8:00AM H10.00001 Suppression of macroscopic quantum tunneling in a large Josephson junction coupled to a resonator\(^1\), BRAD TREES, Ohio Wesleyan University, JOSHUA SCHIFFRIN, Carnegie-Mellon University, YASER HELAL, Ohio Wesleyan University, BRIAN SILLER, University of Illinois at Urbana-Champaign — We calculated the zero-temperature macroscopic quantum tunneling rate of a current-biased Josephson junction weakly coupled to a resonator. We allow for the effects of environmental dissipation on both the junction and the resonator, and we consider both cases of weak and strong junction damping. We find that coupling to the resonator has a suppressive effect on the junction’s tunneling: the stronger the coupling strength between the junction and resonator, the greater the reduction of the tunneling rate. Including damping to the junction also suppresses tunneling, but damping the resonator partially counteracts the suppression provided directly by the junction-resonator coupling. Modeling the dependence of the junction-resonator coupling on the resonator’s frequency \( \omega_R \) in a power law fashion \( U_{int} \propto (\omega_R)^{n} \), we find that for \( 0 < n < 1 \) the tunneling rate exhibits a nonmonotonic dependence on \( \omega_R \), and for \( n = 1/2 \), the tunneling rate is maximally suppressed for \( \omega_R/\omega_1 \approx 1 \), where \( \omega_1 \) is the bias current-dependent plasma frequency of the junction.

8:12AM H10.00002 Identifying the Odd-Frequency Superconducting State by a Field-Induced Josephson Effect\(^1\), JACOB LINDER, Norw Univ of Sci & Tech, TAKEHITO YOKOYAMA, University of Nagoya, ASLE SUDBO, Norw Univ of Sci & Tech — The prevalent symmetry in known superconductors may be described as odd under exchange of spin coordinates, and even under an exchange of spatial or time coordinates of the electrons constituting the Cooper pair. However, other types of pairing are also permitted by the governing Pauli principle. Among these is the so-called odd-frequency pairing state, which has been predicted to arise both in N/S and F/S proximity systems. Extending the possible pairing states compatible with the Pauli-principle will likely have impact on a wide range of sub-disciplines in physics, ranging from astrophysics to extremely compressed quantum liquids. Recent experiments report that such an odd-frequency superconducting bulk state may be realized in certain heavy-fermion compounds. While the Josephson current normally only flows between superconductors with the same symmetry with respect to frequency, we demonstrate that an exchange field may induce a current between diffusive even- and odd-frequency superconductors. This suggests a way to identify the possible existence of bulk odd-frequency superconductors.

8:24AM H10.00003 Tunable current-phase relation in double-dot Josephson junctions, JENS KOCH, KARYN LE HUR, Departments of Physics and Applied Physics, Yale University — The current-phase relation \( I(\phi) \) of a Josephson junction contains information about the microscopic nature of the Cooper pair transfer. In particular, junctions more complicated than the single tunnel junction exhibit characteristic non-sinusoidal forms. Here, we investigate the Josephson effect in a superconducting double dot device, similar to the devices studied experimentally by Y. A. Pashkin et al. [1] and E. Bibow et al. [2]. In the vicinity of a charge degeneracy line, the system reduces to a two-level system equivalent to a charge qubit. In this regime, we find that the interplay between sequential tunneling and cotunneling of Cooper pairs leads to a strongly non-sinusoidal current-phase relation, tunable via gate electrodes. We propose the measurement of \( I(\phi) \) in a SQUID configuration, analyze the implications of flux noise, and compare our results to different types of Josephson junctions such as single-dot systems and microbridges. [1] Y. A. Pashkin et al., Nature (London) 421 (2003), 823 [2] E. Bibow, P. Lafarge, L. Lévy, Phys. Rev. Lett. 88 (2002), 017003

8:36AM H10.00004 Spontaneous spin accumulation in singlet-triplet Josephson junctions, KRISHNENDU SENGUPTA, TCMP division, Saha Institute of Nuclear Physics, Kolkata, India, VICTOR YAKOVEDNO, Department of Physics, University of Maryland — We show that the Andreev bound states in Josephson junctions between singlet \( s \)-wave and triplet \( p \)-wave superconductors carry a net magnetic moment. This magnetic moment depends on the relative phase between the superconductors constituting the junction and changes sign when the relative phase shifts by \( \pi \). We estimate the net magnetization of such junctions and suggest several realistic experiments to detect this magnetization. We also discuss possible magnetization flip in such junctions in the presence of an applied bias voltage.

8:48AM H10.00005 Small Josephson junctions in asymmetric SQUIDs, DAN SULLIVAN, Department of Physics, University of Maryland, College Park, TAUNO PALOMAKI, MARK GUBRUD, MICHAEL DREYER, BARRY BARKER, JAMES ANDERSON, CHRIS LOBB, FRED WELLSTOOD — Ultra-small Josephson junctions are known to be susceptible to quantum fluctuations in the phase difference across the junction, resulting in an effective suppression of the critical current. We have investigated a method for stabilizing this phase difference by shunting a small junction (with a critical current \( I_{01} \approx 1 \text{nA} \)) with an additional capacitance and incorporating the junction in a dc SQUID loop. The second junction in the \( \text{Al/AlO}_x/\text{Al} \) SQUID has a much larger critical current \( I_{02} \approx 1 \text{µA} \), producing a SQUID that is highly asymmetric. Our results show that the SQUID inductively couples the phase differences of the large and small junctions, leading to reduced phase fluctuations, and thus allowing accurate measurement of the small junction’s critical current at millikelvin temperatures. This work was supported by the National Science Foundation and the Laboratory for Physical Sciences.

9:00AM H10.00006 Scanning Josephson Tunneling Microscopy of Single Crystal Bi\(_2\)Sr\(_2\)Ca\(_2\)Cu\(_3\)O\(_{8+\delta}\) from a Conventional Superconducting Tip, HIKARI KIMURA, University of California, Berkeley, RICHARD BARBER, Santa Clara University, SHIMPEI ONO, CRIEPI, YOICHI ANDO, Osaka University, ROBERT DYNES, University of California, Berkeley and LBNL — Using a scanning tunneling microscope with superconducting Pb-coated tips (S-STM), we have observed the thermally fluctuated Josephson Effect between the tip and conventional superconductors. Such STM-based Josephson junctions are a powerful tool that can directly probe the phase of the superconducting condensate via the Josephson Effect as well as characterize the quasiparticle spectrum, both on a nanometer length scale. In this talk we present data from Josephson junctions formed between the S-STM tips and Bi\(_2\)Sr\(_2\)Ca\(_2\)Cu\(_3\)O\(_{8+\delta}\) Single crystals. These results clearly show \( s \)-axis Josephson tunneling between a conventional superconductor and both overdoped and optimally doped Bi\(_2\)Sr\(_2\)Ca\(_2\)Cu\(_3\)O\(_{8+\delta}\). Josephson measurements at various surface locations indicate an inhomogeneous structure of the \( I_{c}R_N \) product in overdoped Bi\(_2\)Sr\(_2\)Ca\(_2\)Cu\(_3\)O\(_{8+\delta}\). These local \( I_{c}R_N \) data of the Bi\(_2\)Sr\(_2\)Ca\(_2\)Cu\(_3\)O\(_{8+\delta}\) are related to the local superconducting gap. This work is supported by DOE Grant No. DE-FG02-05ER46194.

9:12AM H10.00007 Thermal Management in Large Bi2212 Mesas used for Terahertz Sources\(^3\), C. KURTER, K. E. GRAY, Q. LI, Argonne National Laboratory, L. OZYUZER, Izmir Institute of Technology, A. E. KOSELEV, Argonne National Laboratory, T. YAMAMOTO, K. KADOWAKI, University of Tsukuba, U. WELP, Argonne National Laboratory — We report the intrinsic tunneling characteristics of 300x100x1\( \mu \)m\(^3\) mesa on Bi2212 single crystals that have recently shown high-power emission at terahertz frequencies due to the ac Josephson effect. Despite the large mesa volumes compared to those of others, there is an accessible range of voltages for which self-heating does not exceed \( T \). A temperature increase proportional to power, \( P=IV \). We find that the local temperatures along the nonlinear I(V) are consistent with the observed unpolarized thermal radiation from the mesa, thus verifying the model.

9:24AM H10.00008 Quantized energy levels in quantum and classical regimes in current-biased intrinsic Josephson junctions, MYUNG-HO BAE, MITRABHANU SAHU, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801-3080, USA, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology, Pohang 790-784, Republic of Korea, ALEXEY BEZRYADIN, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, Illinois 61801-3080, USA, HU-JONG LEE COLLABORATION — The multiphoton transitions between quantized energy levels in the current-biased $\text{Bi}_x \text{Sr}_y \text{Sr}_z \text{Ca}_u \text{Cu}_v \text{O}_{w+z}$ intrinsic Josephson junctions (IJJs) in the quantum and classical regimes are studied through the switching current distributions. The system shows the saturation behavior of the switching current distributions near $T_c \sim 0.8$ K, which is the crossover temperature between classical and quantum nature of the system. We observe the multiphoton transitions between quantized energy levels in the quantum regime, which is manifested by the enhancement of the escape rate in the microwave radiation with frequencies of 12-16 GHz. This enhancement behavior keeps even in the classical regime and is washed out near $T_c \sim 2$ K, of which thermal energy corresponds to the energy level spacing at the switching currents. This means that the existence of the quantized energy levels even in the classical regime of IJJs, due to the relatively large plasma frequency in the IJJs.

9:36AM H10.00009 Direct observation of a $\sin(2\phi)$ component in the current-phase relation of superconductor-ferromagnet-superconductor (SFS) Josephson junctions, M.J.A. STOUTIMORE, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL USA, A.YU. RUSANOV, Laboratory of Superconductivity, ISSP-RAS, Chernogolovka, Russia, D.J. BAHR, V.A. OBOZNOV, V.V. BOLGINOV, A.N. ROSSOLENKO, V.V. RYAZANOV, D.J. VAN HARLINGEN — We present direct measurements of the current-phase relation (CPR) of SFS Josephson junctions in an rf-SQUID geometry. The junctions are fabricated from $\text{Nb-Cu}_{17} \text{Ni}_{13}-\text{Nb}$ trilayers with a junction area of $2 \times 2 \mu \text{m}^2$ and a CuNi thickness of 7 nm. By measuring the magnetic flux through the rf-SQUID as a function of applied current, we observe transitions between an arbitrary $\phi$-Josephson junction state and a $\phi$-junction state characterized by a phase difference of $\pi$ in the ground state occurring at temperatures between 1.5 K and 3.5 K. Near this temperature crossover, we observe period-doubling of the CPR indicating the existence of a term proportional to $\sin(2\phi)$. Work is underway to determine if this signifies an intrinsic second-order tunneling mechanism or is the result of junction inhomogeneities.

9:48AM H10.00010 Sub-Gap Currents in Nb/Al/AOx/Nb Josephson Junctions and Their Dependence on the Method of Barrier Formation, PAUL B. WELANDER, TIM J. MCARDLE, STEPHANIE LAW, JAMES N. ECKSTEIN, Department of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Urbana, IL 61801 — Josephson tunnel-junctions have been fabricated using two different methods of barrier formation. Both types of devices start with single-crystal Nb/Al bi-layers grown by molecular beam epitaxy on A-plane sapphire. It is found that complete wetting of the Nb layer is achieved with 20 nm of Al evaporated at room temperature. The barrier is then formed either by thermal oxidation of the Al surface in molecular oxygen (the well-known process developed by Gurvitch et al.) or by co-deposition Al in an oxygen background of about 5 micro-torr. A Nb counter-electrode is deposited in situ by evaporation at room temperature. Josephson junctions fabricated from these multi-layers exhibit Fiske resonances and a reduced gap voltage due to the relatively thick Al layer. For devices tested at 4 K, the co-deposition process yields junctions that show a sub-gap current in agreement with theory and no measurable shunt conductance. In contrast, those devices with barriers formed by thermal oxidation show a small shunt conductance in addition to the predicted sub-gap current.

10:00AM H10.00011 Ferromagnetic Josephson Junctions, TRUPTI KHAIRE, WILLIAM PRATT, NORMAN BIRGE, Department of Physics and Astronomy, Michigan State University, East Lansing, MI 48824 — Superconducting correlations cannot penetrate into a ferromagnet over a large distance due to the pair breaking effect of the exchange field. Ferromagnet/Superconductor (F/S) systems are often studied using weak ferromagnetic alloys with smaller exchange energy and correspondingly larger penetration depth. We are studying F/S junctions with the weak ferromagnetic alloy, CuNi [1]. The samples are fabricated by sputtering the S/F/S trilayer onto a Si substrate; they are subsequently patterned using trilayer photolithography and ion milling to obtain pillars of 50 micron diameter. Measurements performed on these pillars at 4K show the Josephson effect with the expected modulation of the critical current as a function of applied magnetic field. Because spin-flip scattering and spin-orbit scattering are strong in weak ferromagnetic alloys such as CuNi, there is an incentive to work with strong ferromagnets. The results from our CuNi data confirm the robustness of the sample fabrication technique and pave the way to future studies of Josephson junctions with strong ferromagnets such as Ni. [1] V. A. Oboznov, Phys. Rev. Lett. 96, 197003 (2006)

10:12AM H10.00012 I-V Characteristics vs. Spatial Dissipation Maps in YBCO Grain Boundary on Bicrystal Substrates, CHUHEE KWON, MEGUMI YAMAMOTO, SAMUEL POTTISH, California State University Long Beach, TIMOTHY HAUGAN, PAUL BARNES, Air Force Research Laboratory, CALIFORNIA STATE UNIVERSITY LONG BEACH COLLABORATION, AIR FORCE RESEARCH LABORATORY COLLABORATION — Grain boundary (GB) properties of YBCO films on SrTiO3 bicrystal substrates with 24 degree misorientations are examined by transport and scanning laser microscopy (SLM) techniques. Thermoelastic SLM clearly shows the location of grain boundaries, and variable temperature SLM confirms that GB has lower Tc. A series of I-V measured in superconducting states exhibit clear step-like features identified in earlier papers as sub-gap structures. The low temperature SLM shows a close relation between the step-like features and the local dissipation pattern in GB. We believe that the activation of Fiske steps is responsible for the step-like I-V, and SLM images show the spatial pattern of the self-excited resonance in GB. We will also discuss how Ca-doping and nanoparticle additions on YBCO affect the junction properties.

10:24AM H10.00013 Vibronic Effects in Superconducting Niobium Nanowires, BRANDON DONEHOO, ZHENTING DAI, ALEXEI MARCENKOV, Georgia Institute of Technology — Research of superconducting transport through microscopic objects with intrinsic vibrational degrees of freedom is a frontier research avenue. Here we report on experimental studies of a few-atom niobium nanowires prepared in a mechanically-controlled break junction set-up. We present evidence for the resonant interaction between the ac Josephson effect and the mechanical motion of atoms in niobium dimer nanowires at frequencies up to about 8 THz. This is application-rich, but a largely unexplored frequency range ("teraertz gap"), which interrogates the lowest frequency vibrational modes of complex organic and biological molecules. We also discuss superconducting transport and noise in niobium nanowires with oxygen contamination.

10:36AM H10.00014 Fluxon dynamics in a Josephson junction parallel array\textsuperscript{1}, NIKHIL FERNANDES, KENNETH SEGALL, USHNISSH RAY, Colgate University, ADAM DIOGUARDI, University of California at Davis — We present experimental measurements on the dynamics of fluxons in an array of Josephson junctions. Fluxons trapped in a parallel array of Josephson junctions upon cooldown experience a potential determined by the junction critical currents and the cell inductances. We probe the dynamics of the fluxon with switching current measurements, which allow determination of the transition rate of the fluxon from its pinned state to a running state. The transition to the running state is initiated by thermal activation at temperatures higher than the quantum crossover temperature for the junctions. Below the crossover, we observe an abrupt change in the critical force needed to move the fluxon. Quantum tunneling of the fluxons is a possible explanation for this observation. We present the data, numerical simulations, and a discussion of the results.

10:48AM H10.00015 Field-dependence of interlayer tunnelling in Bi$_2$Sr$_2$CaCu$_2$O$_8$, TIMOTHY BENSEN-MAN, JOHN COOPER, University of Cambridge, GEETHA BALAKRISHNAN, University of Warwick — Micron-scale ‘mesa’ structures fabricated on the surface of single crystals of strongly anisotropic high-temperature superconducting (HTS) compounds form stacks of ‘intrinsic Josephson junctions’ connected in series. Studying the current-voltage ($I$-$V$) characteristics of HTS mesa is now an established technique for obtaining important information regarding the electronic density of states ($\rho_D$) in these compounds, such as the magnitude $\Delta$ of the superconducting energy gap, and its symmetry in $k$-space. We have fabricated mesas on the HTS compound Bi$_2$Sr$_2$CaCu$_2$O$_8$ (Bi-2212) and studied these at a range of hole-doping levels, temperatures, and applied magnetic fields. Of particular interest is the field-dependent behaviour of the $I$-$V$ characteristic at bias voltages much less than the sum-gap voltage $2\Delta/e$, corresponding to quasiparticles near the gap nodes. We compare our results with predictions for the field-dependent DoS made by Volovik \cite{1} in which the local energy is assumed to be Doppler shifted by the local superfluid velocity. We also discuss features seen in our tunnelling characteristics at voltages above $2\Delta/e$, which may correspond to strong-coupling effects in Bi-2212.\cite{1, 2, 3}

8:00AM H11.00001 Quasi-two-dimensional electronic states in a dense three-dimensional Li-Be alloy\textsuperscript{1}, RICHARD G. HENNIG, Cornell University, JI FENG, Harvard University, ROALD HOFFMANN, N.W. ASHCROFT, Cornell University — High pressure can affect electronic structure and crystal packing, and in some cases even induce compound formation between elements that do not bond under ambient conditions. Our computational study for the Li-Be system shows that the reactivity of Li and Be is fundamentally altered by pressure. These two lightest metallic elements are immiscible at ambient conditions. Using structure search methods we discover four stoichiometric Li-Be compounds that are stable over a range of pressures. The electronic density of states of one of them displays a remarkable step-like feature and plateau at the bottom of the valence band, which is typical of a quasi-2D electronic structure and rather unexpected in a 3D crystal environment. We attribute this feature to large size differences between the ionic cores of Li and Be. Under increased pressure, the Li cores start to overlap and thereby expel valence electrons into quasi-two-dimensional layers characterized by delocalized free-particle-like states in the vicinity of Be ions. These alloys are also interesting from the perspective of superconductivity. The $T_c$ in the LiBe alloy is expected to be substantially higher than the component elements due to the increased density of states at the Fermi energy compared particularly to elemental Be.

8:12AM H11.00002 First-principles search for potential high temperature superconductors in the Mg-B-A (A=alkaline metal) system with high boron content\textsuperscript{1}, ROMAN CHEPULSKYY, Duke University, IGOR MAZIN, Naval Research Laboratory, STEFANO CURTAROLO, Duke University — Possible superconductivity at 50K was recently reported \cite{1} in the Mg-B-A (A=Ca, Sr, Ba) system. Although attempts to reproduce this finding have been unsuccessful so far \cite{2}, if a stable or metastable phase could be found by a first principle search similar to that in Ref. 3, this would have lent credence to the experimental finding \cite{1} and outline possible further directions. The results of Ref. 1 suggest that (a) the superconducting phase is not similar to MgB$_2$ (B site has cubic or similarly high symmetry) and (b) boron content is higher than in MgB$_2$. We report first-principles study of the thermodynamics of alkali and alkaline earth doping in the boron-rich part of the Mg-B phase diagram (MgB$_n$, with $n>2$) searching for a phase that could explain the results of Ref. \cite{1}.\cite{1} A. 8:36AM H11.00004 Electron-Phonon interaction in hexagonal layered compounds, LILIA BOERI, MPI-KFK, Stuttgart, MATTEO GIANTOMASSI, UPCM, Universit`a `La Sapienza`, Roma, Italy, OLE KROGH ANDERSEN, MPI-KFK, Stuttgart, Germany — The discovery of superconductivity in MgB$_2$ has initiated a thorough search for new electron-phonon ($e-\phi$) superconductors, particulary among hexagonal layered compounds. In this talk I will describe, using \textit{ab initio} methods, the factors that determine the electron-phonon properties of two classes of recently discovered superconductors, namely alkali-earth intercalated graphites (highest $T_c$, 15.1 K for CaC$_2$)\cite{1} and metal-intercalated ternary compounds MaAlSi.\cite{2}

8:48AM H11.00005 Structure and Superconductivity of Calcium under Pressure, Z. P. YIN, Dept. of Physics, UC Davis, F. GYG, Dept. of Applied Science, UC Davis, W. E. PICKETT, Dept. of Physics, UC Davis — The structure, phonon spectrum and electron phonon coupling of Ca under pressure is studied by first principle calculations. Experimentally, Ca at room temperature is simple cubic (SC) at pressure between 30 GPA and 109 GPA and goes to unknown structure above 109 GPA. Its superconducting $T_c$ increases significantly in the SC phase, increasing to 23 K at 109 GPA (25 K at 161 GPA). Linear response calculations reveal that SC Ca is horribly unstable in the corresponding pressure range (at $T=0$). Ab initio molecule dynamics calculations on a $4\times4\times4$ supercell find the SC phase is distorted into a four-atom bcc structure that is dynamically stable in the 40-110 GPA range. At even higher pressure, this bcc structure becomes dynamically unstable (imaginary frequencies). T. Ishikawa et al. (private communication) proposed an orthorhombic structure around 120 GPA. We confirmed this structure with minor differences of internal parameters. The theoretical x-ray diffraction (XRD) pattern of this structure has very good match with the experimental XRD pattern of the Ca V phase. Our linear response calculations further confirm that it is dynamically stable, and indications of strong electron-phonon coupling in this phase will be presented.

9:00AM H11.00006 Constraints on $T_c$ for superconductivity in heavily boron-doped diamond, JONATHAN E. MOUSSA, MARVIN L. COHEN, UC Berkeley & LBNL — Calculations of electron-phonon coupling are performed for boron-doped diamond structures without electronically compensating defects over a wide range of boron concentration. The effects of boron substitutional disorder are incorporated through the use of randomly generated supercells, leading to a disorder-broadened distribution of results. After averaging over disorder, this study predicts a maximum bulk $T_c$ near 55 K for boron concentrations between 20% – 30%, assuming the validity of the simple structural model used and a Coulomb pseudopotential of $\mu^* = 0.12$. Considering only the largest electron-phonon coupling values of the distribution, superconductivity may still percolate through the material at higher temperatures, up to 80 K, through the regions of large coupling. A synthesis path is proposed to experimentally access this class of materials.

9:12AM H11.00007 Superconductivity in high-pressure solids, JOHN S. TZE, Department of Physics and Engineering, University of Saskatchewan, Saskatoon, SK S7N 5E2, Canada — The structural principle behind the unusual features in the high-pressure phases of simple alkali elements is reviewed. It is shown that there exists a pressure regime in which the elemental solids are likely to adopt a layer structure. There are two novel characteristics associated with this structure type. The system tends to be at the proximity of phonon and electronic instabilities. The combined effect is a significant enhancement of electron-phonon coupling, resulting in a superconducting state. We demonstrate this empirical observation with selected examples including a recently predicted novel high pressure structure of SH$_4$ which shows very high superconducting critical temperature.

9:48AM H11.00008 Layered Structures Favor Superconductivity in Compressed Solid SiH$_4$, HAI-QING LIN, Chinese University of Hong Kong, XIAO-JIA CHEN, Carnegie Institute of Washington, JIANG-LONG WANG, Chinese University of Hong Kong, VIKTOR V. STRUZHKIN, HO-KWANG MAO, Carnegie Institute of Washington — The electronic and lattice-dynamics properties of compressed solid SiH$_4$ have been calculated over the pressure regime up to 300 GPA with density functional theory. We find that the structures having layered network with eight-fold SiH$_4$ coordination favor the metallization and superconductivity. The layered $\text{Cs}$SiH$_4$ is predicted to have a superconducting transition temperature of 75 K at 70 GPA and opening new possibilities for exploring high temperature superconductivity in the hydrogen-rich system.

10:00AM H11.00009 First-Principles Study of Superconductivity in boron-doped SiC, JESSE NOFFSINGER, FELICIANO GIUSTINO, STEVEN LOUIE, MARVIN COHEN, UC Berkeley — The discovery of superconductivity in materials such as intercalated graphite, alkali-doped fullerences, and boron-doped diamond has drawn significant interest to carbon-based superconductors. Recent experiments indicate that boron-doped cubic SiC may superconduct above 1 K. [1]. We investigate the superconductivity in cubic SiC using a first-principles approach. We describe the electronic structure within density functional theory and the lattice dynamics within density functional perturbation theory. The electron-phonon interaction matrix elements are calculated via a recently developed method based on Wannier functions [2]. The boron doping is accounted for by a virtual crystal approximation. In addition to the coupling of Fermi surface electronic states to optical phonon modes, there appears to be a non-negligible contribution to the electron-phonon coupling arising from acoustics phonons. Superconductivity is discussed by analyzing the similarities and the differences with respect to the closely related boron-doped diamond. [1] Z-A. Ren et al. private communication. [2] F. Giustino et al. Phys. Rev. B 76, 165108 (2007)

10:12AM H11.00010 First principles study of Al and C-doped MgB$_2$: evolution of two gaps and critical temperature, OMAR DE LA PEÑA-SEAMAN, ROMEO DE COSS, Department of Applied Physics, Cinvestav-Merida, Mexico, ROLF HEID, KLAUS-PETER BOHNEIN, Institut fuer Festkoerperforsch. Forschungszentrum Karlsruhe, Germany — We have studied the electronic-phonon and superconducting properties of the Mg$_{1-x}$Al$_x$B$_2$ and Mg$_{1-x}$B$_2$(1-x)C$_{2x}$ alloys within the framework of density functional perturbation theory, using a mixed-basis pseudopotential method and the virtual crystal approximation (VCA) for modeling the alloys. For both systems, the Eliashberg spectral function $(\alpha^2 F(\omega))$ and the electron-phonon coupling parameter $(\lambda)$ have been calculated in the two band model $(\sigma,\pi)$ for several concentrations until $(\lambda/AI) = 0.55$ and $(x(C) = 0.175)$. Using the calculated $\lambda^2 F(\omega)$ and a diagonal expression for the Coulomb pseudopotential matrix, $\mu^*$, we solved numerically the Eliashberg gap equations in the two band model without interband scattering. We reproduce the experimental decreasing behavior of $\Delta_{\sigma}(x)$, $\Delta_{\pi}(x)$, and $T_c(x)$ for both alloy systems. The role of the interband scattering in the observed behavior of the superconducting gaps and $T_c$ in the Al- and C-MgB$_2$ alloys is discussed. This research was supported by Consejo Nacional de Ciencia y Tecnologia (Conacyt) under Grant No. 45360-F.

10:24AM H11.00011 Effects of Quenched Random Gap Inhomogeneities on the Specific Heat of a Model High-$T_c$ Superconductor, DAVID STROUD, Department of Physics, Ohio State University, Columbus, OH 43210, DANIEL VALDEZ-BALDARES, Department of Physics and Astronomy, University of Rochester, Rochester, NY 14627 — In many cuprate superconductors, scanning tunneling microscopy experiments show that the energy gap has substantial quenched random spatial variations. We have calculated how such gap variations affect the specific heat $C_V$ in a model for the most anisotropic of these materials. The model is based on a Ginzburg-Landau free energy functional in which position-dependent coefficients are used to model quenched inhomogeneity. Using Monte Carlo simulations, we evaluate $C_V$ for different disorder strengths. Near optimal doping, we find that quenched gap disorder substantially broadens the specific heat anomaly near the phase ordering transition $T_s$, compared to that due to thermal fluctuations alone. But for strongly underdoped samples, in which $T_c$ is greatly separated from the pseudogap temperature $T_p$, disorder only slightly increases the broadening beyond the already substantial amount due to thermal fluctuations. We compare these results to recent experiments.

The temperature dependent gap edge in strong-coupling superconductors

10:48AM H11.00013 A DFT study of the UCoGe magnetic superconductor, PABLO DE LA MORA, Fac. de Ciencias, UNAM, Mexico, ORACIO NAVARRO, Inst. Inv. Materiales, UNAM, Mexico — Recently Huy et al. (PRL 99, 067006) found that UCoGe is a superconductor coexisting with magnetism. Electronic structure calculations were performed on this compound using the WIEN2k package, results show that its magnetism is anisotropic, with the easy magnetic axis in the c-direction. The magnetic moment of the U atom is quite small, but there is a large moment in the Co atom which is in disagreement the experimental result of Huy et al. These results contrast with the isostructural magnetic superconductor URhGe, in which compound the U-atom moment is relatively large; while for the Rh atom it is small. The main contribution at E_F is due to U-5f and Co-3d. Ge has little contribution. There are many similarities with the MgB2 superconductor, there are many bands at E_F and UCoGe has a distorted MgB2 crystalline structure, but the superconductivity mechanism seems to be of different origin.

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H12 DCMP: Lattice and Magnetic Properties of Multiferroics Morial Convention Center 203

8:00AM H12.00001 Infrared phonon dynamics of multiferroic BiFeO3 single crystal, R.P.S.M. LOBO, CNRS-ESPCI, Paris, France, R.L. MOREIRA, Depto. Fisica, UFMG, Belo Horizonte, MG, Brazil, D. LEBEUGLE, D. COLSON, DSM/DRCAM/SPEC, CEA, Saclay, France — We discuss the first infrared reflectivity measurement on a BiFeO3 single crystal between 5 K and room temperature. The predicted ab-plane E phonon modes are fully and unambiguously determined. The frequencies of the 4 A1 c-axis phonons are found. These results settle issues between theory and data on ceramics. Our findings show that the softening of the lowest frequency E mode is responsible for the temperature dependence of the dielectric constant, indicating that the ferroelectric transition in BiFeO3 is soft-mode driven.

8:12AM H12.00002 Electromagnons and Multiple Phase Transitions in BiFeO3 Multiferroic System, MARIOLA RAMIREZ, A. KUMAR, S. DENEV, J. IHELEFED, D. SCHLOM, VENKATRAMAN GOPALAN, Penn State University, R. RAI, X. XIU, J. MUSEFELDT, University of Michigan, S. LEE, S. CHEONG, Rutgers University, R. RAMESH, J. SEIDEI, E. CHIU, J. ORESTEIN, University of California, Berkeley — Magnetoelastics (ME) multiferroics has recently become an exciting research area due to its potential technological applications. Of special relevance is the case of Bismuth ferrite, BiFeO3 (BFO) where multiferroicity coexist at room temperature. In this work, the Fe-Fe exchange interaction effects on the optical properties of BiFeO3 are analyzed by using both, linear and non linear spectroscopy as a function of temperature. Two and three magnons Raman scattering as well as detectable electromagnons in the second harmonic generation (SHG) signal are reported. Temperature studies up to 750 K reveals a cascade of phase transitions associated to different dynamic reorientations in the magnetic subsystem. These transitions were detectable by several optical methods including linear absorption, Raman spectroscopy and SHG due to the strong electric dipole coupling found between electromagnetic radiation and spin waves in BFO.

8:24AM H12.00003 Temperature studies of multiferroic TbMnO3 with resonant Raman scattering, ILKA MAHNS, M. BASTJAN, B. SCHULZ, S. MUELLER, A. RUSYDI, M. RUEBHAUSEN, IAP, University of Hamburg, Germany, N. ALIOUANE, D.N. ARCYRIOU, HMI, Berlin, Germany, H. BARATH, M. KIM, S.L. COOPER, Dept. of Physics and Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, Illinois — Using temperature dependent resonant Raman scattering with different excitation energies from the ultraviolet (UV) to near infrared (NIR), we have investigated the complex interplay between the orbital, structural and magnetic ordering in the multiferroic material TbMnO3. Depending on the scattering temperature at the Néel temperature at 41 K or the ferroelectric transition at T_F = 28 K is observed. In resonance studies with an incident frequency of 1.91 eV, the Jahn-Teller mode shows a strong softening below T_N. In the low frequency spectra, a quasielastic response is identified. The results give information about the electron-phonon coupling and the correlations between electronic and structural degrees of freedom that contribute to the multiferroic behavior in TbMnO3.

8:36AM H12.00004 Temperature- and field-dependent inelastic light scattering studies of TbMnO3, HARINI BARATH, MINJUNG KIM, S.L. COOPER, Dept. of Physics and Frederick Seitz Materials Research Laboratory, Univ. of Ill., Urbana-Champaign, M. RUEBHAUSEN, Institut fur Angewandte Physik, Universitat Hamburg, Hamburg, Germany, D.N. ARCYRIOU, Hahn-Meitner Institut, Berlin, Germany — TbMnO3 is one of several multiferroic materials that have coexisting magnetic and electric orders that are strongly coupled. Because it is exquisitely sensitive both to structural order and magnetic degrees of freedom, field-dependent inelastic light scattering measurements are ideally suited to studying magnetoelectric coupling and multiferroic phases in materials such as TbMnO3. By carefully examining the temperature- and field-dependent evolution of new magneto-elastic modes in various phases of TbMnO3, our study reveals several new features of the IC-C transition in TbMnO3, including the co-existence of distinct structural phases in the intermediate field regime around the IC-C phase transition and evidence for dynamical fluctuations of the IC and C phases outside the established phase boundaries.

8:48AM H12.00005 Pressure tuned phonon mode splitting in magnetic frustrated spinel ZnCr$_2$O$_4$, TAO ZHOU, ZHEN QIN, New Jersey Institute of Technology, ZHENXIAN LIU, Brookhaven National Lab, CHENGLIN ZHANG, SANG-WOOK CHEONG, Rutgers University — ZnCr$_2$O$_4$ has cubic spinel structure. Below 390 K, the geometrically frustrated magnet enters a paramagnetic state. Below 12.5 K, it undergoes a first-order phase transitions, resulting into an antiferromagnetic order and a structural distortion simultaneously. An IR-active phonon related to the Cr$^{3+}$ ion's motion undergoes a splitting at 12.5 K. This transition is explained as a spin-Peierls like transition. However, the exact cause and effect in such a transition is not clear. Is it because the lattice undergoes transition first, spin just follows, or is it spins' interaction that forces the lattice to undergo changes? Pressure can provide a crucial service in clarifying this issue, since pressure can change spin and lattice interactions in different ways, it can differentiate these two scenarios. We have measured the infrared absorption spectra of ZnCr$_2$O$_4$ under pressure. Our data shows that Tc, at which the spin-Peiers like transition occurs and the phonon at about 370 cm$^{-1}$ starts to show the splitting, increases from its ambient pressure value of 12.5 K to about 15.8 K at 1 GPa. This provides an important clue for the exact nature of this transition.

9:00AM H12.00006 Calculation of the Order Parameter and the Damping Constant in the Ferroelectric Phase for NaNO$_2$, ALI KIRACI, HUSEYIN KARACALLI, Abant Izzet Baysal University, HAMIT YURTSEVEN, Middle East Technical University — The temperature dependence of the order parameter and the damping constant is calculated in the ferroelectric phase in the range of 27 to 162 °C close to the phase transition (T$_{C}$=436 K) for NaNO$_2$. The values of the order parameter calculated from the molecular field theory, are used to evaluate the damping constant as a function of temperature on the basis of the soft phonon-hard phonon coupling model for NaNO$_2$ in the ferroelectric phase. By representing the damping constant calculated at various temperatures in terms of an Arrhenius plot, the activation energy is computed for this crystal in the ferroelectric phase. Our calculated order parameter agrees with the measured one and also the damping constant predicts the critical behaviour exhibited by the NaNO$_2$ crystal near the transition temperature in the ferroelectric phase. From the values of the activation energies obtained here, the mechanism of an order-disorder transition which involves the orientation of the NO$_2^−$ ions is investigated for NaNO$_2$.

9:12AM H12.00007 Pressure Dependence of the Phonon Modes of Hexagonal-RMnO$_3$¹, PENG GAO, TREvor A. TYSOn, Physics Department, New Jersey Institute of Technology, ZHENXIAN LIU, Geophysical Laboratory, Carnegie Institution of Washington, SUNG BAEK KIM, SANG-WOOK CHEONG, Dept. of Physics and Astronomy, Rutgers University — We present high pressure IR measurements of the phonon spectra of HoMnO$_3$ and YMnO$_3$. Measurements were conducted under the pressure range ambient to ~20 GPa. No phase changes were observed over this broad range of hydrostatic pressures. A strong non-linear variation of frequency with pressure is observed suggesting saturation at higher pressures. A discussion of the effect of hydrostatic pressure on the ferroelectric properties of these systems will be given based on comparisons with density functional calculations.

¹This work is supported by DOE Grant DE-FG02-07ER46402.

9:24AM H12.00008 Probing Spin-Lattice Correlations in Hexagonal RMnO$_3$ Multiferroics¹, TREvor TYSOn, ZHIQIANG CHEN, New Jersey Institute of Technology, SUNGBACK KIM, SANG-WOOK CHEONG, Rutgers University — The hexagonal multiferroic system RMnO$_3$ is known to exhibit strong spin-lattice correlations based on bulk thermal expansion measurements. Enhanced correlations at the spin ordering temperatures are observed. In this work, we examine the local structure about the R and Mn sites in order to determine the changes in atomic interactions which coincide with the spin alignments. Measurements over a broad range of temperatures are presented and estimates of the changes in atomic bond distances are given.

¹This work is supported by DOE Grant DE-FG02-07ER46402.

9:36AM H12.00009 Giant magneto-elastic coupling in multiferroic hexagonal manganites, SEONGSU LEE, Rutgers University, USA, A. PIROGOV, M.S. KANG, K.-H. JANG, SungKyunKwan University, Korea, M. YONEMURA, T. KAMIYAMA, KEK, Japan, S.-W. CHEONG, Rutgers University, USA, F. GOZZO, Paul Scherrer Institut, Switzerland, NAMSU SHIN, Pohang Accelerator Laboratory, Korea, H. KIMURA, Y. NODA, Tohoku University, Japan). J.-G. PARK, SungKyunKwan University, Korea — In order to investigate a possible structural change of RMnO$_3$ at the magnetic transition temperature, we have carried out high-resolution structural studies using neutron diffraction. Here we show that the hexagonal manganites RMnO$_3$ undergo an isostructural transition at T$_N$ with unusually large atomic displacements: two orders of magnitude larger than those seen in any other ordinary materials, resulting in a uniquely strong magneto-elastic coupling. For the first time, we could follow the exact atomic displacements of all the atoms in the unit cell as a function of temperature and found consistency with theoretical predictions based on group theories. We argue that this gigantic magneto-elastic coupling of RMnO$_3$ arises from geometrical frustration, and holds the key to the recently observed magnetoelectric phenomenon in this intriguing class of materials.

9:48AM H12.00010 Anomalous low-temperature magnetic ordering and spin-phonon coupling in BiFeO$_3$ thin films, MANOJ SINGH, Department of Physics and Institute of Functional Nano Materials, University of Puerto Rico, PR, USA, RAM KATIYAR, Department of Physics and Institute of Functional Nano Materials, University of Puerto Rico, PR, USA, W. PRELLIER, Laboratoire CRISMAT, CNRS, ENSICAEN, Caen Cedex, France, H.M. JANG, Department of Materials Science and Engineering, Pohang University of Science and Technology, Pohang, Korea, W. PRELLIER COLLABORATION, H. M. JANG COLLABORATION, RAM S. KATIYAR TEAM — Low-temperature magnetic properties and Raman spectra of epitaxial BiFeO$_3$ (BFO) thin films grown on (111) SrTiO$_3$ substrates have been studied. Zero-field-cooled (ZFC) and field-cooled (FC) magnetization curves showed a large discrepancy beginning at a characteristic temperature which did depend on the magnetic-field strength, suggesting a spin-glass-like behavior of the epitaxial BFO film with R3c symmetry. For all three major A$_1$-symmetry Raman modes (138, 170, and 214 cm$^{-1}$), there was a good linear correlation between the mode-frequency softening and the square of the in-plane magnetization in the temperature range between 80 and 300 K. These observations were ascribed to the spin-phonon coupling below the Néel temperature (T$_N$ = 643 K).

10:00AM H12.00011 Magneto-dielectric study of multiferroicity in biferroic YCrO$_3$, RELJA VASIC, HAI Song D. ZHOU, CHRIS R. WIEBE, JAMES S. BROOKS, Florida State University — Magneto-dielectric measurements are used to characterize multiferroicity in the doped monoclinic ferroelectric oxides Y$_{1−x}$Ca$_x$MnO$_3$ (x = 0, 0.15, 0.3). The focus of this study is on the effects of the magnetic field and Ca doping on the temperature- magnetic field dependent dielectric response of polycrystalline samples of rare earth chromates YCrO$_3$. YCrO$_3$ shows dielectric relaxation around 150 K related to the weak ferromagnetic ordering in system. Dipolar response is activated following Arrhenius formalism in the frequency range of 0.01-100 kHz, but it is independent on magnitude of magnetic field. As frequency increases dielectric peaks become broader and smaller. Dielectric constant relaxation behavior and magnetic phase transitions are not coupled through lattice distortions in this ferroelectric ferromagnetic system. YCrO$_3$ is an example of system with dipolar response in magnetic field without coupling with magnetic structure. There is strong dispersion of Debye relaxation peaks but absence of influence of magnetic field on ferroelectric system YCrO$_3$.
10:12AM H12.00012 Multiferroicity in the spin-1/2 quantum matter of LiCu$_2$O$_2$, ANDRIVO RUSYDI, ILKA MAHNS, SONJA MUELLER, MICHAEL RUEBHAUSEN, University of Hamburg, S. PARK, Y.J. CHOI, C.L. ZHANG, S.-W. CHEONG, Rutgers University, SERBAN SMADIC, PETER ABBAMONTE, UIUC, MARTIN VON ZIMMERMANN, DESY, GEORGE SAWATZKY, University of British Columbia — Multiferroicity in LiCu$_2$O$_2$ single crystals is studied using resonant soft x-ray magnetic scattering, hard x-ray diffraction, heat capacity, magnetic susceptibility, and electrical polarization. Two magnetic transitions are found at 24.6 K ($T_1$) and 23.2 K ($T_2$). Our data are consistent with a sinusoidal spin structure at $T_2 < T < T_1$ and with a helicoidal spin structure at $T < T_2$ giving rise to ferroelectricity. Surprisingly, above $T_2$ the correlation lengths of the spin structures increase as the temperature increases with dramatic changes of ~42% occurring along the c-axis. Our results demonstrate the intimate connection between frustration and coupling between electronic and magnetic polarizations in LiCu$_2$O$_2$.

10:24AM H12.00013 Magnetically-induced ferroelectric polarization in a molecule-based quantum magnet, VIVIEN ZAPF, FREDERIK FABRIS, National High Magnetic Field Lab, Los Alamos National Lab, MICHEL KENZELMANN, Laboratory for Solid State Physics, ETH Hönggerberg, Zurich, FEDOR BALAKIREV, NHMFL-LANL, YING CHEN, COLIN BROHOLM, Dept of Physics and Astronomy, Johns Hopkins University — Ferroelectricity coupled to antiferromagnetic (AFM) order has been observed in the organic S=1/2 chain compound CDC (CuCl$_2$ 2(CH$_3$)$_2$SO). For magnetic fields along the orthorhombic a-axis, AFM order occurs below $T_X$ = 0.93 K and $H \sim 4$ T. A spin-flop transition above $H_{sf} = 0.35$ T leads to a magnetically ordered state that breaks inversion symmetry along the b-axis for 0.35 T $< H < 4$ T. Measurements of the pyroelectric effect and the dielectric constant along both indicate ferroelectricity occurring in this same region of HT phase space with the spin polarization closely tracking the magnetic order parameter. A single quantum spin flop can be induced by successive field sweeps in the same direction. While the magnetically-induced ferroelectricity in CDC is far from practical temperatures and fields, it nevertheless demonstrates that this phenomenon can occur in a whole new class of compounds.

10:36AM H12.00014 Spin Dynamics and Spin-flop transition in Magnetoelastic Effect LiMnPO$_4$, J. LI, NCNR, National Institute of Standards and Technology; Dept. Material Science and Engineering, University of Maryland, W. TIAN, Ames laboratory and Dept. of Physics and Astronomy, Iowa State University, Y. CHEN, NCNR, National Institute of Standards and Technology; Dept. Material Science and Engineering, University of Maryland, J.L. ZARESTKY, D. VAKNIN, Ames laboratory and Dept. of Physics and Astronomy, Iowa State University, J.W. LYNN, NCNR, National Institute of Standards and Technology — Neutron scattering techniques were used to study the magnetic phase transition and spin dynamics in single crystal LiMnPO$_4$ both with and without magnetic field. Elastic scattering confirmed that LiMnPO$_4$ has a collinear antiferromagnetic ground state with moments along a-axis in zero-field. The temperature dependent order parameter, calculated from the integrated intensity of the (010) magnetic reflection, was fit to a power law equation, yielding a transition temperature $T_X = 33.8$ K. By applying magnetic field along the a-axis, the moments rotate from a-axis to the c-axis at a critical field of 3.5 Tesla at 5 K. The field dependent (100) and (001) intensities indicate a complicated intermediate state between the ground state and the spin-flop state. The critical field increased from 3.5 Tesla at 5 K to 4.5 Tesla near the transition, $T_X$. Spin-wave dispersion curves along the three principal axes were measured in the antiferromagnetic state at 4.5 K in zero magnetic field and were analyzed using a 3D Heisenberg model.

10:48AM H12.00015 Magnetic Excitations in LiCoPO$_4$, WEI TIAN, Ames laboratory and Dept. of Physics and Astronomy, Iowa State University, Ames, IA 50011, JIYING LI, JEFF LYNN, NCNR, National Institute of Standards and Technology, Gaithersburg, MD 20899, JEREL ZARESTKY, DAVID VAKNIN, Ames laboratory and Dept. of Physics and Astronomy, Iowa State University, Ames, IA 50011 — LiCoPO$_4$ continues to attract much attention due to its exceptionally large magnetoelastic (ME) effect coefficient and the observed weak ferromagnetism and ME “butterfly loop” anomaly. To gain insight into the microscopic magnetic interactions in LiCoPO$_4$, inelastic neutron scattering experiments were performed in the antiferromagnetic phase at $T = 8$ K ($T_X \approx 21.8$ K). Weak dispersion was detected in the magnetic excitation spectra along the three crystallographic axes measured around the (0 1 0) magnetic reflection. A gap of ~4 Tesla was observed below $T_X$ that vanished above $T_X$. The peak energy was fit with a linear spin-wave approximation by explicitly including single-ion anisotropy terms in the Heisenberg spin Hamiltonian. The magnitude of the single-ion anisotropy is found to be comparable to the strongest nearest-neighbor magnetic interaction suggesting that the Co$^{2+}$ single ion anisotropy plays an important role in the spin dynamics of LiCoPO$_4$.

Tuesday, March 11, 2008 8:00AM - 10:36AM
Session H13 DCOMP GSCCM: Focus Session: Simulations of Matter at Extreme Conditions III: Classical MD, Potentials, and Energetic Materials Morial Convention Center 204

8:00AM H13.00001 Theoretical Approach for Developing Accurate Potentials for Molecular Dynamics Simulations: Thermoelastic Response of Aluminum, J.M. WINEY, Wash. State Univ., A. KUBOTA, Lawrence Livermore Nat. Lab., Y.M. GUPTA, Wash. State Univ. — To achieve the correct thermoelastic response of solids in classical simulations, a new approach is presented for developing accurate interatomic potentials. In this approach, the potentials are fitted to values for the atomic volume and the second and third-order elastic constants at $T = 0$K by extrapolating the room temperature values, using classical thermo-mechanical relations. This procedure avoids the low-temperature quantum regime, enabling recovery of the correct response in classical simulations to higher temperature. As an example of this approach, an EAM potential was developed for aluminum. Results using this potential provide consistently better agreement with thermoelastic data at higher temperature compared to previous EAM potentials. Our approach is applicable to the development of other types of potentials as well and is amenable to incorporating the results of first principles calculations performed using the classically extrapolated volume for $T = 0$K. Work supported by DOE.

8:12AM H13.00002 Petaflop simulations of shock-induced particulate ejection from copper, TIMOTHY C. GERMANN, JAMES E. HAMMERBERG, GUY DIMONTE, Los Alamos National Laboratory — We present the results of several large-scale, Non-Equilibrium Molecular Dynamics (NEMD) simulations of shock-induced surface instability development. We consider single crystal Cu described by an embedded atom method (EAM) potential and driven by a shock wave along the [111] crystallographic direction, impinging upon a roughened Cu/vacuum or Cu/Ne interface. The initial temperature is 300K and the NEMD simulation cell is a quasi-2D 2.23µm × 5.67µm slab geometry, 1.5 nm thick in the (periodic) third dimension. The first third of the sample length (1.89µm) is occupied by Cu (5.3 × 10$^8$ atoms), and the remainder either empty vacuum or Ne gas at a pressure of 0.67 MPa (1.95 × 10$^8$ atoms). The Cu/Ne (or Cu/vacuum) interface has an initial perturbation with average amplitude 30 nm and dominant wavelength of 0.74µm. A shock wave is created by driving the free end of the Cu slab at a fixed particle velocity $u_p = 2.0$ to 3.5 km/s. Single-mode and multi-mode simulations were considered using 212,992 CPUs of the LLNL BlueGene/L supercomputer for times approaching 1 ns. At the higher particle velocities, the Cu release state is in the fluid-solid mixed phase. We discuss the evolution of the density and velocity distributions of the ejected mass, the modes of particle breakup, and comparisons to source theories of ejecta formation and Richtmyer-Meshkov instabilities.
8:24AM H13.00003 Interatomic bond-order potentials for molecular dynamics simulations of materials at extreme conditions. ROMAIN PERRIOT, MIKALAI BUDZEVICH, IVAN OLEYNIK, University of South Florida — Molecular dynamics (MD) is a powerful research tool for studying materials at extreme conditions. At the heart of MD are the interatomic potentials, whose quality in describing a variety of chemical effects, including bond-breaking and bond-making, plays a decisive role in delivering meaningful results. We have performed extensive MD simulations of shock compression of covalently bonded materials, such as diamond and silicon, and found that REBO interatomic potential for diamond and EDIP potential for Si have substantial deficiencies at large pressures and temperatures in spite of the fact that the near equilibrium properties of both diamond and silicon are well reproduced. We are addressing this outstanding issue by developing analytic bond-order potentials (BOPs) specifically for the simulation of covalently bonded materials at extreme conditions. These BOPs include explicit analytic expressions for both the $\sigma$ and $\pi$ bonds. We will discuss important steps of BOP construction which includes devising a first-principle database of fundamental materials properties, fitting this database by the orthogonal tight-binding, and devising the analytic BOPs using the direct link between TB and analytic BOPs via the bond orders.

8:36AM H13.00004 Interatomic Potentials for Large-Scale Simulations of High-Pressure, High-Temperature Phenomena, RAMON RAVELO, University of Texas at El Paso; Applied Physics Division, Los Alamos National Laboratory — The use of large-scale atomistic simulations in the study of high-compression, high strain-rate phenomena has dramatically increased in the last decade. Most of this type of simulations utilize classical empirical or semi-empirical potentials to describe the inter-atomic interactions. The regime of validity of most of these potentials is however often limited to a narrow region of the pressure-temperature phase diagram. In the development of accurate inter-atomic potentials for material simulations at high-pressures or temperatures, a high degree of transferability is desirable without resorting to fitting everywhere in phase space. We will review two popular cluster functional models: the embedded-atom-method (EAM) and the modified embedded-atom-method (MEAM). The embedded atom method provides a very good description of metallic properties at a low computational cost and has become the workhorse of large-scale atomistic simulations of metallic systems. The modified embedded-atom-method is an improvement of EAM which includes the effect of angular bonding. We outline inherent limitations of these models and present a systematic approach to improving their transferability and predictive accuracy at high pressures and/or temperatures.

9:12AM H13.00005 Ultrafast semi-metallic layer formation in detonating nitromethane, EVAN REED, M. RIAD MANAA, LAURENCE FRIED, KURT GLAESERMANN, Lawrence Livermore National Laboratory, JOHN JOANNOPOLOS, Massachusetts Institute of Technology — We present the first quantum molecular dynamics simulations behind a detonation front (up to 0.2 ns) of the explosive nitromethane (CH$_3$NO$_2$) represented by the density-functional-based tight-binding method (DFTB). This simulation is enabled by our recently developed multi-scale shock wave molecular dynamics technique (MSST) that opens the door to longer duration simulations by several orders of magnitude. The electronic density of states around the Fermi energy initially increases as metastable material states are produced but then later decreases, perhaps unexpectedly. These changes indicate that the shock front is characterized by an increase in optical thickness and conductivity followed by a reduction around 100 picoseconds behind the front. We find that a significant population of intermediate metastable molecules are charged and charged species play an important role in the density of states evolution. The transient transformation to a semi-metallic state can be understood within the Anderson picture of metalization.

9:24AM H13.00006 Reactive Molecular Dynamics Studies of Thermal Induced Chemistry in HMX, JASON QUENNEVILLE, TIMOTHY GERMANN, THOMAS SEWELL, EDWARD KOBEN, Los Alamos National Laboratory — Equilibrium molecular dynamics (MD) simulation of high explosives can provide important information on their thermal decomposition by helping to characterize processes with timescales that are much longer than those attainable with non-equilibrium MD shock studies. A reactive force field is used with MD to probe the chemistry induced by intense heating (‘cook-off’) of octahydro-1,3,5,7-tetranitro-1,3,5,7-tetrazocine (HMX). The force field (ReaxFF) was developed by van Duin, Goddard and coworkers at CalTech and has shown promise in predicting the chemistry in a variety of systems, including RDX and TATB under either shock compression or intense heat. In the current work, we investigate the effect of initial equilibration temperature (1000 to 1500 K), volumetric compression, crystal polymorph ($\beta$ and $\delta$), and system size (ranging from 150 to 1200 molecules) on the reaction rate and reaction products. Finally, we will compare these results with those from our previous work on TATB. A C. T. Van Duin, et al., J. Phys. Chem. A, 1005, 9396 (2001).

9:36AM H13.00007 Anisotropic Constitutive Relationships in Energetic Materials: TATB, MIKALAI M. BUDZEVICH, AARON LANDERVILLE, MIKE CONROY, IVAN I. OLEYNIK, University of South Florida, CARTER T. WHITE, Naval Research Laboratory — One of the principal thrusts in energetic materials (EM) research is the acquisition of accurate equations of state (EOS) for various important classes of EMs. In the past, both theoretical and experimental studies concentrated on hydrostatic EOS. However, these isotropic EOS still need to be expanded to include anisotropic materials response, including uniaxial compression which are more relevant to shock initiation of detonation. To this end, we performed first-principles density functional calculations of the EOS for TATB, including uniaxial compressions in the [100], [010], [001], [110], [101], and [111] crystallographic directions. Equilibrium properties, such as lattice parameters and elastic constants, as well as the hydrostatic EOS were calculated and compared with experimental results. Finally, we discuss the possible relationship between shear stresses induced by the uniaxial compression of TATB and the relative shock sensitivities of different crystallographic directions.

9:48AM H13.00008 First-Principles Reactive Molecular Dynamics of Chemistry in Detonating Energetic Materials, AARON LANDERVILLE, IVAN I. OLEYNIK, University of South Florida, MORTKO A. KOZHUSHNER, Russian Academy of Sciences, CARTER T. WHITE, Naval Research Laboratory — We investigated the initial chemistry of shock compressed energetic materials that results from inter-molecular collisions behind the shock wave front by performing first-principles MD simulations of bimolecular collisions for PETN and RDX with different crystallographic orientations and velocities. For each orientation, we determined the threshold collision velocity for reaction, the reaction timescales, and the products of decomposition. We find that the calculated threshold velocities lie within the range of typical particle flow velocities in detonating materials. Owing to the extremely short reaction timescales ($\sim 10^{-14}$s), these initial chemical events are largely driven by the direct collision dynamics, instead of temperature.
10:00AM H13.00009 Reactive MD simulations of anisotropic response of PETN under high-rate shear deformation1. XU PENG, SERGEY ZYBIN, California Institute of Technology; AIDAN P. THOMPSON, Sandia National Lab; WILLIAM A. GODDARD, California Institute of Technology — Several experiments have indicated that the shock sensitivity of single crystal energetic materials can depend on the crystallographic direction. We develop a compress-and-shear modeling approach to study the mechanisms of anisotropic shock sensitivity using the ReaxFF reactive molecular dynamics. ReaxFF is a first-principles based force field capable to reproduce the quantum chemical energies of the reactants, intermediates and transition states with functional forms suitable for large-scale molecular dynamics simulations of chemical reactions under extreme conditions. In this presentation we will discuss the results of high-rate shear simulations of uniaxially compressed PETN. We found noticeable differences in the physical and chemical responses of PETN for different combinations of the slip system and compression direction. The simulation results agree well with the experimental shock-initiation sensitivity data and Dick’s steric hindrance theory.

Supported by DoD/ARO (W911NF-05-1-0345) and DoD/ONR (N00014-05-1-0778)

10:12AM H13.0009 First-Principles Constitutive Relationships in PETN and HMX under Hydrostatic and Uniaxial Compressions1. SERGEY V. ZYBIN, California Institute of Technology, MICHAEL W. CONROY, IVAN I. ÖYLENIK, University of South Florida, CARTER T. WHITE, Naval Research Laboratory — The physical mechanisms leading to shock-induced detonation at the atomic level are ultimately related to energetic materials response to uniaxial compression at the shock front. Due to the intrinsic anisotropy of the constitutive relationships, a description of the compressed state should be extended beyond hydrostatic equations of state that are frequently used for analysis of precursor states of EMs. In this presentation, we will discuss the results of first-principles density functional theory calculations of both hydrostatic and uniaxial compressions in the [100], [010], [001], [110], [101], [011], and [111] directions applied to the energetic materials PETN-I and β-HMX. A comparison will be made of available experimental data with calculated physical properties such as unit cell geometry, isothermal equations of state, and elastic constants. The presentation will focus on the anisotropic nature of the constitutive relationships in molecular crystals under uniaxial compression. The behavior of the shear stress projections on available slip systems upon uniaxial strain and their possible relationship to experimental shock-initiation sensitivity data will be discussed.

Supported by DoD/ARO and DoD/ONR

10:24AM H13.00011 Reactive molecular dynamics simulations of shocked PETN2. JOANNE BUDZIEN, AIDAN P. THOMPSON, Sandia National Laboratories, SERGEY V. ZYBIN, California Institute of Technology — We have performed molecular dynamics simulations of PETN crystals subjected to shock along the [100] direction. Using the reactive forcefield, ReaxFF, and the molecular dynamics code, GRASP, allows us to track the chemical reactions that occur as both a function of time and position. By simulating larger systems, we can observe the formation of both primary and secondary products to make comparisons with experiments. Composition profiles of these products will be shown along with profiles of stress, temperature, and potential energy.

Supported by DoD/ARO (W911NF-05-1-0345) and DoD/ONR (N00014-05-1-0778)

Tuesday, March 11, 2008 8:00AM - 10:48AM — Session H14 DAMOP: Cold Gases: One Dimensional Phenomena Morial Convention Center 205

8:00AM H14.00001 Feshbach physics in a one-dimensional optical lattice, NICOLAI NYGAARD, RUNE PIIL, KLAUS MØLMER, Lundbeck Foundation Theoretical Center for Quantum System Research, Department of Physics and Astronomy, University of Aarhus — We consider a pair of atoms in a one-dimensional optical lattice interacting via a Feshbach resonance. Using a two-channel description of the resonance, we derive the analytic form of the Fano scattering resonance inside the continuum band and the discrete bound states outside the band. We suggest experiments to probe and utilize the special properties of the system, which arise from the continuum having an upper edge.

8:12AM H14.00002 Pairing states of a polarized Fermi gas trapped in a one-dimensional optical lattice, ADRIAN FEIGUIN, University of Maryland, College Park, and Microsoft Station Q, FABIAN HEIDRICH-MEISNER, Institut für Theoretische Physik C, RWTH Aachen, Germany — We study the properties of a one-dimensional (1D) gas of fermions trapped in a lattice by means of the density matrix renormalization group method, focusing on the case of unequal spin populations, and strong attractive interaction. In the low density regime, the system phase-separates into a well defined superconducting core and a fully polarized metallic cloud surrounding it. We argue that the superconducting phase corresponds to a 1D analogue of the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state, with a quasi-condensate of tightly bound bosonic pairs with a finite center-of-mass momentum that scales linearly with the magnetization. In the large density limit, the system allows for four phases: in the core, we either find a Fock state of localized pairs or a metallic shell with free spin-down fermions moving in a fully filled background of spin-up fermions. As the magnetization increases, the Fock state disappears to give room for a metallic phase, with a partially polarized superconducting FFLO shell and a fully polarized metallic cloud surrounding the core.

8:24AM H14.00003 The FFLO Phase in Imbalanced Spin Fermions in 1-d1. MIRIAM HUNTLEY, MIT, RICHARD SCALETTAR, UC Davis, GEORGE BATROUNI, Université de Nice-Sophia Antipolis, VALERY ROSSEAU, Universiteit Leiden Instituut Lorentz — Pairing in imbalanced spin populations has lately been the focus of many experimental and theoretical studies. Different mechanisms have been proposed to explain how pairing takes place between the two fermionic species. In this talk we will present exact Quantum Monte Carlo simulations of imbalanced spin populations in one dimension. We will first discuss the case where no confining potential is imposed. Here we have found that the pair-pair correlation function develops oscillations at nonzero polarizations, corresponding to a pair momentum distribution that, instead of being peaked at zero, is peaked at a momentum equal to the difference in the Fermi momenta. This indicates that the pairing mechanism is described by the Fulde Ferrel Larkin Ovchinnikov (FFLO) picture, and not by other proposed phases which require zero-momentum pairing. When a confining potential is included in the simulations, we find that the FFLO oscillations are still present. In addition, we show that the local polarization displays a dip in the center of the trap, similar to experimental observations performed with 3-dimensional optical traps.

3MHH is supported by NSF PHY-0649297 (REU), RTS by DARPA/AFOSR, GGB by the CNRS (France) PICS 18796, and VGR by the research program of the ‘Stichting voor Fundamenteel Onderzoek der Materie (FOM)’. 
8:36AM H14.00004 One dimensional trapped fermions with attractive contact interactions

MICHELE CASULA, DAVID CEPERLEY, Department of Physics, University of Illinois at Urbana-Champaign — Recent advances in cold atomic physics allow creation of optical lattices which reproduce well defined model Hamiltonians. This opens the route to resolve the phases of strongly correlated systems by carrying out experiments with trapped cold atoms. In this work, we study the properties of one dimensional trapped spin 1/2 fermions with attractive contact interactions by means of exact quantum Monte Carlo techniques. According to the local density approximation (LDA), such a system is expected to show phase separation between a Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state and either fully polarized or fully paired outer shells.[1] Here we show how the size and temperature affect the LDA phase boundaries. Mapping out the dependence on the number of particles, temperature, and interaction strength is extremely useful to benchmark experiments where cold atoms are trapped in arrays of cigar-shaped tubes, and understand whether the related setup will be able to detect the signatures of the FFLO state.

3We acknowledge support from the DARPA grant W911NF-07-1-0464 and the computer facilities at NCSA.

8:48AM H14.00005 Quantum Monte Carlo study of the visibility of one-dimensional Bose-Fermi mixtures

CHRISTOPHER VARNEY, University of California, Davis, VALERY ROUSSEAU, Institut Lorentz, RICHARD SCALETTAR, University of California, Davis — The study of ultra-cold, optically trapped atoms has opened new vistas in the physics of correlated quantum systems. Much attention has now turned to mixtures of bosonic and fermionic atoms. A central puzzle is the disagreement between the experimental observation of a reduced bosonic visibility \( V_b \), and quantum Monte Carlo (QMC) calculations which show \( V_b \) increasing. In this talk, we present new QMC simulations which evaluate the density profiles and \( V_b \) of mixtures of bosons and fermions in one-dimensional optical lattices. We resolve the discrepancy between theory and experiment by identifying parameter regimes where \( V_b \) is reduced, and where it is increased. We present a simple qualitative picture of the different response to the fermion admixture in terms of the superfluid and Mott insulating domains before and after the fermions are included. Finally, we show that \( V_b \) exhibits kinks which are tied to the domain evolution present in the pure case, and also additional structure arising from the formation of composite boson-fermion particles.

9:00AM H14.00006 Molecular superfluid phase in one-dimensional multicomponent fermionic cold atom systems

GUILLAUME ROUX, LPT, IRSAMC, CNRS, Universite Paul Sabatier, Toulouse, France and Institut fur theorethische Physik C, RWTH Aachen, SYLVAIN CAPPONI, LPT, IRSAMC, CNRS, Universite Paul Sabatier, Toulouse, France, PHILIPPE LECHEMONNANT, LPTMC, Universite Pierre et Marie Curie, CNRS, Paris, France, EDOUARD BOULAT, LMPQ, Universite Paris Diderot - Paris 7, CNRS, France, STEVEN R. WHITE, Department of Physics and Astronomy, University of California, Irvine, USA — We study a simple model of \( N \)-component fermions with contact interactions which describes fermionic atoms with \( N = 2F + 1 \) hyperfine states loaded into a one-dimensional optical lattice. We show by means of analytical and numerical approaches that, for attractive interaction, a quasi-long-range molecular superfluid phase emerges at low density. In such a phase, the pairing instability is strongly suppressed and the leading instability is formed from bound-states made of \( N \) fermions.

1Support of the NSF under Grant DMR-0605444.

9:12AM H14.00007 Spin and charge velocities of one-dimensional boson-fermion mixture

SHIH-JIAN GU, Department of Physics and ITP, The Chinese University of Hong Kong, Hong Kong, China, JUNPENG CAO, Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China, HAIO-QING LIN, Department of Physics and ITP, The Chinese University of Hong Kong, Hong Kong, China — We study the ground state and elementary excitations of a one-dimensional mixture of scalar bosons and spin-1/2 fermions with repulsive delta-function interaction by the Bethe-ansatz method. Though the ground state properties are dramatically changed once bosons are mixed into fermions, the spin and charge excitations still feature linear dispersions, and their velocities satisfy a simple universal relation.

2This work is partly supported by HKRGC of No. CUHK-401504, and NSFC under Grant No. 10574150.

9:24AM H14.00008 The ground state properties of two-component ultra-cold Fermi gas in hard wall confinement

BO-BO WEI, Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Shatin, NT, Hong Kong, China, JUN-PENG CAO, Institute of Physics and Laboratory of Condensed Matter Physics, The Chinese Academy of Sciences, China, SHI-JIAN GU, HAI-QING LIN, Department of Physics and Institute of Theoretical Physics, The Chinese University of Hong Kong, Shatin, NT, Hong Kong, China — We investigate the ground state properties of a one-dimensional two-component ultra-cold Fermi gas subjected to a hard wall trap. The explicit form of the wave function is obtained by solving the Bethe Ansatz equations numerically. Then we obtain the one-body density matrix of the system for different interaction strengths. Results of the momentum distribution of the atoms, which are obtained from the Fourier transform of the one-body density matrix, are reported for different interaction strengths. This interacting system may be experimentally accessible using ultra-cold atoms.

9:36AM H14.00009 Quantum Phase Transition between (Luttinger) Liquid and Gas of Cold Molecules

DIMA FELDMAN, KAM TUEN LAW, Brown University — We consider cold polar molecules confined in a helical optical lattice similar to those used in holographic microfabrication. An external electric field polarizes molecules along the axis of the helix. The large-distance inter-molecular dipolar interaction is attractive but the short-scale interaction is repulsive due to geometric constraints and thus prevents collapse. The interaction strength depends on the electric field. We show that a zero-temperature liquid-gas transition occurs at a critical field. It can be observed under experimentally accessible conditions.

1We acknowledge the support by NSF under Grant No. DMR-0544116

9:48AM H14.00010 Dynamics of excitations in a one-dimensional Bose liquid

MAXIM KHODAS, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA, MICHAEL PUSTILNIK, School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332, USA, ALEX KAMENEV, School of Physics and Astronomy, University of Minnesota, Minneapolis, Minnesota 55455, USA, LEONID I. GLAZMAN, Department of Physics, Yale University, New Haven, Connecticut, USA, 06520 — We studied the dynamical structure factor \( S(q, \omega) \) of interacting bosons in one-dimension. The sharp resonant peak \( S(q, \omega) \propto \delta(\omega - \epsilon(q)) \) as predicted by the Bogolubov theory is transformed into a power law singularity, \( S(q, \omega) \propto (\omega - \epsilon(q))^{-\theta(q)} \) due to the strong quantum fluctuations. The corresponding momentum dependent exponent \( \mu(q) \) is evaluated using the Lieb-Liniger model. The full momentum dependence \( \mu(q) \) has been found in the strongly interaction regime using the Fermi Bose mapping. For the large momentum \( q \) the different method allows us to express the exponent through the Luttinger liquid parameters. The two results agree in their common region of applicability.

1Research in University of Minnesota is supported by DOE (Grant No. DE-FG02-06ER46310) and A. P. Sloan Foundation. Research in Georgia Tech is supported by NSF (Grant No. DMR-0604107).
scales as we analyze the dependence of the density of created excitations on the ramp rate $\delta$. We find that for strongly interacting commensurate bosons this density scales as $\sqrt{\delta}$, while for weakly interacting bosons it scales as $\delta^2$.

We compute experimentally relevant response functions and we derive asymptotically exact expressions near the quantum critical points separating the Haldane insulator from the conventional Mott and density wave insulators. In particular, we predict a narrow absorption peak in Bragg spectroscopy experiments, due to the excitation of a single domain wall in the string order.

10:24AM H14.0011 Bosonic Mixtures in one-dimensional optical lattices I., LUDWIG MATHEY, NIST, Gaithersburg, and JIQ, UMD, ANZI HU, JIQ, UMD, and NIST, Gaithersburg, IPPEI DANSHTA, JIQ, UMD, and Waseda University, Tokyo, CARL WILLIAMS, JIQ, UMD, and NIST, Gaithersburg, CHARLES CLARK, NIST, Gaithersburg, and JIQ, UMD — We study binary bosonic mixtures of ultra-cold atoms, confined to one dimension in an optical lattice, for various densities. Within a Luttinger liquid description, using renormalization group equations at second order, we determine both ordered and quasi-ordered phases of these mixtures. At commensurate filling, e.g., unit-filling and half-filling, we find different types of localized phases, whereas for densities that are incommensurate to the lattice, but equal for the two species, we find the behavior of a spin gap transition. We discuss the properties of the various phases, and how they could be detected in experiment.

Tuesday, March 11, 2008 8:00AM - 11:00AM – Session H15 GQL: Focus Session: Superconducting Qubits I Morial Convention Center 207

8:00AM H15.00001 Designing quantum-information-processing superconducting qubit circuits that exhibit lasing and other atomic-physics-like phenomena on a chip\(^1\), FRANCO NORI, Frontier Research System, RIKEN, Saitama, Japan; and Physics Dept., Univ. of Michigan, Ann Arbor, USA. — Superconducting (SC) circuits can behave like atoms making transitions between a few energy levels. Such circuits can test quantum mechanics at macroscopic scales and be used to conduct atomic-physics experiments on a silicon chip. This talk overviews a few of our theoretical studies on SC circuits and quantum information processing (QIP) including: SC qubits for single photon generation and for lasing; controllable couplings among qubits; how to increase the coherence time of qubits using a capacitor in parallel to one of the qubit junctions; hybrid circuits involving both charge and flux qubits; testing Bell’s inequality in SC circuits; generation of GHZ states; quantum tomography in SC circuits; preparation of macroscopic quantum superposition states of a cavity field via coupling to a SC qubit; generation of nonclassical photon states using a SC qubit in a microcavity; scalable quantum computing with SC qubits, and information processing with SC qubits in a microwave field. Controllable couplings between qubits can be achieved either directly or indirectly. This can be done with and without coupler circuits, and with and without data-buses like EM fields in cavities (e.g., we will describe both the variable-frequency magnetic flux approach and also a generalized double-resonance approach that we introduced). It is also possible to “turn a quantum bug into a feature” by using microscopic defects as qubits, and the macroscopic junction as a controller of it. We have also studied ways to implement radically different approaches to QIP by using “cluster states” in SC circuits. For a general overview of this field, see, J.Q. You and F. Nori, Phys. Today 58 (11), 42 (2005)

\(^1\)Work supported by RIKEN, NSA, LPS, ARO, NSF, CREST, JSPS.

8:36AM H15.00002 A Tunable Coupling Architecture For Josephson Phase Qubits, RADOSLAW BIALCZAK, M. ANSMANN, M. HOFHEINZ, E. LUCERO, R. MCPHERSTON, M. NEELEY, A.Q. O’CONNELL, H. WANG, A. CLELAND, J. MARTINIS, U.C. Santa Barbara — Previous coupled-qubit experiments with Josephson phase qubits have used a fixed coupling scheme. However, in order to create high-fidelity multi-qubit gates, a tunable coupling scheme is needed. Fixed coupling schemes cannot be used because single-qubit operations on a coupled-qubit system cannot be performed with high fidelity due to the errors induced by always-on coupling. Fixed coupling also allows for crosstalk between coupled qubits during measurement. We show how to implement a tunable-coupling architecture for Josephson phase qubits using simple linear elements. This architecture can be used to vary the interaction strength from fully-off to fully-on allowing us to get around the problems inherent with the use of a fixed coupling scheme.

8:48AM H15.00003 High-fidelity gates in Josephson phase qubits, ERIK LUCERO, University of California at Santa Barbara, MARKUS ANSMANN, RADOSLAW BIALCZAK, MAX HOFHEINZ, NANDA KATZ, The Hebrew University of Jerusalem, MATTTHEW NEELEY, AARON O’CONNELL, HAOMIAO WANG, ANDREW CLELAND, JOHN MARTINIS — Complex algorithms for a quantum computer will require error correction, which calls for logic gates with fidelity below a fault tolerant threshold. We present significant progress towards this goal with our detailed measurements of gate fidelity. We carefully separate out gate and measurement error and construct a complete error budget to demonstrate single qubit gate fidelities of 0.98, limited by energy relaxation. We introduce a new metrology tool ‘a Ramsey interference error filter’ that can measure the excited two-state population down to $10^{-4}$, a magnitude near the fault tolerant threshold. This measurement demonstrates that our quantum system remains in the two-state qubit manifold during our single qubit operations. This precision and accuracy is made possible by custom control electronics that can create arbitrarily shaped microwave pulses.
9:00AM H15.00004 Recent progress towards violating the CHSH Bell inequality in Josephson phase qubits. MARKUS ANSGMANN, University of California at Santa Barbara, RADOUSŁAW BIALCZAK, MAX HOFHEINZ, NADAV KATZ, The Hebrew University of Jerusalem, ERIK LUCERO, MATTHEW NEELEY, AARON O’CONNELL, HAOHUA WANG, ANDREW CLELAND, JOHN MARTINIS — Improvements of gate fidelity and control electronics for Josephson phase qubits have provided the foundation for revisiting Bell’s inequality. The violation of Bell’s inequality is the primary argument against the possible existence of a hidden-variable-theory as an alternative to quantum mechanics. It also serves as a convincing demonstration that a given system behaves in a truly non-classical way. The most widely accepted form of Bell’s inequality follows closely along a correlation measurement proposed by Clauser, Horne, Shimony and Holt (CHSH) in 1969. Here we present our latest attempt to implement the CHSH Bell test using Josephson phase qubits. The nature of this experiment places high demands on the current state of the art in solid state qubits — on qubit performance measures such as the energy relaxation time $T_1$, the decoherence time $T_2$, single and two qubit gate fidelities, and measurement fidelities. We will examine these demands with respect to the number of fronts we have improved upon in our system.

9:12AM H15.00005 Analysis of Bell inequality violation in superconducting phase qubits$^1$. ABRAHAM G. KOFMAN, ALEXANDER N. KOROTKOV, University of California, Riverside — We analyze conditions for violation of the Bell inequalities, focusing on experiments with Josephson phase qubits. In the ideal case we discuss all possible situations of maximum violation, but mainly focus on two important types of optimal qubit-measurement directions in the pseudospin space, lying within either horizontal or vertical planes. Only the vertical type remains optimal in presence of local measurement errors, while in the case of local decoherence of qubits either the horizontal or vertical configuration is optimal. Besides local measurement errors and decoherence, we also discuss the effect of measurement crosstalk, which affects both the classical inequality and the quantum result. In particular, we propose a version of the Bell inequality which is insensitive to the crosstalk.

9:24AM H15.00006 High Fidelity Universal Quantum Gates in Superconducting Qubit Systems Using Non-adiabatic Rapid Passage. FRANK GAITAN, RAN LI, Southern Illinois University — Recent theoretical work$^2$ has suggested that a class of non-adiabatic rapid passage sweeps first realized experimentally in NMR systems in 1991, can be used to produce a high fidelity universal set of quantum gates. We show how this class of sweeps can be implemented in both superconducting charge and flux qubit systems. We discuss the current challenges facing the use of these sweeps to produce a universal set of high fidelity quantum gates in superconducting qubit systems.

$^1$Supported by the DTO/ARO grant

9:36AM H15.00007 Improving dc SQUID Phase Qubit Lifetimes through Increased Isolation from Bias Leads$^3$. ANTHONY PRZYBYSZ, TAUNO PALOMAKI, SUDEEP DUTTA, FRED WELLSTOOD, RUPERT LEWIS, HANHEE PAIK, HYEOKSHIN KWON, BEN COOPER, KAUSHIK MITRA, BOB ANDERSON, ALEX DRAGT, CHRIS LOBB, QJI, University of Maryland — The dc SQUID phase qubit has been plagued by a relatively short coherence time, $T_2$, and relaxation time, $T_1$ (tens of ns). By using a sapphire substrate and small (15 $\mu$m$^2$ or less) Al/AIO$_x$/Al junctions the performance of the qubit has improved to the point where the impedance of the bias leads is the main source of dissipation and decoherence in the device. We identify the main circuit parameters that effect the isolation (junction capacitance, loop inductance, etc.), and present designs to improve the qubits isolation from the bias leads.

$^3$This work was funded by the Joint Quantum Institute, the Center for Nanophysics and Advanced Materials, and the Department of Defense.

9:48AM H15.00008 Anomalous Avoided Level Crossings in a Cooper-Pair Box Spectrum$^4$. ZAEILL KIM, V. ZARETSKEY, Y. YOON, Department of Physics, University of Maryland, J.F. SCHNEIDERMAN, M.D. SHAW, Department of Physics and Astronomy, University of Southern California, P.M. ECHTERNACH, Jet Propulsion Laboratory, California Institute of Technology, F.C. WELLSTOOD, QJI, CNAM, Department of Physics, University of Maryland, B.S. PALMER, LPS — We have used a radio-frequency superconducting single-electron transistor to measure the detailed spectrum of an Al/AIO$_x$/Al Cooper-pair box (CPB) qubit. The CPB had a charging energy $E_C/k_B=0.58$ K and a Josephson energy $E_J/k_B$, which can be tuned by an external magnetic flux, between 0.1 and 1 K. From 15 to 50 GHz we have found four anomalous avoided level crossings in the excited state spectrum of the CPB. We note the splitting size has a strong dependence on the Josephson energy and the location of the splitting depends on the gate voltage of the CPB, evidence that the CPB is coupled to other quantum systems that are charged. We compare our results to a model Hamiltonian that describes a charge fluctuator coupled to a CPB and extract fit parameters that provide microscopic information about the charge fluctuators.

$^4$This research was supported by the National Security Agency.

10:00AM H15.00009 Detailed Study of the Excited State Lifetime of a Cooper-Pair Box$^5$. VITALEY ZARETSKEY, Z. KIM, Y. YOON, Department of Physics, UMD, J. F. SCHNEIDERMAN, M. D. SHAW, Department of Physics and Astronomy, USC, P. M. ECHTERNACH, JPL, Caltech, F. C. WELLSTOOD, QJI, CNAM, Department of Physics, UMD, B. S. PALMER, LPS — We have used a radio-frequency superconducting single-electron transistor (rf-SET) to measure the lifetime of the excited state ($T_1$) of an Al/AIO$_x$/Al Cooper-pair box (CPB) qubit with a charging energy $E_C/k_B=0.58$ K. We measured the lifetime by continuously measuring the decay of the qubit from a mixed state. By effectively decreasing $E_J/k_B$ from 1 K to 0.1 K we could increase $T_1$ from 50 ns to 5 s which indicates that charge is the dominant noise source. Additionally we noted that the decay rate as a function of transition frequency had several narrow peaks in the range 15 to 50 GHz. These peaks correlated with the locations of anomalous avoided level crossings we observed in the excited state spectrum of the CPB$^4$, suggesting that interaction with microstates is a source of dissipation for these qubits.

$^5$This research was supported by the NSA.

$^2$Anomalous Avoided Level Crossings in a Cooper-Pair Box Spectrum, ZAEILL KIM et al., BAPS (March 2008)
voltage. Measurements are performed using RF reflectometry to measure the quantum capacitance of each device.

We discuss the dependence of these rates on a variety of experimental parameters, such as RF power, microwave power, magnetic flux, sample temperature, and gate voltage. Measurements are performed using RF reflectometry to measure the quantum capacitance of each device.

10:24AM H15.00011 Robust optimal quantum gates for Josephson charge qubits, SIMONE MONTANGERO, NEST-CNR-INFM & Scuola Normale Superiore, P.zza dei Cavalieri 7, Pisa, Italy, TOMMASO CALARCO, ITAMP, Harvard University, Cambridge, MA 02138, U.S.A., ROSARIO FAZIO, NEST-CNR-INFM & Scuola Normale Superiore, P.zza dei Cavalieri 7, Pisa, Italy — Quantum optimal control theory allows us to design accurate quantum gates. We employ it to design high-fidelity two-bit gates for Josephson charge qubits in the presence of both leakage and noise. Our protocol considerably increases the fidelity of the gate and, more importantly, it is quite robust in the disruptive presence of 1/f noise. The improvement in the gate performances discussed in this work (errors ∼10^{-3}±10^{-4} in realistic cases) allows to cross the fault tolerance threshold.

10:36AM H15.00012 Suppression of decoherence due to classical noise by dynamical decoupling, LUKAZS CYWINSKI, ROMAN M. LUTCHYN, CODY P. NAVE, SANKAR DAS SARMA, Condensed Matter Theory Center and Joint Quantum Institute; Department of Physics; University of Maryland — We consider a pure dephasing model in the context of superconducting qubits. We show that the coherence time T2 can be significantly increased by the application of a series of π pulses. The most well known example, spin echo, a one pulse sequence, removes inhomogeneous broadening. However, T2 can be further increased by applying more pulses. We discuss the experimental implications of various pulse sequences in the context of classical 1/f noise in a Cooper-pair box qubit. We show that a recently proposed coherence-restoring pulse sequence [1, 2], discovered in the context of the spin-boson model, is optimal in certain regimes of parameter space. [1] G. S. Uhrig Phys. Rev. Lett. 98, 100504 (2007) [2] B. Lee, W. M. Witzel, S. Das Sarma, arXiv:0710.1416 (2007).

10:48AM H15.00013 The effect of dynamical decoupling in the case of a single fluctuator coupled to a qubit, CODY NAVE, ROMAN LUTCHYN, LUKAZS CYWINSKI, SANKAR DAS SARMA, Condensed Matter Theory Center and Joint Quantum Institute; Department of Physics; University of Maryland - College Park — We consider the role of dynamical decoupling in the case of a single classical fluctuator coupled to a qubit which is operated in a pure dephasing regime. We study the effect of various pulse sequences on the decoherence time for both weakly and strongly coupled fluctuators described by random telegraph noise (RTN). For a strongly coupled two-level system, the application of multiple pulses leads to a large enhancement of qubit coherence time. By theoretically comparing various dynamic decoupling schemes, we conclude that the Car-Purcell-Meiboom-Gill (CPMG) pulse sequence, well-known in NMR spectroscopy and recently discussed in the context of electron spin qubits in semiconductors [1], is the most optimal coherence-restoring scheme for the single fluctuator problem of relevance to superconducting qubits. We also find that for a large number of applied pulses the Gaussian approximation for the noise reproduces the exact results even in the strongly coupled regime.

This work is supported by the LPS-NSA-CMTC grant and by a fellowship from the Joint Quantum Institute (RL).

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H16 DBP DFD: Focus Session: Biochip Physics I Morial Convention Center 208

8:00AM H16.00001 Size Scaling of Protein Sensitivity on the BioCD, KEVIN O’BRIEN, MING ZHAO, XUEFANG WANG, DAVID NOLTE, Purdue University — We investigate size scaling of the surface-height sensitivity of spinning-disk interferometry (SDI) implemented on the in-line-quadrature BioCD as a function of laser focal radius. The in-line-quadrature BioCD consists of a silicon wafer with a 120 nm layer of silicon dioxide that creates a quadrature condition between the incident and reflected light. When a laser beam is focused on the BioCD, proteins printed on the silicon dioxide substrate create a phase shift leading to quadrature interference, which is detectable as an intensity shift. The purpose of this scaling experiment is to determine the practical and fundamental limits on the sensitivity of the BioCD, and how those limits change as a function of the size of the focal spot. We imaged a single 100 micron wide protein spot with focal spot sizes of 1, 5 and 10 microns and observe a square-root scaling as a function of the number of pixels per protein spot.

