rolling motion on surfaces.

1:27PM B36.00010 Using a Geophone for Vibration Cancellation in a STM. ALAN FANG, ZHANYEBEK ALPICHSHEV, AHARON KAPITULNIK, Stanford University — We demonstrate a method for using a geophone (velocity-sensitive vibration sensor) for reducing the vibration-induced tunnel current noise in a Scanning Tunneling Microscope (STM). Some simple analog circuitry compensates for the transfer function of the vibration-induced noise for the experimental setup. Almacel-Lucent — Study of the energy gap of the fractional quantum Hall effect (FQHE) in the second Landau level will be presented. Two symmetrically doped GaAs/AlGaAs quantum well samples with densities $n = 3.2 \times 10^{11}$ cm$^{-2}$ and $n = 2.8 \times 10^{11}$ cm$^{-2}$ with respective mobilities of $\mu = 28.3 \times 10^5$ cm$^2$/Vs and $\mu = 10.5 \times 10^5$ cm$^2$/Vs were studied. In the higher mobility sample, clear FQHE states are observed at filling factor $\nu = 5/2, 7/3, 8/3, 14/5, 11/5, 12/5, 16/7, and 19/7$. Some of the higher order FQHE states disappear in the lower mobility sample, and clear FQHE states are observed at $\nu = 5/2, 7/3, 8/3, 14/5, and 11/5$. The energy gaps of the FQHE states at $\nu = 5/2, 7/3$ and 8/3 in the higher mobility sample are found to exceed 500mK. The energy gaps of the $\nu = 5/2, 7/3$ and 8/3 states in the lower mobility sample are typically reduced by more than 50% in comparison. Our measured gap for $\nu = 5/2$ state, which is less than 1/5 of the theoretical gap, can be understood when the finite width correction and disorder broadening is taken into account. Evolution of the energy gaps with mobility shows that the even-denominator FQHE state at $\nu = 5/2$ is the most robust FQHE state in the second Landau level. In addition, the $\nu = 7/3$ and 8/3 states are unlikely to be the second Landau level analog of the Laughlin states at $\nu = 1/3$ and 2/3 in the lowest Landau level.

Monday, March 10, 2008 11:15AM - 2:15PM — Session B37 FIAP: FQHE in Higher Landau Levels Morial Convention Center 229

11:15AM B37.00001 Evolution of the Fractional Quantum Hall States in the Second Landau Level. H.C. CHOI, W. KANG, University of Chicago, S. DAS SARMA, University of Maryland, L.N. PFEIFFER, K.W. WEST, Alcatel-Lucent — Study of the energy gap of the fractional quantum Hall effect (FQHE) in the second Landau level will be presented. Two symmetrically doped GaAs/AlGaAs quantum well samples with densities $n = 3.2 \times 10^{11}$ cm$^{-2}$ and $n = 2.8 \times 10^{11}$ cm$^{-2}$ with respective mobilities of $\mu = 28.3 \times 10^5$ cm$^2$/Vs and $\mu = 10.5 \times 10^5$ cm$^2$/Vs were studied. In the higher mobility sample, clear FQHE states are observed at filling factor $\nu = 5/2, 7/3, 8/3, 14/5, 11/5, 12/5, 16/7, and 19/7$. Some of the higher order FQHE states disappear in the lower mobility sample, and clear FQHE states are observed at $\nu = 5/2, 7/3, 8/3, 14/5, and 11/5$. The energy gaps of the FQHE states at $\nu = 5/2, 7/3$ and 8/3 in the higher mobility sample are found to exceed 500mK. The energy gaps of the $\nu = 5/2, 7/3$ and 8/3 states in the lower mobility sample are typically reduced by more than 50% in comparison. Our measured gap for $\nu = 5/2$ state, which is less than 1/5 of the theoretical gap, can be understood when the finite width correction and disorder broadening is taken into account. Evolution of the energy gaps with mobility shows that the even-denominator FQHE state at $\nu = 5/2$ is the most robust FQHE state in the second Landau level. In addition, the $\nu = 7/3$ and 8/3 states are unlikely to be the second Landau level analog of the Laughlin states at $\nu = 1/3$ and 2/3 in the lowest Landau level.
We give numerical evidence that at $\nu_{\text{Hall}}$ states in the first excited Landau level including $1$ induce a partially or fully polarized superconducting state. Field theory for coexisting order parameters, and show that even if repulsion is smaller than that required for a Stoner instability, ferromagnetic fluctuations can be crucial to recent proposals of topologically protected quantum computation. Most schemes to determine the statistics of the quantum Hall quasiparticles rely on the Coulomb interaction. In this work we consider the finite thickness of the electrically polarized quasi-2D quantum confinement in three models: Zhang-Das Sarma, infinite square-well, and Fang-Howard potentials, respectively. We calculate overlap between the Laughlin (fillings $1/3$ and $1/5$) or Pfaffian (filling $1/2$) and the corresponding exact state, obtained by exact diagonalization, in the lowest, second, and third LLs as a function of the layer thickness. We find that the Pfaffian state becomes a nearly exact description of the physics at filling factor $1/2$ in the SLL for a finite value of thickness. We also show the comparative trends in the ground state energy and the excitation gap as a function of layer thickness, comparing among the first, second, and third LLs. We acknowledge support from Microsoft Q Project. [1] Das Sarma et al. PRL 94, 166802(2005)

Our high density $(n=10^{11}$cm$^{-2}$) and high mobility GaAs samples are of sufficient quality such that well-defined quantum Hall states are resolved at $\nu=8/3$, $5/2$, and $7/3$ in the bulk at low temperature. In particular, we have studied the impact of confining geometry design and the size of the qpc opening on the stability of higher order fractional states in the qpc.

12:15PM B37.00006 Confinement of Fractional Quantum Hall States, ROBERT WILLETT, MICHAEL MANFRA, KEN WEST, LOREN PFEIFFER, Bell Laboratories — The quasiparticles of certain exotic quantum Hall states in the first excited Landau level including $\nu=5/2$ and $\nu=12/5$ are believed to obey non-Abelian statistics. Manipulation of such quasiparticles is crucial to recent proposals of topologically protected quantum computation. Most schemes to determine the statistics of the quantum Hall quasiparticles rely on the manipulation of the correlated state in confined geometries. As a preliminary step in this direction, we report on the magnetic field and temperature dependences of transport through quantum point contacts (qpc’s) in the regime where the first excited Landau level is partially occupied in the confined region. Our high density $(n=4x10^{11}$cm$^{-2}$) and high mobility GaAs samples are of sufficient quality such that well-defined quantum Hall states are resolved at $\nu=8/3$, $5/2$, and $7/3$ in the bulk at low temperature. In particular, we have studied the impact of confining geometry design and the size of the qpc opening on the stability of higher order fractional states in the qpc.

12:27PM B37.00007 Fractional Quantum Hall Hierarchy and the Second Landau Level, PARSAN BONDERSON, Microsoft Station Q, J.K. SLINGERLAND, Dublin Institute for Advanced Studies — We generalize the Haldane-Halperin hierarchy picture to apply to non-Abelian fractional quantum Hall states, and propose trial wave functions to describe the observed Hall conductance plateaux in the second Landau level. These hierarchy states are constructed over the Moore-Read state, the expected description of the $\nu=5/2$ plateau, and thus all have electron pairing in the ground state and an excitation spectrum that includes non-Abelian anyons of the Ising model $\sigma$-vortex type.

12:39PM B37.00008 Edge States and Interferometers in the Pfaffian and anti-Pfaffian States, WAHEB BISHARA, California Institute of Technology, CHETAN NAYAK, Microsoft Station Q, UCSB — In this work we use two theoretical candidates for describing the $\nu=5/2$ Quantum Hall state, the Moore-Read Pfaffian and its particle-hole conjugate, to calculate the conductance of a two point contact interferometer in the weak tunneling regime. We invoke the appropriate edge theory and calculate the conductance as a function of temperature and voltage, and we establish the connection to the underlying bulk topological theory.
12:51PM B37.00009 Spectrum of Quantum Entanglement in Fractional Quantum Hall States

HUI LI, F.D.M. HALDANE, Princeton University — We present numerical studies of the bipartite entanglement in fractional quantum Hall (FQH) states. We partitioned the (spherical geometry) Landau-level orbitals into two hemispheres: the entanglement spectrum derived from the Schmidt decomposition \(|\psi = \sum \exp(-\beta r/2)|\psi_A^\alpha \otimes |\psi_B^\beta\rangle\), where \(|\psi_A^\alpha\) (or \(|\psi_B^\beta\rangle\) are orthonormal. The \(\beta\)s are “energy levels” of a system with thermodynamic entropy at “temperature” \(k_B T = 1\) equivalent to the entanglement entropy. The entanglement spectrum, i.e., the relation between the \(\beta\) and the quantum numbers that classify \(|\psi_A^\alpha\) (or \(|\psi_B^\beta\rangle\) serves as a “fingerprint” of the topological phase of the FQH state, and reveals much more information than just the entanglement entropy, a single number. The spectrum of, e.g., the 1/3 Laughlin state has far fewer levels than expected for a generic wavefunction, and its low-energy spectrum corresponds to that of a conformal field theory (CFT). We studied the wavefunctions that interolate between the Laughlin state and the ground state of a realistic Coulomb interaction potential at \(\nu = 1/3\): the generic number of levels is restored, but the low-lying CFT structure remains essentially unchanged. We also describe the interpolation between the Moore-Read state and the Coulomb interaction ground state at \(\nu = 5/2\).

1:03PM B37.00010 Model Wavefunctions For Non-Abelian Quasiparticles

B. ANDREI BERNEVIG, F.D.M. HALDANE, Princeton University — We present model wavefunctions for quasiparticle (as opposed to quasihole) excitations of the Zk parafermion sequence (Laughlin/Moore-Read/Read-Rezayi) of Fractional Quantum Hall states. These states satisfy two generalized clustering conditions: they vanish when either a cluster of \(k+2\) electrons is put together, or when two clusters of \(k+1\) electrons are formed at different positions. For Abelian Fractional Quantum Hall states (\(k = 1\)), our construction reproduces the Jain quasielectron wavefunction, and elucidates the difference between the Jain and Laughlin quasiparticle constructions. For two (or more) quasiparticles, our states differ from those constructed using Jain’s method. By adding our quasiparticles to the Laughlin state, we obtain a hierarchy scheme which gives rise to a non-abelian \(\nu = \frac{3}{2}\) FQH state.

1:15PM B37.00011 Jack Polynomials, Exclusion Statistics, and non-Abelian FQHE States at \(\nu = k/(km + r)^1\)

F. D. M. HALDANE, B. ANDREI BERNEVIG, Princeton University — We describe a general family of non-Abelian FQHE states at \(\nu = k/(km + r)\) with polynomial wavefunctions \(\prod_{i<j}(z_i - z_j)^m J_k^{(m)}(z_1, \ldots, z_N)\), where \(J_k^{(m)}\) is a symmetric Jack polynomial with negative (coprime) rational parameter \(\alpha = -(k+1)/(r-1)\), and \(\lambda\) is the “most compressed” \(\{k, r, N\}\)-admissible” partition. These polynomials are dominated by an occupation-number pattern maximally-obeying the generalized Pauli rule that no (consecutive) group of \(km + r\) orbitals contains more than \(k\) particles and \((m > 0)\) no group of \(m\) orbitals contains more than one. This exclusion rule defines a space of polynomials characterized by how they vanish as clusters of particle coordinates contract to a point. The edge of these FQHE states has a fractionally-quantized thermal Hall effect with \(e_{\text{eff}} = k/(km + r)\), derived from the exclusion rule. The \(r = 2\) family are the Laughlin, Moore-Read, and Read-Rezayi states, related to unitary conformal field theories. The \(r > 2\) families are related to non-unitary \(W_{k + 1 + r}^*\) cft, but (as polynomials) have well-defined quasi-hole propagators, which overcomes the principal objection to the proposition that non-unitary cft’s can describe FQHE states. The \(m = 1, r = k + 1\) set are a non-Abelian alternative construction of states at 2/5, 3/7, 4/9, \ldots.

1Supported in part by NSF MRSEC DMR02-13706.

1:27PM B37.00012 Searching for anyons in a realistic model of fractional quantum Hall liquids

ZI-XIANG HU, Zhi-Xiang Hu, Dept. Phys, ZheJiang Univ, PR China, XIN WAN, Dept. Phys, ZheJiang Univ, PR China, PETER SCHMITTECKERT, Institute of Condensed Matter Theory, University of Bonn — We study quasihole/particle excitations in a microscopic model of fractional quantum Hall liquids with long-range Coulomb interaction and an edge confining potential. We find with a local trapping potential quasihole/particle states can emerge from the Laughlin and the Moore-Read states. The presence of Abelian and non-Abelian quasiholes has a distinct effect on the corresponding edge spectra. The stability of quasiholes/particles depends on the detail of the confining potential and the trapping potential. We discuss the relevance of the calculation to the high-accuracy generation and control of individual anyons in potential experiments, in particular, in the context of topological quantum computing.

2Supported in part by NSF MRSEC DMR02-13706.

1:39PM B37.00013 Probing Non-Abelian Statistics in \(\nu = 12/5\) Quantum Hall State\(^1\)

KAM TUEN LAW, Brown University — The tunneling current and shot noise between two Fractional Quantum Hall edges in \(\nu = 12/5\) state in electronic Mach-Zehnder Interferometer with two quantum point contacts (QPCs) is studied. We show that the tunneling current and shot noise can be used to probe the existence of non-Abelian statistics in the \(k = 3\) Read-Rezayi state. More specifically, the dependence of the current on the Aharonov-Bohm flux in the Read-Rezayi state is asymmetric under the change of the sign of the applied voltage. This property is absent in the Laughlin states. Moreover the Fano factor can exceed \(3\). The dependence of the current on the applied voltage is exactly \(12.7\) electron charges in the \(k = 3\) Read-Rezayi state. This number is much greater than the maximum possible Fano factor in all Laughlin states and the Moore-Read state which was shwon previously to be \(e\) and \(3.2e\) respectively.

1:51PM B37.00014 Effect of Landau Level Mixing on Braiding Statistics

STEVEN H. SIMON, Alcatel-Lucent Bell Labs — We examine the effect of Landau level mixing on the braiding statistics of quasiparticles of abelian and nonabelian quantum Hall states. While path dependent geometric phases can perturb the abelian part of the statistics, we find that the nonabelian properties remain unchanged to an accuracy that is exponentially small in the distance between quasiparticles.

2:03PM B37.00015 Studying topological order in quantum Hall states using entanglement entropy calculations

MASUD HAQUE, MPI-PKS Dresden, Germany, OLEKSANDR ZOZULYA, KARELJAN SCHOUTENS, University of Amsterdam, The Netherlands, ED REZAYI, California State Univ, Los Angeles, NICOLAS REGNAULT, Ecole Normale Superieure, Paris, France — We present calculations of the entanglement entropy in fractional quantum Hall (FQH) states. Calculating the entanglement entropy between spatially separated regions allows us to probe the topological order in Laughlin and Moore-Read states. The entanglement entropy is also found to be a sensitive indicator of quantum phase transitions between FQH and non-FQH states.

11:15AM B38.00001 Perturbed Angular Correlation Study of ZrSiO$_4$ and HfSiO$_4$, HERBERT JAEGGER, Miami University, SEAN MCBRIDE, Kansas State University — Time-differential perturbed angular correlation spectroscopy is a powerful technique to study short-range interactions between probe nuclei and host crystals. The technique requires a very low concentration of radioactive probe nuclei and relies on the probes substituting for atoms of the host crystal. We report on PAC measurements of synthetic zircon and hafnon using $^{181}$Ta-probes to study the EFG at Zr and Hf lattice-sites. The quadrupole coupling constants for both zircon and hafnon decrease linearly with increasing temperature. The slope of $\nu_Q$ vs. $T$ increases above 800°C (zircon) and 1100°C (hafnon) as a consequence of a change in the Zr-O and Hf-O coordination. We also observe a systematic reduction of the anisotropy value $\Delta_{22}$ that is correlated with the onset of the structural change. Changes in the anisotropy are usually related to dynamic interaction and can be due to nuclear decay after effects. In our case we believe that we see evidence of a trapped electronic defect, giving rise to a rapidly decaying high-frequency quadrupole interaction. At higher temperatures the defect detraps and no longer causes a reduction in the anisotropy.

11:27AM B38.00002 Stability and lattice dynamics of SiO$_2$ cristobalite, SINISA COH, DAVID VANDELBILT, Department of Physics and Astronomy, Rutgers University — Among the phases of SiO$_2$ are alpha and beta cristobalite. Despite early indications that the higher-temperature beta phase might be cubic (Fe3m), it is now accepted that it is in fact tetragonal (I42d), and that the experiments suggesting a cubic structure were averaging spatially or dynamically over tetragonal domains. Recently, Zhang and Scott (J. Phys. Cond. Matt. 19, 275201) suggested that the lower-temperature alpha phase, widely accepted to be tetragonal (P412121), might be an artifact in a similar way. With this motivation we investigate the energy landscape in the vicinity of cristobalite phases using first-principles calculations. We use the ABINIT implementation of density-functional theory in a plane-wave pseudopotential framework. We find that both the P412121 alpha and I42d beta phases are local minima, thus reinforcing that the identification of the alpha phase as belonging to the P412121 structure. We compute the frequencies of phonon modes at high-symmetry k-points in both structures and compare with experiment. We also identify a minimum-energy path connecting the alpha and beta phases through an intermediate orthorhombic phase (P212121), and find a surprisingly low barrier of ~5 meV per formula unit. We note that a simple rigid-unit mode picture gives a good rough description of these energetics, and we map out the minimum-energy path in the space of rigid unit rotations in a physically insightful way.

11:39AM B38.00003 First Principles Modeling of BaCeO$_3$: Stabilization of O Vacancies, JOSEPH BENNETT, ANDREW RAPPE, University of Pennsylvania — We use first-principles density functional theory (DFT) calculations to investigate the ground state structures of both BaCeO$_3$ (BC) and Pd-doped BC (BCP) perovskites of general formula ABO$_3$. The relaxed structures match closely with recent experimental scattering studies, and also provide a local picture of how the BC perovskite lattice accommodates Pd. Both stoichiometric and oxygen-deficient materials are considered, and structures with an O vacancy adjacent to each Pd are predicted to be favored. The oxidation state of Pd in each doped structure is investigated through a structural analysis, the results of which are supported by an orbital-resolved projected density of states. The local bonding environments around Pd as well as the electron fillings of atomic orbitals on Pd and its neighbors are examined. A particular focus is the character of the highest occupied molecular orbital (HOMO) and the few lowest unoccupied molecular orbitals (LUMO). These electronic states are compared with expectations based on crystal field splittings in the computed atomic geometries. The vacancy stabilization by Pd in BCP is explained through redox chemistry and lattice strain relief.

11:51AM B38.00004 Dynamical structure factor of LiF for all wave vector transfers: New results and insights1, Q. KOU, M.C. TROPAREVSKY, A.G. EGIULUZ(1), Univ. of Tenn.; MSTD-ORNL(2), B.C. LARSON, J.Z. TISCHLER, MSTD-ORNL(2), P. ZSCHACK, APS-ANL(3) — We report a theoretical-experimental investigation of the dynamical structure factor of LiF. The calculations are done within the TDLDA of time-dependent density functional theory; the measurements correspond to non-resonant inelastic x-rays scattering (NIXS) cross sections, obtained in absolute units. The TDLDA spectra contain one adjustable parameter: a “scissors-operator” shift of the conduction bands. This parameter is determined in view of the NIXS line shape for $q=6\AA^{-1}$ ($q//c111$). The TDLDA spectra display a non-trivial semi-quantitative agreement with the NIXS data, for all wave vectors (directed along the three high-symmetry directions); indeed, the line shape changes drastically from the coherente-response small-$q$ regime, to the incoherent-response large-$q$ regime. The picture of the excitations which emerges offers an alternative view relative to a seminal investigation involving an approximate solution of the Bethe-Salpeter equation; W. A. Caliebe et al. Phys. Rev. Lett. 84, 3907 (2000).

11:53AM B38.00005 Simulation of Li ion diffusion near electrolyte-metal interface – Li$_3$PO$_4$ and Li**, YAOJUN DU, XIAO XU, N.A.W. HOLZWARTH, Wake Forest U. — Motivated by recent technological interest in Li$_3$PO$_4$-based electrolytes developed at Oak Ridge National Laboratory for use in rechargeable solid-state batteries and other technologies, we have used first-principles modeling techniques to study Li ion diffusion near idealized interfaces between Li$_3$PO$_4$ and Li metal. Using the nudged elastic band method, migration energy barriers for Li ion diffusion across interfaces in different crystallographic directions are calculated for both vacancy and interstitiality mechanisms. Preliminary results find interface migration barriers as low as 0.2 eV and 0.26 eV for the vacancy and interstitiality mechanisms, respectively. This suggests that interface diffusion barriers are likely to be comparable or lower than the corresponding migration barriers within crystalline Li$_3$PO$_4$.

12:03PM B38.00006 QNS study on superprotonic conductor, YUTAKA IKEDO, Toyota CRDL, HIROSHI NOZAKI, MASAHIKO HARADA, JUN SUGIYAMA, TAKU SATO, YASUMITSU MATSUO, YIMING QIU, JOHN COPLEY — Cesium hydrogen selenate, CsHSeO$_4$, and related materials M(H)X$_2$O$_4$, where M = Cs, Rb, K and X = S, Se, are considered to be a promising candidate as electrolyte materials for fuel cells. In order to clarify the mechanism of their high proton conductivity, quasielastic neutron scattering (QNS) measurements were carried out using single crystal samples of CsHSeO$_4$ on disk chopper spectrometer (DCS) in NIST Center for Neutron Research at temperatures mainly above T$_C$ (401 K), at which CsHSeO$_4$ undergoes a structural phase transition from a low-T orthorhombic phase (Phase II) to a high-T tetragonal phase (Phase I). High proton conductivity, i.e., super-protonic ionic conductivity is observed only in Phase I. The analysis of the QNS spectrum suggests an anisotropic proton diffusion in Phase I, in spite of the isotropic behavior reported by AC conductivity measurements. The present QNS result thus provides crucial information on the proton diffusion pass in these materials.

12:27PM B38.00007 Proton Transport in Mixed Rare-Earth/Alkaline Earth Metaphosphate Glasses1, GABRIEL HARLEY, UC Berkeley/Lawrence Berkeley National Laboratory/Max Planck Institute (FKF), LUTGARD C. DE JONGHE, UC Berkeley/Lawrence Berkeley National Laboratory — The transport properties of [La$_{1-x}$M$_x$]$_2$P$_2$O$_7$ metaphosphate glasses, where M is Ba, Sr, Ca, and $0.0 < x < 0.8$ were investigated in the 300 – 500 °C range. Protons are found to be incorporated as charge compensation for the substituting divalent cation. A model for proton conduction in phosphate glasses is presented where aliovalent cations within the phosphate network act as trapping sites for protons. Protons are transported via trapping center to trapping center along phosphate tetrahedra. The diffusion of protons is found to be between $10^{-8}$ cm$^2$/s and $10^{-6}$ cm$^2$/s in the 300–500 °C range. The conductivity increases two orders of magnitude from the unsubstituted to the 60% substituted glass reaching a maximum conductivity of $10^{-6}$ S/cm at 450 °C. The average transport distance between proton centers predicted by the electrical analysis is on the order of tens of nanometers, which is the same magnitude of proton-proton distance calculated from the structural data. The activation energy is found to be independent of concentration though dependent on modifying substitutional cation, and increases from 0.92 eV for Ba to 1.02 for Sr.

12:39PM B38.00008 Evidence of structure dependence of hyperpolarizability in octupolar molecules, CLAUDIA CARDOSO, CFC, Departamento de Física, Faculdade de Ciências e Tecnologia, Universidade de Coimbra, PAULO ABREU, Departamento de Química, Faculdade de Ciências e Tecnologia, Universidade de Coimbra, FERNANDO NOGUEIRA, CFC, Departamento de Física, Faculdade de Ciências e Tecnologia, Universidade de Coimbra — It was recently reported that second-order hyperpolarizability increases significantly upon introduction of positive charges at the pyridyl end groups in tripyridyl octopolar chromophores, when compared with the neutral species. We performed ab-initio and semi-empirical calculations for the geometries, electronic localization function and first hyperpolarizabilities of a series of 6 tripyridyl molecules in neutral and protonated forms. Ab-initio calculations correctly reproduce the large hyperpolarizability values of the protonated octopolar molecules. Semi-empirical calculations predict somehow smaller hyperpolarizability values but reproduce the trend of the experimental and ab-initio values. Linear response TDDFT calculations are in good agreement with the experimental absorption spectra, reproducing the red-shift of the peaks with protonation. A correlation between the molecular structures and the first hyperpolarizability was established.

12:51PM B38.00009 UV Spectra of rutile and anatase phases of TiO$_2$ using ABINIT2NBSE1, H.M. LAWLER, J.J. REHR, U. Washington, S. DALOSTO, Z.H. LEVINE, E.L. SHIRLEY, NIST — We have developed an interface between the electronic structure code ABINIT and the optical spectroscopy code NBSE developed at NIST. NBSE calculates dielectric spectra at various levels of theory, including iterative solution of the Bethe-Salpeter equation (BSE) for electron-hole states. From a single input file the interface executes a complete calculation, from the self-consistent ground-state to the dielectric spectrum. The interface can also treat momentum-transfer dependence of the dielectric function. As an application, we present calculations of the birefringent spectra of rutile and anatase TiO$_2$. Not surprisingly, we find that excitonic interactions dominate low-energy features of the spectra. We also address the role of planar-bonding, oxygen π-orbitals near the Fermi level, and the unfilled titanium d-band in the birefringent properties of these systems.

1:03PM B38.00010 Zeeman Effect in TiO$_2$:Cr$^{3+}$, MICHAEL CRAWFORD, DuPont Company, XING WEI, STAN TOZER, National High Magnetic Field Laboratory — We will describe the results of Zeeman effect measurements for single crystals of rutile TiO$_2$ doped with Cr$^{3+}$. These measurements, performed at the National High Magnetic Field Laboratory in magnetic fields with strengths up to 45 T, utilized the near-infrared luminescence of Cr$^{3+}$ at a temperature of T = 14 K. The Cr$^{3+}$ luminescence spectra show the evolution with field strength of the splitting of the Cr$^{3+}$ zero-phonon line at 12,684 cm$^{-1}$ in magnetic fields applied parallel or perpendicular to the crystallographic c-axis. In the former case the zero-phonon line splits into four Zeeman components, while for the latter case three components appear. These results will be discussed and compared to earlier measurements made in weaker magnetic fields.

1:15PM B38.00011 Raman elastic paramagnetic resonance (Raman-EPR) of Cr$^{3+}$ in ruby1, X. LU, Purdue University, S. VENUGOPALAN, SUNY, Binghamton, HYUNJUNG KIM, Sogang Univ. Korea, M. GRIMSDITCH, Argonne National Lab, S. RODRIGUEZ, A.K. RAMDAS, Purdue University — We have observed the Raman-EPR of the Zeeman split $^4A_2$ ground state of the Cr$^{3+}$ ion in Al$_2$O$_3$ :Cr, i.e., ruby, exploiting the resonance conditions associated with the R$_1$ line. Employing a tunable dye laser with a photon energy $E_Z$ in the vicinity of the Zeeman components of the R$_1$ luminescence, we observe the Stokes and anti-Stokes Raman transitions with shifts corresponding to the intra $^4A_2$ ground state level splitting by the external magnetic field (B). The proximity of the incident and the scattered radiation to the Zeeman components of R$_1$ leads to selective dramatic resonance enhancements of the intensities of EPR transitions brought about as a function of B and $E_Z$. The microscopic mechanism for the resonance enhancement involves the ‘in resonance’ and ‘out resonance’ conditions fulfilled by the virtual transitions from the sublevels of $^4A_2$ ground state to the sublevels of $^4E$ by the incident and the scattered radiation in a two step process. Raman-EPR of the Zeeman sublevels of $^4E$ excited state of R$_1$ is also observed.

1:27PM B38.00012 Trivalent chromium probes in mixed dicyanoargentate-dicyanoaurate single crystals, C.L. LAROCHELLE, J.K. KREBS, Franklin & Marshall College — Single crystals of the form R[M(CN)$_3$]$_3$ (R=trivalent ion, such as a rare earth; M=Ag, Au, or both) have a layered structure consisting of alternating layers of M(CN)$_3$ ions and R$^{3+}$ ions. Recent work on this type of crystal has focused on energy transfer from the metal dicyanide donor to the rare earth acceptors, specifically Tb$^{3+}$, Eu$^{3+}$, Sm$^{3+}$, and Ce$^{3+}$. Crystals of this type are particularly interesting because the luminescence energies are tunable, changing with changes in the temperature as well as Ag/Au ratio. Doping these single crystals with chromium can provide an opportunity to study the crystal field strength at the ion site because the energy levels in chromium are very sensitive to the ion’s environment. We present steady-state excitation and emission results, along with lifetime measurements for a series of crystals of the type C$_6$H$_5$-Ar$_9$[Ag$_{1-x}$Au$_x$(CN)$_3$]$_3$, with $x=1, 0.5, 0.75, 0.9$. These measurements indicate that the chromium emission is of an unusually low energy in these crystals.

1:39PM B38.00013 Ce:Cr:YAG Based Yellow/Red Phosphors, JINKE TANG, WENDONG WANG, University of Wyoming, SHENG TENG HSU, Sharp Laboratories of America, BRIAN SULLIVAN, University of Wyoming — Ce:YAG (yttrium aluminum garnet) is the current industrial material of choice for phosphor for white LEDs, but suffers from poor color rendering index. We have investigated Cr and Ce co-doped YAG. Our investigation suggests Cr addition can drastically enrich the emission spectrum of Ce:YAG in the red region, which is realized by a non-radiative energy transfer from the Ce$^{3+}$ 2D$^3/2$ level to Cr$^{3+}$ 4T level. The emission spectrum excited at 467 nm blue wavelength shows that the addition of Cr induces strong peaks in the red region. Comparison with the emission spectrum of the Cr-only sample reveals that the intensity of red Cr emission is much higher in Ce and Cr co-doped samples, which suggests energy transfer from Ce to Cr. Excitation spectra collected at the Cr red emission show a large excitation peak at 458 nm and suggest energy transfer from the 2D$^3/2$ level of Ce$^{3+}$ to the 4T level of Cr$^{3+}$, which is responsible for the enhanced red emission from Cr. At the same time, radiative transfer from Ce$^{3+}$(2D$^3/2$) to Cr$^{3+}$(4T) through the absorption of the yellow emission by Cr seems limited. The orders of magnitude increase in the Cr red emission in Ce/Cr:YAG compared to Cr:YAG suggests that the former is an efficient red and yellow phosphor.
1:51PM B38.00014 Spectral Intensities of Transitions Between Stark Levels of Er$^{3+}$(4f$^{11}$) in Single Crystal, Ceramic, and Nanocrystalline Y$_2$O$_3$, KELLY NASH, JOHN GRUBER, DHIRAJ SARDAR, University of Texas at San Antonio, UYGUN VALIEV, National University of Uzbekistan, NIKOLAI TER-GABRIELYAN, LARRY MERKLE, AROCKIASAMY MICHAEL, Army Research Laboratory — Similarities and differences among the optical properties of Er$^{3+}$Y$_2$O$_3$ in single crystal, polycrystalline (ceramic), and nanocrystalline forms are discussed based on spectra obtained between 400 nm and 1700 nm and temperatures between 8 K and 300K. The observed crystal-field splitting and the measured intensities of transitions between the $^{2S+1}L_J$ manifolds of Er$^{3+}$(4f$^{11}$) in both the C$\alpha$ and C$\beta$ sites are analyzed in terms of models that invoke the mixing of states of opposite parity through the odd terms in the crystal-field Hamiltonian. The inversion symmetry of C$\beta$ sites limits electronic transitions to magnetic dipole transitions between the $^1L_{1/2}$ and $^1L_{5/2}$ manifolds. For Er$^{3+}$ ions in C$\beta$ sites, the forced electric-dipole transitions along with some magnetic dipole contribution in certain cases, are allowed between the J+1/2 Stark levels within all manifolds. Within the instrumental resolution, there are some important differences between intensities of transitions depending on particle size of the Er$^{3+}$Y$_2$O$_3$.

2:03PM B38.00015 Judd-Olfelt analysis and crystal-field modeling of Er$^{3+}$ transitions in YAlO$_3$, SREE R. CHANDRASEKHARAN, University of Texas at San Antonio, KELLY L. NASH, JOHN B. GRUBER, AND DHIRAJ K. SARDAR TEAM — Optical absorption and emission intensities are investigated for trivalent Er$^{3+}$ ions in YAlO$_3$ crystal. The Judd-Olfet model is applied to the room temperature absorption intensities of Er$^{3+}$(4f$^{11}$) transitions in YAlO$_3$ to obtain the intensity parameters which are then used to calculate the spontaneous emission probabilities, branching ratios, radiative decay rates, and radiative lifetimes of the Er$^{3+}$ transitions from the upper multiplet manifolds to the corresponding lower-lying multiplet manifolds in YAlO$_3$. The room-temperature fluorescence lifetimes and the emission cross sections of selected intermanifold transitions are determined. From the calculated radiative lifetimes and the measured fluorescence lifetimes, the quantum efficiency of the sample has been found. The 8K absorption spectrum has been examined as well. Selected manifolds have been analyzed in terms of crystal field splitting using current models and minimization methods to establish the parameters of Er$^{3+}$ in C$_\alpha$ symmetry sites. The optical and spectroscopic characteristics of Er$^{3+}$YAlO$_3$ show that this material has a potential for both 1.5µm and 544.96 nm stimulated emissions.

Monday, March 10, 2008 11:15AM - 2:15PM —
Session B39 GSNP DFD: Focus Session: Collective Dynamics of Self-Driven Particles
Morial Convention Center 231

11:15AM B39.00001 Polar and apolar active matter$^1$, M. CRISTINA MARCHETTI, Syracuse University — Assemblies of interacting self-driven units form a new type of active soft matter with collective behavior qualitatively different from that of its individual constituents, nonequilibrium phase transitions, and unusual mechanical and rheological properties. Examples include cytoskeletal filaments crosslinked by motor proteins, bacterial colonies, migrating cells, and vibrated layers of granular rods. In this talk I will review our work on using nonequilibrium statistical physics to derive a continuum description of these systems from specific models of single particle dynamics. This approach aims at understanding the interplay between physical mechanisms (such as formation or loss of physical connections, excluded volume effects, directional forces) and biochemical or other processes in regulating the large-scale organization and function of active matter. I will contrast the behavior of units with a head and a tail that can exhibit a macroscopic polar state, where all organisms move coherently in a preferred direction, with that of units with head-tail symmetry, that can order in a nematic state, with no net motion on macroscopic scale. Finally, I will use a simple model of active rod on a substrate to discuss the interplay between equilibrium steric effects and self-propulsion in controlling order and fluctuations in active fluids.

$^1$Work done with T. B. Liverpool, A. Ahmadi and A. Baskaran. Supported by DMR-0705105

11:51AM B39.00002 Swarming and swirling in self-propelled polar granular rods, ARSHAD KUDROLLI, Department of Physics, Clark University, Worcester, MA, GEOFFROY LUMAY, GRASP, Physics Department, University of Liège, B-4000 Liège, DMITRI VOLFSON, LEV TSIMRING, Institute for Nonlinear Science, University of California, San Diego, La Jolla, CA 92039 — We discuss the dynamics of “self-propelled” polar rods experimentally and numerically. In the experiment, the polar motion was achieved by vibrating rods with asymmetric mass distribution. In the numerics, we postulate a driving force acting along the axis of the rod. We observe aggregation of rods at the boundaries because of the inability of rods to turn around and escape for high enough density under low noise conditions. As vibration strength and thus noise is increased, the aggregation reduces and a uniformly distributed state displaying local orientation order and swirls are observed. We observe greater than $\sqrt{\pi}$ density fluctuations which are in a qualitative agreement with the Toner-Tu model, but this agreement should not be over-emphasized since the model is directly applicable to a nematic regime. Our findings elucidate an important and interesting interplay between the shape and the directed motion in realistic self-propelled rods which affects the phenomenology of their collective dynamics.

12:03PM B39.00003 Rectification of Swimming Bacteria and Self Driven Particle Systems by Arrays of Asymmetric Barriers, CHARLES REICHHARDT, Los Alamos National Laboratory, Los Alamos NM, MEW BING WANG, Department of Physics, Washington University, St Louis, MO 63160, CYNTHIA OLSON REICHHARDT, Los Alamos National Laboratory, Los Alamos NM 87545, ZOHAR NUSSINOV, Department of Physics, Washington University, St Louis, MO, 63160 — We show that the recent experimental observation of the rectification of swimming bacteria in a system with an array of asymmetric barriers occurs due to the ballistic component of the bacteria trajectories introduced by the bacterial “motor.” Each bacteria selects a random direction for motion and then moves in this direction for a fixed period of time before randomly changing its orientation and moving in a new direction. In the limit where the bacteria undergo only Brownian motion, rectification by the barriers does not occur. We also examine the effects of steric interactions between the bacteria and observe a clogging effect upon increasing the bacteria density.

12:15PM B39.00004 Delay induced instabilities in self-propelling swimming particles$^1$, ERIC FORGOSTON, IRA SCHWARTZ, Naval Research Laboratory — We consider a general model of self-propelling biological or artificial individuals interacting through a pairwise attractive force in a two-dimensional system in the presence of noise and communication time delay. Previous work has shown that a large enough noise intensity will cause a translating swarm of individuals to transition to a rotating swarm with a stationary center of mass. In this work, we use numerical simulations to show that with the addition of a time delay, the model possesses a transition that depends on the size of the coupling parameter. This transition is independent of the swarm state (traveling or rotating) and is characterized by the alignment of all of the individuals along with a swarm oscillation. By considering the mean field equations without noise, we show that the time delay induced transition is associated with a Hopf bifurcation. The analytical result yields good agreement with numerical computations of the value of the coupling parameter at the Hopf point.

12:27PM B39.00005 ABSTRACT WITHDRAWN —
12:39PM B39.00006 From Cannibalism to Active Motion of Groups , PAWEL ROMANZUK, LUTZ SCHIMANSKY-GEIER, Institute of Physics, Humboldt University Berlin — The detailed mechanisms leading to collective dynamics in groups of animals and insect are still poorly understood. A recent study by Simpson et. al. suggests cannibalism as a driving mechanism for coordinated migration of mormon crickets [1]. Based on this result we propose a simple generic model of brownian particles interacting by asymmetric, non-conservative collisions accounting for cannibalistic behavior and the corresponding avoidance strategy. We discuss our model in one and two dimensions and show that a certain type of collisions drives the system out of equilibrium and leads to coordinated active motion of groups.

12:51PM B39.00007 Spatial instability and bioturbulence in highly concentrated bacterial suspensions1 , ANDREY SOKOLOV, IGOR ARANSON, Argonne National Laboratory — We present an experimental study of spatio-temporal organization and transition to complex collective swimming regimes in highly concentrated suspensions of Bacillus subtilis. Experiments are performed in a free-standing thin-film sample with controlled thickness. Novel non-invasive high-resolution optical coherence tomography technique is used to probe the density distributions in the film in real time. Increasing the film thickness beyond certain threshold triggered a transition from quasi-to-dimensional collective swimming to three-dimensional turbulent state which is attributed to Oxygentaxis. We have studied effect of the controlled oxygen concentration on the bacterial collective behavior and transition to turbulent bioconvection.

1:03PM B39.00008 Non-Coalescent, Self-Assembling Water Drops: Phase transitions, flows and hydrodynamics , MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, VIVEK SHARMA, School of Polymer, Textile and Fiber Engineering, Georgia Institute of Technology, Atlanta GA 30332 — We study the collective nucleation, growth and self-assembly of non-coalescent water drops. These form and organize over evaporating polymer solutions exposed to a draft of moist air. The creation and evolution of a population of drops towards a closed packed array occurs in response to heat and mass fluxes involved in droplet condensation and solvent evaporation. We elucidate the kinetics and dynamics of droplet growth and assembly, by accounting for various transport and thermodynamic processes. These water drops template hexagonally ordered arrays of holes in polymer films. We thus have a useful and economical method for manufacturing porous films requiring only a drop of polymer solution (dilute) and a whiff of breath!

1:15PM B39.00009 Active nematics: fluctuations and coarsening1 , SRIRAM RAMASWAMY, CCMT, Department of Physics, Indian Institute of Science, Bangalore 560 012, SHRADHA MISHRA, CCMT, Department of Physics, Indian Institute of Science, Bangalore 560 012, INDIA, FRANCESCO GINELLI, HUGUES CHATE, Service de Physique de l’Etat Condense’, CEA/Saclay, 91191 Gif-Sur-Yvette, FRANCE, SANJAY PURI, School of Physical Sciences, Jawaharlal Nehru University, New Delhi 110 067, INDIA — Nonequilibrium steady states with spontaneous nematic order are known to arise in collections of amoeboid cells as well as granular-rod monolayers. 1:27PM B39.00010 Long-range correlations in simulations of suspensions of swimming microorganisms , PATRICK UNDERHILL, University of Wisconsin-Madison, JUAN HERNANDEZ-ORTIZ, Universidad Nacional de Colombia Sede Medellin, MICHAEL GRAHAM, University of Wisconsin-Madison — Simulations of large populations of hydrodynamically interacting swimming particles have been performed at low Reynolds number in periodic and confined geometries. Our simulations show that the interactions of the particles lead to long-range spatial correlations in the fluid at scales larger than the size of a single organism. These long-range correlations lead to a large enhancement in the fluid transport properties. The diffusion coefficient of passive, non-Brownian tracer particles diverges in the periodic geometry with increasing the simulation box size. This collective motion depends on the method the organism uses for propulsion. Simple scaling arguments have also been developed that can capture much of the physics of both the swimmer and tracer motions.

1:39PM B39.00011 Simulated Flocking Dynamics of 2D Self-propelled Hard Particles , DONALD BLAIR, University of Massachusetts Amherst — Following a recent demonstration of long-lived giant number fluctuations in a swarming, granular nematic (Narayan et. al, Science 317, 105 (2007)), we perform 2D simulations of hard, self-propelled particles which communicate only through contact. We vary particle end-shape, polarity, and aspect ratio and explore the effects on order, on the development of density fluctuations, and on the evolution of the swarm boundary. Connections to various forms of active matter (swimming bacteria, crawling cells) will be discussed.

1:51PM B39.00012 Cell swarming leads to vortex flow in early embryo formation , ARIEL BALTER, Biocomplexity Institute, Indiana University, JAMES A. GLAZIER, Biocomplexity Institute, Indiana University — A forming embryo can be thought of as a confined region of incompressible medium. Vortex flow is observed in early embryo formation from drosophila fruit flies to mammals. The Navier-Stokes equation for fluid flow in a cavity is known to have stable vortex solutions. A model for cell motion in which cells move independently of their neighbors corresponds to high Reynolds number (Re) incompressible flow. An alternative cell-swarming model in which cells do influence their neighbors motion (through a mechanism known as contact following) corresponds to a flow model that is similar to low Re incompressible flow. Both models can potentially lead to stable vortex formation in a confined cavity. We investigate the applicability of both models to real biological systems

2:03PM B39.00013 Active elastic dimers: self-propulsion and current reversal on a featureless track , VIJAY KUMAR KRISHNA MURTHY, SRIRAM RAMASWAMY1, CCMT, Dept. of Physics, Indian Institute of Science, Bangalore 560012, MADAN RAO2, Raman Research Institute, Bangalore 560080. — Directed motion without an imposed external gradient is seen not only in living systems but also in agitated granular matter. The essential ingredients are an external energy input and inherent asymmetry. Unlike traditional “Brownian ratchet models”, the asymmetry of interest in the above systems is internal to the motile objects, and does not lie in an external periodic potential. In this work, we present a Brownian inchworm model of a self-propelled elastic dimer in the absence of an external potential. Nonequilibrium noise together with a stretch-dependent damping form the propulsion mechanism. Our model connects three key nonequilibrium features – position-velocity correlations, a nonzero mean internal force, and a drift velocity. Our analytical results, including striking current reversals, compare very well with numerical simulations. The model unifies the propulsion mechanisms of DNA helicases, polar rods on a vibrated surface, crawling keratocytes and Myosin VI. We suggest experimental realizations and tests of the model.

11:15 AM B40.00001 Summer 2007: My SPS intern experience and working with ComPADRE\textsuperscript{1}, ANDREW COUGHLIN, Society of Physics Students — For the summer of 2007 I was enrolled in the Society of Physics Students Internship program hosted by the American Institute of Physics in College Park, Maryland. My time at was spent working for the American Physical Society outreach department. My primary task was to expand and maintain Physicstogo.com which is part of the ComPADRE group of outreach websites funded by the National Science Foundation. More specifically, I searched for materials to add to the website, cataloged citation information, and updated the biweekly magazine portion of the website. Work experience was not the only thing gained from this internship. As a group of 8 interns we attended an event on Capitol Hill, met with members of congress, and toured nearly every monument and museum in the area. The 2007 SPS internship was an amazing opportunity and a summer memory that will remain with me for the rest of my life.

11:27 AM B40.00002 Demonstrating Levitation and Suspension of a Superconductor on a Magnetic Track\textsuperscript{1}, CHARLES P. STREHLOW, M.C. SULLIVAN, Ithaca College — The suspension and levitation of superconductors by permanent magnets is one of the most fascinating consequences of superconductivity, and a wonderful instrument for generating interest in low temperature physics. We present a novel classroom demonstration of the levitation/suspension of a superconductor over a magnetic track that maximizes levitation/suspension time, separation distance between the magnetic track and superconductor as well as insulator aesthetics. A theoretical explanation of the levitation/suspension and a simple mathematical model of the lateral restoring forces are discussed.

\textsuperscript{1}Supported by NSF Grant DMR-0706557.

11:39 AM B40.00003 Comprehensive study on deformation of metal samples based on measurements of temperature, in-plane displacement and stress-strain characteristics , JOHN GAFFNEY, CHRISTOPHER SCHNEIDER, SANICHIRO YOSHIDA, Southeastern Louisiana University — We have studied the dynamics of deformation of metal samples. Our efforts are directed at finding some correlation between the stage of deformation (elastic, plastic, pre-fracturing stage, etc) and changes in properties of the sample such as the change in temperature across the surface, the stress strain characteristics, and the in-plane displacement on the sample surface. To study this, we simultaneously applied three independent data collection systems; a tensile machine to obtain the stress strain curve, an optical interferometer to study both the vertical and horizontal displacement of the surface, and two thermistors to obtain a continuous temperature reading as the sample deformed. With two thermistors, we were able to study how the temperature changed in different locations on the surface of the sample.

11:51 AM B40.00004 Low-temperature calorimeter for magnetocaloric-effect measurements in high magnetic fields , TRAVIS MILLER\textsuperscript{2}, YASUMASA TAKANO, University of Florida — The magnetocaloric effect, in which sweeping a magnetic field results in a temperature variation, is a powerful tool for detecting phase transitions in magnetic samples. The effect is particularly useful near the zero-temperature limit where a transition line becomes horizontal in the field-temperature phase diagram, a temperature region in which specific heat fails to exhibit sharp anomaly at the transition. At temperatures below 200 mK, however, eddy current heating produces a temperature background that becomes relative in magnitude to the temperature change of genuine features, seriously limiting sensitivity. This causes numerous problems in trying to extracting clear data. We describe a new calorimeter design which overcomes this problem in experiments using a dilution refrigerator in magnetic fields up to 20 T.

\textsuperscript{2}Funded by The University Scholars Program at The University of Florida.

12:03PM B40.00005 Driven Intrinsic Localized Modes in a Coupled Pendulum Array, RITOBAN BASU THAKUR, Dickinson College, LARS ENGLISH, ALBERT SIEVERS, Cornell University, DICKINSON COLLEGE, PHYSICS TEAM — Intrinsic localized modes (ILMs), also called discrete breathers, are directly generated via modulational instability in an array of coupled pendulums. These ILMs can be stabilized over a range of driver frequencies and amplitudes. They are characterized by a \( \pi \) -phase difference between their center and wings. At higher driver frequencies, these ILMs are observed to disintegrate via a pulsating instability, and the mechanism of this breather instability is investigated.

12:15PM B40.00006 Quartz tuning fork as a viscometer for Helium liquids\textsuperscript{1}, J. JHAVERI, M. GONZALEZ, P. BHUPATHI, Y. LEE, Department of Physics, University of Florida, Gainesville, FL 32611-8440 — Oscillating beams serve as simple systems for measuring effects of energy dissipation as a result of interaction with their environment. Especially in miniature mechanical oscillators, the enhanced surface-to-volume ratio signifies the importance of damping caused by drag force. We have investigated the mechanical response of commercial miniature quartz tuning forks with a natural resonant frequency of 32.768 kHz. The changes in resonance frequency and damping have been measured at various Helium and Nitrogen gas pressures and various temperatures. Our results will be compared with theoretical predictions in order to extend its application to the sub-millikelvin temperature range as an effective thermometer in superfluid \( ^3 \)He.

12:27PM B40.00007 Demonstrating the Principle of an rf Paul Ion Trap, ANDREW JOHNSON, JAMES RABCHUK, Western Illinois University — An rf ion trap uses a time-varying electric field to trap charged ions. This is useful in applications related to quantum computing and mass spectroscopy. There are several mechanical devices described in the literature which have attempted to provide illustrative demonstrations of the principle of rf ion traps, including a mechanically-rotating “saddle trap” and the vertically-driven, inverted pendulum\textsuperscript{1,2}. Neither demonstration, however, successfully demonstrates BOTH the sinusoidal variation in the electric potential of the rf trap AND the parametric stability of the ions in the trap described by Mathieu’s equation. We have modified a design of a one-dimensional ponderomotive trap\textsuperscript{3} so that it satisfies both criteria for demonstrating the principle of an rf Paul trap. Our studies indicate that trapping stability is highly sensitive to fluctuations in the driving frequency. Results from the demonstration apparatus constructed by the authors will be presented.\textsuperscript{1} Rueckner, W., et al., “Rotating saddle Paul trap.” Am. J. Phys., 63 (2), February 1995. \textsuperscript{2} Friedman, M.H., et al., “The inverted pendulum: A mechanical analogue of a quadrupole mass filter,” Am. J. Phys., 50 (10), October 1982. \textsuperscript{3} Johnson, A.K. and Rabchuk, J.A., “A One-Dimensional Ponderomotive Trap,” ISAAPT 2007 spring meeting, WIU, March 30, 2007.
12:39PM B40.00008 Experimental characterization of piezoelectric THUNDER actuator shape, PAUL HARRIS — A new type of piezoelectric composite actuator called THUNDER, which was originally developed by NASA, has potential applications in micro robotics, aeronautics, acoustics and hydraulics. The manufacturing process produces internal stresses with accompanying structural deformation. It is the aim of this research to characterize these deformations. Detailed measurements were taken by a motion control LabView data acquisition system and measured with a laser micrometer on several different types of actuators. Several functional forms were used in an attempt to fit the data. The data was best fit by a circular segment function. We also used a transcendental equation to be able to compare to other single point published values. We found the range of dome heights to be between 10.15 mm and 1.45 mm. For one particular model, the manufacturing difference was found to be 16% with an experimental error of 0.5%. The robust experimental data is vital to the development of our finite elements models. Preliminary experimental results of voltage induced deformations will be presented.

12:51PM B40.00009 A Relativistic Understanding of Rotating Reference Frames, KACEY MEAKER, TOM MICHALIK, Randolph College (founded as Randolph-Macon Woman’s College) — The purpose of this research is to obtain a greater understanding of relativistic acceleration and rotation. Particles in a rod experiencing constant acceleration have hyperbolic worldlines. A simple global rigid rotating frame cannot be physically realized, because the force needed to maintain an object in circular motion approaches infinity. This understanding will be discussed in this presentation.

C1.00001 POLYMERIC AND ORGANIC MATERIALS I —

C1.00002 Molecular Dynamics of Polymer Systems on Graphic Processing Units (GPUs)¹, JOSHUA ANDERSON, Iowa State University and Ames Laboratory, CHRIS LORENZ, Kings College London, ALEX TRAVESSET, Iowa State University and Ames Laboratory — Molecular dynamics (MD) is a powerful, but computationally intensive, simulation technique capable of modeling a wide range of systems in and out of thermodynamic equilibrium. Using traditional computers, simulations large enough to explore the phases of polymer systems require the use of expensive distributed memory clusters. Graphics Processing Units now offer an unprecedented amount of computing power for general purpose applications. They are inexpensive ($500) and can be added to almost any standard desktop system. MD algorithms are adapted to execute on a single GPU, which is able to attain the same performance as 32 processor cores on a cluster. It is possible for a single system to host up to 4 GPUs, putting the power of a 128 processor core cluster on the desktop. This performance is illustrated in a variety of polymer systems such as low density micellar phases with cubic symmetry, high density lamellar and nanocomposite gyroid systems. GPUs offer unprecedented opportunities for the simulation of polymer systems.

C1.00003 An Efficient Algorithm to Calculate Density of State in Large Systems: Generalized Ensemble Means and Compression-Variable Transformation¹, XIN ZHOU, T7, Los Alamos National Laboratory — We present a high efficient algorithm to calculate density of state (DOS, or its logarithm, \( S(U) \)) of large systems in any macroscopic variable \( U \). The algorithm calculate the ensemble means and fluctuations of \( U \) in a series of generalized ensembles to form \( S(U) \) and its derivative in some adaptively generated \( U \), then interpolate whole the \( S(U) \) curve within the required accuracy. We also apply a compression transformation in the \( U \) space to focus the most computation cost on extrapolating \( S(U) \) in new \( U \) region. The algorithm is found to be order of \( O(N^{1/2}) \) (or faster) as the increasing system size \( N \), which is far faster than all current available methods (at least \( O(N^{3/2}) \)). The algorithm satisfies the detailed-balance condition in whole simulations by averaging the ensemble means in each segment of simulation by using their errors as weight, so that it has great numerical stability. The method can be combined with the parallel tempering (PT) algorithm to simulate the low-temperature properties of large complex fluids and decrease the number of the needed replica in original PT, \( O(N^{1/2}) \), to one in each macroscopic phase. The validity of the new approaches are demonstrated by presenting the simulated results of Lennard-Jone liquids with different size \( N \). The approaches even generate DOS of each super-saturated macroscopic phase in the unstable liquid/solid coexistence region, respectively, which provides much more information to understand the phase coexistence and transitions.

C1.00004 Understanding Thermodynamics and Surface Dynamics of Pom-pom Branched Polystyrene, SEWOO YANG, The University of Akron, DAVID T. WU, Colorado School of Mines, ZHANG JIANG, SURESH NARAYANAN, Argonne National Laboratory, MARK D. FOSTER, The University of Akron — We have studied the effect of varying the relative length of the central linear portion of the pom-pom chain on the size of a single chain and on the bulk thermodynamics of blends of the pom-pom branched polystyrenes (PS) with linear analogs. A novel set of pom-pom PS with well-defined molecular architecture was synthesized anionically. The value of the interaction parameter contribution of the bulk chains and both the scattering of a single pattern analyzed and time correlation performed to obtain correlation functions. The temperature dependence for the \( q \)-dependent relaxation time was determined and estimates of the surface tensions of the different polymers derived from the static structure factors.

C1.00005 Synthesis and characterization of erbium (III)-doped polyimide nanofibers for low temperature thermophotovoltaic applications¹, ZHENXIN ZHONG, DARRELL RENEKER, Dept of polymer science, University of Akron — Thermophotovoltaic conversion technology is a promising way to convert waste heat to electricity via photons. In this research, erbium (III)-doped polyimide nanofiber mats were prepared as selective emitters to explore the selective thermal emission efficiency in a low operating temperature range (< 500 °C). The selective emission at 6500 cm\(^{-1}\) of erbium (III)-doped polyimide nanofiber mats was measured on mats characterized with scanning electron microscopy, transmission electron microscopy, FT-IR spectroscopy, and thermogravimetric analysis. A small but potentially useful amount of power was obtained from a 2 mg mat.

Characterization of an electrospinning jet from videographic observations of glints

KAIYI LIU, CAMDEN ERTLEY, DARRELL RENEKER, Dept. of Polymer Sci., The Univ. of Akron — Detailed relationships between glints of light reflected from the electrical bending coils of an electrospinning jet and the path of the jet were established. The path of the jet was observed by illuminating the jet with a short, intense flash of light. Glints were formed simultaneously by a continuous, intense beam of light from a chosen set of directions. As the jet path moved through the continuous beam of light, some segments of the path were oriented so that intense specular reflection (a glint) was recorded by a camera. The motion of the jet path caused a glint to create a trace in the videographic image. A linear glint trace divided into two traces when the segment producing the glint became involved in a bending instability. A smooth turn of a coil of the jet path usually produced two glints in a particular observation direction. When the smooth turn became involved in a smaller electrical bending coil, the two glints divided into many glints. Observations of this sort are expected to lead to new ways to reduce the variability in the diameter of electrosyn polymer nanofibers.

Viscoelastic Electrospinning Jets: Initial Stresses and Elongational Rheometry

HAN, Dept. of Polymer Science, U of Akron, ALEXANDER YARIN, Dept of Mechanical and Industrial Engineering, U of Illinois at Chicago, DARRELL RENEKER, Dept of Polymer Science, U of Akron — A novel method of characterization of longitudinal stresses in electrospinning jets is introduced. The measured initial longitudinal stresses in jets of a 6 wt% aqueous solution of polyethylene oxide (Mn = 400 kDa) were of the order of 100 kPa, which is two orders of magnitude larger than in other free viscoelastic jets. This is attributed to strong stretching of polymeric liquids in the transition zone between the Taylor cone and the beginning of the jet, where the stretching rates are 100 to 1000 s⁻¹. The velocity of the fluid along the straight segment was determined from the observed jet diameter combined with the laser Doppler velocimeter data. The tensile stress was measured by creating a lateral displacement, near the beginning of the jet, and observing its propagation along the jet. Combination of the velocity with the stress data provided the information needed to determine the modulus and relaxation time of a polymeric liquid subjected to rapid stretching.

We acknowledge the financial support from NSF grant # DMI-0600733.

Molecular Modeling of Thermosetting Polymers

SOUMYA PATNAIK, Air Force Research Laboratory, VIKAS VARSHNE, Universal Technology Corporation, BARRY FARMER, Air Force Research Laboratory — In this work we present molecular modeling of thermosetting polymers with special emphasis on building atomistic models. Different approaches to building highly cross-linked polymer networks starting from un-crosslinked systems are discussed. A multi-step procedure for relaxing the molecular topology during crosslinking was proposed which allows for minimizing the increase in the residual internal stresses with increasing degree of crosslinking. This methodology was applied to epoxy based thermosets and several materials properties such as density, Young’s modulus, glass transition temperature, thermal expansion coefficient and volume shrinkage during curing were calculated and found to be in good agreement with experimental results. Along with the materials properties, the simulations also highlighted the distribution of molecular weight build up and inception of gel point during the network formation.

Nafion/poly(1-vinyl imidazole) composite membranes for fuel cell application

DUKJOON KIM, Sungkyunkwan University, SUNGYUNKWAN UNIVERSITY TEAM — A base monomer (1-vinyl imidazole, VIdz) was polymerized in Nafion® 112 membrane by UV irradiation in order to reduce methanol permeability of the latter. With increasing content of poly 1-vinyl imidazole (PVI), equilibrium water uptake was decreased due to reduced size of hydrated ion cluster in the composite membrane as confirmed by a small angle X-ray scattering analysis. The electrochemical properties of the membrane such as ion conductivity, methanol permeability and electro-osmotic drag were also affected by equilibrium water uptake and hydrated pore size. Even a minute incorporation of the base polymer showed a significant effect on proton conductivity and methanol permeability. Methanol transport by electro-osmotic drag was evaluated by using relating equations and methanol permeability and limiting current density data obtained in this study. Although the absolute number of electro-osmotic drag was hard to determine, the trend of change could be studied in relation to bulk-like water in composite membranes. This novel composite membrane exhibited an increased cell performance compared with a plain Nafion membrane due to reduced methanol crossover rate.

Metastable Structures of poly(lactic acid)

JEFF KALISH, SHAW L. HSU, University of Massachusetts Amherst, KAORU AOU, Dow Chemicals, MEG STARKWEATHER, University of Massachusetts Amherst — The coexistence of two poly(lactic acid) crystals (alpha and alpha’) and its impact on the double melting peaks in differential scanning calorimetry is investigated. Solubility differences as well as irreversibility of the alpha to alpha’ transformation process indicates that the alpha’ crystal is the less stable crystal form. The difference in thermal stability is quantified by measurement of crystal melting enthalpies using the Pyda/Wunderlich method. The relative composition of the crystalline fraction can also be determined by the same method. Crystal annealing is found to be accompanied by an increase in both overall crystallinity and the fraction of the alpha crystal relative to the alpha’ crystal. Infrared spectroscopy is used to probe the crystal structures. In comparison to the alpha crystal, the alpha’ crystal is found to have a weakened carbonyl-carbonyl intermolecular interaction. Results also suggest that the alpha’ crystal does not have a 10/3 helix which constitutes the alpha crystal. The coexistence of the two crystal forms has profound implications in interpretation of double melting peaks in its DSC thermogram.

Perturbing Effects of Bulky Comonomers on the Chain Conformation of Poly(vinylidene fluoride)

SURYIYAKALA RAMALINGAM, YUNING YANG, SHAW L. HSU, University of Massachusetts Amherst — The comonomer effect on structures of poly(vinylidene fluoride- hexafluoropropylene) copolymers (PVDF-HFP) was analyzed by Raman spectroscopy. The HFP content of these copolymers varies from 5% to 15%. Because of steric interactions involving the bulky HFP comonomers, the predominant chain conformation has extensively more gauche conformers in comparison to pure PVDF. Based on both experimental and simulation studies, specific spectroscopic features in the 700 cm⁻¹ region have been identified that are characteristic of irregular chain conformations elucidating the perturbing effect of HFP on the equilibrium chain statistics of PVDF in the amorphous phase. In addition, these spectroscopic features were revealed to be extremely sensitive to the relative placement of CF₃ units respective to other fluorine atoms along the chain.

Single Crystals of Diblock Copolymers: Tethered Chain Study

RYAN M. VAN HORN, JOSEPH X. ZHENG, HUIMING XIONG, RODERIC P. QUIRK, University of Akron, BERNARD LOTZ, Institut Charles Saudron, EDWIN L. THOMAS, Massachusetts Institute of Technology, STEPHEN Z.D. CHENG, University of Akron — Tethered polymer chains have become an important area of research over the last few decades. Their unique properties make them appealing for various applications. The tethering density of the chains is the most important parameter in determining their properties, as shown by various theoretical and experimental works. Our group uses single crystals of crystalline-amorphous diblock copolymers to study tethered polymer chains. This system provides better control of tethering density and molecular weight as compared to previous methods. Previous work on PS-b-PEO and PS-b-PLLA shows, for the first time, the values of the interacting and brush regime transitions. The systems studied have addressed some issues, molecular weight dependence and solvent quality, but they do not provide general results. The work presented here will look at the role of chain adsorption and crystallization of the tethered chain, using PMMA-b-PLLA and PEO-b-PCL systems.
C1.00013 Morphological Control of Segmented Polyurethanes via Crystallization Confinement of Soft Segments, MATTHEW HOOD, BINGBING WANG, JOHN LASCALA, JAMES SANDS, FREDRICK BEYER, JOSH ORLUCKI, MARK VANLANDINGHAM, CHRISTOPHER Y. LI, U.S. ARL COLLABORATION — Segmented polyurethane (SPU) is a linear, high molecular weight block copolymer comprised of regions of soft and hard segments. The phase separation between these mechanic-contrasting segments is partly the cause of SPU’s superior mechanical strength as the hard domains reinforce the soft domains, while the soft domains provide the toughness that allow for good energy adsorption. To achieve the greatest impact absorption the soft segments must remain amorphous surrounding the crystallized hard domains which are held together via hydrogen bonding. We systematically investigated a SPU system with poly(ethylene glycol) (PEG) of various molecular weights as the soft segments. Using differential scanning calorimetry, small angle X-ray scattering and wide angle X-ray diffraction it was observed that as hard segment content increased there was a decrease in soft segment crystallization till PEG crystallization was no longer observed, thus achieving the desired structure. By tailoring the composition it is also possible to control the nano-sized structure altering the morphology on the macro-scale thus increasing the interface density of the SPU such that we produce a transparent film possessing structural capabilities suitable for transparent body armor.

C1.00014 Crystal Size Effect on Dielectric Property of PVDF at High Electric Field and Its Effect on Energy Storage and Discharging Behaviors, FANGXIAO GUAN, STEVEN BOGGS, LEI ZHU, Institute of Material Science and Department of Chemical, Materials and Bimolecular Engineering, University of Connecticut, Storrs, CT 06269-3136 — Improvement of the high energy density capacitor can be achieved by choosing a material with relatively high dielectric constant and/or high electric breakdown strength. In general, their relationship can be described as $E_0 R_0^2$. For certain dielectric polymers, such as poly (vinylidene fluoride) (PVDF), dielectric constant shows strong electric field dependence. Therefore, the energy density cannot be described simply by this equation. In this work, electric field dependent dielectric response of PVDF is studied, and its relation to the energy density stored is discussed. Although the dielectric constants of PVDF with different crystal sizes can be different at high electric field, they all have similar stored energy density. Intriguingly, their energy discharging behaviors are different. The smaller the crystal size, the faster the energy discharging process, and the lower the dielectric loss. From this study, we conclude that a high energy density with fast discharge and low dielectric loss could be obtained by tuning the crystal sizes.

This work was supported by ONR Grant N00014-05-1-0338.

C1.00015 Reducing Dielectric Loss by PVDF-CTFE Graft Copolymers, JING WANG, ZHONGZHE YUAN, FANGXIAO GUAN, STEVEN BOGGS, LEI ZHU, Institute of Material Science and Department of Chemical, Materials and Bimolecular Engineering, University of Connecticut, Storrs, CT 06269-3136 — Polymer film capacitors with high energy density and low loss are very attractive in potential applications. Maintaining the high dielectric breakdown strength in high dielectric constant films with a low loss will also be a challenge. Poly(vinylidene fluoride) (PVDF) and its copolymers are well-known ferroelectric polymers that exhibit excellent electromechanical properties as candidates for high-performance, high-energy-density capacitor. However, the dielectric loss of commercially extruded PVDF films is high (0.02). In our work, lower dielectric loss polystyrene (PS) were introduced to improve PVDF dielectric properties. PVDF-CTFE-g-PS graft copolymers were synthesized via the “graft from” process. The quality of films from graft polymer was improved, resulting high energy density and low loss. A series of graft polymers with different electric properties were prepared, since the breakdown strength and dielectric loss of PVDF were influenced by the crystallinitities and crystal sizes.

This work was supported by ONR Grant N00014-05-1-0338.

C1.00016 Semicrystalline Polymers: A special case of polymer brushes, VIKRAM KUPPA, GREGORY RUTLEDGE, Massachusetts Institute of Technology — Monte Carlo (MC) molecular simulations are employed to evaluate the interface between crystalline and amorphous polyethylene. The simulation setup mimics the interlamellar region of a semicrystalline polymer with a low effective molecular weight. All polymer chains are tethered to the crystal surface at one of their ends, thus forming tails with their other (free) ends distributed in the space between crystal lamellae. Two different systems are explored: one, in which the simulations explore a range of molecular weights due to the use of MC moves that exchange beads between different chains; and another, in which strict control of the molecular weight is exercised, thereby constraining chain lengths to a narrow window. The effects of temperature, grafting density, molecular weight distribution and the interaction between brushes on opposing crystal surfaces are investigated by examining monomer density profiles, chemical potentials and bond orientation order parameters.

C1.00017 Polydomain Simulation of Liquid Crystalline Polymer Orientation in Channel Flows, JUN FANG, WESLEY BURGHARDT, Northwestern University — The properties of liquid crystalline polymers are strongly affected by the molecular orientation state induced by processing flows. LCP structure development under flow is quite complex, due to the propensity towards ‘director tumbling’ dynamics in rodlike nematics, and the resulting complicated ‘polydomain’ distributions of orientation. Many models of LCP structure & rheology begin with a detailed description of the molecular orientation state, possibly including a molecular description of distortional elasticity. While well suited for simulations of fundamental phenomena in simple flows, application of these models to processing flows is far out of reach. Conversely, the phenomenological polydomain model of Larson & Doi is sufficiently simple to allow for its application to process simulations. This is further facilitated by a nearly exact analogy between the Larson-Doi model and the Folger-Tucker model for predicting orientation in fiber dispersions, which is incorporated in commercial process simulation software. We use this available modeling infrastructure to test the ability of the Larson-Doi model to predict orientation distributions in kinetically complex but isothermal channel flows of liquid crystalline polymers, comparing simulation results orientation distribution data previously obtained using in situ x-ray scattering methods.

C1.00018 Thin Film morphologies of rod-coil block copolymers, MANAS SHAH, VENKAT GANESAN, University of Texas at Austin — The interplay of microphase separation and liquid crystalline ordering in rod-coil block copolymers leads to complex morphologies distinct from that of conventional flexible block copolymer phases. For many electronic and semi-conducting applications, rod-coil block copolymers need to be patterned into thin films. The final morphology and the nature of orientation of rod units would now depend (in addition to the constituent interactions) on the interactions of the blocks with the confining surfaces. We combine the self-consistent field theory models of rod-coil block copolymers in a thin film framework to understand the effect of confinement on the morphology and the nature of orientation of rod-units.

C1.00019 Structural Recovery of Epoxy Films Subjected to CO$_2$ Pressure Jumps, SHANKAR KOLLENGODU-SUBRAMANIAN, Texas Tech University, MATAZ ALcoutlabi, University of Utah, LAMECK BANDA, The Dow Chemical Company, GREGORY MCKENNA, Texas Tech University — This group has previously investigated the impact of structural recovery and physical aging on thermodynamic and mechanical properties of polymers after temperature jumps and compared with plasticizer jumps [1]. Increasing plasticizer content depresses the glass transition temperature ($T_g$) in glassy polymers and this results in changes in the mechanical, optical and dielectric properties. Plasticizer jumps using a strong polar molecule have been previously studied by our group and have shown qualitatively similar behavior to temperature jump experiments [2]. In the current work, we report the results on plasticization effects using a weakly polar molecule (CO$_2$) on the structural recovery of glassy polymers after plasticization jumps and compare the behavior with temperature formed glasses.

C1.00020 Strain induced non-linear effects in Dynamic Viscosity measurements1. J.P. IBAR, IPREM University of Pau, 64013 Cedex — Melt viscosity measurements conducted at increasing \( \omega \) and strain, in a parallel plate dynamic rheometer, trigger a roaster of non-linear effects which we review, such as variation from the commanded strain, non-linearity between stress and strain, time dependence of the G' and G" moduli, and appearance of slip. In addition, melt fracture, at the surface or in the bulk has been reported. Both the Torque and the Normal Force are studied. Results from both a constant strain rheometer (RDAII) and a constant stress rheometer (Bohlin SVO are reviewed. We examine the many aspects of non-linearity and explore the origin(s) of these manifestations, whether due to measurement limitations, melt instability, or purely the expression of non-linear viscoelasticity.

1 Under Fulbright Grant

C1.00021 Topology of Branched Polymers: Effect on Structure and Dynamic Properties1. RAMNATH RAMACHANDRAN, GREGORY BEAUCAGE, AMIT S. KULKARNI, University of Cincinnati, VASSILIOS GALIATSAOS, DOUGLAS C. MC-FADDIN, LyndellBasell Industries — We investigated linear and branched polyethylene (PE) using small-angle neutron scattering (SANS). The experiments were conducted on dilute solutions of PE in deuterated p-xylene. A variety of structural information1 such as fractal dimension \( d_f \), connectivity dimension \( c \), minimum path dimension \( d(min) \), long chain branch fraction \( \phi_b \), radius of gyration \( R_g \) and persistence length \( l_p \) were obtained. Such information presents a qualitative and quantitative assessment of branching in polymers. Theoretical models such as ‘binary contacts per pervaded volume’ model were employed to correlate the structural information of the polymer to its entanglement molecular weight \( (M_e) \). \( M_e \) was used to predict physical properties of the polymer such as plateau modulus \( (G'_{\infty}) \) and zero-shear viscosity \( (\eta_0) \). 

C1.00022 Entanglement Percolation Effects on the Dynamics of Polymer Rheology. RICHARD WOOL, Department of Chemical Engineering, University of Delaware — The percolation model of entanglements (Wool 1983) makes unique predictions regarding the dynamics of polymer chains, in the terminal relaxation zone of reptating linear polymer melts of molecular weight M. When percolation occurs during relaxation of entangled chains in the terminal zone, we observe some unusual results. These include: (a) for homopolymers of molecular weight \( M >> M_e \), reptating chains appear to be non-reptating as their ends and centers relax at the same rate during percolation. (b) During stress relaxation, the random coil dimensions \( R_g(\perp) \) and \( R_g(\parallel) \) are predictably not fully relaxed when the stress and birefringence relax to zero. (c) The matrix molecular weight \( P \) effects on relaxation time \( \tau \) of the probe chain \( M >> M_e \) are as follows: Rouse-like dynamics is observed for reptating chains with \( \tau \sim PM^2 \) when \( M >> P \) and (d) the relaxation time \( \tau \sim P^{-3}M^2 \) when \( P >> M \), in accord with reptation. These unusual results predicted by entanglement percolation are supported by significant experimental data from selectively deuterated polystyrene chains HDH, DHD and DPS. Entanglement Percolation replaces Constraint release and Chain End Fluctuation mechanisms in the understanding of the dynamics of polymers in the melt and concentrated solutions.

C1.00023 Determining Local Mechanical Properties of Soft Materials with Cavitation Rheology. JESSICA ZIMBERLIN, NAOMI SANABRIA-DELONG, GREGORY TEW, ALFRED CROSBY, University of Massachusetts — To guide the development of tissue scaffolds and the characterization of naturally heterogeneous biological tissues, we have developed a method to determine the local modulus at an arbitrary point within a soft material. The method involves growing a spherical cavity at the tip of a syringe needle and monitoring the pressure of the cavity at the onset of a mechanical instability. This critical pressure is directly related to the local modulus of the material. Using model hydrogel, materials, we demonstrate the ability for this technique to quantify the local stiffness of hydrogel networks and its relation to the macroscopic stiffness as measured by shear rheometry. In addition to heterogeneities in equilibrium hydrogel networks, we quantify differences in local stiffness during the gelation of hydrogels. Lastly, we consider the influence of surface energy on the onset of cavitation by using different injected agents to induce the instability.

1 Authors would like to acknowledge NSF-IGERT and NSF-MRSEC for their support.

C1.00024 Caviation Rheology of Polyacrylamide Hydrogels. SANTANU KUNDU, JESSICA ZIMBERLIN, ALFRED CROSBY1, University of Massachusetts-Amherst — Cavitation rheology is a new characterization technique for the measurement of mechanical properties on small length scales, e.g. 10 -100 \( \mu \)m, at any arbitrary location within a soft material. The technique involves growing a cavity at the tip of a syringe needle and monitoring the pressure of the cavity at the onset of instability. This critical pressure is directly related to the local modulus of the material. We used this technique to characterize the network mechanics of polyacrylamide hydrogel materials, a common material used in many biological applications. We applied the cavitation rheology results with that obtained from shear rheometry. This technique was used to investigate the rheological properties of gels with different dimensions and different moduli, which were obtained by varying initial monomer to water ratio. These results provide a quantitative foundation for the extension of this technique to in vivo characterization of biological tissues.

C1.00025 Polyurea segmented multi-block copolymers: structure and dynamics. JAI PATHAK, JEFFREY TWIGG, C. M. ROLAND, PETER MOTT, NRL, Chemistry, DEREK HO, ERIC LIN, NIST, Polymers, MARY VUKMIR, THOMAS EPPS, JAI PATHAK, University of Delaware, Chemical Engineering — We study a Polyurea copolymer by measuring its stress-strain behavior between 100 and 1000 inv. s strain rate and by oscillatory shear rheology, respectively. Polyurea shows elastomeric mechanical response over a wide temperature range, as the rigid domains physically cross-link the soft domains. The modulus increases, while the residual strain in samples stretched to failure decreases with increasing strain rate. SAXS on undeformed specimens reveals two peaks: a higher wave-vector peak from semi-crystalline hard segments (long period 6 nm), and a lower wave-vector peak from micro-phase separated domains of spacing 70 nm. Polyurea specimens quasi-statically stretched to failure show anisotropic scattering, suggesting that deformation effects on morphology are controlled by rigid domain response over the deformation time-scale. Greater molecular reorganization and alignment take place at low strain rates. At large strain rates no molecular reorganization is possible, yielding identical structure as undeformed materials, pronounced strain-rate hardening and low residual strain.
C1.00026 Nanoscale Superstructures in Copolymers with Evenly Spaced Charged Groups.

WENQIN WANG, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6272. SHARLENE R. WILLIAMS, TIMOTHY E. LONG, Department of Chemistry, Virginia Tech, Blacksburg, VA 24061-0334. RALPH H. COLBY, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802-5007. KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania, Philadelphia, Pennsylvania 19104-6272. — Multiple copolymers with evenly spaced charged groups have been synthesized: poly(ethylene-PE)-based ionenes, poly(tetramethylene oxide)-PTMO)-based ionenes, and poly(alkylene oxide)-based sulfonated polyester ionomers. The morphologies of these copolymers are investigated using differential scanning calorimetry, X-ray scattering, and electron microscopy. In both PE- and PTMO-based ionenes, the bulky cationic groups in the backbone reduce the crystallinity of the copolymer and form cation-rich channels perpendicular to the polymer backbone, where the extent of association is influenced by the size of the ionic liquid moiety. In the sulfonated polyester ionomers, the crystallization of long poly(alkylene oxide) segments promotes the formation of ion-rich layers. These results will be compared with our recent work with linear poly(ethylene-co-acrylic acid) copolymers and ionomers with precisely spaced acid groups.

C1.00027 Phase behavior of polyelectrolyte multilayers investigated by thin film calorimetry.

H. HUTH, University Rostock, Institute of Physics, Uniplatz 3, 18051 Rostock, Germany. R. MUELLER, MPI fuer Kolloid-und Grenzflaechenforschung, Am Muelchenberg, 14424 Potsdam, A. FERY, University Bayreuth Physical chemistry II, Universitaetsstr. 30, 95447 Bayreuth, C. SCHICK — Polyelectrolyte multilayer can be easily assembled using spraying or dipping of the different polyelectrolytes [1]. The thickness of the produced layers (nanometer range) is well controlled by the preparation conditions. Only few methods are available for dynamic investigations, as afo for mechanical properties [2]. AC-chip calorimetry is used as a very sensitive tool for calorimetric investigations of such thin films as demonstrated for thin polymeric films [3]. To investigate the phase behavior of polyelectrolytes the humidity is used as a new parameter in addition to temperature for calorimetry. First measurements with the modified calorimeter for the PSS/PDADMAC polyelectrolyte multilayer system are shown. Further extensions of the calorimeter for better understanding of the phase behavior are discussed.

C1.00028 Stimulus-Response of Charged Diblock Copolymer Brushes.

DONG MENG, QIANG WANG, Colorado State University. — We have performed self-consistent field calculations to study the stimulus-response of diblock copolymer brushes on a planar substrate. One of the two blocks carries either weakly or strongly dissociating charges, making the brush surface responsive to the solution pH, ionic strength and applied electric field, in addition to the solvent selectivity. We have investigated in detail the influence of these stimuli on the polymer segmental distribution and surface switchability of the brush. Our result can be used to guide the experimental design of “smart surfaces” from diblock copolymer brushes.

C1.00029 Characterization of polyelectrolyte behavior of the polysaccharides chitosan, heparin, and hyaluronan, by light scattering and viscometry.

SOHEIL BODDI, SUSAN YONEMURA, MATT KIPPER, Colorado State University. — This study on the polyelectrolyte behavior of polysaccharides in solution is motivated by our recent work in development of nanostructured polysaccharide-based surface coatings. Chitosan behaves as a weak polyanion, and hyaluronan behaves as a weak polyanion, while heparin behaves as a strong polyanion. The ability to control the conformation of these polysaccharides in solution, by changing the solution ionic strength and pH may offer the opportunity to further tune the nanoscale features of polysaccharide-based surface coatings assembled from solution. In the work reported here, the solution conformation of these polymers is determined from gel permeation chromatography coupled to differential refractive index, light scattering, and viscometry detection. These results are related to the nanostructure of chitosan-heparin and chitosan-hyaluronan surface coatings based on polyelectrolyte multilayers.

C1.00030 Competition between liquid crystalline (LC) ordering and block copolymer (BCP) microphase separation in a series of LCBCPs.

KISHORE TENNETI, Drexel University, XIAOFANG CHEN, Peking University, CHRISTOPHER LI, Drexel University, XINHUA WAN, QI-FENG ZHOU, Peking University, LIXIA RONG, BENJAMIN HSIAO, Stony Brook University, DREXEL UNIVERSITY TEAM, PEKING UNIVERSITY COLLABORATION, STONY BROOK UNIVERSITY COLLABORATION — A comprehensive study displaying a rich variety of liquid crystalline (LC) phase structures (SmA, ColN, ColH, ColR) and block copolymer (BCP) morphologies (tetrangular perforated and transverse-parallel lamellae) observed in liquid crystalline LCBCP systems will be presented. The systems under investigation differ in the flexibility of interactions between the mesogen and polymer backbone. Both non-covalent and covalent interactions are investigated in a series of mesogen-jacketed-, side-chain- and hydrogen bonded- LCBCPs and the influence of composition and molecular architecture on the final phase behavior will be presented. The factors that lead to the domination of either LC ordering or BCP microphase separation will also be reported.

C1.00031 Symmetry transition in multilayer films of block copolymer/homopolymer blends.

VINDHYA MISHRA, E.J. KRAMER, UCSB — Multilayer films of spherical domain poly(styrene-b-2vinyl pyridine) (PS-PVP Mn:65000, f_pvp = .12) blended with 5 vols % low molecular weight PS homopolymer (Mn:13000) is characterized with grazing-incidence small angle x-ray diffraction (GISAXD) to determine the lattice symmetry and stacking of layers. The structure was also imaged by transmission electron microscopy (TEM). In such films competition between packing preferred at the surfaces with that preferred by the internal layers leads to a transition in the packing symmetry as n, the number of sphere layers, increases. Pure PS-PVP exhibits hexagonal close packed (HCP) symmetry up through n=4. At n=n* =5 the in-plane symmetry becomes face centered orthorhombic whose lattice parameters approach those of the BCC (110) plane for n>>10. GISAXD and TEM data from the blend films one to ten layers thick shows that the addition of 5 vol % PS increases n* to 7. We think that the PS segregates to the interstices in the HCP structure reducing the stretching of the PS blocks and the free energy penalty of HCP versus BCC inner layers. Significant improvement in translational order is also seen in all the films over the copolymer alone.

1GISAXD experiments conducted at Advanced Photon Source, Argonne National Laboratory

C1.00032 Hierarchical Assemblies of Block Copolymer-Based Supramolecules in Thin Films.

SHIH-HUANG TUNG, NISHA C. KALARICKAL, THOMAS SCHILLING, TING XU, Department of Materials Science and Engineering, University of California at Berkeley — Diblock copolymer-based supramolecules can be constructed by associating small molecules to the side chain of one block. In bulk, supramolecules self-assemble into a rich library of hierarchical structures. However, the phase behaviors of such systems in thin films have been rarely studied. Here, we present a structural investigation of polystyrene-b-poly(4-vinylpyridine) (PS-b-P4VP) with hydrogen-bonded 3-pentadecylphenol (PDP) to P4VP block in thin films. We show that using the same diblock copolymer, a variety of hierarchical structures can be obtained by varying the stoichiometry of P4VP to PDP. More importantly, the lamellar and cylindrical microdomains can be oriented normally to the substrates after annealed under chloroform atmosphere. The assembly of P4VP/PDP complex, ca. 4nm in size, is oriented within the microdomain as confirmed by GISAXS and AFM. Thus, control over the supramolecular assemblies at two length scales, i.e. tens of nanometers and a few nanometers, can be simultaneously achieved in thin films.

3We acknowledge APS for facilitating the GISAXS experiments performed as part of this work.
C1.00033 Solvent annealing of block copolymer thin films combined with controlled dewetting

TAE HEE KIM, CHEOLMIN PARK, Yonsei University — The treatment of block copolymer thin film with its solvent vapor has been known as an effective way to control both orientation of microdomains with respect to the surface and their registration into a well defined periodic lattice structure. We have recently demonstrated hierarchically ordered cylindrical microdomains in a poly(styrene-b-ethylene oxide) (PS-b-PEO) thin film combined with microcontact printing. Well ordered PEO microdomains in large area was successfully produced by confined dewetting of thin PS-b-PEO films micropatterned on chemically modified surfaces with self-assembled monolayers during solvent annealing. In order to further control block copolymer thin films upon solvent annealing, we introduce a new patterning method of block copolymer thin films, Plasma Enhanced Polymer Transfer Printing (PEPTP) where a block copolymer thin film spin cast directly on a patterned PDMS mold is easily transferred to a substrate with oxygen plasma. The microstructure of the block copolymer film micropatterned by PEPTP is ordered by the subsequent solvent annealing. The controlled microstructures were characterized by Atomic Force Microscope (AFM), Field Emission Scanning Electron Microscope (FESEM) and Grazing-Incidence Small Angle X-ray Scattering (GISAXS).

C1.00034 Morphological Study of ABC Triblock Terpolymers

SATOSHI AKASAKA, AKIKO MITANI, HIROKAZU HASEGAWA, Department of Polymer Chemistry, Kyoto University, NIKOS HADJICHRISTIDIS, Department of Chemistry, University of Athens — Triblock terpolymers form richer variety of microdomain structures than diblock copolymers. In this study We investigated the microdomain structures in the toluene-cast films of several kinds of ABC triblock terpolymers consisting of polystyrene, polyisoprene and poly(dimethyl siloxane) (PS-b-PI-b-PDMS) by transmission electron microscopy (TEM). As the result we observed various structures composed of lamellae, cylinders and spheres. In addition, we employed electron tomography to analyze the two complex network-forming structures using their three-dimensional images. Consequently, we found that one of them forms core-shell type double gyroid structure in PS matrix, and the other forms core-shell type single gyroid-like structure in PS matrix.

C1.00035 Stimuli-responsive block copolymers in ionic liquids

TAKESHI UEKI, University of Minnesota, MASAYOSHI WATANABE, Yokohama National University, TIM LODGE, University of Minnesota, YOKOHAMA NATIONAL UNIVERSITY COLLABORATION — Ionic liquids (ILs) are room temperature molten salts and have attracted much attention because of their unique properties. The characteristics of ILs (non-volatility, non-flammability, chemical stability, high ionic conductivity) can contribute to high performance energy-conversion materials. On the other hand, some polymers greatly change their solubility in ILs in response to external stimuli such as temperature and light. We have found that poly(N-isopropylacrylamide) (PNIPAm) and poly(benzyl methacrylate) (PBnMA) show upper critical solution temperature (UCST)-type phase behavior and lower critical solution temperature (LCST)-type phase behavior in an ILs, respectively. Most recently, we also discovered that certain polymers change their solubility induced by photo stimuli. In this study, we describe temperature and photo stimuli responsive self-assembly of AB type block copolymers having at least one stimuli-responsive segment in IL solution. Based on the results, we will apply to construct stimuli-responsive physical gels by using ABA triblock copolymer self assembly in an IL.

C1.00036 Polymer translocation through a nanopore in presence of attractive binding particles

ANIKET BHATTACHARYA, University of Central Florida, KAIFU LUO, TAPIO ALA-NISSILA, Helsinki University of Technology, SEE-CHEN YING, Brown University — We use Brownian dynamics simulation to study the translocation of a flexible linear polymer chain through a nanopore into a cell containing particles those bind reversibly to the chain. We study the role of these binding particles [1] by monitoring the mean first passage time, the diffusion of the center of mass, and the net force on the translocating chain as a function of the density of these particles and the strength of the attractive interaction.

C1.00037 Thin Film Morphology of Block Copolymers Containing Polydimethylsiloxane as a Function of the Surface Tension of the Opposing Block

Maurice Wadeley, kevin cavicchi, Dept. of Polymer Engineering The University of Akron — The self-assembly of block copolymers into ordered nanostructures such as spheres, cylinders, and lamellae in the range of 10-100 nm makes them interesting materials for patterning surfaces. Thin films of block copolymers containing poly(dimethylsiloxane) (PDMS) are attractive for patterning due to their high oxygen etch resistance compared to other polymers. The main disadvantage of these polymers for patterning is the low surface tension of PDMS. This causes the preferential migration of PDMS to the air/film interface driving the formation of domains parallel to the interface and surface wetting layers. In this work a series of AB block copolymers containing PDMS have been prepared where the surface tension of the opposing block was varied. The effect of changing the surface tension mismatch between the blocks on the thin film morphology will be discussed.

C1.00038 Novel diblock copolymer morphologies under cylindrical confinement

PRIYANKA DOBRIYAL, THOMAS P. RUSSELL, University of Massachusetts, Amherst — Cylinder forming polystyrene-b-polystyrene diblock copolymers were introduced inside nanoparticles of alumina membrane. The pore diameter was varied in order to study the effect of confinement on diblock copolymer morphologies. The molecular weights of the polymers were also varied and similar morphologies were obtained for similar degree of confinement. The morphologies observed were dependent on the structural frustration (D/Lo), where D is the pore diameter and Lo is equilibrium period spacing. D/Lo was varied from 0.75 to 2. A rich variety of novel morphologies that include single helix, toroids and double helices were observed which are not observed in the bulk. These morphologies also depended upon the surface of the pore walls. Different morphologies were obtained when the pore wall was neutral for same structural confinement.

C1.00039 Hard-Surface Effects in Diblock Copolymer Systems

DONG MENG, YUHUA YIN, JACQUELINE ACRES, QIANG WANG, Colorado State University — Polymer chains near a hard (impenetrable) surface have different conformations from those in the bulk. For diblock copolymers (DBC), a hard surface has both energetic and entropic effects. The decrease of polymer segmental density near a hard surface reduces A-B repulsion and favors self-assembled morphologies with more B-A interfaces near the surface, while the enrichment of chain ends and depletion of middle segments near the surface favor parallel morphologies where chains orient mainly perpendicular to the surface. Using parallel self-consistent field calculations with high accuracy, we have studied in detail the hard-surface effects in three DBC systems: DBC thin films confined between two flat homogeneous surfaces, DBC in nanopores, and DBC nanocomposites.

C1.00040 Structural Rearrangement of Miscible Polymer Blends at the Polymer/Substrate Interface

XIGUO ZENG, SHAH L. HSU, University of Massachusetts Amherst, BRIGITTE WANG, CHARLES W. PAUL, National Starch & Chemical — Structural rearrangement of miscible polymer blends upon contact with a hard substrate has been investigated using Raman Micro-spectroscopy. In this study, blends of crystallizable poly(hexamethylene adipate) (PHEMA) and acrylic random copolymer resin were observed on substrates of polycarbonate (PC), polypropylene (PP), and polymethyl methacrylate (PMMA). Results showed distinct selective migration and subsequent adsorption of polymer at the polymer/substrate interface. The final compositional distribution at the interface is determined by the type of substrate. Theoretical calculations based upon the Flory-Huggins theory were carried out relating the interaction parameter (chi) and miscibility of polymer blends and different substrates. The combined experimental and theoretical results clearly demonstrate that specific interactions at the interface are primary causes for structural rearrangement. Furthermore, the chain mobility and molecular weight of polymer blends were also found to be important factors affecting the migrations and consequent surface adsorption ratios.
C1.00041 A Deuterium NMR Study of Water in a Blend of Soy and Polyether Polyols , VUE ZHAO, XIA TONG, SHAW L. HSU, University of Massachusetts Amherst — The reaction of water with disocyanate is crucial in formation of polyurethane foams. It yields polyurea hard segments whose lengths and segregation from the polyether soft segments depends, among other things, on the reaction kinetics largely determined by the miscibility of water in the polyether. For soy polyol-based polyurethane formulations, the miscibility issue is further complicated by the use of hydrophobic soy polyols. The question of where water molecules are located in the multicomponent blend is of importance; the answer is key to understanding how the morphology and phase separation evolve and are correlated with foam performance. With water content typically around 5%, it has long been challenging to find a technique that can provide this critical information. We developed an NMR method based on the use of deuterium oxide and found that the signal of resonance of deuterium is sensitive to the chemical environment, which allows water molecules to be quantitatively traced in the phase-separated blend of soy and polyether polyols. Moreover, the resonance signal could serve as a probe to monitor the evolution of phase separation upon composition and temperature change.

C1.00042 Surface segregation of end-functionalized homopolymers in a homopolymer matrix , MICHAEL DIMITRIOU, CRAIG HAWKER, EDWARD KRAMER, UCSB — Surface segregation of end-functional poly(2-vinylpyridine) in a blend with P2VP was measured by X-ray photoelectron spectroscopy. A series of chain end functionalized P2VP homopolymers were synthesized via either anionic polymerization or Reversible Addition Fragmentation Chain Transfer RAFT and end capped with either a single fluorinated oligomer or a perfluorinated dendrimer. The degree of end functionalization was characterized using NMR spectroscopy, IR spectroscopy and gel permeation chromatography (GPC).

C1.00043 Identification of self consistent field interaction parameter from continuum Monte Carlo simulation of model polymer blends , JUN KYUNG CHUNG, DAVID MORSE, University of Minnesota — Monte Carlo simulations of binary AB polymer blends have been performed to evaluate the effective interaction parameter \( \chi \) of self consistent field theory, and to quantify corrections to RPA predictions for fluctuations. We consider a model with a non-bonded pair interaction \( v_{ij}(r) = v_{1}(r) \) for which \( f(r) = \) the repulsive Lennard-Jones form, \( \epsilon_{AA} = \epsilon_{BB} \), and \( \epsilon_{AB} = \epsilon_{AA} + \Delta \epsilon \). Using thermodynamic perturbation theory, to first order in \( \Delta \epsilon \), we obtain an interaction free energy with the composition dependence predicted by Flory-Huggins theory, with an effective interaction parameter \( \chi_{e} = \chi_{e} \). Here, \( z_{e} \) is an effective coordination number given by the average of the sum of values of \( f(r) \) for interactions between a test monomer and nearby monomers on other chains, in a reference system with \( \Delta \epsilon = 0 \). Results for composition fluctuations in semigrand ensemble simulations of blends with a range of values of \( \Delta \epsilon \neq 0 \), for several chain lengths, are compared to RPA predictions calculated using this perturbatively defined \( \chi_{e} \) parameter.

C1.00044 Theory For The Miscibility Windows In Blends Of Polypropylene And Ethylene-\( \omega \)-Olefin Copolymers , DAVID WU, HUIMIN LI, Colorado School of Mines, JOHN CURRO, University of New Mexico, COLORADO SCHOOL OF MINES COLLABORATION, UNIVERSITY OF NEW MEXICO COLLABORATION — The miscibility of isotactic polypropylene (iPP) and ethylene-and \( \omega \)-olefin (C2Cs) copolymers has been intensively studied both for its industrial importance and as a model system for complex polymer miscibility behavior. Experiments generally show a window of miscibility in particular regions in the parameter space defined by copolymer composition, volume fraction, and branch chain length. Since the cost of systematic molecular dynamics studies of such systems is still prohibitive, a statistical mechanical approach with the molecular interaction potentials and chain structure as the only input is highly desirable. We present self-consistent Polymer Reference Interaction Site Model (SC-FRISM) calculations for blends of iPP and C2Cs copolymer, where \( C_{x} \) is propylene, butene, and hexene. The calculated enthalpy of mixing is shown to correlate well with experimental trends for the miscibility window. Furthermore, since the theory allows access to molecular-level correlations, insight is provided into the mechanisms for the specific miscibility behavior, including contributions due to chain conformations.

C1.00045 MALDI-ToF Analysis of Model Copolymer Blends , DAVID PAN, MARK ARNOULD, Xerox Corporation — MALDI-ToF mass spectrometry was used to determine the composition of a low MW styrene (S) / n-butyl acrylate (nBA) copolymer. Bernoullian chain statistics were used to predict the copolymer distribution and confirm that MALDI-ToF detects the correct composition. The copolymer was blended with a low MW polystyrene homopolymer having the same end group as the copolymer at several levels to determine if MALDI-ToF could be used to calculate the amount of homopolymer by subtracting the iPP and C2Cs copolymer peaks, where \( C_{x} \) is propylene, butene, and hexene. The calculated enthalpy of mixing is shown to correlate well with the experimental trends for the miscibility window. A model to improve the accuracy of the calculated amount of homopolymer in the blend is discussed.

C1.00046 Tuning the morphology of polymer nanocomposites: Effect of film thickness and nanoparticle shape1,2, SANGAH GAM, AYESNUR CORLU, RUSSELL J. COMPOSTO, University of Pennsylvania — Adding nanoparticles (NPs) to polymer blend films is an attractive route towards enhancing the mechanical, optical, and electronic properties. Previously, we showed that NPs can segregate to the interphase, jam and produce stable bicontinuous structures. In this study, we show how film thickness effects the phase behavior of poly(methyl methacrylate): poly(styrene-ran-acrylonitrile) (PMMA:SAN) blends containing PMMA-modified silica NPs that partition to the PMMA/SAN interface. As NP loading increased and film thickness decreased, the growth of PMMA domains and correlation length was slowed down. As film thickness increased, the critical concentration to achieve jamming decreased suggesting that lower loading can be used to create bicontinuous structures. To investigate NP shape, hydroxyl and methyl-modified silica nanorods (NRs) were added to PMMA:SAN films. These NRs partitioned into the PMMA-rich domains and produced smaller domain size with increased loading. Compared to spherical NPs, NR loading was more effective at slowing down phase evolution.

C1.00047 Synthesis and Characterization of Polyamide Nanocomposites Using Functionalized Carbon Nanotubes , MOHAMMAD MONIRUZZAMAN, KAREN WINEY, University of Pennsylvania, JAYANTA CHATTOPADHYAY, W. EDWARD BILLUPS, Rice University — We have synthesized nylon 6,10 nanocomposites using functionalized single-walled carbon nanotubes using our interfacial \textit{in situ} polycondensation method. The specific functional groups \(- (C_{2}H_{4})_{n}COCI \) on the sidewalls of SWNT were designed to covalently link the nanotubes to the nylon matrix via alkyl segments. The composites show significant improvements in tensile modulus, strength and toughness. The alkyl linkages at the SWNT/nylon 6,10 interface contribute significantly to improving the toughness of the composites. Two extensions of this work will be presented. First, our method will be altered to synthesize nylon 6 via ring opening polymerization in the presence of functionalized nanocomposites. Second, we will adapt our method to other functionalized nanoparticles, possibly graphite. We expect to achieve similar improvements in mechanical properties in these composites.

C1.00048 Bulk and Thin film Properties of Nanoparticle-based Ionic Materials , JASON FANG, MSE CORNELL UNIVERSITY, ITHACA, NY TEAM — Nanoparticle-based ionic materials (NIMS) offer exciting opportunities for research at the forefront of science and engineering. NIMS are hybrid particles comprised of a charged oligomeric corona attached to hard, inorganic nanoparticle cores. Because of their hybrid nature, physical properties — rheological, optical, electrical, thermal — of NIMS can be tailored over an unusually wide range by varying geometric and chemical characteristics of the core and canopy and thermodynamic variables such as temperature and volume fraction. On one end of the spectrum are materials with a high core content, which display properties similar to crystalline solids, stiff waxes, and gels. At the opposite extreme are systems that spontaneously form particle-based fluids characterized by transport properties remarkably similar to simple liquids. In this poster I will present our efforts to synthesize NIMS and discuss their bulk and surface properties. In particular I will discuss our work on preparing smart surfaces using NIMS.
C1.00049 Natural Rubber - Layered Silicates Nanocomposites: Mechanical Properties, Structure & Dynamics. HARIS RETSSOS, MSE CORNELL UNIVERSITY, ITHACA, NY TEAM, IPST-CSIC, MADRID, SPAIN TEAM — Natural Rubber (NR) is one of the most industrially relevant elastomers due to unique elastic properties. Recently we have been developed NR composites with incorporated natural or synthetic clays. We present structural, dynamical and mechanical properties to justify the influence of different parameters, like silicate dispersion, cross-linking density and strength of polymer/silicate interface, on the reinforcement phenomena of those composites. To understand the improvement of the mechanical properties we have investigated the possibility of any bound rubber formation on the outer surface of fillers like in carbon black or silica composites. Evidence from a rather similar situation have been found in silicate nanocomposites by dielectric spectroscopy and the existence of a possible relaxation mode suggests a strong adhesion with the fillers (interfacially adsorbed polymer IA) that corresponds to a glass transition around 100 °C higher than the bulk glass transition.

C1.00050 Multilayered Polymeric Photonic Structure for THz applications. CHEN XIA, LOUIS KOSNOSKY, JIE SHAN, Physics Department, Case Western Reserve University, JOSEPH LOTT, MATTHEW MACKEY, VISHVAS PETHE, ERIC BAER, ANNE HILTNER, CHRISTOPH WEDER, Department of macromolecular science and engineering, Case western Reserve University — Photonic crystal have been widely studied in the visible, and recently become of interest in the THz regime of the electromagnetic spectrum. We have developed a rapid, easy and cost effective method for the preparation of polymeric materials with high refractive indices (RI) for the terahertz (THz) frequencies through extrusion of polymer and nanoparticles of inorganic materials. Using this method, we have fabricated a one-dimensional photonic crystal of polymer/polymer ferroelectric nanoparticles composite with a nearly complete stop band in the THz regime. The result will also be compared to a transfer-matrix calculation.

C1.00051 Controlled Transdermal Iontophoresis by Polypyrrole/Poly(Acrylic Acid) Hydrogel. PHITHUPHA CHANSAI, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — Transdermal drug delivery system delivers a drug into a body at desired site and rate. The conductive polymer-hydrogel blend between polypyrrole (PPy) doped with anion drug and poly(acrylic acid) (PAA) were developed as a matrix/carrier of drug for the transdermal drug delivery system that characteristic releases depend on the electrical field applied. The PAA films and their blend films were prepared by solution casting using ethylene glycol dimethacrylate (EGDMA) as a crosslinking agent. A mechanical blending of PPy particles and PAA matrix was then carried out. Drug diffusions in the blended PPy/PAA hydrogel and the non-blended one were investigated and determined by using a modified Franz-diffusion cell with an acetate buffer, pH 5.5, at 37 °C, for a period of 48 hours to determine the effects of crosslinking ratio and electric field strength. Amounts of the released drug were measured by UV-Visible spectrophotometry. The diffusion coefficient of drug was determined through the Higuchi equation via different conditions, with and without an electric field. Moreover, thermal properties and electrical conductivity of the polypyrrole and drug-loaded polypyrrole were investigated by means of the thermogravimetric analysis and by using a two-point probe meter, respectively.

C1.00052 Development of PEDOT-PSS/Zeolite Composites as a Gas Sensor. POJJAWAN CHANTHAANONT, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — Polymer-based gas sensors have received considerable interest in recent years, due to the gas sensing ability through the electrical conductivity changes when exposed to a particular gas. In our work, poly(3,4-ethylenedioxythiophene) doped with poly(styrene sulfonic acid), PEDOT-PSS, was synthesized via an oxidative polymerization and zeolites were used as selective microporous adsorbent to improve selectivity and electrical conductivity sensitivity of the sensors. PEDOT-PSS were fabricated with zeolites by dry mixing and compressed to form PEDOT-PSS/zeolite composites. Zeolite ZSM-5 of various Si/Al mole ratios were chosen. The composites of zeolite ZSM-5 with different Si/Al mole ratios were investigated for the effect of Si/Al mole ratio on the electrical conductivity sensitivity response when exposed to CO and H2.

C1.00053 Effect of Elastomers Types to the Dielectrophoresis Force and Electromechanical Responses. RUKSAPONG KUNANURAKSAPONG, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — Electroactive polymers have been well known as materials for using in many applications such as actuators, MEMS devices, and artificial muscles. In our work, we investigated the effect of elastomers type on the dielectrophoresis force and the electromechanical responses at various electric field strengths. The specimens were prepared by solvent casting method and cut into thin films. We studied the dielectrophoresis forces of all elastomers by measuring the deflection distance under various electric field strengths (0-600 V/mm), and calculated the force from non-linear deflection theory of cantilever. Our data show that the electromechanical responses and the dielectrophoresis forces of all elastomers increase almost linearly with increasing electric field strength. The acrylic elastomers (AR71) has the lowest electrical yield point (75 V/mm) and it generates the highest force (389 µN at E = 600 V/mm). On the other hand, AR70 had the highest electrical yield point (300 V/mm) and it generates the lowest force (321 µN at E = 600 V/mm). The dielectrophoresis forces appear to depend on several factors such as dielectricity, electrical conductivity, and the storage modulus of elastomers.

C1.00054 Development of poly(ether ether ketone)(PEEK) derived from bisphenol-S for proton exchange membrane (PEM) in direct methanol fuel cells (DMFC). SAIRUNG CHANGKHAMCHOM, ANUVAT SIRIVAT, The Petroleum and Petrochemical College — The currently used Proton Exchange Membrane (PEM) in Direct Methanol Fuel Cell (DMFC) is Nafion®, an excellent proton conductivity in fully hydrated membrane. However, it has major drawbacks such as very high cost, and lost of conductivity at elevated temperature and low humidity. In our work, the novel PEM was based on sulfonated poly(ether ether ketone) (S-PEEK) which was synthesized by the nucleophilic aromatic substitution polycondensation of bisphenol-S, 4,4’-dichlorobenzophenone (DCBP), and sodium 5,5’-carbonylbis(2-chlorobenzenesulfonate) (SDCBP). Bisphenol-S is expected to improve thermal stability due to its high melting point (245°C). S-PEEK was characterized by FTIR, 1H-NMR, TGA, DSC, and titration to determine the degree of sulfonation (D.S.). Composite membranes were prepared by using S-PEEK as polymer matrix and heteropolyacid (HPA) as an inorganic filler. The phosphotungstic acid (PTA) was used due to its highly proton conductivity at high temperature and low water uptake. The membranes were characterized by SEM, TGA, DSC, DMA, and by the measurements of the water uptake (%), the swelling ratio (%), the ion exchange capacities (IEC), the melinum diffusion coefficient, and the proton conductivity.