1NSF REU Program

8:12AM H16.00002 Detection Limits of Captured Protein on the BioCD, DAVID NOLTE, XUEFANG WANG, KEVIN O’BRIEN, MING ZHAO, Purdue University — The BioCD is an interferometric biosensor that detects protein captured by antibody arrays. The sensor readout is performed on a spinning disc using a common-path interferometric configuration that is stable and sensitive to sub-monolayer coverage of captured protein. Protein is detected using phase quadrature that converts phase to intensity modulation using local generation of signal and reference to lock the relative phase of the waves. The purpose for spinning is to move far from 1/f noise to achieve high surface mass sensitivity. Several different classes of the BioCD have been developed, differentiated by the means of generating the phase-locked reference. These include the microdiffraction (MD) class, the phase contrast (PC) class, the adaptive optical (AO) class and the in-line (IL) class of BioCD. Of these different quadrature classes, the in-line BioCD has the highest sensitivity with a detection sensitivity of 0.25 pg/mm. The minimum detectable mass is set by simple scaling relations. The metrology limit is set by surface roughness combined with repositioning offset between pre- and post-incubation scans. Optimal sensitivity is achieved by critical sampling of protein spots in radial arrays.

8:24AM H16.00003 Docetaxel-loaded Nanohorn-streptavidin-antibody for Anti-cancer Drug Delivery, JIANXUN XU, MASAKO YUDASAKA, MINFANG ZHANG, JST/SORST, NEC, 34 Miyukigaoka, Tsukuba, Ibaraki 305-8501, SIMUO IJIMA, Meijo University, Nagoya 468-8502, Japan — Single wall carbon nanotube (SWNH) is a new kind of nano-carbon tubule having horn-like structure at its tip. The tube diameters are 2 to 5 nm, and about 2,000 SWNHs assemble to form a spherical aggregate. SWNH is an attractive candidate for drug delivery, especially promising to carry anticancer drug, many of which are not water soluble and highly toxic. We incorporated Docetaxel (Doc), an anticancer drug used for stomach cancer and others, into hydrogen peroxide treated SWNH (SWNHox). By using carboxylic groups on SWNHox, we attached amine-PEO3-biotin, and then streptavidin to biotin. The streptavidin moiety on SWNH makes it easy to attach some other biotinylated molecules, thus we introduced a cancer targeting ligand, anti-tumor associated glycopolypeptide, to the SWNH system. Due to the targeting effect of the antibody, the cells were effectively killed when they were incubated with the Doc SWNHox-streptavidin-antibody system.
8:36AM H16.00004 Detection limits and scalability of miniaturized antibody assays in real-world applications
BRIAN HAAB, Van Andel Institute — Antibody-based analytical assays have increasing importance in biological and biomedical applications. The ability to miniaturize the assays can lead to increased multiplexing and throughput, thus increasing information content while saving on the consumption of valuable samples and reagents. However, several challenges need to be addressed to enable the implementation of such technologies. This talk will address the factors affecting detection limits and scalability in real-world applications of antibody microarrays for the study of proteins in human blood serum.

9:12AM H16.00005 InAs quantum well μ-Hall sensors for magnetic biosensing
KHALED ALEDEALAT, S. HIRA, K. CHEN, Florida State Univ, G. MIHALOVIĆ, Materials Science Division, Argonne National Lab, P. XIONG, G. STROUSE, P.B. CHÄSE, S. VON MOLNAN, Florida State Univ, M. FIELD, C. SULLIVAN, Teltronic Scientific Company LLC — Magnetic sensing is potentially a sensitive and rapid technique for monitoring DNA-DNA and protein-DNA interactions. Here we present an effort on the noise characterization and selective biofunctionalization of InAs μ-Hall sensors for magnetic detection of DNA hybridization. Room-temperature noise measurements were performed in the frequency range from 20 Hz to 104 kHz. The noise equivalent magnetic moment resolution were estimated to be \( \sim 10^5 \mu_B/\sqrt{Hz} \) and \( \sim 10^4 \mu_B/\sqrt{Hz} \). The active region of the InAs μ-Hall device was covered with sputter-deposited SiO₂ and Au pads were patterned on top of some of the Hall crosses. Thiolated ssDNA were assembled on the Au pads and the rest of the device platform was passivated with PEG-silane. Biotinylated and fluorescently-tagged complementary ssDNA were labeled with commercial streptavidin-coated 350 nm superparamagnetic beads, which were found to assemble selectively onto the Au pads through DNA hybridization using laser scanning confocal microscopy. This work was supported by NIH NIGMS GM079592.

9:24AM H16.00006 Ligand-receptor binding kinetics in surface-plasmon resonance devices: A Monte Carlo simulation study
MATTHEW T. RAUM, Department of Physics, Virginia Tech, Blacksburg, VA 24061-0435, MANOJ GOPALAKRISHNAN, Harish-Chandra Research Institute, Allahabad 211019, India, KIM FORSTEN-WILLIAMS, Department of Chemical Engineering, Virginia Tech, Blacksburg, VA 24061-0435 — We use lattice Monte-Carlo simulations to probe the kinetics of ligand-receptor association and dissociation. Simulations were run under conditions approximating the geometric configuration of surface plasma resonance devices. These conditions include viscous flow of ligand over a surface of receptors which is achieved by using a spatially varying biased random walk. Our simulations allow for the occurrence of multiple rebinding events which result in long deviations from the standard mean-field rate equation approximation. Our simulations also allow us to test improved theoretical predictions for the binding dynamics and to determine their range of applicability.

9:36AM H16.00007 Comparative study of different DNA chip preparation methods by means of Surface Plasmon Resonance
YANNICK SARTENAER, Laboratoire Lasers et Spectroscopies - FUNDP - University of Namur, 61 rue de Bruxelles, B-5000 Namur, Belgium, RUYJI HARA, HARUMA KAWAGUCHI, Laboratory of Polymer Chemistry - Keio University, 3-14-1 Hiyoshi, Kohoku-ku, Yokohama 223-8522, Japan, PAUL A. THIRY, Laboratoire Lasers et Spectroscopies FUNDP - University of Namur, 61 rue de Bruxelles, B-5000 Namur, Belgium — Recently, we demonstrated that SPR vibrational spectroscopy allows the detection of the specific recognition between the two molecules of a model ligand-protein biosensor. Moreover, we studied by this technique, the formation of thiolated single stranded DNA (ssDNA) monolayers immobilized on metallic substrates which are the basis for various biotechnology applications. Before going further into monitoring the hybridisation process in DNA based sensors, it is important to identify a preparation method providing good quality DNA chips with respect to the recognition process. Therefore, we performed investigations by Surface Plasmon Resonance (SPR). Practically, we used four different methods of chip preparation on gold surfaces and we measured the amount of deposited molecules when the sensor is exposed to a target DNA solution. By this way, we monitored for each case the sensitivity and the selectivity of the sensor by comparing the hybridisation of complementary and non complementary target ssDNA, respectively.

9:48AM H16.00008 Nanoscale Building Blocks for Bioensor Development
AMANDA J. HAES, Department of Chemistry, University of Iowa — The development of new technologies based on nano- and microscale phenomenon is important and significant for many reasons. One of the most prominent of these is biological sensors for the diagnosis of diseases, detection of environmental toxins, and drug discovery. Research in our group focuses on the microscopic and spectroscopic analysis of the optical properties of nanostuctures and their integration with microfluidic devices with applications in biological sciences. In this talk, we will show results for an optical sensor based on localized surface plasmon resonance spectroscopy. It will be demonstrated that this nanoparticle based sensor can be used to detect a variety of ligands, including a biomarker for Alzheimer’s disease.

10:24AM H16.00009 Predictive Model for Label-free Electrical Detection of Bio-molecules
PRADEEP NAIR, MUHAMMAD ALAM, School of Electrical and Computer Engineering, Purdue University — Biosensors based on MOSFETs, silicon nanowires, and carbon nanotube nanocomposites promise highly sensitive, dynamic, label-free, electrical detection of bio-molecules with potential applications in genomics and proteomics. Although tremendous improvements in sensitivity have been reported in electrical detection of bio-molecules, many aspects of experimentally observed sensor response (S) are unexplained within the theoretical frameworks of kinetic response or electrolyte screening. In this paper, we combine analytic solutions of Poisson-Boltzmann and reaction-diffusion equations to show that the electrostatic screening within an ionic environment limits the response of nanobiosensor such that \( S \sim c_1 \left( \ln(c_0) - \ln(c_f) + \ln(c_r) + \frac{pH}{D_F} \right) + c_2 \) where \( c_1 \) are geometry-dependent constants, \( c_0 \) is the concentration of target molecules, \( c_f \) the salt concentration, and \( D_F \) the diffusion dimension of sensor surface. Our analysis provides a coherent theoretical interpretation of wide variety of puzzling experimental data that have so far defied intuitive explanation and have important implications for the design and optimization of nanoscale biosensors.

10:48AM H16.00010 Hybrid CMOS/Microfluidic Dielectrophoresis and Magnetic Manipulator Chip
DAVID ISSADORE, Harvard School of Engineering and Applied Sciences (SEAS), THOMAS P. HUNT², Harvard Physics, KEITH A. BROWN, HARVEY SEAS, R.M. WESTERVELT, Harvard SEAS and Physics — We present hybrid CMOS/microfluidic chips that combine the biocompatibility of microfluidics with the programmability of CMOS integrated circuits (ICs). The chips use a two-dimensional array of RF-electrode pixels that use dielectrophoresis (DEP) to simultaneously and independently control the location of many objects, including biological cells and chemical droplets. We highlight our next generation of CMOS/microfluidic chips that combine a two-dimensional array of high voltage (50 V) RF pixels to produce large DEP forces, a microelectromagnetic matrix that can independently trap and move magnetic beads, and integrated temperature sensors. We describe the design, fabrication, and testing of the hybrid chips as well as ongoing work to interface and package the chips for robust biological and chemical experiments.

8:00 AM H17.00001 Linking enzyme conformational dynamics to catalytic function with single-molecule FRET, YAN-WEN TAN, JEFFREY A. HANSON, Dept of Chemistry, UC Berkeley, KARL DUDERSTADT, Biophysics Graduate Group, UC Berkeley, SUCHARITA BHATTACHARYYA, Dept of Chemistry, UC Berkeley, HAW YANG, Dept of Chemistry, Biophysics, UC Berkeley & Physical Biosciences Division, LBNL — Enzymes exhibit endurable conformational remodeling on a timescale comparable to their catalytic cycle. These conformational dynamics may be critical to the enzymes’ catalytic function. In adenylate kinase (AK) from E. coli, this involves a large-amplitude rearrangement of the enzyme’s lid domain. We use high-resolution single-molecule FRET developed in our laboratory to measure AK’s domain movements on its catalytic timescale. We utilize maximum entropy-based methods to remove photon-counting noise from raw data, so that the enzyme’s entire conformational distribution can be quantitatively recovered without a presumed model. Multiple sequence alignment suggests regularities between the conserved residues and their structural-functional roles. Armed with precise single-molecule FRET dynamics measurements and comprehensive bulk kinetic studies of the mechanism, we were able to quantitatively correlate AK’s stochastic lid dynamics with its deterministic catalytic rates. Implications on the structure-function conservation and protein engineering will be discussed.

8:12 AM H17.00002 Concentration-dependent Cu(II) binding to prion protein, MIROSLAV HODAK, NC State U, WENCHANG LU, JERRY BERNHOLC, NC State U and ORNL — The prion protein plays a causative role in several neurodegenerative diseases, including mad cow disease in cattle and Creutzfeldt-Jakob disease in humans. The normal function of the prion protein is unknown, but it has been linked to its ability to bind copper ions. Experimental evidence suggests that copper can be bound in three distinct modes depending on its concentration, but only one of those binding modes has been fully characterized experimentally. Using a newly developed hybrid DFT/DFT method [1], which combines Kohn-Sham DFT with orbital-free DFT, we have examined all the binding modes and obtained their detailed binding geometries and copper ion binding energies. Our results also provide explanation for experiments, which have found that when the copper concentration increases the copper binding mode changes, surprisingly, from a stronger to a weaker one. Overall, our results indicate that prion protein can function as a copper buffer. 1. Hodak, Lu, Bernholc, JCP, in press.

8:24 AM H17.00003 Solvable model of mechanical unfolding of proteins, OLEG VOROV, UNC at Charlotte, DENNIS LIVESAY, DONALD JACOBS, UNC at Charlotte — We present exact analytical results describing single-molecule experiments on mechanical unfolding of proteins within a realistic model [1]. The corresponding relation between the extension at a given temperature of the macromolecule and the applied force is derived [2]. The configuration partition function is calculated exactly for a distance constraint protein model that describes the beta-hairpin to coil transition. The resulting extension-force curve is derived, and the results agree with the data from the single-molecule pulling experiments.

8:36 AM H17.00004 Dynamical Transition in polypeptides, YUNFEN HE, ANDREA MARKELZ, University at Buffalo, SUNY, Buffalo, NY, USA — Two of the possible causes for the so called dynamical transition (the rapid increase in flexibility for biomolecules at ~ 200 K) are: thermally activated side chain diffusive motions with hydration dependent activation energies; or a glass transition in the biological water directly adjacent to the biomolecule. If the transition is strictly due to side chain activation, it should not depend on protein structure. Previously we demonstrated that the dynamical transition remains after tertiary structure was removed using THz time domain dielectric spectroscopy (0.2 -2.0 THz, 0.5-5ps). Here measurements on polyalanine as a function of chain length show that the dynamical transition does not occur for peptide length shorter than 5. However, the transition is observed for 5 mer and higher. Structural and simulation studies indicate that the 5 mer transiently occupies structured forms [1,2]. These results suggest that A) the dynamical transition is not due to thermally activated side chain motion and B) secondary structure is necessary for the dynamical transition. Secondary structure possibly induces sufficient ordering in the adjacent water to result in a fragile to strong glass transition resulting in increased protein flexibility [3].

8:48 AM H17.00005 Dynamically stable beta-sheets in Cu-initiated misfolding of α-synuclein, FRANCIS ROSE, MIROSLAV HODAK, JERRY BERNHOLC, NC State University — The human protein α-synuclein has been implicated as a central constituent in multiple neurodegenerative diseases. In Parkinson disease it is even thought to be the causative link. α-synuclein can be stimulated to aggregate into deleterious fibrillar structures by mutation, metal binding, and agitation. In particular, Cu$^{2+}$ has been found in high concentrations in neural tissues of Parkinson sufferers. We propose a scenario involving the metal ion Cu$^{2+}$ as the misfolding β-sheet initiator of fibrillogenesis. A model fragment of the metal-bound protein was investigated using DFT to obtain conformational details of the energetically favorable geometries. Feasible β-sheet structures incorporating the DFT geometries were explored using heuristic β-sheet guidelines and inverse kinematics. The resulting structures were tested for dynamic stability by simulating the fully solvated protein by classical MD constrained by the DFT geometries. Our results indicate that dynamically stable structures exist and that the metal binding is directly responsible for initiating misfolding.
9:00AM H17.00006 Dynamics of Lysozyme in Trehalose solutions, PAVAN GHATTY, The University of Akron, EDWARD C. UBERBACHER, Oak Ridge National Laboratory — Anhydrobiosis in Tardigrades and Nematodes has been a topic of constant interest and intrigue in the scientific community. An increase in the concentration of Trehalose has been attributed to the ability of some organisms to survive extreme conditions of temperature, pressure and pH. Although there exist many experimental studies attributing this effect to Trehalose, the molecular details governing the interaction between Trehalose and proteins remains unclear. We have conducted a 20ns study of Lysozyme in varying concentrations of Trehalose in water. Strong and weak hydrogen bonds and hydrophobic interactions between water, Trehalose and protein seem to dictate the interactions in the system. We have observed a hydrogen bonded network of Trehalose around the protein entrapping a layer of water between itself and protein. Lysozyme remains in a near-native conformation throughout the simulation giving hints on the ability of Trehalose in preserving the structure of proteins.

9:12AM H17.00007 Spectral and Hydration Dependence of Protein Dynamical Transition1, FERDINAND LIPPS, J. R. KNAB, JING YIN CHEN, YUNFEN HE, A. G. MARKElz, Physics, University at Buffalo, SUNY — The protein dynamical transition, a rapid increase in flexibility at ~200K, is hydration dependent suggesting that the transition may in fact be due to a transition in the surrounding water. Previously we have shown that the terahertz dielectric response is sensitive to the dynamical transition using terahertz time domain spectroscopy [1]. The broadband technique allows the determination of what motions are affected by the transition, that is whether long time scale motions such as side chain rotations, or faster vibrational motions. Here we examine both the frequency and hydration dependence of the protein dynamical transition for hydrated myoglobin powder for the 0.2 – 2.0 THz and 80-295 K ranges. The transition is observed in both the real and imaginary parts of the dielectric response. Our earlier measurements of solutions did not show a transition in the real part of the permittivity, likely due to bulk solvent dominating the index. There is a strong frequency dependence with hydration. While a slight transition is observed at frequencies higher than 1 THz which is nearly hydration independent, for frequencies below 1 THz the strength of the transition rapidly increases with hydration. [1] A. G. Markelz, J. R. Knab, Jing Yin Chen, Yunfen He, Chem. Phys. Lett. 442, 413 (2007).

9:24AM H17.00008 Vibrational Dynamics of Heme Model Compounds, ALEXANDER BARABANSCHIKOV, Northeastern University, TIMOTHY SAGE, Northeastern University, MINORU KUBO, PAUL CHAMPION, Northeastern University, JIYONG ZHAO, WOLFGANG STURHAHN, ERCAN ALP, Advanced Photon Source, Argonne, IL — Synchronous and laser-based measurements supported by DFT calculations identify vibrational modes of the iron atom in Fe(P)(Cl) and Fe(P)(Br). These compounds are large enough to capture many essential aspects of heme geometry and vibrations. On the other hand, porphine models are small enough to simplify the vibrational spectrum and enable accurate analysis using DFT methods. Nuclear resonance vibrational spectroscopy (NRVS) and femtosecond coherence spectroscopy (FCS) provide a rare opportunity to identify both dometing and Fe-hemide stretch components of the reaction coordinate with confidence. Correlation analysis between 4-coordinate and 5-coordinate compounds suggests significant mixing between Fe-ligand and heme modes. Comparison with the larger model Fe(III)(OEP)(Cl) reveals the effect of peripheral group substitutions.

9:36AM H17.00009 Ligand-Modulated Free Energy Landscapes of Glucose/Galactose Binding Protein1, TROY MESSINA, Centenary College of Louisiana — Glucose/galactose binding protein (GBP) functions as part of a larger system of proteins for molecular recognition and signaling in enteric bacteria. Here we report on the thermodynamics of conformational equilibrium distributions of GBP. From both time-resolved fluorescence experiments and computational umbrella sampling molecular dynamics analyses by the weighted histogram analysis method (WHAM). Three conformations appear at zero concentration of GBP and systematically transition to three conformations at high glucose concentration. Fluorescence anisotropy correlations, fluorescent lifetimes, thermodynamics, computational structure minimization and molecular dynamics, and previous work were used to identify the three components as open, closed, and twisted conformations of the protein. The existence of three states at all glucose concentrations indicates that the protein continuously fluctuates about its conformational state space via thermodynamically driven state transitions, and the glucose biases the populations by reorganizing the free energy profile. These results and their implications are discussed in terms specific and non-specific interactions GBP has with cytoplasmic membrane proteins.

9:48AM H17.00010 Ligand Binding Kinetics in Myoglobin and Solvent Relaxation at High Pressure, ALFONS SCHulte, University of Central Florida, SILKI ARORA, SANGHOON PARK — Pressure is increasingly used as a variable to examine protein structure-function relationships, since it is crucial for chemical equilibria, reaction rates, and protein conformational states. We investigate pressure effects for the prototype reaction of ligand binding to myoglobin over a wide dynamic range in time and temperature. The distribution of rebinding rates is evaluated from terahertz time domain spectroscopy (THz-TDS) measurements of Fe(III)(OEP)(Cl) and Fe(III)(OEP)(Br) myoglobin for the 0.1 – 1.0 GPa pressure range and temperature (180 – 300 K) in aqueous and 75 % glycerol/buffer solutions. The data demonstrate that pressure significantly affects the amplitudes (not just the rates) of the component processes. The amplitude of the geminate process increases with pressure corresponding to a smaller escape fraction of ligands into the solvent and a smaller inner barrier. Solvent relaxation rates at variable pressure are determined independently from specific heat spectroscopy. We discuss the role of solvent dynamics, hydration shell, and internal protein cavities in the binding reaction.

10:00AM H17.00011 Magnetic Hyperfine Interactions in Heme Unit of Metmyoglobin, N.B. MAHARJAN, Tribhuvan University, Nepal, S.R. BADU, SUNY Albany, ARCHANA DUBEY, UCF Orlando, R.H. SCHEICHER, Upsala University, Sweden, R.H. PINK, SUNY Albany, LEE CHOW, A. SCHULTE, H.P. SAHA, UCF Orlando, T.P. DAS, SUNY Albany, UCF Orlando — The 14N and 57Fe hyperfine interactions in the heme unit of metmyoglobin are available experimentally by electron-nuclear double resonance (ENDOR) and Mossbauer spectroscope techniques. We have carried out electron structure investigation on the heme system including the H2O and proximal imidazole ligands by the first-principles Hartree-Fock procedure and studied the magnetic hyperfine and nuclear quadrupole coupling constants for the 57Fe nucleus and all the six 14N nuclei on the four pyrrole and imidazole ligands as well as the 17O nucleus on the H2O ligand. Comparison will be made with available experimental data [1, 2] and earlier theoretical investigations [3] by the approximate self-consistent charge Extended Hückel procedure. Results will also be presented for the optical frequencies and intensities of transitions between ligand-like and iron d-like states and the Fe-N, vibrational frequency [1]. G. Lang, Q. Rev. Biophys. 3 (1970) [2] C.P. Scholes, R.A. Isaacson and G Feher, Biochim. Biophys. Acta 263:448(1972) [3] S.K. Mun, Jane C. Chang and T.P. Das J. Am. Chem. Soc. 101, 5562(1979).

10:12AM H17.00012 Hartree-Fock Investigation of Electronic Structure and Associated Properties of Heme Unit in Deoxyhemoglobin, S.R. BADU, SUNY Albany, ARCHANA DUBEY, UCF Orlando, K. RAMANI LATA, SUNY Albany, R.H. SCHEICHER, Upsala University, Sweden, R.H. PINK, SUNY Albany, A. SCHULTE, LEE CHOW, H.P. SAHA, UCF Orlando, K. NAGAMINE, UC Riverside, T.P. DAS, SUNY Albany, UCF Orlando — Using the Hartree-Fock-Roothaan procedure and the most recent version of the Gaussian set of programs we have studied the electronic structure of the heme unit including the imidazole ligand of iron from the proximal histidine using x-ray data for the positions of all the atoms except the hydrogen. The positions of the latter have been obtained through energy optimization. The results obtained from the calculated electronic structure for the magnetic and electronic hyperfine interactions of the 57Fe and 14N nuclei will be discussed. Comparison will be made with available experimental data and earlier theoretical investigations [1]. Results will also be presented for the proximal Fe-N, vibrational frequency and the frequencies and intensities of optical transitions between ligand like states and d-like states of Fe [1]. K Ramani Lata PhD Thesis SUNY Albany (1993) (Unpublished).

Tuesday, March 11, 2008 8:00 AM - 11:00 AM — Session H18 DPOLY: Block Copolymers in Solution and Blends Morial Convention Center 210

8:00 AM H18.00001 Polymer Physics Prize Break

8:36 AM H18.00002 Competitive Adsorption, Exchange and Binding of Polymers and Proteins at the Oil/Water Interface. Daniel Carvajal, Kenneth Shull, Igal Szleifer, Northwestern University — Drop Shape Analysis (DSA) of pendant drops was used to study competitive adsorption, exchange kinetics and binding of macromolecules at the oil/water interface. Amphiphilic diblock and triblock copolymers were dissolved in the oil drop phase, while proteins were added to the water phase. By using DSA to monitor the interfacial tension of the system, we were able to gather data on how the polymers and proteins are behaving and interacting at the oil/water interface. Some polymer systems were found to fully inhibit both specific and non-specific adsorption of proteins to the interface. Adding biological receptors to these polymers allowed us to study the specific binding of proteins to polymers located at the interface. In other systems, proteins were able to penetrate the amphiphilic block copolymer layer and reach the interface. The dynamics of exchange and competitive adsorption in these polymer/protein systems were also studied.

8:48 AM H18.00003 Interfacial Properties of Semifluorinated Alkane Diblock Copolymers. Flint Pierce, Dvora PERAHA, Department of Chemistry Clemson University. MESPIN TSIGE, Department of Physics Southern Illinois University. Oleg Borodin, Department of Materials Science and Engineering and Department of Chemical and Fuels Engineering University of Utah. Gary Grest, Sandia National Laboratory — The surface interaction of semifluorinated alkane diblock copolymers with water and normal alkanes are studied using explicit atomistic molecular dynamic (MD) simulations. At the diblock/air interface, the surface is dominated by fluorinated alkane chains, with a low surface tension, and these groups reside at the interface for longer periods of time than the hydrogenated groups. Flouroalcohols even a single end group on an otherwise hydrogenated chain results in low surface tensions, close to that of perfluoroalkanes and far from normal alkanes. For the interface with water, results for the rate of water uptake by alkanes, perfluoroalkanes, and SFAs will be presented. Additionally, we report the interfacial surface tensions and equilibrium density profiles for these samples, focusing on the prevalence of fluorinated and hydrogenated segments at each interface. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under Contract DE-AC04 - 94AL85000.

9:00 AM H18.00004 Amphiphilic copolymer assemblies formed by interfacial instabilities of oil-in-water emulsions. Jintao Zhu, Ryan C. Hayward, Department of Polymer Science and Engineering, University of Massachusetts at Amherst — Self-assembly of amphiphiles into discrete nano-objects is of fundamental interest and is important for applications including encapsulation and drug delivery. We will discuss a new method by which amphiphilic block copolymers can be controllably assembled into hierarchically-structured microparticles and various micellar morphologies. We first form oil-in-water emulsion droplets, where the dispersed phase consists of a volatile organic solvent containing a dilute concentration of amphiphilic polystyrene-block-poly(ethylene oxide) diblock copolymer. Upon extraction of the organic solvent, the droplets undergo interfacial instabilities which lead to formation of microparticles with budding vesicle, foam-like, or dendritic structures, or micelles with spherical, cylindrical, or more complicated morphologies. We will discuss the structure of these assemblies can be tuned, and the difficulties that they present for encapsulation of hydrophobic species.

9:12 AM H18.00005 Helical cylinders or multicompartment cylinders through the solution assembly of charged block copolymers with multivalent organic counterions. Darrin Pochan, Sheng Zhong, University of Delaware. Honggang Cui, Northwestern University. Zhiyuan Chen, Rhodia. Karen Woolley, Washington U. St. Louis — By manipulating the interaction of charged block copolymer hydrophilic corona blocks with multivalent organic counterions, and controlling the kinetics of block copolymer solution self-assembly, desired micelle geometries can be formed. Specifically, polyacrylic acid-b-poly(methylacrylate-b-polyethylene oxide) amphiphilic triblock copolymers were studied in water/THF solvent mixtures with organic multianions as counterions. By manipulating block copolymer and solvent composition, different micelle geometries were formed. However, by altering the chemical structure and/or concentration of the multianion counterions, as well as the kinetic pathway through which the molecules are assembled, complex nanostructures were formed. An example of nanostructure from kinetic control includes spherical micelles that can be controllably assembled into 1-d multicompartment cylinders. Examples of nanostructure from control of the type and amount of multivalent organic counterion added are helical cylinder superstructures many micrometers in length. The system has been investigated by means of cryogenic transmission electron microscopy (cryo-TEM) and small angle neutron scattering (SANS).}

9:24 AM H18.00006 Spotted Polymersomes and Striped Worms - a theoretical analysis of lateral segregation of diblock copolymers. Wouter G. Ellenbroek, Department of Physics and Astronomy, University of Pennsylvania. David A. Christian, Aiwei Tian, Chemical & Biomolecular Engineering and the Laboratory for Research on the Structure of Matter, University of Pennsylvania. Andrea J. Liu, Department of Physics and Astronomy, University of Pennsylvania. Tobias Baumgart, Dennis E. Discher, Chemical & Biomolecular Engineering and the Laboratory for Research on the Structure of Matter, University of Pennsylvania — Lipids and amphiphilic block copolymers are both known to assemble into vesicle and worm-like micelle morphologies, but only mixtures of lipids in vesicles have been directly seen to phase separate into meso-scale lateral domains. Here we show direct visualization of meso-scale spots in tough polymersomes and microphase separated diblock copolymers, which result from strong lateral segregation of polyamionic and neutral diblock copolymers. We present a model for understanding the crucial role of calcium ions on segregation behavior, which incorporates counterion condensation and “crosslinking” (ion bridging). We find a tendency towards segregation near the isoelectric point as a result of competition among counterion entropy, repulsion due to the net charge, and attraction due to crosslinking. These results portend new classes of robust membranes and cylinders that exhibit lateral patterns at the meso-scale.
9:36AM H18.00007 Pathways of Spontaneous Vesicle Formation of ABA Amphiphilic Molecules in Selective Solvent. — WEI JIANG, HONGBO DU, Changchun Institute of Applied Chemistry, Chinese Academy of Sciences — We study the pathways of spontaneous vesicle formation of the ABA amphiphilic molecules in selective solvent by Monte Carlo simulation. Simulation results reveal that the pathway for the spontaneous vesicle formation of the amphiphilic molecules in selective solvent depends strongly on the annealing speed. We can not use one pathway model to describe the vesicle formation even though for the same system and condition. Hydrophobic molecules diffusing in spherical micelles and oblate membrane closing may coexist for the vesicle formation.

9:48AM H18.00008 Effects of depletion interactions on block copolymer micelles. — SAYEED ABBAS, TIMOTHY P. LODGE, Department of Chemical Engineering and Materials Science, University of Minnesota — Block copolymer micelles exhibit two levels of hierarchical self-assembly: the process of micellization itself, and the ordering of these micelles onto a lattice. By a combination of small angle x-ray scattering and neutron scattering, we show that both levels of self-assembly are affected when non-adsorbing homopolymer is added to the solutions. The phenomena are analogous to depletion interactions in colloid/polymer mixtures. We have chosen poly(styrene-b-isoprene) micelles dissolved in diethyl phthalate as the model system. To these solutions polystyrene homopolymer was added. The effects strongly depend on the molecular weight and concentration of the added homopolymer. We find an induced attraction between micelles at moderate micelle concentrations, and a preference for fcc over bcc lattices in more concentrated solutions.

10:00AM H18.00009 Influence of Electric Fields on the Phase Behavior of Concentrated Block Copolymer Solutions. — KRISTIN SCHMIDT, HEIKO SCHOBERTH, ALEXANDER BOKER, University Bayreuth — We investigate the influence of the electric field on the phase behavior of diblock copolymer concentrated solutions using synchrotron SAXS. We find a significant dependence of the characteristic domain spacing on the electric field strength. For lamellae aligned parallel to the electric field direction we observe that the lamellar spacing decreases with increasing field strength, while for perpendicularly oriented lamellae the domain spacing increases. We also find that the electric field can induce an order-order transition if the block copolymer has a composition close to the predicted phase boundary. Due to the lower free energy of aligned anisotropic microdomains structures parallel to the electric field, we can induce a transition from the metastable hexagonally perforated lamellar phase to the lamellar phase without perforations by applying strong electric fields. Similarly an isotropic cubic gyroid phase, which is stable in the absence of, but cannot be aligned by, the field, transforms to aligned cylinders when a strong electric field is applied.

10:12AM H18.00010 Well Ordered Melts from Low Molar Mass Pluronic Copolymers Blended with Poly (acrylic acid): Effect of Homopolymer Molar Mass. — VIKRAM DAGA, University of Massachusetts - Amherst, VIJAY TIRUMALA, Polymers Division, National Institute of Standards and Technology, ALVIN ROMANG, University of Massachusetts - Amherst, ERIC LIN, Polymers Division, National Institute of Standards and Technology, JAMES WATKINS, University of Massachusetts - Amherst — The use of short chain block copolymer melts as nanostructured templates is often limited by their low segregation strength. We have recently shown that block copolymer melts with a molar mass less than 15 kg/mol undergo disorder-to-order transition without a significant increase in interdomain spacing when blended with a selectively associating homopolymer, due to an apparent increase in effective \(\chi\). Here, we study the effect of homopolymer molar mass on the segregation of a disordered poly (oxyethylene-oxypropylene-oxyethylene) copolymer melt that forms lamellar microstructure in the ordered phase. Based on small-angle scattering measurements, we find that the melts remain ordered over a broad range of homopolymer chain lengths, ranging up to ten times that of the copolymer. This approach has many implications for the use of commodity block copolymer surfactants as inexpensive nanostructured templates for commercial applications.

10:24AM H18.00011 Novel Characterization of Critical Micelle Concentrations of Block Copolymers and Gradient Copolymers in Homopolymer. — ROBERT SANDOVAL, DANIEL WILLIAMS, CHRISTOPHER WONG, JUNGKI KIM, JOHN TORKELSON, Northwestern University — Here we demonstrate a new method based on the intrinsic fluorescence of styrene-containing block copolymers and gradient copolymers to determine the critical micelle concentrations (cmc) of copolymers present at low levels in homopolymer. The method relies on the fact that the when styrene/methyl methacrylate (S/MMA) block copolymers and gradient copolymers are well dispersed in a glassy homopolymer such as poly(methyl methacrylate) (PMMA), only monomer fluorescence and no excimer fluorescence is observed from the copolymers. When micellization occurs, then excimer fluorescence is present. With this simple method, we have found that gradient copolymers yield much lower cmc values (about an order of magnitude smaller) than comparable block copolymers of similar molecular weight and overall composition. We are extending these studies to consider the effects of block copolymer molecular weight and composition as well as homopolymer molecular weight on the cmc values. While these parameters have received heavy consideration from a theoretical standpoint, little experimental work has focused on these issues.

10:36AM H18.00012 The influence of macromolecular architecture on the micellization in block copolymer/homopolymer blends. — E. PAVLPOULOUI, K. CHRISSOPOULOUI, S.H. ANASTASIADIS, G. PORTALE, W. BRAS, ESF-DUBBLE, Grenoble, France, H. IATROU, S. PISPAS, N. HADJICHRISTIDIS, Univ. of Athens, Greece — We investigate the micellar formation and micelle characteristics of block copolymers of varying architecture within homopolymer matrices. A series of symmetric (polyisoprene) \((I_nS_n)\), (polystyrene) \((S_nI_n)\), and (methyl methacrylate) \((I_nS_n)\) mictom star block copolymers, with \(n\) identical pairs of arms, and a series of \((\text{polysoprene})_2\) (polystyrene), \(I_2S\), graft copolymers with constant total MW and varying composition, \(f_{PS}\), are added to a low MW PI homopolymer matrix and the blends are investigated by small-angle X-ray and light scattering as a function of copolymer concentration and \(f_{PS}\). The functionality of the junction point of the copolymer does not influence the characteristics of the \(I_nS_n\) micelles, while \(f_{PS}\) controls the behavior of the \(I_2S\) grafts. A simple thermodynamic model is developed that describes theoretically the micellization of \(A_B\) copolymers within B homopolymers and its predictions agree very well with the experimental data both qualitatively and quantitatively. Sponsored by NATO’s Scientific Affairs Division, by the Greek GSRT and by the EU.

10:48AM H18.00013 Phase Behavior and Dimensional Scaling of Symmetric Block Copolymer-Homopolymers Ternary Blends in Thin Films. — GUILIANG LIU, MARK STOYKOVICH, SHENXIANG JI, PAUL NEALEY, Department of Chemical and Biological Engineering, University of Wisconsin-Madison, 1415 Engineering Drive, Madison, WI, 53706 — We have studied the phase behavior and dimensional scaling of symmetric ternary blends of PS-PMMA block copolymers and the respective PS and PMMA homopolymers in thin films. Below the order disorder transition (ODT) temperature, the symmetric ternary blends form lamellae, microemulsion and macrophase separated phases as a function of \(\chi N\), \(\alpha\) (a ratio of degree of polymerization of homopolymers to that of the block copolymer), and \(\phi_H\) (volume fraction of homopolymers). The phase transition compositions from lamellae to microemulsion and from microemulsion to macrophase separation depend weakly on \(\chi N\) and \(\alpha\) in the range of \(12.7 \leq \chi N \leq 37.6\) and \(0.20 \leq \alpha \leq 0.99\). The dimensions of swollen lamellae and microemulsion \((L_0)\) can be determined as a function of \(\phi_H\) and \(\alpha\), explicitly, \(L_0 = L_{0h}/(1-\phi_H)^{b}\), where \(L_{0h}\) is the natural bulk period of pure block copolymer, and \(b\) is a parameter depending strongly on \(\alpha\).
8:00AM H19.00001 Competition between intermolecular and substrate interactions in a multi-component lattice gas model. QIANG LIU, University of Maryland at College Park, JOHN WEEKS, University of Maryland, E.D.WILLIAMS'S GROUP, J.REUPT-ROBEY'S GROUP TEAM — Recent experiments have shown that acidine-9-carboxylic acid (ACA) molecules form a dense phase consisting of chain-like structures on Ag(111) with alternating orientations along the chain direction that permit the formation of strong hydrogen bonds. Despite the anisotropy in intermolecular interactions that leads to chain formation, molecular boundaries along and normal to the chain direction have very similar thermodynamic properties and fluctuations. We introduce a multicomponent lattice gas model where molecules with different orientations are treated as different species with different intermolecular interactions as well as different interactions with the substrate. This a generalization of the familiar Blume-Emery-Griffiths model of a binary lattice gas but in a region of parameter space not usually explored. We argue that the novel domain shapes, boundary fluctuations and phase densities seen in experiment arise from a competition between favorable anisotropic pair interactions in the chain phase and less favorable substrate interactions due to the different orientations. Detailed results of Monte Carlo simulations of this model and analytic work using mean field and pair approximation theories will be presented.

Work supported by the UMC NSF-MRSEC grant DMR 05-20471

8:12AM H19.00002 Van der Waals interactions at the molecule-metal interface: PTCDA on Ag(111). LORENZ ROMANER, DIMITRI NABOK, PETER PUSCHNIG, Department of Materials Physics, University of Leoben, Franz-Josef-Straße 18, A-8700 Leoben, Austria — EGBERT ZOJER, Institute of Solid State Physics, Graz University of Technology, Petersgasse 16, A-8010 Graz, Austria, CLAUDIA AMBROSH-DRAXL, Department of Materials Physics, University of Leoben, Franz-Josef-Straße 18, A-8700 Leoben, Austria — A detailed understanding of the processes governing the adsorption of molecules on metallic surfaces is of major interest for the field of molecular electronics. In this context, the molecule 3,4,9,10-perylene-tetracarboxylic acid dianhydride (PTCDA) has been extensively studied on a variety of metallic surfaces and has so gained fundamental, academic importance. The theoretical description of the adsorption is, however, still controversial as standard density functional theory (DFT) does not include van der Waals interactions, which, for PTCDA and many other molecules, yields the dominant binding contribution. We present DFT calculations of PTCDA adsorbed on Ag(111) where a recently developed exchange-correlation functional was adopted to include van der Waals interactions. Adsorption energy and distances, molecular distortions, charge rearrangements and orbital occupancies are discussed in detail.

8:24AM H19.00003 Tilt Angle Determination in Thin Films with Anisotropic Molecules. THOMAS GREDIG, Dept of Physics, California State Univ, Long Beach, CA 90840, GE LIU, IVAN K. SCHULLER, Dept of Physics, University of California, San Diego, La Jolla, CA 92039 — Many electronic properties of organic semiconductors depend critically on their physical and chemical arrangement of atoms. Here, a method is described to extract information about the molecular tilt angle and to determine the center electron density of anisotropic molecular thin films by means of specular x-ray diffraction. Thin films of phthalocyanine (Pc), an anisotropic molecule with a metal ion in the center, have been deposited in an organic molecular beam deposition system and studied with high-resolution x-ray diffraction. In particular, two isomorphous molecules, H2-Pc and Cu-Pc, are compared experimentally and then studied with numerical simulations. The results show that the intensity distribution of the diffraction peaks belonging to the same series of lattice planes provides important structural information such as the molecular tilt angle or the center electron density of the anisotropic molecule.

This work is supported by AFOSR-MURI grant No. F.49620-02-1-0288.

8:36AM H19.00004 The role of defects and phonons in O2 adsorption on Cu(100). MATTI ALATALO, ANTTI PIUSTO, Lappeenranta University of Technology — We present the results of an extensive ab initio study for O2 adsorption on the Cu(100) surface. The calculated potential energy surfaces and first principles molecular dynamics trajectories reveal that on the clean surface without defects the dissociation probability is low at small translational energies of the incoming molecule whereas at higher energies the molecules dissociate directly without a barrier. Of the different defects, steps turn out to be less reactive than expected and adatoms rather lower than enhance the reactivity. In contrast, vacancies act as dissociative centers, which locally enhance the reactivity. This result is in agreement with the molecular beam surface scattering experiments which show an increase at the oxygen sticking probability at low energies. We also discuss the role of phonons in O2 dissociation, showing that the open space involved at certain phonon modes lowers the dissociation barrier, an effect analogous to the vacancy induced dissociation. Our results clearly demonstrate the importance of including both defects and surface dynamics in a realistic description of the adsorption process.

8:48AM H19.00005 Vibrational spectroscopy and ab initio dynamics of the O-induced added-row reconstructed Cu(110) surface. TALAT S. RAHMAN, M. ALCANTARA ORTIZOZA, University of Central Florida, R. HEID, K.P. BOHNNEN, Forschungszentrum Karlsruhe, K. BRUEGEMANN, H. IBACH, Forschungszentrum Juelich — It is known that O2 molecules dissociatively adsorb on Cu(110) and, upon subsequent annealing, Cu and O atoms catenate along the [100] direction arranging themselves in a striped periodic super-grating, depending on O coverage and annealing temperature. It has been proposed that stress along the [110] direction in the regions that locally hold a (2x1)O added-row on Cu(110) and, upon subsequent annealing, Cu and O atoms catenate along the [100] direction arranging themselves in a striped periodic super-grating, depending on O coverage and annealing temperature. We present DFT calculations of PTCDA adsorbed on Ag(111) where a recently developed exchange-correlation functional was adopted to include van der Waals interactions. Adsorption energy and distances, molecular distortions, charge rearrangements and orbital occupancies are discussed in detail.

Work supported in part by NSF under grant CHE-0548632.

9:00AM H19.00006 Insights from surface stress calculations on the structure of c(2×2)-N overlayer on Cu(001). SAMPYO HONG, TALAT RAHMAN, University of Central Florida — We present results of calculated changes in surface stress for N overlayers on Cu(001), in an effort to discriminate between several proposed structural models. Our calculations of the surface geometry and electronic structure are based on the density functional theory in the generalized gradient approximation and the pseudopotential method. We find that a c(2×2) N overlayer causes a large change in the surface stress (≈ 5 N/m) on Cu(001) turning it from tensile to compressive. We also perform calculations for several stress relief models to find that the so-called “rumpling” and “clock reconstruction” models fail to relieve the N induced stress. On the other hand, formation of strips of clean Cu(001) areas, aligned along the [100] direction, and trench-like steps of Cu atoms, along the [110] direction on Cu(001), relieve the induced stress most effectively, in agreement with predictions from experiments. We consider the implications of these results on surface phonon dispersion curves for unreconstructed c(2×2)-N/Cu(001), which are in good agreement with experiment.

Work supported in part by NSF under grant CHE-0548632.
9:12AM H19.00007 First principles calculations of the vibrational dynamics of c(2x2)-CO on Ag(001).1 M. ALCANTARA ORTIGOZA, T.S. RAHMAN, University of Central Florida, R. HEID, K.P. BOHNEN, Forschungszentrum Karlsruhe, Germany — The reaction pathway of CO oxidation on Ag surfaces is still a subject of debate because of the complicated chemistry of O and the possibility that contaminants stabilize CO. Indeed, at ~150 K, the dissociative O₂ adsorption is scarcely triggered while the CO adsorption on clean Ag(001) is hardly stable. The nature of the CO adsorption is thus by itself a matter of discussion and the characteristic energy losses for exciting the phonon modes introduced by the adsorbed species have an uncertain assignment. We present an ab initio study of the structure and phonon dispersion of a c(2x2), atop, CO overlay on Ag(001). Comparison with a similar study of c(2x2) CO on Cu(001) indicates that CO chemisorbs on Ag(001) despite the low binding energy. The frequency of the C-O stretch mode at the Γ-point is in excellent agreement with HREELS measurements and is reduced on Ag(001) almost as much as on Cu(001). The weak Ag-CO bond is reflected in the low frequency of the rest of the CO modes. Yet, in the Ag-CO stretch, the Ag surface atoms are strongly coupled, as in the case of CO on Cu(001). Likewise, the CO frustrated translation mode couples to the substrate in the vicinity of the Γ-point but, unlike that on Cu(001), the CO frustrated rotation mode on Ag(001) couples to the substrate inside the surface Brillouin zone.

9:24AM H19.00008 Oxygen-Induced Reconstructions on the β-Si₃N₄ (10̂10) Surfaces , WERONIKA WALKOsz, JUAN CARLOS IDRÓBO, SERDAR OGUT1. University of Illinois at Chicago — Motivated by recent electron microscopy studies at the Si₃N₄/rare-earth oxide (REO) interfaces, we present first principles calculations for the preferred bonding sites and configurations of oxygen on various terminations of the β-Si₃N₄ (10̂10) surface as a function of coverage and surface stoichiometry. We predict that oxygen induces various surface reconstructions, and it has a strong tendency to replace N on the surface. The structural stability of most low-energy surface structures is driven by the tendency of Si to saturate its dangling bonds and of oxygen to bridge two Si atoms similar to the bonding in SiO₂. The present ab initio results resolve the discrepancy between the experimental observations at the Si₃N₄/REO interfaces and previous theoretical studies for bare surfaces regarding the lowest energy surface termination.

9:36AM H19.00009 Insight into water molecules bonding on 4d metal surfaces , JAVIER CARRASCO, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Faradayweg 4-6, 14195, Berlin, Germany, ANGELOs MICHAELIDES, MATTHIAS SCHEFfLER — Water-metal interactions are of capital importance to a wide variety of phenomena in materials science, catalysis, corrosion, electrochemistry, etc. Here we address the nature of the bond between water molecules and metal surfaces through a careful systematic study. Specifically, the bonding of isolated water molecules to a series of close-packed transition metal surfaces - Ru(0001), Rh(111), Pd(111) and Ag(111) - has been examined in detail with density functional theory (DFT). Aiming to understand the origin behind energetic and structural trends along the 4d series we employ a range of analysis tools, such as decomposition of the density of states, electron density differences, electronic reactivity function and inspection of individual Kohn-Sham orbitals. The results obtained allow us to rationalize the bonding between water and transition metal surfaces as a balance of covalent and electrostatic interactions. A frontier orbital scheme based on so-called two-center four-electron interactions between molecular orbitals of water and d band states of the surface proves incisive in understanding these systems.

9:48AM H19.00010 Water uptake on thin film MgO using ambient pressure XPS, JOHN T. NEWBERG, DAVID E. STARR, ERIN MYSAK, Lawrence Berkeley National Laboratory, SÜSUMU YAMAMOTO, ANDERS NILSSON, Stanford Synchrotron Radiation Laboratory. HENDRIK BLUHM, Lawrence Berkeley National Laboratory, LAWRENCE BERKELEY NATIONAL LABORATORY TEAM, STANFORD SYNCHROTRON RADIATION LABORATORY TEAM — Understanding the molecular level interactions of water with metal oxide surfaces is important in both industrial processing and environmental chemistry. MgO(100) is one of the most widely studied metal oxide surfaces due to its simple rock salt cubic structure. However, whether water adsorbs dissociatively (hydroxylation) or molecularly (thin film wetting) remains unanswered. We have characterized the uptake of water on 7ML MgO(100) on Ag(100) at RT using ambient pressure XPS. Surface compositions were measured in-situ under water vapor pressures ranging up to 1 Torr. Our results indicate that initial hydroxylation occurs at low pressures mostly at Mg(2+) sites up to about 0.1 mTorr. At higher coverages both hydroxylation and thin film wetting continues through 1 Torr. We will also discuss results from: 1. water uptake under higher/lower effective vapor pressures, 2. additional MgO(100) film thickness, and 3. water uptake on MgO(111)/Ag(111) surfaces.

10:00AM H19.00011 Surface-induced solid-phase transitions in ultra-thin water films at T > 0 °C, ANIMEsh CHAKRABORTY, ANDREW GELLMAN, LAYTON BAKER, ESTEBAnH BROITMAN, carnegie Mellon University — We report here the measurements of both the adsorption isotherms and the dissipation in ultra-thin films of water adsorbed on the surfaces of SiO₂. The measurements were made in a small high vacuum chamber in which we have mounted a QCM. The chamber was evacuated to ~10⁻⁸ Torr (the vapor pressure of water at room temperature is ~22 Torr). In addition the temperature of the apparatus can be varied in the range 10 – 60 °C. This is sufficient to measure the adsorption isotherm and to probe the phase of adsorbed water films over the range of conditions. Recently published work studying the adsorption of water on the SiO₂ layer formed on Si single crystals has suggested that the phase of the water at temperatures well above 0 °C is actually that of a solid, ice-like structure rather than liquid water [1]. That work is based on the comparison of the vibrational spectrum of thin water films with those of liquid water and ice. In our study we are using the QCM to investigate the possibility of formation of Ice-like structures. However, whether water adsorbs dissociatively (hydroxylation) or molecularly (thin film wetting) remains unanswered. We have characterized the uptake of water on 7ML MgO(100) on Ag(100) at RT using ambient pressure XPS. Surface compositions were measured in-situ under water vapor pressures ranging up to 1 Torr. Our results indicate that initial hydroxylation occurs at low pressures mostly at Mg(2+) sites up to about 0.1 mTorr. At higher coverages both hydroxylation and thin film wetting continues through 1 Torr. We will also discuss results from: 1. water uptake under higher/lower effective vapor pressures, 2. additional MgO(100) film thickness, and 3. water uptake on MgO(111)/Ag(111) surfaces.

10:12AM H19.00012 Relaxation of the (111) Surface of δ-Pu and Effects of Atomic Adsorption: An Ab Initio Study1 RAYMOND ATTA-FYNN, ASOK RAY, Physics Department, The University of Texas at Arlington — The full-potential all-electron linearized augmented plane wave plus local orbitals (FP-LAPW+lo) method has been employed to study the relaxation of the δ-Pu (111) surface and the consequent effects for atomic adsorption of C, N and O atoms on this surface. The surface was modeled by a 5-layer slab with a (2x2) surface unit cell. Upon relaxation of the surface, the interlayer separation between the surface and the subsurface layers expanded by 7.1% with respect to the bulk interlayer separation while the separation between the subsurface and central layers expanded by 0.4%. The hollow fcc adsorption site was found to be the most stable site for C and N with chemisorption energies of 6.420 eV and 6.549 eV respectively, while the hollow fcc adsorption site was found to be the most stable site for O with a chemisorption energy of 7.858 eV. The adsorbate-induced changes in the surface properties, namely the Pu magnetic moments, work function, and electronic structure will be discussed.

by thermal diffusion. Sites formed by single HV or pairs of adjoining HVs were found to be unreactive toward H₂. Thanks to LT-STM atomic observations, we show that this new description of H₂ dissociative adsorption onto transition metal surfaces is not an exotic particular catalytic case relevant only to Pd(111) and close-packed faces of fcc metals, but that it also applies to close-packed faces of hcp metals such as Ru(001) [1, 2]. Close to saturation of 1 ML, HVs were observed either as single entities or forming transient aggregations. Vacancies diffuse and aggregate to form active sites for the dissociative adsorption of H₂. We have found that H₂ dissociation takes place only on Ru sites where the metal atom is not bonded to any H atom [3]. Such active sites are formed when at least 3 HVs aggregate by thermal diffusion. Sites formed by single HV or pairs of adjoining HVs were found to be unreactive toward H₂. [1] T. Mitsui, et al., Nature 422 705 (2003) [2] M. Tatarkhanov, et al., Surf. Sci., in Press (2007) [3] F. 8:00AM H20.00001 Formation and Properties of CdS-Ag₃S Nanorod Superlattices¹. DENIS DEMCHENKO, RICHARD ROBINSON, BRYCE SADTLER, LIN-WANG WANG, A. PAUL ALIVISATOS, Lawrence Berkeley National Laboratory, CAN ERDONMEZ, University of California, Berkeley — The mechanism of formation of recently fabricated ordered CdS-Ag₃S nanorod superlattices is explained and their elastic and electronic properties are predicted theoretically. We show that diffusion-limited growth of Ag₃S islands in CdS nanorods partially contributes to the observed ordering, but cannot account for the full extent of the ordering alone. The valence force field (VFF) model results for the nanostructure show significant repulsion between Ag₃S segments due to strain created by the lattice mismatch between the two materials. This suggests that the interplay between the chemical interface energy and strain drives the spontaneous pattern formation. A first principles calculation of the energy levels in the superlattice shows a nested band alignment. The nanorod superlattice therefore corresponds electronically to a sequence of quantum wells of Ag₃S separated by barriers of CdS. The minibands formed in such superlattices make them desirable for applications in the solar cells. 1. R. D. Robinson, B. Sadtler, D. O. Demchenko, K. C. Erdonmez, L.-W. Wang, and A. P. Alivisatos, Science 317, 355 (2007).

8:12AM H20.00002 Transport studies on ultrathin silicide nanowires. VOLTAIA IANCU, CHANGGAN ZENG, Department of Physics and Astronomy, University of Tennessee, Knoxville, TN, 37996, STEPHEN JESSE, ARTHUR BADDORF, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN, 37831, HANNO WEITERING, Department of Physics and Astronomy, University of Tennessee, Knoxville, TN, 37996 — Minute amounts of yttrium deposited on a silicon (100) surface assemble into ultrathin YSi₂ nanowires. Ultrathin nanowires receive a great deal of interest due to their possible uses as interconnects in nano electronic devices or as nano-electrodes to measure e.g. the transverse current across DNA molecules in nanofluidic channels. Here we present electrical conductance measurements of a nanowire bridged by macroscopic electrodes and the characterization of the nanowire/ electrode contact by scanning probe microscopy. The stability of the nanowires after exposure to air, water, and a KCl solution is also addressed for future use in nanofluidics. Research was conducted in part at the Center for Nanophase Materials Sciences, sponsored at Oak Ridge National Laboratory by the Division of Scientific User Facilities, U.S. DOE.

8:24AM H20.00003 Copper Incorporation into ZnO Nanowires. SUSIE EUSTIS, DOUGLAS MEIER, BABAK NIKOBAKHHT, NIST — The applications of zinc oxide (ZnO) nanowires (NWs) in devices are promising due to the optical, mechanical and electrical properties of these one-dimensional structures, but current uses are limited by the ability to produce high quality nanowires at desired locations. Copper is an attractive catalyst for generating zinc oxide nanowires due to the long length and high density of ZnO NWs produced. However, defects due to impurities, oxygen deficiencies, and structural defects lead to decreased optical and electrical transport. Photoluminescence (PL) microscopy found that ZnO NWs grown by high temperature evaporation on a bulk copper substrate display the expected band gap emission at 380nm. A larger visible emission is also observed in the PL spectrum around 580nm due to defect states. High-resolution transmission electron microscopy (HR-TEM) shows the ZnO nanowires are single crystalline with hexagonal structure. The metallic tip shows a polycrystalline structure in HR-TEM images. Energy dispersive x-ray spectroscopy (EDS) mapping and auger electron spectroscopy (AES) clearly show copper throughout the length of the nanowire, which is most likely responsible for the strong deep trap emission from these nanowires. AES also finds large amounts of oxygen on the surface of these NWs, a further contributor to defect emission states.
8:36AM H20.00004 Self-organization of atom wires on vicinal surfaces 1

Paul Snijders, Oak Ridge National Laboratory — Self-organization is possibly the best way to produce nanostructures in large quantities. This also holds for the ultimate 1D system, atom wires; they can be self-assembled in large arrays on vicinal Si surfaces. Such atom wire systems often show intriguing electronic properties such as competing charge density waves and spin-orbit split one-dimensional bands. However, because of their low dimensionality, these wires also frequently show profound thermodynamic fluctuations that limit their structural uniformity and have a large influence on their electronic properties. Therefore, in this talk I will focus on structural fluctuations in Ga atom wires self-organized on the Si(112) surface. In these atom wires, strain-relieving adatom vacancies self-organize into meandering vacancy lines (VLs) similar to the well-known nx2 superstructures for Ge on Si(100). The average spacing between these line defects can be experimentally controlled continuously by adjusting the chemical potential $\mu$ of the Ga adatoms. Significant VL correlations are discovered in STM experiments that cannot be captured within a mean field analysis. These structural fluctuations are well described by a new lattice model that combines Density Functional Theory (DFT) calculations for perfectly ordered structures with the fluctuating disorder seen in experiment, and the experimental control parameter $\mu$. This hybrid approach of lattice modeling and DFT can be applied to other examples of line defects in hetero-epitaxy, especially in cases where correlation effects are significant and a mean field approach is not valid.

9:12AM H20.00005 Growth and Properties of Self-Aligned MgO Nanowires

Elena Cimpoiasu, Dept. of Physics, United States Naval Academy, Annapolis, MD 21402, Robert F. Klue, Dept. of Physics, University of Illinois at Chicago, Chicago, IL 60657, Ryan A. Mundie, Dept. of Applied Physics, Yale University, New Haven, CT 06520, Mark A. Reed, Depts. of Electrical Engineering and Applied Physics, Yale University, New Haven, CT 06520 — A simple VLS route was used to produce self-aligned MgO nanowires on both polished crystalline (c-axis sapphire) and ceramic (alumina) surfaces. Growth on alumina produces vertically-aligned, very thin nanowires, indicating enhanced growth at the liquid-solid interface. Growth on polished sapphire results in faceted MgO nanowires which are perpendicular to the r-plane of sapphire and show evidence of competing vapor-solid-growth mechanism. The difference in the morphology and structure of the nanowires growing on the two different substrates clearly illustrates the affect of substrate on the growth process. This work was partially supported by DARPA, by the Department of Homeland Security, and by the National Science Foundation.

9:24AM H20.00006 Novel Nanocomposites for Energy and Electromagnetic Applications via 3D self-assembly 1

Amit Goyal, Sung-Hun Wee, Yanfei Gao, Junsou Shin, Karren More, Yuri Zuev, Claudia Canton, Jianxin Zhong, Malcolm Stocks, Oak Ridge National Laboratory — Nanocomposites comprising ordered 3D arrays of nanodots of one type of ceramic material coherently embedded in another ceramic matrix comprise are expected to exhibit novel physical properties tunable by adjusting the overall composition, concentration, feature size and spatial ordering of the nanodots. Wide-ranging applications such as photovoltaics, solid state lighting, ultra-high density storage and high temperature superconductivity are of interest. We report here on a joint experimental, theoretical and computational study on achieving 3D ordering via 3D self-assembly of nanodots of a complex ceramic material within another complex ceramic material, such as 3D self-assembly of BaZrO3 nanodots in REBCO superconducting films. Examples will also be given for other ceramic and metal/ceramic systems. In all cases 3D self-assembly was obtained in epitaxial thick films grown via pulsed laser ablation on single-crystal or single-crystal-like substrates.

Research was sponsored by the U.S. Department of Energy under contract DE-AC05-00OR22725 and by an internal Laboratory Directed Research & Development (LDRD) project.

9:36AM H20.00007 Terrace-width Distributions on Vicinal Surfaces: Effective Attraction Between Noninteracting Touching Steps 1

Rajesh Sathiyarayanan, Ajimi Bhadja Hammouda, T.L. Einstein, University of Maryland, College Park — Terrace-width distributions (TWDs) characterize equilibrium as well as non-equilibrium morphology of vicinal surfaces. Using the terrace-step-kink (TSK) model, we apply Monte Carlo simulations (both Metropolis and kinetic) to study TWDs. Steps interact via inverse-square entropic and elastic interactions. Steps cannot touch each other (except at corners) have monatomic height; their configurations, correspond to the worldlines of fermions in 1D. The associated TWDs are well described by the generalized Wigner surmise. The fit parameter $\gamma$ is directly related to the dimensionless energetic interaction strength $A[\gamma]$ if steps are allowed to touch, one can find some double (or greater) height steps. For closely spaced steps, this can alter the TWD considerably. We simulated the TWD of steps with $A = 0$ but touching allowed. Our results indicate an effective attraction between steps, as reflected by a value of $\gamma$ significantly less than 2 (the $A = 0$ value with touching forbidden). As expected, this effective attraction becomes weaker as the terraces become wider; we discuss the crossover behavior.

1Supported by NSF MRSEC Grant DMR 05-20471

9:48AM H20.00008 Study of Fe atomic chains on Pt(997) vicinal surface

Elijah Ayieta, Indiana University—Purdue Uni, Ya.B Losovyi, LSU, Cheng Ruihua, IUPUI — The vicinal substrates form the promising templates for low cost effective bottom-up fabrications of nanostructures. A variety of one-dimensional atomic chains can be synthesized on the stepped surfaces. The electronic structure of a vicinal surface plays a significant role in determining the physical properties of atomic chains on stepped surface as well as the surface morphology. The Pt(997) surface is cut 6.5° of Pt(111) surface forming terrace width of 2nm. The surface of the substrate is then characterized using scanning tunneling microscopy STM and angle resolved photoemission spectroscopy from synchrotron radiation source. The data shows that the surface has uniform steps with no reconstructions. Electron confinement is observed with wave vector perpendicular to the step direction. Fe atomic chains were then carefully deposited on the surface of Pt(997) and then finally characterized. The exchange splitting of Fe 3d bands is estimated according to the photoemission spectroscopy data.

10:00AM H20.00009 Thermoelectric properties of Bi2Te3 films and nanowire arrays

Cheng Lung Chen, Yang Yuan Chen, P. C. Lee, C. T. Chen, S. R. Harutyunyan, S. J. Lai, C. D. Chen, S. J. Lin, Institute of Physics, Academia Sinica Team — The n-type Bi2Te3 nanowire arrays with diameter ~120 nm and thin films with thickness ~10 μm have been fabricated by electrochemical deposition from nitric acid bath, containing bismuth nitrate and tellurium dioxide. Extensive characterizations of the morphology, structure, and composition of the films and nanowires were performed by means of SEM, XRD, EDS, and TEM. The films have nanocrystalline structure whereas the nanowires are single crystallines. The influence of microstructure on thermoelectric properties was investigated by comparison charge carrier transport in two mutually perpendicular crystallographic directions. The measurements of Seebeck coefficient and electrical resistivity were carried out in temperature region of 180 to 300 K. The highest value of $\sigma^2 = 840 \text{TW/m·K}^2$ was obtained at 285 K for film. The electrical resistivity of an individual Bi2Te3 nanowire is ~4.3 μΩ·m using e-beam lithography technique. Based on the Seebeck coefficient obtained from nanowire arrays, the calculated value of $\sigma^2$ for single nanowire is ~1000 μWm·K−2 which is higher than that of the film. These results may help in designing processes for thermoelectric microdevices.
STM images will be presented and a detailed analysis of the electronic structure of all the proposed structures will be discussed.

formed by single or pair of atoms; and the first layer may be commensurate or incommensurate with the substrate. Comparison between calculated and observed

From the theoretical side, we propose several structures of Si on Ag(110) where Si atoms occupy either single or double layers, with the second layer may be

wires 5 lattice constants wide, we observed 4 distinct bright spots across the wire with a periodicity of 2 times the Ag nearest neighbor distance along the wire.

studies

multi-component alloys provide a natural means of tuning the band gap and other parameters to optimize and extend the application of semiconductor elec-

conducting nanowires.

Curved tips have been observed at one end of the nanowires which contain same elemental components as the body of the nanowires. This technique is proven

to be a successful approach to eliminate the need for external catalyst which can have detrimental consequences affecting the performance of an optoelectronic
device. As-synthesized nanowires were characterized using TEM, SEM, XRD, EDS, photo luminescence, Vis-IR absorption and Raman spectroscopy. Results of transport properties of individual nanowires will also be presented.

10:36AM H20.00012 Low melting metal-induced synthesis of multi-component III-V semi-

conducting nanowires. , ROMANEH JALILIAN, ZHIQIANG CHEN, GAMINI SUMANASEKERA, University of Louisville — Semiconductor multi-component alloys provide a natural means of tuning the band gap and other parameters to optimize and extend the application of semiconductor electronic/optoelectronic devices. In this study, multi-component nanowires have been synthesized in vapor phase by laser ablation of solid targets consisting of initial bulk materials. Growth of nano-crystals is believed to seed from low melting metallic droplets generated from laser bombardment and heating of the target. Curved tips have been observed at one end of the nanowires which contain same elemental components as the body of the nanowires. This technique is proven to be a successful approach to eliminate the need for external catalyst which can have detrimental consequences affecting the performance of an optoelectronic device. As-synthesized nanowires were characterized using TEM, SEM, XRD, EDS, photo luminescence, Vis-IR absorption and Raman spectroscopy. Results of transport properties of individual nanowires will also be presented.

Si nanowires on Ag(110): an experimental and electronic structure studies1 , A. KARA, Department of Physics, University of Central Florida, B. EALET, C. LEANDRI, CRMCN-CNRS, Luminy, France, H. OUGHADDOU, Universite de Cergy, France, G. LEILAY, B. AUFRAY, CRMCN-CNRS, Luminy, France — Si nanowires images on Ag(110) were obtained using Scanning Tunneling Microscopy. Wires with tailored width and very large lengths were observed with the wires growing along the open channels of Ag(110). For those wires 5 lattice constants wide, we observed 4 distinct bright spots across the wire with a periodicity of 2 times the Ag nearest neighbor distance along the wire. From the theoretical side, we propose several structures of Si on Ag(110) where Si atoms occupy either single or double layers, with the second layer may be formed by single or pair of atoms; and the first layer may be commensurate or incommensurate with the substrate. Comparison between calculated and observed STM images will be presented and a detailed analysis of the electronic structure of all the proposed structures will be discussed.

Tuesday, March 11, 2008 8:00AM - 10:48AM — Session H21 DCP: Focus Session: Clusters, Cluster Assemblies, Nanoscale Materials III Morial Convention Center 213

8:00AM H21.00001 Probing electronic and magnetic properties of atomic and molecular clusters with sharp tips1 , JEAN-PIERRE BUCHER, Université LouisPasteur, Institut de Physique et Chimie des Matériaux de Strasbourg — Probing magnetic and transport properties on a local basis with the tip of a scanning tunneling microscope (STM) allows establishing close links with the exciting field of magnetic read and write processes. Some examples of applications of this approach to magnetic nanostructures will be shown. First of all, the fundamental properties of Co nanoclusters, on metal surfaces will be presented. These clusters have been probed by low temperature dl/dV spectroscopy (STS). It is found that occupied electronic surface states of the Co clusters are sensitive to the crystallographic stacking and furthermore exhibit a downward energy shift as the cluster size decreases. Ab initio calculations confirm that the observed shift is due to the size dependent mesoscopic relaxation in the clusters. When a magnetic tip is used in low temperature spin polarized (SP)-STM experiment, it is possible to reveal spin polarized feature in the local density of states. For example, one is able to identify two magnetization states of the nanometer Co clusters, corresponding to the parallel or antiparallel configuration with respect to the tip polarization. Progress in the emerging field of spintronics strongly relies on the fundamental understanding of electron/spin transport and magnetic phenomena in reduced dimensions, down to the extreme limit of individual molecules, or even single atoms where sizeable quantum effects are expected. Electronic and magnetic properties of Co atoms and metal-based molecular magnets adsorbed on magnetic nano-islands or on non magnetic surfaces will be presented. On the example of Co-pherrocyanines prepared in UHV at 4.6 K, it will be shown that dl/dV characteristics are representative of both, the nature of the molecule and also its interaction with the substrate.

8:36AM H21.00002 First Principles Theory of Supported Clusters with Complex Magnetic Order. , OLLE ERIKSSON, Uppsala University — It is demonstrated that the magnetic interactions can be drastically different for nano-sized systems compared to those of bulk or surfaces. In a real-space formalism we have developed a technique to calculate non-collinear magnetization structures and hence exchange interactions. Our results for magnetic Cr, Mn and Fe clusters supported on a Cu(111) surface show that the magnetic ordering as a rule is non-collinear and can not always be described using a simple Heisenberg Hamiltonian. We argue that the use of ab initio calculations allowing for non-collinear coupling between atomic spins constitute an efficient and reliable way of analyzing nano-sized magnets.
9:12AM H21.00003 Magnetic properties and stability of mettalloinorganic clusters1, ROBERTO ROBLES, SHIV KHANNA, Dept. of Physics, Virginia Commonwealth University, Richmond, VA 23284 — Theoretical studies on the structure, stability, electronic structure and magnetic properties of binary clusters Si,TMg (n=1-8, TM=Cr,Mn) have been carried out within a density functional formalism using the generalized gradient approximation. The stability of the clusters as a function size is analyzed in terms of several criteria, like the progression in bonding energy and HOMO-LUMO gap, with the ultimate objective of identifying the simple rules that can guide the search of stable species. The magnetic properties of the clusters are investigated by considering different ferromagnetic and antiferromagnetic arrangements of the local spin moments and optimizing the geometry and the spin state to determine the ground state including possible isomers. The possible use of these clusters as building blocks of cluster assemblies is discussed, and finally, the interest of these assemblies in the design of materials which could be used in the field of spintronics is briefly considered.

9:24AM H21.00004 Intermediate valence, local antiferromagnetic coupling and the Kondo effect in ytterbium organometallic molecules, C.H. BOOTH, R.W. LUKENS, Lawrence Berkeley National Laboratory (LBNL), M.D. WALTER, D. KAZHDAN, K.A. ANDERSEN, LBNL and University of California, Berkeley, E.D. BAUER, Los Alamos National Laboratory, L. MARON, INS A Toulouse, O. EISENSTEIN, Universite Montpellier — Studying magnetic ions coupling to aromatic rings in organometallic molecules provides an analogous route to studying the Kondo effect in nanoscale systems. We extend the number of molecules displaying such effects in their magnetism and X-ray absorption spectroscopy from cerocene [Ce(Cp₃H₅)₂] and Cp*Yb(bipy) [Cp* = pentamethylcyclopentadienyl, bipy = bipyridine] to a collection of Cp*₃Yb(L) molecules, where L is one of various bipyridyl or diazadiene ligands. Clear trends are observed in both the magnetic susceptibility and the Yb valence that indicate changes in the fundamental temperature scale. CASSCF calculations indicate the intermediate valence is primarily due to a configuration interaction between the open-shell f₁₃/₂₋₁ and the closed-shell f₁₄/₂₋₁ spin-singlet states, in direct analogy to the Kondo effect in intermetallic systems. These studies increase the range of molecular species where such properties are observed, and point toward understanding the ubiquity of such effects and their involvement in fundamental bonding and magnetism in organometallic molecules.

9:36AM H21.00005 The structure, stability, and magnetic properties of Au(111)/NiO(111) interface: density functional theory study1, K.L. YAO, Y.L. LI, Z.L. LIU, Huazhong University of Science and Technology — We studied the electronic structure of Au(111)/NiO(111) interface in accordance with the two models of NiO(111) surface. The work of adhesion, the spin magnetic moment, the stability and the electronic properties of the Au(111)/NiO(111) interface were calculated by density functional theory (DFT). The calculated results of Au(111)/NiO(111) interface were then compared with non-polar Au(100)/NiO(100) interface. At the same time, the total density of states (DOS) of Au(111)/NiO(111) interface corresponding to the two models were also calculated. The calculations reveal that the Ni-terminated and the oxidized interfaces have antiferromagnetic properties, while the O-terminated interface exhibits ferromagnetic properties.

9:48AM H21.00006 Investigating the Molecular Level Details of Catalytic Oxidation Reactions1, GRANT JOHNSON, Pennsylvania State University — Gas-phase cluster reactivity studies are providing significant insight into the molecular level mechanisms of oxidation reactions occurring on catalytic surfaces. Our experimental approach, employing tandem mass spectrometry, uses mass selected metal oxide clusters to model specific catalytic active sites. This technique enables investigation of the influence of factors such as size, stoichiometry, charge state, and elemental composition on the reactivity of catalytic materials. Particular emphasis is on identifying species with enhanced activity for the selective oxidation of simple hydrocarbons and atmospheric pollutants. Recent findings pertain to the kinetics of ethylene oxidation in the presence of vanadium oxides and the oxidation of carbon monoxide in the presence of gold and iron. Through a combination of experiments and theoretical calculations we establish structure-reactivity relationships and propose general reaction mechanisms for these catalytic processes.

10:24AM H21.00007 Effect of ligand on the geometric and electronic structure of Au₁₃ cluster1, GHAZAL SHAFAI, SAMPYO HONG, TALAT RAHMAN, University of Central Florida, MASSIMO BERTINO, Virginia Commonwealth University — We have carried out calculations based on the density functional theory in the projector augmented wave scheme (PAW) and the pseudopotential approach, to examine the effect of the ligand on the geometric and electronic structure of Au₁₃ cluster. We find bare Au₁₃ to form a flat flake, in agreement with previous theoretical calculations. This structure is lower in energy by 2.60 eV in comparison with the well ordered icosahedron geometry. Our results show, however, that the Au₁₃ cluster covered with ligands of phosphine (PH₃) forms a stable spherical structure (icosahedron) in agreement with the experiment [1] which is by 0.08 eV lower in energy when compared to the flatflake complex. If the phosphine is replaced by H, the well ordered icosahedron structure is no longer stable, but it still maintains a 3 dimensional form, signifying the effect of the ligand in stabilization of the structure. We observe a narrow d-band for flat-flake gold atoms in the complex, while in the icosahedron structure the d-band is wider. We also find a stronger overlap between the p orbitals of the P atom with d orbitals of gold atoms in the icosahedron complex. [1] M. F. Bertino et. al. Phys. Chem. B Lett. 110, 21416 (2006)

10:36AM H21.00008 Superheating, Melting and Precursors to Melting in Metal Nanoparticles, DIMITRI SCHEBARCHOV, Victoria University of Wellington, SHAUN HENDY, Industrial Research Ltd — We have investigated precursors to melting in metal nanoparticles using molecular dynamics in the microcanonical ensemble. At the onset of solid-liquid phase coexistence, we find first-order transitions in clusters of non-melting facets (i.e. facets that are not wet by the melt such as Pb (111)), and continuous transitions otherwise. In sufficiently small clusters however, we find that static solid-liquid coexistence is unstable. Further, the size at which the instability arises, and even the melting temperature, depends on the ability of the melt to wet the solid facets of the cluster. In particles with non-melting facets we show that the melting temperature can exceed that of the bulk material. Finally, we also discuss a range of solid-solid transitions that have been observed to occur during solid-liquid phase coexistence, some of which are again driven by the preference of the melt to wet certain crystal facets.

Tuesday, March 11, 2008 8:00AM - 10:36AM – Session H22 DPOLY: Electrically and Optically Active Polymers – Morial Convention Center 214

8:00AM H22.00001 Polymer Physics Prize Break –
8:36 AM H22.00002 Periodic Polymers for Technology, Edwin Thomas, M.I.T. — Periodic polymeric materials comprised of solid polymer and air have interesting interactions with electromagnetic and mechanical waves giving rise to complex dispersion relations including zero density of states (band gaps). The key concern for photonic materials is dielectric contrast, whereas for phononic materials, it is density contrast and relative speed of longitudinal and transverse waves in the two media that is important. The creation of a material with a dual band gap, that is a complete band gap for light and a complete band gap for sound would allow strong coupling in localized defect regions. Progress in this area requires the ability to design and model targeted geometries and excellent control of structure fabrication. Top-down, and bottom-up approaches, involving interference lithography and self-assembly respectively are demonstrating good success in fabricating the requisite structures and creating desired properties for photonics and phononics.

8:48 AM H22.00003 First-principles investigation of high energy density in PVDF copolymers, V. Ranjan, Liping Lu, NC State U., Raleigh, Michael Bongiorno Nardelli, J. Bernholdt, NC State U., Raleigh and ORNL, TN — PVDF and its copolymers exhibit excellent electromechanical properties and in the case of PVDF-CTFE also a very high energy density [1]. We have investigated the phase diagram of these systems and can quantitatively explain the observed energy density of PVDF-CTFE as due to a para to ferroelectric phase transition in a disordered, multidomain structure [2]. Our results show that pure PVDF prefers the α phase at zero field. Electric field lowers the free energy of the β phase, resulting in a structural phase transition at a sufficiently high field. Copolymer admixture lowers the critical field and eventually leads to an energetic preference for the β phase even at zero field. For PVDF-CTFE with CTFE content below 17 %, the α phase is still preferred and the field-induced phase transformation reversibly stores large amounts of energy. For PVDF-TeF, the total energy difference between the two phases is much smaller, resulting in substantially smaller energy density. [1] B. Chu et al., Science 313, 334 (2006). [2] V. Ranjan et al., PRL 99, 047801 (2007).

9:00 AM H22.00004 High and Stable Light Induced Birefringence from Spacer-Free Dye-Polyelectrolyte Liquid Crystal Complexes, Qian Zhang, C. Geraldine Bazuin, University of Montreal, Christopher J. Barrett, McGill University, Christian Pellerin, University of Montreal — Azo materials are promising in photonic applications due to the well-known photoisomerization of azo groups, which, for example, allows efficient inscription of gratings using light induced birefringence (LIB). The incorporation of liquid crystal (LC) character in these materials can be desirable to improve LIB properties, such as in side chain liquid crystal polymers (SCLCPs). However, SCLCPs are costly, and flexible alkyl spacers tend to diminish LIB properties. Here, we present LC azo materials obtained by simple ionic polymerization procedures involving commercially available (or easily synthesized) dyes and oppositely charged polyelectrolytes; for example, methyl orange (MO) and methylated poly(4-vinyl pyridine) (PVPMe). The latter complex, which possesses neither flexible spacer nor tail, has a single-layer smectic A-like structure until degradation and provides exceptionally high and stable LIB properties. These materials can be inscribed with surface relief gratings. Moreover, we have successfully obtained a photoresponsive electrospun mat from a solution of the MO/PVPMe complex mixed with poly(ethylene oxide).

9:12 AM H22.00005 Reducing radiation-induced conductivity in polymeric dielectrics by small molecule electron traps, Robert J. Klein, John L. Schroeder, Shannon M. Lacy, Michael E. Belcher, Phillip J. Cole, Joseph L. Lenhart, Sandia National Laboratories — Polymeric dielectrics, when exposed to ionizing radiation, undergo the formation of electron-hole pairs and consequently exhibit radiation-induced conductivity (RIC), severely limiting the insulating capability of polymeric dielectrics used in ionizing environments. RIC can be significantly reduced by the incorporation of small-molecule traps: in the appropriate concentration range, small molecules consisting of aromatic rings and strongly electron-withdrawing groups can reduce RIC by more than 95 % in poly(ethylene terephthalate) films. The dopant structure is critical: the addition of one nitro group, the strongest electron-withdrawing substituent, leads to > 98 % RIC reduction when placed on fluorenone, pyrene, acenaphthene, and anthracene cores. Other substituents, such as cyano or amino, improve RIC reduction over the isolated cores, but not as effectively as the nitro group. The electron-withdrawing capability of each substituent side group can be quantified using the Hammett parameter.

9:24 AM H22.00006 Dynamics of acoustic phonons in exciton self-trapping in a quasi-one-dimensional system, F.X. Morrissey, S.L. Dexheimer, Washington State University — The localization of electronic excitations via electron-lattice interactions is an important fundamental process in molecular-based electronic materials. In our previous work, we directly time-resolved the electronic and vibrational dynamics of the exciton self-trapping process in the quasi-one-dimensional mixed-valence metal-halide linear chain (MX) complexes [Pt(en)2]2[Pt(en)2]2X2, (X = Cl, Br, I) using femtosecond coherent phonon techniques. In this work, we present transient absorption measurements on PtBr(en) at low temperature that reveal a large amplitude, strongly damped oscillatory component at a frequency of 11 cm−1 that is consistent with the generation of a coherent acoustic wave associated with the formation of the localized lattice deformation that stabilizes the self-trapped state. Comparison with models for polaron formation provides an estimate of the spatial extent of the local deformation of ~ 5 unit cells. This work is supported by the NSF under grant DMR-0305403.

9:36 AM H22.00007 THz time domain spectroscopy of low-frequency vibrations in a quasi-one-dimensional system, A. Bandypadhyay, S.L. Dexheimer, Washington State University — The mixed-valence halide-bridged transition metal linear chain (MX) complexes are prototypical quasi-one-dimensional systems, with a charge density wave ground state and localized electronic excitations analogous to those of conjugated organic polymers. In this work, we present studies of the low-frequency infrared-active vibrational modes of the MX complex [Pt(ethbylendiamine)2]2[Pt(ethbylendiamine)2]2[PF6]2 in the frequency range 0.3 - 3 THz using terahertz time-domain spectroscopic techniques. Distinct polarization-dependent complex refractive indices are observed in single-crystal samples of this highly anisotropic material. The measurements reveal a strong absorption at a frequency of 2.24 THz (75 cm−1) polarized along the chain axis, which we assign to the infrared-active ω1 vibrational mode, involving relative motion of the mixed-valence ions in the charge density wave configuration. This work is supported by NSF grant DMR-0706407.

9:48 AM H22.00008 Optical studies of Pt-rich π-conjugated Polymers, Tomer Drori, M. Tong, A. Gambetti, S. Singh, C. Yang, Z. V. Vardeny, Physics Department, University of Utah, S. Tretiak, Theoretical Division, LANL, Los Alamos — We have used a variety of steady state and ultrafast spectroscopies for studying the photophysics of platinum-containing conjugated polymers, which have potential applications as the active layer of light-emitting diodes. The heavy metal Pt atom that is incorporated in the polymer chain dramatically increases the spin-orbit coupling, and this influences both the intersystem crossing time, T1, and the phosphorescence emission intensity. The Pt-polymers were newly synthesized, where the intrachain Pt atom was incorporated into the polymer either in each (Pt-1) or in every three (Pt-3) monomer units. We will discuss an interesting effect for the photoexcited triplets, which dramatically influence the phosphorescence spectral shape vs. temperature. We also observed the existence of circular polarization memory of the phosphorescence emission in Pt-1 polymers, in which the platinum atoms are separated by only one phenyl ring; but not in Pt-3.

Improving the Morphology of As-Deposited Films

relatively shallow absorption depths and a high local density of vibrational excitation. The data and model are consistent with a steady-state ablation mechanism, modified by plume shielding late in the microseconds-long FEL functions of individual C-H and C-C bonds with the spectral profile of the picosecond FEL micropulses. Data from ablation rate, ablation depth, time-resolved free-electron laser (FEL) with an unusual micropulse-macropulse temporal structure. We have fully characterized the resonant and non-resonant IR ablation the IR excitation of complex polymer materials is poorly understood, and partly because most of the experiments have been conducted with a tunable infrared the ablation of intact polymers by resonant infrared (IR) laser irradiation has been demonstrated, the mechanism has remained mysterious. This is partly because lasers naturally pump and probe vibrational transitions, but it is also useful to think of vibrational energy as being conducted from one location in a molecule to another. We have developed a new technique where energy is driven into a specific part of molecules adsorbed on a metal surface, and ultrafast nonlinear coherent vibrational spectroscopy is used to watch the energy arrive at another part. This technique is the analog of a flash thermal conductance apparatus, except it probes energy flow with angstrom spatial and femtosecond temporal resolution. Specific examples to be presented include energy flow along alkane chains, and energy flow into substituted benzenes. Ref: Z. Wang, J. A. Carter, A. Lagutchev, Y. K. Koh, N.-H. Seong, D. G. Cahill, and D. D. Dlott, Ultrafast flash thermal conductance of molecular chains, Science 317, 787-790 (2007).

perennial problem in chemical physics. Usually vibrational energy dynamics are viewed through the lens of time-dependent level populations. This is natural because lasers naturally pump and probe vibrational transitions, but it is also useful to think of vibrational energy as being conducted from one location in a molecule to another. We have developed a new technique where energy is driven into a specific part of molecules adsorbed on a metal surface, and ultrafast nonlinear coherent vibrational spectroscopy is used to watch the energy arrive at another part. This technique is the analog of a flash thermal conductance apparatus, except it probes energy flow with angstrom spatial and femtosecond temporal resolution. Specific examples to be presented include energy flow along alkane chains, and energy flow into substituted benzenes. Ref: Z. Wang, J. A. Carter, A. Lagutchev, Y. K. Koh, N.-H. Seong, D. G. Mechanism of Resonant Infrared Laser Ablation of Polystyrene. — STEPHEN JOHNSON, RICHARD HAGLUND, Vanderbilt University, DANIEL BUBB, Rutgers University, Camden, KANNÄSSEN APPIWOO, Berea College — Although the ablation of intact polymers by resonant infrared (IR) laser irradiation has been demonstrated, the mechanism has remained mysterious. This is partly because the IR excitation of complex polymer materials is poorly understood, and partly because most of the experiments have been conducted with a tunable infrared free-electron laser (FEL) with an unusual micropulse-macropulse temporal structure. We have fully characterized the resonant and non-resonant IR ablation of polystyrene (PS) at several IR wavelengths. The energy input at each wavelength was ascertained by convoluting the temperature-corrected lineshape functions of individual C-H and C-C bonds with the spectral profile of the picosecond FEL micropulses. Data from ablation rate, ablation depth, time-resolved photoacoustic and photothermal measurements and nanosecond pulsed-laser shadowgraphy were fed into a simple finite-element model of energy deposition and relaxation. The data and model are consistent with a steady-state ablation mechanism, modified by plume shielding late in the microseconds-long FEL macropulse. Thus the mechanism of the resonant IR laser ablation process is apparently connected primarily with the bond-selective absorption leading to relatively shallow absorption depths and a high local density of vibrational excitation.

Support is acknowledged from NSF Grant number CMMI-0727713.
9:00AM H23.00004 Laser Ablation Electrospray Ionization: A Molecular Probe for Biological Tissues, PETER VEMES, ALEXIS A. BARTON, YUE LI, AKOS VERTES, George Washington University — Interaction of light and matter has long served as the basis of probing and modifying physical and chemical properties of materials. Recent biomedical applications focus on the mid-infrared (mid-IR) region to couple the laser energy into samples through absorption by the native water. For example, mass spectrometry (MS), relying on atmospheric pressure mid-IR matrix-assisted laser desorption ionization, takes advantage of the small amount of ions in the laser plume. In mid-IR laser ablation, owing to the recoil pressure buildup in the sample, most of the material is expelled in the form of neutral molecules, clusters, and particulates. To enhance ion production, we intercept this plume with a cloud of charged droplets to post-ionize them for MS. As a result, laser ablation electrospray ionization (LAESI) can directly probe the molecular makeup of water-rich targets with superior ion yield and dramatically extended mass range (up to 66,500 m/z). LAESI also enables two and three dimensional imaging of live tissues. Fast imaging of the plume-plume interaction reveals the mechanistic aspects of LAESI.

9:12AM H23.00005 Deposition of functional nanoparticle thin films by resonant infrared laser ablation, RICHARD HAGLUND, STEPHEN JOHNSON, Vanderbilt University, HEE K. PARK, AppliFlex LLC, KANNATESSEN APPAVOO, Berea College — We have deposited thin films containing functional nanoparticles, using tunable infrared light from a picosecond free-electron laser (FEL). Thin films of the green light-emitting molecule Alq3 were first deposited by resonant infrared laser ablation at 6.68 μm, targeting the C=C ring mode of the Alq3. TiO2 nanoparticles 50-100 nm diameter were then suspended in a water matrix, frozen, and transferred by resonant infrared laser ablation at 2.94 μm through a shadow mask onto the Alq3 film. Photoluminescence was substantially enhanced in the regions of the film covered by the TiO2 nanoparticles. In a second experiment, gold nanoparticles with diameters in the range of 50-100 nm were suspended in the conducting polymer and anti-static coating material PEDOT:PSS, which was diluted with mixing with N-methyl pyrroldinone (NMP). The gold nanoparticle concentration was 8-10% by weight. The mixture was frozen and then ablated by tuning the FEL to 3.47 μm, the C-H stretch mode of NMP. Optical spectroscopy of the thin film deposited by resonant infrared laser ablation exhibited the surface-plasmon resonance characteristic of the Au nanoparticles. These experiments illustrate the versatility of matrix-assisted resonant infrared laser ablation as a technique for depositing thin films containing functionalized nanoparticles.

9:24AM H23.00006 Photochemical ablation of Polytetrafluoroethylene (PTFE) under 157-nm irradiation, SHARON R. JOHN, STEVEN C. LANGFORD, J. THOMAS DICKINSON, Washington State University — We report time- and mass-resolved measurements on neutral molecular particles emitted from polytetrafluoroethylene during exposure to 157-nm laser radiation at fluxes where relative rapid etching is observed. By comparing the time-of-flight signals from a range of masses, we conclude that (CF2)N fragments for N=1-6 are emitted directly from the surface in substantial quantities. In contrast, the monomer (N=2) is the principal product during irradiation at 248 nm, due to a thermal decomposition mechanism. The time-of-flight signals of all the (CF2)N fragments show fast components with kinetic energies of ~0.6 eV, indicating a non-thermal mechanism. These high kinetic energies are consistent with photochemical scission of the polymer backbone, where a part of the excitation energy is delivered to the fragment as kinetic energy. Although clean etching is observed under these conditions, the great majority of the mass removed appears as much larger fragments with a size distribution of 10 nm to 1 μm. The time-of-flight signals also show a slow component. We present a collisional model to explain the slowing down of neutrals molecules created by photochemical scission. Intense electron, positive and negative ion emissions are also observed. Their formation and emission mechanism will be discussed.

9:36AM H23.00007 Rational Design of Two-Photon Absorbing Photographic Materials for Optical Switching and Data Storage1, I.A. MIKHAILOV, K.D. BELFIELD, A.E. MASUNOV, University of Central Florida — Diarylenes are able to undergo light-induced transition from the open to closed ring isomer (photoisomerization) accompanied by the change in optical properties (photochromism). This ability holds a great promise for photonic applications, including optical data storage and ultrafast optical switching. Photoisomerization initiated by absorption of two photons could drastically increase the density of these devices. However, attachment of fluorine substituent to diarylethenes increased two-photon absorption cross-section led to the loss of photochromatic activity. Analysis of the Kohn-Sham orbitals reveals that the relaxation of the lowest excited state of diarylethene fragment leads to photoisomerization, while the occupied level of the chromophore substituent generates an excited state below the photoreactive one. To design the molecular switch active in two-photon regime we suggest stabilizing the highest occupied orbital, which can be accomplished by fluorination of the chromophore. We applied time dependent Density Functional Theory to predict potential energy surfaces of excited states and two-photon absorbing profiles. The obtained results are in agreement with the qualitative orbital description.

1Supported by the NSF Grant CCF 0740344, NERC, and UCF I2lab.

9:48AM H23.00008 Toward molecular switches and biochemical detectors employing adaptive femtosecond-scale laser pulses1, ROLAND ALLEN, PETRA SAUER, Texas A&M University — The following topics will be discussed: (1) Photoisomerization of azobenzene, with nuclear motion allowing extra electronic transitions for pulse durations ~ 50 fs. (2) Photoinduced ring-opening in a model dithienylethene. (3) Response of dipicolinic acid to femtosecond-scale laser pulses, including excited states and nuclear motion. Although real applications such as molecular switches and biochemical detectors involve more techniques — with femtosecond-scale laser pulses whose durations, photon energies, fluences, shapes, etc. are tailored for specific applications — we will explain the screening effect with excited carrier density. Fourier Transform analysis shows the bare LO phonon and the lower branch of the LO phonon-plasmon coupled modes (L-). With increasing photocarrier density, the LO phonon response is essentially unaffected, while the L- peak red shifts to the TO phonon limit. Time windowed FT analysis reveals complex carrier density dependent spectral evolution. The coupled-carrier phonon dynamics are discussed in the context of photochemical potential scattering and high field transport.

10:00AM H23.00009 Ultrafast carrier-phonon dynamics under intense optical excitation of GaAs, AMLAN BASAK, Univ of Pittsburgh, M. HASE, Univ of Tsukuba, M. KITAJIMA, NIMS, Tsukuba, HRVOJE PETEK, Univ of Pittsburgh — We report the response of n-doped GaAs (n = 2×10^18 cm^-3) when excited by an e-h pair density n_exc ~ 10^19–10^20 cm^-3 with a 10 fs laser pulse centered at 400 nm. The experiment is performed in resonant electo-optic sampling geometry. The experiment was performed in reflective electro optic sampling geometry. Coherent LO phonon oscillations are excited through both ultrafast screening of the depletion field and the deformation potential scattering. The time domain signal contains near-instantaneous transient electronic response as well as coupled phonon-plasmon oscillation. The amplitude of reflectivity is sub-linearly possibly indicating saturation of the screening effect with excited carrier density. Fourier Transform analysis shows the bare LO phonon and the lower branch of the LO phonon-plasmon coupled modes (L-). With increasing photocarrier density, the LO phonon response is essentially unaffected, while the L- peak red shifts to the TO phonon limit. Time windowed FT analysis reveals complex carrier density dependent spectral evolution. The coupled-carrier phonon dynamics are discussed in the context of photochemical potential scattering and high field transport.

10:12AM H23.00010 Effect of Hot Electron Pressure in Ultrafast Laser Interaction with Metals, ZHIBIN LIN, LEONID ZHIGILEI. Department of Materials Science and Engineering, University of Virginia — Ultrafast laser irradiation can transiently bring a metal into a highly nonequilibrium state in which the electron temperature can reach thousands of Kelvin while the lattice remains cold. Under these conditions the thermal pressure from the hot conduction electrons can play an important role in defining the initial relaxation dynamics of the irradiated target. In this work, a description of the hot electron pressure due to the presence of the excited electrons is incorporated into a continuum-atomistic computational model combining the molecular dynamic method with the two temperature model. Computer simulations employing this approach are performed for Al, Au, and Ni metal films and bulk targets. The effect of the hot electron pressure on the generations of acoustic phonons in the laser-irradiated metal film will be discussed and compared with existing experimental data. The relative contributions of the hot electron pressure and thermoelastic stresses due to the lattice heating to the dynamics of the irradiated target and spallation/ablation process are discussed based on the results of the computer simulations.

10:24AM H23.00011 Coherent LO phonon self-energy renormalization under high photoexcited carrier densities in Si, ANCA-MONIA CONSTANTINESCU, University of Pittsburgh, MUNEAKI HASE1, University of Tsukuba, MASAHIRO KITAJIMA2, National Institute for Material Science, HRVOJE PETEK, University of Pittsburgh — The study of hot carrier-phonon interaction dynamics is motivated by their influence on optical and electrical properties of semiconductors. Following high-density (10^{19}–10^{20} carriers/cm^3) photoexcitation of Si(001) with 10 fs duration 400 nm laser pulses, the complex self-energy (i.e. frequency and decay rate) of coherent LO phonon (k=0) renormalize due to deformation potential interaction with the photogenerated non-equilibrium plasma. We evaluate the time dependent LO phonon frequency and dephasing time by analyzing the transient electro-optic reflectivity of variously doped Si(100). We measure the coherent LO phonon mode oscillations in the transient reflectivity over a delay time of 6 ps between pump and probe pulses. Varying the pump power from 50 to 5 mW, we observe that the electronic softening of the lattice (i.e. LO phonon frequency change) and the quasi-exponential dephasing time of the phonon depend on the initial photoexcited carrier density.

10:36AM H23.00012 Mechanistic study of negative ion emission from single crystal alkali halide surfaces due to pulsed UV laser irradiation, J. T. DICKINSON, Washington State University, KENICHI KIMURA, Research Institute, National Printing Bureau of Japan, Odawara, Kanagawa 256-0816 Japan, S. C. LANGFORD, Department of Physics, Washington State University, Pullman, WA 99164 — We report on extensive measurements of negative alkali ion emission from four alkali halides during exposure to 248-nm pulsed excimer laser radiation at fluences well below the threshold for optical breakdown. A detailed study on the emissions from single crystal KCl shows no evidence for negative halide ions, suggesting that negative alkali ions are not formed by electron attachment to thermally emitted neutral particles. Furthermore, the KCl surface charges positively during laser irradiation (due to electron emission from defects), which would hinder direct emission of negative ions from the surface. We present strong evidence for a negative ion formation mechanism involving double electron attachment to singly charged positive alkali ions. Extension of these measurements to single crystal KBr and to other dielectric materials confirm this mechanism.

10:48AM H23.00013 Observation of Saturable and Reverse Saturable Absorption in Silver Nanodots, ULLAS GURUDAS, DANIEL BUBB, Rutgers-Camden, THOMAS LIPPERT, SEBASTIAN HEROITH, PSI — Saturable absorption (SA) and reverse saturable absorption (RSA) were observed in Ag nanodots prepared by pulsed laser deposition. The Real [Re \(\chi^{(3)}\)] and Imaginary [Im \(\chi^{(3)}\)] part of the third order nonlinearity of these films are measured as and respectively, using Z-scan technique. The decrease of absorption under strong optical illumination results in a negative Im \(\chi^{(3)}\) at the photon energy used. At higher input irradiance RSA becomes dominant. The transformation from SA to RSA suggests that another nonlinear process takes place and become dominant. To evaluate the recovery time of these nonlinear processes and get an idea about the underlying mechanism, we conducted a degenerate pump-probe experiment with 25 psec, 532 nm laser pulses. The increased \(\chi^{(3)}\) and fast response time of the Ag nanoparticles can be used for optical pulse compressor, optical switching, laser pulse narrowing and protecting optical sensors from intense laser pulses.

3Support from and IEEE supplemental award to NSF Grant DMI-0613837.

Tuesday, March 11, 2008 8:00AM - 11:00AM – Session H24 DMP: Focus Session: Optical Properties of Nanostructures III: Functional Nanowires Morial Convention Center 216

8:00AM H24.00001 Polarized Photoluminescence from Single Wurtzite and Zincblende InP Nanowires, A. MISHRA, L.V. TITOVA, T.B. HOANG, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, Y. KIM, H.J. JOYCE, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — We use polarized photoluminescence spectroscopy of single InP nanowires to compare the optical properties of vapor-liquid-solid growth of single zincblende (ZB) and wurtzite (W) nanowires. Since ZB and W nanowires have different symmetries and selection rules, their optical properties should also be different. The emission from single W nanowires is observed to be \(\sim\)80 meV higher than for ZB nanowires. Low temperature polarization measurements show that ZB nanowires are strongly polarized along the nanowire axis, while the W nanowires are polarized perpendicular to the NW axis. The temperature dependence of the ZB and W NW emissions are compared with a bulk InP epiayer. Apart from the 80 meV shift in bandgap, the temperature dependencies are similar.

8Support for this work was provided by NSF (#0701703) and the Australian Research Council.

8:12AM H24.00002 Investigation of the Electronic Structure of GaAs/AlGaAs Core Multi-Shell Nanowires, S. PERERA, M.A. FICKENSCHER, T.B. HOANG, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, H.J. JOYCE, Q. GAO, Y. KIM, H.H. TAN, C. JAGADISH, Australian National University — We use photoluminescence and PL excitation spectroscopy to study the electronic structure of GaAs/AlGaAs core multi-shell NWs. Using Au-catalyst assisted MOVD, a 10 nm GaAs quantum well tube (QWT) with AlGaAs barriers is formed surrounding a central \(\sim\)50 nm GaAs core. With resonant excitation at 780 nm emission is seen from both the core as well as the QWT. The QWT emits in a narrow intense peak \(-\)22 meV above the exciton emission from the core suggesting quantum confinement in a 10 nm quantum well. NWs with QW at 100 nm InGaAs core grown shows a similar peak at \(\sim\)100 ns as recombination lifetime, while the core decays in \(\sim\)1 ns. Preliminary PLE measurements exhibit possible excited state structure of this novel quantum-confined nanostructure.

1Support for this work was provided by NSF (#0701703) and the Australian Research Council.
8:24AM H24.00003 Photoluminescence Dynamics of GaAs/AlGaAs Core-Shell Nanowires1
H.J. JOYCE, Y. KIM, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University, M.A. FICKENSCHER, S. PERERA, T.B. HOANG, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, X. ZHANG, J. ZOU, University of Queensland — We use time-resolved PL spectroscopy to study the excitation dynamics of GaAs/AlGaAs core-shell nanowires (NWs) at 20 K. NWs were prepared by Au catalyst-assisted MOCVD. PL emission from single NWs exhibits an excitonic peak at ~1.515 eV. The exciton lifetime depends on the morphology and crystallographic defect density of the GaAs core, which are in turn dependent upon the growth conditions. Nanowires cores grow at higher temperatures (450 °C) give short exciton lifetimes (<100 ps). Reducing defects within the nanowire (twinning) or at the interface should increase exciton lifetime and improve luminescence efficiency. Indeed, twin-free minimally tapered nanowires achieved using a low growth temperature (375 °C), exhibit high quantum efficiency with an exciton lifetime approaching 1.6 ns at 20 K.

1Support for this work was provided by NSF (#0701703) and the Australian Research Council.

8:36AM H24.00004 Ultrafast dynamics in semiconductor nanowires, ROHIT PRASANKUMAR, SUGKEUN CHOI, Center for Integrated Nanotechnologies, Los Alamos National Laboratory, GEORGE WANG, Sandia National Laboratories, SAMUEL PICRAUX, ANTOINETTE TAYLOR, Center for Integrated Nanotechnologies, Los Alamos National Laboratory — Semiconductor nanowires (NW) have recently attracted much interest due to their novel electronic and optical properties along with their potential for device applications in areas including nanoscale lasers and thermoelectrics. However, the further development and optimization of NW-based devices will depend critically on an understanding of carrier relaxation in these unique nanostructures. Here, we present the first all-optical time-resolved measurements of carrier dynamics in free standing semiconductor nanowires. Optical pump-probe measurements on GaN NW reveal a rapid transfer (<500 fs) of photoexcited carriers into states responsible for deleterious yellow luminescence, which can be modified by varying the growth and annealing temperatures. Polarization, angle, and wavelength-resolved measurements on vertically aligned Ge NW allow us to independently measure electron and hole dynamics parallel and perpendicular to the NW axis. Carriers propagating parallel to the NW axis have significantly longer lifetimes, clearly demonstrating the influence of two dimensional confinement on carrier dynamics in semiconductor nanowires.

8:48AM H24.00005 Optical Switching of Porphyrin-Coated Silicon Nanowire Field Effect Transistors, VINCENT BOUCHIAT, Neel Institute, CNRS-Grenoble, CLEMENS WINKELMANN, CNRS-Grenoble, IRINA IONICA, IMEP-MINATEC, XAVIER CHEVALIER, CHRISTOPHE BUCHER, GUY ROYAL, LEOPR — We study [1] porphyrin coated silicon nanowire field effect transistors, which display a large, molecule-dependent photoconversion process from the charge-to-current transducing effect of the semiconducting channel. The spectral dependence of the illumination wavelength and temperature. The decay kinetics from the high- to the low-conductance state is governed by charge recombination via tunneling, with a rate depending on the state of the SINW-FET. The comparison to porphyrin sensitized Carbon Nanotube FETs allows to distinguish the environment- and molecule-dependent photocurrent conversion process from the charge-to-current transducing effect of the semiconducting channel. The spectral dependence of the photoconductance agree with the UV-visible absorption spectrum of the isolated molecule [1]. Winkelmann et al, Nano Lett., vol. 7, p. 1454 (2007).

9:00AM H24.00006 Spectral dependence of thermal radiation from metallic nanowires on wire geometry, YAT-YIN AU, HELGI SKULI SKULASON, SNORRI INGVARSSON, Science Institute, University of Iceland, Dunhaga 3, Reykjavik IS-107, Iceland — We have studied the polarized Rayleigh back-scattering from individual silver nanowires. The nanowires were prepared by aqueous solution method and characterized by TEM lattice images and selected area diffraction (SAD) patterns. We found enhanced LO and TO phonon scattering near the tip of the nanowires. Spectra taken by Fourier Transform Infrared Spectrometry reveal strong suppression of radiation polarized perpendicular to the heater long axis as the heater width shrinks, while at the same time radiation polarized along the long axis of the heater approaches a constant value, resulting in highly polarized emission for heaters with very narrow width. We also observe a 2/θ-like resonance that we believe is associated with surface plasmon oscillations across the heater width. These findings have important implications for nanoscale thermal light generation.

9:12AM H24.00007 Anisotropic plasmon excitation and dispersion of Ag nanowires on Cu(110)1, T. SENEVIRATNE, ASOKA SEKHARAN, RICHARD KURTZ, PHILLIP SPRUNGER, Louisiana State University — Epitaxial Ag nanowires have been found to self-assemble on Cu(110) exceeding 1.2 ML. The plasmon excitation and dispersion of these nanowires have been characterized by low-energy reflection EELS. Previous STM images reveal that the Ag nanowires are approximately 2 nm (~12 nm) in height (width). However, the nanowires orientate with the long axis parallel to the [1 1 0] substrate direction and possess an anisotropic morphology. EELS reveals that the Ag plasmon excitation of 3.7 eV at the zone-center and is nearly dispersionless perpendicular to the nanowire direction. However, parallel to the Ag nanowires, EELS shows a slight red-shift of the plasmon at q = 0 and disperses to higher energy with increasing momentum transfer. These results will be discussed in light of recent ARPES band-structure measurements, electronic calculations, and anisotropic optical measurements of the Ag nanowires.

9:24AM H24.00008 Enhanced Raman Scattering Near the Tip of Semiconducting Nanowires, QIUJIE LU, JIAN WU, AWNISH GUPTA, Department of Physics, Penn State University, PETER EKLUND, Department of Physics, Department of Materials Science and Engineering, Penn State University — Results of polarized microRaman scattering experiments are presented on individual ~20μm long crystalline GaP nanowires (NWs) using 514.5 nm excitation. The NWs were supported on Transmission Electron Microscope (TEM) grids. The diameters of the NWs were characterized by TEM lattice images and selected area diffraction (SAD) patterns. We found enhanced LO and TO phonon scattering near the tip of the nanowire, i.e., the scattering is at least a factor of 5x stronger at the tip than observed at distances many microns away from the tip. The polarized scattering patterns I(θ), where θ is the angle between the incident electric field and the NW axis, also change as the probe beam approached the tip of the nanowires. The effects observed here should be general and apply to other semiconducting nanowire systems as well.

9:36AM H24.00009 Polarized Rayleigh Back Scattering from Individual GaP Nanowires, JIAN WU, G. CHEN, QIUJIE LU, P.C. EKLUND — Results of polarized Rayleigh back-scattering studies are reported for individual ~20 μm long crystalline GaP Nanowires (NWs) using 514.5 nm excitation. The NWs were determined by TEM. Positions of characteristic LO, TO phonon Raman bands were found to agree with bulk GaP. The Rayleigh back-scattering intensity polar pattern I(θ) was measured at room temperature, where θ is the angle between the incident electric field and the NW axis. The scattered radiation was polarized parallel to the incident electric field. For small NW diameter (d~70) nm, we observed ~ cos^4[θ] polar patterns. With increasing NW diameter above 100 nm, the polar scattering patterns rotate by 90° with respect to those seen in small diameter NWs and then they broaden to a circle. Our experimental data will be compared to the calculated Rayleigh back-scattering efficiency calculated via the Discrete Dipole Approximation (DDA). Our DDA calculations show that the polar patterns are sensitive to both the diameter and the NW length. Although the calculated polar patterns qualitatively support our data, improvement in the modeling is still needed. This work is supported by NSF NIRT, grant DMR-0304178.
10:00AM H24.00011 Optical Antenna Effect in Semiconducting Nanowires, P.C. EKLUND, JIAN WU, G. CHEN, QIUI JIE LIU, H.R. GUTIERREZ, QIHUA XIONG, M.E. PELLEN, J.S. PETKO, D. WERNER — Using Raman scattering, we have observed strong optical antenna effects which we identify with internal standing wave photon modes of the wire. The antenna effects were probed in individual GaP NWs whose diameters are in the range 40<\text{d}<300 \text{ nm}. The data and our calculations show that the nature of the backscattered light is critically dependent on the interplay between a photon confinement effect and bulk Raman scattering. At small diameter, d<65 \text{ nm}, the NWs are found to act like a nearly perfect dipole antenna and the bulk Raman selection rules are masked leading to a polarized scattering intensity function I(\theta) \sim \cos^2 \theta. For larger wires, many other different polar patterns are found. Underscoring the importance of this work is the realization that a fundamental understanding of the “optical antenna effect” in semiconducting NWs is essential to the analysis of all electro-optic effects in small diameter filaments.

10:12AM H24.00012 Spatially-Resolved Photoluminescence Mapping of Single CdS Nanosheets1, M. FICKENSHIER, T.B. HOANG, L.V. TITTOVA, A. MISHRA, L.M. SMITH, H.E. JACKSON, University of Cincinnati, J.M. YARRISON-RICE, Miami University, H. RHÖ, K.-Y. LEE, Chonbuk National University, Y.-J. CHOI, K.J. CHOI, J.-G. PARK, KIST — We present results of spatially-resolved low temperature photoluminescence of single 5 micron wide CdS nanosheets. The sheets, grown by pulsed laser deposition using vapor-phase transport, are uniform in size and shape and exhibit a hexagonal wurtzite structure. The orientation of the c-axis determined by PL polarization analysis and HR TEM varies from sheet to sheet. The spatially-resolved PL reveals spectral variation across the sheet, with A-like excitons at the edges showing a spectral peak at 2.54eV, and B-like excitons at the center showing a peak at 2.563eV. Exciton lifetimes of \sim 200 ps are observed, which are significantly longer than CdS nanowires of identical diameter, but shorter than measured in bulk CdS.

1Support provided by NSF (\#0701703), Korea Research Foundation and KIST.

10:24AM H24.00013 Anomalous Photoluminescence in CdSe Quantum Dot Solids at High Pressure due to Non-uniform Stress, S. SEBASTIEN HAMEL, C. CHRISTIAN GRANT, J. JONATHAN CROWHURST, A. ANDREW GUPTA, JIAN WU, P.C. EKLUND — Results of polarized micro-Raman scattering from LO and TO phonons in individual GaP nanowires (NWs) with different diameter and length are reported. The NW diameters were determined by Atomic Force Microscope (AFM) and length was measured by Scanning Electron Microscope (SEM). NWs with the same growth direction but variable length were prepared by cutting \sim 40 \mu m long wires into segments using a Focused Ion Beam. The polar plots of the back scattered intensity I_{\text{TO,LO}}(\theta) from these segments were collected, where \theta is the angle between the incident electric field and the NW axis. Interestingly, the shapes of these polar patterns depend on both the length and diameter of the NWs. The Raman scattering intensities for short wires (i.e., L<<1\mu m) also exhibit a non-linear dependence on the incident laser power I_0. The non-linearity increases with decreasing NW length and behaves as \sim I_0^4, for the shortest wires measured so far (i.e., L\sim 500 \mu m). Our results strongly suggest strong enhancement in the internal electric field via antenna effects. This work is supported by NSF NIRT, grant DMR-0304178.

10:36AM H24.00014 Dynamics of Photo-Excited Carriers in Single InP Nanowires Under High Excitation Density1, L.V. TITTOVA, T.B. HOANG, H.E. JACKSON, L.M. SMITH, University of Cincinnati, J.M. YARRISON-RICE, Miami University, Y. KIM, H.J. JOYCE, Q. GAO, H.H. TAN, C. JAGADISH, Australian National University — The dynamics of photo-excited carriers in single InP nanowires at low temperature is investigated using time-resolved photoluminescence spectroscopy. Under highly intensity excitation, the photoluminescence spectrum from a single nanowire shows a broad emission band at early times after the excitation pulse indicating the presence of a degenerate, high density electron-hole plasma. At later times (> 600 ps) when the density of carriers decreases, the emission spectrum becomes narrower and converges toward the free exciton emission band. The lifetime of free excitons in a single nanowire is measured to be close to the lifetime of excitons in high quality InP epilayers, indicating the relative insensitivity of the carriers to the InP nanowire surface. These results indicate that significant state filling and band gap renormalization occur in single InP nanowires.

1Support for this work was provided by NSF (\#0701703) and the Australian Research Council.

10:48AM H24.00015 Near Infrared Photoresponse in Annealed CdSe Nanocrystal Films, LIWEI LIU, PAUL STOKES, ARTEM E. MASUNOV, SAIFUL I. KHONDAKER, NANOSCIENCE TECHNOLOGY CENTER, DEPARTMENTS OF PHYSICS & CHEMISTRY, UNIVERSITY OF CENTRAL FLORIDA TEAM — We found unexpected near infrared (NIR) photoresponse in CdSe nanocrystal superlattice film annealed above 400 C in air. The current voltage characteristic measured in a planar device geometry show a large increase in NIR current over dark current. The calculated external quantum efficiency of the device is up to 10.6 % at -5V and the responsivity is 0.7A/W obtained under 1.32 \mu W IR irradiation. UV-VIS absorption of annealed CdSe shows the redshifting and broadening of exciton peak and a decrease of band gap as the annealing temperature is increased. TEM image show that CdSe nanocrystals have been melted to fuse to different size distribution nanoparticles during annealing. We discuss possible reason for this unexpected behavior.

Tuesday, March 11, 2008 8:00AM - 11:00AM – Session H25 DPOLY: Adsortion of Organics on Surfaces Morial Convention Center 217

8:00AM H25.00001 Polymer Physics Prize Break –
8:36AM H25.00002 Examining the air-water interfacial activity of beta-peptides using molecular simulation and experiment. CLARK A. MILLER, JUAN J. DE PABLO, Department of Chemical and Biological Engineering, University of Wisconsin-Madison — Amphiphilic beta-peptides (oligomers of beta-amino acids) are predicted to adsorb at the air-water interface using computer simulation and verified using experiments. Molecular dynamics simulations are used to calculate the free energy of adsorption for different degrees of amphiphilicity and different display of hydrophilic groups. Adsorption of selected peptides is examined by measuring the surface tension of a solution of beta-peptides at different concentrations and agreement with simulation results is found. Simulations show that 2/3 hydrophobic residues lead to favorable adsorption at the air-water interface while 1/3 hydrophobic residues is unfavorable. We analyze changes in the conformational properties and angle with the interface to understand the manner of adsorption. We further investigate the behavior of multiple peptides at the interface using computer simulation and determine the surface pressure and peptide-peptide interactions at the interface.

8:48AM H25.00003 Why are hyperactive ice-binding-proteins so active? IDO BRASLAVSKY, YELIZ CELIK, NATALYA PERTAYA, YOUNG EUN CHOI, Physics Department, Ohio University, Athens, OH, MAYA BAR, Structural Biology, Weizmann Institute of Science, Rehovot, Israel, PETER L. DAVIES, Department of Biochemistry, Queen’s University, Kingston, Ontario, Canada — Ice binding proteins (IBPs), also called ‘antifreeze proteins’ or ‘ice structuring proteins’, are a class of proteins that protect organisms from freezing injury. These proteins have many applications in medicine and agriculture, and as a platform for future biotechnology applications. One of the interesting questions in this field focuses on the hyperactivity of some IBPs. Ice binding proteins can be classified in two groups: moderate ones that can depress the freezing point up to ~1°C and hyperactive ones that can depress the freezing point several-fold further even at lower concentrations. It has been suggested that the hyperactivity of IBPs stem from the fact that they block growth out of specific ice surfaces, more specifically the basal planes of ice. Here we show experimental results based on fluorescence microscopy, highlighting the differences between moderate IBPs and hyperactive IBPs. These include direct evidence for basal plane affinity of hyperactive IBPs, the effects of IBPs on growth-melt behavior of ice and the dynamics of their interaction with ice.

9:00AM H25.00004 Probing (bio)-organic monolayers at the metal/air and metal/liquid interface by sum-frequency generation spectroscopy, FRANCESCA CECCHET, DAN LIS, YVES CAUDANO, CHRISTOPHE SILIEN, ALAA ADIN MANI, PAUL THIRY, ANDRÉ PEREMANS, LLS Laboratory of Lasers of Spectroscopies, FUNDP - University of Namur — In the present work, ordered monolayers of thios prepared by self-assembly (SAM), and of lipids obtained by the Langmuir-Blodgett technique (LB), have been studied by sum frequency generation spectroscopy (SFG) at the metal/air and metal/liquid interface, in different sets of polarizations. This study is focused on the determination of the molecular orientation (i.e. the tilt angle and the twist angle of the axis and of the plane of the molecular groups, respectively) and on the analysis of the interactions occurring within the layers or with outer target molecules.

9:12AM H25.00005 Flow Induced Growth of Striped Alkane Monolayers, M. BAI, H. TAUB, A. DIAMA, U. Mo.-Columbia, K. KNORR, U. des Saarlandes, U. G. VOLKMANN, P. U. Catolica Chile, F. Y. HANSEN, Tech. U. of Denmark — We report our observation of the growth of striped monolayer phases of alkanes when deposited from a solution under flow. AFM measurements show that the structure and morphology of dotriacontane (n-C32H66 or C32) films grown from solution depend sensitively on the flow direction over a SiO2-coated Si(100) substrate. The C32 film exhibits one or two layers adjacent to the SiO2 surface in which the molecules are oriented with their long axis parallel to the interface followed by a striped monolayer of perpendicularly oriented molecules. The stripes form along the direction of solution flow with typical dimensions of a few micrometers wide and a few hundred micrometers long, depending on the solution concentration. A striped morphology is also observed for C29 grown under similar conditions. Grazing incident-angle x-ray diffraction measurements indicate that the C32 stripes are crystalline and can be indexed by a rectangular unit cell. We offer some speculations on the origin of the striped morphology.

9:24AM H25.00006 Molecular dynamics studies of the structure and dynamics of “perpendicular” layers of n-alkane molecules adsorbed on a solid substrate, F.Y. HANSEN, Tech. Univ.of Denmark, P. SOZA, P.U. Catolica Chile, H. TAUB, U.Mo.-Columbia, U.G. VOLKMANN, P.U. Catolica Chile — Both AFM and ellipsometry studies of n-alkane films adsorbed on a solid substrate from a solution have shown wetting and de-layering phenomena. It was found that on top of one or two “parallel” layers of molecules, where the long axis of the molecules is parallel to the surface, “perpendicular” layers of molecules are formed with the long axis of the molecules perpendicular to the surface. MD simulations of layers of tetracosane, n-C32H66, molecules are set up to answer the following questions about the “perpendicular” layers: a) Is the melting transition driven by gauche defect creations in the alkane chains like in the parallel layers?, b) can a rotator phase be identified?, c) is there a lateral translational mobility of the chains prior to melting?, and d) what is the mechanism driving the wetting and de-layering transitions in the films? 2H. Mo et al. Chem. Phys. Lett. 377, 99 (2003)

1Supported by Grant Nos. U.S. NSF DMR-0705974, FONDECYT 1060628, CONICYT, and the Danish Center for Scientific Computing .

9:36AM H25.00007 Structure and Phase Transitions of Vapor-Deposited C32 Films, V. DEL CAMPO, E.A. CISTERNAS, I. VERGARA, T. CORRALES, U.G. VOLKMANN, P.U. Catolica Chile, M. BAI, S.-K. WANG, H. TAUB, U.Mo.-Columbia, H. MO, S.N. EHRLICH, Brookhaven Nat. Lab — We have compared the structure, topography, and phase transitions of dotriacontane films (n-C32H66 or C32) that have been vapor-deposited onto a SiO2-coated Si(100) wafer with those that have been deposited from solution. X-ray reflectivity measurements indicate that the as-deposited films differ in their morphology but share the following structural features at room temperature: adjacent to the substrate there is a nearly complete bilayer in which the molecules are oriented with their long axis parallel to the surface. Above the parallel film are partial layers of molecules oriented perpendicular to the surface. After a heating cycle above the bulk C32 melting point (Tm), AFM images of all films show the presence of 3D mesa-shaped bulk particles. On a second heating, AFM reveals the same succession of phase transitions for both film types in which a perpendicular monolayer spreads outward from the mesa-shaped particles below Tm, followed by a delaying transition to a 3D fluid droplets just above Tm. 2M. Bai et al., Europhys. Lett. 79, 26003 (2007).

1Supported by Grant Nos. NSF DMR-0705974 and FONDECYT 1060628 and 7070248.
9:48AM H25.00008 Thermodynamic Studies of n-Octane Thin Films Adsorbed on Magnesium Oxide(100), DAVID FERNANDEZ-CANOJTO, J.Z. LARESE, Oak Ridge National Laboratory — Thermodynamic properties of n-octane adsorbed on the MgO(100) surface were investigated using high-resolution adsorption isotherms in the temperature range of 225 K to 295 K. Two distinct adsorption steps were observed in all isotherms. The average area occupied by an n-octane molecule was estimated to be 139.1 Å². The temperature variation of the two dimensional compressibility was used to identify phase transitions near 265.9 K and 271.4 K for the first and second layers, respectively. COMPASS force field has been used to calculate the minimum energy configuration of a single n-octane molecule sited on the MgO (100) facet. Calculations suggest that the most likely configuration for the adsorbed molecule is with the carbon backbone parallel to the (100) plane, and with the center of mass atop the Mg²⁺ site. U.S. DOE, Materials Science Division under contract No. DE-AC05-00OR22725 operated by UT-Battelle, LLC, and the NSF under grant DMR-0412231.

10:00AM H25.00009 X-ray Atomic-Scale Analysis of Self-Assembled Monolayer Growth on Silicon, J.C. LIN, J. KELLAR, J. KIM, N. YODER, K. BEVAN, S. DATT, S. NGUYEN, M. HERSAM, M. BEDZYK — Organic functionalization of silicon is of interest for applications ranging from biosensing to molecular electronics. The efficiency of molecular devices heavily depends on the ordering of the structure. Traditionally spectroscopy is used to characterize bonding, but often the overall structure can be ambiguous. Our strategy is to combine a compliment of techniques, including AFM, XPS, XRR(X-ray reflectivity), XSW(X-ray standing wave), XRF(X-ray fluorescence), and DFT(Density functional theory) to determine the molecular configuration and packing density of Self-Assembled Monolayers (SAMs) grown on H-passivated Silicon. Our periodic DFT study of 4-bromo-phenyl-acetylene (BPA) predicts that the local packing density can affect the Br height by as much as 2 angstrom. XSW, which is used to measure the 3D Br distribution shows that the local structure is unchanged when the average SAM coverage is increased. This indicates the type of 2D island nucleation growth process being observed. Comparison between 4-bromostyrene (BrSty) and BPA SAMs provides direct evidence that the double bond root of the BPA contributes to a stiffer configuration than the single bond root. With the aromatic rings in the structure for conducting electrons, BrSty and BPA molecules are a starting point for future molecular electronic designs with more complex molecules.

10:12AM H25.00010 ABSTRACT WITHDRAWN

10:24AM H25.00011 STM/S of Polydiacetylene Nanowires on Gold and Graphite, LILI WANG, RAJIV GIRDHARAGOPAL, KEVIN KELLY, Rice University — The structural and electronic properties of 10,12-pentacosadiynoic acid (PCDA) monolayer films and polydiacetylene (PDA) nanowires on Au islands on a HOPG substrate have been studied using STM. Our results indicate that PCDA monolayer films can be formed on both HOPG and 1-2 monolayer (ML) Au islands, but arrange in small domains due to the dense Au clusters. The arrangement of PDA nanowires exhibits different collapse density, length and bending between Au and HOPG areas due to differing chemical and electronic interactions, which play an important role in the charge transfer between conducting polymers and electrodes in commercial devices. STM-tip induced nanowire cutting, desorption and polymerization is also observed, with the surrounding PCDA molecules restoring the packing nearly instantaneously. This implies that the interaction with Au clusters is not strong enough to weaken the intramolecular interactions that produce the reordering cascade effect, although it strongly influences the arrangement of the nanowires. Furthermore, the local work function and dI/dV images indicate electronic structure differences between PCDA monolayer films on 1 ML Au islands and those on 2 ML islands, and between PDA nanowires on HOPG and those across Au islands.

10:36AM H25.00012 Thermodynamic and Neutron Scattering Investigation of Ethylene Wetting on MgO (100), ANDI BARBOUR, University of Tennessee, CRAIG BROWN, NIST Center for Neutron Research, J. Z. LARESE, Oak Ridge National Laboratory and University of Tennessee — The adsorption properties of a molecular film on a solid substrate are governed by the relative strength of the molecule-substrate versus molecule-molecule interaction. The wetting properties of ethylene (C₂H₄) molecular thin films on graphite are of fundamental interest because the number of observed adlayers increases as the intermolecular temperature increases with T<104K (bulk triple point). In adsorbate/substrate systems like C₂H₄/graphite, it is accepted that triple point wetting occurs. For our studies, we employed MgO nanocubes because they represent a prototypical metal oxide with a wide variety of technological uses including catalyst support. Of particular interest are wetting/layering transitions and the changes that take place in the neighborhood of the bulk triple point. We report our experimental investigation of the adsorption behavior of evidence C₂H₄ on MgO (100) using high-resolution adsorption isotherms and neutron diffraction and scattering. We demonstrate the dominance role that molecule-molecule interaction plays in the wetting phenomena by comparing the behavior of ethylene on graphite and MgO. U.S. Department of Energy (DE-AC05-00OR22725) at ORNL managed and operated by UT-Battelle, LLC, and the NSF (DMR-0412231).

10:48AM H25.00013 Importance of Van Der Waals Interaction for Organic Molecule-Metal Junctions, PRIYA SONNY, PETER PUSCHNIG, DMITRI NABOK, CLAUDIA AMBROSCH-DRAXL, Chair of Atomistic Modelling and Design of Materials, University of Leoben, Franz-Josef-Strasse 18, A–8700 Leoben, Austria — We present calculations to study the interface energetics of a weakly adsorbed organic molecule on metallic surfaces, which serve as model interfaces relevant for organic electronics. Thereby we focus on the role of the exchange-correlation potential and, in particular, the van der Waals interaction. To this extent the thiophene molecule is relaxed on clean Cu(110) and Cu(110)-(2x1)O, and the adsorption energy corresponding to various positions and orientations of the molecule is calculated on the search for the most favorable adsorption site. The molecule is found to be more strongly bound on the clean Cu(110) surface with an adsorption energy of −0.50 eV, as compared to −0.30 eV on Cu(110)-(2x1)O. Nonlocal correlations, i.e., the van der Waals interaction is found to be solely reponsible for the binding in such weakly bound systems, while the commonly used generalized gradient approximations not only underestimate the adsorption energy but also provide the wrong physical picture for the binding. The adsorption of thiophene lowers the work function of the metallic substrate due to the formation of surface dipoles while no sizeable charge transfer is found.

Tuesday, March 11, 2008 8:00AM - 11:00AM
Session H26 DCP; Focus Session: Photophysics of Cold Molecules IV, Morial Convention Center 218

8:00AM H26.00001 Reactions of cold trapped anions, ROLAND WESTER, Physikalisches Institut, Albert-Ludwigs-Universitaet Freiburg, Herrmann-Herder-Str. 3, 79104 Freiburg, Germany — Interactions of negative ions with small organic molecules represent model systems for the investigation of reaction dynamics in few-body systems. Their corrugated potential energy landscape, originating in long-range attractive and short-range repulsive forces, requires the coupling of different degrees of freedom for reactions to occur. We have adopted two complementary approaches to study anion-molecule reaction dynamics. Using velocity map imaging in combination with crossed beams at low energy we study the differential cross section of negative ion reactions. For nucleophilic substitution reactions we have observed several distinct reaction mechanisms when varying the collision energy [1]. Total reaction rate measurements, which we carry out in the box-shaped potential of a 22pole ion trap [2], have revealed unexpected temperature-dependences for proton transfer and for cluster stabilisation at low temperatures. In addition, laser-induced photodetachment is studied in the trap to obtain absolute destruction cross sections for negative ions in light fields [3]. These results are relevant for the understanding of the negative ion abundances in interstellar molecular clouds.

8:36AM H26.00002 Cold reactive collisions between laser-cooled ions and velocity-selected neutral molecules, MARTIN BELL, STEFAN WILLITSCH, ALEXANDER GINGELL, SIMON PROCTOR, TIMOTHY SOFTLEY, Department of Chemistry, University of Oxford — The recent development of a range of techniques for producing cold molecules at very low translational temperatures T < 1 K in the gas phase has provided the opportunity for studying molecular collisions in a new physical regime. We report a new experimental method to study reactive collisions between ions and neutral molecules at very low temperatures which allows for tunable collision energies and a variety of chemically diverse reaction partners. Our technique relies on the combination of a quadrupole-guide velocity selector for the generation of cold polar molecules with a facility to provide strong electric fields at low velocities to control the trajectories of the ions. We present results from the collisions of cold OH atoms with He atoms with the goal of creating molecular complexes of low rotational and vibrational energy. From the quadrupole-guide, the strong localization and long trapping times of the ions allows chemical reactions to be studied at the single-particle level. In a proof-of-principle experiment, we have studied the chemical reaction between translationally cold CH$_2$F molecules and laser-cooled Ca$^+$ ions in a collision energy range corresponding to 1-10 K. The characteristics of our cold-molecule sources and the performance of the new technique as well as perspectives for further developments will be discussed.

8:48AM H26.00003 Demonstration of a three-dimensional trap for state-selected Rydberg atoms, STEPHEN HOGAN, FREDERIC MERK, ETH Zurich, Switzerland — Recent progress in the development of methods by which to decelerate and manipulate the translational motion of Rydberg atoms and molecules in the gas phase using static and time-varying inhomogeneous electric fields has led to the experimental realization of Rydberg atom optics elements including a lens, a mirror and a two-dimensional trap. These experiments exploit the very large electric dipole moments associated with Rydberg Stark states, and have demonstrated the possibility to stop a seeded, pulsed, supersonic beam of atomic hydrogen traveling with an initial velocity of 700 ms$^{-1}$ within 3 mm and 5 µs using electric fields of only a few kVcm$^{-1}$. With the goal of achieving complete control of a cloud of Rydberg atoms or molecules in three-dimensions, we have recently designed and constructed a three-dimensional electrostatic trap for these particles. The design of this trap will be presented along with the results of a series of experiments in which we have used the trap to confine, in three dimensions, a cloud of atomic hydrogen Rydberg atoms in states with principal quantum numbers around n = 50. The dynamics of the Rydberg atoms in the trap have been investigated by pulse field ionization and imaging techniques. Under favorable conditions, trapping times on the order of 150 µs have been observed, corresponding to the radiative lifetimes of the excited states.

9:00AM H26.00004 Measuring the role of alignment in a molecule optical lens, SIMON M. PURCELL, PETER F. BARKER, University College London — Far off-resonant pulsed lasers have been used to deflect and focus molecules via the molecular dipole force, which is proportional the effective polarisability of the species [1]. Molecules have an anisotropic polarisability, which in the presence of an intense linearly polarised optical field (10$^{12}$ Wcm$^{-2}$) causes the molecule to align with the field polarisation vector. This alignment occurs due to the creation of paddles states, which are superpositions of field free rovibronic states of the molecule [2]. alignment of the molecule with the electric field can result in a higher effective polarisability leading to an increased dipole force that can be used to tailor the properties of molecular optical elements. Using this property, we are studying how the field polarisation can be used to modify the focal length of the molecule optical lens, created by a focused laser beam. We will present calculations of this process and a comparison with our experiments on cold (3 K) carbon disulphide molecules focused by a Nd:YAG laser beam. [1] H.S Chung, B.S Zhao, S.H. Lee et al., J. Chem. Phys 114, 8293 (2001) [2] B. Friedrich, D. Herschbach, J. Phys. Chem. 99, 15688 (1995)

9:12AM H26.00005 Cold and ultracold polar molecules, JUN YE, JILA, NIST and Univ. of Colorado — Study of ultracold molecules promises important benefits such as novel control of chemical reactions and molecular collisions, precision measurement of fundamental physical properties, and new methods for quantum information processing and quantum simulations. We undertake two approaches aimed to produce cold, polar molecular samples. In the first approach, we work directly with ground-state polar molecules such as hydroxyl radicals (OH) or formaldehyde molecules (H$_2$CO): After Stark deceleration through an inhomogeneously distributed electric field, OH molecules are loaded into a magnetic trap at a density $\sim 10^{13}$ cm$^{-3}$ and temperature of 50 mK. An important advantage of magnetically trapping OH molecules is the freedom in applying an external electric field without significantly affecting the trap dynamics. The open geometry of the trap will enable experimental studies of cold, dipolar collisions subject to an external electric field. We will report our latest progress towards this goal. In the second approach we explore the possibility of producing ultracold polar molecules via association of two different atoms from ultracold atom gas mixtures near quantum degeneracy. Specifically, an interspecies Feshbach resonance between bosonic 87Rb and fermionic 40K permits efficient creation of heteronuclear Feshbach molecules. Subsequent optical spectroscopy reveals promising paths to efficiently transfer populations from the weakly bound to more deeply bound states. Progress on the production of these ultracold fermionic polar molecules will be reported.

9:48AM H26.00006 Experimental demonstration of electrostatic surface guiding for cold polar molecules, YONG XIA, YALING YIN, JIANPING YIN, Key Laboratory of Optical and Magnetic Resonance Spectroscopy, Department of Physics,East China Normal University — We demonstrate an electrostatic surface guiding for cold polar molecules over a long distance of 44.5 cm on a substrate by using a hollow electrostatic field. Cold molecules are generated by two parallel charged wires and a grounded metal-plate. We measure the transverse spatial distribution of the guided supersonic D$_2$O (including CH$_3$Br) molecular beam and its longitudinal velocity one, and study the dependence of the relative guiding efficiency and the transverse temperature of the guided molecular beam on the guiding voltage, also perform Monte-Carlo simulations and theoretical studies for the molecular guiding process, and our guiding scheme has some potential applications in molecule optics, such as molecular-beam splitter, integrated molecular optics, etc.

10:00AM H26.00007 Rotational Spectra of Methane in Helium-4, ROBERT ZILLICH, Kepler University, Linz, BIRGITTA WHALEY, University of California, Berkeley — We extend correlated basis function (CBF) theory, in combination with diffusion Monte Carlo simulations, to spherical top molecules solvated in superfluid He$^4$ droplets. Similarly to our previous CBF work on linear molecules, the rotational excitations of a spherical top molecule are renormalized by a self energy which contains the 4He density modulation around the molecule as coupling. Due to the high symmetry of this density in the case of solvated spherical molecules the rotation-4He coupling turns out to be weak, and the corresponding reduction of the effective rotational constant is small. Therefore, unlike for linear molecules, for spherical top molecules the symmetry of the gas phase rotational spectrum is not preserved. Instead, for excitations of total angular momentum $J > 2$, we find that the self energy induces a splitting of the rotational energies. We present here the rotational spectra of solvated linear C$_2$H$_6$ and rotational spectra of solvated spherical CH$_4$ and CD$_4$. The spectra of Ar-H$_2$O and O$_2$-H$_2$O exhibited the splitting of the rotational lines, which is due to the anisotropy of their intermolecular potential. We have analyzed the observed splittings in the spectra to determine the intermolecular potentials of Ar-H$_2$O and O$_2$-H$_2$O in droplets. These results are compared with the corresponding potentials previously studied in both experimentally and theoretically.

10:12AM H26.00008 Water containing molecular complexes studied by superfluid helium droplet spectroscopy, SUSUMU KUMA, The University of British Columbia, MIKHAIL SLIPCHENKO, Iowa State University, TAKAMASA MOMOSE, The University of British Columbia, ANDREY VILESOV, University of Southern California — Superfluid helium droplets offer an ideal environment for spectroscopic studies of molecular complexes by virtue of the controllable aggregation process of embedded molecules and its weak interaction as a matrix medium. Here, we report the infrared spectroscopy of Ar-H$_2$O, N$_2$-H$_2$O, and O$_2$-H$_2$O complexes picked up in He droplets. The observed spectra in the anti-symmetric stretching vibrational region ($\nu_2$) of water around 3750 cm$^{-1}$ indicated that the water molecule in complexes rotates nearly freely in Ar-H$_2$O and O$_2$-H$_2$O, while not in N$_2$-H$_2$O. The spectra of Ar-H$_2$O and O$_2$-H$_2$O exhibited the splitting of the rotational lines, which is due to the anisotropy of their intermolecular potential. We have analyzed the observed splittings in the spectra to determine the intermolecular potentials of Ar-H$_2$O and O$_2$-H$_2$O in droplets. These results are compared with the corresponding potentials previously studied in both experimentally and theoretically.
10:24AM H26.00009 Microwave spectroscopy of doped helium clusters and doped helium droplets, WOLFGANG JÄGER. University of Alberta — High resolution microwave and infrared spectroscopy of small to medium sized doped helium clusters, e.g. He$_2$-OCS with $N$ from 2 to 70, has given detailed insights into how superfluidity, a bulk phase property, evolves from the microscopic scale. Some of the most significant findings were oscillatory behavior of cluster rotational constant $B$ with number of helium atoms, $N$, and the observation of very narrow lines (15 kHz in microwave and 0.001 cm$^{-1}$ in the infrared region), even for the largest $N$. How can this be reconciled with the broad (up to several GHz wide) lines of rotational and ro-vibrational transitions of molecular dopants in helium droplets? Microwave experiments of molecular dopants embedded in helium nanodroplets can help answer this question. We have measured the pure tunneling inversion transition of ammonia in helium droplets at about 20.7 GHz. A complex line shape, consisting of a sharp (15 MHz wide) line on top of a broad background (1.5 GHz wide) was observed. The line shape could be simulated by assuming identical energy sublevels of the initial and final state of the transition. This provides direct evidence for the existence of an energy level substructure of molecular states in doped helium droplets. Microwave rotational transitions of carbonylsulfide, OCS, in helium droplets show increase in line width with increasing rotational quantum number $J$ and, in some cases, prominent fine-structures. Some of these features can be interpreted in terms of droplet size distribution.

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H27 DCMP: Correlated Electrons: Heavy Fermions and Exotic Magnets

8:00AM H27.00001 Magnetism and metallicity in FeSb2-xTex, CEDOMIR PETROVIC, RONGWEI HU, Condensed Matter Physics, Brookhaven National Laboratory; VESNA MITROVIC, Physics Department, Brown University — Single crystals of FeSb2-xTex (0<x<1) were grown by molten metalin technique. A rich variety of electronic and magnetic ground states will be presented.

8:12AM H27.00002 Phase transitions in R$_5$NiPb$_3$ (R=Ce,Nd,Gd), V. GORUGANTI, K. D. D. RATHNAYAKA, JOSEPH H. ROSS, JR., Department of Physics, Texas A&M University — We report magnetic and thermodynamic measurements for recently-synthesized R$_5$NiPb$_3$ (R= Ce,Nd,Gd) (hexagonal Hf$_5$CuSn$_3$-type structure), as well as non-magnetic La-based analogs. High-temperature Curie-Weiss fits yield effective moments of 2.43, 3.70 and 9.3 $\mu_B$ for Ce$_5$NiPb$_3$, Nd$_5$NiPb$_3$ and Gd$_5$NiPb$_3$, respectively. These are close to the R$^{12}$$_{12}$ $\mu_B$ values, showing that Ni is nonmagnetic in all cases. For Ce$_5$NiPb$_3$, a peak seen in both the magnetization and specific heat at 48 K indicates an apparent ferromagnetic transition at that temperature, which is also confirmed by field dependent heat capacity and a positive Curie-Weiss temperature. Nd$_5$NiPb$_3$ exhibits two magnetic transitions, an antiferromagnetic transition at 42 K and an apparently weak ferromagnetic canting transition at 8 K. Ce$_5$NiPb$_3$ shows a kink in both the magnetization and specific heat at 68 K indicating a ferro- or ferrimagnetic transition at that temperature, which is also confirmed by a positive Curie-Weiss temperature. For this material, ZFC and FC measurements show irreversibility at transition temperature. For Ce and Nd samples $M$-$H$ curves show metamagnetism at low temperatures. We will compare the results with the non magnetic analog La$_5$NiPb$_3$.

8:24AM H27.00003 Universal heat transport in the heavy-fermion superconductor CeIn$_5$, HAMIDEH SHAKERIPOUR, M.A. TANATAR, Département de Physique, Université de Sherbrooke, Sherbrooke, Canada, P. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, NY 11973, USA, LOUIS TAILLEFER, Département de Physique, Université de Sherbrooke, Sherbrooke, Canada — In superconductors with nodes in the gap, zero-energy quasiparticles give rise to a residual linear term in the thermal conductivity at T=0. When the quasiparticle density of states is linear in energy, this term is universal, in the sense that it does not depend on impurity concentration. Such universal heat transport has been observed in cuprates and ruthenates but never in heavy-fermion superconductors. Here we show that heat transport in the heavy-fermion superconductor CeIn$_5$ is unchanged by the doping of La impurities. This universal transport confirms the presence of a line node in the gap [1].

1$^{1}$Work supported by Office of Basic Energy Sciences US Department of Energy

8:36AM H27.00004 Fermi Surface Investigation of Cd doped CeCoIn$_5$, CIGDEM CAPAN, University of California Irvine, LUIS BALICAS, YOUN JUNG JO, National High Magnetic Field Laboratory, ROY GOODRICH, Louisiana State University, ANDREA BIANCHI, Université de Montréal, JOHN DITUSA, Louisiana State University, ZACHARY FISK, University of California Irvine — CeCoIn$_5$ is a 2.3K superconductor member of the 115 family of heavy fermion compounds that have attracted much attention due to the competing magnetism and superconductivity. The superconductivity in CeCoIn$_5$ emerges from a metallic state that exhibits strong deviations from the Fermi Liquid theory, with the presence of a field-tuned antiferromagnetic quantum critical point near the upper critical field. Recently it was shown that Cd substitution can tune the ground state from superconducting to antiferromagnetic. One important question is how the shape of the Fermi surface influences the stability of the ground state. We will present de-Haas van-Alphen results in Cd doped LnCoIn$_5$ (Ln=La,Ce) and discuss the origin of magnetic order in this system.

8:48AM H27.00005 Two fluid analysis of La and Cd doped CeIn$_5$, NICHOLAS BERRY, University of California Irvine, ANDREA BIANCHI, Université de Montréal, ZACHARY FISK, University of California Irvine — The heavy fermion superconductor CeIn$_5$ has been shown to have a ground state dependence on Cd doping which induces antiferromagnetism while suppressing superconductivity. This system provides an interesting regime in which to study the whole range of the heavy fermion superconducting and antiferromagnetic ground states as well as the interplay between the different electronic interactions at low temperatures. The Two Fluid Model has quantified the energy scales in the related La doped CeCoIn$_5$. We attempted a two fluid analysis on specific heat and susceptibility measurements of La and Cd doped CeIn$_5$ single crystals.

9:00AM H27.00006 Anisotropic effect of Cd-doping on superconducting phase in CeIn$_5$ at high fields, YOSIFUMI TOWIKI, ROMAN MOVSHOVICH, FILIP RONNING, ERIC BAUER, Los Alamos National Laboratory, ANDREA BIANCHI, Département de Physique, Université de Montréal, Montreal, QC, H3C 3J7, Canada; LOS ALAMOS NATIONAL LABORATORY TEAM, DEPARTEMENT DE PHYSIQUE, UNIVERSITE DE MONTREAL, MONTREAL, QC, H3C 3J7, CANADA COLLABORATION — Unconventional superconductor CeCoIn$_5$, at high magnetic field displays first order superconducting (SC) transition, and an additional high field-low temperature SC phase (previously proposed to be an inhomogeneous superconducting FFLO state). We have studied Cd-doping effect on the FFLO state and the first order SC transition by measuring specific heat C(T) of CeCoIn$_{5-x}$Cd$_{x}$ (x=0.01, 0.02 and 0.03) at low temperatures and high fields. Our data show that the FFLO state is already destroyed by 1% Cd-doping. The effect of Cd doping on the first order SC transition is anisotropic. The cross-over temperature $T_{c}$, where the superconducting transition changes its nature from first to second order, decreases rapidly with increasing doping for $H/H_{c1}$ and disappears already at $x=0.02$, while it remains rather temperature-independent for $H/H_{c1}$ up to $x=0.03$. 

9:12AM H27.00007 Angular Dependent Magnetic Properties of CeCoIn$_5$ at Low Temperatures$^\ddagger$
J.-H. PARK, R.L. STILLWELL$^\ddagger$, T.P. MURPHY, E.C. PALM, S.W. TOZER, NHMFL, Florida State University, Tallahassee, FL 32310, J.C. COOLEY, LANL, MST-6, Los Alamos, NM 87545 — The heavy-fermion compound CeCoIn$_5$ exhibits a superconducting transition at 2.3 K. As an unconventional superconductor, many unusual physical properties of the compound have been actively studied. In particular, evidence of a Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) superconducting state in this compound was reported first by Radovan and co-workers. At the lowest temperature (20 mK), the FFLO state of CeCoIn$_5$ was observed in fields between 10 and 11.7 T when the ab-plane of the compound was placed parallel to the external magnetic field. In addition, at these low temperatures, the angular dependent peak effect was observed and interpreted as a crossover between Abrikosov and Josephson vortex lattices. Further experimental studies of the low temperature (> 20 mK) magnetic properties of CeCoIn$_5$, performed in various sample orientations with respect to magnetic field will be presented. H.A. Radovan, et al., Nature 425 (2003) 51. H.A. Radovan, et al., Philosophical Magazine 86 (2006) 3569.

9:24AM H27.00008 Evolution of the FFLO state of CeCo(In$_{1−x}$Hg$_x$)$_5$ by incommensurate antiferromagnetic order. SEIKO OHIRA-KAWAMURA, Ochanomizu Univ., HIROAKI SHISHIDO, Kyoto Univ., AKARI YOSHIDA, Ochanomizu Univ., RYUJI OKAZAKI, Kyoto Univ., HAZUKI KAWANO-FURUKAWA, Ochanomizu Univ., TAKASADA SHIBAUCHI, Kyoto Univ., HISATOMO HARIMA, Kobe Univ., YUJI MATSUDA, Kyoto Univ. — CeCoIn$_5$ shows superconductivity (SC) below 2.3 K, while the SC is highly suppressed in a related system CeRhIn$_5$, which exhibits the antiferromagnetic (AF) order below 3.8 K. Then the mixed compound CeRh$_{1−x}$CoIn$_5$ is expected to have a complex $x$-T phase diagram where the SC and magnetism coexist. In order to understand the relationship between the SC and the antiferromagnetism in CeRh$_{1−x}$CoIn$_5$, we have performed neutron diffraction measurements on this system for various $x$. A commensurate (C) AF order with a propagating vector $q_c = (1/2, 1/2, 1/2)$ simultaneously appears. We interpret that there is no intrinsic coexistence between the IC- and C-AF orders and that the SC competes with the IC-AF order but coexists with the C-AF one. These results imply that particular areas on the Fermi surface nested by $\vec{q}_c$ play an active role in forming the superconducting state in CeCoIn$_5$.

9:36AM H27.00009 Supression of superconductivity in CeRh$_{1−x}$CoIn$_5$ by incommensurate antiferromagnetic order. SEIKO OHIRA-KAWAMURA, Ochanomizu Univ., HIROAKI SHISHIDO, Kyoto Univ., AKARI YOSHIDA, Ochanomizu Univ., RYUJI OKAZAKI, Kyoto Univ., HAZUKI KAWANO-FURUKAWA, Ochanomizu Univ., TAKASADA SHIBAUCHI, Kyoto Univ., HISATOMO HARIMA, Kobe Univ., YUJI MATSUDA, Kyoto Univ. — CeCoIn$_5$ shows superconductivity (SC) below 2.3 K, while the SC is highly suppressed in a related system CeRhIn$_5$, which exhibits the antiferromagnetic (AF) order below 3.8 K. Then the mixed compound CeRh$_{1−x}$CoIn$_5$ is expected to have a complex $x$-T phase diagram where the SC and magnetism coexist. In order to understand the relationship between the SC and the antiferromagnetism in CeRh$_{1−x}$CoIn$_5$, we have performed neutron diffraction measurements on this system for various $x$. A commensurate (C) AF order with a propagating vector $q_c = (1/2, 1/2, 1/2)$ simultaneously appears. We interpret that there is no intrinsic coexistence between the IC- and C-AF orders and that the SC competes with the IC-AF order but coexists with the C-AF one. These results imply that particular areas on the Fermi surface nested by $\vec{q}_c$ play an active role in forming the superconducting state in CeCoIn$_5$.

9:48AM H27.00010 Chiral d-wave superconductivity in the heavy fermion compound CeIrIn$_5$. ADITYA RAGHAVAN, KAZUMI MAKI, STEPHAN HAAS, University of Southern California — A recent experiment by Shakeripour et al indicates that the superconductivity in heavy fermion compound CeIrIn$_5$ is very different from the one in CeCoIn$_5$. We have re-examined their data and concluded that it belongs to the chiral d-wave SC or $\Delta(k) \sim e^{i\pi k_x} \cos(k_z)$.

10:00AM H27.00011 Fabrication of artificial heavy fermion superlattices by the molecular beam epitaxy. HIROAKI SHISHIDO, TOMONARI KATO, MANABU IZAKI, TAKASADA SHIBAUCHI, YUJI MATSUDA, Department of Physics, Kyoto University, Kyoto 606-8502, Japan, TAKAKIOTO TERASHIMA, Research Center for Low Temperature and Materials Sciences, Kyoto University, Kyoto 611-0011, Japan — We have grown artificial superlattices of CeIn$_3$ ($m$) / LaIn$_3$ ($n$), in which $m$-layers of heavy-fermion antiferromagnet CeIn$_3$ and $n$-layers of a non-magnetic isostructural compound LaIn$_3$ are stacked alternately, by a molecular beam epitaxy. Growth process were monitored by reflection high energy electron diffraction (RHEED). Sharp streak pattern of RHEED indicates the epitaxial growth of thin films. Satellite peaks observed in a X-ray diffraction pattern also indicates the superlattice structure. By reducing the thickness of CeIn$_3$, we observe a suppression of antiferromagnetic order and an enhancement of effective mass inferred from the resistivity coefficient, which both imply new ‘dimensional tuning’ towards a quantum critical point.

10:12AM H27.00012 Antiferromagnetism in the Kondo lattice system Ce(Ni$_{0.25}$In$_{1−x}$)$_5$. W.H. LEE, H.H. WU, H.H. SONG, K.J. SYU, Department of Physics, National Chung Cheng University, Ming-Hsuing, Chia-Yi, Taiwan, ROC, Y.Y. CHEN, Academia Sinica, Nankang, Taipei, Taiwan, ROC, W.H. LEE/Y.Y. CHEN TEAM — The pseudobinary compound Ce(Ni$_{0.25}$In$_{1−x}$)$_5$, which crystallizes in a hexagonal AlB$_2$ type structure with space group P6/mmm, exhibits antiferromagnetic ordering below the temperature 3.9 K, as revealed in the magnetic susceptibility, electrical resistivity and low-temperature specific-heat data. A ln(T) dependence is seen in the high temperature region for the magnetic contribution to the resistivity $\rho_{mn}$, which is one of the characteristic features of dense Kondo systems. The magnetic entropy $S_m(T,N)$ associated with the magnetic structure of Ce(Ni$_{0.25}$In$_{1−x}$)$_5$ is found to be only 62% of Rin(2), corresponding to a reduction of 38% of the cerium moment. This large magnetic reduction may be able to be attributed to Kondo effect. The heat capacity C(T) of Ce(Ni$_{0.25}$In$_{1−x}$)$_5$ in the paramagnetic state at temperatures between 8 and 20 K, can be fitted to the expression $C_m = \gamma T + \beta T^3$ by a least squares analysis, which yields the value $\gamma = 123 mJ/mol K^2$ and $\beta = 1.2 mJ/mol K^4$, the latter value corresponding to the Debye temperature $\Theta_D = 169 K$.

10:24AM H27.00013 Angle dependent quasiparticle weights in correlated metals. POUYAN GHAEMI, Massachusetts Institute of technology, SENTHIL TODADIRI, Massachusetts Institute of Technology, PIERS COLEMAN, Rutgers University — The variation in the quasiparticle weight $Z$ on moving around the fermi surface in correlated metals is studied theoretically. Our primary example is a heavy Fermi liquid treated within the standard hybridization mean field theory. The most dramatic variation in the quasiparticle weight happens in situations where the hybridization vanishes along certain directions in momentum space. Such a “hybridization node” is demonstrated for a simplified model of a Cerium-based cubic heavy electron metal. We show that the quasiparticle weight varies from almost unity in some directions, to values approaching zero in others. This is accompanied by a similar variation in the quasiparticle effective mass. Some consequences of such hybridization nodes and the associated angle dependence are explored. Comparisons to somewhat similar phenomena in the normal metallic state of the cuprate materials are discussed. A phenomenological picture of the pseudogap state in the cuprates with a large Fermi surface with a severely anisotropic spectral weight is explored.
10:36AM H27.00014 Magnetic properties of RFe₂Zn₂₀ (R = Y, Gd - Lu): 4f moments embedded in strongly correlated electron host, SHUANG JIA, NI NI, A. SAFA-SEFAT, S.L. BUD'KO, P.C. CANFIELD, Ames Laboratory, USDOE and Department of Physics and Astronomy, Iowa State University, HYUNJIN KO, Ames Laboratory, USDOE and Department of Chemistry, Iowa State University — The RFe₂Zn₂₀ series of compounds manifest varied magnetic properties, from near ferromagnetism (R = Y, Lu), to enhanced ferromagnetic (FM) ordering of local moments (R = Gd to Tb), to heavy Fermi ground state (R = Tb). Thermodynamic and transport measurement results reveal that these varied magnetic states can be understood in the framework of 4f moments embedded in a nearly ferromagnetic Fermi liquid. In such a highly polarizable electronic host, the different type of 4f moments, null moments for Y³⁺ and Lu³⁺, pure spin- contributed Gd⁵⁺, spin-orbital-coupling contributed Tb⁵⁺ to Tb³⁺, and the hybridized Yb ions, correlated with the itinerant electrons, lead to this magnetic versatility. For local moment members (R = Gd to Tb), the Curie temperatures roughly scale with the de Gennes parameter, indicating negligible crystal electric field (CEF) effect on the magnetic ordering, although the CEF on the 4f local moments leads to anisotropic FM ground state for R = Tb to Tb. For hybridized moment member (R = Yb), the Kondo temperature seems to be enhanced, associated with the electronic host.

10:48AM H27.00015 Low-Energy Magnetic Excitations in the Itinerant Quantum Ferromagnet ZrZn₂, STEPHEN HAYDEN, EDWARD YELLAND, University of Bristol — High resolution de Haas-van Alphen measurements offer a powerful method to probe the low energy magnetic excitations in ferromagnets. Here we report measurements of the temperature dependence of the exchange splitting Δ(T) in the weak itinerant ferromagnet ZrZn₂ (Curie temperature Tc = 28 K) using the de Haas-van Alphen (dHvA) effect. Quantitative comparison with the magnetic moment M(T) shows that longitudinal or 'Stoner' excitations dominate, in strong contrast with observations on metallic ferromagnets like Fe and Ni, where spin-waves dominate at low T. We ascribe the difference to the proximity of a quantum critical point (QCP) in ZrZn₂. The results are discussed in terms of a phenomenological Ginzburg-Landau model which includes effects of thermal fluctuations and enhanced fluctuations due to the nearby quantum critical point. We find that the model accurately predicts both the rate of collapse of M(T) with T and the relative reduction of Δ(T) and M(T). We suggest a picture for the evolving nature of magnetic excitations within the ferromagnetic state as the QCP is approached.

Tuesday, March 11, 2008 8:00AM - 10:36AM –

Session H28 DCMP: Photonic Crystals Morial Convention Center 220

8:00AM H28.00001 Moving the band gaps and changing the transmission of magnetic photonic crystals, SHIYANG LIU, JUNJIE DU, ZHIFANG LIN, Fudan University, SIU TAT CHUI, University of Delaware — We classify different types of the photonic band gaps (PBGs) of two dimensional magnetic photonic crystals (MPCs) consisting of arrays of magnetic cylinders and study the different tunability (by an external static magnetic field) of these PBGs. One type of the band gaps comes from infinitely degenerate flat bands and is closely related to those in the study of plasmonics. We calculate the transmission of the PBG’s and found excellent agreement with the results of the photonic band structure calculation. Positional disorder of the lattice structure affects the different types of PBGs differently.

8:12AM H28.00002 Probing states with macroscopic circulations in magnetic photonic crystals, SIU TAT CHUI, University of Delaware, ZHIFANG LIN, Fudan University — We predict that when light is reflected off a magnetic photonic crystal (MPC) there is a grazing component that is parallel to the surface; the magnitude of this component can be changed by an external field. The direction of this parallel component is reversed (dotted line) as the direction of the magnetization is reversed. This provides a way to probe states with macroscopic circulations inside the MPC.

8:24AM H28.00003 Experimental investigation of photonic gaps in optical Thue-Morse multilayers fabricated using nanostructured thin films, MATTHEW HAWKEYE, University of Alberta, MICHAEL BRETT — One-dimensional Thue-Morse (TM) multilayers are realized by stacking together layers of different refractive index according to simple rules. The result is a deterministically generated aperiodic system representing an intermediate stage between a periodic medium and a random one. This work focuses on the formation of photonic gaps at musings frequencies relating to local positional correlations in the TM structure. TM multilayers are realized in the visible and near-IR spectral regions using glancing angle deposition (GLAD), a single-step nanofabrication technique providing control over the internal columnar structure of a deposited thin film. The effective refractive index of the deposited layer is tuned by controlling the columnar structure leading to great flexibility over the choice of refractive index in the experiment. Using GLAD, TM multilayers are fabricated out of titanium dioxide by varying the density of the columnar structures. The resulting photonic gaps are characterized using transmittance and reflectance spectroscopy and compared with the results of transfer matrix simulations. The creation of gaps in different generations of the TM system will also be examined.

8:36AM H28.00004 Effective medium theory of photonic crystals¹, W.T. LU, Department of Physics and Electronic Materials Research Institute, Northeastern University, Boston, MA 02115, S. ZHANG, Department of Mechanical Engineering, University of California at Berkeley, Berkeley, CA 94720, Y.J. HUANG, S. SRIDHAR, Department of Physics and Electronic Materials Research Institute, Northeastern University, Boston, MA 02115 — We develop an effective medium theory for photonic crystals including negative index metamaterials. This theory is based on field summation over the choice of refractive index in the experiment. Using GLAD, TM multilayers are fabricated out of titanium dioxide by varying the density of the columnar structures. The resulting photonic gaps are characterized using transmittance and reflectance spectroscopy and compared with the results of transfer matrix simulations. The creation of gaps in different generations of the TM system will also be examined.

¹This work was supported by the Air Force Research Laboratories, Hanscom (Contract # FA8718-06-C-0045) and the National Science Foundation (contract # PHY-0457002).

8:48AM H28.00005 Refraction at a photonic crystal surface: exact characterization¹, PRABASAJ PAUL, Denison University — Refraction at plane air-photonic crystal surfaces in a class of photonic crystals is studied. The class of photonic crystals has particularly simple band-structure and Bloch wave solutions, which make the evaluation of exact reflection and transmission coefficients relatively simple. New analytical results are presented, and the effects of variation in surface location and orientation are explored. A close look is taken at two important issues – negative refraction, and the validity of the Rayleigh hypothesis. The results obtained are consistent with those in existing literature.

¹Supported in part by the Research Corporation.
9:00AM H28.00006 Quantum interference near a photonic band edge beyond the weak field approximation. PAUL M. ALSING, DAVID A. CARDIMONA, DANHONG H. HUANG, Air Force Research Laboratory — We investigate spontaneous emission and quantum interference effects involving a three level atom in the vicinity of a photonic band edge, beyond the weak driving field approximation. We consider two different three-level atoms, each subject to a probe field from the ground state, and each embedded within a different photonic crystal (PhC). The first atom has the two excited states separated by a dipole transition in the optical frequency range, with this frequency being close to the surrounding PhC’s band edge. The probe field couples the ground state and the highest excited state, and is well outside the PhC bandgap. If a coupling field is applied between the two upper levels, Electromagnetically Induced Transparency (EIT) may occur, depending on the position of the band edge. The second atom has the two upper levels each dipole-coupled to the ground state, and close enough that the emissions from each can coherently interfere. This atom is embedded within a PhC whose band edge lies near the lower of the two excited states, and a probe field is applied that lies just beyond this band edge. This atom exhibits a quantum interference phenomenon related to EIT called Field-Induced Transparency (FIT), again depending on the position of the band edge relative to the lower excited state.

9:12AM H28.00007 Microwave transmission measurements through wire array photonic crystals. GRAEME DEWAR, University of North Dakota, NATHAN SOUTHER, MICHAEL JOHNSON — We have measured the microwave transmission between 12.4 and 18.0 GHz through wire arrays formed into two dimensional square lattices. One array made of copper wire 0.16 mm in radius consisted of five rows by 21 columns having a lattice constant of 5.15 mm. This array exhibited a pass band above 15 GHz, in good agreement with the calculated plasma frequency found from an expression for the permittivity derived in the long wavelength limit. A second array was made with wire of radius 18 microns and lattice constant 0.8 mm. This array was filled with dielectric loaded with powdered magnetite. A sample of this metamaterial 5.8 mm thick and with no externally applied magnetic field exhibited a pass band above 16 GHz. Implications for creating metamaterials with a negative index of refraction from wire arrays embedded in a magnetic host will be discussed.

9:24AM H28.00008 Tailoring Self-Assembled Metallic Photonic Crystals for Modified Thermal Emission. SANG EON HAN, Department of Chemical Engineering and Materials Science, University of Minnesota, ANDREAS STEIN, Department of Chemistry, University of Minnesota, DAVID NORRIS, Department of Chemical Engineering and Materials Science, University of Minnesota — Photonic crystals are solids that are periodically structured on an optical length scale. Previous work has shown that specific photonic crystal structures can lead to changes in the thermal emission spectra of a material. This may allow elimination of unwanted heat from emission sources, such as tungsten filaments in conventional light bulbs, or lead to new materials for thermophotovoltaics. Here, we study the possibility that metallic photonic crystals obtained via self-assembly can modify thermal emission. These structures, known as inverse opals, are easy to fabricate. However, experiments on tungsten inverse opals suggest that they also have strong optical absorption. In this case, the light does not interact sufficiently with the periodicity of the crystal and modification of thermal emission does not occur. We consider the origin of this effect and show theoretically how to tailor both absorption and surface coupling in experimentally realizable metallic inverse opals. Calculations for tailored inverse opals made from tungsten, molybdenum, and tantalum show that their optical properties can be similar to or even better than the tungsten woodpile structure, which has previously shown modified thermal emission.

9:36AM H28.00009 Integrated lenses for enhanced coupling into terahertz photonic crystal slab waveguides. CRISTO YEE, STEPHEN PARHAM, MARK SHERWIN, Physics Department and Institute for Quantum and Complex Dynamics, University of California Santa Barbara — The fundamental property of a photonic crystal (PC), its optical band gap, can be exploited by the introduction of defects that allow the existence of spatially localized states within the optical band gap. A PC waveguide consist of a line of defects in which the localized states will coalesce to form bands that allow the transmission of light otherwise prohibited. Coupling light directly from a source into the waveguide is restricted by the impedance mismatch of the PC waveguide and the surrounding media. In this work we use integrated lenses to enhance coupling of light into PC waveguides. PC slabs with lattices constants ranging from 56 to 64 microns were fabricated with Reactive Ion Etching on a high-resistivity Si wafer. An narrow band tunable source was employed to measure the transmission trough the waveguides. The results are compared with a full 3D FDTD calculations. This work was supported by NSF under grant CCF0507295 and CONACYT-UCMEXUS.

9:48AM H28.00010 Modeling Conformal Growth in Photonic Crystals and Comparing to Experiment. ANDREW BRZEZINSKI, YING-CHIEH CHEN, PIERRE WILTZIUS, PAUL BRAUN, Dept. of Mat. Sci. & Eng. / Beckman Institute / U. of Illinois, Urbana — Conformal growth, e.g. atomic layer deposition (ALD), of materials such as silicon and TiO$_2$ on three dimensional (3D) templates is important for making photonic crystals. However, reliable calculations of optical properties as a function of the conformal growth, such as the optical band structure, are hampered by difficulty in accurately assessing a deposited material’s spatial distribution. A widely used approximation ignores “pinch off” of precursor gas and assumes complete template infilling. Another approximation results in non-uniform growth velocity by employing iso-intensity surfaces of the 3D interference pattern used to create the template. We have developed an accurate model of conformal growth in arbitrary 3D periodic structures, allowing for arbitrary surface orientation. Results are compared with the above approximations and with experimentally fabricated photonic crystals. We use an SU8 polymer template created by 4-beam interference lithography, onto which various amounts of TiO$_2$ are grown by ALD. Characterization is performed by analysis of cross-sectional scanning electron micrographs and by solid angle resolved optical spectroscopy.

10:00AM H28.00011 The couple between modes of planar wave guides and the evanescent fields produced in the total internal reflection. RAUL GARCIA-LLAMAS, JORGE GASPAR-ARMENTA, Universidad de Sonora, RAMON MUNGUIA-ARVAYO, Posgrado en Fisica — The coupling between the modes of planar wave guides and the evanescent fields produced in the total internal reflection (TIR) system is studied theoretically. The planar guides are assumed as a semi-infinite inhomogeneous periodic medium (IM) with modulation only in the $y$-direction and period $a$, which is perpendicular to the propagation ($z$-axis) of the modes. This medium is separated by a vacuum (VA) gap, of uniform thickness $d_z$, from a semi-infinite homogeneous dielectric medium (HM). Then, two interfaces are found, one at $z = 0$ between HM/VA and other at $z = d_z$ between VA/IM. A transverse magnetic electromagnetic plane wave with wavelength $\lambda_0$, impinging the VA/IM interface and its wave vector, in the $z-\ y$ plane, is doing an angle $\theta_l$ with the $z$-axes. The solution of the electromagnetic diffracted field in the IM is a multimodal expansion as proposed by Burckhardt [J. Opt. Soc. Am. 56 (1966) pp. 1502]. Following the approach used by Glass and Maradudin [Phys. Rev. B 29 (1984) pp. 321] a matrix equation for the amplitudes of the diffracted field is found. Following the approach used by Glass and Maradudin [Phys. Rev. B 29 (1984) pp. 321] a matrix equation for the amplitudes of the diffracted field is found. Numerical solutions of the near field intensity are presented.

SEP-Conacyt 2004 PROYECTO C01-47391/A-1.
10:12AM H28.00012 Negative bi-refraction of acoustic waves in sonic crystals, YAN-FENG CHEN, Nanjing University, NATIONAL LABORATORY OF SOLID-STATE MICROSTRUCTURE COLLABORATION — Optical birefringence and dichroism are classical and important effects originating from two independent polarizations of optical waves in anisotropic crystals. However, it is impossible for acoustic waves in the fluid to show such a birefringence because only the longitudinal mode exists. The emergence of an artificial sonic crystal (SC) has significantly broadened the range of acoustic materials in nature that can give rise to acoustic bandgaps and be used to control the propagation of acoustic waves. Recently, negative refraction has gained a lot of attention and has been demonstrated in both left-handed materials and photonic crystals. Similar to left-handed materials and photonic crystals, negative refractions have also been found in SCs. Here we report the acoustic negative-birefringence phenomenon in a two-dimensional SC, even with the same frequency and the same “polarization” state. By means of this feature, double focusing images of a point source have been realized. This birefrigence concept may be extended to other periodic systems corresponding to other forms of waves, for example, electron for semiconductors, photon for photonic crystals, and plasmon for plasmonic crystals, showing great impacts on both fundamental physics and device applications.

10:24AM H28.00013 Random high-Q cavities in disordered photonic crystal waveguides, FRANK VOLLMER, JURAJ TOPOLANCÍK, Rowland Institute at Harvard — We demonstrate experimentally that structural perturbations imposed on highly dispersive photonic crystal-based waveguides give rise to spectral features that bear signatures of Anderson localization. Sharp resonances with effective Q’s of over 30,000 are found in scattering spectra of disordered waveguides. The resonances are observed in a ~20-nm bandwidth centered at the cutoff of slowly guided Bloch modes. The origin of the spectral features can be explained by the interference of coherently scattered electromagnetic waves which results in the formation of a narrow impurity (or localization) band populated with spectrally distinct quasistates. http://webmac[rowland.org]/rj/vollmer/index.php

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H29 DMP: Focus Session: Carbon Nanotubes and Related Materials VI: Graphene Transport Morial Convention Center 221

8:00AM H29.00001 Binary memory switching in zigzag-edge graphene nanostrips, DANIEL GUN-LYCKE, Naval Research Laboratory, DENIS A. ARESHKIN, George Washington University, JOHN W. MINTMIRE, JUNWEN LI, Oklahoma State University, CARTER T. WHITE, Naval Research Laboratory — Owing to a peculiar boundary condition, the ground state of any hydrogen-terminated zigzag-edge graphene nanostrip is predicted to exhibit spin-polarized edge states. We capture this physics in a model which has a Hamiltonian that consists of tight-binding terms and terms describing the potential from a spin-dependent scalar field. The model is solved in the presence of a ballistic current passing through the nanostrip. Studying the grand canonical potential for the system, it is shown that the spin-polarized state collapses above a certain bias. Below that threshold there is a bi-stable regime which could be exploited in a possible memory device. The memory could be both set and cleared through the bias and be read by measuring the current through the device.

8:12AM H29.00002 Graphene and Graphite Nanoribbons: phonon-scattering limit of conductivity from tight-binding, DANIEL FINKENSTADT, U.S. Naval Research Laboratory, GARY PENNINGTON, U.S. Army Research Laboratory, MICHAEL MEHL, U.S. Naval Research Laboratory — To understand nanoribbons of graphene, and multilayers of such ribbons, we developed an ab initio parametrized fit to Carbon and Hydrogen chemical data, out to arbitrary neighbor interactions, including relaxations [Phys. Rev. B 76, 121405R (2007)]. Our computed band structure shows a decrease in the armchair edge band gap when ribbons are multilayered. Further, the well-known three-family behavior of armchair bangaps is confirmed and shown here to apply also to the drift velocity of charge carriers, which can have ±20% deviation from the ideal Fermi velocity. Boltzmann carrier transport simulations from calculated phonon spectra also show a familiar dependence of conductance, peak field-effect mobility and “on” conductance that increase linearly with ribbon width. We will also discuss phonon-limited scattering of charge carriers in graphene multilayers and the temperature dependence of transport.