C1.00055 The Titanium-Boron Nitride interaction. GERARDO J. VAZQUEZ, FERNANDO MAGANA, EDUARDO RANGEL, GREGORIO RUIZ, Instituto de Fisica — The Boron Nitride (BN) has a structure very similar to that of graphite and this what makes it interesting to study. A sheet of BN has a structure similar to that of the graphene. In this work it was studied, using molecular dynamics based on pseudopotentials theory and Density Functional Theory (DFT), the energy of interaction of a titanium atom with a sheet of BN to obtain the position of adsorption of the titanium in this system.
BULENT AKGUN, NIST Center for Neutron Research/ Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742, SUSHIL SATJIA, NIST Center for Neutron Research, National Institute of Standards and Technology, Gaithersburg, MD 20899, HOSUB KIM, KOOKEON CHAR, School of Chemical Engineering and Institute of Chemical Process, Seoul National University, Seoul 151-744, Korea — Surface structure and swelling behavior of polyelectrolyte multilayer films of poly(allylamine hydrochloride) (PAH)/poly(sodium 4-styrenesulfonate) (PSS)/poly(methacrylic acid) (PMAA) have been studied using X-ray and neutron reflectivity (NR). Samples have been prepared either using spin-assisted self assembly or dip coating. Swelling measurements were done in a chamber by using saturated salt solutions. PSS/PMAA blend composition was varied from pure PSS to pure PMAA. We experiment the effect of strong polyelectrolyte on the swelling of the multilayer film. Multilayer films prepared by spin assisted deposition yields well defined films with much smooth interfaces than the films prepared by dip coating. NR results showed that incorporation of strong polyelectrolyte, PSS, into the multilayer decreases the swelling capacity of the film.

C1.00057 Drop retention force as a function of drop size, AISHA LEH, RAFAEL TADMOR, PREETI YADAV, PRASHANT BAHADUR, KUMUD CHAURASIA, LAN DANG, Lamar University — In literature, the force, f, required to slide a drop on a surface is often considered as linear with the width of the drop, w, so that f/w is constant. Dussan’s equation further simplifies this proportionality in the case of advancing and receding contact angles constant with drop size, to show that f/V^{1/3} is constant; V being the drop volume. We show experimentally, however, that f/V^{1/3} is usually a decaying function of V. The Dussan equation shows that the change of f/V^{1/3} with V is also expressed in contact angle variation. Our results, however, illustrate that contact angle variation within the scatter suffices to explain the force variation. It becomes easier to predict contact angle variation based on force variation than vice versa. f/V^{1/3} appeared to decrease more with V in the systems studied.

C1.00058 Comparison of AFM and Density Functional Theory Force Profiles, KEENAN DOTSON, JOHN MCCOY, DANIEL MCCOY, Materials Department, New Mexico Tech, Socorro, NM 87801, SERGIO MENDEZ, JOHN CURRO, BRETT ANDRZEJEWSKI, GABRIEL LOPEZ, DAVID KELLER, Chemical and Nuclear Engineering Department, Univ. of New Mexico, Albuquerque, NM 87131 — Monolayer films of tethered poly(N-isopropylacrylamide) in water (and related systems) are investigated with Atomic Force Microscopy. The resulting profiles are analyzed with Density Functional Theory. Of interest are the effects of temperature, degree of polymerization, and surface coverage upon the colloidal force. A particular challenge is the modeling of the adhesive behavior of the film to the coated AFM tip.

C1.00059 Influence of Molecular Weight and Processing Conditions on the Thermal Stability of Nanoimprinted Polymer Structures, YIFU DING, HYUNWOOK DING, KYLE ALVINE, BRIAN OKERBERG, National Institute of Standards and Technology, JING ZHOU, JACK DOUGLAS, ALAMGIR KARIM, CHRISTOPHER SOLES, National Institute of Standards and Technology — We study the influence of both molecular weight of a polymer resist and the nanoimprint process conditions on the thermal stability of the patterned polymer structures. Specifically, we measure the decay rate of the imprinted polymer patterns during thermal annealing by combining diffraction/reflectance of X-ray light and AFM. As a result, highly entangled polymers are found to contain large amount of residual stresses introduced by the imprinting process, which dominates the pattern decay during the annealing. Levels of the residual stresses can be controlled by the imprinting conditions. On the contrast, unentangled polymers behave like a Newtonian liquid with no sign of residual stress resulted from the patterning process. Furthermore, we also observe correlated lateral pattern instability during the annealing, in addition to the vertical pattern decay. This lateral instability is greatly enhanced when the surfactants were added during the imprint process. Implications of these findings on the nanoimprint fabrication processes will be discussed.

C1.00060 Transitions in Nanometer thin films - Investigations by AC Chip calorimetry, H. HUTH, A. MINAKOV, C. SCHICK, University Rostock, Institute of Physics, Uniplatz 3, 18051 Rostock, Germany — Calorimetry is known as a very powerful tool for the characterization of a wide variety of materials and their transitions. The combination of silicon technology and calorimetry opens up new possibilities in this research area as demonstrated recently. Based on a differential AC calorimeter we show an improved experimental setup combining the advantages of the different methods. The measurements are done at slow scanning or at constant bath temperature. The frequency chosen provides a well defined time scale of the experiment. In several cases, e.g. at glass transition, a direct comparison with results from other dynamic methods like dielectric spectroscopy is possible. Due to the differential setup we achieve a sensitive in the pico Joule per Kelvin range allowing to measure samples below one nanogram and consequently films down to 1 nm thickness. Because of the small total heat capacity (addenda + sample) not only a high sensitivity is achieved but AC measurements at relative high frequencies are possible too.

C1.00061 Adhesion of Surface Ribbons, CHELSEA DAVIS, ALFRED J. CROSBY, University of Massachusetts Amherst — Inspired by numerous examples in nature, significant research advances have recently demonstrated the ability to use topographic surface patterns to control critical surface properties such as adhesion and friction. Although most efforts have focused on the use of lithographically-fabricated fibribular structures, alternative patterns such as surface wrinkles have also been shown to be advantageous for the control of adhesion. We present a new surface structure for soft, elastomeric materials called surface ribbons. These surface structure shells are formed by the controlled buckling of a surface-attached film, and offer many advantages for the control of adhesion, including on-command responsiveness. We present methods for the fabrication of these structures, results demonstrating the ability for these structures to enhance adhesion, and scaling relationships that link the structures’ geometry, materials properties, and measured surface properties. In addition to providing attractive avenues for the creation of responsive surfaces, these structures offer fundamental insight into the mechanisms controlling general patterned surface adhesion.

C1.00062 Analysis of the spincoating of thickness gradient polymer films, MONIKA MICHALEK, JOHN DUTCHER, University of Guelp — Thickness polymer films can be prepared by dropping one drop of a polymer solution onto a spinning substrate at a position that is displaced from the axis of rotation, resulting in films in which the thickness increases with increasing radial distance. We have studied the spincoating of polystyrene thickness gradient films in two ways: (1) by fitting the measured radial thickness profiles of the dry films to a simple analytical model; and (2) by measuring the drying of the films during the spincoating process by monitoring the time dependence of the intensity of laser light reflected from the film. The results obtained for solutions of polystyrene dissolved in solvents of different volatility will be compared.

C1.00063 Segmental dynamics of thin polymer films probed by dye reorientation, KEEWOOK PAENG, HAU-NAN LEE, STEPHEN SWALLEN, MARK EDIGER, Department of Chemistry, University of Wisconsin-Madison — We have studied the dynamics of both freestanding and supported polymer thin films (down to 25 nm) by probing reorientation of dilute dye molecules. Well below Tg, dye molecules were photobleached using intense linearly polarized light creating an anisotropic distribution. Anisotropy was measured using circularly polarized light and probing fluorescence parallel and perpendicular to the bleaching beam. Temperature was linearly ramped during anisotropy measurement; near Tg, the anisotropy dropped to zero. The dynamics of a 50 nm poly (tert-butyl styrene) film were faster than bulk dynamics by an amount equivalent to a 5 K shift in Tg. Faster dynamics compared to bulk films were also found for polystyrene and these results will be compared to the previous Tg measurements. Four different polymers, polystyrene, poly (tert-butyl styrene), poly (methyl methacrylate), and poly (2-vinyl pyridine) were studied.
C1.00064 Drop retention force as a function of rested time . RAFAEL TADMOR, AISHA LEH, KUMUD CHAURASIA, PRASHANT BAHADUR, LAN DANG — The force, f, required to slide a drop past a surface is shown to be a growing function of the time, t, the drop waited resting on the surface prior to the commencement of sliding along it. In this first report on the “rest time” effect we demonstrate the existence of this phenomenon in different systems, which suggests that this phenomenon is general. We show that df/dt is never negative. The shorter the resting times, the higher df/dt is. As the resting time increases df/dt decreases towards zero (plateau) as t tends to infinity. We attribute this phenomenon to the corragation of the surface by the drop due to the unsatisfied normal component of the Young equation.

C1.00065 Controlled Growth of Organic Semiconductor Films Using Liquid Crystal Solvents . KEVIN BUFKIN, BROOKS OHLSON, BEN HILLMAN, BRAD JOHNSON, DAVID PATRICK — Interest in using organic semiconductors in applications such as liquid crystal displays, photovoltaic devices, and RFID tags stems in part from their prospects for enabling significantly reduced manufacturing costs compared to traditional inorganic semiconductors. However, many of the best performing prototype devices produced so far have involved expensive or time-consuming fabrication methods, such as the use of single crystals or thin films deposited under high vacuum conditions. It presents a new approach for growing low molecular weight organic crystalline films at ambient conditions based on a vapor-liquid-solid growth mechanism using thermotropic nematic liquid crystal (LC) solvents. Tetracene is deposited via atmospheric-pressure sublimation onto substrates coated by a LC layer oriented using rubbing polyimide, producing films that are highly crystalline, with large grain sizes, and possessing macroscopic uniaxial orientation. This poster will describe the growth mechanism, discuss the effects of processing conditions such as LC layer thickness, substrate temperature and flux rate, and compare the results to a model of diffusion limited aggregation accounting for the finite thickness of the solvent layer.

C1.00066 Single-chain conformation and dynamics in connected chambers: Theory and simulation of translocation and threading . ERICA SALTZMAN, CHIUTAI ANDREW WONG, MURUGAPPAN MUTHUKUMAR, University of Massachusetts at Amherst — Confinement in a series of small chambers connected by narrow pores may be viewed as a model system for translocation in the absence of an applied force, as well as for more general instances of spatially heterogeneous confinement relevant to biological and materials applications. Brownian dynamics simulations are performed for single chains equilibrated in this system, and a theoretical treatment is developed. Short chains undergo translocation between chambers, while long chains thread several chambers and diffuse more rapidly. Measures of chain size and mobility are analyzed and compared.

C1.00067 Monte Carlo simulations of the selective adsorption of heteropolymers on heterogeneous surfaces . YONGMEI WANG, JESSE ZIEBARTH, University of Memphis — Lattice Monte Carlo simulations are used to study selective adsorption of heteropolymers on heterogeneous surfaces. We focus on how statistical correlation between sequence types and surface patterns affects the critical adsorption point (CAP). We show that statistically patchy and statistically alternating surfaces selectively adsorb blocky and alternating chains, respectively, while surfaces with a random distribution of attractive sites do not selectively adsorb any types of chains. We also show that selectivity is maximized near the CAP. Selectivity of checker-board surfaces have also been examined and we show that higher order parameters describing sequences and surface patterns are needed to fully characterize the selectivity of these surfaces toward different sequences.

C1.00068 Progress on a ‘spectral filtering’ for SCFT algorithms: Removing topological defects in block copolymer simulations . SCOTT SIDES, Tech-X Research Corporation, BOBBY SUMPTER, Oak Ridge National Labs — Using block copolymers as mesoscale templates has potential applications for improved photovoltaic devices, fuel-cells and magnetic storage media. For many of these applications the long-range order and orientation of the copolymer phase-separated domains is crucial. Self-consistent field theory (SCFT) for dense polymer melts has been highly successful in describing complex morphologies in block copolymers. Field-theoretic simulations based on SCFT theory are able to access large length and time scales that are difficult or impossible for particle-based simulations such as molecular dynamics. It has been shown that real-space numerical SCFT calculations can describe certain features of topological defects in a bulk copolymer. However, for large SCFT simulations the presence of these topological defects can obscure the identification of the appropriate lowest-energy space group for a complex block copolymer mixture. A ‘spectral filtering’ algorithm has been shown to help reduce the presence of topological defects in SCFT calculations of block copolymer structure by removing certain frequency components of the chemical potential fields during the simulation. Further progress on this filtering method will be presented and shown to improve the removal of defects in large, 3D-SCFT simulations.

C1.00069 Computer simulation of the formation of random-blocky copolymers . LAWRENCE STRICKLAND, JAN GENZER, CAROL HALL, North Carolina State University — A recent computational study described a new method for producing random copolymers (RCPs) with tunable monomer sequence distribution; the technique is based on adjusting the size of a homopolymer (say A) coil and performing a chemical reaction (“coloring”) with certain chemical mienities (say B) on the accessible monomers of the homopolymer chain. While experimental evidence exists that can relate the comonomer distribution in the A-B copolymer to the original homopolymer dimension in the solvent, the “coloring” mechanism is difficult to reconcile as there exists competing mechanisms, involving the coloring process itself and the tendency for the copolymer to change conformation during the “coloring” driven by the changing solubility of the resultant A-B copolymer relative to that of the A homopolymer. In this work we use discontinuous molecular dynamics (DMD) to comprehend the formation of A-B copolymers. Our RCPs were constructed by reacting homopolymers in varying solvents and reagent concentrations. We show how we can selectively tune the randomness by varying chain length and system temperature. While increasing system temperature leads to formation of A-B copolymers with random distribution of segments, increasing monomer solubility leads to A-B copolymers with random-blocky co-monomer sequences.

C1.00070 Computer simulation of formation of random-blocky diblock copolymers in dilute solutions . JESSE BOER, APICHART LINHANANTA, Department of Physics, Lakehead University — The formation of micelles and vesicles in dilute solutions of amphiphilic diblock copolymers is investigated by the real-space self-consistent field theory (SCFT) in two dimensions and by a Monte Carlo lattice model in three dimensions. The real-space SCFT method produced rodlike and spherelike micelles and vesicles. It is found that the shapes of the microstructures are determined by the initial conditions in the SCFT algorithms, and that, in general, vesicles have lower free energy than micelles. In contrast, the Monte Carlo simulation of the lattice model, it is found that as the volume fraction of copolymer increases, the microstructure go from spherelike micelles to rodlike micelles to vesicles and, at high fraction, to the lamellar phase.

Secondary Forces as a Driving Mechanism for Thermally Induced Drug Release in ROMP based Polymers, CASEY KIMBALL, SHAW L. HSU, GREG TEW. University of Massachusetts Amherst — To control drug release via a thermal mechanism is important from both a fundamental and application standpoint. Traditionally, biocompatible polymers with secondary interactions in the backbone have been investigated. Instead, we have synthesized a novel poly(ethylene oxide) crosslinked Ring Opening Metathesis Polymerization based polymer comprised of a polyboroborone derived backbone with multiple substituent groups, including a tetra-ol, diamine, dicarboxylic acid and amino acid based side chains. The strength of secondary interactions based on the functional groups present plays a critical role in chain dynamics and thermal properties. DSC measurements revealed a substantial change in the thermal transitions to be as high as thirty degrees, depending on substituent group and crosslinking properties. Inspired spectroscopy has been employed to characterize the functional groups present. It has been revealed that the strength of the hydrogen bonds is strongly correlated with the transition temperature. Additionally, the presence of water has a perturbing effect of disrupting the hydrogen bonding network and affecting the chain dynamics of the overall crosslinked system.

DNA Electrophoresis using entropic trapping, HAOBIN LUO, DILIP GERSAPPE, Dept of Materials Science and Engineering, Stony Brook University, Stony Brook, NY 11794 — We examine the effects of surface patterning on DNA electrophoresis. Using chemically patterned stripes of different widths we can control the separation of DNA. Due to entropic trapping of the chains on the stripes, depending on the width of the stripe and the length of the DNA, we show (using MD simulations) that it is possible to separate chains in increasing order of length and in decreasing order.

We show an experimental realization of this effect and illustrate how DNA motion on the surface can be influenced by both the width of the stripe and the periodicity of the pattern.

Protein adsorption at calcium oxalate monohydrate crystal surfaces, J. WESSON, Department of Veterans Affairs, X. SHENG, Abbott Laboratories, J. RIMER, New York University, T. JUNG, Seoul University, M. WARD, New York University — Calcium oxalate monohydrate (COM) crystals are the dominant inorganic phase in most kidney stones, and kidney stones form as aggregates of COM crystals and organic material, principally proteins, but little is known about the molecular level events at COM surfaces that regulate COM aggregation. We have examined the influence of polyelectrolytes on the force of adhesion between chemically modified atomic force microscopy (AFM) tips and selected COM crystal faces in saturated solution. In general, we found that polyanions bind to COM surfaces and block adhesion of a carboxyfunctionalized AFM tip, while polycations had no measurable effect on adhesion force under the same conditions. We did observe a unique absence of interaction between poly(glutamic acid) and the COM (100) face compared to other synthetic polycations, and some native urinary protein structures also exhibited unique face selective interactions, suggesting that simple electrostatic models will not completely explain the data.

Phase Transitions in Superparamagnetic Polymer Brush Particles, ANNETTE SCHMIDT, Heinrich Heine-Universitaet Duesseldorf, ANDREAS KAISER, Heinrich Heine-Universitaet Duesseldorf — Nanostructured inorganic / organic hybrid materials play an outstanding role in modern technology. We present results on the synthesis and characterization of novel thermo- and magnetoresponsive polymer brush coated particles. The investigated system is composed of nanocrystalline magnetite (Fe3O4) as an inorganic core and a covalently anchored polystyrene (PS) shell. In cyclohexane, a thermostressive magnetic fluid is obtained due to a critical solution behaviour of the PS arms. Cyclohexane. Beside the phase transition of Fe3O4@PS particles, the well known coil-to-globule transition of Fe3O4@PS particles in cyclohexane is investigated. Both phenomena are compared to the behaviour of linear polymeric brushes. The presented results show that magnetic brush particles are well-suited as a model system for the investigation of temperature transitions of surface-attached polymers.

3D Analysis of Lattice Defects in the Gyroid Network Structure of a Block Copolymer/Homopolymer Blend, SATOSHI AKASAKA, TETSURO OKAMOTO, VINCENT H. MAREAU, HIROKAzu HASEGAWA, Department of Polymer Chemistry, Kyoto University — The bicontinuous microdomain structures known as gyroid cubic phase (a = 3d) can be observed in a narrow composition region of a block copolymer system. In the study of the casting process of the polystyrene-block polysoprene (SI)/homopolystyrene (hS) blend with a particular composition from toluene solution, we observed that sponge phase, an irregular network structure, transformed into gyroid phase by expelling excess hS outside of the gyroid grains. During the growth of the gyroid grains, a variety of interesting lattice defects appear due to the remaining excess hS in the grains. Such defects may be useful in designing photonic band-gap devices based on gyroid cubic phase if we can control them. However, the analysis of the defect structures in gyroid network is not easy since gyroid network itself is too complex. So, we employed a novel technique, electron tomography, to visualize the 3D defect structures in gyroid network. In this presentation, we demonstrate how useful it is and clarify the defects structure in 3D

Phase Behavior of Polymer Blends Containing End-Associating Polymers, MICHELLE WRUE, MITCHELL ANTHAMATTEN, University of Rochester — Polymer blending is an important route to the creation of new polymeric materials with superior processing and tunability. We are studying the effects of strong, site-specific, hydrogen-bonding groups on the phase behavior of traditional polymer blends exhibiting upper critical solution temperature (UCST) behavior. Ureidopyrimidinone (UPy) functional groups self-associate through the formation of four hydrogen bonds. We have synthesized telechelic telepolyureidopyrimidinone (TPU-P and TPY-P) and poly(4-methyl styrene) (P4MS). We have characterized these materials in ternary polymer-polymer-solvent systems to investigate the miscibility of blends containing UPy-functionalized polymers. Polymer pairs studied include PS/polybutadiene (PS) and PB/P4MS. Phase behavior and end-association were studied using laser light scattering and dilute solution viscometry. Data from PS/PB/toluene blends containing only one functionalized polymer, PS, indicate a reduction in miscibility relative to the corresponding parent blend. PS/P4MS blends in which both polymer components contain the UPy functional group are also being studied.

Self-assembly of rod-coil block copolymers from weakly to moderately segregated regimes, RAFFAELE MEZZENGA, NICHOLAS SARY, University of Fribourg, Physics Department, GEORGES HADZIOANNOU, CYRIL BROCHON, University Louis Pasteur, France — We report on the self-assembly behaviour of two homologue series of rod-coil block copolymers in which, the rod, a π-conjugated polymer, is maintained fixed in size and chemical structure, while the coil is allowed to vary both in molecular weight and chemical nature. This allows maintaining constant the liquid crystalline interactions, expressed by Maier-Saupe interactions, ω, while varying the tendency towards microphase separation, expressed by the product between the Flory-Huggins parameter and the total polymerization degree, ΧN. Therefore, the systems presented here allow testing directly some of the theoretical predictions for the self-assembly of rod-coil block copolymers in weakly segregated regime. The two rod-coil block copolymer systems investigated, were poly(DEP-phenylenevinylene-b-styrene), whose self-assembly takes place in the very weakly segregated regime, and (DEP-phenylenevinylene-b-4vinylpyridine), for which self-assembly behaviour happens under increased tendency towards microphase separation, hereby referred as moderately segregated regime. Experimental results for both systems are compared with predictions based on Landau expansion theories.

Self-Organization on Multiple Length Scales in “Hairy-Rod”–Coil Block Copolymer Supramolecular Complexes, RAFFAELE MEZZENGA, MATTHEW HAMMOND, University of Fribourg, Physics Department, HARM-ANTON KLOK, EPFL, Lausanne — A peptide-synthetic hybrid block copolymer, poly(ethylene oxide)-block-poly(L-glutamic acid), is demonstrated to form supramolecular complexes with primary alkylamines of varying alkyl chain length (8 to 18 methylene units) in organic solvents via acid-base proton transfer and subsequent ionic bonding. The peptidic block being in the α-helical conformation, these materials behave as coil–“hairy rod” block copolymers, and show hierarchically self-organized nanostructures in the solid state; X-ray scattering measurements show mesomorphic behavior at the length scales of both the overall block copolymer and the polypeptide-alkylammonium complex.
C1.00079 Self-Consistent Field Theory Simulations of Confined 2D Block Copolymer Thin Films, SU-MI HUR, GLENN FREDRICKSON, UC Santa Barbara, AUGUST BOSS, EDWARD KRAMER, CARLOS GARCIA-CERVERA, UC Santa Barbara — We present self-consistent field theory (SCFT) simulations of block copolymers confined in a square well in order to guide self-assembly towards defect-free in-plane arrays. In particular, tetragonal (square) packing, which is thought to be crucial to developing novel information storage and electronic devices, has been observed in simulations of thin films of AB diblock copolymers with suitable A homopolymer additives confined in square wells. While the A-B + A system only supports square lattices of limited sizes (up to 4x4), we were able to produce large-area defect-free square lattices using blends of chemically different diblock copolymers with suitable attractive interactions between blocks. Our simulations demonstrate that order originates at the walls and then permeates throughout the system.

C1.00080 Orientation Control of Diblock Copolymer Thin Films by the Addition of Amphiphilic Surfactants, JEONG GON SON, KOOKHEON CHAR, Seoul National University, PAUL F. NEALEY, HUIMAN KANG, University of Wisconsin — The precise control of the orientation of block copolymer (BCP) thin film is crucial to fully exploit the potential of these materials for applications in nanotechnology. The orientation control is, however, challenging as BCP nanodomains spontaneously self-assemble in a configuration that minimizes the total free energy of the system. The perpendicular orientation of BCP domains, in particular, has potential for device applications. In this presentation, we would like to introduce a new approach for the perpendicular orientation of BCP domains from the top of a BCP film toward a bottom substrate. Our concept is based on the properties of surfactants that naturally locate at interfaces to tailor the surface properties of materials. We demonstrate how the segregation of low molecular weight surfactants, oleic acid (OA) in present case, at the top surface of a PS-b-PMMA BCP thin film can easily create energetically neutral conditions for the BCP, resulting in the desired perpendicular orientation. The main advantage of this new approach is that nano-scale patterns can be generated at the top of a BCP film after short annealing time on any substrates. We verified the structures and mechanisms of the surfactant-assisted perpendicular orientation of thin block films using AFM, SEM, GISAXS and Neutron Reflectivity.

C1.00081 Diblock copolymer thin films: Compressed fluid induced order, PETER GREEN, ABRHAM ARCEO, University of Michigan — We show that liquid and super critical CO2 induces long-range order into thin film, symmetric, polystyrene-b-polymethylmethacrylate (PS-b-PMMA) diblock copolymers, supported by SiO2/Si substrates, in a temperature range where both bulk and thin films of these materials remain ordered. Under vacuum conditions the substrate induces order the thin films at temperatures significantly above the bulk order-disorder transition temperature. Ordering occurs at $N \approx 7.94$, where $N$ is the Flory-Huggins interaction parameter and $N$ is the degree of polymerization, which is below the bulk value of $N_{bulk} = 10.5$. In the presence of CO2, the transition shifts to yet lower values of $N$, indicating a more significant degree of incompatibility between the PS and PMMA systems of $N > 10.5$ become phase mixed in the presence of liquid or super critical CO2.

C1.00082 Crystal Orientation of Polyethylene oxide in a Defect-Free 1D Confined System of Polyethylene oxide-b-Polystyrene Diblock Copolymer Single Crystals, MING-SIAO HSIAO, JOSEPH X. ZHENG, RYAN M. VAN HORN, RODERICK P. QUIRK, STEPHEN Z. D. CHENG, The University of Akron, BERNARD LOTZ, EDWIN L. THOMAS, HSIN-LUNG CHEN, THE UNIVERSITY OF AKRON TEAM, MIT COLLABORATION, INSTITUT CHARLES SADRON COLLABORATION, NATIONAL TSING-HUA UNIVERSITY COLLABORATION — Highly oriented crystalline-amorphous block copolymers under a large amplitude shear open a window for studying crystal orientation evolution within a one-dimensional confined environment at different degrees of supercooling, however, inevitable defects and internal stresses are the main cause of releasing the confinement effect on crystal polymeric orientation, which is a 1-D confined lamellae of 10 nm PS-b-PBEO solution grown single crystal were used to study the crystal orientation evolution as a function of crystallization temperature (Tcr) via recrystallization. From DSC and temperature dependent SAXS, it was found that a high quality PS layers can induce the formation of oriented crystals, which is in good agreement with the recent model of some groups. In this paper, we report a detailed analysis of this and other systems, which can be described as the model of a charge transport in confined polymer systems, which are used as a foundation for other research.

C1.00083 Well-Defined Fullerene-Containing Diblock Copolymers Based on Regioregular Poly(3-hexylthiophene) and Poly(methyl methacrylate): Synthesis and Photovoltaic Properties, JEA UK LEE, WON HO JO, Materials Science and Engineering, Seoul National University, ALI CIRPAN, TODD EMRICK, THOMAS RUSSELL, POLYMER SCIENCE AND ENGINEERING, UNIVERSITY OF MASSACHUSETTS — Polymeric solar cells based on conjugated polymer and fullerene materials have opened a new avenue to develop economically renewable energy resources. Recently, bulk heterojunction solar cells fabricated by simplifying blending regioregular poly(3-hexylthiophene) with fullerene derivatives have resulted in great improvement in the power conversion efficiency. Although a remarkable progress has been made, bulk heterojunction solar cells still have several problems. First, in all of the bulk heterojunction solar cells, the conjugated polymer and electron acceptor have been randomly intermixed throughout the film. Second, the blend of conjugated polymer and fullerene derivatives usually results in a morphophase separation, limiting the charge separation and thus the power conversion efficiency in a photovoltaic device. We have designed and synthesized novel diblock copolymers composed of regioregular poly(3-hexylthiophene) and fullerene containing poly(methyl methacrylate) (PMMA). The diblock copolymers self-assemble into nanostructured morphologies (lamellae or hexagonally packed cylinder), which provide exons with large interfaces for charge separation on the nanometer scale.

C1.00084 Point Mutations Effects on Charge Transport Properties of the Tumor-Suppressor Gene p53, RUDOLF A. ROEMER, Department of Physics and Centre for Scientific Computing, University of Warwick, UK, CHI-TIN SHIH, Department of Physics, Tunghai University, Taiwan, STEPHAN ROCHE, CEA/DSM/DRFMC/SPSMS Grenoble, France — We report on a theoretical study of point mutations effects on charge transport properties in the DNA sequence of the tumor-suppressor p53 gene. On the basis of effective tight-binding models which simulate hole propagation along the DNA, a statistical analysis of mutation-induced charge transfer modifications is performed. In contrast to non-cancerous mutations, mutation hotspots tend to result in significantly weaker changes of transmission properties. This suggests that charge transport could play a significant role for DNA-repairing deficiency yielding carcinogenesis.

1 CTS (National Science Council grant 95-2112-M-029-003), RAR (Leverhulme grant F/00215/AH)

C1.00085 Endohedral Fullerenes in Organic Thin Film Photovoltaic Devices, RUSSEL ROSS, EDWARD VANKEUREN, Georgetown University, MARTIN DREES, CLAUDIA CARDONA, BRIAN HOLLOWAY, Luna Nanoworks, DIRK GULDI, Friedrich-Alexander-Universitat Erlangen-Nurnberg — Cost factors in inorganic solar cells have opened up a new path to less expensive manufacturing techniques using bulk heterojunction polymer/fullerene based solar cells. Using empty cage fullerene derivatives as the acceptor material, state-of-the-art organic photovoltaics currently display ~5% overall conversion efficiency. One of the main factors limiting the efficiency in organic solar cells is the low open circuit voltage. The open circuit voltage is governed by the molecular orbitals of the donor and acceptor material; therefore better matching of the orbitals will lead to improved voltages. We present a novel acceptor material based on TRIMETASPHHERE® carbon nanomaterials (TMS). TMS are endohedral metallofullerenes that consist of a trivalent nitride cluster enclosed in a C80 cage. First-generation TMS derivatives have been synthesized; electrochemical and photophysical studies show behavior consistent with C60 but with improved molecular orbitals. The electrochemical data suggests a maximum voltage increase of up to 280 mV over C60-PCBM-based devices. Organic solar cell devices are currently under construction and performance results will also be presented.

3 AFRL MANTECH program (contract # USAF571004C0001) & AFOSR (contract # FA9550-07-C-0050).
C1.00086 Multilayer polymer light emitting diode (PLED) devices studied using resonant soft x-ray reflectivity. CHENG WANG, B. WATTS, T. ARAKI, H. ADE, NCSU, A. HIXEMER, LBNL, A. GARCIA, T.-Q. NGUYEN, G.C. BAZAN, K.E. SOHN, E.J. KRAMER, UCSB — The performance of multilayer PLED devices is likely to be strongly affected by the structure of the interface between the active layers. Using resonant soft x-ray reflectivity (RSoXR), the contrast between polymer components can be greatly enhanced by tuning the photon energy to absorption resonances near 285 eV and the interfacial width can be measured. The interfacial widths of model bilayers of poly(9,9-bis(6’-N,N,N-trimethylammoniumhexyl)fluorene-co-alt-1,4-phenylene bromide) (PFNBr)/poly(2-methoxy-5-(2’-ethylhexyloxy)-p-phenylene vinylene) (MEH-PPV) on SiO2 substrates were manipulated by changing the sample preparation process and were measured by RSoXR, allowing w to be correlated to device performance. In addition, for a real PLED device with a more complicated multilayer structure, but missing the top Al electrode, it was demonstrated that the top four interfaces can be fully characterized using RSoXR, adjusting the material contrast in order to selectively observe different layers by tuning to different photon energies.

C1.00087 Breath Figure Templated Assembly of Ordered and Disordered Array of Holes in Polymer Films. VIVEK SHARMA, School of Polymer, Textile and Fiber Engineering, SAI M. GOGNENI, MATIJA CRNE, School of Chemistry and Biochemistry, MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332 — Breath figures are patterns formed when water vapor from our breath condenses over a cold substrate. These patterns, which mimic the behavior of dew or chemical vapor deposition, comprise of drops with range of self-similar sizes, and form through coalescence assisted growth. Water drops that condense over evaporating polymer solutions can organize into close packed arrays, and template nicely ordered arrays of holes in polymer films. Using experiments and theory, we examine the role of various parameters that contribute to the formation of ordered assembly. We will present our findings about how the choice of polymer and polymer concentrations and air flow conditions influences the extent of order and the pore size.

C1.00088 Carbon nanotube based gecko inspired self-cleaning adhesives. SUNNY SETHI, LIEHUI GE, The University of Akron, PULICKEL AJAYAN, Rensselaer Polytechnic Institute, DHINOWALA ALI, The University of Akron — Wall climbing organisms like geckos have unique ability to attach to different surfaces without use of any viscoelastic material. The hairy structure found in gecko feet allows them to obtain intimate contact over a large area thus allowing them to adhere using van der Waals interactions. Not only high adhesion, the geometry of the hairs makes gecko feet self-cleaning, thus allowing them to walk continuously without worrying about loosing adhesive strength. Such properties if mimicked synthetically could form basis of a new class of materials, which, unlike conventional adhesives would show two contradictory properties, self-cleaning and high adhesion. Such materials would form essential component of applications like wall climbing robot. We tried to synthesize such material using micropatterned vertically aligned carbon nanotubes. When dealing with large areas, probability of defects in the structure increase, forming patterns instead of using uniform film of carbon nanotubes helps to inhibit crack propagation, thus gives much higher adhesive strength than a uniform film. When carbon nanotube patterns with optimized aspect ratio are used, both high adhesion and self cleaning properties are observed.

C1.00089 Understanding the Structure and Phase Behavior of Model DNA-Linked Nanoparticles by Monte Carlo Simulations. JUAN ARAQUE, Rice University, ATHANASSIOS PANAGIOTOPoulos, Princeton University, MARC ROBERT, Rice University — The high specificity and selectivity of DNA hybridization makes nucleic acid recognition a powerful tool for bottom-up assembling approaches. Here, we propose a coarse-grained model to address the question of how nanoparticles tethered with single stranded DNA self-assemble in solution. Our approach employs a computationally efficient discretization of hard-core interactions and a high-coordination lattice, in combination with parallel tempering and multicanonical Monte Carlo simulations. This simplified model of DNA strands not only accounts for all physically relevant interactions, but also enables an significant reduction of the problem dimensionality. We discuss the effects of a number of system parameters and assembling architectures on the equilibrium structures and phase behavior. In addition, we establish the relation of these results with experimental observations.

C1.00090 Relationship Between Interfacial Strength and Materials Properties in Hybrid Organic/Inorganic Nanomaterials. CHAD SNYDER, MICKEY RICHARDSON, JING ZHOU, GALE HOLMES, ALAMGIR KARIM, NIST Polymers Division, NANDIKA D’SOUZA, University of North Texas, Dept. of Materials Science and Engineering — Thermal interface materials (TIM’s) are critical to the semiconductor electronics industry for heat dissipation, a potential show-stopper for future technology nodes. Essentially, an epoxy nanocomposite, TIMs suffer from a series of typical nanocomposite limitations including heat conduction in nanoscale inclusions, nanoparticle dispersion, void formation with thermal cycling, and interfacial resistance between the matrix and filler. It is postulated that the interfacial adhesion between the matrix and nanofiller is at the root cause of many of these difficulties, however, few techniques exist to characterize this critical property. Compounding this are the overall difficulties associated with characterizing these materials in their ultimate applications, i.e., thin films. To this end, a novel series of organic/inorganic hybrid nanostructured materials based on layered double hydroxides in epoxy matrices were designed as a test bed to develop the measurement techniques needed to elucidate the relationship between the material structure and dynamics and the ultimate materials properties. Initial results are presented based on characterization by mechanical, dielectric, and thermal spectroscopies.

C1.00091 Control of Polymer Translocation with External Forcing. SANTTU OLLILA, Helsinki University of Technology, Finland, KAIFU LIO, TAPIO ALA-NISSILA, Helsinki University of Technology, SEE-CHEN YING, Brown University — We investigate the dynamics of driven polymer translocation through a nanopore using two-dimensional Langevin dynamics simulations within the bead-spring model. A pulling force F is exerted on the first monomer whilst there is an opposing force F_{E_0} in the pore. For this setup, we calculate the distribution of translocation time τ, which is defined as the time for the polymer to traverse from one side of the membrane to the other, and the waiting time t_{W}, which is defined as the time between the translocations of the i-th and the (i+1)-th bead. As our main result, we characterize the fluctuations and the positions of the beads along the direction of F with respect to the position of the segments in the nanopore, and with respect to the position of the pore. Implications of these results to actual sequencing experiments are discussed.

C1.00092 Structural Relaxation of Stacked Ultrathin Polystyrene Films. YUNG P. KOH, SINDEE L. SIMON, Texas Tech University — The kinetic behavior of stacked polystyrene ultrathin films is investigated by differential scanning calorimetry (DSC) and compared to the behavior of bulk polystyrene. The fictive temperature (T_f) was measured as a function of cooling rate and as a function of aging time for aging temperatures below the nominal glass transition temperature (T_g). The stacked thin films show enthalpy overshoots in DSC heating scans which are reduced in height but occur over a broader temperature range relative to the bulk response for a given change in fictive temperature. The cooling rate dependence of the limiting fictive temperature, T_f', is also found to be higher for the stacked thin film samples; the result is that the magnitude of the T_g depression between the thin film samples and the bulk is inversely proportional to the cooling rate consistent with other results in the literature. We also find that the rate of physical aging of the stacked thin films is comparable to the bulk when aging is performed at the same distance from T_g; however, when conducted at the same aging temperature, the thin film samples show accelerated physical aging due to their depressed T_g values. This result is in contrast to recent work in the literature on PMMA ultrathin films and on o-TP confined in nanopores.
Surface Dynamics Of Homopolymer Brushes

C1.00093

MARK D. FOSTER, The University of Akron, Akron, OH 44325-3909 — The surface dynamics of polystyrene (PS) and poly(n-butyl acrylate) (PnBA) homopolymer brushes were investigated by X-ray photon correlation spectroscopy for the first time. Within the range of time (0.2 - 1100 s) and length scale (0.2-5 nm) studied, no fluctuations of the brush surfaces were detectable. When PS brushes of thicknesses in the range of 9-101 nm and high grafting density (>0.5 chains/nm²) were considered at temperatures up to Tg+130°C, no relaxation was visible within our window of in-plane wave-vector. Even reduction of the grafting density from 0.6 to 0.1 chains/nm² did not bring the relaxation into the window. Likewise, no relaxation was observed for PnBA brushes up to 170°C above Tg. The suppression of surface fluctuations is a result of covalent tethering.

Mass Transport through Dynamic Polymer Networks Containing Reversibly Associating Side-Groups

C1.00094

JIAHUI LI, ANDREW HILMER, MITCHELL ANTHAMATTEN, Department of Chemical Engineering, University of Rochester, HUNG CHUNG, JAMES MCGRATH, Department of Biochemical Engineering, University of Rochester — Dynamic polymer networks containing both covalent crosslinks and reversibly associating side-groups were synthesized. Those polymers exhibit novel shape-memory properties due to strong temperature dependence of side-group association. Diffusion of different molecules through polymer networks were studied using three techniques: gravimetric sorption, dye permeation, and fluorescence recovery after photo-bleaching. The dependence of diffusion on temperature, network architecture, solute size, and the interaction between the solute and the network will be discussed. Results show polymer networks with reversibly associating side-groups exhibit unusually strong temperature dependence. This study highlights the potential of these and other dynamic networks to serve as precision drug or reagent release devices.

Nanoscale building blocks for the development of novel proton-exchange membranes

C1.00095

XIAORONG WANG, Bridgestone Americas, Center for Research and Technology, 1200 Firestone Parkway, Akron, OH 44317-0001, USA. Email: WangXiaorong@BFUSA.com — The reinforcement of nano-sized polymeric hard core-hairy shell particles in a polymer matrix of chemically identical chains was investigated by dynamical mechanical measurements. We found that the magnitude of reinforcement depended strongly on the phase behavior of the nanoparticles in the polymer matrix. In one phase region, the mechanical response was nearly linear, and the reinforcement was approximately described by the Guth-Smallwood relationship in terms of filler concentration. In two phase region, however, the mechanical response was largely nonlinear, even for strain lower than 1%, and the reinforcement at low strains was an exponential function of the filler concentration. We show that by tailoring the filler interaction potentials the entire reinforcing mechanism can be changed.

Meso-scale modeling of block copolymer/colloid nano-composites

C1.00096

MARCO PINNA, School of Computing, Engineering and Physical Sciences, University of Central Lancashire, Preston, UK, IGNACIO PAGONABARRAGA, Department of Fundamental Physics, University of Barcelona, Spain, ANDREI ZVELINDOVSKY, Centre for Materials Science, University of Central Lancashire, Preston, UK — We develop a coarse grained simulation technique to study dynamics in soft nano-composites. The system consists of block copolymer melt or solution with nano-size colloidal particles. The time evolution of the system is described by a multiscale approach: a field based simulation for block copolymer component and a particle based method for nano-cohoids. The block copolymer is modelled by cell dynamics simulation technique, and colloids are modelled in a spirit of dissipative particles dynamics. A cross interaction term is controlling the interplay of dynamics of both components. The influence of colloids on block copolymer morphology is investigated.

Fundamentals of the reinforcement of hairy nanoparticles in rubber compunds

C1.00097

XIAORONG WANG, Bridgestone Americas, Center for Research and Technology, 1200 Firestone Parkway, Akron, OH 44317-0001, USA. Email: WangXiaorong@BFUSA.com — The reinforcement of nano-sized polymeric hard core-hairy shell particles in a polymer matrix of chemically identical chains was investigated by dynamical mechanical measurements. We found that the magnitude of reinforcement depended strongly on the phase behavior of the nanoparticles in the polymer matrix. In one phase region, the mechanical response was nearly linear, and the reinforcement was approximately described by the Guth-Smallwood relationship in terms of filler concentration. In two phase region, however, the mechanical response was largely nonlinear, even for strain lower than 1%, and the reinforcement at low strains was an exponential function of the filler concentration. We show that by tailoring the filler interaction potentials the entire reinforcing mechanism can be changed.

Thermoporosimetric Measurements of Network Heterogeneity: Melting Point Depression

C1.00098

JINRONG WU, GREGORY MCKENNA1, Department of Chemical Engineering, Texas Tech University — To improve understanding the heterogeneity and structure of polymer networks, thermoporosimetry was performed on four model networks of polydimethylsiloxanes (PDMS), which were obtained by tetrakis(dimethylsiloxy)silane crosslinking vinyl terminated PDMS having different molecular weights. The effects of solvent molecular size, solvent quality and PDMS chain length between cross-links on the anomalous melting point depression of solvents in these model networks were systematically investigated. The results are analyzed in terms of both the Gibbs-Thomson (GT) equation and the Flory-Huggins (FH) model. Furthermore, we also compared the the pore size distributions obtained from thermoporosimetry for these model networks with the molecular distribution of their oligomers as determined by Matrix Assisted Laser Desorption/Ionization Time of Flight Mass Spectrometry.

Statistics and dynamics of blends of linear and ring polymers

C1.00099

MICHAEL LANG, Leibniz-Institute for Polymer Research, MICHAEL RUBINSTEIN, Department of Chemistry, University of North Carolina, 27599 Chapel Hill, N.C., USA — This work focuses on conformations and dynamics of blends of linear and ring polymers. Rings in a melt of homo-polymer rings are compressed due to topology, if rings are significantly larger than the entanglement length. Dilute rings with degree of polymerization, N_1, immersed in a melt of linear polymers with degree of polymerization, N_2, are almost ideal if N_1 > N_2^{1/2} and swell if N_1 < N_2^{1/2}. Dynamics of pure ring melts is enhanced as compared to pure linear melts. Thus, minority of linear chains immersed in ring melt experiences enhancement of diffusion and relaxation. On the other hand, minority of long entangled rings immersed in melt of long entangled linear chains gets temporarily trapped. This leads to a clear reduction in diffusion coefficient while keeping relaxation (as determined by half ring relaxation) almost unaffected.
C1.00100 Spectroscopic Analysis of Amorphous Structure in Fluorinated Polymers, SHAW L. HSU, YUNING YANG, SURIYAKALA RAMALINGAM, University of Massachusetts Amherst — High-quality polarized Raman spectra have been obtained for various poly(vinylidene fluoride) (PVDF) structures, crystalline and amorphous. These data encouraged us to revisit the Raman band assignment, especially within the conformational sensitive region (400-1100 cm\(^{-1}\)) and use the new understanding to characterize the amorphous region. Vibrational bands have been assigned on the basis of observed polarization characteristics and the calculated potential energy distribution (PED). The simulated results agree well with the experimental polarized Raman study. On the basis of the calculated PED, combined with simulation of different conformational sequences (tttt, ttggt, tggg, gggg), spectroscopic features (band intensity at 648 cm\(^{-1}\) and the frequency change of the 856 cm\(^{-1}\) band) were associated with the distribution of rotational isomeric states. Two rotational isomeric state (RIS) models were analyzed and compared in the simulation study of the amorphous state. On the basis of the spectroscopic features of experimental and simulated Raman spectra, the conclusion was reached that the model which predicts a higher gauche population more accurately describes the amorphous state. This analysis provides an opportunity to describe the amorphous state in a quantitative manner.

C1.00101 Equilibrium Pathway of Spin-coated Polymer Films, OPHELIA TSUI, Physics Department, Boston University, Boston, MA02215, YONG JIAN WANG, Physics Department, Hong Kong University of Science & Technology, Clear Water Bay, Hong Kong, FUK KAY LEE, Physics Department, Boston University, Boston, MA02215, C.-H. LAM, Department of Applied Physics, Hong Kong Polytechnic University, Hung Hom, Hong Kong, ZHAOHUI YANG, Physics Department, Boston University, Boston, MA02215 — Spin-coating is a common method of making thin polymer films. Recent experiments show that polymer films produced by this method are highly non-equilibrated. By monitoring the temporal evolution of the surface structure of freshly sin-cast polystyrene films on Si with molecular weights, 2.3 ≤ M\(_{\text{w}}\) ≤ 393 kg/mol, we find that the relaxations can be fully accounted for by thermal excitations of surface capillary waves on the film surface. Modeling of the data based on this relaxation scheme leads to excellent agreement between the viscosity of the films and that of the bulk polymers. Our results provide compelling evidence that thickness uniformity is the major cause of the non-equilibration of the films.

C1.00102 COMPLEX STRUCTURED MATERIALS —

C1.00103 Crystal structures and physical properties of nanostructured [(PbSe)\(_{0.99}\)\(_{m}\)(WSe\(_2\))\(_n\)] (m, n=1-5), QIYIN LIN, Materials Science Institute, University of Oregon, Eugene, Oregon 97403, COLBY HEIDEMAN, CLAY MORTENSEN, NGOC NGUYEN, DAVID C. JOHNSON, Materials Science Institute, University of Oregon, Eugene, Oregon 97403, PAUL ZSCHACK, Advanced Photon Source, Argonne National Laboratory, Argo, IL 60439, CATALIN CHIRITEASCU, DAVID G. CAHILL, Department of Materials Science and Engineering, University of Illinois, Urbana, IL 61801. — We report a class of nanostructured mist layer compounds [(PbSe)\(_{0.99}\)\(_{m}\)(WSe\(_2\))\(_n\)] (m,n=1-5) synthesized using a modulated elemental reactant technique. The structures are built of two subsystems alternately stacking along the c direction - a distorted rock salt structure (PbSe)\(_5\) and a transition metal dichalcogenide (WSe\(_2\)). These nanostructured compounds have ultra low thermal conductivities, as small as 0.06 Wm\(^{-1}\)K\(^{-1}\), which can be attributed to the structural mist between the components resulting in an unusual balance of order and disorder. Annealing samples under different partial pressures of selenium can be used to control electrical conductivity and the value of the Seebeck coefficient. The relationship between nanostructures and physical properties will be discussed.

C1.00104 Low Temperature Study of Mechanically Alloyed EuFeO\(_3\), SUMAN KATHIWADA, DEREJE SEIFU, Morgan State University — Rare-earth (R) and transition metal (T) perovskite Oxides RTO\(_3\) are of great interest in Physics, besides potential applications in variety of devices. Here, we present study of EuFeO\(_3\) synthesized by mechanical alloying. The Mössbauer measurement on EuFeO\(_3\) is one of the rare cases where both the R and the T sites are probed in the same compound. Room temperature Mössbauer study is already reported [1], here we report low temperature Mössbauer measurements. Measurements indicate that hyperfine magnetic field increased with decreasing temperature. The \(^{157}\)Fe Mössbauer spectra depicts that there is only a magnetic sextet at 20K implying pure ferromagnetic state. As temperature increased two non-magnetic states appeared and their propensity increased with temperature. The \(^{157}\)Eu Mössbauer measurements show that the line width at half maxima has a peak between 50K and 100K. [1] Seifu, D., Takacs, L., Kebede, A., “Mössbauer Study of Mechanically Alloyed EuFeO\(_3\).” J. of Mag. and Mag. Matt., 302, pp 479 – 483, 2006.

C1.00105 Production of metal cluster patterns using Focused Ion Beams (FIB), FARHAD GALEH, NIKLAS GRÖNHAGEN, HEINZ HÖVEL, Technische Universität Dortmund, Experimentelle Physik I, Germany, LARS BRUCHHAUS, SVEN BAUERDICK, JÜRGEN THIEL, RALF JEDE, Raith GmbH, Dortmund, Germany — Nanometer sized pits on graphite (HOPG) substrates can be used as nucleation centers to produce clusters with a narrow size distribution. In previous experiments [1] nanometer sized pits were produced by sputtering and oxidizing the sample. As a result we get nanoparticles which are a few nanometers wide and only one monolayer deep, distributed at random locations on the surface. In the present study a focused beam of gallium ions is used to produce nanoparticles in a given pattern on the substrate. The FIB instrument (Raith ionLine) is capable of a resolution below 10 nm [2]. Using the nanoparticles as nucleation centers we are able to produce gold islands as well as silver clusters in a given pattern by depositing metal atoms. Furthermore the nanopatterning on the surface in combination with Monte Carlo simulations helps investigating the ion beams, e.g. ion distribution, recoils as well as the penetration depth of the ions [3]. In this respect the oxidation of HOPG-samples provides a method to study the ion impact effects. [1] H. Hövel, Appl. Phys. A 72 (2001) 295; [2] J. Gierak et al., Appl. Phys. A 80 (2005) 187; [3] F. Gahle, R. Köster, H. Hövel, L. Bruchhaus, S. Bauer, J. Thiel, R. Jede, J. Appl. Phys. 101 (2007) 044301.

C1.00106 The role of low frequency vibrational modes localization properties in the glass transition and mechanical stability of glasses, GERARDO NAUMIS, Depto. de Física-Química, Instituto de Física, UNAM — It is surprising that although glasses present low frequency vibrational anomalies like floppy modes or the Boson peak, not so much effort has been made in order to understand the relationship between glass transition and low frequency anomalies, which we know are fundamental in the stability of solids. We will show that rigidity theory allows to understand in a systematic way such relationship. Then, the effects of flexibility and chemical composition in the variation of the glass transition temperature are obtained by using the Lindemann criteria, that relates melting temperature with atomic vibrations, and rigidity theory. Using this criteria and that floppy modes at low frequencies enhance in a considerable way the average quadratic displacement, we show that the consequence is a modified glass transition temperature. This approach allows to obtain in a simple way the empirically modified Gibbs-DiMarzio law, which has been widely used in chalcogenide glasses to fit the changes in the glass transition temperature with the chemical composition [1]. The method predicts that the constant that appears in the law depends upon the ratio of two characteristic frequencies (or temperatures). This constant is estimated for the Se\(_{1-x}\)As\(_{1-x}\)\(_{2-y}\)\(_{y}\) glass by using the experimental data of vibrational states, and the result shows a good agreement with the experimental fit from glass transition temperature variation. [1] G.G. Naumis, Phys. Rev. B 73, 172202 (2006).
Glassy systems under confinement have been studied with great enthusiasm and effort for the last decades. They are relevant both fundamentally and technically because there is still debate about the nature of glass transition in small geometries which is important for lithographic processes in the semiconductor and other industries. In this work we are using the Wang-Landau approach also known as Density of States Monte Carlo to study glassy systems in bulk and under confinement. We apply the technique to a model binary Lennard Jones glass as well as the small organic glass former Ortho-terphenyl (OTP). For Lennard Jones glasses we use a well tested model. For OTP we start from a united atom model and then derive systematically a coarse grained representation by replacing each phenyl ring with a bead and using the Iterative Boltzmann Inversion. The properties of bulk Lennard Jones model show very good agreement with literature values. The atomistic and coarse grained representations of ortho-terphenyl in the bulk are in good agreement with experiments. Unsupported freestanding films show a lower glass transition than the bulk value.

C.1.00114 Quantum conductance of carbon nanotube at finite temperature: effect of electron-phonon interactions

NARJES GORBIZADEH, Tohoku University, AMIR A. FARAJIAN, Wright State University, YOSHIIYUKI KAWAZOE, Tohoku University — Effect of inelastic electron-phonon interaction is studied on electronic transport of semiconducting carbon chains and carbon nanotubes. Absorption and emission of individual phonon modes are investigated as well as collective modes in order to reveal the nature of the interactions and the role of vibrations in quantum transport at finite temperature. The conductance in this study is calculated using non-equilibrium Green’s function formalism combined with a tight-binding Hamiltonian description. The phonon spectrum is obtained from frozen-phonon approach and the electron-phonon interaction appears in the calculations as a coupling matrix determined by atom-displacements and phonon eigenvectors. Our results show that the effect of individual electron-phonon interaction on quantum conductance depends on temperature and energy of the phonon mode, regarding absorption and emission processes. The type of the phonon mode is in fact a determining part of the interactions. Decrease of conductance due to e-ph scattering is stronger when the process is scattering of electron out of in-plane phonons which make the in-plane C-C bonds of nanotube or chain vibrate with higher length. The effect of collective modes also suggests the temperature dependent nature of the conductance of a finite size carbon chain and nanotube.

C.1.00115 Detection of multiple tumor markers using ultra-long carbon nanotube devices

HYE-MI SO, DONG-WON PARK, BEOM SOO KIM, KI-JEONG KONG, GYOUNG-HO BUH, HYUNJU CHANG, JEONG-O LEE, Korea Research Institute of Chemical Technology, JING KONG, Massachusetts Institute of Technology — For the simultaneous detection of multiple tumor markers, we have fabricated ultra-long carbon nanotube sensors that can detect carcinoembryonic antigen (CEA) and prostate specific antigen (PSA), simultaneously. Ultra-long carbon nanotubes, several millimeters long, were grown by ethanal CVD, and fabricated as FET sensors by using conventional photolithography. To functionalize each segment of a single ultra-long nanotube device with multiple-tumor markers, we first functionalize the entire device with CDI-Tween 20 linking molecules, and then immobilized CEA and PSA antibodies using the micorfluidic channel. The electrical conductance from CEA-antibody functionalized and PSA-antibody functionalized segment of a ultra-long carbon nanotube device was monitored simultaneously with Ag/AgCl reference electrode as a liquid gate. We will discuss the advantages of long-nanotube device in detail.

C.1.00116 Low-temperature electronic transport in ferromagnetic cluster embedded carbon nanotubes

CATERINA SOLDANO, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, SWASTIK KAR, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, ROBERT VAJTAI, Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, SAIKAT TALAPATRA, Department of Physics, University of Southern Illinois at Carbondale, SAROJ NAYAK, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, PULICIKEL AJAYAN, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute — We present the electronic transport properties of ferromagnetic material embedded alumina template grown carbon nanotubes. Zero-field temperature dependence of the conductance in ferromagnetic cluster-embedded tubes (FM-MWNT) reveals a Lüttinger liquid type of behavior in the higher temperature region. Differential conductance measurements for discrete applied magnetic field show the appearance of field-dependent oscillations at low temperatures. The properties of the FM-MWNT were found to change permanently under the application of a magnetic field, indicating that the charge transport is sensitive to the relative magnetic orientations (random or aligned) of the nanoclusters. Those measurements suggest differences between charge transport in a Lüttinger liquid under the influence of "random" and "ferromagnetically aligned" impurities.

C.1.00117 Local-gated single-walled carbon nanotube field effect transistors assembled by AC dielectrophoresis

PAUL STOKES, SAIFUL I. KHONDATER, NANOSCIENCE TECHNOLOGY CENTER & DEPARTMENT OF PHYSICS, UNIVERSITY OF CENTRAL FLORIDA, ORLANDO, FL TEAM — Carbon nanotube field effect transistors (CNT-FETs) have displayed exceptional electrical properties that are superior to the traditional silicon MOSFET. Directed assembly of individually addressable CNT-FETs at selected positions of the circuit with high throughput needs to be demonstrated for future integrated circuits. Here, we present a simple and scalable technique for the fabrication of CMOS compatible & local gated CNT-FETs. The approach is based on directed assembly of individual single-walled carbon nanotube from dichloroethane via AC dielectrophoresis (DEP) onto pre-patterned source and drain electrodes with a local Al gate in the middle. We find that both metallic and semiconducting nanotubes can be assembled and the centered aluminum gate does not affect the DEP assembly. We also show that the measured device performance such as subthreshold swing of local-gated semiconducting nanotube FET is superior compared to the global back gated device possibly due to channel controlled operation. Directed assembly of local gated CNT-FETs at selected position of the circuit via DEP pave the way for large scale fabrication of CMOS compatible nanoelectronic devices.

C.1.00118 Microwave Magnetolectric Coupling in Ferromagnetic-Piezoelectric Nanostructures

YU.J. PUKINSKY, M.I. BICHURIN, V.M. PETROV, A.V. FILIPPOV, S.V. BELY, Novgorod State Univ. Russia, G. SRINIVASAN, Oakland Univ., MI — A theory is presented on the effect of an external electric field on ferromagnetic resonance (FMR) spectra of nanobilayers, nanopillars and nanowires of ferrite and piezoelectrics on MgO or gadolinium gallium garnet substrates. Expressions have been obtained relating the FMR line shift to ME coupling constants. Estimates of ME coupling constants are given. With increasing substrate thickness, the theory predicts a decrease in the ME interaction due to the clamping effect. The strongest ME coupling is expected for ferrite nanopillars in a piezoelectric matrix when the pillar height is large compared to substrate thickness. Numerical estimations are obtained for nanostructures of nickel ferrite and PZT or PMN-PT, yttrium iron garnet and PZT or PMN-PT on MgO or gadolinium gallium garnet substrates. The theory is useful for measurements of ME constants and for the design and analysis of electrically controlled high frequency devices.

C.1.00119 Enhancement of Magnetolectric Effect in Ferromagnetic-Piezoelectric Nanostructures at Electromechanical Resonance

A.V. KOZIN, M.I. BICHURIN, YU.J. PUKINSKY, V.M. PETROV, Novgorod State Univ. Russia, G. SRINIVASAN, Oakland Univ., MI — A theoretical model is presented for giant magnetolectric (ME) coupling in nanobilayers, nanopillars and nanowires of ferrite and piezoelectrics on MgO substrates or templates in the electromechanical resonance region (EMR). We take into account clamping effect of the substrate in determining the ME voltage coefficient. ME coefficients are obtained from known material parameters (piezoelectric modules, magnetostiction, stiffness, geometrics) using the solution of the elastodynamic and electrostatic equations. With increasing substrate thickness the theory predicts a shift in the resonance frequency along with a decrease in the ME interaction due to the clamping effect. The strongest interactions are expected for ferrite nanopillars in a piezoelectric matrix when the pillar height is large compared to substrate thickness. As an example, the ME voltage coefficients are estimated for nanostructures based on nickel and cobalt ferrites and piezoelectric PZT and PMN-PT. Although the estimates here are based on bulk material parameters, it can easily be refined to take into account parameters for nanosized components.

C1.00120 Electronic Properties of XB₆ rods: a theoretical study¹, GUANGPING LI, JING LU, R.F. SABIRIANOV, W.N. MEI, Department of Physics, University of Nebraska at Omaha, Omaha, NE 68182, C.L. CHEUNG, X.C. ZENG, Department of Chemistry, University of Nebraska - Lincoln, Lincoln, NE 68588 — Metal hexaborides have varieties of interesting properties and are utilized frequently in technological applications: LaB₆ has low work function (WF=2.6 eV), and is used as electron emitter. Experiments indicated LaB₆ nanorods generate stronger electric current than in the bulk case. We focus on the electronic structure of quasi-1D XB₆ nanorods (X = Si, Ca, Sr, Y, Ba, and most of the rare earth elements) with various widths and breadths for studying the relationship between WF and rod shape by using density functional theory with many-body and relativistic effect included. Then the electronic structure properties such as Fermi energy and electrostatic potentials can be calculated to deduce the work function. Cluster model with several cross section areas is used to investigate the size dependence of ionization potential which is found to decrease with the increasing number of unit cells: 3.3 eV for 1-cell and 2.7 eV for 6-cell cluster. The trend is in reasonable agreement with the experimental studies.

¹This work is supported by Nebraska Research Initiative.

C1.00121 Optical Determination of the Flexural Rigidity of Carbon Nanotube Ensembles¹, PRABHAKAR BANDARU, CHUNING NI, CHRISTIAN DECK, Materials Science, UC, San Diego — We demonstrate two simple and consistent optical methods for quantitatively determining the flexural rigidity (EI, where E is the elastic modulus and I the moment of inertia), a quantity of practical importance in determining the deflection and buckling characteristics of carbon nanotubes (CNTs). This is done through monitoring the deflection of patterned arrays of CNTs subject to fluid flow. In addition to mechanical characterization of filamentous nanostuctures, the implications of our work extend to the monitoring of nanoscale fluid flows, for tactile and shear force sensors and the characterization of the mechano-sensor response of cilia in physiology.

¹We acknowledge financial support from the NSF and the Office of Naval Research.

C1.00122 ABSTRACT WITHDRAWN —

C1.00123 Crystallization of titania nanotubes powders synthesized by anodization in chloride ions containing solutions, EUGEN PANAITESCU, LATIKA MENON, Physics Department, Northeastern University — Titanium oxide nanotubes show good promise in solar energy harvesting for photovoltaic cells and photocatalysis. Pristine anodic titania nanotubes are amorphous, and annealing procedures are employed for their crystallization. We investigated the crystallization process of titania nanotubes powders - obtained by anodization of titanium foils in chloride ions containing solutions - by means of differential scanning calorimetry. We analyzed the influence of parameters such as annealing temperature, annealing time, and temperature scan rate on the phase transition, and on the crystalline properties of the final product. The crystalline powders have been characterized using XRD, RAMAN and diffuse reflectance measurements. SEM and TEM imaging has been employed for the investigation of structural properties before and after annealing, and optimal annealing conditions have been identified.

C1.00124 The size controlled structural and optical properties of ZnO nano-rod arrays, YANWEI CHEN, GUOLIANG YANG, Drexel University, QIAN QIAO, YICHUN LIU, Northeast Normal University — In comparison with zero dimensional (0D) nanostuctures, one-dimensional (1D) semiconducting nanostructures can facilitate more efficient carrier transport due to decreased grain boundaries, surface defects and disorder, and discontinuous interfaces. In order to utilize 1D ZnO nanostructures for optoelectronic nanodevices, it is essential to have detailed information about their size and other properties and to have the ability to tune these properties in the fabrication process. The application of the 1D nanostructures depends on this tenability. At present, it is still a challenge to fabricate well-controlled 1D ZnO nanostructures and to characterize their properties. We used convenient and flexible sol-gel and hydrothermal methods to synthesize 1D ZnO nanorods with diameters in the order of 10 to 20 nm. The crystalite size, morphology, the structural and optical properties could be well controlled by modulating the crystal nuclei quantity, the solution concentration and the reaction time. We obtained a strong ultraviolet exciton emission for the ZnO nanorods with a size about 10 nm, and also observed the size effect on the photoluminescence.

C1.00125 Linear optical response of (6,0) boron nitride nanotubes adsorbed with molecular hydrogen¹, N. NORBERTO ARZATE, RAUL A. VAZQUEZ-NAVA, Centro de Investigaciones en Optica, Mexico, JORGE E. MEJIA, Centro Universitario de los Lagos, Universidad de Guadalajara, Mexico — We performed a study of the molecular adsorption of hydrogen on BN nanotubes. We present ab initio calculations for the linear optical response of single wall zigzag BN(6,0) nanotubes as a function of the hydrogen adsorption on the exterior surface of the nanotube. The calculation of the linear optical response is performed by using density functional theory with the use of plane waves and pseudopotentials. We consider four different nanotube-structures adsorbed with different coverage of molecular hydrogen. We find optimized atomic coordinates for such structures and calculate binding energies for the molecule of hydrogen on the nanotube. After having the linear response of the considered structures, we have calculated their energy loss function spectra.

¹This work has been partly supported by CONACYT, Mexico, grants: SEP-2004-C01-48142 and SEP-2003-C02-12576, SEP-2005-C01-49678-F.

C1.00126 Magnetostrictive effects in a bilayer of PZT and magnetostriction-graded ferrite¹, G. SRINIVASAN, Oakland University, Rochester, MI, V.M. PETROV, Novgorod State University, Russia — Magnetostrictive (ME) effects in a piezoelectric-magnetostrictive composite are mediated by mechanical stresses. The effect, in particular, will be enhanced in the electromechanical resonance region (EMR) where the electronic subsystem shows resonance. We show here that further enhancement of the strength of ME interaction is possible with the use of magnetostriction-graded ferromagnet. A material with the grading axis perpendicular to the sample plane is considered. In this case, the thickness dependence of the piezomagnetic coefficients leads to additional bending strain, resulting in an increase in the EMR voltage. Estimates are provided for a bilayer of Zn-doped nickel ferrite and lead zirconate titanate, length 12 mm in length and 2 mm in thickness. The EMR voltage coefficient is predicted to increase by a factor of two compared to bilayers with homogeneous ferrite compositions.

¹Supported by grants from NSF and Russian Foundation for Basic Research.

C1.00127 Magnetoelectric properties of a bilayer of magnetostrictive and piezoelectric nanofilms- studies on substrate pinning effects¹, GOPALAN SRINIVASAN, Oakland Univ., V.M. PETROV, Novgorod State University, Russia — A model is presented for magnetoelectric (ME) effects in the electromechanical resonance region (EMR) for bilayers of magnetostrictive and piezoelectric films on a substrate. The clamping effect of the substrate has been considered in determining the ME voltage coefficient for longitudinal (or radial) and bending modes. The ME effect is predicted to be weak due to pinning and is dependent on the substrate volume. It is shown that the dependence of ME effect on the substrate thickness is much weaker for bending modes than for radial or longitudinal modes. For increasing volume of the substrate, the EMR frequency decreases dramatically. In the case of a rectangular nickel ferrite-PZT nanobilayer on an MgO substrate, the EMR frequency is predicted to be minimum when the substrate is clamped at one end.

¹Supported by grants from NSF and Russian Foundation for Basic Research.
C.1.00128 Theory of magnetoelectric coupling in magnetostrictive-piezoelectric bilayer at bending modes\textsuperscript{1}, A.V. FILIPPOV, N.A. FEDOTOV, M.I. BICHURIN, V.M. PETROV, Novgorod State Univ., Russia, G. SRINIVASAN, Oakland Univ., MI, CE-WEN NAN, Tsinghua Univ., China — Magnetoelastic (ME) couplings in bilayers of magnetostrictive and piezoelectric phases result from mechanical deformation. Reports to-date focused mainly on enhancement of the ME effect in the electromechanical resonance (EMR) corresponding to radial modes. Recent investigations, however, showed a similar enhancement and a giant ME effect for the bending modes of EMR in ferromagnetic-piezoelectric layered structures. Such bending modes are expected to occur at a much smaller frequencies than radial modes. Here we provide the frequency dependence for longitudinal and transverse ME voltage coefficients using a simultaneous solution of electrostatic, magnetostrictive and elastodynamics equations. The resonance ME effect in a bilayer is shown to be strong, depending on boundary conditions. A giant ME coefficient for bending modes is predicted for a bilayer fixed at one end and free at the other. The ME voltage coefficients are estimated from known material parameters (piezoelectric coupling, magnetostriction, elastic constants, etc.) and are compared with data.

C.1.00129 Photo-formation of Gold Nanoparticles in Au(III)-chitosan-silica aerogels: Dependence on Wavelength and Duration of Exposure\textsuperscript{1}, NARAYANAN KUTHIRUMMAL, ADAM DEAN, RICHARD SMITH, ALEM TEKLU, College of Charleston — Porous transparent monoliths of Au(III)-chitosan-silica aerogels have been exposed to UV light (320 nm and 207 nm). The photoacoustic spectra of UV-exposed sample revealed a new peak around 526 nm, which corresponded to the plasmon resonance band of gold nanoparticles. Scanning electron microscopic and elemental analysis revealed the presence of gold particles. The plasmon peak is found to shift significantly to the blue side upon irradiating the sample for a longer time interval. It is possible that the nanoparticle heats a bit and could anneal its surface surrounding leading to a slight reduction in size. Electron microscopic observations show morphological changes upon increasing the UV exposure time. A relative larger shift observed upon exposing the sample to 200 nm light. Based on the present results, it is concluded that the gold particle size can be altered by changing the duration of light exposure or by using a different wavelength.

\textsuperscript{1}This work was supported by the Nanotechnology Undergraduate Education (NUE) program of the National Science Foundation (Award No.EEC-0634142).

C.1.00130 Elasticity and mechanical properties of nanostructured carbon\textsuperscript{1}, MARIA FYTA, Department of Physics, Harvard University, IOANNIS REMEDIARIS, Department of Materials Science and Technology University of Crete, Heraklion, Crete, Greece, PANTELIS KELIRES, Department of Mechanical Engineering and Materials Science and Technology, Cyprus University of Technology, Limassol, Cyprus — We present a theoretical study of nanostructured carbon, emphasizing on diamond nanocomposites. These are materials that consist of diamond nanocrystals surrounded by a dense amorphous carbon matrix, in a highly stable configuration. We study the properties of such materials by employing a combination of tight-binding molecular-dynamics and empirical-potential Monte-Carlo simulations. We aim to investigate the role of the sp\textsuperscript{2} component and the grain size on the mechanical properties of these structures. We calculate the rigidity of these materials and their elastic recovery under hydrostatic pressure, and find them to be considerably high compared to those of dense single-phase amorphous carbon. We find that the inter-grain fracture of these materials under shear and tensile load on these materials occurs at the weakly bonded sp\textsuperscript{3} sites in the amorphous matrix.

\textsuperscript{1}Work done at Physics Department, University of Crete, Heraklion, Crete, Greece.

C.1.00131 Thermal conductivity of Cu/carbon nanotube composite films, JUNG JOON YOO, Korea Advanced Institute of Science and Technology, HO-KI LYEO, JAE YONG SONG, SUNGJUN LEE, Korea Research Institute of Standards and Science, JIN YU, Korea Advanced Institute of Science and Technology — We report the thermal conductivity of Cu/carbon nanotube (CNT) composite films measured by time-domain thermoreflectance, an optical pump-probe method, which measures the time-evolution of temperature change. The thermal and electrical conductivities of sputter-deposited Cu, electroplated nanocrystalline (nc) Cu, and Cu/CNT composite films are measured with a varying content (0 ∼ 2 wt%) of CNT in Cu matrix. Both conductivities of nc-Cu films grown on a seed layer of sputtered Cu decrease significantly compared to those of bulk Cu. The thermal conductivity of Cu/CNT composite films made of nc-Cu and randomly oriented CNTs decreases further with the increase of CNT in the films. With the increasing amount of CNT, we also measure the decreasing thermal conductance of interface between Cu/CNT composite film and Al layer that is used as a transducer for the measurement. We will discuss the relations between CNT content and the measured reduction of thermal conductivity and conductance, depending upon the microstructure and impurities of composite films.

C.1.00132 Percolation Studies of Metal-insulator Composites at Microwave Frequencies\textsuperscript{1}, KELLY MARTIN, JEREMY CARDELLINO, EARNIE JOHNSON, NICHOLAS MISKOVSKY, GARY WEISEL, DARIN ZIMMERMANN, The Pennsylvania State University, Altoona College, JUNKUN MA, Southeastern Louisiana University — We present a systematic study of the effective dc conductivity (σ_{eff}), complex permittivity (\varepsilon_{eff}) and complex permeability (\mu_{eff}) at microwave frequencies, of metal-insulator mixtures up to and beyond the critical volume fraction (\phi_{c}) for conductive percolation. Samples made with varying concentrations of Teflon and micron-sized metallic inclusions of copper, silver, cobalt, and tungsten were subjected to separated microwave electric and magnetic fields of a 2.45 GHz, TM_{010} resonant cavity. Using cavity perturbation techniques, the real and imaginary components of \varepsilon_{eff} and \mu_{eff} were thus measured at room temperature. We observe the expected strong dependence of \sigma_{eff}, \varepsilon_{eff}, and \mu_{eff} on volume fraction \phi_{c} and analyze the results using Mclachlan’s Generalized Effective Medium (GEM) theory to extract \phi_{c} and the percolation exponents s and t.

\textsuperscript{1}This work is supported in part by a grant from the National Science Foundation (NSF/RUI: DMR-0406584), The Pennsylvania State University, and Altoona College.

C.1.00133 The electronic spectrum of a quasiperiodic potential: from the Hofstadter butterfly to the Fibonacci chain, GERARDO NAUMIS, Depto. de Fisica-Quimica, Instituto de Fisica, UNAM — We show that the electronic spectrum of a tight-binding Hamiltonian defined in a quasiperiodic chain with an on-site potential given by a Fibonacci sequence, can be obtained as a superposition of Harper potentials. Since the spectrum of the Harper equation as a function of the magnetic flux is a fractal set, known as Hofstadter butterfly, here we show that is possible to follow the transformation of the butterfly to a new one that contains the Fibonacci potential and related approximants. As a result, the equation in reciprocal space for the Fibonacci case has the form of a chain with long range interaction between Fourier components. Then we explore the transformation between both spectra, and specially the origin of energy gaps due to the analytical calculation of the components in reciprocal space of the related potentials. As an application, we calculate the correlator of each potential, which allows to obtain some of the localization properties.
C1.00134 Ab initio studies of molecular physisorption on graphene¹, DAVID CAREY, DANIEL HENWOOD, University of Surrey — Ab initio studies of the hydrogen and oxygen molecular physisorption have been made on a graphene using both the local density approximation (LDA) and generalized gradient approximation (GGA) PW91 functionals. Binding energies and optimal molecular separations for different graphene lattice sites have been calculated. It was found that the most stable binding energy is for the hydrogen molecule to lie at a hexagon mid-point with a binding energy of 93 meV as calculated for a 96 carbon atom graphene layer using the LDA functional. Lower values of hydrogen molecular binding were found with the GGA functional. [1] Analysis of the charge distribution showed little charge transfer between the molecule and graphene sheet. Oxygen physisorption is shown to be significantly stronger than hydrogen physisorption with calculations using the LDA functional showing binding energies of 280 meV. [1] Daniel Henwood and J David Carey, Phys. Rev. B 75, 245413 (2007).

C1.00135 The Transport of Graphene in a Parallel Field, ADAM FRIEDMAN, ANISH MOKASHI, LATIKA MENON, Northeastern University Dept. of Physics — The recent discovery of graphene and its remarkable properties has generated an enormous amount of research and has led some to contemplate it as a replacement for silicon in the next generation of computer chips. A large amount of theoretical work has been completed, but very little experimental work has been done to verify the theory. In particular, experiments have neglected the effect of a magnetic field applied parallel to the 2-D surface plane. Theory [1] has predicted that this orientation of magnetic field will split the spectra of particles and holes, which will then interact with each other through attractive Coulomb forces, driving a metal to gapped insulator transition. We will report the results of experimental studies of the transport in graphene at a parallel magnetic field at low temperatures. [1] I. L. Aleiner, D. E. Kharzeev, and A. M. Tsvelik, arXiv:cond-mat/0708.0394

C1.00136 Numerical study of electronic transport in a graphene superlattice, DI WU, WEI-QIANG CHEN, FU-CUN ZHANG, Department of Physics and the Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China — Using tight-binding model, We calculate the transport properties of charge carriers through graphene superlattices consisting of monolayer or bilayer graphene with an applied external potential barrier. Emphasis is placed on inter-valley scattering between two inequivalent Dirac cones in our systems. It is shown that transmission probabilities for two kinds of graphene structure exhibit different features due to distinct intrinsic properties of charge carriers in these superlattices. The co-existence of inter-valley and intra-valley scattering in the monolayer lattice declines the phenomenon of perfect transmission predicted by Klein paradox.

C1.00137 Magnetic edge states in graphene, SUNGHUN PARK, H.-S. SIM, Korea Advanced Institute of Science and Technology — We theoretically study the magnetic edge states of the Dirac fermions in graphene, formed along the boundary between the two domains in a spatially nonuniform magnetic field, Bᵢ in one domain and Bᵣ in the other domain, in the quantum Hall regime. The energy spectra of the magnetic edge states depend on whether Bᵢ is parallel or antiparallel to Bᵣ. For the parallel case, the n=0 magnetic edge states are dispersionless, while they split into electron-like and hole-like levels for the antiparallel case. Here, n is the graphene Landau level index. These features are attributed to the coupling between the pseudo-spin of the magnetic edge states and the direction of the external magnetic field. We also study the modification of the energy spectra when the finite Zeeman splitting or an electrostatic step-like potential is considered. An Aharonov-Bohm interferometry, which can identify the existence of the magnetic edge states, is suggested for experimental study.

C1.00138 Organic-inorganic Schottky diode based on few layers of graphene, MARIA ABREU, IDALIA RAMOS, NICHOLAS PINTO, University of Puerto Rico- Humacao — A Schottky diode was fabricated using several layers of graphene and a n-doped semiconductor and electrically characterized. The diode current-voltage characteristics show that it is forward biased in the first quadrant and reverse biased in the third. The diode turn on voltage is weakly dependent on temperature and increases slightly upon lowering the temperature. The diode rectification ratio is parallel or antiparallel to Bᵢ. For the parallel case, the n=0 magnetic edge states are dispersionless, while they split into electron-like and hole-like levels for the antiparallel case. Here, n is the graphene Landau level index. These features are attributed to the coupling between the pseudo-spin of the magnetic edge states and the direction of the external magnetic field. We also study the modification of the energy spectra when the finite Zeeman splitting or an electrostatic step-like potential is considered. An Aharonov-Bohm interferometry, which can identify the existence of the magnetic edge states, is suggested for experimental study.

C1.00139 Ferromagnet proximity effect in graphene bilayer, YURIY SEMENOV, North Carolina State University, JOHN ZAVADA, U.S. Army Research Office, KI WOOK KIM, North Carolina State University — A well-known effect of ferromagnet proximity in metallic thin film results in the giant magneto-resistance (GMR). In case of graphene monolayer, the effect of dielectric ferromagnet layer (DFL) proximity leads to formation of spin-dependent electron potential and electron spin rotation in effective exchange field. We theoretically consider the ferromagnet proximity effect in a graphene bilayer (GBL), where bottom and top layers are affected by arbitrary oriented DFL. Our calculations show a drastic reconstruction of energy bands structure with the top DFL magnetization rotation compared to the bottom one, which is assumed to be fixed by an antiferromagnetic substrate. If the top and bottom magnetic moments are parallel and equal, we obtain a simple spin split gapless band structure. As soon as symmetry between the top and the bottom GBL is broken by rotation of top DFL magnetization, the gap is opening; it reaches the magnitude of exchange field at antiparallel configuration. Calculated conductivity of GBL strongly depends on magnetic configuration demonstrating efficiency of the new mechanism of GMR.

²This work was supported in part by US ARO and the FCRP on FENA.

C1.00140 The Magnetic effect of Nonmagnetic Defect on Graphene, HIDEKI KUMAZAKI, DAI HIRASHIMA, Nagoya University — We study the effect of a nonmagnetic defect on magnetism of graphene. Magnetism in carbon-based materials has been a controversial problem. Apart from magnetic defects, the nonmagnetic-defect-induced mechanism is the most probable mechanism in those materials. In this presentation, we focus on vacancy-induced magnetism. Electrons in graphene can be described with a half-filled Hubbard model on a honeycomb lattice. We then introduce a vacancy as a short-range strong scattering potential on a lattice point. Resorting to a mean field approximation and diagonalizing the approximated Hamiltonian, we can determine the electron number and spin densities at each lattice point. We then find that a vacancy induces short-range ferrimagnetic order around itself. This order is caused by a quasilocalized vacancy state induced by a strong potential. In cases with extended vacancies, the moment formation depends on the geometrical structure and the difference in the numbers of vacancies on two sublattices. The magnetic moment is necessarily induced when the number of vacancies on one sublattice is unequal to that on the other sublattice, in accordance with Lieb’s theorem. We further discuss the possible magnetic moment formation on realistic edges in graphene.

C1.00141 Pseudospin Magnetism in Graphene¹, HONGKI MIN, The University of Texas at Austin, GIOVANNI BORGHI, MARCO POLINI, NEST-CNR-INFN and Scuola Normale Superiore, Italy, ALLAN H. MACDONALD, The University of Texas at Austin — We predict that neutral graphene bilayers are pseudospin magnets in which the charge density-contribution from each valley and spin spontaneously shifts to one of the two layers. The band structure of this system is characterized by a momentum-space vortex which is responsible for unusual competition between band and kinetic energies leading to symmetry breaking in the vortex core. We discuss the possibility of realizing a pseudospin version of ferromagnetic metal spintronics in graphene bilayers based on hysteresis associated with this broken symmetry.

¹Work at UT Austin was supported by the Welch Foundation, NRI-SWAN, ARO, and DOE.
C1.00142 Electron-electron and spin-orbit interactions in armchair graphene ribbons1. MAHDI ZAREA, NANCY SANDLER, Ohio University — The effects of intrinsic spin-orbit and Coulomb interactions on low-energy properties of finite width graphene armchair ribbons are studied by means of a Dirac Hamiltonian. It is shown that metallic states subist in the presence of intrinsic spin-orbit interactions as spin-filtered edge states, in contrast with the insulating behavior predicted for graphene planes. A charge-gap opens due to Coulomb interactions in neutral nanotubes, that vanishes as $D \sim 1/W$, with a gapless spin sector. Weak intrinsic spin-orbit interactions do not change the insulating behavior. Explictic expressions for the width-dependent gap and various correlation functions are presented.

1Ohio University postdoctoral fellowship and NSF DMR 0710581

C1.00143 Electrical modulation in Graphene based devices1. HASSAN RAZA, EDWIN KAN, School of Electrical and Computer Engineering, Cornell University Ithaca NY 14853 — Graphene due to its unique dispersion has attracted great attention lately. In a nanobrion form, it can result in unique ‘bulk like’ states for armchair and edge states for zigzag nanoribbon. Both can be manipulated by an applied bias in the width direction and can result in interesting device concepts. Furthermore, the edge states can be engineered by modifying the edge termination, although atomic-precision is likely required. Moreover, a bandgap can be introduced in a bilayer using an electric field in the bilayer direction. This bandgap opening critically depends on the numbers of graphene layers. Motivated by this rich physics in one and two dimensional graphene structures, we present different bandstructure calculations of nanoribbons and multilayers of graphene. We extract important dispersion parameters from the above calculations. We further study the effect of electric field on these structures. Finally, we present the substrate effect on the electronic structure of graphene layers. We conclude by presenting transport calculations through nanoribbons in longitudinal direction with gate electric field in the width direction.

The work is supported by National Science Foundation (NSF) and by Nanoelectronics Research Institute (NRI) through Center for Nanoscale Systems (CNS) at Cornell University.

C1.00144 Spin channels in functionalized graphene nanoribbons, GIOVANNI CANTELE, CNR-INFM and University of Napoli “Federico II”, YOUNG-SU LEE, Korean Institute of Science and Technology, DOMENICO NINO, University of Napoli “Federico II”, NICOLA MARZARI, Massachusetts Institute of Technology — Graphene nanoribbons have attracted lot of interest, due to high potentiality in technological applications, mostly in graphene-based nanoelectronics. Electronic and transport properties may strongly be influenced by the crystallographic orientation as well as by the presence of defects and different chemical functionalizations. Among the possible edges, the zigzag ones deserve special attention, because it has been shown that magnetic ordering is obtained in the ground state, so as half-metallicity and spin-filtering behavior could in principle be observed under suitable experimental conditions. Here we show how the chemistry of the ribbon edge and surface may strongly affect the transport properties. Quantum conductance is calculated, with ab-initio accuracy, by combining a maximally localized Wannier function approach and the Landauer formula. We show that proper functionalization of the edges may strongly modify the electronic properties. Chemical species adsorbed on the nanoribbon surface can, on the other hand, significantly affect the spin channels, giving rise in some cases to an almost perfect spin-filtering behavior.

C1.00145 Ab initio study of alkali metal adsorption on various forms of graphene nanoribbons . SEON-MYEONG CHOI, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology — Electronic and magnetic properties of graphene nanoribbons (GNRs) are very unique depending on their edge shape. While many theoretical studies of GNRs show such intriguing features, clear experimental proofs of atomic edges and their effect on electronic structures have not been explicitly demonstrated. One of the issues is the difficulty of identifying GNRs edges. In this study, we calculated the adsorption energy of alkali metal atoms on various forms of GNRs using the pseudopotential density-functional method. We present the distribution of adsorbed atoms on armchair- and zigzag-edged GNRs using the calculated adsorption energy. This approach can help classify the edge of GNRs from the distribution of adsorbed atoms.

C1.00146 Electronic structure and bonding properties of hydrogen on K(2x2)/Graphene1. CÉSAR ACOSTA, JORGE ALEJANDRO TAPIA, Facultad de Ingeniería, Universidad Autónoma de Yucatán, ROMEO DE COSS, Departamento de Física Aplicada, Cinvestav-Mérida — The effect of the adsorption of hydrogen atom on the electronic properties of K(2x2)/graphene system, are studied by means of first-principles calculations. The results were obtained with the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. The structural parameters, bonding properties, and electronic structure of the H atoms on K/graphene system are calculated by molecular dynamics. We find an important charge transfer from the substrate towards the H atomates. The strong H-C chemical bond produced a considerable deformation in the graphene layer. The bonding energy of hydrogen is larger for the K/graphene system than for the single layer of graphene. The present results suggest that the hydrogen adsorption on layered carbon systems could be stimulated by the pre-adsorption of simple metals.

1This research was supported by PRIORI-UADY under Grant No. FING-05-004 and Consejo Nacional de Ciencia y Tecnología (CONACYT-México) under Grant No. 43830-F.

C1.00147 Spontaneous Decay and Two-Qubit Entanglement in Ion-Doped Carbon Nanotubes2. IGOR BONDAREV, NC Central University, NATALIA NOGINOVA, Norfolk State University — We study theoretically surface electromagnetic phenomena, such as spontaneous decay and entanglement of two-level atoms (qubits) close to a carbon nanotube surface[1]. The research is motivated by the progress in growth of cm-long single-walled nanotubes[2], single atom encapsulation into nanotubes[3], and the need for nanomaterials with long quantum coherence lifetimes with ab-initio accuracy, by combining a maximally localized Wannier function approach and the Landauer formula. We show that proper functionalization of the single layer of graphene. The present results suggest that the hydrogen adsorption on layered carbon systems could be stimulated by the pre-adsorption of simple metals.

2Supported by NSF via grant No ECS-0631347.

C1.00148 Uptake and isosteric heats of gases adsorbed inside carbon nanotubes1. DANIEL ROBERTSON, SILVINA GATICA, Department of Physics, Howard University — We studied the properties of gases adsorbed in the interior of open-ended single wall carbon nanotubes for a wide range of pressures and temperatures from tens to hundreds of Kelvin. The gases studied are Argon, Methane, Hydrogen and Helium in a classical regime. Using the method of Grand Canonical Monte Carlo Simulations we computed the adsorption isotherms, the isosteric heat of adsorption and the configurations at different T,P values. The thresholds values of the pressure and maximum uptake were calculated as a function of the temperature. At the lower temperatures the adsorption of atoms on the axis of the tube is observed as a discontinuous step in the isotherms.

1This research used resources of the National Energy Research Scientific Computing Center, which is supported by the Office of Science of the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.
C1.00149 Acetylene-Boosted Growth of Vertically Aligned SWNTs by Alcohol CCVD Method1, RONG XIAO, JUN OKAWA, ERIK EINARSSON, YUHEI MIYAIUCHI, SHICGO MARUYAMA, Department of Mechanical Engineering, The University of Tokyo, Japan — We present an interesting growth boost of vertically aligned SWNTs achieved by introducing a very small amount of acetylene into the conventional Alcohol Catalytic CVD (ACVD) system. This acetylene assisted ACCVD, as investigated in situ by optical absorption, not only provides us a way to enhance the SWNT growth rate by an order of magnitude, but also confirms that 0.1% of acetylene can reach the same activity as ethanol. Considering that acetylene is one of the products of thermal decomposition of ethanol at growth temperature, we might consider the chemical pathway from SWNTs via acetylene besides the direct pathway from ethanol. A no-flow ACCVD condition fully utilizes this decomposed acetylene as the growth promoter. Since this highly efficient growth through acetylene is only observed with sufficient accompanying ethanol, the critical roles of ethanol and acetylene are discussed.

1The present work was supported in part through the 21st Century COE program, “Mechanical Systems Innovation,” by the Ministry of Education, Culture, Sports, Science and Technology.

C1.00150 The evolution of helical forms in nanotube and nanofiber growth: Thermodynamic Model and Experiment, PRABHAKAR BANDARU, Materials Science, UC, San Diego, APPARAO RAO, Department of Physics, Clemson University — Several models, none of them completely satisfactory, have been proposed to understand the synthesis of nanotubes and nanocoils. In this presentation, we first briefly review the models in vogue and point out their shortcomings. Second, we introduce a thermodynamic model, based on exclusion volume principles, common in chemical and biological systems that could potentially explain coiling in nanostructures. Here, the observation of helices and coils in nano-tube/-fiber syntheses is explained on the basis of the interactions between specific catalyst particles and the growing nanostructure. Third, we make specific predictions for the optimal growth of nano-coils/-helices with the hope that these could be used as a guide for rational synthesis. Finally, our own experimental results conforming to the above model, on the role of Indium catalyst particles and local CVD reactor temperature in influencing the coil pitch in coiled nanostructures, will be presented.

C1.00151 Electroluminescence of a ZnS-based powder phosphor1, SO YEON JUN, Hankuk Univ. Foreign Studies, JIN-YOUNG KIM, Sungkyunkwan Univ., SANG HYEUN PARK, Samsung Adv. Inst. Technol., SEGY YU, Hankuk Univ. Foreign Studies — Electroluminescence (EL) and photoluminescence (PL) spectra of carbon nanotube (CNT) incorporated ZnS:Cu,Al inorganic powder phosphors under an AC voltage were analyzed by comparing with bare ZnS:Cu,Al powder. The spectra was obtained at room temperature with a He-Cd laser and a single grating monochrometer. By varying the frequency of the applied ac voltage, the PL and EL spectra yield distinct difference in the peak position, width, and intensity of the luminescence. As the concentration of CNTs were increased, the separation between the two luminescence peaks, which were analyzed by the Gaussian fitting, shrank. However, the spectra showed little different behavior for the voltage variation at fixed frequency. The underlying mechanism for this frequency dependence on CNT incorporation and EL performance enhancement will be mentioned in this poster.

C1.00152 Oscillatory Behavior of a Double Wall Carbon Nanotube Near an Infinite Surface2, ADRIAN POPESCU, LILIA WOODS, University of South Florida, IGOR BONDAREV, North Carolina Central University — Theoretical calculations of a double wall carbon nanotube oscillator with its axial direction perpendicular to an infinite surface are presented. The model for this work is based on the continuum approach of the pair-wise Lennard-Jones type of interaction in the double wall nanotube and between the nanotube and the surface. We investigate the oscillation frequency as a function of the distance between the nanotube and the surface, the length of the nanotube, and the magnitude of the initial excitation. Our calculations show that the oscillatory behavior is in the GHz region and it can be changed significantly by these factors. Based on these results, we suggest that the carbon nanotube oscillator can be used as a scanning device for surfaces in a similar manner as an atomic force microscope tip.

2Supported by DOE (DE-FG02-06ER46297).

C1.00153 Influence of surfactant concentration on the absorption and emission of light in single-wall carbon nanotubes, CRISTIANO FANTINI, Centro de Desenvolvimento da Tecnologia Nuclear — Optical absorption and photoluminescence have been largely used in the study and characterization of carbon nanotube samples, usually dispersed in aqueous solution wrapped with some surfactant. In this work we present a systematic investigation about the influence of the surfactant on the absorption and emission of light by carbon nanotubes. Carbon nanotubes dispersed in solution at different concentrations and wrapped with some different surfactant such as sodium dodecyl sulfate, sodium cholate, sodium dodecyl benzenesulfonate and segments of DNA were used in the experiments. Optical absorption and photoluminescence spectra were measured and the effects of both the kind of surfactant and the nanotube and surfactant concentrations on the photoluminescence efficiency were investigated. By comparing the intensities of absorption and emission it is possible to obtain the best nanotube and surfactant concentration for a higher efficiency in the emission of light. Changes in the absorption and emission energies are observed due to the environment screening on the exciton binding energies. Finally, we determine the structural assignment of the nanotubes and compare the dependence of the photoluminescence efficiency as a function of the surfactant and nanotube concentrations for different nanotube chiralities in the samples.

C1.00154 Theory of superplasticity and atomic relaxation in nanotubes and fullerenes, FENG DING, KUN JIAO, YU LIN, MS&MS Dept., Rice University, JIANYU HUANG, Center for Integrated Nanotechnologies, Sandia National Laboratories, BORIS I. YAKOBSON, MS&MS Dept., Rice University, YAKOBSON TEAM, JIANYU HUANG COLLABORATION — Plastic relaxation of carbon nanotubes under tension and at high temperature have been described in terms of dislocation theory and with atomistic computer simulations. Now we show how the glide of pentagon-heptagon defects and a particular type of their pseudo-climb [1], with the atoms directly breaking out of the lattice, work concurrently to maintain the tension and at high temperature have been described in terms of dislocation theory and with atomistic computer simulations. Finally, we make specific predictions for the optimal growth of nano-coils/-helices with the hope that these could be used as a guide for rational synthesis. Finally, our own experimental results conforming to the above model, on the role of Indium catalyst particles and local CVD reactor temperature in influencing the coil pitch in coiled nanostructures, will be presented.

YAKONSON, MS&MS Dept., Rice University, 6100 Main street, Houston TX 77005, FENG DING TEAM, GOTHEBURG UNIVERSITY COLLABORATION, UPPSALA COLLABORATION, UNIVERSITY COLLEGE CORK COLLABORATION — We report on formation of highly conductive SrTiO$_3$ and Technology (KAST) — We report on formation of highly conductive SrTiO$_3$ and Technology (KAST), TOSHIHIRO SHIMADA, TETSUYA HASEGAWA, Department of Chemistry, University of Tokyo / Kanagawa Academy of Science and Technology (KAST), YUTAKA FURUBAYASHI, YASUSHI HIROSE, Kanagawa Academy of Science, University of Tokyo / Kanagawa Academy of Science and Technology (KAST). Base on the optimized process 15 mm long CNT arrays were synthesized and preliminary data were obtained on spinning them into yarns.

C1.00156 Structural dependence of carbon nanotube orbital magnetic susceptibility: tight binding calculations, O. N. TORRENS, J. M. KIKKAWA, Department of Physics and Astronomy, University of Pennsylvania — Recent ab initio calculations of the orbital magnetic susceptibility anisotropies in carbon nanotubes (CNTs) have shown large, systematic differences among zigzag CNTs of similar diameters [1]. We theoretically investigate the origin of these trends by applying the zone-folding method within the nearest-neighbor tight-binding approximation to all chiral and achiral semiconducting CNT species with diameters between 0.6 nm and 1.7 nm. Our results show qualitative agreement with the "mod 1" and "mod 2" trends of the ab initio theory and additionally distinguish between trigonal warping and curvature-related effects as physical reasons for the predicted species-dependent spread. Our calculations show (2n+m) patterns similar to those in a recent, experimentally-motivated "fan-out" diagram [2] and can be likewise fit to an analytical four-term chirality expansion. [1] Marques, M. A. L.; d’Avezac, M. & Mauri, F., Phys. Rev. B, 2006, 73, 120543 [2] Torrens, O. N.; Milkie, D. E.; Ban, H. Y.; Zheng, M.; Onoa, G. B.; Gerke, T. D. & Kikkawa, J. M., J. Am. Chem. Soc., 2007, 129, 252-253

C1.00157 Calculations of optical injection and coherent control in graphene, JULIEN RIOUX, JOHN E. SIPE, Department of Physics and Institute for Optical Sciences, University of Toronto — We calculate injection spectra for one- and two-photon absorption in graphene, as well as optically injected currents from coherent control of one- and two-photon absorption in graphene, as well as optically injected currents from coherent control of 1 + 2 excitation. We compare ab initio pseudopotential calculations to analytical expressions of an effective tight-binding model expanded in $\vec{k}$ about the $K$ symmetric point. We find that the spectra from full-zone band structure calculations deviate from the simple model at energies above a few hundred meV’s.

C1.00158 Titanium Doped Carbon Nanotubes for Hydrogen Storage, JAKE FENNICK, JAMES LEWIS, West Virginia University — An efficient method of storing hydrogen is necessary before fuel cells can become practical. Previous computational results show that a single titanium atom adsorbed on the surface of a carbon nanotube can bind up to 4 hydrogen molecules. We pursue simulations of hydrogen packed between two titanium-doped carbon nanotubes. The highest percentage weight of storage and the manner in which these parallel nanotubes pack is of particular interest. Calculations are performed with the classical MD program GULP. After computation, automated analysis will choose the combination of parameters that results in the most efficient hydrogen storage for these titanium-doped carbon nanotube systems. [1] Yildirim, T.; Ciraci, S. Phys. Rev. Lett. 2005, 94, 175501.

C1.00159 Organic Light Emitting Diodes Using a Single Wall Nanotube Film Anode, EVAN DONOHUE, Dept. of Physics, University of Florida, KEN GRAHAM, Dept. of Chemistry, University of Florida, MATTHEW CRAPS, ZHUANGCHUN WU, Dept. of Physics, University of Florida, RYAN M. WALCZAK, JOHN R. REYNOLDS, Dept. of Chemistry, University of Florida, ANDREW G. RINZLER, Dept. of Physics, University of Delaware — To investigate single-wall carbon nanotube (SWNT) films as a replacement for indium tin oxide (ITO) as the anode in organic light emitting diodes (OLEDs), OLEDs constructed on SWNT films are compared to OLEDs on PEDOT:PSS/ITO. It is found that a single, simple polymer based device design of SWNT /poly[2-methoxy-5-(2’-ethyl-hexyloxy)-1,4-phenylene vinylene] (MEH-PPV)/Ca/Al can perform comparably with PEDOT:PSS/ITO OLEDs. For thick polymer layers of 300nm, both devices achieve a maximum light output of 700 cd/m$^2$ with efficiencies between 0.7-0.8 cd/A. The ITO device performance improves when a thinner MEH-PPV layer is used however variations in the SWNT film surface cause shorting if the MEH-PPV layer is substantially reduced in the SWNT anode devices. The advantages of a SWNT anode as well as the potential for future improvements will be discussed.

C1.00160 Extremely Long Multiwall Carbon Nanotube Arrays for Spinning Yarn, CHAMINDA JAYASINGHE, PRAVANAH SALUNKE, LUCY LEE, EMILY HEAD, Department of Chemical and Material Engineering, University of Cincinnati, Cincinnati, OH 45221-0012, NILANJAN MALLIK, YEHOEUNG YUN, Department of Mechanical Engineering, University of Cincinnati, Cincinnati, OH 45221-0072, CHANDRASHEKHAR PENDYALA, Department of chemical engineering, University of Louisville, Louisville, KY 40292, MARK J. SCHULZ, Department of Mechanical Engineering, University of Cincinnati, Cincinnati, OH 45221-0072, VESSELIN N. SHANOV, Department of Chemical and Material Engineering, University of Cincinnati, Cincinnati, OH 45221-0012 — Centimeter long Multiwall Carbon Nanotube (MWCNT) arrays have been grown by CVD from H$_2$-C$_2$H$_4$-$\text{H}_2$:Ar gas mixture at 750 °C in an Easy Tube furnace from First Nano Inc. The arrays were characterized by AFM, SEM, TEM and Raman spectroscopy. The diameter and chirality of the nanotubes were controllable by the choice of catalysts used. The full-length of 10 cm was the greatest impact on the nanotube diameter. The CVD growth has been optimized with respect to the length and the purity of theCNT. It was found that the CVD growth conditions affect dramatically the quality of the arrays. Base on the optimized process 15 mm long CNT arrays were synthesized and preliminary data were obtained on spinning them into yarns.

C1.00161 Formation of highly-conductive SrTiO$_3$-$\delta$ by pulsed laser deposition of TiO$_2$ on SrTiO$_3$ substrate, KUNITADA HATABAYASHI, Department of Chemistry, University of Tokyo, TARO HITOSUGI, Department of Chemistry, University of Tokyo / Kanagawa Academy of Science and Technology (KAST), YUTAKA FURUBAYASHI, YASUSHI HIROSE, Kanagawa Academy of Science and Technology (KAST), TOSHIHO SHIMADA, TETSUYA HASEGAWA, Department of Chemistry, University of Tokyo / Kanagawa Academy of Science and Technology (KAST) — We report on formation of highly conductive SrTiO$_3$-$\delta$ by pulsed laser deposition of TiO$_2$ on SrTiO$_3$ substrate under relatively reducing atmosphere. Anatase TiO$_2$ thin films were grown on SrTiO$_3$ (001) and (LaAlO$_3$)$_{0.3}$Sr$_2$AlTaO$_6$$_{0.7}$ (LSAT)(001), for comparison, by pulsed laser deposition under oxygen pressure of $P_{O_2}$ = 5x10$^{-8}$ Torr. In-situ RHEED (reflection high energy electron diffraction) measurements during film deposition revealed a clear streak pattern of 4K reconstruction, indicating growth of high quality anatase (001) films. Meanwhile, the anatase (001) films deposited on LSAT with thickness of >2 nm showed spotty RHEED patterns, indicating formation of oxygen-poor TiO$_2$-$\delta$. These facts lead us to a conclusion that oxygen atoms in SrTiO$_3$ substrate diffuse into anatase TiO$_2$ during the film growth process. In the TiO$_2$/SrTiO$_3$-$\delta$ heterostructure, we observed high mobility of 1x10$^4$ cm$^2$/Vs (5K) and Subnikov-de Haas oscillation (0.5K), proving formation of clean SrTiO$_3$-$\delta$ without structural deformation.
C1.00162 On the Electronic Structures of Ge Based Nanotubes.1 SOMILKUMAR RATHI, ASOK RAY, The University of Texas at Arlington — In the context of elucidating the properties of Ge-based nanotubes, we provide here a systematic ab initio study of the electronic and geometric structures of three different types of armchair silicon germanium nanotubes from (3, 3) to (11, 11) and compare them with the corresponding properties of Ge and GeC nanotubes. The finite cluster approach with dangling bonds terminated with hydrogen has been used. The theoretical formalism used is hybrid density functional theory incorporating HF exchange with DFT exchange-correlation functional. Full geometry and spin optimizations with unrestricted symmetry have been performed. A detailed comparison of the structures and stabilities of the nanotubes with dependence of the electronic band gaps on the respective tube diameters, energy density of states, dipole moments as well as Mulliken charge distributions have been investigated for all the tubes. Radial buckling of the tubes along with bond length variations is also studied and implications for band gap engineering will be discussed.

Work is supported by the Welch Foundation, Houston, Texas (Grant No. Y-1525)

C1.00163 Wigner Function for a Quantum Wire with an Impurity, YI TANG, TOMAS MATERDEY, University of Massachusetts Boston — We present the Wigner function for a Gallium Arsenide (GaAs) quantum wire subjected to a magnetic field with an off-center donor impurity. The Wigner function is more sensitive to detecting changes than the variational wavefunction for smaller scale differences in a quantum wire with an impurity.

C1.00164 Computational Models for Catalyzed Growth of Si Nanowire. SEUNGHWA RYU, Department of Physics, Stanford University, WEI CAI, Department of Mechanical Engineering, Stanford University — We present molecular simulation models for the growth of silicon nanowires from gold catalyst particles. Because the number of atoms involve in this process is above 1000, it is infeasible to use ab initio models. Hence our first step is to develop an interatomic potential model for Au-Si using the modified embedded-atoms method (MEAM) framework. For the first time, we computed the Au-Si phase diagram entirely from the interatomic potential. The melting points are computed from free energy methods with uncertainties less than 1K. Molecular simulation of the interaction between the gold nanoparticle with the Si substrate and Si NW is presented.

C1.00165 Rapid Beam Shaping For Pulsed Laser Processing Using Tunable Acoustic Gradient Index Lenses, CRAIG ARNOLD, ALEXANDER MERMILLOD-BLONDIN, EUAN MCLEOD, Princeton University — Rapid shaping of an incident Gaussian laser beam enables spot-to-spot control over local material properties in pulsed and CW applications. Here we present a new device, the tunable acoustic gradient index (TAG) lens, which provides a rapid, high throughput alternative for spatially modifying incident beams and we discuss its effect on pulsed laser micromachining. The TAG lens is a resonant cylindrical cavity for acoustic radial standing waves that modulate the density and thereby create a gradient in index of refraction within the filling fluid. With CW illumination, a single driving frequency will produce a multiscale Bessel beam, or under multiple-frequency operation it can generate a superposition of Bessel beams, approximating any radially-symmetric pattern. When synchronizing a pulsed laser illumination to the lens, rapid switching between instantaneous patterns at frequencies as high as 100-1000 kHz is possible. The theory behind the operation of the lens, its speed, and applicability to pulsed laser processing will be presented.