8:24AM H29.00003 Spin transport in rough graphene nanoribbons, INANÇ ADAGIDELI, MICHAEL WIMMER, Universitaet Regensburg, SAVAS BERBER, DAVID TÓMANEK, Michigan State University, KLAUS RICHTER, Universitaet Regensburg — We investigate spin conductance in zigzag graphene nanoribbons and propose a spin injection method based only on graphene. Combining density functional theory with tight-binding transport calculations, we find that nanoribbons with asymmetrically shaped edges show a non-zero spin conductance and can be used for spin injection. Furthermore, we show that nanoribbons with rough edges exhibit mesoscopic spin conductance fluctuations with a universal value of rmasG ≈ 0.4e/4τ.

8:36AM H29.00004 Electron Transport in Graphitic Nanostructures, PHILIP KIM, Columbia University — Local control of the electrostatic potential in graphene nanostructures can provide a new insight into Dirac fermions in confined geometries in electric and magnetic fields. In this presentation, we report electronic transport measurements in patterned locally gated graphene nanoconstrictions and locally gated single walled carbon nanotubes with tunable transmission and bipolar heterojunctions. We observe various unusual transport phenomena, such as energy gap formation in confined graphene structures and series of fractional quantum Hall conductance plateaus at high magnetic fields as the local charge density is varied in the graphene heterojunction regions. These observed results can be explained in terms of equilibration of chiral edge states at the heterojunction interfaces, indicating charge polarity dependence of quantum Hall edge state equilibration.

9:12AM H29.00005 ABSTRACT WITHDRAWN —

9:24AM H29.00006 Coulomb blockade effects in graphene nanoribbons, FERNANDO SOLS, Universidad Complutense de Madrid, FRANCISCO GUINEA, ICM-CSIC (Madrid), ANTONIO CASTRO NETO, Boston University — We propose that recent transport experiments revealing the existence of an energy gap in graphene nanoribbons may be understood in terms of Coulomb blockade. Electron interactions play a decisive role at the quantum dots which form due to the presence of necks arising from the roughness of the graphene edge. With the average transmission as the only fitting parameter, our theory shows good agreement with the experimental data.

1Work supported by MECS (Spain) and NSF.
9:36AM H29.00007 Distinct Transport Properties of Mono-Layer and Bi-Layer Graphene Nanoribbons, YU-MING LIN, ZHIHONG CHEN, PHAEDON AVOURIS, IBM T. J. Watson Res. Center — Graphene holds promise for future electronic applications owing to its exceptional carrier mobility and a Dirac-like, massless dispersion relation for charge carriers. Here we report on experimental studies of electrical transport properties of graphene nano-ribbon devices. Graphene nano-ribbons devices, consisting of mono-layer and bi-layer graphene, were fabricated by e-beam lithography and plasma etching process. These nano-ribbon devices exhibit size-dependent transport properties due to quantum confinement at low temperatures. We observed distinct transport behaviors for mono-layer and bi-layer devices, and this may be related to a tunable bandgap that can be induced in bi-layer graphene. In particular, in bi-layer devices, we observed a significantly lower noise level than that of single-layer graphene. These findings provide insight into the intrinsic noise mechanisms in graphene layers and also elucidate the impact of the coupling between the two layers in the bi-layer graphene on transport properties.

9:48AM H29.00008 Transverse Field Effect in Graphene Nanoribbons, KATHRYN TODD, HUNG-TAO CHOU, DAVID GOLDHABER-GORDON, Stanford University — We describe transport measurements on graphene nanoribbon devices with separately addressable side gates. Applying the same voltage to both side gates allows us to resolve the Dirac points in the nanoribbon and in the 2-dimensional graphene lead. In conjunction with the side gates, a back gate allows us to separately tune the nanoribbon and the leads between p-type and n-type. Source-drain measurements illustrate the importance of charging effects in these short nanoribbons. Applying opposing voltages to the two side gates allows us to test predictions about the effect of a transverse electric field in graphene nanoribbons.

1Kathryn Todd acknowledges support from the Intel Foundation. This work was supported by the MARCO/FENA program.

10:00AM H29.00009 High-Bias Electronic Transport in Graphene Ribbon Devices, MELINDA HAN, INANC MERIC, KIN FAI MAK, STEPHANE BERCIAUD, TONY HEINZ, KEN SHEPARD, PHILIP KIM, Columbia University — We present experimental studies of electronic transport in graphene under high electric fields. Graphene ribbon devices with varying widths and lengths are fabricated from mechanically exfoliated single-layer graphene sheets using electron beam lithography followed by oxygen plasma etching. Conductance measurements show a trend of current saturation under high source-drain bias. In addition, we employ micro-Raman spectroscopy simultaneously with transport measurement on the current carrying device in vacuum. We observe an enhancement of the G-band anti-Stokes/Stokes intensity ratio, where the optical phonon temperature is estimated to be over ~500K before device failure.

1Supported in part by NSF Grant DMR-0531159.

10:24AM H29.00011 Rough edges in graphene, VLADIMIR CVETKOVIC, ZLATKO TESANOVIC, Department of Physics and Astronomy, The Johns Hopkins University, Baltimore, MD — Recent progress in fabrication of graphene and the understanding of its properties make the graphene a strong contender for a building block of future electronic devices. We analyze the effects of the scattering off rough edges on the transport in graphene nanoribbons. The confinement of the Dirac particles in a nanoribbon is achieved either by means of a large mass term in the Hamiltonian or by imposing boundary conditions appropriate for graphene sheets on the quantum mechanical wave-functions. Variations in the nanoribbon width lead to a nontrivial lateral channel-mixing and provide important limitations to quantum transport. We present a perturbative solution for the problem and derive experimentally measurable conductivity up to the leading order in the case of a nanoribbon with such randomly varying width.

10:36AM H29.00012 Ab initio study of edge functionalization effects on electronic transport through graphene nanoribbons, AMIR FARAJIAN, Wright State University, NARJES GORJIZADEH, YOSHIYUKI KAWAZOE, Tohoku University — We investigate quantum transport through graphene nanoribbons with and without hydrogen saturation. Both armchair-edged and zigzag-edged ribbons with and without hydrogen saturation are considered. For calculating transport properties, we make use of ab initio electronic structure calculations followed by Green’s function implementation of the Landauer’s formalism. The calculated conductance characteristics show significant dependence on the edge functionalization, i.e., whether or not the armchair and zigzag nanoribbons are saturated by hydrogen atoms. The effects of the carrier spin orientations are also discussed. These results are useful in interpreting the experimental data, and in using functionalized graphene nanoribbons for nanoelectronics and sensor applications.

10:48AM H29.00013 Thermoelectric effects in ballistic graphene ribbons, EDUARD BOGACHEK, IGOR ROMANOVSKY, UZI LANDMAN, School of Physics, Georgia Inst. of Technology — A theoretical analysis of electrical and thermal transport in ballistic graphene strips and carbon bilayers, connected to electrodes, is presented. Gate voltage and temperature dependences of thermoelectric coefficients and thermocurrent due for different ratios of strip lengths and widths are studied both in the linear and nonlinear regime (finite applied voltage and temperature differences). Violation of the Onsager relation between the Peltier and thermopower coefficients in the nonlinear regime is considered. Results obtained for carbon bilayers are compared with those in single layers. The effect of transverse voltage applied between layers on the thermoelectric transport in carbon bilayers is investigated.

1Supported by the US D.O.E. (FG05-86ER-45234)

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H30 DCMP: Electronic Properties of Graphene and Related Structures II Morial Convention Center 222
8:00AM H30.00001 Electronic structure of graphene in the presence of disorder¹, ALEXANDER KEMPER, MANOJ SRIVASTAVA, HAI PING CHENG, University of Florida, Gainesville — Graphene, a single layer of the carbon structure graphite, has a number of interesting electronic properties. To aid in the understanding of these properties we have performed first-principles calculations of single graphene layers in the presence of disorder of various forms, including single and double vacancies, Stone-Wales defects, and metallic dopants. We report the effects of defects and dopants on the charge density and electronic density of states. Furthermore, we discuss energetics of these systems and defect-induced spin-states.

¹DE-FG02-97ER45660 & DE-FG02-02ER45995

8:12AM H30.00002 Density of states in graphene with charged impurities¹, BEN YU-KUANG HU, University of Akron, E. H. HWANG, S. DAS SARMA, University of Maryland — We discuss the density of states of graphene in the presence of charged screened impurity scattering. The density of states is obtained from the imaginary part of the single-particle Green’s function, which is evaluated in the Born and the self-consistent Born approximations, and the screened Coulomb impurity potentials are evaluated within the random phase approximation. The density of states in the presence of impurities is typically larger than that of clean graphene at any given energy. In particular, the density of states at the Dirac point, which is zero in a clean sample, becomes non-zero, with a magnitude that is given by an expression akin to that for the BCS superconducting gap.

¹Supported by ONR

8:24AM H30.00003 Topological Frustration in an Alkali-Graphene-Halogen System, YOUJIAN TANG, VINCENT CRESPI, Physics Department, Penn State University — We theoretically studied a system with alkali and halogen adsorbed to opposing sides of a graphene sheet, their mutual interactions then being modulated and constrained by the interposing presence of the sheet. Charge transfer from alkali to halogen generates a substantial dipole moment and large local electric field. Trends with respect to electron affinity, ionization energy, areal density, and the character of the bounding layer (i.e. BN versus graphene) will be discussed.

8:36AM H30.00004 Energy gaps and Stark effects in boron nitride nanoribbons, CHEOL-HWAN PARK, STEVEN G. LOUIE, Department of Physics, University of California at Berkeley, Berkeley, CA 94720 — Graphene nanoribbons, which have been recently synthesized, are regarded as promising candidate materials for nanoscale electronics. It is expected that boron nitride nanoribbons may be produced in a similar way. Notwithstanding their structural similarity, the electronic properties of boron nitride nanoribbons are qualitatively different from those of graphene nanoribbons. Here, we present first-principles calculations of the electronic properties of boron nitride nanoribbons with widths up to 10 nm both without any external potential or under a transverse electric field. The results show a rich set of behaviors and promise for possible applications of boron nitride nanoribbons in nanoscale electronics.

This work was supported by the NSF under Grant No. DMR07-05941, and the U.S. DOE under Contract No. DE-AC02-05CH11231. Computer time was provided by NERSC and NPACI.

8:48AM H30.00005 Band Engineering in C/BN Super-stripes, JEFFREY MULLEN, MARCO BUONGIORNOR- NARDELLI, North Carolina State University — Using electronic structure calculations from first principles, we have studied the electronic characteristics of graphene/BN sheets in a planar “super-striped” geometry. Similarly to Hydrogen-terminated graphene nanoribbons, also C/BN super-stripes show a variation of band gaps associated with the stripe size. Moreover, the bonding with BN introduces confinement effects that can be potentially exploited to enhance the electronic transport properties of these systems. We have characterized these effects by evaluating the band offsets and the electrostatic potential profile across the super-stripe structures.

9:00AM H30.00006 Selective nesting and sensing of molecules on optimally modified material surfaces, JOHN RUSSELL, BOYANG WANG, PETR KRAL, University of Illinois at Chicago, PROF. KRAL’S RESEARCH GROUP TEAM — We develop a methodology of optimal modifications of material surfaces allowing us to design selective nesting sites for inorganic, organic and biological molecules [1]. The idea is to modify material surfaces by atomic dopants and charged ligands in such a way that the created local electric fields form selective Coulombic traps for the adsorbed molecules. We demonstrate this methodology by molecular dynamics simulations of short peptides docked in nesting sites designed on graphene sheets substitutionally doped with B and N atoms. We show that the same approach can be used to selectively dock proteins in water solvent on graphene layers modified by short charged ligands. As a practical application of this methodology, we design and model chemical sensors that could detect the selectively nested molecules. The detection is realized by evaluating the change of the electrical conductivity of the graphene sheets upon the docking of the molecules. [1] B. Wang and P. Kral, Small, 3, 580, (2007). [2] J. Russell, B. Wang and P. Kral, in preparation.

9:12AM H30.00007 Anisotropic Electron-Phonon Coupling on Graphene-Derived Fermi Surface in CaC₆¹, TONICA VALLA, J. CAMACHO, Brookhaven National Laboratory, Z-H. PAN, A.V. FEDOROV, Lawrence Berkeley National Laboratory, A.C. WALTERS, C.A. HOWARD, M. ELLERBY, University College London — Superconductivity in graphite intercalated compounds had been studied for more than 40 years and it is still not fully understood, despite the recent progress and the discovery of relatively high Tc superconductivity in CaC₆ and YbC₆. Initially, even unconventional mechanisms, such as excitonic and plasmonic pairing were considered, but recent studies now suggest that superconductivity in graphite intercalated compounds is more conventional and that the electron-phonon coupling is responsible for pairing. However, it is still not clear whether the graphene-derived electronic states and vibrations or the intercalant-derived ones play more important role, or if some particular combination of graphene-intercalant states and vibrations dominates the coupling. Here, we present angle-resolved photoemission studies of electronic structure in CaC₆. We find that the electron-phonon coupling on the graphene-derived Fermi surface is very strong and anisotropic, reflecting the interaction of graphene-derived states with high-frequency graphene-derived vibrations.

9:24AM H30.00008 Fractional statistics of topological defects in graphene and related structures¹, BABAK SERADJEH, MARCEL FRANZ, University of British Columbia — We show that fractional charges bound to topological defects in the recently proposed time-reversal-invariant models of spinless fermions on the honeycomb lattice with Kekule distortion and on the n-flux square lattice with Peierls distortion obey fractional statistics. The continuum effective low-energy description is given in terms of a “doubled” level-2 Chern-Simons field theory, which is parity and time-reversal invariant and implies two species of semions (particles with statistical angle ±π/2) labeled by a new emergent quantum number that we identify as the fermion axial charge.

¹Work supported by NSERC, CIAR, NSF and the Killam Foundation.
of 2 MeV. Motivated by this experiment, we tested interaction between an Ar $^+$ not the structural change but electronic excitation. An experiment [2] showed fluorescence from Ar A highly-charged-ion interacting with graphite causes structural change in nano-scales [1]. While when the ion's kinetic energy reaches few MeVs, the induced is voltages. The behaviour of the gap is discussed as a function of both attractive interaction strength and filling for various graphene-reservoir couplings and in graphene is formulated using the Keldysh path integral formalism, and we obtain generalized gap and number density equations valid for both zero and finite quantum phase transition that occurs at half-filling in equilibrium graphene with attractive interactions. Our system consists of a graphene sheet sandwiched in graphene+nanoparticles system. We find that covered nanoparticles interact weakly with graphene, and that the main effect of the nanoparticles on the electronic structure of graphene is a doping effect that can be modified with the application of an electric field perpendicular to the graphene plane. The system is always metallic, without the opening of a bandgap, even if the nanoparticles are charged: neither the Coulomb potential nor the weak nanoparticle-graphene interaction is able to break the graphene sublattice symmetry. In contrast, in the case of deposited bare (non-covered) Au nanoparticles, there is a relatively strong interaction between low-coordinated Au atoms and graphene carbon atoms beneath. This leads to a symmetry breaking of the graphene sublattices and to the opening of a small bandgap of a few tens of meV.

This work is supported by the Next Generation Supercomputing Project, MEXT, Japan, and by NSAF 10676025.

10:00AM H30.00011 ABSTRACT WITHDRAWN

10:12AM H30.00012 Possible bandgap opening in graphene due to deposited Au nanoparticles: First-principles calculations, RONALDO J.C, BATISTA, SABRINA S. CARARA, HELIO CHACHAM, Universidade Federal de Minas Gerais, Brazil — We perform first-principles calculations to investigate electronic and structural properties of graphene with a layer of deposited Au nanoparticles. We consider Au$_{18}$ nanoparticles that can be either covered with methylthiol molecules, or not. We also consider that the nanoparticles are arranged in a hexagonal lattice, and we focus on the effect of net charge, applied electric fields, and molecular coverage on the electronic structure of the graphene+nanoparticle system. We find that covered nanoparticles interact weakly with graphene, and that the main effect of the nanoparticles on the electronic structure of graphene is a doping effect that can be modified with the application of an electric field perpendicular to the graphene plane. The system is always metallic, without the opening of a bandgap, even if the nanoparticles are charged: neither the Coulomb potential nor the weak nanoparticle-graphene interaction is able to break the graphene sublattice symmetry. In contrast, in the case of deposited bare (non-covered) Au nanoparticles, there is a relatively strong interaction between low-coordinated Au atoms and graphene carbon atoms beneath. This leads to a symmetry breaking of the graphene sublattices and to the opening of a small bandgap of a few tens of meV.

10:24AM H30.00013 Nonequilibrium-induced metal-superconductor quantum phase transition in graphene, SO TAKEI, YONG BAEK KIM, University of Toronto — We study the effects of dissipation and time-independent nonequilibrium drive on an open superconducting graphite monolayer, or graphene. In particular, we investigate how dissipation and nonequilibrium effects modify the semi-metal-BCS quantum phase transition that occurs at half-filling in equilibrium graphene with attractive interactions. Our system consists of a graphene sheet sandwiched by two semi-infinite three-dimensional Fermi liquid reservoirs, which act both as a particle pump/sink and a source of decoherence. A steady-state charge current is established in the system by equilibrating the two reservoirs at different, but constant, chemical potentials. The nonequilibrium BCS superconductivity in graphene is formulated using the Keldysh path integral formalism, and we obtain generalized gap and number density equations valid for both zero and finite voltages. The behaviour of the gap is discussed as a function of both attractive interaction strength and filling for various graphene-reservoir couplings and voltages.

10:36AM H30.00014 Detecting single graphene layer by using fluorescence from high-speed Ar$^{7+}$ ion, YOSHIYUKI MIYAMOTO, Nano Electronics Res. Labs. NEC, HONG ZHANG, School of Physical Science and Technology, Sichuan Univ. — A highly-charged-ion interacting with graphite causes structural change in nano-scales [1]. While when the ion’s kinetic energy reaches few MeVs, the induced is not the structural change but electronic excitation. An experiment [2] showed fluorescence from Ar$^{7+}$ ions penetrating through carbon foil with kinetic energy of 2 MeV. Motivated by this experiment, we tested interaction between an Ar$^{7+}$ ion and a graphene sheet by the time-dependent density functional approach, and found that the electronic excitation in the Ar$^{7+}$ ion is also the case even when the incident kinetic energy is 500 KeV and the target thickness is only mono-atomic layer. This simulation suggests the possibility of detecting a suspended mono-atomic layer of graphene [3] by monitoring fluorescence from the penetrated Ar$^{7+}$ ions. We will discuss its importance for analyzing bombardment of solids by highly charged, high-speed ions and possible experiments according to the present result. References: [1] T. Tuesday, March 11, 2008 8:00AM - 11:00AM – Session H31 DMP DCOMP: Focus Session: Computational Nanoscience III: Ferroelectrics, Surfaces, and Water Morial Convention Center 223
8:00AM H31.00001 Properties of Ferroelectric Nanostructures\textsuperscript{1}, INNA PONOMAREVA, Physics Department, University of Arkansas — Ferroelectric nanostructures (FENs) such as thin films, nanowires and nanodots are receiving a lot of attention due to their potential for technological applications and to the rich variety of underlying physics. Interestingly, properties of FENs can substantially deviate from their bulk counterpart due to their sensitivity to many factors. Examples of such factors are the electrical boundary conditions (associated with the full, partial or non-existent screening of polarization-induced surface charges) and mechanical boundary conditions (arising from the lattice mismatch between the FEN and its substrate).

Here, we developed and used computational schemes to predict many properties in various FENs, as well as, to provide atomistic insight to their complex phenomena. In particular, we will show the striking following features and reveal their origins:

- The interplay between electrical boundary conditions, mechanical boundary conditions and growth direction results in the appearance of novel dipole patterns and new low-symmetry phases possessing superior dielectric properties in ferroelectric dots, wires and films\textsuperscript{[1,2]}.
- FENs can exhibit dielectric anomalies, such as a negative dielectric susceptibility\textsuperscript{[3]}.
- Nanobubbles can form in ferroelectric films under an external electric field\textsuperscript{[4]}.
- An homogeneous electric field can be used to control the chirality of vortex structures in asymmetric ferroelectric dots, via the creation of original intermediate states\textsuperscript{[5]}.

8:36AM H31.00002 Internal electric field effects in ferroelectric nanostructures\textsuperscript{1}, BYOUNGHAK LEE, ZHENGJI ZHAO, LIN-WANG WANG, Lawrence Berkeley National Lab — A ground state dipole moment of ferroelectric nanostructures is a long-standing problem. A permanent dipole moment can alter optical and electronic properties of nanostructures, causing state localizations and electron hole separations. A dipole moment in the bulk can have a self-screening effect. In a nanostructure, the different shape of the system can result in an effective screening different from the bulk. In ferroelectric nanostructures, this can lead to a shape dependent total dipole moment, different from the volumetric result derived from its bulk value. Direct ab initio theoretical study on the nanostructure dipole moment is scarce due to the large computational cost. We present a first principles study of this problem using a recently developed Linear Scaling 3-Dimensional Fragment method. We investigated shape and size dependence of the electric dipole moment in various ferroelectric nanorods. We compared our results with experiments and provided an insightful physical picture by analyzing the ab initio numerical results with a classical dielectric model.

8:48AM H31.00003 Nanowettability by saline solutions in electric field\textsuperscript{1}, ALENKA LUZAR, Department of Chemistry, Virginia Commonwealth University (VCU), 1001 West Main Street, Richmond, VA 23284-2006, C.D. DAUB, D. BRATKO, Department of Chemistry, VCU — Molecular simulations of nanosized aqueous droplets and films next to apolar surfaces show a remarkable sensitivity of water contact angles on the applied electric field polarity and direction relative to the liquid/solid interface. We explain the effect by analyzing the influence of the field on interfacial hydrogen bonding which in turn affects the interfacial tensions. When electric field is applied on the aqueous film in the direction perpendicular to the confining hydrophobic surfaces, the competition between field-induced alignment and orientational preference of interfacial water molecules relative to the surfaces results in asymmetric wettability of opposing surfaces (Janus interface). The observed anisotropy in droplet or film wetting is a new nanoscale phenomenon that has so far been elusive as, in current experimental setups, surface molecules represent a very low fraction of the total number of molecules, affected by the field. We discuss amplification of these effects in saline solutions. The work gives basic understanding of field charge effects that can modulate local hydrophilicity of engineered and biological interfaces, as well as surface manipulation in nanofluidic devices.

9:12AM H31.00005 Adsorption of water on anatase TiO$_2$ nanoparticles: the role of a wire of undercoordinated Ti sites. 1, M. POSTERNAK, A. BALDERESCHI, EPFL-Lausanne, Switzerland, B. DELLEY, Paul Scherrer Institut, Switzerland — Presence of hydroxyl groups is known to be an important element for the initial integration of titania-coated implants in natural tissues. The existence of OH$^-$ radicals due to water dissociation is indeed responsible for major changes in their surface reactivity, and depends in particular on the preparation of the surface. The stable phase for nanoparticle-sized microstructures is anatase, and crystallites are expected to expose different surface terminations and edges. In this work, we study water adsorption on a model system, consisting of an edge along the [11T] direction, at the intersection of two major (101) surfaces. Using the DMO3$^2$ approach within DFT, we find that water dissociative adsorption occurs at the four-fold coordinated Ti atoms present on this edge, in contrast with the case of the unreactive (101) surface. These results provide evidence of an increased chemical activity of such binding sites for adsorption of atoms and molecules. The mechanisms of the hydroxilation process are discussed in terms of the geometric arrangement, coordination numbers, and acidic/basic character of the relevant Ti and O sites.

1This work is supported by a grant from the ITI Foundation for the Promotion of Implantology, Switzerland.

9:24AM H31.00006 Characterization of Anatase Nanoparticles Using Tight Bonding DFT Simulation . HONG WANG, NING MA, HAO WANG, JAMES P. LEWIS, Department of Physics, West Virginia University, CONDENSED MATTER COMPUTATIONAL GROUP TEAM — The structure and electronic properties of anatase nanoparticles with size ranging from 1.5nm to 2.4 nm have been presented in this paper under ab initio Density Functional Theory computational method. Based on the relaxed structures obtained in our calculation, we propose that the portion of surface in the whole structure effects the geometric configuration of anatase nanoparticles. However, as long as the nanoparticles grow bigger, this affection decreases obviously. The analysis of the frontier orbitals of the nanoparticles in our work make us believe that the frontier orbitals (so called HOMOs) are mostly localized on some corner positions of the whole structure. These corner positions are consist of 4-coordinated Ti atom lack of bridge oxygen atoms. When we adsorb water molecule on different positions on the facets of the smallest particle (TiO$_2$)$_{14}$, it turns out the corner position where the frontier orbitals are mostly localized are most energetic favorable adsorption position for water molecule. These special corner positions will likely act as high attractive spots for the external molecules existing in the nanoparticles’ environment.

9:36AM H31.00007 Single oxide overlayers grown on top of another oxide: Their stability, interaction with metal nanoparticles, and contribution to catalytic activity . SERGEY RASHKEEV, Idaho National Laboratory — Oxides are widely used as catalysts as well as supports for catalytically active metal nanoparticles. The catalytic activity of the system depends on many different factors such as anchoring, sintering, decomposition, and diffusion of metal atoms/clusters on the oxide surface. Here we use a combination of first-principles density-functional calculations and molecular dynamics simulations to investigate how all of these factors may change when the surface of the oxide support is modified by an additional single overlayer of another oxide positioned on it. In particular, we found that deposited monolayer oxide films may show instabilities that result in formation of strong anchoring sites for metal atoms/clusters. Also, an atomic-scale roughness introduced in such a way may slow down the surface diffusion processes and inhibit nanocluster growth/sintering. For example, a single layer of SiO$_2$ on a TiO$_2$ substrate may significantly increase the stability of Au nanoparticles and the efficiency of the catalytic CO oxidation. The author thanks Dr. Steven Overbury (Oak Ridge National Laboratory) for attracting his attention to this problem and INL Laboratory Directed Research and Development program and the U. S. Department of Energy, Office of Nuclear Energy under DOE Idaho Operations Office Contract DE-AC07-05ID14517 for financial support.

9:48AM H31.00008 Role of hydrogen on catalytic reduction of nitric oxide on selected transition metal surfaces . FAISAL MEHMOOD, ANAND U. NILEKAR, MANOS MAVRIKAKIS, University of Wisconsin-Madison — Self-consistent periodic DFT-GGA calculations are used to investigate the NO reduction reaction in presence of atomic H on seven close-packed transition metal surfaces namely, Cu(111), Ag(111), Pd(111), Pt(111), Rh(111), Ir(111), and Ru(0001). The chemisorption of atomic (N, O, H) and molecular (NO, NH, OH, HNO, HNOH, H$_2$NO) reaction intermediates has been systematically studied on each metal surface and the preferred sites and binding energies are determined for a 1/4 ML surface coverage. The activation energy barriers for the relevant set of reactions have also been calculated. Based on these results, the potential energy surfaces (PESs) for direct and H-assisted NO reduction reaction on all the metal surfaces have been constructed. These PESs are used for elucidating the trends for various elementary steps involved in the NO reduction reaction, across the periodic table. These PESs indicate that on (111) surfaces of Cu, Ag, Pd and Pt, H assisted NO reduction is quite favorable by either NOH or HNO reaction intermediate. For remaining three close-packed metal surfaces, i.e. Rh, Ir and Ru we do not find significant change due to presence of H. We also find that the presence of extra H may contribute in formation of HNOH or H$_2$NO on the surface that cause barrier to reduce even further.

10:00AM H31.00009 First-principles study of surface stresses induced by target-receptor interactions on a cantilever sensor . VARADHARAJAN SRINIVASAN, Computational Nanoscience Group, Univ. of California, Berkeley, GIANCARLO CICERO, Dept. of Physics, Polytechnic of Torino, JEFFREY C. GROSSMAN, Computational Nanoscience Group — Nanoscale cantilevers have shown great promise as ultrasensitive, low-power chemical sensors based on the surface stresses induced by interactions between the target species and the receptor coating layer. However, the basic mechanism of these induced stresses is yet to be fully understood, and it is therefore of great fundamental and practical interest to elucidate their electronic and structural origins via the weak interactions that lead to cantilever deflection. An example of such a device is the Au-SiN$_x$ cantilever sensor using functionalized long-chain alkanethiols as a coating layer. Even though the target-receptor interactions are often weak, the induced stresses are quite sensitive to the chemistry of the interacting species. Taking water molecules as a model target and either H- or ω-hydroxy and ω-carboxy alkanethiols as the receptor layer on a Au(111) surface, we use first-principles surface stress calculations to provide a detailed atomistic-level understanding of the various contributions leading to the deflection of a cantilever.

10:12AM H31.00010 Atomic motion and electronic structure of alkanethiol monolayer covered gold surfaces . SABRI ALKISI, HAI-PING CHENG, JEFFREY KRAUSE, University of Florida — Self-assembled alkanethiol monolayers are subjects of great interest because of potential applications in future nano-electronics. In this talk, we report our recent studies of the motions of Au atoms on alkanethiol monolayers using molecular dynamics in conjunction with first-principles calculations. Guided by accurate quantum mechanical calculations, we have calibrated the interactions between Au atoms and monolayers for classical simulations. We then investigate the motions of Au atoms as a function of coverage and temperature. Simulations with improved potential parameters show a good agreement with experimental observations. In addition, we discuss the electronic structure and charge transfer at the interface between the molecular monolayer and gold (111) surfaces.

3 channel and the surface quality of the Alq heterostructures. Moreover, conductance maps for biased voltages above the Alq metal. In contrast, using STM in the tunneling mode we can determine the ballistic charge transport length by varying the Alq addition, we can compare the Alq transport has been studied in Fe/Si(001) Schottky diodes using ballistic electron emission microscopy. Spin dependent scattering of polarized ballistic electrons

 Overall, the average stretching mode vibrational frequency increases with decreasing hydrogen bonding density. This density depends strongly on temperature. The water dissociation percentage at the surface can be correlated with the ratio between the weights of the stretching and the bending modes. Our results are in good agreement with inelastic neutron scattering measurements done on wet titania nanoparticles.

Tuesday, March 11, 2008 8:00AM - 11:00AM –
Session H32 GMAG DMP: Focus Session: Magnetic Imaging  Morial Convention Center 225

8:00AM H32.00001 Measuring Spin Dependent Hot Electron Transport Using Spin-Polarized Ballistic Electron Emission Microscopy, VINCENT LABELLA, The University at Albany, ANDREW STOLLENWERK, Harvard University, JOHN GARRAMONE, EVAN SPADAFORA, ILONA SITNITSKY, JOSEPH ABEL, The University at Albany — Spin polarized ballistic electron transport has been studied in Fe/Si(001) Schottky diodes using ballistic electron emission microscopy. Spin dependent scattering of polarized ballistic electrons injected from an Fe coated Au tip into the Fe films has been shown to affect the BEEM current. The spin dependent attenuation lengths were determined by measuring this effect with Fe thickness and found to be 1.8 ± 0.2 nm for the minority spin electrons and 2.5 ± 0.3 nm for the majority spin electrons at a tip bias of 1.5 eV. In addition, the attenuation lengths were measured as a function of tip bias, which indicated that the Fe/Si(001) interface band structure has an effect on the hot electron transport through the diode. Applications of the SP-BEEM technique to other systems will also be discussed.

8:12AM H32.00002 Magnetic properties of single and bilayer MnGa on GaN(0001) investigated by spin-polarized STM, Y. QI, G. SUN, M. WEINERT, L. LI, University of Wisconsin, Milwaukee — We investigated the magnetic properties of ultrathin GaMn layers grown on GaN(0001) by spin-polarized tunneling microscopy (SP-STM) using an Fe coated W tip. The GaN films are grown by plasma-assisted MBE on 6H-SiC(0001), and exhibit a metallic pseudo-1x1 surface structure, consisting of 2.3 ML Ga on top of the Ga-terminated GaN. At room temperature, Mn deposition on this surface resulted in the formation of GaMn islands, with the second layer islands begin to nucleate before the first layer is completed. With a Fe coated W tip, contrast between odd and even layers is observed, indicating layered antiferromagnetic magnetization of the GaMn layers. When Mn is deposited on the pseudo (1x1) at 200 C, a GaMn (3x3) structure is observed. First principles calculations show that Mn substitution of Ga leads to virtual bound states with bandwidth of 1.5 eV, indicating significant Mn-Ga interactions. As a result, top layer Ga atoms form covalent-like bonds. The Mn and the liberated Ga atoms from the “1x1” form the (3x3) structure, with the adatom on the T site.

8:24AM H32.00003 Localized spectroscopic and topographic studies of heterostructures of OSE/M (OSE: organic semiconductor, M: metal) using scanning tunneling microscopy (STM) and atomic force microscopy (AFM), C. R. HUGHES, M. L. TEAGUE, S. MITROVIC, N. C. YEH, Phys. Dept., Caltech, Pasadena CA — We employ STM with AFM to study the charge transport and domain structures of OSE/M heterostructures fabricated under differing growth conditions [OSE: sublimated tris(8-hydroxyquinoline) aluminum (Alq3), M: paramagnetic Au or ferromagnetic La0.7Ca0.3MnO3 (LCMO)]. Specifically, using STM in the point contact mode we are able to determine the work function of the heterostructures by measuring the differential conductance versus bias voltage. In addition, we can compare the Alq3 resistivity variations for heterostructures prepared under different Alq3 annealing conditions and with Au or LCMO as the metal. In contrast, using STM in the tunneling mode we can determine the ballistic charge transport length by varying the Alq3 thicknesses in the OSE/M heterostructures. Moreover, conductance maps for biased voltages above the Alq3 band-gap provide spatially resolved information for the local conductance channel and the surface quality of the Alq3 film, the latter further compared with the surface morphology taken with AFM. This work was supported by NSF under the Center for Science and Engineering of Materials at Caltech.
8:36AM H32.00004 Current-induced magnetization switching with a spin-polarized scanning tunneling microscope. STEFAN KRAUSE, Institute of Applied Physics, University of Hamburg, Germany — In present data storage applications magnetic nanostructures are switched by external magnetic fields. Due to their non-local character, however, cross-talk between adjacent nanomagnets may occur. An elegant method to circumvent this problem is magnetization switching by spin-polarized currents, as observed in GMR [1] as well as in TMR [2] studies. However, the layered structures of these devices do not provide any insight to the details of the spatial distribution of the switching processes. Spin-polarized scanning tunneling microscopy (SP-STM) is a well-established tool to reveal the magnetic structure of surfaces at spatial resolution down to the nanoscale. Besides, SP-STM takes advantage of a perfect TMR junction consisting of an isolating vacuum barrier separating two magnetic electrodes, which are represented by the foremost tip atom and the sample. Our experiments demonstrate that SP-STM serves as a tool to manipulate the switching behavior of uniaxial superparamagnetic nanoislands [3]. Furthermore, we show how SP-STM can be used to switch the magnetization of quasistable magnetic nanoislands at low temperature \( T = 31 \) K. Besides its scientific relevance to investigate the details of current-induced magnetization switching (CIMS), this technique opens perspectives for future data storage technologies based on SP-STM.

9:12AM H32.00005 Bloch line ‘crystallization’ as intrinsic pinning mechanism in ferrimagnetic YIG films 1. JOHN NEAL, Department of Physics, University of Bath, UK, MILORAD MILOSEVIC, Department of Physics, University of Bath, UK, and Department Fysica, Universiteit Antwerpen, Belgium, SIMON BENDING, Department of Physics, University of Bath, UK, IRINA GRIGORIEVA, ALEXANDER GRIGORENKO, Department of Physics and Astronomy, University of Manchester, UK — The present intense drive to develop current-switched magnetic storage media has lead to a renewed interest in ferrimagnetic garnet films which, for several decades, were the focus of devices exploiting manipulation of magnetic ‘bubbles’. In such uniaxial materials, the appearance of Bloch lines in structured domain walls strongly influences their dynamic properties in an applied magnetic field. Here we show that the static magnetic properties of garnet films can also be profoundly influenced due to crystallization of Bloch lines into a square lattice. When a long range order characterizes the domain wall, the magnetic contribution from the isolation of magnetic domains in an applied field. Even in the pinned regime, ultra-sensitive scanning Hall probe measurements reveal the nanoscale motion of magnetic blocks in the walls comprising an integer number of Bloch-lines. Although the estimated displacements (~25 nm) are very much smaller than the domain period, we observe highly correlated motion across many domain walls, driven by the strongly interacting Bloch line lattice.

9:24AM H32.00006 Evolution of magnetic domain reversal with temperature in Co/Pt multilayers observed by magneto-optical Kerr imaging. X.P. XIE, X.W. ZHAO, J.W. KNEPPER, F.Y. YANG, R. SOORYAKUMAR, The Ohio State University — The nucleation and evolution of magnetic domain structures at temperature and magnetic field in Co(4 Å)/Pt(tPt) multilayers with perpendicular anisotropy have been studied by magneto-optical imaging techniques. Relatively large Pt layer thicknesses \( t_{Pt} = 43 \) Å and 63 Å are chosen for this study because the interlayer coupling strength in the multilayers varies from weak at room temperature to strong at low temperature. Kerr imaging during the magnetization reversal processes shows the transformation of domain patterns with temperature, which correlates directly with enhancement of interlayer exchange coupling with decreasing temperature. As the domain period is reduced, the domain wall propagation becomes more and more difficult leading to the conversion from domain-wall-propagation dominated reversal at room temperature to nucleation-dominated reversal at low temperatures. The enhanced interlayer coupling at low temperatures leads to the entire multilayer switching as a single ferromagnet: while at higher temperatures, when the interlayer coupling weakens, quasi-independent layer-by-layer magnetic reversal is observed. The transformation from propagation- to nucleation-dominated magnetic reversal can be understood by the competition between activation energies for domain nucleation and propagation. Zeeman energy and thermal energy.

9:36AM H32.00007 Adding depth sensitivity to photoelectron microscopy using the standing wave/wedge method. FLORIAN KRONAST, BESSY GmbH, Berlin, ALEXANDER KEISER, CARSTEN WIEMANN, IF9, Juelich Research Center, RUSLAN OVSYANNIKOV, BESSY GmbH, Berlin, ANDREA LOCATELLI, Elettra, Trieste, DANIEL BUERGLER, REINERT SCHREIBER, IFF-9, Juelich Research Center, CHARLES FADLEY, UC Davis and LBNL Mat. Sci. Div. — Photoelectron microscopy (PEEM) is by now a well-established technique for studying many types of multilayer or multicomponent structure, including samples of relevance to spintronics, semiconductor technology, and polymer-based materials. The lateral resolution in such microscopes is typically 20 nm, but with the prospect of going down to ca. 1 nm in the near future. However, resolution perpendicular to the surface is limited to ca. 100 nm due to electron optics limitations. Here we demonstrate PEEM using photoelectrons with a standing wave created by soft x-ray reflection from a multilayer substrate, and growing one layer of the sample in a wedge form. This standing wave/wedge method has been demonstrated for the first time in experiments with a PEEM located at BESSY in Berlin.

9:48AM H32.00008 Study of the correlation between structural and magnetic properties of MnAs/Si. S. HEGDE, J. KWON, E. FRASER, H. LUO, Department of Physics, University at Buffalo, SUNY, D.H. LEE, C.R. WIE, Department of Electrical Engineering, University at Buffalo, SUNY, LUN COLLABORATION, WIE COLLABORATION — Ferromagnetic MnAs has been widely studied because of its ferromagnetic properties and structural compatibility with conventional semiconductors. Magnetic properties of MnAs grown on Si(001) vary depending upon the growth conditions. To understand the variations, we carried out experiments using X-ray diffraction, atomic force microscopy (AFM) and magnetic force microscopy (MFM), together with magnetization measurements. For this study, MnAs was grown by molecular beam epitaxy (MBE) on Si(001) and Si(111) substrates. The surface structure of MnAs is correlated with the magnetic properties. For samples with no in-plane anisotropy, both AFM and X-ray diffraction measurements show the coexistence of MnAs with orthogonal orientations. The magnetic domains are very different from those observed in MnAs grown on GaAs(001). Significant differences in surface morphology are observed between MnAs layers grown on Si(001) and Si(111) because of the different orientations of MnAs.

10:00AM H32.00009 Magnetic domains in Nd2Fe14B on various length scales. A. KREYSSLIG, Ames Laboratory; JF, TU Dresden, Germany, R. PROZOROV, Ames Laboratory; Dept. of Physics and Astronomy, Iowa State Univ., C. DEWURST, ILL Grenoble, France, P.C. CANFIELD, Ames Laboratory; Dept. of Physics and Astronomy, Iowa State Univ., R.W. MCCALLUM, Ames Laboratory, A.I. GOLDMAN, Ames Laboratory; Dept. of Physics and Astronomy, Iowa State Univ. — Detailed knowledge about the structure of ferromagnetic domains provides a link between microscopic properties, and macroscopic magnetic response. In the well known, and already widely used compound, Nd2Fe14B, the dimension, shape and arrangement of magnetic domains are still in discussion due to lack of suitable methods to study magnetic domain structures in the bulk and due to the geometric complexity observed on the surface. Here, we demonstrate that domain patterns revealed by quantitative Kerr and Faraday microscopy, exist well below the surface as detected by small angle neutron scattering. At room temperature, the easy-axis magnetic anisotropy yields very complex structures of domains on various length scales. In contrast, the cone-like magnetic anisotropy below 135 K reduces the complexity of the domain arrangement to a more regular and anisotropic structure of much larger domains. As a consequence the bulk magnetization increases due to the significant volume reduction of the domain walls. — The support by U.S. DOE (DE-AC02-07CH11358), DFG (SFB463) and the Alfred P. Sloan foundation is acknowledged.
10:12AM H32.00010 Collective Dynamics and Slow Relaxation of Charge/Spin Density Wave domains in Antiferromagnetic Chromium. OLEG SHPYRKO, University of California San Diego, ERIC ISAACS, Argonne National Laboratory and University of Chicago. JONATHAN LOGAN, HYEKYUNG KIM, University of Chicago, MARTIN HOLT, MICHAEL SPRUNG, ZHONGHOU CAI, ALEC SANDY. Argonne National Laboratory — We present coherent x-ray diffraction and x-ray microscopy measurements of slow fluctuations and relaxation of charge- and spin-density wave domains in antiferromagnetic Chromium. Intensity fluctuations of the coherent x-ray speckle of incommensurate charge density wave satellite, combined with time-resolved x-ray microscopy measurements, reveal the collective nature of the uncharacteristically slow domain wall and phase defect fluctuation as well as non-equilibrium charge- and spin-density wavevector relaxation. The observed dynamics of pinned charge- and spin-density wave condensate in Chromium is similar to other examples of elastic media in presence of quenched disorder, ranging from dynamics of vortex lattices in disordered superconductors and sliding friction to snow avalanches and earthquakes. A particularly interesting analogy is dynamics of soft matter undergoing jamming transition, which show similar compressed exponential relaxation behavior.

10:24AM H32.00011 Color properties, hydrogen bonding and magnetic interactions in (TBA)$_3$[Ni(NCS)$_3$]$^\ddagger$. T. V. BRINZARI, O. A. -I. SWADER, J. L. MUSFELDT, University of Tennessee, C. TIAN, M. -H. WHANGBO, North Carolina State University, J. A. SCHLUETER, Argonne National Laboratory — We investigated the optical and vibrational properties of (TBA)$_3$[Ni(NCS)$_3$] a pentacoordinate Ni compound, and compared the results with the more traditional hexacoordinate analog (TEA)$_3$[Ni(NCS)$_3$]. Based upon electronic structure calculations, color properties of this high spin complex can be understood in terms of the crystal field splitting of the d-orbitals and their strong hybridization with the ligands. Temperature dependent vibrational studies show an additional splitting and softening of some of the modes at low temperature, which indicates enhanced hydrogen bonding between sulfur centers and organic ligands at low temperature as well as weak structural phase transitions.

10:36AM H32.00012 Ferrofluid Photonic Dipole Contours. MICHAEL SNYDER, JONATHAN FREDERICK, Department of Engineering and Physics, Murray State University, Murray, KY 42071 — Understanding magnetic fields is important to facilitate magnetic applications in diverse fields in industry, commerce, and space exploration to name a few. Large electromagnets can move heavy loads of metal. Magnetic materials attached to credit cards allow for fast, accurate business transactions. And the Earth's magnetic field gives us the colorful auroras observed near the north and south poles. Magnetic fields are not visible, and therefore often hard to understand or characterize. This investigation describes and demonstrates a novel technique to visualize the magnetic fields. Two ferrofluid Hele-Shaw cells have been constructed to facilitate the imaging of magnetic field lines [1,2,3,4]. We deduce that magnetically induced photonic band gap arrays similar to electrostatic liquid crystal operation are responsible for the photographed images and seek to mathematically prove the images are of exact dipole nature. We also note by comparison that our photographs are very similar to solar magnetic Heliosphere photographs.

1Undergrad paper

10:48AM H32.00013 Magnetic Reversal Time in Open Long Range Systems. FAUSTO BORGONOVI, Dipartimento di Matematica e Fisica, Università Cattolica, via Musei 41, 25121, Brescia, Italy, LUCA CELARDO, Department of Physics, Tulane University, New Orleans, LA 70118, BRUNO GONCALVES, Emory University, Atlanta, Ga 30322, LUCA SPADAFORA, Dipartimento di Matematica e Fisica, Università Cattolica, via Musei 41, 25121, Brescia, Italy — Topological phase space disconnection has been recently found to be a general phenomenon in isolated anisotropic spin systems. It sets a general framework to understand the emergence of ferromagnetism in finite magnetic systems starting from microscopic models without phenomenological on-site barriers. Here we study its relevance for finite systems with long range interacting potential in contact with a thermal bath. We show that, even in this case, the induced magnetic reversal time is exponentially large in the number of spins, thus determining stable (to any experimental observation time) ferromagnetic behavior. Moreover, the explicit temperature dependence of the magnetic reversal time obtained from the microcanonical results, is found to be in good agreement with numerical simulations. Also, a simple and suggestive expression, indicating the Topological Energy Threshold at which the disconnection occurs, as a real energy barrier for many body systems, is obtained analytically for low temperature.

Session H33 GMAG FIAP DMP: Focus Session: Optical Properties of Magnetic Semiconductors
Morial Convention Center 224

8:00AM H33.00001 Full band structure calculations of optical spin injection in Si and CdSe. JULIEN RIOUX, FRED NASTOS, JOHN E. SIPE, Department of Physics and Institute for Optical Sciences, University of Toronto — We present a theoretical study of optical electron spin injection (optical orientation) in the bulk semiconductors Si and CdSe from direct optical excitation with circularly polarized light[1]. To describe excitation at energies significantly above the band edge, we use full-zone band structures from pseudopotential calculations. For Si, we find that there can be up to 30% spin polarization from direct transitions. The relatively low symmetry of wurtzite CdSe leads to an orientation dependent spin injection, which can be up to 100% polarized at the band edge. Averaging over crystal orientation gives a 50% spin polarization for band edge excitation.

8:12AM H33.00002 Ultrafast optical injection of magnetization in non-magnetic semiconductors, F. NASTOS, R. NEWSON, H. M. VAN DRIEL, J. E. SIPE, Department of Physics, University of Toronto — We discuss the optical injection of magnetization into a nonmagnetic semiconductor by absorption of circularly polarized light. A microscopic approach, based on Fermi's golden rule and k·p band models, is used to quantify the magnetization-injection rate in GaAs. We find that under usual experiment conditions, relevant to optical orientation, the magnetization-injection rate of holes is approximately 20 times larger than it is for electrons, which reflects the large hole magnetic moment. We then turn to the ultrafast excitation regime and explore the possibility that the injected magnetization can radiate a detectable THz field. Using a phenomenological approach for the magnetization relaxation dynamics, we predict that the THz field from optical orientation is at the limit of current THz detection technology.
8:24AM H33.00003 Direct and non-demolition optical detection of pure spin currents in semiconductors1. R.-B. LIU, Department of Physics, The Chinese University of Hong Kong, J. WANG, Department of Physics, The Chinese University of Hong Kong and Department of Physics, Tsinghua University, B.-F. ZHU, Department of Physics, Tsinghua University — We put forward a scheme of direct and non-demolition measurement of a pure spin current in a direct-gap semiconductor by a polarized light beam, which may be view as a “photon spin current” [1]. The effective coupling between the “photon spin current” and the electron spin current is realized via the spin-orbit coupling in valence bands, but involves neither Rashba effect from structure inversion asymmetry nor Dresselhaus effect from bulk inversion asymmetry. Thus a pure spin current, though bearing no net magnetization, induces Voigt and Faraday rotation of a polarized light beam. For the pure spin current studied in Ref. [2], a light beam, if oblique instead of normal incident, would present Voigt and Faraday rotation in the order of 1 millionth rad in the center region of the sample where the spin current flows without spin accumulation. [1] J. Wang, B. F. Zhu, and R. B. Liu, cond-mat/0708.0881. [2] Y. K. Kato, R. C. Myers, A. C. Gossard, and D. D. Awschalom, Science 306, 1910 (2004).

8:36AM H33.00004 Theory of Optical Manipulation of Electron Spin in Semiconductors. ALEXANDER EFROS, Naval Research Laboratory — No abstract available.

9:12AM H33.00005 Carrier Dynamics in Microdisk Photonic Molecules1. FELIX M. MENDOZA, ROBERTO C. MYERS, GREG CALUSINE, ARTHUR C. GOSSARD, DAVID D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106, XIA LI, B.J. COOLEY, NITIN SAMARTH, Materials Research Institute, Penn State University, University Park, PA 16802 — Semiconductor microcavities offer unique means of controlling light-matter interactions, which may be important in optical communications and for quantum information processing schemes. The cavities under study here are coupled microdisks that behave like “photonic molecules” (PMs) with bonding and antibonding states for the confined photon modes. We study different PM geometries consisting of laterally coupled GaAs/GaAlAs microdisks of both circular and elliptical shape. Steady-state photoluminescence measurements reveal bonding and antibonding modes with distinct polarization characteristics. Additionally, we present direct time-resolved spectroscopy of the carrier and spin dynamics in these structures. The combination of static and dynamic spectroscopies is used to explore the evolution of spin coherence in photonic molecule structures.

9:24AM H33.00006 Ultrafast Coherent Precession of Interfacial Electron Spin in Fe/AlGaAs (001). YICHUN FAN, 1327A, Mount Vernon Avenue, Williamsburg 23185, VA, HAIBIN ZHAO, GUNTER LUPKE, AUBREY HANBICKI, C. LI, BEREND JONKER — Magnetic second harmonic generation (MSHG) is used to selectively study the spin dynamics of the interface magnetization for Fe films on AlGaAs(001) in both the dc and time-resolved domain. The interface spin precession is compared with the bulk Fe precession obtained by MOKE. We find: (a) the coherent precession of the interface magnetization is largely non-collinear to the bulk Fe electron spins even at the picosecond time scale; (b) higher frequency spin precession occurs at the interface than in the bulk; (c) the phase of the interface precession is opposite to that of the bulk at low fields; and (d) the interface and bulk precession exhibit different hysteretic behavior. Model calculations of the field dependence of precession frequencies show a large out-of-plane magnetic anisotropy and a large ratio of in plane uniaxial to cubic anisotropy at the interface, attributed to its tetragonal structure and Fe-As bonding. These may account for the significant reduction in exchange coupling between the interface and bulk magnetization. These effects are studied as a function of Fe film thickness and the corresponding evolution of the anisotropy, as well as for the Fe/Si(001) and Fe/AI2O3 interfaces.

9:36AM H33.00007 Spin galvanic effect between subband of InGaAs/AlGaAs 2DEG. JUNFENG DAI, XIAODONG CUI, The University of Hong Kong, THE UNIVERSITY OF HONG KONG TEAM — We report the electric current induced by optically injected spin current on the vicinity of a crossbar shaped InGaAs/AlGaAs two dimensional electronic gas (2DEG) without external electric or magnetic field at room temperature. The electric current is either both in-ward or both out-ward flowing through the crossbar, while the total Hall voltage or current remains negligibly. The geometric size, temperature and external magnetic field dependence of the electric current have been examined and the corresponding mechanism has been discussed.

9:48AM H33.00008 Manipulating nonlinear optical response from electron spins in a 2D electron gas via exciton injection. SHANNON O’LEARY, HAILIN WANG, University of Oregon — The well-known robustness of electron spin coherences in semiconductors has stimulated intense interest in the use of electron spins in semiconductors for spintronics, quantum information processing, and coherent nonlinear optics. Of special importance to these efforts is the understanding and the manipulation of nonlinear optical processes of electron spins. Here, we report experimental studies of coherent nonlinear optical processes of electron spins in a modulation-doped CdTe semiconductor quantum well. These studies elucidate the important roles of trions and excitons and the underlying manybody interactions in the nonlinear optical process. By exploiting a two-color three-pulse pump-control-probe technique, we demonstrate that nonlinear optical responses of electron spins can be effectively manipulated through the injection of an exciton population at an appropriate time. The manipulation of the nonlinear response takes place without electron spin rotation, providing a new approach for the control and applications of electron spins in semiconductors.

10:00AM H33.00009 Rate equation modeling of semiconductor spin-polarized lasers and diodes1. CHRISTIAN GOTHGEN, ATHOS PETROU, IGOR ZUTIC, SUNY Buffalo — Optically or electrically pumped spin-polarized carriers into semiconductor lasers can provide important advantages as compared to the conventional lasers in which the carriers are unpolarized. Motivated by recent experiments in spin-polarized lasers which demonstrate the feasibility of polarization modulation and threshold current reduction [1,2], we model these structures using rate equations. Our approach allows a direct comparison of the analytical and numerical results applied to the steady-state laser response. In the absence of material gain, our findings describe the behavior of spin-polarized diodes. We calculate the dependence of threshold reduction on the degree of pumped spin polarization and suggest how a change in the spin polarization could provide several useful device functionalities.

10:12AM H33.00010 Theory of spin-polarized semiconductor lasers\textsuperscript{1}, RAFAL OSZWALDOWSKI, CHRISTIAN GOTHGEN, IGOR ZUTIC, SUNY Buffalo — In semiconductor systems spin-polarized electrons couple to photons with definite angular momentum. This effect is the basis for numerous existing and proposed devices \textsuperscript{[1]}. Quantum-well based Vertical Cavity Surface Emitting Lasers (VCSELs) take advantage of this phenomenon to produce circularly-polarized light by using either optical or electrical pumping \textsuperscript{[2]}. We describe the VCSEL system employing Semiconductor Bloch Equations. We include the influence of spin-orbit coupling and the dependence of dipole matrix elements on carrier’s wavevectors. We reduce this description to an effective four-level model, incorporating such effects as different spin lifetimes for electrons/holes and laser-cavity birefringence. Applying this approach to a spin-polarized system, we calculate the threshold current, the polarization of the emitted light and other relevant quantities. \textsuperscript{[1]} I. Zutic, J. Fabian, S. Das Sarma, Rev. Mod. Phys. 76, 323 (2004). \textsuperscript{[2]} M. Holub et al., Phys. Rev. Lett. 98, 146603 (2007). J. Rudolph et al., Appl. Phys. Lett. 82, 4516 (2003).

10:24AM H33.00011 Disorder and many-body effects in transport and optical conductivities of diluted magnetic semiconductors\textsuperscript{1}, FEDIR KRYCHENKO, CARSTEN A. ULLRICH, Department of Physics University of Missouri - Columbia — The nature of itinerant carriers in diluted magnetic semiconductors like GaMnAs is a subject of intense current debate. The valence-band picture has been widely used, but recent experimental results suggest that the carriers reside in impurity bands. Theoretical results have not been fully conclusive. Most studies within the valence-band picture treat band structures in detail, while disorder and many-body effects are only treated with simple relaxation time and static screening models. We present a more complete theory for electron dynamics in DMSs, combining a multiband approach to a spin-polarized system, we calculate the threshold current, the polarization of the emitted light and other relevant quantities. \textsuperscript{[1]} I. Zutic, J. Fabian, S. Das Sarma, Rev. Mod. Phys. 76, 323 (2004). \textsuperscript{[2]} M. Holub et al., Phys. Rev. Lett. 98, 146603 (2007). J. Rudolph et al., Appl. Phys. Lett. 82, 4516 (2003).

10:36AM H33.00012 Theory for Beats Observed in Optical Orientation Experiments on n-GaAs\textsuperscript{1}, NICHOLAS HARMON, WILLIAM PUTIKKA, Ohio State University, ROBERT JOYNT, University of Wisconsin — At low temperatures in n-type semiconductors optical orientation experiments can create two types of spin states: itinerant states in the conduction band and localized states on the donor sites. These two states will in general have different gyromagnetic ratios, and will thus precess at different frequencies when the system is put into a magnetic field. Strong evidence for two types of spins would be to see beats in optical orientation experiments. We have developed a model in the context of coupled Bloch equations to describe this phenomenon. Unpublished data by Awschalom and Kikkawa on n-GaAs at a temperature of 5 K and in a magnetic field of 6 T show beats. We apply our model to this data and interpret it in terms of spins in a Landau level formed from the conduction band states and localized spins on the donor sites.

Session H35 FLAP: Focus Session: Negative Index Materials III
Morial Convention Center 227

8:00AM H35.00001 Plasmonic metamaterials with tuneable optical properties, ANATOLY ZAYATS, The Queen’s University of Belfast — Negative refraction in metamaterials has recently attracted significant attention due to its possible numerous applications in high-resolution imaging and photolithography with the so-called “perfect lenses,” for electromagnetic shielding (visibility cloak), optical signal manipulation, etc. Among various realizations of negative index materials, plasmonic nanostructures play a prominent role as they allow negative refraction properties to be engineered in the visible and near infrared spectral ranges. The coupling of light to plasmonic modes, that are collective electronic excitations in metallic nanostructures, provides the possibility to confine the electromagnetic field on the sub-wavelength scale and manipulate it with high precision to achieve the desired mode dispersion and, thus, reflection, absorption and transmission properties of the nanostructures. In this talk we will discuss various pathways to control dispersion of the electromagnetic waves in plasmonic metamaterials, including plasmon polaritonic crystals and plasmonic nanorod arrays, and the approaches to active tuneability of their optical properties using optical and electric control signals. Both approaches take advantage of the very high sensitivity of surface plasmon mode dispersion on the refractive index of the dielectric adjacent to metallic nanostructure. Hybridization of plasmonic nanostructures with molecular species exhibiting nonlinear optical response allows the development of metamaterials with high effective nonlinear susceptibility due to the electromagnetic field enhancement related to plasmonic excitations. Signal and control light are then coupled to plasmonic modes that strongly interact via nonlinearity introduced by the hybridization. Concurrently, the use of electro-optically active dielectrics incorporated into plasmonic nanostructures provides the route to control optical signals electronically. Plasmonic metamaterials with tuneable optical properties can be used to control negative refraction and electromagnetic field propagation in various applications in nanophotonics, optoelectronics and optical communications.

8:36AM H35.00002 Tunable plasmonic negative index nanostructures and nanolenses in optical domain\textsuperscript{1}, E.V. PONIZOVSKAYA, A.M. BRATKOVSKY, Hewlett-Packard Labs, Palo Alto — We have designed with means of the use of FDTD method a metamaterial, which is a stack of metallic films with periodic hole arrays separated by dielectric layers (usually called fishnet, FN) to have negative index at IR frequencies. Optical modulation of the effective refractive properties of a FN Ag/Si metamaterial structure in the near-IR range has been confirmed experimentally \textsuperscript{[1]}. Pump excitation of the amorphous Si layer was found to be responsible for the observed modulation of the effective refractive index \textsuperscript{[1]}. We discuss the use of gain material to compensate the losses. Arrays of metallic nanoparticles or holes support individual and collective plasmonic excitations that contribute to surface enhanced Raman scattering (SERS), anomalous transparency, negative index, and subwavelength resolution in various metamaterials \textsuperscript{[2]}. Using the FDTD and a boundary integral method we design 2D plasmonic nanolenses with thousand-fold field enhancement factor that can be used for single-molecule SERS detection. \textsuperscript{[1]} E. Kim, et al., Appl. Phys. Lett. 91, 173105 (2007) \textsuperscript{[2]} E.V. Ponizovskaya, A.M.Bratkovsky, Appl.Phys. A 87, 161 (2007)

\textsuperscript{1}Collaboration: E. Kim, W. Wu, Z. Yu, S-Y Wang, R.S. Williams, Y.R. Shen
8:48AM H35.00003 Novel acoustic surface plasmons on Cu(111)1, KARSTEN POHL, BOGDAN DIACONESCU, University of New Hampshire, LUCA VATTUONE, MARIO ROCCA, Universita di Genoa, Italy — The recent discovery of a fundamentally new sound-like plasmon on a bare metal surface of beryllium introduced a new research direction in the area of plasmonics [1]. While conventional surface plasmons are optical modes and have a finite excitation energy of a few eV, the novel acoustic mode can be excited with very low energies of a few meV. This allows, in principle, for a coupling with visible light for signal processing and advanced microscopies as well as new catalysts on metallic surfaces. In order to show that this novel excitation is a general phenomenon on closed-packed noble metal surfaces, as predicted by our theoretical collaborators [2], we have measured the dispersion of the acoustic surface plasmon on Cu(111) by electron energy-loss spectroscopy for a parallel momentum-transfer range from 0 to 0.15 Å⁻¹. We can report that the dispersion is indeed linear (acoustic) with a slope (sound velocity) in good agreement with theory [2].

9:00AM H35.00004 Thickness dependent plasmon excitation and damping in metallic thin films, ZHE YUAN, SHIWU GAO, Department of Applied Physics, Chalmers University of Technology, Gothenburg — We present a theoretical study of collective plasmon excitation and lifetime in metallic thin films using a jellium model [1,2]. The excitation spectra are calculated with linear response theory and time-dependent local density approximation. The plasmon energy dispersion follows qualitatively the classical electrodynamical model. For ultrathin films with a few atomic layers, the collective plasmon resonances evolve into single particle transitions at small momenta. The plasmon linewidth due to Landau damping is found to depend exponentially on the film thickness. Quantum oscillations are found in ultrathin films with a period that is about three times longer than the universal period λp/2 observed in many other quantities. This long period results from the dynamical Friedel oscillations in the collective excitation normal to the films. [1] Z. Yuan and S. Gao, Phys. Rev. B 73, 154541 (2006). [2] Z. Yuan and S. Gao, Surf. Sci. in press.

9:12AM H35.00005 Surface Plasmon Polariton Amplification at Telecommunication Frequencies,1, MURALIDHAR AMBATI, SUNGYUN NAM, DENTCHO GENOV, ERICK ULIN-AVILA, XIANG ZHANG, UNIVERSITY OF CALIFORNIA, BERKELEY. TEAM — Active plasmonics describes the interaction between an active medium and surface plasmons, and it offers a foundation for fundamental studies and an opportunity to expand surface plasmon based applications. In order to overcome the challenges posed by surface plasmons - primarily the metal losses - recent studies have focused extensively on surface plasmon amplification; however, there has been very limited headway from the experimental front. We present an experimental evidence of the amplification of long range surface plasmon polaritons (SPPs) by stimulated emission at telecom frequencies. We design SPP waveguides - thin gold metal strips - embedded in a gain medium, erbium doped phosphate glass. We confirm SPP amplification by showing an increase in the propagation length of surface plasmons in both pulsed and continuous modes. We present the design, fabrication and measurements of the gold SPP waveguides in erbium doped glass. Such structures will be suitable as integrated coupling devices as well as for the study of plasmon-exciton interface in cavity quantum electrodynamics.

9:24AM H35.00006 Novel electromagnetic effective medium based on nanocoaxes1, KRZYSZTOF KEMPA, XIWEN WANG, ZHIFENG REN, MICHAEL J. NAUGHTON, Boston College — A thin film of an opaque material, pierced with an array of subwavelength coaxial nanocavities, decomposes an incident electromagnetic wave into spatially discrete wave components, propagates these components without frequency cut-off through the film, and reassembles them on the far side. The propagation of these wave components is fully controlled by the physical properties of the waveguides and their geometrical distribution in the array. This allows for an exceptional degree of control over the electromagnetic response of this effective medium, with numerous potential applications, including metamaterial functionality enabled in the visible frequency range.

9:36AM H35.00007 Controlling surface plasmons and local field by two-dimensional arrays of metallic nano-bottles, HEI IU, DANIEL H.C. ONG, JONES T.K. WAN, JIA LI, Chinese University of Hong Kong — In recent years, studies of surface plasmon polaritons (SPPs) have been intensive. It is of great interest to control SPPs with great precision and flexibility. In this talk, we present our recent work on SPPs manipulation by using two-dimensional arrays of bottle-shaped, metallic cavities. We propose that by tuning the geometry of such “nano-bottle” contained in a two-dimensional nano-scale array it is possible to control the resonance frequencies and near field patterns of different SPP modes. The dispersion relations are not sensitive to the sizes and depths of the nano-bottles, but depends strongly on the polarization in particular, by using different polarizations, it is observed that different types of SPPs, either propagating or localized, can be excited independently. Moreover, we attempt to control the local field by closing up the aperture of the nano-bottle. We have found that the local field slowly moves up from the bottom to the neck of bottle by increasing its depth. In addition, the field intensity can be fine-tuned by controlling the topology of the bottleneck, for example, a smaller and thinner neck leads to stronger field intensity. As a result, we believe these nano-bottle arrays are good candidates for making high sensitivity chemical and biological sensors.

9:48AM H35.00008 Inverse Mapping Structures onto Transparency1, KIM F. FERRIS, XIN SUN, PAUL A. WHITNEY, Pacific Northwest National Laboratory — Composite materials have continued to make a number of improvements in physical properties (mechanical moduli), but lag behind in optical responses such as transparency. The hybrid nature of the composite material, particle and host matrix, divides light scattering issues into particle size regimes, where the particle size d >> lambda and approximations such as anomalous dispersion have proven useful, and d<< lambda where more exacting methods are necessary. The real-life difference between the ‘design’ particle size and the practical particle size distribution often finds contributions to light scattering losses from both regimes. Using a ceramic-polymer composite as a case example, we have used black box optimization methods to examine the practical bounds for each regime and to assess design rules. These guidelines suggest limitations for particle morphologies and the optical properties of the component materials.

10:00AM H35.00009 A method for determining refractive indices of epilayers of multi-structure active layer, GAGIK SHMAVONYAN, State Engineering University of Armenia — The refractive indices of bulk and epitaxially grown materials differ. Besides, it is very difficult to experimentally determine and theoretically calculate the refractive indices of compound semiconductor epitaxial layers of quantum hetero-structures, especially the refractive indices of active layer of multilayer compound semiconductor devices. For that reason the precise determination of the refractive indices of epilayers is actual. A new method for the determination of the refractive indices of epitaxially grown compound semiconductor materials of multilayer heterostructure is suggested. This method is a combination of experimental measurements and theoretical calculations. The equipment for the fulfillment of the suggested method is also elaborated.
10:12AM H35.00010 Electromagnetic field distributions of perfect and imperfect cloaks, TAI HANG FUNG, LAI LAI LEUNG, KIN WAH YU, Chinese University of Hong Kong, Shatin, NT, Hong Kong — In this work, based on the ideal cloaking model proposed by Pendry et al. [1], we calculate, by first-principles approach, the electric field distributions of ideal cloaks (both spherical and cylindrical) subject to different external electric field sources. The results show that the external electric field of an ideal cloak remains unperturbed and the field inside the cloaking region vanishes, thus verifying that Pendry et al.’s model is indeed perfect. We then extend the investigation to imperfect cloaks, whose permittivity tensors can be perturbed due to dispersion or loss, by solving the appropriate boundary-value problems [2]. The resultant electric field distributions can become nonzero inside the vertical cantilevers along region as expected. We further evaluate the visibility of the imperfect cloak against the perturbation. We find small visibility under appropriate conditions.

10:24AM H35.00011 Design of cloaking metamaterials using spectral representation theory, LAI LEUNG, TAI HANG FUNG, KIN WAH YU, Chinese University of Hong Kong — Controlling the propagation of electromagnetic (EM) waves, for instance in cloaking problems, has become an important topic in nanophotonics. So far, following the cloaking model proposed by Pendry et al. [1], the experimental realization was only limited to the microwave region [2]. Since practical application lies in the visible range, we have extended the investigation to that region by utilizing nanocomposites with reference to the material parameters proposed by Pendry et al. and Shalaev et al. [3]. The calculations can be made much simpler by invoking the spectral representation theory [4]. The loss and dispersion effects, as well as the propagation of EM waves are assessed for the designed cloaking models in order to investigate the cloaking performance. Further analyses show that our models can accomplish the desired cloaking effect in the visible range. Moreover, the loss and dispersion effects are found to be small and acceptable.

10:36AM H35.00012 Nonlinear Cerenkov radiation in a two-dimensional nonlinear photonic crystal waveguide, S.N. ZHU, Y. ZHANG, Z. YAN, Z. QI, G. ZHAO, National Laboratory of Solid State Microstructures, Nanjing University — We present a new type of quasi-phase-matched Cerenkov radiation generation from a two-dimensional nonlinear photonic crystal waveguide: a hexagonally poled LiTaO3 waveguide. The waveguide was fabricated by field poling followed by proton exchange technique. The fundamental source was a LD-pumped, 90-ns pulsed Q-switch double wavelength Nd:YAG laser at 1064-µm and 1319-µm. The pulse repetition rates was 8-kHz. When the fundamental beams at 1064-µm and 1319-µm were co-linearly focused into the waveguide and propagated along its x-axis, multiple radiation spots at red, yellow, green with different propagation directions and radiation angles are simultaneously exhibited from such a hexagonally poled waveguide. Scattering involved Cerenkov arc is also observed. These frequency conversion processes were realized by guided-to-radiated mode interaction. Phase-matching for these processes in the waveguide was automatically achieved by a quasi-phase-matched Cerenkov configuration.

Tuesday, March 11, 2008 8:00AM - 10:48AM
Session H36 GIMS: Focus Session: Advances in Scanned Probe Microscopy II: Force Methods Morial Convention Center 228

8:00AM H36.00001 Multi-dimensional Scanning Probe Microscopy, HANS J. HUG, Empra, Materials Science and Technology, CH-8600 Duebendorf, Switzerland and Institute of Physics, University of Basel, CH-4056 Basel, Switzerland — Since the first demonstration of atomic force resolution with a scanning force microscope in 1995 a large variety of samples have been imaged with atomic resolution. In 2000 Gießel obtained atomic resolution with a (macroscopic) tuning fork operated with small oscillation amplitudes that correspond to the length of the inter-atomic interaction potentials. However, tuning fork sensors have a number of disadvantages that can all be overcome by optimized micro-fabricated cantilevers operated at similarly small or even smaller oscillation amplitudes. With their small mass and high mechanical quality factor, particularly after appropriate annealing in UHV force sensitivities that are orders of magnitude better than that of tuning forks and also far better than that of the best NEMS sensors is obtained. Recently Kawai et al and Sugimoto et al obtained atomic resolution with cantilevers with a operated in higher oscillation modes with sub-nanometer amplitudes. In order to make use of the excellent force sensitivity we developed a Fabry-Perot type interferometer optical sensor that maps flexural and torsional cantilever oscillations with ultra-high sensitivity. This deflection sensor allows the use of sub-A canrilever oscillation amplitudes and thus the direct measurement of atomic interaction force gradients and, in principle, the use of advanced tunnelling spectroscopy techniques that are well-established in the field of scanning tunnelling microscopy. The simultaneous mapping of flexural and torsional oscillation modes further allows the measurement of vertical and lateral tip-sample interaction forces and corresponding atomic scale energy loss processes.

8:36AM H36.00002 A Low Temperature Scanning Force Microscope with a Vertical Cantilever and Interferometric Detection Scheme, JEEHOON KIM, T.L. WILLIAMS, SANG LIN CHU, HASAN KORRE, MAX CHALFIN, J.E. HOFFMAN, Harvard University — We have developed a fiber-optic interferometry system with a vertical cantilever for scanning force microscopy. A laser, mounted on a Pan-type walker, was used to collect the interference signal in the cavity between the cantilever and the single mode fiber. This vertical geometry has several advantages: (1) it is directly sensitive to lateral forces; (2) low spring constant vertical cantilevers may allow increased force sensitivity by solving the “snap-in” problem that occurs with soft horizontal cantilevers. We have sharpened vertical cantilevers by focused ion beam (FIB), achieving a tip radius of 20 nm. We will show test results of a magnetic force microscope (MFM) with this vertical cantilever system.

8:48AM H36.00003 New Interpretation of Non-contact Atomic Force Microscopy Images of Dihydride Si(001) Surface Based on Simulation, AKIRA MASAGO, SATOSHI WATANABE, The University of Tokyo, KATSUNORI TAGAMI, MASARU TSUKAKA, Waseda University — Dihydride Si(001) surfaces have attracted attention as a substrate of organic semiconductor devices. In non-contact atomic force microscopy (NC-AFM) observation of dihydride Si(001) surface, 1x1 and 2x1 images were observed depending on the preset frequency shift value [1]. For both images, bright spots were assigned to hydrogen atoms. Recently, we have developed a simulator on the basis of the density-functional based tight-binding method, and have simulated NC-AFM image of the dihydride Si(001) surface. As a result, we obtained frequency shift images with the 1x1 and 2x1 periodicities, which agree well with the experiments. Surprisingly, we have found that the bright spots of the 2x1 image do not correspond to hydrogen atoms. Each spot corresponds to the bridge site, where the sum of the attractive forces from two nearby hydrogen atoms becomes large.

10:00AM H36.00009 Fabricating overhanging magnets for use in magnetic resonance force microscopy using a XeF2 isotropic etch. SARAH WRIGHT, Cornell Department of Chemistry and Chemical Biology. STEVEN HICKMAN, JOHN MAROHN, Cornell Department of Chemistry and Chemical Biology — Pushing magnetic resonance force microscopy towards single proton sensitivity demands meeting the nanofabrication challenge of producing an attonewton-sensitivity cantilever with a magnetic tip whose diameter is 50 nm or less. At the same time, the cantilever should also experience low force noise (and force gradient noise) near the sample. As proof of concept, we will show a 50-nm overhanging cobalt magnet made by a process involving KOH etching, as well as preliminary work on making overhanging magnets by FIB micro machining. We have characterized high coercivity Sm2Co17 MRFM probes fabricated by Focused Ion Beam (FIB) micro machining and mounted on a commercial Si cantilever (characteristic dimension 1 mm x 1 mm x 1 mm). We report vibrating cantilever magnetometry measurements of probe coercivity. Low temperature (4 K) probe coercivity as high as 1 T has been observed. Probe characteristics have also been deduced from deconvolution of MFM data obtained on 5.3 μm diameter permallloy dots. We also discuss energy dissipation in the micromechanical cantilever when the tip approaches a ferromagnetic sample.

10:12AM H36.00010 Bimodal AFM imaging of individual protein molecules with sub-pico Newton force sensitivity. NICOLAS F. MARTINEZ, SHIVA PATIL, JOSE R. LOZANO, RICARDO GARCIA, Instituto de Microelectronica de Madrid, CSIC — The capability of atomic force microscopes (AFM) to generate atomic or nanoscale resolution images of surfaces has deeply transformed the study of materials. However, high resolution imaging of biological systems has proved more difficult than obtaining atomic resolution images of crystalline surfaces. In many cases, the forces exerted by the tip on the molecules (1-10 nN) either displace them laterally or break the noncovalent bonds that hold the biomolecules together. Here, we apply a force microscopy concept based on the simultaneous excitation of the first two flexural modes of the cantilever (bimodal excitation). The coupling of the modes generated by the tip-molecule forces enables imaging under the application of forces (around 35 pN) which are smaller than those needed to break noncovalent bonds. With this instrument we have resolved the intramolecular structure of antibodies in monomer and pentamer forms. Furthermore, the instrument has a force sensitivity of 0.2 pN which enables the identification of compositional changes along the protein fragments.

10:24AM H36.00011 Rheological Measurements by AFM of the Formation of Polymer Nanofibers, MEHDI YAZDANPANAH, MAHDI HOSSEINI, SANTOSH PABBA, electroOptics Research Institute and Nanotechnology Center University of Louisville, SCOTT BERRY, VLADIMIR DOBROKHOV, ABEDELILAH SAFIR, ROBERT KEYNTON, ROBERT COHN, electroOptics Research Institute and Nanotechnology Center University of Louisville, ELECTROOPTICS RESEARCH INSTITUTE AND NANOTECHNOLOGY CENTER UNIVERSITY OF LOUISVILLE COLLABORATION, DEPARTMENT OF MECHANICAL ENGINEERING COLLABORATION — Polymer fiber can be formed by pulling a thread of polymeric liquid if the fiber solidifies before it breaks up by capillary thinning. Fiber diameter is well correlated with a processing parameter that is a simple function of viscosity, surface tension and evaporation rate. The fundamental material parameters can also be determined with the same AFM setup. The usual problem with tapered AFM tips, of liquids wetting unstably up the tapered AFM tip and even onto the cantilever, is resolved by the use of long cylindrical tips of constant diameter. We recently demonstrated a method of growing Ag-Ga nanowires onto AFM tips at room temperature. These constant diameter nanowires are shown to give clearly measurable force-distance curves when inserted through the surface of a liquid, which provides clean measurements of surface tension, contact angle, and evaporation rate, while shear viscosity is determined through cantilever Q-damping as a function of insertion distance into the liquid.

10:36AM H36.00012 Micromechanical force detectors for measuring magnetization at high magnetic fields and the magnetic response of Ba3Cr2O8, K. NINIOS, Y. J. JO, L. BALICAS, A. ACZEL, G. M. LIKE, H. B. CHAN, DEPT OF PHYSICS, UNIVERSITY OF FLORIDA TEAM, NHMFL, TALLAHASSEE COLLABORATION — We report magnetization measurements of Ba3Cr2O8 using micromechanical faradary balance magnetometers. The magnetometers consist of a movable polysilicon plate (500 by 500 micrometers) supported by four springs 2.75 micrometers above a fixed electrode. When small samples of the magnetic material are placed at the center of the movable plate, the natural gradient of the field creates a force on the sample that can changes the capacitance between the plate and electrode, while the response to magnetic torque is minimized. The absolute magnetization of the sample can be determined provided that the magnetic field gradient is known. The device is used to measure the magnetization of a small sample of Ba3Cr2O8 with mass of 1 microgram. At high fields, our measurements reveal an asymmetrical dome-like structure in the temperature-magnetic field phase diagram, possibly related to the Bose-Einstein condensation of spin triplet degrees of freedom.

Tuesday, March 11, 2008 8:00AM - 10:48AM — Session H37 FLAP: Optical Properties of Semiconductors (mostly oxides) Morial Convention Center 229

8:00AM H37.00001 Density-functional theory study of the effects of atomic doping on the band edges of monoclinic WO3, MUHAMMAD N. HUDA, YANFA YAN, SU-HUAI WEI, MOWAFAK M. AL-JASSIM, National Renewable Energy Laboratory, Golden, CO 80401 — The effects of impurities in room temperature monoclinic WO3 were studied using the local density approximation to density-functional theory. Our main focus is on nitrogen impurity in WO3, where both substitutional and interstitial dopings were considered. We have also considered doping with transition-metal atoms and some co-doping approaches in WO3. We found that, in general, band gap reduction was a common result due to the formation of impurity bands in the band gap. Also, the changes of band-edge positions, valence-band maxima and conduction-band minima, were found to depend on the electronic properties of the foreign atom and their concentration. Our results, therefore, provide guidance for making WO3 a suitable candidate for photo-electrodes for hydrogen generation by water splitting.

8:12AM H37.00002 Materials for Transparent Electronics: Ab initio calculation of wide bandgap semiconductor interfaces, SKYE DORSETT, GUENTER SCHNEIDER, Oregon State University — Materials used in transparent electronics (TE) must be transparent in the visible portion of the electromagnetic spectrum which requires the use of wide bandgap semiconductors as contacts and rectifiers as well as passivation and barrier-shaping layers. Of particular importance are the source and drain contacts of transparent thin-film transistors (TTF). The contact characteristics at the interface between the channel material (e.g. ZnO, SnO2) and the contact material (commonly Indium Tin Oxide) are determined by the band offset which can be estimated from a heterojunction model based on material properties alone. The development of new materials for TE greatly benefits from estimates of interface properties but for most materials which hold promise for use in TE (e.g. indium gallium zinc oxide) the relevant material parameters such as work function, electron affinity and in particular the charge neutrality level are not known. To close this gap we report ab-initio density functional theory calculations of band offsets for wide bandgap semiconductors which are commonly used or hold promise for use in TTF.

8:24AM H37.00003 Ab initio calculations of the dielectric functions of semiconductors including the electron-hole interactions via LASTO method, HYEJUNG KIM, YIA-CHUNG CHANG, University of Illinois at Urbana-Champaign and Research Center for Applied Sciences, Academia Sinica, Taipei, Taiwan — We calculate dielectric functions of semiconductors including the electron-hole interactions within the ab initio framework. The Bethe-Salpeter equation is constructed using a full-potential linear augmented-Slater-type orbital (LASTO) method [1, 2]. Using the LASTO method allows us to compute optical matrix element for large number of k points efficiently. Due to requirements of a dense k-point mesh, we use quasi-minimum residual (QMR) method to solve the equation. The inclusion of the electron-hole interactions both shifts the peak positions and changes peak heights of the imaginary part of the dielectric functions, resulting in better agreement with experimental data than the spectra obtained without including the electron-hole interactions. The calculated dielectric functions are compared to experimental data of ZnSe, CdSe, CdTe, InP, InAs, AlAs and GaN. The self-energy correctives are described by an empirical tight-binding formula. [1] J. W. Davenport, Phys. Rev. B 29, 2896 (1984) [2] Y.-C. Chang, R.B.James, and J.W.Davenport, Phys. Rev. B 73, 035211 (2006)

8:36AM H37.00004 Structural and optical properties of a transparent conductor oxide: Nb:In2O3, O. LOZANO, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX, P.V. CHINTA, P.V. WADEKAR, L.H. CHU, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX., H.W. SEO, Department of Physics, University of Alaska, Little Rock, AK, O.Q. CHEN, X.M. WANG, D. WIJESUNDERA, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX., L.W. TU, N.J. HO, Departments of Physics and Materials and Optoelectronic Engineering and Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, TW, W.K. CHU, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, TX. — Thin films of niobium-doped indium oxide, Nb:In2O3, have been deposited on YSZ(001) and MgO(111) substrates by magnetron sputtering at 450 °C. The transparent semiconducting films obtained on YSZ(001) were epitaxial, but when deposited under the same conditions on MgO(111), the film qualities worsen upon Nb doping. The structural and optical properties in relation to the Nb content and the general growth conditions were studied by Rutherford backscattering, ion channeling, optical absorption spectroscopy, x-ray diffraction, and atomic force microscopy. The magneto-transport behaviors will also be discussed.
8:48AM H37.00005 Nature of the bandgap in In$_2$O$_3$ revealed by first-principles calculations and X-ray spectroscopy, ARON WALSH, JUAREZ L.F., DA SILVA, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, CO 80401, USA, CHRISTOPH KÖRBER, ANDREAS KLEIN, Darmstadt University of Technology, Darmstadt, Germany, L.F.J. PIPER, ALEX DEMASI, K.E. SMITH, Department of Physics, Boston University, Boston, MA 02215, USA, G. P Aceccio, J., Laboratorio TASC, INFN-CNR, Area Science Park, 34012 Trieste, Italy, P. TORELLI, CNR-INFN-S3, Via Campi 213/A, I-41100 Modena, Italy, D.J. PAYNE, A. BOURLANGE, R.G. EGDELL, Chemistry Research Laboratory, Mansfield Road, Oxford OX1 3TA, UK — The origin of weak absorption 1 eV below the onset of strong optical absorption in In$_2$O$_3$ has previously been attributed to the presence of an indirect fundamental bandgap or surface band bending. We demonstrate conclusively that this is not the case. Through the application of bulk and surface sensitive X-ray spectroscopic techniques, we reveal that the valence band edge is found much closer to the bottom of the conduction band than expected on the basis of the widely quoted bandgap of 3.75 eV. First-principles theory shows that the upper valence bands of In$_2$O$_3$ exhibit small dispersion and the conduction band minimum is positioned at Γ; however, direct optical transitions give minimal dipole intensity until 0.8 eV below the valence band maximum. Our results set an upper limit on the fundamental bandgap of 2.9 eV.

9:00AM H37.00006 Raman scattering properties of SnO$_2$, RALF MEYER, Theoretical Physics, University of Duisburg-Essen, 47048 Duisburg, Germany, CEDRICK MEIER, AXEL LÖRKE, Experimental Physics, University of Duisburg-Essen, 47048 Duisburg, Germany — Oxide semiconductors like ZnO and SnO$_2$ have recently attracted a lot of attention as possible optical materials for novel technological applications. Results from Raman scattering experiments and ab initio calculations of the Raman scattering properties of bulk SnO$_2$ and SnO$_2$-δ have been performed. Raman spectra derived from these calculations compare qualitatively well with the experimental findings. From this, it is concluded that the differences in the experiments are an effect of the bulk materials. An analysis of the nature of the calculated Raman active vibrational modes makes it possible to draw further conclusions on the reasons behind the differences between the stochiometric SnO$_2$ and the understochiometric SnO$_2$-δ.