C1.00166 Floating Tip Nanolithography YEHIAM PRIOR, KAIYIN ZHANG, ALEXANDER MILNER, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel 76100, MICHAEL KARPOVSKI, Department of Physics, Tel Aviv University, Tel Aviv, Israel — We introduce a new mode of operation to standard atomic force microscopes, working under ambient conditions, for truly noncontact nanolithography. A phase-locked loop, based on tiny oscillations (<1 nm) of the cantilever at a frequency far from its mechanical resonance, is used to maintain the gap between the tip and the sample at a predetermined value of 1 - 4 nanometers continuously for long times without the tip ever touching the surface. In a geometry characteristic for Apertureless Scanning Near Field Optical Microscope, the tip is illuminated by a focused beam of a femtosecond laser (800 nm, 20 fsec, 100 mw ) for nano-patterning of the area under the tip. Under the laser irradiation the tip apex heats to a few hundred degrees as verified by a direct measurement of Raman line shifts, and the electromagnetric enhancement under the tip is used when the laser irradiates the actual tip apex. We demonstrate Floating Tip Nanolithography of two different types, both with lateral resolution of 10-20 nm. With a hot tip (the laser is not in contact with the surface) we thermally pattern the surface of a polymer film, and based on the electromagnetic field enhancement under the sharp tip we ablate narrow lines on a gold film. Future applications will be discussed.

C1.00167 Laser Desorption Ionization from Laser Induced Silicon Microcolumns: Surface Morphology and Chemistry, BENNETT N. WALKER, George Washington University, GUERMAN PASMANIK, Passat Inc., MD, AKOS VERTES, George Washington University — Nanomaterials and mesostructures, such as laser induced silicon microcolumn arrays (LISMA), offer new matrix-free platforms for laser desorption ionization (LDI) of biomolecules. The morphology and surface chemistry of LISMA depend on the processing environment and the laser parameters. Column diameters and lengths as well as periodicity, observed by AFM and SEM, depend on processing conditions (processing medium, laser pulse energy, pulse length and angle of incidence, etc.). Capillary waves at the molten silicon-processing liquid interface seem to initiate the development of LISMA structures. This is reflected by the correlation between the array morphology and the processing liquid density and interfacial tension. Ion yields from the various surfaces are dramatically affected by the pH of the processing environment, indicating a strong influence of the OH-terminated sites on the silicon surface. Ion generation from LISMA also significantly depends on the angle of the desorbing laser incidence, potentially suggesting energy coupling through an antenna array mechanism.

C1.00168 Internal Energy of Ions Produced by Laser Desorption/Ionization from Laser Induced Silicon Microcolumn Arrays, JESSICA A. STOOLEE, AKOS VERTES, George Washington University — Laser induced silicon microcolumn arrays (LISMA) were demonstrated as effective matrix-free laser desorption/ionization substrates for the mass spectrometry of biomolecules. Structure specific fragmentation of the produced ions primarily depends on their internal energy. To gain insight into the internal energy of ions laser desorbed from native LISMA and LISMA derivatized through sliane chemistry, the cations of eight benzyl-substituted benzylpyridinium salts were used as thermometer ions (TI). Survival yields of their unimolecular decomposition were determined and correlated to their internal energy through RRKM calculations. On both native and perfluorophenyl-derivatized surfaces, TIs showed no change in their internal energy over a wide range of laser fluence. While the survival yields for these preformed ions are stable, results on peptides indicate fluence dependent fragmentation. These results point to a different fragmentation mechanism for peptides mediated by hydrogen radicals formed through the recombination of protons, produced from residual solvents, and electrons, emitted from the silicon surface upon laser irradiation.
C1.00169 Nanoparticle Formation of Compound Materials, OMAR MUSAEV, VLADIMIR DUSEVICH, DAVID WIELICZKA, JERZY WROBEL, MICHAEL KRUGER, UMKC — UV pulsed laser radiation was applied to synthetic polycrystalline hydroxyapatite, the mineral that is the main component of bone. The process was carried out in deionized water. The ablated nanoparticles have been studied with Raman spectroscopy, TEM and XPS. According to transmission electron microscopy micrographs, the ablated particles were approximately spherical and had a size of ≈ 100 nm. Raman spectroscopic analysis indicated that particles had the same structure as the original crystal. XPS demonstrated that the surface chemical composition is similar to that of the original material. The advantage of this method in comparison with ablation in vacuum and gas is that due to the confinement conditions produced by the water, the composition of the ablated nanoparticles remains the same as the target material. Another advantage is in the simplicity of the method in comparison to both ablation in vacuum or low pressure gas and to chemical methods for nanoparticle synthesis.

C1.00170 Universal disorder in the microwave conductance spectra of doped silicon nanowire arrays, CLARK HIGHTRETE, MARK LEE, Sandia National Laboratories, AARON VALLETT, SARAH EICHFELD, JOAN REDWING, THERESA MAYER, Penn State University — Microwave conductance spectra of doped silicon nanowire (SiNW) arrays were measured from 0.1 to 50 GHz at temperatures between 4 K and 293 K. SiNWs were synthesized by VLS growth, assembled into arrays on co-planar waveguides and measured using microwave vector network analysis. The complex conductance of the arrays was found to increase with frequency at all temperatures as $\tilde{\sigma}^2$, with 0.25 < $s$ < 0.4, and to agree with the expected Kramers-Kronig relations. This AC conductance is consistent with behavior found universally in disordered systems. The likely cause is disorder from Si/SiO$_2$ interface states dominating the conduction due to the high surface-to-volume ratio of the nanowires. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000. Penn State authors acknowledge partial support from NSF DMR-0213623 and NSF NRT ECCS-0609282.

C1.00171 Size-dependent ionization of impurities in GaN nanowires, JOONAH YOON, ILAN SHALISH, School of engineering and applied sciences, Harvard University, L. R. RAM-MOHAN, Physics, Worcester Polytechnic Institute of Technology, VENKATESH NARAYANAMURTI, School of engineering and applied sciences, Harvard University. — The integration of nanowires into devices requires having dielectric materials in contact with the nanowire. Therefore understanding the effect of surrounding dielectric materials on properties of nanowires becomes quite relevant for the device integration of nanowires. In this work we present the effect of dielectric surroundings on electrical properties of gallium nitride nanowires. The conductivity of unintentionally n-doped gallium nitride nanowires is measured from 4.2 to 300 Kelvin. The ionization energies of impurities are extracted from the conductivity versus temperature measurements. These ionization energies are found to display a dependence on the radius of nanowires. This size dependence is explained by the self-energy correction due to the image charges formed at the surface of nanowires. We would like to emphasize this work is the first experimental work to report on the size-dependent ionization of impurities in nanowires

C1.00172 Highly electron-emitting states of boron-nitride nanotubes derived from the free-electron-like conduction band states, BINGCHAI YAN, Center for Advanced Study, Tsinghua University, Beijing, 100084, China, CHANGWON PARK, JISOO IHM, Department of Physics, Seoul National University, Seoul 143-747, Korea, GANG ZHOU, WENHUI DUAN, Center for Advanced Study, Tsinghua University, Beijing, 100084, China, NOEJUNG PARK, Department of Applied Physics, Dankook University, 44-1, Jukjeon-dong, Yongin-si, Gyeonggi-do, 448-701, Korea. — We investigate electronic structures and field emission properties of boron-nitride nanotubes (BNNTs) using the first-principles method and electronic dynamic simulations. To introduce a feasible transport channel we choose to dope alkali atoms to BNNTs. We show that the nearly free electron (NFE) state of a BNNT could shift down to the Fermi level, preserving the free-electron-like dispersion along the axial direction. Meanwhile the downshifted NFE state bears s-wave characters, which is necessary for an efficient electron field emission. Our dynamic simulations of emission current reveal that the BNNTs are much favorable for electron field emission, owing partially to the presence NFE states as well as low electron affinity. We suggest that a high-performance field emission devices could be fabricated using n-type doped BNNTs.

C1.00173 ABSTRACT HAS BEEN MOVED TO SESSION S30
C1.00174 ABSTRACT HAS BEEN MOVED TO SESSION S30
C1.00175 ABSTRACT HAS BEEN MOVED TO SESSION V30

C1.00176 Free standing carbon nanotubes growth on large-area by nanoimprint and plasma-enhanced chemical vapor deposition, WON SEOK CHANG, DAE-GEON CHOJ, JUN-HO CHUNG, KAB-SOO HUH, KIMM, NEMS TEAM — Among various synthesis methods for carbon nanotube growth, chemical vapor deposition (CVD) method has been widely used for various advantageous such as high quality, vertical alignment, controlled diameter and length of nanotubes and so on. Especially, vertically aligned multi-wall carbon nanotube could be grown using plasma-enhanced chemical vapor deposition (PECVD). In this paper, we presented growth of free standing carbon nanotubes by PECVD for the fabrication of nano-electrode. For the growth of nanotubes on the large area 50 mm x 50 mm, catalyst dots were formed by nanoimprint and lift-off process. The synthesis of carbon nanotube requires a metal catalyst layer, etchant gas, and a carbon source. Ammonia (NH$_3$) and acetylene (C$_2$H$_2$) were used as the etchant gas and carbon source, respectively. And iron (Fe) of catalyst metal was deposited on silicon wafer substrates. To form Fe nano dots with diameter of 150 nm and thickness of 50 nm, nano holes patterned imprint resin was used for lift-off process. Carbon nanotubes were grown on pretreated substrates at approximately 30% C$_2$H$_2$:NH$_3$ flow ratios for 40 min.

C1.00177 Ab initio calculation of intrinsic spin-Hall effect in graphene nanostructures, BIN WANG, JIAN WANG, Department of Physics, The University of Hong Kong, Pokfulam Road, Hong Kong, China, HONG GUO, Center for the Physics of Materials and Department of Physics, McGill University, Montreal, PQ, Canada H3A 2T8 — We report a theoretical analysis of intrinsic spin-Hall effect in a four-probe graphene nanostructure in the absence of spin orbit interaction and magnetic field. The nanostructure consists of a finite size graphene sheet connected to the outside world by two zigzag graphene nano-ribbons (ZGNR) and two armchair graphene nano-ribbons (AGNR), forming a cross- shaped two-dimensional device. Due to edge states induced magnetism at ZGNR boundaries, our result suggests that a pure spin-current without an accompanying charge current, is intrinsically induced giving rise to a spin-Hall effect. We have calculated the spin-Hall conductance by an atomic first principles method where density functional theory is carried out within the Keldysh nonequilibrium Green’s function framework.
C1.00178 Electronic properties of bilayer graphene ribbons with Bernal stacking in a strong magnetic field. YUAN-CHENG HUANG, Center for General Education, Kao Yuan University, CHENG-PENG CHANG, Center for General Education, Tainan University of, MING-FA LIN, Department of Physics, National Cheng Kung University — We employ the Peierl coupling tight-binding method to study magneto-electronic properties of bilayer graphene ribbons with Bernal stacking. Because of the interlayer interactions, the magnetic energy bands of a bilayer graphene ribbon are different from those of a monolayer ribbon in the Landau-level energies, the energy spacing, the state degeneracy, and the number of the Landau levels. The low-frequency magneto-absorption spectra reveal the characteristics of the electronic properties. The spectra exhibit denser Landau peaks than those of a monolayer ribbon do. Meanwhile, the transition channels of the Landau peaks are also identified. The selection rule is $\Delta n = \pm 1$.

C1.00179 NEGF Transport Simulation on Pd-cluster Functionalized CNTs. CHAO CAO, Quantum Theory Project and Department of Physics, University of Florida, ALEXANDER KEMPER, Quantum Theory Project and Department of Physics, YUAN-HE, Quantum Theory Project, University of Florida, HAI-PING CHENG, Quantum Theory Project and Department of Physics, University of Florida — We have investigated the conductance response of the Pd-cluster functionalized CNTs to hydrogen environment using DFT+NEGF method. Experiments find that the semiconducting CNTs behave very differently from metallic CNTs, and suggest that the semi-conducting ones are good candidates for hydrogen sensors. By comparing the simulation results for the (5,5) metallic and the (8,0) semiconducting CNTs, we are able to reveal the underlying physics behind this phenomena. This work is supported by the DOE grant number DE-FG02-02ER45995. The authors want to thank NERSC, CNMS/ORNL and the University of Florida High Performance Computing Center for providing computational resources and support that have contributed to the research results reported within this paper.

C1.00180 QUANTUM FLUIDS AND SOLIDS —

C1.00181 Spin-charge separation in a strongly correlated spin-polarized chain. SHIMUL AKHANJEE, YAROSLAV TSERKOVNYAK, UCLA — We combine the first-quantized path-integral formalism and bosonization to develop a phenomenological theory for spin-charge coupled dynamics in one-dimensional ferromagnetic systems with strong interparticle repulsion, at low temperatures. We assume an effective spin-charge separation and retain the standard Luttinger-liquid plasmon branch, which is explicitly coupled to a Heisenberg ferromagnetic spin-wave texture with a quadratic dispersion. The dynamic spin structure severely suppresses the plasmon peak in the single-particle propagator, in both fermionic and bosonic systems. Our analysis provides an effective theory for the new universality class of one-dimensional ferromagnetic systems, capturing both the trapped spin and propagating spin-wave regimes of the long-time behavior.

C1.00182 Implementation of High Temperature Superconducting Leads in research cryostats. YUKO SHIROYANAGI, Ohio State University, GOKUL Gopalakrishnan, DONGKYUN KO, SANGHUN AN, Thomas Gramila, Ohio State University, THOMAS GRAMILA, Ohio State University — High Temperature Superconducting (HTSC) Magnet Leads are available for use in high current applications, which combined with active cryocoolers, they are typically not used in liquid Helium based research cryostats because of the difficulty of implementation. We have successfully implemented a HTSC lead system for Helium based cryostats in which baffles provide thermal coupling to the outgoing Helium gas. The increase in the Helium boiloff rate at full current (110amps) has been measured to be 0.4L/day as compared with the zero current boiloff. An essential element of the design is maintaining a temperature at the warm end of the HTSC leads which is well below the critical temperature. Measurements indicate that this temperature is roughly 65K at 110A. The basic design approach and actual implementation of this novel HTSC lead system, as well as its measurement, are discussed.

C1.00183 QUANTUM INFORMATION, CONCEPTS, AND COMPUTATION I —

C1.00184 PT-Symmetric Quantum Evolution and Logic. TOREY SEMI, MARK COFFEY, Colorado School of Mines — There has been much recent interest in PT-symmetric quantum mechanics (QM) as an alternative formulation of quantum theory. We investigate the potential of this formulation for quantum computation and simulation. PT-symmetric QM replaces the usual postulate that a system’s Hamiltonian must be Hermitian. It argues instead that the Hamiltonian can be symmetric with respect to combined parity and time-reversal and, for certain parametric regions, still produce real eigenvalues and maintain unitary time evolution. Besides being of fundamental interest, this approach allows for a fresh perspective on many QM applications. It is known that for one-qubit PT-symmetric systems the evolution time from an initial state to a final state can be made arbitrarily small. We report on applying PT-symmetric Hamiltonians for two-qubit systems to quantum logic.

C1.00185 Two-particle Interferometry with Filtering Operations. S.-S. B. LEE, H.-S. SIM, Korea Advanced Institute of Science and Technology — We generalize the conventional two-particle interferometer by including filtering operations. We find that after appropriate local filtering operations, the concurrence, a two-particle entanglement measure, can be directly obtained from the visibility of the two-particle interference, even for mixed states. This indicates that entanglement is associated with experimentally feasible properties.

C1.00186 Entanglement of magnetic impurities via electron scattering with asymmetric coupling constants. GUILLEMERO CORDOURIER-MARURI, ROMEO DE COSS, Cinvestav Unidad Mérida, YASSER OMAR, Technical University of Lisbon — We study the entanglement generated by electron scattering between two fixed magnetic impurities, located in a 1-D quantum wire. The impurities were considered distant and only interact through the spin of a scattered electron. We analyzed the asymmetric case produced by the effect of considering different exchange coupling electron-impurity factor for each impurity. We used the quantum waveguide theory approach to find the probability of electron transmission for each spinorial configuration of the system, taking into account the possible changes in the directions of the impurities and electron spins. We find resonance behavior in the evolution of the probability of electron transmission with respect to the impurities separation. We show results for the cases where the average and the difference of the exchange coupling electron-impurity factor are constant. From the probabilities of electron transmission the entanglement is calculated using the von Neumann entropy. We show that the entanglement can be maximized changing the initial conditions of the system, like the impurities separation distance and the ratio of the electron-impurity exchange coupling factor.
C1.00187 Squeezed State Effects on Continuous Variable Quantum Erasing. PETER BONANNO, VIJAY KASISOMAYAJULA, ONOFRIO RUSSO, New Jersey Institute of Technology — Experimental verification of complementarity using quantum erasing for the continuous variable (CV) infinite dimensional Hilbert space has been considered. [1] The complementary pair is that of the canonically conjugate amplitude and phase quadratures of light. The amplitude quadrature is labeled to a squeezed meter signal by quantum nondemolition (QND) [2] entanglement coupling. [3] Knowledge of which eigenstate (WE) can be obtained by measuring this amplitude in the meter state, and can thereafter be ‘lost’ by measuring the quadrature phase of the meter, thus restoring the quadrature phase of the signal beam in a process known as quantum erasure. [4] The coupling, i.e., the labeling of the signal state to the meter state, is implemented with a beam splitter coupled to the squeezed light meter beam. [4] We investigate the effects of using the unitary squeeze operator $S(z) = \exp(2z^2 - z^2)$ where $z = \exp(i\phi)\sqrt{s_{\text{q}}}$. [5] We show that the final state of the meter is a displaced squeezed coherent state $|\alpha\rangle$. [5] The experiment is performed using a squeezed beam as input. The results show that the phase of the meter, thus restoring the quadrature phase of the signal beam in a process known as quantum erasure. [6] The experiment demonstrates the complementarity of amplitude and phase quadratures. 

C1.00188 Hidden variables in quantum mechanics: Generic models, set-theoretic forcing, and the appearance of probability. ROBERT A. VAN WESEP — The hidden-variables (HV) program in quantum mechanics proposes that physical states have properties that are not observable in the ordinary sense and which uniquely determine the outcome of any observation. It is well known that one cannot consistently assign values to all propositions in a Hilbert space of dimension $\geq 3$, but for systems of commuting propositions one always can, so there is some interest in HV in this limited setting. But the same objection has been raised against HV as against the many-worlds view (MW), viz., that it cannot accommodate the notion of probability, specifically the Born rule. We have shown that the Born rule is actually derivable in MW[1]. In the present work we do the same in the HV setting[2]. Specifically, we show that the HV premise implies that the sequence of values assigned by a given HV state to a set of commuting propositions is indistinguishable from a sequence randomly generated according to the Born rule. In fact, the same is true for systems of noncommuting propositions satisfying a natural condition[3]. The sequences demanded by HV are generic in the set-theoretic sense. The fascinating ontology of generic objects in set theory therefore applies to HV states in physics.

C1.00189 Intrinsic Friction Microscopy. DANIEL KNORR, RENE OVERNEY — A novel scanning probe methodology based on lateral force microscopy is presented wherein kinetic friction measurements, obtained as a function of velocity for various temperatures, are used to deduce apparent Arrhenius-type activation energies for surface and subsurface molecular mobilities. Depending on the coupling strength (cooperativity) between molecular mobilities involved the dissipation energy can carry a significant entropic energy contribution, accounting for the majority of the apparent Arrhenius activation energy. The intrinsic friction methodology also provides a means of directly separating enthalpic energy contributions from entropic ones by employing absolute rate theory. As such, the degree of cooperativity in the system is readily apparent. This methodology is illustrated with nanoscale tribological experiments on two systems, (1) monodisperse, atactic polystyrene and (2) self assembling molecular glassy chromophores. In polystyrene, dissipation was found to be a discrete function of loading, where the $\gamma$-relaxation (phenyl group rotation) was recovered for ultra low loads and the $\beta$-relaxation (local backbone translation) for higher loads in the same temperature range, indicating sensitivity to surface and subsurface mobilities. For self assembling glassy chromophores, the degree of intermolecular cooperativity was deduced using the methodology, resulting in an increased understanding of the interactions between self assembling molecules.

C1.00190 HIGH PRESSURE PHYSICS –

C1.00191 Influence of Shockwave Profile on Ejection of Micron-Scale Material From Shocked Tin Surfaces. MICHAEL ZELLNER, JIM HAMMERBERG, ROBERT HIXSON, RUSSEL OLSON, PAULO RIGG, Los Alamos National Lab, GERALD STEVENS, WILLIAM TURLY, National Security Technologies, WILLIAM BUTTLER, Los Alamos National Lab — This effort investigates the relationship between shock-pulse shape and the amount of micron-scale fragments ejected (ejecta) upon shock release at the metal/vacuum interface of shocked Sn targets. Two shock-pulse shapes are considered: supported shock created by impacting a Sn target with a sabot that was accelerated using a powder gun; and an unsupported or triangular-shaped Taylor shockwave, created by detonation of high explosive that was press-fit to the front-side of the Sn target. Ejecta production at the back-side or free-side of the Sn coupons were characterized through use of piezoelectric pins, Asay foil, optical shadowgraphy, and X-ray attenuation.

C1.00192 Pressure induced valence changes in YbTe studied by resonant inelastic x-ray emission (RXES)1. RAVHI KUMAR, ANDREW CORNELIUS, HiPSEC, Dep.Physics and Astronomy, UNLV, Las Vegas, NV 89154, YUMING XIAO, PAUL CHOW, HPCAT and Carnegie Institution of Washington, Advanced Photon Source, Argonne, IL, MALCOLM NICOL, HiPSEC, Dep.physics and Astronomy, UNLV, Las Vegas, NV 89154 — We have performed high resolution x-ray absorption (XAS) and resonant inelastic x-ray emission (RXES) experiments to probe the pressure dependence of Yb valence in YbTe as high as 20 GPa. XAS spectra were collected in the partial fluorescence yield (PFY) mode at the Yb L3 edge. The RXES spectra were recorded by fixing the incident energy and collecting the transferred energy as a function of pressure in 2eV steps. The results show a continuous valence change of Yb towards 3+ from the mixed valent state, similar to other mixed valent Yb compounds under pressure [1, 2]. The experimental details with the PFY and RXES results will be presented. 1. C. Dallera, M. Grioni, A. Shukla, G. Vanko, L. Bravicoh, A. Shukla and M. Grioni, Phys. Rev. B., 68, 245114 (2003)

C1.00193 Sugar pucker in nucleosides as a function of pressure. SCOTT LEE, University of Toledo — Infrared and Raman experiments of adenosine (rA), deoxyadenosine (dA), cytidine (rC) and deoxycytidine (dC) have been performed at room temperature as a function of pressure. Phase transitions are observed to occur near 2 and 4 GPa in rA and dA and near 4 GPa in rC and dC. Based on theoretical calculations of the vibrational frequencies, these transitions appear to be due to changes in the sugar moiety. The most likely explanation is that the sugar pucker changes at these pressures. These observations are relevant to our understanding of the A-to-B transition observed in DNA.

1HiPSEC is supported by DOE, NNSA under co-operative agreement DE-FC08-01NV14049.
C1.00194 First-order polymorphic phase transition in supercooled liquid Silicon. P. GANESH, Carnegie Institution of Washington, MIKE WIDOM, Carnegie Mellon University — We perform first-principles molecular dynamics simulation of liquid and supercooled liquid Silicon. Looking at the volume dependence of the pressure at different supercooled liquid temperatures, we find a van der Waals loop, indicating a possible liquid-liquid first-order phase transition. It appears that the transition can be seen only at pressures of about a few GPa. We analyze our data using the zero-th moment of the tetrahedral order parameter, \( q_i = 1 - \frac{1}{3} \sum_{j<k} \cos[\theta_{ijk} + \frac{1}{2} \pi^2/i(1)] \), where \( \theta_{ijk} \) is the angle formed among neighbors ‘\( j \)’ and ‘\( k \)’ and the central atom ‘\( i \).’ For a perfect tetrahedral arrangement (\( \cos[\theta_{ijk} + \frac{1}{2} \pi^2/i(1)] \)) the value of the order-parameter is ‘1’ and for an uncorrelated system its distribution is peaked at ‘0’. We find that the low temperature liquid has a more tetrahedral open network than the high temperature one, indicating that the transition is between a high-density and a low-density liquid. The electronic density of states along an isocore indicates a sharp drop in metallicity across the transition temperature, which we believe lies around \( T = 1100K \). [1] M. Scott Shell and Pablo G. Debenedetti and Athanassios Z. Panagiotopoulos, Physical Review E 66, 011201, (2002)

C1.00195 Formation of nano-domains during the ZB-B1 high-pressure transition in bulk ZnSe , R.E. TALLMAN, B.A. WEINSTEIN, P. ZHANG, Physics Dept., SUNY at Buffalo, V. IOTA, H. RHEE, Lawrence Livermore National Laboratory, M.A. MARCUS, Lawrence Berkeley Laboratory — Raman scattering and x-ray absorption spectroscopy (XAS) are applied to explore the early-stage nucleation of the zincblende-rocksalt high-pressure transition in ZnSe. The Raman spectra (300K) of both natural ZnSe and high-quality vapor-grown ZnSe exhibit extreme broadening in the region of the TO(\( \Gamma \)) phonon for pressures \( \sim 2.5 \) GPa below the onset of the opaque high-pressure phase. At the same time sharp features persist in the spectra, e.g., due to the resonantly enhanced LO(\( \Gamma \)) peak and the 2TA(\( X \)) and 2TA(\( L \)) critical points. These results indicate that the high-pressure rocksalt phase in ZnSe tends to form in nanoscale domains due to a high density of nucleation sites. In order to explore the nucleation process further, XAS measurements are carried out under applied pressure on a ZnSe film containing \( \sim 10^{21} \) cm\(^{-3} \) As-impurities as an easily identifiable source of nucleation sites. Comparisons of the XAS results at 1 atm. and 6.5 GPa support the early onset of disorder consistent with nano-domain formation and the Raman findings.

C1.00196 A first-principles investigation of ionic vacancies and diffusion in high-pressure silica polymorphs, ASHOK VERMA, BIJAYA KARKI, Department of Computer Science, Louisiana State University, Baton Rouge, Louisiana 70803, USA — We have performed the density functional theory based simulations within the local density and pseudopotential approximations to investigate the effects of pressure and structural changes on the formation and migration energies of the ionic vacancies in crystalline silica. The simulations use supercells of 72 atoms for \( \alpha \)-quartz, stishovite and \( \text{CaCl}_2 \)-type and 96 atoms for \( \alpha \)-\( \text{Fe}_2 \text{O}_3 \) and pyrite type silica. The simulations are performed up to 250 GPa pressure. The atomic positions are fully optimized. Our results show a discontinuous change in Schottky formation enthalpy at phase transitions which involve cation coordination number change. In fact increase in cation coordination number leads in reduction of Schottky formation enthalpy. For example, at 0 GPa pressure Schottky formation enthalpies of 4-fold (\( \alpha \)-quartz), 6-fold (stishovite) and 6(=2)-fold (pyrite) coordinated silica are 16.12 eV, 11.02 eV and 7.73 eV respectively. Calculations of migration enthalpies, activation enthalpies and activation volumes all are also carried out up to 250 GPa pressure.

C1.00197 GENERAL —

C1.00198 Two Theories Are Better Than One , ROBERT JONES, Emporia State University — All knowledge is of an approximate character (B. Russell, Human Knowledge, 1948, pg 497 and 507). Our formalisms abstract, idealize, and simplify (R. L. Epstein, Propositional Logics, 2001, Ch XI and E. Bender, An Intro. to Math. Modeling, 1978, pg v and 2). Each formalism is an idealization, often times approximating in its own DIFFERENT ways, each offering somewhat different coverage of the domain. Having MULTIPLE overlapping theories of a knowledge domain is then better than having just one theory (R. Jones, APS general meeting, April 2004). Theories are not unique (T. M. Mitchell, Machine Learning, 1997, pg 65-66 and Cooper, Machine Learning, vol. 9, 1992, pg 319). In the future every field will possess multiple theories of its domain and scientific work and engineering will be performed based on the ensemble predictions of ALL of these. In some cases the theories may be quite divergent, differing greatly one from the other. This idea can be considered an extension of Bohr’s notion of complementarity, "...different experimental arrangements...described by different physical concepts...together and only together exhaust the definable information we can obtain about the object." (H. J. Folse, The Philosophy of Niels Bohr, 1985, pg 238)

C1.00199 What’s in a Name?FRAMING:Martin-Bradshaw DYSfunctionality = Siegel “Buzzwordism,Bandwagonism&$Sloganeering For: Fun, Profit,Survival,Ego”: From SOC to FLT Proof to High-Tc to Spintronics to Giant-Magnetoresistance: Ethics?? SHMETHICS!!!

Rampant Sociology , EDWARD SIEGEL — Buzzwordism,Bandwagonism,Sloganeering for Fun,Profit,Survival,Ego: From SOC to FLT Proof to High-Tc to Spintronics to Giant-Magnetoresistance: Ethics?? SHMETHICS!!!

C1.00200 GENERAL THEORY INCLUDING COMPUTATIONAL METHODS: MANY BODY AND STRONGLY CORRELATED SYSTEMS —

C1.00201 A nonlinear quantum master equation symmetric with respect to particles and holes , C.F. HUANG, CMS/ITRI, K.-N. HUANG, Department of Physics, NTU — A nonlinear master equation symmetric with respect to particles and holes has been introduced for systems composed of non-interacting identical fermions. [1,2] It can be reduced to semiclassical irreversible equation in the incoherent limit, and can be generalized to model interacting and/or open quantum systems. [2,3] To prove the validity of Pauli’s exclusion principle, we note that such a principle holds true if and only if the density matrix for holes is a positive one. Suitable mathematical structures have been constructed to complete the proof when there exists an upper bound for the transition rate. Extensions based on BCS-type symmetry are taken into account to incorporate both particle-particle and particle-hole pairings. References: [1] K. Burke, R. Car, and R. Gebauer, Phys. Rev. Lett. 94, 146803 (2005) [2] C. F. Huang and K. –N. Huang, quant-ph/0604054. [3] R. Alickij and K. Lendi, “Quantum Dynamical Semigroups and Applications” (Springer, Berlin Heidelberg 2007)
C1.00202 A new Variational Approach to the Hydrogen Atom, I. DJURIC, F.A. CORVINO, Stevens Institute of Technology, V. FESSATIDIS, Fordham University, J.D. MANCINI, Kingsborough College of CUNY — Over a decade ago, a systematic scheme for improving the variational wave functions and corresponding energy levels for quantum systems was developed. By expanding the wave function around a variational parameter value(s), a family of independent functions may be systematically generated. The eigenstates are then obtained by diagonalizing the Hamiltonian basis and optimized with respect to variational parameter(s). In this work we wish to apply this scheme to the well studied and understood ground state of the hydrogen atom. For a trial (starting vector) state we make two choices: \( e^{-\alpha r} \) and \( e^{-\beta r} \) where \( \alpha \) and \( \beta \) are variational parameters. Our two (variational) basis are then constructed by taking derivatives with respect to these parameters. We then choose a linear combination of the two states \( e^{-\alpha r} \) and \( e^{-\beta r} \) as our initial state and minimize with respect to both parameters. This leads to questions of the optimal number of each derivative \( \frac{\partial \psi}{\partial \alpha} \), \( \frac{\partial \psi}{\partial \beta} \), which will yield the lowest ground state energy for a given basis size \( N \) (\( \mu + q = N \)).

C1.00203 Variational Bond States of Screened Potentials, J.D. MANCINI, Kingsborough College of CUNY, V. FESSATIDIS, Fordham University, S.P. BOWEN, Chicago State University, W.J. MASSANO, SUNY Maritime — A number of years ago, a calculational scheme was introduced by Stubbins (Phys. Rev. A48, 220 (1993)) to compute the energies of both the Hulthén and Yukawa potentials. The method introduces a particular ansatz for solving the Schrödinger equation with screened Coulomb type potentials. In this work we wish to review the method of Stubbins and to show that it is, in fact, equivalent and a subset of a more systematic (and hence more useful) variational scheme (Zhou et al. Phys. Rev. A51, 3337 (1995)). This variational approach involves the construction of a basis by taking derivatives of the variational parameters of the system. The eigenvalues of the Hamiltonian matrix are then minimized with respect to these parameters yielding a “best guess” upper bound on the energies.

C1.00204 Translational Invariance in Parameter Space: An Alternate Variational Coupled Cluster Method, V. FESSATIDIS, Fordham University, J.D. MANCINI, Kingsborough College of CUNY, S.P. BOWEN, Chicago State University, R.K. MURAWSKI, Drew University — Over the past few decades the Coupled Cluster Method (CCM) has proven to be a useful tool for both chemists and physicists in the calculation of ground state energies. The CCM scheme is also a viable method in calculating the correlation energies of a number of diverse quantum systems such as atoms, molecules, electron gases as well as for magnetic lattice systems. In this work a new many-body calculational scheme is developed by merging the CCM scheme with a relatively new variational ansatz wherein a basis is constructed by taking derivatives with respect to the variational parameters of the system. A novel translational operator is then introduced leading to a generalization of Bloch’s Theorem in parameter space.

C1.00205 Microsolvation Effects on the Excited-State Dynamics of Protonated Tryptophan, MATTEO GUGLIELMI, SEBASTIEN MERCIER, OLEG BOYarkin, ANTHI KAMARIOTIS, IVANO TAVERNELLI, MICHELE CASCELLA, URSULA ROETH- LISBERGER, THOMAS RIZZO, LCPC COLLABORATION — To better understand the complex photophysics of the amino acid tryptophan, which is widely used as a probe of protein structure and dynamics, we have measured electronic spectra of protonated, gas-phase tryptophan solvated with a controlled number of water molecules and cooled to ~10 K. We observe that, even at this temperature, the bare molecule exhibits a broad electronic spectrum, implying ultrafast, nonradiative decay of the excited state. Surprisingly, the addition of two water molecules sufficiently lengthens the excited-state lifetime that we obtain a fully vibrationally resolved electronic spectrum. Quantum chemical calculations at the Rl-CC2/aug-cc-pvdz level, together with TDFT/pw based first-principles MD simulations of the excited-state dynamics, clearly demonstrate how interactions with water destabilize the photodissociative states and increase the excited-state lifetime.

C1.00206 The One-Hole, One-Dimensional Hubbard Model at \( U = \infty \), WILLIAM HODGE, NATALIE HOLZWARTH, WILLIAM KERR, Wake Forest University — The Hubbard Hamiltonian is the simplest model that describes interacting electrons on a lattice. In this work, we use the properties of stochastic matrices to examine the ground state with an even number of lattice sites and one electron less than half-filling. We show that there exists a highly symmetric state with energy \(-2\) (in units where \( t = 1 \)) at all \( U \). At \( U = \infty \) this state becomes the lowest energy state, consistent with the established lower energy bound.\footnote{S. A. Trugman, Phys. Rev. B 42, 6612 (1990)} Using this result, several properties of the strongly coupled ground state are derived, including the chemical potential and momentum distribution. This method may be applicable to other models as well. Disagreements between our results and previous work are examined.

C1.00207 Direct extension to \( n \)-leg models in the density-matrix renormalization group method: An approach on the ground state of two-dimensional triangular Hubbard model, SUSUMU YAMADA, MASAIKO ÔKUMURA, MASAIKO MACHIDA, CCSE, Japan Atomic Energy Agency — In order to examine the ground state of two-dimensional triangular Hubbard model, we directly extend the density-matrix renormalization group (DMRG) method to \( n \)-leg lattice model. The leg extension requires not only an enormous memory space but also a huge CPU cost. Therefore, we propose an efficient and scalable parallel algorithm of the direct DMRG method and actually perform parallel numerical simulations of triangular 4- to 6-leg Hubbard models using 128 to 512 CPUs on SGI Altix 3700Bx2 in JAEA. In this presentation, we will briefly introduce the parallelization strategy, the implementation way, and show its performance including its scalability and accuracy. Furthermore, we reveal peculiar particle density distributions on \( n \)-leg triangular Hubbard models. These results are compared with the future experiments on atomic Fermi gases loaded on triangular optical lattices.\footnote{CREST (JST)}

C1.00208 s-Wave Superconductivity Phase Diagram in the Inhomogeneous Two-Dimensional Attractive Hubbard Model, KARAN ARYANPOUR, Department of Physics, SUNY at Buffalo, THEREZA PAIVA, Universidade Federal do Rio de Janeiro, Brazil, WARREN E. PICKETT, RICHARD T. SCALLETAR, Department of Physics, University of California, Davis — We study s-wave superconductivity in the 2-D square lattice attractive Hubbard Hamiltonian for inhomogeneous patterns of interacting sites. Using the Bogoliubov-de Gennes ( BdG) mean field approximation, we obtain the phase diagram for inhomogeneous patterns with on-site electron interaction \( U \) taking on two values, 0 and \(-U/(1-f)\) (\( f \) the non-interacting sites concentration) as a function of electron density per site \( n \) as \( f \) varies. Inhomogeneity can result in a larger average pairing amplitude at \( T = 0 \) and also a higher superconducting \( T_c \), relative to a uniform system. Superconductivity can also vanish due to charge ordered phase formation. \( T_c \) enhancement due to inhomogeneity is robust as long as \( n < 2(1-f) \) regardless of the pattern. Also, for certain inhomogeneous patterns, when \( n = 2(1-f) \), raising temperature works against the stability of existing charge ordered phases for large \( f \) and as a result, enhances \( T_c \).

\footnote{We acknowledge NSF Grants DMR-0421810, DMR-0426826, US ONR, CNPq-Brazil and FAPERJ-Brazil.}
C1.00209 Simple dynamic exchange-correlation kernel of the uniform electron gas\(^1\), LUCIAN constatin, J.M. pitarke, Tulane University — We propose a simple dynamic exchange-correlation kernel of the uniform electron gas. We model the reduction of the electron-electron interaction due to short-range exchange-correlation effects by introducing a frequency-dependent error-function effective interaction. By imposing the fulfillment of the compresibility and the third-frequency-moment sum rules, as well as the correct asymptotic behavior at large wave vectors, we find an accurate and simple dynamic exchange-correlation kernel that accurately reproduces the wave-vector analysis and the imaginary-frequency analysis of the correlation energy of the uniform electron gas.

\(^1\) We acknowledge partial support by the University of the Basque Country, the Basque Unibertsitate eta Ikerketa Saila, the Spanish Ministerio de Educacion y Ciencia, and the EC 6th framework Network of Excellence NANOQUANTA-Grant No. NMP4-CT-2004-500198.

C1.00210 Critical parameters for the disorder-induced metal-insulator transition in FCC and BCC lattices, Andrzej eilmes, Department of Computational Methods in Chemistry, Jagiellonian University, Krakow, Poland, Andrea M. Fischer, Rudolf A. Roemer, Department of Physics and Centre for Scientific Computing, University of Warwick, UK — We use a transfer matrix method to study the disorder-induced metal-insulator transition for. We take isotropic nearest- neighbour hopping and an onsite potential with uniformly distributed disorder. Following previous work done on the simple cubic lattice, we perform numerical calculations for the face centred cubic (FCC) and body centred cubic (BCC) lattices, which are more common in nature. We obtain the localisation length from calculated Lyapunov exponents for different system sizes. This data is analysed using finite size scaling to find the critical parameters. We create an energy-disorder phase diagram for both lattice types, noting that it is symmetric about the band centre for the BCC lattice, but not for the FCC lattice. We find a critical exponent of approximately 1.5-1.6 for both lattice types for transitions occurring either at fixed energy or at fixed disorder, agreeing with results previously obtained for other systems belonging to the same orthogonal universality class. We notice an increase in critical disorder with the number of nearest neighbours, which agrees with intuition.

C1.00211 The Gutzwiller Ansatz: A new Approach, J.D. Mancini, Kingsborough College of Cuny, V. Fessatidis, Fordham University, I. Djuric, Stevens Institute of Technology, S.P. Bowen, Chicago State University — The search for calculational methods for dealing with strongly correlated electron systems ranging from high Tc superconducting compounds and other transition metal oxide materials to f-electron bearing elements is a long and continuous one. There are a number of well documented failures of such schemes as the local density approximation and the generalized gradient approach. Although these methods partially address the issues related to the strongly correlated electrons, a comprehensive theory is still lacking. The choice of including electrons correlations using the Gutzwiller variational wave function has proved over the years to be a useful one in the interpolation between the strong electron correlation (large U) and weak electron correlation (small U) limits. In this work a novel variational ansatz is applied to strongly correlated systems by using the Gutzwiller wave function as our initial vector, and then systematically constructing a basis by taking derivatives with respect to the variational parameters of the system. The eigenvalues of the Hamiltonian matrix with this basis are then minimized to yield a variational upper bound on the ground state energy.

C1.00212 Solution of the Electron Fluid Dynamical Equations, Mostafa Hemmati, Arkansas Tech University — To describe the breakdown waves, we use a one-dimensional, steady-state, three-fluid, hydro-dynamical model with a shock front. We assume that the electron gas partial pressure is much larger than the partial pressures of the other species and therefore provides the driving force for the propagation of the wave. The wave is composed of two distinct regions: a thin dynamical transition layer followed by a relatively thicker thermal layer. In the transition region, the electrons slow down to speeds comparable to those of heavy particles as the electric field fails to zero. In the thermal layer, the high temperature electron gas will cool, resulting in more ionization. The set of equations used to investigate these waves consists of the equation of conservation of mass, momentum, and energy coupled with Poisson’s equation, and is known as the electron fluid dynamical (EFD) equations. We have replaced the assumption of ionization rate being a function of temperature only, by a computation based on the free trajectory theory by Fowler; in which the ionization rate changes from accelerationnal ionization at the front of the wave to directed velocity ionization in the intermediate stages of the wave to thermal ionization at the end of the wave. Using Fowler’s equation to calculate the ionization rate, we have been able to integrate the EFD equations through both, the transition and thermal layers of the wave. The results conform to the expected conditions at the end of both layers. Wave profile for the electric field, ionization rate, and electron velocity, temperature, and number density will be presented.

C1.00213 INSTRUMENTATION AND MEASUREMENTS —

C1.00214 Branching Transport Model of NaI (Tl) Scintillator\(^1\), Boian Alexandrarov, Lanl and University of New Mexico, Kiril Ianakiev, Lanl, Peter Littlewood, Cavendish Laboratory, UK — The time dependence of NaI(Tl) fluorescence was measured long time ago with the delayed coincidences method and two decay time components were observed. Because 95% of the total light yield is collected within the first 800 ns, the influence of the second component has been neglected. We claim that there are two dominant time components with strong temperature redistribution. We experimentally measured the time dependence of the NaI(Tl) light-emission pulses and found that the amplitude ratio of these two components shows Arrhenius temperature dependence. We found that the slow component occupies up to 40% of total light at -20\(^\circ\)C temperature. We analyze the time shape of the light pulse to directed velocity ionization and rotation K\(^\theta\).

\(^1\) Work supported by NSF through career DMR-0547887, the Nebraska Research Initiative, and the NSF MRSEC Program DMR-0213808.

C1.00215 Optimization of MOKE Setups: Analyzing Experimental Assemblies Using Jones Matrix Formalism\(^1\), Srinivas Polisetty, jeremy scheffler, Sarbeswar sahoo, Christian binek, University of Nebraska-Lincoln — We report on the optimization of Magneto Optical Kerr setups. Photoelastic modulation and phase sensitive detector methodology have been used to measure the first and second harmonics of the reflected light intensity related to the magnetization-dependent off-diagonal reflection coefficients \(r_{pa}/sp\) of the sample’s dielectric tensor. The latter elements determine the Kerr ellipticity \(\varepsilon_K\) and rotation \(\theta_K\). Jones matrix formalism has been used to analyze a large variety of arrangements of the optical elements involved in setups for longitudinal Kerr measurements with incoming s-polarized light. Relative analyzer and polarizer orientations have been varied with respect to each other and with respect to the retardation axis of the modulator. Different configurations have been analyzed and experimentally studied by measuring magnetic Kerr-hysteresis loops on a Co/CoO bilayer sample. We find that one configuration stands out by doubling the first as well as second harmonic intensities and, hence, the signal to noise ratio. Inefficient setups show first and second harmonic signals involving non-magnetic background contributions of \(r_p\) and \(r_s\).

\(^1\) Work supported by NSF through career DMR-0547887, the Nebraska Research Initiative, and the NSF MRSEC Program DMR-0213808.
C1.00216 Electromagnetic modulation of the ultrasonic signal for nondestructive detection of small defects and ferromagnetic inclusions in thin wall structures, PETER FINKEL, Drexel University — We report on new nondestructive evaluation technique based on electromagnetic modulation of ultrasonic signal for detection of the small crack, flaws and inclusions in thin-walled parts. The electromagnetically induced high density current pulse produces stresses which alter the ultrasonic waves scanning the part with the defect and modulate ultrasonic signal. The excited electromagnetic field can produces crack-opening due to Lorentz forces that increase the ultrasonic reflection. The Joule heating associated with the high density current, and consequent thermal stresses may cause both crack-closure, as well as crack-opening, depending on various factors. Experimental data is presented here for the case of a small crack near holes in thin-walled structures. The measurements were taken at 2-10 MHz with a Lamb wave wedge transducer. It is shown that electromagnetic transient modulation of the ultrasonic echo pulse tone-burst suggest that this method could be used to enhance detection of small cracks and ferromagnetic inclusions in thin walled metallic structures.

C1.00217 Detection of nerve agents and biological molecules using embedded piezoresistive microcantilever sensors, TIMOTHY PORTER, TIM VAIL, AMANDA WOOLEY, Northern Arizona University — Embedded piezoresistive microcantilever (EPM) sensors have been used in the detection of a variety of analyte species. EPM sensors utilize a tiny piezoresistive microcantilever partially embedded into a sensing material to produce a sensing element that is compact, simple, resistant to movement and shock, and suitable for remote sensing applications. In the current project, we have used sensing materials comprised of an immobilizing polymer functionalized with either target enzymes or antibodies to detect two biological agents, bacillus globigi (BG) and Dilsopropyl fluorophosphate (DFP). DFP is an organophosphate used as a simulant for organophosphate nerve agents, while BG is a large bacterial spore used as a simulant for other bacterial spores such as bacillus anthracis. Sensing results are presented for both types of EPM sensors.

C1.00218 Micro-Oscillators for Ultra-Sensitive Force Detectors, WEI LU, JOHN MARKERT, Physics Department, University of Texas at Austin — Recently, we have improved the microfabrication process for ultra-sensitive double-torsional mechanical micro-oscillators. Starting with silicon-on-insulator wafers (with 300 nm Si surface layers), we grow a protective layer of oxide, then pattern 2-mm × 0.5-mm “windows” that result in a thin Si film after two-sided wet chemical etching. Patterning these film windows with electron-beam lithography then provides the final micro-oscillator structures. Our designs include multimode structures, particularly double-torsional modes; we have achieved excellent geometric symmetry and small sizes (~30 μm laterally and 300 nm thick). These oscillators have excellent force sensitivity, yet provide stronger mechanical structures than typical ultrafloppy cantilevers designs. For example, an antisymmetric double-cantilever mode provides a minimum detectable force of 1.6 × 10⁻¹⁶ N/√Hz at 3He temperatures. A double torsional mode typically provides enhanced sensitivity, so minimum detectable forces on the order of 10⁻¹⁹–10⁻²⁰ N/√Hz are now targeted.

C1.00219 Surface Plasmon Based Spectrometer, ANDREW WIG, Benedictine University, ALI PASSIAN, PHILIP BOUDREAU, TOM FERRELL, University of Tennessee — A spectrometer that uses surface plasmon excitation in thin metal films to separate light into its component wavelengths is described. The use of surface plasmons as a dispersive medium sets this spectrometer apart from prism, gratings, and interference based variants and allows for the miniaturization of this device. Theoretical and experimental results are presented for two different operation models. In the first case surface plasmon tunneling in the near field is used to provide transmission spectra of different broad band-pass, glass filters across the visible wavelength range with high stray-light rejection at low resolution as well as absorption spectra of chlorophyll extracted from a spinach leaf. The second model looks at the far field components of surface plasmon scattering.

C1.00220 Atomic Force Microscopy Simulation in Aqueous Environment by RISM Theory, MASANORI HARADA, MASARU TSUKADA, Waseda University — Many theoretical simulations of atomic force microscopy (AFM) have been performed so far to clarify the underlying physics in experimental AFM images which were difficult to understand intuitively. Most of the simulations use the models consisting of only tip and sample atoms and successfully reproduce experimental AFM images obtained in vacuo. However, those models are not suitable to simulate the AFM experiments performed in liquid or gaseous environments. Reference Interaction Site Model (RISM) is used in our simulation to incorporate liquid effect. This method is based on statistical mechanics and has the advantage of low computational cost over all-atom molecular dynamical simulations. To investigate the efficiency of the method, we simulated the force-distance curves and 2D force maps in constant height mode for two different operation models. In the first model the flight path is a factor of two longer than used in previous TOF-PAES systems. The longer flight path is expected to result in a fractional energy width: δE/ E = 5 × 10⁻¹⁸ N/√Hz at 3He temperatures. A double torsional mode typically provides enhanced sensitivity, so minimum detectable forces on the order of 10⁻¹⁹–10⁻²⁰ N/√Hz are now targeted. 1

C1.00221 Two Meter Flight Path - Time of Flight Positron Annihilation Induced Auger Electron Spectrometer, S. MUKHERJEE, K. SHASTRY, W. ADDOX, A. H. WEISS, U. Texas at Arlington — Details of the design and construction of a new time of flight positron annihilation induced Auger electron (TOF-PAES) spectrometer are presented. The new spectrometer will be equipped with a 2 meter long “TOF” tube that can be biased at a potential different from that of the sample in order to increase or decrease the kinetic energy of the electrons traveling through the tube. The time of flight will be determined from timing signals obtained from the detection of the annihilation gamma (signaling the start of the flight) and detection of the annihilation induced Auger electron at the end of the 2 meter flight path (signaling the end of the flight). The 2 meter long flight path is a factor of two longer than used in previous TOF-PAES systems. The longer flight path can be expected to result in a fractional energy width: δE/ E that is 1/2 as large as the current UTA lab based TOF-PAES spectrometer.

1Y-1100 Welch Foundation

C1.00222 Theoretical simulation of nc-AFM images of mica surface in water, KATSUNORI TAGAMI, MASARU TSUKADA, Waseda University — Based on molecular dynamics simulations, the non-contact atomic force microscopy (nc-AFM) images are simulated of mica surface in water. The tip is modeled by the carbon nanotube apex and the temperature is assumed to be 300 K. The interatomic interactions used in the calculations are listed in CHARMM22 and CLAY force field models. The force curves show oscillatory behaviours near the surface and their amplitudes are found to significantly depend on the scanning points, which produces highly resolved images of the surface structure. In the talk we will make a presentation on the relationship between the normal force and water density profile.
C1.00223 Micromechanical force detectors for measuring magnetization at high magnetic fields and the magnetic response of Ba3Cr2O8. K. NINIOS, H.B. CHAN, UF, Y. J. JO, L. BALICAS, FSU, A. ACZEL, McMaster University, G. M. LUKE, FSU — We report magnetization measurements of Ba3Cr2O8 using micromechanical Faraday balance magnetometers. The magnetometers consist of a movable polysilicon plate (500 by 500 micrometers) supported by four springs 2.75 micrometers above a fixed electrode. When small samples of the magnetic material are placed at the center of the movable plate, the natural gradient of the field creates a force on the sample that changes the capacitance between the plate and electrode, while the response to magnetic torque is minimized. The absolute magnetization of the sample can be determined provided that the magnetic field gradient is known. The device is used to measure the magnetization of a small sample of Ba3Cr2O8 with mass of 1 microgram. At high fields, our measurements reveal an asymmetric dome like structure in the temperature-magnetic field phase diagram, possibly related to the Bose-Einstein condensation of spin triplet degrees of freedom.

C1.00224 Characterization and Modeling of Off-Specular Neutron Scattering for Analysis of Two Dimensional Ordered Structures. CHRISTOPHER J. METTING, ROBERT M. BRIBER, University of Maryland, JULIE A. BORCHERS, BRIAN MARANVILLE, PAUL KIENZLE, CHUCK F. MAJKRZAK, JOSEPH A. DURA, NCNR — Work is currently being done to expand further neutron reflectometry to the off-specular regime for the characterization of thin films with two-dimensional, ordered in-plane structures. The combination of this two-dimensional, in-plane information with the depth-profile that is routinely obtained from reflectivity data can produce a complete, 3-D description of both the structure and magnetic characteristics of these films. The University of Maryland along with the NIST Center for Neutron Research (NCNR) are developing software which can easily be integrated into existing neutron modeling package such as ReflpaK, and will expand the accessibility of off-specular neutron reflectometry to the general scientific community. In this presentation, we show data obtained using a position sensitive detector on the AND/R instrument at the NCNR facility for a range of model systems. Preliminary analysis has been completed on several sample sets with wire and diffraction grating geometries. In addition, patterned gold samples are being lithographically produced in order to test models for a variety of standard feature structures and patterns.

C1.00225 Upgraded varied-line-space PCM beamline at CAMD. PINCHENG ZHOU, EZIZI MORIKAWA, CAMD, Louisiana State University, 6980 Jefferson Hwy, Baton Rouge, LA 70806 — CAMD is a synchrotron research center at the Louisiana State University. Recently, the center’s aging plane-grating vuv soft x-ray monochromator beamline was upgraded to a varied-line-space plane-grating monochromator beamline. Preliminary experiments show performance improvements in the resolving power from 1000 to 5000 and the throughput from 109 to 1011 photons/sec.100 mA. A polarization aperture providing right and left circular polarized photon beams from the bending magnet radiation is scheduled to be installed in the front-end section of this beamline that will provide the opportunity to perform X-ray Magnetic Circular Dichroism(XMCD) spectrum experiments spectroscopy in the future.

C1.00226 Free-electron laser-based pulsed electron paramagnetic resonance, SUSUMU TAKAHASHI, MARK S. SHERWIN, GERALD RAMIAN, University of California Santa Barbara, LOUIS-CLAUDE BRUNEL, JOHAN VAN TOL, National High Magnetic Field Laboratory — High-power pulsed electron paramagnetic resonance (EPR) is extremely useful to study the ultrafast dynamics of spins. At present, most high-power pulsed EPR spectrometers operate near the X-band frequency of 9.5 GHz with kW-level power. A trend in the evolution of next generation pulsed EPR is for higher magnetic field and frequency, both for finer spectral and time resolution and because motional averaging becomes negligible. Since the linewidth of resonances studied by pulsed EPR tends to be extremely narrow, the source radiation also has to be stable and have narrow bandwidth. High-power pulsed EPR, using few-ns pulses to rapidly manipulate spins for spin-echo and related experiments, has been demonstrated at 98 GHz using kW-power Klystron-based sources. A bottleneck for higher frequency pulsed EPR spectroscopy is a lack of sources with high power and narrow bandwidth. The University of California Santa Barbara (UCSB) free-electron lasers (FEL) are potential sources for high-power pulsed EPR because they generate kW of power tunable from 120 GHz to 4.7 THz. We present the current status of the UCSB FEL-based 240 GHz pulsed EPR spectrometer.

C1.00227 Directed Self-assembly of Nanostructures to Develop AFM-Based Biomaterial-to-Electronic Interface, MEHDI YAZDANPANAH, MAHDI HOSSEINI, SANTOSH PABBA, SCOTT BERRY, VLADIMIR DOBRKOTOV, ABDELLILAH SAFIR, ROBERT KEYNTON, ROBERT COHN, University of Louisville, ELECTROOPTICS RESEARCH INSTITUTE AND NANOTECHNOLOGY CENTER TEAM — Very flexible and rugged Ag2xGa nanoneedles of constant diameter (sub 100 nm diameter, 7-70 microns long) can be securely grown onto AFM tips at room temperature. These nanoneedles are electrically conductive and have stiffness well matched to viscoelastic properties of complex fluids and biological materials. This talk specifically presents the abilities of the needles to (1) make precise AFM measurements of surface tension, contact angle, evaporation rate, and shear viscosity of polymeric liquids, (2) measure complex viscoelastic properties of cell membranes and organelles of blood and endothelial cells, (3) capture and be surrounded by single live endothelial cells within a few seconds, (4) polymerize and detect the growth of protein nanofibers on the end of the nanoneedles and (5) functionalize the end of the needles with protein nanofibers and use them for imaging the cell receptors.

C1.00228 Force measurement with a scanning tunneling microscope, KAI-FELIX BRAUN1, SAW-WAI HLA, Ohio University — We present a method to measure the interaction force between single atoms with a scanning tunneling microscope [1]. During experiments for atomic manipulation with a scanning tunneling microscope the tip height curve is recorded. It is shown here that the amplitude of the manipulation curve is a measure for the interaction force between the microscopes tip and a single atom adsorbed on a surface. A simple formula is derived and tested. Extensions of this scheme to different surfaces shall be discussed. [1] K.-F. Braun and S.W. Hla, Physical Review B 75 (2007), 033406.

C1.00229 ESR-MRI Using Low-Temperature Magnetic Resonance Force Microscopy, SHIGENORI TSUIJI, TATSUYA FUJIMOTO, YOHSUKE YOSHINARI, JEOL Ltd., CREST, KOHSUKE INOMATA, Kyoto Univ., CREST — The low-temperature operation of Magnetic Resonance Force Microscopy (MRFM) leads to a significantly better signal-to-noise ratio (SNR) than at room temperature, because of an increase of the spin magnetization and a reduction of the thermo-mechanical noise of the cantilever. We have built a low-temperature equipment, which is capable of operating in vacuum at liquid helium temperature. Our setup employed the sample-on-cantilever design at present. A magnetic needle with 100Å in diameter was placed on a stage to generate magnetic field gradient 11.3 G/µm at the magnetic field 7 T. The 3D closed-loop stage based on slip-stick principle allows a 200 x 200 x 200 µm3 scan range with 50 nm resolution. The experimental results of the 2D magnetic resonance force map carried out on diphenylcyclohexatriene (DPH) at T = 1.1 K are shown and an improvement of the SNR by 154 compared with the results at room temperature is confirmed. The 2D reconstructed images will be as well.

1Presenting Author
C1.00230 High-Resolution Combined Low-Temperature Scanning Tunneling/Atomic Force Microscope for 3D Force Spectroscopy , B.J. ALBERS, M. LIEBMANN, T.C. SCHWENDEMANN, M.Z. BAYKARA, Yale University, M. HEYDE, M. SALMERON, Lawrence Berkeley Nat. Lab., E.T. ALTMAN, U.D. SCHWARZ, Yale University — We present the design and first results from a new home-built low-temperature scanning probe microscope enabling high-resolution experimentation in both scanning tunneling microscopy (STM) and non-contact atomic force microscopy (NC-AFM) modes. A tuning fork based Q-plus style sensor is used to allow for flexibility in choosing probe tip materials. The system features an on-top cryostat, where the microscope is enclosed in a double set of thermal shields. Tip as well as sample can be changed in-situ at low temperatures to keep turn-around times low. By opening the front shutters of the shields, unrestricted access from dedicated flanges permits the direct deposition of molecules or atoms on either tip or sample while they remain cold. As examples for the microscope’s performance, we present data measured on Cu(111) in STM mode as well as on graphite in NC-AFM mode, featuring atomic resolution with corrugations of 4-5 pm and corrugations below 1 pm could be measured. In addition, atomic resolution data obtained by local force spectroscopy is shown.

C1.00231 Using Nuclear Magnetic Resonance Force Microscopy with Cross-Polarization for Nuclear Magnetization Enhancement and Heteronuclear Decoupling1 , ROSA ELIA CÁRDENAS, JOHN T. MARKERT, Department of Physics, University of Texas at Austin — We report our progress in applying Nuclear Magnetic Resonance Force Microscopy (NMRFM) to study position-dependent cross-polarization effects in ammonium hexafluorophosphate (NH4PF6). Cross polarization (CP) is typically used either to enhance the polarization of a weak or rare species, or to decouple one species from its dipolar interactions with another, that is, for line narrowing. With the added local probe abilities of NMRFM, particularly the presence of a strong field gradient, new techniques for coupling spins in nearby resonant slices are possible. The NH4PF6 system has three NMR-active nuclei: the stronger 1H and 19F nuclear moments, and the weaker and more rare 31P moments. We will examine the various effects of coupling 1H and/or 19F with 31P, including efficient frequency-sweep matching for optimization of the CP rate. We will also examine local effects dependent on excitation and detection slice geometry, and the dynamical effects of NH4 and PF6 reorientations.

C1.00232 Tip-Sample Gap control for truly noncontact operation on an AFM , YEHIAM PRIOR, ALEXANDER MILNER, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel 76100 — A new mode of operation is introduced to standard atomic force microscopes, working under ambient conditions, for noncontact operation at a small predetermined Tip Sample Gap (TSG) of a few nanometers. A phase-locked loop, based on tiny oscillations (<1 nm) of the cantilever at a frequency far from the cantilever mechanical resonances, is used to maintain the gap between the tip and the sample at a range of 1 - 4 nanometers. The noncontact hovering of the tip is maintained for long times without the tip ever touching the surface. The TSG is calibrated by the far field scattering of evanescent fields over transparent samples. A typical measurement run provides, in addition to the standard topography, information about the amplitude and phase of the new oscillations, as well as information about the shear forces based on lateral oscillation of the sample relative to the tip. In a geometry characteristic for Apertureless Scanning Near Field Optical Microscope, the tip is illuminated by a focused beam of a femtosecond laser (800 nm, 20 fs, 100 mw) for nano-patterning of the area under the tip.

C1.00233 A physically founded model of the efficiency curves of coaxial Germanium detectors , YUNXIA GUAN, LIANBIN NIU, YAN MA, JIANZHANG XUE, QING KANG, Department of Physics, Chongqing Normal University — A semi-empirical formula for the full energy peak efficiency of coaxial Germanium detectors in the range of 60 to 2614 keV is presented. Both equations are linear with respect to the fitting parameters. They were obtained by combining, and minor adjusting, the terms in the asymptotic expressions for the probabilities of the processes (photoelectric absorption, Compton Scattering and pair production) through which γ-rays interact with matter. Both equations were found to be able to fit very well in wide energy ranges the efficiency curves of coaxial Ge detectors detecting γ-rays from point or plane sources, as well as from cylindrical volume sources.

C1.00234 Derivation of sensitivity of a Geiger mode APDs detector from a given efficiency to estimate total photon counts , KIYOTAKA HAMMURA, Hitachi Cambridge Laboratory, Cavendish Laboratory, UK — In quantum key distribution (QKD) experiments based on a single photon stream, a single photon detector incorporating Geiger mode avalanche photodiodes (APDs) is mostly used in order to detect photons. It is important to estimate prior to experiments how many photons the detector can detect in total for a simple single photon stream. We propose a method of estimating it using intrinsic detection sensitivity (DS) instead of extrinsic detection efficiency (DE). We derive DS using figures to examine the various effects of coupling H and/or F with P, including efficient frequency-sweep matching for optimization of the CP rate. We will also examine local effects dependent on excitation and detection slice geometry, and the dynamical effects of NH4 and PF6 reorientations.

\[
DS = \frac{\text{How many photons have been counted per second}}{\text{How many photons have arrived per second} - N_B} \quad (1)
\]

resulting in 0.27. Applying this value of DS to our experimental configuration, the total photon counts are estimated at 81,000 counts/second. DE under these configurations is estimated at 0.16, which is found to be smaller than that at a lower triggering rate configuration.

C1.00235 METALS —

C1.00236 ABSTRACT WITHDRAWN —

C1.00237 Dynamic acoustic effects and hysteresis in dislocation-based kinking nonlinear elastic solids under stresses , PETER FINKEL, Drexel University — We argue that proposed recently mechanism explaining inelastic hysteresis in non-linear elastic systems indeed can be explained by means of formation of dislocation-based incipient kink bands (IKB). Using acoustic waves we investigated possible dislocation related mechanisms responsible for nonlinear dynamic response of IKB solids. In this work, for the first time we observed and reversibility of IKB formation directly under stress using ultrasonic waves and acoustic emission signatures during compression test of nanolaminated layered ternary carbide (MAX phases) and hexagonal metal samples. We confirm here that the dynamic behavior of these non-linear elastic systems is due to the interaction of dislocations with the stress waves.
C1.00238 Direct Estimation of Strain Gradient Maps in Plane Strain Indentation. TEJAS MURTHY, CHIHYUNG HUANG, SRINIVASAN CHANDRASEKAR, Purdue University — Indentation is a widely used non-destructive means for assaying mechanical properties of metals. In-situ Experimental investigations on the extent of deformation and the distinct features of the deformation field around a plane strain wedge indenter were performed. A rigid plastic material (lead) was indented under plane strain conditions with different deformation rates and wedge angles. The region around the indenter was directly observed by tracking asperity movements on the surface of the specimen using high-speed imaging. The digitized images were analyzed using particle image velocimetry (PIV) to obtain velocity fields. Strain rate fields and strain maps were also obtained through analysis of this velocity field. Estimates of the strain gradients at a macro scale have afforded detailed analysis of the size effects in indentation and validation of flow theories at a macroscopic scale.

C1.00239 Ab initio simulations of grain boundary sliding in aluminum and nickel. JITESH GARG, Department of Mechanical Engineering, Massachusetts Institute of Technology, NICOLA MARZARI, Department of Materials Science and Engineering, Massachusetts Institute of Technology — The Hall-Petch relationship predicts an increase in material yield strength with decreasing grain size. However, a breakdown has been reported at smaller grain sizes, where plastic deformation gradually becomes grain-boundary dominated. Studying grain-boundary sliding processes is therefore key to understanding the mechanical properties of polycrystalline materials. In the present work, we use density-functional theory to examine the microscopic processes that accompany grain boundary sliding in aluminum and nickel for different grain boundary structures. Sliding of tilt boundaries is also accompanied with grain boundary migration, where grain boundary movement normal to the boundary surface takes place. The effect of adding W to the sliding process in Ni-W alloys is also reported.

C1.00240 Laser induced patterning of metal films via weakly bound layers on surfaces. MICHA ASSCHER, ORI STEIN, YIGAL LILACH, The Hebrew University of Jerusalem, LEONID V. ZHIGILEI, ZHIBIN LIN, University of Virginia, Charlottesville — Pulsed laser heating of weakly binding layers has been employed for selective removal of these layers. The ablated films (Xe) are then used as templates for metallic clusters and film patterning. The method enables patterning over most substrates that absorb the laser light, e.g. Ru(001) single crystal, soft surfaces prepared from self-assembled monolayers (SAM) and SiO$_2$/Si(100). Patterns obtained from interfering laser beams result in a ratio of laser wavelength to width of pattern’s edge less than 1:40, better than most standard optical, mask-less patterning techniques. In-situ optical diffraction has been utilized to study the thermal stability of the patterned weakly bound films against surface diffusivity and desorption. Molecular Dynamics simulations of a Xe film composed of 15,000 atoms attached in 14 layers, has demonstrated a threshold for ablation at 100J/m$^2$. At identical laser energy above threshold and 3-10 ps pulse duration range, longer pulses result in better patterning resolution.

C1.00241 Laser-induced dewetting nanomorphology and nanostructure in immiscible bilayer metal films. H. KRISHNA, Dept. of Physics, Washington University in St. Louis, MO, R. SURESHKUMAR, Dept. of Energy, Environmental and Chemical Engineering, Washington University in St. Louis, MO, R. KALYANARAMAN, Dept. of Physics, Washington University in St. Louis, MO — Spatially ordered patterns of nanoparticles result under ns laser-induced dewetting of immiscible bilayer metallic films (Co and Ag) on inert substrates like SiO$_2$. The morphological pathway during dewetting is different for the two individual metals: occurring through development of bicontinuous structures in the case of Ag and by progression of cellular networks for Co. On the other hand, dewetting in bilayer structures of Ag/Co/SiO$_2$ or Co/Ag/SiO$_2$ shows that the morphology evolution is dictated by the thicker of the two films. Linear stability analysis predicts that the self-organized length scales from the bilayer film dewetting is smaller than a single layer of either metal with the same total thickness. This was also verified experimentally and shows that the metal-metal interfacial dynamics significantly influences bilayer dewetting. Electron microscopy investigations show that the individual nanoparticles consist of Ag and Co in their individual elemental crystal phase. These ns laser dewetting experiments provide novel ways to create multi-metal patterns and nanostructures.

C1.00242 An Evaluation of the Rigid Band Model and the Virtual Crystal Approximation in the Transition Metals. DIMITRIOS PAPACONSTANTOPOULOS, FRED IACOLETTI, ALEX KOUFOS, George Mason University — The Schrodinger equation was solved using the Augmented Plane Wave (APW) Method for transition metals in both the body centered cubic (bcc) and face centered cubic (fcc) structures. This method accurately predicts the equilibrium lattice parameter and the ground state of all transition metals. The Rigid Band Model tests based on the group eight and group nine transition metals was applied to predict the density of states (DOS) at the Fermi level for the rest of the transition metals. This test agreed with direct calculations quite well with only a few exceptions in the hexagonal structures. The APW method was also applied using the virtual crystal approximation to obtain the DOS of binary alloys. The results will be compared with direct calculations of ordered and disordered structures.

C1.00243 The Density Functional Calculation for Surface Capacitance of Metal-Semiconductor Junction. CHIN-SHENG WU, Yuan Ze University — We use the density functional theory to find the density of the surface electronic charge around metal-semiconductor junction. We use the local approximation for the inhomogeneous dielectric function around the junction. Therefore this surface charge can be applied to find dielectric constant, which is a function of the electron density. The capacitances are calculated on the junction by their shapes and dielectric constants for various metal and semiconductor densities.

C1.00244 Comparison of the Phase Field Crystal Free Energy Functional and the Second Order Density Functional Theory of Freezing. AKUSTI JAATINEN, CRISTIAN ACHIM, JARI JALKANEN, TAPIO ALA-NISSILA, Laboratory of Physics, Helsinki University of Technology, Espoo, Finland, KEN ELDER, Department of Physics, Oakland University, Rochester, Michigan, USA — We present a numerical study of the recently established connection between the phenomenological free energy functional of the phase field crystal model (PFC) and the second-order density functional theory of freezing (DFT) [1]. We have used liquid state structural data of iron and copper near their melting points to study their freezing properties by both DFT and PFC functionals. The results obtained by the two functionals differ from each other significantly. DFT being superior to PFC in predicting crystal structures, density profiles and coexistence densities. We conclude that the fitting procedure outlined in [1] does not provide quantitatively accurate predictions of phase diagrams. [1] K. R. Elder, N. Provatias, J. Berry, P. Stefanovic and M. Grant, Phys. Rev. B 75, 064107 (2007)

C1.00245 ABSTRACT WITHDRAWN

C1.00246 STATISTICAL AND NONLINEAR PHYSICS
Doebner-Goldin Equation for Electrodynamic Model Particle & Applications

J.X. ZHENG-JOHANSSON — We set up based on Maxwell’s equations the classical wave equation for the total wave of a particle composed of an oscillatory charge of zero rest mass and the resulting electromagnetic waves traveling in the force field of an usual potential and an additional fractional force \( f \). The equation decomposes into a component equation describing the particle kinetic motion, which for \( f = 0 \) identifies with the usual Schrödinger equation. The \( f \)-dependent probability density presents generally an observable diffusion current of a real diffusion constant; this and the particle’s usual quantum diffusion current as a whole are under adiabatic condition conserved and obey the Fokker-Planck equation. The extra, \( f \)-dependent Hamiltonian operator identifies with that obtained by Doebner and Goldin. The friction produces to the particle’s wave amplitude a damping that can describe well the effect due to a radiation (de)polarization (RD) field, which is always by-produced by the particle’s oscillatory charge in a (nonpolar) dielectric medium; such a friction and the resulting observable diffusion as intrinsically accompanying the particle motion was as strikingly conjectured in the Doebner and Goldin original discussion. The RD field in a dielectric vacuum exerts on another particle an attractive, depolarization radiation force which on the whole resembles Newton’s gravity, and on the particle itself an attractive, self depolarization radiation force whose time rate gives directly the \( f \) (full paper: SNMP2007).

C0.00248 The Effects of Popping Popcorn Under Reduced Pressure

PAUL QUINN, AMANDA COOPER, Kutztown University — In our experiments, we model the popping of popcorn as an adiabatic process and develop a process for improving the efficiency of popcorn production. By lowering the pressure of the popcorn during the popping process, we induce an increase in popcorn size, while decreasing the number of remaining unpopped kernels. In this project we run numerous experiments using three of the most common popping devices, a movie popcorn maker, a stove pot, and a microwave. We specifically examine the effects of varying the pressure on total sample size, flake size and waste. An empirical relationship is found between these variables and the pressure.

1Thanks to the students of the New Jersey Governor’s School of the Sciences for assistance in carrying out portions of this project.

C0.00249 Dynamic localization and transport of a quantum particle in an optical lattice.

PANAGIOTIS MANIADIS, Los Alamos National Laboratory, Los Alamos NM, GEORGE P. TSIRONIS, Department of Physics and FORTH, University of Crete, Greece — We study the localization and the transport of a quantum particle in an optical lattice under the influence of an AC electric field. For the description of the particle we use a generalized Discrete Nonlinear Schrödinger equation with local and nonlocal nonlinearities Depending on the parameters of the system, and the external driving field, different behavior is observed (hopping, diffusion, dynamic localization). We explore numerically the behavior of the particle for different values of the external field and the internal nonlinearity parameters, and we compare our results with experimental observations.

C0.00250 Hysteresis-induced long-time tails

GUENTER RADONS, Institute of Physics, Chemnitz University of Technology — Many systems ranging from magnetic materials to shape memory alloys, or fluids in porous structures show complex hysteretic behavior in the sense that besides major loops, subloops and non-local memory effects are observed. The most prominent phenomenological model to account for such effects is the so-called Preisach model [1]. For this model it is shown analytically that uncorrelated input in time is transformed into output showing power-law decay of correlations and 1/f-noise. The characteristic exponents are shown to depend on the tails of the input density and the Preisach density. Universality classes leading to these results are identified.

C0.00251 Reaction-Diffusion Processes on Networks

KYUNSGIK KIM, Department of Physics, Pukyong National University, Pusan 608-737, Korea, SOO YONG KIM, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea, KI-HO CHANG, Global Environment System Research Laboratory, National Institute of Meteorological Research, KMA, Seoul 156-720, Korea — We study the novel reaction-diffusion process of three-species on scale-free networks, which is significantly different from the numerical calculation manipulated on regular and small-world lattices. The inverse particle density for three-species process scales as the power-law behavior with \( \alpha = 1.5 \) for \( \gamma > 3 \). However we find that the inverse particle density scales in a different way depending on time \( t \) when \( \gamma < 3 \). In the early time regime, \( \alpha \simeq 1.5 \) but the inverse particle density increases exponentially as time increases. We also discuss the possible relationship to the dynamical properties of random walks. Particularly, we measure the ratio between the number of inactive and active bonds which shows the segregation of the particles.

C0.00252 A node-weight description on a kind of cooperation-competition networks

DAN SHEN, DA-REN HE, Yangzhou University — Cooperation and competition between elements usually appear together in complex systems. We consider the kind of the systems, which can be described by bipartite graphs. In the networks there are two types of nodes: some activities, organizations or events, and the participators. The traditional bipartite graph statistical properties may describe the configuration of the cooperation-competition, and the statistical properties about a node weight may describe the different role of a node in cooperation or competition result. We shall present some empirical investigations on Chinese Movie Network, Beijing Restaurant Network and IT product Network as examples.

1supported by the National Natural Science Foundation of China under the key project Grant No. 10635040 and the Grant No. 70371071

C0.00253 IT product competition Network

XIULI-LIAN XU, LEI ZHOU, JIAN-JUN SHI, YONG-LI WANG, AI-XIA FENG, DA-REN HE, Yangzhou university — Along with the technical development, the IT product competition becomes increasingly fierce in recent years. The factories, which produce the same IT product, have to improve continuously their own product quality for taking a large piece of cake in the product sale market. We suggest using a complex network description for the IT product competition. In the network the factories are defined as nodes, and two nodes are connected by a link if they produce a common IT product. The edge represents the sale competition relationship. 2121 factories and 265 products have been investigated. Some statistical properties, such as the degree distribution, node strength distribution, assortativity, and node degree correlation have been empirically obtained.

C0.00254 The combined traffic network of China

CHANG-GUI GU, SI-JUN PAN, KAI-JUN LI, YAN-QING QU, CHAO QIAO, YU-MEI JIANG, DA-REN HE, Yangzhou University — From a new viewpoint, we study the combined traffic network of china including the intercity bus network, the railway network, and the airplane network. Some statistical properties, such as averaged distance, clustering coefficient, assortativity, degree distribution, and degree correlation have been empirically investigated for each traffic network and the combined one. From the results we found that the cumulative distribution of cluster coefficient is in a good agreement with the node degree distribution. In order to describe the jumping between the sub-networks, we define and discuss some new statistical properties, such as the jump-convenience and average jumping distance. This may be the first investigation on a combined traffic network.

C1.00255 A network description on fruit nutritive factor system1, YAN-QING QU, YU-MEI JIANG, DA-REN HE, Yangzhou University — We propose describing a kind of cooperation-competition systems by node-weighted bipartite graphs. In the systems the nodes can be divided into two types. One type expresses a kind of activities, organizations or events, named “acts”; the other expresses the “actors” participating the acts. In each act the actors basically show collaboration relationship, however they play different role in the cooperation. This is a kind of competition. The node weights usually signify the role or “importance degree” of each actor. We propose using some statistical properties for the description of such kind of systems. The properties without considering node-weight can describe the cooperation situation and configuration. The properties with node-weight considered may describe the competition results. We report an example system, the fruit nutritive factor network, to show the description method and the corresponding empirical investigation results. It is our wish that the description method could be widely effective for the kind of systems in variety different scientific fields.

C1.00257 A Collaboration Network Model Of Cytokine-Protein Network1, SHENG-RONG ZOU, TA ZHOU, YU-JING PENG, ZHONG-GUI GUO, CHANG-GUI GU, DA-REN HE, Yangzhou University — Complex networks provide us a new view for investigation of immune systems. We collect data through STRING database and present a network description with cooperation network model. The cytokine-protein network model we consider is constituted by two kinds of nodes, one is immune cytokine types which can be regarded as collaboration acts, the other one is protein type which can be regarded as collaboration actors. From act degree distribution that can be well described by typical SPL (shifted power law) functions [1], we find that HRA, TNFSF13C, S100A8, S100A1, MAPKI, S100A7, LIF, CCL4, CXCL13 are highly collaborated with other proteins. It reveals that these mediators are important in cytokine-protein network to regulate immune activity. Dyad in the collaboration networks can be defined as two proteins and they appear in one cytokine collaboration relationship. The dyad act degree distribution can also be well described by typical SPL functions. [1] Assortativity and act degree distribution of some collaboration networks, Hui Chang, Bei-Bei Su, Yue-Ping Zhou, Daren He, Physica A, 383 (2007) 687-702

C1.00258 An Empirical Study of Immune System Based On Bipartite Graphs1, YU-JING PENG, SHENG-RONG ZOU, ZHONG-GUI GUO, TA ZHOU, CHANG-GUI GU, DA-REN HE, Yangzhou University — Immune system is the most important defense system to resist human pathogens. We present an immune bipartite graph model. Firstly we collect data through COPE database and then construct an immune cell-mediator network. In the net the immune cells can be regarded as collaboration acts and the mediators can be regarded as collaboration actors. The act degree distribution of this network is proved to be power-law with a scaling exponent 1.8. From our analysis, we found that some mediators with high degree are very important in the process of regulating immune activity, such as TNF-alpha, IL-8, TNF-alpha receptors, CCL5, IL-6, IL-2 receptors, TNF-beta receptors, TNF-beta, IL-4 receptors, IL-1 beta, CD54 and so on. We also found that the assortativity coefficient of the immune network is -0.27.

C1.00260 Triangle-3star-Correlations in the mean-field solution of equilibrium ensembles of undirected networks with 3-edge interactions, PETER FLECK, Center for Complex Systems Research, University of Illinois at Urbana-Champaign, NOSHIR CONTRACTOR, IEMS, Northwestern University — We study the equilibrium statistical mechanics of ensembles of undirected networks with triangle- and 3-star-type interaction among bi-valued edges. We discuss the analytical expressions for the statistics' averages in mean-field approximation as a function of these interaction parameters. We find these averages to be highly correlated for a large region of the parameter space. Quantifying these correlations we especially find triangle- and 3-star-motifs to correlate with one another. Markov Chain Monte Carlo simulations confirm the analytical mean-field results in an important part of parameter space. Implications for the analysis of network topologies are being discussed.

C1.00261 Multifractal Behaviors in Foreign Exchange Markets, KYUNGSIK KIM, Department of Physics, Pukyong National University, Pusan 608-737, Korea — The market information process can be essentially different from the fully developed turbulence.

C1.00262 Universality in rank distributions due to multiplicative processes: from power laws to stretched exponentials. GERARDO NAUMIS, Depto. de Física-Química, Instituto de Física, UNAM, GERMINAL COCHO, Instituto de Física, SISTEMAS COMPLEJOS-FISICA-QUIMICA COLABORATION — Although power laws have been used to fit rank distributions in many different contexts, they usually fail at the tails. Stretched exponentials and log-normal distributions have been used to solve the problem, but unfortunately they are not able to fit at the same time both ending tails. Here we show that many different data in rank laws, like in granular materials, codons, author impact in scientific journal, etc. are very well fitted by a beta-like function (a,b distribution). Since this distribution is indeed ubiquitous, it is reasonable to associate it to the product of correlated probability distributions. In particular, we have found that the macrostates of the product of discrete probability distributions imply stretched exponential-like frequency-rank functions, which qualitatively and quantitatively can be fitted with the a,b distribution in the limit of many random variables [1]. We prove this by transforming the problem into an algebraic one: finding the rank of successive products of a given set of numbers. [1] New J. Phys. 9 (2007) 286. (2007).

C1.00263 Dynamical Behaviors of rainfalls in Korean peninsula. KYUNGSIK KIM, Department of Physics, Pukyong National University, Pusan 608-737, Korea, SOO YONG KIM, GYUCHANG LIM, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea, KI-HO CHANG, JAE-WON JUNG, Global Environment System Research Laboratory, National Institute of Meteorological Research, KMA, Seoul 156-720, Korea, SANG-BUM PARK, Department of Business Administration, Hankuk Aviation University, Goyang 412-791, Korea, MYUNG-KUL YUM, Department of Pediatric Cardiology, Hanyang University, Kuri 471-701, Korea — Application of ideas from fractal and chaos theories to characterize rainfall is one of the most active and exciting areas of research in this field. Many studies performed thus far have yielded evidence of the existence of fractal and chaos properties in rainfall. In this work, we present a singularity spectrum of a rainfall time series to provide strong evidence of multifractality. A curdling cascade process in a well developed turbulence is considered as a candidate to describe the rainfall, and the analogy between the rainfall and turbulence is confirmed via the validity of the binomial multiplicative process to describe both systems.

C1.00264 Colloids in a periodic potential: driven lattice gas in continuous space, RONALD DICKMAN, UFMG, FABRICIO POTIGUAR — Motivated by recent studies of colloidal particles in optical tweezer arrays, we study a two-dimensional model of a colloidal suspension in a periodic potential. The particles are confined to stay near potential minima, approximating a lattice gas. The interparticle interaction, a sum of Yukawa terms, features short-range repulsion and attraction at somewhat larger separations, such that two particles cannot occupy the same potential well, but occupation of adjacent cells is energetically favored. Monte Carlo simulation reveals that the equilibrium system exhibits condensation, as in the Ising model/lattice gas with conserved magnetization; the transition appears to be continuous at half occupancy. We study the effect of biased hopping, favoring motion along one lattice direction. This system is found to exhibit features of the driven lattice gas: the interface is oriented along the drive, and appears to be smooth. A weak drive facilitates ordering of the particles into high- and low-density regions, while stronger bias tends to destroy order, and leads to very large energy fluctuations. We also study ordering in a moving periodic potential. Our results suggest possible realizations of equilibrium and driven lattice gases in a colloidal suspension subject to an optical tweezer array.

C1.00265 Disordered contact process in two and three dimensions: rare regions, Griffiths effects, and infinite randomness, ADAM FARQUHAR, JASON MAST, THOMAS VOJTA, University of Missouri-Rolla — We investigate the effects of quenched spatial disorder on the directed percolation universality class in two and three space dimensions. To this end we perform large-scale Monte-Carlo simulations of the contact process on a randomly diluted lattice for times up to $10^{10}$ and system sizes up to $6 \times 10^3$ sites. We study both the nonequilibrium phase transition and the associated Griffiths region between the clean and disordered critical points. Rare strongly coupled regions lead to slow dynamics characterized by a nonuniversal power-law density decay in the entire Griffith region. In two dimensions, we also perform a detailed scaling analysis of the critical behavior right at the phase transition. We find an infinite-randomness critical point with activated rather than power-law dynamical scaling. However, the critical region is narrow and the approach to the asymptotic dynamics is extremely slow, which hampers the precision of our critical exponent estimates. We discuss the generality of our findings and relate them to a broader theory of rare region effects at phase transitions with quenched disorder.

C1.00266 Phase diagram, depinning and sliding friction in the Phase Field Crystal model. TAPIO ALA-NISSILA, CRISTIAN BASILE ACHIM, Helsinki University of Technology, Laboratory of Physics, Espoo, Finland, KEN R. ELDER, Oakland University, Department of Physics, Rochester, United States, MIKKO KARTTUNEN, The University of Western Ontario, Department Of Applied Mathematics, London, Canada, ENZO GRANATO, Instituto Nacional de Pesquisas Espaciais, Laboratório Associado de Sensores e Materiais, São José dos Campos, Brazil, SEE CHEN YING, Brown University, Department of Physics, Providence, United States — We present results for commensurate-incommensurate transitions and non-linear sliding friction for a two-dimensional crystal lattice in the presence of an external pinning potential in the Phase Field Crystal model. This model provides a continuum description of lattice system, such as adsorbed monolayers or two-dimensional vortex lattice. The competition between the length scales associated with the intrinsic ordering and the pinning potential leads to commensurate-incommensurate transitions. The dynamical response of the system in the presence of a driving force has also been studied via the time dependent Ginzburg-Landau equation. We present results on non-linear dynamics and sliding mechanisms for commensurate phases.

C1.00267 Development of a Fracture Network: blocks and springs model, MARTIN FERER, ADAM JOZWICK, Physics, West Virginia University, DUANE SMITH, U.S., D. O. E., National Energy Technology Laboratory — Since flow in fractured reservoirs is significantly enhanced by clusters of inter-connecting fractures, it's important to understand their inter-connectedness. In these fractured reservoirs, one often finds two sets of fractures: the primary and secondary fractures. The secondary fractures intersect the first generation of. We find a percolation-like transition where the cluster size grows with increasing strain leading to system-spanning fractal clusters. Increasing the thickness of the layer being fractured leads to sparser system-spanning fracture clusters with smaller fractal dimension. We have studied how the thickness of the layer affects the fractal character of the fracture clusters as well as their number distribution, and the correlations within the large fracture cluster.

C1.00268 Cyclic deformation of polymer glasses in the yield regime by a contact method. ANTOINE CHATEAUMINOIS, CHRISTIAN FREITIGNY, ESPCI — Cyclic strains in the yield regime are characterized by a slow evolution of the mechanical response of polymer glasses toward a poorly understood stationary state. In this study, the dynamics of plastically deformed polymer glasses is analysed by a contact method where a thin film is geometrically confined and sheared within a contact between two elastic substrates. As opposed to conventional mechanical testing using bulk polymers, this approach allows to investigate the cyclic plastic behavior without the complications arising from fracture. From a measurement of the lateral contact response, we have shown that the shear properties of the film can be determined both in the linear and in the non linear regime. Using this approach, the time and strain dependent shear response of polymer glasses in the yield regime will be discussed. In addition, linear viscoelastic measurements carried out after the application of cyclic yield provides information about the dynamics of plastically deformed glass and its recovery.

C1.00260 Numerical studies of the Zaitsev (Robin Hood) model, PERRY FOX, GABRIEL CWILICH, SERGEY BULDYREV, FREDY ZYPMAN. Department of Physics - Yeshiva University — The Zaitsev[1] model of depinning of interfaces has been widely used to discuss motion of dislocations, low temperature flux creep, and more recently dry friction. The properties of this model have been discussed theoretically in one dimension, and numerically verified with precision in the isotropic case. We are studying here the effect of anisotropy in the distribution of the “mass” among the neighbors in the updating of the sites, which is known to modify the critical exponents of the model in one dimension. We have considered the validity of the scaling laws in higher dimensions, which might be relevant for the case of friction [2], by computing several of the exponents of the model for the avalanche size distribution, avalanche fractal dimension and distribution of jumps between external sites of activity. The much richer space of parameters of anisotropy in two dimensions has been explored. [1] S.I. Zaitsev, Physica A189, 411 (1992). [2] S. Buldyrev, J. Ferrante and F. Zypman Phys. Rev E64, 066110, (2006)

C1.00270 A physical mechanism for enhanced orientational order of self propelled hard rods, APARNA BASKARAN, CRISTINA MARCHETTI. Syracuse University — We consider a model of 2D hard rods on a substrate. The rods interact through energy and momentum conserving binary collisions. Self propulsion is implemented as a center of mass force acting along the long axis of each rod. The nonequilibrium statistical mechanics for this microscopic model is systematically developed. In the overdamped regime, the dynamics is described by a modified Smoluchowski equation that includes new momentum transfer contributions that arise from self propulsion. Hydrodynamic equations for the density, polarizability and nematic order parameter are derived by coarse graining the Smoluchowski equation. The homogeneous equations yield an isotropic-nematic transition at lower densities than the Onsager density corresponding to an equilibrium system of hard rods. This enhanced ordering arises from the additional momentum transfer associated with self propulsion and is expected to be a generic feature of a broad class of active systems.

C1.00271 Statistics preserving formation of chaotic swarmers, IULIANA OPREA, Colorado State University, IOANA TRIANDAF, IRA SCHWARTZ, Naval Research Laboratory — We present a class of models for self-propelled multi-agent systems of autonomous vehicles that accomplish common tasks while preserving the formation moments of inertia. The models are based on simple, local interaction rules that create prescribed overall complex patterns in which coupling and communication are key elements. We use a statistics-preserving algorithm with a Duffing-like term added to the equations of motion to control the moments of the pattern formation. We concentrate on those parameters in the neighborhood of a resonant situation. This allows us to obtain interesting patterns of behavior similar to those observed in parametrically forced systems near resonance.

1Work supported by the Office of Naval Research.

C1.00272 Modular Networks in the Neocortex, H.G.E. HENTSCHEL, Emory University — We will describe our approaches to characterizing the network architecture of active neurons in mouse neocortex in terms of modules and functional motifs, in order to extract their information processing capabilities. The raw data comes from fast two photon microscopic techniques recently developed using fluorescent Ca2+ indicators to record the spontaneous and evoked activity from hundreds of identified cells in mouse. This ensemble of active neurons can be considered as a complex network linked by synaptic connections, and represented as a graph of nodes connected by edges. Information processing in the network requires interaction of neurons in different functional assemblies (microcircuits) over time. We will describe the information we have been able to uncover on these microcircuits and their function.

C1.00273 Study on the hierarchical property between the functional classes in protein-protein interaction network, YOUNG-JIN KO, SOON-HYUNG YOOK, YUP KIM, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — Detecting community structures and hierarchy among communities have been one of the most attractive research topics in complex network studies. In this study we regard each protein as an oscillator which interacts with its neighboring proteins. In order to define the hierarchy among the functional classes based on the synchronizability of each functional classes, we introduce a parameter $r_{\text{link}}$. Here $r_{\text{link}}$ represents the fraction of all possible links whose ends nodes are synchronized. From the numerical simulations we find that the hierarchical structure between functional classes does not depend on the coupling strength. We expect that this result provides a clue to understand the mechanism to form the specific structure of PIN. Some possible relationships between the observed hierarchical structure of the functional classes and the properties of the PIN are also discussed.

C1.00274 Phase synchronization induced by common external telegraphic noise, KEN NAGAI, Kyoto University — Generally, noise desynchronizes phase of nonlinear oscillators. However, when a neuron receives a randomly fluctuating input current, its reliability of spike generation improves compared with the case of a constant input current [Mainen and Sejnowski, Science 268, 1503 (1995)]. Like this phenomenon, phase synchronization between uncoupled nonlinear oscillators subject to a common external noise occurs in some systems. Phase synchronization between uncoupled limit-cycle oscillators is induced by common external telegraphic noise that jumps between two values randomly [Nagai and Nakao, Phys. Rev. E, 71, 036217 (2005)]. We observed this phenomenon with an electric circuit and analyzed it. When the switching time of the input current is sufficiently long, the internal state of the oscillator randomly jumps between two limit cycles corresponding to the input values, which can be described by random phase maps. We determined the phase maps experimentally and discussed the synchronization of oscillators subject to fluctuating inputs, using this maps. The Lyapunov exponents of the maps corresponded to damping rate of the variance of the phase.

C1.00275 Thin-film morphology dependence on adatom-substrate interaction energy, NUNO A.M. ARAUJO, GCEP-Centro de Fisica da Universidade do Minho, 4710 Braga, Portugal; T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA; CRISTOVAO S. DIAS, GCEP-Centro de Fisica da Universidade do Minho, 4710 Braga, Portugal, ANTONIO CADILHE, T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA. — The influence of adatom-substrate interaction energy on the morphology of heteroepitaxial film growth. We take the case of (1+1)-dimensions for sake of simplicity. We also define $\alpha$ as the quotient between the above interaction and the adatom-adatom interaction. We measure the roughness in time. We show that changing the value of $\alpha$ it is possible to range from a wetting regime to a non-wetting one. We also show that above a critical thickness, film growth becomes independent of adatom-substrate interaction.

C1.00276 Agent based spin model for financial markets on regular lattices and complex networks, HONG-JOO KIM, SOON-HYUNG YOOK, YUP KIM, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — We study an agent based microscopic model for price formation in financial markets on various topologies motivated by the dynamics of agents. The model consists of interacting agents (spins) with local and global couplings. The local interaction denotes the tendency of agents to make the same decision with their interacting partners. On the other hand, the global coupling to the self-generating field represents the process which maximizes the profit of each agent. In order to incorporate more realistic situations, we also introduce an external field which changes in time. This time-varying external field represents any internal or external interference in the dynamics of the market. For the proper choice of model parameters, the competition between the interactions causes an intermittency dynamics and we find that the distribution of logarithmic return of price follows a power-law.
C1.00277 Complexity and Ability in Ising Games, Ayax Ramirez, Southwestern College, Michael George, Southwestern College - In previous work [1, 2], we discussed various facets of designs in games, and considered the evolution [2] of Ising games. The traditional aspect of game theory, with its focus on rational decisions, was not considered in this work. Instead, there was a predominant interest in the time evolution of design toward a goal, and resulting levels of frustration. There was also a concern with time-reversal of meaningfulness. In the new work, our goal is to consider the "molecular structure" of the Ising model as it evolves, and to associate this molecular structure with feedback into the structure that can be understood in algorithmic terms. We develop an analogy with the famous Maltesian argument concerning exponential population increase, associating ability to cope with complexity, and algorithmic complexity, and discuss biological implications of the ideas associated with these games. [1] M. George, A nonequilibrium statistical model based on latin squares, paper presented at WorldComp'07, Las Vegas, Nevada, June 25-28, 2007. [2] M. George, Classical and quantum Ising games, paper presented at Fourth International Conference in Applied Mathematics and Computing, Plovdiv, Bulgaria, August, 2007.

C1.00278 Wrinkled induced by poking a free-floating film under tension1, Narayan Menon, Jiangshui Huang, Dept of Physics, UMass Amherst. Enrique Cerdá, Universidad de Santiago de Chile, Wim De Jeu, Thomas Russell, Dept of Polymer Science, UMass Amherst - We study experimentally and theoretically the out-of-plane deformation in a floating polystyrene film induced by depressing the centre of the film by a distance, d. When this depth exceeds a critical value d_c, the smooth conical deformation of the film becomes unstable to an elastic e^-w-term expansion: d < d_c. Changes; only digit-integer-differences=quanta! Quo vadis digit

C1.00279 Percolation density profiles and lattice structures, Robert Ziff, University of Michigan, Peter Kleban, University of Maine, Jacob Simmons, Oxford University, Christian Scullard, University of Chicago - This paper presents a visual display of results on percolation density profiles from anchor points and intervals along the side, demonstrating our theoretical predictions of various forms of factorization of the three point functions into products of two-point functions (some with square roots). We also show a gallery of numerous lattice structures where the percolation threshold can be found exactly through the triangle-triangle transformation, or approximately (to very high precision) by generalizations of known formulas. Studies of various classes of lattices shows slight but non-zero corrections for most non-triangular configurations. Methods to numerically find the threshold (null generation, cluster growth, and cluster-coalescence) are also presented.

C1.00282 Beijing restaurant network1, Chun-Hua Fu, Pei-Fang Zhnag, Yong-Li Wang, Jian-Jun Shi, Ai-Xia Fang, Da-Ren He, Yangzhou University — We have empirically studied the restaurants in Beijing and suggested a network description on the system. We define the restaurants as nodes and connect a link between two nodes if the two restaurants sell a common dish. The edge represents the sale competition relationship. In order to describe the competition, we define a node weight, which is the mark given by consumers on an evaluation network (http://www.dianping.com), to restaurants as nodes and connect a link between two nodes if the two restaurants sell a common dish. The edge represents the sale competition relationship. We find that both the total node weight, which is defined as the sum of the node weight in all the dishes, and the so-called dish weight, which is defined as the sum of the node weight in one dish, show a rather nice power law distribution.

C1.00283 PHASE TRANSITIONS AND STRONGLY CORRELATED SYSTEMS
C1.00284 Adsorption and Dissociation of Molecular Oxygen on the (0001) Surface of Double Hexagonal Close Packed Americium, PRATIK DHOLABHAI, RAYMOND ATTA-FYNN, ASOK RAY, The University of Texas at Arlington — Oxygen molecule adsorption on (0001) surface of double hexagonal packed americium has been studied in detail within the framework of density functional theory using a full-potential all-electron linearized augmented plane wave plus local orbitals method. The most stable configuration corresponded to molecular dissociation with the oxygen atoms occupying neighboring three-fold hollow h sites. Chemisorption energies and adsorption geometries for the adsorbed species, and change in work functions, magnetic moments, partial charges inside muffin-tins, difference charge density distributions and density of states for the bare Am slab and the Am slab after adsorption of the oxygen molecule will be discussed. The effects of chemisorption on Am 5f electron localization-de-localization in the vicinity of the Fermi level and the reaction barrier calculation for the dissociation of oxygen molecule to the most stable h sites will be discussed.

This work is supported by the U. S. Department of Energy and the Welch Foundation, Houston, Texas.

C1.00285 Mott transition studied by cellular dynamical mean field theory, YUZHONG ZHANG, Johann Wolfgang Goethe-Universität, Institut für Theoretische Physik, MASATOSHI IMADA, Department of Applied Physics, School of Engineering, University of Tokyo, CLAUDIUS GROS, ROSE VALENTI, Johann Wolfgang Goethe-Universität, Institut für Theoretische Physik — We study metal-insulator transitions between Mott insulators and metals. The transition mechanism completely different from the original dynamical mean field theory (DMFT) emerges from a cluster extension of it. A consistent picture suggests that the quasiparticle weight $Z$ remains nonzero through metals and suddenly jumps to zero at the transition, while the gap opens continuously in the insulators. This is in contrast with the original DMFT, where $Z$ continuously vanishes but the gap opens discontinuously.

The present results arise from electron delocalization in momentum space agree with recent puzzling bulk-sensitive experiments on CaV$_3$O$_7$ and SrVO$_3$. Details of the mechanism of Mott transition is studied through doublon-doublon, doublon-holon and spin-spin dynamical susceptibilities.

C1.00286 Pressure Induced Metallization In ACrO$_3$ Perovskite Compounds, CHANGQING JIN, L.X. YANG, Y.W. LONG, Institute of Physics, Chinese Academy of Sciences, Beijing, China, H.Z. LIU, G.Y. SHEN, H.K. MAO, HPCAT at Advanced Photon Source, Argonne National Lab, USA, J.S. ZHOU, J.B. GOODENOUGH, Texas Materials Institute, University of Texas at Austin, USA — We have studied the electrical conductivity and magnetic susceptibility of ACrO$_3$ (A = alkaline earth) perovskites performed at various pressures up to 60 GPa using diamond anvil cell techniques. The samples were synthesized under high pressure high temperatures. Pressure induced metallizations were observed in both samples. However, the x-ray diffraction experiments with resonant radiation source indicated no discernable crystal structural transition up to 60 GPa. Therefore the pressure induced metallizations were ascribed to electronic type phase transitions. It possibly came from the change of electronic structure due to an orbital ordering evolution induced by pressure.

C1.00287 Ultrasonic Study of the Yb-based Heavy Fermion Compound YbCo$_2$Zn$_{30}$, YOSHIKICANAKISHI, Iwate University — We present experimental results of elastic constants as a function of temperature and magnetic field performed on a single crystal of the Yb-based heavy fermion system YbCo$_2$Zn$_{30}$. A marked elastic softening toward low temperature was observed in a longitudinal elastic constant C11 and transverse ones (C11-C11)/2, C44. The softening is suppressed unexpectedly in a weak applied field of 2 T. Our results strongly suggest a large degeneracy of a 4f state of the Yb ion at low temperature and the Heavy Fermion state is quenched by the applied weak field. Thus, it is expected that this highly degenerated situation due to the almost spherical CEF, realized by the unique crystal structure, would form such a heavy fermion state and a lift of the degeneracy would bring about the disappearance. We discuss these results in the context of a crystalline electric field (CEF) ground state.

C1.00288 Multifractal Analysis of the Metal to Insulator Transition in the Three-Dimensional Anderson Model, LOUELLA VASQUEZ, Department of Physics and Centre for Scientific Computing, University of Warwick, CV4 7AL United Kingdom, ALBERTO RODRIGUEZ, Department of Physics and CSC, University of Warwick, CV4 7AL, UK, and Òptico de Física Fundamental, Universidad de Salamanca, 37008 Salamanca, Spain, RUDOLF ROEMER, Department of Physics and Centre for Scientific Computing, University of Warwick, CV4 7AL United Kingdom — The wavefunctions at the metal to insulator transition (MIT) of a disordered system within the Anderson model of localization have been shown to be of multifractal nature. In this paper we use a multifractal analysis to compute for the singularity spectra of very large wavefunctions at the band center. We will show that the singularity spectrum at the MIT is independent of the system size. We compare our results with recent findings and the Wegner prediction.

C1.00289 Superconductivity induced by non-local electron-phonon interaction, KA-MING TAM, University of Waterloo — The effects from commensurate filling, typically in the one-dimensional half-filled systems, often lead to finite charge gap and instability of long wavelength density wave ordering. Various proposals have been suggested recently that some of the one-dimensional electron-phonon coupled systems can be metallic with zero charge gap. However, subsequent studies of these proposals have obtained divergent results. We study an electron-phonon model with non-local electron-phonon interaction, its low energy effective theory unambiguously possess dominant charge gapless superconducting phase at half filling. In this model, the spin-charge coupling at high energy is weakened by the non-local electron-phonon interaction and the charge gap can be destroyed by the suppression of the umklapp process. The existence of the dominant pairing instability in the half-filled system may have an implication on the role plays by the phonon modes in the cuprate superconductor, suggesting that non-local or long range electron-phonon interactions may favor the formation of pairing.

C1.00290 $^1$H NMR Measurements on the Phase Transition of (NH$_4$)$_3$H(SO$_4$)$_2$ Single Crystal, S.H. CHOI, K.S. HAN, S.K. KWON, S.K. NAM, H.H. CHOI, MOOHHEE LEE, Konkuk University, Seoul 143-701 Korea, AE RAN LIM, Jeonju University, Jeonju 560-759, Korea — $^1$H nuclear magnetic resonance (NMR) experiments have been performed in the temperature range of 30 - 300 K at 7 T to investigate the phase-dependent nature of the dynamic network of hydrogen bonds in a (NH$_4$)$_3$H(SO$_4$)$_2$ single crystal. The crystal has six phases, which are ferroelectric, antiferroelectric, incommensurate, antiferroelectric, ferroelastic, and superionic conductor with the respective transition temperatures of 63, 133, 139, 256, and 413 K. The half-filled $^1$H NMR is similar for the ammonium protons and the hydrogen-bonded protons in all range of experimental temperatures. $T_1$ of $^1$H NMR gradually decreases down to 120 K and then starts to steeply increase below 100 K. Then $T_1$ shows an abrupt decrease below 68 K with a sharp minimum at 63 K, where the ferroelectric transition occurs. The $^1$H NMR spectrum shifts to the high frequency side below 63 K due to the ferroelectric phase transition. This temperature dependence of $T_1$ and spectrum confirms a dramatic change in the dynamics of hydrogen bonds associated with the ferroelectric phase transition at 63 K.

C1.00291 Exact thermodynamics of electron hole pairing and ferroelectricity in attractive Hubbard nanoclusters, ARMEN KOCHARIAN, Department of Physics and Astronomy, California State University, GAYANATH FERNANDO, KALUM PALANDAGE, Department of Physics, University of Connecticut, JIM DAVENPORT, Computational Science Center, Brookhaven National — Using analytical diagonalization and symmetries in the small Hubbard clusters, we demonstrate exact mapping between $U > 0$ and $U < 0$ models in the ground state and at finite temperatures for general electron concentration and magnetic fields. We establish equivalency between corresponding phase diagrams for one hole off half-filling at $U > 0$ and in the low spin region for half filled $U < 0$ models. The $U < 0$ model exhibits Fulde-Ferrell-Larkin-Ovchinnikov phase separation into spin-rich and spin-poor analogues to electron pairing for $0 < U < U_C$ [1,2], while at strong coupling regime it provides a mechanism of electron instability with spontaneous (saturated) ferroelectricity, similar to Nagaoka ferromagnetism at $U > U_C$ [1]. The calculated phase diagrams resemble a number of metal dielectric transitions, inhomogeneous paired phases, superconductivity, ferromagnetism and ferroelectricity found recently in transition metal and Nb nanoparticles [3], etc. [3] X. Xu et al., Phys. Rev. Lett. 93, 086803 (2004).
C1.00292 Reversible pressure-induced phase change in eutectic GeSb, DMITRY SHAKHVOROSTOV, University of Western Ontario, London, Ontario, Canada, LIA KRUSIN-ÉLBAM, GLENN J. MARTYNA, DENNIS M. NEWNS, CYRIL CABRAL, JR., IBM T.J. Watson Research Center, Yorktown Heights, NY, USA, SIMONE RAOUX, IBM Almaden Research Center, Almaden, CA, USA, ZAK E. HUGHES, MARTIN H. MÜSER, YANG SONG, University of Western Ontario, London, Ontario, Canada — In phase-change materials (PCMs), typically Ge-Te-Sb based glassy semiconductors, a reversible transformation between a highly resistive (amorphous) and a highly conductive (crystalline) phase is accomplished by Joule heating that melt-quenches PCM into the amorphous state, and thermally anneals it back to the crystalline state. Here we report a room-temperature pressure driven reversible phase change in a binary eutectic GeSb system. From structural and Raman spectroscopy studies, we demonstrate abrupt hysteretic amorphous-to-crystalline and intra-crystalline transitions under a compressive load—unique to the Te-free system—that access with pressure the two extreme GeSb states previously obtained by thermal programming. Using ab-initio molecular dynamics simulations we show that the reverse process occurs under a tensile load. The role of the Peierls gap and Anderson localization in the pressure induced phase change accompanying a metal-insulator transition will be discussed.

C1.00293 Micron-Scale Observation of Nucleating Water Vapor Bubbles, SCOTT PARKER, SUNG CHUL BAE, CHANG-KI MIN, DAVID CAHILL, STEVE GRANICK, University of Illinois at Urbana-Champaign — Surface plasmon microscopy is used to detect nucleation and lift-off of vapor bubbles. Vapor bubbles are generated under pool boiling conditions by heating with a focused Ti-Sapphire laser in the near-infrared region. These bubbles modulate the local index of refraction, thereby altering the local excitation of the surface plasmon which are excited in the Kretschmann geometry and observed with a CCD camera. Altering the surface roughness, we observe how bubbles interact in their earliest stages.

C1.00294 The condensation phenomena of conserve-mass aggregation model with mass-dependent fragmentation, DONG-JIN LEE, SUNGCHUL KWON, YUP KIM, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University — We study a conserved mass aggregation model with mass-dependent fragmentation in regular lattice and scale-free networks. In the model, the whole mass m of a site isotropically diffuse with unit rate. With rate $\omega$, a mass $m^k$ is fragmented from the site and moves to a randomly selected nearest neighbor site. Since the fragmented mass is smaller than the whole mass $m$ of a site for $\omega > 1$, the on-site attractive interaction exists for the case. For $\omega = 1$, the model is known to undergo the condensation phase transitions as the density of total masses ($\rho$) increases beyond a critical density $\rho_c$. For $0 < \lambda < 1$, we numerically confirm for several values of $\lambda$ that $\rho_c$ diverges with the system size $L$. Hence in thermodynamic limit, the condensed phase disappears and no transitions take place in one dimension. We also explain that there are no transitions in any dimension. On scale-free networks with degree distribution $P(k) \sim k^{-\gamma}$, we numerically confirm for $\gamma > 3$ that the condensation transitions occurs at $\rho_c > 0$ and its nature is the same as that in regular lattice. However, for $\gamma \leq 3$, the condensation always takes place for $\lambda < \lambda_c$, and masses distribute uniformly without aggregation for $\lambda \geq \lambda_c$. We derive $\lambda_c = 1/\gamma - 1$ via mean-field argument.

C1.00295 Universal and nonuniversal supercritical adsorption in pores, HYE-YOUNG KIM, Department of Chemistry and Physics, Southeastern Louisiana University, Hammond, LA, S.M. GATICA, Department of Physics and Astronomy, Howard University, Washington, D.C., A.D. LUEKING, Department of Energy and Mineral Engineering, The Pennsylvania State University, University Park, PA, J.K. JOHNSON, Department of Chemical and Petroleum Engineering, University of Pittsburgh, Pittsburgh, PA, M.W. COLE, Department of Physics, The Pennsylvania State University, University Park, PA — A recent study of gas adsorption in porous carbons found a common trend in the gas uptake as a function of reduced pressure at the same relative supercritical temperature, with the exception of hydrogen [1]. Using analytical expressions (Henry’s law) and computer simulations (quantum and classical) we demonstrate that the “universal” behavior of the classical gases and the “deviant” behavior of hydrogen can both be understood from simple combining rules and the role of quantum effects. Thus, we reject a hypothetical explanation of the data in terms of small pores permitting just hydrogen to permeate.

C1.00296 ABSTRACT WITHDRAWN

C1.00297 Observation of field-induced magnetic disorder state in one-dimensional antiferromagnet BaCo$_2$V$_2$O$_8$ from NMR, C.S. LUE, C.N. KUO, T.H. SU, ZHANGZHEN HE, MITSURU ITOH, DEPARTMENT OF PHYSICS, NATIONAL CHENG KUNG UNIVERSITY, TAINAN 70101, TAIWAN TEAM, INSTITUTE FOR SOLID STATE PHYSICS, UNIVERSITY OF TOKYO, KASHIWA 277-8581, JAPAN COLLABORATION, MATERIALS AND STRUCTURES LABORATORY, TOKYO INSTITUTE OF TECHNOLOGY, 4259 NAGATSUTA, MIDORI, YOKOHAMA COLLABORATION — We report the results of a $^{51}$V nuclear magnetic resonance (NMR) study on the single crystal BaCo$_2$V$_2$O$_8$ at temperatures between 3k and 300k. This material has been a subject of current interest due to indications of the field-driven magnetic order-disorder transition above 4T. For the present NMR study, we found no abrupt changes in the NMR shift and line width at low temperature as a constant field 7.06T was applied along the $c$-axis, indicative of the absence of magnetic long-range ordering under this field. Hence, the NMR results establish unequivocally the field-induced magnetic disorder state in BaCo$_2$V$_2$O$_8$.

C1.00298 Reentrant Morin Transition in Natural Haematite Crystal at Low Temperature, SEONG-JOO LEE, HYUNOK JUNG, SOONCHIL LEE, Department of Physics, Korea Advanced Institute of Science and Technology, Daejeon 305-701, Korea, JOONGHOE DHO, Department of Physics, Kyungpook National University, Daegu 702-701, Korea — We investigate the magnetic properties of natural haematite ($\alpha$-Fe$_2$O$_3$) crystal at low temperature using a SQUID and $^{57}$Fe nuclear magnetic resonance (NMR). The $M(T)$ curve shows that the net magnetization in the (111) plane vanishes at Morin transition occurring around 260 K but reappears as temperature decreases below 30 K. The $M(H)$ curve shows that the hysteresis exists in the (111) plane and the spin-flop transition also occurs when strong external field is applied in parallel with the [111] direction at low temperature. We obtain the NMR spectra in external magnetic field of up to 7 T at 4.2 K. Comparison of the $M(H)$ curve and the field dependence of the NMR resonance frequency suggests that the antiferromagnetic and the weak-ferromagnetic phases coexist at low temperature. Assuming that the weak-ferromagnetic state at low temperature is the same with that above Morin transition, the amount of the weak-ferromagnetic phase in the antiferromagnetic bath at low temperature is about 3%.

C1.00299 New Phase transitions in ceramic SrSnO3: Raman scattering and differential thermal analysis, MANOJ SINGH, N.K. KARAN, RAM S. KATIYAR, Department of Physics, University of Puerto Rico, PR, USA, J.F. SCOTT, Department of Earth science, University of Cambridge, UK, H.M. JANG, Department of Materials Science and Engineering Pohang University of Science and Technology, Pohang, Korea, J. F. SCOTT COLLABORATION, H. M. JANG COLLABORATION, R. S. KATIYAR TEAM — We report a continuous or nearly continuous order-disorder transition from orthorhombic (pseudo-tetragonal) to orthorhombic on heating in SrSnO3 at 377 °C. The transition at 377 °C is manifested in an order of magnitude increase in Raman linewidths and in a λ-shaped anomaly in the specific heat. Previous work [Mountstevens et al., Phys. Rev. B71, 220102R (2005)] has interpreted the Pnma – Imma transition at ca. 636 °C as a continuous order-disorder transition and emphasized that this would be unique for an octahedron-tilting transition in oxide perovskite, which are always displacive. Our work on Raman scattering and Differential Thermal Analysis shows that the disorder sets in at much lower temperatures 377 °C, so that the 636 °C transition is disorder-disorder, or a dispersive transition within an already highly-disordered lattice. Hence it may not be as unusual as had been claimed.

C1.00300 11B NMR Study of Spin Structure and Dynamics in TbB4 Single Crystal, S.K. KWON, B.J. MEAN, S.K. NAM, S.H. CHOI, H.H. CHOI, MOOHEE LEE, Konkuk University, Seoul 143-701 Korea, B.K. CHO, GIST, Gwangju 500-712, Korea — 11B NMR measurements have been performed on the single crystal of TbB4 to investigate 4f/3spin structure and dynamics. 11B NMR spectrum, shift, 1/T1 and 1/T2 are measured down to 5 K at 8 T perpendicular to the (110) plane. 11B NMR shift and linewidth are huge and strongly temperature-dependent due to the 4f moments of Tb. In addition, both are proportional to the magnetic susceptibility, indicating that the hyperfine field at the boron site originates from the 4f spins of Tb. Below TN = 43 K, the single broad resonance peak of 11B NMR splits into several peaks reflecting the onset of internal magnetic fields due to the antiferromagnetic spin arrangements. The 11B NMR spectrum at 5 K are generally consistent with the calculation confirming that the collinear spin arrangement is correct. The longitudinal and the transverse relaxation rates, 1/T1 and 1/T2, are independent of temperature above TN and then decreases tremendously indicating the huge suppression of spin fluctuations below TN.

C1.00301 11B NMR Study of Spin Structures and Dynamics in GdB4 Single Crystal, S.K. NAM, B.J. MEAN, S.K. KWON, S.H. CHOI, H.H. CHOI, MOOHEE LEE, Konkuk University, Seoul 143-701 Korea, B.K. CHO, GIST, Gwangju 500-712, Korea — We have performed 11B NMR measurements on a single crystal of GdB4 to investigate 4f/3spin structures and dynamics. 11B NMR spectrum, shift, 1/T1 and 1/T2 are measured down to 5 K at 8 T perpendicular to the c-axis. 11B NMR shift and linewidth are huge and strongly temperature-dependent due to the 4f moments of Gd. In addition, both are proportional to the magnetic susceptibility, indicating that the hyperfine field at the boron site originates from the 4f spins of Gd. Below TN = 42 K, the single broad resonance peak of 11B NMR splits into several peaks reflecting the onset of internal magnetic fields due to the antiferromagnetic spin arrangements. Assuming that the 4f moments of are aligned noncollinearly along the <110> direction in the basal plane perpendicular to the c-axis, we have calculated dipolar fields at the 16 boron nuclear sites from the 4f spins of Tb. The results show that the various peaks of 11B NMR spectrum at 5 K are generally consistent with the calculation confirming that the collinear spin arrangement is correct. The relaxation rates, 1/T1 and 1/T2, are independent of temperature above TN and then decreases tremendously indicating the huge suppression of spin fluctuations below TN.

C1.00302 ABSTRACT HAS BEEN MOVED TO SESSION B33

C1.00303 Atomic Adsorptions on the (020) Surface of α-Pu: A Density Functional Study1, RAYMOND ATTA-FYNN, ASOK RAY, Physics Department, The University of Texas at Arlington — Adsorptions of atomic carbon, nitrogen, and oxygen on the (020) surface of α-Pu have been investigated using the full-potential linearized augmented plane wave plus local basis method. The surface was modeled by a 4-layer periodic slab consisting of a total of 32 Pu atoms. Adsorption energies have been optimized with respect to the distance of the atom from the Pu surface for four adsorption sites, namely the one-fold top, one-fold hollow, two-fold short bridge, and the two-fold long bridge sites. The short bridge site was the most stable adsorption site for C with chemisorption energy of 6.03eV. The long bridge site was the most stable adsorption site for N and O with chemisorption energies of 6.067 eV and 7.32 eV respectively. The work function and net spin magnetic moments respectively increased and decreased in all cases upon chemisorption compared to the bare surface. The density of states and change charge density have been used to analyze the adsorbate-induced changes in the surface electronic structure.

C1.00304 Valence Instability and Mass Enhancement in an Extended Periodic Anderson Model, TAKASHI SUGIBAYASHI, YASUHIRO SAIGA, DAI HIRASHIMA, Nagoya University — In CeCu2Si2, CeCu2Ge2 and CeRh1−xIrxIn2, the shape of the superconducting region is asymmetric and the superconducting transition temperature TC reaches its maximum far away from the antiferromagnetic quantum critical point. Onishi and Miyake ascribed the asymmetric behavior of TC to the enhanced valence fluctuations. They introduced the repulsive interaction Ueff between a conduction electron and an f electron, in addition to the Coulomb interaction Uf between f electrons and studied the periodic Anderson model (PAM) with both U and Uf (which is the so-called extended PAM). We investigated the valence instability in the extended PAM and two-fold degenerate extended PAM with the dynamical mean field theory. In these models, we found that the valence instability is observed when Uf is larger than the conduction band width 2V and the f-electron level Ef is deeper than the lower bound of the conduction band, −W. It is also found that the orbital degeneracy suppresses the valence instability. In the parameter region of inducing the valence instability, we investigate the mass enhancement factor Zf which is related to the specific heat.

C1.00305 Experimental Evidence of Fermi-Luttinger Liquid State,1, PHILIPPE DEBRAY, MUSTAFA MUHAMMAD, University of Cincinnati, Cincinnati, OH 45221, STEVEN HERBERT, Xavier University, Cincinnati, OH 45207, RICHARD NEWROCK, University of Cincinnati, Cincinnati, OH 45221 — We have measured Coulomb drag between spatially separated parallel quantum wires, made on AlGaAs/GaAs heterostructures by the split-gate technique, in the absence of tunneling to experimentally probe drag by small forward momentum transfer. Drag between wires of lengths 500 and 300 nm was measured in the one-dimensional transport regime at temperatures in the range 30 mK – 1.2 K. We have observed both positive and negative drag. The temperature dependence of drag of both types is in excellent agreement with that predicted by the recently proposed Fermi-Luttinger liquid (FLL) theory that takes into account the curvature in the fermionic dispersion. Positive drag occurs when the curvature is positive, while negative drag occurs when it is negative.

C.00306 Low Temperature Differential Conductance in Al/AlOx/Sc Tunnel Junctions, SHENG-SHIUAN YEH, JUHN-JONG LIN, Institute of Physics, National Chiao Tung University, Hsinchu 30010, Taiwan — We have fabricated several Al/AlOx/Sc tunnel junctions and measured the differential conductances $G \equiv dI/dV$ at low temperatures. Our objective is to study the effect of the coupling between tunneling electrons and localized magnetic impurities (which sit in the insulating barrier) on $G(V,T)$. We observed a crossover from the weak coupling regime to the strong coupling regime. We found that, in both regimes, the $dI/dV$ spectra could be well described by the Appelbaum’s $s$-$d$ exchange interaction theory, with a Kondo temperature $T_{K}^{\text{Appelbaum}} \approx 3.4$ K. On the other hand, we measured zero-bias conductances could be well described by a scaling form predicted by the NRG calculations and a $T_{K}^{\text{NRG}} \approx 38$ K was deduced, being close in agreement with the value of $T_{K}^{\text{Appelbaum}}$. A magnetic field of 4 T was applied at 2.5 K, but no Zeeman splitting in the $dI/dV$ spectra was observed. This absence of Zeeman splitting resulted as a consequence of the high $T_{1}^{\text{K}}$ value found in our junctions.

C.00307 Large drop in dielectric constant at ferrimagnetic ordering of CoCr$_2$O$_4$ thin film as observed by terahertz time domain spectroscopy$^1$, K.R. MAVANI, M. NAGAI, M. SHIRAI, K. TANAKA, Dept. of Physics, Kyoto University, D.S. RANA, I. KAWAYAMA, M. TONOUCHI, Inst. of Laser Engr., Osaka University — Multiferroic spinel CoCr$_2$O$_4$ shows ferrimagnetic transition at $\sim$95 K and, at low temperatures, it shows development of magnetic spin spirals simultaneous to a ferroelectric transition. We have deposited epitaxial CoCr$_2$O$_4$ thin film on MgO(100)substrate and studied the film using temperature dependent terahertz (THz) time-domain spectroscopy. There is a large drop in the dielectric constant ($\varepsilon_1$) to nearly half of its initial value at ferrimagnetic transition of CoCr$_2$O$_4$ thin films in the THz frequency range. This is contrary to few earlier studies by capacitance measurements which showed no significant change in the dielectric constant ($\varepsilon_1$) at ferrimagnetic transition [1]. At lower temperatures, two dielectric anomalies were observed in the temperature dependent $\varepsilon_1$, which correspond to the onset of short-range magnetic spin spirals ($\sim$50 K) and the long-range ordering of the spirals at lower temperature ($\sim$26 K). Our results indicate a magnetoelectric effect at the ferrimagnetic transition of CoCr$_2$O$_4$ thin film in THz frequency range. [1] G. Lawes et al., Phys. Rev. B 74, 24413 (2006).

C.00308 Consequences of magnetoelectric interactions on ferroelectric domain structures, P. MAHANANDIA, A.S. TATARENKO, G. SRINIVASAN, Oakland University, Rochester, MI — The standard lift mode of electrostatic force microscopy (EFM) has been utilized to study the influence of magnetoelectric (ME) effect on ferroelectric domain structures in a YIG-PZT bilayer. A PZT disk of thickness=$250 \mu m$ was bonded on to a (111) single crystal YIG on GGG substrates. Randomly oriented domains of PZT are observed in the absence of a dc magnetic filed H. The domains are transformed into a columnar structure when H> 120 Oe is applied to the bilayer. The H-induced changes are mediated by mechanical forces; when a magnetic field is applied to the layered composite, the magnetostriction exerts a stress on PZT, resulting in an induced electric polarization and changes in the domain structure.

C.00309 MIS and MFIS Devices: DyScO$_3$ as a gate-oxide and buffer-layer, R. MELGAREJO, N.K. KARAN, J. SAAVEDRA-ARIAS, D.K. PRADHAN, R. THOMAS, R.S. KATIYAR, Department of Physics and Institute for Functional Nanomaterials, University of Puerto Rico, P O Box 23343, PR 00931 — Metal-Ferroelectric-Insulator-Semiconductor (MFIS) structure is of importance in nonvolatile memories, as insulating buffer layer that prevents interdiffusion between the ferroelectric (FE) and the Si substrate. However, insulating layer has some disadvantages viz. generation of depolarization field in FE film and increase of operation voltage. To overcome this, it is important to find a FE with low $\varepsilon_r$ (compared to normal FE) and an insulating buffer layer with high $\varepsilon_r$ (compared to $\varepsilon_r$ = 3.9 of SiO$_2$). High-k materials viz. LaAlO$_3$, SiN, HfO$_2$, HfAlO etc. have been studied as buffer layers in the MFIS structures and as gate-oxide in metal-insulator-silicon (MIS). Recently, a novel gate dielectric material, DyScO$_3$ was considered and studies indicate that crystallization temperature significantly increased and the film on Si remained amorphous even at 1000 °C annealing. Considering the requirements on crystallization temperature, $\varepsilon_r$, electrical stability for high-k buffer layers, DyScO$_3$ seems to be very promising for future MISFET device applications. Therefore, the evaluations of MOCDV grown DyScO$_3$ as gate-oxide for MIS and the buffer layers for Bi$_{22}La$_{0.75}Ti$_{12}$O$_{30}$ based MFIS structures are presented.

C.00310 Magnetodielectric Effects and Transport Study in LuFe$_2$O$_4$ Single Crystal, TAE HWAN JANG, SANG YOUNG PARK, eSSC & Dept. of Physics, POSTECH, Korea, HAI JOON LEE, SUN HEE KANG, Dept. of Physics, Ulsan Univ., Korea, TAE YEONG KOO, PAL, POSTECH, Korea, SONG BAEK KIM, I-PEM & Dept. of Physics, POSTECH, Korea, ILL WON KIM, Dept. of Physics, Ulsan Univ., Korea, YOON HEE JEONG, eSSC & Dept. of Physics, POSTECH, Korea, SANG WOOK CHEONG, R-CEM and Dept. of Physics & Astronomy, Rutgers Univ., USA — Magnetic, dielectric, and magnetodielectric properties of geometrically frustrated mixed valance LuFe$_2$O$_4$ single crystal are discussed to clarify the charge order, magnetic long range ordering of the spirals at lower temperature ($\sim$26 K). Our results indicate a magnetoelectric effect at the ferrimagnetic transition temperature $T_{M} \sim$100 K in both magnetization and dielectric constant versus temperature curve below the ferrimagnetic transition temperature $T_{M} \sim$225 K has been observed. The sign of magnetodielectric effect (MDE) also changes from positive $T_{N} <$ 26 K to negative $T_{N} < T_{M}$. No field hysteresis in positive MDE temperature region was found. However a large hysteretic behavior in negative MDE below $T_{M}$ with the same magnetic coercive field measured in M (H) curve was observed. This indicates a strong coupling between magnetism and ferroelectricity in the charge and spin frustrated ferrimagnetic LuFe$_2$O$_4$ system.

C.00311 Effect of epitaxial strain on magnetization and photo-control of spontaneous polarization in BiFeO$_3$ films on (LaAlO$_3$)$_{0.3}$Sr$_{0.7}$AlTaO$_{3}$ substrate, D.S. RANA, I. KAWAYAMA, H. MURAKAMI, M. TONOUCHI, Institute of Laser Engineering, Osaka University, Japan — Recent researches on thin films of BiFeO$_3$ have been driven by the need to obtain better multiferric properties by either inducing epitaxial strain or fabrication of magnetoelectric superlattices. The BFO (100) thin films on (LaAlO$_3$)$_{0.3}$Sr$_{0.7}$AlTaO$_{3}$ (100) substrate are highly strained with different physical properties than that of bulk [1]. Given the dependence of ferroelectric polarization of BFO on crystallographic directions, epitaxial thin films $\sim$70nm and 180nm - of BFO were deposited on LSAT (110) substrate. Structure and surface morphology of BFO/LSAT(110) films show that the films with thickness < 80 nm possess a strong in-plane strain while thicker films (150-200nm) are partially relaxed with a bulklike structure. Though the magnetic properties of BFO/LSAT(110) films are nearly independent of structure, the spontaneous polarization and the ferroelectric properties (probed by terahertz emission) are strong characteristic of structure. These results emphasize the importance of epitaxial strain induced tailoring of the ferroelectric properties of BiFeO$_3$ film along (110) crystallographic direction. 1. D.S. Rana et al, Phys. Rev. B 75, 060405 (2007).

C.00312 Anomalies in the thermoelectric power in cuprates from strong electron correlation, SHILADITYA CHAKRABORTY, DIMITRIOS GALANAKIS, PHILIP PHILLIPS, University of Illinois at Urbana- Champaign — The thermoelectric power data in hole-doped cuprates show a sign change on increasing the hole doping from the underdoped to the overdoped regime. The origin of this anomaly is debatable, and there exist multiple explanations for it. Phonon drag is one of the more widely accepted explanations. Our approach, instead, is to investigate the behavoir of the thermoelectric power from a purely electronic perspective. We employ Cluster Dynamical Mean Field Theory (CDMFT) on a four site square plaquette to study the thermoelectric power in the 2-d Hubbard model as a function of hole doping, temperature and $U/t$ ratio. We observe a sign change in the thermoelectric power in qualitative agreement with experimental data. The sign change vanishes for small values of $U/t$, suggesting that strong electron correlations are responsible for this phenomenon.
C1.00315 Rectification effects in InAs/AlGaSb three-terminal ballistic junctions, MASATOSHI KOYAMA, Nanomaterials Microdevices Research Center, Osaka Institute of Technology, TATSUYA INOUE, NAOKI AMANO, TOSHIHIKO MAEMOTO, SHIGEHIKO SASA, MASATAKA INOUE, NANOMATERIALS MICRODEVICES RESEARCH CENTER, OSAKA INSTITUTE OF TECHNOLOGY TEAM — We report on the fabrication and the DC characterization of InAs/AlGaSb three-terminal ballistic junctions consisting of three quantum-wire T-shaped structures. InAs/AlGaSb quantum wells were grown by molecular beam epitaxy, and the three-terminal ballistic junctions were defined using electron beam lithography. Typical electron mobility of 80,000 – 200,000 cm²/Vs and sheet carrier density of 1.0 – 2.0 x 10¹² cm⁻² were observed at 77K. Ballistic electron transport properties are due to the one-dimensional (1D) nature of electrons in InAs and dramatic changes in scattering probability from the 2D electron system, which are expected to occur at higher temperatures. We measured the rectified output voltage, Vᵣ at the central branch of the devices at various temperatures. Nonlinearity and negative voltages at the central branch, regardless the polarities of the source-drain (left and right branch) voltage, were observed at each temperature. Clear rectification effects were observed in the ballistic junctions even at room temperature. Details of the triode characteristics in the InAs/AlGaSb ballistic devices will be discussed at the conference.

C1.00316 MnScN(001)/MgO(001) films grown by molecular beam epitaxy: a possible dilute magnetic semiconductor, ARTHUR R. SMITH, Ohio University, COSTEL CONSTANTIN, Seton Hall University, UTKUR MIRSAIDOV, University of Illinois at Urbana Champagne, JOHN MARKERT, University of Texas at Austin — Considerable interest has been of late in finding a room temperature dilute magnetic semiconductor. Recently, theoretical calculations had predicted Curie temperature to be above 400 K for the films with 3% Mn concentration into the MnₓSc₁₋ₓN system. In this study, MnₓSc₁₋ₓN films (with x = 3-5%) were grown on ScN(001)/MgO(001) substrates by radio frequency plasma assisted molecular beam epitaxy. The buffer layer of ScN(001) was grown on top of MgO(001) at Tₑ ≈ 800 °C and with a thickness of ~50 nm. The MnScN film was grown at Tₑ ~ 520 °C and with a thickness of ~290 nm. Post-growth x-ray diffraction measurements show that MnₓSc₁₋ₓN alloys follow the Vegard’s law. The hysteresis magnetic data measured with the superconducting quantum interference device show possible ferromagnetic behavior for the MnₓSc₁₋ₓN films with a Curie temperature of ~50 K, but additional data is needed to establish the conclusiveness of the results. Work supported by NSF.

C1.00317 Characterization of p-InGaAsSb/n-GaSb and p-GaAs/n-GaAs Structures for the Fabrication of Fusion-Stacked Solar Cells, M.L. GOMEZ-HERRERA, J.L. HERRERA-PEREZ, CICATA-IPN, U. Legaria, P. RODRIGUEZ-FRAGOSO, J.G. MENDOZA-ALVAREZ, Physics Dept. Cinvestav-IPN, I. RIECH, Fac.Ing.Fisica. UAdEY, G. TORRES-DELGADO, U.Queereto. Cinvestav-IPN — We are developing a two-stacked solar cell, using for the infrared portion a p-InGaAsSb/n-GaSb heterostructure, and a p-GaAs/n-GaAs for the visible part. Both structures were grown using the liquid phase epitaxy growth technique, and doping at different levels the p-type layers in order to obtain p-n junctions with different electrical characteristics and depletion layer depths. We present results on the characterization of both structures using the photoluminescence spectroscopy to characterize the layer crystalline quality, and the photoacoustic effect to characterize the layer-substrate interface for both structures. Also, we present the results on the I-V characterization and spectral response of both p-n structures for the different doping levels in the p-type layers used. Finally, details on the fusion process to stack the two solar cells are discussed.

We acknowledge financial support from Conacyt-Mexico.

C1.00318 Optical Properties of GaNₓAs₁₋ₓ Thin Films Grown on Si Substrates by r f. Sputtering, J.G. MENDOZA-ALVAREZ, O. ZELAYA-ANGEI, A. CRUZ-OREA, Physics Dept. Cinvestav-IPN, J.S. ARIAS-CERON, CICATA-IPN. U. Legaria, J.A. CARDOÑA-BEDOYA, Depto. Fisica. U. del Tolima — GaNₓAs₁₋ₓ ternary alloys in the GaN-rich side, are expected theoretically to have band-gap energies in the full range of the visible spectrum for just a small change in the nitrogen concentration in the range of about 70-85%. Using the r. f. sputtering and the laser ablation film deposition techniques, we have reported the growth of ternary GaNAs layers with band-gap energies in the range between 1.4 to 2.6 eV. In this work we report the growth of GaNAs thin films on Si substrates using the r. f. sputtering technique at high substrate temperatures; the r. f. power was varied in order to control the nitrogen incorporation in the films. The low temperature photoluminescence (PL) and the photoacoustic (PA) spectroscopies were used to characterize the optical properties of the series of GaNₓAs₁₋ₓ As films grown with different stoichiometries. We discuss the origin of the transitions observed in the PL spectra and the shoulders around 2.5 eV observed in the PA spectra.

We acknowledge financial support from Conacyt-Mexico.

C1.00319 Differential Magnetoresistance Oscillations induced by Microwave and DC Electric Fields, MAXIM KHODAS, University of Minnesota, MAXIM VAVILOV, University of Wisconsin Madison — We study magnetoresistance oscillations in two-dimensional electron systems induced by AC and DC fields. We find the position of the maxima and minima in the differential magnetoresistance, r(εₓ,kₓ) and evaluate the amplitude of magneto-oscillations in terms of various microscopic parameters of the system. We compare our findings with the results of recent experiments by W. Zhang, Phys. Rev. Lett. 98, 106804 (2007).
C1.00320 First-Principles Theory of Ordering, Phase Separation, and Phonon Scattering in Thermoelectric LAST (Lead-Antimony-Silver-Telluride) alloys\(^1\), SERGEY V. BARABASH, VIDVUDS OZOLINS, UCLA, CHRIS WOLVERTON, Northwestern University — Bulk LAST (Pb\(_{1-x-y}\)Ag\(_x\)Sb\(_y\)Te\(_2\)) alloys exhibit high thermoelectric figure of merit (ZT \(\sim\) 2 at 800K, considerably exceeding ZT of pure PbTe or AgSbTe\(_2\), and nano-scale inhomogeneities, origin of which is poorly understood. The atomic structure of the nano-regions, as well as that of the pure AgSbTe\(_2\), remains the subject of an experimental debate. Using density-functional theory (DFT), we calculate the composition-temperature phase diagram and vibrational spectra of Pb\(_{2-x-y}\)Ag\(_x\)Sb\(_y\)Te\(_2\) alloys. We predict that the experimentally observed nanoscale inhomogeneities are due to the precipitation of ordered AgSbTe\(_2\) phases. Two types of cation order type closely compete in AgSbTe\(_2\), the dominant order type being D4; the predicted hypothetical order-disorder transition temperature exceeds the melting temperature of pure AgSbTe\(_2\). The miscibility gap between solid PbTe and AgSbTe\(_2\) phases is highly asymmetric, with a high solubility of PbTe in ordered AgSbTe\(_2\). We also characterize the shape of coherent precipitates. Finally, the phonon spectra of AgSbTe\(_2\) and PbTe suggest that boundary scattering of acoustic phonons causes the observed suppression of thermal conductivity.

C1.00321 Oxygen adsorption on Cu/ZnO (0001) – Zn. \(^{1}\)PATRICIO HÄBERLE, UTFSM, Valparaiso, MATTHIAS BATZILL, Univ. of South Florida, ULRIKE DIEBOLD, Tulane Univ., PAOLA LAZCANO, UTFSM, Valparaiso — By using plasma assisted deposition we have adsorbed oxygen onto the Cu/ZnO(0001)-Zn surface. Cu was deposited on the sputtered-annealed ZnO substrate at room temperature, which was later exposed to oxygen. Using X-ray photoelectron spectroscopy (XPS) we verified the effect of the oxidation procedures on the electronic structure of the interface. Our results are consistent with a partially oxidized Cu layer, in which CuO is mainly located at the interface between ZnO and the adsorbed Cu islands. Further Cu deposition induces the formation Cu2O. Annealing the sample in UHV induces further oxide reduction. The oxidation is reversible and metallic Cu is recovered on the top layer.

C1.00322 Nucleation and stochiometry dependence of rutile-TiO\(_2\) thin films grown by plasma-assisted molecular beam epitaxy. COSTEL CONSTANTIN, Seton Hall University, KAI SUN, University of Michigan, R.M. FEENSTRA, Carnegie Mellon University — Considerable interest has been shown of late in transition-metal oxides. One case is the titanium dioxide system, which can have a high degree of disorder, as compared to the samples prepared WITH the pseudo 1 × 1 Ga-rich surface reconstruction, and the other set, WITHOUT the pseudo 1×1. On top of these two type of surfaces, the rutile-TiO\(_2\) thin films were grown at T\(_s\) \(\sim\) 600 \(^\circ\)C, and with a thickness \(\sim\) 40 – 50 nm. During growth, reflection high-energy electron diffraction indicated a reversible stochiometry transition from O-rich to Ti-rich growth. Post-growth x-ray diffraction measurements performed on the samples WITHOUT the GaN pseudo 1×1, show the presence of additional peaks at 2\(θ\) \(=\) 52.9\(^°\), which implies the existence of additional phases. In addition, the high-resolution transmission electron microscopy performed on these samples show a high degree of disorder, as compared to the samples prepared WITH the pseudo 1×1. Work supported by ONR.

C1.00323 Study of the crystalline structures of the syndiotactic polystyrene (sPS) under mechanical deformation. SUGURU NAGASAKA, ATSUSHI HOTTA, Department of Mechanical Engineering, Keio University, Japan — Polystyrene (PS) has become one of the important, yet complicated semi-crystalline materials since the successful synthesis of the syndiotactic PS (sPS) by Ziegler-Natta catalyst. Since then, sPS has been actively investigated and four different crystalline forms (\(α\), \(β\), \(γ\) and \(δ\)), two mesomorphic forms and various clathrate forms have been found, indicating complex feature of its crystalline structures. Among the four crystalline forms, \(α\) and \(β\)-crystals can be obtained by different annealing processes and both crystalline structures comprise the same all-trans planar conformation. In this work, \(β\)-crystal structure was made by high temperature annealing and the sPS with \(β\)-crystal structure was mechanically stretched above the glass transition temperature of sPS, followed by the crystalline transition analysis studied by FT-IR.

C1.00324 Magnetic Field Effects on Intersystem Crossing in Polaron-Pair, Excitonic, and Charge-Transfer States in Organic Semiconducting Materials\(^1\), LIANG YAN, BIN HU, University of Tennessee — The singlet-triplet intersystem crossing can be magnetic field dependent in organic semiconductor molecules. This field-dependent intersystem crossing accounts for the magnetic properties of these non magnetic organic semiconductor molecules. Therefore, the study of the dependence of magnetic field on the intersystem crossing can enhance the understanding of intrinsic magnetic responses of excited states and also exped the application of non magnetic organic materials to magnetic devices. In this report we will present our recent investigations: magnetic field effects on singlet-triplet intersystem crossing based on the selected polaron-pair, excitonic, and charge-transfer excited states by using magnetic field-dependent electroluminescence, photoluminescence, and photocurrent. Our experimental results show that the intersystem-crossing dependence of magnetic field significantly decreases as the internal electron-hole distance is reduced in an excited state. This phenomenon indicates that the electron-hole distance essentially determines the intersystem-crossing dependence of magnetic field through the competition between the Zeeman splitting of triplet sublevels caused by applied magnetic field and the intrinsic singlet-triplet energy difference generated by the distance-dependent spin-exchange interaction. As a result, changing the electron-hole distance presents a new mechanism to magnetically tune the optoelectronic properties of non magnetic organic semiconductor molecules.

C1.00325 Using genetic algorithms to search for an optimal portfolio strategy and test market efficiency , HAOWEN XI, EDWARD MANDERE, Bowling Green State University — In this numerical experiment we used genetic algorithms to search for an optimal portfolio investment strategy. The algorithm involves having a “manager” who divides his capital among various “experts” each of whom has a simple fixed investment strategy. The expert strategies act like population of genes which experiencing selection, mutation and crossover during evolution process. The genetic algorithm was run on actual portfolio with stock data (DowJones 30 stocks). We found that the genetic algorithm overwhelmingly selected optimal strategy that closely resembles a simple buy and hold portfolio, that is, evenly distribute the capital among all stocks. This study shows that market is very efficient, and one possible practical way to gauge market efficiency is to measure the difference between an optimal portfolio return and a simple buy and hold portfolio return.
C1.00326 Magnetic Study of Exciton-Charge Reaction in Organic Phosphorescence-Based Light-Emitting Diodes

MING SHAO, BIN HU, University of Tennessee — The capture of electron and hole leads to the singlet and triplet excitation formation at 1.3 ratio in organic light-emitting diodes (OLEDs) of fluorescent conjugated molecules. This significantly limits the quantum efficiencies of singlet light emission from OLEDs. The alternative option is to use triplet emission from phosphorescent molecules to ultimately increase the quantum efficiencies of OLEDs. In this report we will present our recent studies of triplet excitation-charge reaction in most efficient phosphorescence-based OLEDs by using magnetic field-dependent electroluminescence and excited state-related magnetoresistance. Our experimental results show that the electrically generated excitons can react with charge carriers with two consequences: detrapping charge carriers or splitting electrons and holes in excited states. Nevertheless, the triplet excitation-charge reaction presents a significant challenge to increase the quantum efficiencies of OLEDs towards the theoretical limit of 100%. Furthermore, we observed that the charge-trapping reaction can be adjusted by changing the balancing degree of bipolar electron and hole injection. Therefore, tuning the bipolar injection can form a mechanism to control the triplet-trapping reaction and to consequently improve the quantum efficiencies of phosphorescence-based OLEDs.

1The research is supported by NSF and AFOSR.

C1.00327 Enhanced Photovoltaic Effect from Nanocomposite of Treated PbS Quantum dots and π-conjugated polymers

XIAOMEI JIANG, JIAN ZHANG, University of South Florida — We report novel type of hybrid solar cells based on nanocomposites of conjugated polymers (polythiophene) and IR-sensitive PbS nanocrystals that have a size-tunable energy gap between ca. 0.7 and 1.6 eV. Thin film cells show very good diode characteristics and sizable photovoltaic response. The good performance of our devices in both photovoltaic and photodiode regimes indicates quite efficient charge separation between the polymer and QD components. To further facilitate charge separation and transport in these composite structures, we applied various ligands exchange (pyridine, butylamine and octylamine) to the quantum dots prior to device fabrication. We find noticeable increase of photocurrent due to more efficient charge separation when the original bulky oleic acid ligand of the nanocrystals was replaced by these much smaller ligands. We have conducted mobility measurement of PbS QDs with different sizes, both in pure QD film and the hybrid nanocomposite with polymers. Both electronic and optical device characterizations were carried out. Specifically, we observe indications of a rapid increase in the photocurrent at spectral energies in correlation with the size-dependent energy gap of the QD component.

C1.00328 Studies on the parameters affecting the adhesion between Diamond-Like Carbon (DLC) films and polyolefin substrates

YUUMA NAKAMURA, Department of Mechanical Engineering, Keio University, Japan. TERUMITSU HASEBE, Department of Radiology, Tachikawa Hospital, Japan. AKI KAMURO, Department of Transfusion Medicine, University of Tokyo Hospital, Japan. TETSUYA SUZUKI, ATSUSHI HOUTTA, Department of Mechanical Engineering, Keio University, Japan. Polyolefins coated with thin Diamond-Like Carbon (DLC) films are particularly attractive for effective control of the surface and mechanical properties of the polyolefins and the adhesion between the DLC and the polyolefins determines the major properties: if the adhesion force is not sufficient, DLC film is easily peeled off from the polyolefin substrate, eventually degrading the whole highly-controlled DLC-polyolefin system. In this work, we evaluated the adhesion between DLC films and various polyolefin substrates through T-peel testing using tensile tester. DLC films were deposited on each polyolefin substrate by plasma enhanced chemical vapor deposition (CVD) method using acetylene gas. High-density polyethylene (HDPE), low-density polyethylene (LLDPE), linear-low-density polyethylene (LLDPE), isotactic polypropylene (iPP) and syndiotactic polypropylene (sPP) were introduced as polyolefin materials. It was found that molecular structures and annealing conditions had significant effects on the adhesion between DLC and the polyolefins.

C1.00329 Raman scattering from the CaC$_6$ superconductor

A. MIALITISIN, Rutgers University, J. KIM, R. KREMER, MPI fuer Festkoerperforschung, G. BLUMBERG, Bell Labs, Alcatel-Lucent — A polarized Raman scattering study has been performed on bulk 1st stage intercalated graphite CaC$_6$ crystals at sub-T$_c$ temperatures. We identify all three Raman active E$_g$ bands expected for the R$_m$6 space group of CaC$_6$ at 440, 1120 and 1508 cm$^{-1}$ and find them to be in agreement with zone center modes predicted by first principles calculations of phonon dispersion. In addition the equivalents of the graphite G and D bands are observed at respective frequencies. Inherent to the disorder induced double resonant scattering process the D band shifts from 1308 cm$^{-1}$ to 1332 cm$^{-1}$ upon the change of the excitation laser wavelength from 647 nm to 476 nm. Assuming linear dependence of the D band peak position as a function of excitation energy this translates to the frequency shift of 35 cm$^{-1}$/eV. By comparing the integrated intensity of the G band at 1582 cm$^{-1}$ in CaC$_6$ to the one in kish graphite the relative fraction of higher stage domains to the 1st stage intercalation is estimated to be less than 0.2%. Finally upon the superconducting phase transition we observe a $\Delta$ peak with the frequency of 24 cm$^{-1}$ at 5 K. With temperature increase this peak persists roughly up to the SC phase transition at 11.6 K and shows temperature dependence consistent with the strong coupling regime.

M. Calandra and F. Mauri, PRL 95, 237002 (2005).

C1.00330 Ni-Impurity Effect in High-T$_c$ Cuprates Studied by Neutron Scattering and XAFS Spectroscopy

HIARUHI HIRAKA, SHUICHI WAKIMOTO, MASAKI MATSUDA, DAIJU MATSUMURA, YASUO NISHIHATA, JUN-ICHIRO MIIZUKI, KAZUYOSHI YAMADA, Tohoku University — Neutron scattering experiments using La$_{2-x}$Sr$_x$Cu$_{1-y}$Ni$_y$O$_4$ clarified that the parallel spin-density modulations (SDMs) in the superconducting phase are susceptible to Ni, in the same way as the diagonal SDMs in the insulating spin-glass phase. Ni substitution reduces the mobile hole concentration from x to y. Polarized XAFS measurements using Ni K-edge probe two types of Ni valence states; Ni$^{2+}$ and Ni$^{2+}$+Ni$^{3+}$. It indicates that a strong hole localization occurs around Ni, resulting in an effective spin-1/2 value at Ni sites. Therefore, a charge dopant nature of Ni is most likely realized when x $>$ y.

C1.00331 Spin transfer torque switching in perpendicular magnetic tunnel junctions with Co based multilayer

TOSHIHIKO NAGASE, Corporate R&D Center, Toshiba Corporation, KATSUYA NISHIHATA, MASAHIKO NAKAYAMA, NAOHARU SHIMOMURA, MINORU AMANO, TATSUYA KISHI, HIROAKI YODA — It has been reported that spin transfer torque switching in the perpendicular magnetic device has the advantage of improving the spin-torque efficiency in comparison with the in-plane one [1, 2]. Our previous study was the first time to demonstrate the spin transfer switching in perpendicular magnetic tunnel junctions (MTJs) using TbCoFe alloy. In this paper, we report studies on the spin-torque efficiency in MgO based perpendicular MTJs consisting of CoFeB wedge/Co/PtCo/Co/Pd free layer and FePt/CoFeB reference layer. The damping constant $\alpha$ of the free layer increases in the thinner parts of the CoFeB thickness because of the effect of spin pumping. The ratio of the switching current density to the thermal stability factor (Jc/\Delta), which corresponds to the spin-torque efficiency, was estimated. It was found that the free layer with the thicker CoFeB had a lower Jc/\Delta because of its smaller $\alpha$. Our results experimentally clarify that reducing $\alpha$ leads to achieving the low switching current.

This work was partially supported by NEDO.
C1.00332 Electric Field-Induced Effects on Single-Walled Carbon Nanotube Photoluminescence, ANTON NAUMOV, SERGEI BACIHOLO, R. BRUCE WEISMAN, Rice University, Houston, TX — An investigation of the fluorescence emission of single-walled carbon nanotubes (SWNTs) in electric fields will be described. HiPco SWNTs were embedded in poly(methylmethacrylate) (PMMA) films deposited onto the surface of microscope slides with ITO or interdigitized gold electrodes. The fluorescence of individual semiconducting SWNTs was then observed using a microscope coupled to a near-IR spectrophotograph and an InGaAs 2-D camera. Bulk samples of SWNTs in polymer were studied with a spectrofluorometer. When SWNTs in PMMA were subjected to electric fields of up to $10^7$ V/m, a drastic decrease in fluorescence intensity was observed. This quenching is well described as a single-parameter inverse hyperbolic cosine function of applied field. The quenching effect is also dependent on the angle between SWNT and field, the length of the SWNT, and SWNT diameter (exciton binding energy). The quenching mechanism may involve both exciton dissociation in an electric field and free carrier effects. The latter were suggested by studies of long nanotubes.

C1.00333 Scaling Laws for NanoFET Sensors, QI-HUO WEI, FU-SHAN ZHOU, Liquid Crystal Institute, Kent State University — In this paper, we report our numerical studies of the scaling laws for nanoplate field-effect transistor (FET) sensors by simplifying the nanoplates as random resistor networks. Nanowire/tube FETs are included as the limiting cases where the device width goes small. Computer simulations show that the field effect strength exerted by the bonding molecules has significant impact on the scaling behaviors. When the field effect strength is small, nanoFETs have little size and shape dependence. In contrast, when the field-effect strength becomes stronger, there exists a lower detection threshold for charge accumulation FETs and an upper detection threshold for charge depletion FET sensors. At these thresholds, the nanoFET devices undergo a transition between low and large sensitivities. These thresholds may set the detection limits of nanoFET sensors. We propose to eliminate these detection thresholds by employing devices with very short source-drain distance and large width.

C1.00334 Fabrication and magnetic characterization of ferromagnetic nanotubes, REHANA SHARIF, SHAMAILA SHAHZADI, HAN YUNAN, MING MA, HAN XIU-FENG, Institute of Physics Chinese Academy of Sciences — During the last decade, interesting properties of magnetic nanowires have attracted much attention. Besides their interesting basic properties, there is evidence that these can be used in the fabrication of new nanodevices. Recently, magnetic nanotubes have successfully fibred in graphene and have become a symbol of new and fast developing research area of nanotechnology because of their technological applications in patterned recording media, magnetic sensors and magnetic biotechnology. Ferromagnetic nanotubes have been fabricated using templates (Alumite, PCTE) which can provide us a straight forward route to fabrication of the nanotubes. The anisotropy of the tubes is governed by shape anisotropy and the switching field of the tubes is consistent with that expected from curling mechanism in which the magnetization rotates within the plane of the tube wall.

C1.00335 Possible nano-graphene devices having topology origin edge states, KOICHI KUSAKABE, Graduate School of Engineering Science, Osaka University — In nanometer scale graphene structures, edge-localized surface states may appear in specified edges. Evidences of the edge states has been given by the ultra high vacuum STM/STS observation of well-characterized edges of graphene structures.[1,2] The density functional theory supported both appearance of edge states and existence of localized magnetism in a characterized Hydrogenated graphene structures within the local-spin-density approximation.[3] In this study, we reconsider appearance of the edge states due to network topology of π orbitals of graphene, which is used in designed structures for nano-meter scale graphene-based devices. We consider graphene structures bridging two metallic Ni electrodes. For the Ni (111) surface, epitaxial growth of graphene is possible. We assume that the Ni electrode has a sharp straight edge. The interface between graphene and Ni structure creates a boundary condition for conducting electrons in the graphene, since it is known that a gap is formed in the electronic states of graphene pasted on Ni. The gap is much enhanced by fluorination of graphene on Ni. There are two types of boundary for the graphene structures, which may be classified into zigzag and Klein’s edges. Thus, we can design a graphene-based magnetic FET structure with Ni electrodes by possible partial fluorination of graphene. First-principles electronic structure calculations for this structure is given. [1] Y. Kobayashi, K. Fukui, T. Enoki, K. Kusakabe and Y. Kaburagi, Phys. Rev. B 71, 193406-1-4 (2005). [2] Y. Kobayashi, K. Fukui, T. Enoki and K. Kusakabe, Phys. Rev. B 73, 125415-1-8 (2006). [3] K. Kusakabe and M. Maruyama, Phys. Rev. B 67, 092406-1-4 (2003).

C1.00336 Demixing of Charged Nanoparticle-Polymer Mixtures: A Simulation Study, BEN LU, ALAN R. DENTON, North Dakota State University — The phase behavior of mixtures of charged nanoparticles and neutral polymers is studied by computer simulation. Adapting the classic Asakura-Oosawa-Vrij model, the polymers are modeled as coarse-grained effective spheres that are mutually ideal (theta solvent), but can overlap the nanoparticles with a penetration energy that mimics a loss of chain conformational entropy. Although monodisperse in chain length, the polymers fluctuate in radius of gyration in response to the nanoparticles. Within the primitive model of charged colloids, the nanoparticles are modeled as charged hard spheres, governed by effective electrostatic interactions, including a repulsive screened-Coulomb (Yukawa) pair potential and a one-body volume energy. To investigate demixing behavior, constant-NPT Gibbs ensemble Monte Carlo simulations are performed over ranges of nanoparticle-polymer size ratio, nanoparticle charge, and salt concentration. In the limit of neutral nanoparticles, simulation results are compared with predictions of density-functional theory.

C1.00337 Topological Validation of Morphology Modeling by Reverse Monte Carlo Analysis of Two-dimensional Scattering Patterns, KATSUMI HAGITA, National Defense Academy, JAPAN, TAKASHI TERAMOTO, Chiose Institute of Science and Technology — We presented a new method of morphology modeling using coarse-grained particles from multiple two-dimensional (2D) patterns of structure factors, which can be obtained from small angle x-ray scattering (SAXS). Reverse Monte Carlo (RMC) technique is extended for multiple 2D patterns. It is motivated by SAXS experiments of kinetic pathway from hexagonal perforated lamellar structure to double gyroid (DG) structure in the surfactant/water systems. For the first test, we examine reproducibility of a DG morphology. As a reference configuration, we obtain positions of particles forming DG morphology are generated in a computer using the equation of DGs surface. Inputs of this extended RMC method are calculated from this reference configuration. The configurations obtained from this extended RMC method are examined by the Betti numbers which are mathematical indexes to classify complicated inter-connected three-dimensional structures and are given by Computational homology (Chomp) analysis. Combination of RMC and Chomp is examined as a new and useful approach for connecting scattering experiments to mathematics for 3D morphology.

C1.00338 Thermal Deflection of Nanojets, WEI KANG, UZI LANDMAN, School Of Physics, Georgia Institute of Technology — Generation of fluid jets of reduced sizes, down to the nanoscale [1], is a topic of continuing interest from both basic science and technological perspectives. One of the challenges pertains to the ability to control the direction of propagation of the jet. For macroscopic jets, including those with radii in the several micron range, a common method to vary the propagation direction is through the deflection of charged droplets, or as suggested more recently, via asymmetric heating that affects the surface tension and viscosity of the jet. Here we discuss a jet-bending method based on asymmetric heating of a fluid flowing in a cylindrical nozzle, where the main contribution to the deflection of the emanating nanojet is due to asymmetric evaporation near the exit, which results in a directional thrust that deflects the nanojet. Molecular dynamics simulations demonstrating bending of propane nanojets are discussed. [1] M. Moseler, U. Landman, Science 289, 1165 (2000); W. Kang, U. Landman, Phys. Rev. Lett. 98, 064504 (2007).
C1.00339 Clustering Dynamics of Ultra-fine Particulate Systems, MEENAKSHI DUTT, JAMES ELLIOTT, University of Cambridge — Length scales of particles and their surrounding medium strongly determines the nature of their interactions with one another and their responses to external fields. We are interested in systems of ultrafine particles (0.1 - 1.0 micron) such as volcanic ash, solid aerosols, or fine powders for pharmaceutical inhalation applications. We develop a numerical model for these systems using the Derjaguin-Muller-Toporov (DMT) adhesion theory along with the van der Waals attraction between the particles and their contact mechanical interactions. We study the dynamics of these systems in the absence and presence of gravity by controlling the particle size, and thereby, the surface properties of the particles. The high surface energies of these particles cause them to agglomerate as they gravitationally settle. We explore their internal structure as a function of their particle size.

C1.00340 Qubit Entanglement Driven by Remote Optical Fields, MUHAMMED YONAC, University of Rochester — We examine the entanglement between two qubits, supposed to be remotely located and driven by independent quantized optical fields. No interaction is allowed between the qubits, but their degree of entanglement changes as a function of time. We report a collapse and revival of entanglement that is similar to the collapse and revival of single-atom properties in cavity QED.

C1.00341 Optical Characterization of Biological Tissues, FREDERICK BARRERA, DHIRAJ SARDAR, ANDREW TSIN — University of Texas at San Antonio, San Antonio, Texas 78249. An in-depth characterization of optical properties of biological tissues has been performed. The wavelength-dependent total diffuse reflection ($R_d$) and total transmission ($T_d$) measurements have been taken for individual tissue by using a double-integrating sphere setup. The index of refraction of the tissue will be determined using conventional optical techniques. The Inverse Adding Doubling (IAD) computational method is applied to the measured values of $n$, $R_d$, and $T_d$ to calculate the optical absorption and scattering coefficients as well as the scattering anisotropy coefficients of these tissues. The $R_d$ and $T_d$ determined by the IAD method were compared with those generated by the Monte Carlo simulation technique. A thorough comparison of the scattering characteristics of these tissues has been made. Furthermore, a comparison of these optical scattering and absorption coefficients calculated by IAD method were compared to the values determined by the Kubelka-Munk model.

3:06PM D1.00002 Density-functional theory of superconductivity, E.K.U. GROSS, Freie Universitat Berlin — A prominent challenge of modern condensed-matter theory is to predict reliably material-specific properties of superconductors, such as the critical temperature. The traditional model of Bardeen, Cooper and Schrieffer (SCS) properly describes the universal features that all conventional superconductors have in common, but it is not able to make accurate predictions of material-specific properties. To tackle this problem, a density-functional formalism has been developed [1] which describes superconductors in thermal equilibrium in terms of three quantities: the ordinary density, the superconducting order parameter, and the nuclear N-body density. These three “densities” are determined self-consistently through a set of Kohn-Sham equations. Approximations of the universal exchange-correlation functional are derived on the basis of many-body perturbation theory. In this way, a true ab-initio description is achieved which does not contain any adjustable parameters such as the $\mu^*$ of Eliahouberg theory. Numerical results for the critical temperature, the isotope effect, the gap function and the jump of the specific heat will be presented for simple metals, for MgB$_2$ and CaBeSi, and for calcium intercalated graphite (CaC$_6$) [3]. Furthermore, results for Li, Al, K, and H under pressure will be discussed. The calculations explain why Li and Al behave very differently, leading to a strong enhancement of superconductivity for Li and to a clear suppression for Al with increasing pressure [4]. For K we predict a behavior similar to Li, i.e. a strong increase of $T_c$ with increasing pressure. Finally, hydrogen is found to be a three-gap superconductor whose critical temperature increases with increasing pressure until about 100K (at 500 GPA).

3:42PM D1.00003 Remarks on Molecular Density Functional Theory, ROBERT PARR, University of North Carolina — The dft of finite molecular systems possesses unique special characteristics that produce challenges not yet met and promises not yet realized. I describe several of the problems in this subject with which we have been struggling.

4:18PM D1.00004 The Partition Problem; Insights from Density Functional Theory, MORREL H. COHEN, Rutgers University; Princeton University — How to partition a system into its components, the atoms in molecules problem and its multi-atomic generalizations, arises ubiquitously in physics, chemistry, and materials science. It is central to population analysis, chemical reactivity theory, issues of transferability, and relevant to computational methods for very large systems such as QM-MM and O(N) schemes. At issue is the decomposition of the total electron density into contributions from each part, whence the relevance of density functional theory. My collaborators and I have developed a new, exact scheme, partition theory, for that decomposition. It is based on the Perdew, Parr, Levy, and Baldiz ensemble formulation of density functional theory. In this talk, the elements of partition theory will be described, including its formal structure, a dynamical version for efficient computation, and quantitative illustrations of its central features via the partition of very simple systems.
2:30PM D2.00002 Doping Dependent Anisotropic Electronic Scattering rate in LSCO, JOEL MESOT, ETH Zurich and PSI — An angle-resolved photoemission study of the scattering rate in the normal and superconducting states of the high-temperature superconductor La(2-x)Sr(x)CuO(4) as a function of binding energy and momentum will be presented. We report that, close to optimal doping, the scattering rate scales linearly with binding energy up to a high-energy scale E1. The scattering rate is found to be strongly anisotropic, with a minimum along the nodal direction of the superconducting gap. Since both the degree of anisotropy and the energy dependence of the scattering rate appear to be strongly doping dependent, possible connections to a quantum-critical point will be discussed.

3:06PM D2.00002 Doping Dependent Anisotropic Electronic Scattering rate in LSCO. JOEL MESOT, ETH Zurich and PSI — An angle-resolved photoemission study of the scattering rate in the normal and superconducting states of the high-temperature superconductor La(2-x)Sr(x)CuO(4) as a function of binding energy and momentum will be presented. We report that, close to optimal doping, the scattering rate scales linearly with binding energy up to a high-energy scale E1. The scattering rate is found to be strongly anisotropic, with a minimum along the nodal direction of the superconducting gap. Since both the degree of anisotropy and the energy dependence of the scattering rate appear to be strongly doping dependent, possible connections to a quantum-critical point will be discussed.

3:42PM D2.00003 Fermi surface of underdoped cuprate revealed by quantum oscillations and Hall effect. CYRIL PROUST, Laboratoire National des Champs Magnétiques Pulses (CNRS) — Despite twenty years of research, the phase diagram of high temperature superconductors remains enigmatic. A central issue is the origin of the differences in the physical properties of these copper oxides doped to opposite sides of the superconducting region. In the overdoped regime, the material behaves as a reasonably conventional metal, with a large Fermi surface [1]. The underdoped regime, however, is highly anomalous and appears to have no coherent Fermi surface, but only disconnected ‘Fermi arcs’ [2]. We have reported the observation of quantum oscillations in the electrical resistance of the oxygen-ordered cuprates, YBa$_2$Cu$_3$O$_{6.5}$ [3] and YBa$_2$Cu$_3$O$_{6.9}$ [4], establishing the existence of a coherent closed Fermi surface at low temperature in the underdoped side of the phase diagram of cuprates, once superconductivity is suppressed by a large magnetic field. The low oscillation frequency reveals a Fermi surface made of small pockets, in contrast to the large cylinder characteristic of the overdoped regime. Moreover, the negative sign of the Hall effect at low temperature reveals that these pockets are electron-like rather than hole-like. We propose that the Fermi surface of these Y-based cuprates consists of both electron and hole pockets, probably arising from a reconstruction of the FS [5].

Work in collaboration with N Doiron-Leyraud, D. LeBoeuf and L. Taillefer from the University of Sherbrooke, J. Levallois and B. Vignolle from the LNCMP, A. Bangura and N. Hussey from the University of Bristol and R. Liang, D. Bonn, W. Hardy from the University of British Columbia.

4:18PM D2.00004 Fermi orbits versus Fermi arcs. NEIL HARRISON, Los Alamos National Laboratory — We consider the effect of a short antiferromagnetic correlation length $\xi$ on the electronic bandstructure of the underdoped cuprates. Starting with a Fermi-surface topology thought to be consistent with that determined from magnetic-quantum-oscillation experiments, we show that a reduced $\xi$ gives an asymmetric broadening of the quasiparticle dispersion, resulting in simulated ARPES data very similar to those observed in experiment. Predicted features include the presence of 'Fermi arcs' close to $k=(\pi/2, \pi/2)$, where $\alpha$ is the in-plane lattice parameter, without the need to invoke a $\delta$-wave pseudogap order parameter. The statistical variation in the $k$-space areas of the reconstructed Fermi-surface pockets causes the quantum oscillations to be strongly damped, even in very strong magnetic fields, in agreement with experiment. (I would like to extend special thanks to the coauthors John Singleton and Ross McDonald and to E. Yelland and L. Taillefer for useful discussions.)

This work is supported by the DOE project Science in 100 tesla and also by the National Science Foundation.
4:54PM D2.00005 Fermi surface and anisotropic scattering in overdoped cuprates. NIGEL HUSSEY, University of Bristol — In the light of recent results detailing the emergence of small Fermi pockets and anomalous Hall coefficients in overdoped cuprates, we review here our measurements on the Fermiology and low temperature transport of cuprates that reside on the other side of the superconducting dome. Analysis of angle-dependent magnetoresistance and Hall coefficient data in $Tl_2Ba_2CuO_{6+x}$ and $La_{2-x}Sr_xCuO_4$ has uncovered a wealth of structure, not only in the (un-reconstructed) Fermi surface in overdoped cuprates, but also in the basal-plane transport scattering rate, in both the elastic and the inelastic channels. A striking correlation between the superconducting transition temperature and the strength of the anisotropic scattering is also revealed suggesting an intimate link between anisotropic scattering and the pairing mechanism itself. Finally, we discuss possible origins of these various anisotropic terms and how they might impact on our understanding of the evolution of the resistivity and the Hall coefficient across the entire cuprate phase diagram.

Monday, March 10, 2008 2:30PM - 5:30PM –
Session D3 DMP: Materials Physics in the Fast Lane Morial Convention Center RO2 - RO3

2:30PM D3.00001 The Art and Materials Physics of the Motorcycle. CHARLES M. FALCO, University of Arizona — In 1871 Louis Perreux installed a compact steam engine in a commercial bicycle, and thus produced the world’s first motorcycle. A steam engine was a logical choice, having steadily developed from the work of Savery and Newcomen in the 17th century to the point where Perreux was able to make one small enough to use for this purpose. Unfortunately, it was a technological dead-end the moment it was created, since nine years earlier Alphonse Beau de Rochas had published the description of his four-cycle internal-combustion process. Significantly, the Michaux-Perreux engine produced 1-2 hp in an overall contraption that weighed 88 kg, whereas modern motorcycles produce 200 times more power while weighing only twice as much. Examples I will show illustrate that developments in materials science over the past century are almost entirely responsible for making this possible. After a period of extraordinarily-rapid technological advance, by 1903 essentially all the components of a modern motorcycle were in place, and changes since then have been largely the result of evolutionary refinement in step with advances in materials science, rather than further revolutionary invention. Also, like many other objects of industrial design, motorcycles have played a variety of roles in society over the 137 years since the Michaux-Perreux. I will discuss the interrelationship of the relevant technological, cultural, and aesthetic factors over the past century that have, amongst other things, resulted in standard production motorcycles incorporating such materials as carbon-fiber composites, maraging steels, and “exotic” alloys of magnesium, titanium and aluminum – that can exceed 190 mph straight from the show room floor. For more information see http://www.optics.arizona.edu/sad/aotm.html. Acknowledgment: I am grateful for the contributions of Ulan Guifoyle to our joint work on the Solomon R. Guggenheim’s “The Art of the Motorcycle.”

3:06PM D3.00002 Materials at 200 mph: Making NASCAR Faster and Safer, DIANDRA LESLIE-Pelecky, University of Nebraska — You cannot win a NASCAR race without understanding science. Materials play important roles in improving performance, as well as ensuring safety. On the performance side, NASCAR limits the materials race car scientists and engineers can use to limit ownership costs. “Exotic metals” are not allowed, so controlling microstructure and nanostructure are important tools. Compacted Graphite Iron, a cast iron in which magnesium additions produce interlocking microscale graphite reinforcements, makes engine blocks stronger and lighter. NASCAR’s new car design employs a composite called Tegris$^{TM}$ that has 70 percent of the strength of carbon fiber composites at about 10 percent of the cost. The most important role of materials in racing is safety. Drivers wear firesuits made of polymers that carbonize (providing thermal protection) and expand (reducing oxygen access) when heated. Catalytic materials originally developed for space-based CO$_2$ lasers filter air for drivers during races. Although materials help cars go fast, they also help cars slow down safely—important because the kinetic energy of a race car going 180 mph is nine times greater than that of a passenger car going 60 mph. Energy-absorbing foams in the cars and on the tracks control energy dissipation during accidents. To say that most NASCAR fans (and there are estimated to be 75 million of them) are passionate about their sport is an understatement. NASCAR fans understand that science and engineering are integral to keeping their drivers safe and helping their teams win. Their passion for racing gives us a great opportunity to share our passion for science with them. NASCAR® is a registered trademark of the National Association for Stock Car Auto Racing, Inc. Tegris$^{TM}$ is a trademark of Milliken & Company.

3:42PM D3.00003 Sox and Drugs: Baseball, Steroids and Physics, ROGER TOBIN, Tufts University — The sports world is in an uproar over performance-enhancing drugs. In the United States steroids in baseball have received the most attention, in part because the purported effects are much more dramatic than in any other sport. From 1995-2003 a few players hit home runs at rates 20-50% higher than the best sluggers of the preceding century. Could steroids really increase home-run performance that much? I will describe a model that combines estimates of the physiological effects of steroids, known baseball physics, and reasonable models of batting effectiveness for highly skilled hitters. A 10% increase in muscle mass, which can reasonably be expected from steroid use, increases the speed of a batted ball by 3%. Because home runs are relatively rare events on the tail of a batter’s range distribution, even this modest change in ball speed can increase the proportion of batted balls that result in home runs by 30 – 70%, enough to account for the record-shattering performances of the recent past. I will also describe some of the attention — both welcome and not — that comes to the unsuspecting physicist who wades into such emotionally troubled waters.

4:18PM D3.00004 Zero CTE Glass in the Hubble Space Telescope, JOHNN WOOD, NASA Goddard Space Flight Center — Orbiting high above the turbulence of the earth’s atmosphere, the Hubble Space Telescope (HST) has provided breathtaking views of astronomical objects never before seen in such detail. The steady diffraction-limited images allow this medium-size telescope to reach faint galaxies fainter than 30th magnitude. Some of these galaxies are seen as early as 2 billion years after the Big Bang in a 13.7 billion year old universe. Up until recently, astronomers assumed that all of the laws of physics and astronomy applied back then as they do today. Now, using the discovery that certain supernovae are “standard candles,” astronomers have found that the universe is expanding faster today than it was back then: the universe is accelerating in its expansion. The Hubble Space Telescope is a two-mirror Ritchey-Chrétien telescope of 2.4m aperture in low earth orbit. The mirrors are made of Ultra Low Expansion (ULE) glass by Corning Glass Works. This material allows rapid figuring and outstanding performance in space astronomy applications. The paper describes how the primary mirror was mis-figured in manufacturing and later corrected in orbit. Outstanding astronomical images taken over the last 17 years show how the application of this new technology has advanced our knowledge of the universe. Not only has the acceleration of the expansion been discovered, the excellent imaging capability of HST has allowed ground-breaking research on cosmology, dark matter and dark energy in distant clusters of galaxies. The HST has touched practically every field of astronomy enabling astronomers to solve many long-standing puzzles. It will be a long time until the end of the universe when the density is near zero and all of the stars have long since evaporated. It is remarkable that humankind has found the technology and developed the ability to interpret the measurements in order to understand this dramatic age we live in.
Coherent tunneling of electron and hole spin between two quantum dots using optical spectroscopy [1,2]. In the case of a hole spin, a very large and resonant enhancement or reduction of g-factor is controlled with an applied electric field [3]. This effect arises because of the corresponding enhancement or suppression of the hole wavefunction in the tunnel barrier for the bonding (symmetric) and anti-bonding (anti-symmetric) states, respectively. This effect was discovered for single holes, but also occurs for two-particle states (two holes or 1 hole and 1 electron). Using this effect to identify the symmetry of the wavefunction, we have now found that the energetic order of the bonding and anti-bonding molecular states goes through a reversal as a function of tunnel barrier thickness. That is, the bonding state is the low energy state for a 2nm barrier thickness (as expected in the simple particle-in-a-box model, or the one-band effective mass theory). But for thicknesses larger than 3nm, a transition occurs such that the anti-bonding state becomes the low energy state. This dramatic and non-intuitive effect arises from the spin-orbit interaction.

Monday, March 10, 2008 2:30PM - 4:54PM –
Session D4 DCMP: Probing Spin and Charge States in Semiconductor Quantum Dots and Molecules  Morial Convention Center 206

2:30PM D4.00001 Spin tunneling in optically excited quantum dot molecules: Controlling g-factors with electric field , MATTHEW DOTY, Materials Science and Engineering, University of Delaware — We have recently demonstrated coherent tunneling of electron and hole spin between two quantum dots using optical spectroscopy [1,2]. In the case of a hole spin, a very large and resonant enhancement or reduction of g-factor is controlled with an applied electric field [3]. This effect arises because of the corresponding enhancement or suppression of the hole wavefunction in the tunnel barrier for the bonding (symmetric) and anti-bonding (anti-symmetric) states, respectively. This effect was discovered for single holes, but also occurs for two-particle states (two holes or 1 hole and 1 electron). Using this effect to identify the symmetry of the wavefunction, we have now found that the energetic order of the bonding and anti-bonding molecular states goes through a reversal as a function of tunnel barrier thickness. That is, the bonding state is the low energy state for a 2nm barrier thickness (as expected in the simple particle-in-a-box model, or the one-band effective mass theory). But for thicknesses larger than 3nm, a transition occurs such that the anti-bonding state becomes the low energy state. This dramatic and non-intuitive effect arises from the spin-orbit interaction.

3:06PM D4.00002 Universal Quantum Gates for Two- and Three-Spin Qubits in Coupled Quantum Dots , GUIDO BURKARD, RWTH Aachen University, Germany — The ability to control the exchange coupling between coupled quantum dots allows for quantum gate operations on quantum dot spin qubits. Supplemented with single-spin rotations, the exchange coupling is universal for quantum computation on qubits that are formed by the spin 1/2 of single electrons. If qubits are formed by two spins, the requirement for single-spin rotations is reduced to the presence of a fixed inhomogeneous magnetic field, while for three spins, the exchange coupling is universal on its own. In this talk, we discuss the implementation of universal gate operations for two- and three-spin qubits in coupled quantum dots. In the case of the two-spin singlet-triplet qubit on a double quantum dot, we propose a set of universal gates that can be generated by controlling the electrostatic potential between the two dots without time-dependent control of the tunnel coupling between the dots [1]. This simplification should facilitate the implementation of quantum gates in the systems that are presently studied experimentally. We present explicit gate sequences for single-qubit rotations about two orthogonal axes, and a CNOT gate sequence, completing the universal gate set. Finally, the trade-off between leakage errors and simple operations will be briefly discussed.

3:42PM D4.00003 Nondestructive optical probe of coherent single spin dynamics in a quantum dot , JESSE BEREZOVSKY, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — Understanding the coherent dynamics of a single electron spin in a quantum dot (QD) is important for potential applications in solid-state, spin-based quantum information processing. Here, results will be presented focusing on optical detection of a single spin and observation of the temporal evolution of the spin state. First, we demonstrate the detection of a single electron spin in a QD using a continuously averaged magneto-optical Kerr rotation (KR) measurement [2]. In contrast to many other single spin detection schemes, the KR measurement minimally disturbs the system, making it potentially useful for exploring quantum measurement phenomena or spin-photon entanglement. This continuous single QD KR technique is then extended into the time domain using pulsed pump and probe lasers, allowing the observation of the coherent evolution of an electron spin state with nanosecond temporal resolution [3]. This provides a direct measurement of the electron g-factor and spin lifetime, and additionally serves as a sensitive probe of the local nuclear spin environment. Finally, we perform ultrafast coherent optical manipulation of the electron spin state in the QD using the optical Stark effect [4] where an off-resonant optical pulse induces rotations of the spin state through angles up to $\pi$ radians on picosecond timescales.

Yamamoto, Yu. A. Pashkin, and J.S. Tsai. This work has been supported by RIKEN Frontier Research System and CREST-JST.

is pumped incoherently to the upper state and emits photon into the cavity. This work is in collaboration with O. Astafiev, K. Inomata, A.O. Niskanen, T. J. M. Gambetta, Jens Koch, B. R. Johnson, J. A. Schreier, L. Frunzio, D. I. Schuster, A. A. Houck, A. Wallraff, A. Blais, M. H. Devoret, S. M. Girvin and R. J. Schoelkopf, ALEXANDRE BLAIS, Universite de Sherbrooke — Coupling of superconducting qubits to resonant cavities and mechanical oscillators has opened new possibilities for quantum information processing and for the realization of quantum optics in solid-state devices. Together with steady improvements in superconducting qubits [1], this is due to the qubit-resonator coupling which can readily be made very large with respect to all dissipation rates. As a result, these solid-state systems can reach new parameter regimes currently unexplored in atomic based quantum optics [2]. A resonant cavity can also be used as quantum bus allowing entanglement to be generated controllably between qubits coupled to the same cavity, and regardless of the distance separating the qubits [3]. Because of the relatively large size of these cavities, this allows to couple and entangle multiple qubits, opening new avenues for scalable solid-state quantum computation. In this talk, I will review some of the key properties of superconducting qubits and how they can be strongly coupled to various types of resonant cavities. Focusing on superconducting charge qubits coupled to transmission line resonators, I will explain how the quantum state of the qubits can be coherently manipulated and probed by microwave irradiation of the resonator [4]. I will also present some of the recent theoretical proposals for the generation of entanglement in this system [5].

3:06PM D5.00002 Coherent manipulation of quantum information using two Josephson phase qubits coupled to a resonant cavity, MIKA SILLANPAA, National Institute of Standards and Technology — We have taken the first step towards the implementation of circuit quantum-electro dynamics (QED) quantum information processing with Josephson phase qubits. We have observed for the first time a coherent interaction between two phase qubits and an LC cavity formed by a 7 mm long coplanar waveguide resonator at 9 GHz. When either qubit is resonant with the cavity, we observe the vacuum Rabi splitting of the qubit’s spectral line. In a time-domain measurement, we observe coherent vacuum Rabi oscillations between either qubit and the oscillator. Using controllable shift pulses, we have shown coherent transfer of a arbitrary quantum state. We first prepare the first qubit in a superposition state, then this state is transferred to the resonant cavity and then after a short time, we transfer this state into the final qubit. These experiments show that quantum information can be coherently stored and transferred between superconducting quantum bits using a resonant cavity. This opens up new possibilities for performing circuit QED and studying quantum information science.

3:42PM D5.00003 Circuit QED: Coupling Superconducting Qubits via a Cavity Bus on a Chip, JOHANNES MAJER, Yale University, Applied Physics — Circuit quantum electrodynamics is a system, which allows us to do new experiments in quantum optics with a superconducting integrated circuit on a chip. In circuit QED, microwave photons are guided and confined by superconducting transmission lines and cavities, and can then be coherently coupled to a transmon qubit. This system leads to much stronger coupling of the “light” and “matter” than is possible with traditional atomic systems. Making use of that strong coupling it is possible to couple two qubits via the cavity[1]. I will show how one can use the cavity as a coupling bus which provides non-local and non-nearest neighbor coupling. The interaction is mediated by the exchange of virtual rather than real photons, avoiding cavity-induced loss. The same cavity is also used to perform multiplexed control and read-out of the two qubits. The coupling is effectively switchable which allows for time domain transfer of the quantum states between the qubits. [4] Coupling superconducting qubits via a cavity bus, J. Majer, J. M. Chow, J. M. Gambetta, Jens Koch, B. R. Johnson, J. A. Schreier, L. Frunzio, D. I. Schuster, A. A. Houck, A. Wallraff, A. Blais, M. H. Devoret, S. M. Girvin and R. J. Schoelkopf. Nature 449 443 (2007)

4:18PM D5.00004 Single artificial-atom maser, YASUNOBU NAKAMURA, NEC Nano Electronics Research Laboratories — MASERS and lasers usually involve ensemble of atoms to be excited and stimulated for emission. As those atoms are only weakly coupled to the cavity mode, a large number of atoms and strong pumping are needed for lasing in order to overcome the cavity loss and the relaxation of atoms due to spontaneous emission into other modes. However, when the coupling becomes strong even a single atom is enough for lasing, as have been demonstrated with atoms in microwave/optical cavities. We have realized an analogous single artificial-atom maser in a superconducting circuit [1]. Josephson-junction charge qubit is used as an artificial atom with a large dipole. The qubit is coupled to a superconducting Nb coplanar-waveguide resonator at around 10 GHz and with a quality factor of 7600. The coupling strength between the qubit and the resonator is 80 MHz. Population inversion is generated by current injection: A current is injected through a voltage-biased electrode attached to the charge qubit via a highly resistive tunnel junction. In the so-called Josephson-quasiparticle process, the qubit is pumped incoherently to the upper state and emits photon into the cavity. This work is in collaboration with O. Astafiev, K. Inomata, A.O. Niskanen, T. Yamamoto, Yu. A. Pashkin, and J.S. Tsai. This work has been supported by RIKEN Frontier Research System and CREST-JST.

4:54PM D5.00005 Process Tomography of Quantum Memory in a Josephson Phase Qubit. MATTHEW NEELEY, University of California, Santa Barbara — Quantum memory that can protect qubit states against decoherence is an important piece of a scalable quantum computing architecture. Coupling a qubit to a high-Q harmonic oscillator memory element is one example, but many other quantum systems could serve this role. We have used an atomic two-level state (TLS) in the amorphous AlOx tunnel barrier of a Josephson phase qubit as a prototype quantum memory element. The frequency-tunability of the phase qubit allows us to switch on and off the qubit-TLS coupling and thereby transfer arbitrary qubit states into the TLS, store them for some time and recall them later. We performed quantum process tomography to completely characterize the memory operation and the errors that occur during the state transfer and recall. The overall process fidelity is 78%. The dominant operator-sum errors are dephasing-like (~12%) and relaxation-like (~9%), consistent with the measured $T_1$ and $T_2$ of the TLS.

Monday, March 10, 2008 2:30PM - 5:30PM –
Session D6 FIAP DPOLY: Long-Distance Charge Transfer in Biological Systems Morial Convention Center RO4

2:30PM D6.00001 Theory of Electron Transfer and Transport Pathways in Biomolecules. DAVID BERATAN, Duke University — Electron transfer in proteins and nucleic acids occurs over large distances by a combination of short and long range tunneling mechanisms. Electron tunneling is facilitated by virtual oxidized and reduced states of the bridging macromolecule, and theoretical analysis reveals how a macromolecule’s fold, energetics, and fluctuations influence the electron-transfer kinetics. Recent studies of protein electron transfer indicate when and why electron tunneling kinetics is sensitive to the structure of the protein’s tunneling pathways. Electron transfer across protein-protein interfaces involves thin structured water layers that play a key role in tunneling mediation as well. Tunneling analysis that takes the dynamical fluctuations of the macromolecules into explicit account provides a unified view that links structure and function in protein electron transfer. In the case of DNA electron transport, a critical role is found for structural fluctuations and transport mediated by carrier injection to intervening bases, even at very short distances.

3:06PM D6.00002 Long-Range Electron Transfer through Proteins and Solvents. JAY WINKLER, California Institute of Technology — Reactions in which electrons tunnel long distances from donors (D) to acceptors (A) pervade solid-state physics, chemistry and biology. Theory suggests that the barriers to these tunneling processes depend strikingly on the composition and structure of the intervening medium. Poor coupling across nonbonded interfaces produces a strong bias in favor of covalent and hydrogen-bonded pathways between redox sites in proteins. The coupling disparity between bonded and nonbonded interfaces accounts in large part for the finding that protein electron-transfer rates do not exhibit a uniform dependence on distance, but instead depend critically on the composition of the medium between redox sites. Rates at a single D-A separation can differ by more than one order of magnitude in D-A distances that differ by much as 0.5 nm can produce identical rates. Our investigations of electron tunneling through proteins and solvents are aimed at elucidating the factors that determine long-range D-A couplings.

3:42PM D6.00003 Correlated electron and proton transport in cytochrome c oxidase: Coulomb proton pump with kinetic gating1, ALEXEI STUCHEBRUKHOV, University of California at Davis — I will discuss correlated transport of electrons and protons in cytochrome c oxidase, the terminal enzyme in the respiratory electron transport chain of aerobic organisms. This enzyme catalyzes the reduction of atmospheric oxygen to water in our cells, and utilizes the free energy of oxygen reduction for the creation the proton gradient by pumping protons across the membrane. The proton gradient subsequently drives the synthesis of ATP. The details of the mechanism of this redox-driven proton pump are unknown. Computer simulations and theoretical modeling point to a possible mechanism of this biological molecular machine in which electron transport is coupled to proton translocation.
3:06PM D7.00002 Theory of swimming filaments in viscoelastic media. HENRY FU, Brown University — Microorganisms often encounter and must move through complex media. What aspects of propulsion are altered when swimming in viscoelastic gels and fluids? Motivated by the swimming of sperm through the mucus of the female mammalian reproductive tract, we examine the swimming of filaments in nonlinearly viscoelastic fluids. We obtain the swimming velocity and hydrodynamic force exerted on an infinitely long cylinder with prescribed beating pattern. We apply these results to study the swimming of a simplified sliding-filament model for a sperm flagellum. Viscoelasticity tends to decrease swimming speed. The viscoelastic response of the fluid can change the shapes of beating patterns, and changes in the beating patterns can even lead to reversal of the swimming direction.

3:42PM D7.00003 Undulatory swimming in a viscoelastic fluid. LISA FAUCI, Tulane University — Mammalian spermatozoa encounter complex, non-Newtonian fluid environments as they make their way through the female reproductive tract. The beat form realized by the flagellum varies tremendously along this journey. We will present recent progress on the development of computational models that couple the internal force generation of undulating flagella with the external dynamics of a complex fluid. An immersed boundary framework is used, with the complex fluid represented either by a continuum Oldroyd-B model, or a Newtonian fluid overlaid with discrete viscoelastic elements.

4:18PM D7.00004 Large and limbless: the locomotion of snakes. DAVID HU, Courant Institute — In efforts to understand snake locomotion, we consider one of their various gaits. By contracting and extending their bodies unidirectionally like a slinky, large snakes propel themselves in a straight line. In a combined experimental and theoretical investigation, we here report on the dynamics of a boa constrictor alongside the analysis of an n-linked extensible crawler model. Constraints on their locomotion are quantified and discussed, such as the elasticity, frictional anisotropy and abrasive wear of their skin. Also presented are certain snake behaviors that culminate in their tying themselves into knots.

4:54PM D7.00005 Biological and robotic movement through granular media. DANIEL GOLDMAN, Georgia Institute of Technology — We discuss laboratory experiments and numerical simulations of locomotion of biological organisms and robots on and within a granular medium. Terrestrial locomotion on granular media (like desert and beach sand) is unlike locomotion on rigid ground because during a step the material begins as a solid, becomes a fluid and then re-solidifies. Subsurface locomotion within granular media is unlike swimming in water for similar reasons. The fluidization and solidification depend on the packing properties of the material and can affect limb penetration depth and propulsive force. Unlike aerial and aquatic locomotion in which the Navier-Stokes equations can be used to model environment interaction, models for limb interaction with granular media do not yet exist. To study how the fluidizing properties affect speed in rapidly running and swimming lizards and crabs, we use a trackway composed of a fluidized bed of of 250 μm glass spheres. Pulses of air to the bed set the solid volume fraction 0.50 < φ < 0.63; a constant flow rate Q below the onset of fluidization (at Q = Qf) linearly reduces the material strength (resistance force per depth) at fixed φ for increasing Q. Systematic studies of four species of lizard and a species of crab (masses ≈ 20 grams) reveal that as Q increases, the average running speed of an animal decreases proportionally to √(M/A - const*(1 - Q/Qf)) where M is the mass of the animal and A is a characteristic foot area. While the crabs decrease speed by nearly 75% as the material weakens to a fluid, the zebra tailed lizard uses long toes and a plantigrade foot posture at foot impact to maintain high speed (≈ 1.5 m/sec). We compare our biological results to systematic studies of a physical model of an organism, a 2 kg hexapedal robot SandBot. We find that the robot speed sensitively depends on φ and the details of the limb trajectory. We simulate the robot locomotion by computing ground reaction forces on a numerical model of the robot using a soft-sphere Molecular Dynamics code.

Monday, March 10, 2008 2:30PM - 5:30PM — Session D8 DFD GSNP: Focus Session: Granular Flows: Vibrated Morial Convention Center RO6

2:30PM D8.00001 Particle kinematics in a 3-dimensional vibration-fluidized granular medium. HONG-QIANG WANG, NARAYANAN MENON, University of Massachusetts Amherst — We report a study by high speed video imaging of particle motions in the bulk of a three dimensional granular gas. We fluidise with intense vertical vibration, delrin spheres of diameter, d=1.6 mm confined in a 3-dimensional volume (32d)3. We isolate particles moving in a thin slice of this volume by illuminating with a laser sheet. We have developed a new algorithm to track with sub-pixel precision particles that are only partially illuminated or eclipsed by other particles. We will present data in the low-volume fraction regime for spatial profiles of the the kinetic temperature and number density, as well as for the velocity distribution. These results will be compared to predictions from hydrodynamic models.

3This work was supported through NASA NNC05AA35A and NSF DMR 0606216.

2:42PM D8.00002 Heating mechanism affects equipartition in a binary granular system. NARAYANAN MENON, HONGQIANG WANG, Dept of Physics, U. of Massachusetts — Two species of particles in a binary granular system typically do not have the same mean kinetic energy, in contrast to the equipartition of energy required in equilibrium. We investigate the role of the heating mechanism in determining the extent of this non-equipartition of kinetic energy. In most experiments, different species of particle are unequally heated at the boundaries. We show by event-driven simulations that this differential heating at the boundary influences the level of non-equipartition even in the bulk of the system. This conclusion is fortified by studying a numerical model and a solvable stochastic model without spatial degrees of freedom. In both cases, even in the limit where heating events are rare compared to collisions, the effect of the heating mechanism persists.

2We gratefully acknowledge support from NASA NNC05AA35A and NSF DMR 0606216

2:54PM D8.00003 Energy fluctuation, diffusivity and mobility in a 2D vibrated granular packing. ERIC CLEMENT, RIM HARICH, ESPCI -Université Paris 6, NICOLAS VANDEWALLE, GEOFFROY LUMAY, GRASP-Université Li`ege — We present an experimental realization of a 2D vibrated granular packing. The new agitation method allows a spatially non synchronized influx of energy and the study of the vibrated packing at steady state. By image analysis of fast-camera movies, we obtain the velocity fluctuation spectra at different vertical levels and then, we separate the agitation velocities from the velocity fluctuations corresponding to the “thermalized” degrees of freedom. By measuring the corresponding particle diffusivities, we show that, in spite a large heterogeneity and anisotropy of the vibration, a relation between diffusivity and “thermalized” kinetic energy can be identified. We relate this type of fluctuation-dissipation relation to the mobility of macroscopic intruders of different sizes and weight moving in the vibrated granular packing.

4:06PM D8.00007 Numerical Study of Particle Damping Mechanism in Piston Vibration System via Particle Dynamics Simulation, XIAN-MING BAI, BINYO SHAH, LEON KEER, JANE WANG, RANDALL SNURR, Northwestern University — Mechanical damping systems with granular particles as the damping media have promising applications in extreme temperature conditions. In particle-based damping systems, the mechanical energy is dissipated through the inelastic collision and friction of particles. In the past, many experiments have been performed to investigate the particle damping problems. However, the detailed energy dissipation mechanism is still unclear due to the complex collision and flow behavior of dense particles. In this work, we use 3-D particle dynamics simulation to investigate the damping mechanism of an oscillating cylinder piston immersed in millimeter-size steel particles. The time evolution of the energy dissipation through the friction and inelastic collision is accurately monitored during the damping process. The contribution from the particle-particle interaction and particle-wall interaction is also separated for investigation. The effects of moisture, surface roughness, and density of particles are carefully investigated in the simulation. The comparison between the numerical simulation and experiment is also performed. The simulation results can help us understand the particle damping mechanism and design the new generation of particle damping devices.

4:18PM D8.00008 Breaking of granular jams with mechanical shocks, KE CHEN, ANDREW HARRIS, JOHN DRASKOVIC, PETER SCHIFFER, Department of Physics, Penn State University — We studied the brief granular flows initiated by breaking the jamming in a hopper using mechanical shocks. Jamming near the orifice of a hopper prevents granular materials from flowing spontaneously under gravity. Controlled mechanical shocks were applied from the bottom of the hopper to break the jamming and to initiate brief flows. The magnitude and the duration of the flows were measured. Preliminary results show that the probability of initiating a flow increases with the intensity of the shock, and reaches almost 100% at the highest shock intensities. We also investigated the flow probability as a function of the ratio between the diameters of the orifice and the bead. Statistical characteristics of the flow magnitude and duration evolve with shock intensity as well as the ratio between the diameters of the orifice and the bead. This research was supported by the NASA through grant NAG3-2384 and the NSF REU program through grant DMR 0305238.

4:30PM D8.00009 Spreading of a granular droplet, ERIC CLEMENT, PMMH, UMR7636 (CNRS), ESPCI Univ. P6-P7, 10 Rue Vauquelin, 75005 Paris, France, IVAN SANCHEZ, Centro de Fisica, IUC, Apartado Postal 21827, Caracas 1020-A, Venezuela, FRANCK RAYNAUD, MSc, UMR 7057 (CNRS), Univ. Paris 7, JOSE LANUZA, BRUNO ANDREOTTI, PMMH, UMR7636 (CNRS), ESPCI Univ. P6-P7, 10 Rue Vauquelin, 75005 Paris, France, IGOR ARANSON, Materials Science Division, Argonne National Laboratory, Argonne, IL60439, USA — The influence of controlled vibrations on the granular rheology is investigated in a specifically designed experiment in which a granular film spreads under the action of horizontal vibrations. A nonlinear diffusion equation is derived theoretically that describes the evolution of the deposit shape. A self-similar parabolic shape (the "granular droplet") and a spreading dynamics are predicted that both agree quantitatively with the experimental results. The theoretical analysis is used to extract effective friction coefficients between the base and the granular layer under sustained and controlled vibrations. A shear thickening regime characteristic of dense granular flows is evidenced at low vibration energy, both for glass beads and natural sand. Conversely, shear thinning is observed at high agitation.

4:42PM D8.00010 2D granular avalanches with imposed vibrations, BRIAN UTTER, DAN AMON, James Madison University — We present work on a 2D free surface granular flow experiment under vertical vibration. The experiment consists of photoelastic grains in a 2D circular drum which is rotated at a constant rate (f < 1 mHz). We measure time series of the slope, particle trajectories, and image the bulk force network. Avalanche and build-up distributions exhibit a power-law dependence as previously observed. We then vibrate the drum vertically to determine the effect of external vibrations on this "unjamming" transition. While larger vibrations destabilize the pile and decrease the maximum angle of repose, small vibrations lead to a strengthening of the pile and tend to increase the critical angle of failure. In the absence of vibration, when the drum is rotated opposite the direction of steady rotation, the critical angle of the first failure decreases slightly from the steady-state value due to the lack of an established steady-state force network.
4:54PM D8.00011 Bouncing trimer¹. STEPHANE DORBOLO, FNRS, NICOLAS VANDEWALLE, University of Liege, GRASP TEAM — Trimers are composed of three stainless steel beads (1 cm of diameter) forming a solid equilateral triangle (2.5 cm of side). They are placed on a plate of an electromagnetic shaker. The system is shaken vertically. According to the acceleration, the trimer may spin, jump once every two periods or even every three periods. Between these stable regimes, the system is chaotic. By measuring the time delay between two successive shocks (beam-plate), a mapping of the different regimes has been constructed. The spinning, 2-period and 3-period orbits occurs for the same acceleration whatever the frequency. However, the spin speed has been measured with respect of the frequency.

5:06PM D8.00012 Dynamics of a single particle on a 2D driven granular lattice. JEFFREY OLAFSEN, KRISTIN COMBS, Department of Physics, Baylor University, G. WILLIAM BAXTER, Physics Department, Penn State Erie, The Behrend College — Previous measurements have demonstrated interesting behavior in a novel bi-layer granular gas experiment of mechanically shaken particles. The results are of importance because the two layers are in “thermal contact” and yet have very different dynamical behaviors. The lower layer of particles demonstrates velocity statistics that are strongly correlated and non-Gaussian, while the upper layer of particles concurrently demonstrates a lack of correlations and Gaussian velocity statistics. Details of the collisions within each layer (intralayer) and between the layers (interlayer) are clearly of interest to understand the simultaneous behavior. Measurements are made for a single particle in the upper layer to examine the effects of interlayer collisions. In addition, velocity statistics in both layers are analyzed to determine effects of the sideways.

5:18PM D8.00013 Structure and dynamics of a vibrated granular bead-chain. KEVIN SAFFORD, ARSHAD KUDROLLI, Clark Univ. Physics Dept., YACOV KANTOR, Tel Aviv Univ. Physics Dept., MEHRAN KARDAR, MIT Physics Dept. — We investigate the dynamics of a vibrated granular bead-chain with experiments and numerical simulations of random-walk models of polymers. Experiments are conducted with a chain composed of hollow 3 mm steel beads connected by flexible links confined to move on a 300 mm diameter rough circular bed. Observations made with digital imaging. We analyze the radius of gyration $R_g$, the structure factor of the chain configurations, and the diffusion of the center of mass. We find that $R_g$ and the structure factor scale with the exponent $\nu \sim 3/4$, consistent with the two dimensional self-avoiding random-walk model. Further, we observe confinement effects in the scaling of $R_g$ as the chain length increases relative to the size of the container. We perform simulations of non-self-avoiding walks confined to the same sized domain and find good agreement with experiment. The simulations show confinement effects dominate over self-avoided crossings in the experiments even when the length of chain is smaller than system size. We then experimentally examine the chain dynamics and find that the center of mass diffusion scales inversely as the length of the chain, consistent with the Rouse model of polymers. We observe an exponential decay in the dynamical structure factor and compare this exponent with the measurement of the center of mass diffusion.

2:30PM D9.00001 Turbulent Viscosity Coefficient in 3-Dimesional Turbulence. HIROSHI SHIBATA, Sojo University — A new model for the large-eddy simulation (LES) is proposed. The LES has been accepted as the standard formalism for calculating observables concerning turbulence. In the application of the LES, several models are chosen. The purpose of the present paper is for us to propose one of the most physical models. The LES is usually written down as

$$\frac{\partial U_i}{\partial t} + (\vec{U} \cdot \nabla)U_i = - \frac{1}{\rho} \frac{\partial P}{\partial x_i} + \nu_0 \Delta U_i - \frac{\partial Q_{ij}}{\partial x_j}. \quad (2)$$

The above equation is rewritten as

$$\frac{\partial U_i}{\partial t} + (\vec{U} \cdot \nabla)U_i = - \frac{1}{\rho} \frac{\partial P}{\partial x_i} + \nu \Delta U_i \quad (3)$$

2:42PM D9.00002 Exploring the dynamics of the velocity gradient tensor. MARCO MARTINS AFONSO, CHARLES MENEVEAU, Dept. of Mech. Engineering - Johns Hopkins University - Baltimore, MD — The dynamics of the velocity gradient tensor is investigated by means of analytical and numerical computations. Our starting point is the Lagrangian evolution equation of this tensor and a model for the pressure Hessian and viscous term proposed in Chevillard and Meneveau (Phys. Rev. Lett. 97, 174501, 2006). The model is based on the Recent Fluid Deformation (RFD) closure, which was introduced in order to overcome the unphysical finite-time blowup of the Restricted Euler model that neglects anisotropic pressure Hessian effects. Using matrix exponentials, the RFD closure takes into account both the geometry and the dynamics of the recent history of the deformation of a fluid particle, and requires the specification of a decorrelation time scale $\tau$. When this time scale is chosen too short (or, equivalently, the Reynolds number is too high), unphysical statistics are observed in the model. In order to understand this model in greater detail, the original, full matrix-exponential-based model is compared with its power- series expansion for small $\tau$. In particular, the time evolution in the so-called $R-Q$ plane is studied for the two approaches, and also, the effects of adding a Gaussian white noise are examined.

2:54PM D9.00003 The Generalized Fractal Dimensions of a 2-D Compressible Turbulence¹. JASON LARKIN, WALTER GOLDBURG, University of Pittsburgh, MAHESH BANDI, Los Alamos National Laboratory — Steady-state turbulence is generated in a tank of water 1m x 1 m x 0.3 m and the trajectories of particles floating on the surface are tracked in time. Initially the floaters are uniformly distributed. As time goes on they coagulate and form a fractal structure. The surface pattern reaches a steady state in approximately $t^* = 1$ s. In the time interval $0 \leq t < 2t^*$, measurements are made of the generalized fractal dimensions $D_q(t)$ of the floating particles starting with the uniform distribution $D_0(0) = 2$. In the steady state, the pattern formed by the floaters continues to fluctuate at a time scale dictated by the underlying turbulent flow. This time scale is also of the order of 1 s. To understand the origin of the coagulation phenomenon, one must remember that the floaters form a compressible system, unlike the water molecules that drive them. The time evolution of the $D_q(t)$ are measured for a range of $q$ less than 10. The coagulated particles form into string-like structures having values of $D_q$ ranging down to approximately 1.5.

3:06PM D9.00004 Particle Dynamics in Turbulence. HAITAO XU, Max Planck Institute for Dynamics and Self-Organization — The interaction between particles and turbulence features in many environmental and engineering problems, e.g., the formation of rain, the dispersion of particulate pollutants, and sedimentation in rivers and oceans. In addition, tracer particles are routinely used in scientific research to study the flow itself. Understanding the behavior of particles in turbulent flows is not only an important practical problem, but also an intriguing scientific challenge. Our group has developed a three-dimensional Lagrangian Particle Tracking (LPT) system. Using high speed CMOS cameras, the system is capable of following simultaneously hundreds of particles in a turbulent flow with Taylor microscale Reynolds numbers \( R_\lambda \) up to \( 10^5 \). The LPT measurements provide both single- and multi-particle statistics following Lagrangian trajectories, at temporal resolutions better than the Kolmogorov time scales of the turbulence. Due to its ability to follow individual particles, the LPT system is an ideal tool to study the behavior of non-tracer particles in turbulence. The inertial particles have density different from the fluid, but size smaller than the Kolmogorov length scale of turbulence. On the other hand, neutrally buoyant particles with size larger than the Kolmogorov scale behave very differently from inertial particles. We will present results from both cases.

3:42PM D9.00005 Craig’s XY-distribution and the statistics of Lagrangian power in two-dimensional turbulence.1. COLM CONNAUGHTON, University of Warwick, MAHESH BANDI, Los Alamos National Laboratory — We study the probability distribution function (PDF) of injected power in numerical simulations of stationary 2D turbulence in the Lagrangian frame. The simulation mimics an electromagnetically driven fluid layer, a well-documented system for generating 2D turbulence in the laboratory. The forcing and velocity fields in the numerics are close to Gaussian, but the injected power PDF is sharply peaked at zero (suggesting a singularity) with asymmetric exponential tails. Large positive fluctuations are more probable than large negative ones leading to a net positive mean energy input. The main features of the power distribution are well described by Craig’s XY distribution for the PDF of the product of two correlated normal variables. We show that the power distribution should exhibit a logarithmic singularity at zero and decay exponentially for large absolute values of the power. We calculate the asymptotic behaviour and express the asymmetry of the tails in terms of the correlation coefficient of the force and velocity and compare the measured PDFs with theoretical calculations.

3:54PM D9.00006 Multiscale Sample Entropy of 2D Decaying Turbulence. ILDOO KIM, University of Pittsburgh, MATTHEW SHTRAHMAN, Western Pennsylvania Hospital, XIAO-LUN WU, University of Pittsburgh — Kolmogorov-Sinai entropy has been used to quantify degrees of complexity of spatiotemporally chaotic systems. However, it is not always convenient to implement in real experiments. Recently a Multiscale Sample Entropy (MSE) measure has been proposed, which allows easier analyses of time series. In this study, we have generated decaying turbulence in a two-dimensional soap film and have measured velocity fluctuations as functions of time and downstream distance using a laser Doppler velocimeter. We performed MSE analysis and found there is a time scale \( \tau_0 \) at which the MSE is maximized. The value of \( \tau_0 \), which correlates well with the large-eddy turn-over time, gets larger as turbulence decays. Other aspects of 2D turbulence are also analyzed using the velocity time series.

4:06PM D9.00007 Conformal invariance in two-dimensional turbulence. GUIDO BOFFETTA, University of Torino, Italy, DENIS BERNARD, Ecole Normale Superieure, Paris, ANTONIO CELANI, Institut Pasteur, Paris, GREGORY FALKOVICH, Weizmann Institute, Israel — We show that some features of two-dimensional turbulence display conformal invariance. In particular, the statistics of vorticity clusters in the inverse cascade is equivalent to that of critical percolation, one of the simplest universality classes of critical phenomena. Vorticity isolines are therefore described by Stochastic Loewner Equation curves SLE\(_c\). This result is generalized to a class of 2d turbulent systems, including Surface Quasi-Geostrophic turbulence (which corresponds to SLE\(_c\)) and Charney-Hasegawa-Mima turbulence. The picture emerging from our results is that conformal invariance may be expected for inverse cascades in two-dimensions therefore opening new perspectives in our understanding of 2d turbulent flows. References: D. Bernard, G. Boffetta, A. Celani, and G. Falkovich, Nature Physics 2 124 (2006) D. Bernard, G. Boffetta, A. Celani, and G. Falkovich, Phys. Rev. Lett. 98 024501 (2007)

4:18PM D9.00008 Mixing and entrainment of oceanic overflows: Implications for global climate evolution. ROBERT ECKE, JUN CHEN, PHILIPPE ODIER1, MICHAEL RIVERA, Los Alamos National Laboratory — Oceanic overflows are important elements of the Earth’s global thermohaline circulation but the mixing and entrainment that occur for such overflows is poorly understood. In particular, as overflow water moves down an inclined slope its stability is governed by the competition between stratification, which stabilizes the flow, and vertical shear, which tends to destabilize the flow. The properties of our laboratory experiment are designed to mimic oceanic overflows to the extent achievable on laboratory-accessible length scales. The flow exits a nozzle and flows along an inclined plane such that there is gravitational forcing of the flowing gravity current. Velocity and density fields are measured simultaneously using particle image velocimetry and planar laser induced fluorescence. The flow structure and dynamics of mixing at different downstream locations are investigated for a different levels of stratification and shear. The role of turbulence is examined by comparing cases of turbulent and laminar gravity currents. The implication of these results for ocean simulations and for understanding global climate are discussed.

1permanent address: ENS Lyon, France

4:30PM D9.00009 Experimental Investigation of Homogeneity, Isotropy, and Circulation of the Velocity Field in Buoyancy-Driven Turbulence. QUAN ZHOU, Department of Physics, the Chinese University of Hong Kong, CHAO SUN, Department of Applied Physics, University of Twente, KEQING XIA, Department of Physics, the Chinese University of Hong Kong — We present a direct multipoint velocity measurements of the 2D velocity field in the central region of turbulent Rayleigh-Bénard convection. The local homogeneity and isotropy of the velocity field are tested using a number of criteria and are found to hold to an excellent degree. The distribution of \( \Gamma_r \) is found to depend on the scale \( r \), reflecting strong intermittency. Besides, the slight asymmetry of the distribution tails reflects the fact that the velocity circulation structure functions (CSFs) are able to capture anisotropic coherent structures, such as thermal plumes, more effectively than longitudinal structure functions (LSFs) and transversal structure functions (TSFs). It is further found that velocity circulation has the same anomalous scaling exponents as LSFs and TSFs for low-order moments \( \langle p \rangle < 5 \). Whereas, for high-order moments \( \langle p \rangle > 5 \), the anomalous scaling exponents for circulation are found to be systematically smaller than those of LSFs and TSFs.

4:42PM D9.00010 Flow mode transitions in turbulent thermal convection¹, HENG-DONG XI, KE-QING XIA, The Chinese University of Hong Kong — We report an experimental study of structures and dynamics of the large-scale mean flow in Rayleigh-Bénard convection cells with aspect ratio (Γ) 1, 1/2 and 1/3. It is found that both a single circulating roll flow structure and two vertically stacked counter-rotating rolls exist in the three aspect ratio cells. The average percentage of time that the large-scale mean flow spends in the single-roll mode (SRM) and the double-roll mode (DRM) are 87.1% and 0.8% for Γ = 1; 69.5% and 7.9% for Γ = 1/2; and 26.7% and 34.1% for Γ = 1/3. Several routes of transitions among the different flow modes are identified. In addition, fluctuations in the flow structures are found and their relative weights are determined. We also show direct evidence that the SRM is more efficient for heat transfer than the DRM. Although the difference is very small, it shows how changes in internal flow state can manifest in the global transport properties of the system. It is also found that the time interval between successive flow mode transitions has an exponential distribution, suggesting a Poisson process for the underlying dynamics. The duration of the flow mode transition is found to be log-normally distributed.

4:54PM D9.00011 The properties of elastic turbulence in semi-dilute polymer solutions, YONGGUN JUN, Physics of Complex Systems, Weizmann Institute of Science, VICTOR STEINBERG — We studied elastic turbulence in Karman swirling flow of semi-dilute polymer solution. The concentrations of polymer solution used in the experiment were 100, 300, 500, 700, and 900 ppm, and the velocity fields to calculate the rms of the gradients of the tangential velocity, \( \omega_{rms} \), were obtained using PIV. First we checked the saturation of \( \omega_{rms} \) in the bulk, which represents the saturation of elastic stress. We found that \( \Omega_{bulk} = \omega_{rms} \tau \) saturates and approaches to unitary value as the polymer concentration increases. Here \( \tau \) is the longest polymer relaxation time. Also we studied existence of the velocity boundary layer which is related to boundary layer of elastic stresses of elastic turbulence. The thickness of the boundary layer is the decreasing function of polymer concentration near the rotating upper plate but independent of concentrations near the wall.

5:06PM D9.00012 Geometry of plane Couette flow transitional turbulence, PREDRAG CVITANOVIC, JOHN GIBSON, JONATHAN HALCROW, Georgia Tech — We propose to use a hierarchy of exact unstable invariant solutions of the Navier-Stokes equations — corresponding to the recurrent coherent structures observed in experiments — to construct a description of the spatio-temporally chaotic dynamics of turbulent fluid flows as a walk through the space of such structures. This description should allow us to obtain quantitative predictions of transport properties of fluid flows such as bulk flow rate and mean wall drag.