9:12AM H37.00007 Studies of electronic relaxation and coherent control in sensitized semiconductor surfaces, VICTOR BATISTA, Yale University, LUIZ REGO, Universidade Federal de Santa Catarina (UFSC) — This talk addresses the feasibility of using sequences of unitary pulses for coherent-control of quantum dynamical phenomena, including superecho and tunneling in sensitized TiO$_2$ surfaces and control of tunneling and decoherence in archetypal model systems. The proposed dynamical decoupling scenario is based on the repetitive application of unitary pulses, affecting the interference phenomena between wave-packet components. The pulses affect the overall relaxation dynamics without collapsing the coherent-quantum evolution of the system. It is shown that both bound-to-bound state tunneling and bound-to-continuum tunneling processes can be inhibited and eventually halted with sufficiently frequent pulses that exchange energy with the system but do not collapse the unitary evolution or affect the potential energy tunneling-barriers. The reported results are therefore particularly relevant to the understanding of coherent optical manipulation of electronic excitations in semiconductor devices where performance is limited by quantum tunneling and decoherence.

1Supported by the Deutsche Forschungsgemeinschaft (SFB 445)

9:24AM H37.00008 Electron-phonon interaction and charge carrier mass enhancement in electron doped alkali earth titanate semiconductors, DOOK VAN MECHELEN, DIRK VAN DER MAREL, CLAUDIO GRIMALDI, PETER ARMITAGE, ALEXEY KUZMENKO, HANS HAGEMANN, NICOLAS REYREN, ROLF LORTZ, IGOR MAZIN, University of Geneva, Geneva — We have studied the electron-phonon coupling in electron doped SrTiO$_3$ for which the carrier concentration ranges from a dilute gas of polarons to a polaron liquid. Here we report a THz, far-infrared and optical study together with DC conductivity, Hall effect and specific heat measurements. The THz spectra at 7 K show the presence of a very narrow (< 2 meV) Drude peak, the spectral weight of which shows approximately a factor of three enhancement of the band mass for all carrier concentrations. The missing spectral weight is regained in a broad ‘mid-infrared’ band which originates from electron-phonon coupling. Analysis of the results yields an electron-phonon coupling parameter of an intermediate strength, α ~ 4. Specific heat measurements below 4 K show the mass enhancement to be about eight times the band mass for all carrier concentrations. The outstanding discrepancy with the optical mass is interpreted together with the temperature dependence of the Hall constant, the optical spectral weight and the dc scattering rate within the framework of a polaron liquid.

9:36AM H37.00009 Non-resonant inelastic x-ray scattering spectra of lithiumated titanium oxides for battery applications, KENNETH NAGLE, University of Washington, MALI BALASUBRAMANIAN, Advanced Photon Source, Argonne National Laboratory, CHRISTOPHER JOHNSON, Chemical Engineering Division, Argonne National Laboratory, GERALD SEIDLER, University of Washington, KENNETH NAGLE, University of Washington, MALI BALASUBRAMANIAN, Advanced Photon Source, Argonne National Laboratory, CHRISTOPHER JOHNSON, Chemical Engineering Division, Argonne National Laboratory, GERALD SEIDLER, University of Washington, KENNETH NAGLE, University of Washington, MALI BALASUBRAMANIAN, Advanced Photon Source, Argonne National Laboratory, CHRISTOPHER JOHNSON, Chemical Engineering Division, Argonne National Laboratory, GERALD SEIDLER, University of Washington — Many lithium ions are used in batteries, and for this reason it is important to understand the electronic structure of lithiumated titanium oxides. We present non-resonant inelastic x-ray scattering (NRIXS) spectra from Li$_2$O initial states in TiO$_2$; these spectra are among the first recorded for such states in a transition metal. These spectra were obtained using the lower energy resolution inelastic x-ray scattering (LERIX) spectrometer, which is capable of making simultaneous non-resonant inelastic x-ray scattering (NRIXS) spectra from 2p initial states in titanium; these spectra are among the first recorded for such states in a transition metal. Theoretical calculations have shown that the band mass enhancement to be about eight times the band mass for all carrier concentrations. The results demonstrate the interpretation of experiment, the electronic excitations in semiconductor devices where performance is limited by quantum tunneling and decoherence.

9:48AM H37.00010 New green phosphor Ba$_3$Si$_2$O$_6$N$_2$:Eu for white LED: crystal structure and optical properties, MASAYOSHI MIKAMI, KYOTA UHEDA, SATOSHI SHIMOKA, HIROYUKI IMURA, NAOTO KIJIMA, Mitsubishi Chemical Group Science and Technology Research Center, Inc. — A new oxynitride, Ba$_3$Si$_2$O$_6$N$_2$, has been synthesized. The crystal structure has been successfully determined by close collaboration between experiment and first-principles band calculation based on density functional theory. This compound doped with Eu exhibits intense green photoluminescence with high color purity under near-ultraviolet to blue light excitation. It has much less thermal quenching at room temperature. The optical properties of these compounds have been interpreted from theoretical and crystallographic viewpoint.

10:00AM H37.00011 Optical properties of group-II oxides — excitons and absorption in MgO, ZnO and CdO, ANDRE SCHLEIFE, CLAUDIA RÖDL, FRANK FUCHS, FRIEDHELM BECHSTEDT, Institut fuer Festkoerpertheorie und -optik, Friedrich-Schiller-Universitat and European Theoretische Spectroscopy Facility (ETSF) — ZnO is a material that has been very attractive for researchers for many decades by now. However, recently also alloys and heterostructures with other group-II oxides are becoming more and more interesting. Together with MgO or CdO the tuning of electronic and optical properties becomes possible with potential applications for optoelectronic devices in the blue or UV spectral region. For the three materials we study the influence of excitonic effects on the dielectric function in the region of interband transitions and on the electron-hole binding near the absorption edge by solving the Bethe-Salpeter equation. As starting point we compute the electronic structure using a GGA+U approach. The U is chosen to widely reproduce more sophisticated HSE06+G(W) calculations. We combine two efficient approaches to calculate the spectrum and bound excitonic states, using a large number of k-points in combination with hybrid k-point meshes to ensure convergence. We find good agreement of our challenging ab initio calculations with experimental absorption spectra as well as values for the binding energies.
10:12AM H37.00012 Mechanistic model for the influence of Ag thickness on the electrical and optical properties of ZnO/Ag/ZnO nanoscale multilayers, TERRY ALFORD, HAUK HAN, School of Materials and Flexible Display Center at Arizona State University, N. THEODORE, Analog & Mixed-Signal Technologies, Freescale Semiconductor Inc. In this study, we have engineered TCO structures with greatly improved electrical conductivity by introduction of a thin layer of Ag. Results show that carrier concentration, mobility, and conductivity increase with Ag thickness. The electrical conductivity decreased from 1 Ω-cm to 8×10⁻⁵ Ω-cm for a 14 nm Ag middle layer, by increasing carrier concentration and mobility. AFM and TEM results indicate that low Ag thickness results in Ag island formation. The optical transmittance of the composite structure decreases when compared to a single ZnO layer of comparable thickness. However, we demonstrate that an optimum Ag thickness exists (12 nm) to fulfill the conductivity and transmittance requirements for optoelectronic devices. Moreover the optical band-gap of ZnO/Ag/ZnO composite multilayer films decreases with increasing Ag thickness and also increases with carrier concentration. Based on these results, we propose a mechanistic model for the influence of Ag thickness on the electrical and optical properties of this system.

10:24AM H37.00013 Soft X-Ray Spectroscopic studies of Intrinsic Quantum Well States, Shallow Core Level Hybridization, and Valence Band Structure in CdO and InN1, L.F.J. PIPER, L. COLAKEROL, A. DEMASI, T.D. MOUSTAKAS, K.E. SMITH, Boston University, J. ZUNIGA-PÉREZ, V. MUNOZ-SANJOSÉ, Universitat de Valncia, ALEXEI FEDOROV, Advanced Light Source, LBNL, T. VEAL, C. MCCONVILLE, University of Warwick — InN and CdO are post-transition metal compounds that display significant metal-ligand shallow core level hybridization [1], and have recently been discovered to possess intrinsic quantum well states in electron accumulation layers near their surfaces [2]. We report here new synchrotron-based soft x-ray spectroscopic measurements of the electronic structure of CdO and InN single crystal thin films. Resonant x-ray emission spectroscopy has been employed to study the detailed valence band and shallow core level electronic structure, while high resolution angle-resolved photoemission spectroscopy was used to measure quantized electron subbands at the near-surface of both InN and CdO. [1]. L. F. J. Piper et al., Phys. Rev. B (2007) in press; [2]. L. Colakeroi et al., Phys. Rev. Lett. 97, 237601, (2006)

1 Experiments performed at the ALS and the NSLS. Work supported in part by the Department of Energy and the ACS Petroleum Research Fund.

10:36AM H37.00014 Probing defects in ZnO nanostructures by Photoluminescence and Positron Annihilation Spectroscopy1, MANORANJAN GHOSH, A.K. RAYCHAUDHURI, S.N. Bose National Centre for Basic Sciences, S.K. CHAUDHURI, DIPANKAR DAS, UGC-DAE Consortium for Research — We have investigated defect related emission in the blue green region (2.2 eV - 2.5 eV) of ZnO nanostructures having spherical (5 nm-15 nm) as well as those with hexagonal platelet and rod like morphologies (20nm-100 nm), synthesized by solvo-thermal route. This emission show anomalous size dependence. Emission energy near 2.2 eV, shifts to higher energy (2.5 eV) for increase in size beyond 20nm when shape of the nanostructures changes. This change in photoluminescence has a close correlation with the size (and shape) induced change in the positron trapping rate which is directly proportional to the defect concentration. The trapping rates show non-monotonous dependence on size. It increases initially as the size increases (5nm-15nm) and then decreases as the size increases beyond 20nm. While increase of the trapping rate on size reduction is expected due to accumulation of more defects at the surface, the initial dependence of the trapping rate on the size (below 20nm) is anomalous. The data are explained by the presence of defects like Zn vacancy and confinement due to size reduction.

1 DST Unit for Nanoscience

Tuesday, March 11, 2008 8:00AM - 11:00AM — Session H39 GSNP: Student Prize Session followed by Focus Session: Friction Morial Convention Center 231

8:00AM H39.00001 Restricted Defect Dynamics in Colloidal Peanut Crystals, SHARON GEBOD, Physics - Cornell University, STEPHANIE LEE, Materials Science and Engineering - Cornell University, BETTINA JOHN, Chemical Engineering - Cornell University, ANGIE WOLFGANG, Physics - Cornell University, CHAKESHA LIDDELL, Materials Science and Engineering - Cornell University, FERNANDO ESCOBEDO, Chemical Engineering - Cornell University, ITAI COHEN, Physics - Cornell University — We report that monolayers of hard peanut-shaped colloidal particles consisting of two connected spherical lobes order into a crystalline phase at high area fractions. In this “lobe- close-packed” (LCP) crystal, the peanut particle lobes occupy triangular lattice sites, much like closed-packed spheres, while the connections between lobe pairs are randomly oriented, uniformly populating the three crystalline directions of the underlying lattice. Using optical microscopy, we directly observe defect nucleation and dynamics in sheared LCP crystals. We find that many particle configurations form obstacles blocking dislocation glide. Consequently, in stark contrast to colloidal monolayers of close-packed spheres, single dislocation pair nucleation is not the only significant energetic barrier to relieving an imposed shear strain. Dislocation propagation beyond such obstructions can proceed only through additional mechanisms such as dislocation reactions. We discuss the implications of such restricted defect mobility for the plasticity of LCP crystals.

8:12AM H39.00002 Elastic Theory of Defects in Toroidal Crystals, LUCA GIOMI, MARK BOWICK, Syracuse University — Crystalline assemblages of identical sub-units packed together and elastically bent in the form of a torus have been found in the past ten years in a variety of systems of surprisingly different nature, such as viral capsids, self-assembled monolayers and carbon nanomaterials. We investigate the structural properties of toroidal crystals and we provide a unified description based on the elastic theory of defects in curved geometries.

8:24AM H39.00003 Hopping Conduction and Bacteria: Transport Properties of Disordered Reaction-Diffusion Systems, ANDREW MISSEL, KARIN DAHMEN, University of Illinois, Urbana-Champaign — Reaction-diffusion (RD) systems are used to model everything from the formation of animal coat patterns to the spread of genes in a population to the seasonal variation of plankton density in the ocean. In all of these problems, disorder plays a large role, but determining its effects on transport properties in RD systems has been a challenge. We present here both analytical and numerical studies of a particular disordered RD system consisting of particles which are allowed to diffuse and compete for resources (2λ → A) with spatially homogeneous rates, reproduce (A → 2A) in certain areas (‘oases’), and die (A → 0) everywhere else (the ‘desert’). In the low oasis density regime, transport is mediated through rare “hopping events” in which a small number of particles diffuse through the desert from one oasis to another; the situation is mathematically analogous to hopping conduction in doped semiconductors, and this analogy, along with some ideas from first passage percolation theory, allows us to make some quantitative predictions about the transport properties of the system on a large scale.

8:36AM H39.00004 Hard Discs on the Hyperbolic Plane, CARL MODES, RANDALL KAMIE, University of Pennsylvania — We examine a simple hard disc fluid with no long range interactions on the two dimensional space of constant negative Gaussian curvature, the hyperbolic plane. This geometry provides a natural mechanism by which global crystalline order is frustrated, allowing us to construct a tractable model of disordered monodisperse hard discs. We extend free area theory and the virial expansion to this regime, deriving the equation of state for the system, and compare its predictions with simulation near an isostatic packing in the curved space.
8:48AM H39.00005 Experimental Observation of Quantized Vortex Reconnection and Turbulence in Superfluid Helium
Matthew PAOLETTI, University of Maryland, KATEPALLI SREENIVASAN, International Centre for Theoretical Physics and University of Maryland, DANIEL LATHROP, University of Maryland — We present experimental studies of the first direct visualization of reconnecting quantum vortices and the decay of superfluid turbulence in $^4$He. Micron-sized solid hydrogen particles are used for particle tracking. The cores of the superfluid vortices trap the hydrogen particles, thereby allowing direct visualization of the dynamics of the line-like defects. We generate superfluid turbulence by driving a thermal counterflow. After pulsing the counterflow, the system relaxes through a cascade of reconnection events. We examine the dynamics of pairs of particles trapped on reconnecting vortices and observe that these particles separate as power laws in time with a scaling exponent distributed about the predicted value of $1/3$. We show that reconnection leads to power-law tails in the velocity probability distribution function, which is in stark contrast to the Gaussian tails that are ubiquitous in classical turbulence and thermal motion.

9:00AM H39.00006 Slippery or sticky boundary conditions: control of wrinkling in metal-capped thin polymer films by selective adhesion to substrates
Hugues VanDeParre, Julien Leopoldes, Christophe Pouillard, Sylvain Desprez, Cyprien Gay, Gwenaelle Derue, Pascal Damman, Laboratoire de Physicochimie des Polymères, Université de Mons-Hainaut Team, Centre de Recherche Paul-Pascal, Université de Bordeaux Collaboration — As demonstrated by countless studies, sheets are more easily bent than stretched. Under planar forces, a thin sheet will thus deform out of plane by forming wrinkles. Surface buckling or wrinkling can be generated in various systems such as rigid thin films supported on elastomers, or gels that could be swollen or dried. Here, we describe an original and simple method to control the spatial layout of wrinkles in polymer/metal bilayer systems. To generate surfaces with a tailor-made buckling pattern, we have tuned the boundary conditions at the polymer-substrate interface using chemically patterned substrates with highly contrasted surface free energies ($\gamma$), easily produced by microcontact printing of alkanethiols on gold substrates. In addition, to explain our original variant of the experiments, we will also expand the existing mechanisms and models described in the literature to take into account the adhesion at the polymer-substrate interface.

9:12AM H39.00007 Shrinky Dinks: Dynamic Shape Transformations
Ajay Gopinathan, Michelle Khine, Arnold Kim, University of California, Merced — Biaxially oriented polystyrene thermoplastic sheets (shrinky dinks) have been recently used by one of us (Khine, Lab on a Chip, 2008) as a template for rapid and non-photolithographic microfluidic pattern generation. This method utilizes the shrinkage properties of the shrinky dinks upon heating to generate microscale structures. During the heating process the sheets show a variety of non-trivial three dimensional intermediate structures before returning to a shrunken flat state upon completion of the process. We show that these structures arise due to the imposition of a non-uniform spatial metric on the sheet which in turn is governed by the dynamic temperature gradients generated in the sheet. Our results allow us to quantitatively describe the dynamic sequence of structures generated and suggest routes to the design and fabrication of different structures in a controlled fashion.

9:24AM H39.00008 The Roll of Friction in the Mechanical Failure Properties of a Polymer Particulate Composite
Donald Wiegand, Brett Reddingius, ARDEC, Picatinny, NJ USA, Kevin Ellis, Claire Leppard, AWE, Aldermaston, U — The mechanical failure properties of a composite containing an organic crystalline particulate and a polymer-plastizer binder have been investigated as a function of hydraulic pressure between 0.1 and 138 MPa. The results indicate that in a low pressure range between about 0.1 and 7.0 MPa crack processes are important in failure. The pressure dependence of the compressive strength is attributed to coulomb friction between surfaces of closed cracks, and from the observed linear increase of the strength with pressure a friction coefficient is obtained. Friction coefficients can also be obtained from the ratio of compressive to tensile strength and in addition from the angle which the failure plane makes with the direction of the applied stress. Both at 0.1 MPa and 138 MPa friction coefficients were obtained from these three separate observations in agreement and this is taken as strong evidence for the importance of this friction in determining strength and mechanical failure for this composite.

9:36AM H39.00009 Force-driven transport in entropy barriers
Kevor Kevorkian, Nabil Laachi, Martin Kenward, University of Minnesota, Ehud Yariv, Technion — We consider theoretically the transport of a point-sized Brownian particle in a two-dimensional channel with a slowly varying, periodic cross-section. Such channels are associated with the concept of an “entropy barrier,” where the change in the number of available states for a system depends on the transport through the channel. Using generalised Taylor-Aris dispersion theory and long-wavelength asymptotics, we exactly compute the mean particle velocity and effective diffusivity (dispersivity) for two cases: electrohydroptic transport in an insulating channel and motion under the influence of a constant force. At the same time, we arrive at rational definitions for the concept of an entropy barrier as a function of the driving force. The agreement between simulations and the exact calculation for a constant force is excellent and represents a significant advance over existing models of the transport process.

9:48AM H39.00010 Friction and wear of nanocrystalline diamond coatings
Abhishek Kothari, Brian Sheldon, Brown University, Xingcheng Xiao, GM research, Kyung-Suk Kim, Brown University, Leo Levy, GM — Nanocrystalline diamond films were tested for friction and wear response using a pin on disc tribometer. COF, starting with 0.7 successively drops to 0.1 as the wear progresses. Understanding this friction and wear response is important to minimize wear of these materials as tool coatings. SEM images at the periphery of wear tracks indicate the presence of ring cracks which are due to stress at the circle of contact exceeding the tensile strength. Effects of engineering the stress on the wear have been verified experimentally. Estimation of wear rate in these coatings is of high importance. AFM was used to obtain topography information on wear tracks of the film successively after 2K-200K pin revolutions in the tribometer. It is noted that peak heights of the asperities were decreasing with wear. Image analysis of the topographical evolution of the successive wear tracks could provide an estimation of the wear rate. This analysis also indicates that the distribution ofasperity contact size shifts towards larger size with successive wear of the film. Previous studies of Krim, Hurtado and Kim revealed that the frictional stresses of individual asperities are dependent on theasperity contact sizes — the larger the asperity contact size, the lower the frictional stresses. The micromechanics model ofasperity friction explains well the decreasing coefficient of friction with progression of wear.

10:00AM H39.00011 Ultra-high vacuum cryotribology of diamond and diamond-like films
Matthew Aggleton, P. Taborek, University of California, Irvine — We have used a sliding block tribometer (described in J.C. Burton, P. Taborek, and J.E. Rutledge, TRIBOLOGY LETTERS 23, 131, 2006) to measure the temperature dependence of the kinetic friction coefficient of single crystal diamond on various types of CVD diamond films including microcrystalline diamond, nanocrystalline diamond, and diamond-like carbon. We have also studied various other solid and fluid lubricants. These measurements have been performed in ultra-high vacuum and at temperatures ranging from 6 to 300 Kelvin. Although microcrystalline diamond has a low friction coefficient in air, in vacuum, the friction coefficient rises to approximately 0.7 and is independent of temperature. Nanocrystalline diamond is a much better tribological material in vacuum, particularly for T $>$ 240K. Near 240K there is a reversible transition to a higher friction state. We will discuss the correlation between the tribological properties and the material properties such as sp2/sp3 ratio, hydrogen content, and grain size. This work is supported by Extreme Friction: MURI AFOSR # FA9550-04-1-0381.
10:12AM H39.00012 Quartz Crystal Microbalance Studies of Temperature Rise in a Sliding Contact, JACQUELINE KRIM, BENJAMIN DAWSON, MATTHEW WALKER, CHERNO JAYE, DOUGLAS IRVING, DONALD BRENNER, North Carolina State University — The exact relation between temperature rise in a sliding contact and frictional energy dissipation is of great technological importance, but poorly understood at a fundamental level. Temperature rise is presumably due to frictional heating that results from phononic and electronic excitations, but efforts to relate temperature rise to friction and sliding velocity have proven very difficult. We have performed QCM studies of adsorbed Krypton monolayers, and also joint QCM-STM studies, to examine temperature rise associated with friction in two well characterized geometries. In the first, we utilized the static phase diagram of two-dimensional Kr adsorbed on graphite as compared to the dynamic phase diagram (with the Kr layer sliding) to determine temperature rise. In the second study, we have recorded frequency shift data for a QCM with indium electrodes in contact with an STM tip while increasing the sliding speed to a point where melting is indicated. A temperature rise on the order of 10 (40-100) degrees is observed in the first (second) geometry. Comparisons to theory yield plausible fit parameters.

10:24AM H39.00013 Combined ab initio and classical molecular dynamics simulations of the tribological properties of rare gas monolayers sliding on metal surfaces, MARIA CLELIA RIGHI, CNR-INFM S3 National Research Center, Via Campi 213/a Modena, Italy, MAURO FERRARIO, Universita' di Modena e Reggio Emilia — Progress in the ability of understanding tribological properties in adsorbed film systems is of paramount importance to unravel fundamental issues in the emerging field of nanoscale science and technology. Many extensive studies have used a quartz-crystal microbalance (QCM) to measure the friction between adsorbed rare gas monolayers and metal substrates. In this work, we report a theoretical investigation of the tribological behavior of different rare gas-metal adsorbate systems, namely, Ar, Kr, Xe on Cu(111), and Xe on Ag(111), based on combined ab initio and classical molecular dynamics simulations. The frictional properties are analyzed in details as a function of system temperature, presence of interlayer defects, and load. The numerical simulations suggest that the simultaneous presence of thermal effects and of interlayer defects, lowering significantly the activation energy barrier, causes a considerable reduction of the static friction threshold. An unexpected dependence on load is also predicted. In particular, we show that friction of anticorrupting systems can be dramatically decreased by applying an external load [1]. The counterintuitive behavior that deviates from the macroscopic Amonton law is dictated by quantum mechanical effects that induce a transformation from anticorruption to corrugation in the near-surface region. [1] M. C. Righi and M. Ferrario, Phys. Rev. Lett. 99, 176101 (2007).

10:36AM H39.00014 Solid-fluid transitions at high sliding rates at Al/Al interfaces, J.E. HAMMERBERG, B.L. HOLIAN, Los Alamos National Laboratory, R. RAVELO, University of Texas, El Paso, T.C. GERMANN, Los Alamos National Laboratory — Large scale NonEquilibrium Molecular Dynamics (NEMD) simulations (1.4 \times 10^6 \text{ atoms}) for single crystal Al have shown a transition as a function of sliding velocity from a defective solid phase to a fluid phase beyond a critical velocity, \( v_c \), which depends very nearly linearly with the homologous temperature \( T/T_m \), where \( T_m \) is the melting temperature and \( T \) is the sample temperature far from the interface. Above \( v_c \), a Couette flow pattern develops with a slope which is independent of velocity. We discuss the properties of this transition and the power law dependence of the frictional force with velocity observed in this regime.

Session H40 DMP DCOMP: Focus Session: Earth and Planetary Materials I Morial Convention Center 232

8:00AM H40.00001 Elasticity of (Mg,Fe)O through the spin transition of iron in the lower mantle, JONATHAN CROWHURST, Lawrence Livermore National Laboratory — Recently, the important question of spin-pairing transitions of iron from high-spin (HS) to low-spin (LS) states in ferropericlase (Ref. 1 and references therein) affecting the lower mantle’s density and seismic-wave velocities has been recognized (2,3). Since knowledge of this deep and inaccessible region is derived largely from seismic data, it is essential to determine the influence of the spin transition on elastic wave velocities at lower-mantle pressures. We here discuss the results of measurements of the elastic tensor of (Mg,9.4Fe0.6)O up to 60 GPa using impulsive stimulated light scattering. We find that all tensor elements soften substantially through the HS to LS transition, and that the softening occurs over an extended pressure range from 40 GPa to at least 60 GPa at room temperature. By invoking a simple thermodynamic description (4) of the transition we can compare our results to literature compression data (2,5) obtained from material with the higher iron concentrations likely to be found in ferropericlase in the lower mantle. The agreement is good and thus suggests that the thermodynamic description is reasonable. This in turn allows us to predict the effect of high temperature on the transition; we find that as temperature is increased the transition region is extended (see also Ref. 6) and the magnitude of the softening decreases. We conclude that although the spin transition in (Mg,Fe)O is too broad to produce an abrupt seismic discontinuity in the lower mantle, the transition will produce a correlated negative anomaly for both compressional and shear velocities that extends throughout most if not all of the lower mantle.

This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory in part under Contract W-7405-Eng-48 and in part under Contract DE-AC52-07NA27344.

8:36AM H40.00002 Elasticity of ferropericlase at Earth’s lower mantle conditions, RENATA WENTZCOVITCH, JOAO JUSTO, ZHONGQING WU, CESAR DA SILVA, U of Minnesota — The thermoelastic properties of ferropericlase Mg1-xFe xO (x = 0.1875) across the iron high-to-low spin crossover at lower mantle conditions have been investigated by combining first principles calculations with a thermodynamics model of this system. At room temperature the transition is somewhat sharp and the effect on the bulk modulus is quite dramatic. Along a typical geotherm the transition should occur across most of the lower mantle with a noticeable bulk modulus reduction in the mid lower mantle. This transition should also alter noticeably the magnitude of velocity heterogeneities caused by lateral temperature changes.

8:48AM H40.00003 Inter-site Partitioning of Iron in Wadsleyite at High Pressures. ROSE PEREA, BORIS KIEFER, Department of Physics, New Mexico State University — (Mg1-x,Fex)2SiO4 — wadsleyite is thought to be the most abundant metal in the upper part of the Earth’s transition zone (410 -520 km depth). Wadsleyite contains three crystallographically non-equivalent octahedral sites, M1, M2, and M3. Experimentally, it has been observed that the M2 site is depleted in iron relative to the M1 and M3 sites. This asymmetric partitioning may affect the melting temperature and the density of iron bearing wadsleyite and influence the transport of mass, momentum, and energy across the transition zone. We performed LDA and GGA first-principle calculations of ferrous iron substitutions in the three crystallographically distinct octahedral sites: M1, M2, and M3. At low pressures, we find that the pressure sensitivities of the iron occupancies are consistent with the experimental observations that the M2 site is depleted in iron and independent of the magnetic moment of iron. This finding indicates that the inter-octahedral site partitioning of iron is due to the presence of the d-orbitals. If this finding can be corroborated our results will affect the understanding of the partitioning of other divalent transition metals and geochemical trace elements in wadsleyite, the most abundant mineral in the upper part of the Earth’s transition zone.

9:00AM H40.00004 First principles studies on several major phase transitions in Earth upper mantle. YONGGANG YU, Univ. of Minnesota, ZHONGQING WU, U of Minnesota, RENATA WENTZCOVITCH, U of Minnesota, CHEMICAL ENGINEERING AND MATERIALS SCIENCE TEAM — First principles quasi-harmonic free energy calculations have been conducted to study several important phase transitions in mantle minerals with compositions Mg2SiO4 and MgSiO3 under realistic Earth’s mantle conditions. We find encouraging and similar level of agreement with experiments for thermodynamic and vibrational properties and phase transition boundaries in all cases where comparisons between results and data are possible. We also find systematic trends: 1) equations of state and thermodynamic properties of single crystalline phases are best described by the LDA; 2) phase boundaries are bracketed by LDA and GGA results, with GGA offering the upper bound transition pressure and being somewhat closer to the experimental ones. A summary of these results is offered for forsterite, wadsleite, ringwoodite, periclase, perovskite, post-perovskite, low clin-, and high clin-enstatite, and garnet, as well as phase transitions between them. In overall these results can supplement high-PT experimental data on these minerals. (Research supported by NSF/EAR 013533, 0230319, 0635990, and NSF/ITR 0428774 (VLab), and Minnesota Supercomputing Institute.)

9:12AM H40.00005 The Phase Diagram of Portlandite, Ca(OH)2 at Pressures up to 40 GPa. BORIS KIEFER, MEGAN LOCKWOOD, Department of Physics; New Mexico State University — Hydroxides have attracted significant scientific interest over the past decades. They have been used as analogues to further our understanding of hydrogen bonding in complex materials. Several experimental observations suggest that portlandite undergoes reversible solid state amorphization at high pressures but the cause for this transition and its appearance in portlandite remains unknown. We performed static (0 K) first-principle calculations based on the GGA within the framework of Density-Functional-Theory in order to explain the phase diagram of portlandite for pressures up to 40 GPa. All structures were fully relaxed to determine the ground state energy. We find that a split-site model for the hydrogen array is energetically preferred consistent with neutron diffraction experiments. At a pressure of ~4.5 GPa we observe a phase transition from trigonal to monoclinic symmetry in agreement with previous studies. At all higher pressures we find that the monoclinic structure is the ground state of portlandite. However, we identified several energetically comparable structures. This indicates that the potential energy surface of portlandite has a surprisingly complex structure. The interplay of these structures suggest that the solid state amorphization is driven by non-hydrostatic stress and allows to rationalize experimentally observed differences between portlandite powders and single-crystals.

9:24AM H40.00006 High PT elasticity within the quasiharmonic approximation with relaxed thermal stresses. PIERRE CARRIER, JOAO F. JUSTO, RENATA M. WENTZCOVITCH, Department of Chemical Engineering and Materials Science and Minnesota Supercomputing Institute, University of Minnesota, Minneapolis, 55455. — We describe in detail a method to compute high PT elasticity within the quasiharmonic approximation (QHA). This approach differs from the usual formulation used to compute the statically constrained high PT elastic constants by including corrections due to deviatoric thermal stresses. The formulation is general and valid for crystals with up to triclinic symmetry. We use perovskite and post-perovskite phases of MgSiO3 to exemplify the use of the method to calculate elasticity and crystal structures at high PT.

9:36AM H40.00007 Quantum Monte Carlo Study of Elastic Instability in Stishovite. K.P. DRIVER, Ohio State, R.E. COHEN, Carnegie Institution of Washington, P.L. RIOS, M.D. TOWLER, R.J. NEEDS, Cambridge, J.W. WILKINS, Ohio State — Stishovite is an octahedrally coordinated polymorph of silica which is stable at pressures within Earth’s lower mantle (10 GPa). Elastic properties of stishovite are important for explaining seismic structure and it serves as a model system for other six-coordinated silicates. Near 50 GPa, stishovite transforms to the CaCl2-type structure due to an instability in the elastic shear modulus. The instability was first predicted by density functional theory (DFT) calculations and later confirmed by Raman spectroscopy and X-ray diffraction. Quantum Monte Carlo accurately predicts elastic constants and benchmarks previous DFT results on the stishovite elastic instability. Over the pressure range of 0 to 50 GPa, QMC shows the elastic shear modulus softens from 270 to 0 GPa in agreement with previous DFT and experimental results. Computations were performed at NERSC. Funding provided by the NSF (EAR-0530282, EAR-0310139) and the DOE (DE-FG02-99ER45795).

9:48AM H40.00008 Pressure dependence of lattice anharmonicity and phonon lifetime in MgO: a first-principles calculation and implications for lattice thermal conductivity. XIAOLI TANG, JIANJUN DONG, Auburn University — We report a recent first principles calculation of harmonic and anharmonic lattice dynamics of MgO. The 2nd order harmonic and 3rd order anharmonic interatomic interaction terms are computed explicitly, and their pressure dependences are discussed. The phonon mode Grüneisen parameters derived based on our calculated 3rd lattice anharmonicity are in good agreement with those estimated using the finite difference method. The phonon lifetime due to lattice anharmonicity is calculated based on the single mode excitation approximation (SMEA). We have further estimated the isotope effect on phonon lifetime within the random mass disorder approximation. The implications for lattice thermal conductivity at high pressure are discussed based on a simple kinetic transport theory.

10:12AM H40.00010 First-principles study of MgSiO₃ at core-mantle boundary conditions.
SIU-CHUNG SUNG, The Chinese University of Hong Kong; JONES TSZ-KAI WAN — Perovskite MgSiO₃, is an important mineral in geoscience studies. It
plays a crucial role in the understanding of geophysical and geochemical activities taken place in the Earth’s interior. In this talk, we report our recent work on
First-principles molecular dynamics (FPMD) simulations of solid MgSiO₃ perovskite and post-perovskite, and molten MgSiO₃ at core-mantle boundary (CMB)
conditions. The equations of state are determined at pressures up to 200 GPa and temperatures up to 6000K. The post-perovskite phase is found to be favoured
over the perovskite at pressures above 102 GPa at zero temperature. Melting of MgSiO₃ has been observed by heating both perovskite and post-perovskite at high
temperatures (≥6000 K). The melting curve and electronic structures of solid and molten MgSiO₃ are also presented. Our simulated results thus provide
useful constraints on structure and phase stability of MgSiO₃, which is the key to the understanding of deep-earth phenomena, such as the D''' discontinuity and
seismic anisotropies in D'' layer. More importantly, the phase transformation of MgSiO₃ studied in this work provides insights into other aspects of geosciences
like chemical heterogeneity and mantle convection, which may lead to a better model of the Earth’s evolution.

11:15AM J1.00001 Oliver E. Buckley Prize Talk: Why are we so excited about carbon nanostructures?
MILDRED DRESSELHAUS, MIT — There is much current excitement about the interesting new physics and unusual physical properties of carbon nanostructures, particularly carbon nanotubes and graphene. A brief review will be given of the physical underpinnings of carbon nanostructures that were developed over the past 60 years, starting with the electronic structure and physical properties of graphene and graphite, and then moving to graphene intercalation compounds which contained the first carbon nanostructures to be studied experimentally. Liquid carbon studies were precursors to the fullerene family of nanostructures and vapor grown carbon fibers were precursors to carbon nanotubes. Particular emphasis is given to the recent developments in our understanding of the photophysics of carbon nanotubes and graphene, with perspectives on future research directions for these fields.

JULIA PHILLIPS, Sandia National Laboratories — Securing a viable, carbon neutral energy future for humankind will require an effort of gargantuan proportions. As outlined clearly in a series of workshops sponsored by the DOE Office of Basic Energy Sciences (http://www.sc.doe.gov/bes/reports/list.html), fundamental advances in scientific understanding are needed to broadly implement many of the technologies that are held out as promising options to meet future energy needs. Technologies of interest range from solar energy, to nuclear energy, to approaches to clean combustion. Using solid state lighting based on inorganic materials as an example, I will discuss some recent results and new directions, emphasizing the multidisciplinary, team nature of the endeavor. I will also offer some thoughts about how to encourage translation of the science into attractive, widely available products – a significant challenge that cannot be ignored. This case study offers insight into approaches that are likely to be beneficial for addressing other aspects of the energy security challenge.

12:27PM J1.00003 James C. McGroddy Prize Talk: Superconductivity in alkali-metal doped Carbon-60
ARTHUR HEUBARD, University of Florida — Carbon sixty (C₆₀), which was first identified in 1985 in laser desorption experiments, is unquestionably an arresting beautiful molecule. The high symmetry of the 12 pentagonal and 20 hexagonal faces symmetrically arrayed in a soccer-ball-like structure invites special attention and continues to stimulate animated speculation. The availability in 1990 of macroscopic amounts of purified C₆₀ derived from carbon-arc produced soot allowed the growth and characterization of both bulk and thin-film samples. Crystalline C₆₀ is a molecular solid held together by weak van der Waals forces. The fcc structure has a 74% packing fraction thus allowing ample opportunity (26% available volume) for the intercalation of foreign atoms into the interstitial spaces of the three dimensional host. This opportunity catalyzed much of the collaborative work amongst chemists, physicists and materials scientists at Bell Laboratories, and resulted in the discovery of superconductivity in alkali-metal doped C₆₀ with transition temperatures (T_c) in the mid-30-kelvin range. In this talk I will review how the successes of this initial team effort stimulated a worldwide collaboration between experimentalists and theorists to understand the promise and potential of an entirely new class of superconductors containing only two elements, carbon and an intercalated alkali metal. Although the cuprates still hold the record for the highest T_c, there are still open scientific questions about the mechanism that gives rise to such unexpectedly high T_c's in the non-oxide carbon-based superconductors. The doped fulleranes have unusual attributes (e.g., narrow electronic bands, high disorder, anomalous energy scales, and a tantalizing proximity to a metal-insulator Mott transition), which challenge conventional thinking and at the same time provide useful insights into new directions for finding even higher T_c materials. The final chapter of the 'soot to superconductivity' story has yet to be written.

1:03PM J1.00004 James C. McGroddy Prize Talk: What Was New About C60
ROBERT HADDON, University of California at Riverside — C₆₀ was named molecule of the year by Science in 1991, and in this talk I will discuss what I consider to be the most novel features of the molecule. In some ways C₆₀ is truly unique and the discovery of the molecule in 1985 and its subsequent synthesis in 1990 blazed a trail of new chemical and physical properties that is unlikely to be surpassed by any other molecule. I will discuss the electronic structure of C₆₀, its magnetism, and the conductivity and superconductivity shown by the alkali metal-doped phases.

12:27PM J2.00003 Condensed Matter Theory: From Models to First Principles1, MARVIN COHEN, University of California, Berkeley — It can be argued that modern condensed matter theory (CMT) started 100 years ago. Models of materials explained many solid state phenomena and properties. However, only in the past 50 years—during the “PRL Era”—can it be argued that a significant number of ab initio calculations for real materials have been done. After some historical comments, the primary conceptual models will be described. This discussion will be followed by examples of current theoretical work on explaining and predicting properties and phenomena associated with “real materials.”

1This work was supported by National Science Foundation Grant No. DMR07-05941, and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231.

1:03PM J2.00004 NMR and the BCS Theory, CHARLES P. SLICHTER, University of Illinois at Urbana-Champaign — The talk will review the status of superconductivity research in the early 1950s, Bardeen’s thoughts about the role of an energy gap in producing superconductivity, our ideas that NMR experiments might test his ideas, and about the experimental challenge my student Chuck Hebel and I had to overcome: How can one do NMR in a perfect diamagnet (which therefore excludes magnetic fields!), the surprising results we found, then the arrival of the theory of Bardeen, Cooper, and Schrieffer, and how applying their theory to relate NMR to ultrasonic absorption verifies the essential idea of the theory (their wave function of electron pairs).

Tuesday, March 11, 2008 11:15AM - 2:15PM — Session J3 DCMP: Kondo Screening and Quantum Criticality from the Spatial Limit: From Single Spins to Droplets to Lattices Morial Convention Center RO2 - RO3

11:15AM J3.00001 How does a Kondo impurity respond to its local environment?1, ANDREAS HEINRICH, IBM Research — The interplay between localized electrons on a magnetic atom and the conducting electrons in a metal can lead to intriguing many-body ground states such as the Kondo effect. When a spin is Kondo screened by conduction electrons the entire spin system performs a complicated dance that results in the formation of a spin singlet at sufficiently low temperature. For simplicity, most theoretical considerations of Kondo screening focus on magnetic impurities with the lowest possible spin $S = 1/2$. Such systems can be studied experimentally in exquisite detail and with great control using quantum dots in semiconductor heterostructures or carbon nanotubes. However, in Kondo systems consisting of localized magnetic atoms, the spin is often larger, making the Kondo effect richer and more complex. Here we use the imaging and spectroscopy capabilities of a scanning tunnelling microscope to study how the Kondo screening of a known high-spin atom is determined by its local environment. Co and Ti atoms were deposited on a thin insulating layer ($Cu_2$) on a copper substrate. We study the influence of external magnetic fields, crystalline magnetic anisotropy, as well as spin-coupling to surrounding atomic spins on the Kondo effect that forms on the Co or Ti atoms. We find that the anisotropy of the crystalline field quenches the high-spin system of Co ($S = 3/2$) into an effective $S = 1/2$ Kramers doublet. Surprisingly, much of the impact of these environmental factors on the complex many-body ground state can be understood simply through their effects on the energy levels of the unscreened spin.

1This work was done in collaboration with A.F. Otte, C.F. Hirjibehedin, H. Brune, M. Ternes, and C.P. Lutz.
11:51AM J3.00002 Geometric Manipulation of Quantum Phase and Correlations in Nanoassembled Spin Systems*1, HARI C. MANOHARAN, Department of Physics, Stanford University — The single-impurity Kondo problem, in which an isolated magnetic impurity in a non-magnetic metallic host has its spin screened by spins of conduction electrons, has been extensively studied both theoretically and through bulk experiments. Recently new methods have allowed detailed experimental probing of the prototype single-impurity Kondo effect of individual magnetic atoms. In addition, spin interactions with confined electron states were used to materialize “quantum mirages” consisting of a nonlocal single-impurity Kondo effect. When many spin and spatial states are present in a bulk conductor or on its surface, the interactions between them may engender novel collective effects. Using a scanning tunneling microscope we assembled and studied atomically precise arrangements of (magnetic) Co atoms and (non-magnetic) CO molecules on the Cu(111) surface. The spin degeneracy of single magnetic atoms and the conduction electrons alone provide necessary ingredients for Kondo physics. When combined with quantum resonators, Kondo phase shifts can be measured by using the nanostructures as quantum interferometers. We study the effects of adding to the degeneracy of the system in two controlled ways: engineering degeneracies in the spatial states of confined electrons coupled to the spins, and engineering lattices of many spins coherently coupled through electrons. The first type of experiment has enabled a novel method to read out and geometrically manipulate the quantum phase associated with state superpositions. The second class of experiments has enabled investigation of the finite size spin physics of Kondo droplets. In these periodic structures we observe signs of quantum interference and spin correlation effects when the geometries are suitable tuned relative to the Fermi wavelength of the host electron systems. These new quantum materials act as model systems for understanding complementary physics in complex matter.

*This work was done in collaboration with L. S. Mattos, C. R. Moon, B. K. Foster, G. Zeltzer, and C. P. Lutz.

12:27PM J3.00003 Kondo Physics at the Nanoscale*1, DIRK MORR, University of Illinois at Chicago — Recent experimental advances have made it possible to study the Kondo effect in nanoscale structures. These achievements are of great importance because they do not only allow us to manipulate the Kondo screening of single magnetic impurities, but also provide us with the unique opportunity to study how Kondo screening and coherence evolve on different length-scales from a single Kondo impurity to the Kondo lattice. In this talk, I present two examples of novel Kondo physics emerging in nanostructures. First, I demonstrate that the presence of electronic eigenmodes in a nanostructure gives rise to unconventional properties of a Kondo screened magnetic impurity [1]. In particular, the Kondo temperature, $T_K$, of a magnetic impurity located inside the nanostructure varies with the impurity’s location and is determined by the eigenmodes’ spatial structure. Moreover, the modes’ frequency dependence leads to a linear relation between $T_K$ and the local density of states, in stark contrast to the conventional Kondo effect. Second, I discuss Kondo screening and the onset of coherence in finite size Kondo lattices, so-called Kondo droplets. I show that in such Kondo nanostructures, the hybridization and the coherent coupling of the Kondo resonances can be resonantly enhanced or suppressed via changes in the droplet’s geometry and lattice constant. Moreover, I demonstrate how these properties of the Kondo droplet evolve with increasing droplet size. Finally, I discuss how the ability to manipulate the properties of Kondo droplets might provide novel insight into the origin of quantum criticality, which is a central point in understanding the unconventional non-Fermi liquid properties of Kondo lattice systems, such as the heavy-fermion materials.

1:39PM J3.00005 Quantum Criticality in 3He bi-layers, CATHERINE PEPIN, SPHT, CEA-Saclay — No abstract available.

11:15AM J4.00001 Scientists in an alternative vision of a globalized world*1, AYSE ERZAN, Department of Physics, Istanbul Technical University, Maslak, Istanbul — Why should “increasing the visibility of scientists in emergent countries” be of interest? Can increasing the relevance and connectedness of scientific output, both to technological applications at home and cutting edge basic research abroad contribute to the general welfare in such countries? For this to happen, governments, inter-governmental and non-governmental organizations must provide incentives for the local industry to help fund and actively engage in the creation of new technologies, rather than settling for the solution of well understood engineering problems under the rubric of collaboration between scientists and industry. However, the trajectory of the highly industrialized countries cannot be retraced. Globalization facilitates closer interaction and collaboration between scientists but also deepens the contrasts between the center and the periphery, both world wide and within national borders; as it is understood today, it can lead to the redundancy of local technology oriented research, as the idea of a “local industry” is rapidly made obsolete. Scientists from all over the world are sucked into the vortex as both the economic and the cultural world increasingly revolve around a single axis. The challenge is to redefine our terms of reference under these rapidly changing boundary conditions and help bring human needs, human security and human happiness to the fore in elaborating and forging alternative visions of a globalized world. Both natural scientists and social scientists will be indispensable in such an endeavor.

*Partial support from the Turkish Academy of Sciences is gratefully acknowledged.
11:45 AM J4.00002 Globalizing Science and Engineering, VENKATESH NARAYANAMURTI, Harvard University — In this talk I will review recent trends in Science and Engineering Research and Education in an increasingly interconnected, “flat” world. The enormous economic transformation being fueled by technology will, over a period of time, lead to new models of interaction among universities, industry and governments. Scientists and Engineers in “emergent” countries may be expected to play a key role in this “new” world order.

12:15 PM J4.00003 The Mutual Benefit of International Research Interactions, MONICA OLVERA DE LA CRUZ, Northwestern University — Emergent economies provide a fruitful source of scientific knowledge. We have the responsibility to nurture interactions to increase scientific knowledge in the world. Moreover, we have benefited greatly from discoveries and education provided to scientists and engineers in emergent economies. I will give examples of successful modes of interactions between the US and emergent economies, and in particular with Latin American countries. I will review the impact of our interactions in their countries and in ours, and ways to increase the impact.

12:45 PM J4.00004 The Invisible Scientist in India – a case study for emergent countries, ANITA MEHTA, S D Bose National Centre — Emergent countries such as India, China, and Brazil, face unique problems in the realisation of their science and technology potential. I will discuss the situation in India, which may be relevant at least in part to the others. The basic focus of the talk will be the possible ways in which the invisible scientist, the person on the ground who has no part in the pyramid of the science establishment, can be rendered more visible both for her or his own sake, and to prevent the erosion of an enormous intellectual potential by a still continuing brain drain.

1:15 PM J4.00005 Panel Discussion —

Tuesday, March 11, 2008 11:15AM - 1:39PM —
Session J5 CSWP FGSA: Where is the Center of Mass for Family, Career, and Self? Morial Convention Center R01

11:15 AM J5.00001 Career Planning in Harmony with Family Values and Needs, ARCHANA DUBEY, UCF — Balancing career and family! Balancing what you love and who you love!! It is such an attention getting topic. And yet, if you really think about it, people have been doing it for ages. What makes it challenging in today’s world is the dual income families that throw off-balance of traditional style of balancing family and profession. Balancing family and career is not as difficult. The question is more meaningful when you ask how do you find the right balance, and in fact, what is the right balance? How do you know you are there? Happiness at home and self esteem due to work is genderless issue however, it is essentially talked more in the context of women. Some of the things that could be helpful in achieving the right balance, are time management, proper prioritization, asking for help, a caring family, friends, and most importantly colleagues. In the portfolio of professional passions, it is important to identify the areas that are conducive to possibilities of changing family needs, international families, spouse’s career and job relocation, etc. So, the bottom line question is whether it is possible to find a right balance between family and career? I would submit to you that with passion, courage, open-mindedness, and proper career planning, it is definitely possible. We just need to utilize the same techniques in choosing and sustaining the right balance that we use in identifying research topics and executing it. This discussion will look into further details of the challenges of balancing family and career from the perspective of also an immigrant, and possible ways of overcoming them.

11:51 AM J5.00002 Faculty Work-Family Issues: Finding the Balance at a Liberal Arts College, SUZANNE AMADOR KANE, Physics Department, Haverford College — The demands and expectations on science faculty at liberal arts colleges are in many ways distinct from those at research universities. While these differences can work in favor of easing work-family conflicts, there are also unique problems that faculty can confront in a setting of smaller departments and undergraduate-only institutions. I will discuss how these issues play out for junior and senior faculty, with an emphasis on how concrete policy changes can make the workplace a more family-friendly and supportive environment for all faculty, as well as making liberal arts colleges more attractive options for those seeking physics faculty jobs.

12:27 PM J5.00003 The eye of the storm: Balancing my storm of family, career and self, K. RENEE HORTON, University of Alabama — In knowing that the path I travel is not the usual path traveled by most; this has turned out to be the best path for me and my family. It is very important to prioritize what is important to you and then define the best path for you versus choosing a path and the path chooses your priorities. Coming from a loving and supportive middle class upbringing created a deep sense of family and the importance of family. Early in my life I was determined to have children and a career. Over the last ten years there have been several obstacles to overcome in my storm, but with careful planning, due diligence, and a support system to help maintain calm at the center of my storm I have been able to achieve my goals of pursuing my Doctorate. A complete research plan was put into place into choosing the institution that I would further my academic endeavors in the same manner in which my dissertation research topic has been defined. Just as any successful business, all persons involved in my future success were consulted with equal input into the new endeavor with the full understanding of what this new plan entailed. We decided on the University of Alabama for several reasons: location, weather, flexibility, policies, research and my ability to make a change in the face of science. According to my advisor, I will do that in about two and half years at my graduation ceremony when I become the first African American to receive a PhD in Material Science from the University of Alabama.

1:03 PM J5.00004 Balancing academic career and children: a personal perspective, NINA MARKOVIC, Johns Hopkins University — For women in academia, the tenure review and the desire to have children often happen around the same time. How does one cope with the challenges of an academic career while raising small children? From a personal perspective of an assistant professor and a mother, I will discuss the great challenge of efficient time management and the practical strategies to deal with it.

Tuesday, March 11, 2008 11:15AM - 2:15PM —
Session J6 DCOMP: Effective Potentials and Force Fields for Simulating Biological Macro-molecules Morial Convention Center R04
11:15AM J6.00001 Artifact or reality? Force field issues in the simulation proteins and nucleic acids\(^1\), THOMAS CHEATHAM, University of Utah — Access to ever-increasing computational power is providing the means to critically evaluate the performance of atomistic force fields of biomolecules. With greater sampling, and more detailed comparisons to experiment, limitations and artifacts in the applied simulation protocols and force fields can be discovered and ultimately overcome. Additionally, we are able to more carefully validate and assess the performance of the simulations in comparison with experiment. In this talk, we will outline our experiences in large-scale simulations of protein and nucleic acid systems in the context of the AMBER biomolecular simulation program. Issues related to salt and dihedral parameters will be highlighted in applications ranging from ligand-induced remodeling of dihydrofolate reductase and cytochrome P450 2B4 protein structures to large-scale decoy sets and NMR comparisons of various RNA structures.

\(^1\)Computer time from NSF LRAC MCA0115027 and U. Utah CHPC is greatly acknowledged.

11:51AM J6.00002 Development of a polarizable force field based on the classical Drude oscillator\(^1\), ALEXANDER MACKERELL, Department of Pharmaceutical Sciences, School of Pharmacy, University of Maryland — Empirical force field development requires a systematic approach allowing for the development of a practical potential energy function and optimization of physically realistic parameters that reproduce a range of target data. Ongoing efforts in our laboratory include the development of a polarizable force field based on the classical Drude oscillator for a range of molecules representative of biological systems. A central theme in these efforts is the accurate treatment of both atomic interactions as well as condensed phase properties. To achieve this goal extensions of the energy function have been implemented and parameter optimization has been performed targeting a variety of quantum mechanical results and experimental condensed phase properties. An overview of these studies will be presented.

\(^1\)Financial support from the NIH (GM051501 and GM072558) is acknowledged.

12:27PM J6.00003 The AGBNP implicit solvent model: recent advances and applications to biological macromolecules\(^1\), EMILIO GALLICCHIO, BioMaPS Institute, Rutgers University — The Analytical Generalized Born plus Non-Polar (AGBNP) model is an analytical implicit water model suitable for molecular dynamics simulations of small molecules and macromolecules. It is based on an analytical pairwise descreening implementation of the continuum dielectric Generalized Born (GB) model and a non-polar hydration free energy model. AGBNP computes the descreening scaling factors that account for atomic overlaps from the geometry of the solute rather than treating them as geometry-independent parameters fit to numerical or experimental data. The non-polar hydration free energy model is decomposed into a cavity component based on the solute surface area and a solute-solvent van der Waals dispersion energy estimator. The goal of the model is to achieve atomic-resolution accuracy for modelling the many biological systems in which global conformational features are regulated by small and localized control elements. Since its introduction AGBNP has been employed to study a variety of biological problems ranging from peptide conformational propensity and folding, protein allostery, conformational equilibria of protein-ligand complexes, binding affinity prediction, and, more recently, to intrinsically disordered proteins, protein aggregation, the design of virus vaccine carriers, and macromolecular X-ray structure refinement. Recent development work has focused on computational performance enhancements and on improving the accuracy of the model with respect to explicit solvent simulation results. By comparing the details of the solvent potentials of mean force of several peptides calculated with explicit and implicit solvation, we have identified some aspects of the AGBNP model in need of improvement. We are exploring several strategies to address them including the adoption of a molecular surface description of the solute volume, the modelling of high-occupancy hydration sites, and the optimization of the non-polar free energy model.

1:03PM J6.00004 Atomic-level simulations of biomolecular systems with a modified Amber force field\(^1\), CARLOS L. SIMMERLING, Stony Brook University — Experimental methods have been highly successful in determining 3-dimensional biomolecular structures. However, most approaches provide only time- or ensemble-averaged data, making it much more difficult to study the dynamic and energetic aspects of biological systems. Atomic-resolution simulations are highly complementary to experiments, and can provide data with unparalleled resolution in time and space. Due to the long timescales of biologically relevant events, as well as the complexity of the energy function, accurate and precise simulations remain highly computationally challenging. This seminar will highlight recent progress in both areas, illustrating how energy functions that have been trained on simple peptide models can be successfully used for the study of much more complex systems. We demonstrate that our newly trained energy parameters significantly reduce the secondary structure bias reported for previous Amber parameter sets. Applications of the parameters include studies of folding behavior of peptides and small proteins, and the dynamic behavior of larger biomolecular systems such as conformational changes during drug binding in HIV-1 protease.

1:39PM J6.00005 Beyond force fields. QM/MM conformational searches in biomolecules using Replica Exchange molecular dynamics\(^1\), ADRIAN ROITBERG, Department of Chemistry, University of Florida — Force fields have been extremely successful for our understanding of structure, energetics and dynamics of biomolecules. However, they neglect, for the most part, quantum effects such as charge transfer and polarization. In this talk I will present our work using our newly developed QM/MM interface in the program Amber, which can very efficiently treat small peptides in explicit solvent using a number of different semiempirical methods. We use Replica Exchange molecular dynamics to sample the surface properly and ensure convergence. A comparison of the conformational space sampled by different semiempirical methods in explicit water classical models will be presented. The computational results will be compared against NMR experiments.

Tuesday, March 11, 2008 11:15AM - 2:15PM
Session J7 FEd: Undergraduate Nanotechnology and Materials Physics Education I

Morial Convention Center R05
11:15AM J7.00001 NCLT Contributions to Nanoscience Education at the Undergraduate Level. ROBERT CHANG, Northwestern University — The National Center for Learning and Teaching in Nanoscale Science and Engineering (NCLT) has a mission to build national capacity in Nanoscale Science and Engineering Education (NSEE) by reaching to millions of learners. This mission calls for the development of a globally competitive national nano workforce and national cadre of leaders in NSEE. Part of the NCLT’s integrated program focuses on higher education initiatives and the development of undergraduate resources in NSE. The Center has developed an online educational resource repository for the NSEE community, the NanoEd Resource Portal at http://www.nclt.us. This talk involves a description of the applications and context for integrating NSE into undergraduate courses. It will provide research and development examples on new degree programs and concentrations in NSEE. The following are a few highlights of NCLT’s contributions in undergraduate education:

- Example of several short introductory units on Scanning Tunneling Microscopy, Scanning Electron Microscopy and Nanopatterning Techniques
- Simulations that can be incorporated into undergrad courses on Information Storage Technology (i.e. Nanomagnetism simulations and accompanying introductory material)
- Archive of seminars on various topics on NSE concepts
- Working prototype of Nanoconcentration in Physics
- Database of Degree Programs highlighted on the NCLT NanoEd Resource Portal
- Rubric for course development criteria
- Potential venue for professors to post their courses, degree programs, etc. for national and global dissemination

1NCLT support provided by the National Science Foundation Grant # 0426328.

11:51AM J7.00002 A Cutting-Edge Education: Incorporating Nano into the Undergraduate Curricula. GREG M. ZENNER, University of Wisconsin-Madison — The Interdisciplinary Education Group (IEG) of the Materials Research Science and Engineering Center (MRSEC) on Nanostructured Interfaces at the University of Wisconsin-Madison (UW) develops and uses hands-on, interactive education and outreach materials to engage a variety of audiences in learning about nanotechnology and advanced materials. Many of the education products created are inspired by UW MRSEC research; and faculty, staff, and students regularly contribute to the IEG’s work to share nanotechnology with a broader audience. The UW MRSEC has developed numerous teaching modules, labs, and education resources devoted to nanotechnology concepts, and many of these materials have been integrated into key introductory and advanced undergraduate courses at UW and other institutions, including small liberal arts colleges and community colleges. This effort has taken place through both the creation of new courses and the modification of existing courses to include cutting-edge content based on current research and emerging applications in nanotechnology. In this talk, I will present some of the new instructional materials we have developed based on advances in nanoscale science and technology, the implementation and integration of these materials into undergraduate curricula, and an overview of the UW MRSEC education efforts.

12:27PM J7.00003 Integrating Condensed Matter Physics into a Liberal Arts Physics Curriculum. JEFFREY COLLETT, Department of Physics, Lawrence University, Appleton, WI — The emergence of nanoscale science into the popular consciousness presents an opportunity to attract and retain future condensed matter scientists. We inject nanoscale physics into recruiting activities and into the introductory and the core portions of the curriculum. Laboratory involvement and research opportunity play important roles in maintaining student engagement. We use inexpensive scanning tunneling (STM) and atomic force (AFM) microscopes to introduce students to nanoscale structure early in their college careers. Although the physics of tip-surface interactions is sophisticated, the resulting images can be interpreted intuitively. We use the STM in introductory modern physics to explore quantum tunneling and the properties of electrons at surfaces. An interdisciplinary course in nanoscience and nanotechnology is open to all majors in science and engineering, especially those in second and third year who are interested in future careers in science and technology. This general education course is team-taught with chemists to present recent advances in nanoscale science and technology, the implementation and integration of these materials into undergraduate curricula, and an overview of the UW MRSEC education efforts.

1Work supported by grants from the W.M. Keck Foundation and the NSF-NUE program.

1:03PM J7.00004 Engaging undergraduate students in interdisciplinary courses in nanotechnology. FIONA GOODCHILD, University of California, Santa Barbara — Two new courses at UCSB engage both undergraduate and graduate students in situated learning so that they can acquire the knowledge and skills they will need for future academic courses and career development. These courses are designed and taught by research faculty and education staff at the California Nanosystems Institute (CNSI) at UC Santa Barbara. The speaker, Dr. Goodchild, Education Director at CNSI, collaborated in the course design and is advisor on assessment and pedagogy for both courses. The first course, entitled INSITES, is aimed at first and second year students who are interested in the impacts of science and technology in society. This general education course is team taught by three Graduate Teaching Scholars from across engineering, science and social sciences. They collaborate with lead faculty from Materials Science and History to design both the curriculum and instructional format for the 10 week course that is supported by the National Science Foundation. INSITES was taught for the first time in Spring 2007 and feedback indicated that the course had convinced the undergraduate students that they would like to take further courses outside their majors. The second course, entitled the Practice of Science is open to all majors in science and engineering, especially those in second and third year who are interested in scientific research and related career opportunities. The course has been taught for the past 4 years as a two-quarter course by two research faculty who focus on the nature of scientific discovery, the role of graduate researchers and faculty, the challenges of collaboration across disciplines and the mechanisms for funding research in academia and industry. In the first quarter each students is expected to identify a mentor and a research group in which they can pursue an individual research project, to be completed during the second quarter when the classes are designed to operate like research group meetings. Evaluation indicates that both courses attract students from underrepresented groups in science who value gaining a broader perspective about nanotechnology and the career opportunities that it offers to undergraduate students.
11:15AM J8.00001 Washboard Road: The dynamics of granular ripples formed by rolling wheels. NICOLAS TABERLET, ANNE-FLORENCE BITBOL, ENS Lyon, France, STEPHEN MORRIS, University of Toronto. JIM MCELWAIN, University of Cambridge — We report laboratory experiments on rippled granular surfaces formed under rolling wheels. Ripples appear above a critical speed and drift slowly in the driving direction. Ripples coarsen as they saturate, and exhibit ripple creation and destruction events. All of these effects are captured qualitatively by 2D soft particle simulations in which a disk rolls over smaller disks in a periodic box. The simulations show that compaction and segregation are insensitive to the ripple phenomenon. We describe a simplified scaling model which gives some insight into the mechanism of the instability.

11:27AM J8.00002 Evolution of sand ripples in pulsed flow. JOSÉ EDUARDO WESFREID, CNRS, JOACHIM KRUITHOEF, PMMH - CNRS — We present high-resolution experiments showing the temporal evolution of sand ripples formed by oscillatory flow. We discuss the decompaction process observed during the formation of the ripples pattern. We have also studied the evolution of different parameters during the transition of rolling grain ripples to vortex ripples, as the slope of these ripples and we tested the validity of the Sleath criterion to discriminate the transition.

11:39AM J8.00003 Granular Erosion of Pebbles. ADAM ROTH, DOUGLAS DURIAN, University of Pennsylvania — Flowing grains are strongly abrasive, and cause erosion both of themselves and their surroundings. In a geophysical setting, the erosion of pebbles has traditionally been quantified by global measures such as aspect ratio. Recently we have focused on curvature, and its distribution around the contour, as a local measure more directly related to the microscopic action of erosion. Here we apply this method to linoleum shapes, eroded by rotation in an abrasive grit. Several shape parameters are measured at different stages in the erosion process, including the curvature distribution. A simple model of erosion is developed, and its predictions are compared to the data. The results are in reasonable agreement, and could be useful for understanding natural erosion processes.

11:51AM J8.00004 Impact and Penetration of Granular Materials by Discrete Element Simulations. JUSTIN W. GARVIN, Air Force Research Lab, JEREMY B. LECHMAN, J. MATTHEW D. LANE, Sandia National Labs — Granular materials are an important example of hfi fields, discrete materials deliver 1) to meteorite collision and crater formation. Recently a model for the force experienced on a penetrator has been proposed [L.S. Tsimring and D. Volvon, Powders and Grains 2005, 1215-1223] and shown to fit experimental data well [H. Katsuragi and D.J. Durian, Nature Physics, Vol. 3, June 2007]. This model describes two components of the force: i) a velocity dependent, depth independent term related to the inertial force required to mobilize a volume of grains in front of the penetrator; and ii) a velocity independent, depth dependent, Coulomb friction-like term. In the current study, massively parallel, discrete element simulations have been performed to study the penetration of a large spherical impactor into a multi-million particle bed of granular material. Results agree with previous work for slow impact speeds (< 400cm/s). In addition, the current work extends the comparison with the proposed model to higher speeds (~1000cm/s). The physics of the phenomenon is discussed along with the challenges for modeling and simulation in the even higher velocity regime.

12:03PM J8.00005 Gas-Mediated Impact Dynamics in Fine-Grained Granular Materials. JOHN ROYER, ERIC I. CORWIN, BRYAN CONVYERS, MARK L. RIVERS, PETER J. ENG, HEINRICH M. JAEGGER, James Franck Institute, University of Chicago — Non-cohesive granular media exhibit complex responses to sudden impact that often differ from those of ordinary solids and liquids. We investigate how this response is mediated by the presence of interstitial gas between the grains. Using high-speed x-ray radiography we simultaneously track the motion of a steel sphere through the interior of a bed of fine-grained granular material and measure local changes in the bed packing density below the sphere. In an initially loosely packed granular bed, the sphere causes a near-instantaneous compaction of the bed below itself and an increase in the bulk density of the bed immediately above it. The interstitial gas plays the opposite role, strengthening the bed and inhibiting the penetration of the sphere. These two seemingly incongruous effects are both due to the low permeability of the fine-grained bed, which traps the interstitial gas in the bed. This trapped gas resists changes in the bed packing density, inhibiting compaction in the loose bed and inhibiting dilution in the dense bed.

This work was supported by NSF through DMR-MRSEC and by DoD/AFSOR.

12:15PM J8.00006 Impact cratering in fluidized granular matter. PATRICK MAYOR, HIROAKI KATSURAGI, DOUGLAS J. DURIAN, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PA 19104 — Impacts by projectiles dropped into granular media are an important example of how particulate materials respond to externally applied forces. Beyond the obvious geophysical case of planetary craters, understanding the details of impact mechanisms can provide valuable information on these systems, and the phenomenon has been actively investigated. In particular, recent experiments have studied the penetration depth of projectiles impacting granular materials at relatively low speeds, and measured the dynamics of the impact process, yielding force laws accounting for the observations. We have studied how the impact phenomenon is affected when the granular medium is submitted to a vertical upward (or downward) gas flow, in a range of flow rates below the bubbling regime. These fluidized granular systems yield, logically, deeper impacts, and dynamics measurements reveal that the stopping time is also longer, contrary to what is observed when deeper craters are obtained by increasing the impact velocity. We observe that the parameters involved in previously obtained force laws are modified in a simple way as a function of the flow rate and find a velocity-dependent inertial term and a depth-dependent friction force that vanishes as the flow rate approaches the fluidization threshold.

12:27PM J8.00007 Drag Force in a Gas Fluidized Granular Bed. T.A. BRZINSKI, D.J. DURIAN, University of Pennsylvania, Dept. of Physics — We use a rheometer to measure the torque acting on a rotating bar in a bed of gas-fluidized glass beads. We vary rotation rate from .001-100ps, vary depth from 1-10 cm, and increase the fluidizing gas flow from no flow well into the fluidized regime. We observe that at high rotation rates the drag is roughly proportional to velocity squared. At low rates we can resolve the measured torque by depth, and observe a collapse of the data. These results agree with the predictions of a granular drag force model which has proven effective in predicting granular impact dynamics. The model consists of an inertial drag term, which is depth-independent and scales as velocity squared, and a frictional drag term, which is independent of rate and varies linearly with depth. We find, as expected, that while the frictional term is airflow-dependent the inertial term is uncoupled from the fluidization.
12:39PM J8.00008 Exploring penetration through granular media

DANIEL J. COSTANTINO, Department of Physics; Pennsylvania State University, THOMAS J. SCHEIDEMANTEL, MATTHEW B. STONE, JULIA COLE, CASEY CONGER, KIT KLEIN, MATTHEW LOHR, WILLIAM MCCONVILLE, ZACHARY MODIG, KRYSSEN SCHEIDLER, PETER SCHIFFER — The motion of objects through granular media is an important physical problem involving local jamming of the grains. We report on an experiment dealing with the force needed to initiate upward motion through a granular pile, \( F_{\text{in}} \). As expected, this force scales monotonically with the depth of the intruder as well as its size, \( D_{\text{plate}} \). However, unlike previous experiments this force also depends on the size of the particles making up the pile, \( d_{\text{grain}} \). The force can be represented by the function \( F_{\text{in}} = AD_{\text{plate}}^{-2} d_{\text{grain}}^{-2} + BD_{\text{plate}}^{-2} \), which can be qualitatively explained within a simple model. Finally, preliminary results from a new experiment dealing with horizontal motion through a granular pile will be discussed. In this study, the effect of interstitial fluids on a granular material’s resistance to an intruder will be investigated. Research supported by NASA grant NAG-2384 and the NSF REU program.

12:51PM J8.00009 Fluctuations in an agitated granular fluid

KIRI NICHOL, MARTIN VAN HECKE, Leiden University — The clogging of granular materials at the exit of a silo or hopper is a matter of tremendous practical importance, as well as a canonical example of jamming. We investigate the effect of particle aspect ratio (length/width) on the jamming probability through experiments and discrete element simulations. Preliminary experimental results on particles with aspect ratios of 16 and 32 show that the probability of \( P(m) \) for \( m \) grains to exit the hopper has an exponentially decaying tail that, when scaled by the mean number that exit, is independent of exit aperture size. This scaling of \( P(m) / m \) is also observed in hopper flow of ordinary round particles, but the proposed phenomenological explanation of uncorrelated behaviors seems unlikely in long, thin rods. Furthermore, while the mean exit number obviously increases with aperture size, it is not clear which length scale is most relevant: particle length, width, or some combination of the two. We are also writing new discrete element simulations that can be compared with the experiments, and I will discuss some of the computational nuances introduced by particle asymmetry and present initial results.

1:03PM J8.00010 Jamming in Hopper Flow of Large Aspect Ratio Granular Materials

SCOTT FRANKLIN, Rochester Institute of Technology — The clogging of granular materials at the exit of a silo or hopper is a matter of tremendous practical importance, as well as a canonical example of jamming. We investigate the effect of particle aspect ratio (length/width) on the jamming probability through experiments and discrete element simulations. Preliminary experimental results on particles with aspect ratios of 16 and 32 show that the probability of \( P(m) \) for \( m \) grains to exit the hopper has an exponentially decaying tail that, when scaled by the mean number that exit, is independent of exit aperture size. This scaling of \( P(m) / m \) is also observed in hopper flow of ordinary round particles, but the proposed phenomenological explanation of uncorrelated behaviors seems unlikely in long, thin rods. Furthermore, while the mean exit number obviously increases with aperture size, it is not clear which length scale is most relevant: particle length, width, or some combination of the two. We are also writing new discrete element simulations that can be compared with the experiments, and I will discuss some of the computational nuances introduced by particle asymmetry and present initial results.

H. KING, D. ERTAS, A. KUSHNICK, F. ZHOU, ExxonMobil, P. CHAIKIN, NYU — Gravity-driven flows of granular materials are often influenced by interstitial fluids. Using the rotating half-filled drum geometry, we investigated particle and fluid velocities for granular flows of nearly monodisperse spherical glass particles with interstitial fluids of varying dynamic viscosity (air to 4 cP). We utilize direct particle imaging and PIV methods. For dry flows the fundamental time scale is set by the gravitational constant and particle size. We observe two primary influences of the interstitial fluid on the granular rheology. First, density of the fluid changes both the driving force (due to buoyancy) and the inertial response (due to added mass), increasing the characteristic time scale. Second, the intrinsic time scale is influenced by the dynamic viscosity of the fluid. As a result, the changes associated with the 1 cP viscosity increase in going from air-to-water are considerably larger than those for subsequent viscosity increments. We also see that the surface drag associated with the fluid boundary layer progressively affects the grain velocity profile near the surface as the viscosity increases, giving a several-particle-deep zone of constant velocity.

1:27PM J8.00012 Rheology and structure of granular flows in split-bottom geometries

JOSHUA DIJKSMAN, MARTIN VAN HECKE, Leiden University — Combining rheological methods with surface flow imaging, we probe the flow of slow dry granular media as function of driving rate and geometry. The flow rate affects the spatial structure of the flow much stronger than the stresses, while details of the boundary conditions significantly modify both stresses and flow. We discuss our results in the context of recent numerics on rapid flows in these split-bottom geometries, and various theories developed for slow flows.

1:39PM J8.00013 Self-diffusion in bulk sheared granular materials

ANDREEA PANAITESCU, ASHISH ORPE, ARSHAD KUDROLLI, Department of Physics, Clark University — We will discuss the diffusion and structural properties of granular particles in the bulk of a cycledly sheared three dimensional rectangular cell. The particles are visualized away from the side walls using a fluorescent refractive index matched interstitial fluid. Previous studies have shown that the diffusion is anisotropic with respect to the vorticity plane, but these results have been confined to either two dimensional systems or small three dimensional systems where the boundary effects could not be decoupled. In a cyclic shear cell, the packing fraction the particles and their orientational order vary smoothly over time. The particle positions are identified and tracked over long durations to obtain particle diffusivity, mean-squared displacements and probability distributions of particle displacements. An analysis of the effect of structural order on the motion of the particles will be presented.

1:51PM J8.00014 Studies in a 2D granular pure shear experiment

JIE ZHANG, Department of Physics and CNCS, Duke University, NC 27708, USA, PEIDONG YU, TRUSH MAJUMDAR, ROBERT P. BEHRINGER — We have performed two dimensional granular experiments under pure shear using bidisperse photo-elastic disks. Starting from a stress free state, a square box filled with granular particles is subject to shear. The forward shear involved thirty steps, leading to maximum strain of 0.1. The network of force chains gradually built up as the strain increased, leading to increased pressure and shear stress. Backward shear was then applied to return the system to zero strain in the next thirty steps. Following each change of the system, contact forces of individual disks were measured by applying an inverse algorithm. We also kept track of the displacement and angle of rotation of every particle from frame to frame. We present the results for the contact forces, particle displacement, particle rotations, fabric, etc. Work supported by NSF grant DMR0555431.

Tuesday, March 11, 2008 11:15AM - 1:27PM –
Session J9 DFD: Fluid Structure and Properties Morial Convention Center R07

11:15AM J9.00001 The Interplay of Short- and Long-Range Forces in Simulations of Confined Water using Local Molecular Field Theory

JOCELYN RODGERS, JOHN WEEKS, University of Maryland, College Park — A molecular model of water confined between walls is studied using local molecular field (LMF) theory. LMF theory splits the long-ranged Coulomb 1/r potential between charge sites into a short-ranged core potential and a long-ranged, slowly-varying potential ideal for mean-field averaging. The core potential may be treated explicitly by simulations using the minimum image convention with a renormalized external field defined by mean field averaging of the longer-ranged potentials. Here we apply local molecular field theory to molecular dynamics simulations of molecular water confined between walls, with and without an electric field. This is a geometry where short-ranged spherical truncations of Coulomb interactions can fail spectacularly, but in tandem with the effective external field defined by LMF theory such truncations correctly predict structural and electrostatic properties of water. Further the concepts behind LMF theory elucidate the varying contributions of hydrogen-bonding and dipolar interactions in determining the structure of water at surfaces.
11:27AM J9.00002 Effects of a solute on a simple model solvent\(^1\), PAOLO DE GREGORIO, JONATHAN C. TOLEDO, B. WIDOM, Department of Chemistry, Baker Laboratory, Cornell University, Ithaca NY, USA — We studied the effect of the addition of a solute on a one-dimensional model solvent (high density, low compressibility, low coefficient of thermal expansion), at infinite dilution. The solute has a solubility which is low and decreases with increasing temperature. The effect of the addition of solutes on the chemical potential of the solvent at constant volume differs from that at constant pressure in a way similar to that of non-polar solutes in water. The solvent-solute pair distribution function determines fully the modes of decay of the solute-solute counterpart. At the largest distances, the ultimate decay is strictly monotonic (exponential) for both. But while for the solvent-solute correlations the amplitude is strongly associated with the solute solubility, it is negligible for the solute-solute case. Physically, the correlations vanish in identical fashion at infinite distances, but they differ substantially over an extended range of physical interest. The osmotic second virial coefficient is very large and negative, not only as an effect of the proximity ‘attraction’ between the solutes, but also of the very long tail in the correlations.

\(^1\)NSF support is acknowledged.

11:39AM J9.00003 Ultrafast Phase-Contrast Imaging Study of Finite-time Hydrodynamic Singularities\(^1\), YUJIE WANG, Argonne National Lab — Most of the nonlinearity induced hydrodynamic singularities are transient and requires high-speed imaging to be studied. There exist some intrinsic problems of visible-light imaging on fluid mechanical research. The key advantage of x-ray phase-contrast imaging is that it is interface-based technique and the boundaries are highlighted naturally. It is a highly penetrative technique in which all complex structures along the path will be picked up. Additionally, it is naturally immune of the complexity of multiple scattering and strong optical reflection or refraction.

11:51AM J9.00004 Liquid State Properties from \textit{ab initio} Density Functional Theory Calculations\(^1\), NICOLAS BOCK, TRAVIS PEERY, ERIC CHISOLM, GIULIA DE LORENZI-VENNERI, DUANE WALLACE, Los Alamos National Laboratory, ERIK HOLMSTRÖM, RAQUEL LIZARRAGA, Instituto de Física, Universidad Austral, Chile — For the solid state, density functional theory (DFT) has been successfully applied to calculate material properties in a large range of materials. In the liquid state however, thermodynamic properties are calculated by molecular dynamics (MD) simulations in which the forces are calculated with DFT. These simulations are computationally significantly more expensive than comparable solid state calculations. We present a novel approach which does not rely on MD simulations, but instead uses Vibration-Transit (V-T) theory to make predictions of the thermodynamic properties of the liquid phase. This approach is computationally significantly less expensive than an MD simulation. The accuracy of this approach is demonstrated by a comparison to experiment.

12:03PM J9.00005 Reconstructing the structure and dynamics of density fluctuations in water near a moving proton, ROBERT CORIDAN, GHEE HWEE LAI, NATHAN SCHMIDT, Department of Physics, University of Illinois, Urbana-Champaign, PETER ABBAMONTE, Department of Physics and Seitz Materials Research Lab, University of Illinois, Urbana-Champaign, GERARD C. L. WONG, Department of Materials Science Engineering, Department of Physics, and Seitz Materials Research Lab, University of Illinois, Urbana-Champaign — The structure and dynamics of water on femtosecond timescales is relevant to many topics in physical chemistry such as ion solvation. We computationally reconstruct the angstrom-scale spatial and femtosecond-scale temporal evolution of density fluctuations in water using high-resolution inelastic x-ray scattering (IXS). The imaginary part of density propagator \(\chi(q,\omega)\) is directly extracted from the IXS data, and the real part recovered using Kramers-Kronig relations. The resultant complex-valued \(\chi(q,\omega)\) is the Fourier transform of the real-space density-density response function \(\chi(r,t)\) which measures the dynamical density fluctuations of water due to a point-like instantaneous pulse. We use this density propagator from IXS data and linear-response theory to reconstruct the hydration behavior of a proton moving at different instantaneous speeds through water.

12:15PM J9.00006 Classical Density Functional Theory of Inhomogeneous Polar Molecular Liquids, JOHANNES LISCHNER, T.A. ARIAS, Cornell University — We show how free energy functionals for classical assemblies of interacting rigid molecules, composed of an arbitrary number of atoms, can be constructed, such that the entropy of the noninteracting assembly, the thermodynamic properties and the microscopic order of the uniform phase and the dielectric properties in both weak and strong electrostatic fields are reproduced. We use our approach to predict density profiles of liquid hydrogen chlorides in a parallel plate capacitor with different wall potentials and varying external fields. We show that our theory can easily be coupled to electronic structure calculations within the Joint Density Functional approach and will comment on potential application to water.

12:27PM J9.00007 Localized Voronoi analysis of quenched liquid configurations, TRAVIS PEERY, NICOLAS BOCK, GIULIA DE LORENZI-VENNERI, DUANE WALLACE, Theoretical Division, Los Alamos National Laboratory, ERIK HOLMSTROM, Instituto de fisica, Universidad Austral de Chile — We developed a set of localized statistical tools to explore and characterize condensed matter particle configurations, particularly amorphous distributions associated with the liquid state. Typically global measures of atomic packing are used to characterize atomic configurations, such as pair distribution functions. For large systems, such calculations can be computationally expensive and tend not to be sensitive to localized symmetries. Our localized tools are based upon the geometric or topological analysis of (static) atomic arrangements using Voronoi polyhedra. As each atom in the configuration has a unique Voronoi polyhedron defined by its near neighbors, our tools can describe the geometry and symmetry of local neighborhoods. We have defined, for example, a local, Shannon-type entropy for the Voronoi coordination number for each atom in a 500-atom, monatomic system. This localized entropy tool was able to find small (9–40 atom) crystallites or regions of high symmetry in an otherwise random 500-atom configuration quenched from the liquid state. These tools will help to define and characterize not only random liquid state configurations and the minimum structures associated with liquid potential energy surfaces, but also the symmetry properties of the quenching process itself.

12:39PM J9.00008 Phase Separation in the Dipolar Hard-Sphere System Revisited\(^1\), WONKI ROH, ERIK LUIJTEN, University of Illinois at Urbana-Champaign — We investigate the liquid-vapor transition in the dipolar hard-sphere system. Since the suggestion of de Gennes and Pincus [Phys. kondens. Mater. 11, 189 (1970)] this phase transition has proven both elusive and controversial, with conflicting numerical results regarding its existence and stability. Employing extensive and efficient grand-canonical Monte Carlo simulations, we revisit this issue. High-precision results on the low-temperature heat capacity are presented along isotherms as well as isochores. In addition, we study the density distribution function and its moments for a wide range of chemical potentials, and identify anomalous finite-size effects that can give rise to incorrect conclusions.

\(^1\)This work was supported by the U.S. Department of Energy under Grant No. DE-FG02-07ER46471.

12:51PM J9.00009 X-ray tracer study of Rheology and Hydrodynamics of Fatty acids, MENGNING LIAO, University of Illinois at Urbana Champaign, ROSS HARDER, IAN ROBINSON, University College London, UNICAT TEAM — In wormlike micelles, the breaking and reforming of the micelle rods and the shearing of the rods and between the carbon chains themselves result in a complex diffusive behavior with more than one characteristic time constant. This is one of the characteristics of a Maxwellian fluid. We have studied the rotational Brownian motion of an alumina crystal suspended in a fatty acid liquid. Synchrotron generated hard x-rays are used to do single particle tracking of the rotational orientation by tracking the Bragg intensity of alumina crystals in diffraction geometry. This technique allows the tracking of particles to sub-milladian precision. We have observed multiple time scales of relaxation which is evidence of subdiffusive behavior.
1:03PM J9.00010 Statics and dynamics of a cylindrical droplet under an external body force, JAMES SERVANTIE, MARCUS MÜLLER, Institute For Theoretical Physics, Goettingen — We study the rolling and sliding motion of droplets on a corrugated substrate by Molecular Dynamics simulations. Droplets are driven by an external body force (gravity) and we investigate the velocity profile and dissipation mechanisms in the steady state. The cylindrical geometry allows us to consider a large range of droplet sizes. The velocity of small droplets with a large contact angle is dominated by the friction at the substrate and the velocity of the center of mass scales like the square root of the droplet size. For large droplets or small contact angles, however, viscous dissipation of the flow inside the volume of the droplet dictates the center of mass velocity that scales linearly with the size. We develop a simple analytical description predicting the dependence of the center of mass velocity on droplet size and the slip length at the substrate. In the limit of vanishing droplet velocity we quantitatively compare our simulation results to the predictions and good agreement without adjustable parameters is found.

1:15PM J9.00011 Velocity-dependent friction coefficient at the interface between a polymer melt and a solid substrate, NIKOLAI PRIEZJEV, ANOOSEH NIJAVARNI, Michigan State University — Molecular dynamics simulations are carried out to investigate the dynamic behavior of the slip length in thin polymer films confined between atomically smooth thermal surfaces. For weak wall-fluid interactions, the shear rate dependence of the slip length acquires a distinct local minimum followed by a rapid growth at higher shear rates. With increasing the fluid density, the position of the local minimum is shifted to lower shear rates. We found that the ratio of the shear viscosity to the slip length, which defines the friction coefficient at the liquid/solid interface, undergoes a transition from a nearly constant value to the power law decay as a function of the slip velocity. In a wide range of shear rates and fluid densities, the friction coefficient is determined by the product of the value of surface induced peak in the structure factor and the contact density of the first fluid layer near the solid wall. A relation to recent slip flow experiments is discussed. Reference: A. Njavarni and N.V. Priezjev, Phys. Rev. E (2008) (cond-mat/0711.0187).

Tuesday, March 11, 2008 11:15AM - 2:15PM — Session J10 DCMP: Superconductivity: Vortex I Morial Convention Center R08

11:15AM J10.00001 Progression of the vortex-solid to vortex-liquid phase boundary with oxygen doping in Y_{0.8}Ca_{0.2}Ba_{x}Cu_{y}O_{4} Films, BENJAMIN TAYLOR, RYAN BAUMBACH, M. BRIAN MAPLE, UCSD — By extending magneto-transport measurements to magnetic fields of 35 tesla we have been able to examine the vortex-solid to vortex-liquid transition of thin film Y_{0.8}Ca_{0.2}Ba_{x}Cu_{y}O_{4} samples (6.45 \leq x \leq 7.0) over a field-temperature range larger than heretofore reported. It is found in this work that the shape of the phase boundary, H_{c2}(T), evolves from a very shallow low-field temperature dependence to an extremely rapid high field temperature dependence in the highly underdoped regime (x \approx 6.45). However, in the lightly overdoped regime (x \approx 6.9 - 7.0), H_{c2}(T) displays an increasingly steep low-field temperature dependence followed by a lessening of the steepness of the high-field region as oxygen content increases. This trend suggests that the boundary of the dissipation-less superconducting region of this unconventional high-T_{c} cuprate based compound is evolving in the overdoped state towards a form that is consistent with what is observed in conventional superconductors. This research was supported by U.S. DOE Grant No. DE-FG02-04ER46105. A portion of this work was performed at the National High Magnetic Field Laboratory, which is supported by NSF Cooperative Agreement No. DMR-0084173, by the State of Florida, and by the DOE.

11:27AM J10.00002 Measurements of the anisotropic irreversibility field in the electron-doped high-T_{c} superconductor P_{2-x}Ce_{x}CuO_{4-y}, GUOQING WU, W.G. CLARK, S.E. BROWN, UCLA, R.L. GREENE, U. Maryland, H. BALCI, U. of Illinois, Urbana, A.P. REYES, P. KUHNS, W.G. MOULTON, NHMFL, Tallahassee — We report measurements of the irreversibility field (H_{irr}) in single crystals of the electron-doped high-T_{c} superconductor (HTSC) P_{2-x}Ce_{x}CuO_{4-y} (x = 0.15 and 0.17) with an applied magnetic field (H_{0}) up to 28 T, using the method of the shift in a nuclear magnetic resonance (NMR) probe circuit resonance frequency (f) caused by the susceptibility of the sample. It is observed that for temperatures above 10 K and in the vicinity of H_{0} \perp c, a phase diagram that involves the vortex solid and/or vortex liquid states depending on the alignment of H_{0} relative to the lattice c-axis is proposed, and the obtained anisotropic H_{c2} character along with the evaluated zero T coherence length [\xi_{ab}(0) \parallel c \rightarrow 0] and penetration depth [\lambda_{ab}(0) \rightarrow 0] at H_{0} \parallel c is compared with that of hole-doped HTSCs. This work is supported at UCLA by NSF Grants DMR-0334869 (WGC) and 0520552 (SEB), at U. Maryland by 0352735 (RLG), and NHMFL by 0084173 and the State of Florida.

11:39AM J10.00003 Evolution of Vortex Phase diagram in heavy ion irradiated YBCO, R. XIE, A. RYDH2, U. WELP, W.-K. KWOK, Material Science Division, Argonne National Laboratory, M.R. ESKILDSEN, Department of Physics, University of Notre Dame, LISA PAULIUS, Department of Physics, Western Michigan University — We present a systematic study of the effect of columnar defects induced by heavy ion irradiation on the vortex phase diagram of single-crystal YBCu3O7 using ac-specific heat measurements obtained with a micro-calorimeter. The first order vortex melting line where the vortex lattice transforms into a vortex liquid at intermediate magnetic fields is tracked by the peak in the specific heat. In our pristine untwinned YBCO crystal, the vortex melting line extends from a lower critical point H_{c2}=0.2T to an upper critical point H_{c2}=6T. The crystal was cleaved into several pieces and then irradiated along the c-axis with 1.4GeV Pb ions with different dose matching fields, B_{y}, ranging from 100G to 3000G. We explored the behavior of H_{c1} and H_{c2} in the presence of increasing columnar defects to determine whether the transformation of the first order melting line to higher order occurs abruptly at a defect threshold value or continuously with increasing amount of defects.

1:11PM J10.00004 Evidence for Hexatic Bose Glass in the Mixed Phase of Type-II Superconductors with Material Line Defects, JOSE P. RODRIGUEZ, Physics & Astronomy, California State University at Los Angeles, CHARLES E. CREFFIELD, Fisica de Materiales, Universidad Complutense de Madrid — Dislocation lines and nano-rods inclusions in thin films of YBa_{2}Cu_{3}O_{y} aligned parallel to the c-axis are known to significantly enhance the critical current in external magnetic field that is also aligned in parallel. In contrast to correlated pinning centers created by irradiation, the former material line defects notably arrange themselves in a “liquid” fashion that shows no clusters or voids. Theoretical calculations predict the existence of a hexatic Bose glass at low temperature in such case[1]. We test that prediction by performing Monte-Carlo simulations of the corresponding two-dimensional Coulomb gas ensemble with close to 3000 vortices. In the regime of weak (“liquid”) pinning centers, we find a 2D hexatic vortex liquid at non-zero temperature characterized by isolated edge dislocations. It freezes into a phase-coherent hexatic vortex glass in the zero-temperature limit in accordance with theory [1].

12:03PM J10.00005 Competition of Point and Correlated Vortex Pinning in Irradiated YBCO\textsuperscript{1}, WAI-KWONG KWOK, ULRICH WELP, JOHN SCHLUETER, RUOBING XIE, Materials Science Division, Argonne National Laboratory, JIONG HUA, ZHILI XIAO, Dept. of Physics, Northern Illinois University, LISA M. PAULIUS, Dept. of Physics, Western Michigan University, MORTEN R. ESKILDSEN, Dept. of Physics, University of Notre Dame. We present a systematic study of vortex pinning on an optimal-doped unwinned YBa\textsubscript{2}Cu\textsubscript{3}O\textsubscript{7-\textdelta} single-crystal irradiated with 1.4 GeV Pb ions and subsequently irradiated with protons. Irradiation to a dose matching field of B\textsubscript{p}=2T completely transforms the first order vortex melting transition to a higher order Bose glass transition. The transformation is also marked by a pronounced increase in vortex pinning at all temperatures, determined from SQUID measurements. We compare the irreversibility line and the remanent moment of the irradiated sample after subsequent irradiation with protons to determine the contribution to vortex pinning from point and correlated defects on the same sample.

\textsuperscript{1}This work was supported by the U.S. Department of Energy, Office of Science, BES - Materials Science and Division of Nuclear Physics (ATLAS) under grant no. W-31-109-ENG-38.

12:15PM J10.00006 Dynamics of driven vortices in type-II superconductors in the presence of strong point or columnar pinning centers\textsuperscript{1}, THANANART KLONGCHEONGSAN, Department of Physics, Virginia Tech, Blacksburg, VA 24061-0435, THOMAS J. BULLARD, National Air and Space Intelligence Center, Wright-Patterson AFB, OH 45433-5648, UWE C. TAUBER, Department of Physics, Virginia Tech, Blacksburg, VA 24061-0435. We investigate the nonequilibrium steady state of driven magnetic flux lines in type-II superconductors with unidirectional twin boundaries (TBs). We also discuss the matching effect of vortex lattice with TBs, which reflects vortex pinning characteristics of superconductors with TBs. We have studied the dynamics of vortices interacting with unidirectional twin boundaries in a superconductor using molecular dynamics simulation. Current-voltage curves and critical currents have been calculated as a function of vortex density. We found that the critical current as a function of vortex density reveals a staircase pattern and this pattern depends on the pinning strength. This behavior corresponds to discontinuous change of vortex configurations, which reflects vortex pinning characteristics of superconductors with TBs. We also discuss the matching effect of vortex lattice with TBs, and reveal its behavior is different from the one in superconductors with columnar pinning.

\textsuperscript{1}Research in part funded through the National Science Foundation, NSF DMR-0075725.

12:27PM J10.00007 Vortex dynamics and critical current in superconductors with unidirectional twin boundaries, HIDEHIRO ASAI, SATOSHI WATANABE, Department of Materials Engineering, The University of Tokyo. The pinning of superconducting vortices is important in device applications of superconductors, because immobilization of vortices at pinning sites is essential for lossless transport. Twin boundary (TB) is one of possible candidates for effective pinning centers, in particular in YBa\textsubscript{2}Cu\textsubscript{3}O\textsubscript{7-\textdelta}. Thus, their pinning properties have been actively studied both experimentally and theoretically. However, the pinning characteristics of high-density TBs, which have recently been fabricated successfully, are still unclear. We have studied the dynamics of vortices interacting with unidirectional twin boundaries in a superconductor using molecular dynamics simulation. Current-voltage curves and critical currents have been calculated as a function of vortex density. We found that the critical current as a function of vortex density reveals a staircase pattern and this pattern depends on the pinning strength. This behavior corresponds to discontinuous change of vortex configurations, which reflects vortex pinning characteristics of superconductors with TBs. We also discuss the matching effect of vortex lattice with TBs, and reveal its behavior is different from the one in superconductors with columnar pinning.

12:39PM J10.00008 Non Arrhenius creep motion of interacting vortices in high-\textit{Tc} cuprate superconductors, A. MAEDA, D. NAKAMURA, Dep. Basic Sci., Univ. Tokyo. Dynamics of driven vortices attracted much attention in many different fields of physics. In addition to the understanding of the dynamic phase diagram, the understanding of the elementary process of the vortex motion is crucially important. For a rather large driving force, the existence of a so-called washboard motion has been well established (Y. Togawa et al. : PRL 83 (2000) 3716.). On the other hand, very close to the critical driving force (critical current density), the Anderson-Kim creep picture has been believed for a long time, which is characterized as the Arrhenius process with the linear decrease of the potential barrier as a function of the external driving force. Quite recently, Luo and Hu proposed the possibility of the non-Arrhenius creep process for the vortex motion in Bragg glass phase, based on a numerical simulation (M. B. Luo and X. Hu, PRL98(2007) 267002.). Stimulated by this theoretical work, we performed a detailed \textit{I-V} study in a high-\textit{Tc} cuprate, LSCO, and found (1) The creep process is non-Arrhenius like in the Bragg glass phase. (2) With increasing magnetic field, the creep process changes into the Arrhenius type one suddenly. (3) The field where the process changes roughly agrees with the Bragg-glass-Vortex glass transition, (4) Aging effect of the critical driving force also changes close to the Bragg glass - Vortex liquid boundary. These features agree well with predictions by Lou and Hu.

12:51PM J10.00009 Anisotropy of the Vortex Magnetic Field Distribution in LuNi\textsubscript{2}B\textsubscript{2}, M. R. ESKILDSEN, L. DEBEER-SCHMITT, University of Notre Dame, K. ROVIRA, Florida International University, N. JENKINS, University of Geneva, Switzerland, C. D. DEWHURST, Institut Laue-Langevin, France, S. L. BUD’KO, P. C. CANFIELD, Ames Laboratory and Iowa State University. It is well known that the vortex lattice (VL) symmetry and orientation in type-II superconductors is very sensitive to any anisotropy within the screening current plane. A classic example is the sequence of transitions from hexagonal to rhombic to square symmetry, which was first observed in the borocarbide superconductors and explained by a Fermi surface anisotropy coupled with the non-local electrodynamics responsible for vortex-vortex interactions. Recently, however, this is mounting experimental evidence for a strong gap anisotropy and possible point nodes in the basal plane of these materials. Here we report on small-angle neutron scattering studies of the VL in a carefully annealed, high quality LuNi\textsubscript{2}B\textsubscript{2} single crystal, which permitted us to measure the VL form factor for a large number of reflections. These measurements allow a reconstruction of the real space profile of the magnetic field around the vortices, reflecting the basal plane anisotropy of the screening currents in LuNi\textsubscript{2}B\textsubscript{2}. The results will be compared to predictions for both Fermi surface and gap anisotropies, and will serve as a valuable reference for more complicated compounds as e.g. Sr\textsubscript{2}RuO\textsubscript{4}, heavy fermions and high-\textit{Tc}’s.

1:03PM J10.00010 An infrared study of the pancake vortex state in La\textsubscript{2-\delta}Sr\textsubscript{2}CuO\textsubscript{4} across the phase diagram, ALEXANDER SCHAFGANS, ANDREW LAFORGE, Department of Physics, University of California, San Diego, SASA DORDEVIC, Department of Physics, University of Akron, MUHAMMAD QAZILBASH, Department of Physics, University of California, San Diego, SEIKI KOMIYA, Central Research Institute of Electric Power Industry, Iwato- kita, Komae, Tokyo, YOICHI ANDO, Institute of Scientific and Industrial Research, Osaka University, DIMITRI BASOV, Department of Physics, University of California, San Diego. We report on a doping dependent study of the far-infrared interlayer response in the high-temperature superconductor La\textsubscript{2-\delta}Sr\textsubscript{2}CuO\textsubscript{4} (La214). A magnetic field up to 8 Tesla applied perpendicular to the CuO\textsubscript{2} planes is found to increasingly suppress the Josephson plasma resonance (JPR) with decreased doping. By 6 Tesla at a temperature of 8 Kelvin, the c-axis reflectivity is identical to that of the normal state in the most underdoped samples, suggesting the sample is in a two dimensional superconducting state. This behavior is in contrast to fields parallel to the CuO\textsubscript{2} planes, where only a small suppression of the JPR is seen up to 17 Tesla. Vortex wandering and static spin density waves are considered as possible mechanisms for plane decoupling.
1:15PM J10.00011 Torque magnetometry on the electron-doped high-temperature superconductor Pr$_{0.88}$LaCe$_{0.12}$CuO$_{4-\delta}$, J.I. OH, P. DHAKAL, Boston College, S. LI, P. DAI, U. Tennessee, M.J. NAUGHTON$^1$, Boston College — We have used cantilever and extraction magnetometry to measure magnetization in optimally doped n-type high-temperature superconductors Pr$_{0.88}$LaCe$_{0.12}$CuO$_{4-\delta}$ ($T_c = 24K$) for magnetic field aligned close to the c-axis, over the temperature range (4K to 300K). We observed a distinct irreversibility line below which the torque magnetization is irreversible. Also, we observed a complex torque behavior where the sign of normal state torque response with field ($dI/dh$) is the same as that of the superconducting counterpart. From dc magnetization experiments, we conclude that superconducting torque signal arises primarily from out-of-plane diamagnetism, whereas in-plane paramagnetism dominates for the normal state.

$^1$Supported by NSF grant DMR-0605339.

1:27PM J10.00012 Vortex pinning and local density of states in an inhomogeneous d-wave superconductor$^1$, DANIEL VALDEZ-BALDERAS, Department of Physics and Astronomy, University of Rochester, DAVID STROUD, Department of Physics, The Ohio State University — We study a model for vortex pinning in a two-dimensional, inhomogeneous, type-II superconductor at low temperatures. The model is based on the Ginzburg-Landau free energy functional with position dependent coefficients, which we chose in such a way that regions with large gap also have large penetration depth. This choice of parameters (suggested by scanning tunneling spectroscopy experiments) results in vortices being pinned by superconducting regions where the gap is large, in contrast to the usual pinning picture. We also compute the density of states of a model BCS Hamiltonian with d-wave symmetry, in which the pairing field is given by the superconducting order parameter appearing in the free energy functional described above. We find that the type of inhomogeneity that we introduce is an indispensable ingredient for our model to reproduce some of the most salient experimental features of the local density of states spectra of cuprates.

$^1$NSF Grant No. DMR04-13395

1:39PM J10.00013 Superconducting Froth$^2$, RUSLAN PROZOROV, ANDREW F. FIDLER, JACOB HOBERG, PAUL C. CANFIELD, Ames Laboratory, Ames, IA 50011 — Studying the structure and dynamics of froths helps to understand the behaviour of complex systems where topological intricacy prohibits exact evaluation of the ground state. Though exact solutions are difficult, general laws that take into account both, the topological constrains and physics and chemistry of the froth matter have been developed. We used low temperature magneto-optical imaging in superconducting lead to add a new member to the froths family, - superconducting quantum froth, in which the boundaries are the superconducting and the interior is the normal phase. Despite very different microscopic origin, the topological analysis of the structure has shown that von Neumann’s and Lewis’ laws apply. Furthermore, for the first time in the froths analysis there is an external global parameter of known behaviour - the total magnetic moment. We show that the statistical laws are in a good agreement with the predicted macroscopic response. We assert that superconducting froth is the new playground for the analysis of complex physics of froths with magnetic field and temperature as tuneable control parameters.

$^2$Supported by the DOE-BES (contract No. DE-AC02-07CH11358) and Alfred P. Sloan Foundation

5:15PM J10.00014 Vortex relaxation of the noncentrosymmetric CePt$_3$Si, A.C. MOTA, Festkoerperphysik, ETH-Zurich, C.F. MICLEA, F. STEGLICH, Max-Planck-Inst. for Chemical Physics of Solids, Dresden, M. SIGRIST, Theoretische Physik, ETH-Zurich, E. BAUER, Inst. für Festkörperphysik, T.U. Wien — The discovery of superconductivity (SC) in CePt$_3$Si by Bauer et al. (PRL 92, 027003 (2004)), has attracted much interest since the compound lacks an inversion center and it has an unusually high upper critical field $H^\text{c}_2$. Theoretical studies have pointed out that spin-orbit coupling could lead to a pairing state of mixed parity. For CePt$_3$Si it has been proposed that the combination of spin triplet p-wave and spin-singlet s-wave symmetries could explain most of the experimental facts consistently. Here we report on flux dynamics on a single crystal of CePt$_3$Si. The SC probed by means of magnetic susceptibility and specific heat shows a sharp transition at $T_c = 0.45 K$ with a width of 0.1 K. Decays of the remnant magnetization display a clean logarithmic time dependence with rates that follow the temperature dependence expected from the Kim – Anderson theory. However, the creep rates are extremely low, lower than observed in any other superconductor. The low rates are not caused by high critical currents. On the contrary, the critical current in CePt$_3$Si is considerably lower than in other superconductors with higher vortex relaxation rates.

2:03PM J10.00015 Model for nodal quasiparticle scattering in a disordered vortex lattice, MARIANNA MALTSEVA, PIERS COLEMAN, Rutgers University — Recent experiments by T. Hanaguri et al. on underdoped Ca$_{2-x}$Na$_x$CuO$_{2}$Cl$_2$ [1] have observed quasiparticle interference effects [2], which are sensitive to the sign of the d-wave order parameter. In a magnetic field, they observe a sizable transfer of scattering weight from quasiparticles to scattering events between anti-nodes of opposite sign to scattering events between anti-nodes of the same sign. We interpret high momentum phase-coherent scattering in terms of the quasiparticle scattering off the vortex walls. The reduction of scattering at even-odd scattering points indicates that the vortices “screen” some of the underlying impurity scattering, as the impurities get trapped inside the vortex cores. [1] T. Hanaguri, Y. Kohsaka, J. C. Davis, C. Lupien, I. Yamada, M. Azuma, M. Takano, K. Ohishi, M. Ono, H. Takagi, cond-mat/0703728. [2] Y. Kohsaka, C. Taylor, K. Fujita, A. Schmidt, C. Lupien, T. Hanaguri, M. Azuma, M. Takano, H. Eisaki, H. Takagi, S. Uchida, J. C. Davis, Science 315, 1380-1385 (2007).

11:15AM J11.00001 Muon spin rotation study of perturbation of the crystalline-electric-field induced by interstitial muon in PrOs$_3$Sb$_{12}$ and PrRu$_3$Sb$_{12}$, LEI SHU, D.E. MACLAUGHLIN, U. of Calif, Riverside, R.H. HEFFNER, Los Alamos National Laboratory, O.O. BERNAL, Calif, State U., Los Angeles, W.P. BEYERMANN, U. of Calif, Riverside, N.A. FREDERICK, W.M. YUHASZ, T.A. SAYLES, T. YANAGISAWA, M.B. MAPLE, U. of Calif, — Muon spin rotation measurements of the temperature dependence of the positive muon Knight shift in single crystals of PrOs$_3$Sb$_{12}$ and PrRu$_3$Sb$_{12}$ reveal a linear scaling of the Knight shift with the bulk magnetic susceptibility at high temperatures. A small deviation from the linear relation appears in PrOs$_3$Sb$_{12}$ below 0.3 K. However, a large magnitude of deviation is observed in PrRu$_3$Sb$_{12}$ below 32 K. The deviation can be explained by the positive muon induced modification of the susceptibility of neighboring Pr$^{3+}$ ions due to a change of the crystalline-electric-field (CEF) splitting. The data indicate that this modification is much smaller in PrOs$_3$Sb$_{12}$ than in PrRu$_3$Sb$_{12}$. A model calculation based on CEF theory is in progress.

$^1$Supported by NSF Grants 0422674(Riverside), 0203524(Los Angeles), 0335173(San Diego), and by DOE DE-FG02-04ER46105 (San Diego)
11:27AM J11.00002 Interplay of superconductivity and rattling phenomena in β-pyrochlore KOs₂O₆ studied by photoemission spectroscopy, TAKAHIRO SHIMOJIMA, YUKI SHIBATA, KYOKO ISHIZAKA, TAKAYUKI KISS, ASHISH CHAINANI, TAKAYOSHI YOKOYA, TADASHI TOGASHI, XIADONG WANG, CHUANGTIAN CHEN, SHUNTORE WATANABE, JUNICHI YAMAURA, SHIGEKI YONEZAWA, YUJI MURAOKA, ZENJI HIROI, TOMOHIKO SAITO, SHIK SHIN, UNIVERSITY OF TOKYO TEAM, THE INSTITUTE OF PHYSICAL AND CHEMICAL RESEARCH TEAM, OKAYAMA UNIVERSITY TEAM, TOKYO UNIVERSITY OF SCIENCE TEAM, CHINESE ACADEMY OF SCIENCE TEAM — The electronic structure near Fermi level of KOs₂O₆ is studied by a laser-excited photoemission spectroscopy. The superconducting(SC) gap clearly opens across the SC transition at 9.6 K, with the strong electron-phonon coupling value of 2Δ(0)/k_BTc ≥ 4.56. Fitting analysis identifies clear anomalies at 7.5 K in the temperature dependences of the SC gap size and the quasiparticle relaxation lifetime. These anomalies and the fine spectral structures arising from phonons, suggest that the existence of the rattling behavior of K ions significantly affects the superconductivity in KOs₂O₆.

11:39AM J11.00003 Controlling physical parameters of layer-structured nitride-halide superconductors, YASUJIRO TAGUCHI, RIKEN — Metal-intercalation into band insulators sometimes affords superconductors, well-known examples of which are carbon-based materials, such as fullerides and graphite. Layer-structured nitride-halide Li₅₋ₓZrNCl and Li₅₋ₓHfNCl (M denotes molecule) belong to another class of intercalation-induced superconductors with relatively high Tc, in which doping level and interlayer distance (and hence interlayer hopping interaction) can independently be controlled by changing Li concentration and the size of the co-intercalated molecule. The controllability provides a unique and interesting opportunity to investigate the effect of the two important physical parameters on Tc in a single system. Recent progress in the synthesis technique enabled us to obtain for the first time a series of single-phase samples of Li₅₋ₓZrNCl with finely controlled doping-levels which were notoriously difficult to prepare. Using these samples, we have established[1] an electronic phase diagram to find anomalous doping evolution of Tc, which takes a maximum value on the verge of superconductor-insulator transition. Based on this phase diagram and the results of systematic Raman scattering and transport measurements, we will discuss possible roles in producing relatively high Tc played by charge fluctuation and reduced disorder scattering in the layered structure reminiscent of modulation-doped semiconductors. We will also briefly refer to our very recent results on the Hf-based materials in which both of the doping level and interlayer distance were varied.

12:15PM J11.00004 Independent control of carrier concentration and interlayer spacing in Li₂HfNCl layered superconductors, TAKUMI TAKANO, ATSUSHI KITORA, TSUKASA KISHIUME, Institute for Materials Research, Tohoku University, YASUJIRO TAGUCHI, FRS-CMGR, RIKEN, YOSHIHITO IWASA, Institute for Materials Research, Tohoku University, INSTITUTE FOR MATERIALS RESEARCH, TOHOKU UNIVERSITY, SENDAI 980-8577, JAPAN TEAM, FRS-CMGR, RIKEN, WAKO, Saitama 351-0198, JAPAN TEAM, CREST, JAPAN SCIENCE AND TECHNOLOGY CORPORATION, KAWAGUCHI 352-0012, JAPAN COLLABORATION — Alkali-metal and organic molecule co-intercalated HfNCl is a new class of layered superconductors with relatively high transition temperature (Tc) of 25.5 K. Recently, we have succeeded in synthesis of single phase samples of Li₅₋ₓHfNCl with a wide range of doping concentration of 0.10 ≤ x ≤ 0.50, where we are able to, continuously and independently, control the carrier density and interlayer distance d between the conducting Hf-N layers by means of co-intercalation of Li and organic molecule. Without any molecule, superconductivity appears at x ≈ 0.15 and Tc is almost constant against x above this critical value. Furthermore, we found that Tc is enhanced (~30%) from 20 K to 25.5 K with increasing of d.

12:27PM J11.00005 Unconventional superconductivity in single crystal Lu₂Fe₃Si₂[1], R. GORDON, M.D. VANNETTE, C. MARTIN, Ames Laboratory, T. TAMEGAI, Y. NAKAJIMA, Department of Applied Physics, The University of Tokyo, Japan, R. PROZOROV, Ames Laboratory — Dynamic magnetic susceptibility for a single crystal of the ternary superconductor Lu₂Fe₃Si₂ has been measured using a tunnel diode resonator (TDR) technique. The London penetration depth exhibits non-exponential temperature dependence. We analyze the obtained superfluid density by comparing models of two-gap superconductivity, a gap with nodes or a highly anisotropic gap. The upper critical field is highly anisotropic and is unusually large. Furthermore, hysteresis in the susceptibility implies unusually strong temperature dependence of the critical current. The results are discussed in terms of possible unconventional behavior of this low-Tc superconductor.

1[1]Supported by the DOE-BES (contract No. DE-AC02-07CH11358) and the Alfred P. Sloan Foundation.

12:39PM J11.00006 Two-Gap Superconductivity in Lu₂Fe₃Si₂, TSUYOSHI TAMEGAI, YASUYUKI NAKAJIMA, GUOJIL LI, Department of Applied Physics, The University of Tokyo — Lu₂Fe₃Si₂ is a superconductor with Tc ≈ 6 K containing nonmagnetic iron. Anomalous temperature dependence of specific heat in the superconducting state has been reported in polycrystalline samples; reduced specific heat jump at Tc and apparent residual T-linear term in the limit of T = 0 K. We have successfully grown high-quality single crystals of Lu₂Fe₃Si₂ using the floating-zone technique, and characterized its superconducting and normal state properties. The anomalies of the specific heat reported in polycrystalline samples are reproduced in the single crystals. In addition, we find a second drop of the specific heat below 1 K. We can fit the temperature dependence of the specific heat by assuming two superconducting gaps as in the case of MgB₂. Temperature dependence of Hall coefficient is nonmonotonic, and also suggests the presence of multiple bands in this compound.

12:51PM J11.00007 Point-contact Andreev reflection tunneling spectroscopy (PCARTS) of the superconducting gap structure in LuNi₅B₂C, XIN LU, W.K. PARK, L.H. GREENE, Physics and FSMRL, UIUC, SUNMOK YEO, KYU-HWAN OH, SUNG-IK LEE, Pohang, Korea, SERGEY L. BUD’KO, PAUL C. CANFIELD, Ames Lab and ISU — The PCARTS technique is employed to investigate the gap anisotropy and proposed existence of point-nodes in LuNi₅B₂C (Δc ≈ 18 K). Differential conductance spectra are taken from two different sets of single crystal samples along three major orientations: [001], [110], and [100]. Analyzing using the single-gap Blonder-Tinkham-Klapwijk (BTK) model reproduces shows the gaps along these directions are 2.4, 2.6, and 2.3 meV, respectively, for one set of samples and 2.4, 2.8, and 2.7 meV, respectively, for the other set. This is smaller than the gap anisotropy reported by other groups[1]. At low temperatures, the single-gap BTK model does not satisfactorily fit our data. Models employing an anisotropic gap are being investigated, as are experiments parameterizing the tunneling cone effect.

1Supported by the U.S. DoE DEFG02-91ER45439 through FSMRL and CMM at UIUC and NSF DMR 07-06013 and by DoE DE-AC02-07CH11358 at Ames Lab.
1:03PM J11.00008 Anisotropic properties of aligned weak-ferromagnetic superconductor Ru$_3$Sr$_2$GdCu$_2$O$_8$ — H.C. KU, B.C. CHANG, C.H. HSU, Y.F. CHEN, M.F. TAI, Department of Physics, National Tsing Hua University, Hsinchu 300, Taiwan, Republic of China. SUPERCONDUCTIVITY AND MAGNETISM LABORATORY TEAM — The ab-plane aligned powder in epoxy matrix for the tetragonal Ru$_3$Sr$_2$GdCu$_2$O$_8$ weak-ferromagnetic superconductor was achieved using a field powder alignment method with ab-plane parallel to the applied magnetic field. The c-axis aligned powder can also be obtained using the field-rotation method where c-axis is perpendicular to the applied magnetic field and along the rotation axis. The temperature dependence of magnetic moment m (T) for the aligned powder provides the desired anisotropic properties where larger magnetic moment along the ab-plane was observed. The field-cooled (FC) and zero-field-cooled (ZFC) data in low applied field (1 G) for both directions indicate a weak-ferromagnetic (canted-antiferromagnetic) transition of Ru moment at $T_X$(Ru) = 131 K and a superconducting transition in the Cu$_2$O$_8$ plane at $T_c$ = 39 K. The low temperature antiferromagnetic ordering of the rare earth Gd moment is observed at $T_X$(Gd) = 2.5 K. Diamagnetic superconducting shielding signal is much weaker than bulk sample due to small powder diameter (1-10 $\mu$m), long penetration depth $\lambda$ and the two-dimensional (2D) character of Cu$_2$O$_8$ plane. Low temperature, low field magnetization data m(B, T) will be discussed.

1:15PM J11.00009 Order parameter suppression and structure of the surface states in noncentrosymmetric superconductors — ANTON VORONTSOV, University of Wisconsin-Madison, ILYA VEKHTER, Louisiana State University, MATTHIAS ESCHRIG, Universitaet Karlsruhe. We consider the structure of the surface states at the pairbreaking boundaries of non-centrosymmetric superconductors. In the region of the order parameter suppression multiple Andreev reflections significantly modify the energy and the intragap density of states due to bound states. We elucidate the physics behind this modification by considering a simple model of gap suppression, and comparing it with a fully self-consistent microscopic calculation. We emphasize the experimentally relevant consequences of the lack of inversion symmetry for the surface states. As the discontinuity in the spin-orbit coupling at the boundary makes the interface spin-active, we analyse the resulting spin structure of the bound states.

1:27PM J11.00010 Superconductivity in Sn(1-x-d)In(x)Te and Pb(1-y)Tl(y)Te — ANN ERIKSON, THEODORE GEBALLE, IAN FISHER, Stanford University. Recent evidence for a charge-Kondo effect in superconducting samples of Pb$_{1-y}$Tl$_y$Te [PRL 94, 157002 (2005)] raises the possibility that systems of degenerate semiconductors doped with valence skipping elements may be an ideal realm in which to study suggested negative U pairing mechanisms in superconductors [PRL 61, 2713 (1988)]. However, questions of exactly how the proposed charge-Kondo behavior relates to superconductivity in Pb$_{1-y}$Tl$_y$Te remain. In this work, we study the relationship between the DOS at the Fermi level and Tc in the related superconductor Sn$_{1-x-d}$In$_x$Te, where enhancement of Tc is found above a critical concentration $x_c > d/2$, where the Fermi level is pinned in the impurity band and the DOS is enhanced [Phys. Rev. B 28, 612 (1983)]. We find that the elevated DOS is insufficient to explain the enhanced Tc for these samples, suggesting an additional pairing mechanism is involved, such as the negative U mechanism mentioned above.

1:39PM J11.00011 Novel superconductivity in a new noncentrosymmetric superconductor — LEI FANG, XIYU ZHU, GANG MU, HAI-HU WEN, National Lab for Superconductivity, Institute of Physics, CAS — Low temperature specific, resistivity and magnetization are measured in a newly fabricated superconductor. It is found that this material has no central inversion symmetry. Specific heat measurement show that the major part of the system has a s-wave symmetry and the superconducting gap is thus derived. However, when the superconductivity is suppressed by the magnetic field, a further drop of specific heat coefficient is observed just above Tc. This unexpected behavior remains to a very high magnetic field and without any obvious shift of the transition temperature. It is tempting to argue that this drop of specific heat coefficient may be induced by the spin triplet pairs.

1:51PM J11.00012 Superconductivity in the new Platinum Germanides APt$_4$Ge$_{12}$ (A=Sr,Ba,La,Pr) — HELGE ROSNER, ROMAN GUMENIUK, WALTER SCHNELLE, MICHAEL NICKLAS, ANDREAS LEITHE-JASPER, YURI GRIN, Max-Planck-Institute for Chemical Physics of Solids Dresden, Germany — New germanium-platinum compounds with the filled-skutterudite crystal structure were synthesized. Magnetic susceptibility, specific heat, and electrical resistivity measurements find superconductivity in LaPt$_4$Ge$_{12}$ and PbPt$_4$Ge$_{12}$ below ca. 8 K. The parameters of the normal and superconducting states were established. Strong electron-phonon coupling and a crystal electric field singlet groundstate is found for the Pr compound. Electronic structure calculations show a large density of states at the Fermi level, predominantly due to Ge $4p$ orbitals. Similar behavior, albeit with lower Tc, was observed for SrPt$_4$Ge$_{12}$ and BaPt$_4$Ge$_{12}$.

Session J12 DCMP: Experimental Studies of the Heavy Fermion 115 Compounds Morial Convention Center 203

11:15AM J12.00001 3D Fermi Surface Mapping of Ce$_3$RhIn$_5$ — J.D. DENLINGER, Lawrence Berkeley National Lab, F. WANG, J.W. ALLEN, U. of Michigan, M.B. MAPLE, U.C. San Diego, S. ELGAZZAR, P.M. OPPENEER, Uppsala University — Photon-dependent multi-Brillouin zone angle-resolved photoemission (ARPES) measurements are presented for the antiferromagnet heavy fermion bilayer compound Ce$_3$RhIn$_5$. Highly automated Fermi Surface (FS) mapping for excitation energies of 90-120 eV allow visualization of $k_z$-variations of the electronic structure and permit a $k_z$-tomographic determination of the three-dimensional (3D) FS topology with sufficient detail for quantitative comparison to dHvA orbit areas and LDA-predicted topological shapes. In addition to confirming the quasi-2D circular and square topologies centered on the Brillouin zone corner, highly 3D $k_z$-variations are observed along the (100) directions $\Gamma$-X (Z-R). Results are compared to a similar ARPES determination of the 3D electronic structure and FS of the single layer compound CeCoIn$_5$.

11:27AM J12.00002 Anisotropic quantum criticality in heavy-fermion metal CeCoIn$_5$ — RAMZY DAOU, MAKARY TANATAR, Department of Physique, Universite de Sherbrooke, Quebec, Canada, CEDOMIR PETROVIC, Brookhaven National Laboratory, JOHNPIERRE PAGLIONE, Dept. of Physics, University of Maryland, LOUIS TAILLEFER, Dept. of Physique, Universite de Sherbrooke, Quebec, Canada, Canadian Institute for Advanced Research — We previously reported a violation of the Wiedemann-Franz law in the heavy-fermion metal CeCoIn$_5$ when tuned to its quantum critical point, depending on the direction of electron motion relative to the crystal lattice, which points to an anisotropic destruction of the Fermi surface [1]. Here we present new measurements of electric, thermal and thermo-electric transport coefficients which reveal different anisotropic responses. [1] M.A. Tanatar et al., Science 316, 1320 (2007).

1 Supported by the U.S. DOE (DE-AC02-05CH11231 at the Advanced Light Source, DE-FG02-07ER46379 at UM), by the U.S. NSF (DMR-03-02825 at UM) and by the Swedish Research Council (VR) and the European Commission (JRC-ITU).

11:39 AM J12.00003 Nature of the superconducting state of CeCoIn$_5$ as revealed by NMR. GEORGIOS KOUTROULAKIS, VESNA MITROVIC, MARC-ANDRÉ VACHON, Brown University, MLADEN HORVATIC, CLAUDE BERTHIER, GHMFL, GEORG KNEBEL, GERARD LAPERTOT, JACQUES FLOQUET, SPSMS — We report low temperature nuclear magnetic resonance (NMR) measurements of the heavy-fermion superconductor CeCoIn$_5$ in high magnetic fields. The effect of the RF penetration on the NMR spectrum for the different parts of the phase diagram is studied. The implications of this study for the nature of a possible inhomogeneous superconducting state, the Fulde-Ferrell-Larkin-Ovchinnikov (FFLO) state, are discussed.

11:51 AM J12.00004 Thermal transport in the vortex state of heavy-fermion superconductor CeCoIn$_5$. M.A. TANATAR, J.P. REID, Département de physique, Université de Sherbrooke, Sherbrooke, Canada, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Physics Department of University of Maryland, Washington, DC, USA, C. PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, Upton, NY 11973, USA, LOUIS TAILLEFER, Département de physique, Université de Sherbrooke, Sherbrooke, Canada — The thermal conductivity of heavy-fermion superconductor CeCoIn$_5$ was measured as a function of temperature and magnetic field throughout the vortex state. An anomalous decrease is found in the field dependence at low fields and low temperature. We discuss the origin of this behavior and its possible relation to the presence of uncondensed electrons, found in a previous doping study of this material [1].

12:03PM J12.00005 NMR investigation of a hole doped CeCoIn$_5$. R. R. URBANO, N. J. CURRO, V. A. SIDOROV, J. D. THOMPSON, Los Alamos National Laboratory, Los Alamos-NM, 87545, U. S. A., L. D. PHAM, University of California, Davis-CA, 95616, U. S. A., Z. FISK, University of California, Irvine-CA, 92697, U. S. A. — We have investigated the local environment of In and Co sites of the heavy fermion compound CeCoIn$_{1-x}$Cd$_x$$_5$ ($x = 0.0, 0.10$ and $0.15$) using Nuclear Magnetic Resonance (NMR) and Nuclear Quadrupole Resonance (NQR) measurements. Recently, it was found that Cd-doping acts as an electronic tuning agent in CeCoIn$_5$ and that superconductivity (SC) and antiferromagnetism (AFM) coexist at ambient-pressure for $0.05 < x < 0.15$. It has also been observed on Cd doped compounds that pressure $P$ recovers the SC, ground-state observed for the undoped compound suggesting it as a reversible tuning parameter. In this work we report data indicating that these phases indeed coexist microscopically. The NMR/NQR spectra of In and Co indicate the presence of electronic inhomogeneity, and the spin-lattice relaxation measurements $T_1^{-1}$ suggest that Cd doping induces changes to the low frequency spin dynamics only below $T \approx 5K$. Furthermore, $T_1^{-1}$ measurements for $x = 0.10$ under pressure show a different spin dynamics response in the paramagnetic state, in contrast with the effect of the chemical pressure. We show that chemical doping and pressure are not equivalent.

12:27PM J12.00007 Evolution of the superconducting properties of CeCoIn$_5$ with Yb substitution. D. HURT, C. CAPAN, Z. FISK, Department of Physics & Astronomy, UC Irvine, Irvine, CA, USA, A. D. BIANCHI, Dpt. de physique, U. de Montréal, Montréal, QC, Canada — We report on the evolution of the physical properties of the Yb substitution series starting from the unconventional superconductor (SC) CeCoIn$_5$ to the isostuctural normal metal YbCoIn$_5$. This study was motivated by the recent results of Cd or Hg substitution at the percentage level on the In site in CeCoIn$_5$, which for low concentrations first was shown to lead to the coexistence of antiferromagnetism with SC and to a complete suppression of SC at higher concentrations. At the same time, the lattice constant of YbCoIn$_5$ indicates that Yb enters this compound in a partially valent configuration suggesting that Yb could also be suitable for doping holes into CeCoIn$_5$. In our substitution series we find that the unit cell volume stays roughly constant up to an Yb concentration of about 40 %, after which the cell volume begins to decrease gradually to the value of YbCoIn$_5$. At the same time we observe a gradual suppression of the transition temperature $T_c$ to zero at an Yb concentration of 60 %. Interestingly, the shape of $H-T$-phase diagram remains the same when the axis is scaled with the respective $T_c$ and upper critical field $H_{c2}$, suggesting that the ratio between Pauli $H_p$ and the orbital critical field $H_{c2}$ remains constant.

12:39PM J12.00008 Quantum oscillations in heavy fermion CeRhIn$_5$. HUIQIU YUAN, TUSON PARK, ERIC BAUER, JOE THOMPSON, JOHN SINGLETON, Los Alamos National Laboratory — Construction of Fermi surface is the key to understand the physical properties of variant materials. In correlated electron systems, the heavy carrier mass strongly attenuates the amplitude of quantum oscillations, and, therefore, the Fermi surface sheets from the heavy electrons are usually not observable at low fields. High magnet fields are an indispensable tool to uncover these important features of electronic structure. Furthermore, strong magnetic field above the Neel critical field may lead to the reconstruction or a volume change of Fermi surface in f-electron antiferromagnets (N. Harrison et al. PRL 99, 056401, 2007). Using the unique facilities in the national high magnetic field lab at LANL, in this presentation we will study the quantum oscillations in the heavy fermion compound CeRhIn$_5$ with a field up to 65T.

12:51PM J12.00009 Pressure effect of single ion Kondo temperature in Ce$_{0.02}$La$_{0.89}$RhIn$_5$. H. LEE, V.A. SIDOROV, Los Alamos National Laboratory, Los Alamos, NM 87544, L.M. FERREIRA, Instituto de Fisica Gleb Wataghin, UNICAMP, 13083-970, Campinas, Brazil, T. PARK, F. RONNING, E.D. BAUER, J.D. THOMPSON, Los Alamos National Laboratory, Los Alamos, NM 87544 — Near a critical pressure $P_c \sim 25$ kbar, CeRhIn$_5$ assumes characteristics of CeCoIn$_5$ at atmospheric pressure: they have comparable $T_c$, similar dHvA frequencies, and display quantum-critical behaviors. Many properties of CeCoIn$_5$ can be interpreted within a two-fluid phenomenology in which there are interpenetrating fluids, a localized $f$-electron Kondo gas (energy scale $T_K$) and an interacting Kondo liquid (energy scale $T^*$). We have measured transport properties of Ce$_{0.02}$La$_{0.89}$RhIn$_5$ under pressures to 50 kbar to determine $T_K(P)$, which at $P=0$ is estimated to be $\sim 0.03K$ from specific heat measurements. $T_K(P)$ increases rapidly, reaching $\sim 1.35K$ at 25 kbar, where it becomes comparable to $T_K(\sim 1.8K)$ of CeCoIn$_5$ at $P=0$. A comparison of $T_K(P)$ with $T^*(P)$, determined from the pressure studies of CeRhIn$_5$, reveals the same correlation between $T_K$ and $T^*$ inferred from a two-fluid analysis of CeCoIn$_5$, further supporting the similarity of these two compounds and the two-fluid phenomenology. [1] S. Nakatsuji et al., Phys. Rev. Lett. 92, 016401 (2004).
1:03PM J12.00010 Uniaxial Pressure and the Superconducting Transition of CeIrIn\(_5\)\(^1\), OWEN DIX, ADRIAN SWARTZ, RENA ZIEVE, UC Davis, TODD SAYLES, BRIAN MAPLE, UCSD — We measure the superconducting transition temperature of CeIrIn\(_5\) with applied uniaxial pressure. Heat capacity shows almost no shift in \(T_c\) as pressure is applied along the \(c\)-axis, contrary to the large decrease expected from earlier thermal expansion measurements. With \(a\)-axis pressure, however, \(T_c\) increases about 20 mK per kbar. These results indicate that another factor besides the \(c/a\) ratio has a strong effect on \(T_c\). Furthermore, applied pressure along either crystal axis strongly reduces the size of the heat capacity transition. We will also discuss the effect of uniaxial pressure on the resistive transition, which at ambient pressure occurs at a temperature well above the heat capacity transition. Finally, we present x-ray diffraction measurements correlating our applied pressures with changes in the crystal lattice constants.

\(^1\)Supported by NSF through DMR-0454869.

1:15PM J12.00011 Evolution of the superconducting state through quantum criticality in CeRh\(_{1-x}\)Co\(_x\)In\(_5\), JOHNPIERRE PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, M.A. TANATAR, J.P. REID, LOUIS TAILLEFER, Département de Physique, Université de Sherbrooke, Canada, M.B. MAPLE, Department of Physics and Institute of Pure and Applied Physical Sciences, University of California, San Diego — The Ce-based 115 materials exhibit a host of novel ground states separated by experimentally tunable quantum instabilities. In the single-crystal alloy series CeRh\(_{1-x}\)Co\(_x\)In\(_5\), long range antiferromagnetic order is gradually suppressed upon chemical substitution of Co for Rh and followed by a robust superconducting state extending to the 2.3 K transition of the infamous heavy-fermion superconductor CeCoIn\(_5\). Here we present a thorough study of heat transport measurements of high-quality single crystals of CeRh\(_{1-x}\)Co\(_x\)In\(_5\) for several different superconducting samples spanning both the coexistent magnetic and non-magnetic regions of the \(x\)-\(T\) phase diagram. By extracting the residual (\(T \rightarrow 0\) limit) electronic thermal conductivity of samples at several \(x\) values, we analyze the nature of the superconducting state on either side of the incipient quantum critical point near \(x \approx 0.65\) and study the influence of coexistent magnetism on the pairing state of these materials.

1:27PM J12.00012 Electronic Duality in the Pressure-tuned Quantum Critical Metal CeRhIn\(_5\), TUSON PARK, M.J. GRAF, LEV BOULAEVSKII, J.L. SARRAO, J.D. THOMPSON, Los Alamos National Laboratory — The heavy fermion compound CeRhIn\(_5\) is a prototypical strongly correlated antiferromagnet where the localized 4f electron of Ce hybridizes weakly with ligand electrons. Applying pressure to this material increases hybridization and induces bulk unconventional superconductivity that arises from pressure-enhanced itinerancy of 4f electrons and that simultaneously coexists with large-moment antiferromagnetic order among localized 4f electrons. This microscopic coexistence of local-moment magnetic order and superconductivity in CeRhIn\(_5\) is distinctly different from conventional models that attribute coexisting spin-density wave magnetism and superconductivity to a Fermi-surface instability. Electronic duality, which is unambiguously revealed in the single 4f electron of cerium in CeRhIn\(_5\), is a new framework emerging from strongly correlated electron matter, ranging from the high-\(T_c\) cuprates and heavy fermion superconductors to plutonium.

1Work at Los Alamos National Laboratory was performed under the auspices of the US Department of Energy, Office of Science, and supported by the Los Alamos Laboratory Directed Research and Development program.

1:39PM J12.00013 ABSTRACT Withdrawn –

2:03PM J12.00015 \(d_{x^2-y^2}\) paring symmetry of heavy fermion CeIrIn\(_5\) remote from antiferromagnetic quantum critical point, YUICHI KASAHARA, T. IWASAWA, Y. SHIMIZU, H. SHISHIDO, T. SHIBAUCHI, Kyoto University, I. VEKHTER, Louisiana State University, Y. MATSUDA, Kyoto University, Institute for Solid State Physics, University of Tokyo — Quasi-two dimensional heavy fermion CeIrIn\(_5\) involves two distinct superconducting domes in the phase diagram, which appear as a function of pressure or Rh substitution of Ir. In the analogy to CeCu\(_2\)Si\(_2\), two distinct superconducting domes with different symmetry has been invoked. We report on the results of low-temperature transport of CeIrIn\(_5\) in the second dome, which locates away from an antiferromagnetic quantum critical point. The thermal conductivity is measured under a magnetic field rotated with respect to the crystal axes, which give direct evidence for superconducting gap structure. Clear fourfold oscillation with minima at [110] and [1-10] directions is observed as rotating magnetic field within the basal \(ab\)-plane, while no oscillation is observed within the \(bc\)-plane. In sharp contrast to previous reports that suggested \(E_g\) symmetry with horizontal line node within the \(ab\)-plane \([1]\), our results are most consistent with \(d_{x^2-y^2}\) symmetry with vertical line nodes along the \(c\)-axis. These results imply that two superconducting domes have the same gap symmetry which appears to be mediated by antiferromagnetic spin fluctuations.

Tuesday, March 11, 2008 11:15AM - 2:03PM –

Session J13 DCOMP GSCCM: Focus Session: Simulations of Matter at Extreme Conditions IV: Crystalline Solids, Liquids, and Methods Morial Convention Center 204
11:15AM J13.00001 Structure and dynamics of supercooled liquid silicon under pressure: A first-principles molecular-dynamics study. , TETSUYA MORISHITA, Research Institute for Computational Sciences, National Institute AIST — Recent investigations have suggested that silicon (Si) may exhibit liquid-liquid transitions under pressure and/or supercooling [2]. Here, we report first-principles molecular-dynamics simulations of supercooled liquid Si focusing on the pressure dependence of structure and dynamics [2]. The pair correlation function of deeply supercooled liquid Si (1100 K) for pressures 0 - 18 GPa shows considerable structural changes resulting from the collapse of tetrahedral configurations. The power spectrum of the velocity auto-correlation function also confirms the reduction of the tetrahedral order by pressurization. The self-diffusion coefficient as a function of pressure shows a broad maximum around 10 GPa. However, at a higher temperature (1500 K), the diffusion coefficient simply decreases with increasing pressure, indicating conspicuous dependence of the dynamics and relevant structure upon temperature. [1] T. Morishita, Phys. Rev. Lett. 93, 055503 (2004); ibid. 97, 165502 (2006). [2] T. Morishita, Phys. Rev. E 72, 021201 (2005).

11:27AM J13.00002 Molecular dynamics simulation of the shock-induced wurtzite-to-rocksalt transition in CdSe and CdS1. , AIDAN THOMPSON, MARCUS KNUDSON, Sandia National Laboratories — The shock-induced wurtzite-to-rocksalt structural transformation is studied using large-scale molecular dynamics simulation. The primary goal is to understand the atomicistic mechanisms underlying the interesting transformation kinetics observed in the case of cadmium sulfide [M. D. Kudson and Y. M. Gupta, J. Appl. Phys. v. 91, p. 9561, 2002]. Since the mechanical and structural properties of CdS are very similar to those of CdSe, we have performed multi-million atom MD simulations of the shock-induced phase transformation in CdSe single-crystals using the well-established interatomic potential of Rabani, which has been shown to correctly describe the wurtzite and rocksalt phases and the transformation pressure. In MD simulations of shock along the wurtzite c-axis, the elastically-compressed wurtzite transforms directly to grains of rocksalt. Along the a-axis, a three-wave structure is observed; the wurtzite first transforms to a tetragonal crystal phase, which in turn transforms to rocksalt grains.

11:39AM J13.00003 Large-scale molecular dynamics modeling of shock wave propagation in silicon. , XIANG GU, MIKALAI BUDZEVICH, IVAN OLEYNIK, University of South Florida, SERGEY ZYBIN, California Institute of Technology. CARTER WHITE, Naval Research Laboratory — We performed molecular dynamics simulations of shock wave propagation in silicon. The different regimes of materials response were studied as a function of shock wave intensity and crystalline orientation of shock wave propagation. The shock Hugoniot is predicted in a wide range of piston velocities (0-12 km/s), and for several crystallographic orientations <100>, <110>, and <111>. Shock Hugoniots were used for a detailed analysis of a material's response to complex, split shock-wave structures. The special regime of an anomalous response of the material which is characterized by absence of plastic deformation in the intermediate interval of shock wave intensities was investigated.

11:51AM J13.00004 Shock front broadening in polycrystalline materials. , JOHN BARBER, KAI KADAU, Los Alamos National Laboratory — We analyze a model for the evolution of weak shock fronts (or elastic precursor waves) in polycrystalline materials. This model is based on the ideas of Wayers and Carvalho [Mater. Sci. Eng., 292-293 (1976)] that the shock velocity anisotropy within the polycrystal is the most important factor in shock front broadening. Our analysis predicts that the shock front width increases as the 1/2 power of the front penetration distance into the crystal. Our theoretical prediction is in plausible agreement with previous experimental results for the elastic precursor rise time, and it should therefore provide a useful shock width estimate. Furthermore, our theoretical framework is also applicable to other problems involving front propagation in heterogeneous media.

12:03PM J13.00005 Large Scale Molecular Dynamics Simulations of Dense Plasmas. , JEROME DALIGAULT, GUY DIMONTE, Los Alamos National Laboratory. Plasmas are generally created and probed by depositing energy into matter, driving it far from equilibrium. Knowledge over a wide range of physical conditions of the rate at which the electronic and ionic subsystems come into thermal equilibrium is important for explicit practical purposes. The microscopic mechanisms vary with the strength of the coupling among particles and the degree of degeneracy of the electrons. Though a variety of models for the electron-ion energy equilibration rate were proposed, these models apply to specific regimes, their range of validity and the transition from one regime to another remains unclear. Molecular dynamics (MD) simulations provide a powerful tool to investigate the validity of the various models. In order to study the temperature relaxation rates over a wide range of plasma coupling, from very weakly coupled to strongly coupled multi-million particles simulations are necessary. To this end, we have developed a parallel MD code that employs the particle-particle particle-mesh algorithm and allow the simulation of very large, complex Coulomb systems and over long time scales. We have performed detailed, multi-million particle MD simulations to investigate and shed some new light on the electron-ion energy relaxation in hot, dense plasmas. In this talk, we will describe the MD code and discuss the original results obtained for the temperature relaxation rates.

12:15PM J13.00006 Effect of Crystalline Anisotropy on Shock Propagation in Sapphire. , W.J. NELLISS, Harvard U., G.I. KANEL, S.V. RAZORENOV, A.S. SAVINYKH, Russian Academy of Sciences, A.M. RAJENDRAN, U.S. Army Research Office — The major impediment to measuring resoshock temperatures is opacity induced in anvil/windows by shock. We report measured shock profiles of c-, d-, and r-cut single crystals and comparison of these mechanical responses with optical snapshots measured by Hare et al. Profiles were measured at three peak stresses and two sample thicknesses. Particle velocity histories were recorded for sapphire/LIF interfaces. VISAR waveforms are noisy as a result of heterogeneous inelastic deformation and noise depends on crystal orientation and stress amplitude. Heterogeneity is least for r-cut and most for c-cut, which correlates with observed optical heterogeneity. At 2.4 mm thickness r-cut has a three-wave structure that might indicate several elastic-wave speeds off an axis of symmetry. The small signal of the third wave might also indicate a phase transition in the small volume of the sample at higher temperatures. The Hugoniot elastic limit of c-sapphire is defined by the lack of scattered from shot to shot; scatter in the HEL of r- and d-cut are smaller. Radial pre-stressing of c-sapphire resulted in some increase of the rise time of the second wave; no significant effect of pre-stressing was observed for d- and r- samples.

12:27PM J13.00007 Shock Pulse Effects in PTFE Shocked to the Crystalline Phase II–III Transition. , ERIC N. BROWN, Los Alamos National Laboratory, ADWP, GEORGE T. GRAY III, PHILIP J. RAE, Los Alamos National Laboratory, MST-8, NEIL K. BOURNE, AWE, UK — We present an experimental study of crystalline structure evolution of polytetrafluoroethylene (PTFE) due to pressure-induced phase transitions in a semi-crystalline polymer using soft-recovery, shock-loading techniques coupled with mechanical and chemical post-shock analysis. Gas-launched, plate impact experiments have been performed on pedigreed PTFE 7C, mounted in momentum-trapped, shock assemblies, with impact pressures above and below the phase II to phase III crystalline transition. Below the phase transition only subtle changes were observed in the crystallinity, microstructure, and mechanical response of PTFE. Shock loading of PTFE 7C above the phase II–III transition was seen to cause both an increase in crystallinity from 38% to ~53% (by Differential Scanning Calorimetry, DSC) and a finer crystalline microstructure, and changed the yield and flow stress behavior. We particularly focus on the effect of pulse duration on the microstructure evolution.

12:39PM J13.00008 Electrical Breakdown and Lock-On in Photoconductive Semiconductor Switch (PCSS) Devices 1, HAROLD HJALMARSON, KENNETH KAMBOUR, FRED ZUTAVERN, Sandia National Laboratories, CHARLEY MYLES, Texas Tech University — Optically-triggered, high-power photoconductive semiconductor switches (PCSS’s) using semi-insulating GaAs are being developed at Sandia Labs. These switches carry current in high carrier-density filaments. The properties of these filaments can be explained by redistribution of carrier energy caused by carrier-carrier scattering within the filament. This process enhances the impact ionization rate thus allowing these filaments to be sustained by relatively low fields, a process called lock-on. For GaAs, the sustaining field is approximately 4.5 kV/cm. For this talk, the physics mechanisms for lock-on and high-field electrical breakdown are described. Also, a continuum implementation of these physics mechanisms is used to compute the properties of these filaments. These continuum calculations are based on previous calculations in which the filament properties are computed using a Monte Carlo method to solve the steady-state Boltzmann equation.

12:51PM J13.00009 Ideal Strength of Hexagonal Diamond and Related B-C-N Compounds 1, CHANGFENG CHEN, YI ZHANG, University of Nevada, Las Vegas, ZICHENG PAN, HONG SUN, Shanghai Jiao Tong University, China — We have performed first principles calculations on the ideal strength of h-diamond, w-BN, and Φ-BCN. We have considered structural deformation under pure tensile, pure shear or biaxial stress fields. The calculated results reveal new atomistic fracture mechanism for these materials.

1 This work was supported by the Department of Energy Cooperative Agreement DE-FC52-06NA26747 at UNLV and the NNSF of China grants 10574089 and 5053020, Chinese National Minister of Education Program for Innovative Research Team in University at SJTU.

1:03PM J13.00010 Equation of state of crystalline FeO from diffusion Monte Carlo simulations 1, JINDRICH KOLORENC, LUBOS MITAS, North Carolina State University, Raleigh — We investigate equation of state of stoichiometric FeO (at T = 0 K) by means of the diffusion quantum Monte Carlo method (DMC). We find a pressure induced transition from the B1 (rocksalt) structure, which represents the ambient pressure ground state, to the inverse B8 (NiAs) lattice. Experimental evidence for such a transition is still rather controversial, being detected in some measurements and not seen in others. Our DMC estimate for transition pressure, P = 65 ± 5 GPa, is compared to outcome of other computational approaches, such as the density functional theory combined with hybrid exchange-correlation functionals.

1:15PM J13.00011 An efficient method for calculating high PT elastic constants 1, ZHONGQING WU, University of Minnesota — First-principles quasi-harmonic calculations play a very important role in mineral physics because they can accurately predict the structure and thermodynamic properties of materials at pressure and temperature conditions that are still challenging for experiments. It also enables calculations of thermoelastic properties by obtaining the second-order derivatives of the free energies with respect to strain. However, these are exceedingly demanding computations requiring thousands of large jobs running on 10^4 processors each. Here we introduce a simpler approach that requires only calculations of static elastic constants and phonon density of states for unstrained configurations. This approach decreases the computational time by more than one order of magnitude. We show results on MgO and forsterite that are in very good agreement with previous first-principles results and experimental data.

1:27PM J13.00012 Radiation in Particle Simulations of Hot Dense Matter 1, FRANK GRAZIANI, RICHARD MORE, Lawrence Livermore National Laboratory — The variety of complex processes that take place in hot dense radiative plasmas where temperatures are in excess of several keV and densities are higher than metals, has forced computational physicists in ICF and astrophysics to make a number of assumptions regarding how to model non-equilibrium plasmas undergoing thermal relaxation. In order to make the simulations feasible, variations on the Landau-Spitzer model are frequently invoked. There has been recent work on the theoretical properties of thermal relaxation in such plasmas, but there is controversy due to the various approximations needed to make the calculations tractable. Experimental validations in the regimes of interest are prohibitive. Direct Numerical Simulation (DNS) of the many-body interactions of plasmas is a promising approach to model validation but unfortunately, previous work either relies on the collisionless approximation or radiation is entirely absent. We present a new numerical simulation capability that will address a currently unsolved problem: the extension of molecular dynamics to collisional plasmas where Bremsstrahlung and Compton scattering are present. This new tool provides a method for assessing the accuracy of energy and momentum exchange models in hot dense plasmas.

1:39PM J13.00013 Trajectories and escape rates from a collapsing basin: dependence on the rate of collapse of the basin 1, ANTONIO CADILHAC, T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA; GCEP-Centro de Física da Universidade do Minho, 4710 Braga, Portugal, A.F. VOTER, T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545 — It has been shown that trajectories with different initial conditions synchronize in harmonic basins during Langevin-thermostatted molecular dynamics under the same time-noise sequence. Synchronization leads to exponential trajectory coalescence onto a single master trajectory [1]. We present our preliminary results extending previous research to include time dependent harmonic potentials, of the form V(x,t) = A(1 - e^{-αt})V∞, where A, α, and V∞ are constants, which are relevant for understanding the dynamics of driven systems. We present analytical results for the synchronization behavior in the various regimes arising in this context. We also complement the study with numerical estimates of the escape rates for basins with escape paths and compare them to static, conventional rates of escape. [1] Blas P. Uberuaga, Mariang Anghel, and Arthur F. Voter, J. Chem. Phys. 14, 6363 (2004).

1:51PM J13.00014 Momentum Transfer in Soft X-ray - Induced Shock Loading of Meteorite and Planetary Materials 1, JOHN REMO, Harvard University Center for Astrophysics, MICHAEL FURNISH, Sandia National Laboratories — The response of meteorite and planetary materials to high- intensity <1 keV x-rays from Z-pinch sources is described. These materials include iron and stony meteorites, magnesium rich olivine (dunite), and Al and Fe calibration samples. Input stresses varied from 6.1 to 12.4 GPa, attenuating to ~1.4 to 2.5 GPa for the iron meteorites, ~0.3 to 1.9 GPa for the stony meteorites, and 1.64 to 1.91 GPa for dunite. The calibration (pure) metals showed less attenuation than the highly inhomogeneous natural materials. 9.5 to ~5 GPa for Fe and 12.4 to 10.6 GPa for Al. Methods for deducing momentum and energy coupling into these materials from the radiation are discussed. These data are useful for planetary and astrophysical modeling and for near-Earth object mitigation studies requiring momentum coupling, and momentum enhancement coefficients.

Session J14 DAMOP: Focus Session: Berezinskii-Kosterlitz-Thouless Regime and Rotating Quantum Gases Morial Convention Center 205
11:15AM J14.00001 Kosterlitz-Thouless Transition in Finite-Size BEC Systems¹, GARY WILLIAMS, UCLA — The Kosterlitz-Thouless transition in two-dimensional BEC condensates is calculated taking into account the fact that these are finite-size systems. The outer boundaries of the condensate effectively act as hard walls, and this has a polarizing effect on the vortex pairs. As a consequence the superfluid fraction becomes strongly anisotropic, with the tensor component perpendicular to a wall falling to zero there, while the parallel component remains finite. The decreased pair energy near the walls results in an enhanced vortex density near the boundaries. Possible experiments are proposed to probe the anisotropic properties of the superfluid density, including an unusual sharp dip in the superfluid density that is predicted to occur down the middle of a long superfluid strip.

11:27AM J14.00002 Interference of a stack of coupled two-dimensional BEC pancakes, DAVID PEKKER, VLADIMIR GRITSEV, EUGENE DEMLER, Harvard University — We study the superfluid-normal transition in a stack of Josephson coupled two-dimensional BEC pancakes. Using a combination of the Renormalization Group and the self-consistent harmonic approximation we look at the transition from Kosterlitz-Thouless type behavior to 3D XY type behavior in this finite sized system. We compute the form of the interference patterns that can be observed experimentally if the gas is allowed to expand. In particular, we concentrate on the amplitude modulations in the direction normal to the two-dimensional pancakes, i.e. the direction of fastest expansion.

11:39AM J14.00003 Evolution from BCS to BKT superfluidity in one-dimensional optical lattices, MENDERES ISKIN, CARLOS A.R. SA DE MELO¹, Joint Quantum Institute, National Institute of Standards and Technology and University of Maryland, Gaithersburg, Maryland 20899-8423, USA. — We analyze the finite temperature phase diagram of Fermi-Fermi mixtures in one-dimensional optical lattices as a function of fermion-fermion interaction strength. At low temperatures, the Fermi-Fermi mixture evolves from a three-dimensional (3D) Bardeen-Cooper-Schrieffer (BCS) to a two-dimensional (2D) Berezinskii-Kosterlitz-Thouless (BKT) superfluid as the interaction strength increases. We show that the Ginzburg- Landau-Wilson action near the critical temperature is of the Lawrence-Doniach type for all interaction strengths, and explore the phase space of interaction strength versus hopping (or lattice depth) to determine the characteristic line where the behavior of mixture changes from 3D to 2D. Furthermore, we discuss the existence of vortex loop excitations, and how they evolve as a function of interaction strength.

¹School of Physics, Georgia Institute of Technology, Atlanta, GA 30332-0432, USA.

11:51AM J14.00004 Berezinskii-Kosterlitz-Thouless Crossover in a Trapped Atomic Gas, ZORAN HADZIBABIC, University of Cambridge — Physics of a Bose gas in 2D is quite different from the usual 3D situation. In a homogeneous 2D fluid of identical bosons long-range order is always destroyed by long wavelength thermal fluctuations and this system cannot undergo conventional Bose-Einstein condensation. Nevertheless, it can become superfluid at a finite critical temperature. This phase transition does not involve any symmetry breaking and in the Berezinskii-Kosterlitz-Thouless (BKT) paradigm it is explained in terms of binding and unbinding of pairs of vortices with opposite circulations. Above the critical temperature, proliferation of unbound vortices is expected. Using optical lattice potentials we can create two parallel, independent 2D atomic clouds with similar temperatures and chemical potentials. When the clouds are suddenly released from the trapping potential and allowed to freely expand, they overlap and interfere. This realizes a matter wave heterodyning experiment which gives direct access to several features of the phase distributions in the two planes. Long wavelength phase fluctuations create a smooth and random variation of the interference fringes and free vortices appear as sharp dislocations in the interference pattern. Both the temperature study of these effects and the measurements of the critical point support the BKT picture of the development of quasi-long-range coherence in these systems.

12:27PM J14.00005 Density Matrix Renormalization Group study of rapidly-rotating two-dimensional bosons¹, DMITRY KOVRIZHIN, Theoretical Physics, Oxford University, 1 Keble road, Oxford, OX1 3NP, United Kingdom — We study a system of two-dimensional bosons with contact interactions in a rapidly-rotating anisotropic trap. The ground state phase diagram and the excitation spectra are investigated using the Density Matrix Renormalization group (DMRG) and the exact diagonalization methods.

¹This work was supported by EPSRC grant EP/D066379/1

12:39PM J14.00006 A vortex dipole in a trapped 2D Bose condensate, WEIBIN LI, MASUD HAQUE, STAVROS KOMINEAS, MPI-PKS Dresden, Germany — We study the dynamics and the stationary states of a vortex-antivortex pair in a two-dimensional Bose condensate in a circular trap. The dynamics of this system turns out to be surprisingly complicated, reflecting the nonlinearity of the underlying Gross-Pitaevskii equation. We use a combination of methods — a time-dependent variational calculation, explicit numerical solutions of the time-dependent and time-independent Gross-Pitaevskii equations, and an exact solution of the non-interacting case — to uncover the physics of the vortex dipole system.

12:51PM J14.00007 Vortex lattices of bosons in deep rotating lattices¹, DANIEL GOLDBAUM, ERICH MUELLER, Cornell University — We study vortex-lattice phases for a Bose gas trapped in a rotating optical lattice near the Mott-Hubbard transition. Unlike the case of shallow lattices, the physics in this regime is dominated by the strong on-site interaction between bosons. We find a series of first-order structural transitions between square lattices where vortices are pinned with their cores on plaquettes/sites. We discuss connections between these vortex structures and the Hofstadter butterfly spectrum of free particles on a rotating lattice. We also investigate vortex configurations in a harmonic trap, where superfluid and Mott phases can coexist in a shell structure.

¹This material is based upon work supported by the National Science Foundation under grant PHY-0450261.

1:03PM J14.00008 Trapped Fermi Gases in Rotating Optical Lattices: Realization and Detection of the Topological Hofstadter Insulator, MEHMET OKTEL, Department of Physics, Bilkent University, 06800, Ankara Turkey, HUI Zhai, Department Of Physics, University of California, Berkeley, California, 94720, USA, ONUR UMCALILAR, Department of Physics, Bilkent University, 06800, Ankara, Turkey — We consider a gas of non-interacting spinless fermions in a rotating optical lattice and calculate the density profile of the gas in an external confinement potential. The density profile exhibits distinct plateaus, which correspond to gaps in the single particle spectrum known as the Hofstadter butterfly. The plateaus result from insulating behavior whenever the Fermi energy lies within a gap. We discuss the necessary conditions to realize the Hofstadter insulator in a cold atom setup and show how the quantized Hall conductance can be measured from density profiles using the Streda formula.

1:39PM J14.00011 Vortex lattice transitions in cyclic spinor condensates , SUBROTO MUKERJEE, UC Berkeley, RYAN BARNETT, UC Berkeley — We study the energetics of vortices and vortex lattices produced by rotation in the cyclic phase of $F = 2$ spinor Bose condensates. In addition to the familiar triangular lattice predicted by Tkachenko for $^3$He, many more complex lattices appear in this system as a result of the spin degree of freedom. In particular, we predict a magnetic-field-driven transition from a triangular lattice to a honeycomb lattice. Other transitions and lattice geometries are driven at constant field by changes in the temperature-dependent ratio of charge and spin stiffnesses, including a transition through an aperiodic vortex structure.

1:51PM J14.00012 Condition for the existence of complex modes in a trapped Bose-Einstein condensate with a highly quantized vortex , MAKOTO MINE, ERIKO FUKUYAMA, Department of Physics, Waseda University, MASAHIKO OKUMURA, Japan Atomic Energy Agency, and CREST (JST), TOMOKA SUNAGA, Department of Physics, Waseda University, YOSHIYA YAMANAKA, Department of Electronic and Photonic Systems, Waseda University — We consider a trapped Bose-Einstein condensate (BEC) with a highly quantized vortex. For the BEC, with a doubly, triply, or quadruply quantized vortex, the numerical calculations have shown that the Bogoliubov-de Gennes equations, which describe the fluctuation of the condensate, have complex eigenvalues. In this talk, we show the analytic expression of the condition for the existence of complex modes, using the method developed by Rossignoli and Kowalski$^1$ for the small coupling constant. To derive it, we make the two-mode approximation. With the derived analytic formula, we can identify the quantum numbers of the complex modes for each winding number of the vortex$^2$. Our result is consistent with those obtained by the numerical calculation in the case that the winding number is two, three, or four. We prove that the complex modes always exist when the condensate has a highly quantized vortex$^2$.

2:03PM J14.00013 Control of atomic currents using a quantum stirring device , MORITZ HILLER, MPI for Dynamics and Self-Organization, Goettingen, Germany and Department of Physics, University of Goettingen, Germany, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, CT, USA and MPI for Dynamics and Self-Organization, Goettingen, Germany, DORON COHEN, Department of Physics, Ben-Gurion University, Beer-Sheva, Israel — We propose a BEC stirring device which can be regarded as the incorporation of a quantum pump into a closed circuit. It produces a DC circulating atomic current in response to a cyclic adiabatic change of the on-site potentials and the tunneling rates between adjacent sites of an optical trap. We show that the nature of the transport process depends crucially on the sign and on the strength of the interatomic interactions, ranging from a one-by-one transport of atoms (for strong repulsive interaction) to a regime where the particles are glued together and behave like a huge classical ball that rolls from site to site (for strong attractive interaction). We demonstrate the feasibility of this concept and point out that such device can be utilized in order to probe the interatomic interactions.

11:15AM J15.00001 Quantum simulated annealing , SERGIO BOIXO, UNM, ROLANDO SOMMA, Perimeter Institute, HOWARD BARNUM, LANL — We develop a quantum algorithm to solve combinatorial optimization problems through quantum simulation of a classical annealing process. Our algorithm combines techniques from quantum walks and quantum phase estimation, and can be viewed as the quantum analogue of the discrete-time Markov Chain Monte Carlo implementation of classical simulated annealing.

11:27AM J15.00002 Domain Nucleation as a Failure Mode of Adiabatic Quantum Computation$^1$, WILLIAM KAMINSKY, SETH LLOYD, MIT — The bottleneck limiting the runtime of an adiabatic quantum algorithm is generally a quantum phase transition point for the computer’s qubits. We show that if the qubits undergo this phase transition simultaneously as in a continuous quantum phase transition in a homogeneous system, then the runtime is only polynomial in the number of qubits. However, we next show that if the qubits have finite range interactions in 3 or fewer dimensions, then it is much more likely that they undergo this phase transition in piecemeal fashion by nucleating domains. The runtime then grows faster than any polynomial, though it often remains subexponential. We show this via a scaling argument based on the Suzuki-Trotter mapping. Our argument extends previous similar ones in that it explicitly shows how domain excitations typically must lead to computational errors as inter-domain couplings typically are insufficient to allow the excitations to reconcile with one another and lead back to a valid solution. We close by remarking on ways to minimize domain nucleation, identifying algorithms with continuous symmetries and/or nearly fully-connected topologies as promising.

11:39AM J15.00003 A quantum algorithm for finding the modal value 1, MARK COFFEY 2, ZACHARY PREZKIUTA, Colorado School of Mines — We present a quantum algorithm for finding the most often occurring (or modal) value of a data set. We thereby supplement other algorithms that can determine the mean value or similar quantities. Our algorithm [1] requires the combined use of quantum counting and extended quantum search, and gives a quadratic speedup over the classical situation. For a data list of N elements, each entry an integer in the range [1,d], our method requires O(d N^{1/2}) oracle calls, and further complexity results are described. [1] to appear in Quantum Information Processing.

11:51AM J15.00004 A Many Body Eigenvalue Problem for Quantum Computation 1, SELMAN HERSHFIELD, University of Florida — A one dimensional many body Hamiltonian is presented whose eigenvalues are related to the order of G_N. This is the same order of G_N used to decode the RSA algorithm. For some values of N the Hamiltonian is a noninteracting fermion problem. For other values of N the Hamiltonian is a quantum impurity problem with fermions interacting with a spin-like object. However, the generic case has fermions or spins interacting with higher order interactions beyond two body interactions. Because this is a mapping between two different classes of problems, one of interest in quantum computing and the other a more traditional condensed matter physics Hamiltonian, we will show (i) how knowledge of the order of G_N can be used to solve some novel one dimensional strongly correlated problems and (ii) how numerical techniques, particularly for quantum impurity limit, can be used to find the order of G_N.

12:03PM J15.00005 Generating Pseudo-Random Quantum States with Cluster Computation 3, WINTON G. BROWN, Dartmouth College, YAAKOV S. WEINSTEIN, The MITRE Corporation, LORENZA VIOLA, Dartmouth College — We revisit existing algorithms for generating pseudo-random pure quantum states in the light of cluster-state quantum computation. Reformulation of previous network-based algorithms in terms of appropriate measurement patterns suggests a (nearly) optimal distribution of local single-qubit gates, which results in a significant improvement in the asymptotic rate of purity decay. Surprisingly, this distribution is not the one corresponding to arbitrary random single qubit rotations. We find that the rate at which the expected purity approaches the prediction based on the Haar measure is asymptotically constant with respect to the number of logical qubits. Connectivity of the underlying qubit coupling topology as well as the occurrence of saturation and cut-off effects are analyzed.

3 Partially supported from Constance and Walter Burke through their Special Projects Fund in Quantum Information Science.

12:15PM J15.00006 Ground States as Resources for Universal Measurement-Based Quantum Computing 1, ADAM G. D’SOUZA, DAVID L. FEDER, University of Calgary — Measurement-based quantum computation (MBQC) requires a massively entangled resource state (such as a cluster state) as input. Experimental efforts towards generating such states have typically focused on performing global entangling operations on uncorrelated qubits. As the states that result from this type of procedure are not generally ground states, they are very sensitive to decoherence effects. A more robust resource would be one that is in fact a ground state of some Hamiltonian that exhibits a reasonably large energy gap between the ground state and the various excited states. We will discuss the possibility of finding simple two-body spin Hamiltonians whose ground states are equivalent to resource states for MBQC under stochastic protocols comprised solely of local operations and classical communication.

12:27PM J15.00007 Quantum Non-demolition measurements of single spins in semiconductors 3, MOHAN SAROVAR, KEVIN YOUNG, University of California, Berkeley, THOMAS SCHENKEL, Lawrence Berkeley National Laboratory, K. BIRGITTA WHALEY, University of California, Berkeley — For the development of large-scale quantum computers, electron spin-encoded qubits in solid-state are appealing because of their favorable decoherence time scales, high potential for scalability, and many handles for precision control. However, an additional requirement that is traditionally challenging in the solid-state is a capacity for high-fidelity qubit readout. We propose a scheme for measuring the state of a single donor electron spin using a field-effect transistor induced two-dimensional electron gas and electrically detected magnetic resonance techniques. The scheme is facilitated by hyperfine coupling to the donor nucleus. We analyze the potential sensitivity and outline experimental requirements. Our measurement provides a single-shot, projective, and effectively quantum non-demolition measurement of an electron spin-encoded qubit state.

3 We thank NSA (grant MOD713106A) for financial support.

12:39PM J15.00008 Adiabatic optical two-qubit operation with electron spins in separate quantum dots 1, SEMION SAIKIN, University of California, San Diego, LA Jolla, CA 92093, CLIVE EMARY, Institut fur Theoretische Physik, TU Berlin, D-10623 Berlin, Germany, DUNCAN STEEL, University of Michigan, Ann Arbor, MI 48109, LU SHAM, University of California, San Diego, La Jolla, CA 92093 — We develop an adiabatic scheme to control the entanglement of two electron spins localized in separate InAs/GaAs quantum dots via the Coulomb interaction between two negative trions optically excited in the different dots. The scheme gives a unitary operation in the spin subspace and can be used as a two-qubit gate for quantum information processing. The slowly-varying adiabatic pulses drive the system in a such way that effects of pulse imperfections and relaxation of the trion states are minimized. For spin dynamics we provide an exact numerical solution that accounts for dissipation and analyze the essential processes within a “dressed state” model. Our calculations for vertically-stacked quantum dots show that for a broad range of dot parameters a two-spin state can be prepared coherently from an initially polarized state by four optical fields with the pulse duration \Delta t \sim 1 ns.

12:51PM J15.00009 Universal sets of quantum gates based on geometric phases 1, YU SHI, Fudan University, QIAN NIU, University of Texas at Austin — We rigorously study adiabatic and nonadiabatic geometric phases of two Heisenberg-coupled identical spins in a rotating magnetic field. The geometric phase of the total system is still a solid angle, and is independent of random Heisenberg coupling constant. The adiabatic geometric phase is also independent of the magnetic field rotating speed. Using this result, for both adiabatic and nonadiabatic cases, we explicitly and exactly construct novel robust dynamic-geometric-hybrid two-qubit square root of swap and controlled-NOT gates, as well as purely geometric single qubit gates, including \pi/8 and Hadamard gates, thus presenting a complete scheme of robust universal quantum computing. This scheme can be implemented in NMR, quantum dots and cold atoms.
effect. Several different conditions for existence of infinite hitting time are proven by analyzing the analytical structure of the formula for the infinite hitting that in the two limits of the measurement rate going to 0 or infinity the hitting time diverges, where the second limit is representative of the quantum Zeno and printed photodiode.

or 2D arrays of photodiodes can be printed onto diverse materials. Besides the dramatically reduced production costs for printed photodiodes, the presented modulation technique allows us to achieve a high signal to noise ratio even for high particle speeds. Combining our technique with a cell sorting mechanism would allow for on-the-chip characterization and sorting of untagged cells.

Physics and Astronomy, U. of Basel, P. STAMP, Dept. Physics and Astronomy, U. of British Columbia — Polyoxometalates (POMs) are discrete fragments of metal oxides, clusters of regular MOₙ polyhedra. POMs show a remarkable flexibility in composition, structure and charge state, and thus can be designed according to specific electric and magnetic needs. The two localized spins with S = 1/2 on the V atoms in [PMo₁₂O₄₀(V₂O₃)₈]⁶⁺ can be coupled through the delocalized electrons of the central core. This system was recently used for a theoretical scheme involving two-qubit gates and readout: the electrical manipulation of the molecular redox potential changes the charge of the core and thus the effective magnetic exchange between the qubits. Polyoxometalates can encapsulate magnetic ions, protecting them by a diamagnetic shell of controlled geometry. A great potential of POMs as spin qubits is that they can be constructed using only even elements, such as O, W, Mo and/or Si. Thus, there is a high abundance of polyoxometalate molecules without any nuclear spin, which could result in unusually low decoherence rates. There is currently an effort involving highly anisotropic, high magnetic moment, lanthanide@polyoxometalate molecules acting as spin qubits.

Tuesday, March 11, 2008 11:15AM - 2:15PM –

11:15AM J16.00001 Direct-Print Organic Photonics for Biodetection Chips — MAX SONNLEITNER, BIOIDENT Technologies Inc. — The development of commercial portable Biodetection applications based on optical detection is hindered by the lack of imaging systems that can be directly integrated into the chip itself. Currently, fluorescence/luminescence signals are read out with power-hungry, bulky and expensive off-chip imaging systems, like CCD cameras or photomultiplier tubes. Here we present an enabling technology that for the first time allows cheap and easy integration of imaging systems directly into disposable Biodetection systems. Our technology is based on organic semiconductor materials that can be processed in liquid form by inkjet and screen printing, in a process much faster and cheaper than the complicated fabrication of silicon-based imaging sensors. Organic photodiodes can be printed on various substrate materials like plastic foil or glass or directly onto Biochip systems. The ultra thin photodiodes with an overall thickness of only 300 to 500 nm show quantum efficiencies better than 0.5 and linear light-response over 6 orders of magnitude. The pixel size can range from 50 to over 1000 μm and inkjet fabrication allows tailoring the sensor layout to the needs of the specific application. Single photodiodes, photodiode line-arrays or 2D arrays of photodiodes can be printed onto diverse materials. Besides the dramatically reduced production costs for printed photodiodes, the presented readout architecture allows detection of e.g. chemiluminescence signals with highest sensitivities and minimum crosstalk due to the close proximity of sample and printed photodiode.

11:51AM J16.00002 On-the-flow differentiation between cells based on native fluorescence spectroscopy on a chip — MARKUS BECK, MICHAEL BASSLER, PETER KIESEL, NOBLE M. JOHNSON, OLIVER SCHMIDT, Palo Alto Research Center, 3333 Coyote Hill Rd, Palo Alto, CA 94034 — Native fluorescence spectroscopy is a promising approach for the detection of pathogens without specific binding or tagging of the analyte. The distinction between different species is possible with (multi-color) UV excitation together with the detection of several spectral bands. We have developed a compact platform that combines a microfluidic quartz channel with chip-size wavelength-selective detection of the fluorescence from particles traversing the channel. The interaction between the UV excitation light and the analyte is enhanced by anti-resonantly guiding the light within. We have recorded the intrinsic fluorescence of single cells (e.g. yeast, e-coli, and BT) passing the detection area. Knowing the particle speed and the physical dimensions of the observation window, we are able to determine particle positions with microscopic (∼10 microns) resolution. A special modulation technique allows us to achieve a high signal to noise ratio even for high particle speeds. Combining our technique with a cell sorting mechanism would allow for on-chip characterization and sorting of untagged cells.
12:03PM J16.00003 Toward directed evolution of unicellular organisms for efficient hydrogen production1 | DAVID LIAO, CALEB HOWE, CECILIA MULDOON, PETER GALAJDA, KEITH MORTON, PRINCETON UNIVERSITY — To provide an energy resource alternative to fossil fuels, photosynthetic organisms must increase their energy conversion efficiency. The green algae C. reinhardtii stores light energy in hydrogen gas at 0.1% efficiency, less than the 10% required to compete with established fuels. This work combines hydrogen sensing in liquid culture with micro habitat patch (MHP) chips for directing hydrogen-producing organisms to evolve improved energy conversion efficiency. A MHP chip contains 87 mm x 1 mm x 100 mm interconnected chambers. By measuring hydrogen output from different chambers, we will select those with greater hydrogen production. We microfabricated chips from poly(dimethylsiloxane). Color changes in fluorescence micrographs confirm that 254 nm radiation kills algae in MHPs, liberating nutrients and space for exploitation by adjacent populations. We demonstrated colorimetric detection of hydrogen gas production at a rate of 10^{-11} mol H2 mL^{-1} s^{-1} using tungsten film on sub-ML liquid cultures of C. reinhardtii during 2-hrs. of fermentation in darkness.