5:18PM D9.00013 The heat transfer of water-based Al₂O₃ nanofluid in turbulent Rayleigh-Bénard convection¹, SHENG-QI ZHOU, RUI NI, KE-QING XIA, Dept. of Physics, The Chinese University of Hong Kong, Hong Kong — We report experimental measurements of the convective heat transfer in water-based Al₂O₃ nanofluid in a cylindrical convection cell, which has 19 cm in both height and diameter. The nanofluid has been supplied by Nanophase Technologies Inc. with an initial volume fraction (φ) 22%. It has been diluted into deionized water to obtain nanofluid of low volume fraction. The nominal diameter of Al₂O₃ particle is 45 nm. At the fixed heating power, \( Q = 500W \), it has been found that the convective heat transfer coefficient (h = Q/\( \Delta T \)) decreases to 2% when φ varies from 0.03% to 1.1%. At φ = 1.1%, we have measured the Nusselt number (Nu) as a function of Rayleigh number (Ra). It has been found that Nu of nanofluid collapses on the Nu ∼ Ra scaling curve of pure water at higher Ra (4 × 10⁹ to 1 × 10¹⁰). While the deterioration of convective heat transfer has been observed at lower Ra (8 × 10⁸ to 4 × 10⁹), and the deterioration becomes more pronounced with decreasing Ra. Additional measurement on the thermal and flow structures is in progress to understand the convective heat transfer in nanofluid.

Monday, March 10, 2008 2:30PM - 5:06PM — Session D10 DMP: Focus Session: Hybrid Magnetic-Superconducting Systems I Morial Convention Center R08

2:30PM D10.00001 Odd-frequency pairing state in superconducting junctions, YUKIO TANAKA, Nagoya University — We have theoretically studied the induced odd-frequency pairing states in ballistic normal metal/superconductor (N/S) junctions where a superconductor has even-frequency symmetry in the bulk. We demonstrate that the pair amplitude in the junction has an admixture of an odd-frequency component due to the breakdown of translational invariance near the N/S interface [1]. We have also studied about the proximity effect in junctions between diffusive normal metals (DN) and superconductors. It is revealed for spin-triplet superconductor that the resulting symmetry in DN is always odd-frequency component due to the breakdown of translational invariance near the N/S interface [1]. We have also studied about the proximity effect in junctions between diffusive normal metals (DN) and superconductors. It is revealed for spin-triplet superconductor that the resulting symmetry in DN is always odd-frequency component due to the breakdown of translational invariance near the N/S interface [1]. We have also studied about the proximity effect in junctions between diffusive normal metals (DN) and superconductors. It is revealed for spin-triplet superconductor that the resulting symmetry in DN is always odd-frequency component due to the breakdown of translational invariance near the N/S interface [1]. We have also studied about the proximity effect in junctions between diffusive normal metals (DN) and superconductors. It is revealed for spin-triplet superconductor that the resulting symmetry in DN is always odd-frequency component due to the breakdown of translational invariance near the N/S interface [1].

3:06PM D10.00002 Superfluid density in the ferromagnetic layers of superconductor-ferromagnet hybrid structures, THOMAS LEMBERGER, MICHAEL HINTON, ADAM HAUSER, JULIAN HETEL, FENGYUAN YANG, JULIA MEYER, The Ohio State University — We have measured the areal superfluid density of superconductor-ferromagnet bilayers and trilayers. Samples are made by sputtering Nb and Ni films sequentially in an ultrahigh vacuum chamber with base pressure <10⁻¹⁰ torr. Interfaces are cleaner when Ni is sputtered onto Nb for reasons related to disorder at the initial growth of Nb films. Superfluid density is measured using a low-frequency (50 kHz) two-coil technique with coils on opposite sides of the sample. These measurements provide the true \( T_C \), i.e., the temperature below which superfluid exists. We find a nonmonotonic dependence of \( T_C \) on ferromagnetic layer thickness, in agreement with resistive measurements of \( T_C \). The superfluid density is also nonmonotonic. Even at large ferromagnetic layer thicknesses where \( T_C \) is essentially constant, the areal superfluid density continues to increase, indicating that superfluid extends deeply into the ferromagnet layers. We will discuss these measurements in the context of theory of the superconductor-ferromagnet proximity effect.
3:18PM D10.00003 Study of Inverse Proximity Effect in Ferromagnet/ Superconductor Bilayers Using a Sagnac Interferometer\(^1\), JING XIA, Stanford University, A. PALEVSKI, Tel Aviv University, A. KAPITULNIK, Stanford University — It was recently proposed theoretically that ferromagnetic order can be induced in the superconductor in a ferromagnet/superconductor \((S/F)\) bilayer structure through a so-called inverse proximity effect. The proposal predicts a sizable magnetic moment in the \(S\) layer that couples antiferromagnetically to the moment in the \(F\) layer due to Cooper pairs near the interface formed with one electron in the \(F\) layer and one in the \(S\) layer. The induced magnetic moment is expected to penetrate the superconductor over a size of the Cooper pairs, i.e. \(\xi_s\). In order to directly test this interesting scenario, we fabricated \(Ni/Pb\) and \(Ni/Al\) bilayer samples and probed the possible induced magnetic moments in the \(S\) layer through high resolution Surface Magneto Optical Polar Kerr Effect (PKE) measurements on the \(S\) layer side through the bilayer’s \(T_C\) using a Sagnac interferometer. The thickness of the \(S\) layer was fabricated to be larger than the optical skin depth in order to make sure that our experiment doesn’t pickup any magnetic moment from the \(F\) layer. \(\xi_s\) dependence of the effect is studied by comparing the results in \(Ni/Pb\) and \(Ni/Al\) samples.

3:30PM D10.00004 Investigation of the role of Al/CoFe interface in proximity effect of Nb/Al/CoFe \(^1\), K. CHAR, JUNHYUNG KWON, WENJIAN LU, Seoul National University, MDPL TEAM — When a few nm-thick Al layer is inserted between Nb and ferromagnetic (F) layers such as CoFe, Ni, or CuNi, the superconducting critical temperature of the trilayers increases rapidly almost to a level of Nb/Al bilayers. In order to understand the role of Al/CoFe interface in the proximity effect of Nb/Al/CoFe, we have added Mg and Au scattering centers and found different behavior. The Mg scattering center did not change the critical temperature behavior of Nb/Al/CoFe, while the Au scattering centers reduced the critical temperature. The results point toward the importance of spin-orbit scattering. In addition, tunneling spectroscopy data on Nb/Al/F vs. on Nb/F will be presented in order to further characterize the role of Al/F interfaces.

3:42PM D10.00005 Magnetic property change by superconductivity in Py-Nb Hybrid system\(^1\), DAVID MURAKAMI, MICHAEL HETMAN, JIYEONG GU, Department of Physics and Astronomy, California State University, Long Beach — Recently ferromagnet/superconductor systems have attracted a great attention due to their scientific interest and potential for the technological application. So far, most of the work focused on the superconducting property change by magnetism in the hybrid system, and only few researches focused on the magnetic property change by superconductivity. In this presentation we will focus on the magnetic property change of the system by superconductivity when the system goes through the superconducting transition. We have investigated different types of hybrid structures including Py/Nb bilayer, multilayer, and composite systems. To separate out the signal from superconductor, we also measured the single Nb film. We measured the magnetization as a function of temperature and compared it between in a normal state and a superconducting state for the different types of structures. It showed strong magnetic history dependence.

\(^1\)This project is supported by Research Corporation Grant #CC6756 and NSF MRI Grant #0619909

3:54PM D10.00006 Proximity effect in MgB\(_2\)-Permalloy hybrid system\(^1\), APRIL O’BRIEN, JIYEONG GU, Department of Physics and Astronomy, California State University, Long Beach — Recently ferromagnet/superconductor systems have attracted a great attention due to their scientific interest and potential for the technological application. So far, most of the work has been done for Nb with ferromagnetic metals or high temperature oxide superconductors with magnetic oxides. In this presentation we will discuss the proximity effect in magnesium diboride (MgB\(_2\))/Py thin films, where the superconducting property changes due to the adjacent Py layer. Even though the good electronic properties such as large critical current density and large coherence length of MgB\(_2\) make it a good candidate for superconducting electronic applications, depositing a good-quality in-situ MgB\(_2\) thin film is still challenging. Especially for the multilayer deposition, it is ideal to deposit all the layers in-situ without ex-situ treatment. We used a sputtering to deposit the MgB\(_2\) layer in-situ and made a hybrid system with Py. We found that the substrate temperature during the MgB\(_2\) deposition is the most important parameter to determine the superconducting transition temperature of the sample. In addition to the proximity effect we will also discuss the problem with a sputtering method for MgB\(_2\) deposition.

4:06PM D10.00007 Spin-switch effect in Permalloy-Niobium hybrid system\(^1\), JIYEONG GU, MICHAEL HETMAN, Department of Physics and Astronomy, California State University, Long Beach — Proximity effect in ferromagnet (F)/superconductor (S) systems has become a center of attention recently. It has been well known that the superconducting property is modified when the magnetization of the adjacent F layer changes. Especially when the superconducting transition temperature changes as a function of the magnetization of the F layers, the system can work as a switching device. In this presentation we compare three different Py-Nb hybrid structures; Py/Nb bilayer, Py/Nb/Py/FeMn spin valve, and Nb/Py/Nb/Py/FeMn \((S-F-F)\) structure. We discuss the similarity and the difference in magnetic and transport properties of these three structures. When the Nb layer is thick in bilayer or \(S - F - F\) structure, the device showed a change between zero resistance (superconducting state) and finite resistance (normal state) by applying a small external magnetic field, where the shift in transition temperature is greater than the transition width, and this gave a large magnetoresistance effect \((|R(0)-R(H)|)/R(0)=\infty)\).

4:18PM D10.00008 Anomalous transport property in the single-crystal Co nanowire with superconducting electrodes\(^1\), JIAN WANG, NITESH KUMAR, MINGLIANG TIAN, QI ZHANG, JAINENDRA JAIN, THOMAS MALLOUK, MOSES H.W. CHAN, Center for Nanoscale Science, Penn State University — Transport measurements were made on individual single-crystal Co nanowire with four focused ion beam (FIB) deposited tungsten (W) electrodes, which are superconducting below 5 K. It was found that the 2 microns long Co nanowire shows a sharp and large resistance peak near the onset transition temperature \(T_C\) of W and a rapid resistance drop below \(T_C\). The large, 50% resistance drop at low temperature suggests the proximity effect from superconducting W electrodes extends to a large fraction of the ferromagnetic Co nanowire. The resistance peak is not seen in the Au nanowire with same superconducting W electrodes. Measurements on a Co nanowire contacted with FIB deposited non-superconducting Pt electrodes show no change in resistance.

\(^1\)Work supported by NSF MRSEC program under grant DMR-0213623.
4:30PM D10.00009 Transport properties of hybrid superconductor/ferromagnet nanowires fabricated by electrodeposition.\(^1\). NITESH KUMAR, JIAN WANG, QI ZHANG, MINGLIANG TIAN, MOSES H.W. CHAN, Center for Nanoscale Science, Penn State University — We have fabricated multilayer nanowires with alternating superconducting and ferromagnetic segments using template-based electrodeposition. Nanowires are fabricated with different diameters and length, with individual segments on the length scale of few hundreds of nm to few microns, using both porous polycarbonate and anodized alumina membranes. We have used Pb as the superconducting and Co or Ni as the ferromagnetic components. Structural characterizations done with X-ray diffraction and Transmission Electron Microscope demonstrated that Pb and Co segments are good single crystal whereas Ni segments are polycrystalline. We have done electrical transport measurements on arrays of multilayer nanowires (embedded inside the template) showing interesting magnetoresistance behaviors below the superconducting transition temperature of Pb. Four terminal electrical measurements on a single multilayer nanowire are in progress.

4:42PM D10.00010 Ferromagnetic Josephson Resonance, IVANA PETKOVIC, MARCO APRILI. Laboratoire de Physique des Solides, Univ. Paris-Sud, CNRS, UMR 8502, F-91405 Orsay Cedex, France — Ferromagnetic Josephson junctions with negative ($\pi$-) coupling behave as phase sources, a potentially very useful component of quantum electronics. In order to elaborate sophisticated circuits, it is crucial to understand the interplay between spin- and superconducting phase dynamics. For that purpose, we fabricated strongly underdamped sub-micron Josephson junctions. We measured the critical current at zero voltage as a function of the applied magnetic field. The finite magnetization in the junction induces a shift in the Fraunhofer pattern which is invariant under time reversal. For a voltage such that the Josephson frequency matches the ferromagnetic resonance, we observe a reduction of the critical current due to the absorption of the Josephson radiation by the ferromagnetic layer. We have investigated the effect of an external microwave radiation and of the magnetic field. The resonances appear as satellites at every Shapiro step and they are shifted in energy by the magnetic field as expected. The high sensitivity of the ac Josephson effect to a small amount of spins opens up new routes for ESR in nano-magnetism.

4:54PM D10.00011 Theory of spin wave excitation by Josephson current in a superconductor/ferromagnet/superconductor junction, SHIN-ICHI HIKINO, MICHIAYASU MORI, SABURO TAKAHASHI, SADAMICHI MAEKAWA, Institute for Materials Research, Tohoku University — The Joseph effect in a superconductor/ferromagnet/superconductor junction has been of considerable interest in recent years. Current-voltage (I-V) characteristics of superconducting weak links are studied by the resistively shunted junction (RSJ) model, which describes phase dynamics of superconductors (SC). The ferromagnet (F) has spin waves (SW). Therefore, in an S/F/S junction, it is important to treat the spin- and phase dynamics in an equal footing. However, the spin dynamics has not received much attention in the study of an S/F/S junction. We study the effect of the spin dynamics on the phase dynamics in an S/F/S junction. The RSJ model is extended to include the spin dynamics using gauge invariant phase difference between superconducting leads. We find that the I-V characteristics show step structures. The voltage at the steps is proportional to the SW energy in F. The origin of step structures will be discussed.

Monday, March 10, 2008 2:30PM - 5:18PM – Session D11 DCMP: Inhomogeneous Superconductors and Transport Morial Convention Center R09

2:30PM D11.00002 Disorder, Metal-Insulator crossover and Phase diagram in high-T\(_c\) cuprates, FLORENCE RULLIER-ALBENQUE, SPEC - CEA, HENRI ALLOUL, LPS - CNRS, FEDOR BALAKIREV, NHFML - Los Alamos, CYRIL PROUST, LNCMP - CNRS — We have studied the influence of disorder induced by electron irradiation on the normal state resistivities \(\rho(T)\) of optimally and underdoped YBa\(_2\)Cu\(_3\)O\(_y\) single crystals, using pulsed magnetic fields up to 60T to completely restore the normal state. We evidence that point defect disorder induces low \(T\) upturns of \(\rho(T)\) which saturate in some cases at low \(T\) in large applied fields as would be expected for a Kondo-like magnetic response. Moreover the magnitude of the upturns is related to the residual resistivity, that is to the concentration of defects and/or their nanoscale morphology. These upturns are found quantitatively, K. H. SARWA, B. TAN, KEVIN A. PARENDO, YEN-HSIANG LIN, Disorder-Tuned Superconductor-Insulator Transition, Department of Physics, University of Virginia — Highly disordered superconducting thin films exhibit a variety of novel phenomena, such as a possible metallic phase intervening the superconducting and the insulating state, and a huge peak in the magnetoresistance curve. Different theories have been proposed, including the quantum-vortex theory, the percolation picture of superconducting islands embedded in a normal metal, and the Bose metal theory. We propose that a drag resistance measurement in a bilayer setup would easily be able to determine which of the models applies. In such an experiment, two thin film superconductors are fabricated parallel to each other, separated by a thin insulator. A current bias is applied in one layer, and a voltage appears in the other due to the interaction between vortices (as in a Giaever transformer), or charge carriers (e.g., Coulomb drag), in different layers. Our calculation of the drag resistance in the various pictures will be discussed.

2:54PM D11.00003 Drag resistance in bilayer disordered superconducting thin films, YUE ZOU, ALLEN M. GOLDMAN, University of Minnesota, Minneapolis, MN 55455, USA — The effect of a perpendicular magnetic field on disordered, amorphous and insulating indium oxide thin films has been investigated. The temperature dependence of the resistance in zero magnetic field, the magnetoresistance pattern which is invariant under time reversal. For a voltage such that the Josephson frequency matches the ferromagnetic resonance, we observe a reduction of the critical current due to the absorption of the Josephson radiation by the ferromagnetic layer. We have investigated the effect of an external microwave radiation and of the magnetic field. The resonances appear as satellites at every Shapiro step and they are shifted in energy by the magnetic field as expected. The high sensitivity of the ac Josephson effect to a small amount of spins opens up new routes for ESR in nano-magnetism.

2:42PM D11.00010 Ferromagnetic Josephson Resonance, IVANA PETKOVIC, MARCO APRILI. Laboratoire de Physique des Solides, Univ. Paris-Sud, CNRS, UMR 8502, F-91405 Orsay Cedex, France — Ferromagnetic Josephson junctions with negative ($\pi$-) coupling behave as phase sources, a potentially very useful component of quantum electronics. In order to elaborate sophisticated circuits, it is crucial to understand the interplay between spin- and superconducting phase dynamics. For that purpose, we fabricated strongly underdamped sub-micron Josephson junctions. We measured the critical current at zero voltage as a function of the applied magnetic field. The finite magnetization in the junction induces a shift in the Fraunhofer pattern which is invariant under time reversal. For a voltage such that the Josephson frequency matches the ferromagnetic resonance, we observe a reduction of the critical current due to the absorption of the Josephson radiation by the ferromagnetic layer. The resonances appear as satellites at every Shapiro step and they are shifted in energy by the magnetic field as expected. The high sensitivity of the ac Josephson effect to a small amount of spins opens up new routes for ESR in nano-magnetism.
3:06PM D11.00004 Granularity-induced field-hysteresis of transport critical current in patterned coated conductors, A. A. GAPUD, A. KHAN, University of South Alabama, D. K. CHRISTEN, F. A. LIST III, R. FEENSTRA, Oak Ridge National Laboratory — In superconducting coated conductors such as RABiTS and IBAD films, intergranular misorientations have been effectively minimized, but a small number of local, higher-angle misorientations remain. One important effect of such weak links is the hysteresis of the critical current density $J_c$ with respect to applied field $H$. Brought about when large circulating currents trapped within adjacent grains produce a focused field within the grain boundaries (GB’s) which can partially cancel out $H$ when applied field is decreasing, thus shifting the maximum $J_c$ from zero $H_{0}$ to a finite field where the local field at the GB is at minimum. This effect has been seen recently in measurements of magnetization (induced) currents, but has not been documented using transport (applied) current. However, in samples that are patterned into conduits 200 μm wide or less, the hysteretic effect on transport $J_c$ is clearly seen. This discrepancy between ‘magnetization $J_c$’ and ‘transport $J_c$’ may be due to differences in voltage criterion between the two types of measurement, as will be discussed. Systematic measurements and analyses will be presented, along with ramifications for applications.

1Research at ORNL sponsored by US Department of Energy

3:18PM D11.00005 Disorder induced resistivity upturns in metallic cuprates, BRIAN M. ANDERSEN, Nano-Science Center, Niels Bohr Institute, University of Copenhagen, WEI CHEN, PETER J. HIRSCHFELD, Department of Physics, University of Florida — We propose that experimentally observed resistivity upturn of cuprates at low temperature may be explained by properly accounting for the effects of disorder in a strongly correlated metallic host. Calculating DC transport using real space exact diagonalization of a Hubbard model treated in an inhomogeneous Hartree-Fock approximation, we find that correlations induce magnetization around impurities with screening length which increases strongly as temperature decreases, giving rise to additional magnetic scattering which causes the resistivity upturn. This paramagnetic response together with the electronic band structure effect is capable of explaining the magnetoresistance as observed in disordered optimally doped YBCO.

3:30PM D11.00006 Interrelations between superconducting properties and defect evolution in neutron irradiated YBa$_2$Cu$_3$O$_{7-x}$. VIOREL SANDU, GHEORGHE ALDICA, National Institute of Materials Physics, ELENA SANDU, National Institute of Nuclear Physics and Engineering “Horia Hulubei”, PETRU NITA, METAV-Research and Development Bucharest — We investigated the effect of neutron irradiation on the electric and magnetic properties, as well as the enhancement of the critical current density, of ceramic YBa$_2$Cu$_3$O$_{7-x}$ (LiF)$_x$ samples. The superconducting properties of the virgin samples reach the optimal values for $x = 0.04$. Up to the same $x$ value, the neutron irradiation up to $5 \times 10^{17}$ neutrons/cm$^2$ enhances the superconducting response (critical temperature, transition width, etc) and double up the magnetic irreversibility. For $x \geq 0.08$, all the superconducting properties are depressed whereas the increase of the irreversible magnetization is still present but less spectacular. The analysis of this behavior suggests a self-organization of the defects at low LiF content while for $x \geq 0.08$ they are uniformly distributed within sample.

3:42PM D11.00007 Negative Nernst effect in simulations of granular superconductors, ANDREAS ANDERSSON, JACK LIDMAR, KTH Stockholm — The Nernst effect has recently become an important probe of superconducting fluctuations in high-Tc superconductors. The sign of the Nernst coefficient $\alpha$ is believed to be negative for metallic cuprates. Using real-space exact diagonalization, we find that $\alpha$ is negative for certain concentrations of dopants.

4:06PM D11.00009 Isotope Effect in High-Tc Superconductors, DALE HARSHMAN, Physikon Research Corp., JOHN DOW, Arizona State University, ANTHONY FIORY, New Jersey Institute of Technology — For high-Tc superconductors in which transition temperatures, $T_c$, are reduced by doping, the oxygen isotope effect (OIE) coefficient in $T_c$ is shown to increase systematically with the pairing-breaking rate and with the valence difference between the substituted and native ions. Moreover, the OIE tends to zero as one approaches optimum (or ideal) stoichiometry at which the quality of the superconducting condensate is maximized. In materials with isovalent substitutions, e.g., Sr for Ba or Zn for Cu in YBCO, the small OIE of the parent compound is magnified, owing to pair-breaking disorder. In materials with heterovalent substitutions, e.g., La or Pr for Ba, where carrier densities are necessarily changed, pair breaking induces a much larger OIE. A seminal case is Pr-doped YBCO, where the decrease in $T_c$ observed with Pr doping arises from pair-breaking caused by Pr-on-Ba-site defects. Without the defects, $T_c$ is invariant, providing strong evidence against phononic mechanisms. The fact that $T_c$ drops when Pr substitutes for Ba, but not for Y, indicates that the superconducting hole condensate resides in the BaO layers, where pair-breaking degrades $T_c$ and dramatically increases the OIE. Superconductive pairing modeled on Coulomb coupling between the hole and the electron layers is shown to resolve the shortcomings in electron-electron interactions.

4:18PM D11.00010 Rich Behavior of the Critical Currents of Magnetically-Doped Superconducting Films in Applied Magnetic Fields, JEFFREY Wasserman, NINA MARKOVIC, Johns Hopkins University — Films of MoGe were grown with varying dopant levels of cobalt contamination. Critical currents curves reveal significantly different behavior depending on the polarity of the current with respect to the applied field. At sufficiently-high dopant concentrations, the critical current increases with increasing magnetic field intensity for one polarity of current. We will discuss these results in terms of pair-breaking effects of magnetic fields and magnetic impurities.

4:30PM D11.00011 Analytic description of the transport $J_\epsilon(B)$ dependence of HTS thin films in small magnetic fields. Jens Hännisch, Francesco Grilli, Los Alamos National Laboratory, Mail Stop T004, Los Alamos, 87545 NM, Sebastian Engel, Bernhard Holzapfel, IFW Dresden, Helmholtzstr. 20, 01069 Dresden, Germany — Often, e.g. for deconvolution processes and field distribution calculations, an analytical function for the $J_\epsilon(B)$ dependence of high-$T_c$ thin films is needed. The parameters of these functions should still have a physical meaning regarding the intrinsic and extrinsic sample properties. Starting with the modified Kim model, described by Xu et al., we found an excellent function by introducing a sharpness parameter $\beta$. This parameter describes the shape of $J_\epsilon(B)$ between the low-field plateau (single vortex pinning regime) and the power-law dependence at higher fields. The temperature dependence of all fitting parameters will be discussed. Furthermore, the importance of the field dependence of the $\nu$ value for distinguishing different pinning regimes will be illustrated.

4:42PM D11.00012 Investigation of Vortex Pinning Anisotropy in the High Temperature Superconductor YBa$_2$Cu$_3$O$_{7-\delta}$, Andra Petrean-Troncalli, Austin College, Lisa Paulius, Western Michigan University, Heather Quantz, Austin College, Valentine Tobos, Lawrence Technological University, Wai-K Kwok, Argonne National Laboratory — Columnar defects have proven to be highly effective at pinning vortices, but most studies have been performed with the defects oriented either perpendicular or at large angles relative to the superconducting Cu-O planes. These studies have shown that the intrinsic pinning anisotropy of the crystal can actually be reversed by sufficiently strong columnar defects oriented parallel to the Cu-O planes. We have preliminary data that indicate that the pinning anisotropy is actually enhanced for columnar defects introduced parallel to the superconducting Cu-O planes. A single crystal of YBa$_2$Cu$_3$O$_{7-\delta}$ was polished down to a narrow width of 27 $\mu$m, allowing heavy ions to penetrate the crystal along the ab-plane. The crystal was irradiated with 1.4 GeV $^{208}$Pb ions to a dose matching field of 1T.

5:06PM D11.00014 Interface superconductivity in bi-layers of insulating and overdoped metallic La$_{2-x}$Sr$_x$CuO$_{4+\delta}$, Adrian Gozar, Gennady Logvenov, Anthony Bollinger, Ivan Bozovic, Brookhaven National Laboratory — We report on properties of thin superconducting (SC) sheets obtained in La$_{2-x}$Sr$_x$CuO$_{4+\delta}$ bi-layers of overdoped, non-superconducting (x = 0.45) and insulating (x = 0) films grown by molecular beam epitaxy. Superconductivity is confined to a thickness of $\approx$ 2 nm from the interface. The observed transition temperatures have values $T_c$ = 15 K, 30 K and 50 K depending on the layering sequence and oxidation state of the insulating material. Transport measurements are used to determine the screening properties of the quasi-2D SC sheets and the data in bi-layers are compared to results from single-phase films and bulk crystals.

Monday, March 10, 2008 2:30PM - 5:18PM – Session D12 DCMP: Theory of Ferroelectric, Multiferroic, and Other Structural Transitions Morial Convention Center 203

2:30PM D12.00001 Dynamics of domains switching in epitaxial BaTiO$_3$/SrTiO$_3$ superlattices from first principles. Sergey Lisenkov, Inna Ponomareva, Laurent Bellaiche, University of Arkansas — Superlattices (SL) consisting of alternating layers of perovskite oxides can possess properties that are dramatically different from those of bulk ferroelectrics. [BaTiO$_3$/SrTiO$_3$]$_n$ (BT/ST) SL with relatively large periods exhibit novel nanostripe domains for some specific epitaxial strains and within a particular temperature window [1]. Here, an effective Hamiltonian approach is used within molecular dynamics method to predict the evolution of these nanostripe domains in BT/ST SL under an ac electric field applied along the SL growth direction. For any investigated frequency, four different regimes occur, depending on the magnitude of the electric field. Region I that consists of nanostripe domains in both BT and ST layers; Region II that exhibits nanostripe domains in BT layers while possessing monodomains in ST layers; Region III where bubble domains in BT layers coexist with monodomains in ST layers; and Region IV where monodomains form in both BT and ST layers. The dependency of the domain velocities, activation and critical fields on the field frequency is revealed. [1] Lisenkov et al., Phys. Rev. B, 76, 020102(R) (2007).

2:42PM D12.00002 Ferromagnetic-like closure domains in ferroelectric ultrathin films: First principles simulation. Javier Junquera, Pablo Agudo-Puente, Dep. CITIMAC, Universitad de Cantabria, Avda. de los Castros s/n, E-39005, Santander, Spain — We simulate from first-principles the energetic, structural, and electronic properties of ferroelectric domains in ultrathin capacitors made of a few unit cells of BaTiO$_3$ between two metallic SrRuO$_3$ electrodes in short circuit. The domains are stabilized down to two unit cells, adopting the form of a domain of closure, common in ferromagnets but only recently detected experimentally in ferroelectric thin films. The domains are closed by the in-plane relaxation of the atoms in the first SrO layer of the electrode, that behaves more like SrO in highly polarizable SrTiO$_3$ than in metallic SrRuO$_3$. Even if small, these lateral displacements are essential to stabilize the domains, and might provide some hints to explain why some systems break into domains while others remain in a monodomain configuration. An analysis of the electrostatic potential reveals preferential points of pinning for charged defects at the ferroelectric-electrode interface, possibly playing a major role in films fatigue.

2:54PM D12.00003 The theory of domain patterns in ferroelastics, ALLAN JACOBS, Physics, University of Toronto — The theory of ferroelastic domain patterns is well developed and it explains qualitatively the domain patterns observed experimentally in many materials. It is known that much of the complexity of these patterns, which differ remarkably from those in conventional order-parameter systems, results from the differential rotation associated with domain walls. But there has been no direct confrontation between theory and experiment at a more quantitative level. I propose here such a confrontation. Specifically, I shall present predictions (obtained from numerical work) of the atomic displacements at the collision of orthogonal domain walls in tetragonal-orthorhombic ferroelastics and suggest that they be compared with HREM images of these materials.

3:06PM D12.00004 Peculiar ordering in flat ferroelectric nanoparticles driven by lattice misfit, IVAN NAUMOV, ALEX BRATKOVSKY, Hewlett-Packard Laboratories — Flat free-standing ferroelectric (FE) nanoparticles tend to have a vortex-like polarization ordering with the in-plane polarization that curls around an out-of-plane vortex core axis. The question is, if such a structure is still a ground state in presence of noticeable misfit strains induced by a substrate, and whether the 180° stripe domains may form, similarly to the case of ultra thin FE films? Here we perform an ab initio based study of disk- shaped Pb(Zr1−Ti1)O3 and BaTiO3 nanoparticles that have the vortex ground state when no stress is applied. Our study leads to the following findings for the disks having circular and square footprint: (i) under strong enough compressive strains the curling state is no longer stable and yields to a multi-domain structure with an out of-plane polarization, and different possible in-plane domains: triangle, stripe-like, or “bubble” states. (ii) each separate domain, regardless of its shape, runs through the entire thickness of a disk, and (iii) the 180° stripes occur only under special conditions depending on the shape and chemical composition of the nanostructures. Further, we discovered that starting with the vortex state and then increasing the compressive strains may lead to a metastable bi- or multi-domain phase different from the ground state obtained by gradual cooling at a fixed strain. This leads to a novel hysteretic behavior as a function of the misfit strain.

3:18PM D12.00005 Static and Dynamic Properties of Ferroelectric Nanostructures and Multiferroic Bulk Systems: A Multiscale Approach1, T. MICHAEL, S. TRIMPER, Martin-Luther-University, Halle, Germany, J.M. WESSELINOWA, University of Sofia, Bulgaria — Ferroelectric nanostructures and multiferroic bulk systems are studied in a multiscale approach. The excitation energy, associated damping of ferroelectric modes and polarization are presented as a function of temperature, defect concentration, size and shape. The softening of the mode is strongly influenced by the kind of doping ions, the surface configuration and the defect composition. The analysis is based on a modified Ising model in a transverse field. A Green’s function technique in real space provides the static and dynamic properties, which differ significantly from the bulk behavior. Additionally, a mesoscopic approach is carried out similar to the Landau-Lifshitz equation with Gilbert damping for ferromagnets. The temperature dependence of the damping parameters is discussed. The analysis is extended to multiferroic bulk systems, where the magnetic moments interact via the Heisenberg model and the multiferroic coupling term differs for hexagonal and orthorhombic materials. We present the dielectric function and the dynamic properties of the coupled model by applying previous methods.

3:30PM D12.00006 A new order parameter in complex dipolar structures, SERGEY PROSANDEEV, LAURENT BELLAICHE, University of Arkansas — Microscopic models have been used to reveal the existence of a new order parameter that is associated with many complex dipolar structures in magnets and ferroelectrics. This overlooked order parameter involves a double cross product of the local dipoles with their positions. It provides a measure of subtle microscopic features, such as the helicity of the two domains inherent to onion states, curvature of the dipolar pattern in flower states or characteristics of set of vortices with opposite chirality (e.g., distance between vortices’ centers and/or magnitude of their local dipoles). This work is mostly supported by DOE grant DE-FG02-05ER46188. We also acknowledge support from ONR grant N00014-04-1-0413 and NSF grants DMR-0701558, DMR-0404335 and DMR-0800504 (C-SPIN). Some computations were made possible thanks to the MRI Grants 0421099 and 0726252 from NSF.

3:42PM D12.00007 Microscopic origin of Magnetic Ferroelectrics in Non-collinear Multiferroics, CHEN FANG, JIANGPING HU, Purdue University — We propose a microscopic mechanism to understand the origin of magnetoelectric coupling in the best known multiferroic family RmOn (R =Tb, Dy...). The mechanism lies in the vanishing of electric current in an insulator. A spontaneous electric polarization is thus necessary, as it causes an electric current through a spin-orbit coupling to cancel another nonzero local electric current induced by a non-collinear modulated magnetic structure. Within this counter-balance mechanism, the magnitude of the ferroelectric order is determined by the magnetic order parameter and the spin-orbit coupling strength. Based on the theory, we predict a general physical limit for the value of ferroelectricity.

3:54PM D12.00008 A theory for the multiferroic compound LiCu2O2, TRINANJAN DATTA, Department of Chemistry and Physics, Augusta State University, CHEN FANG, JIANGPING HU, Department of Physics, Purdue University — We investigate the possible coupling between ferroelectricity and magnetic structure in the zig-zag spin chain compound LiCu2O2. Based on a group theory analysis, we construct a multi-order parameter phenomenological model and show that a coupling involving the inter-chain magnetic structures and ferroelectricity is necessary in order to understand the experimental results of Park et al. The model is able to account for the electric polarization flip through π/2 and explain the occurrence of an electric polarization parallel to an applied external magnetic field.

4:06PM D12.00009 Phase-field model of strain-induced grain-boundary premelting1, NAN WANG, ROBERT SPATSCHEK, ALAIN KARMA, Physics Dept and CIRCs, Northeastern University — Grain-boundary premelting depends in a complex way on the relative magnitude of the solid-liquid interfacial free-energy and grain boundary energy as well as temperature and strain. We study this dependence in a bicrystal geometry using a mesoscale phenomenological three-order parameter phase-field model. This model describes the short scale attractive or repulsive interaction between crystal-melt interfaces and macroscopic linear elasticity including the important effect of the density contrast between solid and liquid. The model exhibits a rich behavior characterized by single or multiple premelting transitions between dry or wet grain boundaries with different liquid layer thicknesses as a function of applied tensile stress. The results have important implications for the phenomenon of liquid metal embrittlement associated with the stress-driven penetration of nanometric liquid films along grain boundaries.

4:18PM D12.00010 Incorporation of plasticity into the Landau-Ginzburg theory of martensitic phase transformations, ROMAN GRÖGER, TURAB LOOKMAN, Los Alamos National Laboratory, Theoretical Division — The Landau-Ginzburg theory of martensitic phase transformations has been utilized to reproduce the evolution of elastic texture in defect-free materials undergoing structural phase transformations. Generalizations of this theory to phase transformations that are accompanied by significant plastic distortions (as in U76Nb) have been little studied. We propose a simple model that demonstrates how to incorporate plasticity into the Landau-Ginzburg theory. In the presence of topological defects such as dislocations, the usual Saint Venant compatibility constraint becomes an incompatibility constraint and this is represented by a tensor field γij. In our case, the components of γij are expressed as gradients of the components of the Nye tensor that represent the dislocation density. The presence of dislocations induces large internal stresses in certain regions of the material, and these act as initiation sites for plastic deformation. When the external loading is applied, dislocations moving from these regions cause strain hardening that is detectable in experimental uniaxial measurements. This model serves as a starting point for further development of the framework of three-dimensional rate-independent theory of plasticity within the Landau-Ginzburg formalism.
4:30PM D12.00011 Phonon Driven BCC to Orthorhombic Transformation in U-Nb Alloys, AVADH SAXENA, TURAB LOOKMAN, Los Alamos National Lab — The martensitic transformation in uranium alloys is of great strategic importance. We study the crystallography and model the well characterized BCC to orthorhombic phase transformation in the shape memory alloy U-Nb for low Nb concentrations. Our predictions are consistent with the experimentally observed relationship between the BCC and orthorhombic phases. We find that this temperature induced transformation is driven by a specific zone boundary phonon that couples to a particular shear mode. We also obtain a Landau free energy for this transformation. In addition, we compare our results with a similar shuffle based mechanism in a related martensitic alloy AuZn.

4:42PM D12.00012 First-Principles Study of the Jahn-Teller Distortion in the Ti$_{1-x}$V$_x$H$_2$ and Zr$_{1-x}$Nb$_x$H$_2$ Alloys, RAMIRO QUIJANO, ROMEO DE COSS, CINVESTAV-Unidad Merida, DAVID SINGH, Oak Ridge National Laboratory, USA — The transition metal dihydrides TiH$_2$ and ZrH$_2$ present the fluorite structure (CaF$_2$) at high temperature but undergoes a tetragonal distortion with $c/a<1$ at low temperature. Electronic band structure calculations have shown that TiH$_2$ and ZrH$_2$ in the cubic phase display a very flat band at the Fermi level. Thus the low temperature tetragonal distortion has been associated to a Jahn-Teller effect. In order to understand the role of band filling in controlling the structural instability of the transition metal dihydrides, we have performed a first-principles total energy study of the Ti$_{1-x}$V$_x$H$_2$ and Zr$_{1-x}$Nb$_x$H$_2$ alloys. The calculations were performed using FP-LAPW method within the (DFT) and we use the GGA for exchange correlation functional energy. The critical concentration for which the Jahn-Teller effect is suppressed, was determined from the evolution of the tetragonal-cubic energy barrier. We discuss the electronic mechanism of the structural-instability, in terms of the band filling. From the obtained results we find that the tetragonal distortion in TiH$_2$ and ZrH$_2$ is not produced only by a Jahn-Teller Effect. This research was supported by Consejo Nacional de Ciencia y Tecnología (Conacyt) under Grant No. 43830-F.

4:54PM D12.00013 Density functional analysis of long range order, T.R.S. PRASANNA, IIT Bombay — A density functional analysis of order-disorder transitions in alloys shows that ordering energy is stored in superlattice wavevectors. Thermal vibrations play a key role and lower the transition temperature, T$_c$, to the experimental value (741 K) from the mean-field value (993 K) in the Bragg-Williams model for beta brass, $\beta$-CuZn. An isotope effect with 4 K difference in T$_c$ is predicted for $^{63}$Cu$^{64}$Zn and $^{65}$Cu$^{64}$Zn in a Modified Bragg-Williams model. The above conclusions are shown to be applicable in magnetic transitions as well. Theoretical analysis shows that thermal vibrations alter the exchange and total magnetic ordering energy. Every microscopic theory of magnetic and alloy phase transitions must satisfy the twin criteria that ordering energy is a) stored in superlattice wavevectors and b) a function of temperature due to thermal vibrations. An isotope effect is predicted to be a universal feature of alloy and magnetic phase transitions. The nuclear-nuclear energy term, $E_{nn}$, converges without artificial parameters if zero point vibrations are included unlike the Ewald sum technique.

5:06PM D12.00014 Ab-initio study of the structural and magnetic properties for the fcc Fe-Co alloy, FILIBERTO ORTIZ-CHI, Cinvestav Unidad Mérida, AARON AGUAYO, Universidad Autónoma de Yucatán, ROMEO DE COSS, CINVESTAV Unidad Mérida — We have studied the structural and magnetic properties of the fcc Fe-Co alloy by means of first-principles calculations. For modeling the alloy we have used the ab-initio self-consistent Virtual Crystal Approximation. The ground state properties was calculated with the Fixed Spin Moment methodology and the Full-Potential LAPW method. For the exchange-correlation potential we have used the Generalized Gradient Approximation. For ferromagnetic fcc-Fe we find an anti-invar behavior (ELS<AEHS) with the co-existence of two ferromagnetic states (metamagnetism). For the fcc-FeCo alloy we find a progressive evolution of the metamagnetism with the Co concentration. Using the calculated total-energy vs the lattice parameter and the Boltzmann distribution function, we have obtained the lattice parameter as function of the temperature, in order to determine the thermal expansion coefficient $\alpha$ as function of the Co-concentration. We find that Fe65Co35 show an invar behavior.

Monday, March 10, 2008 2:30PM - 5:18PM — Session D13 DCOMP: Computational Methods: Strongly Correlated and Many Body Systems
Morial Convention Center 204

2:30PM D13.00001 Maximally-localized Wannier functions for GW quasiparticles, D.R. HAMANN, DAVID VANDERBILT, Department of Physics and Astronomy, Rutgers University — Recent efforts carrying the GW many-body approximation to self-consistency have given improved electronic-structure results. However, one is left with self-energy operators only on the grid of $k$ points used for Brillouin-zone integration, unlike the case of DFT where the local self-consistent potential allows calculation of the band structure on arbitrary $k$ points (e.g., along symmetry lines). As maximally-localized Wannier functions (MLWF) provide a basis for a highly accurate approach to band interpolation, we have combined the WANNIER90 code for MLWF with the self-consistent GW capabilities of the ABINIT code to efficiently extend the GW grid calculation to a full band structure. MLWF also provide an intuitive picture of the orbital character and bonding of groups of bands, as well as a quantitatively accurate measure of electric polarization. Differences between quasiparticles MLWF and their LDA counterparts examined to date (Si and perovskite SrZrO$_3$) have proven small, but the visualization of many-body effects through MLWF remains an intriguing possibility. 1. 2:42PM D13.00002 Ab initio calculation of the excited state properties of spiropyran, KIOUPAKIS, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — The photochromism of spiropyran/merocyanine molecules has been the subject of many experimental and theoretical studies. However, several questions remain open, in particular the excited state dynamics and the role of the triplet state. In this work, we use ab initio techniques based on Density Functional Theory and Green’s functions methods based on the GW approximation to the electron self energy and Bethe-Salpeter equations to study the ground and excited states of spiropyran/merocyanine for various geometries. Our results are compared with previous work. This work was supported by National Science Foundation Grant No. DMR07-05941, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by NERSC and TeraGrid resources provided by SDSC and Indiana University.

2:54PM D13.00003 All-electron GW calculation of vanadium dioxide, REI SAKUMA, TAKASHI MIYAKE, FERDI ARYASETIAWAN, JST-CREST, AIST — We present the results of the GW calculation of metallic and insulating vanadium dioxide using a full-potential LMTO basis set. Our calculations show that it is crucial to take into account both the frequency dependence and the off-diagonal elements of the self-energy. We find that the usual 1-shot GW scheme, where the frequency expansion of the self-energy is truncated in the first-order, yields a large error ($>0.1eV$) in quasiparticle energies due to the unsmoothness of the self-energy. In both phases, the dynamical correlation effect within RPA leads to a plasmon satellite which can be seen in the self-energy in quasiparticle energies due to the unsmoothness of the self-energy. In both phases, the dynamical correlation effect within RPA leads to a plasmon satellite which can be seen in the self-energy.
3:06PM D13.00004 GW-based \textit{ab initio} downfolding aiming at strongly correlated electron system\textsuperscript{1}, KAZUMA NAKAMURA, Dept. of Applied Physics, Univ. Tokyo, TAICHI KOSUGI, Dept. of Physics, Univ. Tokyo, YOSHIHIDE YOSHIMOTO, ISSP, Univ. Tokyo, RYOTARO ARITA, RIKEN, MASATOSHI IMADA, Dept. of Applied Physics and JST-CREST, Univ. Tokyo — Aiming at \textit{ab initio} description of real complex systems under effects of strong electron correlations, we develop a GW-based downfolding scheme formulated in the plane-wave basis set. Our method is successfully applied to organic conductors, the family of (BEDT-TTF)$_2$X. At the heart of our downfolding scheme lies utilizing the energy hierarchy of the system \cite{1}: The low-energy hierarchy near the Fermi level (\(\epsilon \pm 2\sim 3\) eV) determines physics while is affected by the remaining high-energy part of hierarchy. We renormalize the high-energy part into low energy, based on the GW scheme. The renormalization generates a low-energy model characterized by renormalized transfers and effective screened Coulomb/exchange interactions, having frequency dependence arising from retarded screening by eliminated high-energy electrons. Thus, the low-energy frequency-dependent effective model is mapped out from the whole high- plus low-energy system in an \textit{ab initio} procedure. \cite{1} F. Aryasetiawan et al., Phys. Rev. B \textbf{70}, 19514 (2004); I. V. Solovyev and M. Imada, \textit{ibid.} \textbf{71}, 045103 (2005).

3:18PM D13.00005 GW Study of Actinides: \(\alpha\)-Uranium and \(\delta\)-Plutonium, R.C. ALBERS, A.N. CHANTIS, Los Alamos National Laboratory, M. VAN SCHILFGAARDE, Arizona State University, T. KOTANI, Arizona State University — We have applied the recently developed Quasiparticle Self-Consistent GW (QSGW) method to \(\alpha\)-U and \(\delta\)-Pu. This is the first time that the f-orbital electron-electron interactions in actinides have been treated by a first-principles method that goes beyond the level of the generalized gradient approximation. We show that the QSGW approximation for \(\alpha\)-U predicts a significant f-band narrowing when compared to GGA band-structure results. However, because of the low f-electron occupation number in U, ground-state properties are not significantly affected. This provides the first formal justification for the success of the LDA and GGA calculations in describing the ground-state properties of this material. For Pu we find that QSGW, like conventional band-structure calculations, predicts a static magnetic ground-state in contradiction with experiment. A non-magnetic solution is also presented. For \(\delta\)-Pu we show that the QSGW approximation predicts even stronger band narrowing than for U. Because of this and a larger f-occupation, the ground state properties are affected much more significantly than for U. Overall, because of its better treatment of correlation, we suggest that the QSGW solution rather than GGA should be a better starting point for future Dynamical Mean Field Theory (DMFT) and other correlation methods.

3:30PM D13.00006 The formation of stripes and the pairing of charge carriers in anisotropic materials\textsuperscript{1}, K.J.E. VOS, C. POVEY, J.M. TIPPER, University of Lethbridge — We have examined the formation of stripes and pairing in the anisotropic t - J model. We have used exact diagonalization methods on several different cluster sizes to examine the underdoped region. Evidence of unidirectional stripe formation in the charge and spin correlations was found. We have determined that the formation of stripes parallel to the Cu-O-Cu bonds enhances pairing and in the bulk limit there is a finite range of doping concentration where hole pairs will form. As the material becomes more anisotropic there is a phase transition that destroys the stripe. These results are consistent with the experimental data.

\textsuperscript{1}The computational infrastructure was provided by Westgrid. This work is supported by NSERC of Canada.

3:42PM D13.00007 Theory of the Normal State of the Copper-Oxide Superconductors\textsuperscript{1}, TING PONG CHOI, ROBERT G. LEIGH, PHILIP PHILLIPS, University of Illinois at Urbana Champaign — We show here that many of the normal state properties of the cuprates are consequences of the new charge 2e boson which we have recently (Phys. Rev. Lett. \textbf{99}, 46404 (2007) and arXiv:0707.1554) shown to exist in the exact low-energy theory of a doped Mott insulator. In particular, the 1) mid-infrared band, 2) the \(T^2\) contribution to the thermal conductivity, 3) the pseudogap, 4) the bifurcation of the electron spectrum below the chemical potential as recently seen in angle-resolved photoemission, 5) insulating behaviour away from half-filling, 6) the high and low-energy kinks in the electron dispersion and 7) T-linear conductivity all derive from the charge 2e boson. We also calculate the inverse dielectric function and show that it possesses two dispersing particle-hole branches as a function of momentum in the lightly doped regime. The second of the two branches is mediated by a new charge e composite excitation formed from the charge 2e boson and represents a distinctly new prediction of this theory. We propose that electron energy loss spectroscopy at finite momentum and frequency can be used to probe the existence of the second particle-hole branch.

\textsuperscript{1}We thank the NSF DMR-0605769 for partial support. This research was also supported in part by the NSF PHY05-51164.

3:54PM D13.00008 Imaginary-time formulation for strongly correlated transport in steady-state nonequilibrium\textsuperscript{1}, JONG E. HAN, RYAN J. HEARY, SUNY at Buffalo — We formulate steady-state nonequilibrium from the scattering state theory and show that an imaginary-time formalism exists for strongly correlated transport calculations in quantum dot devices\textsuperscript{2}. Equilibrium imaginary-time method is extended to the steady-state nonequilibrium by mapping the chemical potential difference in the quantum dot device into complex Matsubara voltage. Due to this formal similarity between equilibrium/nonequilibrium theories, we readily apply an equilibrium numerical technique to calculate the strong correlation effects in nonequilibrium. We use quantum Monte Carlo method to calculate Green functions at each Matsubara voltage and, after a numerical analytic continuation, we obtain nonperturbative Green function far from equilibrium. We show numerical results for the evolution of Kondo anomaly as a function of finite bias. We also discuss the splitting of Kondo anomaly at finite magnetic fields.

\textsuperscript{1}Supported by NSF DMR-0426826.

4:06PM D13.00009 Electron fractionalization and statistics of holons in doped quantum dimer models\textsuperscript{1}, DIDIER POILBLANC, Laboratoire de Physique Théorique, CNRS & Universite de Toulouse (France) — I introduce a doped two-dimensional quantum dimer model describing a doped Mott insulator and retaining the original Fermi statistics \cite{1}. This model shows a rich phase diagram including a d-wave hole-pair superconductor breaking translation symmetry (supersolid) at small doping, a bosonic superfluid at large doping and an exotic intermediate phase in-between. The hole kinetic energy is shown to favor binding of topological defects to the fermionic holons turning them into bosons, in agreement with arguments based on RVB wave-functions. Results are discussed in the context of cuprates superconductors and compared with those of a related bosonic doped quantum dimer model \cite{2}. \cite{1} D. Poilblanc, arXiv:0711.2229. \cite{2} A. Ralko, F. Mila, and D. Poilblanc, Phys. Rev. Lett. \textbf{99}, 127202 (2007).

4:18PM D13.00010 Improvement on the STLS Approach and its Application to the Spin Fully-Polarized Low-Density Electron Gas, YASUTAMI TAKADA, ISSP, Univ. of Tokyo, KANAKO YOSHIZAWA, Dept. of Physics, Sophia Univ. — Four decades ago, Singwi, Tosi, Land, and Sjölander (STLS) proposed a theory that treats the local-field factor $C(q)$ and the static structure factor $S(q)$ in a self-consistent fashion. Because of its simplicity in practical calculations and reasonably good results for the correlation energy, this STLS framework has been recognized as a powerful theoretical tool to study short-range correlation beyond the RPA. At the same time, however, it has been realized that the STLS scheme has several shortcomings; among others, it does not satisfy the Pauli principle as exemplified by the fact that the on-top parallel-spin pair distribution function $g_{11}(0)$ becomes negative. In view of this situation, we propose an improved STLS approach in which a special procedure is added to the original STLS framework in order to impose the Pauli principle. This new scheme is successfully applied to the spin-fully polarized electron gas with the electron density parameter $r_s$ ranging from 1 to 100 to find that the correlation energy obtained by quantum Monte Carlo simulations is reproduced very accurately, along with satisfying $g_{11}(0) = 0$ and the non-negativity condition $g_{11}(r) \geq 0$. Implications of our results will be given in the context of the contribution to the density functional theory as well as to the spin structure of the Wigner-lattice state.

4:30PM D13.00011 Role of phonons and of finite temperature on the spectral function of a single hole in a quantum antiferromagnet, SATYAKI KAR, Department of Physics, Florida State University, Tallahassee, FL, 32306-4350, EFSTATIOS MANOUSAKIS, Department of Physics and MARTECH, Florida State University, Tallahassee, FL, 32306, and Department of Physics, University of Athens, Greece — Thermal broadening as well as the role of optical phonons are studied for a single-hole in a quantum antiferromagnet within the t-J (and the t-t'-t''-J) model. The non-crossing approximation (NCA) as well as the effect of vertex corrections (up to second order) are used to describe the coupling to spin waves and phonons up to intermediate range of coupling. Phonons at finite temperature are seen to broaden the quasiparticle peak and the string excitations are found to survive up to an intermediate phonon-coupling regime beyond which the NCA is expected to break down. The qualitative features of our results compare reasonable well with the recent high resolution angular resolved photoelectron spectroscopy.

4:42PM D13.00012 The Green’s Function of the 1D Breathing-Mode Polaron, GLEN GOODVIN, MONA BERCIU, University of British Columbia — We apply the Momentum Average approximations MA(0) and MA(1) to study the properties of the one-dimensional breathing-mode polaron. The results are analytical, numerically trivial to evaluate, exact for both zero bandwidth and for zero electron-phonon coupling, and are accurate everywhere in parameter space. Comparison with recent numerical data confirms this accuracy. We also show that by applying MA as a variational method with a suitably chosen enlarged subspace, we can obtain extremely high accuracy for both ground state and higher energy state properties. With only a slight increase in computational effort this allows us to obtain ground state and momentum-dependent results well within 0.1% error of the exact numerical data currently available. Although this work specifically looks at the breathing-mode model, we demonstrate that MA is applicable to all momentum dependent electron-phonon coupling models, and its accuracy can always be improved by systematically improving the approximation itself or by working in an enlarged variational subspace.

5:06PM D13.00014 Extensions of the Momentum Average approximation, MONA BERCIU, LUCIAN COVACI, University of British Columbia — We consider a well studied problem, the formation of polaron. Even for the simplest electron-phonon interaction (the Holstein model), an exact solution is only known in the asymptotic limits of zero coupling or zero free-electron bandwidth. A simple analytical approximation that turns out to be accurate for all coupling strengths (the Momentum Average approximation) has only been found recently. We discuss the extension of this method to various other situations in which polaron physics might be important. We show how the Momentum Average approximation can be used in answering questions regarding coupling of electrons to multiple phonon branches, formation of polarons in the presence of magnetic fields and the existence of multiple electron bands.

Monday, March 10, 2008 2:30PM - 5:30PM — Session D14 DAMOP GQI: Quantum Information Science in AMO — Morial Convention Center 205

2:30PM D14.00001 Quantum Information Aspects of Cold Fermi Systems, RAZVAN TEOODORESCU, Los Alamos National Laboratory — In the limit of fast switching of Feshbach resonance in cold fermionic systems, the dynamics is dominated by non-linear, coherent, multi-frequency quantum oscillations of the order parameter. This theoretical model is very rich and has known connections to several quantum field theories. In this talk, I will analyze the problem from the point of view of quantum information theory and indicate possible practical applications of the fast-switching regime.

2:42PM D14.00002 Coherent Control of Trapped Bosons, ANALABHA ROY, Graduate Student, University of Texas at Austin, LINDA REICHL, Director CQS — We investigate the quantum behavior of a mesoscopic two-boson system produced by number-squeezing ultracold gases of alkali metal atoms. The quantum Poincare maps of the wavefunctions are affected by chaos in those regions of the phase space where the classical dynamics produces features that are comparable to $\hbar$. We also investigate the possibility for quantum control in the dynamics of excitations in these systems. Controlled excitations are mediated by pulsed signals that cause Stimulated Raman Adiabatic passage (STIRAP) from the ground state to a state of higher energy. The dynamics of this transition is affected by chaos caused by the pulses in certain regions of the phase space. A transition to chaos can thus provide a method of controlling STIRAP.

The authors wish to thank the Robert A. Welch Foundation (Grant No. F-1051) for support of this work.
Phase transitions, entanglement and quantum noise interferometry in cold atoms. FLORIAN MINTERT, University of Freiburg. INDUBALA SATIJA, George Mason University. ANA MARIA REY, ITAMP. CHARLES CLARK, NIST. — Quantum entanglement represents one of the most fascinating features of quantum theory and has emerged as an important resource in quantum information science. Recent studies have suggested that the long range correlations that are established close to a quantum phase transition manifest themselves in a pronounced increase of entanglement. However, to show that is not an easy task given the fact that currently there is not consensus about the best method to define an entanglement measure for multi-particle systems. Using an entanglement measure that includes up to four point correlation functions we study the scaling properties of multi-particle entanglement in a one dimensional Ising chain around and at the critical point. Our study reveals that multiparticle entanglement indeed peaks at the phase transition, whereas pure biparticle entanglement measures often fail to reveal this feature. We discuss the connection between multiparticle entanglement measurements with noise correlations and the possibility of using these experimentally accessible quantities as a probe of entanglement in cold atomic systems.

Mapping phononic entanglement into and out of a quantum memory. HUI DENG, KYUNG S. CHOI, JULIEN LAURAT, H. JEFF KIMBLE, California Institute of Technology. — Recent developments of quantum information science critically rely on entanglement. In particular, scalable quantum networks require capabilities to create, store, and distribute entanglement among distant nodes via photon channels. Atomic ensembles can serve as such nodes. In the photon counting regime, heralded entanglement between atomic ensembles has been demonstrated via probabilistic protocols. However, an inherent drawback of such protocols is the compromise between the fidelity of entanglement and its preparation probability, which hinders the schemes’ scalability. Here we present a protocol where entanglement between atomic ensembles is created by coherent mapping of phononic entanglement. By splitting a single-photon and subsequent state transfer, we separate the generation of entanglement and its storage, enabling efficient scaling for high-fidelity quantum communication. After a programmable delay, chosen at 1ns, the stored entanglement is mapped back into photon modes with an overall efficiency of 17%. With improved retrieval efficiency and memory time, along with the development of on-demand single photon sources, our protocol enables the deterministic generation, storage, and distribution of entanglement among remote quantum memories for scalable quantum networks.

Broadband Multi-Spot Optical Beam Steering with Independent 2D Addressability for Quantum Information Processing. CALEB KNOERNSCHILD, CHANGSOON KIM, Duke Univ. FELIX LU, Duke Univ. and Applied Quantum Tech., JUNGSANG KIM, Duke Univ. — While quantum computation utilizing trapped ions or neutral atoms has seen significant advances in recent years, the necessary scalability of such implementations is limited in part by the distribution of laser resources. The capability to address multiple qubit locations with a single laser is an essential element in moving these experiments beyond individual quantum gate demonstrations. An optical system utilizing micro-electromechanical system (MEMS) technology can provide a scalable solution to address a qubit array with multiple independent beams concurrently. Broadband coatings can accommodate a large range of wavelengths, while fabrication techniques allow expansion to multiple parallel laser beams over a large number of trap locations. We demonstrate a two-spot beam steering system using MEMS mirrors that can simultaneously and independently illuminate any of 25 different locations within a 5x5 array with 2 laser beams of different wavelengths. Mirrors with setting times of < 5µs have been fabricated allowing fast access times between qubits. Such systems can be used to implement two-qubit gates in a 1D or 2D array of qubits.

Toward a Wire-mediated Coupling of Trapped Ions. ROBERT CLARK, Institut für Quantenoptik und Quanteninformation, Innsbruck, Austria and Massachusetts Institute of Technology, Cambridge, MA, TONY LEE, NIKOS DANIILIDIS, SANKARANARAYANAN S., HARTMUT HÄFFNER, Institut für Quantenoptik und Quanteninformation, Innsbruck, Austria. — Most schemes for ion trap quantum computation rely upon the exchange of information between ion-qubits in the same trap region, mediated by their shared vibrational mode. An alternative way to achieve this coupling is via the image charges induced in a conducting wire that connects different traps. This was shown to be theoretically possible by Heinzen and Wineland in 1990, but some important practical questions have remained unaddressed. Among these are how the presence of such a wire modifies the motional frequencies and heating rates of trapped ions. We thus have realized this system as a 1 mm-scale planar segmented rf ion trap combined with an electrically floating gold wire of 25 microns diameter and length 1 cm. This wire is placed close to trapped ions using a set of piezoelectric nanopositioners. We present here experimental measurements of the motional frequencies and heating rates of a single trapped calcium ion as the wire is moved from 3.0 mm to 0.2 mm away from the ion. We discuss the implications of these results for achieving wire-mediated coupling in the present apparatus, as well as in future improved setups.
In our experiment, we measure the heating rate out of the motional ground state of a single Sr ion in a closed-cycle 4 K ion trap. The rich internal structure of polar molecular ions makes them attractive for interfacing with solid state systems in quantum information processing, yet it is this structure that makes trapping and detecting molecules difficult. We present an approach to this challenge which allows a superconducting cavity to be used as an integral part of a surface electrode ion trap, based on a closed-cycle cryostat operated at 4 K, and addressing the problem of molecule formation and detecting their presence. A mixture of Sr and SrCl ions is loaded into the trap by laser ablation. Subsequent laser cooling of the Sr ions sympathetically cools the molecular ions, producing a two-component Wigner crystal. This allows detection of the molecules using mass spectroscopy, observed indirectly through imaging of the Sr ions, or through coupling to microwave lines in the trap. Using a closed-cycle cryostat enables rapid testing and evaluation of ablation targets and trap geometries, at the cost of some trap vibration, measured to be below 100 nm in amplitude.

4:20PM D14.00012 Cavity cooling of $^{88}$Sr$^+$. DAVID LEIBRANDB, YAT SHAN AU, ISAAC CHUANG, MIT — Cavity cooling is a method of laser cooling which uses coherent scattering to cool atoms [V. Vuletić and S. Chu, PRL 84, 3787 (2000)]. The closed atomic transition used in Doppler cooling is replaced by a cavity resonance, so cavity cooling can be used to cool to sub-Doppler temperatures and is in principle applicable to complicated atoms or molecules without closed transitions. We describe an experiment to study three-dimensional cavity cooling of a single $^{88}$Sr$^+$ ion confined in a linear RF Paul trap. Large cooling rates can be attained by operating near the 422 nm $S_{1/2} \rightarrow F_{1/2}$ optical dipole transition and using a 5 cm long near-confocal Fabry-Pérot cavity with commercially available mirrors of finesse $10^4$. Given a cavity alignment error $\leq 10$ μm and a trap frequency of 1 MHz, the resolved sideband cavity cooling limit is $\leq 5$ motional quanta. We present details of the experimental proposal and its implementation.

4:44PM D14.00013 Microfabrication of Surface Electrode Ion Traps for Quantum Information Experiments. YUEFEI GE, SHANNON WANG, ISAAC CHUANG, MIT — Surface electrode ion traps, while promising for large-scale quantum computation, have long been challenged by ion heating rates which increase rapidly as trap length scales are reduced. Through a series of measurements on over fifteen traps, we show that ion heating rates are surprisingly sensitive to electrode material and morphology, and in particular, to details of the fabrication procedure. For example, one 75 μm size trap, made of chemically etched silver on a single crystal quartz substrate, showed a minimum heating rate of $\sim 40$ quanta/second, when prepared by annealing at 700°C in vacuum for one hour. This annealing smooths sharp edges, and significantly reduces breakdown voltage. However, if the annealing temperature is lowered to 720°C, leaving the breakdown voltage still robustly high, the heating rate jumps to $\sim 1000$ quanta/second. With electroplated gold, on a silver seed layer, a record low heating rate of $\leq 2$ quanta/second is obtained. We present details of the fabrication procedures, evaluate alternative electrode materials such as niobium nitride, and explain how these measurements were obtained with an ion trap operated at 6 Kelvin, containing a single strontium ion, sideway cooled to its quantum ground state of motion.

5:06PM D14.00014 Temperature dependence of decoherence in ion traps. YUEFEI GE, SHANNON X. WANG, ISAAC CHUANG, Center for Ultracold Atoms, MIT — Dense arrays of trapped ions provide one way of scaling up ion trap quantum information processing. However, miniaturization of ion traps is currently limited by sharply increasing motional state decoherence at sub-100 μm ion-electrode distances. This decoherence has been demonstrated to be thermally driven, providing a plausible route to reduce it. In our experiment, we measure the heating rate out of the motional ground state of a single Sr$^+$ ion in a cryogenic surface electrode ion trap. We present our results on the temperature dependence of the heating rates as a function of electrode temperature in 10-100 K range. Heating rates at 6 K are observed to be as low as two quanta per second, but increase rapidly with temperature.

5:18PM D14.00015 Individual ion addressing using a magnetic field gradient in a surface-electrode ion trap. SHANNON WANG, ISAAC CHUANG, YUEFEI GE, MIT — The ability to address individual ions is an important issue in using multiple trapped ions to perform quantum operations. Previous efforts have included using precisely focused laser beams aimed at only one ion at a time, which poses a significant technical challenge. An alternative is to use field-dependent transitions and a magnetic field gradient to shift the transition frequencies of ions as a function of position. This requires good stability of the local field in order to achieve desired fidelity of quantum operations. In a cryogenic Sr$^+$ ion trap we use the $5S_{1/2} \rightarrow 4D_{5/2}$ transition as an optical qubit, which can be Zeeman shifted using a bias field generated by external coils. We present a scheme to create a local field gradient by integrating current sources onto a microfabricated surface-electrode trap. Taking advantage of the cryogenic environment, we stabilize the field at the trap site using superconducting rings as flux shields. The rings can be integrated with the trap, simplifying implementation and improving alignment to the ions.

Monday, March 10, 2008 2:30PM - 5:18PM — Session D15 GQL: Focus Session: Foundations of Quantum Theory I — Morial Convention Center 207

2:30PM D15.00001 LeRoy Apker Award Talk: Testing Hidden-Variable Theorems with Single-Photon Entangled States. BRYCE GADWAY, SUNY Stony Brook / Colgate University — An ensemble of single photons created in a hyperentangled Bell state were used to test a broad class of Hidden-Variable Theorems (HVTs). Specifically, the class of HVTs based on the joint assumption of Realism and Non-Contextuality (NC) – the premise that values associated with one observable are independent of which commuting observables may be measured simultaneously – known as NCHVTs, and first examined by Bell as Kochen and Specker, uses these single-photon states entangled in polarization and direction of momentum. A Clauser-Horne-Shimony-Holt (CHSH) Inequality was applied, with the factorization condition that is usually satisfied by a Non-Locality assumption being instead satisfied by the assumption of NC, due to the inherently local nature of detection events for single particles. The basis rotations and projections necessary for testing the CHSH Inequality were accomplished using interferometers and standard polarization optical elements. A violation of the CHSH Inequality was observed, ruling out either Realism or Non-Contextuality – or possibly both. The tenability of Contextual HVTs remains, trivially, as the predictions of such a theory can map one-to-one to the predictions of Quantum Mechanics.
3:06PM D15.00002 Weak values and the Leggett-Garg inequality in solid-state qubits, ANDREW JORDAN, University of Rochester — The seminal paper of Aharonov, Albert, and Vaidman introduces the concept of a weak value as a statistical average over realizations of a weak measurement, where the system is both pre- and post-selected. By taking restricted averages, weak values can exceed the range of eigenvalues associated with the observable in question. We discuss how to implement a weak values measurement with solid-state qubits. In parallel activity, Leggett and Garg have devised a test of quantum mechanics for a single system using different ensembles of (projective) measurements at different times and correlation functions of those outcomes. The original motivation was to test if there was a size scale where quantum mechanics would break down. Introduced as a "Bell-inequality in time", the assumptions of macrorealism that could be verified by a non-invasive detector imply that their correlation function obeys a Leggett-Garg inequality that quantum mechanics would violate, formally similar to the inequality of Bell. We demonstrate that the proper notion of a classical weak value also demands these assumptions, and that furthermore a weak value can be non-classical if and only if a Leggett-Garg inequality can also be violated. We will discuss generalized weak values, where post-selection occurs on a range of weak measurement results. Our analysis is presented in terms of kicked quantum nondemolition measurements on a quantum double-dot charge qubit.

3:42PM D15.00003 Negative probabilities and measurement disturbance, LARS M. JOHANSEN, Buskerud University College — Feynman once said that "the only difference between a probabilistic classical world and the equations of the quantum world is that somehow or other it appears as if the probabilities would have to go negative". But what is the essential reason for probabilities going negative? Here it is demonstrated that negative probabilities are a direct consequence of measurement disturbance. The Margenau-Hill distribution, a quasiprobability taking negative values, is expressed in terms of the joint probability obtained in the successive measurement of two projectors. The quasiprobability takes negative values only if the measurement on the second projector is a weak measurement. We show that error-free which-path measurements are possible in this model that do not destroy the fringe visibility. On the other hand, does not require one to measure the fringe visibility. We show that neither the conventional uncertainty principle nor the recently-derived universal uncertainty principle place any restriction on the minimum root-mean-square momentum disturbance, once it is recognized that the which-path determination does not affect the measurement value of x, but only the appropriate two-valued function of x. We then develop a description of the problem in terms of only two-valued variables, and consider a completely general measurement model, which allows us to distinguish between the measurement error and what we call the "preparation error." We show that error-free weak measurement is only possible if the fringe visibility does not destroy the fringe visibility. On the other hand, we also show that there is a general tradeoff relation between preparational error and fringe visibility, which, for measurements obeying the "non-destruction" condition, reduces to Englert's inequality.

3:54PM D15.00004 The meaning of negative weak values, JAMES TROUPE, JEFF TOLLAKSEN, George Mason University — A number of approaches to quantum mechanics incorporate negative values for quantities that were classically positive, such as the Wigner-Moyal density approach or the Feynman negative probability approach, etc. In the re-formulation of quantum mechanics using weak values and weak measurements, we encounter a new situation where weak values of projection operators turn out to be negative. We emphasize the differences between these negative weak values and the negative values encountered in the other formalisms: in the previous formalisms, the mathematical entity whose average yielded the negative values are not density operators. While they do yield the correct average of a function, they also have non-physical aspects, i.e. mathematical artifacts, when the densities become negative. The reason is that if we attempt to actually measure such "negative" properties, then the result does not correspond to a physical observable in Hilbert Space. E.g. if we did attempt to cheat quantum mechanics by projecting onto p and x as densities simultaneously in Wigner-Moyal, then we obtain the parity operator, the most non-local result. On the other hand, in the case of weak values, we obtain a new situation: when we use a bonafide measuring device to measure these properties ideally, then the very same measuring device will yield the predicted negative weak values when the measurement interaction is simply weakened.

4:06PM D15.00005 Frame representations of quantum mechanics and the necessity of negativity in quasi-probability representations, CHRISTOPHER FERRIE, JOSEPH EMERSON, University of Waterloo — Several finite dimensional quasi-probability representations of quantum states have been proposed to study various problems in quantum information theory and quantum foundations. These representations are often defined only on restricted dimensions and their physical significance in contexts such as drawing quantum-classical comparisons is limited by the non-uniqueness of the particular representation. Here we show how the mathematical theory of frames provides a unified formalism which accommodates all known quasi-probability representations of finite dimensional quantum systems. Moreover, we show that any quasi-probability representation satisfying two reasonable properties is equivalent to a frame representation and then prove that any such representation of quantum mechanics must exhibit either negativity or a deformed probability calculus.

4:18PM D15.00006 Towards Testing Quantum Mechanics with Micro-Optomechanical Systems, DUSTIN KLECKNER, SUSANNA THON, University of California - Santa Barbara, EVAN JEFFREY, University of Leiden, DIRK BÖUWMEESTER, University of California - Santa Barbara and University of Leiden — We review our work in micro-optomechanical systems. Motivation for work on these systems is based in proposals to test quantum mechanics in new regimes. Although extremely challenging, creating a quantum superposition of a micro-optomechanical oscillator coupled to an optical cavity seems experimentally feasible with current technology. Additionally, the optomechanical systems used for this type of research have other applications, such as optical cooling, as recently demonstrated by several independent groups. We will briefly discuss the direction of our research in the near future, including the use of conventional cryogenics to cool the resonator and the prospects for several related types of devices.

4:30PM D15.00007 Decoherence and the Uncertainty Principle, DAVID CRAIG, Le Moyne College — The uncertainty principle is normally understood as representing a limit on the fundamental accuracy of simultaneous measurements of incompatible observables. In the context of consistent/decoherent histories formulations of quantum theory, we show that it may also be understood as quantifying the degree of course-graining necessary in order for histories of a quantum system to decohere. This follows as a consequence of a new inequality bounding the interference between histories in a consistent histories formulation of quantum theory.

4:42PM D15.00008 Noncontextuality and the Kochen-Specker Theorem, BRIAN LA COUR, University of Texas at Austin — The question of noncontextuality in a simple, two-qubit system is considered. It is shown that quantum theory is consistent with a noncontextual hidden variable interpretation, contrary to the conclusions of the Kochen-Specker theorem. The key to the proof is the recognition of a subtle but fundamentally important assumption regarding the dependence of the hidden variable probability distribution on the particular set of mutually commensurable observables chosen for measurement. Recent experiments to test noncontextuality will be discussed and their results reconciled with a hidden variable interpretation.

4:54PM D15.00009 Path detection and interference tradeoff in the double-slit experiment, JULIO GEA-BANACLOCHE, University of Arkansas, MASANAO OZAWA, Tohoku University, Japan — We study how the acquisition of "which-path" information leads to a loss of contrast in the double-slit interference setup. We show that neither the conventional uncertainty principle nor the recently-derived universal uncertainty principle place any restriction on the minimum root-mean-square momentum disturbance, once it is recognized that the which-path determination does not require one to measure x, but only an appropriate two-valued function of x. We then develop a description of the problem in terms of only two-valued variables, and consider a completely general measurement model, which allows us to distinguish between the measurement error and what we call the "preparation error." We show that error-free which-path measurements are possible in this model that do not destroy the fringe visibility. On the other hand, we also show that there is a general tradeoff relation between preparational error and fringe visibility, which, for measurements obeying the "non-destruction" condition, reduces to Englert’s inequality.
2:30PM D16.00010 Exact mappings between quantum relativistic and quantum optical models, A. BERMUDEZ et. al, Universidad Complutense de Madrid, E. SOLANO, Ludwig-Maximilians-Universitat — We develop a novel quantum optical perspective into a couple of quantum relativistic systems: i) First we show how the two-dimensional extension of the harmonic oscillator, known as the Dirac oscillator, can be exactly mapped onto a chiral Anti-Jaynes-Cummings model of quantum optics. This equivalence allows us to predict a series of novel relativistic phenomena, such as spin-orbit Zitterbewegung. Furthermore, we also make a realistic experimental proposal, at reach with current technology, for studying the equivalence of both models using a single trapped ion [1], ii) Second, we show that a relativistic version of Schrödinger cat states, here called Dirac cat states, are built in relativistic Landau levels when an external magnetic field couples to a relativistic spin 1/2 charged particle. Under initial suitable conditions, the associated Dirac equation produces unitarily Dirac cat states involving the orbital quanta of the particle in a well defined mesoscopic regime. These states have a purely relativistic origin and cease to exist in the non-relativistic limit [2].

Session D16 DBP: Biological Networks Morial Convention Center 208

2:30PM D16.00001 Cooperation of multiple copies of noisy genes, ALEKSANDRA WALCZAK, Princeton University, PETER WOYNES, UCSD — The regulation of gene expression is influenced by the small numbers of protein and gene copies present in the cell. Noise properties arising from single copies of the gene are well known. In this talk we consider the case when a few copies of the same gene are present and actively transcribed in the cell. We use mathematical models which treat both the DNA and protein degrees of freedom stochastically. We study how the switching of one gene influences the switching behaviour of another gene, to which it is coupled by a mutual protein environment. We show that the genes lose properties defined by their individual parameters and take on the characteristics of a group to reach a new steady state. We show that system with multiple gene copies can be used to reduce noise or to modify the cooperativity of the regulatory characteristics of the circuit. These results can be useful for interpreting and designing bioengineering experiments in which there can be multiple copies of a gene.

2:42PM D16.00002 Chaotic Gene Regulatory Networks Can Be Robust Against Mutations and Noise1. VOLKAN SEVIM, PER ARNE RIKVOLD, Florida State University — Robustness to mutations and noise has been shown to evolve through stabilizing selection for optimal phenotypes in model gene regulatory networks. The ability to evolve robust mutants is known to depend on the network architecture. How do the state-space structures of networks with high and low robustness differ? Here we present large-scale computer simulations of a Random Threshold Network model of gene regulatory networks undergoing biological evolution. We show using damage propagation analysis and an extensive statistical analysis of state spaces of these model gene networks that the change in their dynamical properties due to stabilizing selection is very small. Therefore, conventional measures of stability do not provide much information about robustness in model gene regulatory networks. Interestingly, the networks that are most robust to both mutations and noise are highly chaotic. Chaotic networks are able to produce large attractor basins, which can be useful for maintaining a stable gene-expression pattern.

2:54PM D16.00003 A quantitative model of DNA replication in Xenopus embryos: reliable replication despite stochasticity1. SCOTT CHENG-HSIN YANG, JOHN BECHHOEFER, Simon Fraser Univ — DNA synthesis in Xenopus frog embryos initiates stochastically in time at many sites (origins) along the chromosome. Stochastic initiation implies fluctuations in the replication time and may lead to cell death if replication takes longer than the cell cycle time (~25 min.). Surprisingly, although the typical replication time is about 20 min., in vivo experiments show that replication fails to complete only about 1 in 250 times. How is replication timing accurately controlled despite the stochasticity? Biologists have proposed two mechanisms: the first uses a regular spatial distribution of origins, while the second uses randomly located origins but increases their probability of initiation as the cell cycle proceeds. Here, we show that both mechanisms yield similar end-time distributions, implying that regular origin spacing is not needed for control of replication time. Moreover, we show that the experimentally inferred time-dependent initiation rate satisfies the observed low failure probability and nearly optimizes the use of replicative proteins.

3:06PM D16.00004 Exponential sensitivity of noise-driven switching in genetic networks, PANKAJ MEHTA, Princeton University, RANJAN MUKHOPADHYAY, Clark University, NED WINGREEN, Princeton University — Cells are known to utilize biochemical noise to probabilistically switch between distinct gene expression states. We demonstrate that such noise-driven switching is dominated by tails of probability distributions and is therefore exponentially sensitive to changes in physiological parameters such as transcription and translation rates. However, provided mRNA lifetimes are short, switching can still be accurately simulated using protein-only models of gene expression. Exponential sensitivity limits the robustness of noise-driven switching, suggesting cells may use other mechanisms in order to switch reliably.

3:18PM D16.00005 Effects of coarse-graining on fluctuations in gene expression, JUAN PEDRAZA, JOHAN PAULSSON, Department of Systems Biology, Harvard University — Many cellular components are present in such low numbers per cell that random births and deaths of individual molecules can cause significant ‘noise’ in concentrations. But biochemical events do not necessarily occur in steps of individual molecules. Processes are generally randomized when synthesis or degradation occurs in large bursts of many molecules in a short time interval. Conversely, each birth or death of a macromolecule could involve several small steps, creating a memory between individual events. Here we present generalized theory for stochastic gene expression, formulating the variance in protein abundance in terms of the randomness of the individual events, and discuss the effective coarse-graining of the molecular hardware. We show that common molecular mechanisms produce gestation and senescence periods that can reduce noise without changing average abundances, lifetimes, or any concentration-dependent control loops. We also show that single-cell experimental methods that are now commonplace in cell biology do not discriminate between qualitatively different stochastic principles, but that this in turn makes them better suited for identifying which components introduce fluctuations.

3:30PM D16.00006 ABSTRACT WITHDRAWN —
3:42PM D16.00007 Regulatory control and the costs and benefits of biochemical noise. SORIN TANASE-NICOLA, University of Michigan, PIETER REIN TEN WOLDE, Institute for Atomic and Molecular Physics, AMOLF. The Netherlands — Experiments in recent years have vividly demonstrated that gene expression can be highly stochastic. We present a mathematical model that makes it possible to quantify the effect of protein concentration fluctuations on the growth rate of a population of genetically identical cells. The model predicts that the population’s growth rate depends on how the growth rate of a single cell varies with protein concentration, the variance of the protein concentration fluctuations, and the correlation time of these fluctuations. The model shows that when the average concentration of a protein is close to the value that maximizes the growth rate, fluctuations in its concentration always reduce the growth rate. However, when the average protein concentration deviates sufficiently from the optimal level, fluctuations can enhance the growth rate of the population, even when the growth rate of a cell depends linearly on the protein concentration. We also apply our model to perform a cost-benefit analysis of gene regulatory control. Our analysis predicts that the optimal expression level of a gene regulatory protein is determined by the trade-off between the cost of synthesizing the regulatory protein and the benefit of minimizing the fluctuations in the expression of its target gene.

3:54PM D16.00008 Effects of time-delayed negative feedback loops on noise-induced oscillations on the NF-KappaB signaling network. JAEWOOK JOO, JEAN-LOUP PAULON, Sandia National Laboratories — NF-kappaB is a stimulus-responsive pleiotropic regulator of gene control. Our work was motivated by Nelson et al. [Science 306:704 (2004)], which showed noisy quasi-periodic oscillations of NF-kappaB translocation between cytoplasm and nucleus in single cells. Using both stochastic simulations and analytical approaches, we investigated the dynamic patterns of NF-kappaB translocation with a stochastic two-compartamental model, especially taking into account the interplay between intrinsic noise and delayed negative feedback loops of the NF-kappaB signaling system. We will present noise-induced oscillations of the NF-kappaB shuttling and the effects of time-delayed negative feedback loops on them.

4:06PM D16.00009 How is the fitness landscaped upon which life evolves selected? MICHAEL DEEM, Rice University — We investigate the selective forces that promote the emergence of modularity in nature. We demonstrate the spontaneous emergence of modularity in a population of individuals that evolve in a changing environment. We show that the level of modularity correlates with the rapidity and severity of environmental change. The modularity arises as a synergistic response to the noise in the environment, where the presence of horizontal gene transfer facilitates the evolution of hierarchical structures.

4:18PM D16.00010 Early life was a generalist: protein modularity increase as evolution proceeds. JIANKUI HE, JUN SUN, MICHAEL DEEM, Rice University — We study the evolution of modularity in protein-protein interaction network and protein domain-domain interaction networks. By introducing compositional age, we construct the interaction networks at different points in evolutionary time. We use the average-linkage hierarchical clustering method to reorganize the network matrix to identify the modules. With different settings of the compositional age, we compare the observed modularity at different evolutionary times in both E. coli and S. cerevisiae. We conclude that the modularity of protein-protein interaction network and domain-domain interaction network grows in evolution, validating recent theoretical predictions of spontaneous modularity in evolution [1].

4:30PM D16.00011 Genetic recombination models in molecular evolution. ENRIQUE MUNOZ, Department of Physics and Astronomy, Rice University, JEONG-MAN PARK, Rice University and Department of Physics, Catholic University of Korea, MICHAEL DEEM, Department of Physics and Astronomy, Rice University — We introduce generalizations of two classical models of molecular evolution: the parallel or Crow-Kimura model, and the Eigen model. These generalizations include, in addition to point mutations and selection as driving forces for biological evolution, the presence of different forms of horizontal gene transfer and genetic recombination events between individuals in the population. We will present analytical solutions for these models, and compare our results with numerical solutions of the corresponding system of differential equations. We will also present stochastic simulation results for the single peak fitness case.

4:42PM D16.00012 A minimal stochastic model of cell death signaling. SUBHADIP RAYCHAUDHURI — Cell death (apoptosis) is mediated by a complex intracellular signaling network that involves a large number of components. We propose a minimal model of signaling network that can sense the strength of any extracellular stimuli such as the concentration of ligands and adapt to a fluctuating environment. Based on stochastic simulations we show that a three step slow, fast, slow pathway is enough to generate large cell to cell fluctuations under the conditions of weak stimulus. Such cell to cell stochastic fluctuations persist even in the presence of large number of molecules and cannot be captured by deterministic differential equations. The model is based on stochastic simulations. We develop a probability distribution based approach that can characterize the stochastic fluctuations in such inherently stochastic signaling network. Interestingly, our results match with those obtained from kinetic Monte Carlo simulation of the full scale apoptotic network. Hence, our minimal signaling network can serve as a cell type independent general model of apoptosis signaling. We also discuss implications of our probability distribution based approach for diseases such as cancer that can result from disrupted apoptotic balance.

4:54PM D16.00013 Temperature compensation model for the circadian clock of Neurospora crassa.1 XIAOJIA TANG, HEINZ-BERND SCHÜTTLER, Department of Physics and Astronomy, University of Georgia, JONATHAN ARNOLD, Department of Genetics, University of Georgia — In the lowly bread mould, Neurospora crassa, biomolecular reactions involving the white-collar-1 (wc-1), white-collar-2 (wc2), and frequency (frq) genes and their products constitute building blocks of the biological clock that would respond to temperature as well as light. The frequency of the biological clock remains stable in response to variation in ambient temperature, which is called a compensation phenomenon. Recent experimental results show evidences that the temperature compensation could be explained by the temperature sensitive translational control of production of two isoforms of the main oscillator protein FRQ: a long form FRQ and a short form FRQ, which are more abundantly produced at higher temperature; and a short form FRQ, which is more abundantly produced at lower temperature. With our recently developed method of genetic network identification, we are now simulating the network’s temperature response based on published experimental data. These will serve as the starting point for a simulation-prediction-experiment-simulation workflow cycle. In this cycle, the maximally informative next experiment (MINE) technology will be employed to select the best experimental control parameters specifying the temperature response to be used in the next step of the workflow cycle.

5:06PM D16.00014 Understanding the Role of Housekeeping and Stress-Related Genes in Transcription-Regulatory Networks. ALLISON HEATH, LYDIA KAVRAKI, Rice University, GÁBOR BALÁZSI, University of Texas M.D. Anderson Cancer Center — Despite the increasing number of completely sequenced genomes, much remains to be learned about how living cells process environmental information and respond to changes in their surroundings. Accumulating evidence indicates that eukaryotic and prokaryotic genes can be classified in two distinct categories that we will call class I and class II. Class I genes are housekeeping genes, often characterized by stable, noise resistant expression levels. In contrast, class II genes are stress-related genes and often have noisy, unstable expression levels. In this work we analyze the large scale transcription-regulatory networks (TNR) of E. coli and S. cerevisiae and preliminary data on H. sapien. We find that stable, housekeeping genes (class I) are preferentially utilized as transcriptional inputs while stress related, unstable genes (class II) are utilized as transcriptional integrators. This might be the result of convergent evolution that placed the appropriate genes in the appropriate locations within transcriptional networks according to some fundamental principles that govern cellular information processing.
5:18PM D16.00015 The re-design of a theophylline riboswitch for DNT sensing1, YAROSLAV CHUSHAK, Biotechnology HPC Software Applications Institute, USAMRMC, NANCY KELLEY-LOUGHNAINE, SVETLANA HARBALGA, MORLEY STONE, Air Force Research Laboratory, Wright-Patterson AFB — Riboswitches are noncoding elements of mRNA that recognize and bind to small molecules and regulate the translation process of downstream genes. As an initial study, we used a theophylline riboswitch that regulates the expression of the Tobacco etch virus (TEV) protease placed downstream of the switch as a controlling element. Upon expression of TEV protease, an optical reporter is cleaved producing change in fluorescence resonance energy transfer (FRET) between BFP and eGFP. We altered the sensing domain of the original construct to create a synthetic riboswitch that responds to the presence of 2,4-dinitrotoluene (DNT) molecules. Computational analysis using AutoDock4 and AMBER9 software packages showed that U24A mutant has a significantly higher binding affinity for DNT molecule compared to the original theophylline. Cells expressing the re-designed riboswitch showed a marked optical difference in emission in the presence of DNT molecules, leading to the potential of using this construct in biosensitonal applications of highly nitrated compounds.

Monday, March 10, 2008 2:30PM - 5:30PM — Session D17 DBP: Focus Session: Time-Resolved Structural Investigations on Protein Folding and Function Morial Convention Center 209

2:30PM D17.00001 Folding dynamics of a family of beta-sheet proteins1, DENIS ROUSSEAU, Albert Einstein College of Medicine — Fatty acid binding proteins (FABP) consist of ten anti-parallel beta strands and two small alpha helices. The beta strands are arranged into two nearly orthogonal five-strand beta sheets that surround the interior cavity, which binds unsaturated long-chain fatty acids. In the brain isoform (BFABP), these are very important for the development of the central nervous system and neuron differentiation. Furthermore, BFABP is implicated in the pathogenesis of a variety of human diseases including cancer and neuronal degenerative disorders. In this work, site-directed spin labeling combined with EPR techniques have been used to study the folding mechanism of BFABP. In the first series of studies, we labeled the two Cys residues at position 5 and 80 in the wild type protein with an EPR spin marker; in addition, two singly labeled mutants at positions 5 and 80 in the C80A and C5A mutants, respectively, were also produced and used as controls. The changes in the distances between the two residues were examined by a pulsed EPR method. DEER (Double Electron Electron Resonance), as a function of guanidinium hydrochloride concentration. The results were compared with those from CW EPR, circular dichroism and fluorescence measurements, which provide the information regarding sidechain mobility, secondary structure and tertiary structure, respectively. The results will be discussed in the context of the folding mechanism of the family of fatty acid binding proteins.

3:06PM D17.00002 Ultrafast studies of flavins and flavoproteins, DONGPING ZHONG, Dept. of Physics, The Ohio State University — Flavin molecule plays an essential role as a cofactor in flavoproteins with its rich redox states. We have systematically studied the excited-state dynamics of three different redox states (oxidized, semiquinone, and fully reduced) in bulk solvent and in some important proteins. A series of new results were obtained and a correlation of structure-redox-dynamics-function in proteins was observed. We use two important proteins, photolyase and flavodoxin, to show these significant findings.

3:42PM D17.00003 Coupled folding and binding kinetics in the intrinsically disordered peptide IA31, RANJANI NARAYANAN, Department of Physics, University of Florida, OMJOY GANESH, ARTHUR EDISON, Department of Biochemistry and Molecular Biology, University of Florida, STEPHEN HAGEN, Department of Physics, University of Florida — IA3 is an intrinsically disordered 68 residue peptide and is an endogenous inhibitor of yeast peptidase A (YPaA). X-ray crystallography of the IA3-YPaA complex [Li et al, Nat. Struct. Biol. (7), 113-117 (2000)] indicates that the N-terminus of IA3 adopts an alpha-helical fold when it is bound to the YPaA active site. We have used equilibrium circular dichroism and multi-wavelength, nanosecond time-resolved laser temperature-jump spectroscopy to study the coupled folding and binding interaction of IA3 with YPaA. Our initial measurements of the rate of helix formation in free IA3 indicate mono-exponential folding kinetics that extrapolate to kF ~ 107/s at room temperature in aqueous solutions. By comparing this rate to the kinetics we observe for IA3 interacting with YPaA, we can assess possible mechanisms for the coupled folding and binding of IA3.

3:54PM D17.00004 Impact of Salt and Water on Protein Structural Dynamics, ANU THUBAGERE, LORAND KELEMEN, BEINING NIE, SANDIP KALEDHONKAR, AIHUA XIE, Oklahoma State University — Water is known as the lubricant of life. Without water, most proteins would lose their biological functions. Extensive studies have been carried out on how high concentration salts (dissolved in water) alter the stability and solubility of proteins. Such effects are thought to be mediated via salt-water interactions and water-protein interactions. This classic research field is known as the Hofmeister Series. We report the effects of Hofmeister Salts on the structural dynamics of proteins. Photoactive yellow protein (PYP), a bacterial blue light photoreceptor protein, is employed as a model system in this study. Time-resolved FTIR spectroscopic techniques allow us to probe the structural changes in proteins. Our data reveal that high concentration salt solutions alter the proton transfer pathway and suppress conformational changes in PYP upon photo-excitation. This study opens up a new dimension in the field of Hofmeister series. Further theoretical and experimental studies are needed in order to understand the dynamic properties of salt-water interactions and water-protein interactions.

4:06PM D17.00005 Direct protein photoinduced conformational changes using porphyrins, LORENZO BRANCALEON, IVAN SILVA, NICOLAS FERNANDEZ, ERIC JOHNSON, SAMUEL SANSONE, University of Texas at San Antonio — Most proteins functions depend on their interaction with other ligands. This interactions depend on uniquely structured binding sites formed by the folding of the proteins. Ligands can often prompt intended as well as “accidental” protein structural changes. One can foresee that the ability to prompt and control post-translational protein folding could be a powerful tool to investigate protein folding mechanisms but also to inhibit certain proteins or induce new properties to proteins. One possible way to produce such structural disruption is the combination of light and photoactive ligands. This option has been investigated in recent years by exploiting photosomerization and other properties of non-physiological dyes. We used an alternative approach which uses porphyrins as the “triggers” of structural changes. The advantage of porphyrins is that they can be found naturally in living cells. The photophysical properties of porphyrins can induce local as well as long range effects on the structure of the bound protein. Porphyrins are known to produce structural changes in porphyrin-specific globular proteins, however the novelty of our results is that we demonstrated that these dyes can also produce structural changes in non-porphyrin-specific globular proteins. We will present an overview of our research to-date in this field and its potential applications.
4:18PM D17.00006 Computer simulations of the folding mechanism of the GCN4 Leucine zipper, YANXIN LIU, PREM CHAPAGAIN, JOSE PARRA, BERNARD GERSTMAN, Department of Physics, Florida International University, University Park, Miami, FL 33199 — A modified three-dimensional lattice model incorporating a Monte Carlo Metropolis Algorithm is used to investigate the dimerization of the GCN4 Leucine zipper. The model is validated with heat capacity calculations that are seen to match well with experiment measurements. The free energy landscape is investigated as a function of temperature. Evidence of multiple meta-stable states is found during the simulation. The possible folding and dimerization mechanism of the Leucine zipper will be discussed.

4:30PM D17.00007 Describing protein folding through the evolution of spatial density, XIANG-HONG QI, JOHN J. PORTMAN, Kent State University — The capillary-like structure of folding nuclei is directly characterized for a wide range of two state folding proteins within a variational model that includes “neutral” cooperativity. We find that on average the volume of the folded core depends on the number of monomers as \( V_f \sim N^{0.3} \). The precise relation agrees with the packing of rigid objects that are typically twice the size of a monomer in the native state. Focusing on the growth of the folded core and the interface region, we identify three different growth modes: core and interface consolidation, core dominated consolidation, and balanced growth. We also show in detail how the density of the core and interface of critical nuclei determine the common qualitative characterization as either diffuse or polarized. Such analysis will aid interpretation of \( \phi \)-value distributions in terms of the spatial density or compactness of the critical nucleus which is much more difficult to probe experimentally than the degree of similarity to the native state.

4:42PM D17.00008 The trigger sequence in the protein folding and dimerization of the Leucine zipper coiled-coil motif, PREM CHAPAGAIN, YANXIN LIU, BERNARD GERSTMAN, Department of Physics, Florida International University, University Park, Miami, FL 33199 — The existence of a trigger sequence in the protein folding and dimerization of the Leucine zipper coiled-coil structure is attracting increased interest. Also of interest is the presence of multiple meta-stable states in the folding and unfolding process. Using a computer lattice model, we investigate the effect of the trigger sequence by changing the strength of the propensity of the amino acids in the trigger sequence to form alpha-helix secondary structure. The results show that the trigger sequence is necessary for folding and dimerization. The trigger sequence also creates a folding and dimerization process that includes multiple meta-stable states.

4:54PM D17.00009 Correlation functions of flexible macromolecules, DONALD JACOBS, DENNIS LIVESAY, OLEG VOROV, UNC at Charlotte — We present an ab initio calculation of conformational entropy, radii of gyration, X-ray and neutron scattering form-factors, correlation functions, and other observables describing proteins, polypeptides, nucleic acids, related macromolecules and artificial polymers [1]. The analytic form of the method minimizes computational costs and reveals relations between observables. We apply these methods to study thermodynamics of protein unfolding. The presented results agree with the results from experiment and simulation [2].

5:06PM D17.00010 ABSTRACT WITHDRAWN

5:18PM D17.00011 Photocycle of a single photoactive yellow protein molecule studied by surface-enhanced Raman scattering, KAAN KALKAN, KUSHAGRA SINGHAL, WOUTER HOFF, AIHUA XIE, Oklahoma State University — We have demonstrated the detection of single molecules of photoactive yellow protein (PYP), by employing our novel surface-enhanced Raman scattering (SERS) active substrates. The Raman spectra reveal both “receptor” (G) and “signaling” (B) states of PYP at the single molecule level (at 514 nm excitation). The single molecule spectra are observed in terms of sudden appearance of discernable Raman peaks, each indicative of a PYP molecule finding a hot spot. The SERS spectra also exhibit various peaks, which are not normally Raman-active. Although the PYP has a long-lived signaling state (i.e., \( \sim 0.3 \) s), the Raman peaks identifying this state are found to be dramatically narrow at the single molecule level for signal integration times of 0.25-0.5 s. In several instances, we observed subsequent change of the spectrum from B to G state. Although, the PYP is not chemisorbed on the metal nanoparticles, its short-term psysorption is anticipated to allow for the capture of its photocycle at the single molecule level. In addition to narrower and better resolved peaks, the single molecule spectra also show variation in relative peak intensities. In particular, the C-C stretching and C-H bending modes of the aromatic ring of the chromophore inversely correlate at the single molecule level, while their intensities are comparable in the ensemble-average spectrum.

2:30PM D18.00001 Surface Segregation in Blends of Chains with Two Architectures, MARK FOSTER, SEWOO YANG, NAM-HEUI LEE, The University of Akron, DAVID WU, Colorado School of Mines — Blends of chains of two architectures, e.g. linear chains with pom-pom branched polymers, present opportunities for tailoring bulk rheology and surface character of the blends. Pom-pom chains contain a central linear portion between two junction points from which multiple arms extend. We have studied the effect of varying the relative length of the central linear portion between two junction points from which multiple arms extend. The strength of segregation to the surface and substrate interface of a blend film is seen with neutron reflectivity and surface enhanced Raman spectroscopy to correlate at the single molecule level, while their intensities are comparable in the ensemble-average spectrum.

2:42PM D18.00002 Single chain mobility at an interface of a liquid polymer, JINGFA YANG, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences, Beijing, China — Interfacial diffusion of single chains of polystyrene-b-polyisoprene (PS-b-PI) at the interface between polystyrene and its non-solvent, DMF, was studied by fluorescence correlation spectroscopy. The diffusion coefficient of PS-b-PI probe was found to be two orders of magnitude high than that in the bulk PI, indicating a lower interfacial viscosity. The experimental data also exhibit a very weak dependence of the interfacial diffusion coefficient on the molecular weight of the liquid polymer. The possible mechanism was discussed.

2:54PM D18.00003 Molecular origin of oil resistance of polyacrylonitrile: CN interactions at the surface . VERONIQUE LACHAT, ALI DHINO.IWAL. The University of Akron, DENNIS PEIFFER, MOHSEN YEGANEH, ExxonMobil Corporate Strategic Research Laboratories — Nitrile rubber (NR) is a random copolymer of acrylonitrile and butadiene and is one of the best oil resistance polymers. The superior oil resistance property of nitrile rubber is thought to be directly related to the amount of acrylonitrile used in NR. Here, we report for the first time measurements on materials that fit this description, C_60 reaction conditions was found to influence the observed coverage kinetics, so film swelling was monitored with environmental AFM. The attachment to these surfaces follow different kinetics than those observed for the polymeric substrates. The swelling of the polymeric substrates under the increasing AA and nanoparticle concentration, and time. SAMs containing an acrylic acid moiety were used as a non-swelling control surface, and particle (SAMs) of (3-aminopropyl)triethoxysilane were covalently attached to the PS-ran-PAA films with an EDC/NHS coupling reaction. To measure the kinetics of efforts have focused on the development of nanoparticle arrays with controlled spacing. In this study, poly(styrene-ran-acrylic acid) films were prepared by spin-

3:06PM D18.00004 Effect of Hydrogen Bonding on Colloidal Nanocrystal Growth: The Case for PbS . LIXIN ZHANG, National Renewable Energy Laboratory, Golden, CO 80401, SHENGBAI ZHANG, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180 — The adsorption of methylamine (CH_3NH_2) on rocksalt PbS(111)-S surface is studied by first-principles total energy calculation. It was found that nitrogen lone pairs on the CH_3NH_2 can form dative bonds with surface sulfur atoms. Such an interaction is unique in two ways: first it is non-local. Charge transfer takes place from CH_3NH2 not only to the closest S but also to surface S further away. Second, the interaction is strongly affected by hydrogen bonds formed between CH_3NH2 and solution molecules such as H_2O. Only by the latter effect can the PbS nanocrystals assume the (111) facets in a colloidal growth in agreement with experiment. In the past, studies of nanostructures have taken the assumption that, in the absence of a solution, the relative stability among the various facets will not change, at least not dramatically. Our study shows that such an assumption is not necessarily true. The significance of the study therefore goes beyond just the PbS or PbTe systems. Its basic principles should apply to all colloidal growth of solid-state nanostructures with broad implications.

3:18PM D18.00005 Conformational behavior of polymers adsorbed on nanotubes . SIMCHA SREBNIK, INNA GUREVITZ, Technion - Israel Institute of Technology — We study the interaction of a dilute solution of semiflexible polymers with a weakly attractive infinitely long nanotube using Monte Carlo simulation. Apart for bending stiffness of the polymer chains, the only interactions considered in our model are weakly attractive short-ranged Lennard-Jones interactions between the monomers and with the surface. These nonspecific interactions are found to result in stable helical and multi-helical adsorbed conformations for semiflexible chains. Adsorption of these chains is found to occur in a sequential manner through tight wrapping of the polymer around the nanotube. Adsorption occurs quickly and is characterized by a sharp peak in the heat capacity. A second transition follows whereby opening and reorganization of the adsorbed chains into nearly perfect helices and multiple helices. Extension of the model to block and triblock copolymers reveals rich conformational behavior. These results are discussed on physical grounds and implications towards polymer-carbon nanotubes composites are offered.

3:30PM D18.00006 Origin of glass transition temperature behavior in polymer nanocomposites . JAMIE KROPKA, VENKAT GANESAN, The University of Texas at Austin, PETER GREEN, The University of Michigan — Local composition variations inherent in multi-component materials, even when the material constituents are miscible, generally lead to heterogeneous behavior in the properties of mixtures relative to their single component counterparts. In contrast, experiments have suggested that some polymer nanocomposite materials exhibit changes in their bulk T_g without displaying excess heterogeneity in their dynamics, as measured mechanically, relative to the neat polymer. Incoherent neutron scattering measurements for blends of PMMA and PPO, and this model for PMMA mixtures, suggest that modifications of the polymer melt dynamics are limited to the vicinity of the particles. A model by which the localized modifications of polymer dynamics can account for the apparent homogeneous change in T_g is proposed to explain the experimental findings. Computations based on percolation theory support the model.

3:42PM D18.00007 Directed Self-Assembly of Gradient Concentric Carbon Nanotube Rings . SUCK WON HONG, WONJE JEONG, Iowa State University, HYUNHYUB KO, VLADIMIR TSUKRUK, Georgia Institute of Technology, MICHAEL KESSLER, ZHIQUN LIN, Iowa State University — Hundreds of gradient concentric rings of linear conjugated polymer, (poly[2-methoxy-5-(2-ethylhexyloxy)-1,4-phenylenevinylene], i.e., MEH-PPV) with remarkable regularity over large areas were produced by controlled, repetitive “stick-slip” motions of the contact line in a confined geometry consisting of a sphere on a flat substrate (i.e., sphere-on-flat geometry). Subsequently, MEH-PPV rings exploited as template to direct the formation of gradient concentric rings of multiwalled carbon nanotubes (MWNTs) with controlled density. This method is simple, cost effective, and robust, combining two consecutive self-assembly processes, namely, evaporation-induced self-assembly of polymers in a sphere-on-flat geometry, followed by subsequent directed self-assembly of MWNTs on the polymer-templated surfaces.

3:54PM D18.00008 Use of Fluorescence Correlation Spectroscopy for Studying Polyelectrolyte-Nanoparticle Interaction in Aqueous Solution . NADIA EDWIN, DENIS PRISTINSKI, CHENGQING WANG, VIVEK PRABHU, NIST — Formation of polyelectrolyte complexes is very facile via layer-by-layer sequential adsorption of oppositely charged species method. This method has been used to fabricate versatile materials with tailored properties. However, the fundamental assembly mechanisms of these advanced engineering materials and the adsorption kinetics of these systems is not completely understood. We use fluorescence correlation spectroscopy (FCS), which analyzes fluctuations in the fluorescence emission of molecular ensembles and provides the concentration, mobility, and dynamics of fluorescently labeled molecules, to study the interaction of polyelectrolyte-nanoparticle assembled structures to establish what’s driving the adsorption of these systems, the dependence of molecular weight and the effects of variations in the solution environment with pH and ionic strength. Layer-by-layer assembly was performed on fluorescent dye-labeled spherical nanoparticles and amine and carboxyl functionalized polyelectrolytes in aqueous solution. Changes in the dynamics of the polyelectrolyte-nanoparticle system in response to various salt and pH conditions will be presented.

4:06PM D18.00009 Directed Nanoparticle Assembly onto Random Copolymer Templates: Kinetics and Surface Considerations . MARLA MCONNELL, SHU YANG, RUSSELL COMPOSTO, University of Pennsylvania — Recent efforts have focused on the development of nanoparticle arrays with controlled spacing. In this study, poly(styrene-ran-acrylic acid) films were prepared by spin-casting poly(styrene-ran-t-butyl acrylate), followed by thermal deprotection. Silica nanoparticles (10-15 nm in diameter) coated with self-assembled monolayers (SAMs) of (3-aminopropyl)triethoxysilane were covalently attached to the PS-ran-PAAc films with an EDC/NHS coupling reaction. To measure the kinetics of nanoparticle attachment, films of either 25 or 50 weight percent acrylic acid were reacted with nanoparticle suspensions from 0.005 to 0.1 weight percent for varying lengths of time. SEM imaging of the nanoparticle surfaces showed that the particles were well dispersed, and that particle coverage increased with increasing AA and nanoparticle concentration, and time. SAMs containing an acrylic acid moiety were used as a non-swelling control surface, and particle attachment to these surfaces follow different kinetics than those observed for the polynimeric substrates. The swelling of the polynimeric substrates under the reaction conditions was found to influence the observed coverage kinetics, so film swelling was monitored with environmental AFM.
4:18PM D18.00010 Studies of the Dynamics of Alkane Nanoparticles1, S.-K. WANG, M. BAI, H. TAUB, M. RHEINSTADTER, U. Mo.-Columbia, J. R. D. COLEY, V. GARCIA SAKAI, G. GASPAROVIC, NIST, U. C. VOLKMAN, P. U. Catolica Chile, P. Y. HANSEN, Tech. U. of Denmark — Our AFM and synchrotron x-ray scattering measurements on dotriacontane (C32H66 or C32) deposited on SiO2-coated Si(100) substrates reveal mesa-shaped nanoparticles that have an orthorhombic structure in which the C32 molecules are aligned perpendicular to the SiO2 surface. To investigate their dynamical properties, we have used both the backscattering and disk chopper spectrometers at NIST covering a wide range of time scales (1 ps – 4 ns). Elastic scans obtained on both spectrometers show step-like changes in intensity as a function of temperature indicating the existence of phase transitions below the bulk C32 melting point. One of these steps occurs at the crystalline-to-rotator phase transition of bulk C32, but there is a second step at still lower temperature of unknown origin. The similarity of the elastic scans on the two spectrometers suggests that the crystalline-to-rotator phase transition involves diffuse motion spanning a wide range of time scales. #M. Bai et al., Europhys. Lett. 79, 26003 (2007).