12:27PM J16.00005 Rapid Detection of Microorganisms—State of Art and Future Directions | GEORGE HONG, MILLIPORE CORPORATION — For the last several decades, nutrient-based culture growth methods have been accepted as the standard for microorganism detection and identification. However, since the discovery of nucleic acids and molecular breakthrough technologies such as restriction enzymes and polymerase chain reactions, the detection and identification of microorganisms have advanced to culture-independent methods that fall under the category of rapid microbial detections. Here, we present an overview of major rapid microbial detection technologies. These technologies include both amplification and non-amplification based methods for the detection and identification of target microorganisms. The technologies described can be applied to detecting a wide variety of microorganisms, including bacteria, viruses, mycoplasma, and fungi and have the potential sensitivity to detect a single microorganism. Also in this presentation, we will present examples of real-life applications as well as future challenges for the advancement of the field of rapid microbiology.

1:03PM J16.00006 Guidance and detection of neuronal cells using Si nanomembranes1 | CRISTIAN STAI, W.IDA ENG, HYUK JU RYU, DON E. SAVAGE, YU HUANG, SOOKIN NAM, JUSTIN WILLIAMS, ERIK DENT, MAX G. LAGALLY, SUSAN N. COPPERSMITH, MADISON — "Lab-on-a-chip" microfluidic technology [1] has emerged as a powerful tool for studying biological systems. Unlike standard micro-scale systems used for decades, microfluidics allows the micro-environment of a neuronal cell culture to be finely regulated. The reduction in feature sizes gives control over fluid phenomena such as laminar flow, shear stresses, and velocity profiles. Here we present a new approach to lab-on-a-chip, using microfluidic systems with silicon nanomembrane-based microelectronics. We show that this technology permits rapid production of microchannels with a large variety of shapes/sizes, thereby allowing the exposure of neuronal cell cultures to multiple environments, both mechanical and chemical, simultaneously. In addition, these microfluidic channels can be easily integrated with silicon nanomembrane based electronics. [1] A.J.Blake, T.M.Pearce, N.S.Rao, S.M.Johnson and J.C. Williams, Lab Chip, 2007, 7, 842.

1:15PM J16.00007 Well-Oriented NanoWell Array Metrics for Digital NanoBioChip | HEAYEON LEE, BONGKUK LEE, TOMOKI KAWAI, THE INSTITUTE OF SCIENTIFIC AND INDUSTRIAL RESEARCH (ISIR-SANKEN), OSAKA UNIVERSITY — Recently many researchers have sought new paradigm for nanobiotech that can be miniaturized and integrated to produce intelligent systems in numerous biotechnology. We present a new approach to nanofabrication, utilizing nanowires with novel properties that can be used to detect and manipulate biological molecules. We fabricated arrays containing nanowires with different properties, such as those that release light or electrical signals in response to specific molecules. These arrays can be used to detect and manipulate biological molecules with high sensitivity and specificity.

1:27PM J16.00008 Magnetically Directed Cell Co-Localization for Cell-Cell Interaction Studies | EDWARD FELTON, DANIEL REICH, Dept. of Physics and Astronomy, Johns Hopkins University, CHRISTOPHER CHEN, Dept. of Bioengineering, University of Pennsylvania — The ability to create ordered patterns of cells has enabled new approaches to various areas of biological interest, such as tissue engineering, biosensing, and the study of interactions between cells. In this work, we apply forces to cells through binding with magnetic nanowires. The nanowires feature high remanent magnetization, allowing for effective manipulation in low-strength magnetic fields, and when used in conjunction with lithographically patterned materials based nanopatterning, self-assembly array to address challenging problem in nanobiotechnology. In this work, we present an overview of major rapid microbial detection technologies. These technologies include both amplification and non-amplification based methods for the detection and identification of target microorganisms. The technologies described can be applied to detecting a wide variety of microorganisms, including bacteria, viruses, mycoplasma, and fungi and have the potential sensitivity to detect a single microorganism. Also in this presentation, we will present examples of real-life applications as well as future challenges for the advancement of the field of rapid microbiology.

1:30PM J16.00009 Electromagnetic Sensors of Biological Motors1 | JIE FANG, K. RAJAPAKSHE, D. PAD-MARAJ, H. INFANTE, V. VAJRALA, G. MERCIER, W. WIDGER, W. WOSIK, J. MILLER — Biological motors operate on time scales that readily couple to oscillatory electric fields. Modest ac fields applied to cells in an aqueous medium lead to greatly enhanced fields across the plasma membrane or (at kHz frequencies) internal membranes. Membrane complexes thus contribute to both linear and nonlinear responses to sinusoidal fields. For example, activity of motors in mitochondria and (for chloroplasts) photosynthetic electron transport chains correlate with frequency-dependent second and third harmonics. Our electrode-based biosensors are scalable for micro- and nano-fluidic biochips. At low frequencies (less than 100Hz) we find it advantageous to use SQUIDs, which reduce contact effects and could lead to clinical applications.

**1:15PM J16.00010** Single-molecule stochastic sensors for proteins using engineered nanopores\(^1\), \textsc{Liuviu Movileanu}, Syracuse University — We were able to design an unusual temperature-responsive pore-based nanostructure with a single movable elastin-like-polypeptide (ELP) loop. If a voltage bias was applied, the engineered pore exhibited transient current blockades, the nature of which depended on the length and sequence of the inserted ELP. These blockades are associated with the excursions of the ELP loop into the nanopore. At low temperatures, the ELP is fully expanded and blocks the pore completely, but reversibly. At high temperatures, the ELP is dehydrated and structurally collapsed, thus enabling a substantial ionic flow. Acidic binding sites comprised of negatively-charged aspartic acid residues, engineered within the pore lumen, produced dramatic changes in the functional properties of the nanopore, catalyzing the translocation of cationic polypeptides from one side of the membrane to the other. For example, when two electrostatic binding sites were introduced, at the entry and exit of the nanopore, both the rate constants of association and dissociation increased substantially, diminishing the free energy barrier for translocation.

**2:03PM J16.00011** Imaging Protein-Functionalized Quantum Dot Diffusion and Binding at Surfaces\(^1\), \textsc{Jack Rife, James Long, Lloyd Whitman}, Naval Research Laboratory — Understanding single biomolecule and nanoparticle interactions with surfaces at fluid-solid interfaces is a key to improving molecular transport and binding in many biotechnology applications. Biosensor sensitivity, for example, is typically limited by diffusion\(^2\) and non-specific binding to analytical surfaces. We have assembled a Total Internal Reflectance Fluorescence (TIRF) microscopy system with single-photon-sensitive cameras to image diffusion and binding of fluorescently-labeled biomolecules on surfaces under both static and laminar flow conditions. We have acquired movies (57 frames/s) of streptavidin-functionalized CdSe quantum dots (QDs) diffusing, transiently attaching, and permanently immobilizing on repulsive, hydrophilic silica surfaces. From the single-particle trajectories we have extracted diffusion coefficients and transient attachment lifetimes. The binding of protein-functionalized QDs to our nominally repulsive surfaces can be attributed to surface defects, adsorbates, and protein conformational changes. In flow, the QD elevation above the no-slip surface can be approximated, giving a picture of elevated transport between transient attachments and QD departures to and from the surface. \(^2\) Sheehan and Whitman, Nano Lett. 5, 803 (2005).

**11:15AM J17.00001** Relating biophysical properties across scales: implications for early development and applications for tissue engineering\(^1\), \textsc{Gábor Forgács}, Department of Physics, University of Missouri, Columbia, MO, 65211 — A distinguishing feature of a multicellular system is that it operates at various scales and levels of organization. Genes set up the conditions for physical mechanisms to act, in particular to shape the developing organism and establish its material characteristics. As development continues the changes brought about by the physical processes lead to changes in gene expression. It is through this interplay that the organism acquires its final structure and composition. It is natural to assume that in this multi-scale process the smaller defines the larger. In case of biophysical properties, in particular, those at the subcellular and cellular level are expected to give rise to those at the tissue level and beyond. Indeed, the physical characteristics of tissues vary greatly in physical properties: blood is liquid, bone is solid. In between these extremes lie most of the organs and tissues with intermediate visco-elast properties. However, a blood cell is not the same as a liquid drop and a single bone-forming cell itself is not a solid. Little is known on how tissue and organ level properties are related to cell and subcellular properties. We introduce a novel combined theoretical-computational-experimental framework to address this question. The basis of our approach is a representation of a cell by a network of interacting `organelles` (i.e. modules) with cell-specific properties. Cells form tissues and eventually organs through interactions either directly with each other or through secreted substances. The experimental and theoretical inputs of the formalism are inseparable: it cannot even be set up without one or the other. The method can serve as the basis for “computational tissue engineering”\(^2\).

**11:51AM J17.00002** Dynamics and Mechanics of Zebrafish Embryonic Tissues. \textsc{Eva-Maria Schoetz}, R.D. Burdine, M.S. Steinberg, Princeton University, C.-P. Heisenberg, MPI-CBG, R.A. Foty, UMDNJ, F. Julicher, MPI-PKS — In early zebrafish embryonic development, complex flows of cell populations occur, which ultimately lead to the spatial organization of the three germ layers: Ectoderm, mesoderm and endoderm. Here, we study the material properties of these germ layer tissues which are important for their dynamics and spatial organization in the embryo. In general, tissues can be classified as inherently active complex fluids. However, here we present examples of observed tissue behavior, which can be described satisfactorily in terms of passive visco-elastic fluids. We determined the material properties of the germ layer tissues quantitatively and found that differences in their properties influence tissue interaction. Specifically, quantitative differences in tissue surface tension result in tissue immiscibility and cell sorting behavior analogous to that of ordinary immiscible liquids. Surface tensions were measured with a tissue surface tensiometer. Furthermore, by tracking individual cells in the developing zebrafish embryo, we found differences in the migratory behavior of the different tissue types, which are, to some extent, governed by their mechanical properties. Finally, we generated a 3D velocity flow profile describing the tissue movements during zebrafish embryonic organizer development.

**12:03PM J17.00003** Laser Hole-Drilling as a Probe of Morphogenetic Stresses in Embryonic Epithelia: Experimental Observations\(^1\), \textsc{Xiaoyan Ma, M. Shane Hutson}, Vanderbilt University — During the development of an organism, sheets of epithelial cells expand, contract and bend due to forces generated within the cell sheets. These forces can be probed by laser hole-drilling — a method borrowed from the analysis of residual stress in manufactured widgets — in which a laser microbeam ablates a single cell surface or the edge shared by adjacent cells. We have applied this method to the embryonic epithelia of GFP-labeled fruit fly (Drosophila) embryos. After ablation of one shared edge, we follow the recoil dynamics (strain relaxation) of adjacent cell edges (with time resolution down to 2 ms). The recoils show two distinct phases; and the initial recoil velocity can be consistently retrieved through a double-exponential fit. We observe a strong correlation between the initial recoil velocity and the orientation of the ablated cell edge. This correlation is particularly pronounced in embryos during late dorsal closure. Measuring orientation with respect to the long (anterior-posterior) axis of the embryo, both the recoil velocities and the distribution of cell edge orientations have sharp peaks near 30° and 150°. In early dorsal closure, the distribution of cell edge orientation has three much weaker peaks and the recoil velocities only show a weak maximum near 90°.

12:15PM J17.00004 Laser Hole-Drilling as a Probe of Morphogenetic Stresses in Embryonic Epithelia: Finite Element Models, M. SHANE HUTSON, XIAOYAN MA, Vanderbilt University, JIM VELDHUIS, G. WAYNE BRODLAND, University of Waterloo — During the development of an organism, sheets of epithelial cells expand, contract and bend due to forces generated within the cell sheets. These forces can be probed by laser hole-drilling; however, the observed recoil dynamics (or strain relaxations) depend strongly on the local cellular geometry. To better understand this dependence and help interpret our experimental observations, we have conducted a series of laser hole-drilling simulations using cell-level finite element models. Even the simplest of these simulations (i.e. homotypic cell sheets with constant cell boundary tensions) produce a wide range of initial recoil velocities. The velocities are correlated with particular aspects of the local geometry — most notably the aspect ratio and orientation of cells adjacent to the ablated cell edge. These simulations also produce bi-phase recoils; however, the two phases are not as distinct as those observed experimentally. To more closely reproduce the experimental recoils, the cell edges must include an elastic component. We will discuss using such finite element models to inversely determine local stresses in an epithelial sheet from the observed strain relaxations after laser ablation.

12:27PM J17.00005 Forces driven by morphogenesis modulate Twist Expression to determine Anterior Mid-gut Differentiation in *Drosophila* embryos, EMMANUEL FARGE, MGDET, UMR168 CNRS, Institut Curie11 rue Pierre et Marie Curie, F-75005, Paris, France — By combining magnetic tweezers to *in vivo* laser ablation, we locally manipulate *Drosophila* embryonic tissues with physiologically relevant forces. We demonstrate that high level of Twist expression in the stromodeal primordium is mechanically induced in response to compression by the 60±20 nN force developed during germ-band extension (GBE). We find that this force triggers the junctional release and nuclear translocation of Armadillo involved in Twist mechanical induction in the stromodeum in a Src42A dependent way. Finally, stromodeal-specific RNAi-mediated silencing of Twist during compression impairs the differentiation of midgut cells, as revealed by strong defects in Dve expression and abnormal larval lethality. Thus, mechanical induction of Twist overexpression in stromodeal cells is necessary for subsequent midgut differentiation. In collaboration with Nicolas Desprat, Willy Supatto, and Philippe-Alexandre Pouille, MGDET, UMR168 CNRS, Institut Curie11 rue Pierre et Marie Curie, F-75005, Paris, France; and Emmanuel Beaugeapre, LOB, Ecole Polytechnique, CNRS and INSERM U 696, 91128 Palaiseau, France.

1:03PM J17.00006 Mechanical forces in the development of leaf venation networks, FRANCIS CORSON, AREZKI BOUDAOUD, MOKHTAR ADDA-BEDIA, Laboratoire de Physique Statistique, Ecole Normale Superieure, Paris, France — Leaf venation patterns, like leaf shapes, are extremely diverse, yet their local structure has been shown to satisfy a simple, universal property: the angles veins form at junctions are related to their diameters by a vectorial equation analogous to a force balance. This structure is the signature of a reorganization of vein networks during the development of leaves, a process we investigated numerically using a cell proliferation model. Provided that vein cells are given different mechanical properties, tensile forces develop along the veins during growth, causing the network to deform progressively. The statistics of the patterns obtained in these simulations are in good quantitative agreement with observations on leaves, supporting the notion that the local structure of leaf venation networks reflects a balance of mechanical forces.

1:15PM J17.00007 Pattern Formation in a Synthetic Multicellular System, TING LU, DAVID KARIG, RON WEISS, Princeton University — Pattern formation has been studied for a long history since the Turing’s proposal for a reaction-diffusion system and been found in numerous physical, chemical and biological examples. However, experimental study about pattern formation advances slowly. Here we present an artificial pattern formation system. By engineering cellular communication in bacteria E. Coli and plating these engineered cells onto a solid-phase agarose plate, we are able to program the pattern formation of this multicellular system. The pattern changes dramatically with different levels of an external inducer IPTG. A simple model is developed to explain the experimental results.

1:27PM J17.00008 A Model of R8 Cell Specification in the *Drosophila* Eye, MATTHEW PENNINGTON, DAVID LUBENSKY, University of Michigan — R8 photoreceptors are specified in a precise hexagonal pattern behind an advancing front as it traverses the eye imaginal disc during *Drosophila* development. In an attempt to better understand this patterning event, we have developed a mathematical model consisting of coupled differential equations on a lattice incorporating auto-activation, long-range activation, and short-range inhibition. The model is based on known elements of the regulatory gene network involved in patterning, and an analogy with discrete Nagumo systems is helpful in understanding its dynamics. We have developed analytic and numeric results for its behavior on a 1D lattice. Significantly, this model can reproduce patterns similar to those seen both in wild-type eye discs and in several mutant phenotypes. We argue that much of the model’s behavior is a consequence of the fact that self-activation is cell-autonomous; this behavior represents a novel mode of pattern formation distinct from classical ideas such as Turing patterns or morphogen-dependent positional information.

1:39PM J17.00009 Emergence of hyper-hexagonal patterns in orientation map models of reduced rotation symmetry, WOLFGANG KEIL, MICHAEL SCHNABEL, FRED WOLF, BCCN and MPIDS, Goettingen, Germany — Neurons in the primary visual cortex preferentially respond to visual stimuli of a particular orientation. These orientation preferences are arranged in aperiodic 2-D patterns, known as orientation preference maps (OPMs). Symmetry assumptions have been used successfully to derive a class of theoretical model which accounts for the emergence of aperiodic pinwheel-rich OPMs. Measurements revealed anisotropic coupling statistics in the underlying neural tissue, suggesting that the symmetry of models for the formation of orientation map is reduced from the previously assumed E(2)xO(2) to E(2). In dynamical models for OPMs with E(2)xO(2) symmetry interactions represented by quadratic terms cannot occur but may be present in models of reduced E(2) symmetry. Here, we present a general analysis of the impact of such interactions on the formation of OPMs. We demonstrate that near the onset of pattern formation only two basic types of quadratic interaction terms exist, introduce a general parametric representation of permissible quadratic interactions near pattern formation onset, and derive the most general amplitude equations describing pattern selection in models incorporating quadratic interactions. We study the impact of such interactions on the spatial structure of OPMs, by incorporating them into a Swift-Hohenberg-model of OPM formation.

1:51PM J17.00010 Dynamics of Gas Exchange through the Fractal Architecture of the Human Lung, Modeled as an Exactly Solvable Hierarchical Tree, MICHAEL MAYO, PETER PFEIFER, Department of Physics, University of Missouri, Columbia, MO, 65211, STEFAN GHEORGHIU, Center for Complexity Studies, Alleea Parva 5, Bucharest 061942, Romania — The acinar airways lie at the periphery of the human lung and are responsible for the transfer of oxygen from air to the blood during respiration. This transfer occurs by the diffusion-reaction of oxygen over the irregular surface of the alveolar membranes lining the acinar airways. We present an exactly solvable diffusion-reaction model on a hierarchically branched tree, allowing a quantitative prediction of the oxygen current over the entire system of acinar airways responsible for the gas exchange. We discuss the effect of diffusion screening, which is strongly coupled to oxygen transport in the human lung. We show that the oxygen current is insensitive to a loss of permeability of the alveolar membranes over a wide range of permeabilities, similar to in a constant-current source in an electric network. Such fault tolerance has been observed in other treatments of the gas exchange in the lung and is obtained here as a fully analytical result.
2:03PM J17.00011 Evolution of Optimum Foraging Distributions in Two Dimensions, NATHAN DEES, SONYA BAHAR, FRANK MOSS, University of Missouri - St. Louis — In the pursuit of optimally efficient foraging, preferred distributions of movement characteristics have been shown to exist for many types of animals and environments. Specifically, planktonic organisms such as *Daphnia* use exponential distributions of turning angles, $\alpha$, in a “*hop, pause, turn by angle $\alpha$, hop…*” random walk-type sequence of movement when traversing experimentally prepared feeding solutions consisting of freeze dried *Spiroliana* and water. We investigate the evolution of such random walks in a two-dimensional foraging model. In this model, agents traverse a feeding patch of finite size and for a finite amount of time using hop lengths and turning angles chosen randomly from inherited distributions. Distributions evolve as the choices made by the most efficient forager of one generation influence the distributions available to the succeeding generation. Preliminary results show that initially uniform turning angle distributions evolve to explicit exponential distributions after thousands of generations, consistent with the experimental observations described above.

11:15AM J18.00001 Use DNA solutions to model polymer entanglement in flow: simultaneous rheometric and particle-tracking velocimetric measurements, POUYAN BOUKANY, SHI-QING WANG, Department of Polymer Science, University of Akron — Entangled aqueous DNA solutions are ideal as a model system to examine nonlinear flow features including stress overshoot in startup shear and shear thinning phenomenon. These soft systems can be strongly entangled with 60 entanglement points per chain and a terminal relaxation time as long as 1000 s at 1 % concentration [1-2]. They allow a comparison between the steady state attained with a startup shear and that attained through an “infinitely” slow ramping up of the applied shear rate. Indeed, startup shear in the nonlinear (stress plateau) region causes the DNA solutions to yield inhomogeneously, resulting in persistent shear banding. However, the slowly ramped-up shear into the same final rate as applied in startup shear allowed the solutions to avoid shear inhomogeneity. Thus, we demonstrated that it is possible for the final steady states to be different depending on how an entangled system is brought into the same final experimental condition. This result implies that it is ill-defined to pursue conventional constitutive relationship in flow of entangled polymers.

11:27AM J18.00002 Membrane-Enhanced Surface Acoustic Wave Analysis of Polymer Brushes, DAVID A. BRASS, KENNETH R. SHULL, Northwestern University — We show that detailed structural information about polymer brushes can be obtained from a simple membrane inflation technique in conjunction with a quartz crystal resonator. The sensitivity of these quartz crystal resonators is determined by the propagation of acoustic shear waves through the materials that are placed in contact with the oscillating crystal. Coupling of the shear acoustic waves into the membrane is strongly affected by the thickness of the brush layer, which is in turn affected by specific interactions between the polymer brush and the substrate with which it is brought into contact. The mechanical resonance of the quartz crystal is affected by these brush parameters, and we refer to the accompanying analysis of this resonance as ‘membrane-enhanced surface acoustic wave analysis’. The analysis combines self consistent mean field theory of the polymer brush with the relevant theories of acoustic wave propagation. The model has been tested experimentally with grafted poly(ethylene glycol) brushes in contact with thermoplastic elastomer membranes. We also show how the technique can be used to quantify the strength of specific interactions between the electrode surface of the quartz resonator and functional groups placed at the ends of the PEG brushes.

11:39AM J18.00003 Advances in Organic Single-Crystal Transistors, ALEJANDRO L. BRISENO, Department of Chemistry, University of Washington, ZHENAN BAO, Department of Chemical Engineering, Stanford University, YOUNAN XIA, Department of Chemistry, SAMSON A. JENEKHE, Department of Chemical Engineering, University of Washington — Organic semiconductors, including conjugated small molecules and polymers, constitute next-generation materials for displays, circuits, and a vast array of other electronic applications. The performances of organic single-crystal transistors have recently surpassed the performance levels of amorphous silicon devices. Despite the high mobilities of single-crystal devices, there are many factors limiting their applications. Currently, single crystals are handpicked and made into an individual device. Another challenge is to achieve control of crystallinity in polymer nanostructures. There is a need to explore nanowires as solution-processable materials because of the cost-effective aspect in fabricating devices. Therefore, in order to meet the requirements for fabricating practical devices, we have resolved the aforementioned issues by patterning organic single-crystal transistors and polymers. We have developed solution-phase methods for preparing organic single-crystal nanowires from p- and n-type semiconductors and highly oriented nanowires from polymer semiconductors. Furthermore, we have realized high-performance transistors and demonstrated the first all-polymer complementary circuit.

11:51AM J18.00004 Effect of lithium ion distribution on conductivity of block copolymer electrolytes, ENRIQUE GOMEZ, NITASH BALSARA, University of California, Berkeley — Energy-filtered transmission electron microscopy (EFTEM) was used to determine the distribution of lithium ions in mixtures of bis(trifluoromethane)sulfonimide lithium salt and symmetric poly(styrene-oxide) copolymers (PS-PEO). EFTEM results show that the salt is increasingly localized to the middle of the PEO lamellae as the molecular weight of the copolymers is increased. Computer simulations by Borodin and Smith (Macromolecules, 1998, 31, 8396) demonstrate that coordination between lithium ions and PEO chains is diminished for chains that are stretched. Local stretching in block copolymers is modeled using self-consistent field theory (SCFT). Good agreement between EFTEM and SCFT is obtained by postulating a linear relationship between local chain stretching and lithium ion concentration. AC impedance spectroscopy experiments show an increase in the conductivity of PS-PEO/salt mixtures with increasing molecular weight of PS-PEO. The EFTEM/SCFT results suggest that the increase in ionic conductivity with increasing molecular weight is due to segregation of the lithium salt away from PS/PEO interfaces where segmental motion is retarded due to connectivity to slow-moving PS chains. These results may aid in developing all-solid state rechargeable lithium batteries with PS-PEO serving as a dry electrolyte.

12:03PM J18.00005 Self-assembly of metal–polymer analogues of amphiphilic triblock copolymers, ZHIHONG NIE, DANIELE FAVA, EUGENIA KUMACHEVA, SHAN ZOU, GILBERT WALKER, Department of Chemistry, University of Toronto, Canada, MICHAEL RUBINSTEIN, Department of Chemistry, University of North Carolina, USA, EUGENIA KUMACHEVA TEAM, SHAN ZOU, GILBERT C. WALKER COLLABORATION, MICHAEL RUBINSTEIN COLLABORATION — We proposed a block copolymer approach to the self-assembly of inorganic nanorods terminated with polymer molecules at both ends. We organized metal nanorods in structures with varying geometries by using a striking analogy between amphiphilic ABA triblock copolymers and the hydrophilic nanorods tethered with hydrophobic polymer chains at both ends. The self-assembly was tunable and reversible and it was achieved solely by changing the solvent quality for the constituent blocks. The distance between adjacent nanorods along the self-assembled structures is determined by varying the composition of mixture solvents or the molecular weight of polymer blocks, which allows us precisely control the plasmonic band of self-assembled structures. A systematic study of the self-assembly as a function of solvent composition and the molecular weight of the polymer blocks allowed us to construct a diagram that maps the assembled structures. This approach provides a new route to the organization of anisotropic nanoparticles by using the strategies that are established for the self-assembly of block copolymers.
12:15PM J18.00006 Rod-Coil Block Copolymer Self-Assembly in Thin Films, B.D. OLSEN, University of California Berkeley, V. GANESAN, University of Texas Austin, R.A. SEGALMAN, University of California Berkeley — The phase behavior of rod-coil block copolymers differs from that of traditional block copolymers due to the interplay between liquid crystallinity of the rod blocks and microphase separation of the rods and coils. A universal phase diagram for rod-coil diblock copolymers is prepared using experimental measurements of both the rod aligning interaction and the rod-coil repulsive interaction to transform the temperature-dependent phase transitions of a model-rod coil system into dimensionless parameter space. The rod aligning interaction, parameterized by the Maier-Saupe parameter, may be estimated from the dependence of the nematic-isotropic transition temperature on the molecular weight of the rod homopolymer. The rod-coil interaction, parameterized by the Flory-Huggins parameter, is calculated from the temperature-dependent interfacial segregation of block copolymer to a rod/coil homopolymer interface. The Flory-Huggins parameter is extracted by using it as a fitting parameter in self-consistent field theory to match simulated block copolymer surface excesses to experimental values.

12:27PM J18.00007 Why nanoconfinement may lead to the development of polymer glasses that do not physically age, RODNEY PRIESTLEY, LINDA BROADBELT, JOHN TORKELSON, Department of Chemical and Biological Engineering, Northwestern University — With the advent of nanotechnology, polymers will be used at increasingly smaller length scales, i.e., the nanoscale. Recently, it has been shown that nanoconfined polymers can exhibit astounding changes in glassy-state properties relative to bulk. Physical aging, i.e., the change in properties as a function of annealing time below the glass transition temperature, determines the end-use properties of polymer glasses. How nanoconfinement impacts aging has emerged as a key technological and scientific question. Conventional techniques for monitoring aging of bulk polymers are incapable of doing so for nanoconfined polymers. Here, we present work in which we have developed fluorescence methods to monitor aging in thin polymer films. More importantly, our technique allows for the monitoring of aging at specific locations in films near interfaces. Our work indicates that nanoconfinement and interfacial effects strongly alter aging and that the development of polymer glasses that do not physically age may be possible.

12:39PM J18.00008 Ionic Complexation Enhanced Block Copolymer Alignment with an Electric Field, JIA-YU WANG, THOMAS P. RUSSELL, University of Massachusetts, Amherst — Alignment of microdomains in block copolymer (BCP) films by an electric field offers the possibility of fabricating ordered nanostructures that are used as templates, scaffolds and masks. In polystyrene-block-poly(methyl methacrylate) (PS-b-PMMA) copolymer films, the formation of lithium-PMMA complexes, as a result of the added lithium salts, markedly enhanced the alignment of BCP microdomains under an electric field, due to the increased dielectric contrast and the weakened surface interactions which reduced the critical field strength. The formation of lithium-PMMA complexes also increases the segmental interaction, parameterized by the Maier-Saupe parameter, may be estimated from the dependence of the nematic-isotropic transition temperature on the molecular weight of the rod homopolymer. The rod-coil interaction, parameterized by the Flory-Huggins parameter, is calculated from the temperature-dependent interfacial segregation of block copolymer to a rod/coil homopolymer interface. The Flory-Huggins parameter is extracted by using it as a fitting parameter in self-consistent field theory to match simulated block copolymer surface excesses to experimental values.

12:51PM J18.00009 Polymer Surface Diffusion as a Function of Molecular Weight, JANET WONG, STEVE GRANICK, Dept. Materials Science and Engineering, University of Illinois at Urbana-Champaign — This talk describes the first measurements to elucidate polymer surface diffusion over the full range of surface concentration and as a function of molecular weight. The model system, polystyrene adsorbed onto mica and quartz from chloroform, was selected to allow molecular weight (M) to vary by more than 2 orders of magnitude and the surface coverage to vary by more than 3 orders of magnitude. Spatially-resolved measurements of surface translational diffusion (D_s) were made using fluorescence correlation spectroscopy (FCS), which is a single-molecule technique. The value of D_s was found to scale as a power-law in M. Remarkably, the absolute value of the power-law was -1 for mica and the most homogeneous quartz surfaces, -3/2 for less homogeneous quartz surfaces, and never took intermediate values. Explanations remain speculative but appear to involve the dominance of Rouse and reptation diffusion mechanisms, respectively. In the latter case, curvilinear motion is guided not by entanglement with other chains but instead by patchiness (topographical and chemical) of the surface adsorption sites.

Tuesday, March 11, 2008 11:15AM - 2:15PM –
Session J19 FD: Focus Session: How to Develop an Education Component for an NSF Proposal
Morial Convention Center 211

11:15AM J19.00001 How to develop an education component for an NSF proposal, RANDY RUCHTI, University of Notre Dame — NSF has two merit criteria that must be satisfied for a proposal to be successfully funded: Intellectual Merit and Broader Impact. The development and presentation of a quality broader impact program represents a challenge for many researchers. One option is an education component and there are many possible approaches: in formal or informal education; in engagement of traditional, non-traditional or underrepresented participants; in coverage over a variety of age groups; and in scope. This presentation explores such issues and is intended to elicit discussion.

1Work supported in part by the National Science Foundation.

11:51AM J19.00002 Preparing Scientists for Scientific Careers: Broader Impacts from an NSF CAREER Award, ALFRED CROSBY, University of Massachusetts Amherst — The scientific focus of my NSF CAREER Award is the impact of patterns, topographical and surface chemical in design, on the adhesion of soft polymer interfaces. Although this topic has provided a strong foundation for the mentoring and training of graduate students, the primary broader impacts of my award have focused on the development of “soft” skills in graduate and post-doctoral researchers in STEM disciplines. I have developed a course on “Scientific and Engineering Management,” which provides an open forum for students to explore the skills that, in many ways, define successful careers for many scientists. Topics include: leadership, proposal writing, group management, communication in diverse environments, and ethics. In this presentation, I highlight the primary phases of this program, how it meshes with scientific goals, and general statements about the mission of education outreach within STEM disciplines.

12:03PM J19.00003 Educational Component of an NSF-CAREER Award on State Variables in Dense Granular Materials, KAREN DANIELS, North Carolina State University — I will discuss the design and goals of the educational component of an NSF-CAREER award whose research mission centers around experiments on granular materials. Two of the activities primarily involve undergraduates: providing laboratory research opportunities in support of the scientific goals of the project, and developing and disseminating an introductory seminar course on nonlinear nonequilibrium systems. In addition, the students from both the course and the laboratory will develop, in collaboration with NC State’s Science House, hands-on outreach activities for use with local school/youth groups.
12:15PM J19.00004 Education component of NSF awards – what can be done and where can we make a difference, ALESSANDRA LANZARA, University California, Berkeley — The education component of the NSF awards is often neglected or considered a minor component of the research. In this talk I will share my personal view of the importance of this component. In particular I will provide few examples of situation I have encountered in the past few years as NSF career awardees and will discuss what in my opinion are the aspects one should focus on to make a difference.

12:27PM J19.00005 Introducing Change in Undergraduate Education (Easy Steps for Junior Faculty), ERIC HUDSON, MIT — Bringing change to the undergraduate curriculum – for example, as new faculty might consider proposing for the Faculty (including junior faculty) could make to well established courses while avoiding the difficulties often associated with change. In this talk I will describe TEAL (technology enabled active learning), a major reform to the introductory physics sequence for non-majors at MIT. I will then focus on a few aspects of the course, such as the use of in-class feedback and real world problems. These relatively small changes (in terms of expense and effort) have been very beneficial, and point to a variety of improvements which faculty (including junior faculty) could make to well established courses while avoiding the difficulties often associated with change.

12:39PM J19.00006 Integration of Education and Research: proposed and completed activities, VERA SMOLYANINOVA, Towson University — In my presentation I will share my ideas of integrating education and research in a setting of an undergraduate institution. The proposed educational component of my CAREER proposal will be compared to what has been completed taking into account evolving needs and goals of our department, college and university. Organization of undergraduate research, curriculum development, and outreach activities will be discussed. Future plans will be introduced.

12:51PM J19.00007 Caltech Classroom Connection: An Outreach Partnership Program Between Caltech Scientists and K-12 Teachers, JAMES MALONEY, JENNIFER FRANCK, TARA GOMEZ, CHRISTINA SMOLKE, JOHN KEITH, California Institute of Technology — The Caltech Classroom Connection (CCC) is a volunteer outreach program whose goal is to supplement science, math and engineering education in local K-12 classrooms through individual scientist-teacher partnerships. Caltech graduate students, postdocs, staff and faculty volunteers are paired with teachers to develop a mutually beneficial and sustainable partnership. Targeted schools include the Pasadena Unified School District in which 76% of the student demographic consists of Hispanic and African American students, historically underrepresented in science, math and engineering careers. Student surveys are being developed to follow trends in science attitudes and science appreciation after interaction with a Caltech volunteer throughout the school year. The students are also affected by the increase in science awareness and confidence of the teacher, especially at the elementary level. We will present the program’s results over the past five years as well as future plans for improvement and expansion.

1:03PM J19.00008 Squishy Physics Field Trips, ERIC R. WEEKS, GIANGUIDO CIANCI, Emory University, PIOTR HABDAS, St. Joseph’s University — Our laboratory studies soft condensed matter, which means we investigate squishy materials such as foams, emulsions, and colloidal suspensions. These materials include common things such as peanut butter, toothpaste, mayonnaise, shampoo, and shaving cream. We have conducted several field trips for grade school students, where they come to our laboratory and play with squishy materials. They do both hands-on table-top projects and also look at samples with a microscope. We have also developed some of these activities into labs appropriate for first-year college students. Our first goal for these activities is to show students that science is fun, and the second goal is to get them intrigued by the idea that there are more phases than just solids, liquids, and gases.

1:15PM J19.00009 Moving Research into the Classroom with the Electron Microscopy Database, PAUL VOYLES, University of Wisconsin, Madison — Due to the strongly interdisciplinary nature of research in nanotechnology and materials, a course on transmission electron microscopy (TEM) must often serve student from a very broad range academic disciplines, level of background, and research interests. Someone in the class will want to learn about all the possible capabilities of the TEM, which span diffraction, spectroscopy, and imaging. Research students learn best from real-world examples, which are usually drawn from the research of the instructor, but very few instructors have the breadth of research and instrumentation needed to obtain high-quality examples of all the possible combinations of techniques and materials. I have therefore developed the Electron Microscopy Database (EMdb, http://tem.msa.e.wisc.edu/emdb/) as part of the education plan of my NSF CAREER project. The goal of the EMdb is to enable TEM teachers to easily exchange high-quality TEM example data and associated homework problems. This serves the NSF education goals of promoting excellence in research training and of bringing cutting-edge research into the classroom, and has significantly improved my own teaching.

1:27PM J19.00010 Research Experiences for Teachers: How professional development through directed research can revitalize your classroom teaching, SHELLY HYNES, Louisiana School for Math, Science and the Arts — Research Experiences for Teachers (RET) is an NSF-funded program that provides high school teachers with the opportunity to do research at select institutions across the country in a wide variety of fields. I performed research at two institutions under this program: The National Radio Astronomy Observatory in Green Bank, WV in 2006 and Baylor University in Waco, TX in 2007. My work at NRAO utilized IDL programming to analyze the nonlinearities in the signal processing components of the GBT (Green Bank Telescope). My research at Baylor University required me to write a program in Mathematica to analyze the frequency of pulsation of variable white dwarfs, data that was taken at the Paul and Jane Meyer Observatory in Clifton, TX. I will explain how I have incorporated both research experiences into my courses and how each of these experiences has refocused my teaching.

This work is supported by the NSF CAREER award DMR-0347746.

Research supported via the NSF-RET program, NRAO, Associated Universities, Inc., Baylor University, and the Central Texas Astronomical Society.
Barrier Height on H-Terminated Si(100) Surface

In scanning tunneling microscopy (STM) measurements on semiconductor surfaces, tip-induced band bending (TIBB) occurs due to the applied high bias voltage, and influences the local electronic structures of the surface detected by STM and scanning tunneling spectroscopy (STS). Recently, Yoshida et al. have reported the effect of the TIBB on local tunneling barrier height (LBH) on Si(100) surfaces by light-modulated STS [1]. However, theoretical studies on the TIBB and LBH have not been performed yet on semiconductor surfaces. In this study, we have analyzed the TIBB and LBH on an H-terminated Si(100) surface theoretically using the boundary-matching scattering-state density functional method [2], which can calculate the electron states under applied bias voltages self-consistently. In particular, we focus on the bias voltage dependences of the TIBB and LBH, and show that measured data also confirm such quasi-one dimensional character with a very anisotropic band structure. The surface electronic density of states measured by tunneling spectroscopy is compared with theoretical calculations.

1 Supported by the Research Corporation Cottrell Scholar Award and NSF-CAREER-DMR0449899.

2:03PM J19.00013 Inciting High-School interest in physics,1 JIANDI ZHANG, Florida International University (FIU), Miami, FL 33199 — We report on our outreach effort on material-physics education program as one part of my NSF Career award project. This is a program incorporated with the NSF funded Physics Learning Center at FIU, focusing on the material physics enrichment both high school students and teachers. We particularly pay attention to minority students by taking the advantage of FIU’s composition and location. The program offers a special/session-style workshop, demonstrations, research lab touring, as well as summer research activities. The goal is to enrich teacher’s ability of instruction to their students and inspire students to pursue scientific careers. The detailed outreach activities will be discussed.

1 Supported by NSF DMR-0346826

Tuesday, March 11, 2008 11:15AM - 2:15PM —Session J20 DCMP: Focus Session: Electronic and Lattice Properties of Surfaces and Thin Films Morial Convention Center 212

11:15AM J20.00001 Atomic and Electronic structure of Fe2O3 films on MgO(111). K. PANDE, University of Wisconsin-Milwaukee, A. CELIK-AKTAS, M. GAJDARDZISKA-JOSIFOVSKA, M. WEINERT — Polar oxide surfaces have interesting properties due to the strong ionic character of the metal-oxide bonds and the layering of metal and oxygen planes parallel to the surface. In this first-principles study we investigate the effect of MgO(111) surface polarity on the structure of iron oxide films. The calculated energetics of different surface terminations on the unreconstructed MgO(111) surface suggest that the interface has a Mg-O-Fe stacking with no intermixing of O and Fe atoms at the interface. The magnetic ordering of Fe atoms both within the layers and between neighboring (bi)layers will be described. The calculated structural and electronic properties will be compared to the results of high-resolution transmission electron microscopy (HRTEM) and selective area diffraction (SAD) experiments of Fe2O3 films on MgO(111) surface.

11:27AM J20.00002 ABSTRACT WITHDRAWN

11:39AM J20.00003 The semiconducting surface of In0.53Se1.53, M. KLINKE, E. CAI, I. RODRIGUEZ, JIANDI ZHANG, Florida International University, R. MATZDORF, Univ. Kassel, Y. LOSOVYI, J. LUI, P.A. DOWBEN, Dept. of Physics and Astronomy and the Nebraska Center for Material and Nanoscience, L. MAKINISTIAN, Facultad de Ingeniería, Univ. Nacional de Entre Ríos, E.A. ALBANCESI, INTEC-CONICET, A. PETUKOV, South Dakota School of Mines, Dept. of Physics, YA. FIYALA, P. GALIY, Electronics Dept., Lviv National Univ. — The layered crystal In0.53Se1.53 is of growing interest because of its nano-scale two dimensional structure and interesting transport properties. We have studied both the lattice and electronic band structures of cleaved (001) surface of In0.53Se1.53. Both LEED and STM reveal a p(1x1) surface structure with quasi-one dimensional atomic chains. ARPES data also confirm such quasi-one dimensional character with a very anisotropic band structure. The surface electronic density of states measured by tunneling spectroscopy is compared with theoretical calculations.

1 NSF CHE-0415421

11:51AM J20.00004 Theoretical Study of Tip-Induced Band Bending and Local Tunneling Barrier Height on H-Terminated Si(100) Surface, HIDEOMI TOTSUKA, Nihon University, SATOSHI WATANABE, The University of Tokyo, CREST TEAM — In scanning tunneling microscopy (STM) measurements on semiconductor surfaces, tip-induced band bending (TIBB) occurs due to the applied high bias voltage, and influences the local electronic structures of the surface detected by STM and scanning tunneling spectroscopy (STS). Recently, Yoshida et al. have reported the effect of the TIBB on local tunneling barrier height (LBH) on Si(100) surfaces by light-modulated STS [1]. However, theoretical studies on the TIBB and LBH have not been performed yet on semiconductor surfaces. In this study, we have analyzed the TIBB and LBH on an H-terminated Si(100) surface theoretically using the boundary-matching scattering-state density functional method [2], which can calculate the electron states under applied bias voltages self-consistently. In particular, we focus on the bias voltage dependences of the TIBB and LBH, and show that measured LBHs can be basically understood as the sum of TIBB and intrinsic barrier height. [1] S. Yoshida, et al., e-J. Surf. Sci. Nanotech. 4, 192 (2006). [2] Y. Gohda et al., Phys. Rev. Lett. 85, 1750 (2000). [3] M. McEllistrem, et al., Phys. Rev. Lett. 70, 2471 (1993).
12:03PM J20.00005 Studies of the oxidized Cu(100) surface using positron annihilation induced Auger electron spectroscopy, W. MADDOX, N. G. FAZLEEV, M. P. NADESEILINGAM, A. H. WEISS, Department of Physics, University of Texas at Arlington — We discuss recent progress in studies of an oxidized Cu(100) single crystal subjected to vacuum annealing over a temperature range from 293K to 1073K using positron annihilation induced Auger electron spectroscopy (PAES). The PAES measurements show a large monotonous increase in the intensity of the positron annihilation induced Cu M2,3VV Auger peak as the sample is subjected to a series of isochronal anneals in vacuum up to annealing temperature 573 K. The intensity then decreases monotonically as the annealing temperature is increased to 873 K. Experimental PAES results are analyzed by performing calculations of positron surface states and annihilation probabilities of surface-trapped positrons with relevant core electrons taking into account the charge redistribution at the surface, surface reconstructions, and electron-positron correlations effects. The effects of oxygen adsorption and surface reconstruction on localization of positron surface state wave functions and annihilation characteristics are analyzed. Possible explanations are provided for the observed behavior of the intensity of positron annihilation induced Cu M2,3VV Auger peak with changes of the annealing temperature.

12:15PM J20.00006 Visualization of 2D subband states formed in Si(111)-β-√3x√3-Bi surface by STM, KATSUMI NAGAOKA, SHIN YAGINUMA, TADAAKI NAGAO, TOMONOBU NAKAYAMA, National Institute for Materials Science — We have investigated electronic subbands formed underneath of Si(111)-β-√3x√3-Bi (β-√3-Bi) surface by using STM. The β-√3-Bi surface is semiconducting, and the band gap is larger than that of bulk Si. In the dI/dV images, standing waves are found around defects, and the obtained energy dispersion is in good agreement with the free-electron-like model. Apparently, formation of a 2D electronic state is suggested. However, this standing wave is observed only on p-type, but not on n-type Si substrates, and consequently the 2D state is attributed to the subband formed in the depletion layer just below the β-√3-Bi surface. The subband formation is also consistent with the calculation of electronic states inside a potential-well caused by interfacial band bending.

12:27PM J20.00007 One-Dimensional Electronic Bands of Monatomic Cu Chains, PINGHENG ZHOU1, International Center for Theoretical Physics, Trieste, Italy, PAOLO MORAS, Istituto di Struttura Materia, Consiglio Nazionale delle Ricerche, Trieste, Italy, LUISIA FERRARI, Istituto dei Sistemi Complessi, Consiglio Nazionale delle Ricerche, Roma, Italy, GUSTAV BIHLMAIER, STEFAN BLÜGEL, Institut für Festkörperforschung, Forschungszentrum Jülich, Germany, CARLO CARBONE, Istituto di Struttura Materia, Consiglio Nazionale delle Ricerche, Trieste, Italy — The electronic structure of an array of monatomic Cu chains grown on the Pt(997) surface has been examined by angle-resolved photoemission. The monatomic wires exhibit properties associated to 3d electron confinement in one-dimension. Along the wire direction the 3d bands states display a dispersive character, with periodicity in reciprocal space defined by the wire array geometry. These observations are compared and analyzed with ab initio calculations based the full potential linearized augmented plane wave method.

12:39PM J20.00008 Calculating work functions with density functional theory: the effect of finite temperature, surface alloying, and oxidation, THOMAS R. MATTSSON, DWIGHT R. JENNISON, Sandia National Laboratories, Albuquerque, NM 87185-1186, USA — The work functions for W, Cu, and Al are calculated using density functional theory (DFT). We go beyond the perfect lattice at zero Kelvin by employing molecular dynamics techniques. Effects of surface alloying and oxidation are also investigated. The effect of alloying and oxidation is, as expected, found to be significant, whereas the temperature dependence, although detectable, is small. Furthermore, the exchange-correlation density functional AM05 is compared to the results of LDA and PBE. The calculated work functions compare well to available experimental results. This work was supported by the LDRD office and the simulations were performed at the High Performance Computing facilities at Sandia National Laboratories, NM. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

12:51PM J20.00009 Longitudinal Phonon Resonance of the Cu(111) Surface, VASSE CHIS, BO HELLING, Department of Physics, Göttingen University, Sweden, MARCO BERNASCONI, GIORGIO BENDEK, Dipartimento di Scienze dei Materiali, Università Milano-Bicocca, Milano, Italy, J. PETER TOENNIES, Max-Planck-Institut für Dynamik und Selbstorganisation, Göttingen, Germany — The electronic structure of an array of monatomic Cu chains grown on the Pt(997) surface has been examined by angle-resolved photoemission. The monatomic wires exhibit properties associated to 3d electron confinement in one-dimension. Along the wire direction the 3d bands states display a dispersive character, with periodicity in reciprocal space defined by the wire array geometry. These observations are compared and analyzed with ab initio calculations based the full potential linearized augmented plane wave method.

1:03PM J20.00010 Rashba-type spin-orbit splitting in ultrathin Bi films, G. BIHLMAIER, Inst. f. Festkörperforschung, FZ Juelich, Germany, YU. M. KOROTEEV, Inst. of Strength Physics and Materials Science, Tomsk, Russia, E.V. CHULKOV, Donostia International Physics Center, San Sebastian, Spain, S. BLÜGEL, Inst. f. Festkörperforschung, FZ Juelich, Germany — Due to their electronic similarity with graphene sheets, surfaces and thin films of the semimetal bismuth have recently received considerable interest. A systematic study of thin (1 – 6 bilayers) films in (111) and (110) orientation is presented, employing density functional theory calculations. Due to the different coordination of the surface atoms in these two cases, a large variation of the conducting properties of the films is found. The evolution of surface states is studied as a function of the film thickness and by comparison to thicker films and simulations of the semimetallic crystals. Interesting features arise from the strong spin-orbit effects in Bi and the resulting Rashba-type spin-splitting of the surface states. The spin-polarization of these states changes as these states transform into quantum well states at the Brillouin zone boundary. The results are compared with recent experimental results on Bi films on Si substrates.

1:15PM J20.00011 Lattice Dynamics of RuO2: Bulk and (110) Surface, KLAUS-PETER BOHNEN, ROLF HEID, Forschungszentrum Karlsruhe, IFP, OMAR DE LA PENA SEAMAN, Department of Applied Physics, CINVESTAV-Merida — Although RuO2 has been studied as a prototype catalyst for CO oxidation no careful study of the lattice dynamics for this material has been presented so far. Using modern ab-initio methods we obtain the phonon dispersion and the generalized density of states (GDOS). Inelastic neutron-scattering experiments allow for an experimental determination of the GDOS. In contrast to what is known from structural studies, we find that the local-density approximation gives a much better description of the phonon spectrum than the generalized gradient corrected form. This is also consistent with Raman measurements. Besides the bulk we have also studied the lattice dynamics for the (110) surface. Our calculations indicate an instability over a large range of the BZ. Unfortunately, no complete experimental phonon study of this surface has been carried out so far. Consequences for the structure of the (110) surface will be discussed.
1:27PM J20.00012 Simulation of four-probe measurement based on density-functional tight-binding method, ASAKO TERASAWA, TOMOFUMI TADA, SATOSHI WATANABE, Dept. of Materials Engineering, School of Engineering, The Univ. of Tokyo, CREST, Japan Science and Technology Agency — Four-probe measurements are powerful tools to investigate electric properties of materials precisely. Recently, the minimum probe spacing has reached to the order of 10 nm using nanotube probe tips [1]. However, it is not clear if the procedure used in macroscopic measurements can eliminate the effects of contact resistance even in such microscopic measurements. Keeping this in mind, we have developed a multi-probe transport simulator on the basis of Green’s function method combined with the density-functional tight-binding method [2]. So far, we have succeeded in self-consistent calculations at the limit of zero bias voltage for four-probe models consist of more than 1000 atoms, such as an infinite graphite ribbon with two or four semi-infinite nanotube tips. The calculation results indicate that the effects of the contact are not fully eliminated by the usual procedure.

1:39PM J20.00013 Quantum Blockades and Loop Currents in Graphene with Topological Defects, YAN-YANG ZHANG, JIANG-PING HU, B.A. BERNEVIG, XIANGRONG WANG, XIN-CHENG XIE, WU-MING LIU — We investigate the effect of topological defects on the transport properties of a narrow ballistic ribbon of graphene with zigzag edges. Our results show that the longitudinal conductance vanishes at several discrete Fermi energies where the system develops loop orbital electric currents with certain chirality. The chirality depends on the direction of the applied bias voltage and the sign of the local curvature created by the topological defects. This novel quantum blockade phenomenon provides a new way to generate a magnetic moment by an external electric field, which can prove useful in carbon electronics.

1:51PM J20.00014 Orbital Order in (LaMnO₃)ₘ(SrMnO₃)ₙ Superlattice, CHUNGWEI LIN, Physics Department, Columbia University, CLAUDE EDERER, School of Physics, Trinity College, ANDREW MILLIS, Physics Department, Columbia University — A realistic model for (LaMnO₃)ₘ(SrMnO₃)ₙ is constructed and solved by the semiclassical approximation. The model includes electron-electron, electron-lattice, and lattice-lattice interactions. Technically, we generalize the semiclassical approximation to the multi-orbital system and include the cooperative Jahn-Teller effect in the impurity problem. Within this framework, we present the orbital order in the superlattice.

This work is supported under DOE Grant No.ER-46169.

2:03PM J20.00015 Direct measurement of core-level relaxation dynamics on a surface adsorbate system, JING YIN, LUIS MIAJA-AVILA, GUIDO SAAHTOFF, CHAN LA-O-VORAKIAT, MARGARET MURNANE, HENRY KAPTEYN, JILA, University of Colorado, STEFAN MATHIAS, MARTIN AESCHLIMANN, University of Kaiserslautern, Germany, MICHAEL BAUER, Christian-Albrechts-Universität zu Kiel, Germany — Electronic coupling between an adsorbate and the surface on which it resides is fundamental to the understanding of many surface interactions. However, the interaction of highly-excited adsorbate states is an area that has been explored only indirectly to-date. In this work, we present the first direct time-resolved observations of the lifetime of core-excited states of an atom adsorbed onto a surface. By implementing laser-assisted Auger decay on an adsorbate/surface system, we directly measure the lifetime of the 4d⁻¹ core level of Xenon on Pt(111) to be 7.1 ± 1.1 fs. This result opens up time domain measurements of highly-excited state dynamics in systems where, because of complex interactions, energy-resolved measurements provide incomplete information.

Convention Center 213

11:15AM J21.00001 Quantum Mechanics and Electrodynamics Studies of the Optical Properties of Metal Clusters/Nanoparticles, GEORGE SCHATZ, Northwestern University — This talk will describe the use of electrodynamics and quantum mechanics methods to describe the optical properties of silver and gold nanoparticles and other nanostructures. This work has been done in collaboration with several experimental colleagues, including Chad Mirkin, Rick Van Duyne and Teri Odom. Our recent work has focused on the optical properties of metal nanoparticles that are coated with molecules that are detected either through their influence on plasmon resonance excitation, or via surface enhanced Raman spectroscopy (SERS). Electrodynamics calculations using either the DDA or FDTD methods provide a quantitative tool for characterizing far field properties, and at a more primitive level estimates of SERS intensities. Quantum mechanics, as developed using time dependent density functional theory, is restricted to small metal clusters, but the same methods of far field spectroscopy and SERS can still be studied.

11:51AM J21.00002 Low Temperature Static Dipole Polarizability of Free Sodium Clusters with from 2 to 250 atoms, ANTHONY LIANG, JOHN BOWLAN, GaTech, XIAO- SHAN XU, SHUANG-YE YIN, WALT A. DE HEER, GaTech — The electric dipole polarizabilities of all sodium clusters Naₙ were measured from the atom up to n =250 using the molecular beam deflection method. Clusters were formed in cryogenic laser vaporization source operating at a temperature of 20 K. This complete sequence of high-resolution polarizabilities measurements greatly enhances previous experiments. Electronic shell effects are observed as well as several features that are not readily understood in the shell model. The asymptotic limit of the measurements appears not to converge to the bulk sodium polarizability value. The data are compared with theoretical predictions.

12:03PM J21.00003 Novel Properties of Diamondoid Molecules, WILLIAM CLAY, ZHI LIU, WANLI YANG COLLABORATION, ZHI-XUN SHEN COLLABORATION, NICK MELOSH COLLABORATION, JEREMY DAHL COLLABORATION, ROBERT CARLSON COLLABORATION — The recent isolation of a number of diamond-like hydrocarbons molecules (diamondoids) has sparked renewed interest in these unusual molecular systems. Several unique properties of these molecules are investigated. Diamondoid monolayers have been found to profoundly alter the electron emission tails of metal substrates in recent photoemission experiments, producing a sharp, nearly monochromatic peak. It is postulated that the cause of this effect is negative electron affinity combined with a strong electron-phonon interaction. New data and simulation results are presented to support this theory. Additionally, photoluminescence spectra for a number of diamondoid crystals are presented, taken with a 229 nm laser. To our knowledge, this is the first observation of UV photoluminescence in a saturated hydrocarbon molecule. Possible explanations for this phenomenon are discussed.
12:15PM J21.00004 Room temperature stability of mass selected Ag clusters on C_{60} functionalized surfaces. STEFANIE DUFFE, LUKAS PATRYARCHA, TORSTEN RICHTER, BENEDIKT SIEBEN, HEINZ HÖVEL, Technische Universität Dortmund, Experimentelle Physik I, Germany, CHUNRONG YIN, BERND VON ISSENDORFF, Universität Freiburg, Fakultät fuer Physik, Germany, MICHAEL MOSELER, Fraunhofer-Institut fuer Werkstoffmechanik IWM, Freiburg, Germany — Mass selected clusters from Ag^{−1}_{n=1} to Ag^{−3}_{n=5} were soft landed on HOPG and Au(111) functionalized with 1 and 2 monolayers (ML) of C_{60} molecules [1]. Depositions at 165 K gave extremely narrow cluster height distributions in STM images measured at 77 K. Using C_{60}/HOPG or 2 ML C_{60}/Au(111) the cluster heights are stable for more than 12h at room temperature (RT). For 1 ML C_{60}/Au(111) the cluster height decreases and finally all clusters disappear at RT. Molecular dynamics simulations reveal a process by which the clusters decay by atom through 1 ML C_{60}/Au(111) at RT. A sharp maximum at 1.7 nm cluster height forms during the cluster decay, indicating that there exists some metastable ‘supported magic number’.

12:27PM J21.00005 Modification on the melting of aluminum nanoclusters by a copper atom: heat capacities of CuAl^{−n}_{n=1} nanoalloys, BAOPENG CAO, COLLEEN M. NEAL, ANNE M. STARACE, MARTIN F. JARROLD, Department of Chemistry, Indiana University, 800 E Kirkwood Ave., Bloomington, IN 47405 — The melting of alloy clusters is currently of great interest and emerging as an important research area. In this talk, we report the synthesis and melting transition of CuAl^{−n}_{n=1} nanoalloy clusters (n = 49 – 62). Heat capacities and melting behaviors have been determined for CuAl^{−n}_{n=1} nanoalloy clusters using a novel collision induced dissociation method and are compared with those of pure aluminum cluster Al^{n+m}_{n=1}. All these nanoalloys present a first order melting transition at temperatures well below the melting temperature of the bulk aluminum and the eutectic temperature of their bulk alloys. No eutectic characteristic is detected for these nanoalloy clusters. Upon substitution of Al with a single copper atom, the melting of pure aluminum clusters has been altered considerably. Size and charge effects of the doping atom on the melting of host nanoclusters are discussed.

1We thank the NSF for financial support.

12:39PM J21.00006 Forces between Functionalized Silica Nanoparticles, J. MATTHEW D. LANE, AHMED E. ISMAIL, MICHAEL CHANDROSS, GARY S. GREST, Sandia National Labs — Polymer-coated nanoparticles have a wide variety of applications, including drug delivery, adhesives, coatings, and magnetics. Although, the complexity of these nanoparticles precludes atomistic simulations of large numbers of nanoparticles in solution, it is possible to study the interaction between pairs of nanoparticles in an explicit solvent using molecular dynamics. From these simulations, we can compute the potential of mean force (PMF) between nanoparticles, which can be used in coarse-grained simulations at larger length and time scales. In particular, we present results for PMFs between polymer-grafted silica nanoparticles as a function of chain length, core size, and approach velocity. We report results for explicit-atom models of poly(ethylene oxide)-coated nanoparticles in water and alkylsilsane-coated nanoparticles in decane.

1Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract No. DE-AC04-94AL85000.

12:51PM J21.00007 Photo-fragmentation of the closo-carboranes, JING LIU, DANQIN FENG, P.A. DOWBEN, Dept. of Physics and Astronomy, University of Nebraska-Lincoln, A.P. HITCHCOCK, Dept. of Chemistry, McMaster University, Canada, A.L.D. KILCOYNE, T. TYLISZCZAK, Advanced Light Source, Lawrence-Berkeley Laboratory, J.D. BOZEK, Stanford Synchrotron Radiation Laboratory, E. RÜHL, Institut für Physikalische Chemie, Freie Universität Berlin, Germany — Single and multi-atomic excitation and fragment ion formation of three isomeric carborane cage compounds [closo-1,2-orthocarborane, closo-1,7-metacarborane, closo-1,12-paracarborane (C_{12}B_{10}H_{12})] following B 1s and C 1s excitation were studied by time of flight mass analysis. The energetic cycles were constructed to gain some insights into some decomposition processes. CH^{+} or BH^{+} fragment dominates the single ion fragmentation of the closo-carboranes. Double ion fragmentation yields and charge separation mass spectra of all three isomers are generally quite similar in that H^{+} and BH^{+}/CH^{2+}/CH^{+} ion pairs, BH^{+}/CH^{+} and Y^{+}_{11} ion pairs (where Y = (BH) or (CH)), Y^{+}_{3} and Y^{+}_{4} ion pairs (where Y = (BH) or (CH)) yields dominate. The H^{+} and BH^{+}/CH^{+} ion pairs dominate at the B 1s threshold for ortho- and metacarborane, while Y^{+}_{11} and Y^{+}_{11} ion pairs (where Y = (BH) or (CH)) dominate the multi-fragmentation ion yield of paracarborane at the B1s threshold.

1:03PM J21.00008 Coupled quantum dot / quantum shell systems: optical gain, ultrafast charge transport, and single particle blinking, PATANJALI KAMBHAMPATI, D.M. SAGAR, EVA DIAS, SAMUEL SEWALL, RYAN COONEY, McGill University, AMY GRIMES, DOUGLAS ENGLISH, University of Maryland — The CdSe/ZnS/CdSe core/barrier/shell nanostructure forms an electronically coupled quantum system that is a spherical analog to the quantum well superlattice. The core’s brightness is enhanced via light harvesting by the shell. This material offers an opportunity to study charge transport in spherical nanoscale materials. Here, we present new results on the femtosecond dynamics of radial charge transport in these materials. With a combination of excitonic state selectivity and femtosecond time resolution, we monitor the ultrafast relaxation dynamics of either the core or the shell, having optically excited either phase. The femtosecond experiments reveal strong optical gain as well as evidence of spatially separated bieexcitons, and coupling between phases. Finally, we present single dot data on the two-color blinking kinetics of these coupled quantum dot quantum shell systems.

1:15PM J21.00009 Sampling of stable and metastable cluster structures by a first-principles Monte Carlo approach, RALF GEHRKE, KARSTEN REUTER, Fritz-Haber-Institut, Faradayweg 4-6, D-14195 Berlin — Size-selected nano-scale atomic clusters are now systematically becoming accessible in experiment, but characterizing their ground-state and metastable isomer ensemble averages from first principles requires a global and local exploration of vast configuration spaces. We here explore a first-principles Monte Carlo scheme to efficiently sample the minima of the corresponding total energy landscapes. The energetics is obtained at the density-functional theory level, using an all-electron local orbital basis set.

1:27PM J21.00010 The Effects of pH and Acid Type on Porous Alumina Formation, ADAM FRIEDMAN, DERRICK BRITTAI, LATIKA MENON, Northeastern University Dept. of Physics — Porous aluminum oxide prepared by anodization has an enormous variety of uses in nanomanufacturing, as it can be used as scaffolding to grow nanowires and tubes of exacting size specifications. However, there is no complete physical model for its growth. Three models in particular have been suggested in the past. We experimentally study the stability of porous alumina formation and the effects of changing anodization voltage, acid pH, and acid type. Using this information, we show that the models err in their primary assumptions, we pinpoint the location of these errors, and we suggest a method to correct them.

1:39PM J21.00011 Probing the Coulomb Barrier Towards Ionic Fragmentation, SHAUN ARD, NASRIN MIRSALEH-KOHAN, ROBERT COMPTON, University of Tennessee — Quintessential to understanding the stability of multiply charged anions (MCAs) is the characterization of the so-called “Coulomb Barrier” (CB) toward the loss of an excess electron and/or dissociation into charged fragments. The CB arises due to the superposition of the long-range Coulomb repulsion of the excess electron (or anion), and the short-range attractive polarization binding energy of the anion (or fragment). The CB adds to the stability of MCAs, often rendering thermodynamically unstable species to be metastable toward autodetachment or dissociation. The magnitude and shape of the CB is expected to depend heavily on the decay pathway. Whereas dissociation into charged fragments is often the lowest energy pathway for many MCAs, the vast majority of previous research has focused on electron loss. In this work, collision-induced dissociation (CID) is employed to study fragmentation of disulfonic diamions of increasing “length”. Energy threshold for the production of SO4_2^- plus its conjugate anion are used to estimate the magnitude of the Coulomb barrier to dissociation. These measured thresholds are compared with ab initio calculations of the dissociation energy. The relationship between these magnitudes and the distance between the excess charges will then be discussed.

1:51PM J21.00012 Vibrational modes in metal core-shell nanoparticles, A.S. KIRAKOSYAN, T.V. SHAH-BAZYAN, Jackson State University — We study the spectrum of lowest vibrational modes of bimetallic nanoparticles in dielectric surrounding. For solid spherical particles, the mode’s period and decay time are determined by the ratio of particle radius to longitudinal sound velocities in metal and outside medium, respectively. In contrast, in bimetallic nanoparticles, the dependence of both period and damping time on aspect ratio is highly non-monotonic. In particular, for Au/Ag core-shell nanoparticles, in a wide range of aspect ratios, the fundamental mode period is lower than in both Au and Ag solid particles of the same overall size, while the damping time exhibits a minimum at aspect ratios around 0.5. The unique acoustical signature of complex nanostructures allows unambiguous determination of their composition from ultrafast pump-probe and Raman spectroscopy measurements.

Tuesday, March 11, 2008 11:15AM - 1:39PM –
Session J22 DMP DPOLY: Organic Electronics, Photonics and Magnetics: Theory Morial Convention Center 214

11:15AM J22.00001 Dependence of Mobility on Density of Gap States in Organics by GAMEaS - Gate Modulated Activation Energy Spectroscopy, WOO-YOUNG SO, DAVID LANG, Columbia University, ARTHUR RAMIREZ, Alcatel-Lucent — We develop a spectroscopic method for determining the density of states (DOS) in the energy gap - Gate Modulated Activation Energy Spectroscopy (GAMEaS). We also report the relationship of these gap states to the mobility of organic field-effect-transistors (FETs). We find that the field-effect mobility is parameterized by two factors: (1) the free-carrier mobility and (2) the ratio of the free carrier density to the total carrier density induced by the gate bias. We show that the highest mobility FETs have shallow exponential band tails of localized states with characteristic slope of 1/kT at 300K. Most remarkably, state-of-the-art crystalline FETs fabricated from rubrene, pentacene, and tetracene all have a very high free-carrier mobility, up to 200cm2/Vsec at 300K, with the somewhat lower effective mobilities dominated by localized gap states. This strongly suggests that further improvements in device performance could be possible with enhanced material quality.

11:27AM J22.00002 Charge mobility of discotic mesophases of polyaromatic hydrocarbons: a multiscale quantum/classical study, DENIS ANDRIENKO, VALENTINA MARCON, KURT KREMER, Max Planck Institute for Polymer Research, Ackermannweg 10, 55128 Mainz, Germany, JAMES KIRKPATRICK, JENNY NELSON, Department of Physics, Imperial College London, Prince Consort Road, London SW7 2BW, United Kingdom — Discotic liquid crystals form columnar phases, where the molecules stack on top of each other and the columns arrange in a regular lattice. The self-organization into stacks results in the one-dimensional charge transport along the columns. Using atomistic molecular dynamics (MD) simulations we study columnar discotic phases formed by various polyaromatic hydrocarbons. Combining Kinetic Monte Carlo and MD trajectories a correlation between the material morphology and charge mobility is then established. We are able to reproduce the trends and magnitudes of mobilities as measured by pulse-radiolysis time-resolved microwave conductivity technique.

11:39AM J22.00003 Optical spectra and exchange-correlation effects in molecular crystals, NA SAI, University of Texas at Austin, MURilo L. TIAgO, Oak Ridge National Laboratory, JAMES R. CHELIKOWSKY, University of Texas at Austin, FERNANDO A. REBOREDO, Oak Ridge National Laboratory — We report first-principles GW-Bethe Salpeter Equation and Quantum Monte Carlo calculations of the optical and electronic properties of molecular and crystalline rubrene (C20H16). We predict the formation of intermolecular, charge-transfer spin-singlet excitons with energies in close agreement with the observed yellow-green photoluminescence in rubrene microcrystals. In contrast, spin-triplet excitons are localized and intramolecular with a predicted phosphorescence at the red end of the optical spectrum. We find that the exchange energy plays a fundamental role in raising the energy of intramolecular spin-singlet excitons above the intermolecular ones. Exciton binding energies are predicted to be around 0.5 eV (spin singlet) to 1 eV (spin triplet). The calculated electronic gap is 2.8 eV. The theoretical absorption spectrum agrees very well with recent ellipsometry data.
Recently, a strategy was developed to perform continuous optimization of molecular properties, the linear combination of atomic potentials (LCAP) approach. This approach finds optimal structures among 10^4 molecular candidates with strong structural similarity, the TB-LCAP approach may provide an effective means of identifying structures with optimal properties.

1:15PM J22.00006 Inverse Molecular Design in a Tight-Binding Framework
DEQUAN XIAO, WEITAO YANG, Department of Chemistry, Duke University, Durham, NC 27708, DAVID BERATAN, Department of Chemistry and Department of Biochemistry, Duke University, Durham, NC 27708 — We consider the trapping of a moving electron by a polar impurity in an uncompensated organic semiconductor when the multipole moment of the impurity is coupled to an intramolecular vibration, a dynamical generalization of the Vannikov-Novikov dipole trap model. Due to the slow power-law dependence of the multipolar interaction, the vibrational coordinate shifts adiabatically with the approach of the charge carrier. The fast molecular motion can be decoupled from the electron’s translational motion to first approximation by transforming to the polaron basis, leading to a polaron binding energy which serves to enhance the propensity for the moving charge to be captured. For an isolated impurity, however, the transformed Hamiltonian contains a repulsive ponderomotive term not described in conventional polaron theory. The repulsion can outweigh the attractive force at long range, presenting a barrier to trap formation. [1] S. V. Novikov and A. V. Vannikov, Chem. Phys. 169 (1993) 21-33.

1:27PM J22.00007 Ab initio Evaluation of the Charge-Transfer Integrals and Band Structures of Phenanthroline-based Molecular Crystals
H. LI, J.-L. BREDAS, Georgia Institute of Technology, C. LENNARTZ, BASF Aktiengesellschaft, Germany — Ab initio calculations are carried out to study the charge-transport properties of phenanthroline-based molecular crystals, BCP and Bphen. The charge-transfer integrals in the two crystalline structures and in a quasi-1D chain model for BCP are evaluated based on: (i) a tight-binding approximation for dimers; (ii) the band structures of the periodic systems. In these compounds, the LUMO/LUMO+1 energetics of the isolated molecules are very close, which results in the LUMO and LUMO+1 orbitals both having significant contributions to the LUMO level in the dimer. In this case, the usual definition based on the electronic coupling between the two LUMO orbitals from each molecule cannot be applied to describe the charge-transfer characteristics in the dimer. A new definition of “effective transfer integrals” based on “mixed states” was proposed (H. Li, J.L. Bredas, and C. Lennartz, J. Chem. Phys. 126 (2007) 164704) to address this problem. Within the tight-binding approximation, the “effective transfer integrals” for both hole and electron transfers are found to be in very good agreement with the valence and conduction band dispersions obtained from plane-wave DFT calculations. We acknowledge many stimulating discussions with Vaclav C. Cojocaru and Demetrio da Silva Filho.

1:39PM J22.00008 ABSTRACT WITHDRAWN

1:51PM J22.00009 Electron-phonon coupling in naphthalene crystal
ROEL SÁNCHEZ-CARRERA, PAVEL PARAMONOY, Department of Physics, University of Akron, Akron, Ohio 44325-4001, VEACESLAV COROPCEANU, JEAN-LUC BREDAS, School of Chemistry and Biochemistry and Center for Organic Photonics and Electronics, Georgia Institute of Technology, Atlanta, Georgia 30332-0400 — We investigate the electron-phonon couplings in naphthalene crystal. The electron-phonon couplings were evaluated by means of numerical differentiation; in this approach, the crystal geometry is distorted along normal modes and transfer integrals for several selected molecular pairs are then computed at each distorted geometry. We find that the DFT and force field results for phonon frequencies and electron-phonon couplings compare very well. Interestingly, several phonon modes are calculated to display significant quadratic electron-phonon coupling. In addition, we have also performed electronic band-structure calculations and derived the effective masses for both electrons and holes.

1:03PM J22.00010 Solid state effects on the photophysics of π-conjugated polymer thin films
ALOK SHUKLA, Indian Institute of Technology Bombay, ZHENHONG WANG, SUMIT MAZUMDAR, University of Arizona — The photophysics of thin films of π-conjugated polymers (PCPs) are remarkably different from that of dilute solutions. The difference is generally ascribed to interchain interactions and disorder in films. Microscopic understanding of the consequences of interchain interactions has remained incomplete in spite of intensive investigations. We present a theory of the complete energy spectrum of interacting PCP chains that leads to correct qualitative, and perhaps even semiquantitative description of the photophysics of PCP films. Within our theory of photoexcitations occurs to exciters that occur both below and above the optical excitation. Emission, as well as ultrafast photoinduced absorption (PA) in films are from the lower excimer. The lowest energy PA at 0.35 - 0.4 eV corresponds to the allowed transition from the lower eximer to the lowest polaron-pair. We explain why the energies of the PA at ~ 1.0 eV and higher are the same in films and solutions, even though the origins of these PAs are different. Finally, we give consistent explanations of the peculiarities associated with emission in films, including delayed emission, its quenching by electric field and the reappearance of the delayed emission upon removal of the field.

Tuesday, March 11, 2008 11:15AM - 2:15PM — Session J23 DMP GMAG: Focus Session: Cuprates and Nickelates Morial Convention Center 215

11:15AM J23.00001 Unidirectional charge modulations in underdoped cuprates observed with STM $^{1}$, J. C. DAVIS, Cornell University — No abstract available.

11:51AM J23.00002 Phase Separation and Magnetism in High Tc Superconductors $^{1}$, SAMUEL EMERY, BARRETT WELLS, HASHINI MOHOTTALA, JOSEPH BUDNICK, WILLIAM HINES, Univ. of Connecticut, LINDA UDBY, KIM LEMFANN, NEILS HESSEL ANDERSEN, Risoe National Laboratory, CHRISTOF NIEDERMAYER, NIERS CHRISTENSEN, ETH Zurich and Paul Scherrer Inst., JEFFREY LYNN, NIST, FANGCHENG CHOU, National Taiwan Univ. — Previous work by our group has determined that the low temperature phase diagram of super- oxygenated, La$_2$CuO$_4$ consists of only a few line phases that are either superconducting (SC) or magnetic. Samples with doping levels between the stable phases will segregate into separate domains; this raises the question as to the nature of the interaction between SC and magnetic domains. We have begun a neutron scattering study of the magnetic behavior of two such crystals. The oxidation states vary such that in one sample we have a phase separation between a low Tc (30K) SC phase and a striped magnetic phase, while the other features a high Tc (40K) SC phase and striped magnetic phase. Elastic neutron scattering reveals little field dependence of the magnetic peaks in the former, while in the latter we see an enhancement of the magnetic intensity. We also are deriving a method for separating contributions to the inelastic magnetic scattering by the SC and magnetic phases.

$^{1}$Work supported by the DOE grant DE-FG02-00ER45801

12:03PM J23.00003 Spin order and dynamics in a low doped nickelate $^{1}$, ANDREI SAVICI, Johns Hopkins University, IGOR ZALIZNYAK, GENDA GU, Brookhaven national Laboratory, VASILE GARLEA, Oak Ridge national laboratory — Due to their similarities with high-Tc cuprates, doped 214 layered nickelates attract significant interest. We have recently performed elastic and inelastic neutron scattering experiments studying the low-Sr-doped material La$_{1.55}$Sr$_{0.45}$NiO$_4$. This sample has nominal hole concentration similar to that in optimally doped cuprate superconductors. We observe static spin and charge ordering patterns and dynamic spin correlations, which we will compare to those arising from one dimensional physics expected in the stripe picture.

12:15PM J23.00004 Detection of the Spin Reorientation and Glassy Dynamics in La$_{1.55}$Sr$_{0.45}$NiO$_4$ $^{1}$, SEAN GIBLIN, ISIS, Rutherford Appleton Lab, PAUL FREEMAN, ILL, France, DHARMALINGHAM PRABHAKARAN, ANDREW BOOTHROYD, University of Oxford, UK — the magnetism of charge stripe ordered La$_{1.55}$Sr$_{0.45}$NiO$_4$ was studied by the combined techniques of neutron diffraction, spin relaxation and mass susceptibility. Magnetic ordering was observed at a lower temperature by muon relaxation than neutron diffraction, indicating a glazy transition to the ordered phase, in agreement with the susceptibility. Neutron diffraction determined a second magnetic transition that is observed by all techniques, to be a spin reorientation. On cooling below $T_{f} = 12$ K the spins re-orientate from lying 33.7 $^{1}$ away from the stripe direction at 70 K to 57.4 $^{1}$ away at 10 K. The magnetic order was observed by neutron diffraction to be of both anisotropic 3D and 2D (without any correlation on the $c$ axis) character. Muon relaxation confirmed this to be consistent with a single magnetically ordered spin stripe phase. The muon site associated with the spin stripe indicated critical behavior expected from a two dimensional magnetically ordered state, whereas the site associated with the charge stripe showed three dimensional critical behavior indicating spin frustration at the charge stripe.

12:27PM J23.00005 Anomalous diffusion on a hypersphere and time structure of two-point spin correlations in short-range-ordered doped oxides, $^{1}$, IGOR ZALIZNYAK, Brookhaven National Laboratory, GEORG EHLERS, Oak Ridge National Laboratory, GENDA GU, Brookhaven National Laboratory — Recently, much attention was paid to exploring charge and spin-ordered phases in strongly correlated transition metal oxides, such as superconducting cuprates and related nickelates, manganites and cobaltites. Using elastic neutron scattering, we have investigated the nano-scale structure of short-range charge and spin ordering in a half-doped cobaltite La$_{1.55}$Sr$_{0.45}$CoO$_4$, and found that they can be understood in the framework of an effective anisotropic 3D random field Ising model. Here we report on the measurement of the time-dependence of the spin correlation function in this material by means of Neutron Spin Echo (NSE) spectroscopy. Our high-precision NSE data exclude simple Arrhenius and stretched-exponential relaxations and can be best described by the model of anomalous diffusion on the appropriate hypersphere. We argue that such time dependence is generic for short-range-ordered spin systems.

12:39PM J23.00006 Transverse displacement modulation of the 1D metallic chains in optimally doped yttrium barium copper oxide superconductor $^{1}$, XUERONG LIU, University of California San Diego (UCSD), ZAHIRUL ISLAM, Argonne National Laboratory (ANL), SUNIL SINGHA, UCSD, SIMON MOSS, University of Houston, JONATHAN LANG, ULIRCH WELP, ANL — We report on comprehensive quantitative analyses of x-ray diffuse scattering studies of the 1D metallic chains in optimally doped YBCO superconductor $^{1}$. In addition to previously studied $q_{y} = \left(1, 0, 0\right)$ superstructure due to oxygen vacancy ordered ORTHO-IV phase and Huang diffuse scattering due to coherent long-range strain, we present a clear x-ray scattering observation of a transverse displacement modulation of the 1D CuO$_2$ metallic chains. This modulation co-exists within the well-formed ORTHO-IV patches and persists at temperatures well below $T_{c}$. Interestingly, the periodicity of this modulation is close to that of $\frac{1}{2} a_{x}$ according to electronic band calculations. The significance of these modulation and their role in the formation of the electronic inhomogeneities on a nano-meter length scales will be discussed.

12:51 PM J23.00007 Investigation of a Model for the Magnetic Properties of RuSr$_2$GdCu$_2$O$_8$ based on the Temperature Dependence of Mössbauer Spectra$^1$. D. COFFEY, M. DEMARCO, Dept. of Physics, Buffalo State College, NY 14222, B. DABROWSKI, S. KOLENSIK, M. MAXWELL, Dept. of Physics, Northern Illinois University, DeKalb, IL 60115, S. TOORONGIAN, M. HAKA, Nuclear Medicine Department, State University of New York, NY 14260 — Mössbauer spectra were measured from 4.2K to 145K on a $^{197}$Ru enriched sample of RuSr$_2$GdCu$_2$O$_8$ which magnetically orders at 138K and has a full transition to superconductivity at 8.7K with an onset at ∼13K. The superconducting transition has no effect on the spectrum which is determined by the hyperfine magnetic field. At low temperatures there is a rapid decrease of this hyperfine magnetic field with increasing temperature indicating a gapless magnon spectrum. We use a local moment model which includes coupling between nearest neighbor in-plane Ru moments and between the Ru moments and Gd moments to calculate the magnon spectrum and use this to estimate the strength of the exchange interactions based on the hyperfine field temperature dependence. The coupling strength is ∼250K for Ru-Ru coupling and ∼15K for Ru-Gd coupling. We discuss the possible microscopic origin of these coupling strengths.

1:03 PM J23.00008 Layer Dependence of Charge Distribution and Electronic Structure of HgBa$_2$Ca$_2$Cu$_2$O$_{12+}$ $^2$, WEI-GUO YIN, DMITRI VOLJA, WEI KU, Brookhaven National Laboratory, WARREN PICKETT, University of California,Davis, DEEPA KASINATHAN, Max-Planck Institute for Chemical Physics of Solids — Recent experimental observation of layer-dependent properties of the five-layer superconducting cuprate HgBa$_2$Ca$_2$Cu$_2$O$_{12+}$ has inspired extensive interest. In general, multi-layer cuprates are of great interest because the influence of the apical oxygen $p_z$ states, the main source of the material dependence of cuprate structural and electronic properties [1], could be significantly layer-dependent. In this talk, the layer dependence of the charge distribution and electronic structure of HgBa$_2$Ca$_2$Cu$_2$O$_{12}$ will be investigated via the recently developed many-body Wannier-state method [1]. Possible implications on modulation of local pairing gaps, hole mobility, “super-repulsion” [1], and electron-phonon interaction among these distinct Cu$_2$O$_2$ layers will be discussed, in connection with the intriguing experimental findings of coexisting superconducting and antiferromagnetic orders as well as strong interlayer charge inhomogeneity. Work partially supported by DOE-CMSN. [1] W.-G. Yin and W. Ku, cond-mat/0702469.

1:15 PM J23.00009 Electron doping of cuprates via interfaces with manganites $^3$, ELLIO DAGOTTO, Department of Physics and Astronomy, The University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, SATOSHI OKAMOTO, Materials Science and Technology Division, Oak Ridge National Laboratory, SEIJI YUNOKI, ADRIANA MOREO, Department of Physics and Astronomy, The University of Tennessee and Materials Science and Technology Division, Oak Ridge National Laboratory, SRIVENKATESWARA KANCHARLA, Materials Science and Technology Division, Oak Ridge National Laboratory, ATSUHI FUJIMORI, Department of Physics, University of Tokyo — The possible electron doping of some overdoped high-$T_c$ cuprates via the transfer of charge from undoped manganites (or other oxides) using heterostructure geometries is discussed theoretically [1]. An analysis of photoemission and differential voltage experiments locate the Fermi level of some manganites above the bottom of the upper Hubbard band of some cuprate parent compounds. The addition of electrons to antiferromagnetic Cu oxides may lead to a superconducting state at the interface with minimal quenched disorder. Model calculations support this view. [1] S. Yunoki et al., Phys. Rev. B 76, 064532 (2007) and references therein.

1:27 PM J23.00010 Tuning Hole Mobility, Distribution and Repulsion in High-$T_c$ Cuprates via Apical Atoms$^1$, WEI KU, CMPMSD, Brookhaven National Lab; Physics Department, State University of New York, Stony Brook, WEI-GUO YIN, CMPMSD, Brookhaven National Lab — Using a newly developed first-principles Wannier-states approach that takes into account large on-site Coulomb repulsion, we derive the low-energy effective one-band interacting Hamiltonians for several prototypical cuprate superconductors. The material dependence is found to originate primarily from the different energy of the apical oxygen $p_z$ state. Specifically, the general properties of the low-energy hole state, namely the Zhang-Rice singlet, are significantly modified, via additional intra-sublattice hoppings, near-neighbor “super-repulsion,” and other microscopic many-body processes. Possible implications on modulation of local pairing gaps, charge distribution, hole mobility, electron-phonon interaction, and multilayer effects will be discussed.

1:39 PM J23.00011 Mid-IR band in cuprates : A consequence of strong electron correlations, SHILADITYA CHAKRABORTY, University of Illinois at Urbana - Champaign, DIMITRIOS GALANAKIS, PHILIP PHILLIPS, University of Illinois at Urbana-Champaign — Optical conductivity data in lightly doped cuprates show an anomalous peak - like feature in the mid-IR regime not naturally expected of doped Mott insulators. Investigating this phenomenon in the light of strong electron correlations, we employ Cluster Dynamical Mean Field Theory (CDMFT) on a four site square plaquette to compute the optical conductivity in the 2-d Hubbard model as a function of hole doping and temperature. The computed optical conductivity shows a peak in the mid-IR regime, consistent with experimental data. Using Non - Crossing Approximation (NCA) as our impurity solver for CDMFT, we have identified the plaquette eigenstates that give rise to the mid-IR feature. The relevant eigenstate has 4 electrons on a plaquette with zero total spin and spatial properties consistent with $d_{x^2-y^2}$ symmetry.

1:51 PM J23.00012 Fluctuation corrections to the conductivity and the Hall conductivity near a spin–density–wave quantum critical point$^1$, JIE LIN, ANDREW MILLIS, Department of Physics, Columbia University — On the mean field level, the presence of the spin density wave order gives rise to distinct features in the transport properties of the electron–doped cuprates, which agree qualitatively with experimental data. Here, we determine how fluctuations modify the mean field behavior of the conductivity and the Hall conductivity, with particular attention to the vicinity of the quantum critical point. We developed a theory that respects the spin rotation symmetry. We determine the electron–spin fluctuation vertex and thus the transport and spectral properties of the electrons. Our formulation leads to a correctly gauge-invariant description with particular attention to the vicinity of the quantum critical point. We determine the general properties of the low-energy hole state, namely the Zhang-Rice singlet, are significantly modified, via additional intra-sublattice hoppings, near-neighbor “super-repulsion,” and other microscopic many-body processes. Possible implications on modulation of local pairing gaps, charge distribution, hole mobility, electron-phonon interaction, and multilayer effects will be discussed.