1Supported by Grant Nos. U.S. NSF DMR-0411748 and DMR-0705974, by the U.S. DOE through Grant No. DE-FG02-01ER45912, and FONDECYT 1060628 and 7070248.

4:30PM D18.00011 Hierarchically Ordered Plasmonic Mask for Photo-lithography . WOO SOO KIM, EDWYN L. THOMAS, MIT — A new high density nanolithography method for the fabrication of a hierarchically ordered plasmonic mask employs silver (Ag) nano-particles (NPs) attached to the surface of an amine- functionalized two-dimensional (2D) pattern fabricated by laser interference lithography (IL). The bi-functional sol-gel hybrid material (BFHM) is a negative-tone resist and can be directly patterned by IL. Since the BFHM has both an amine-function and a methacryl function on each polymer chain, photopolymerization provides network formation and a set of binding sites for the Ag NPs. The Ag NPs were then attached onto the BFHM pillars by immersing the patterned sample in a solution. Hierarchically ordered arrays of Ag NPs could be made by a block copolymer comprised of 40nm diameter spherical P2VP domains having a spacing of 88nm, forming a hexagonal pattern covering the hexagonally arrayed BFHM pillars. Lithography experiments using 430 nm light wavelength demonstrate transfer of both a 350 nm periodic pattern and a 88nm patten to a positive-tone photoresist via plasmonic field enhancement arising from the collective and individual excitation of the closely spaced interacting Ag NPs on the hierarchically patterned BFHM.

4:42PM D18.00012 Dynamics of an Adsorbed Polymer Chain . JOSHUA KALB, SANAT KUMAR, Columbia University — Because of the current precision in fluorescent labeling, it is possible to label single polymers such as DNA or PEG and track their dynamical and equilibrium properties in the bulk as well as near attractive surfaces [Maier et. al., Macro 2000] [Sukhishvili et. al., Macro 2002]. Recent evidence from these experiments and related simulations has shown that the dynamics of a single polymer near an attractive surface appear diffusive, however further evidence coming from the ‘diffusion coefficient’ implies a different process other than diffusion is at work such as reptation, ‘hovercrafting’, or ‘hopping’ [Sukhishvili et. al., Macro 2002]. In general, these possible dynamical behaviors are determined by the length of the polymer itself as well as the microscopic details of the attractive surface which include the density, strength, and distribution of attractive surface sites [Desai et. al., PRL 2007] [Qian et. al., PRL 2007]. In this presentation, we investigate the effects of microscopic surface effects on single polymer dynamics through Monte-Carlo and molecular dynamics simulations.

4:54PM D18.00013 Chasing drops: Following escaper and pursuer drop couple systems . AISHA LEH, RAFAEL TADMOR, PREETI YADAV, PRASHANT BHADUR, KUMUD CHAUDRASIA, LAN DANG, Lamar University — We study the Marangoni flow induced by two chemically different drops resting on a solid surface in air. We show that in all the systems studied, the Marangoni flow is induced at the solid-liquid interface as opposed to the air-liquid interface. This is true even for the case of water drop and alcohol drop on a glass surface (corresponding to the classical “tears of wine” case). Thus we explain the drop motion as a result of a surface tension gradient which takes place primarily at the air-surface region (and less at the drop-substrate or drop-air interfaces). The discontinuous motion of the drops, characterized by stops and jumps as in a “stick slip” mechanism is explained by an increase in the Laplace pressure that creates a higher anchoring pinning effect at the front edge of the moving drop. We discuss this in connection to the “tears of wine” case.

5:06PM D18.00014 The Measurement of Surface Rheological and Surface Adhesive Properties using Nanosphere Embedment . STEPHEN HUTCHESON, GREGORY MCKENNA, Department of Chemical Engineering - Texas Tech University — In previous work, we determined the actual rheological behavior at the surface of a polystyrene film with nanometer scale resolution by applying a viscoelastic contact mechanics model to experimental data in the literature. The goal of our current research is to build upon this analysis and use nanosphere embedment experiments to probe the nanorheological behavior of polymer surfaces near the glass transition, in the melt state and in the solid rubbery state. An atomic force microscope (AFM) is used to probe the embedment depth as nanoparticles are pulled into the surface by the thermodynamic work of adhesion. The results show that, with properly designed experiments, both the surface adhesion properties and the surface rheological properties can be extracted from nanosphere embedment rates. We include work on a phase separated copolymer and a commercially available polydimethylsiloxane (PDMS) rubber.

5:18PM D18.00015 Slip behavior of the confined polymer melt near periodically roughened surfaces: comparison between molecular dynamics and continuum simulations . ANOOSHEH NIAVARANI, NIKOLAI PRIEZJEV, Michigan State University — Molecular dynamics (MD) simulations are used to investigate the behavior of the slip length in the Couette flow of a polymer melt. For atomically smooth surfaces and weak wall-fluid interactions, the shear rate dependence of the slip length is a non-monotonic function, with a distinct local minimum. For corrugation wavelengths larger than the radius of gyration of polymers, the decay of the slip length with corrugation amplitude obtained from MD simulations agrees well with the continuum predictions for the following cases: (1) Stokes solution with constant local slip length, (2) Stokes solution with local shear-rate-dependent slip length, and (3) Navier- Stokes solution with local rate-dependent slip length. If the corrugation wavelength is less than or on the order of the radius of gyration, the continuum predictions (the Stokes solution) overestimate the values of the slip length extracted from MD simulations. The analysis of the conformational properties of the polymer melt indicates that polymer chains tend to stretch in the direction of shear at the peaks of the sinusoidal wave and align themselves along the bottom of the grooves.

Monday, March 10, 2008 2:30PM - 5:30PM
Session D19 DMP: Focus Session: Dopants and Defects in Semiconductors 1 Morial Convention Center 211
2:30PM D19.00001 Stability and Dynamics of Frenkel Pairs in Silicon

MATTIEW J. BECK, Physics and Astronomy, Vanderbilt University — Extensive EPR experiments on electron irradiated p-Si observe only signals identified as arising from isolated vacancies and interstitial impurities. Subsequent experiments and calculations demonstrated that isolated interstitials in p-Si diffuse athermally according to a charge-carrier-mediated mechanism. The overall conclusion has been that Si FPs either rapidly recombine or dissociate, even at cryogenic temperatures. More recent X-ray scattering experiments, however, suggest that Si FPs persist at temperatures up to 150 K. We report first-principles calculations of Si FP properties and resolve the apparent conflict between experiments. We find that the vacancy and interstitial components of a proximal FP interact electronically, suppressing the previously identified athermal interstitial diffusion. Such proximal FPs are bound only by the presence of barriers to either recombination or dissociation.

Further, metastable FPs may lower their energy by transferring electrons from the interstitial to the vacancy component. We show that EPR studies of FPs are likely unable to distinguish between FPs and isolated vacancies. In addition, calculated diffusion barriers for FP components indicate that FPs should anneal at temperatures similar to those for isolated vacancies: \( \sim 150 \) K.

3:06PM D19.00002 Defect Formation Energies without the Band-Gap Problem: Combining DFT and GW for the Silicon Self-Interstitial

P. RINKE, A. JANOTTI, C.G. VAN DEWALLE, M. SCHIEFFLER, University of California at Santa Barbara — For the self-interstitial in silicon, a defect of high technological relevance, density functional theory (DFT) in the widely applied local-density approximation (LDA) underestimate the formation energies of different configurations in the neutral charge state by \( \sim 1.5 \) eV compared to diffusion Monte Carlo calculations [1,2]. We attribute this to artificial self-interaction and the absence of the derivative discontinuity in the LDA-exchange-correlation potential that give rise to the band-gap problem. We present a new formalism that combines LDA with quasiparticle energy calculations in the \( G_0W_0 \) approximation to overcome these deficiencies. The formation of the neutral defect is expressed as successive charging of its 2\(^+\) charge state, for which the defect level is unoccupied, permitting a decomposition into a lattice (LDA) and an electron addition part (\( G_0W_0 \)) [3]. The \( G_0W_0 \) corrections increase the LDA formation energy by \( \sim 1.1 \) eV. Moreover, the \( G_0W_0 \)-corrected charge transition levels agree well with recent measurements [4]. [1] Batista et al. PRB 74, 121102(R) (2006), [2] Leung et al. PRL 83, 2351 (1999), [3] Hedström et al. PRL 97, 226401 (2006), [4] Bracht et al. PRB 75, 035211 (2007)

AMITA WADEHRA, JOHN W. WILKINS, Ohio State University, RICHARD G. HENNIG, Cornell University — The self-interstitials in silicon created by ion-beam processing determine migration rate of impurities, time evolution of dislocations and dopant-enhanced diffusion. The large mobility of interstitials makes their experimental observation difficult. Electron-assisted transport mechanism suggests that charged states with different migration barriers and minimum energy positions are responsible for this rapid migration. Therefore, it becomes necessary to identify the stable ground state charges for each geometry and electron chemical potential. Recent studies of energetics and migration of these defects have largely concentrated on neutral defects and a few on charged single interstitials. We present a density functional study of electronic structure and energetics of charged single-, di- and tri-interstitials in silicon. An analysis of stability of five different charged states in various geometries is provided through formation energies. The diffusion pathways of these charged interstitials are also discussed.

3:30PM D19.00004 Large scale ab initio calculations for shallow acceptor levels in bulk Si

LIN-WANG WANG, Lawrence Berkeley National Laboratory — Accurate calculation of shallow donor levels in conventional semiconductors is a long standing challenge due to the large supercell needed for such calculation. We have used the charge patching method and local density approximation (LDA) to study the acceptor levels in bulk Si, including B, Al, Ga, In and Ti acceptors. The atomic positions are relaxed under LDA using 512 atom cells, and 64,000 atom supercells are used to calculate the acceptor energy levels to achieve the converged results. The calculated impurity binding energies reproduce the experimental trend from B to Ti. However, there is still a significant difference between the calculated binding energies and the experimental results, especially for Ti. This raises the question of whether the LDA can be used to calculate the shallow impurity level accurately.

3:42PM D19.00005 Relative stability of extended interstitial defects in silicon: large-scale classical MD and first-principles DFT

HYOUNGKI PARK, JOHN WILKINS, The Ohio State University — Extensive simulations for doped Si reveal the relative thermal and temporal stability of extended interstitial defects: 311 and 111 rod-like defects, and Frank dislocation loops. Classical molecular dynamics simulations provide the atomic configurations of those defects, and show that the energetically favored structures change from 311 rod-like defects to Frank loops as the number of interstitials increases, which is consistent with the experimentally-observed transition from rod-like defects to Frank loops after long, high-temperature annealing processes [1,2]. This relative stability is validated with massively parallelized density-functional calculations of 1500-atoms 2D supercells. Relaxation of experimentally-observed-size defect cluster demonstrates the energetic hierarchy is dependent on the number of interstitials in the defect clusters. [1] L. S. Robertson et al., J. Appl. Phys. 87, 2910 (2000). [2] G. Z. Pan et al., J. Non-Crystalline Solids 352, 2506 (2006).

3:54PM D19.00006 Ortho-para transition of interstitial H\(_2\) in Si

MICHAEL STAVOLA, CHAO PENG, MEGAN LOCKWOOD, Lehigh University — Interstitial H\(_2\) in Si is a nearly-free rotator and has ortho and para species with the nuclear spins of the two protons aligned either parallel or antiparallel [1]. If one waits a sufficiently long time at low temperature, H\(_2\) will relax to its lower energy para state. The ortho-para (o-p) transition for H\(_2\) in Si has been observed in recent Raman studies [2]. We have performed IR absorption experiments to investigate issues that have proved difficult to study by Raman. When a Si sample containing H\(_2\) is stored for a month or more at 77K, the 3618.4 cm\(^{-1}\) IR line assigned to o-H\(_2\) [1] is reduced in intensity because, when the o-p transition occurs, p-H\(_2\) is not seen by IR. When this sample was annealed at room temperature, the ortho population characteristic of room temperature was recovered with a time constant of \( \sim 6\) hrs. Our IR studies of the kinetics of the o-p transition complement recent Raman results and suggest that the cause of the o-p transition is not yet understood.

4:06PM D19.00007 Carbon Impurity Effects on Structural and Magnetic Properties of Manganesne Doped Silicon, JOSHUA LAROSE, ROGER PINK, TARA P. DAS, MENG-BING HUANG, SUNY-Albany, JIAN-QING WANG, SUNY-Binghamton — The recent finding of room temperature ferromagnetism in Mn-doped Si may open up a promising route toward Si-based spintronic. In this work, we investigate effects of co-doped carbon on the structural and magnetic properties of Si:Mn, in a hope to identify possible microstructures responsible for ferromagnetism. Carbon atoms of 0.25 at. % are uniformly doped within the 200-nm surface layer of Si(100) using ion implantation. The C-rich Si and the Mn control are subsequently implanted at 300 °C with Mn ions, yielding a concentration profile of Mn (Mn%) ∼ 0.25 at. % within the depth of 160 nm. Post-implantation annealing is conducted in the range of 800-1000 °C. Ion channeling measurements suggest that Mn could occupy several lattice sites in Si including the tetrahedral interstitial and substitional site, with respective occupancy affected by carbon impurity and thermal annealing. The Hartree-Fock Cluster Method is used to calculate the binding energies of Mn for different lattice sites in Si. These structural information are compared with the results of superconducting quantum interference device (SQUID) experiments.

4:18PM D19.00008 Thermal Stability and Laser Annealing of Si1-fyCf alloys, STEFAN ZOLLNER, P. GRUDOWSKI, V. DHANDAPANI, G. SPENCER, A. THEAN, Freescale Semiconductor, Inc. — Dilute alloys of silicon and carbon are metastable, but can be produced (up to 3% C) using nonequilibrium growth techniques, such as chemical vapor deposition. In such alloys, carbon atoms are located at lattice sites (preferred for device applications) or at interstitial sites. Other impurities (such as H) can be introduced during the growth process. Since Si:C alloys are metastable, they usually do not survive typical source-drain dopant activation anneals (on the order of 1000°C for S). Also, Si:C alloys implanted with NMOS dopants do not recover as Si:C from ion implantation followed by pulsed laser melting and rapid solidification. We observed broadband subthreshold conduction below to a noisy, subthreshold (perhaps even percolative) path at lower voltages, with a significant contribution from the high density of defects at ∼5 V above the standard extrapolated threshold voltage. This field oxide structure has a length of 5 µm. We find that this variation is due to a transition from noisy subthreshold conduction to full conduction in strong inversion at a point that is more than ∼1 ms near the melting point), leading to an increase in the measured substitutional carbon content. This indicates a conversion of interstitial carbon defects into substitutional carbon or an evolution of hydrogen. We describe our results using a multiscale model applicable to thermal processing over a broad range of temperature and anneal times. Our model describes both solid-state regrowth and the loss or gain of substitutional carbon after annealing. We also present NMOS transistor results, where embedded Si:C alloy source-drain stressors lead to a reduction in the channel resistance.

4:30PM D19.00009 Chalcogen dopants for infrared optoelectronic Si, JEFFREY WARRENBERGER, US Army Benet Laboratories, BRION BOB, MICHAEL AZIZ, Harvard School of Engineering and Applied Sciences, SUPAKIT CHARNVANICHBORIKARN, JAMES WILLIAMS, Australian National University, MALEK TABBAL, American University of Beirut, ATSUSHI KOHNO, Fukuoka University — Doping Si with a chalcogen in excess of the solubility limit has been shown to result in subbandgap optical absorption and sensitive photodetection, suggesting potential for chalcogen-doped Si as an infrared optoelectronic material. We investigated optical absorption and photovoltaic energy conversion using S, Se, and Te as dopants. We achieved significant conversion efficiencies at extreme doping levels. We observed a gate-voltage dependence of the photovoltaic conversion efficiency for all dopants over a wavelength range from 1 to 2.3 microns. The subbandgap absorption and photovoltaic response depended sensitively on the chalcogen dose, laser processing, and thermal annealing conditions. We correlate these observations with the corresponding influence of the processing conditions on the material’s crystalline quality, chalcogen dopant depth profile, carrier concentration profile, and dopant activation. We found good agreement between the chalcogen depth profiles obtained from experiments and 1-dimensional model for plane-front melting, solidification, liquid-phase diffusion, and kinetic solute trapping.

4:42PM D19.00010 H-shuttling within a Hf-defect complex in Si/SiO2/HfO2 structures, A.G. MARINOPoulos, I. BATYREV, X. ZHOU, R. SCHRIMPF, D. FLEETWOOD, S.T. PANTELIDES, Vanderbilt University, Department of Physics and Astronomy — It was recently shown that, following irradiation of Si/SiO2/HfO2 structures by X-rays or constant-voltage stress, both oxide- and interface-trap densities exhibit oscillations with switch-bias annealing that are much larger than those previously observed in Si/SiO2 devices. Here we describe a particular defect complex that can account for the observations. The complex comprises a suboxide Hf-Si bond and an interfacial dangling bond (P center). With the aid of first-principles calculations we show that this defect possesses a symmetric double-well minimum and can provide trapping sites for H atoms near the interface. In the first site, the H atom passivates the dangling bond; in the second site the H atom resides near the center of the Hf-Si bond. A moderate intervening barrier (1.2 eV) suggests a relatively easy hopping of H atoms between these two energy minima, aided by the applied field and temperature. This shuffling mechanism can explain the observed oscillations in the interface trap densities during switched-bias conditions. This work was supported in part by the AFOSR and the DOE.

5:04PM D19.00011 Transition from high to low 1/f noise regimes in Field Oxide Field Effect Transistors (FOXFETs), XING ZHOU, DANIEL FLEETWOOD, RONALD SCHRIMPF, Vanderbilt University, LAURA GONELLA, FEDERICO FACCIO, CERN, PH Department, VANDERBILT COLLABORATION, CERN COLLABORATION — The excess low frequency (1/f) noise of parasitic field oxide FET (FOX) transistors from a 130 nm technology has been found to vary by more than ∼6 orders of magnitude with gate voltage, above the nominally measured device threshold. We find that this variation is due to a transition from noisy subthreshold conduction to full conduction in strong inversion at a point that is more than 5 V above the standard extrapolated threshold voltage. This field oxide structure has a length of ∼1 micron and a width of ∼200 micron. We attribute the conduction band modification to a substitution or interstitial carbon impurity at lower voltages, with a significant contribution from the high density of defects at ∼5 V above the Si/SiO2 interface in this parasitic FOXFET structure. The noise above the True threshold (as determined with assistance from the noise measurements) follows a standard number fluctuation model, when the subthreshold conduction regime is separated out in the analysis. This work was supported in part by the US Navy.

5:06PM D19.00012 Effects of Aging and Humidity on Low-Frequency Noise of Metal-Oxide-Semiconductor (MOS) Transistors, ARITRA DASGUPTA, Department of Physics & Astronomy, S.A. FRANCIS, Department of Electrical Engineering and Computer Science, D.M. FLEETWOOD, Department of Electrical Engineering and Computer Science, Vanderbilt University — Low frequency noise measurements can provide a non-destructive method of measuring radiation hardness and/or reliability of MOS transistors. We have been studying the effects of moisture exposure at elevated temperatures on MOS low frequency noise. The devices under test were manufactured in the 1980s and came from two different process lots. The results show that the normalized 1/f noise magnitudes K of the pMOS transistors increased significantly with exposure to humidity at elevated temperatures, while the changes in the 1/f noise magnitudes of the nMOS transistors were mostly much less. To estimate the energy dependence of the defects responsible for the noise, we evaluated the gate voltage dependence (Vg-Vt) of the noise, where Vt is the threshold voltage. We find, for the pMOS transistors, Snd−(Vg-Vt)−1, whereas, for the humidity exposed nMOS transistors, Snd−(Vg-Vt)−1.25. These deviations from an inverse square voltage dependence indicate a strong energy dependence of the defect distribution due to humidity exposure.

5:18PM D19.00013 Disorder–recrystallization effects following low-energy beam–solid interactions, MATTHEW J. BECK, Physics and Astronomy, Vanderbilt University, D. M. FLEETWOOD, R. D. SCHRIMPF, Electrical Engineering, Vanderbilt University, S. T. PANTELIDES, Physics and Astronomy, Vanderbilt University — Classical MD simulations have shown that thermal-spike-related disorder, including local melting, should be widely expected following high energy (>1 keV) recoils resulting from beam– solid interactions during ion-beam processing. In contrast, the formation of isolated point defects by direct atomic displacement is expected for low energy (<1 keV) recoils. Using state-of-the-art dynamical DFT calculations of Si–Si systems we show that recoils of much less than 1 keV result in highly disordered regions which persist for 100s of fs. Therefore, the production of beam-induced defects, as well as the post-implant yield of active dopants, following low-energy beam–solid interactions is controlled by dynamic recrystallization processes. This work was supported in part by the AFOSR through a MURI grant.
2:30PM D20.00001 Silicon Nanomembranes1. MAX G. LAGALLY, University of Wisconsin-Madison — Silicon nanomembranes (SiNMs) are extremely flexible, strain-engineered, defect-free, thin single-crystal sheets, with thicknesses from several 100 nm to less than 10 nm. Their novelty is several-fold: they are flexible, they are readily transferable to other hosts and conform and bond easily, they are stackable, and they can take on a large range of shapes (tubes, spirals, ribbons, wires) by engineering the strain and patterning the geometry. One can thus think of SiNMs as having inexact and tunable dimensionality, from 3-D to 0-D (when growth of quantum dots is included). Many properties of bulk Si are modified by thinness, strain, shape, and size, including band structure and quantum properties, electronic transport, phonon distributions, and mechanical properties. Because they are so close, the two surfaces of the membrane can influence each other’s behavior, and the surface also becomes a significant influence on overall SiN properties. After a review of SiNM fabrication, strain engineering, and transfer, we overview some of the unexpected physical and electronic properties of SiNMs. These include surface transfer doping via surface structures or adsorbed layers, through-membrane elastic interactions to create periodic strain lattices, energy level splitting and shifting with strain and quantum size effects, and orientation-dependent mobility enhancement with strain. SiNMs provide the potential for new or enhanced application of Si in fast flexible electronics; quantum electronics, new nanophotonic, optoelectronic, and thermoelectric devices; and chemical and biological sensors. These applications will be briefly outlined.

3:06PM D20.00002 Controlled displacement of nanoscale structures using an electron wind force. C.G. TAO, W.G. CULLEN, E.D. WILLIAMS, University of Maryland, College Park — Electromigration is widely used to drive mass transfer in the fabrication of nanogaps, and will be a crucial issue for the structural stability, reliability and performance of nanoscale electronic devices. Using a combination of scanning tunneling microscopy and scanning electron microscopy, we directly observe the biased motion of monatomic islands driven by the electron wind force on patterned single-crystal Ag(111) thin films. The island motion can be steered by changing the direction of the applied electric current. For monatomic adatom islands, the biased motion is opposite to the current direction and along the wind force direction, while vacancy islands move in the opposite direction. The measured dependence of the drift velocity on the island size, yields the product of the diffusion constant and the magnitude of the wind force, giving the diffusion constant $D = 1.56 \times 10^{10} \text{cm}^2/\text{s}$ for an effective charge of $e_s = 360 [1]$. The wind force acts even more strongly on Cu-decorated Ag(111) single-crystal pillars, as observed by directionally-oriented bending of step edges. The wind force needed to cause the observed structure distortions is $F = 0.13 \text{meV/\text{nm}}$, about 3 times the corresponding wind force acting on the bare steps. [1] A. Bondarchuk, et al. PRL 99, 206801 (2007).

3:18PM D20.00003 Lateral alloy segregation in thin heteroepitaxial films. CHRISTIAN RATSCH, JASON REICH, XIAOBIN NIU, YOUNGJU LEE, RUSSEL CAFLISCH, UCLA — We have studied the segregation and alloy formation of thin heteroepitaxial films. We use an atomistic strain model that has a cubic geometry and includes nearest neighbor bonds, next nearest neighbor bonds, and bond bending terms. Our motivation is the well established fact that for many heteroepitaxial systems growth proceeds in the Stranski-Krastanov growth mode, where islands form after the formation of a wetting layer. Recent results indicate that intermixing and thus vertical variations of the alloy concentration are a crucial factor in controlling the formation and thickness of the wetting layer. Our results suggest that in addition to vertical segregation there is also lateral segregation. Thermodynamically, the system prefers to have one big feature of the epilayer material that is embedded in the substrate but is near the surface. In practise, there will be a typical separation distance of these features because of kinetic limitations. We postulate that this lateral segregation and the separation of these features is ultimately responsible for the lateral placement of islands on the surface.

3:30PM D20.00004 Two Species Diffusion Model of Self-Organized Evolution on Patterned GaAs(001) Surfaces*. HUNG-CHIH KAN, National Chung Cheng University, Taiwan ROC, ERIN FLANAGAN, TABASSOM TADAYYON-ESLAMI, University of Maryland, SUBRAMANIAM KANAKARAJU, Lab for Physical Sciences, CHRIS RICHARDSON1, RAY PHANEUF, University of Maryland — We report on numerical simulations of the self-organized evolution on GaAs(001) surface, pre-patterned with square arrays of pillars, during homo-epitaxial growth. Our experiments showed that lithographically fabricated, flat-topped cylindrical pillars evolved into a universal, downward paraboloidal shape, for initial diameters of the pillar ranging from 0.7um to several microns. In modeling this behavior, we construct a two-species diffusion model to simulate the growth. We use an atomistic strain model that has a cubic geometry and includes nearest neighbor bonds, next nearest neighbor bonds, and bond bending terms. Our motivation is the well established fact that for many heteroepitaxial systems growth proceeds in the Stranski-Krastanov growth mode, where islands form after the formation of a wetting layer. Recent results indicate that intermixing and thus vertical variations of the alloy concentration are a crucial factor in controlling the formation and thickness of the wetting layer. Our results suggest that in addition to vertical segregation there is also lateral segregation. Thermodynamically, the system prefers to have one big feature of the epilayer material that is embedded in the substrate but is near the surface. In practise, there will be a typical separation distance of these features because of kinetic limitations. We postulate that this lateral segregation and the separation of these features is ultimately responsible for the lateral placement of islands on the surface.

3:42PM D20.00005 Directed Matrix Seeding of Nitride Semiconductor Nanocrystals. A.W. WOOD, B.L. CARDOZO, W. YE, X. WENG, R.S. GOLDMAN, Materials Science and Engineering, Univ. of Michigan, Y.Q. WANG, Materials Science and Tech. Division, LANL — The controlled formation of semiconductor nanocomposites offers a unique opportunity to tailor functional materials with a variety of novel properties. A promising approach to nanocomposite synthesis is matrix-seeded growth, which involves ion-beam-amorphization of a semiconductor film, followed by nanoscale re-crystallization via annealing. In this work, we are studying the formation and evolution of N-ion-implanted InAs and GaAs (InAs:N, GaAs:N). The InAs:N and GaAs:N nanocomposites are synthesized using 100keV ion-implantation with a dose of $5\times10^{15}/cm^2$ for an effective charge of $z_s = 360 [1]$. The wind force acts even more strongly on Cu-decorated Ag(111) single-crystal pillars, as observed by directionally-oriented bending of step edges. The wind force needed to cause the observed structure distortions is $F = 0.13 \text{meV/\text{nm}}$, about 3 times the corresponding wind force acting on the bare steps. [1] A. Bondarchuk, et al. PRL 99, 206801 (2007).

3:54PM D20.00006 Nanofabrication of carbon materials, DINKO CHAKAROV, HANS FREDRIKSSON, BENGT KASEMO, Chalmers University of Technology. DEPARTMENT OF APPLIED PHYSICS TEAM — We demonstrate a process for fabrication of nanostructures on the surfaces of highly oriented pyrolytic graphite (HOPG) and glassy carbon (GC) samples. Using hole-mask colloidal lithography (HCL), nanosized etch masks with three different feature diameters were prepared by identical processes on each of the two surface types. Oxygen reactive ion etching (RIE) was then used to transfer the mask pattern onto the surfaces. The structures were characterized using atomic force- (AFM), scanning electron microscopy (SEM) and optical spectrophotometry. The identical preparation schemes applied to the two materials yield structures with remarkably different shape and sizes. For example the process that yields 361 nm high and 37 nm diameter structures on glassy carbon yields 120 nm high and 119 nm diameter structures on HOPG. In general, the diameters of the fabricated GC nano-features are always at least 80 nm smaller than those of the corresponding HOPG structures, and the GC structure heights are more than three times that of the HOPG structures. These differences are attributed to different (an)isotropic etching behavior of the two materials.

4:06PM D20.00007 Fabrication of Metallic Nanoporous Films by Selective Chemical Etching, SHILPA CHAVA, WEI JIANG YEH, University of Idaho — The objective of this study is to synthesize and characterize different nanoporous structures by chemical etching. The experiments were conducted on three different materials. We treated 6 carat white gold (Au/Au alloy, 1:3 ratio by weight) with 70% HNO3 to grow Au nanoporous, the 50/50 solder wire (Pb/Sn alloy) with 93% H2SO4 to create Pb porous and Imitation Italian gold leaf (Cu/Zn alloy, 82/18 by wt. %) with NaOH solution (5 gm NaOH per 100 ml distilled H2O) for Cu porous. The free-standing porous films have been analyzed by scanning electron microscopy (SEM), energy dispersive x-ray spectroscopy (EDX), high quality x-ray mapping (XRM). We observed the composition of the porous materials at every stage of chemical dealloying and conducted tests with different process parameters to optimize the size of self-ordered porous structures. Our experiments resulted in sponge like Au nanoporous of 10-200 nm, Pb pores of 10-300 nm and Cu pores of 10-150 nm. The results showed a technically improved fabrication of different nanoporous materials with high surface area and well defined pore morphology.

4:18PM D20.00008 Formation of Periodic 2D Metallic Nanostructures by Template-Assisted Electrodeposition, MU WANG, BO ZHANG, YUYAN WENG, RUWEN PENG, NAIBEN MING, Department of Physics, Nanjing University, Nanjing 210093, China — Two-dimensional ordered metallic nanostructures on solid surface with specific patterns may have potential applications in photonics and optoelectronics. Yet it remains a challenge to produce regular nanostructures over a large area with low cost and with a simple method. Here we report a novel method to fabricate well-aligned copper nanowire array on silicon surface by template-assisted electrodeposition. The template is introduced onto silicon surface by nanoimprinting. With our previously reported unique electrodeposition system [1-2], we find that the array of straight copper wires with their width varying from 400 nm to 20 nm can be fabricated. The wire width can be tuned by the control parameters in electrodeposition. It is shown that this method is not limited to straight wires only. It can be used to form more complicated patterns. The physical properties of the metallic nanostructures are also discussed. [1]

4:42PM D20.00010 Fabrication of High-Aspect-Ratio Nanogaps, ALEXANDRA FURSINA, Department of Chemistry, Rice University, 6100 Main St., Houston, TX 77005, SUNGBAE LEE, Department of Physics and Astronomy, Rice University, 6100 Main St., Houston, TX 77005, DOUGLAS NATelson, Department of Physics and Astronomy, Department of Electrical and Computer Engineering, Rice University, 6100 Main St., Houston, TX 77005 — For nanoscale electrical characterization and device fabrication it is often desirable to fabricate planar metal electrodes with separations well below 100 nm running parallel over a macroscopic width. In this work we demonstrate a self-aligned process to accomplish this goal using a thin Cr film as a sacrificial etch layer. The resulting gaps can be as small as 10 nm and have aspect ratios exceeding 1000, with excellent interelectrode isolation. Two separate lithographic patterning steps are used to define first and second electrodes while the interelectrode separation is controlled by the oxidation of a Cr layer deposited upon the first electrode. Advantageously, only a µm-alignment of first and second electrodes is required and the described method effectively does not have limitations on the gap width while the length of the gap is controlled by the Cr layer thickness. In addition to fabrication of Ti/Au electrodes on Si substrates, our technique was also demonstrated to work for other electrode metals (Pt, Fe, etc.) even on such relatively reactive substrates as magnetite, F3O4, films, thus demonstrating the flexibility and utility of this method.

4:54PM D20.00011 Subtle role played by H in Si thin-film growth from radicals: key atomic-scale mechanisms revealed by DFT calculations, F. MONTALENTI, S. CEREDA, LEO MIGLIO, F. ZIPOLI, M. BERNASCONI, L-NESS and Materials Science Department, University of Milano-Bicocca, Milan (Italy), M. CERIOTTI, Department of Chemistry and Applied Biosciences, ETH Zurich — Breaking silane molecules and creating reactive radicals in the gas phase is an efficient strategy for growing Si films at high growth rates and/or moderate temperatures. In a seminal experimental paper [1], the possibility of obtaining crystalline growth down to T~200°C, was clearly demonstrated under high dilution of radicals in H. Several interpretations, in some cases controversial, have been given for explaining this evidence. Here we shall show that a clear understanding can be reached by relying on DFT calculations. Starting by a fully hydrogenated Si(001)(1×2) surface, typical of low-temperature growth, we first illustrate the role played by SiH3 in removing adsorbed H, therefore creating empty sites for further SiH3 adsorption [2]. The adsorbed silyl, however, is frozen in its initial, non-epitaxial configuration, so that crystalline growth cannot take place. We demonstrate that further incoming hydrogen can easily transform silyl into SiH2, which, in turn, incorporates into epilayer sites crossing a barrier of only ~1 eV [3], compatible with Ref. [1] conditions. [1] C.C. Tsai et al., J. Non-Cryst. Solids 114, 151 (1989). [2] S. Cereda et al., Phys. Rev. B 75, 235311 (2007), Phys. Rev. Lett. (in press).
transition metal atoms substituting for Zn atoms within the cage.

Our studies are carried out within a density functional framework employing gradient corrected functionals. The studies cover all the 3d elements and examine the strength of the magnetic moment as substituting Zn atoms by transition metal atoms or by encapsulating transition metal clusters inside the cages. Our studies are carried out within a density functional framework.

Films, SUMEET PANDEY, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — We report results from kinetic Monte Carlo simulations of plasma deposition of silicon thin films under conditions that render the SiH₄ radical the dominant deposition precursor. The transition probabilities for the various kinetic events accounted for in the simulations are based on first-principles density functional theory (DFT) calculations of the corresponding optimal pathways on the H-terminated Si(001)-(2×1) surface and on molecular-dynamics simulations on hydrogenated amorphous silicon film surfaces. The relevant surface transport and reaction processes include SiH₄ diffusion, SiH₄ chemisorption and insertion into Si-Si bonds, surface H abstraction reactions, surface hydride dissociation reactions, as well as SiH₄ and SiH₂ desorption into the gas phase. Surface etching is predominantly observed over the 373-640 K temperature range. The surface compositions obtained are in good agreement with experimental measurements on films deposited under similar growth conditions. At 500 K, surface SiH₂ formed by surface trihydride dissociation reactions is the dominant surface hydride species.

Isotopic interfaces in a structurally anisotropic organic thin film ¹, C. G. TAO ², Q. LIU, B. RIDDICK, W. G. CULLEN, D. EVANS, J. REUTT-ROBEY, J. D. WEEKS, E. D. WILLIAMS, University of Maryland — We investigate the interfacial boundary fluctuations of Acridine-9-Carboxylic Acid (ACA) deposited on Ag(111) using UHV STM. The ACA molecule is anisotropic in shape and intermolecular interactions, and has been shown to exhibit a disordered 2D gas phase on Ag(111) at low coverage. At higher coverage, the molecules arrange in domains of ordered chain-like structures which coexist with the disordered phase. We measure the real-time fluctuations at the phase boundaries, and show that these fluctuations are governed by molecular exchange between the two phases. Due to structural anisotropy, there are two types of domain boundaries with significantly different molecular interactions. Surprisingly, the fluctuation magnitudes, mobilities, and free energies are nearly equal for the two boundary types. A lattice-gas statistical model is presented which includes the influence of molecular conformations on substrate interactions, and reproduces the essential features observed experimentally: domain shapes, boundary fluctuations, and phase densities.

Supports from US AFOSR, ARO and DOE

From Designer Clusters to Synthetic Crystalline Nano-Assemblies ¹, MEICHUN QIAN, S. KHANNA, A. REBER, Dept. of Physics, Virginia Common. Univ., A. CASTLEMAN, A. SEN, A. UGRINOV, K. DAVIS, S. PEPPERNICK, M. MERRITT, Dept. of Chemistry and Physics, Penn. State Univ. — Clusters have the potential to serve as building blocks of materials, enabling the tailoring of materials with novel properties. We have recently proposed a new protocol that combines gas phase investigations to examine feasible units, theoretical investigations of energy landscapes to identify potential motifs, and synthetic chemical approaches to synthesize cluster assemblies. We had earlier applied the protocol to As₃− clusters based cluster assemblies. In this work, we extend our investigations to cluster assembled materials based on As₁₃− units as building blocks. By varying the alkali cation and introducing crypts, it is possible to form materials with arsenic clusters arranged to form one dimensional chains, two dimensional layers or three dimensional lattices and X-ray studies provide information on bond lengths etc. Theoretical studies have been carried out to examine their microscopic structure and electronic properties. It will be shown that these new compounds have the tunable electronic and optical properties. The theoretical predictions on the As₁₃− Crypt(Κ) and [As₁₃−Cs₂]¹− Crypt(Κ) are in good agreement with the experimental observations.

Geometries and stabilities of Ag-doped Siₙ (n = 1 - 13) clusters: a first-principles study ¹, FENG-CHUAN CHUANG, YUN-YI HSIEH, CHIH-CHIANG HSU, MARVIN ALBAO, Department of Physics, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — The structures of AgSiₙ (n = 1 - 13) clusters are investigated using first-principles calculations. Our studies suggest that AgSiₙ clusters with n = 7, and 10 are relatively stable isomers and that these clusters prefer to be exohedral rather than endohedral. Moreover, doping leaves the inner core structure of the clusters largely intact. Additionally, the plot of fragmentation energies as a function of silicon atoms shows that the AgSiₙ are favored to dissociate into one Ag atom and Siₙ clusters. Alternative pathways exist for n > 7 (except n = 11) in which the Ag-Si cluster dissociate into a stable Siₙ and a small fragment Agₙ−7. The Agₙ−7 cluster dissociates into a stable Siₙ−3 and a small fragment Agₙ−10. Lastly, our analysis indicate that doping of Ag atom significantly decreases the gaps between the highest occupied molecular orbital and the lowest unoccupied molecular orbital for n > 7. Reference: J. Chem. Phys. 127, 144313 (2007).

Transition Metal Doped and Encapsulated ZnO Cages, MARCELA R. BELTRAN, Instituto de Investigaciones en Materiales, Universidad Nacional Autonoma de Mexico, ARTHUR REBER, SHIV N. KHANNA, Physics Department, Virginia Commonwealth University — ZnO is a wide band gap semiconductor with potential for applications. We had earlier shown that Zn₁₂O₁₂, Zn₁₅O₁₅, Zn₁₈O₂₈, and Zn₂₁O₂₃ clusters are particularly stable and exhibit cage structures. In this work, we examine the possibility of making magnetic materials by either substituting Zn atoms by transition metal atoms or by encapsulating transition metal clusters inside the cages. Our studies are carried out within a density functional framework employing gradient corrected functionals. The studies cover all the 3d elements and examine the strength of the magnetic moment as well as the nature of the coupling between the local moments. We also present results on the coupling between the endohedral transition metal cluster and the transition metal atoms substituting for Zn atoms within the cage.
3:42PM D21.00005 DFT study of a carotenoid-porphyrin-C_{60} light-harvesting molecular triad
TUNA BARUAH, University of Texas at El Paso — The abundance of solar energy reaching the earth presents an attractive alternative energy source. Nearly 75% of the solar energy striking the upper atmosphere reaches the earth in the form of photons of energy typically higher than 1 eV. Biological light-harvesting systems are highly efficient in utilizing the solar radiation. Bio-mimetic molecules are investigated to mimic the photosynthesis process efficiently in laboratory. We present a computational study of the process in a bio-mimetic carotenoid-porphyrin-C_{60} molecular triad which is about 5 nm long. The description of the photo-induced charge separation process requires accurate excited state energies and coupling between electrons and the phonons of the system. Since charge-transfer excitations create large changes in a molecular dipole moment, changes in excited-state energies due to coupling between a 5 nm molecular photovoltaic and the surroundings (solvent and spectator molecules) also has to be taken into account. A density functional theory based method including all these effects to describe the photo-induced charge separation process will be presented.

4:18PM D21.00006 Spin Accommodation and Reactivity of Superatoms
ARTHUR REBER, Virginia Commonwealth University — We have recently discovered novel effects that may allow tuning of the reactivity of small clusters by controlling their spin excitation, electronic structure, and local geometry. These findings offer the prospect of designing new catalysts through cluster assemblies where chosen clusters, called superatoms, serve as elemental building blocks. Taking aluminum as an example, I will present our recent findings that illustrate how reactive clusters can be made non-reactive while inert species can be made reactive by adding hydrogen atoms. These findings offer a microscopic understanding of the recent experimental reactivity studies on aluminum and aluminum-hydride clusters that show variable reactivity in even electron systems and rapid etching in odd electron systems. It is shown that the reactivity of even electron clusters is governed by a spin transfer, from the triplet oxygen to the cluster, that fills the spin down antibonding orbitals on oxygen. Theoretical investigations show that when the spin transfer cannot occur, the species is unreactive, and when spin accommodation is possible, more subtle effects appear. Secondly, I will examine the reactivity of aluminum clusters with simple nucleophiles such as water. The reactivity and nature of the ensuing products is wildly variable with the size and shape of the cluster. Again, the electronic structure and local coordination of the active sites allow for an understanding of changing barrier heights and resulting reactivity. This work provides a framework with which new catalysts may be designed.

4:54PM D21.00007 Peierls distortion of endohedral atoms in clathrate I. HIDEKAZU TOMONO, KAZUO TSUMURAYA, Meiji University, Japan — The guest atom displacements in type II clathrates have been reported on experimental and theoretical points of view. The displacements are reported to be 0.6 Å from the cage center of the Si_{28} cage to the hexagonal in the hydrogen terminated double caged Si_{28} cluster [1]. The distortion can be expected to occur in the type I clathrate which forms with bamboo structures in the x, y, and z directions. The guest atoms show Peierls distortion when we calculate the equilibrium distances between the two Na atoms which locate at the neighboring Si_{28} cages in the bamboo structure using periodic density functional calculation. The binding energy between the guest atoms is −0.10 eV/Na_{2}. We also confirm the tendency of the Peierls distortion from the force directions of guest atoms in the double unit cells that contain four Na atoms in one dimension; We will propose the cohesion mechanism of the clathrates that the clathrates are precipitated states of the connecting endohedral atoms in the 14 group atoms. So are the hydroclathrates in which the guest molecules bind each other with chains. [1] H. Takenaka and K. Tsumuraya, Mater. Trans. 47, 63 (2006).

5:06PM D21.00008 [Te_{2}As_{2}]^{2−}: A Planar Motif with Potential for Ferromagnetism
SHIV KHANNA, ARTHUR REBER, MEICHUN QIAN, Virginia Commonwealth University, ANGEL UGRINOV, AYUSMAN SEN, Pennsylvania State University — Here we report the synthesis and crystal structure of [K(18-crown-6)][Te_{2}As_{2}], the first four-membered ring Zintl anion of elements from groups XV and XVI, isolated from an ethylenediamine solution of As, K, and As_{2}Te_{2} at room temperature. X-ray analysis indicates that the [Te_{2}As_{2}]^{2−} anion has an unexpected planar rhombic structure with alternating bonds. First-principles electronic structure investigations within the density functional framework, indicate that the Te_{2}As_{2}K_{2} motif possesses a triplet ground state where the spin configuration leads to a distortion of the square geometry into rhombus structure marked by two Te-As shorter bond length pairs joined by longer bond lengths. A NICS analysis reveals that the triplet motif has a net aromatic character. Supercell calculations on the periodic solid show that the spin moments on the individual motifs order ferromagnetically thus offering the potential of an aromatic ferromagnet made of traditionally non-magnetic elements.

2:30PM D22.00001 The role of symmetry and charge delocalization in two-dimensional molecules conjugated molecules for optoelectronic applications
MARY GALVIN — Our group is investigating whether star molecules offer any advantage over linear polymers when used as the active layer in light-emitting diodes (LEDs), organic transistors (OFETs) or in photovoltaics (PVs). Specifically, we are investigating the role of architecture, synthesizing some novel molecules that contain a central tetra substituted phenyl ring. These molecules have a tendency to pi-pi stack, further delocalizing the carriers. The synthetic strategy used to prepare these molecules is versatile so that the four arms in the molecules do not have to be identical. The placement of differing arms also affords the opportunity to study the effect of symmetry on the properties of these molecules. The HOMO and LUMO levels can be changed via the type and placement of arms. Recent results obtained with these materials and their applications in photovoltaics and light-emitting diodes will be described.
1The author thanks NSF for support of this work (DMR0513348).
3:06PM D22.00002 Ultra-pure organic semiconductors with improved charge carrier transport properties, CLARA SANTATO, Département de Génie Physique, École Polytechnique de Montréal, C.P. 6079, Succ. “Centre Ville”, Montréal, QC, Canada H3C 3A7, FABIO CICOIRA, Department of Material Science and Engineering, Cornell University, Ithaca, NY, 14853-1501 and INP - CNR Via alla Cascata 56c Povo (TN), 38050, Italy, FRANCESCA DI MARIA, MANUELA MELUCCI, GIOVANNA BARBARELLA, ISOF -CNR, Via P. Gobetti 101, 40129 Bologna, Italy — The electrical performance of devices based on organic semiconducting films depend critically on the synthesis and processing of the materials. The quality of organic semiconductors depends on synthetic conditions and purification procedures, which have not yet been optimized. Ultra-pure semiconductor materials are required to establish sound correlations between molecular structure, functional properties of the films and performance of devices based thereon, e.g. field-effect transistors (FETs). Understanding structure-property relationships in films is the crucial condition for predicting chemical structures with superior properties. We report on FETs based on oligothiophene that exhibit dramatically improved charge transport, due to the ultra-purity of the organic semiconductors. The latter was achieved using a synthetic methodology that takes advantage of (i) heterogeneous catalysts, (ii) microwave activation to shorten reaction times and suppress side reactions.

3:18PM D22.00003 Side Chain Structure and Density of Polymers in different Complex Fluids, YUNFEI JIANG, DVORA PERAHIA, Chemistry Department, Clemson University, Clemson, SC, 29634, YIQING WANG, UWE H. F. BUNZ, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta, GA 30332 — Pol (para phenyleneethynylene) (PPE) polymers are electro-optically active macromolecules with immense potential in organic electro-optical devices. The polymer backbones are substituted by side chains that affect their conformation, association modes and dynamics. Consequently, they modify the optical response of the polymer. The present work introduces a small angle neutron scattering (SANS) and neutron spin echo (NSE) measurement of PPE substituted with a bulky triisopropylsilyl (TIPS) side chain in toluene. The results are compared with those previously obtained results of alkyl substituted PPEs. While alkyl substituted PPEs interacts via pi-pi stacking and forms a fragile gel, TIPS-PPE associates predominantly via the side chains and forms a stable gel over a large temperature range. The dynamics of PPEs in gel includes both fast and slow components and a cooperative dynamics between the solvent and PPE molecules.

3:30PM D22.00004 Thermal, structural, and electrical characterization of two high performance semiconductor polymers, L.J. RICHTER, NIST, Gaithersburg, MD, A.J. MOAD, D.M. DELONGCHAMP, R.J. KLINE, D.J. GUNDLACH, D.A. FISCHER, NIST, I. MCCULLOCH, Imperial College, London, UK, M. HEENEY, Queen Mary University, London, UK — Polymer semiconductors are expensive solution processable polymers with minimal issues due to the presence of flexible large area electronics. Recently, thin films of spin-cast poly(2,5-bis(3-alkylthieno[3,2-b]thiophene)-2,5-bithiophene) (pTTBT) after heating into a mesophase. Poly(dialkylthiophene)[3,2-b]thiophene-2,5-bithiophene) (pTTBT) is a newly synthesized isomer of pTTBT with side chains attached to the thiophenothiophene rather than the bithiophene unit. This subtle structural change results in a very different response to heating. FTIR, spectroscopic ellipsometry (SE), AFM, X-ray diffraction, and NEXAFS were utilized to determine the root of the different thermal behavior. The structural transitions of the isomers are generally similar; however, the side chain melting transition T_m occurs about 50˚C lower in pTTBT than in pBTBT. The significant drop in T_m appears to correlate with a subtle decrease in main chain packing interactions. Both materials exhibit high hole mobility, even in their respective mesophases. The slight overall higher order in pBTBT is reflected in the device performance.

3:42PM D22.00005 Synthesis and characterization of conducting polymer inserted carbon nanotubes, A. JONG CHOI, YOUNG WOO NAM, YUNG WOO PARK, Department of Physics and Astronomy, Seoul National University — The carbon nanotubes filled with the photo-conducting polymer poly(N-vinyl carbazole) (PVK) as a conducting polymer were prepared by polymerizing the monomers inside the nanotubes using the supercritical carbon dioxide. The endohedral nanotubes were characterized by HRTEM and 1H NMR, which confirmed that the inserted material was indeed the conducting polymer [1]. 1-V characteristics of the polymer inserted carbon nanotubes are presented. [1] Johannes Steinmetz, Soyoung Kwon, Hyun-Jung Lee, Eddy Abou-Hamad, Robert Almainac, Christophe Goze-Bac, Hwayong Kim, Yung-Woo Park., Chem. Phys. Lett. 431, 139 (2006)

3:54PM D22.00006 X-ray scattering Study of Ordering in Liquid Crystalline Semiconducting Polymers, MICHAEL CHABINYC, Palo Alto Research Center, MICHAEL TONEY, Stanford Synchrotron Research Laboratory, IAIN MCCULLOCH, Imperial College, MARTIN HEENEY, Queen Mary University of London — The electrical performance of thin-film transistors, TFTs, formed with semiconducting polymers is approaching that of amorphous silicon. The highest performance TFTs are obtained from semiconducting polymers with liquid crystalline (LC) mesophases. Thermal annealing of these materials after deposition can increase the field effect mobility by as much as an order of magnitude. We will report the results of detailed x-ray scattering studies of the impact of thermal annealing on the crystalline ordering in thin films of poly(2,5-bis(3-n-alkyl-2-yl)thieno[3,2-b]thiophene) (pTTBT). Poly(2,5-bis(3-n-alkyl-2-yl)thieno[3,2-b]thiophene) (pTTBT) is a newly synthesized isomer of pBTBT with side chains attached to the thiophenothiophene rather than the bithiophene unit. This subtle structural change results in a very different response to heating. FTIR, spectroscopic ellipsometry (SE), AFM, X-ray diffraction, and NEXAFS were utilized to determine the root of the different thermal behavior. The structural transitions of the isomers are generally similar; however, the side chain melting transition T_m occurs about 50˚C lower in pTTBT than in pBTBT. The significant drop in T_m appears to correlate with a subtle decrease in main chain packing interactions. Both materials exhibit high hole mobility, even in their respective mesophases. The slight overall higher order in pBTBT is reflected in the device performance.

4:06PM D22.00007 Improving the Electrical Conductivity of Polyaniline Through Molecular and Structural Control, JOYOUNG EUN YOO, Princeton University, University of Texas at Austin, YUEH-LIN LOO, Princeton University — We have investigated the electrical conductivity of polyaniline (PANI) that is template synthesized with a polymer acid of poly(2-acrylamino-2-methyl-1-propanesulfonic acid), PAAMPSA, as a function of the polymer acid molecular characteristics, including its molecular weight and molecular weight distribution. The electrical conductivity of PANI-PAAMPSA increases with decreasing PAAMPSA molecular weight. PANI that is doped with narrow molecular weight distribution PAAMPSA is twice as conductive as PANI that is doped with PAAMPSA of molecular weight and molecular weight distribution. In this case, the conductivity of PANI-PAAMPSA improves by more than two orders of magnitude. UV-vis-NIR spectroscopy and X-ray photoelectron spectroscopy suggest that DCA suppress side reactions.

4:18PM D22.00008 Surface photoisomerization activity vs. functionalization of azobenzene derivatives, LUIS BERBIL-BAUTISTA, JONGWON CHO, NIV LEVY, MATTHEW J. COMSTOCK, DAN POULSEN, JEAN M.J. FRECHET, MICHAEL F. CROMMIE, University of California at Berkeley — Azobenzene and its derivatives can be reversibly photoisomerized between their cis and trans conformations in solution. The photoisomerization process is wavelength selective and results in a large length change. Hence, it is ideally suited to actuating molecular nanomachines on surfaces. However, it has recently been shown [1] that photoisomerization activity on a metallic surface must be functionalized with bulky spacing groups to decouple the optically active part of the molecule from the surface. This results in various trade-offs between molecular optical activity and overall flexibility/functionality. We have explored the photoisomerization activity of different azobenzene derivatives on metallic surfaces using a scanning tunneling microscope (STM) with optical access to the sample. The effects on molecular photo-activity and self-assembly for different substitutional groups has been studied. [1] Matthew J. Comstock, Niv Levy, Armen Kirakosian, Jongweon Cho, Frank Lauterwasser, Jessica H. Harvey, David A. Strubbe, Jean M. J. Frechet, Dirk Trauner, Steven G. Louie, and Michael F. Crommie Phys. Rev. Lett. 99, 038301 (2007)
4:30PM D22.00009 Electrical and Optical Properties of a Novel Nonconjugated Conductive Polymer, Polynorbornene, ANANTHAKRISHNAN NARAYANAN, ADITYA KUMAR PALTII, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL — We report electrical and optical properties of a novel nonconjugated conductive polymer, polynorbornene which has an isolated double bond in the repeat. Electrical conductivity of this polymer increases by more than ten orders of magnitude to about 0.01 S/cm upon doping with iodine. Optical absorption measurements of the polymer film have been made at different dopant concentrations. For a lightly doped polymer, two absorption peaks: one corresponding to cation radicals and the other corresponding to charge transfer between the double bond and the dopant were observed at 4.20 eV (295nm) and 3.13 eV (396nm) respectively. FTIR spectroscopic measurements have shown a reduction in the intensity of the C=C stretching and C-H bending vibration bands upon doping indicating formation of radical cations. Photoluminescence studies have shown an emission band with a peak at ~425nm when excited at 300nm. Nonlinear optical studies of this novel nonconjugated conductive polymer are in progress.

4:42PM D22.00010 Quadratic Electro-optic Measurements in the Nonconjugated Conductive Polymer, Poly(β-pinene) at 800 nm and 1550 nm, JITTO TITUS, ANANTHAKRISHNAN NARAYANAN, MRINAL THAKUR, Photonic Materials Research Laboratory, Auburn University, AL — Electro-optic effect in the nonconjugated conductive polymer, iodine-doped poly(β-pinene) measured at 633 nm has been recently reported. In this presentation, results of quadratic electro-optic measurements at longer wavelengths will be reported. The electro-optic measurement has been made using the field-induced birefringence technique in the cross-polarized geometry with lock-in detection. Films with a medium doping level of iodine have been used in the measurements. Modulation depths of about 1.1% at 800 nm and 0.06% at 1550 nm were observed for an applied ac field of about 1 Volt/µm and for a film thickness of about 1 µm. More detailed measurements are in progress. The results are highly promising for applications of these materials in electro-optic modulators in the channel waveguide configuration. This exceptionally large quadratic electro-optic effect has been attributed to the confinement of this electronic system within a sub-nanometer dimension and the special electronic structure of this doped system.

5:06PM D22.00012 Direct Nanoscale Characterization of Submolecular Mobility in Complex Organic Non-linear Optical Systems, DANIEL KNORR, TOMOKO GRAY, TAE-DONG KIM, JINGDONG LOU, ALEX JEN, RENE OVERNEY — For organic non-linear optical (NLO) materials composed of intricate molecular building blocks, the challenge is to deduce meaningful molecular scale mobility information to understand complex relaxation and phase behavior. This is crucial, as the process of achieving a robust acenctic alignment strongly depends on the availability of inter- and intra-molecular mobilities outside the temperature range of the device operation window. Here, we introduce a nanoscale methodology based on scanning probe microscopy that provides direct insight into structural relaxations and shows great potential to direct material design of sophisticated macromolecules. It also offers a means by which mesoscale dynamics and cooperativity involved in relaxation processes can be quantified in terms of dynamic entropy and enthalpy. This study demonstrates this methodology to describe the mesoscale dynamics of two systems (1) organic networking dendronized NLO molecular glasses that self-assemble into physically linked polymers due to quadrupolar phenyl-perfluorophenyl interactions and (2) dendronized side-chain electro-optic (EO) polymers. For the self assembling glasses, the degree of intermolecular cooperativity can be deduced using this methodology, while for the dendronized side-chain polymers, specific side chain mobilities are exploited to improve EO properties.

Session D23 DMP GMAG: Focus Session: Triangular Lattice and Spinels Morial Convention Center 215

2:30PM D23.00001 Magnetic ordering and structural transition in layered Li$_2$RuO$_3$1, DEVINA PILLAY, MICHELLE JOHANNES, Naval Research Laboratory — Li$_2$RuO$_3$ is a layered, triangular-lattice metal oxide system much like Na$_2$CoO$_2$, NaNiO$_2$ and LiNiO$_3$ with the exception that one of every three transition metal ions (Ru) is replaced by a Li ion. This results in a honeycomb arrangement of spin-carrying ions and eliminates the magnetic frustration intrinsic to the triangular lattice. Here we investigate the electronic structure of Li$_2$RuO$_3$, especially in relation to its magnetic ordering both in-plane and between adjacent planes. We find that the dimerization of Ru atoms within the metal-oxide planes acts in conjunction with magnetic ordering to establish a gapped, magnetic ground state. The change in the energy level spectrum brought on by the formation of spin-polarized Ru-Ru molecular orbitals replaces the expected Jahn-Teller mechanism as a way of relieving a degeneracy at the Fermi energy.

2:42PM D23.00002 Magnetic interactions in geometrically frustrated triangular lattice antiferromagnet CuFeO$_2$, JAIME FERNANDEZ-BACA, FENG YE, RANDY FISHMAN, ORNL, H. J. KANG, J. W. LYN, NIST, TSUYOSHI KIMURA, Osaka University — Geometrically frustrated magnetic systems have received considerable attention due to their extraordinary magnetic properties. The delafossite CuFeO$_2$ is of particular interest because it exhibits multiferroic behavior with either the application of a magnetic field or introduction of nonmagnetic impurities. Our recent [1] on CuFeO$_2$ shows that spin waves in this material can be explained by antiferromagnetic interactions up to third nearest neighbors within the hexagonal plane as well as out-of-plane coupling, indicating that the quasi-like fising nature of this material results from the delicate balance between competing interactions. Two energy dips in the spin dispersion occur at the incommensurate wavevectors associated with multiferroic phase, and are dynamic precursors to the magnetoelectric behavior. In this talk we will present preliminary measurements of the field magnetic field dependence of these excitations as CuFeO$_2$ approaches the multiferroic phase [1] Ye et al. Phys. Rev. Lett. 99, 157201 (2007)
The change in properties has been understood in terms of site preference of the dopant cation. The current study investigated the temperature dependence and GaN.

The results confirm the existence of two phase transitions. The first, near 56 K, is from a paramagnetic state to a collinear ferrimagnetic phase. There is a second simultaneous structural and magnetic transition at 53 K to a tetragonal structure with a non-collinear ferrimagnetic state. The low-temperature magnetic structure has been definitively resolved, and is seen to be associated with a gap in the magnetic excitation spectrum. The magnetic structure is compatible with a staggered orbital ordering. Inelastic scattering has been carried out using both triple axis and time of flight techniques, and several branches of magnetic excitations are visible. These observations put tight constraints on theoretical models for MnV

NIST Center for Neutron Research, CHRIS FROST, Rutherford-Appleton Laboratories — Neutron diffraction and inelastic scattering has been used to study the Magnetic and magnetoelastic properties of Ge-substituted cobalt ferrite.

Neutron Scattering Study of Magnetic and Orbital Order in MnV₂O₄.

We discuss the changes in ground states as a function of Lithium content, and we review magnetic and magnetoelastic properties of germanium substituted cobalt ferrite, C₀₁₋ₓGe₂Fe₂₋ₓO₄, over a temperature range of 10 – 400 K. Both magnetic hysteresis loops and magnetostriction loops have been measured for several selected compositions with 0 ≤ x ≤ 0.8. At room temperature, saturation magnetization, magnetic anisotropy and magnetostriction were seen to decrease with increasing Ge-content. This new class of materials is therefore highly suitable for magnetic sensor and actuator applications in which the magnetic properties can be tailored to meet specific needs.

Charge order and frustrated magnetism in the orbitally-degenerate triangular metallic antiferromagnet AgNiO₂. RADU COLDEA, University of Bristol, UK — We explore the electronic ground state in the orbitally degenerate triangular metallic antiferromagnet AgNiO₂. In high-resolution neutron diffraction we observe a structural transition below 365 K to a trilayer unit cell in the triangular layers with a periodic arrangement of expanded and contracted NiO₆ octahedra, naturally explained by a three-sublattice charge order pattern on the triangular lattice of Ni sites. Band-structure calculations suggest that charge order occurs in order to lift the orbital degeneracy and is favoured by the weak electron delocalization over local Jahn Teller distortions found in more insulating systems. An unusual magnetic order is observed at low temperatures with only one third of sites (the electron-rich Ni sites) carrying a magnetic moment arranged in an unexpected collinear stripe order pattern on an antiferromagnetic triangular lattice. Possible mechanisms stabilizing the observed ground state will be discussed. E. Wawrzynska, R. Coldea, E. M. Wheeler, I. I. Mazin, M. D. Johannes, T. Sörgel, M. Jansen, R. M. Ibberson, P. G. Radaelli, Phys. Rev. Lett. 99, 157204 (2007). We acknowledge support from EPSRC UK.

2:54PM D23.00003 Neutron scattering investigation of Lithium based spinels. WOUTER MONT-FROOU. MARCUS PETROVIC, MICHAEL KRAUS, University of Missouri, ALEXANDER SCHMETS, Technical University Delft — Lithium based spinels LiₓM₂O₄, (with M a transition metal like Mn, V, Ti) offer a rich variety of ground states, depending on the transition metal in question. What makes these materials particularly attractive for both fundamental research as well as for applications is that the Li atoms can easily be extracted from the crystal without affecting the overall spinel structure. The oxidation state of the mixed valent transition metal M will change as a function of Li removal, with the result that the system can go from a disordered state to a long range ordered state. We present new neutron scattering results on a variety of Lithium spinels [LiₓMn₂O₄, LiCoO₂, LiCoₓFe₁₋ₓO₂, LiNiVO₄, and LiNiₓFeₓOₓVO₄]. We discuss the changes in ground states as a function of Lithium content, and we review how the magnetic properties of the transition metal ions influence the electronic properties of the system.

3:06PM D23.00004 Elastic properties of the vanadate spinel MnV₂O₄. V. KEPPENS, Y. LUAN, Dept. Materials Science and Engineering, The University of Tennessee, V.O. GARLEA, Neutron Scattering Sciences Division, Oak Ridge National Laboratory, R. JIN, D. MANDRUS, Materials Science and Technology Division, Oak Ridge National Laboratory — Spinel vanadates AV₂O₄ are known to undergo a cubic-to-tetragonal structural phase transition (SPT) at temperature Tₛ and order magnetically at lower temperature Tₓ. ZnV₂O₄ is characteristic of the entire series and has received extensive theoretical attention. When Mn occupies the A site there is an additional supereexchange interaction between Mn and V. This superechange interaction leads to ferrimagnetic order at about 56 K, involving a ferromagnetic configuration of the V spins. The current work focuses on the elastic properties of MnV₂O₄. Resonant Ultrasound Spectroscopy (RUS) has been used to measure the elastic response of the sample, as a function of temperature (5-300K) and magnetic field (0-7 Tesla). The temperature dependence of the frequencies is found to be quite unusual, displaying a softening over a large temperature range. Measurements in magnetic field reveal an additional feature near 50 K, which could represent a striking manifestation of direct spin-orbital coupling.

3:18PM D23.00005 Neutron Scattering Study of Magnetic and Orbital Order in MnV₂O₄. STEPHEN NAGLER, OVIDIU GARLEA, Oak Ridge National Laboratory, RONYING JIN, DAVID MANDRUS, DOUG ABERNATHY, Oak Ridge National Laboratory, BERTRAND ROESSLI, Paul Scherrer Institute, MARTHA MILLER, ARTHUR SCHULTZ, Paul Scherrer Institute, MARTHA MILLER, ARTHUR SCHULTZ, Argonne National Laboratory, QINGZHEN HUANG, NIST Center for Neutron Research, CHRIS FROST, Rutherford-Appleton Laboratories — Neutron diffraction and inelastic scattering has been used to study the spinel system MnV₂O₄. The results confirm the existence of two phase transitions. The first, near 56 K, is from a paramagnetic state to a collinear ferrimagnetic phase. There is a second simultaneous structural and magnetic transition at 53 K to a tetragonal structure with a non-collinear ferrimagnetic state. The low-T magnetic structure has been definitively resolved, and is seen to be associated with a gap in the magnetic excitation spectrum. The magnetic structure is compatible with a staggered orbital ordering. Inelastic scattering has been carried out using both triple axis and time of flight techniques, and several branches of magnetic excitations are visible. These observations put tight constraints on theoretical models for MnV₂O₄. An initial account of some of the results of this work appears in arXiv:0711.1844v1.

3:30PM D23.00006 Magnetic and magnetoelastic properties of Ge-substituted cobalt ferrite. NARESH RANVANH, IKENNA NLEBEDIM, Cardiff University, YEVGEN MELIKHOV, JOHN SNYDER, DAVID JILES, ANTHONY MOSES, PAUL WILLIAMS, Cardiff University, WOLFSON CENTRE FOR MAGNETICS TEAM — Research in past has shown chemical substitution of Fe²⁺ by trivalent ions (Cr³⁺, Mn³⁺ and Ga³⁺) to alter the properties of these materials, notably reducing Curie temperature and magnetic anisotropy, which lead to increase in permeability. The change in properties has been understood in terms of site preference of the dopant cation. Since its discovery, it has been studied as a minor structural impurity phase in CMR-related CaMnO₃. It was first described [1] in 1963 as a natural mineral called Marokite. Since its discovery, it has been studied as a minor structural impurity phase in CMR-related CaMnO₃ and for its structural similarities to high-pressure phases of spinel-oxide compounds. However, little attention has previously been paid to physical transport, thermal transport, thermal expansion, heat capacity, and magnetization.

CaMnO₃ was first described [1] in 1963 as a natural mineral called Marokite. Since its discovery, it has been studied as a minor structural impurity phase in CMR-related CaMnO₃. What makes these materials particularly attractive for both fundamental research as well as for applications is that the Li atoms can easily be extracted from the crystal without affecting the overall spinel structure. The oxidation state of the mixed valent transition metal M will change as a function of Li removal, with the result that the system can go from a disordered state to a long range ordered state. We present new neutron scattering results on a variety of Lithium spinels [LiₓMn₂O₄, LiCoO₂, LiCoₓFe₁₋ₓO₂, LiNiVO₄, and LiNiₓFeₓOₓVO₄]. We discuss the changes in ground states as a function of Lithium content, and we review how the magnetic properties of the transition metal ions influence the electronic properties of the system.

4:18PM D23.00008 Electrical, Thermal, and Magnetic Properties of Single Crystal CaMn₂O₄ Marokite. B.D. WHITE, J.J. NEUMEIER, J.A. SOUZA, Montana State University, C. CHIORESCU, J.L. COHN, University of Miami — CaMnO₃ was first described [1] in 1963 as a natural mineral called Marokite. Since its discovery, it has been studied as a minor structural impurity phase in CMR-related CaMnO₃ and for its structural similarities to high-pressure phases of spinel-oxide compounds. However, little attention has previously been paid to physical properties beyond its temperature-dependent magnetization. We will present a detailed physical properties study of CaMn₂O₄ single crystals grown by the optical floating zone method. [2] These measurements, several of which display anisotropy as a result of an orthorhombic crystal structure, include electrical transport, thermal transport, thermal expansion, heat capacity, and magnetization.

This material is based upon work supported by the NSF (Grant No. DMR-0504769 at MSU and DMR-0072276 at U. Miami), the Research Corporation and the U.S. DOE Office of Basic Energy Sciences (Grant No. DE-FG-06ER46269).
4:30PM D23.00009 X-ray diffraction and reciprocal space mapping in ZnMnGaO$_4$ films with checkerboard nanostructures, A.A. SIRENKO, S.M. O’MALLEY, P.L. BONANNO, Department of Physics, New Jersey Institute of Technology, Newark, New Jersey 07102, A. KAZIMIROV, Cornell High Energy Synchrotron Source (CHESS), Cornell University, Ithaca, New York 14853, S. PARK, S.-W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy, Rutgers University, Piscataway, New Jersey 08854 — Reciprocal space maps (RSM) in ZnMnGaO$_4$ films with checkerboard nanostructures were measured with the energy of the x-ray beam of 10.53 keV at the A2 beamline at Cornell High Energy Synchrotron Source (CHESS) using a four-circle diffractometer. Structural properties of the checkerboards, such as elastic strain, relaxation effects, twists, and tilts of the nanodomains, were analyzed using H-K, H-L, and K-L cross sections of the RSM’s measured around various symmetric and asymmetric reflections (022), (004), (044), (226), (222) of the spinel structure. Work at Rutgers was supported by the DE-FG02-07ER46382 and the NSF-DMR-0706326. Work at NJIT was supported by the NSF-DMR-0540985. The Cornell High Energy Synchrotron Source is supported by the NSF and the NIH/NIGMS under Award No. DMR-0225180.

4:42PM D23.00010 Magnetic coupling in CoCr$_2$O$_4$ and MnCr$_2$O$_4$; an LSDA+U study, CLAUDE EDERER, Trinity College Dublin, Ireland, MATEJ KOMELJ, Jožef Stefan Institute, Ljubljana, Slovenia — Competing magnetic interactions can lead to very interesting magnetic structures and pronounced effects due to spin-lattice coupling. Chromium spins with additional magnetic $A$-site cations are prime examples for such systems, and have recently regained attention due to the discovery of a small electric polarization in CoCr$_2$O$_4$ [1]. The multiferroic character of CoCr$_2$O$_4$ is supposedly a result of its inversion symmetry-breaking magnetic structure, which has been classified as a “ferromagnetic spiral” [2]. To achieve a better understanding of the complicated magnetic structure in CoCr$_2$O$_4$ and similar systems, an ab initio determination of the magnetic coupling constants is very desirable. Here, we present results of LSDA+U calculations of the magnetic coupling constants in both CoCr$_2$O$_4$ and MnCr$_2$O$_4$ [3]. We carefully assess the predictive power of such calculations, and then give quantitative estimates for the strengths of the most prominent magnetic interactions. Our results highlight the possible importance of $A$ interactions in spin systems with magnetic ions on both $A$ and $B$ sites, and provide an important link between previous theory and experimental observations.

4:54PM D23.00011 Crystal and Magnetic Structure of FeV$_2$O$_4$ with $e_g$ and $t_{2g}$ orbital degeneracies, SUNGDAE JI, J.-H. KIM, S.-H. LEE, Department of Physics, University of Virginia, Charlottesville, VA 22904, USA, Q. HUANG, NIST Center for Neutron Research, Gaithersburg, MD 20899, USA, T. KATSUFUJI, Department of Physics, Waseda University, Tokyo 169-8555, Japan — We have performed neutron diffraction measurements on a powder and a single crystal of a spinel FeV$_2$O$_4$ that has $e_g$ as well as $t_{2g}$ orbital degeneracy. Our data show that upon cooling this system undergoes three successive phase transitions: a cubic-to-tetragonal structural transition at 140 K, a tetragonal-to-orthorhombic transition at 110 K accompanied by a ferri-magnetic order and an orthorhombic-to-orthorhombic phase transition with another magnetic order at 80 K. The magnetic structures of the two magnetic phases were refined by the group theoretical analysis of our powder diffraction data. We will also discuss implication of the magnetic structures regarding to the orbital states of FeV$_2$O$_4$.

5:06PM D23.00012 ABSTRACT WITHDRAWN —

5:18PM D23.00013 The Dzyaloshinskii-Moriya Anisotropy in Hyper-Kagome Lattice for Na$_3$Ir$_4$O$_8$, GANG CHEN, LEON BALENTS, UCSB — The effect of quantum correction on the classical spin order in the iridium antiferromagnet Na$_3$Ir$_4$O$_8$ are considered. The spin-wave spectrum is calculated to the linear order. The nearest-neighbor exchange interactions between the Irspins as well as the Dzyaloshinskii-Moriya interactions are taken into account. Numerical simulation by exact diagonalization and experimental results are used to compare with the theoretical prediction.

Monday, March 10, 2008 2:30PM - 4:42PM — Session D24 DCMP: Superlattices and Nanostructures: Electronic Properties I

2:30PM D24.00001 Recent Progress on Modeling H Passivated CdS Nanocrystals using ab initio techniques, CHAD JUNKERMEIER, JINLING ZHOU, JAMES P. LEWIS, Dept. of Physics, West Virginia University — Spherical CdS nanocrystals with shells of H atoms are studied via an ab initio tight-binding analysis. Starting from the bulk zinc blende structure of CdS, these nanocrystals undergo relaxation as the geometries optimize to configurations that minimize internal forces. H atoms are then attached, to passivate the surface, and then whole structure is relaxed. We will present our latest results.

3This research is funded in part by the National Institute of Standards and Technology grant number 70NANB7H6008. This work was supported in part by a grant from the West Virginia Graduate Student Fellowships in Science, Technology, Engineering and Math.

2:42PM D24.00002 Measurements of Charge Transport in Arrays of Lead Selenide Nanocrystals, KENNETH MACLEAN, TAMAR MENTZEL, SCOTT GEYER, VENDA PORTER, MOUNGI BAWENDI, MARC KASTNER, Massachusetts Institute of Technology — We report electrical transport measurements of self-assembled arrays of PbSe nanocrystals (NC). NCs ~6.2 nm in diameter are colloidally synthesized and drop cast onto an inverted field effect structure. The NCs self assemble into hexagonal close-packed arrays with ~2 nm interparticle spacing. The current is immeasurable in as deposited arrays. After annealing at 400K for ~30 minutes, the arrays become less ordered and the conductance increases by more than 6 orders of magnitude. We measure the current in these devices as a function of source-drain voltage, gate voltage and temperature. We find that the temperature dependence of the conductance is strong at zero-bias and grows weaker with application of a source-drain bias. This implies that the conductance is thermally activated and the field serves to reduce the activation energy. We also find that the gate modulates the activation energy to conduction.

2:54PM D24.00003 Structural and Electronic Properties of IV-VI Semiconductor Nanodots, ROMAN LEITSMANN, FRIEDHELM BECHSTEDT, Institut für Festkörpertheorie und -optik, Friedrich-Schiller Universität Jena — The characterization of nanostructure properties versus dimension and surface passivation is of increasing importance for the nanotechnology. Especially the stoichiometry, geometry, and the electronic states of IV-VI semiconductor nanodots are of special interest [1, 2]. We use ab initio methods to calculate structural and electronic properties of colloidal IV-VI semiconductor nanodots as a function of the dot diameter. A method to passivate the non-directional dangling bonds at the nanodot surfaces is derived and used to study the confinement effect on the HOMO (highest occupied molecular orbital) and LUMO (lowest unoccupied molecular orbital) states. In addition we take the influence of relativistic (spin-orbit coupling – SOC) and excitonic effects into account. While the SOC leads to a considerable decrease of the HOMO-LUMO gap, excitonic effects play a minor role. [1] JACS 128, 10337 (2006) [2] JACS 129, 11354 (2007)

3:06PM D24.00004 Density functional theory studies of core-shell semiconductor nanoparticle quantum dots, BRENT WALKER, SHAUN HENDY, Industrial Research Limited, 69 Gracefield Road, P.O. Box 31-310, Lower Hutt 5040, New Zealand, RICHARD TILLEY, School of Chemical and Physical Sciences, Victoria University of Wellington, P. O. Box 600, Wellington, New Zealand — In going from the macroscale to the nanoscale, quantum-mechanical effects become increasingly important and may mean that nanostructures of a material exhibit very different properties from the corresponding bulk. This is especially noticeable in the case of the optical properties of semiconductor nanoparticles (or quantum dots), which display a number of remarkable features (including very distinct peaks, and tunability across a broad range of wavelengths), due to quantum confinement. Our work involves modeling Si-Ge core-shell nanoparticles using large-scale computer simulations based on the density functional and time-dependent density functional theories. These simulations in particular provide us with predictions of the geometric structures and optical absorption spectra of nanoparticles in an accurate and computationally efficient way, and allow us to study the systematic trends in these properties as the composition and size of the nanoparticle change.

3:18PM D24.00005 Conduction Mechanism in Arrays of Lead Selenide Nanocrystals, TAMAR MENTZEL, KENNETH MACLEAN, SCOTT GEYER, VENDA PORTER, MOUNGI BAWENDI, MARC KASTNER, Massachusetts Institute of Technology — We perform transport measurements of a PbSe nanocrystal solid which serves as the channel of a field-effect transistor. We find that a simple model of hopping between intrinsic localized states describes the conduction mechanism. From the field effect, we see that the majority carriers are holes, which are thermally released from acceptor states. At low source-drain voltages, the activation energy for the conductivity is given by the energy required to generate holes plus the activation over barriers resulting from site disorder. At high source-drain voltages the activation energy is given by the former only. The thermal activation energy of the zero-bias conductance indicates that the Fermi energy is close to the highest-occupied valence level, the 1S, state, and this is confirmed by field-effect measurements, which give a density of states of approximately 8 per nanocrystal as expected from the degeneracy of the 1S, state. Using the Thomas-Fermi screening length in the NC solid, we find that the gate serves to modulate the charge density in the monolayer closest to the gate, while successive monolayers are screened from the field.

3:30PM D24.00006 Quasi 1-D electronic structure of silver nanowires, A. SEKHARAN, W. ZHAO, F. WOMACK, F. WANG, O. KIZILKAYA, R. KURTZ, P. SPRUNGER, Louisiana State University — Epitaxial Ag nanowires have been found to self-assemble on Cu(110) at coverages exceeding 1.2 ML. The low energy electronic structure of these nanowires has been characterized by ARPES. Previous STM, LEED, and LEEM data reveal that the Ag nanowires grown on Cu(110) are approximately 2 nm (∼12 nm) in height (width). The nanowires orient with the long axis parallel to the [1 1 0] substrate direction. The ARPES results reveal that the valence bands within the Ag nanowire are strongly anisotropic with clear band dispersion in the along-wire direction, but no dispersion in the across-wire direction. ARPES identified two low-energy electronic bands, with strong dispersion close to the Fermi energy. The first band, which crosses the Fermi energy, suggests the metallic nature of nanowires. However, there is an avoided crossing of the second band, perhaps due to many-body effects. While discussing the quasi 1-D electronic structure, we will emphasize its connection to many-body effects and the one dimensional nature of nanowires.

3:42PM D24.00007 ABSTRACT WITHDRAWN —

3:54PM D24.00008 Measurements of the conduction band energy surrounding individual InGaAs quantum dots by Cross-Sectional Ballistic Electron Emission Microscopy (XBEEM), C. MARGINEAN, J.P. PEIZ, The Ohio State University, S.Y. LEHMAN, The College of Wooster, J.G. CEDERBERG, Sandia National Laboratories — Cross-sectional ballistic electron emission microscopy (XBEEM) at room temperature was used to measure the conduction band (CB) energy in the “wetting layer” around and behind cleaved InGaAs quantum dots (QDs). Samples with a ∼2 nm thick In0.4Ga0.6As layer embedded in n-doped (5 × 1013 cm−3) GaAs were grown by organometallic vapor phase epitaxy, then cleaved ex situ, and 7nm-thick Au Schottky barrier (SB) contacts deposited on the cleaved edge using a shadow mask [1]. With reverse bias Vrev = 0V, Schottky barrier heights (SBHs) over different QDs were measured to range from ∼0.78 eV − 0.82 eV, compared to ∼ 0.84 eV over the wetting layer next to the QDs and ∼0.913 eV SBH over the adjacent GaAs. With Vrev = 1V, the SBH over the QDs were reduced by ∼30 – 50 meV compared to a much smaller (< 5 meV) measured decrease over the GaAs due to image force lowering, indicating that SBH over the QDs was due to the CB of the wetting layer at an estimated depth of 6 – 9 nm behind the QDs. The XBEEM transmission over the QDs was also strongly enhanced by the applied reverse bias, for reasons that are not yet clear. Work supported by NSF Grant No. DMR-0505165. [1] C. Tivaros et al., PRL 94, 206803 (2005).

4:06PM D24.00009 Shifting the Reference: Co on Cu(775), M.B. YILMAZ, S. WANG, K.R. KNOX, N. ZAKI, J.I. DADAP, R.M. OSGOOD, Brookhaven National Laboratory — The conduction band energy of a semiconductor substrate can be shifted with respect to an energy reference frame. We report on the use of a metal Schottky contact to shift the reference frame to a 1-nm-thick Cu film and measure the conduction band energy (Ecb) of nanostructured Co/Cu(775). The measured Ecb of the Cu film was 0.6 eV, and of the Co/Cu(775) interface was 0.2 eV. Work supported by DOE Contract Nos DE-FG02-04ER46157 and DE-AC02-98CH10886.

4:18PM D24.00010 Experimental separation of entanglements in polymer blends. ERICA SALTZMAN, MURUGAPPAN MUTHUKUMAR, University of Massachusetts at Amherst — We have developed a quantum holographic method to advance information density beyond the areal limits set by the discreteness of matter. We present experiments on information encoding using nonscale writing with degenerate two-dimensional electrons. We show "pages" (letters encoded at specific energies) materialized by precisely engineering electron scattering environments with the tip of a scanning tunneling microscope. We then demonstrate that multiple pages can be encoded into the same region of space, using energy as a third holographic dimension.

This form of holography produces non-volatile subnanometer features, tens of times smaller than the most precise optical or scanned-probe lithography, and information densities exceeding 5 bits per square nanometer.

4:30PM D24.00011 Exploiting Resonances in Laser Photoemission1 . J.J. DADAP, M.B. YILMAZ, K. KNOX, N. ZAKI, R.M. OSGOOD, Columbia University. P.D. JOHNSON, Brookhaven National Laboratory — Laser photoemission is attracting new interest due to its ability to increase photoemission probe depth and to gain insight into surface-electron dynamics. We present new data on the use of energy levels that are resonant with the excitation-photon energy. Our surface system is the regular array of nanometer-scale steps on Cu(775), which yield information on surface electron confinement. We probe this nanostructured system with 2-photon photoemission. Our tunable, fs optical parametric amplifier (OPA) source allows resonance mapping with photon energies ~ 4.2-4.6 eV to obtain a comprehensive map of the unoccupied state manifold. We observe, in addition to the surface state and image states, bandfolding from Umklapp due to the periodic steps, and, for the first time, the existence of a weak unoccupied state. The OPA allows observation of even this relatively weak unoccupied state as well as the rapid interrogation of electronic structure. The origin of this intermediate state is discussed. In addition, we present the intensity dependence of the measured linewidth and the position of the resonances.

Monday, March 10, 2008 2:30PM - 5:30PM — Session D25 DPOLY: Theory and Simulations I Morial Convention Center 217

2:30PM D25.00001 Thermodynamically Consistent Nonrandom Mixing on a Bethe Lattice . SCOTT MILNER, ExxonMobil — For over 40 years, engineering calculations of nonrandom mixing effects in lattice-based calculations of free energies of mixing in both small-molecule and polymeric solutions (e.g., the non-random two-liquid model, or NRTL) have been based on a strange approximation. By "strange", I mean that the approximation violates some commonsense sum rules in how the lattice is filled; namely, that "something is next to everything"; and "everything is next to something". The resulting theories are thermodynamically inconsistent, and explicitly depend on combinations of interaction energies of which the exact mixing free energy is demonstrably independent. To remedy this, I have extended the exact solution of the Ising model on a Bethe lattice to an n-component mixture with arbitrary pairwise interactions. Explicit and practical expressions are obtained for the entropy and average energy per site, which incorporate nonrandom mixing in a thermodynamically consistent way. Although it still has mean-field exponents for the binary mixture critical point, the shape of the coexistence curve lies much closer to the exact results for the Ising model in d = 3 dimensions than do previous engineering-level theories. In addition, the model may be generalized easily to deal with mixtures of species occupying different numbers of sites on the lattice. Thus the model can be used to compute phase behavior for mixtures of molecules of different sizes, including polymeric solutions.

2:42PM D25.00002 Mixture Properties of Flexible Chains: Comparisons between Experiment, Simulation and Theory; Contrasts between Lattice and Continuum . RONALD WHITE, JANE LIPSON, Dartmouth College — We present new theoretical results for a series of binary chain-molecule mixtures using both the hard-sphere, and the square-well potentials. We compare these results to simulation data, and contrast them to those obtained using the analogous lattice version of the theory. We discuss all of our findings in the context of experimental data for hydrocarbon chain mixtures. In the course of these studies we consider mixtures of components with varied chain lengths and energetics, and examine the effects of changing composition, temperature, and density. In addition, by calculating the free energy over a wide range of the P,V,T and composition space, we are able to characterize coexistence, both liquid-vapor as well as liquid-liquid partial miscibility.

2:54PM D25.00003 A Multichain Self-Consistent Field Theory for Correlations in Polymers: Chain Swelling in Polymer Blends . DAVID WU, Colorado School of Mines — The self-consistent mean field theory of polymers has been highly successful as a tractable computational framework for capturing the thermodynamics and structure of polymer systems. One notable limitation has been the neglect of fluctuations and correlations, which can be important in a variety of physical circumstances. One such circumstance involves the non-Gaussian conformations (swelling) of branched polymers. We present a method for calculating these correlations with an extension of the SCF theory when applied to multiple chains. As an example of the methodology, we show how the crossover from swollen to screened conformations occurs in a blends of star and linear polymers.

3:06PM D25.00004 Numerical Renormalization Group for Coarse Graining Field-Theoretic Fluid Models . MICHAEL VILLET, GLENN FREDRICKSON, University of California, Santa Barbara — Statistical field theory models have proven to be valuable tools for studying the equilibrium behavior of polymeric fluids, but direct simulation of these field theories without use of the mean field approximation is computationally demanding. Computational resources can be extended to simulate larger systems by discretizing the field variables with a coarsely spaced lattice, but indelicate coarse graining risks truncation of important short-wavelength physics. We investigate numerical renormalization group transformations in tandem with complex Langevin simulations as a systematic approach to coarse graining field-theoretic fluid models, using a simple repulsive Yukawa fluid as a test system.

3:18PM D25.00005 Continuous translocations in connected chambers under pseudo-hydrodynamic force . ERICA SALTZMAN, MURUGAPPAN MUTHUKUMAR, University of Massachusetts at Amherst — Experimental separation of polydisperse synthetic and biopolymers is frequently conducted via combination of electrophoretic or hydrodynamic flow with a series of obstacles or traps. In order to understand the interaction of entropic escape and biased diffusion processes, we conduct simulations on a generic model system. Brownian dynamics simulations are performed on linear chains confined in a series of chambers connected by narrow pores. A uniaxial force designed to mimic the effect of solvent flow acts on each bead of the chain, leading to translocation between chambers. Translocation events are separated by periods of trapping, which shorten with increasing chain length; for long chains individual translocations become indistinguishable.
A two-scale-two-mode dynamic self-consistent theory of entangled interfaces in polymer fluids under flow. YITZHAK SHNIDMAN, ISMAEL YACOUBOU-DJIMA, College of Staten Island. City University of New York — Tracking conformation statistics on the Kuhn scale is essential for modeling interfacial phenomena in polymer fluids under flow. Successive entanglements partition entangled chains into strands that are in one of two modes: entangled or dangling. Strands follow different differential evolution equations for the second moment of their end-to-end distance, depending on their mode. Dangling strands are governed by the FENE-P equation. For entangled strands, a different evolution equation was proposed by G. Marrucci and G. Ianniruberto, Phil. Trans. R. Soc. Lond. A 361, 677 (2003). On the Kuhn scale, strand’s conformation statistics is sampled by random walks in an effective potential, which are regulated by the evolving second moment of its end-to-end distance. Conformation statistics of a dangling strand is adequately modeled by Wiener (uncorrelated) random walks, but stretching of entangled strands under flow induce correlations between successive steps requiring a persistent random walk model (I. Yacoubo-Djima and Y. Shnidman, http://arxiv.org/abs/0708.2679v1). A two-scale-two-mode subchain propagation scheme, starting from free segments evolved by a probabilistic transport equation, allows a self-consistent calculation of evolving interfacial structure and rheology.

A new approach to the glass transition temperature $T_g$ in polymer fluids under flow. Successive entanglements partition entangled chains into strands that are in one of two modes: entangled or dangling. Strands follow different differential evolution equations for the second moment of their end-to-end distance. Dangling strands are governed by the FENE-P equation. For entangled strands, a different evolution equation was proposed by G. Marrucci and G. Ianniruberto, Phil. Trans. R. Soc. Lond. A 361, 677 (2003). On the Kuhn scale, strand’s conformation statistics is sampled by random walks in an effective potential, which are regulated by the evolving second moment of its end-to-end distance. Conformation statistics of a dangling strand is adequately modeled by Wiener (uncorrelated) random walks, but stretching of entangled strands under flow induce correlations between successive steps requiring a persistent random walk model (I. Yacoubo-Djima and Y. Shnidman, http://arxiv.org/abs/0708.2679v1). A two-scale-two-mode subchain propagation scheme, starting from free segments evolved by a probabilistic transport equation, allows a self-consistent calculation of evolving interfacial structure and rheology.

Fluctuations in Confined Homopolymers Studied by Fast Off-Lattice Monte Carlo Simulations. YUHUA YIN, QIANG WANG — The conventional molecular simulations of many-chain systems are hindered by explicit excluded-volume interactions and expensive pair-potential calculations. The former greatly reduces the chain relaxation towards equilibrium configurations and the efficiency of sampling the configurational space, while the latter becomes computationally very expensive for concentrated polymeric systems. Fast off-lattice Monte Carlo (FOMC) simulations overcome these limitations, where individual polymer segments are modeled as volumeless points with the excluded-volume interactions modeled by either solvent quality, Helfand compressibility, or incompressibility constraint commonly used in polymer field theories. By dividing the simulation box into cells and assigning polymer segments to a cell, the short-range interactions can be readily evaluated without expensive pair-potential calculations. To demonstrate the great advantages of FOMC simulations, we have studied homopolymers confined between two parallel surfaces, and compared the results with self-consistent field calculations and field-theoretic simulations (FTS). Since FOMC simulation is particle-based, it avoids the unsolved 7sign problem encountered in FTS. For the systems we have studied, FOMC simulations can sample the whole spectrum of fluctuations and are several orders of magnitude faster (more efficient) than FTS.

5:06PM D25.00014 Conformation and collapse of a polymer chain in explicit solvent: A solvation potential approach , MARK P. TAYLOR, Dept. of Physics, Hiram College, Hiram, OH — The conformation of a polymer chain in solution is intrinsically coupled to the chain’s local solvent environment. In much of the theoretical work on polymers in solution the effects of solvent are treated implicitly and explicit chain-solvent coupling is ignored. Although a formally exact treatment of chain-solvent coupling can be constructed, the required many-body solvation potential is not practical to compute. We have recently shown that for short hard-sphere and square-well chain-in-solvent systems this many-body solvation potential can be made tractable via an “exact” decomposition into a set of two-site potentials [1]. Here we use these exact short chain results, combined with the pure solvent potential of mean force, to construct approximate two-site solvation potentials for long chains under a range of solvent conditions [2]. Monte Carlo simulations for full chain-in-solvent systems verify the accuracy of our solvation potential approach. We use this approach to study the role of driving and inhibiting chain collapse in square-well systems and discuss the possibility of solvent driven chain collapse in the symmetric hard-sphere chain-in-solvent system. [1] M. P. Taylor and G. M. Petersen, J. Chem. Phys. 127, 184901 (2007). [2] M. P. Taylor and S. Ichida, J. Polym. Sci., Part B: Polym. Phys. 45, 3319 (2007).

5:18PM D25.00015 Statistical Mechanical Theory of Phase Separation and Structure in Dense Polymer-Particle Mixtures , LISA HALL, KEN SCHWEIZER, University of Illinois — Microscopic liquid state theory has been applied to investigate phase separation and structure of dense mixtures of hard spherical particles and flexible polymer chains in the presence of interfacial attractive interactions. The entire range of filler loading, from the dilute particle regime to the colloid science relevant case of ultra-high particle volume fraction with dilute polymer additives, has been studied for the first time. Many body effects can result in large quantitative, or even qualitative, changes of spinodal demixing boundaries compared to a low order virial treatment. In the temperature-particle volume fraction representation both upper and lower critical temperatures are present, separated by a miscibility window. Entropic effects dominate for weak interfacial attractions (high temperature) resulting in depletion phase separation with a critical point at roughly 10% filler loading. At relatively high interfacial cohesion (low temperature) a network bridging transition occurs characterized by a highly asymmetric spinodal boundary which depends sensitively on attraction spatial range. Deep contact or bridging minima in the particle potential of mean force can occur, which raises the possibility that kinetic gelation or aggregation pre-empts equilibrium phase separation. The evolution of the real space correlations and scattering structure factors as phase separation is approached has been studied in detail.

2:30PM D26.00001 Spectroscopy of large hydrogen clusters in He droplets and H2 droplets Ur, TAKAMASA MOMOSE, The University of British Columbia — Clusters of molecular hydrogen (H2) at low temperatures have been attracted much attention because of the possible superfluid phase of molecular hydrogen. Parahydrogen has been predicted to undergo Bose-Einstein condensate (BEC) and to exhibit a superfluid phase below 6 K. However, since the freezing point of H2 (14 K) is much higher than the predicted superfluid transition temperature, the supercooling of bulk H2 system has not been achieved despite many attempts. Clusters are known to exhibit lower freezing and melting temperatures than their bulk system due to the size effect. In addition, the melting temperature may become significantly lower than the freezing temperature in such clusters, and coexistence of liquid and solid phases between the melting and freezing temperatures has been predicted theoretically. Thus, clusters of molecular hydrogen are very appealing system for the observation of possible superfluid phase of molecular hydrogen. Since superfluid is a macroscopic property, we have studied properties of hydrogen clusters with fairly large size (N = 100 – 103) by using He droplet spectroscopy. Some advantages of using droplet spectroscopy for this study include (1) cluster size can be precisely controlled by its pickup process, and (2) the temperature of clusters is well defined. Laser induced fluorescence of several molecules doped in H2 clusters showed clear evidence of non-rigidity of hydrogen clusters at 0.4 K or 4 K. We have also observed a clear difference in the LIF spectra between parahydrogen and orthohydrogen clusters. We will discuss the properties of large parahydrogen clusters from the dependence on the cluster size and concentration of orthohydrogen.

3:06PM D26.00002 Hydrogen clusters that remained fluid Ur, KIRILL KUYANOV-PROZUMENT, ANDREY VILESOV — Para-H2 may constitute the only other superfluid besides helium. The superfluid transition temperature is predicted to be around 2 K, well below freezing of H2 at 13.8 K. Numerous attempts to supercool macroscopic H2 samples proved to be unsuccessful. Our approach includes formation of H2 clusters in a pulsed cryogenic nozzle beam expansion of a neat p=H2 gas as well as x% of p=H2 diluted in He and interrogation via Coherent Anti-Stokes Raman Scattering. At X = 2 – 100 % the frequency of the vibrational Q1(0) line in clusters remains constant at v = 4149.7 cm−1 very similar to 4149.6 cm−1 as in solid p=H2 and lower than in liquid p=H2at 18 K (4151.9 cm−1). The rotational S0(0) transition show some characteristic crystal field splitting having magnitude of about 6 cm−1. The splitting pattern is different from that in the hcp solid, suggesting different structure in solid p=H2 clusters. At X < 2 %, the frequency of the Q1(0) line increases to about 4150.5 cm−1, which is consistent with that expected in the supercooled liquid. The S0(0) transition in these clusters, consisting of about 5 x 104 molecules, appears as a single line at the same frequency as in liquid p=H2. The temperature of these supercooled clusters is estimated to be less than about 1 K. Possible superfluidity of the clusters is discussed.

3:18PM D26.00003 Three-body interactions in liquid and solid hydrogen: Evidence from vibrational spectroscopy , ROBERT HINDE, Univ. of Tennessee — In the cryogenic low-density liquid and solid phases of H2 and D2, the H2 and D2 molecules retain good rotational and vibrational quantum numbers that characterize their internal degrees of freedom. High-resolution infrared and Raman spectroscopic experiments provide extremely sensitive probes of these degrees of freedom. We present here fully-first-principles calculations of the infrared and Raman spectra of liquid and solid H2 and D2, calculations that employ a high-quality six-dimensional coupled-cluster H2–H2 potential energy surface and quantum Monte Carlo treatments of the single-molecule translational degrees of freedom. The computed spectra agree very well with experimental results once we include three-body interactions among the molecules, interactions which we also compute using coupled-cluster quantum chemical methods. We predict the vibrational spectra of liquid and solid H2 at several temperatures and densities to provide a framework for interpreting recent experiments designed to search for superfluid behavior in small H2 droplets. We also present preliminary calculations of the spectra of mixed H2/D2 solids that show how positional disorder affects the spectral line shapes in these systems.
3:30PM D26.00004 Rotational spectrum of small, doped 3He clusters . TATJANA SKRBIĆ, SISSA - DEMOCRITOS (Trieste, Italy), SAVERIO MORONI, DEMOCRITOS - SISSA (Trieste, Italy), STEFANO BARONI, SISSA - DEMOCRITOS (SISSA) — In recent years, symmetry-adapted imaginary-time correlation functions have been extensively used to study the rotational spectrum of doped 3He clusters within the frame of the repulsion quantum Monte Carlo method. The success of this approach relies on the choice of suitable correlation functions, whose spectral resolution is dominated by few, well separated eigenvalues of the Hamiltonian. Under these conditions, reliable excitation energies can be extracted by inverse Laplace transform. This method has been tailored for bosons, due to the positivity of the ground-state wave-function and to the distinctive scarcity of low-lying states. For sufficiently small systems, however, the states of the discrete spectrum can be calculated in the same manner also with Fermi statistics, using appropriate generalizations of the correlation functions. We present rotational spectra for small 3He clusters doped with molecules –such as CO2 and OCS– whose effective moments of inertia, in 4He clusters, feature a non-trivial dependence on the system size, with a pronounced turnaround for less than 10 atoms.

3:42PM D26.00005 Quantum melting and superfluidity of molecular hydrogen clusters , MASSIMO BONINSENGI, University of Alberta — Clusters of parahydrogen comprising between 10 and 50 molecules have been extensively studied by computer simulations based on the continuous-space Worm Algorithm, which allows one to go down to temperatures as low as a few hundredths of a K. These clusters display an intriguing interplay of liquid- and solid-like behavior as a function of both temperature and cluster size. In this sense, their physics is far richer than that of helium clusters. An intriguing phenomenon predicted by our simulations is quantum melting, whereby clusters in some size range (roughly between 22 and 30 molecules) are observed to go from rigid, solid-like, to essentially structureless and liquid-like as the temperature is lowered, due to the onset of quantum exchange cycles involving all the molecules in the cluster. At low temperature these clusters turn superfluid; their local superfluid response has been analyzed, and found to be essentially uniform throughout the system in the $T \to 0$ limit, even in clusters with a pronounced shell structure. In particular, exchanges involving molecules in the inner and outer shells are shown to be underlying the superfluid response. This system can also allow one to gain insight into the relationship of the superfluid properties with Bose condensation, and aspect that has been thoroughly investigated.

4:18PM D26.00006 Alkaline Earth Metal Atom Complexes with HCN Trapped On/In Helium Droplets: Vibrational Excitation Induced Solvation and Desolvation , GARY DOUBERY, University of Georgia — Infrared laser spectroscopy is used to probe the rotational dynamics of the binary HCN-M (M=Ca, Sr) complexes, either solvated within or bound to helium droplets. The “surface bound” spectral signatures reported previously for the HCN-alkali atom complexes are observed for both species, while a second band is observed for HCN-Ca that corresponds to a solvated species. IR-IR double resonance spectroscopy is used to probe the interconversion of the two distinct HCN-Ca populations. Above a threshold droplet size, vibrational excitation results in the solvation of the surface bound HCN-Sr complex.

4:30PM D26.00007 Imaging Photoelectron Dynamics in Doped Helium Droplets , CHIA WANG, University of California, Berkeley, OLEG KORNILOV, Lawrence Berkeley Nat’l Lab, DARCY PETERKA, JEONG KIM, OLIVER GESSNER, Lawrence Berkeley Nat’l Lab, DANIEL NEUMARK, University of California, Berkeley — Photoionization of He droplets doped with Xe and Kr atoms have been investigated by photoelectron imaging utilizing VUV synchrotron radiation. Photoelectron images were recorded over a wide range of He droplet sizes, photon energies, and dopant pick-up conditions. Significant ionization of dopants was observed at 21.6 eV, the absorption maximum of 2P electronic excited state of He droplets, suggesting an indirect ionization via excitation transfer. Photoelectron images and spectra indicate multiple pathways for photoelectrons generated by this process to escape the droplet. Special attention is paid to the excitation transfer dynamics and the electron relaxation in He droplets. It is found that excitation transfer from 2P state to dopants competes with relaxation to the lower 2S state. The excitation is likely a localized excitation that transfers the energy to the dopant via a dipole-dipole hopping mechanism. The conduction band of He droplets as a function of droplet size is also observed. The conduction band edge reaches the bulk limit for the largest He droplets. The electron under the conduction band becomes trapped and forms an electron bubble that escapes the droplet by transoncending a barrier near the liquid/vapor interface.

4:42PM D26.00008 Interchange-Tunneling Splitting in HCl Dimer in Helium Nanodroplets , DMITRY SKVORTSOV, RUSSELL SLITER, Univ of Southern California, MYONG YONG CHOI1, Gyeongsang National University, ANDREY F. VILESOV, Univ of Southern California — Infrared spectra of HCl dimers have been obtained in helium nanodroplets. The splitting in the vibrationally excited state of the bound HCl dimer (2ν) in (HCl - H2) dimers was observed to be 2.7 cm$^{-1}$ as compared to 3.7 cm$^{-1}$ in free dimer. From the splitting, the strength of the interchange-tunneling interaction in liquid helium was obtained to be 0.85 cm$^{-1}$, which is about a factor of two smaller than in the free dimer. The results are compared with the previous spectroscopic study of (HF)$_2$ in He droplets as well as to the theoretical study of (HF)$_2$ and (HCl)$_2$ dimers in small He clusters.

1Gyeongsang National University, Jinju, 660-701, South Korea

4:54PM D26.00009 Path integral studies of methane rotations in 4He clusters$^1$ , NIKOLAY MARKOVSKIY, CHI MAK, University of Southern California — Path integral simulations have been carried out to study the rotations of a methane inside a single shell of 4He atoms at 0.3 K to address the question of whether dopant molecule rotations can be used to probe the quantum statistics and superfluidity of the shell. We examined the effects of the probe molecule on the 4He exchanges and their counter effects on the renormalized rotation constant of the probe systematically by varying the intrinsic moment of inertia of the methane. The observed effects show strong dependence on the intrinsic moment of inertia of the rotating probe, with a heavy probe favoring stronger templating of the 4He density and a corresponding suppression of exchanges in the shell, as well as a large renormalization in the probe’s effective rotation constant, while a light probe shows almost no effect on the shell density or the effective rotation constant. These results can be rationalized in terms of a rotational smearing effect and suggest that there is no clearly quantifiable relationship between the superfluid fraction of the shell and the renormalized rotation constant of the probe for cases where the probe molecule has weak anisotropic interactions with the 4He atoms.

5:06PM D26.00010 Pump-probe spectroscopy of Rg-Br$_2$ linear isomers$^1$ , JORDAN PIO, CRAIG BIELER, WYTZE VAN DER VEER, KENNETH JANDA, University of California-Irvine — We have recorded and analyzed the $X$—$B$ spectra for three Rg–Br$_2$ linear isomers [Rg = He, Ne, Ar] using pump-probe spectroscopy. This work is an interesting test case for the transition from quantum to quasi-classical dynamics, and how the dynamics are interconnected with changes in the potential energy surface. Helium is not only much lighter than argon, but the He–Br$_2$ potential well is much shallower than that of Ar–Br$_2$. Excitation spectra to individual Rg–Br$_2$ (B, $\nu$) intermolecular potentials were recorded by probing the Br$_2$ (B, $\nu$) asymptotic limit of the potential while scanning the pump laser. The continuum spectra of the three species are very different, with the He–Br$_2$ spectrum peaking at threshold while the Ar–Br$_2$ spectrum is negligible at threshold and strongly blue shifted. The linear Ne–Br$_2$ bond energy was measured to be 71 ± 3 cm$^{-1}$ by the threshold energy for the onset of the continuum. Since excitation tends to move electron density to the $\nu^*$ orbital of the Br–Br bond near the rare gas atom, the intramolecular stretching vibration (Br–Br) and the intermolecular stretching vibration (Rg–Br) are strongly coupled. The experiments will be compared to a two dimensional model using the best available potential energy functions.

SANS experiment observes the convolution of the nuclear and magnetic terms, we have implemented and further developed an algorithm to separate the four spin are described elsewhere [1]. An FeSi supermirror polarized the incident neutrons, and a polarized 3He cell was used as a spin analyzer. While a typical magnetic of the magnetic interparticle correlations. These particles were 7 nm in diameter with an average edge-to-edge separation of 2.5 nm. Preparation techniques studied ferromagnetic magnetite monodisperse nanospheres in order to determine the field (0 and 1.3 Tesla) and temperature (50, 100, and 200 K) dependence of the magnetic interparticle correlations. These particles were 7 nm in diameter with an average edge-to-edge separation of 2.5 nm. Preparation techniques are described elsewhere [1]. An FeSi supermirror polarized the incident neutrons, and a polarized 3He cell was used as a spin analyzer. While a typical magnetic SANS experiment observes the convolution of the nuclear and magnetic terms, we have implemented and further developed an algorithm to separate the four spin dependent cross sections. This provides an unambiguous separation and measurement of magnetic and nuclear contributions. At low temperatures, magnetic correlation lengths have been found to be significantly larger than at high temperatures.

2:42PM D27.00002 Artificial Nanomagnet with Lateral Confinement . LIFENG YIN, NOPPI WIDJAJA, JIAN SHEN, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — For artificially low dimensional nanodots, the exchange interaction and dipole-dipole magnetostatic interaction can no longer stabilize the long range magnetic order at finite temperature. However, the electron-mediated indirect exchange interaction could be enhanced at surfaces due to the symmetry broken. A collective ferromagnetic behavior in two-dimensional Fe dot assemblies grown on a single crystal Cu(111) surface has been reported[1]. These Fe nanodots were grown using a novel method called buffer-layer assisted growth. The ferromagnetic ordering temperature appears to depend not only sensitively on the average spacing between the dots, but also strongly associated with the presence of surfaces states. The vicinal surfaces have been found a rich variety of novel behavior that results from broken translational symmetry by surface atomic steps. The presence of a free-electron-like Shockley surface state on the corresponding flat Cu(111) surface will be interrupted on vicinal surface. More interestingly, a switch between two qualitatively different regimes at a miscut of 7° takes place[2]. In this work, a curve-polished Cu(111) (0-8° miscut) substrate is used to tune the surface electronic states, and in turn influences the electron-mediated indirect exchange interaction of Fe nanodots. [1] J. P. Pierce et al., Phys. Rev. Lett. 92, 237201 (2004). [2] J.E. Ortega et al., Phys. Rev. Lett. 84, 6110 (2000).

2:54PM D27.00003 Magnetic Correlations In A Magnetite Nanoparticle Assembly Investigated Using Polarized SANS . KATHRYN KRYCKA, NCNR, NIST, CHARLES HOGLE, Carnegie Mellon University. YUMI IJIRI, Oberlin College. RYAN BOOTH, Carnegie Mellon University. JULIE BORCHERS, WANGCHUN CHEN, MARK LAVER, THOMAS GENTILE, BRIAN MARANVILLE, NCNR, NIST, BENJAMIN BRELSLAUER, SARA MAJETIC, Carnegie Mellon University — Using small angle neutron scattering (SANS) with polarization analysis, we have studied ferromagnetic magnetic monodisperse nanoparticles in order to determine the field (0 and 1.3 Tesla) and temperature (50, 100, and 200 K) dependence of the magnetic interparticle correlations. These particles were 7 nm in diameter with an average edge-to-edge separation of 2.5 nm. Preparation techniques are described elsewhere [1]. An FeSi supermirror polarized the incident neutrons, and a polarized 3He cell was used as a spin analyzer. While a typical magnetic SANS experiment observes the convolution of the nuclear and magnetic terms, we have implemented and further developed an algorithm to separate the four spin dependent cross sections. This provides an unambiguous separation and measurement of magnetic and nuclear contributions. At low temperatures, magnetic correlation lengths have been found to be significantly larger than at high temperatures.

3:06PM D27.00004 Magnetic Nanocheckerboards with Tunable Sizes in the Mn-Doped CoFe₂O₄ Spinel . CHENGLIN ZHANG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, C.M. TSENG, C.H. CHEN, Center for Condensed Matter Sciences, National Taiwan University, Taipei 10617, Taiwan, S. YEO, Y.J. CHOI, S.W. CHEONG, Rutgers Center for Emergent Materials and Department of Physics & Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — In the Mn-doped CoFe₂O₄ spinel, a highly ordered array of two types of rectangular nanorods, ~300 nm in length and a few nanometer in size, is achieved through chemical phase separation mediated by cooperative Jahn-Teller distortions. At room temperature, the magnetic nanorods with composition close to CoFe₂O₄ interlace with the paramagnetic counterpart and form a highly organized checkerboard pattern in the cross section. The checkerboard size, varying in the range of ~3 nm and ~80 nm, is tunable with composition as well as with the isothermal annealing time This may be of potential significance to the next generation magnetic storage. The magnetic nanocheckerboards exhibit a nearly ideal configuration for perpendicular recording media.

3:18PM D27.00005 Magnetic interactions among Co nanowires . HAFSA KHURSHID, MICHAEL BONDER, GEAROGE HADJIPANAYIS, University of DE — Magnetic nanowires have recently gained much attention because of their potential applications in magnetic recording, sensors and optoelectronic devices. The magnetic properties of nanowires are determined by the competition between magnetocrystalline and shape anisotropy resulting from the reduced dimensionality of the system. In this study we present results on the magnetic interactions among arrays of electrodeposited Co nanowires as a function of inter-wire spacing and nanowire diameter. X-Ray diffraction and electron microscopy reveal that the nanowires exhibit the hexagonal closed packed polycrystalline structure. The direction of the magnetic easy axis is controllable as a function of wire diameter. By increasing the diameter of nanowires from 30 to 188 nm, the magnetic easy axis switches from perpendicular to parallel to the nanowire’s major axis. This is further evidenced by a decrease in coercivity from 1200 to 100 Oe and a reduced loop squarness. The magnetic interactions were probed using delta M plots. All samples exhibit a negative delta M curve indicative of magnetostatic interactions. As the inter-wire spacing increases there is a broadening of the dipolar component of delta M plots indicating an increase in the switching field distribution. This work was supported by NSF Grant# DMR-0302544.
studied the magnetic properties of face-centered-cubic (fcc) Co nanoparticles made by the cluster gun. The zero field-cooled (ZFC) and field-cooled (FC) $M(T)$ curves at different fields show that the blocking temperature is shifted to lower temperature when the applied magnetic field is increased. This behavior could be due to a decreased energy barrier at increased filed or to inter-particle dipole-dipole interactions. $M$ vs $H/T$ data above the blocking temperature show that the latter might be responsible for this behavior. The dynamics of the FC magnetization were also studied. The $M(T)$ curves on FC samples obtained with the magnetic field on and off at different temperatures, show that the sample remembered its thermal history and demonstrated a memory effect at temperatures lower than the blocking temperature. However, this memory effects were not observed in the ZFC samples. The magnetic relaxation with a change at low temperature also shows a memory effect at temperature below the blocking temperature. The $M(T)$ curves at different fields and memory effects indicate that the dynamics of nanoparticles are due to the distribution of particle sizes and inter-particle interactions. Work Supported by NSF GRANT # DMR-0302544.

In this work we have studied the magnetic properties of face-centered-cubic (fcc) Co nanoparticles made by the cluster gun. 4:54PM D27.00013 Growth of Co nanoclusters on rutile TiO2 (110) surface1, EN CAI, XUEWEN WANG, JIANDI ZHANG, Florida International University — Fabrication of magnetic nanodots with uniform size and density is one of the key issues of studying the structure and property of a nanomagnet system. We report here our studies on the growth of Co nanoclusters on rutile TiO2 (110) surface. Well ordered TiO2 (110) surface is prepared in the UHV chamber via Ar+ sputtering and annealing. Co deposition is carried out in situ by molecular beam epitaxy and characterized with STM. Growth parameters are tuned to optimize the uniformity of dot size and density. Co dot coverage, size and density are investigated as functions of deposition rate and time as well as post-annealing temperature. Our results show that uniformity of the dots mainly depends on deposition rate, and the density if the dots primarily depends on the coverage of the dots, while the size of the dots mainly depends on the deposition rate and post-annealing temperature instead of coverage. Growth mechanism will be discussed.

5:06PM D27.00014 Tuning of the magnetocrystalline anisotropy in CoFe3−xO4 nanoparticles through cobalt doping1, RONALD TACKETT, SUDAKAR CHANDRAN, RATNA NAIK, GAVIN LAWES, Wayne State University, CORNELIU RABLAU, PREM VAISHNAV, Kettering University — We report on the effect of cobalt doping on the magnetocrystalline anisotropy of CoFe3−xO4 nanoparticles. The CoFe3−xO4 (0 ≤ x ≤ 0.15) nanoparticles were synthesized through the co-precipitation of ammonium hydroxide in an environment of Fe2+, Fe3+, and varying concentrations of Co2+. The size and crystallinity were confirmed using transmission electron microscopy, with a mean size of 17 ± 4 nm which was found to be constant across the different cobalt dopings. The magnetic properties were investigated through the use of dc and ac magnetic susceptibility, with the effective magnetocrystalline anisotropies being extracted from these data. The effective magnetocrystalline anisotropy found from each method were, within acceptable experimental error, found to agree, as well as increase linearly with cobalt doping. The effective anisotropy values were found to increase in magnitude by 100% as the cobalt fraction was increased from x = 0 to x = 0.1. This trend allows for the tuning of the magnetic isotropy of iron oxide nanoparticles through cobalt doping.

5:18PM D27.00015 Preparation of cobalt-ferrite nanoparticles within a biopolymer template1, MARCO GARZA, VIRGILIO GONZÁLEZ, ALEJANDRO TORRES-Castro, MOISÉS HINOJOSA, UBALDO ORTIZ, UANL-FIME — Using an in-situ co-precipitation reaction from solid dissolutions of stoichiometric amounts of Fe (III) and Co (II) inorganic salts, it was prepared highly loaded nanocomposites (as high as 75% w/w) of cobalt-ferrite nanoparticles within a chitosan matrix, with particle size of about 7 nm, narrow particle size distribution and superparamagnetic character. Nanoparticle samples were characterized by high resolution transmission electron microscopy (HRTEM), UV-vis spectrometry and magnetic measurements by SQUID, using magnetization-field dependent, M(H), and magnetization-temperature dependent, M(T), studies.

Session D28 DMP: Focus Session: Transport in Nanostructures III: Single Molecules Morial Convention Center 220

2:30PM D28.00001 Understanding the Conductance of Single-Molecule Junctions from First Principles1, SU YING QUEK, Molecular Foundry, Lawrence Berkeley National Laboratory — Discovering the anatomy of single-molecule junctions, in order to exploit their transport behavior, poses fundamental challenges to nanoscience. First-principles calculations based on density-functional theory (DFT) can, together with experiment, provide detailed atom-scale insights into the transport properties, and their relation to junction structure and electronic properties. Here, a DFT scattering state approach [1] is used to explore the single-molecule conductance of two prototypical junctions as a function of junction geometry, in the context of recent experiments. First, the computed conductance of 15 distinct benzene-diamine-Au junctions is compared to a large robust experimental data set [2]. The amine-gold bonding is shown to be highly selective, but flexible, resulting in a conductance that is insensitive to other details of the junction structure. The range of computed conductance corresponds well to the narrow distribution in experiment, although the average calculated conductance is approximately 7 times larger. This discrepancy is attributed to the absence of many-electron corrections in the DFT molecular orbital energies; a simple physically-motivated estimate for the self-energy corrections results in a conductance that is much closer to experiment [3]. Second, similar first-principles techniques are applied to a range of bipyridine-Au junctions. The extent to which Au-pyridine link bonding is affected by the constraints of forming bipyridine-Au junctions is investigated. In some contrast to the amine case, the computed conductance shows a strong sensitivity to the tilt of the bipyridine rings relative to the Au surfaces. Experiments probing the conductance of bipyridine-Au junctions are discussed in the context of these findings. [1] H. J. Choi et al, Phys Rev B, 76, 155420 (2007) [2] L. Venkataraman et al, Nano Lett 6, 458 (2006) [3] S. Y. Quek et al, Nano Lett. 7, 3477 (2007)

3:06PM D28.00002 Single Molecule Conductance and Contact Chemistry, LATHA VENKATARAMAN, YOUNG PARK, ADAM WHALLEY, MASHÁ KAMENETSKA, MICHAEL STEIGERWALD, COLIN NUCKOLLS, MARK HYBERTSEN, Columbia University — Our previous experiments probing the conductance of single molecule circuits with amine-gold linkages have demonstrated the relationship between the electrical characteristics and the intrinsic molecular properties such as their length, conformation, gap between the highest occupied and lowest unoccupied molecular orbitals and the alignment of these levels to the metal Fermi level. Here we study different chemical linker groups expected to form donor-acceptor bonds to gold. We measure transport through single molecule junctions by repeatedly forming and breaking Au point contacts with a modified STM in a solution of the molecules terminated by Amine, Dimethyl Phosphine and Methyl Sulfide linker groups. The clear molecular signatures allow us to demonstrate a systematic dependence the link group.

3:18PM D28.00003 Conductance Trends in Single Molecule Junctions Formed Using Donor-Acceptor Links: Theoretical Analysis1, MAX B. KOENTOPP, LATHA VENKATARAMAN, MICHAEL L. STEIGERWALD, Columbia University, MARK S. HYBERTSEN, Brookhaven National Laboratory — The conductance of single molecule junctions using amine-gold links has been understood based on formation of a donor-acceptor bond involving the N lone pair and the s-orbital on an undercoordinated Au site on the electrode. Experiments probing junctions formed with alkanes terminated by dimethyl phosphines and methyl sulfides also show an unambiguous conductance signature. The structure and bonding in these junctions is analyzed using density functional theory based calculations. Like the amine link, the dimethyl phosphine and methyl sulfide bond to an under-coordinated Au site through a donor-acceptor motif. While the bond energy for the amine and methyl sulfide links are similar (0.6 eV), the dimethyl phosphine is significantly stronger (1.2 eV). Trends in measured junction conductance (amine < sulfide < phosphine) are analyzed in terms of available electronic channels.

3:30PM D28.00004 Molecular Conductance of oligophenylene-vinylene in Metallic Break-Junctions

PATRICK WHEELER, MENG LU, DAVID CORLEY, JAMES TOUR, DOUG NATELSON, Rice University — Break junctions between a metallic tip and a metallic substrate have proven to be extremely useful tools for characterizing single-molecule electrical conductance. Conductance measurements while repeatedly breaking and reforming junctions are conducive to rapid statistical characterization. We will present preliminary results of room temperature break junction conductance measurements on amine-terminated oligophenylene-vinylene (OPV) oligomers. Recent low temperature measurements of OPV oligomers in the electromigrated gap configuration imply a large renormalization downward of the HOMO-LUMO gap. Since the HOMO-LUMO gap is correlated with the conductance and the tunneling coefficient, beta, break junction measurements should provide clarification about the HOMO-LUMO gap in these molecules.

3:42PM D28.00005 Probing mechanisms of electrical conduction in single organic molecules

LYUDMYLA ADAMSKA, IVAN OLEYNIK, University of South Florida, MORTKÖ KOZHUSHNER, Institute of Chemical Physics, RAS — The electrical conduction of relatively long (1-2 nm) single organic molecules occurs via resonant tunneling of charge carriers, electrons and/or holes, through the energy levels of negative molecular ion (electrons) and/or positive molecular ion (holes). The position of these resonant energy levels with respect to the Fermi levels of the anode and cathode determines the relative contributions of electron and hole conduction to the resonant current. These resonant levels depend on the applied bias, and are also influenced by several physical factors such as the polarization of the molecule, image potential and metal/molecule interfaces that are difficult to control under conditions of real experiment. In this presentation we suggest a method of unambiguous experimental determination of specific type of the conduction mechanism (electron or hole conduction) which is based on the idea of utilizing experimental techniques of nanocalorimetry.

MARC KAMENETSKA, Department of Applied Physics and Applied Math, Columbia University, MICHAEL FREI, MARC HYBERTSEN, CFN, Brookhaven National Laboratory, LATHA VENKATARAMAN — We measure the conductance of single molecules attached to gold electrodes by repeatedly forming and breaking Au point contacts with a modified STM in a solution of molecules. Conductance traces measured while pulling the point-contacts reveal steps due to the formation of single molecule junctions which can be elongated without a significant change in junction conductance. To better understand the mechanical stability of these single molecule junctions, we analyze data sets of 20000 or more individual conductance traces for a series of diamin molecules, measuring the distance over which junctions can persist. We find that the distance that a junction can be pulled is affected by the metal-molecule binding energy. In addition, we see an unambiguous relationship between geometry and stability, where both the length of the molecule as well as the atomic configuration of the contact electrode affect the distance over which a junction can persist.

4:06PM D28.00007 Tunneling Transport through Long Molecular Chains

EMIL PRODAN, Department of Physics, Yeshiva University, New York, NY, ROBERTO CAR, Chemistry Department, Princeton University, Princeton, NJ — The Riemann structure of the bands and other properties of the evanescent Bloch functions have been used to derived an asymptotic expression for the tunneling conductance through long molecular chains. Our results give the contact conductance in terms of an overlap integral of three well defined and physically relevant quantities. In particular, this formula shows how the conducting states of the leads couple to the evanescent Bloch functions of the insulating chain. The theory is applied to amine-linked alkyl and aromatic chains and the results are compared with the experiment. Using these applications, we discuss the key aspects and advantages of the theory. Extensions to spin dependent transport will be also discussed.

1Supported by NSF-MRSEC program through the Princeton Center for Complex Materials (PCCM), grant DMR 0213706, and by DOE through grant DE-FG02-05ER46201

4:18PM D28.00008 Transport properties of molecular wires from ab initio calculations

KENJI HIROSE, NEC Corp., NOBUHIKO KOBAYASHI, Univ. of Tsukuba — Understanding of electron transport through nanostructures becomes important with the advancement of fabrication process to construct atomic-scale devices. Due to the drastic change of transport properties by contact conditions to electrodes in local electric fields, first-principles calculation approaches are indispensable to understand and characterize the transport properties of nanometer-scale molecular devices. Here we focus on the transport properties of molecular wires bridged between metallic electrodes, especially on the effects of contacts to electrodes and on the dependence of the length of molecular wires on transport properties. We use an ab initio calculation method based on the scattering waves, which are obtained by the recursion-transfer-matrix (RTM) method, combined with non-equilibrium Green’s function (NEGF) method. We find that conductance shows exponential behaviors as a function of the length of molecular wires due to tunneling process determined by the HOMO-LUMO energy gap. From the voltage drop behaviors inside the molecular wires, we show that the contact resistances are well separated for the long molecular wires. We will present detailed data of electronic states at contacts to metallic electrodes under strong electronic fields and will discuss the polarization, screening effect, and potential barrier formation at contacts on the transport properties of molecular wires, comparing them with those of metallic atomic wires.

4:30PM D28.00009 The molecular electronics of protein fragments

DAVID CARDAMONE, GEORGE KIR-CZENOW, Simon Fraser University — Small fragments of polypeptide chains provide a uniquely scalable, customizable basis for nanoelectronic devices. Using a combination of ab initio and semi-empirical techniques, we arrive at a quantitative understanding of the charge transport properties of these molecules. This allows us to investigate their chemical and physical properties, such as lead-molecule bonding geometry, lead-induced distortion of molecular structure (e.g., molecular stretching), and device properties. We explain the observed current rectification in these molecules and further predict negative differential resistance, opening the way to protein-based nanoelectronic devices.

4:42PM D28.00010 Ab initio studies of electronic transport through amine-Au-linked junctions of photoactive molecules

DAVID A. STRUBBE, Dept. of Physics, University of California, Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory, SU YING QUEK, Molecular Foundry, LBNL, LATHA VENKATARAMAN, Dept. of Applied Physics, Columbia Univ., HYOUNG JOON CHOI, Dept. of Physics and IPAP, Yonsei Univ., J.B. NEATON, Molecular Foundry, LBNL, STEVEN G. LOUIE, Dept. of Physics, UC Berkeley, M.D. — Molecules linked to Au electrodes via amine groups have been shown to result in reproducible molecular conductance values for a wide range of single-molecule junctions [1,2]. Recent calculations have shown that these linkages result in a junction conductance relatively insensitive to atomic structure [3]. Here we exploit these well-defined linkages to study the effect of isomerization on conductance for the photoactive molecule 4,4'-diaminoazobenzene. We use a first-principles scattering-state method based on density-functional theory to explore structure and transport properties of the cis and trans isomers of the molecule, and we discuss implications for experiment. [1] L Venkataraman et al., Nature 442, 904-907 (2006); [2] L Venkataraman et al., Nano Lett. 6, 458-462 (2006); [3] SY Quek et al., Nano Lett. 7, 3477-3482 (2007).

4:54PM D28.00011 Electronic spectrum and orbital filling in a single-molecule junction. EDGAR A. OSORIO, KEVIN O’NEILL, Delft University of Technology, MAARTEN WEGEWIJS, RWTH Aachen, NICOLAI STUHR-HANSEN, JENS PAAKSE, THOMAS BJORNHOLM, University of Copenhagen, HERRE VAN DER ZANT, Delft University of Technology — We study single-electron tunneling in three-terminal devices in which a single molecule bridges the gap between source and drain electrode. The molecular devices are made by electromigration and at low temperatures excitations appear in the stability diagram. For the OPV-5 molecule more than fifteen different excitations are visible, of which twelve match Raman spectra and the remaining ones are due to vibrations of the molecule attached to gold electrodes at energies below 10 meV. Similar to carbon nanotubes, the observation of a singlet-triplet transition allow us to determine the orbital filling and spin configuration of the molecule.

5:06PM D28.00012 Gate effects on electronic transport in alkanedithiol single molecular junctions. HYUNWOO SONG, TAKHEE LEE, Department of Materials Science and Engineering, Gwangju Institute of Science and Technology, YOUNGSANG KIM, HEEJUN JEE, Department of Applied Physics, Hanyang University — We investigate the gate effects on the electronic transport properties in alkanedithiol single molecular junctions. Using electromigration-induced break junction technique, we fabricated an array type of electrode pairs with nanometer-sized separation on top of naturally oxidized aluminum gate electrodes. The alkanedithiol molecules were bridged between the nanometer-sized gap that was achieved by breaking gold nanowires fabricated using electron-beam lithography with a controlled passage of current. The electric potential applied to the aluminum gate electrode shifts the molecular energy levels relative to the Fermi energy in the metallic contacts. We will discuss the gate-bias dependent current-voltage characteristics and other observed transport properties of alkanedithiol single molecular junctions in the off-resonant tunneling transport regime.

5:18PM D28.00013 Modeling of N@C$_{60}$ single-molecule transistors. CARSTEN TIMM, University of Kansas, JACOB E. GROSE, Cornell University, WOLFGANG HARNEIT, Free University Berlin, DANIEL C. RALPH, Cornell University — We report on recent experimental and theoretical results for single-molecule transistors involving endohedral N@C$_{60}$ fullerene molecules. In this talk, we will focus on the theoretical modeling. The observed differential conductance shows strong evidence for the exchange interaction between electrons in the fullerene LUMO and the nitrogen p-electrons, favoring an antiferromagnetic interaction. In addition, soft vibrational modes are seen, which are attributed to oscillations of the molecule as a whole. We discuss a model Hamiltonian that reproduces the main features of the experimental conductance.

Session D29 DMP: Focus Session: Carbon Nanotubes and Related Materials IV: Graphene
Morial Convention Center 221

2:30PM D29.00001 Electronic properties of Dirac fermions in epitaxial graphene. SHUYUN ZHOU, UC Berkeley & LENL — Graphene, atomically thin layers of graphite, has attracted a lot of research interest because of its intriguing physics as well as its technological potential for next generation electronic devices. I will first present a detailed characterization of the growth of atomically thin films of epitaxial graphene on SiC, by using low energy electron microscopy (LEEM). The electronic properties of the films are hence studied by angle resolved photoemission spectroscopy (ARPES). Data as a function of doping, temperature and sample thickness are presented and the role of disorder and many body interactions will be discussed. Finally, the presence of a bandgap in the spectra of Dirac fermions will be presented and its potential for bandgap engineering will be discussed.

3:06PM D29.00002 Electronic Confinement in Epitaxial Graphene As Seen by ARPES. DAVID SIEGEL, SHUYUN ZHOU, Department of Physics, University of California; Berkeley/Materials Sciences Division, Lawrence Berkeley National Laboratory, ALEXEI FEDOROV, Lawrence Berkeley National Laboratory, ANDREAS SCHMID, FARID EL GABALY, Materials Sciences Division, Lawrence Berkeley National Laboratory — The growth of graphene on 6-H SiC and its electronic structure have been studied with low energy electron microscopy (LEEM) and angle-resolved photoemission spectroscopy (ARPES) respectively. Some of the critical growth parameters that determine sample homogeneity and domain properties have been identified. The resulting electronic structure presents features that generally agree with the conical dispersion of Dirac quasiparticles, however deviations are observed near the Dirac point energy. The dependence of these deviations on real-space electronic confinement is discussed.

3:18PM D29.00003 Tuning the phonon self-energy of a graphene bilayer. JUN YAN, ERIK HENRIKSEN, PHILIP KIM, ARON PINCUK, Columbia University — We use low temperature Raman spectroscopy and the electric field effect to investigate the coupling of long wavelength optical phonons (the G-band) with charge carriers in bilayer graphene. The charge tunable phonon spectra exhibit a remarkable symmetry which reflects the underlying particle-hole symmetry of the electron band structure. The change of phonon line-width is interpreted as a Landau damping of the phonon into resonant electron-hole pair transitions. The phonon energy exhibits an intriguing non-monotonic evolution with charge density. We found that the electron-hole pair excitation stiffness (softens) the lattice vibration when its energy is smaller (larger) than the phonon energy, in agreement with theoretical predictions for deformation electron-phonon coupling.

Support by ONR, NSF and DOE

3:30PM D29.00004 Graphene on a graphite surface: effect of interlayer coupling. ADINA LUICAN, GUOHONG LI, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA — We present low temperature high magnetic field scanning tunneling microscopy and spectroscopy on a sheet of graphene suspended above a graphite substrate. The sheet consists of two regions that couple to the substrate with different strengths resulting in two distinct sequences of Landau Levels (LL). One region exhibits a sequence that reflects the underlying particle-hole symmetry of the electron band structure. The change of phonon line-width is interpreted as a Landau damping of the phonon into resonant electron-hole pair transitions. The phonon energy exhibits an intriguing non-monotonic evolution with charge density. We found that the electron-hole pair excitation stiffness (softens) the lattice vibration when its energy is smaller (larger) than the phonon energy, in agreement with theoretical predictions for deformation electron-phonon coupling.

4:06PM D29.00005 Scanning tunneling microscopy/spectroscopy studies of local electronic structure in Epitaxial Graphene. NIKHIL SHARMA, MICHAEL SPRINKLE, Georgia Institute of Technology, CLAIRE BERGER, Georgia Institute of Technology/ CNRS, France, WALTER DEHEER, PHILIP FIRST, Georgia Institute of Technology — Epitaxial growth of graphene on hexagonal SiC by thermal desorption of Si has produced high quality films, providing a potential route to wafer-scale graphene electronics. However, many aspects of this new electronic material system remain to be understood. Using scanning tunneling microscopy and spectroscopy (STM/STS), we investigate the layer-dependent effect of atomic defects and deposited metal islands on the local electronic structure of epitaxial graphene. Metal islands locally dope the graphene due to the work function difference between materials, and atomic defects can have a similar effect. The lateral gradient in carrier density and the possible transition from hole- to electron- doping (PN junction) is investigated experimentally for these cases.
3:54PM D29.00006 Transport in multilayered epitaxial graphene , CLAIRE BERGER, Georgia Tech-Atlanta and CNRS-France, XIAOSONG WU, MIKE SPRINKLE, XUEBIN LI, Georgia Tech-Physics, Atlanta, FAN MING, WALT DE HEER, Georgia Tech-Physics, Atlanta — We present recent results of electronic transport in multilayered epitaxial graphene (EG) grown by thermal decomposition of SiC wafers. Because of the rotational stacking of the layers, it was recently shown theoretically that the system should retain essentially the same band structure as single layer graphene. The system consists of a charged layer at the SiC/EG interface, as revealed by the period of the Shubnikov-de Haas oscillations (a few 10^{12}/cm^2), and quasi-neutral layers on top. We discuss possible effects of the multilayering in the transport properties, such as the large positive increase in field of the magnetoresistance $\rho_{xx}$, the weak amplitude of the Shubnikov-de Haas and the overall features of the Hall effect, in particular the anomaly of the Hall resistance $\rho_{xy}$ observed at low field.

4:06PM D29.00007 Electronic compressibility of a graphene bilayer , SILVIA VIOLA KUSMINSKYI, Boston University, JOHAN NILSSON, Boston University and Leiden University, DAVID CAMPBELL, ANTONIO CASTRO NETO, Boston University — We calculate the electronic compressibility arising from electron-electron interactions for a graphene bilayer within the Hartree-Fock approximation. We show that, due to the chiral nature of the particles in this system, the compressibility is rather different from either of the two-dimensional electron gas or ordinary semiconductors. We find that an inherent competition between the contributions coming from intra-band exchange interactions (dominant at low densities) and inter-band interactions (dominant at moderate densities) leads to a non-monotonic behavior of the compressibility as a function of carrier density.

4:18PM D29.00008 Charge inhomogeneity in a single and bilayer graphene , HARI DAHAL, Boston College, TIM WEHLING, University of Hamburg, KEVIN BEDELL, Boston College, JIAN-XIN ZHU, ALEXANDER BALATSKY, Los Alamos National Laboratory — We study the possibility of charge ordered state in both single and bilayer graphene using a real space tight binding model. We find that the single layer graphene always remains in a liquid phase; the reason being the higher kinetic energy compared to the potential energy. The bilayer graphene on the other hand can have an inhomogeneous distribution of the charge, namely the charge density wave (CDW) state. The CDW state is commensurate with the lattice. The charge ordered state is stabilized by the Coulomb interaction of the carriers of two layers. We also predicted a kinetic energy driven (KID) inhomogeneous phase. This phase can be stabilized by the inter layer hopping energy. The KID phase and the CDW phase compete with each other below the half filling whereas they cooperate above half filling. For the physical parameter of bilayer graphene CDW phase always wins over the KID phase. Hari P. Dahal, Tim O. Wehling, Kevin S. Bedell, Jian-Xin Zhu, Alexander V. Balatsky

3:30PM D29.00009 Interplay of Coulomb interactions and rippling of monolayer graphene: RG approach , OSKAR VAFEK, NHMFL and FSU, VLADIMIR JURICIC, IGOR HERBUT, Simon Fraser University — The effects of electron-electron Coulomb interactions and rippling disorder of a mono-layer graphene are studied at half-filling using renormalization group. It is found that the system flows to an infra-red stable line of fixed points which is accessible perturbatively and along which the zero temperature minimal metallic conductivity is non-universal and enhanced relative to the clean non-interacting fixed point. An estimate of the typical random vector potential representing ripples in graphene brings the theoretical real value of the minimal conductivity into the vicinity of $4e^2/h$.

4:42PM D29.00010 Graphene in a magnetic field and a superlattice potential, J.M.B. LOPES DOS SANTOS, CFP and Dept. Fisica, Faculdade de Ciencias, Universidade do Porto, N.M.R. PERES, Centro de Fisica e Dept. Fisica, Universidade do Minho, A.H. CASTRO NETO, Physics Department, Boston University — The problem of electrons in a periodic potential in the presence of a magnetic field is revisited here in the context of graphene, by considering a superlattice periodic perturbation on the Dirac-Weyl equation for massless fermions. We solve the problem of a periodic potential for massless Dirac Fermions in a magnetic field. The relevance for graphene physics arises from the possibility of a superlattice modulation, both in single-layer graphene, due to the substrate, and in few layer graphene due to rotational stacking faults, which give rise to long wavelength moire patterns [1,2].

1 JMBLS and NMRP acknowledge financial support from project PTDC/FIS/6440/2006.

4:54PM D29.00011 Quenching of quantum Hall effect and the role of undoped planes in epitaxial graphene, PIERRE DARANCET, NICOLAS WIPF, DIDIER MAYOU, Institut NEEL CNRS/UJF, 25 rue des Martyrs BP166, 38042 Grenoble — We propose a mechanism for the quenching of the Shubnikov de Haas oscillations and the quantum Hall effect observed in epitaxial graphene. This involves a coupling between the uncharged rotationally stacked layers and the charged graphene layer at the interface. In a magnetic field, the extraordinary graphene Fermi level leads to that Mott’s relation holds at low temperature. For higher temperatures, there are strong deviations due to the linear density of states. For strong impurity scattering, near the unitary limit, the formation of a band of impurity states near the Fermi level is unavoidable, and the Mott’s relation is violated. The relevance for graphene physics arises from the possibility of a superlattice modulation, both in single-layer graphene, due to the substrate, and in few layer graphene due to rotational stacking faults, which give rise to long wavelength moire patterns [1,2].

5:06PM D29.00012 Anomalous Thermoelectric Effect in Graphene, TOMAS LOFWANDER, MIKAEL FOGELSTROM, Chalmers University of Technology — We present calculations of the thermal and electric linear response in graphene, including disorder in the self-consistent t-matrix approximation [1]. For strong impurity scattering, near the unitary limit, the formation of a band of impurity states near the Fermi level leads to that Mott’s relation holds at low temperature. For higher temperatures, there are strong deviations due to the linear density of states. The low-temperature thermopower is proportional to the inverse of the impurity potential and the inverse of the impurity density. Information about impurity scattering in graphene can be extracted from the thermopower, either measured directly, or extracted via Mott’s relation from the electron-density dependence of the electric conductivity.

5:18PM D29.00013 Charge Carrier Interaction with a Purely Electronic Collective Mode: “Plasmarons” and the Infrared Response of Semi-metal Bismuth, P. PETER ARMITAGE, The Johns Hopkins University, RICCARDO TEOIDOSI, IN ENRICO GIANNINI, University of Geneve, LASZLO FORRO, Ecole Polytechnique Federale de Lausanne, DIRK VAN DER MAREL, University of Geneve — We present a detailed pressure and temperature dependent optical study of single-crystal bismuth using infrared reflectivity and ellipsometry. In the ambient pressure optical conductivity, an anomalous temperature dependent mid-infrared absorption feature is observed. An extended Drude model analysis reveals that it can be connected to a sharp upturn in the scattering rate, the frequency of which exactly tracks the strongly temperature dependent plasmon frequency. We interpret this absorption and increased scattering as direct optical evidence for a charge carrier interaction with a collective mode of purely electronic origin, here electron-plasmon scattering. The observation of a “plasmaron” as such is made possible by the exceptional properties of semi-metallic bismuth, but it is also likely relevant to the low energy transport and thermodynamic properties of other semi-metals, like graphite and graphene. As a function of pressure, we observe massive changes in bismuth’s optical and infrared conductivity as the material approaches a Lifshitz-like metal/insulator transition.
2:30PM D30.00001 Electrical, Mechanical, and Optical Studies of Carbon Nanotubes of Known Chiral Index. JAMES HONE, Columbia University — Because small changes in the crystal structure (chirality) of carbon nanotubes can produce large changes in their electrical properties, it is important to understand the relationship between structure and transport properties, both for basic science and for applications. We have developed a unique set of tools for characterizing and manipulating nanotubes that allow for detailed studies of the properties of known-chirality nanotubes. Completed and ongoing studies include: structure-correlated optical properties; tube-tube interactions; variable electron-phonon coupling; electromechanical properties; structure-correlated electrical transport; nanotube intermolecular heterojunctions; and mechanical stiffness and strength.

2:30PM D30.00002 Electron field emission from Carbon Nanotube Composites: Transport and Local Electric Fields. DAVID CAREY, THOMAS CONNOLLY, RICHARD SMITH, University of Surrey, JONATHAN COLEMAN, Trinity College Dublin — Electron field emission characterisation of carbon nanotube polymer composites has been performed where emission at low nanotube mass fractions (<10%) has been observed. Nanotubes have been embedded in two different types of polymer: PmPV, a conjugated polymer and PVA, polyvinyl alcohol. It is shown that for nanotubes embedded in PmPV, the field emission is strongly influenced by charge transport through the film. For nanotubes in PVA a transition from bulk transport to a Fowler-Nordheim emission mechanism is seen as the mass fraction exceeds about 1-2%. Estimates of the local field as a function of mass fraction are also shown. The potential role of nanotube — polymer composites produced by solution processing to large area cathodes with a controllable mass fraction will be discussed.

3:18PM D30.00003 Metal-Semiconductor-Metal (MSM) Photodetectors with Single-walled Carbon Nanotube Film Schottky Electrodes on GaAs. ASHKAN BEHNAM, JASON JOHNSON, YONGHO CHOI, LEILA NORIEGA, University of Florida, GÜNHAH ERTOSUN, Stanford University, ZHJANGCHUN WU, ANDREW RINZLER, University of Florida, PAVAN KAPUR, KRISHNA SARASWAT, Stanford University, ANT URAL, University of Florida — We fabricate and experimentally characterize the dark and photocurrent in metal-semiconductor-metal (MSM) photodetectors with transparent and conductive single-walled carbon nanotube (CNT) film electrodes on GaAs. The dark current measurements of MSM structures reveal that the CNT film forms a Schottky contact on GaAs substrates. The Schottky barrier height and the CNT film workfunction are extracted to be approximately 0.85 and 4.6 eV, respectively, based on dark current measurements as a function of temperature. We also study the effect of device geometry on the dark current of the CNT film-GaAs MSM devices. Furthermore, we find that CNT film MSM devices exhibit a significantly lower dark current and higher normalized photo-to-dark current ratio compared to metal control samples. We explain these observations by comparing the interfaces in these structures. This work opens up the possibility of integrating CNT films as Schottky electrodes in conventional semiconductor electronic and optoelectronic devices.

3:30PM D30.00004 Anomalous Coulomb oscillation in crossed carbon nanotubes. SEUNG JAE BAEK, Nano Systems Institute-National Core Research Center, Seoul National University, DONGSU LEE, Department of Physics and Astronomy, Seoul National University, SEUNG JOO PARK. Nano Systems Institute-National Core Research Center, Seoul National University, YUNG WOO PARK, Department of Physics and Astronomy, Seoul National University, JOHANNES SVENSSON, Department of Physics, Gothenburg University, SE-41296 Gothenburg, Sweden, MATS JONSON, Department of Physics, Gothenburg University, SE-41296, Sweden, ELEANOR E. B. CAMPBELL, Department of Physics, Gothenburg University, SE-41296 Gothenburg, Sweden — Single-walled carbon nanotube (SWCNT) crossed junctions separated by an insulating layer were fabricated to investigate the double quantum dot modulated by a single gate (DQD-sg). Anomalous Coulomb oscillations were observed on the lower CNT at low temperature, where the behavior was interpreted by the concept of a double quantum dot (DQD) system http://scitation.aip.org/getabs/servlet/GetabsServlet?prog=normal&id =APPLAB000089000023233107000001&itid=cpsv&gifs=yes [1]. To understand it more clearly, we have intentionally fabricated crossed CNTs without oxide layer in between. The observed anomalous Coulomb oscillations indicate that the contact resistance between the two tubes becomes a potential barrier splitting the initial single QD into the DQD, and the back-gate modulates the energy levels of the DQD.

3:42PM D30.00005 Strain Tuning of the Photocurrent Spectrum in Single wall Carbon Nanotubes. PRASANTH GOPINATH, A. MOHITE, H. SHAH, J. LIN, B. NAGABHIRAVA, T. BANSAL, B. ALPHENAAAR, University of Louisville — The electronic structure of a single-wall nanotube (SWNT) can be substantially modified by the application of uniaxial strain. We use displacement photocurrent spectroscopy to study the effect of uniaxial strain on the optical transitions of a SWNT in the energy range 0.5eV-3eV. This broad energy range allows us to compare the strain dependence of the lowest (E11) and higher order (E22 and E33) optical transitions of semiconducting SWNT’s. As predicted by a simple non-interacting model, we observe an energy shift of each transition with increasing strain. By fitting the model to the magnitude and slope of the energy shift for the lowest energy transition (E11) the nanotube chirality can be identified uniquely. For the higher energy transitions, the data deviates significantly from the non-interacting model, presumably because of the influence of the excitonic binding energy. Finally, we observe a large reversible increase in the magnitude of the photocurrent around the ground state (E11) energy regime with an applied strain of 0.01%. We attribute this to reversible strain induced defect states opening up within the bandgap of the SWNT.

3:54PM D30.00006 Negative magneto resistance in carbon nanotubes: A first principle study. LI CHEN, SAROJ NAYAK — We have studied spin transport through single wall carbon nanotube (SWNT) with nickel contacts using ab initio density functional theory and green’s function based Landauer Büttiker formalism. Our results show enhanced current for anti-parallel alignment compared to that obtained for parallel alignment. This non Julliérè’s model results due to finite size effect and this talk will present a detailed atomic level mechanism of such phenomena. Our results will be discussed in the light of recent experimental studies.
Lowell — We present a model to characterize ensembles of NT networks using properties of individual from measurement and from ab initio computations, and MEG NOAH, YOUNG-KYUN KWON, Nanomanufacturing Center of Excellence and Center for High-rate Nanomanufacturing, University of Massachusetts.

Using this technique we are then able to both image with diffraction-limited resolution and electrically characterize up to hundreds of CNTs rapidly in the displays gate dependence similar to that of overall conductance of the CNT, allowing us to probe the local electronic properties of the CNT simultaneously.

1 nanotubes (CNTs) is a painstaking and time-consuming process, requiring a serial study of individual CNT devices. We present a novel method utilizing a Fourier-transform spectrometer and microscope to induce currents in electrically biased nanotubes. This approach enables the rapid acquisition of high-resolution photocurrent spectra near the bandgap of the larger diameter (> 1.7 nm) nanotubes commonly produced by synthesis using chemical vapor deposition. We have recorded optical transitions with energies as low as 0.4 eV for individual nanotubes. The structures used in these measurements consisted of isolated nanotubes with well-separated metal contacts on a Si back gate. In addition to describing the experimental approach and results, we will discuss the sensitive dependence of the measured photocurrent on the electrical biasing conditions.

Our goal is to optimize nanomanufacturing parameters like channel size for a user-defined application be it gas sensor, pressure actuator, or semiconductor and then compared subjected to different environmental conditions. Validation with experimental data resulting from inhomogeneous NT mixtures is presented.

We investigate the properties of single-walled carbon nanotubes in transverse electric and magnetic fields. We find via band structure calculations that these fields can break particle-hole symmetry as well as that of the two Dirac points. Additionally, the speed of the left and right movers is generally different in the presence of both electric and magnetic fields. We consider the effect of these fields on Coulomb interactions within the tube and show that they can be used to tune the interaction parameter K associated with the Luttinger liquid properties of the tube. Finally, we discuss finite size effects and Coulomb blockade physics for holes. We further show that SO coupling determines the filling order in the many-electron ground states, in a way different than that expected from electron-electron interactions. At low magnetic fields we find that the two-electron ground state is neither a spin-triplet nor a spin-singlet, but a Slater determinant with wave functions that are predominantly spin singlet.

We consider the effect of these fields on Coulomb interactions within the tube and show that they can be used to tune the interaction parameter K associated with the Luttinger liquid properties of the tube. Finally, we discuss finite size effects and Coulomb blockade physics for holes. We further show that SO coupling determines the filling order in the many-electron ground states, in a way different than that expected from electron-electron interactions. 4:30PM D30.00009 Conductance enhancement of carbon nanotubes through metallization.
CATERINA SOLDANO, LI CHEN, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, SWASTIK KAR, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, SAIKAT TALAPATRA, Department of Physics, University of Southern Illinois at Carbondale, ROBERT VAJTAI, Rensselaer Nanotechnology Center, Rensselaer Polytechnic Institute, SAROJ NAYAK, Department of Physics, Applied Physics and Astronomy, Rensselaer Polytechnic Institute, PULICKEL A. JAYAN, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute — A novel method for building high-conductance device using carbon nanotubes is presented. The process involves a systematic, repeatable and controllable enhancement of the conductance using a rapid high-voltage cycling conducted in vacuum; this process leads to orders of magnitude drop in the two-terminal resistance. Electron microscopy analysis indicates that the high-bias cycling of nanotubes causes sufficient Joule heating for the platinum to migrate from the contact regions and decorate the outer surface of the nanotubes, giving rise to enhanced metallization. Pre- and post-metallization characterization is presented. It is believed that the conductance enhancement is due to a combination of a decrease in disorder density in the tube and an increase in the number of available channels for conductance. Those outcomes are investigated in the light of recently predicted theoretical models.

4:42PM D30.00010 Carbon nanotubes as tunable Luttinger liquids.
WADE DEGOTTIARDI, University of Illinois Urbana-Champaign, TZU-CHIEH WEI, Institute for Quantum Computing, SMITHA VISHVESHWARA, University of Illinois at Urbana-Champaign — We investigate the properties of single-walled carbon nanotubes in transverse electric and magnetic fields. We find via band structure calculations that these fields can break particle-hole symmetry as well as that of the two Dirac points. Additionally, the speed of the left and right movers is generally different in the presence of both electric and magnetic fields. We consider the effect of these fields on Coulomb interactions within the tube and show that they can be used to tune the interaction parameter K associated with the Luttinger liquid properties of the tube. Finally, we discuss finite size effects and Coulomb blockade physics for holes. We further show that SO coupling determines the filling order in the many-electron ground states, in a way different than that expected from electron-electron interactions. At low magnetic fields we find that the two-electron ground state is neither a spin-triplet nor a spin-singlet, but a Slater determinant with wave functions that are predominantly spin singlet.

5:06PM D30.00012 Modeling Nanotube Networks For Semiconductor Channels and Sensors.
MEG NOAH, YOUNG-KYUN KWON, Nanomanufacturing Center of Excellence and Center for High-rate Nanomanufacturing, University of Massachusetts, LOWELL — We present a model to characterize ensembles of NT networks using properties of individual from measurement and from ab initio computations, and including changes in the presence of gases like NH$_3$, pressure, or external fields. From these, we simulate networks for user-specified channel shape, size and inhomogeneous NT mixtures. For example, the ensemble IV characteristics of 2 by 2 micron network can readily be compared to ensembles of 20 by 20 micron networks or 50 by 50 micron networks with 1 micron width for a wide variety of nanotubes characterized by independent length distributions for each chirality and then compared subjected to different environmental conditions. Validation with experimental data resulting from inhomogeneous NT mixtures is presented. Our goal is to optimize nanomanufacturing parameters like channel size for a user-defined application be it gas sensor, pressure actuator, or semiconductor answering questions like: “What is the statistical conductivity enhancement in the presence of NO$_2$?” “What radii yield the most semiconducting for 1 micron SWNT?” and “How does conductivity change as a function of gas density?” We focus on the fundamental understanding of nanocomposites.

5:18PM D30.00013 The Control of Electron Transport Related Defects in In situ Fabricated Single Wall Carbon Nanotube Devices.
ZHIXIAN ZHOU, Department of Physics and Astronomy, Wayne State University, ALASKA SUBEDI, GYULA ERES, RONGYING JIN, DAVID MANDRUS, Materials Science and Technology Division, Oak Ridge National Laboratory — Metallic single wall carbon nanotube (SWNT) devices were characterized using low temperature transport measurements to study how the growth conditions affect defect formation in carbon nanotubes. Suspended carbon nanotube devices were grown in situ by a molecular beam growth method on a pair of catalyst islands located on opposing Au electrodes fabricated by electron beam lithography. We present experimental evidence that transport related defect formation in carbon nanotubes, in addition to the well known growth temperature dependence, is also affected by the nature and the composition of the carbon growth gases. [Zhou et al., Appl. Phys. Lett. 89, 133124 (2006)] We have also investigated how the transport related defects affect the performance of SWNT field-effect-transistors, revealing significantly different impacts of the defects on semiconducting SWNT devices with Schottky and Ohmic contacts. [Zhou et al., unpublished]
2:30PM D31.00001 First Principles Studies of Tapered Silicon Nanowires: Fundamental Insights and Practical Applications, ZHI GANG WU, BNNI, University of California at Berkeley and Molecular Foundry, Lawrence Berkeley National Laboratory — Nanowires (NWs) are often observed experimentally to be tapered rather than straight-edged, with diameters (d) shrinking by as much as 1 nm per 10 nm of vertical growth. Previous theoretical studies have examined the electronic properties of straight-edged nanowires (SNWs), although the effects of tapering on quantum confinement may be of both fundamental and practical importance. We have employed ab initio calculations to study the structural and electronic properties of tapered Si NWs. As one may expect, tapered nanowires (TNWs) possess axially-dependent electronic properties; their local energy gaps vary along the wire axis, with the largest gap occurring at the narrowest point of the wire. In contrast to SNWs, where confinement tends to shift valence bands more than conduction bands away from the bulk gap, the unoccupied states in TNWs are much more sensitive to d than the occupied states. In addition, tapering causes the band-edge states to be spatially separated along the wire axis, a consequence of the interplay between a strong variation in quantum confinement strength with diameter and the tapering-induced charge transfer. This property may be exploited in electronic and optical applications, for example, in photovoltaic devices where the separation of the valence and conduction band states could be used to transport excited charges during the thermalization process. In order to gain insight into TNW photovoltaic properties, we have also carried out calculations of the dipole matrix elements near the band edges as well as the role of metal contacts on TNW electronic properties. Finally, a combination of ab initio total energy calculations and classical molecular dynamics (MD) simulations are employed to suggest a new technique for bringing nanoscale objects together to form ordered, ultra high-aspect ratio nanowires. This work was supported in part by the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

3:06PM D31.00002 Structure and electronic properties of silicon nanowires grown along the [110] direction: role of surface reconstruction, T. AKIYAMA, K. NAKAMURA, T. ITO, Dept. of Phys. Eng., Mie Univ., Japan — Silicon single-crystal nanowires (SiNWs) are attracting great interest for future nanoscale devices in recent years. So far, the [110] grown SiNWs with diameters below 4 nm have been successfully fabricated by various methods. Although the size dependence in electronic and optical properties for the [110] grown SiNWs terminated by H-atoms have been intensively studied, effects of surface reconstructions on the electronic structure have rarely examined. Here, we investigate the atomic and electronic structures of SiNWs along the [110] direction with (001) and (111) facets using first-principles pseudopotential method. The calculations for SiNWs whose diameters are ~4 nm demonstrate that the reconstructions on these facets are strongly dependent on H-chemical potential $\mu_H$: The SiNW consisting of monohydride (001) and H-terminated (111) facets is stabilized for high $\mu_H$ ($\geq$0.75 eV) while the pristine SiNW stabilized for low $\mu_H$ ($\leq$-0.82 eV). The reconstructions with partially hydrogenated facets appear for -0.82$<\mu_H<$0.75 eV. Peculiar features in the electronic structure are also found in partially hydrogenated SiNWs.

3:18PM D31.00003 Modeling of Polycrystalline and Wurtzite Si Nanowires with Symmetry-Adapted Objective Molecular Dynamics, TRAIAN DUMITRICA, Department of Mechanical Engineering, University of Minnesota, DONG-BO ZHANG, Department of Chemical Engineering and Materials Science, University of Minnesota, MING HUA, Department of Mechanical Engineering, University of Minnesota — The stability and properties of the most promising ground state candidate Si nanowires with less than 10 nm in diameter is comparatively studied with molecular dynamics coupled with non-orthogonal tight-binding and classical potential models. The computationally-expensive tight-binding treatment becomes tractable due to the substantial simplification in the number of atoms introduced by the presented symmetry-adapted objective molecular dynamics scheme. It indicates that the achiral polycrystalline of five-fold symmetry and the wurtzite wires of three-fold symmetry are the most favorable quasi one-dimensional Si arrangements. Quantitative differences with the classical model description are noted over the whole diameter range. Using a Wulff energy decomposition approach it is revealed that these differences are caused by the inability of the classical potential to accurately describe the interaction of Si atoms on surfaces and strained morphologies.

3:30PM D31.00004 Ab initio calculations for the electronic properties of zinc-doped indium phosphide nanowires, MANUEL ALEMANY, Universidad de Santiago de Compostela, Spain, XIANGYANG HUANG, University of Minnesota, MURILLO L. TIAGO, University of Texas at Austin, L.I. GALLEGO, Universidad de Santiago de Compostela, Spain, JAMES R. CHELIKOWSKY, University of Texas at Austin — p-type indium phosphide nanowires are known to function as working devices when assembled with n-type nanowires, and thus are seen as very promising building blocks for highly integrated electronic devices within the semiconductor industry. In this work, we have characterized the impurity state responsible for current flow in zinc-doped indium phosphide nanowires through first-principles calculations based on a real-space implementation of density-functional theory and pseudopotentials. The binding energy of the acceptor state is predicted to range from the value of the acceptor state in the bulk to upper values of approximately 0.2 eV in the thinner nanowires as a result of the two-dimensional quantum confinement. Our results show that, in thin nanowires, quantum confinement can move the defect level deep into the energy gap.

3:42PM D31.00005 Molecular-Dynamics Simulations of Nanowire Growth, TOMORR HAXHIMALI, Northwestern University and University of California at Davis, DOREL BUTA, MARK ASTA, University of California at Davis, JEFFREY HOYT, McMaster University — This talk will present results of molecular dynamics simulations investigating the mechanisms of nanowire growth from a liquid. We investigate the model system of elemental Si, modeled with the classical Stillinger-Weber potential. The work aims to investigate the effect of nanowire size on the intrinsic growth mechanisms and the relations between solid-liquid interface velocity, growth direction and driving force. Results will be presented for nanowires with diameters ranging from 5-10 nm, and will be compared with simulations for bulk Si modeled with the same potential. The consequences of these findings for the mechanisms of nanowire growth from liquid catalysts by the vapor-liquid-solid mechanism will be discussed.
3:54PM D31.00006 First-principles study of the electronic and magnetic properties of Fe-Co nanowires\(^1\). DANGXIN WU, PING LIU, QIMING ZHANG, University of Texas at Arlington, RUQIAN WU, University of California, Irvine — Fe-Co nanowires provide a potential way to produce high-performance nanocomposite permanent magnets due to their high Curie temperature, large magnetization, and appreciable anisotropy. In this talk we present our recent results of first-principles investigation of this matter. The calculations use both PAW method and FLAPW method, based on density functional theory. The structures of Fe-Co nanowires were optimized by PAW method and then the electronic structure and magnetic properties such as saturation magnetization and anisotropy energies are studied by FLAPW method. The effects of size and composition of the nanowires on the magnetic properties are also studied and compared with those of bulk Fe-Co materials.

\(^1\)This work was supported in part by the U.S. DoD/MURI under the Grant No. N00014-05-1-0497

4:06PM D31.00007 Magnetic Co impurity in Gold Nanowires\(^1\). EDISON DA SILVA, Instituto de Física "Gleb Wataghin", UNICAMP, Brazil, RENATO PONTES, ANTONIO J.R. DA SILVA, ADALBERTO FAZZIO, Instituto de Física, USP, Brazil — Nanoscale electric contacts using suspended gold nanowires (NWs) have recently been made and were imaged by electron microscopy. Using tools derived from Density Functional Theory (DFT) we study the role of magnetic impurities in these NWs with the possibility of spintronic applications. Here we study structural and transport properties of a gold nanowire with one Co impurity as function of tension applied to the NW. Co added new features to the physics of this system. We present studies of structure and also electronic transport using the same DFT formalism [1] that show the effect of the spin anisotropy introduced by Co. In particular, we present results of two geometries, one where the Co atom is connected to two Au atoms of the lead and another where it is in the middle of the suspended neck, in a linear configuration. In the former case we observe an interference between the s and d channels, leading to a Fano-like structure in the transmittance, whereas in the latter configuration there is a decoupling between these two channels and the transmittance has a simple peak around the Co d-states, leading to a large spin polarized transport. [1] F. D. Novaes, A.J.R. da Silva, and A. Fazzio, Braz. J. Phys. 36 (3A): 799-807 (2006)

3:40PM D31.00008 Transport in Carbon Nanotube Junctions\(^1\). HOANG VTU, V.S. MISHRA, University of Texas at Austin — There is growing interest in the use of carbon nanotube thin films as transparent electrical conductors and thin-film transistors owing to their high optical transmittance, low sheet resistivity, and ease of fabrication. [1,2] A major contribution to the sheet resistivity originates at nanotube junctions, as electrical contact is typically poor between adjacent nanotubes. It is thus important to characterize carbon nanotube junctions in order to understand the conduction properties of nanotube thin films. To this end, we have performed ab initio density functional theory calculations to investigate the structural, electronic, and transport properties of carbon nanotube junctions as a function of nanotube chirality and contact geometry.

\(^1\)This work was supported in part by FAPESP and CNPq. CENAPAD-SP is acknowledged for computer time.

4:18PM D31.00008 Transport in Carbon Nanotube Junctions\(^1\). K.H. KHOO, JAMES R. CHELIKOWSKY, University of Texas at Austin — There is growing interest in the use of carbon nanotube thin films as transparent electrical conductors and thin-film transistors owing to their high optical transmittance, low sheet resistivity, and ease of fabrication. [1,2] A major contribution to the sheet resistivity originates at nanotube junctions, as electrical contact is typically poor between adjacent nanotubes. It is thus important to characterize carbon nanotube junctions in order to understand the conduction properties of nanotube thin films. To this end, we have performed ab initio density functional theory calculations to investigate the structural, electronic, and transport properties of carbon nanotube junctions as a function of nanotube chirality and contact geometry.

4:30PM D31.00009 Schottky Barrier Heights in CNT-Metal Junctions from First-principles\(^1\). NICHOLAS SINGH-MILLER, NICOLA MARZARI, Massachusetts Institute of Technology — Fundamental understanding of the electronic properties at the junction between carbon nanotubes and metal electrodes is important for the development of CNT-based devices. Here, we use density functional theory (DFT) to probe the properties of the CNT-metal interface, paying particular attention to the Schottky barrier heights (SBH). We focus on the junction between a semiconducting (8,0)CNT and aluminum or palladium, chosen as paradigmatic examples of a simple metal and a transition metal, respectively. We obtain SBHs from the potential lineup, examining the effects of geometry at the interface and the functionalization of the CNT on the SBH.

\(^1\)This work was supported in part by the National Science Foundation under DMR-0551195 and the Department of Energy under DE-FG02-06ER15760 and DE-FG02-06ER46286.

4:42PM D31.00010 Transport properties of transition-metal-encapsulated Si cages\(^1\). LINGZHU KONG, University of Minnesota, JAMES R. CHELIKOWSKY, University of Texas at Austin — We performed density functional pseudopotential calculations of the spin dependent transport through transition-metal-atom-encapsulated Si cages $\text{Si}_2\text{X}(X=\text{Mn}, \text{Fe} \text{and} \text{Co})$. The effect of the metal atom on conductance is studied. Mn and Fe doped systems show highly spin polarized transmission whereas the magnetization in Co doped system is quenched. It is found that electrons are transferred from Si atoms into the minority d orbitals of the metal atoms. The conductance decreases as these electrons become localized around the encapsulated atoms.

5:06PM D31.00012 Ab initio non-equilibrium Green’s function study on the growth of metallic bridge in mixed conductor atomic switch\(^1\). TOMOFUMI TADA, ZHONGCHANG WANG, TINGKUN GU, SATOSHI WATANABE, Dept. of Materials Engineering, The Univ. of Tokyo, JST-CREST — A novel atomic switch [1] composed of a mixed conductor, $\text{Ag}_2\text{S}$ or $\text{Cu}_2\text{S}$, has attracted much attention. To investigate the electronic properties of the atomic switch, we have examined interface structure and electron transport of $\text{Ag}/\text{Ag}_2\text{S}/\text{Ag}$ and $\text{Cu}/\text{Cu}_2\text{S}/\text{Cu}$ using ab initio non-equilibrium Green’s function method. In $\text{Ag}/\text{Ag}_2\text{S}/\text{Ag}$, we found a spontaneous growth of a metallic bridge composed of an Ag atomic chain when a unidirectional stress is applied to Ag$_2$S [2]. On the contrary, a metallic bridge does not appear in Ag$_2$S and Cu$_2$S without stress. We also examined the influence of Ag/Cu addition on the structural and transport properties of Ag$_2$S and Cu$_2$S atomic switches, and found that the Ag/Cu addition leads to the metallization in the both systems. However, clear growth of the atomic bridge is confirmed only in $\text{Ag}/\text{Ag}_2\text{S}/\text{Ag}$. The metallic nature in $\text{Cu}/\text{Cu}_2\text{S}/\text{Cu}$ is related to the growth of electronic charge network at the Fermi level. [1] K. Terabe, et al., Nature 433, 47 (2005). 2) Z. Wang, T. Kadohira, T. Tada, S. Watanabe, Nano Letters 7, 2688 (2007).
Magnetic field, sharp peaks at zero applied field when a large enough negative d.c. current, I, is applied. The oscillations extend from 0.6 to 4 GHz. They disappear when a 2\textsuperscript{nd} power is applied.

Except for the direction of I, these observations seem to be consistent with the vortex dynamics reported by the NIST and Cornell groups. If time permits, we will present results on magnetic nanopillars where the Py(24) layer has been replaced by NiCr, which inverts the spin asymmetry.

5:18PM D31.00013 Ab initio transport properties of platinum chains calculated by taking into account spin-orbit effects, VICTOR GARCIA-SUAREZ, Lancaster University, DAVID ZSOLT MANRIQUE, Universidad de Oviedo, COLIN LAMBERT, Lancaster University, JAIME FERRER, Universidad de Oviedo — The transport properties of infinite and finite platinum chains are calculated by using a combination of Density Functional Theory and Non-Equilibrium Green’s Functions Formalism, as implemented in the Smeagol Code. We show that spin-orbit effects, which are included fully self-consistently in our calculations, are of paramount importance to determine accurately the electronic and transport characteristics of these systems. For infinite chains we find that under special circumstances which depend on the type of chain (linear or zigzag), length and spin orientation relative to the chain, the conductance can be totally suppressed, giving rise to large magnetoresistive ratios. In the case of finite chains between bulk electrodes the spin-orbit effect plays also a crucial role and gives results which agree better with experiments.

Session D32 GMAG DMP FIAP: Focus Session: Spin Transfer Torque I
Morial Convention Center 225

2:30PM D32.00001 Switching behavior of a Stoner-Wohlfarth particle subjected to spin-torque effect\textsuperscript{1}, HUY PHAM, Advanced Materials Research Institute, University of New Orleans, DORIN CIMPORU, AMRI, University of New Orleans, ALEXANDRU STANCU, “Al. I. Cuza” University, Faculty of Physics, Iasi 700506, Romania, LEONARD SPINU, AMRI, University of New Orleans — The concept of the “spin-transfer torque” proposed by Slonczewski and Berger offers a new way of controlling the magnetization reversal in ferromagnetic multilayer systems, which replaces the conventional method utilizing magnetic field. The novel technology is expected to reduce the switching time of magnetization as well as to increase the recording density of the magnetoresistive random access memories. In this paper the switching properties of a Stoner-Wohlfarth magnetic particle, subject to a continuous or short magnetic field pulses, and to a short current pulse are presented. The theoretical investigation of precessional motion is described by using phenomenological modified Landau-Lifschitz-Gilbert equation with a spin-transfer torque term included. The switching under the influence of spin transfer torque is discussed as a function of the applied field strength and direction, and also as a function of the length of the current pulse. The main goal is to determine the parameters of field pulse for that the fast and stable switching can be achieved.

2:42PM D32.00002 Dynamical Coupling of Nanomagnets due to Spin Transfer\textsuperscript{1}, SERGEI URAZHDIN, West Virginia University, WENG-LEE LIM, NICHOLAS ANTHONY, ANDREW HIGGINS — Spin transfer devices typically incorporate a thick magnet polarizing the electric current, and a thin layer driven by spin torque. However, spin torque acting on both layers is significant in devices with comparable thickness of magnetic layers. Moreover, dynamics of one of the magnetic layers results in oscillations of the polarization of the current flowing through the other layer, which can lead to dynamical coupling between them. We discuss results of simulations and measurements, demonstrating several consequences of such dynamical coupling. First, the dynamics of both layers are always simultaneously excited by the current. Second, the critical current for the onset of magnetic dynamics is scaled by the ratio of the thicknesses of the magnetic layers, diverging when the two are the same. This behavior is caused by the coupled precession of two magnetic layers reducing the efficiency of spin transfer. Below the critical current, a hysteretic regime is found in which a dynamical state and a static parallel configurations are possible. This regime may explain the 1/f noise and broad precession peaks that are often observed in the spectra of current-induced excitations.

2:54PM D32.00003 Magnetic propeller driven by spin transfer\textsuperscript{1}, WENG LEE LIM, NICHOLAS ANTHONY, ANDREW HIGGINS, SERGEI URAZHDIN, Department of Physics, West Virginia University, Morgantown WV 26506 — Spin-transfer devices usually contain two magnetic layers in which the thicker layer polarizes the electron current and the thinner layer experiences dynamics due to spin transfer. However, both magnetic layers can polarize current and experience simultaneous dynamics when the thickness of magnetic layers is similar (symmetric nanopillars). We investigated current-driven magnetization switching in symmetric nanopillars with structure NiFe20/Pt= Py(4nm)/Cu(3.5nm)/Py(4nm). Time-resolved measurements of resistance for both directions of current and magnetic field showed reversible switching of magnetization between parallel (P) and anti-parallel (AP) states with unusual dependence on the current. We observed that the dwell times displayed two different dependences on the current I for different values of applied field H. At large H, the dwell time in the P state t\textsubscript{P} decreases with increasing I while the dwell time in the AP state t\textsubscript{AP} increases, similarly to asymmetric devices. However, at small H, both t\textsubscript{P} and t\textsubscript{AP} decrease with increasing I. We explain this unusual behavior by a thermal activation model involving four-cycle sequential reversal of two magnetic layers.

3:06PM D32.00004 Coherence of spin-torque microwave oscillators, ANDREI SLAVIN, Oakland University — Recently discovered effect of microwave generation in current-driven magnetic nano-structures caused by the spin-transfer torque opens a possibility for the development of a new type of tunable microwave auto-oscillators. The spin-torque oscillators (STO) are strongly nonlinear as their frequency \(\omega(P)\) and total (positive plus negative) damping \(\Gamma(P)\) are dependent on the oscillation power \(P\). We developed a theory of the generation linewidth of a nonlinear auto-oscillator, and showed that the nonlinear frequency shift (characterized by the coefficient \(N = d\omega/dP\)) leads to an effective increase of the phase noise. In a strongly supercritical regime, when the oscillation energy \(E(P)\) is much larger than the thermal energy \(k_BT\), the generation linewidth of a STO can be written as \(\Delta\omega = \Delta\omega_0[1 + (N/T_{\text{eff}})^2]\), where \(\Delta\omega_0 = \Gamma(0)/(k_BT/E(P))\) is the oscillator linewidth without account for the nonlinear frequency shift and \(T_{\text{eff}} = dT/dP\) is the effective nonlinear damping of the oscillator. Our theory explains the following features of the STO linewidth observed in experiment: (i) general linewidth narrowing with the increases in the bias current \(I\) and the oscillation energy \(E(P)\), (ii) presence of a minimum in the linewidth dependence on the orientation of the external bias magnetic field; (iii) linear dependence of the linewidth on the absolute temperature. Our theory also demonstrates that in the array of \(n\) phase-locked STO the generation linewidth decreases linearly with the increase on the number of oscillators \(n\), while the generated power \(P\) increases as \(n^2\).

3:42PM D32.00005 Magnetization excitations in magnetic nanopillars induced by a d.c. spin-polarized current\textsuperscript{1}, NIKOLETA THEODOROPOULOU, AMIT SHARMA, WILLIAM PRATT JR., JACK BASS, Dept. of Physics and Astronomy, Michigan State University — We have measured spin-transfer-torque driven magnetization dynamics at 293K in Py(24nm)/Cu(10nm)/Py(6) magnetic nanopillars, with the top Py(6) magnetic layer and part of the Cu layer shaped into a 140x70 nm\textsuperscript{2} ellipse, and the rest left extended. Among the more interesting results are sharp peaks at zero applied field when a large enough negative d.c. current, I, is applied. The oscillations extend from 0.6 to 4 GHz. They disappear when a magnetic field, \(B_{\text{eff}}\), larger than 10 mT is applied in the plane of the layers, but persist up to 0.2 T when \(B_{\text{eff}}\) is applied perpendicular to this plane. The peaks persist up to 5-9 times the switching current and appear to be current-hysteric. At \(B_{\text{eff}} = 0\), the frequency of the oscillations increases with \(I\) (\(\sim 40\text{MHz}/\text{mA}\)). Except for the direction of I, these observations seem to be consistent with the vortex dynamics reported by the NIST and Cornell groups. If time permits, we will present results on magnetic nanopillars where the Py(24) layer has been replaced by NiCr, which inverts the spin asymmetry.

3:54PM D32.0006 Resonant Spin-Transfer-Driven Switching of Magnetic Spin Valves Assisted by Microwave Current Pulses, YONG-TAO CUI, JACK C. SANKEY, CHEN WANG, KIRAN V. THADANI, ZHI-PAN LI, ROBERT A. BUHRMAN, DANIEL C. RALPH, Cornell University — Spin transfer torque from an electrical current can reverse the magnetization in a nanomagnet. We show experimentally that applying a microwave-frequency current pulse in addition to a DC pulse can improve switching characteristics at low temperature by exciting a nanomagnet resonantly at its precession frequency. We study spin valve nanopillars with the structure IrMn(8 nm)/permalloy(4 nm)/Cu(8 nm)/permalloy(4 nm) where exchange bias causes an initial offset angle of ∼45 degrees between the permalloy magnetizations. We apply nanosecond-scale microwave-frequency current pulses prior to completing the switching with a DC current pulse. We find that the probability of successful switching has a resonant dependence on frequency, and it also depends on the phase of the microwaves at the moment when the DC pulse is applied. With a microwave pulse, the DC pulse length required for switching is shorter and has a narrower distribution compared to switching driven by a DC pulse alone.

4:06PM D32.00007 Phenomenological model for size-dependent switching behavior in spin transfer torque devices, VENKATESH CHEMBROLU, Department of Applied Physics, Stanford University, Stanford, California 94305, USA, YVES ACREMANN, PULSE Centre, Stanford Linear Accelerator Centre, Menlo Park, California 94025, USA, JOHN PAUL STRACHAN, XIAOWEI YU, Department of Applied Physics, Stanford University, Stanford, California 94305, USA, ASHWIN TULAPURKAR, Stanford Synchrotron Radiation Laboratory, Menlo Park, California, 94025, USA, JORDAN KATINE, MATHEW CAREY, Hitachi Global Storage Technologies San Jose Research Center, San Jose, California 95120, USA, TOLEK TYLISZCZAK, Advanced Light Source, Berkeley, California, 94720, JOACHIM STOHR, Stanford Synchrotron Radiation Laboratory, Menlo Park, California 94025, USA — Recent results based on time resolved x-ray imaging of magnetization dynamics in nano-magnetic devices have shown size dependent trends in the switching behavior. Samples with a lateral dimension of 100x180nm show a vortex-driven switching mechanism, whereas smaller samples with a lateral dimension of 110x150nm do not switch by a vortex. Further studies have shown that when a non-zero angle in introduced between the fixed and the free layers, vortex-driven switching becomes manifest in samples with smaller dimensions also. Here, we would like to present a phenomenological model based on linearized LLG equations to explain the various regimes of observed switching behaviors.

4:18PM D32.00008 Linewidths of Spin-Torque-Driven Nanomagnetic Oscillators as a Function of Field Angle and Temperature, KIRAN V. THADANI, Z.-P. LI, O. OZATAY, J.C. SANKEY, I.N. KRIVOROTOV, Y.-T. CUI, R.A. BUHRMAN, D.C. RALPH, Cornell University, G. FINOCCHIO, U. of Messina (Italy) — In a magnetic multilayer device, spin-transfer torque from a direct current can excite steady-state magnetic oscillations. We observe that the linewidths of the oscillations decrease dramatically as an applied magnetic field is rotated away from the magnetic easy axis towards the in-plane hard axis. Micromagnetic simulations show that the spatial coherence of the oscillations improves greatly as the field is rotated, and their amplitude tends to zero, making them less susceptible to thermal fluctuations. We report the temperature dependence of the linewidths for the field directions giving the minimum linewidths. It has been suggested previously that the linewidths are dominated by fluctuations of the precession angle of the nonlinear oscillator [1,2]. We analyze the mechanisms governing our linewidths by comparing them to micromagnetic modeling. [1] J. C. Sankey et al., Phys. Rev. B 72, 224427 (2005). [2] J.-V. Kim et al., cond-mat/0703317.

4:30PM D32.00009 Enhancement in spin-torque efficiency by nonuniform spin current generated within a tapered nanopillar spin valve, P.M. BRAGANCA, O. OZATAY, A.G.F. GARCIA, O.J. LEE, D.C. RALPH, R.A. BUHRMAN, Cornell University — When modeling spin torque related phenomena, it is generally assumed that the polarization of the incident current is spatially uniform and invariant in time across the surface of the free layer nanomagnet. This is not necessarily the case for a relatively thick, low saturation magnetization free layer nanomagnet. Here, we discuss the results of spin-torque micromagnetic simulations, confirmed by both dc and short-pulse switching measurements of nanopillar spin valve structures, which reveal that the use of this type of reference layer can result in non-uniform polarization of the current that impinges onto the free layer. This effect can enhance magnetic reversal in the nanosecond-switching regime over the case of a fixed and uniformly magnetized reference layer, substantially reducing the current amplitude required for magnetic reversal with a given ns pulse-width. We will discuss these results, which differ substantially from descriptions provided using macrospin approximations, and describe a nanopillar-torque device configuration that simulations and experiments indicate could be quite effective in reducing the spin torque switching current for MRAM applications.

4:42PM D32.00010 Theory of Ferromagnetic Resonance in Perpendicularly Magnetized Nanodiscs: Excitation by Injected AC Current1, RODRIGO ARIAS, Departamento de Física, FCFM, Universidad de Chile, DOUGLAS MILLS, Department of Physics and Astronomy, UC Irvine — Recent experiments explore the ferromagnetic resonance (FR) response of nanodiscs incorporated into nanopillars, where a DC spin torque current has a small AC component superimposed. For such a circular perpendicularly magnetized disc, we develop the theory of the FR response via AC current. Earlier we discussed the vortex state induced by the DC Oersted field in such a sample, and the nature of the spin waves in the presence of the vortex2. The present study explores the linear response of the disc, when a small AC current is superimposed on the DC current. A Green’s function approach allows us to describe the linear response of the system. We argue that the AC component of the Oersted field is responsible for spin wave excitation; the modes excited thus differ from those observed in ferromagnetic resonance studies via microwaves. We shall present calculations which explore the spectrum and eigenvectors of modes excited by modulation of the DC current, their width as a function of DC current, and their intensity. 2R. E. Arias and D. L. Mills, Phys. Rev. B75, 214404 (2007).

4:54PM D32.00011 Quantum transport in Spin Torque Transfer Devices, SAYEEF SALAHUDDIN, DEEPANJAN DATTA, PRABHAKAR SRIVASTAVA, SUPRIYO DATTA, Purdue University — We present a simulation of a tunneling based Spin Torque Transfer (STT) devices using the Non Equilibrium Greens Function (NEGF) formalism in the ballistic regime. Our method is based on effective mass treatment of the magnetic contacts and tunneling oxide, including the effect of transverse modes in the transverse direction. We show that it is possible to achieve a quantitative agreement with experiments for both the tunneling magneto resistance (TMR) and the amplitude of the switching current with the same set of device parameters [1]. We shall talk about some implications of these results in the context of improving the device performance. We shall also briefly discuss how the nature of the torque may change if there is spin flip scattering. [1] S.Salahuddin, Deepanjan Datta, Prabhakar Srivastava and Supriyo Datta, proceedings of International Electron Devices Meeting (IEDM), 2007.

5:06PM D32.00012 Spin Pumping of Current in Non-Uniform Conducting Magnets1, WAYNE SASLOW, Texas A&M University — Using irreversible thermodynamics we show that current-induced spin transfer torque within a magnetic domain implies spin pumping of current within that domain. This has experimental implications for samples both with conducting leads and that are electrically isolated. These results are obtained by deriving the dynamical equations for two models of non-uniform conducting magnets: (1) a generic conducting magnet, with net conduction electron density $n$ and net magnetization $M$; and (2) a two-band magnet, with up and down spins each providing conduction and magnetism. For both models, in regions where the equilibrium magnetization is non-uniform, voltage gradients can drive adiabatic and non-adiabatic bulk spin torques. Oseen relations then ensure that magnetic torques likewise drive adiabatic and non-adiabatic currents – what we call bulk spin pumping. For a given amount of adiabatic and non-adiabatic spin torque, the two models yield similar but distinct results for the bulk spin pumping, thus distinguishing the two models. As for recent spin-Berry phase work, we find that within a domain wall the ratio of the effective emf to the magnetic field is approximately given by $\mu(2\mu B/e)$, where $\mu$ is the spin polarization. The adiabatic spin torque and spin pumping terms are shown to be dissipative.

1Supported by Department of Energy grant DE-FG02-06ER46278.

5:18PM D32.00013 First principles calculation of the spin transfer torques, KE XIA, YUAN XU, SHUAI WANG, Institute of Physics, Beijing — A first principles method was developed to calculate the spin transfer torques in the noncollinear magnetized system. We found that the behavior of spin torques in a spin valve depends on the materials(Co, Ni and NiFe20), taken into account). The formalism is also applied to the antiferromagnetic domain wall. It is found that the spin torques could be exerted over a long range in the anti-ferromagnetic materials and move the domain wall away, which can be detected by measuring the resistance of an antiferromagnetic point contact.

Session D33 DMP GMAG FIAP: Focus Session: Spin Dependent Phenomena in Semiconductors: III Morial Convention Center 224

2:30PM D33.00001 Theory of Current-Induced Domain Wall Creep in (Ga,Mn)As, JUN’ICHI IEDA, Institute for Materials Research, Tohoku University — A magnetic domain wall (DW) can interact with electrical current and as a result its displacement is induced by the application of the current, showing the possible electrical control of the magnetization direction. Thus electrical current in this non-uniform spin texture is now drawing much attention from the technological point of view, in addition to the longstanding interests from the fundamental physics points of view. Recently, systematic experimental data of the dependence of DW velocity spanning five decades on current density have been obtained in a microstructure made from a ferromagnetic semiconductor (Ga,Mn)As, providing deep insight to outstanding physics of DW dynamics. The quantitative analyses showed that the current-driven motion in (Ga,Mn)As can be explained by spin-transfer mechanism under currents beyond a threshold value. The linear mobility tempts ones to expect that there is always an equivalent magnetic field which has the same effect upon DWs as the current does. Here we make a detailed comparison between these two sources of drive but in the subthreshold, “creep,” regime, where the velocity obeys an Arrhenius scaling law. The observed scaling law for the two drives is incompatible different from each other, i.e., the effect of a driving current and field are not equivalent. We offer theory which explains the important features of experiment. When described by an Arrhenius law it is found that the barriers diverge as the drive approaches zero, manifesting the system is in a “glassy” state. While the field driven case is compatible with the random field universality class, the case of current induced creep is not to fit any known such class. The work reported is the result of collaborations with M. Yamanouchi, F. Matsukura, S. E. Barnes, S. Maekawa, and H. Ohno. [Ref. Science 317, 1726-1729 (2007)].

3:06PM D33.00002 Analyzing the influence of magnetic domain walls on longitudinal and transverse magnetoresistance in tensile strained (Ga,Mn)As, GANG XIANG, Dept. of Physics, Ohio State University, NITIN SAMARTH, Dept. of Physics, Pennsylvania State University — We present a theoretical analysis of magnetoresistance in (Ga,Mn)As epilayers with perpendicular magnetic anisotropy [Phys. Rev. B 76, 054440 (2007)]. The model reproduces the field-antisymmetric anomalies observed in experimental measurements [Phys. Rev. B 71, 241307(R) (2005)] of the longitudinal magnetoresistance in the planar geometry (magnetic field in the epilayer plane and parallel to the current density), as well as the unusual shape of the accompanying transverse magnetoresistance. As in the case of metallic ferromagnets with perpendicular anisotropy [Phys. Rev. Lett. 94, 017203 (2005)], the magnetoresistance characteristics are attributed to circulating currents created by the presence of magnetic domain walls.

3:18PM D33.00003 Manipulation of Magnetic Domain Walls in Patterned (Ga,Mn)As Devices, ANDREW BALK, Dept. of Physics, The Pennsylvania State University, MENG ZHU, Dept. of Physics, Penn State University, NITIN SAMARTH, Dept. of Physics, The Pennsylvania State University, DAVID AWSCHALOM, Dept. of Physics, University of California, Santa Barbara — Ferromagnetic semiconductors such as (Ga,Mn)As provide new opportunities for electrical manipulation of magnetic domain walls in a different regime of parameter space compared with ferromagnetic metals [Chiba et al, PRL 96, 096602 (2006)]. Here, we discuss different approaches to pinning and controlling magnetic domain walls in laterally patterned (Ga,Mn)As microdevices with perpendicular magnetic anisotropy. The pinning/postinning of domain walls is monitored using measurements of the magnetoresistance, the anomalous Hall effect and high speed Kerr microscopy. The domain wall pinning potential is engineered using a variety of schemes, including lateral shape engineering and lithographically integrated micromagnets. We find that even simple schemes (such as lateral notches) can significantly enhance domain wall pinning in relatively large (micron scale) devices. Supported by ONR MURI.

3:30PM D33.00004 Spin valve effect in self-exchange biased ferromagnetic metal/semiconductor heterostructures1, MENG ZHU, MARK WILSON, BEN-LI SHEU, PARTHA MITRA, PETER SCHIFFER, NITIN SAMARTH, Pennsylvania State University — The systematic engineering of exchange biased ferromagnetic semiconductor spin valve devices is important for developing proof-of-concept semiconductor spintronics devices (such as spin torque oscillators). Here, we report magnetization and current-perpendicular-to-the-plane (CPP) magnetoresistance measurements in hybrid ferromagnetic metal/semiconductor heterostructures built from MnAs and (Ga,Mn)As. [Appl. Phys. Lett. 91, 192503 (2007)]. We observe an exchange biased CPP spin valve effect in MnAs/(Ga,Mn)As bilayers, and discuss the dependence of the exchange field and the spin valve effect on (Ga,Mn)As layer thickness. We also demonstrate the CPP spin valve effect and exchange biasing in MnAs/p-GaAs/ (Ga,Mn)As trilayers, and discuss the dependence of both phenomena on the doping and thickness of the non-magnetic spacer layer.

1Work supported by the ONR MURI program.
The influence of the Doping Profile on Spin Transport in Fe/GaAs Schottky Tunnel Barrier Heterostructures, Q. Hu, E.S. Garlid, K.S.M. Reddy, J. Zhang, T. Kondo, P.A. Crowell, C.J. Palmström, University of Minnesota—A strong non-monotonic dependence of the spin polarization on the bias across the injector has been observed in recent studies of spin transport in Fe/GaAs heterostructures. We have conducted a study of spin transport in non-local Fe/GaAs spin valves in which the doping profile of the Schottky barrier has been systematically modified. The samples were Fe/n+/n-GaAs heterostructures in which the thickness d of the n+ layer (n+ fixed at 5 × 10¹⁸ cm⁻³) was varied from 5 nm to 50 nm while n ≈ 5 × 10¹⁶ cm⁻³ in the 2.5 μm thick channel. We performed non-local spin valve measurements at 15 K for unannealed samples and after annealing at 200°C and 250°C. For d less than 10 nm, no spin accumulation is observed under either forward or reverse bias. For d ≥ 15 nm, spin accumulation is observed under forward bias only. Spin accumulation is observed for both bias polarities at larger thicknesses, with an optimal d ≈ 20-25 nm. Although this overall trend with d is observed in both unannealed and annealed samples, the sign and magnitude of the non-local signal can change upon annealing. These results suggest that spin accumulation is sensitive to both the tunnel barrier profile and interfacial conditions. This work was supported by ONR and the NSF MRSEC, IGERT, and NNNI programs.

Single domain switching by spin-polarized current in GaMnAs nanodevice, A. Chernyshov, M. Overby, L.P. Röhrinson. Department of Physics, Purdue University, West Lafayette, IN 47907, J.K. Furdyna, X. Liu. Department of Physics, University of Notre Dame, Notre Dame, IN 46556—Dilute magnetic semiconductors (DMS) have a potential to bring electrostatic control into magnetic domain and bridge the gap in control efficiency between conventional ferromagnetic materials and semiconductors. A significant progress has been demonstrated in current-induced magnetization reversal, where DMS materials show a few orders of magnitude current reduction compared to the conventional ferromagnets. In this work we demonstrate and investigate in-plane single domain magnetization rotation and reversal in GaMnAs nanodevices by spin-polarized dc electric field. Single domain is defined lithographically, which eliminates ambiguity associated with previously investigated multi-domain switching. The magnetization orientation can be controllably switched between two 100 and 010 easy axes or reversed. Current alone is not sufficient to switch the magnetization and have been aided by small in-plane magnetic field (~10mT). We observe linear dependence of critical currents with respect to magnetic field and analyze it in terms of current induced torque on the domain walls. The critical current densities are of the same order as for out-of-plane magnetization switching reported by Ohno, et al.

Magnetoresistance Enhancement through a Resonant Tunneling Diode based in the GaMnAs/AlGaAs Materials System, Edward Likovich, Kasey Russell, Wei Yi, Venkatesh Narayanamurti, Harvard University, Keh-Chiang Kuo, Meng Zhu, Nitin Samarth, Penn State University—A resonant tunneling diode was fabricated with ferromagnetic GaMnAs emitter and quantum well regions and a nonmagnetic p-GaAs collector. Negative differential resistance (NDR) associated with resonant tunneling of holes was observed at 4K, which is below the Curie temperature for GaMnAs. If the device bias is held constant and the magnetic field is swept, our device exhibits either positive or negative tunneling magnetoresistance (TMR) up to 30%, depending on device bias. Current-voltage sweeps reveal the source of the magnetoresistance as a shift in the NDR features to higher bias when the magnetizations of the GaMnAs films become antiparallel. We attribute this bias shift to an increase in tunneling conductivity from the emitter to quantum well for antiparallel GaMnAs magnetization alignment.

Dissipationless transport properties and Mott relation in Ga₁₋ₓMnₓAs, Yong Pu, Jiyong Sheng, Dept. of Physics, UC-Riverside, Daichi Chiba, Erato, JST, Rie, Tohoku University, Fumihiro Matsukura, Hideo Ohno, Rie, Tohoku University, Erato, JST—We have found an anomalously large Nernst effect (ANE) accompanying the anomalous Hall effect (AHE) in a series of Ga₁₋ₓMnₓAs (x=0.04-0.07) ferromagnetic semiconductor samples with perpendicular anisotropy. Without applying a magnetic field, none-zero ANE and AHE are observed, and both effects are very well scaled with the sample magnetization. We have developed a method, which does not depend on the accuracy of magnetization measurement, to study the anomalous transport effects. By measuring AHE and ANE under zero magnetic field and over a wide range of temperatures, we have demonstrated the dissipationless origin of the anomalous electrical and thermolectric transport properties in these samples. Furthermore, we have successfully verified the Mott relation for the off-diagonal transport coefficients in the regime of dissipationless transport that may not depend on scattering.

Localization effects in ferromagnetic Ga₁₋ₓMnₓSb random alloys, M. Eginligil, G. B. Kim, H. Luo, B. D. Mccombe, Dept. of Physics, University at Buffalo, Sunny Y. S. Yoon, J. P. Bird, Dept. of Electrical Engineering, University at Buffalo, SUNY—We have investigated temperature and magnetic field dependence of resistance (Rₓₓ) in MBE-grown ferromagnetic Ga₁₋ₓMnₓSb films in which ferromagnetism is mediated by holes. Samples with higher carrier densities (6.7 × 10¹⁷ cm⁻³ - 3.0 × 10²⁰ cm⁻³) with Curie temperatures, Tc, of 13 K and 24 K respectively show metal-like behavior in the temperature dependence of Rₓₓ. These samples exhibit small positive magnetoresistance (MR) up to 0.5 Ω between 1.6 K and 20 K, followed by negative MR up to 10 and 11 Ω (at 2.4 K), respectively. Samples with lower carrier densities (2.9 × 10¹⁷ cm⁻³ - 3.9 × 10¹⁶ cm⁻³), with Tc’s of 13 K and 24 K, respectively show “weak” thermally activated behavior and negative MR between 1.6 K and 50K (but no positive MR at low fields). The latter samples exhibit low-field positive MR between 35 mK and ~ 400 mK, followed by negative MR up to 8 T. Rₓₓ increases with decreasing temperature for both zero field, and the magnitude of the change increases with applied magnetic field. These results will be discussed in terms of localization behavior in this system. [1] Eginligil et al., in press PhysicaE (2007)

Huge tunneling magnetoresistance (>18300%) in semiconductor based magnetic tunnel junctions with zinc-blende MnAs nanoparticles, Pham Nam Hai, Byungho Yu, Dept. of Electronic Eng., The Univ. of Tokyo, Shindou Ohya, Masaoaki Tanaka, Dept. of Electronic Eng., The Univ. of Tokyo; JST—Zinc-blende (ZB) MnAs nanocrystalline is a new prospective material for semiconductor spintronics, since it is expected to be half-metallic. However, there is no report on the magneto-transport characteristics of ZB MnAs nanoparticle system. In this paper, we report on the huge tunneling magnetoresistance (TMR) effect in MBE-grown magnetic tunnel junctions (MTJs), whose structure is (from the top to the bottom) hexagonal MnAs film (20 nm)/GaAs (1 nm)/AlAs (2.1 nm)/GaAs:MnAs (10 nm), revealing the half-metallicity of ZB MnAs nanocrystallite. Here, the GaAs:MnAs layer contains ZB MnAs nanoparticles embedded in a GaAs matrix. The tunnel resistance decreases sharply with increasing the magnetic field, resulting in a huge TMR ratio = (R₉₀₀₋₅₅₀ / R₅₅₀). The TMR ratio decreases quickly with increasing the bias voltage and temperature, but survives up to 100 K. Such a huge TMR effect can be explained by an unique combination of Coulomb Blockade effect and large Zeeman splitting in half-metallic ZB MnAs nanoparticles. A magnetic-field dependent electromotive force emerged from those MTJs was also observed.
4:54PM D33.00011 Ultrafast Photoinduced Demagnetization in (III,Mn)V Ferromagnetic Semiconductors1, LUKASZ CYWINISKI, Condensed Matter Theory Center, University of Maryland — Ultrafast light-induced demagnetization, in which photoexcitation leads to a decay of magnetization in less than a picosecond, has been recently observed in (III,Mn)V materials [1]. To explain these measurements, we have proposed a theory of ultrafast magnetization dynamics within the sp-d model [2]. We have calculated the spin-flip scattering between the localized spins and the carriers strongly excited by the laser pulse. In this process the energy is pumped into the localized spin system, while the angular momentum is transferred to the carriers, leading to their dynamical spin polarization. For significant ultrafast demagnetization, this polarization has to be efficiently relaxed by spin-orbit assisted scattering of carriers - otherwise a “spin bottleneck” can occur, in which the carriers’ spin relaxation quickly becomes large enough to suppress further spin-flip scattering. Because of that, and also due to their larger exchange coupling to Mn spins, the holes (having a very short spin relaxation time) are much more important than photoelectrons for demagnetization. Since the spin-flip transition rate is proportional to the carrier temperature, the time-scale for this two-step process of demagnetization is given by the energy relaxation time of very hot holes. I will discuss in detail the application of this theory to (III,Mn)V semiconductors taking into account their valence band structure, and the fact that their optical properties are strongly affected by disorder inherent to these materials.

Monday, March 10, 2008 2:30PM - 5:18PM — Session D35 FIAP: Focus Session: Negative Index Materials II Morial Convention Center 227

2:30PM D35.00001 Negative Index Metamaterials for Superlenses Based on Metal-Dielectric Nanocomposites1, LATIKA MENON, WENTAO LU, ADAM FRIEDMAN, STEVEN BENNETT, DONALD HEIMAN, SRINIVAS SRIDHAR, Northeastern University — Negative index metamaterials are demonstrated based on metal-dielectric nanocomposites. The nanocomposites are prepared using a versatile bottom-up nanofabrication approach involving the incorporation of vertically aligned metal nanowires such as Au and Ag inside dielectric aluminum oxide nanotemplates. Aluminum oxide nanotemplates with specific pore dimensions are fabricated by means of electrochemical anodization. Following this, Au/Ag nanowires with specific wire dimensions are electrodeposited inside the pores. Optical absorbance measurements show resonance peaks corresponding to transverse and longitudinal surface plasmon modes. Peak position and intensity are found to be strongly dependent on nanocomposite dimensions, filling factor (ratio of the volume of metal versus the volume of dielectric) and angle of incidence with respect to the wire axis. A quantitative model based on effective medium theory in excellent agreement with experimental data, and points to specific composite configurations and wavelength regimes where such structures can have applications as negative refraction media for superlens imaging.

1 AFRL Hanscom,FA8718-06-C-0045, PHY-0457002, DMR-0305360

2:42PM D35.00002 Anisotropic nanostructured metamaterials for broadband all-angle negative refraction and flat lens imaging1, WENTAO LU, SRINIVAS SRIDHAR, Department of Physics and Electronic Materials Research Institute, Northeastern University, Boston, Massachusetts 02115, USA — We show that a metamaterial consisting of aligned metallic nanowires in a dielectric matrix has strongly anisotropic optical properties. For filling ratio f < 1/2, the composite medium shows two surface plasmon resonances (SPRs): the transverse and longitudinal SPR with wavelengths \( \lambda_t < \lambda_l \). For \( \lambda_t > \lambda_l \), the longitudinal SPR, the material exhibits \( \text{Re} \varepsilon \perp < 0 \), \( \text{Re} \varepsilon_\parallel > 0 \), relative to the nanowires axis, enabling the achievement of broadband all-angle negative refraction and flat lens (superlens) imaging systems. High performance systems made with Au, Ag or Al nanowires in nanoporous templates are designed and predicted to work from the infrared up to ultraviolet frequencies.

2:54PM D35.00003 Achieving sub-diffraction imaging through bound surface states in negative-refracting photonic crystals at the near-infrared, ROHIT CHATTERJEE, Optical Nanostructures Laboratory, Solid-State Science and Mechanical Engineering, Columbia University, New York, NICOLAE PANOIU, Department of Electronic and Electrical Engineering, University College London, London, KAI LIU, ZACHARY DIOS, Optical Nanostructures Laboratory, Solid-State Science and Mechanical Engineering, Columbia University, New York, MING BIN YU, MY THE DOAN, The Institute of Microelectronics, Singapore, LAURA KAUFMAN, Department of Chemistry, Columbia University, New York, RICHARD OSGOOD, Department of Applied Physics and Applied Mathematics, Columbia University, New York, CHEE WEN WONG, Optical Nanostructures Laboratory, Solid-State Science and Mechanical Engineering, Columbia University, New York — We report the observation of imaging beyond the diffraction limit due to bound surface states in negative refraction photonic crystals. We achieve an effective negative index figure-of-merit \([\text{Re}(\varepsilon_\parallel)/\text{Im}(\varepsilon_\parallel)]\) of at least 380, \( \sim 125 \times \) improvement over recent efforts in the near-infrared, with a 0.4 THz bandwidth. Supported by numerical and theoretical analyses, the observed near-field resolution is 0.47\( \lambda \), clearly smaller than the diffraction limit of 0.61\( \lambda \). Importantly, we show this sub-diffraction imaging is due to resonant excitation of surface slab modes, allowing evanescent wave amplification.

3:06PM D35.00004 Optical Super Lens: from near-field to far field1, XIANG ZHANG, Chancellor’s Professor and Director — Recent theory predicted a new class of meta structures made of engineered sub wavelength entities - meta “atoms” and “molecules” which enable the unprecedented electromagnetic properties that do not exist in the nature. For example, artificial plasma and artificial magnetism, and super lens that focuses far below the diffraction limit. The metamaterials may have profound impact in wide range of applications such as nano-scale imaging, nanolithography, and integrated nano photonics. I’ll discuss a few recent experiments that demonstrated these intriguing phenomena. We showed, for the first time, the high frequency magnetic activity at THz generated by artificially structured “meta molecule resonance”, as well as the artificial plasma. Our experiment also confirmed the key proposition of super lens theory by using surface plasmon. We indeed observed optical superlensing which breaks down so called diffraction limit. I’ll also discuss nano plasmonics for imaging and bio-sensing. The surface plasmon indeed promises an exciting engineering paradigm of “x-ray wavelength at optical frequency.”

2:30PM D36.00001 Nanoscale Hydrides in Porous Carbon Scaffolds, JOHN VAJO, HRL Laboratories, Malibu, California, USA — Light element and complex anion hydrides (such as LiH, MgH\(_2\), NaAlH\(_4\), and LiBH\(_4\)) are being studied intensely as reversible hydrogen storage materials for fuel cell powered vehicles because they have high gravimetric and volumetric capacities. However, the rates of dehydrogenation and rehydrogenation of these hydrides are typically much too slow to be compatible with proton exchange membrane fuel cell temperatures. The slow rates originate, at least in part, from the high activation energies for diffusion associated with the ionic and covalent bonds found in these materials. In contrast to metallic systems, ionic and covalent bonds are directional. Thus, the transition states for atomic rearrangement occur in particularly unfavorable bonding configurations. This increases the activation energies for diffusion and results in slow phase transformation and hydrogen sorption kinetics. Overcoming these kinetic limitations has become a critical element in the development of light-metal complex hydrides for practical storage applications. Small quantities of catalytic additives have been shown to greatly improve the rates of hydrogen exchange in MgH\(_2\) and NaAlH\(_4\). Another approach involves formation of nanoscale hydrides by incorporation into nanoporous scaffolds. The small pores of the scaffold limit the sizes of the hydrogenated and dehydrogenated phases and thus the diffusion lengths to nanoscale dimensions. These relatively short diffusion lengths reduce diffusion times and therefore, increase overall rates of hydrogen sorption. The size limitations also result in increased interfacial area between reacting phases, which improves hydrogen capacity retention during cycling. This talk will focus on the preparation, characterization, and hydrogen sorption behavior of LiBH\(_4\), MgH\(_2\), and NaAlH\(_4\) incorporated into nanoporous carbon aerogels.

3:06PM D36.00002 A Study of the Structural and Dynamical Properties of Lithium Borohydride Confined within Nanoporous Framework Structures using Neutron Scattering Investigations, CERIS HAMILTON, MICHAEL R. HARTMAN, University of Michigan, HUI WU, University of Maryland / National Institute of Standards and Technology, TERRENCE J. UDOVIC, National Institute of Standards and Technology, JOHN J. RUSH, University of Maryland / National Institute of Standards and Technology, ADAM F. GROSS, HRL Laboratories LLC. JOHN J. VAJO, HRL Laboratories LLC, THEODORE F. BAUMANN, Lawrence Livermore National Laboratory — Lithium borohydride, LiBH\(_4\), is a complex metal hydride that shows great promise as a hydrogen storage medium with a volumetric hydrogen density of 122 kg H\(_2\)/m\(^3\) and a gravimetric hydrogen density of 18.5 wt. %. We have previously reported on the structural and dynamical properties of neat \(^{7}\)Li\(^{11}\)BH\(_4\) as determined by neutron powder diffraction, neutron vibrational spectroscopy, and quasielastic neutron scattering. Here we report on recent measurements undertaken to investigate the changes in the structural and dynamical properties that are observed when this material is confined within nanoporous structures with pore sizes ranging from 4 nm to 25 nm. These materials exhibit a reduction in the structural transition and melting temperatures, which we associate with a marked decrease in the activation energy for reorientational motions of the [BH\(_4\)]\(^{-}\) tetrahedra.

3:18PM D36.00003 Density Functional Screening of Metal Hydride Reactions\(^1\), KARL JOHNSON, University of Pittsburgh, SUDHAKAR ALAPATI, Carnegie Mellon University, BING DAI, University of Pittsburgh, KI-CHUL KIM, DAVID SHOLL, Georgia Institute of Technology — The on-board storage of hydrogen is one of the most vexing problems associated with the development of viable fuel cell vehicles. Hydrides of period 2 or 3 metals can store hydrogen at high gravimetric and volumetric densities. However, existing hydrides either have unacceptable thermodynamics or kinetics. New materials for hydrogen storage are therefore needed. We demonstrate how first principles density functional theory (DFT) can be used to screen potential candidate materials for hydrogen storage. We have used DFT calculations in conjunction with a free energy analysis to screen over a million reactions involving 212 known compounds. This approach has identified several interesting reaction schemes that have not yet been explored experimentally. We have computed the phonon density of states and used this information to predict the van’t Hoff plots for some of the most promising candidate reactions identified through our modeling. We have also examined the thermodynamics of thin films and nanoparticles for selected metal hydrides by accounting for the surface energies of the films or nanoparticles.

3:30PM D36.00004 Reversible Hydrogen Storage in the Lithium Borohydride – Calcium Hydride Coupled System, FREDERICK PINKERTON, MARTIN MEYER, General Motors Research and Development Center — We report large reversible hydrogen storage in a new coupled system, LiBH\(_4\)/CaH\(_2\), via the reaction 6 LiBH\(_4\) + CaH\(_2\) → 6 LiH + CaB\(_6\) + 10 H\(_2\) having a theoretical hydrogen capacity of 11.7 wt% and an estimated reaction enthalpy of ΔH = 59 kJ/mole H\(_2\). Samples that include 0.25 mole (18.2 wt%) TiCl\(_4\) reproducibly store 9.1 wt% hydrogen, corresponding to 93% of the available hydrogen. H\(_2\) is the only evolved gas detected by mass spectrometry. X-ray diffraction confirms that the sample cycles between LiBH\(_4\) and CaH\(_2\) in the hydrogenated state and LiH and CaB\(_6\) in the dehydrogenated state.

3:42PM D36.00005 Structures and Bonding of Li-B-N-H Quaternary Hydrides, HUI WU, 1. NIST Center for Neutron Research 2. University of Maryland, WEI ZHOU, TERRENCE UDOVIC, JOHN RUSH, TANER YILDIRIM, NIST Center for Neutron Research — Complex metal hydrides are of great interest for hydrogen-storage applications due to their potential high hydrogen capacity. Intense efforts has been made on the Li-B-N-H system, with the discovery of several novel quaternary phases. There have been prior studies investigating the structure of one of these new phases (Li\(_3\)BN\(_3\)H\(_10\)). However, all these studies were undertaken on hydrides without any isotopic enrichment, thus resulted in diffraction data of limited quality and yielded structures with questionable bond lengths and unit cell structures determined anion groups. So far, no studies have been reported on the isotopically labeled samples, which are necessary to determine correct structures for these hydrides. We report for the first time the crystal structures of Li\(_2\)BN\(_2\)H\(_4\) and Li\(_4\)BN\(_3\)H\(_4\) derived from high-resolution neutron diffraction data on samples labeled with \(^{1}\)Li, \(^{11}\)B, and D. Our refined structures clarify the prevailing structural discrepancies. We also report corresponding neutron vibrational spectra combined with first-principles calculations to gain more insight between structure and bonding. The configurations of both BH\(_3\) and NH\(_3\) anions and the structural variations upon compositional changes will be discussed. Our study provides implications to the mechanisms of hydrogen absorption/desorption in these complex hydrides.

3:54PM D36.00006 Thermodynamic guidelines for the prediction of hydrogen storage reactions and their application to destabilized hydride mixtures\(^1\), DONALD SIEGEL, Ford Motor Company, C. WOLVERTON, Northwestern University, V. OZOLINS, University of California at Los Angeles — We propose a set of thermodynamic guidelines aimed at facilitating more robust screening of hydrogen storage reactions. The utility of the guidelines is illustrated by reasessing the validity of reactions recently proposed in the literature and through vetting a list of more than 20 candidate reactions based on destabilized LiBH\(_4\) and Ca(BH\(_4\))\(_2\) borohydrides. Our analysis reveals several reactions having both favorable thermodynamics and relatively high hydrogen densities (ranging from 5–9 wt % H\(_2\) and 85–100 g H\(_2\)/l), and demonstrates that chemical intuition alone is not sufficient to identify valid reaction pathways.

\(^{2}\)Does Metal Hydride Center of Excellence
Crystallography of the Perovskite-type Hydride NaMgH₃. TERRENCE UDOVIC, HUI WU, WEI ZHOU, JOHN RUSH, TANER YILDIRIM, NIST Center for Neutron Research, Gaithersburg, MD 20899 — The crystal structure, lattice dynamics, and local metal-H binding configuration of the perovskite hydride NaMgH₃ were investigated using combined neutron powder diffraction, neutron vibrational spectroscopy, and DFT calculations. NaMgH₃ crystallizes in the orthorhombic GdFeO₃-type perovskite structure (Pnma) with α-β-α octahedral tilting in the temperature range of 4-370 K. In contrast with previous structure studies, the refined Mg-H lengths and H-Mg-H angles indicate that the MgH₂ octahedra maintain a near ideal configuration, which is corroborated by both valence methods and our DFT calculations, and is consistent with perovskite oxides with similar tilt factor values. The temperature dependences of the lattice distortion, octahedral tilting angle, and atomic displacement of H are consistent with the recently observed high H mobility at elevated temperatures. The stability and dynamics of NaMgH₃ are discussed and rationalized in terms of lattice distortion, cation octahedra tilting, and local bonding configurations in the observed perovskite structure. Further experiments reveal that its perovskite crystal structure can be used to improve the slow hydrogenation kinetics of some strongly bound light-metal-hydrate systems such as MgH₂ and to design new alloy hydrides with desirable hydrogen-storage properties.

Bonding changes in compressed NaBH₄ probed by inelastic X-ray scattering1. ANDREW CORNELIUS, RAVHI KUMAR, MALCOLM NICOL. University of Nevada, Las Vegas, MICHAEL HU. HPCAT and Carnegie Institution of Washington, PAUL CHOW. Argonne National Laboratory — Hydrogen storage for commercial applications is an ongoing challenge in materials science research in recent years. Complex borohydrides are technologically promising materials due to their light weight and high gravimetric and volumetric hydrogen density. So far knowledge of the structural and bonding changes in these systems is elusive due to low z elements and lack of in-situ experimental probes. Here we present the first experimental results of boron K-edge inelastic X-ray scattering performed on NaBH₄ revealing the nature of bonding changes during compression up to 12 GPa. NaBH₄ undergoes structural phase transition from cubic (Fm-3m) to tetragonal (P421/c) above 6 GPa and to orthorhombic (Pnma) above 8.3 GPa. The high pressure tetragonal and orthorhombic phases show weakening of B-H bonding during phase transition. Further, NaBH₄ may be considered as a representative example for isostructural systems since a similar structural sequence is also observed in KBH₄ on compression. The experimental details and the inelastic x-ray scattering results will be presented.

On the Formation of LaFe₃H₈. JAN HERBST, LOUIS HECTOR, JR., GM R&D Center — Formation of a LaFe₃H₈ hydride is explored by means of density functional theory. Enthalpies of formation ∆H with respect to the elemental metals and H₂ are calculated for various hydrogen configurations in four prototype crystal structures. We find ∆H < 0 in many cases, suggesting the existence of LaFe₃H₈, as does Miedema's semi-empirical model. ∆H is a minimum for the LaFe₃H₈ stoichiometry with hydrogen occupying the 4e, 8g, and 16m sites in the orthorhombic Cmcm structure. Phonon dispersion relations and elastic constants computed for that structure exhibit no anomalies, demonstrating vibrational stability. Similar results for LaFe₅ indicate that compound may form under pressure.

Magnetooptic Ellipsometry: Determination of free charge carrier properties in semiconductor device structures1. MATHIAS SCHUBERT, TINO HOFMANN. Dept. of Electrical Engineering and Nebraska, University of Nebraska-Lincoln — The standard tool for the electrical characterization of free charge properties in semiconductor layer structures is the electrical Hall effect. However, besides the requirement for electrical contacts, the application of this technique to investigate complex heterostructures is very difficult and reliable deconvolution of the individual layer contributions to the measured Hall-Voltage virtually impossible. In our contribution we show that magnetooptic ellipsometry at long wavelengths when applied to conducting or semiconducting multilayer structures can yield equivalent and even much increased information. Our technique allows the independent measurement of free charge carrier density, type, mobility, and effective mass including anisotropy without any electrical contact in buried structures, and which may have been inaccessible to any true electrical evaluation thus far. We present results for multilayer AlGaP and GaInP samples with different doping concentrations. Furthermore, multilayer LED device structures were investigated and we demonstrate that magnetooptic ellipsometry allows deconvolution of the individual free charge carrier contributions of the p- and n-type regions of the device structure. We predict a realm of applications for magnetooptic ellipsometry in future materials research and engineering.

Cyclotron mass of two-dimensional holes in (100) oriented GaAs/AlGaAs heterostructures. T.M. LU, Z.F. LI, D.C. TSUI, Princeton University, M.J. MANFRA, L.N. PFEIFFER, K.W. WEST. Bell Laboratories — We have measured the microwave cyclotron resonance of low-density two-dimensional hole gases in (100) oriented heterostructures, including single interface heterostructures (SiHs) and 20nm-wide quantum wells(QWs). It was found that in the case of the SiHs, the cyclotron mass is relatively insensitive to the hole density, ranging from 0.25 x 10¹⁰/cm² to 1.31 x 10¹⁰/cm², and has a value of approximately 0.5mₑ. On the other hand, for holes in the QWs, the cyclotron mass decreases from 0.48mₑ at density $p = 6.9 	imes 10^{10}$/cm³ to 0.29mₑ at $p = 0.8 	imes 10^{10}$/cm³. In this talk, the absorption spectra will be shown, and a qualitative explanation will be presented.

High-Gap Semiconductors and Their Absorption Mechanisms at Millimeter and Submillimeter Wavelengths. J.M. DUTTA, C.R. JONES, North Carolina Central University, V. PARSHIN, Applied Physics Institute, RAS, B. GARIN, V. POLYAKOV, A. RUKOVISHNIKOV, Institute of Radio Engineering & Electronics, RAS — Experimental data has been applied to extend the available theoretical models to elucidate the predominant mechanisms of absorption for mm and sub-mm electromagnetic waves in high-gap semiconductors, especially CVD diamond and SiC, which are among the most promising low-loss materials commercially available. Dielectric properties of CVD diamonds, as measured by several laboratories, over a wide range of temperature and frequency will be discussed. The experimental data gathered, both from dielectric and electrical measurements, has been applied to extend available theoretical models for CVD diamonds. Similar studies are undertaken on SiC to determine the primary loss mechanisms for SiC in the mm wavelength range. Preliminary experimental results will be presented.

Propagation of light in birefringent tilings. ANGELO MASCARENHAS, BRIAN FLUEGEL, LEKHNATH BHUSAL, National Renewable Energy Laboratory — Two-dimensional tilings of an optically birefringent material are proposed as an orientational superlattice for light. The light modes that result from loss-free refraction are analyzed. It is shown that the behavior for light propagation in such lattices leads to totally bound as well as propagating states. The behavior of light propagation in several such tilings is compared.
Properties of Bulk GaN Crystals grown from the Solution, MADHU MURTHY, George Mason University, Fairfax, VA. JAIME A. FREITAS JR., MICHAEL A. MASTRO, RACHEL M. FRAZIER, Naval Research Laboratory, Washington DC.

3:18PM D37.00005 — WE investigated the structural and optical properties of bulk GaN single crystal grown from solution at temperatures < 900°C and a pressure of ~ 0.3 MPa. The X-ray diffraction peaks measured on both Ga- and N-face of the epitaxial film are 34.561 and 34.612 arcsec, respectively, which are two orders of magnitude lower than the substrate. The photoluminescence measurements performed on both faces of the sample, showed a dominant intense emission near 3.47 eV, which is assigned to recombination process involving shallow impurities and excitons. The two additional bands observed at 3.25 eV and 2.25 eV are assigned to donor-acceptor recombination process and the yellow band, respectively. The relative intensities of these bands intensities suggest a reduction of the concentration of defects incorporated in the epitaxial film, as compared with the substrate. These variations are consistent with different incorporation rate of point defects at different crystal surface polarity.

1 This work was partially supported by the Office of Naval Research. M. Murthy is supported by NSF Award # ECS-0330226.

3:30PM D37.00006 — D.Y. SONG, A. CHANDOLU, L. TIAN, N. STOJANOVIC, S.A. NIKISHIN, M. HOLTZ, Texas Tech University — Selective area growth (SAG) is useful for overcoming mismatch between non-native substrates and epitaxial materials. SAG of GaN is carried out using metalorganic chemical deposition with silicon dioxide as the mask material with openings ranging from 500 nm to several microns. This talk addresses optical properties of completed GaN pyramidal islands grown using SAG. SEM-based cathodoluminescence (CL) is used to investigate the bandgap emission. The optical properties at different positions on the pyramids are related to overgrowth conditions which determine the luminescence properties. The apex region is almost fully relaxed, while the pyramid base exhibits a red-shifted CL spectrum. This shift is attributed to stress and impurity incorporation in the overgrown sidewall region. The red shift observed in CL spectra on the pyramid sidewall region gradually increases from apex to base, varying by ~ 40 meV, when they exceed the size of the opening in the silicon dioxide mask. However, the pyramid has almost uniform luminescence properties when overgrowth does not occur. The CL line width is narrowest at the pyramid apex, suggesting a decrease in the disorder density. The authors acknowledge support from the National Science Foundation (ECS-0609416 and ECS-0304224) and the J. F Maddox Foundation.

3:42PM D37.00007 — JOSEPH BRADLEY, GERALD SEIDLER, University of Washington, RAFAEL DALMAU, North Carolina State University, KENNETH NAGLE, University of Washington, ZLATKO STAR, North Carolina State University — A fundamental description of the mechanisms underlying the diverse applications of w-AlN requires a complete understanding of its short-range and long-range electronic structure. Here, we report momentum-transfer (q) dependent nonresonant inelastic x-ray scattering (NRIXS) measurements of single crystal w-AlN, surveying the low-energy plasmon regime, as well as the complex behavior at the Al K and L edges. This complete determination of the dynamic structure factor S(q,w) over a wide range of q and w both within and perpendicular to the basal plane allows for a uniquely detailed perspective on chemical bonding and low-energy electronic response in w-AlN. Our results are compared and contrasted with two independent ab initio theoretical treatments.

3:54PM D37.00008 — A. SEDHAIN, N. NEPAL, M.L. NAKIRMI, J.Y. LIN, H.X. JIANG, Department of Physics, Kansas State University, J.H. EDGAR, Department of Chemical Engineering, Kansas State University — Polar and non-polar AlN homo- and hetero-epitaxial layers were grown on sapphire and AlN substrate materials by metal organic chemical vapor deposition. Polarization resolved deep ultraviolet photoluminescence (PL) spectroscopy was employed to investigate the optical properties of these samples. For the first time, B and C valence band related free exciton (FX) transitions without a dominant S(0) polarization were directly observed from PL. The emission energy peaks of B and C excitons were found to locate at 199 and 212 meV higher than that of the A-exciton transition position possessing the Ec polarization. A more comprehensive picture of the valence band structure of AlN is thus directly observed from PL measurements. AlN homo-epilayers in all orientations (a-, c-, and m-plane) were found to be strain free and have a nearly identical band gap of 6.099 eV at 10 K. The band edge peak intensity ratios of a-, c-, and m-plane homo-epilayers were roughly 32.5:1 and line width was found to be the smallest in a-plane homo-epilayer. Our results also indicated that built-in electric fields are almost absent in all AlN homo-epilayers.

4:06PM D37.00009 — NIELS E. CHRISTENSEN, Dept. of Physics and Astronomy, University of Aarhus, DK-3000 Aarhus, Denmark, ROBERT LASKOWSKI, Inst. of Materials Chemistry, Techn. University of Vienna, A-1060 Vienna, Austria — First-principles calculations based on solution of the Bethe-Salpeter equation of excitons in the high-pressure AlN phase show that a delocalization-localization transition occurs as applied pressure. The transition, which is associated with a sudden increase in exciton binding energy, is related to a pressure-induced rearrangement of the energy bands.

4:18PM D37.00010 — WAN-TSANG WANG, Department of Physics, Center of Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan — The wurtzite bulk inversion asymmetry (WBIA) terms in the k·p Hamiltonian have been derived from the linear combination of atomic orbital method, and the analytic form of Dresselhaus effect is obtained via an eight-band k·p Hamiltonian. It is found that WBIA terms lead to not only a spin-degenerate line (along the kz axis) but also a minimum-spin-splitting surface. Furthermore, they can induce large spin splitting energies in wide-gap wurtzite materials such as GaN. Consequently, the D’yakonov-Perel’ (DP) spin-relaxation mechanism can be effectively suppressed for all spin components in the [001] wurtzite quantum wells (QWs) at a resonance condition through appropriate sample design or the application of a suitable gate bias. Therefore, wurtzite QWs (e.g., InN/GaN or AlN) are potential candidates for spintronic devices such as the resonance spin lifetime transistor.

4:30PM D37.00011 — D. Y. SONG, P. PANDIT, A. CHANDOLU, M. BASAVARAJ, S.A. NIKISHIN, M. HOLTZ, Texas Tech University — The intrinsic phonon decay properties of high-quality crystalline III-nitrides are found to be critical to device self-heating. As well as for understanding the properties of phonons, micro-Raman scattering and piezoelectric studies of the Al(1)(TO), E(2)(TO), E(2)(LO), and A(1)(LO) symmetry phonons of GaN and the A(1)(TO), E(2)(TO), E(2) and A(1)(LO) symmetry phonons of AlN from 13 to 375 K. By applying anharmonic decay theory to the observed temperature dependences of the phonon energies, the phonon decay mechanisms of these center-energy vibrations have been determined. Thermal expansion is taken into account in using published temperature-dependent coefficients. Both GaN and AlN A(1)(TO) and E(2)(TO) vibrations are described by symmetric two-phonon decay. The GaN E(2) decays via creation of three phonons, however, the AlN E(2) decays symmetrically into two phonons. The GaN and AlN LO bands are interpreted by an asymmetric two-phonon decay. Phonon lifetimes are obtained based on the observed linewidths, and the dependence allows us to estimate the intrinsic phonon lifetime for each vibration. The authors acknowledge support for this work by the National Science Foundation (ECS-0609416 and ECS-0304224) and the J. F Maddox Foundation.

4:42PM D37.00012 — ABSTRACT WITHDRAWN —
The use of classical interatomic potentials. An embedded atom method (EAM) potential for titanium-vanadium is presented, and thermodynamic and mechanical properties of this alloy are calculated using the potential. The results are compared to density functional theory results and experimental results when available.

Vanadium is an important alloying element for titanium since its addition stabilizes the high temperature bcc phase of titanium at lower temperatures, and bcc-stabilized titanium alloys generally showed improved hardness and applications due to their large strength-to-weight ratio and their ability to resist corrosion. Vanadium is an important alloying element for titanium since it stabilizes the high temperature bcc phase of titanium at lower temperatures, and bcc-stabilized titanium alloys generally showed improved hardness and formability [1].

Titanium-vanadium is also a reasonable starting point in the study of more complex titanium alloys of commercial importance. The calculation of many alloy properties requires the use of large numbers of atoms simulated over long periods of time. These calculations are currently only feasible through the use of classical interatomic potentials. An embedded atom method (EAM) potential for titanium-vanadium is presented, and thermodynamic and mechanical properties of this alloy are calculated using the potential. The results are compared to density functional theory results and experimental results when available.

The effect could play a role in the observed efficiency droop of LEDs and play a major role in the limitations of GaInN/GaN laser diodes. This work was supported by DOE/NETL.

2:30PM D38.00001 Atomic short-range order effects on magnetostriction in Fe-rich Fe-Ga . YEVGENIY PUZYREV, G. E. ICE, G. M. STOCKS, Oak Ridge National Laboratory, R. MCQUEENEY, Ames National Laboratory, YINGZHOU DU, Iowa State University — We have measured diffuse x-ray scattering from an Fe-rich Fe-Ga BCC single crystal. Measurements were made on beamline 33-ID at the Advanced Photon Source using a wavelength dispersive spectrometer to suppress Compton, Fluorescence and Resonant Raman backgrounds. Data was collected over a large volume in reciprocal space and measurements were made at two energies to maximize and minimize the x-ray scattering contrast between Fe and Ga. We recovered short-range order (SRO) parameters for the crystal. Using these SRO parameters we use KKR-CPA and locally self-consistent multiple scattering (LSMS) calculations to study the effects of local atomic environment on electronic and magnetic structure of the alloy. Research sponsored by the Division of Materials Sciences and Engineering.

2:42PM D38.00002 First-principles study of helium bubble formation at a palladium lattice vacancy . PEI LIN, YAN WANG, MEI-YIN CHOU, Georgia Institute of Technology — Helium (4He) generated from the tritium decay is one of the main reasons for macroscopic radiation damage in the structural components of nuclear devices such as fission reactors and tritium storage media. In contrast to the hydrogen isotopes, helium with its closed electron shell is inert inside metals and tends to aggregate into bubbles which can cause deterioration of materials and influence the lifetime of reactor components. To examine this behavior, we have performed ab initio calculations of helium atoms inside palladium (Pd) using density functional theory (DFT) and the projector augmented wave (PAW) method within the generalized gradient approximation (GGA). We find that He diffuses easily in a defect-free Pd lattice. However, it is energetically favorable for multiple He atoms to be trapped at an isolated Pd vacancy site, forming a cluster of up to 8 atoms. The atomicistic mechanisms of He-vacancy interaction in Pd are investigated by studying the corresponding electronic structural properties.

2:54PM D38.00003 Embedded Atom Method Potential for Titanium-Vanadium Alloys1 . MICHAEL R. FELLINGER, JOHN W. WILKINS, The Ohio State University, Department of Physics — Titanium alloys are important materials for aerospace applications due to their high strength-to-weight ratio and their ability to resist corrosion. Vanadium is an important alloying element for titanium since it stabilizes the high temperature bcc phase of titanium at lower temperatures, and bcc-stabilized titanium alloys generally showed improved hardness and forgeability [1]. Titanium-vanadium is also a reasonable starting point in the study of more complex titanium alloys of commercial importance. The calculation of many alloy properties requires the use of large numbers of atoms simulated over long periods of time. These calculations are currently only feasible through the use of classical interatomic potentials. An embedded atom method (EAM) potential for titanium-vanadium is presented, and thermodynamic and mechanical properties of this alloy are calculated using the potential. The results are compared to density functional theory results and experimental results when available.

3:06PM D38.00004 Atomistic dislocation simulation of aluminum using a tight-binding method, CHEE GAN, Institute of High Performance Computing, Singapore, SIU-SIN QUEK, Institute of High Performance Computing — Atomistic simulation of dislocation in aluminum has been performed using a tight-binding method where the parameters are based on the works of Mehl and Papaconstantopoulos at the Naval Research Laboratory. We study the dissociation of a perfect edge dislocation (the dislocation line is along the [112] direction) of Burgers vector of $\frac{a}{2}[10\bar{1}]$ into two partials of $\frac{a}{2}[\bar{2}1\bar{1}]$ and $\frac{a}{2}[\bar{1}2\bar{1}]$ on the (111) slip plane. By performing a large scale atomistic relaxation, we observe a separation of partials of about 14 Å and a stacking fault region. We will comment on the estimate of partials separation predicted by the elasticity theory, which relates to certain quantities such as the stacking fault energy.

3:18PM D38.00005 First-principles calculation of dislocation properties of ductile rare-earth intermetallic compounds, MIN JI, CAI-ZHUANG WANG, Ames Laboratory, US DOE, Ames, IA 50011, USA, KAI-MING HO, Ames Laboratory, US DOE, Ames, IA 50011, USA and Department of Physics, Iowa State University, Ames, IA 50011, QIAN CHEN, XIANG-YANG LIU, BULENT BINER, Ames Laboratory, US DOE, Ames, IA 50011, USA — We have used first-principles calculations to study the mechanical properties of rare-earth intermetallic B2 compounds which exhibit significant ductility. According to Peierls-Nabarro model and slip plane observed in tensile experiments, we have calculated and compared the 110 gamma surface energy for both brittle NiAl and ductile YCu. We also compared unstable stacking fault and twinning energy for a series of B2 compounds with different ductility. Correlation between these energetics and the ductility are discussed.

3:30PM D38.00006 Effect of Chemistry on Dislocation Core Properties in α-Fe: AB INITIO-BASED APPROACH, ZHENZHENG CHEN, NICHOLAS KIOUSSIS, Dept. of Physics, California State Univ., Northridge, NASR GHONIEM, Dept. Mechanical and Aerospace Engr., UCLA, TADASHI HASEBE, Dept. of Mechanical Engr., Kobe Univ., Japan — Screw dislocations in α-Fe and its alloys play an important role on the low-temperature mechanical property. The solute atom can cause a significant local reconstruction of the dislocation core and therefore affect the mobility. Since direct investigations of the solute-dislocation interaction by first principles calculation remains a difficult problem, we employ a hybrid coupling approach that includes atomistic dislocation modeling with ab initio parameterization of the inter-row interactions, proposed by Suzuki. Using this approach, we have investigated the change of core structure and the $a/2[11\bar{1}]$ screw dislocation mobility induced by impurities of Cu and Cr. We find that Cu induces a change from a non-degenerate (P=0, where P is the core polarization) core structure in α-Fe to a degenerate (P=1) one, while Cr impurity does not change the P at any concentration. We have also studied the behavior of these systems under stress, and found that Cr impurities lower the mobility of the screw dislocation, while Cu induces that the dislocation of Fe-Cu system under stress exhibits a peculiar stable $\rightarrow$ metastable $\rightarrow$ stable transition, and strengthens α-Fe. The above conclusions are supported by molecular dynamics calculation, which also show that Cu impurities, in addition to changing the core polarization, dramatically increase the edge components of screw dislocation in Fe.

3:42PM D38.00007 Dependence of the Strain Rate Sensitivity of Crystalline Materials on the Distribution of Obstacles to Dislocation Motion, RENGE LI, ZHIJIE XU, CATALIN PICU, Rensselaer Polytechnic Institute — The strength and strain rate sensitivity of metals is usually described in terms of the concentration of obstacles to dislocation motion, i.e. the mean of the obstacle spatial distribution function. In this study we investigate the role of higher moments of this distribution function on these parameters. It is shown that large local fluctuations of obstacle density influence to a large extent the strain rate sensitivity of the material, while the effect on the strength (critical resolved shear stress) is smaller. It is shown that a large reduction of the strain rate sensitivity is associated with a change in the dislocation motion mode from smooth to jerky. Populations composed from obstacles of same strength but different activation energy, as well as obstacles of same activation energy and different strength are also studied.

3:54PM D38.00008 Elastic properties of γ-Pu by Resonant Ultrasound Spectroscopy, IZABELA STROE, Los Alamos National Laboratory, A. TRUGMAN, J. BETTS, A. MIGLIORI, C. H. MILEKE — Despite of intense experimental and theoretical work on Pu, there is still little understanding of the strange properties of this metal. We used resonant ultrasound spectroscopy method to investigate the elastic properties of pure polycrystalline Pu at high temperatures. Shear and longitudinal elastic moduli of the γ-phase of Pu were determined simultaneously and the bulk modulus was computed from them. A smooth linear and large decrease of all elastic moduli with increasing temperature was observed. We calculated the Poisson ratio and found that it increases from 0.242 at 519K to 0.252 at 571K.

4:06PM D38.00009 The 50 K anomaly in the shear modulus of β-PdH$_{0.71}$, DOUGLAS SAFARIK, RICARDO SCHWARZ, Los Alamos National Laboratory — When palladium hydride, PdH$_x$, is rapidly cooled to liquid helium temperature and then slowly reheated, both the heat capacity and electrical resistivity show a peak in the range 50 < T < 80 K, depending on the composition x. This “50 K anomaly” has been previously explained in terms of formation of long-range ordered hydrogen superlattice structures. However, several aspects of the 50 K anomaly are inconsistent with an ordering phase transition, namely, the temperature of the anomaly depends on the rate of cooling, and the magnitude of the anomaly is larger for a fast cooling rate than for a slow cooling rate. We have studied the 50 K anomaly by measuring the elastic constants of single-crystal PdH$_{0.71}$ in the temperature range 1.4 < T < 300 K during both fast cooling and slow warming. During warming, we observed a peak in the shear modulus $C'' = (C_{11} - C_{12}/2)$ at 55 K, which we attribute to the 50 K anomaly. In contrast, we observed no peak in the temperature dependence of the shear modulus $C_{14}$ or of the bulk modulus $B$. We propose that the 50 K anomaly arises not from the formation of long-range ordered hydrogen superlattice structures, but from freezing of the hydrogen short-range order as the hydride is cooled.

4:18PM D38.00010 Field theoretical approach to deformation dynamics, SANICHIRO YOSHIDA, Southeastern Louisiana University — Based on a recent gauge theory called physical mesomechanics, an attempt is made to formulate the deformation dynamics of solid-state materials comprehensively. In this formalism, deformation is described as a linear transformation of the position vector connecting two nearby points of the material; the transformation is global in the elastic regime and local in the plastic regime. The demand of local invariance leads to a Maxwell-type field equation, in which a symmetry charge analogous to the electric charge is defined. Dynamics in the plastic regime is characterized by transverse force proportional to rotational displacement, as opposed to translational displacement in the elastic regime, and longitudinal force proportional to velocity. The transverse force is a restoring force, which can be interpreted as the recoverability mechanism that the material regains in the plastic regime. The longitudinal force can be interpreted as a field force acting on the above-mentioned charge, which is basically an energy-dissipating force causing the irreversibility of plastic deformation. Fracture is considered to be the situation where the material completely loses recoverability. Supporting experimental data will be presented.
4:30PM D38.00011 Where is the Simple Hexagonal Structure in Tin?1, MICHAEL MEHL, DANIEL FINKENSTADT2. Naval Research Laboratory — The heavier elements of periodic table column IV exhibit number of structural phase transitions under pressure. Si and Ge transform from the ground-state diamond structure to, successively, the β-Sn structure, a body-centered orthorhombic structure, the simple hexagonal structure, etc., ending at a close-packed phase (fcc or hcp) near 200 GPa. Tin also transforms from diamond to β-Sn, but then to a body-centered tetragonal phase, ending with the body-centered cubic phase. The simple hexagonal phase is not seen, despite the fact that numerous tin-rich alloys exhibit a simple hexagonal structure. To understand this we performed DFT calculations on tin in various crystal structures, using both full-potential LAPW and VASP with a PAW potential. Surprisingly, we find that the simple hexagonal phase is degenerate with a simple hexagonal structure. To understand this we performed DFT calculations on tin in various crystal structures, using both full-potential LAPW and tetragonal phase, ending with the body-centered cubic phase. The simple hexagonal phase is not seen, despite the fact that numerous tin-rich alloys exhibit a simple hexagonal structure, etc., ending at a close-packed phase (fcc or hcp) near 200 GPa. Tin also transforms from diamond to β-Sn over pressures at which the β-Sn phase is seen experimentally. This holds both for LAPW and VASP calculations, in both the LDA and the GGA. We explore reasons for the lack of a tin simple hexagonal phase, including zero point and spin-orbit effects.

4:42PM D38.00012 Ab initio study of Fe-rich Fe-Cu alloys1, DAVID REITH, RAIMUND PODLOUCKY, Department of Physical Chemistry, University of Vienna — Cu precipitates are important for strengthening steel. Our ab initio study aims to model the thermodynamical stability of Cu precipitations in α-Fe. As a first step, a density functional theory (DFT) supercell approach is applied to study Fe_{1-x}Cu_x alloys at small concentrations x. From the DFT total energies a strongly nonbonding substitutional energy E_{sub} ≈ 0.7 eV is derived, which is significantly larger than results of a previous DFT study [1]. Based on force constants derived by the same DFT approach the temperature dependent vibrational free energy is determined [2]. In particular at higher temperatures the vibrational entropy significantly reduces the formation energy. Finally, by using the entropy of mixing the dilute Fe-Cu alloy becomes stabilized. The derived phase diagram is in good agreement with experimental data [3]. According to our analysis, the vibrational free energy is very important for a correct modelling of the phase stability of Fe-rich Fe-Cu alloys. [1] C. Domain et al., PRB, 65, 024103 (2001) [2] D. Alfe et al, PRB, 65, 045123 (2001) [3] B. Predel, Landolt-Börnstein - IV, Springer, Volume 5d (1994)

4:54PM D38.00013 Strain-induced interactions in size-mismatched alloys: A Kanzaki force approach1, ALEJANDRO DIAZ-ORTIZ, OLEG SCHIGYLO, VLADIMIR BUGAEV, HELMUT DOSCH, ALEXANDER UDYANSKY, HARALD REICHERT, Max Planck Institute for Metals Research, RALF DRAUTZ, Department of Materials, University of Oxford — A perturbative approach to determining the strain-induced effective interactions in binary alloys with large atomic-size mismatch is presented. Using the chemical energy as the reference state, the strain-induced energy of the alloy is cast into a many-body (Kanzaki) force expansion that depends on both the configurational and displacive degrees of freedom. It is shown that the k-space energy expansion is valid for all wave-lengths. The theory is then applied to the Cu_{13}Au alloy where, due to the large difference among atomic sizes, considerable relaxations are observed from first-principles calculations. We found that the inhomogeneous contribution (k≠0) dominates the strain energy in Cu_{13}Au, whereas the homogenous part (k=0), notwithstanding its configurational dependence, contributes only a few percent.

5:06PM D38.00014 New candidates for the Pt_{33}Ti structures in intermetallics, ERIN GILMARTIN, JACQUELINE CORBITT, GUS HART, Brigham Young University — The only known intermetallic structure with an 8:1 stoichiometry is that of Pt_{33}Ti. Because of its uniqueness, this structure has been studied in Pt, Pd, and Ni rich systems. However, these metals have only been paired with a handful of other elements. Are there more elements that when alloyed with Pt, Pd, or Ni order with the Pt_{33}Ti structure? We explored 40 different Pd- and Pt-based binary systems. We calculated their formation enthalpies for the Pt_{33}Ti structure. Compared to the value in the tie line between pure Pd/ Pt and experimentally-observed ground states. We find that there are other (beyond those experimentally observed) possible alloys with this structure. These new Pt/Pd-rich alloys could fin application in the jewelry and catalysis industries.

5:18PM D38.00015 Properties of the type I Ge-based clathrates Ba_{x}Al_{13}Ge_{33} and Ba_{x}Al_{16}Ge_{30}, EMMANUEL NENGHABI, Texas Tech University, CHARLES MYLES, Texas Tech University — The type I clathrate lattice is simple cubic with 46 atoms per unit cell. The cages in this lattice can host “guests” and the framework can have substituted atoms. Here, we focus on the “alloy” system Ba_{x}Al_{13}Ge_{33-x} (x is an integer; 0<x<15). The Ba are guests and Al substitutes for some Ge framework atoms. Using the local density approximation (LDA), we have calculated some properties of the type I clathrates Ba_{2}Al_{13}Ge_{31} and Ba_{2}Al_{16}Ge_{30}. Our calculations of the equilibrium structures predict that Ba_{2}Al_{13}Ge_{31} and Ba_{2}Al_{16}Ge_{30} have approximately the same lattice constant and that Ba_{2}Al_{13}Ge_{31} is expected to be slightly more stable than Ba_{2}Al_{16}Ge_{30}. Our band structures and electronic density of states results predict that Ba_{2}Al_{13}Ge_{31} is metallic and that Ba_{2}Al_{16}Ge_{30} is a semiconductor with an indirect fundamental band gap of 0.3 eV. The vibrational spectrum predicts low frequency rattling modes caused by the Ba guests that are loosely bound in the Al-Ge framework cages. Such modes may scatter the heat-carrying acoustic vibrational framework modes, potentially reducing the thermal conductivity.

Monday, March 10, 2008 2:30PM - 5:30PM - Session D39 GSNP: Focus Session: Econophysics and Applications Outside of Physics - Morial Convention Center 231

2:30PM D38.00001 Image Segmentation in Linear Time using the Potts Model. FRANK W. BENTREM, Marine Geosciences Division, Naval Research Laboratory, Stennis Space Center, Mississippi 34552 — A computational method is described which efficiently segments digital grayscale images using the Q-state Ising (or Potts) model. Since the Ising model was first proposed in 1925, physicists have studied lattice models to gain deep insights into ordered/disordered systems. Some researchers have realized that digital images may be modeled in much the same way as these physical systems (i.e., as a square lattice of numerical values). A major drawback in using this technique for image segmentation is that it processes in exponential time. Advances have been made via certain approximations to reduce the segmentation process to power-law time. However, real-time processing (such as for sonar imagery) requires much greater efficiency. We describe an energy minimization technique using four Potts (Q-Ising) models which processes in linear time. The technique is demonstrated on acoustic seafloor images as well as medical images.
2:42PM D39.00002 Battles between an insurgent army and an advanced army - focus on strategy. SURAJIT SEN, LINDA SHANAHAN, Physics Dept, SUNY-Buffalo — Detailed and aggregate analyses of the outcome of past battles focusing on rates of troop losses or on the ratios of forces on each side is at the heart of present knowledge about battles. Here we present non-equilibrium statistical mechanics based studies of possible outcomes of well matched strategic battles by a “blue” army against insurgency based attacks by well matched opponents in a “red” army in red territory. We assume that the red army attacks with randomly varying force levels to potentially confuse and drive the blue’s strategies. The temporal evolution of the model battles incorporate randomness in the deployment of the reds and hence possess attendant history dependence. Our results reveal that while unpredictable events play a major role in battles, a balance between risk of exposure in a battlefield and the use of short range intelligence is needed in determining whether one side can decimate the other, and hence force a battle to end.

2:54PM D39.00003 Understanding individual human mobility patterns, MARTA C. GONZÁLEZ, Northeastern University, CESAR A. HIDALGO, Notre Dame University, ALBERT-LÁSZLO BARABÁSI, Northeastern University and Notre Dame University — Understanding human mobility patterns is of major importance for a number of areas, ranging from urban planning to traffic forecasting, transportation geography, and preventing the spread of biological and mobile viruses. Yet, in the absence of tools to monitor the time resolved location of a large number of individuals, our understanding of the basic laws governing human trajectories remains limited. Here we study the individual mobility pattern of mobile phone users whose position is tracked in a time resolved manner. We find that the displacement distribution of the whole population can be approximated with a truncated Lévy statistics, in agreement with earlier measurements. We show, however, that the main contribution to the observed distribution comes from the differences in the travel pattern of individuals. Furthermore, we find that the individual trajectories are bounded in space and are highly anisotropic, an effect that increases with the trajectory’s radius of gyration. After we correct for differences in the radius of gyration and anisotropy all individuals are described by the same universal mobility pattern. These results open new avenues for modeling human motion, with important impact on agent based modeling, epidemic prevention, emergency response and urban planning.

3:06PM D39.00004 Epidemics with Multistrain Interactions: Cross Immunity and Antibody-Dependent Enhancement. SIMONE BIANCO, LEAH SHAW, College of William and Mary — Dynamics of epidemic spread is a problem of global interest. In this work we investigate the dynamical properties of a multistrain disease in a population where the strains interact via antibody-dependent enhancement (ADE) and cross immunity. ADE is a property of some multistrain diseases, such as dengue fever and Ebola, in which the antibodies generated by a primary infection with a strain tend to increase the infectiousness of a secondary infection with a different strain. After a primary infection, cross immunity provides temporary reduced susceptibility to the other strains. The presence of chaotic outbreaks and desynchronization between strains has already been observed in a model with no cross immunity if the ADE is sufficiently strong. The addition of weak cross immunity provides a stabilizing effect, while strong cross immunity leads to large amplitude chaotic outbreaks. A stochastic version of the model is also considered.

3:18PM D39.00005 Panic reactions and global disease dynamics. RAFAEL BRUNE, CHRISTIAN THIEMANN, Max-Planck-Institute for Dynamics and Self-Organization, Goettingen, Germany, BERND BLASIUS, ICBM Oldenburg, Germany, THEO GEISEL 1, DIRK BROCKMANN, Max-Planck-Institute for Dynamics and Self-Organization, Goettingen, Germany — We analyze spatially extended disease dynamics in a system in which individuals change their dispersal characteristics in response to the local infection level. The key question is to what extent infectious wave front dynamics and the time course of the global infection change in response to host awareness and individuals trying to avoid infection by increased dispersal. We investigate two qualitatively different responses to the local degree of infection. In one system (panic reaction) the local diffusion coefficient increases with the concentration of infecteds, in the other system (directed reaction) individuals drift proportional to infection level gradients. For both systems we develop a mean field model. Although one expects that the individual rationale of avoiding an epidemic wave mitigates disease dynamics we find extended parameter regimes in which this rationale actually facilitates epidemic spread. Finally we investigate the dynamics of a fully stochastic system in which the effects prevail but which also show an increased extinction probability of the epidemic as a function of increasing dispersal response.

2:54PM D39.00001 Nonstationary increments and variable diffusion processes in financial markets. JOSEPH L. MCCAULEY, KEVIN E. BASSLER, GEMUNU H. GUNARATNE, University of Houston, U OF H ECONOPHYSICS GROUP COLLABORATION — Fat tailed returns distributions and Hurst exponent scaling for financial markets have been reported for more than a decade. The sliding interval technique used in those analyses implicitly assumes that the increments are stationary, an assumption that generally contradicts the facts that the increments are uncorrelated. We show that the data exhibit nonstationary, uncorrelated increments, implying diffusive dynamics with a variable diffusion coefficient, but there is no evidence for either fat tails or Hurst exponent scaling in daily FX returns.
4:30PM D39.00009 A Model for Nonstationary Market Dynamics with Nontrivial Dynamical Scaling

MIN LIU, KEVIN E. BASSLER, University of Houston — In a recent empirical analysis of the Euro/Dollar exchange rate [Bassler, et al., PNAS 104, 17287 (2007)] it was found that during certain periods of the day the market returns scale with Hurst exponents $H$ that are significantly different from 1/2. In some of these periods it is less than 1/2, while in others it is greater than 1/2. In this talk we will propose a possible origin for this behavior and other stylized market facts, including short time negative autocorrelations of returns, in terms of a nonstationary compound Poisson process with a time-dependent intensity rate function that results from a changing bid-ask spread in the microscopic market. The model correctly describes the dynamic scaling behavior of a simple reaction-diffusion model of a limit-order book. That model, like the Euro/Dollar exchange rate, has nonstationary return increments and a Hurst exponent $H$ not equal to 1/2.

4:42PM D39.00010 path integral approach to closed form pricing formulas in the Heston framework

DAMIAAN LEMMENS, MICHEL WOUTERS, JACQUES TEMPERE, Universiteit Antwerpen, SVEN FOULON, KBC Bank, TFVS TEAM — We present a path integral approach for finding closed form formulas for option prices in the framework of the Heston model. The first model for determining option prices was the Black-Scholes model, which assumed that the logreturn followed a Wiener process with a given drift and constant volatility. To provide a realistic description of the market, the Black-Scholes results must be extended to include stochastic volatility. This is achieved by the Heston model, which assumes that the volatility follows a mean reverting square root process. Current applications of the Heston model are hampered by the unavailability of fast numerical methods, due to a lack of closed-form formulae. Therefore the search for closed form solutions is an essential step before the qualitatively better stochastic volatility models will be used in practice. To attain this goal we outline a simplified path integral approach yielding straightforward results for vanilla Heston options with correlation. Extensions to barrier options and other path-dependent option are discussed, and the new derivation is compared to existing results obtained from alternative path-integral approaches (Dragulescu, Kleinert).

4:54PM D39.00011 Modeling income distribution as a sum of additive and multiplicative stochastic processes

ANAND BANERJEE, VICTOR YAKOVENKO, University of Maryland — We obtained an analytical stationary solution of the Fokker-Planck equation for a stochastic process that is a sum of the additive and multiplicative processes. The stationary probability distribution function smoothly interpolates between an exponential distribution at the low end and a power law at the high end. It may have different applications in physics. Here we apply it to income distribution in a society by modeling income as a stochastic process. We analyze the personal income distribution data in USA from the Internal Revenue Service. Using just three fitting parameters (the average income in the exponential part, the power-law exponent, and the crossover point between the exponential and the power laws), we obtain very good fits of the IRS data for a range of years.

5:06PM D39.00012 Power-law behavior and condensation phenomena in disordered urn models: Analysis and its application to macro-economics

JUN-ICHI INOUE, Hokkaido University, JUN OHKUBO, Institute for Solid State Physics, University of Tokyo — We investigate equilibrium statistical properties of a disordered urn model. New types of urn models are proposed, in which quenched disorder parameters play an important role in generating power-law behavior. By choosing an arbitrary energy function for each urn, one can construct a lot of urn models, and we assume that the energy function contains a disordered parameters. We evaluate the occupation probability $P(k)$ that an arbitrary urn has $k$ balls by using the concept of statistical physics of disordered systems. In our new disordered urn model, we find that above critical density $p_c$ for a given temperature, condensation phenomenon occurs and most of the balls are condensed into an urn with the lowest energy level. As the result, the occupation probability changes its scaling behavior from an exponential-law to a heavy tailed power-law in large $k$ regime. We also discuss an application of our results for explaining of macro economy, in particular, emergence of wealth differentials.

5:18PM D39.00013 The Macro Model of the Inequality Process and the Surging Relative Frequency of Large Wage Incomes

JOHN ANGLE, Inequality Process Institute, Maryland, USA — Particles are randomly paired in the Inequality Process (IP), a particle system scattering a positive quantity, wealth. Each particle has a parameter, $\omega$, the fraction of wealth lost in a loss whose probability is 0.5. The stationary distribution of the wealth of particles with $\omega_P$ is approximated by a $\Gamma$ pdf, the IP’s macro model, with shape and scale parameters expressed in terms of $\omega_P$. The model’s dynamics are driven by the product, $\omega_P\mu_t$, where $\omega_P$ is the harmonic mean of the $\omega$’s in the population at time $t$ and $\mu_t$, the population mean of wealth at time $t$. This $\Gamma$ pdf model fits the annual distribution of annual wage income in the U.S. 1961-2003. These data also confirm that the time-series of scalar statistics of wage income that labor economists think are produced by the U.S. distribution of wage income being “hollowed out” (bimodal), the increasing dispersion of wage income and the surging relative frequency of large wage incomes, are produced by the distribution being stretched over larger wage incomes, as implied by the IP’s macro model when $\omega_P\mu_t$ increases. The IP’s macro model includes wage income distribution dynamics into statistical mechanics. To appear in The Econophysics of Markets and Business Networks.

2:30PM D40.00001 Oxide Reliability of SiC MOSFETs

ENRIQUE CARRION, Student, MOSHE GURFINKEL, JOHN SUEHLE — SiC is one of the materials that presents the most promise for harsh environment electronics. Its ability to operate under high temperature and high power, as well as under radiation, made it the material of choice for this study. SiC MOSFETs constitute an important step towards the development of the next generation of resistant electronics. The eventual industrial manufacturing of this type of field effect transistor depends on the effectiveness to improve its performance. Currently, a sudden current degradation, and an unsatisfactory low mobility are observed during the operation of these devices. In this work, we studied both of these drawbacks as a function of temperature. The devices used were SiC nMOSFETs with a SiO$_2$ oxide. Two types of measurements (ultra fast and conventional) were performed during this experience in order to observe 8 decades of current degradation. From our experience, it was observed that as the temperature was lowered the threshold voltage ($V_{TH}$) increased, while the mobility and the drain current ($I_D$) decreased.

2National Institute of Standards and Technology
2:42PM D40.00002 X-ray degradation studies of Nafion in a PEM fuel cell. REBECCA JENKINS, JUAN FRAGOSO — The overall goal of this research is to test for degradation of the Polymer Electrolyte Membrane (PEM) fuel cells due to exposure to ionizing radiation. We have successfully developed a Membrane Electrode Assembly (MEA) that can be fully disassembled down to the bare Proton Exchange Membrane (PEM) and reassembled repeatedly. This is crucial for testing the degradation effects on the individual components of the MEA. It was also important to establish baseline repeatability of the polarization curves of the MEAs. Therefore, we systematically varied different parameters to test their effect as well as to establish consistent experimental procedures. Hydration of the fuel cell has been found to be crucial for repeatable results. These polarization curves should also have voltages that ranged from 500 V to 1.0 V and current densities up to 11 mA/cm². The Nafion can then be exposed to an x-ray source and the respective polarization data can be studied. A working fuel cell has also been built that fits into the microwave cavity of an electron paramagnetic resonance spectrometer. This allows for the study of behavior of freely radicals formed in a normal operational fuel cell as well as fuel cells with x-ray exposed membranes.

2:54PM D40.00003 Polymer Nanocomposite Gyroids1. CHRIS KNOROWSKI, Virginia Tech, JOSHUA ANDERSON, ALEX TRAVESSET, Iowa State University and Ames Laboratory — Self-assembled polymer phases are increasingly being used in the development of nanocomposite materials. The polymer matrix provides a template for nanoparticles added to the system, transferring the structure of the polymer to the nanoparticles. We perform Molecular Dynamics simulations of these polymer nanocomposite materials and characterize their phase diagrams. Two striking results are found. First, a specific interaction of the polymer and the nanoparticles is required for a successful templating. Second, the presence of nanoparticles can change the pure polymer phase entirely. For instance, a small nanoparticle concentration turns a polymer system from a hexagonal phase into a gyroid phase, both for the polymers and the nanoparticles. In fact, the gyroid is the most prevalent phase over a wide range of interaction strengths and polymer composition.

3:06PM D40.00004 Sol-gel synthesis and characterization of terbium doped tin-oxide1. REBECCA SOBEL, CHRISTIE LAROCHELLE, Franklin and Marshall College — Rare earth doped tin oxide nanocrystals emit visible light when excited in the ultra-violet. Using a sol-gel process, we embedded Tb³⁺ doped SnO₂ nanocrystals in silica glass and characterized the samples using x-ray diffraction, photoexcitation and emission spectroscopy, and transmission electron microscopy. We synthesized four sets of samples, SnO₂:995SiO₂, 35SnO₂:975SiO₂, 55SnO₂:955SiO₂, 75SnO₂:935SiO₂ with constant weight ratios of Tb³⁺ to measure the effects of varying the molar concentrations of Tin-Oxide on the photoluminescence properties of the nanocrystals.

3:18PM D40.00005 Generation of 279nm Light for Single Photon Ionization of Laser Cooled Rubidium. LUCAS WILLIS, MICHAEL LIM, Rowan University — The ionization of rubidium for the formation of ultracold plasma is often done by the nanocrystals.

3:30PM D40.00006 Bio-Photonic Detection of Various Cellular Cultures. PATRICK HANN, MARIA GARZON, ERIK PFEIFFER, SAMUEL LOFLAND, ERNST KNOESEL, Rowan University — Since it is non-invasive, there has been increased research in the field of research addresses some of the challenges associated with growing epitaxial thin films of the CMR manganite material, Nd(SC) grown on substrates Al₂O₃, MgO and seed layers of VC, and TiC at room temperature up to 850°C. HETTINGER, SAMUEL LOFLAND, Rowan University, TED SCABAROZI, Drexel University — We have synthesized and characterized Cr₂AlC thin films with such schemes in place, there exists a mismatch between the thermal expansion coefficients of Silicon (αSi=2.618×10⁻⁶K⁻¹ at 300K) and NSMO (αNSMO =3×10⁻⁶ K⁻¹). This large mismatch induces thermal stresses that deteriorate the film properties. Our research investigates how the thermal stress evolves as a function of the thickness of the multi-layers, and how the process parameters such as the film growth kinetics and thermal kinetics can be optimized to minimize the stress. We are using the Pulsed Laser Deposition technique for thin film growth and characterizing the properties of the sensor layer using X-ray diffraction, electrical resistance measurements, optical microscopy and atomic force microscopy. Acknowledgement: We acknowledge support for this research from Lawrence Livermore National Laboratory.

3:42PM D40.00007 Epitaxial Thin Film Growth of CMR Manganites on Silicon: The Effect of Thermal Stress. SANJAY ADHIKARI, BAO HA, GRACE YONG, DAVID SCHEFER, RAJESWARI KOLAGANI, Towson University — Our algae will be presented and compared to other reports in the literature and procedure for the detection of these ultra-weak photonic emissions using a single photon detection device. The results of bread yeast, saccramyces, and

3:54PM D40.00008 Synthesis and Characterization of Cr₂AlC Thin Films. JUAN ROCHE, JEFFREY HETTINGER, SAMUEL LOFLAND, Rowan University, TED SCABAROZI, Drexel University — We have synthesized and characterized Cr₂AlC thin films grown on substrates Al₂O₃, MgO and seed layers of VC, and TiC at room temperature up to 850°C. Texture films were successfully grown above 550°C while Raman spectroscopy shows vibrations down to 500°C. Films below 500°C down to room temperature show texturing upon annealing at 750°C. The films were prepared using RF magnetron sputtering from elemental targets. Electrical transport shows metallic behavior of the films down to 10 K. EDS was used to verify chemistry from which the MA ratios were found that a slight deviation still allowed formation of the MAX phase. X-ray diffraction shows that when the chemistry is off it results in secondary phases of Cr₂6C₆ and Cr₂Al. Atomic Force Microscopy (AFM) shows smoother films at lower temperatures and rougher films at higher temperatures with a surface roughness > 20 nm. Friction test results will be presented.

4:06PM D40.00009 Spatially resolved quasi-particle tunneling spectra in the vortex state of optimally hole-doped YBa₂Cu₃Oₓ (Y-123). M.S. GRINOLDS, A.D. BEYER, M.L. TEAGUE, N.-C. YEH, Phys. Dept., Caltech, Pasadena, CA — We report cryogenic scanning tunneling spectroscopic (STS) studies of superconducting single crystalline Y-123 (Tc = 93 K) as a function of magnetic field. We study and model the influence of competing orders (COs), which coexist with superconductivity (SC), on the quasiparticle (QP) excitation spectra. The spatial dependence of the QP tunneling spectra is probed via STS to quantify the presence and spatial extent of SC and CO. Zero-field spatial maps of the QP spectra (100×100 nm²) in Y-123 exhibit long-range spatial homogeneity of SC (ΔSC = 23±1 meV) associated with the spectral coherence peaks and the presence of CO (ΔCO = 33±2 meV) that gives rise to the spectral satellite features at ΔCOeff = [2(DCO)² + (VCO)²]¹/². Conductance maps of the Y-123 in finite fields demonstrate spatially varying spectra consistent with the periodicity a₀ of the vortex lattice, with pseudogap (PG) like features at ΔCOeff inside the vortex core and SC gap features remaining at ∼ΔSC outside the vortex core. Moreover, conductance histograms of the vortex state reveal that the ratio of the areas associated with ΔSC and VCO is comparable to (a₀/ξab)², (ξab: in-plane SC coherence length). These results therefore suggest the important role of COs in the cuprate QP excitations. This work is supported by NSF Grant DMR-0405088.
4:18PM D40.00010 High Frequency Electrical Properties of Carbon Nanotubes

DOBROMIR KAMBUROV, BETH PARKS, Colgate University, ZHAOHUI ZHONG, PAUL MCEUEN, Cornell University — We report on measurements of the high frequency electrical properties of single-walled carbon nanotubes. These measurements are accomplished by incorporating a single nanotube into a microwave stripline and using optical pulses from a femtosecond laser to create short electrical pulses on the stripline. By varying the time delay between the pulses, it is possible to determine the frequency dependence of the response of the nanotube.

This work was supported by the NSF through the Center for Nanoscale Systems. Sample fabrication was performed at the Cornell Nanoscale Science and Technology Facility, a National Nanotechnology Infrastructure Network node, funded by NSF.

4:30PM D40.00011 Current State of Research of Alternate Fuel Sources for Passenger Vehicles

LEE MASSEY, University of Wisconsin at River Falls — The purpose of this project is to report on the current state of research in the field of alternate fuel sources for passenger vehicles. Because the number of alternate fuel options is very large, this study focuses on selected bio-fuels and briefly describes a couple of the most popular non-bio and non-renewable alternatives. The fuel and energy sources studied are compared using well-to-wheel and well-to-tank net energy balances. Data also includes relative production capabilities by volume in terms of current fossil fuels. Qualitative data includes production methods and transportability.

Research funded by APS Fellowship in the Forum on Physics and Society.

4:42PM D40.00012 Universal Properties of Population Dynamics with Fluctuating Resources

SAIYAK MUKHERJEE, Virginia Tech, HANS-KARL JANSEN, Heinrich-Heine-Universitat, Dusseldorf, BEATE SCHMITTMANN, Virginia Tech — Starting from the well-known field theory for directed percolation, we describe an evolving population, near extinction, in an environment with its own nontrivial spatio-temporal dynamics. Here, we consider the special case where the environment follows a simple relaxational (Model A) dynamics. Two new operators emerge, with upper critical dimension of four, which couple the two theories in a nontrivial way. While the Wilson-Fisher fixed point remains completely unaffected, a mismatch of time scales destabilizes the usual DP fixed point, suggesting a crossover to a first order transition from the active (surviving) to the inactive (extinct) state.

4:54PM D40.00013 First-principles density-functional theory investigation of FOX-7

BRIAN VOHASKA, MICHAEL CONROY, IVAN OLEYNIK, University of South Florida, CARTER WHITE, Naval Research Laboratory — Due to the expense and difficulty of experimental investigation of the chemical and physical properties of energetic materials (EMs), computational methods provide a unique opportunity for accurate determination of the chemical and physical properties of EM molecular crystals based on underlying atomic structure. In this presentation, we discuss the results of first-principles density functional theory (DFT) calculations of hydrostatic and uniaxial compression of the important energetic material, FOX-7. The calculated equilibrium properties, such as lattice parameters, elastic constants, and bulk modulus will be reported and compared with experiment, as well as the isothermal equation of state. Due to the anisotropic nature of energetic molecular crystals, physical properties such as cohesive energy, band gap, and stress-strain relationships are reported as functions of uniaxial compression studied. In addition, the shear stress behavior upon uniaxial compression will be discussed, as well as its possible relation to anisotropic shock-sensitivity in FOX-7.

5:06PM D40.00014 Variational Wavefunction Monte Carlo method applied to electrons in a two dimensional square lattice with zero doping

SUNITA KANNAN, COURTNEY LANNERT, Wellesley College — We present the theoretical results from the Variational Wavefunction Monte Carlo method applied to electrons in cuprates, of a two dimensional square lattice with zero doping. Since the true Hamiltonian of the cuprates is not definitively known, much study has gone into identifying the best possible Hamiltonian. To do this, we vary the terms in the Extended Heisenberg Hamiltonian - the neighbor spin coupling term J, the spin next-neighbor term J' and the spin ring exchange term Jring, where each variable represents a different electronic interaction. We then use the variational approach to find the best groundstate wavefunction for each Hamiltonian. Once we find the best groundstate wavefunction for each Hamiltonian, we can deduce the magnetization predicted by that model. Hence, by comparing our results for the magnetization to known experimental results, we can identify the most suitable model.

5:18PM D40.00015 Quantum Criticality and Neutron Scattering Solutions for a Spin-1/2 Ladder Model

JUSTIN COHEN, JEREMIAH BARRY, MARK MEISEL, University of Florida — Exact solutions for a two dimensional, S = 1/2 quantum spin ladder model are obtained through mapping the Hamiltonian and correlation functions onto those of a one dimensional Ising chain model [1]. These solutions include a three dimensional ground state phase diagram, establishing states of ladder rung singlets, triplets, and alternating singlets and triplets in terms of interaction parameters and applied magnetic field. Evidence of quantum criticality is uncovered for select regions of the phase diagram through explorations into ladder site correlations and correlation lengths. Neutron scattering solutions for scattering intensities provide insight into the energy spectra associated with various rung spin configurations.

This work was supported, in part, by the National Science Foundation via DMR-0701400 and grants for the NHMFL and UF Physics REU Summer 2007 Programs.

Session G1 APS: 25 Years of Scanning Probe Microscopy New Orleans Marriott Carondelet (3rd floor)

8:00PM G1.00001 Classical Computation in Quantum Nanostructures: A Long Road to an Uncertain Future

DONALD EIGLER, IBM Almaden Research Center — We have extended the spectroscopic abilities of the scanning tunneling microscope to include the measurement of spin-excitation spectra, making it possible to measure the g-value of single atoms. Utilizing spin-excitation spectroscopy as our primary tool, we are now capable of extracting exchange coupling energies, anisotropy energies, and information on the ground and excited state spin configurations of nanometer-scale structures. These experiments are playing an integral role in our efforts to engineer the "energy landscape" of a system of spins in order to achieve nanometer-scale binary logic circuits that operate using only the spin degree of freedom.

Work done in collaboration with Cyrus Hirjibehedin, Andreas Heinrich, Christopher Lutz, Jay Gupta, and Bruce Melior.
Magnetic Exchange Force Microscopy (MExFM), offers a powerful new tool to investigate different types of spin-spin interactions based on direct-, super-, or RKKY-type exchange down to the atomic level. By combining MExFM with high-precision measurements of damping forces, localized or confined spin excitations in magnetic systems of reduced dimensions now become experimentally accessible. Moreover, the combination of spin state read-out and spin state manipulation, based on spin-current induced switching across a vacuum gap by means of SP-STM [9], provides a fascinating novel type of approach towards ultra-high density magnetic recording without the use of magnetic stray fields.

Hole-Mediated Interactions

8:36AM H1.00002 Atom-by-Atom Substitution of Mn in GaAs and Visualization of their Hole-Mediated Interactions, ALI YAZDANI, Princeton Univ — No abstract available.

9:12AM H1.00003 Zero-field optical manipulation of magnetic ions in semiconductors1, ROBERTO C. MYERS2, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — For coherent spin information processing, spin coherence times must be long enough to perform multiple state operations, thus requiring a balance between gating time and spin lifetime. Because single magnetic spins in semiconductors can be strongly coupled to both itinerant carriers and to other magnetic ions, these interactions can be rapidly manipulated optically and electrically. We show that small numbers of magnetic spins in III-V GaAs quantum wells can be polarized by optical spin injection without the need for applied magnetic fields, and exhibit unusually long coherence times: Nm ions provide acceptor states within the bandgap of GaAs enabling optical readout and control of the magnetic ions in a manner distinct from paramagnetic II-VI materials. Spin polarized electrons created within the quantum well dynamically orient the Mn spins in a manner analogous to dynamic nuclear polarization, generating a dynamic exchange splitting of the magnetic spins. The Mn ions’ magnetic moments can be flipped from +1 to -1 by optical excitation and optical power densities as low as 100 mW/mm² are sufficient to invert the population. These results indicate that hole-mediated Mn-Mn interactions dominate the decoherence, and suggest that long lifetimes may be expected for single Mn spins in GaAs.

8:36AM H2.00002 From high Tc superconductivity to quantum spin liquids, PATRICK A. LEE, MIT

The underdoped cuprates exhibit many unusual properties going under the name pseudogap. These observations lend support to the notion that high Tc superconductivity is intimately tied to doping of a Mott insulator. Building on earlier work on the quantum spin liquid, the resonating valence bond (RVB) idea of Anderson provides an adequate physical understanding of the pseudogap. The problem can be formulated as a gauge theory even though many details are beyond the powers of current calculational tools. Part of the difficulty is that the pseudogap phenomenology occurs only at finite temperature where precise statements about excitations and possible emergent gauge fields cannot be made. Meanwhile the problem of the quantum spin liquid is a simpler version of the high Tc problem where significant progress has been made recently. It is understood that the existence of a matter field can lead to deconfinement of the U(1) gauge theory, and novel new particles such as fermionic spinons which carry spin 1/2 and no charge, and gapless gauge bosons can emerge in a new critical state at low temperatures. Two experimental systems, the organic compound and the Kagome lattice, have emerged as promising examples of a spin liquid. I shall argue that these may be described by a spinn Fermi surface and Dirac spinons coupled to a U(1) gauge field, respectively. Further experimental tests will be discussed.

— 9:12AM H2.00003 On the pseudogap in high temperature superconductors, ANDREW MILLIS, Department of Physics, Columbia University — The “pseudogap,” a suppression of the density of states observed in at least some high temperature copper-oxide superconductors at carrier concentrations lower than that which maximizes the superconducting transition temperature, presents a long-standing and still unresolved problem in condensed matter physics. Basic questions including whether it is a signature of a new phase of matter or a consequence of thermal or quantal disordering of a superconducting or spin density wave state, remain unresolved. This talk will summarize the present status of the problem, including what is known about the form of the low temperature gap function (one gap or two), the role of thermal scattering in the formation of “fermi arcs” and the significance of recent recent high-field quantum oscillation experiments.

References:

— Second round of contributed talks: 9:48AM H2.00004 Superconductivity, quasi-particle dynamics and strong-coupling physics, JOERG SCHMALIAN, Ames Laboratory, Iowa State University — I discuss the problem of superconductivity from the perspective of pairing mediated by a boson and compare with the situation of “no-glue” superconductivity in a strongly correlated material. This is done for Ti-doped PbTe, where recent experiments support superconductivity due to quantum valence (charge Kondo) fluctuations, and for the doped Mott insulator SrCu2(BO3)2, where d-wave superconductivity emerges due to a reorganization of a valence bond crystal state. I discuss the implications of these results for high temperature superconductivity in the cuprates.

Tuesday, March 11, 2008 8:00AM - 11:00AM
Session H3 DPOLY: Polymer Physics Prize Morial Convention Center RO2 - RO3

8:00AM H3.00001 Polymer Prize Talk: Segmental Dynamics in Polymers: From Cold Melts to Aging and Stressed Glasses, STEVEN KIVELSON, Stanford

In the cold molten state they exhibit chemically-specific and strongly non-Arrhenius segmental relaxation which sets the time scale for the generic chain scale dynamics. In the amorphous solid or plastic state the temperature dependence of the alpha relaxation time changes, physical aging emerges, and a rich mechanical response occurs characterized by the dynamic yielding, strain softening and strain hardening processes. We have developed a statistical mechanical theory of activated segmental relaxation in cold melts by combining and extending methods of mode coupling, dynamic density functional and activated hopping theories. The approach is built on the concept of a confining nonequilibrium free energy which quantifies local dynamical constraints and the barrier hopping process. The localizing consequences of interchain caging forces are quantified by the amplitude of nanometer scale density fluctuations (compressibility) and backbone stiffness. Predictions for the kinetic glass and dynamic crossover temperatures, dynamic fragility, and thermal dependence of the segmental relaxation time are consistent with experiments. The theory has been generalized to treat alpha relaxation, physical aging, and nonlinear mechanical properties in the glass. The structural component of density fluctuations become (partially) frozen resulting in a crossover to Arrenhius relaxation. Physical aging is modeled based on a kinetic equation for collective density fluctuations. At intermediate time scales the relaxation time (shear modulus) grows as a power law (logarithmic) function of aging time with a temperature dependent exponent. Applied stress weakens dynamical constraints thereby accelerating relaxation and softening the elastic modulus. A constitutive equation has been constructed from which the temperature dependent dynamic yielding and mechanical response under constant strain rate, constant stress (creep), and other modes of deformation can be calculated. This work was done in collaboration with Drs. Kang Chen and Erica J. Saltzman.

and scanning tunneling probes. The change in dissipation of the device will translate into a magnitude change of the reflected signal. Non-dissipative devices
and non dissipative nanodevices can be measured in this way. Typical examples of dissipative devices are single electron transistors, quantum point contacts
with resonant circuits using rf and microwave techniques. We will review a number of nanodevices probed with rf and microwave methods, both dissipative
and non dissipative nanodevices. Such devices can be extremely sensitive sensors, but they typically operate at low temperatures and have high impedances.
These studies are motivated by a desire to understand properties of polymer nanocomposites where the role of particle/polymer segment interactions is
poorly understood but the state of particle dispersion is key to composite properties. In this talk I explore equilibrium and nonequilibrium phases of this system
and compare with extant theoretical approaches.

9:12AM H3.00003 Complex Fluid Microstructure, Rheology and Glass Transitions: Effect of Continuous Phase Molecular Weight , CHARLES ZUKOSKI, University of Illinois — The mechanical properties of suspensions depend dramatically on the suspension microstructure. Microstructure in turn depends on the nature of particle interaction potentials. For those systems that are thermodinamically activated there will be an equilibrium microstructure and thus equilibrium transport properties. One of the model systems used to understand the links between interactions, microstructure and transport properties is that of hard spheres suspended in a Newtonian continuous phase. This model system can be studied experimentally and direct comparisons made with model predictions. With the increase in particle volume fraction, if the particles cannot crystallize, the suspension forms a glass where long range self diffusion is essentially eliminated. The approach to the glass transition has been studied experimentally and agreement with models is strong. In this talk we discuss what changes as the continuous phase takes on a granularity where the continuous phase molecules have substantial degrees of freedom. In particular, we investigate the mechanics and microstructure of hard sphere suspensions in polymer melts. The particles are composed of silica while we use polyethelene glycols of different weights ranging from small degrees of polymerization through the entanglement molecular weight. These studies are motivated by a desire to understand properties of polymer nanocomposites where the role of particle/polymer segment interactions is poorly understood but the state of particle dispersion is key to composite properties. In this talk I explore equilibrium and nonequilibrium phases of this system and compare with extant theoretical approaches.

9:48AM H3.00004 Dynamics of fluids in complex environments , ARUN YETHIRAJ, University of Wisconsin — No abstract available.

10:24AM H3.00005 The Theta Point Of Long Flexible Polymer Chains: When Does It Exist?1 , K. BINDER, Institut für Physik, Johannes-Gutenberg-Universität Mainz, 55099 Mainz, Germany — The standard description of the conformation of a long flexible polymer coil in dilute solution implies a swollen state under good solvent conditions, while deterioration of solvent quality (by decrease of temperature) causes a (gradual) chain collapse below the Theta point. At the Theta point, the chain follows Gaussian statistics, apart from logarithmic corrections. Monte Carlo simulations of the bond fluctuation model will be discussed that provide evidence for a second scenario, where the chain experiences a first order transition from the swollen state to a dense solid phase, provided the range of effective attractive interactions is sufficiently short. This scenario then implies that in solution at finite concentration no vapor-liquid-like phase separation occurs. The analogy between this prediction and the behavior of some colloidal dispersions is discussed.

1In collaboration with W. Paul, F. Rampf, and T. Strauch.

Tuesday, March 11, 2008 8:00AM - 11:00AM – Session H4 DMP: Selected Applications Using Materials Science Morial Convention Center 206

8:00AM H4.00001 Integrated Functionality: Nanosensors , JOZEF T. DEVREESE, Theoretical Physics of the Solid State (TFVS), Universiteit Antwerpen, Belgium — Integrated nanosensors are nanostructured systems in which several sensors of different types have been integrated on a single platform including those sensitive to optical, magnetic, chemical, or biological stimuli [1,2]. Nanoparticle-based detector systems rely on the development of nanoparticles as sensing species. I discuss state-of-the-art nanosensors which are based on various advanced materials: nanoshells and nanorice, gold nanoparticles with attached fluorescent dyes, nanopores, carbon nanotubes, neuroelectronic hybrid systems, semiconductor nanocrystals and quantum-dot quantum wells (QDQW’s). Phonon-assisted optical processes in semiconductor nanocrystals and QDQW’s are highly sensitive to their shape and geometry i. a. due to the non-adibaticity of the exciton-phonon systems. This sensitivity opens new perspectives for applications of quantum dots in optical sensing. For example, the simultaneous consideration of the tetrahedral shape of a CdS/HgS/CdS QDQW, interface optical phonons, and non-adibatic phonon-assisted transitions allows for control of the photoluminescence of a QDQW [3]. Quantum-dot-based systems are also considered as examples of communication with nanodevices, which is a prerequisite of their integration. Nanosensors allow for building a new class of integrated devices, which provide the elemental base for “intelligent sensors” capable of data processing, storage and analysis. The development of integrated nanosensors could have many applications in several fields such as process monitoring, robotics, environmental, medical, consumer, homeland security... [1] I. K. Schuller, http://nanosensors.ucsd.edu/Introduction.htm. [2] J. T. Devreese and Y. Bruynseraede, Integrated Nanosensors. McGraw-Hill 2008 Yearbook of Science & Technology, McGraw-Hill, 2008. [3] V. A. Fonoberov, E. P. Pokatilov, V. M. Fomin, and J. T. Devreese, Phys. Rev. Lett. 92, 127402 (2004).

8:36AM H4.00002 ABSTRACT WITHDRAWN —

9:12AM H4.00003 Nanodevice sensors measured with rf- and microwave reflectometry1 , PER DELSING, Chalmers University of Technology — Nanodevices can be extremely sensitive sensors, but they typically operate at low temperatures and have high impedances. This makes it hard to measure these devices at high frequencies, however this problem can be overcome by impedance matching these devices with resonant circuits using rf and microwave techniques. We will review a number of nanodevices probed with rf and microwave methods, both dissipative and non dissipative nanodevices can be measured in this way. Typical examples of dissipative devices are single electron transistors, quantum point contacts and scanning tunneling probes. The change in dissipation of the device will translate into a magnitude change of the reflected signal. Non-dissipative devices like parametric capacitances or inductances of superconducting circuits give rise to a shift in the resonance frequency of the resonant circuits which results in a phase shift of the reflected signal. Using these methods drastically increases the operation frequency and often also the sensitivity of the measured quantity. The non dissipative devices also have very low back-action and can potentially approach the limits set by quantum mechanics.

1Work in collaboration with Christopher Wilson, Timothy Duty, Jonas Bylander, Sergey Kafanov, Martin Sandberg, Fredrik Persson, Martin Gustavsson, and Simon Abay.
Materials Informatics: Using machine learning techniques with large amounts of ab-initio computed or experimental data, GERBRAND CEDER, Massachusetts Institute of Technology — Machine learning techniques can be applied to large amounts of experimental or computed materials data in order to identify the underlying factors that determine a target property. While the use of experimental data is complicated by the fact that it is mostly non-standardized in property or structure databases, experimental data still tends to be richer in information than computed data. One problem that can be addressed with machine learning techniques is the prediction of structure. By using structure prototype as a mathematical descriptor, and constructing its correlation in chemical spaces through machine learning techniques, it is possible to create a highly effective structure prediction method. Previously, we demonstrated that by simply applying maximum entropy ideas to a large experimental structure database of binary metals, it was possible to suggest a short list of candidate structures for new compounds which contains the proper ground state with very high probability [Ref]. This list of probable structures can then be computed with ab initio energy methods. We have now extended this method to multi-component and non-metal systems by prototyping the ≈ 100,000 structure records in the International Crystallographic Structure Database, and a similar accuracy of prediction is achieved in these high component spaces. We believe that such a machine learning approach solves the crystal structure prediction for many practical purposes. Machine learning techniques can also be used to point at likely errors in experimental structure databases and I will give some examples. In the long-term computed data is more likely to form the input for machine learning techniques as it is well defined and obtained under controlled conditions. Using high-throughput ab-initio computing techniques we have determined the structure and energy for several thousand compounds and have begun to data mine this information for property models relevant to energy generation and storage.

Tuesday, March 11, 2008 8:00AM - 10:24AM – Session H5 DCMP: CeMn5 (115) Heavy Electron Materials: A Rosetta Stone for the Kondo Lattice? Morial Convention Center R01

8:00AM H5.00001 Angle-resolved Photoemission of CeCoIn₅: Detailed Comparison to LDA and LDA+DMFT, J.W. ALLEN, University of Michigan — Highly-activated photon-dependent angle resolved photoemission spectroscopy (ARPES) in the energy range of 80-200 eV has been used to characterize the three dimensional (3D) Fermi surface (FS) topology and electronic band structure of cleaved single crystals of CeCoIn₅. The sample temperature of ≈ 20K is well below the lattice coherence onset temperature at ≈ 45K found in a recent "two fluid" analysis of transport data. Detailed comparison of ARPES FS contours to LDA calculations for the Ce 4f electrons treated as itinerant or confined to the core reveals remarkable agreement to fine topological details of the f-core calculations. Also in agreement to the f-core calculations is the experimental absence of extra electron-like contours predicted in the f-itinerant calculation, originating from α and β bands re-enterant below E_F along Z-A. Finally, the areas enclosed by FS contours for the α and β bands are significantly smaller than are found in very low temperature CeCoIn₅ de Haas van Alphen data that agrees generally with the f-itinerant calculation. It is concluded that clear signatures of coherence in the transport data can develop at temperatures for which the f-electrons are not yet included in the FS. In this connection, comparison will also be made to recent DFT-LDA+DMFT calculations for CeIrIn₅. This work was done in collaboration with J. D. Denlinger, Peng Wang, R. S. Singh, K. Rossnagel, S. Elgazzar, P. M. Oppeneer, V. S. Zapf and M. B. Maple. and was supported by the U.S. DOE (DE-AC02-98CH10886 and the ALS) and NSF (DMR-04046105 at UCSD), by the U.S. NSF (DMR-03-02825 at UM for initial work, DMR-03-35173 at UCSD) and by the Swedish Research Council (VR) and the European Commission (JRC-ITU).

8:36AM H5.00002 Modeling the Localized to Itinerant Electronic Transition in the Heavy Fermion System CeIrIn₅, KRISTJAN HAULE, Rutgers University — Within the ab-initiation calculation we adress the crossover from localized itinerant state of a heavy fermion material CeIrIn₅. The temperature evolution of the one electron spectra and the optical conductivity is predicted from first principles. The buildup of coherence in the form of a dispersive many body feature is followed in detail and its effects on the conduction electrons of the material is revealed. We find multiple hybridization gaps and link them to the crystal structure of the material. Our theoretical approach explains the multiple peak structures observed in optical experiments and the sensitivity of CeIrIn₅ to substitutions of the transition metal element and may provide a microscopic basis for the more phenomenological descriptions currently used to interpret experiments in heavy fermion systems.

9:12AM H5.00003 Andreev reflection in heavy fermions and the superconducting order parameter in CeCoIn₅, WAN KYU PARK, Department of Physics and the Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign — Andreev reflection, a retro-reflection of an incoming electron as a hole at a normal-metal/superconductor interface, is well understood in conventional superconductors. However, Andreev reflection in heavy-fermion superconductors, the microscopic consequences of the heavy electronic mass remain an open question. According to the Blonder-Tinkham-Klapwijk (BTK) theory, no Andreev process is allowed because of the large mismatch in the Fermi velocities [1]. However, conductance enhancement due to Andreev reflection, albeit reduced, has been frequently observed in heavy-fermion superconductors [2]. In this talk, I will present such conductance spectra obtained along three different crystallographic orientations of the heavy-fermion superconductor CeCoIn₅ [3]. Qualitative analysis using the extended BTK model shows the first spectroscopic evidence for dₓ²−ᵧ²-wave (instead of dₓᵧ-wave) symmetry, resolving the controversy over the node locations. In order to explain the reduced Andreev signal and the conductance asymmetry, both commonly observed in heavy-fermion superconductors, we propose a conductance model based on the two-fluid phenomenology [4] and an assumed energy-dependent density of states. I will discuss the significance of this model and possible clues for developing it into a microscopic theory. [1] G. E. Blonder, M. Tinkham, and T. M. Klapwijk, Phys. Rev. B 25, 4515 (1982); [2] G. E. Blonder and M. Tinkham, Phys. Rev. B 27, 112 (1983); [3] Y. G. Naidyuk and I. K. Yanson, J. Phys.: Condens. Matter 10, 8905 (1998); [4] W. K. Park et al, arXiv:0709.1246 (submitted to Phys. Rev. Lett.).
of passive and active microrheology. Measured the dynamics and mechanical properties of a simple three-component model system, consisting of myosin II, actin filaments, and crosslinkers. Stresses forces using their mechanical framework, the cytoskeleton, which is a non-equilibrium, composite material including polymers and motor proteins. We have, CHRISTOPH SCHMIDT, Georg-August-Universität, Fakultät für Physik, III. Physikalisches Institut — Cells both actively generate and sensitively react to

8:36AM H6.00002 Tornadoes and Severe Thunderstorms: Physical Understanding and Climate Questions, HAROLD BROOKS, National Severe Storms Laboratory — Severe thunderstorms (those that produce large hail, high winds and/or tornadoes) are of importance because of the threat to life and property they pose. This talk will review our understanding of the physical processes that lead to them and their distribution in time and space. The basic approach follows that of weather forecasting, focusing on the atmospheric “ingredients” in the environment necessary to produce severe thunderstorms and tornadoes, particularly the thermodynamic state of the atmosphere and the organizing effects of vertical wind shear that leads to the most severe storms. We will look at the challenges of reconciling our limited reporting databases of events and our physical expectations derived from the distribution of those environmental conditions. Consistent (and inconsistent) aspects of the various databases around the world will be discussed with their implications for what we can and cannot say about the basic physical processes. Of particular interest is the record from the United States. Some simple efforts to deal with the spatial and temporal inhomogeneities in the observational record will be developed with the limits that are implied on our ability to detect past changes. Finally, the talk will close with a discussion of the possible effects of anthropogenic global warming on severe thunderstorms, particularly in the United States. Global climate model studies of this problem are very recent, with the first peer-reviewed results appearing in 2007. The limitations of the climate models and possible scenarios for the future will be discussed.

9:12AM H6.00003 Factors Influencing Hurricane Surges along the Louisiana-Mississippi Coast, DONALD T. RESIO, U.S. Army Engineer Research and Development Center — The effects of recent hurricanes along U.S. Coastlines, along with expected future sea level rise and the potential for increased storm activity all point to a critical need for improved methods for estimating coastal hazards and associated risks. Many of the models used today to assess hazards and risk incorporate considerable empiricism in their formulation. Unfortunately, most of the empirical evidence is drawn from small to moderate storm events and cannot be effectively extrapolated to extreme storms such as Hurricane Katrina. This presentation will critique the state of the art in hurricane surge prediction, including the adequacy of numerical models, coefficients within these models, and the wind fields utilized to force them. Once the predictive system and its physical basis are introduced and discussed, a methodology will be described for utilizing information from such a system to estimate risk for coastal areas, including the effect of uncertainties in both the modeling system and storm climate. Using the methodology introduced here, maps of estimated storm surge levels for selected recurrence intervals in the New Orleans area will be presented along with a comparison to some previously derived values to provide perspective.

9:48AM H6.00004 Wetland Loss and Restoration Options in Southern Louisiana, ROBERT G. DEAN, University of Florida — Wetlands are productive landscape features of the broad Mississippi River Delta system. In addition to their ecological services of providing habitats for a variety of species including juvenile commercial and recreational fish, they provide a valuable wave reduction role during severe storm events characterized by elevated water levels and high waves. Currently, these wetlands are stressed by a combination of natural and human-related forces resulting in rapid loss rates. Although many factors contribute to wetland loss rates, the single greatest factor is the shunting of river borne sediments offshore into deep water. Navigational interests benefit greatly from the present fixed location of the main navigation channel at Southwest pass with its terminus at the edge of the continental shelf such that the sediment load is discharged into deep water. The Mississippi River Delta region is subsiding at up to more than 10 times the Eustatic rate of sea level rise and thus the wetland and barrier island systems require these sediments for maintenance and growth. With the increasing scarcity and costs of energy, it is highly desirable that wetland restoration be done using natural forces to the degree possible. Absent legal issues, a pragmatic approach could be to identify those areas where progress can be made with realistic investments of economic and energy resources and to accept that areas with less benefit per investment will continue to degrade. The paper will review various options and discuss obstacles and opportunities.

Tuesday, March 11, 2008 8:00AM - 11:00AM —

Session H7 DBP DPOLY: Complex Active Biomaterials: Mechanics and Microrheology Morial Convention Center R05

8:00AM H7.00001 Non-equilibrium mechanics of motor-driven cytoskeletal polymer networks, CHRISTOPH SCHMIDT, Georg-August-Universität, Fakultät für Physik, III. Physikalisches Institut — Cells both actively generate and sensitively react to forces using their mechanical framework, the cytoskeleton, which is a non-equilibrium, composite material including polymers and motor proteins. We have measured the dynamics and mechanical properties of a simple three-component model system, consisting of myosin II, actin filaments, and crosslinkers. Stresses arising from motor activity control network mechanics: both increasing stiffness by a factor of nearly 100 and qualitatively changing the viscoelastic response of the network in an ATP-dependent manner. We have quantified the mechanical properties as well as the active fluctuations in these networks by a combination of passive and active microrheology.
8:36AM H7.00002 Non-equilibrium mechanics and dynamics of active gels and living cells. FRED
MACKINTOSH, Vrije Universiteit — Much like the bones in our bodies, the cytoskeleton consisting of filamentous proteins largely determines the mechanical response and stability of cells. Such important cellular processes as locomotion, cell division, and mechanosensing are largely governed by complex networks of cytoskeletal biopolymers and associated proteins that cross-link these and/or generate forces within the network. In addition to their important role in cell mechanics, cytoskeletal biopolymers have also provided new insights and challenges for polymer physics and rheology. In the cell, however, these polymer networks or gels are far from equilibrium in a way unique to biology: they are subject to active internal force generation by molecular motors. We describe recent theoretical and experimental results on active in vitro networks that demonstrate significant stiffening and non-equilibrium fluctuations due to motor activity [1]. We show how this activity leads generically to a colored, 1/ω spectrum of force fluctuations, which can account for surprisingly Brownian-like motion in elastic networks. We also discuss how the fluctuations of individual cytoskeletal filaments can be used to probe both mechanical properties and non-equilibrium activity in living cells [2].

9:12AM H7.00003 Cytoskeletal mechanics: Structure and Dynamics. ANDREAS BAUSCH, Technische
Universität München — The actin cytoskeleton, a dynamic network of semiflexible filaments and associated regulatory proteins, is responsible for the extraordinary viscoelastic properties of cells. Especially for cellular motility the controlled self assembly to defined structures and the dynamic reorganization on different time scales are of outstanding importance. A prominent example for the controlled self assembly are actin bundles: in many cytoskeletal processes cells rely on the tight control of the structural and mechanical properties of the actin bundles. Using an in vitro model system we show that size control relies on a mismatch between the helical structure of individual actin filaments and the packing symmetry within bundles. While such self assembled structure may evoke the picture of a static network the contrary is the case: the cytoskeleton is highly dynamic and a constant remodeling takes place in vivo. Such dynamic reorganization of the cytoskeleton relies on the non-static nature of single actin/ABP bonds. Here, we study the thermal and forced unbinding events of individual ABP in such in vitro networks. The binding kinetics of the transient crosslinkers determines the mechanical response of such networks – in the linear as well as the non-linear regime. These effects are important prerequisites for the high adaptability of cells and at the same time might be the molecular mechanism employed by them for mechanosensing.

9:48AM H7.00004 Micro rheology in Active Cytoskeletal Networks. ALEX LEVINE, UCLA, Department of
Chemistry & Biochemistry — The mechanics of the in vivo cytoskeleton is controlled in part by the details of its non-equilibrium steady-state. In this "active" material, molecular motors (e.g. myosin) exert transient contractile stresses on the F-actin filament network, driving it into a particular non-equilibrium state. Since micro rheology traditionally relies on the linear response properties of the soft materials in thermal equilibrium, this departure from equilibrium has profound implications for the interpretation of rheological properties from the interior of living cells and in vitro active networks. In active networks, such as the in vitro systems of Mizuno et al. [Science 315 (5810) pp. 370-373 (2007)] and in living cells, the underlying theoretical foundation of the interpretation of microrheology – the Fluctuation-Dissipation theorem – does not apply. New ideas are needed. In this talk, I review micro rheology, and then discuss a new theoretical interpretation of microrheology in active (i.e. molecular motor driven) networks. To develop this theory, I introduce a motor-driven, two-fluid model of the active network and background (aqueous) solvent. Using this model and knowledge of the statistical properties of the molecular-motor induced forces, I calculate the non-equilibrium fluctuation spectrum expected for single- and two-particle micro rheology in the driven system. I then compare these results to the data of Mizuno et al..

10:24AM H7.00005 Force fluctuations and polymerization dynamics of intracellular microtubules. CLIFFORD BRANGWYNE, Max Planck Institute — Microtubules are dynamic biopolymers within the cytoskeleton of living cells. They play a central role in many biological processes including cell division, migration, and cargo transport. Microtubules are significantly more rigid than other cytoskeletal biopolymers, such as actin filaments, and are insensitive to thermal fluctuations on cellular length scales. However, we show that intracellular microtubules exhibit bending amplitudes with a surprisingly thermal-like wavevector dependence, but with an apparent persistence length about 100 times smaller than that measured in vitro. By studying the time-dependent bending fluctuations of individual filaments, we find that the thermal-like bends are fluctuating significantly only on short length scales, while they are frozen-in on longer length scales [1], reminiscent of non-ergodic behavior seen in systems far from equilibrium. Long wavelength bends are suppressed by the surrounding elastic cytoskeleton, which confines bending to short length scales on the order of a few microns [2]. These short-wavelength bending fluctuations naturally cause fluctuations in the orientation of the microtubule tip. Tip fluctuations result in a persistent random walk trajectory of microtubule growth, but with a small non-equilibrium persistence length, explaining the origin of quenched thermal-like bends. These results suggest that intracellular motor activity has a highly fluctuating character that dominates over thermal fluctuations, with important consequences for fundamental biological processes.

Tuesday, March 11, 2008 8:00AM - 11:00AM
Session H8 DFD: Focus Session: Glassy Dynamics in Colloids
Morial Convention Center RO6

8:00AM H8.00001 Are colloidal and molecular glass formation related? JOHAN MATTSSON, Chalmers
University of Technology — Understanding why and how a glass is formed on a microscopic level remains an outstanding problem in condensed matter physics. A molecular glass is normally formed by cooling of a liquid. Upon entering the supercooled state, the structural dynamics slows down dramatically and eventually the liquid enters the non-equilibrium glassy state. On route towards the glass, the behaviour shows a range of highly general, near universal characteristics, such as stretched exponential behaviour of dynamic correlation functions and cooperative dynamics. Such generalities exist even though molecular glasses can be formed from liquids encompassing a wide range of molecular structures and interactions. Glass formation also occurs in altogether very different systems. One of the most interesting, both from a fundamental and an applications point of view, is that of colloidal suspensions. There, the binding kinetics of the transient crosslinkers determines the mechanical response of such networks – in the linear as well as the non-linear regime. These effects are important prerequisites for the high adaptability of cells and at the same time might be the molecular mechanism employed by them for mechanosensing.

8:36AM H8.00002 Applications of patchwork dynamics for glassy systems. CREIGHTON THOMAS, ALAN MIDDLETON, Syracuse University, OLIVIA WHITE, MIT — We present work on “patchwork dynamics” as a technique for studying the nonequilibrium properties of glassy systems. In patchwork dynamics, we replace local Monte Carlo simulations, which require exponentially long times to equilibrate at a given length scale, with exact equilibration on patches at a given length scale, which can be done rapidly in models such as the 2D Ising spin glass and disordered dimer models. We have demonstrated some interesting applications of patchwork dynamics to such systems: 1) as a heuristic ground state algorithm for the 2D Ising spin glass on a torus (for which there are no known fast exact algorithms) and the 3D Ising spin glass; 2) as a method to study aging effects, persistence, and memory in 2D and 3D Ising spin glasses; 3) as a sampling procedure to study the nonequilibrium properties of disordered dimer models at finite temperatures.
8:48AM H8.00003 Aging of a Binary Colloidal Glass , JENNIFER M. LYNCH, GIANGUO C. CIANCI, ERIC R. WEEKS, Department of Physics, Emory University — After having undergone a glass transition, a glass is in a non-equilibrium state, and its properties depend on the time elapsed since vitrification. We study this phenomenon, known as aging. In particular, we study a colloidal suspension consisting of micron-sized particles in a liquid — a good model system for studying the glass transition. In this system, the glass transition is approached by increasing the particle concentration, instead of decreasing the temperature. We observe samples composed of particles of two sizes \( d_1 = 1.0 \mu m \) and \( d_2 = 2.0 \mu m \) using fast laser scanning confocal microscopy, which yields real-time, three-dimensional movies deep inside the colloidal glass. We then analyze the trajectories of several thousand particles as the glassy suspension ages. Specifically, we look at how the size, motion and structural organization of the particles relate to the overall aging of the glass. We find that areas richer in small particles are more mobile and therefore contribute more to the structural changes found in aging glasses.

9:00AM H8.00004 Structural signatures of dynamical heterogeneity in supercooled liquids , HEIDI PERRY, DAVID REICHMAN, Columbia University, Department of Chemistry — The underlying mechanism of the transition from liquid to glass is a long-standing open question in condensed matter physics. One long sought after clue to understanding the glass transition is a link between the structure and dynamics of a vitrifying fluid. The dynamics of a supercooled liquid near the glass transition have proven to be collective and heterogeneous, with the length scale of the dynamic regions increasing as the glass transition temperature is approached. Using computer simulations and a normal mode analysis, we demonstrate a link between the structural properties of a super-cooled liquids and the collective dynamical regions.

9:12AM H8.00005 ABSTRACT WITHDRAWN —

9:24AM H8.00006 Fluctuations in the aging regime of a polymer glass\(^1\) , AZITA PARSAEIAN, HORACIO E. CASTILLO, Department of Physics and Astronomy, Ohio University — We perform numerical simulations to investigate the fluctuations in the aging regime of a system of polymers which are interacting via the Lennard-Jones potential. We characterize how the fluctuations evolve by studying (i) probability distributions of local observables such as individual particle displacements \( \Delta x \) and intermediate scattering functions \( C_\ell \) associated with small regions and (ii) dynamic correlation functions such as the four-point density correlation \( g_4(\mathbf{r},t,\mathbf{r},t) \). We find that, similar to small molecule glasses, the probability distributions of local observables approximately collapse when the global two-time correlation \( C_{\text{global}}(t,\mathbf{r},t) \) is held fixed. We test for universality by comparing the probability distributions in the small molecule glass with those in the polymer glass.

\(^1\)Work supported in part by DOE under grant DE-FG02-06ER46300 and by Ohio University.

9:36AM H8.00007 Equipartition theorem in glasses and liquids , VALENTIN A. LEVASHOV, TAKESHI EGAMI , University of Tennessee, RACHEL S. AGA , JAMES R. MORRIS, Oak Ridge National Laboratory — In glasses and liquids phonons have very short life-time, whereas the total potential energy is not linear with temperature, but follows the \( T^{3/5} \) law. Thus it may appear that atomic vibrations in liquids cannot be described by the harmonic oscillator model that follows the equipartition theorem for the kinetic energy and potential energy. We show that the description of the nearest neighbor oscillation in terms of the atomic level stresses indeed provide such a description. The model was tested for various pair-wise potentials, including the Lennard-Jones potential, the Johnson potentials, and only the repulsive part of the Johnson potential. In all cases each of the local elastic energies of the six independent components of the stress tensor is equal to \( kT/4 \), thus the total potential energy is equal to \( (3/2)kT \). Thus this model provides the basis for discussing the thermodynamic properties of glasses and liquids based on atomic excitations. An example of this model leading to the description of the glass transition temperature in metallic glasses is discussed [1].

9:48AM H8.00008 Exceptionally Stable Organic Glasses with Low Enthalpy and High Kinetic Stability Prepared by Vapor Deposition , KENNETH L. KEARNS, STEPHEN F. SWALLEN, M.D. EDIGER, Department of Chemistry, University of Wisconsin-Madison, YE SUN, TIAN YU, LIAN YU, School of Pharmacy, University of Wisconsin-Madison — Vapor deposition can be used to prepare glasses of 1,3,5-(tris)naphthylbenzene (TNB) and indomethacin (IMC) that are much more stable than those created by cooling from the liquid. By vapor deposition we have also been able to create glasses of 1,3,5-(tris)naphthylbenzene (TNB) and indomethacin (IMC) that are much more stable than those created by cooling from the liquid.

10:00AM H8.00009 Magnetic Analogies for the Dynamics of Glass Forming Liquids , JACOB STEVENSON, PETER WOLYNES, University of California San Diego — We present a direct mapping between the dynamics of glass forming liquids and a general random field / random coupling Ising model using the replica effective potential approach. Using the overlap between two structural states of a supercooled liquid we construct a constrained overlap free energy that can be mapped directly onto that of an Ising Hamiltonian. For a Lennard-Jones glass the fluctuations and mean values of the random fields and interactions place it within the universality group of the random field Ising spin glass, not the Ising spin glass. This corresponds with the explanation for a random first order transition.

10:12AM H8.00010 Direct imaging of particle dynamics in attractive colloidal glasses\(^1\) , PIOTR HABDAS, ANDRZEJ LATKA, Department of Physics, Saint Joseph’s University, YILONG HAN, Physics Department, Hong Kong University of Science and Technology, AHMED ALSAYED, ARJUN G. YODH, Department of Physics and Astronomy, University of Pennsylvania — We use confocal and fluorescent microscopy to study the dynamics of glassy colloidal suspensions. The suspensions are composed of PMMA colloidal particles in density and index-of-refraction matched liquid and stained with a fluorescent rhodamine dye. A controllable depletion attraction is induced between hard-sphere PMMA particles by adding different amounts of polystyrene polymer to the suspension. Our dynamical measurements focus on jumps experienced by PMMA particles that escape the cage formed by its neighbors. We track these particles over time and correlate particle fluctuations with its changes in average position. We find that as the strength of the attractive potential increases, and the system enters an "attractive liquid" phase, the number of jumping particles increases. We calculate the distribution of particle jump sizes, time between jumps, and spatial distribution of particle jumps; these observations are compared to predictions of molecular dynamics simulations.

\(^1\)This research was supported by an award from Research Corporation.
much more work possibly remains to be done in this important area of space physics. S. Sen et al. Phys. Rev. Lett. 88, 185001 (2002). This article therefore concludes while much work has been done on the ionospheric oscillations much more work possibly remains to be done in this important area of space physics.

10:36AM H8.00012 Accentuated shear thinning of soft sphere suspensions, HANS M. WYSS, Harvard University, JOHAN MATTSSON, Chalmers University of Technology, Sweden, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology, GIOVANNI ROMEO, University of Naples Federico II, Italy, MELAKU MULUNE, Harvard University, ZHIBING HU, University of North Texas, DAVID A. WEITZ, Harvard University — Suspensions of soft colloidal particles exhibit highly unusual rheological behaviors; surprisingly, despite the importance of these materials in a wide range of applications, the underlying physical mechanisms remain poorly understood. Experiments show that suspensions of soft particles exhibit a highly pronounced shear thinning; this decrease in viscosity with increasing shear rate far exceeds the shear thinning observed in suspensions of solid particles. We use soft microgel particles as a model system to elucidate this behavior. Our experimental system allows us to study the mechanical behavior both macroscopically and locally, at the scale of the colloidal particles themselves. We combine data obtained at different length scales to arrive at a simple picture of the observed accentuated shear thinning.

10:48AM H8.00013 Investigation of Rejuvenation and Overaging in Glassy Energy Landscapes, MYA WARREN, JOERG ROTTLER, University of British Columbia — Many glassy systems experience a change in their aging dynamics under the influence of mechanical load. It has long been known that large stresses can cause an apparent decrease in relaxation times (rejuvenation) in polymer glasses, but in colloidal glasses an increase (overaging) has also been observed depending on the strain amplitude. The conditions under which rejuvenation or overaging occur are not yet fully understood. Additionally, there is still considerable controversy over the nature of the resultant states. In order to gain intuition on these outstanding questions, we investigate the aging dynamics under load though stochastic simulations of the Soft Glassy Rheology (SGR) model. For both stress controlled and strain controlled loading, the SGR model exhibits clear regions of overaging and rejuvenation in a parameter space defined by the noise temperature, the quench history, and the strain. Additionally, results show that the states produced under loading are distinct from those that would naturally be visited during aging, and this has effects on the subsequent aging trajectory. Results from the energy landscape picture are compared to pertinent molecular dynamics studies.

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H9 DFD: Instabilities and Fluid Dynamics Morial Convention Center R07

8:00AM H9.00001 Low Frequency Oscillations in the Upper Atmosphere, SUDIP SEN, Kyoto University, Japan & Delhi University, India — No definitive theory exists which explains the origin of various low frequency oscillations observed in the ionosphere. Various authors, over the course of time, have put forward various explanations of this important phenomenon. Most recently it has been proposed that the spatial transverse shear in the parallel flow destabilizes many low frequency oscillations and this may be the origin of low frequency oscillations in the ionosphere [V Gavrishchaka et al., Phys. Rev. Lett. 85, 185001 (2002)]. In this article we review the various theories proposed till date to explain the origin of low frequency oscillations. We address the most recent theories in more detail. We show that the recent proposition of the spatial transverse shear may excite many instabilities may not be so obvious. Parallel flow curvature when taken into account might actually act to stabilize various instabilities [S. Sen et al. Phys. Rev. Lett. 88, 185001 (2002)]. This article therefore concludes while much work has been done on the ionospheric oscillations much more work possibly remains to be done in this important area of space physics.

8:12AM H9.00002 Capillary-controlled instability in immiscible, parallel flow in porous media, THOMAS RAMSTAD, ALEX HANSEN, Department of Physics, NTNU, N-7491 Trondheim and Numerical Rocks AS, Stiklestadaveien 1, N-7041 Trondheim, Norway — When two immiscible fluids flow in parallel in a strongly wetted porous medium the global interface separating them tend to be kept in place by local capillary barriers. However, above a certain threshold in the flow rate, the separating interface may become unstable and mobilized. We study this instability theoretically by using a two-dimensional network as a model for porous media in a flow regime where capillary forces cannot be neglected. It is found that a boundary zone with a sharp saturation profile occurs between the regions originally saturated with either a wetting or a non-wetting phase. This zone has a well defined width and moves with constant speed towards the non-wetting region. In the opposite direction, a current of non-wetting bubbles is set up, but wetting bubbles into the non-wetting region are absent. This behavior is genuinely different from shear-induced Kelvin-Helmholtz instabilities.

1Supported by the Norwegian Research Council

8:24AM H9.00003 Stability of multi-layer Hele-Shaw flows with and without diffusion, PRABIR DARIPA, Texas A&M University — In this talk, we will provide some results in the context of multi-layer Hele-Shaw flows. We will address issues related to collective effects of individually unstable interfaces on the overall stability of multi-layer Hele-Shaw flows in the presence of interfacial surface tensions. We will also discuss complications in the analysis resulting from making, in the above set-up, individual layers also unstable. We obtain some sufficient conditions for suppressing instability of two-layer flows by introducing arbitrary number of constant viscosity fluid layers in between. For stabilization purposes, this condition allows selection of fluids in internal layers based on interfacial surface tensions and viscosities of fluids. Time permitting, we also examine the effects of species diffusion on the stability of the three-layer Hele-Shaw flows. This has relevance to enhanced oil recovery by polymer flooding. Analytically, we will prove the diffusive slow-down of unstable waves. It will be shown that a strong enough diffusion can almost stabilize the flow, though the magnitude of this diffusion coefficient required to completely stabilize the flow will depend on the magnitude of interfacial viscosity jumps and the viscosity gradient of the basic viscous profile of the internal layer. This work has been done in collaboration with Gelu Pasa.
8:36AM H9.00004 Meandering instability of a rivulet on a partially wetting incline. ADRIAN DAERR1, MSC*, Denis-Diderot-University of Paris, LAURENT LIMAT2, MSC*, CNRS & Denis-Diderot-University of Paris — It is common to observe small rivulets in sinks or on window-panes which follow sinuous paths (stationary or not) instead of flowing down along the direction of steepest slope. A laboratory experiment shows that these meandering rivulets exist only for certain ranges of the control parameters (flow rate and substrate inclination). The geometrical properties of the resulting paths can be understood in terms of force balances between inertia, capillarity and contact line pinning. The nature of the instability, i.e. why the straight rivulet becomes unstable, however remains unclear. We study the rivulet near the onset for meandering to understand the role of noise and surface defects.

1CNRS UMR 7057
2CNRS CNRS 7057

8:48AM H9.00005 A quasi 2-D molecular dynamics study of the initiation and evolution of the Kelvin-Helmholtz instability. KYLE CASPERSEN, ROBERT RUDD, DAVID RICHARDS, JIM GLOSILI, Lawrence Livermore National Laboratory, JOHN GUNNELS, IBM, FREDRICK STREITZ, Lawrence Livermore National Laboratory — Typically hydrodynamic phenomena are modeled with continuum mechanics via integration of the Navier-Stokes (NS) equation or a closely related variant. However, as fluids are studied at smaller and smaller length scales atomistic effects can, and will, ultimately dominate; furthermore, even at micron scales it is not clear that the NS equation provides a complete description of the fluid, e.g. due to the initiation of instabilities at the molecular scale in initially quiescent fluids. To assess the effect of atomistic behavior on one particular hydrodynamic phenomenon—the Kelvin-Helmholtz instability—we have performed a very large molecular dynamics simulation of molten metals undergoing shear flow. Nine billion copper and aluminum atoms were sheared at a speed of 2000 m/sec for a total simulated time of more than a nanosecond. We present here results showing the initiation of the instabilities, the crossover to hydrodynamics, and the evolution and scaling behavior of the KH instability in a quasi 2-D geometry. Prepared by LLNL under Contract DE-AC52-07NA27344.

9:00AM H9.00006 A fully 3-D molecular dynamics study of the initiation of the Kelvin-Helmholtz instability. ROBERT E. RUDD, K.J. CASPERSEN, D.F. RICHARDS, J.N. GLOSILI, Lawrence Livermore National Laboratory, J.A. GUNNELS, IBM, F.H. STREITZ, Lawrence Livermore National Laboratory — The modeling of hydrodynamic phenomena has almost exclusively been the purview of continuum mechanics, specifically, through the use of the Navier-Stokes equation and closely related variants. Nevertheless, at the smallest length scales, where atomistic effects become important, it is not clear that this continuum approach provides a complete description of fluid behavior. To understand the effects of atomistics, we have performed a 62.5-billion-atom, fully 3-D molecular dynamics simulation of a cubic micron of molten copper and aluminum. The shear flow at 2 km/s exhibits complex phenomena associated with a Kelvin-Helmholtz (KH) instability. In this presentation we will discuss the initiation and early evolution of the KH instability, focusing specifically on the effects of full atomistic resolution.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory in part under Contract W-7405-Eng-48 and in part under Contract DE-AC52-07NA27344.

9:12AM H9.00007 Bubble Pinch-off at High Pressures. J.C. BURTON, R. WALDREP, and P. TABOREK, University of California, Irvine — Previously we have studied the pinch-off of conventional air bubbles in water [1]. For inviscid fluids, the shrinking of the neck radius of the bubble can be described by a power-law in time with an exponent close to 1/2. As the density of the interior gas is increased, instabilities are expected to occur in the liquid/gas interface [2]. We present high-speed videos and numerical simulations of the pinch-off of high-pressure gaseous bubbles in and exterior inviscid fluid. The density ratio between the exterior fluid and interior gas is $D=\rho_{ext}/\rho_{int}$. In the simple case of small $D\sim 0.001$, the pinch-off is similar to that of a water drop pinching-off in air, while at large $D\sim 1000$, the pinch-off is that of an air bubble in water. By using sulfur hexafluoride as a working gas, we are able to span a wide ranging of density ratios simply by increasing the pressure of the gas. A high-pressure (~30 atm) chamber with optical access through sapphire windows was constructed in order to view the pinch-off. The numerical simulations are performed assuming perfectly inviscid fluids using boundary-integral techniques. Instabilities in the interface are seen for intermediate density ratios. Comparisons between experimental and numerical results will be discussed.

9:24AM H9.00008 First order phase transition in the height of a meniscus in a tapered capillary. MICHAELA PETTERSEN, Washington and Jefferson College, ETIENNE ROLLEY, Laboratoire de Physique Statistique, Ecole Normale Superieure — When a fluid rises in a capillary of non-uniform cross section, additional terms arise in the balance of capillary forces, compared to the case of a capillary of uniform cross section, due to the changing area of the meniscus. Recently, it has been pointed out that this can lead to a first order phase transition, resulting in a discontinuous jump in the equilibrium position of the meniscus. We present the results of an experiment using isopropanol and silicone oil in cones with apex cross section, due to the changing area of the meniscus.

9:36AM H9.00009 Luminescence from Laser-Induced Bubbles in Water-Glycerol Mixtures: Effect of Viscosity1. ERIN ENGLERT, ALLISON MCCARN, GARY A. WILLIAMS, Dept. of Physics and Astronomy, UCLA — We have studied the luminescence emitted from collapsing laser-induced bubbles in water-glycerol mixtures, as a function of the mixture concentration and applied hydrostatic pressure. The primary effect of increasing the glycerol concentration is to increase the viscosity of the fluid. We find that the pulse duration of the luminescence increases by more than a factor of two as the concentration increases up to 33% by volume, where the viscosity is nearly four time that of pure water. At higher concentrations the pulse duration remains nearly unchanged, until no luminescence can be observed at concentrations above 60% (viscosity greater than 15 times that of water). The pulse duration further increases with applied pressures up to 8 bars, similar to that seen earlier in pure water.

H9.00011 A Temporal Period Doubling Route to Spatiotemporal Chaos in a System of Amplitude Equations for the Nematic Electroconvection

10:00AM H9.00011 A Temporal Period Doubling Route to Spatiotemporal Chaos in a System of Amplitude Equations for the Nematic Electroconvection1, JULIANA OPREA, GERHARD DANGELMAYR, Colorado State University — We analyze the transition from periodic solutions to spatiotemporal chaos in a system of four globally coupled Ginzburg Landau equations describing the dynamics of instabilities in the electroconvection of nematic liquid crystals, in the weakly nonlinear regime. If spatial variations are ignored, these equations reduce to the normal form for a Hopf bifurcation with O(2) x O(2) symmetry. Coexistence of low dimensional and extensive spatiotemporal chaotic patterns, as well as a temporal period doubling route to spatiotemporal chaos, corresponding to a period doubling cascade towards a chaotic attractor in the normal form, are also identified and discussed, for values of the parameters including experimentally measured values of the nematic I52.

H9.00012 Angular momentum transport in complex fluids1, XIAOYU ZHENG, Kent State University, PETER PALFFY-MUHORAY, Liquid Crystal Institute, KSU, MICHAEL SHELLEY, Courant Institute of Mathematical Sciences, NYU — When dyes are dissolved in nematic liquid crystals, the light intensity required for the optical Freedericksz transition can be dramatically decreased. This is due to the torque exerted by the dye on the liquid crystal. The dye molecules absorb light energy and rotate; torque balance is mediated by angular momentum transport from the cell walls via shear flow generated by the rotation [1]. We present a model which accounts for the transport of angular momentum caused by singular vortices present in these complex fluids. The singular vortices generate flow, and are transported by the flow which they generate. For simple fluids, the distribution of vorticity satisfies the biharmonic equation in the Stokes limit, which can be solved analytically. In the case of the non-Newtonian fluids, such as liquid crystals, Leslie-Ericksen continuum theory is used to describe the interactions between the rod-like molecules. [1] P. Palffy-Muhoray, T. Kosa and Weinan E, “Brownian Motors in the Photoalignment of Liquid Crystals”, Appl. Phys. A 75, 293-300 (2002).

H9.00013 Particle Dynamics in Bi-Disperse Liquid Fluidized Beds, PHIL SEGRE, Emory University Physics Dep, GARY L. HUNTER, JAMES DAVIDHEISER, ELIZABETH BAKER, Emory Univ. Physics Dep. — We study particle velocities and concentration profiles of mixtures of 2 different sized particles in concentrated liquid fluidized beds. For binary systems of particles of the same density, we find that there is always a complete phase separation in the bed. The larger particles occupy a zone in the lower part of the bed, and the smaller ones a zone in the upper part. For binary systems of particles of different density materials, conditions are found where the binary particles are either fully separated, partially mixed together, and at a single point called the inversion point, fully mixed into a one phase state. Results will be presented on the phase diagrams of several binary suspensions as well as the properties of the velocity fluctuation magnitudes and spatial correlation lengths.

H9.00014 Polygonal hydraulic jump on microtextured surfaces, EMILIE DRESSAIRE, LAURENT COURBIN, SEAS, Harvard University, JEROME CREST, Dept. of Mechanical Engineering, MIT, HOWARD A. STONE, SEAS, Harvard University — Fluid motion can be drastically influenced by the nature of boundaries. For instance, we have shown recently [1] that a substrate with a regular array of micron-size posts can cause partially wetting fluids to take on polygonal shapes. Here, we report on the hydraulic jump that occurs when a water jet impinges a topographically patterned surface, i.e. an array of micron-size posts arranged on square or hexagonal lattice. By varying the topographic features (shape and height of the posts, lattice distance) and the jet properties (size of the nozzle, flow rate), we obtain a variety of stable shapes including hexagons, eight corner stars and circles. We rationalize our results by taking into account a fluid velocity that depends on the orientation of the lattices.

H9.00015 Enstrophy-constrained stability analysis of beta-plane Kolmogorov flow with drag, YUE-KIN TSANG, WILLIAM YOUNG, Scripps Institution of Oceanography, UCSD — For forced two-dimensional flows, energy injected at a certain wavenumber is redistributed to both larger and smaller wavenumbers. This results in a constraint on the time evolution of the difference between the energy and enstrophy. By incorporating this constraint in an energy stability analysis of Kolmogorov flow on a beta-plane with drag, we establish an extended region in the parameter space of beta and the drag coefficient where the flow is stable to arbitrary perturbations. Complementary to this nonlinear stability result, linear instability theory is used to determine the part of the parameter space where the flow is unstable to infinitesimal perturbations. We also find that the most unstable mode in the linear stability analysis has a discontinuous change in structure as beta decreases below a certain value. Results from numerical simulations spanning the parameter space support the theoretical predictions.