2:03 PM J23.00013 Inhomogeneous phases of itinerant antiferromagnets, LEONID ISAEV, GERARDO ORTIZ, Indiana University - Dep. of Physics, CRISTIAN D. BATISTA, Los Alamos National Lab — Although magnetic properties of high-Tc cuprates and heavy fermion compounds have received great attention, only little investigation was performed in the purely antiferromagnetic (AF) phases of these materials. For instance, the mechanism of suppression of the magnetic order was never addressed. In the present work we use a 3D repulsive Hubbard model in an external magnetic field with anisotropic hopping parameters to show that this suppression occurs through a sequence of inhomogeneous states, which are coexisting charge/spin density waves and can be mapped onto the usual Larkin-Ovchinnikov states of type-II superconductors. At the mean-field level we compute the phase diagram of this model as a function of doping and lattice anisotropy. It is shown that morphology of the inhomogeneous phases is determined by the topology of the Fermi surface, which is controlled by the anisotropy (Lifshitz transitions). Insight into the properties of collective modes, such as damping, is gained by computing the magnetic response function in the random phase approximation. Our results are directly applicable to the striped phase of the nickels and may be useful for understanding the interplay between AF and superconducting orders in the underdoped phase of high-Tc and heavy fermion materials.

11:15AM J24.00001 Assessment of carrier multiplication in semiconductor nanocrystals by transient photoluminescence spectroscopy, GAUTHAM NAIR, SCOTT GEYER, MOUNGI BAWENDI, Massachusetts Institute of Technology — The enhancement of carrier multiplication (CM) is an important aim that could increase solar cell performance and widen the range of materials suitable for future solar technologies. Pump-probe measurements have shown evidence of strongly enhanced CM in lead chalcogenide, InAs, and CdSe nanocrystals (NCs). However, the nature of the enhancement mechanism is not well understood. We have carried out an experimental assessment of CM yields in semiconductor NCs by carefully studying exciton and biexciton signatures in transient photoluminescence decays. In the case of CdSe NCs, though the technique is particularly sensitive due to the biexciton’s relatively fast radiative rate, we have found no evidence for CM up to photon energies as high as 3.1 Eg. This result is strongly in disagreement with previous reports on CM in CdSe NCs. The implications of our findings on the efficiency and material dependence of CM are discussed within a general physical framework.

11:27AM J24.00002 The shape and symmetry dependence of excitonic radiative decay in CdSe nanocrystals, QINGZHONG ZHAO, ALBERTO FRANCESCHETTI, PETER A. GRAF, WESLEY B. JONES, KWINSEON KIM, National Renewable Energy Laboratory, LIN-WANG WANG, Lawrence Berkeley National Laboratory — For the last decade, the exciton recombination dynamics of nanocrystal quantum dots (NQDs) through radiative decay have been extensively studied by experimental and theoretical methods, because some NQDs, like CdSe and CdS/ZnS, show near unity quantum yield. Using atomistic, semiempirical pseudopotential calculations, we investigate the radiative decay of band-edge excitons in CdSe nanocrystals with perfect and imperfect shapes. While the lifetimes of bright excitons are in the nanosecond range and not sensitive to size and shape, we find that the radiative lifetimes of the ground state dark excitons are highly dependent on the surface shape and symmetry. The introduction of one [100] or [111] facet can drastically reduce the dark exciton lifetime from milliseconds to microseconds, and such faceting is observed by STEM. This provides an alternative to the explanation by spin-flip assisted or surface-assisted recombination mechanisms of the observed microsecond dark exciton lifetime. Our results highlight the importance of QD surface shape and broken symmetry in exciton dynamics.

11:39AM J24.00003 Peculiar many-body effects revealed in the spectroscopy of highly charged quantum dots, M. EDIGER, Heriot Watt University, GABRIEL BESTER, National Renewable Energy Laboratory, A. BADOLATO, P. PETROFF, University of Santa Barbara, K. KARRAI, Ludwig-Maximilians-Universität, A. ZUNGER, National Renewable Energy Lab, R. WARBURTON, Heriot Watt University, NREL COLLABORATION, HERIOT WATT COLLABORATION, LMU COLLABORATION, UCSB COLLABORATION — We have discovered new consequences of Coulomb interactions in self-assembled quantum dots by interpreting experimental spectra with results of atomistic pseudopotential calculations. The Coulomb effects are evident in the photon emission process and we can tune them in situ by controlling the quantum dot charge in the range from −6e to +6e. We find two regimes in the same dot: J ≤ ΔE for electron charging yet J ≃ ΔE for hole charging. We discover a breakdown of the Aufbau principle for holes; clear proof of non-perturbative hole-hole interactions; promotion-demotion processes in the final state of the emission process; and pronounced configuration hybridizations in the initial state. The level of charge control and the energy scales result in Coulomb effects with no obvious analogues in atomic physics.

11:51AM J24.00004 Anomalous Polarization Behavior of a Zeeman Doublet in CdSe Nanocrystal Quantum Dots, H. HTOON, Chemistry Division, Los Alamos National Laboratory, M. FURIS, S. A. CROOKER, National High Magnetic Field Laboratory, Los Alamos, AL, L. EFROS, Center for Computational Material Science, Naval Research Laboratory, S. JEONG, V. I. KLIMOV, Chemistry Division, Los Alamos National Laboratory — It is well known that a Zeeman doublet observed in emission spectra of a degenerate quantum state in the case of detection along an applied magnetic field (B field) is characterized by left and right circular polarizations. However, our single nanocrystal quantum dot (NQD) studies conducted in B-fields up to 5 T indicate that the Zeeman doublet of some of the CdSe NQDs exhibits a completely different polarization behavior. Specifically, we observe that the lower-energy state of the doublet becomes increasingly circularly polarized with increasing B field, while the higher-energy state shows a zero degree of circular polarization (i.e. remains linearly polarized). We explain this anomalous polarization behavior in terms of mixing between the Zeeman split levels derived from the low- and high-energy bright exciton states. This mixing relies on strong long-range electron-hole exchange interactions that are unique to ultrasmall nanocrystals.

12:03PM J24.00005 Influence of the electronic structure and the multi-exciton spectral density on the multiple exciton generation in semiconductor nanocrystals, CHRISTOPHE DELERUE, IEMN-ISEN, Lille, France, GUY ALLAN, IEMN-ISEN — Several experimental works have reported that a single high-energy photon could generate multiple excitons in semiconductor nanocrystals and several theories are proposed to explain these results. We calculate the electronic structure of InAs, Si and PbSe nanocrystals and we investigate two models of the multiple exciton generation (MEG). We show that the impact ionization process is efficient at high energy, with lifetimes as small as 10 fs. We present simulations of the MEG showing that, in PbSe and Si nanocrystals, the impact ionization alone cannot explain the observed efficiencies, even without relaxation by electron-phonon scattering. We calculate the spectral densities of multi-exciton states and we evaluate the possibility of direct photo-generation of multi-excitons. We confirm the importance of the multi-exciton spectral densities because of their rapid variation over several orders of magnitude. The high MEG efficiencies in PbSe and Si nanocrystals imply a very efficient relaxation in multi-exciton states characterized by a negligible density.

12:15PM J24.00006 State-resolved optical pumping and single exciton gain in CdSe quantum dots, RYAN COONEY, PATANJALI KAMBHAMPATI, SAMUEL SEWALL, D.M. SAGAR, McGill University — Optical gain in semiconductor quantum dots has been under intense investigation. Optical gain has been difficult to produce unless special geometries were employed such as thin films of CdSe quantum dots, or more recently, type II CdS/ZnS core/shell structures. The prototypical CdSe quantum dots in dispersion typically show small gain even at extremely high carrier concentrations. The key problem is induced absorptions due to multi-exciton interactions which result in losses that cancel the expected gain. Our recent state-selective approach can be used to prepare initial excitonic states, which has yielded much insight on exciton relaxation dynamics. This approach was used here to generate some of the largest gains ever measured, at the lowest thresholds, for all sizes of CdSe quantum dots in dispersion. These results show that gain in quantum dots is general, if the system is driven correctly.
12:27PM J24.00007 Optical conditional gates in laterally coupled quantum dots: the role of electron-hole exchange interaction. SOPHIA ECKDOMOU, THOMAS REINECKE, Naval Research Lab — We propose a fast, optically induced two-qubit C-PHASE gate in laterally coupled quantum dots. We use a model potential with two asymmetric local minima to account for the difference in size and composition of the two dots. By making use of the excited bound states of the total potential, which extend over both dots and which gives rise to an effective coupling between the two resident electron spins, we avoid the need for an external bias, such as that typically used in vertically coupled dots. The electron-hole exchange interaction is shown to play an important role in our proposal. By lowering the symmetry of the eigenstates, it allows for a simple design of a fast (about 50 ps) C-PHASE gate. The dissipative dynamics of the excited states have been taken into account in our numerical simulation of the fidelity. The calculated fidelity depends on the values of the decay rates. Our proposal is consistent with the single qubit operations we proposed [Phys. Rev. Lett. 99, 217401 (2007)], and the combination of the two allows for universal quantum gates.

12:39PM J24.00008 Fine Structure of Charged Excitons and Multiexcitons in Self-Assembled InGaAs/GaAs Quantum Dots. VLADAN MLINAR, JUN-WEI LUO, GABRIEL BESTER, ALEX ZUNGER, National Renewable Energy Laboratory, 1617 Cole Blvd., Golden, Colorado 80401 — As a quantum-dot is loaded with Ne electrons and Nh holes, complex charged excitons and multiexcitons are formed. Their fingerprint is the splitting of each exciton line into a set of multiplets separated by “fine structure” splitting, whose calculation [1] poses a serious test to many-body theories. Previously, such fine-structure splittings were calculated and measured for charged excitons with (Ne,Nh) of (2,1), (1,2), (3,1), and (1,3), demonstrating good agreement with experiment. Here, we extend the calculation to both charged and neutral multiexcitons with (Ne,Nh) of (2,2), (3,2), (2,3), (3,3), (4,3), (3,4), and (4,4). The energy splittings, oscillator strength, and polarizations of the optical emission are obtained from many body pseudopotential calculations. We present here predictions for the optical emission from negatively and positively charged biexcitons which reveal fine structure splittings in the order of 100 micro-eV, within the experimental accuracy of single dot micro photoluminescence. We will discuss the evolution of the patterns of multiplet lines, their spacings, and regularities vs. the number of particles (Ne,Nh). [1] M. Ediger, G. Bester, et al., Phys. Rev. Lett 98, 36808 (2007).

12:51PM J24.00009 Absorption spectroscopy of quantum dot molecules. DANNY KIM, Naval Research Laboratory, M.F. DOTY, University of Delaware, M. BASKHANSKY, M. SCHEINBER, A.S. BRACKER, D. GAMMON, Naval Research Laboratory — The energy levels of a vertically-coupled self-assembled InAs/GaAs quantum dot pair are probed using differential transmission spectroscopy. This technique offers very fine spectral resolution (< 0.1 µeV) allowing us to resolve the linewidths and fine structure for the various energy levels found in the rich spectrum of coupled quantum dots. For example, we observe increased broadening of the neutral exciton as it approaches the anticrossing point, as a result of a non-zero tunneling term well away from resonance. Excitons particular to coupled dots — i.e. a positive trion/biexciton, where the additional hole is on the spectator dot — exhibit polarization and power-dependent behavior that is in marked contrast to their single dot counterparts. Finally, the occupation of these exciton states are manipulated by using a second laser that is resonant on a related energy level. These experiments are a crucial step in using these molecules for coherent nonlinear optical processes.

1:03PM J24.00010 Förster optical signatures in quantum dot molecule photoluminescence. JUAN E. ROLON, SERGIO E. ULLOA, Ohio University — We formulate a realistic model that predicts the optical signatures of the Förster resonant energy transfer processes (FRET) in InAs/GaAs self-assembled quantum dot molecules (QDMs) in presence of laser illumination and electric fields. We study the time evolution of a multie excitonic Hamiltonian and construct a map of its dressed spectrum, resulting in effective coupling of the different states under laser illumination. In addition to interdot hole- and electron-tunneling, FRET is found to be an important quantum coupling mechanism in QDMs. We find FRET optical signatures to be highly dependent on structural parameters and severely constrained by the narrow spectral overlap between excitonic transitions in the donor-acceptor pair. However, detailed analysis of the orbital character of the localized hole reveals that it is possible to obtain strong spectral overlap between the first excited single exciton level in the donor dot and the lowest energy single exciton level in the acceptor dot. Remarkably, although FRET occurs via a single pair of exciton levels, its effects are evident throughout the calculated dressed spectrum. We observe a redistribution of spectral weights of direct and Stark shifted exciton lines, and a set of anticrossings among exciton states not directly coupled by FRET. Our results suggest experimental schemes to quantify FRET in photoluminescence experiments.

1:15PM J24.00011 Excited-state absorption and quantum confined Stark effect in embedded silicon and germanium nanocrystals. CEYHUN BULUTAY, Bilkent University — Realistic-sized Si and Ge nanocrystals (NCs) embedded in wide band-gap matrices are studied theoretically using an atomistic pseudopotential Hamiltonian. Based on this electronic structure, first the interband absorption is studied which shows the importance of surface polarization effects that significantly reduce the absorption when included. This reduction is found to increase with decreasing NC size or with increasing permittivity mismatch between the NC core and the host matrix. The intraconduction and interband absorption coefficients are also obtained in the wavelengths range from far-infrared to visible region. Next, we introduce the Stark effect which leads to an effective coupling between the two resident electron spins, we avoid the need for an external bias, such as that typically used in vertically coupled dots. Molecular resonances between energy levels of the two QDs are measured purely optical as sequences of anti-crossing patterns in the electric field dependent PL spectrum. These sequences provide in situ characterization of the level structure. We anticipate that such measurements will precede more sophisticated quantum control demonstrations, allow precise reverse engineering and boost detailed theoretical modeling of QD structures. This work is supported by NSA/ARO.

1Supported by TUBITAK with the Project No. 106T048

1:27PM J24.00012 Level Anti-Crossing Spectroscopy - Optically Mapping the Electronic Structure of Coupled Quantum Dots1, M. SCHEINBER, M. YAKES, A. S. BRACKER, I. V. PONOMAREV, M. F. DOTY2, C. S. HELLBERG, L. J. WHITMAN, T. L. REINECKE, D. GAMMON, Naval Research Laboratory — We introduce an all optical anti-crossing spectroscopy (LACS) with which the ground and the excited state energy levels of quantum dot (QDs) can be measured for a hole(electron) by itself and in the presence of other charges. Analogies are drawn to the atomistic shell-model and connections are made in an average way to structural STM measurements. An applied bias provides an electric field between two InAs/GaAs QDs which “tilts” the energy levels of both QDs relative to each other. Molecular resonances between energy levels of the two QDs are measured purely optical as sequences of anti-crossing patterns in the electric field dependent PL spectrum. These sequences provide in situ characterization of the level structure. We anticipate that such measurements will precede more sophisticated quantum control demonstrations, allow precise reverse engineering and boost detailed theoretical modeling of QD structures. This work is supported by NSA/ARO.

Although the model predictions are consistent with classical cooperativity signatures, stable intermediates appear, in violation of the two-state assumption. The extent to which hybridization in solution conforms to two-state thermodynamics is also analyzed. Monte Carlo simulations with parallel tempering are routinely carried out to quantify and to interpret genomic information. At a surface, molecular interactions are amplified by the two-dimensional nature of the immobilized layer which focuses the nucleic acid charge and concentration to levels not encountered in solution, and which impacts the hybridization behavior in unique ways. We find that, at low ionic strengths, an electrostatic balance between the concentration of immobilized oligonucleotide charge and solution ionic strength governs the onset of hybridization. As ionic strength increases, the importance of electrostatics diminishes and the hybridization behavior becomes more complex. Suppression of hybridization affinity constants relative to solution values, and their weakened dependence on the concentration of DNA counterions, indicate that the immobilized strands form complexes. Moreover, an unusual regime is observed in which the surface coverage of immobilized oligonucleotides does not significantly influence the hybridization behavior, despite physical closeness and hence compulsory interactions between sites. These results are interpreted and summarized in a diagram of hybridization regimes.

11:15AM J25.00001 Conformation and Trapping of DNA at a Convergent Stagnation Point . JENNIFER KREFT, Department of Chemistry, University of Texas, Tyler, YENG-LONG CHEN, Institute of Physics, Academia Sinica, HSUEH-CHIA CHANG, Chemical and Biomedical Engineering, University of Notre Dame — We use a lattice-Boltzmann based Brownian dynamics simulation to investigate the elongation of DNA at a convergent stagnation point trapped by a uniform attractive potential. Surprisingly, we find that the coiled state is favored over the stretched state at high Peclet number, Pe. The final elongation is determined by conformation changes during transport to the stagnation point, rather than hydrodynamic stretching at that point. The trapping rate of the DNA is consistent with the classical mean-field convection-diffusion theory and scales as $Pe^{1/3}$. This scaling is insensitive to the attractive potential used.

11:27AM J25.00002 DNA Surface Hybridization Regimes . RASTISLAV LEVICKY, Polytechnic University, PING GONG, Columbia University — Surface hybridization reactions, in which sequence-specific recognition occurs between immobilized and solution nucleic acids, are routinely carried out to quantify and to interpret genomic information. At a surface, molecular interactions are amplified by the two-dimensional nature of the immobilized layer which focuses the nucleic acid charge and concentration to levels not encountered in solution, and which impacts the hybridization behavior in unique ways. We find that, at low ionic strengths, an electrostatic balance between the concentration of immobilized oligonucleotide charge and solution ionic strength governs the onset of hybridization. As ionic strength increases, the importance of electrostatics diminishes and the hybridization behavior becomes more complex. Suppression of hybridization affinity constants relative to solution values, and their weakened dependence on the concentration of DNA counterions, indicate that the immobilized strands form complexes. Moreover, an unusual regime is observed in which the surface coverage of immobilized oligonucleotides does not significantly influence the hybridization behavior, despite physical closeness and hence compulsory interactions between sites. These results are interpreted and summarized in a diagram of hybridization regimes.

11:39AM J25.00003 Hybridization Pathways and Mechanisms of Model DNA Oligonucleotides in Solution . JUAN ARAQUE, Rice University, ATHANASSIOS PANAGIOTOPoulos, Princeton University, MARC ROBERT, Rice University — We propose a coarse-grained lattice model of short DNA strands to investigate the microscopic pathways and mechanisms of oligonucleotides hybridization in solution. The extent to which hybridization in solution conforms to two-state thermodynamics is also analyzed. Monte Carlo simulations with parallel tempering are performed to estimate the equilibrium population of single- and double-stranded states and the associated free-energy landscapes. Sequence complexity is shown to largely dominate the nucleation and helix propagation pathways. The two-state nature of the transition is found to exhibit strong sequence dependence. Although the model predictions are consistent with classical cooperativity signatures, stable intermediates appear, in violation of the two-state assumption.

1:39PM J24.00013 Charged Quantum Dots in High Quality Micropillar Cavities . MATTHEW RAKHER, Physics Dept., University of California Santa Barbara, NICK STOLTZ, LARRY COLDREN, PIERRE PETROFF, Materials Dept., University of California Santa Barbara, DIRK BOUWMEESTER, Physics Dept., University of California Santa Barbara — We report on nanodevices that for the first time allow for charge tuning of single InAs quantum dots located near the field maximum of high quality micropillar cavities. Through the innovation of a novel trench style cavity design, we are able to embed doped layers for electrical gating within a microcavity and obtain Q values greater than 50,000. Using these devices, we demonstrate record high single photon count rates with a capture efficiency of 38% and a Purcell effect up to 8. We also show high frequency polarization modulation of single photons enabled by Stark shift tuning a charged quantum dot between two polarization modes of a slightly elliptical micropillar with frequencies up to 100 kHz. Furthermore, we demonstrate a charge tunable quantum dot coupled to a micropillar cavity mode, which is an important step in quantum communication protocols involving trapped single electrons or holes. This type of device enables a quick, non-destructive measurement of the spin state of the trapped charge.

2:03PM J24.00015 Control of sp-d exchange interactions in pseudo-type II Mn:ZnSe/CdSe core-shell nanocrystal quantum dots . DAVID BUSSIDAN, MING YIN, LANL, SCOTT CROOKER, NHMFL, LANL, VICTOR KLIMOV, LANL — Dilute magnetic semiconductors (DMSs) have been the focus of considerable research due to their potential usability in spin-based electronic devices. Unpaired electrons of dopant atoms, such as Mn$^{2+}$, can couple strongly to electrons of the semiconductor (sp-d exchange interaction), which should allow for the manipulation of the spin degree of freedom using traditional microelectronic circuitry. We have developed a novel approach for manipulating sp-d interactions between the dopant and the semiconductor wherein Mn ions are incorporated into cores of ZnSe/CdSe core-shell semiconductor nanocrystal quantum dots (QDQs). These NCs represent quasi-type II hetero-structures that allow one to tune both the band edge transition energy and dopant-carrier wavefunction overlap by changing the size of the core and/or shell thickness. We will report our recent results from a set of doped heterostructures for which we demonstrate tunability of both the magnitude and the sign of the sp-d exchange interaction energy as a function of hetero-NQD geometry.

1:51PM J24.00014 Photoluminescence spectra of thin films containing CdSe/ZnS quantum dots irradiated by 532-nm laser radiation and gamma-rays . SURESH SHARMA, JAY MURPHREE, TONMOY CHAKRABORTY, AJANI ROSS, CECIL SHIVE, University of Texas at Arlington — We have investigated temporal behavior of the photoluminescence (PL) spectra of thin films containing CdSe/ZnS quantum dots irradiated by 532 nm laser radiation and gamma-rays. Under $\sim 100$ W/cm$^2$ laser radiation, the PL intensity ($I_{PL}$) increases with irradiation time up to about 500s and thereafter declines linearly. The wavelength of the PL emission ($\lambda_{peak}$) exhibits a blue-shift with exposure time. Upon simultaneous irradiation by 100 W/cm$^2$ 532-nm laser, as well as 0.57 and 1.06 MeV gamma-rays, the temporal behaviors of both $I_{PL}$ and $\lambda_{peak}$ are significantly different; $I_{PL}$ increases to a saturation level, and the magnitude of the blue-shift in $\lambda_{peak}$ is reduced. We also present data on the effects of the density of the quantum dots on the temporal behavior of the PL spectra, as well as additional data on samples synthesized with CdSe/ZnS quantum dots embedded in conducting polymer films. We discuss possible mechanisms underlying our observations.

Supported in part by a grant from Strategic Partnership of Research in Nanotechnology (SPRING) administered by Air Force Office of Scientific Research.
11:51 AM J25.00004 Structure and applications of a temperature responsive recombinant protein hydrogel based on silk- and elastin-like amino acid motifs, LAWRENCE DRUMMY, MELANIE TOMCZAK, Air Force Research Laboratory, JOSEPH MACAULIFFE, Genencor Inc., RICHARD VAIA, RAJESH NAIK, Air Force Research Laboratory — Proteins form the main components of many natural materials, and they can be designed to offer tailored functionality and material properties. Silk elastin-like proteins (SELPs) come from a family of repeat sequence protein polymers based on Bombyx mori silk and mammalian elastin that are recombiantly expressed in E. coli. SELP gels are formed by heating the protein solutions in order to induce physical crosslinking of the silk β-sheet regions, they contain approximately 80-90% water by weight and they can be used for encapsulation of enzymes or nanoparticles. For example, horseradish peroxidase demonstrates added resistance to drying and heat treatment on the gel morphology. During gel formation, small angle X-ray scattering shows intensity increases in two distinct regions of reciprocal space, one reversible with temperature and one irreversible. By fitting the scattering data to a unified power-law/Gunier model, morphological parameters are extracted. The thermally reversible intensity changes are attributed to a hydrophilic/hydrophobic transition in the elastin segments, while the irreversible intensity change is due to the crystalline regions formed by the silk blocks.

12:03 PM J25.00005 Fractal Nature of Semiflexible Networks in beta-Hairpin Peptide Hydrogels, ROHAN HULE, DARRIN POCHAN, Materials Science and Engineering, University of Delaware — De novo designed beta hairpin peptides with asymmetric beta strands, capable of self-assembly and hydrogel formation, were investigated. The stimuli responsive self-assembly occurs via a strand-interdigitation mechanism, resulting in physically crosslinked fibrillar networks. Fibrils with distinct nanostructures varying from non-twisted, twisted to laminated morphologies were rationally designed by modulating the peptide strand registry. The fractal dimension and correlation lengths of these networks, both, at the network as well as individual fibril length scales vary significantly with concentration and is directly related to the fibril morphology, as evidenced by SAXS and cryogenic TEM. In case of the laminated fibrils, an increase in the peptide concentration induces a change from surface to mass fractal behavior at high q due to the disruption of fibril lamination as a result of faster assembly kinetics from higher peptide concentration. Non-twisting peptide fibril morphologies exhibit an increase the network density with higher peptide concentration and, therefore, an increase in mass fractal dimension. Oscillatory rheology of hydrogels reveals enhanced moduli for laminating networks over non-twisting or twisting networks. These interdigitating peptides constitute a model system to study structure-property relations in other semiflexible networks.

12:15 PM J25.00006 A molecular model for toughening in double-network hydrogels, WEN-LI WU, VIJAY TIRUMALA, NIST, TAIKI TOMINAGA, Hokkaido University, SANGHUN LEE, PAUL BUTLER, ERIC LIN, NIST, JIAN PING, GONG, HIDEUMITSU FURUKAWA, Hokkaido University — A molecular mechanism is proposed for the toughness enhancement in double network (DN) hydrogels prepared from poly (2acrylamido, 2-methyl,1-propanesulfonicacid) (PAMPS) polyelectrolyte network and polyacrylamide (PAAm) linear polymer. It is an extension of the phenomenological model set forth recently by Gong et al. This mechanism takes into consideration all the observed changes in molecular structure of the constituents during the single neutron scattering (SANS) measurements, the composition dependence of the solution viscosity and the thermodynamic interaction parameters of PAMPS and PAAm molecules from our previous neutron scattering studies. More specifically, this proposed mechanism provides an explanation of the observed periodic compositional fluctuation in the micrometer range induced by large strain deformation.

12:27 PM J25.00007 De novo designed peptide and peptide-polymer conjugate for biomolecular materials, TING XU, University of California, Berkeley — Peptides, nature’s “own” building blocks, provide control of functional groups over nanometer distances with sub-Angstrom resolution and can be de novo designed to self-assemble into multidimensional molecular constructs that mimic natural proteins or perform functions not found in nature. Conjugating synthetic peptides to polymers, forming peptide-polymer conjugates, takes advantages of both the stability and processibility of synthetic polymers and the built-in peptide functions. Helical bundles, a ubiquitous folding motif, underpin many structural and catalytic functions of natural proteins. By attaching a polymer chain to a helical bundle-forming peptide, the polymer chain will mediate the interactions between the helical bundle and its external environment, enable the macroscopic self-assembly and, potentially, allow the helical bundle to function in non-biological environments. A new design of peptide-polymer conjugates will be presented where the polymer chain is covalently linked to the side chain of the peptide. Upon attaching poly(ethylene glycol) (PEG) to the exterior of the helix bundle, the peptide secondary structure and also the tertiary structure, i.e., coiled-coil helix bundle formation, are stabilized. More importantly, using a photoactive heme-binding 4-helix bundle peptide as an example, this new design preserves the built-in functionalities in the interior of the helix bundle.

1:03 PM J25.00008 Single polymer stretching in elastic turbulence of polymer solution, YONGGANG LIU, VICTOR STEINBERG, Department of Physics of Complex Systems, Weizmann Institute of Science — Coil-stretch transition of single T4 DNA molecule in an elastic turbulence is studied in a polymer solution with the same molecules. Two mechanisms of saturation of polymer stretching in elastic turbulence, the nonlinearity of polymer stretching and the back reaction of stretched polymer chains to the flow, are demonstrated based on experiments of single polymer dynamics at different polymer concentrations. The elastic stress calculated from single polymer stretching agrees with the PIV measurement of the flow properties, indicating that polymer stretching can be used as an elastic stress probe of the flow properties.

1:15 PM J25.00009 Shape and conformation of confined biopolymers,1, YA LIU, BULBUL CHAKRABORTY, Brandeis University — Biological macromolecules living in cells are confined on length scales comparable to their intrinsic persistence length. In these environments, the bending rigidity plays a decisive role in determining shape and conformations. We have used numerical simulations to investigate the statistical properties of a semiflexible polymer confined in a square box. Simulations exhibit a sharp transition when the bare persistence length becomes comparable to the box size. An order parameter is introduced to quantify and analyze the nature of this transition. The shape change is accompanied by a qualitative change in the effective persistence length, which starts differing significantly from the intrinsic persistence length. A mean-field model, including Gaussian fluctuations around the saddle point solution, provides a quantitative description of the evolution of the tangent-tangent correlation function with increasing confinement.

1:27 PM J25.00010 Raft Formation of Rod-like Polyelectrolytes1, DANIEL W. SINKOVITS, ERIK LUIJTEN, University of Illinois at Urbana-Champaign — We investigate the formation of raft-like aggregates by charged rod-like polyelectrolytes, as reported from experiments employing F-actin as well as from theoretical analyses. Through extensive molecular-dynamics simulations of pairs of rods at different salt concentrations we construct free-energy landscapes, which in turn elucidate the most likely kinetic pathways to aggregation. Additional simulations of layers of rods at varying skew orientations and lateral spacings demonstrate to what extent the lessons learned from pair simulations apply to large aggregates.

1:39 PM J25.00011 Vapor-liquid coexistence of patchy attractive fluids: Wertheim theory study, HONGJUN LIU, SANAT KUMAR, Columbia University, GLENN EVANS, Oregon State University — Our system consists of spherical particles whose pair potential contains hard core repulsion, short-ranged square well attraction and several distributed attractive patches on its surface. The simplicity of the model makes it possible to compare simulations and theoretical predictions based on Wertheim’s thermodynamic perturbation theory (TPT). Wertheim’s TPT is in good agreement with simulation data. In the broader parameter ranges, we show the patchy hard sphere fluids obey a generalized law of corresponding states (GLCS) and GLCS seems to hold for all patchy square well fluids with four to six interaction sites.
1:51PM J25.00012 Strong Keratin-like Nanofibers Made of Globular Protein, YAEI DROR, VADIM MAKAROV, Technion, Mechanical Eng. Dep., ARIE ADNON, Technion, Biology Dep., EYAL ZUSSMAN, Technion, Mechanical Eng. Dep. — Protein fibers as elementary structural and functional elements in nature inspire the engineering of protein-based products for versatile bio-medical applications. We have recently used the electrospraying process to fabricate strong sub-micron fibers made solely of serum albumin (SA). This raises the challenges of turning a globular non-viscous protein solution into a polymer-like spinnable solution and producing keratin-like fibers enriched in inter S-S bridges. A stable spinning process was achieved by using SA solution in a rich trifluoroethanol-water mixture with \(\beta\)-mercaptoethanol. The breakage of the intra disulfide bridges, as identified by mass spectrometry, together with the denaturing alcohol, enabled a pronounced expansion of the protein. This in turn, affects the rheological properties of the solution. X-ray diffraction pattern of the fibers revealed equatorial orientation, indicating the alignment of structures along the fiber axis. The mechanical properties reached remarkable average values (Young’s modulus of 1.6GPa, and max stress of 36MPa) as compared to other fibrous protein nanofibers. These significant results are attributed to both the alignment and inter disulfide bonds (cross linking) that were formed by spontaneous post-spinning oxidation.

2:03PM J25.00013 Electrosprinning of Natural Polymers\(^1\), AIHUA HE, Institute of Chemistry, Chinese Academy of Sciences, SHANSHAN XU, HUARONG NIE, JUNXING LI, CHARLES C. HAN, STATE KEY LAB OF POLYMER PHYSICS AND CHEMISTRY, INSTITUTE OF CHEMISTRY, CHINESE ACADEMY OF SCIENCES — Electrosprinning is an effective and simple method to fabricate polymer fibers in the range of nano scale. However, electrosprinning of natural polymers is a challenge. The key reason for this problem is that natural polymers have very different chain conformation and hydrodynamic responses in solution, especially in aqueous solution, when compared with synthesized polymers. The objective of our study is to find the key parameters in order to have a good control in the electrosprinning process. We studied the electrosprinnings of gelatin from its aqueous solution, of hyaluronic acid without airblowing, and of pure alginate. It was found that electrosprinning of those natural-polymer solutions could be successfully carried out when key parameters were properly adjusted, such as viscosity, elasticity (chain entanglement) and surface tension.

Tuesday, March 11, 2008 11:15AM - 1:51PM –
Session J26 DCP: Focus Session: Quantum Control I Morial Convention Center 218

11:15AM J26.00001 Quantum Control of Femtochemistry in the Gas Phase, Liquid Phase and on Surfaces, GUSTAV GERBER, Univ. of Wurzburg, Institute of Physics — By using coherent control techniques we control the behavior of quantum systems on their natural time scale, by applying ultrashort coherent light fields in the wavelength range from the IR to the UV. These laser pulses can be variably shaped in space and time using a laser pulse shaper consisting of a liquid-crystal display \([1]\). Laser-optimized femtochemistry in the gas phase and liquid phase is one field in which this new technique is successfully employed. Automated optimization of branching ratios and total product yields of gas phase photodissociation reactions as well as chemically selective molecular excitation in the liquid phase is performed \([2]\)\([3]\). Structural changes of a molecule in the liquid phase have been controlled by laser-optimized photoisomerization of a cyanine dye molecule \([4]\) and of retinal in bacteriorhodopsin \([5]\). So far, optimal control techniques have been restricted to gas phase and condensed phase optimization experiments. Recently we have demonstrated femtosecond laser-assisted catalytic reactions on a Pd(100) single crystal surface. By applying a closed-loop optimal control scheme, we manipulate these reactions and selectively optimize the ratio of different bond-forming reaction channels, in contrast to previous quantum control experiments aiming at bond-cleavage. The results represent a first step towards selective photocatalysis of molecules.

11:51AM J26.00002 Quantum control spectroscopy with multipulses, MARCUS MOTZKUS, Philipps Universität Marburg — The manipulation of molecular vibrations by laser light has been always considered as a very promising means to control chemical reaction. The coherently controlled time-dependent superposition of vibrational states may represent motion along a reaction coordinate and therefore allows for a high degree of selectivity. Pulse shapes for manipulating vibrations can be predicted to be trains of pulses with temporal spacing between the sub-pulses equal to an integer of the vibrational phase. If the manipulation of molecular vibrations with pulse trains is expected to be one of the important mechanisms on the natural standing time of mode selective chemistry, it is necessary to understand its application limits. In this work, the interaction of pulse trains with matter is discussed under the light of time-resolved nonlinear experiments and density matrix simulations. Emphasis is given to the role of electronic coherence between excited and ground-state, to the excited state population relaxation time and to the electronic resonance. In particular the lifetime of the excited state poses a challenge for the coherent control with multipulses and, thus, for the mode filtering capability in the excited state. This is investigated by applying a shaped femtosecond excitation pulse to different molecules in solution and probing the response by transient absorption, nonlinear Raman and DFWM spectroscopy. Finally, the effect of the phase of sinusoidal modulation on the envelope of the multipulse sequence and its consequences on pump-probe spectroscopy is discussed, particularly near zero delay between pump and probe pulses.

12:27PM J26.00003 Strategies for optimal control in complex systems, ROLAND MITRIĆ, Department of Chemistry, Humboldt-University Berlin, Brook-Taylor-Str. 2, 12489 Berlin, Germany — We present strategies for the optimal control of the ground and excited state dynamics in complex systems, based on the combination of the quantum chemical molecular dynamics ‘on the fly’ with the semiclassical Wigner distribution approach \([1]\). We first demonstrate our strategy for the optimal control of the ground state dynamics based on the MD ‘on the fly’ with explicit treatment of the interaction with the laser field which is optimized using a genetic algorithm \([2]\). This approach will be illustrated on two prototype systems representing rigid symmetrical molecules and floppy biomolecules with low frequency modes. Our results show that the ground state isomerization process can be selectively driven by ultrashort laser pulses with different shapes which are characteristic for the prototype systems. Furthermore, for the optimal pump-dump control involving ground and excited electronic states we have developed a new ‘field induced surface hopping’ method in which the nuclear dynamics is treated classically while the laser induced electronic transitions are treated fully quantum mechanically. We illustrate our approach on the optimal control of cis-trans isomerization in prototype Schiff base molecular switches. Our theoretical approach allows us to explore the controllability of dynamics in complex systems and to unravel the mechanisms underlying the control of molecular processes. Furthermore, the outlook for laser selective photochemistry of nanoparticles and nanoparticle-biomolecule hybrid systems will be given.

, MASANORI KOHNO, Computational Materials Science Center, NIMS, LEON BALENTS, Department of Physics, UCSB,
, ALBRECHT LINDINGER, FU Berlin — Optimal control
of photo-induced molecular processes has attained considerable success in recent years. An important issue in this regard is the information coded in the
optimized laser pulse shape which supplies insight about the underlying processes. Small alkali systems are suitable since they exhibit bound states available
for resonant transitions with weak fields which aids the theoretical description and thus the interpretation. New control methods are presented to extract the
most relevant information from the optimized laser field. Moreover, novel pulse shaper schemes for simultaneous phase, amplitude, and polarization pulse
control were designed and applied to alkali dimers, even in a parametric encoding. The results demonstrate the perspectives of adding the polarization and
hence all properties of the light field in the pulse modulation. Currently, coherent control was applied to ultracold ensembles motivated by the perspective to
perform photoassociation and photostabilization of alkali systems. First results are received regarding optimized multi-photon excitation to molecular ions and
pump-probe experiments exposing signal oscillations. They provide indications for photoassociation and open the perspective for transitions to lower vibrational
levels in the electronic ground state, which would be a first step to an internally cold molecular Bose Einstein condensate.
1:27PM J26.00006 Direct frequency comb measurement and control of vibrational dynamics
in ultracold molecular samples . AVI PE’ER, JILA, University of Colorado, EVGENY SHAPIRO, MOSHE SHAPIRO, University of British Columbia, Vancouver, JUN YE, JILA, University of Colorado and NIST — We propose a new class of control schemes for robust transfer of population between quantum states via a wave packet that utilize trains of coherent pulses (optical frequency comb). Our approach draws from analogy to adiabatic passage techniques in three-level systems, but is more general. We show that breaking a slow adiabatic passage into a train of short, perturbative pulses, enables highly

cold and ultracold molecular samples.
1:39PM J26.00007 Formation of a gas of ultracold LiCs molecules , J. DEGLMAYR, J. LANGE, S.D. KRAFT, A. GROCHOLA, R. WESTER, M. WEIDEMÜLLER, Albert-Ludwigs-University Freiburg, Germany, M. AYMAR, O. DULIEU, Laboratoire Aime Cotton, Orsay, France — Ultracold molecules offer intriguing perspectives for the study of many-body effects in strongly interacting gases and the manipulation by external
fields. A promising approach to the creation of a large ensemble of ultracold polar molecules in the absolute translational and electronic ground state is the direct
formation of ultracold molecules through photoassociation of ultracold atoms. We recently observed the spontaneous formation of ultracold LiCs molecules in
a double species magneto optical trap. After spontaneous decay into the electronic ground state, the molecules were ionized by one-color two-photon ionization
and detected with a high-resolution time-of-flight mass spectrometer [1]. Here we present the active photoassociation of ultracold LiCs molecules and discuss

creation of molecules. We present ab-initio calculations of excited molecular states of LiCs including spin-orbit coupling and study the alignment and orientation

Tuesday, March 11, 2008 11:15AM - 2:15PM —
Session J27 GMAG: Focus Session: Triangular Lattice Morial Convention Center 219

11:15AM J27.00001 Mean filed study of disordered spin-\(\frac{1}{2}\) antiferromagnetic systems , VLADIMIR DOBROSALJEVIC, SEN ZOUH, Florida State University, EDUARDO MIRANDA, Universidade Estadual de Campinas — We present a mean field theory picture of disordered spin-\(\frac{1}{2}\) antiferromagnetic system as a function of the degree of disorder, in connection to the insulating doped semiconductors. The system is a resonant valence bond (RVB) liquid state at zero disorder, and a possible RVB glass state when the disorder is finite but weak. For a highly disordered system, we show that the essential physics is the formation and decimation of strongly coupled bonds, and the thermodynamics shows an effective power-law singularity, in qualitative agreement with renormalization group result of Bhatt and Lee.

11:27AM J27.00002 Dynamical properties of spatially anisotropic frustrated Heisenberg models in a magnetic field , MASANORI KOHNO, Computational Materials Science Center, NIMS, LEON BALENTS, Department of Physics, UCSB, OLEG. A. STARYKH, Department of Physics, University of Utah — We investigate spectral features of spatially anisotropic spin-1/2 frustrated antiferromagnets in a magnetic field in terms of fractional excitations. Restricting the Hilbert space to that spanned by the eigenstates of the Heisenberg chain [1], we calculate dynamical structure factor \(S(k,\omega)\) in the two-dimensional momentum space. We obtain sharp peaks and broad continuum depending on the momentum. We interpret the sharp peaks as signatures of bound states of psinons and antipsinons, fractional excitations in a magnetic field. We compare these spectral features with available experimental results on CuS\(\text{CuCl}_4\) [2], and make detailed predictions on momentum- and field-dependence of peak structures and line shapes of \(S(k,\omega)\) for CuS\(\text{CuCl}_4\) in a magnetic field. [1] M. Kohno, O. A. Starykh, and L. Balents, Nature Phys. 3, 790 (2007). [2] R. Coldea, et al., Phys. Rev. Lett. 79, 151 (1997).

11:39AM J27.00003 Quantum Order by Disorder in Frustrated Diamond Spinel Antiferromagnets , JEAN-SEBASTIAN BERNIER, MICHAEL J. LAWLER, YONG BAEK KIM, University of Toronto — We study the effect of quantum fluctuations on the frustrated diamond lattice antiferromagnet where frustration arises from the presence of second neighbor interactions. Such an antiferromagnet describes the magnetic properties of spinel \(\text{AB}_2X_4\) where magnetic ions are located on A-sites. We compare the resulting phase diagram of the quantum model and that of its classical counterpart, and discuss the difference/similarity between the quantum and thermal order by disorder phenomena. Implications for experiments on \(\text{CoRh}_2\text{O}_4\), \(\text{Co}_2\text{O}_3\), and \(\text{Mn}_2\text{Sc}_2\text{O}_4\) will be discussed.
11:51 AM  J27.00004  Random Fields and the Partially Paramagnetic State of CsCoO$_{3.93}$Mg$_{0.17}$Br$_3$
, JOHN-PAUL CASTELLAN, Argonne National Lab., MSD, B.D. GAULIN, McMaster University, W.J.L. BUYERS, NPMR, NRC, Chalk River Laboratories — Partially paramagnetic Neel states are among the exotic magnet states known to exist in nature as a consequence of geometrical frustration. This unusual magnetic structure occurs in the stacked triangular lattice antiferromagnets such as CsCoBr$_3$ and CsCoCl$_3$. CsCoBr$_3$ displays at least 2 magnetic phase transitions. The first, $T_{n1} \approx 28 K$ where the system enters a 3-sublattice state in which one of the sublattices remains disordered and the second, $T_{n2} \approx 13 K$ where the remaining disordered sublattice orders[1]. Critical neutron scattering measurements were performed on the doped system CsCo$_{1-x}$Mg$_x$Br$_3$ with $x=0.17$. We will discuss the evolution of the observed two component scattering below $T_{n1}$ in terms of a Random Field Ising model in both zero applied magnetic field and an applied magnetic field of 2.6T along the c-axis. [1] M.Mao et al. Phys. Rev. B 66, 184432 (2002).

12:03PM  J27.00005  New ordered phases of the spin-1/2 triangular-lattice antiferromagnet Cs$_2$CuBr$_4$
, NATHANALE FORTUNE, Smith College, SCOTT HANNAHS, National High Magnetic Field Laboratory, YASUO YOSHIDA, YASU TAKANO, University of Florida, TOSHI O NO, HIDEKAZU TANAKA, Tokyo Institute of Technology — Quantum fluctuations and geometric frustration are theoretically expected to produce a gapped, collinear ‘up-down’ phase in spin-1/2 Heisenberg and XY antiferromagnets on a triangular lattice. Experimentally, this phase should manifest itself as a magnetization plateau at 1/3 of the saturation value. Despite being a fundamental theoretical property of such systems, this behavior has to date only been observed in one triangular lattice antiferromagnet: Cs$_2$CuBr$_4$. We have investigated the magnetic phase diagram of this compound by means of specific-heat, magnetocaloric-effect, and magnetic torque measurements in magnetic fields up to the saturation field of about 30 T, finding a cascade of new ordered phases adjacent to the up-up-down phase. The evolution of these phases as a function of the field orientation with respect to the crystallographic bc plane suggests that they arise from the competition between the scalar exchange interaction and the symmetry-breaking Dzyaloshinskii-Moriya interaction.

12:15PM  J27.00006  Dynamics of the Spin Liquid Phase of Cs$_2$CuCl$_4$
, OOKIE MA, MARC-ANDRE VACHON, VESNA F. MITROVIC, BRAD MARSTON, Brown University — The dynamics of a spin-liquid phase of an antiferromagnet on the anisotropic triangular lattice and in a magnetic field are studied with a combination of Gutzwiller-projected wavefunctions and mean-field theory. Candidate ground states that support fermionic gapless spinon excitations include four different U(1) spin liquids. The lattice and the states interpolate between limiting cases of 1D decoupled chains ($J'/J = 0$) and the isotropic 2D square lattice ($J'/J = \infty$). Parameters of the mean-field theory are chosen to minimize the ground state energy of the corresponding Gutzwiller-projected wavefunction. The spin-lattice relaxation rate $1/T_1$, calculated within the mean-field approximation, is compared to NMR measurements in the spin liquid phase of Cs$_2$CuCl$_4$[1].

12:27PM  J27.00007  Photoemission study of triangular lattices in NiGa$_2$S$_4$, FeGa$_2$S$_4$, and Fe$_2$Ga$_2$S$_5$
, KOU TAKUBO, Department of Physics, University of Tokyo, TAKASHI MIZOKAWA, Dept. of Complexity Science and Engineering, Univ. of Tokyo, YUSUKE NAMBU, KEISUKE ONUMA, HIROSHI TONOMURA, OSAMU SAKAI, SATORU NAKATSUJI, YOSHIHITERO MAENO, Dept. of Physics, Kyoto Univ. — The newly-discovered NiGa$_2$S$_4$ (Ni$^{2+}$, S=1) and FeGa$_2$S$_4$ (Fe$^{2+}$, S=2) form frozen spin-disordered states within the triangular lattice [1,2]. The spins of both compounds have no long range order even at lowest temperature. We have performed photoemission spectroscopy of NiGa$_2$S$_4$, FeGa$_2$S$_4$, and Fe$_2$Ga$_2$S$_5$. The photoemission results and subsequent model calculations indicate that the ground state of NiGa$_2$S$_4$ has the $d^1_L$ character (L is a 3 $\bar{3}$p hole) and that the strong S $3p$ hole character of the ground state provides the enhanced superexchange interaction between the third nearest neighbor sites. In contrast, the ground state of FeGa$_2$S$_4$ is dominated by the $d^6$ configuration and the superexchange interactions between the second and third neighbor sites are less important. [1] S. Nakatsuji, et al., Science 309, 1697 (2005). [2] S. Nakatsuji, et al., Phys. Rev. Lett. 99, 157203 (2007).

12:39PM  J27.00008  The origin of anomalous 3rd neighbor exchange in 2D triangular magnets (NiGaS$_4$ and others)
, IGOR MAZIN, Center for Computational Materials Science, Naval Research Laboratory — 2D magnetic materials with triangular lattices have been attracting much interest. Among them one finds the parent compound of an exotic superconductor, Na$_2$CoO$_2$:yH$_2$O, A-type antiferromagnets like NaNiO$_2$, in-plane antiferromagnetism (LiCrO$_2$), spin-liquid type materials (NiGa$_2$S$_4$, charge-order (AgNiO)$_2$. The main structural motif in all of them is the AB$_3$ plane, where A is a transition metal and B is oxygen or sulfur. Experiments and calculations inevitably find anomalously strong 3rd neighbor exchange coupling in all these triangular planes, despite different band fillings and different magnetic ground states. I will explain why this happens, why this effect is so universal, and why it can be understood entirely on a one-electron level. I will use as an example NiGa$_2$S$_4$, with a reference to Na$_2$CoO$_2$ as well.

12:51PM  J27.00009  Elementary excitations in the spin liquid phase of Cs$_2$CuCl$_4$ as revealed by $^{133}$Cs NMR spin-lattice relaxation rate measurements.
, MARC-ANDRE VACHON, GEORGIOS KOUTROULAKIS, OOKIE MA, BRAD MARSTON, VESNA F. MITROVIC, Brown University, ARNEIL P. REYES, PHILIP L. KUHNS, NHMF, RADU COLDEA, Bristol University, Z. TYLCZYSKNI, Adam Mickiewicz University — We present $^{133}$Cs NMR spin-lattice relaxation rate measurements in the spin liquid phase of Cs$_2$CuCl$_4$ as a function of temperature and external magnetic field. At fixed temperature, we found that the rate increases with increasing field, reaching a maximum at a phase boundary of the spin liquid phase. The results are compared with the calculated NMR rates in different proposed spin liquid states. The implications of the results on determining the fermionic or bosonic nature of the elementary excitations in the spin liquid phase will be discussed.

1:03PM  J27.00010  Spin-1/2 Heisenberg Antiferromagnet on the Spatially Anisotropic Kagome Lattice
, ANDREAS SCHNYDER, Kavli Institute for Theoretical Physics, University of California, California, BART STARKKH, Department of Physics, University of Utah, LEON BALENDS, Physics Department, University of California, Santa Barbara — We study the quasi-one-dimensional limit of the Spin-1/2 quantum antiferromagnet on the Kagome lattice, a model Hamiltonian that might be of relevance for the mineral volborthite [1,2]. The lattice is divided into antiferromagnetic spin-chains (exchange $J$) that are weakly coupled via intermediate "dangling" spins (exchange $J'$. Using bosonization, renormalization group methods, and current algebra techniques we determine the ground state as a function of $J/J'$. The case of a strictly one-dimensional Kagome stripe is also discussed.

1:15PM J27.00011 Magnetic Order and Spin Fluctuations in the Spin-1/2 Three-Dimensional Frustrated Magnet Clinatoacamite, Cu$_2$(OH)$_3$Cl. JOEL HELTON, KITTIWIT MATAN, Massachusetts Institute of Technology, JAE-HO CHUNG, NIST Center for Neutron Research, MATTHEW SHORES, BART BARTLETT, EMMY NYTKO, Massachusetts Institute of Technology, YING CHEN, QINGZHEN HUANG, JEFFREY LYNN, NIST Center for Neutron Research, DANIEL NOCERA, YOUNG LEE, Massachusetts Institute of Technology — We have performed thermodynamic and neutron scattering measurements on the $S=1/2$ three-dimensional antiferromagnet clinatoacamite, Cu$_2$(OH)$_3$Cl. The crystal lattice feature Cu$^{2+}$ ions arranged on a distorted kagomé lattice with weak magnetic coupling between adjacent planes. Long range magnetic order with a weak ferromagnetic moment emerges at the Neél ordering temperature, $T_N = 6.2$ K. The value of $T_{CW}$ is roughly 30 times larger than $T_N$, demonstrating that the material is highly frustrated. Magnetic Bragg peaks are not observed above background for temperatures between 6.2 and 18 K, even though previous µSR measurements observed muon oscillations in this temperature range. We present a possible model of the magnetic transitions and analyze the inelastic spectrum of the ordered state, taking into account anisotropic terms in the spin Hamiltonian.

1:27PM J27.00012 Magnetic Properties of Yb$_2$Pt$_2$Pb with the Shastry-Sutherland Lattice. MOO SUNG KIM, Brookhaven National Laboratory, MARCUS BENNETT, University of Michigan, MEIGAN ARONSON, Brookhaven National Laboratory — We have synthesized single crystals of Yb$_2$Pt$_2$Pb, which crystallize in the tetragonal $P4_2$ $2$-Sn-type structure. Comparison of the crystal structure with that of other compounds reveals a structure dependent Yb valence state of Yb$^{2+}$ Tm$^3$ (T=transition metal; M=Cd, In, Sn, and Pb). The magnetic susceptibility $\chi$ of Yb$_2$Pt$_2$Pb is highly anisotropic. The $\chi_{[100]}$ for $B|[110]$ is 30 times larger than $\chi_{[001]}$ for $B|[001]$ at the lowest temperatures. A broad maximum in $\chi_{[100]}$ is found around 3 K just above magnetic transition temperature 2.07 K. In agreement, the electrical resistivity shows a broad maximum around 5 K and the specific heat shows a long tail up to 8 K, due to the magnetic frustration originating from antiferromagnetic exchange interaction between Yb ions arranged in the network of the Shastry-Sutherland lattice.

1:39PM J27.00013 Dynamic Frustration in PrAu$_2$(Si$_{1-x}$Ge$_x$)$_2$. RAYMOND OSBORN, EUGENE GOREMYCHKIN, Argonne National Laboratory, J.B. RAINFORD, University of Southampton, UK, ROBIN MACALUSO, University of Northern Colorado, D.T. ADROJA, Rutherford Appleton Laboratory, UK, MAREK KOZA, Institut Laue Langevin, France — We have recently proposed that frustration is dynamically induced in PrAu$_2$(Si$_{1-x}$Ge$_x$)$_2$. It has been demonstrated that these compounds have a structure dependent Yb valence state of Yb$^{2+}$ Tm$^3$ ($T = $transition metal; $M= $Cd, In, Sn, and Pb). The magnetic susceptibility $\chi$ of PrAu$_2$(Si$_{1-x}$Ge$_x$)$_2$ is highly anisotropic. The $\chi_{[100]}$ for $B|[110]$ is 30 times larger than $\chi_{[001]}$ for $B|[001]$ at the lowest temperatures. A broad maximum in $\chi_{[100]}$ is found around 3 K just above magnetic transition temperature 2.07 K. In agreement, the electrical resistivity shows a broad maximum around 5 K and the specific heat shows a long tail up to 8 K, due to the magnetic frustration originating from antiferromagnetic exchange interaction between Yb ions arranged in the network of the Shastry-Sutherland lattice.

1:51PM J27.00014 KTi(SO$_4$)$_2$.H$_2$O - a possible candidate for a new spin-Pierles system. DEEPA KASINATHAN, MPI CPS - Dresden, Germany, GORAN NILSEN, HENRIK RONNOW, LQM-EPFL, Lausanne, Switzerland, STEFAN-LUDWIG DRECHSLER, IFW Dresden, Germany, HELGE ROSNER, MPI CPS, Dresden, Germany — Recently a large number of compounds belonging to the family of J$_{(OH)}$ reveals that this system is a quasi 1D spin 1/2 chain compound with both J$_1$-J$_2$ chain models with competing ferromagnetic (FM) and antiferromagnetic (AFM) interactions have been discovered. In most cases, FM-J$_1$ and AFM-J$_2$ is observed, leading to helical order with no spin gap (for frustration ratio $\alpha$). Models with competing ferromagnetic (FM) and antiferromagnetic (AFM) interactions have been discovered. In most cases, FM-J$_1$ and AFM-J$_2$ is observed, leading to helical order with no spin gap (for frustration ratio $\alpha$). Systems with both J$_1$ and J$_2$ being AFM causing a spin gap are rather rare. The thermodynamic data of the recently prepared KTi(SO$_4$)$_2$.H$_2$O reveal that this system is a quasi 1D spin 1/2 chain compound with both J$_1$ and J$_2$ being AFM, and a frustration ratio $\alpha \approx 0.29$. Here we report the results of electronic structure calculations within the LSDA+U method along with tight-binding models. Our calculations confirm that both J$_1$ and J$_2$ are AFM. In contrast to the experiments we obtain a larger $\alpha$, slightly depending on the choice of the Coulomb repulsion $U$. Therefore KTi(SO$_4$)$_2$.H$_2$O might be a new candidate for a spin-Pierles ground state. A brief comparison with other systems belonging to the class of frustrated chain materials is given with respect to their position in the general phase diagram of the 1D J$_1$ - J$_2$ model.

2:03PM J27.00015 Valence bond solid phases in the spin-1 XXZ model on the kagome lattice. SERGEI ISAKOV, EUTH Zurich, YONG BAEK KIM, University of Toronto — We study the spin-1 XXZ model on the kagome lattice using quantum Monte Carlo simulations. We find a rich phase diagram including two different valence bond solids and other quantum paramagnetic phases. We also characterize the nature of quantum phase transitions between these phases. These results are compared with various effective field theory approaches.

Tuesday, March 11, 2008 11:15AM - 2:15PM – Session J28 DMP FIAP: Focus Session: Thermoelectricity in Semiconductor Nanostructures Morial Convention Center 220

11:15AM J28.00001 Theory of enhancement of thermoelectric properties of materials with nanoinclusions. SERGEY FALEEV, FRANCOIS LEONARD, Sandia National Laboratories — Based on the idea of Schottky potential as an energy filter for the electrons, we developed a theory that explains the enhancement of the thermoelectric properties of semiconductor materials with metallic nanoinclusions. The Boltzmann transport equation with relaxation time approximation is used for description of both electron and phonon scattering. The theory has been applied to optimize the ZT factor for n-doped PbTe with metallic nanoinclusions. We found that the contribution of electron scattering to optimized ZT is important for high electron concentration ($n \times 10^3$ cm$^{-3}$), while at low concentrations ($n \times 10^2$ cm$^{-3}$) enhancement of the ZT factor is primarily due to decrease of the phonon thermal conductivity.

11:27AM J28.00002 Measurement of Cross-plane Thermoelectric Properties of Thin Film Structures with UHV Scanning Thermoelectric Microscopy. YONG LEE, ANASTASIOS MAVROFEALOS, MICHAEL PETTES, LI SHI, The University of Texas at Austin — Recently, various thin film structures have been under intense research in the hope for achieving increased thermoelectric figure of merit (ZT) compared to bulk materials. Accurate measurements of three quantities ($S$ : Seebeck coefficient, $\sigma$ : electrical conductivity, and $\kappa$:thermal conductivity) used to calculate ZT have been a challenge especially for thin film structures which may have very different values between in-plane and cross-plane directions due to the anisotropy. Here, we report our progress toward accurately measuring these thermoelectric properties of thin films along the cross-plane direction with a ultrahigh vacuum (UHV) scanning probe microscope. In particular, cross-plane Seebeck coefficient and electrical conductivity measurement of a thin film with a conductive AFM or STM probe will be discussed.
11:39 AM J28.00003 Micro- and nanomachined tools for measuring thermopower and in-plane thermal conductivity of thermoelectric thin films, AZURE AVERY, RUBINA SULTAN, GREG STIEHL, BARRY ZINK, University of Denver. — Many of the potential next-generation thermoelectric materials being studied are either thin films or nanostructures that are expected to have anisotropic properties. Techniques such as the 3ω method and picosecond thermoreflectance allow accurate measurements of k⊥ at temperatures relevant to thermoelectrics, but measuring k∥ is often difficult. In this talk we discuss our efforts to design and demonstrate accurate measurements of k∥ of thin films from 77 – 475 K using micro- and nanomachined thermal isolation platforms. Using thin-film structures to support the thin-film sample reduces background contributions, and careful control of the geometry keeps radiation errors small. We will discuss the optimization and micromachining of the measurement platforms and their application for studying the growth and characteristics of our first doped amorphous thin films. We will present our first tests of the devices on materials established thermal properties. Finally, we will discuss the use of these measurement platforms to determine k and ZT for doped amorphous silicon thin films.

11:51 AM J28.00004 Thermopower and Electrical Conductivity of PbSe Nanocrystal Thin Films, ROBERT WANG, JOSEPH FESER, University of California, Berkeley, JONG-SOO LEE, DMITRI AL TALAPIN, University of Chicago, RACHEL SEGALMAN, ARUN MAJUMDAR, University of California, Berkeley — Thin films assembled of solution-processed PbSe nanocrystals have a thermopower 2 – 3 times greater than bulk PbSe. In addition, the thermopower and electrical conductivity both exhibit a size-dependence on nanocrystal size. As the nanocrystal diameter changes from 4 to 9 nm, the thermopower and electrical conductivity change from 850 to 650 μV/K and 10−1 to 10−2 S/cm, respectively. If electrical conductivity can be improved, these materials represent a new class of inexpensive and scalable thermoelectric materials.

12:03PM J28.00005 ABSTRACT WITHDRAWN

12:15PM J28.00006 First Principles Studies of Phonon Dispersion and Lattice Thermal Conductivity of Silicon Nanowires, TRINH VO, TADASHI OGITSU, ERIC SCHWEGLER, LLNL, GIULIA GALLI, UC Davis — We present phonon dispersions of Si nanowires using ab initio and linear response theory. The effects of nanowire surface structures, growth directions, and quantum confinement on phonon dispersions and phonon confinement are also discussed. The thermal conductivity of Si nanowires using the obtained full dispersion curves are also evaluated, using Boltzmann Transport Equation. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory in part under Contract W-7405-Eng-48 and in part under Contract DE-AC52-07NA27344.

12:27PM J28.00007 Enhanced Thermoelectric Performance in Rough Silicon Nanowires1, RENKUN CHEN, Dept. of Mech. Engr., UC Berkeley, ALLON I. HOCHBAUM, RAUL DIAZ DELGADO, WENJIE LIANG, ERIK C. GARNETT, Dept. of Chemistry, UC Berkeley, MARK NAJARIAN, Dept. of Materials Sci. & Engr., UC Berkeley, ARUN MAJUMDAR, Dept. of Mech. Engr., UC Berkeley, PEIDONG YANG, Dept. of Chemistry, UC Berkeley — Due to the disparity between electron (<10 nm) and phonon (~100 nm) mean free paths in silicon, nanostructured Si could effectively block phonon transport by boundary scattering while maintaining electron transport, thereby enhancing thermoelectric figure of merit, ZT. Here we report the wafer-scale electrochemical synthesis and thermoelectric characterization of rough Si nanowires with enhanced ZT, relative to the bulk material. Single nanowire measurements show that their electrical resistivity and Seebeck coefficient are similar to those of bulk Si with similar dopant concentration. Thin nanowires, however, exhibit a 100-fold reduction in thermal conductivity (k), yielding a large ZT = 0.6 at room temperature. Although bulk Si is a poor thermoelectric material, Si nanowire arrays show promise as high-performance, scalable thermoelectric materials.

The authors acknowledge the support of the office of BES, DOE. A.I.H., R.C. and R.D.D. wish to thank the NSF-IGERT, ITRI-Taiwan and Gen-Cat/Fulbright programs, respectively, for support.

12:39PM J28.00008 Enhanced thermoelectric properties in silicon nanowires, SLOBODAN MITROVIC, JEN-KAN YU, AKRAM BOUKAI, JAMIL TAHIR-KHELI, WILLIAM A. GODDARD III, JAMES R. HEATH, Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, CA 91125. — Recently, we demonstrated that silicon nanowires can be designed and fabricated to achieve an approximately 100-fold enhancement in thermoelectric efficiency compared to bulk silicon. Independent measurements of thermoelectric power, and thermal and electrical conductivities suggest that this improvement is due to phonon effects rather than quantum confinement. Here, we present the study of the scaling laws (i.e. nanowire length/width dependence) for the phonon dynamics and transport. We investigate the influence of the phonon drag, carrier mobility and doping on the thermoelectric properties, and the universality of these findings. This work is supported by the Office of Naval Research, the Defense Advanced Research Projects Agency.

12:51PM J28.00009 Atomic Modeling and Optimization of thermoelectric properties of SiGe nanowires1, M. MARIA CHAN, YING SHIRLEY MENG, TIM MUELLER, GERBRAND CEDER, Massachusetts Institute of Technology, JOHN REED, TRINH VO, ANDREW WILLIAMSON2, Lawrence Livermore National Laboratory, GIULIA GALLI, University of California, Davis. — Nano-structured thermoelectric materials have been shown experimentally to have superior figure of merit compared to bulk materials. To understand the origin of this superiority, it is of interest to develop physically accurate methods to compute the thermoelectric transport coefficients of nanowires. In addition, computationally inexpensive parameterization of these physical models are needed in order for efficient sampling, e.g. in atomic configuration space, so as to design systems with optimal thermoelectric properties. We consider aspects of electron and phonon transport in SiGe nanowires. For electronic transport, we work in the diffusive regime with Boltzmann transport, combining ab initio density functional theory (DFT) calculations with a perturbative treatment of electronic scattering to obtain electronic relaxation times, conductivity and thermopower. The phonon contribution to thermal conductivity is obtained from classical equilibrium molecular dynamics simulations using the Green-Kubo formalism. Cluster expansion and effective potential techniques are used to parameterize the transport coefficients for efficient sampling and optimization.

1:15PM J28.00011 Thermoelectric Properties of Semiconducting Silicide Nanowires, SONG JIN, JEANNINE SCZECH, JEREMY HIGGINs, University of Wisconsin-Madison, FENG ZHOU, LI SHI, University of Texas-Austin — Semiconducting silicides are promising thermoelectric materials. In addition to their respectable thermoelectric figure-of-merit ($ZT$ up to 0.8), silicides have the advantages of low cost, excellent thermal stability and mechanical strength, and outstanding oxidation resistance, making them suitable for high temperature applications. We have developed general synthetic approaches to single crystal nanowires of silicides to investigate the enhancement of thermoelectric properties due to the reduced nanoscale dimension and to explore their applications in thermoelectrics. We will discuss the synthesis and structural characterization of nanowires of chromium disilicide ($\text{CrSi}_2$) prepared via a chemical vapor transport (CVT) method and chemical vapor deposition (CVD) of organometallic precursors to synthesize the Novotnyon Chimney ladder phase MnSi$_{1.75}$. The Seebeck coefficient, electrical conductivity, and thermal conductivity of individual CrSi$_2$ nanowires were characterized using a suspended microdevice and correlated with the structural information obtained by microscopy on the same nanowires. This combined Seebeck coefficient and electrical conductivity measurements also allow an effective approach to probing the Fermi level, carrier concentration and mobility in nanowires. We will also discuss our progress in using individual nanostructures combined well-defined structural characterization to conclusively investigate the complex thermoelectric behaviors of silicide materials.

1:27PM J28.00012 Tuning of Thermoelectric Transport in Individual Bismuth Nanowires, ARDEN MOORE, MICHAEL PETTES, ANASTASSIOS MAVROKEFALOS, LI SHI, University of Texas-Austin — Bismuth is a material of special interest for studying nanoscale transport behavior. Its extremely small effective mass and long electron mean free path suggest that quantum and classical confinement effects might be observed at realistic dimensions and higher temperatures than in other material systems. In addition, the predicted enhancement of the thermoelectric figure of merit $ZT$ due to confinement effects of these systems increases the desire to measure the transport properties of individual bismuth nanowires. However, efforts to measure the thermoelectric properties of bismuth nanowires have been hindered thus far by the presence of a highly stable surface oxide layer, making reliable ohmic contact to individual nanowires problematic. In this work, we present the synthesis and measurement methods used by our group to make electrical contact with individual nanowires in order to measure the thermal conductivity, thermopower, and electrical conductivity of individual bismuth nanowires of varying diameter. The obtained data is presented with comparison to bulk values and analysis of the transport behavior.

1:39PM J28.00013 Thermopower Measurements of Pure and Sn (Te) Doped Bismuth Nanowires$^1$, TITO HUBER, Howard University. Washington DC 20059, A. ADEYEYE, Howard University. Washington, DC 20059, A. NIkolaeVA, L. KONOPOKO, Academy of Sciences Moldova, R. JOHNSON, Department of Physics, Boston College, Chestnut Hill, MA 02467, M.J. GRAF, Department of Physics. Boston College. Chestnut Hill MA 02467 — Theoretical work based on one-dimensional (1D) models indicates that Bi wires with diameter smaller than 50 nm can exhibit superior thermoelectric properties since the density of states at the Fermi level of a 1D system can be tuned to very high values. Also, recently, angle-resolved photoemission spectroscopy (ARPES) studies of Bi thin films have shown that Bi nanowires support Rashba spin-orbit surface states, with high carrier densities of around $5 \times 10^{12}$ cm$^{-2}$, that are hybridized with “bulklike” electrons and holes, a phenomenon that has not been considered in current models of Bi nanowires. We carried out an experimental study of the transport properties and thermopower of bismuth nanowire arrays (NWA) with wire diameters ranging between 60 nm and 13 nm at temperatures ranging between 4 K and 300 K, for magnetic fields of up to 1 T. Both pure bismuth and doped Bi were studied. The results are interpreted in a multicarrier diffusion thermopower model.

1:51PM J28.00014 Tuning the Thermoelectric Properties of Metal-Molecule-Metal Junctions, K. BAHETI, J.A. MALEN, P. DOAK, T.D. TILLEY, A. MAJUMDAR, R. SEGALMAN, Univ. of California, Berkeley — Thermoelectric materials have application in power generation and refrigeration, with several advantages over conventional power cycles including lack of moving parts, silent operation, miniaturization, and CO2 free conversion of heat to electricity. Nonetheless, low thermodynamic efficiency has limited their applicability. Here we examine a new class of inexpensive thermoelectric materials composed of organic-inorganic heterostructures. Thermopower measurements of 1,4-Benzenediethyl (BDT) molecule between Au electrodes, using a modified scanning tunneling microscope (STM), have been previously reported. This method is used to interrogate junctions where, the BDT molecule has been doped by the addition of substituent groups on the benzene ring. Our measurements show that we can tune the thermoelectric properties of such junctions in a controllable way by the addition of substituents. This in conjunction with a calculated transmission function imply a simultaneous increase in the thermopower and conductance, which has hitherto been impossible to attain in simple materials. We observe an increase of $\sim 50\%$ in the power factor, defined as $S^2\sigma$, of the junction upon substitution of electron donating groups in benzenediethyl. Hence, a ground up approach to building thermoelectric materials, from an endless array of possible organic-inorganic heterostructures, evokes hope for efficient thermoelectric energy conversion.

2:03PM J28.00015 Transport properties and the thermoelectric figure-of-merit of single molecule systems, PADRAIG MURPHY, Department of Physics, UC Berkeley, SUBROTO MUKERJEE, JOEL MOORE, Department of Physics, UC Berkeley, and Materials Sciences Division, Lawrence Berkeley National Laboratory — The thermoelectric properties of molecules are both of fundamental interest and of interest for the construction of energy conversion devices. These transport properties are sensitive to interactions within the molecule, the hybridization energy between the molecular energy levels and the leads, and to the temperature. We present numerical and theoretical results on the conductance and thermopower, and discuss the parameter values for which the figure-of-merit, which parametrizes the efficiency of energy conversion devices, is optimal. The numerical results for the thermopower can be obtained at fixed particle number for finite systems using an appropriate generalization of the approach of Gogolin and Prokof'ev to electrical conductance.

11:15AM J29.00001 Biased bilayer graphene: Hall effect and zero-energy Edge States, NUNO PERES, University of Minho — We demonstrate that the electronic gap of a graphene bilayer can be controlled externally by applying a gate bias. From the magneto-transport data (Shubnikov-de Haas measurements of the cyclotron mass), and using a tight binding model, we extract the value of the gap as a function of the electronic density. We show that the gap can be changed from zero to mid-infrared energies by using fields of $\lesssim 1$ V/nm, below the electric breakdown of SiO$_2$. The opening of a gap is clearly seen in the quantum Hall regime. We further report the existence of zero energy surface states localized at zigzag edges of bilayer graphene. It is shown that zero energy edge states in bilayer graphene can be divided into two families: (i) states living only on a single plane, equivalent to surface states in monolayer graphene; (ii) states with finite amplitude over the two layers, with an enhanced penetration into the bulk.
11:51AM J29.00002 Cyclotron resonance in bilayer graphene, ERIK HENRIKSEN, Columbia University, ZHIGANG JIANG, LI-CHUN TUNG, NHMFL, MOLLIE SCHWARTZ, Columbia University, MAIKA TAKITA, Barnard College, YONG-JIE WANG, NHMFL, PHILIP KIM, HORST STORMER, Columbia University — The hyperbolic dispersion of bilayer graphene leads to a Landau level (LL) spectrum that is linear in the magnetic field, B, at low energies but shifts to a $\sqrt{B}$ dependence with increasing energy. Here we present the first infrared transmission measurements of the unique B-field dependence of LL transitions in bilayer graphene, in a gated 400$\mu$m$^2$ sample in fields up to $B = 18$ T. Eight intraband transitions are observed among LL indices $|n| \leq 4$, including the unusual zero-energy $n = 0$ level, and are found to follow a selection rule of $\Delta n = \pm 1$. We find the change in field dependence is plainly visible between the behavior of the transition energies for $n = -1 \rightarrow 0$ and $n = 0 \rightarrow +1$, which are close to linear in B, as compared with all other transitions which display a clear $\sqrt{B}$ behavior. However, the shift in field dependence occurs at energies well below where it is expected based on nearest-neighbor tight-binding calculations, and a single set of fitting parameters within this theory fails to describe our results.

12:03PM J29.00003 Graphene as an electronic membrane, EUN-AH KIM, Stanford University, ANTONIO CASTRO NETO, Boston University — Experiments are finally revealing intricate facts about graphene which go beyond the ideal picture of relativistic Dirac fermions in pristine two dimensional (2D) space, two years after its first isolation. While observations of rippling [1, 2, 3] added another dimension to the richness of the physics of graphene, scanning single electron transistor images displayed prevalent charge inhomogeneity [4]. The importance of understanding these non-ideal aspects cannot be overstated both from the fundamental research interest since graphene is a unique arena for their interplay, and from the device applications interest since the quality control is a key to applications. We investigate the membrane aspect of graphene and its impact on the electronic properties. We show that curvature generates spatially varying electrochemical potential. Further we show that the charge inhomogeneity in turn stabilizes ripple formation.[5]

12:15PM J29.00004 Demonstration of one-parameter scaling at the Dirac point in graphene, JENS H. BARDARSON, J. TWORZYDLO, P. BROUWER, C.W.J. BEENAKKER, Instituut-Lorentz, Universiteit Leiden — We numerically calculate the conductivity $\sigma$ of an undoped graphene sheet (size $L$) in the limit of vanishingly small lattice constant. We demonstrate one-parameter scaling for random impurity scattering and determine the scaling function $\partial T/L \sigma = -\partial L/L \sigma$. Contrary to a recent prediction, the scaling flow has no fixed point ($\beta > 0$) for conductivities up to and beyond the symplectic metal-insulator transition. Instead, the data supports an alternative scaling flow for which the conductivity at the Dirac point increases logarithmically with sample size in the absence of intervalley scattering — without reaching a scale-invariant limit.

12:27PM J29.00005 Electron localization in gapped bilayer graphenes with disorder, MIKITO KOSHINO, Columbia University, Tokyo Institute of Technology — The bilayer graphene is a zero-gap semiconductor, and it is known that the width of energy gap can be controlled by the electric field perpendicular to the layer [1,2]. Even in zero magnetic field, the electronic states carry the non-zero Hall conductivity in presence of the gap, while the Hall currents cancel out in summation over two valleys (K and K' points). Here we numerically calculate the electronic states in gapped bilayer graphenes with the smooth disorder potential, and estimate the localization length as a function of the gap width $\Delta$. We find that the conductivity at zero Fermi energy does not simply go down as $\Delta$ increases, but has a maximum at a certain finite $\Delta$, and the localization length diverges there. We show that this can be interpreted as a “Hall plateau transition” in each decoupled valley, even though the total Hall conductivity remains zero. [1] Meyer, J.C., et al., Nature 446, 60 (2007). [2] Stolyarov E. et al., PNAS, 104, 9209 (2007). [3] Ishigami, M. et al., Nano Letters 7, 1643 (2007). [4] Martin, J. et al., unpublished, cond-mat/0705.2180 (2007). [5] E.-A. Kim and A. Castro Neto, cond-mat/0702562

12:39PM J29.00006 Effect of electron interactions on the infrared conductivity of a monolayer graphene, M. M. FOGLER, L. M. ZHANG, UCSD — Recent experiments on the infrared spectroscopy of a monolayer graphene has revealed an unexpected non-Lorentzian form of the Drude peak and an anomalously large broadening of the interband absorption edge in this material. We present a theoretical investigation that attributes these features to Coulomb scattering between Dirac quasiparticles. This scattering shows up in the dynamical conductivity up to and beyond the symplectic metal-insulator transition. Instead, the data supports an alternative scaling flow for which the conductivity at the Dirac point increases logarithmically with sample size in the absence of intervalley scattering — without reaching a scale-invariant limit.

12:51PM J29.00007 Excitonic Effects in the Optical Spectra of Graphene Nanoribbons, LI YANG, MARVIN COHEN, STEVEN LOUIE, Department of Physics, University of California at Berkeley and Materials Sciences Division of Lawrence Berkeley National Laboratory — We present a first-principles calculation of the optical properties of graphene nanoribbons (GNRs) with many-electron effects included, employing the GW-BSE approach. The reduced dimensionality of GNRs gives rise to an enhanced electron-hole binding energy for both bright and dark exciton states and changes the optical spectra significantly. The characteristics of the excitons of different types of GNRs are compared and discussed. The enhanced excitonic effects found here are expected to be of importance in considering possible applications (such as optoelectronics) of graphene-based nanostructures. This work was supported by National Science Foundation Grant No. DMR07-05941, the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by Datastar at the San Diego Supercomputer Center.

1:03PM J29.00008 Localized states at zigzag edges of graphene multilayers and graphite steps, EDUARDO V. CASTRO, J.M.B. LOPES DOS SANTOS, CFP and Departamento de Física, Faculdade de Ciências Universidade do Porto, Portugal, N.M.R. PERES, Center of Physics and Departamento de Física, Universidade do Minho, Portugal, F. GUINEA, Instituto de Ciencia de Materiales de Madrid, CSIC, Cantoblanco, Spain, A. H. CASTRO NETO, Department of Physics, Boston University, USA — Among the uncommon features of graphene monolayer we find the presence of zero energy states localized at zigzag edges, leading to the self-doping phenomenon and inducing edge magnetization. Here we report the existence of zero energy surface states at zigzag edges of bilayer graphene and stacks with any number of layers. Working within the tight-binding approximation we derive an analytic solution for the wavefunctions of these peculiar surface states. It is shown that zero energy edge states in bilayer graphene can be divided into two families: (i) states living only on a single plane, equivalent to surface states in monolayer graphene; (ii) states with finite amplitude over the two layers, with an enhanced penetration into the bulk. The effect of edge states on the electronic structure and magnetic order of bilayer graphene nanoribbons is also studied. We show that edge states measured through scanning tunneling microscopy and spectroscopy of graphite step edges belong to family (i) or (ii) mentioned above, depending on the way the top layer is cut.
1:15PM J29.00009 Minimal conductivity of graphene: role of the Coulomb interaction, VLADIMIR JURICIC, IGOR F. HERBUT, Department of Physics, Simon Fraser University, Canada. OSKAR VAPEK, National High Magnetic Field Laboratory and Department of Physics, Florida State University, USA — The effect of the Coulomb interaction on the zero-temperature low-frequency conductivity in undoped graphene is studied. We will show that the Coulomb interaction introduces a universal and positive leading logarithmic correction to the gaussian value of the dc conductivity [1]. This finding suggests that the origin of the unusually large minimal conductivity observed in graphene may be intrinsic, and arises from the Coulomb correction effectively cut off by finite temperature/disorder/size effects. A mechanism of such a cutoff based on the non-trivial interplay between the Coulomb interaction and the ripples, both unavoidably present in the graphene sheet, will be briefly discussed. References: [1] I. F. Herbut, V. Juricic, and O. Vafek, arXiv:0707.4171.

1:27PM J29.00010 Low density ferromagnetism in a biased bilayer graphene, TOBIAS STAUBER, Instituto de Ciencia de Materiales de Madrid (CSIC), EDUARDO CASTRO, CFP and Departamento de Física, Facultade de Ciencias Universidade do Porto, NUNO PERES, NUNO SILVA, Centro de Física e Departamento de Física, Universidade do Minho — We compute the phase diagram of a biased graphene bilayer. The existence of a ferromagnetic phase is discussed with respect both to carrier density and temperature. We find that the ferromagnetic transition is first order, lowering the value of $U$ relatively to the usual Stoner criterion. We show that in the ferromagnetic phase the two planes have unequal magnetization and that the electronic density is hole like in one plane and electron like in the other.

1:39PM J29.00011 Minimal conductivity of rippled graphene with topological disorder, ALBERTO CORTIJO, MARIA VOZMEDIANO, Instituto de Ciencia de Materiales de Madrid-CSIC — We study the transport properties of a neutral graphene sheet with curved wrinkles induced or stabilized by topological defects. The proposed model gives rise to Dirac fermions in a random magnetic field and a random space dependent Fermi velocity induced by the curvature. This last term leads to singular long range correlated disorder with special characteristics. The Drude minimal conductivity at zero energy is found to be inversely proportional to the density of topological disorder, a signature of diffusive behavior.

1:51PM J29.00012 Weak Localization of Dirac Fermions in Graphene, XIN-ZHONG YAN, C. S. TING, TCS, University of Houston — In the presence of the charged impurities with screened Coulomb potentials, we study the weak localization (WL) effect by evaluating the quantum interference correction (QIC) to the conductivity of Dirac fermions in graphene. With the inelastic scattering rate due to electron-electron interactions obtained from our previous calculation, we investigate the dependence of QIC on the carrier concentration, the temperature and the size of the sample. It is found that WL is present in large size samples at finite temperature while the strength of the intervalley scatterings due to the charged impurities is not weak. In addition, we argue that the system is delocalized at very low doping. We also analyze the absence of WL in experiment. It is found that WL is quenched at low temperature for small size samples as studied in the experiments.

2:03PM J29.00013 Electric Transport Theory of Dirac Fermions, YOUSEF ROMIAHI, Department of Physics, University of Houston, TX. 77204 and Texas Center for Superconductivity, University of Houston, TX. 77204, XIN-ZHONG YAN, Chinese Academy of Sciences, P. O. Box 603, Beijing 100080, China, CHIN-SEN TING, Department of Physics, University of Houston, TX. 77204 and Texas Center for Superconductivity, University of Houston, TX. 77204 — The self-consistent Born approximation is employed to calculate transport properties in graphene with finite-range impurity potentials. The current-current correlation function is determined by a system of four coupled integral equations, unlike the case of short-range impurity scattering, and yet the results for the latter can exactly be reproduced in our formalism. As a test, we numerically calculate the dc electric conductivity of graphene for charged impurities with screened Coulomb potential, the linear dependence of the dc conductivity on the carrier concentration and the extrapolated value for zero-doping is shown to be finite, in a qualitative agreement with the experimental observations.

Tuesday, March 11, 2008 11:15AM - 2:15PM
Session J30 DMP: Optical Properties and Experimental Characterization of Graphene and Related Structures — Morial Convention Center 222

11:15AM J30.00001 Photo-induced structural dynamics of graphitic carbon studied by ultrafast electron nanocrystallography, RAMANI K. RAMAN, YOSHIE MUROOKA, RYAN A. MURDICK, CHONG-YU RUAN, Michigan State University — We report the studies of photo-induced structural dynamics of graphite and multi-wall carbon nanotubes (MWCNT) using ultrafast electron nanocrystallography. Graphite, upon excitation, contracts along its c-axis causing a reduction of the interlayer distance, which is the first step towards diamondization. MWCNT on the other hand, display an energy-dependent electron-phonon coupling mechanism. Upon excitation at 400nm, the promoted carriers can transfer their excess energy to the lattice rapidly within 5-10 ps whereas at 800nm it takes around 20-30ps for the same. This indicates a more efficient electron-phonon coupling at 400nm where the excited carriers are more strongly coupled to the lattice. Both graphite and MWCNT also exhibit a transient photovoltaic effect where an accumulation of excited charge carriers at the sample interface causes a collective shift of the Bragg peaks. We found that the charge dynamics and atom dynamics are intimately correlated at interfaces.

11:27AM J30.00002 Non-destructive optical characterization of DNA-wrapping of single-walled carbon nanotubes, S. E. SNYDER, S.V. ROTKIN, Lehigh University — Single-stranded DNA can form a stable hybrid structure with a single-walled carbon nanotube, allowing dispersion of individual nanotubes in aqueous solution and facilitating the development of methods to separate nanotubes by type. Optical and electronic properties of specific DNA-nanotube structures are the focus of our study due to potential optoelectronic device applications. Within a semi-empirical tight-binding approach, we have studied changes in optical absorption of a single-walled carbon nanotube resulting from a helical wrap of ionized single-stranded DNA. The one-electron absorption spectrum for light polarized across the tube is sensitive to bandstructure modulation due to the wrapping. For a non-chiral tube, the helical perturbation generates “natural” optical activity in the DNA-nanotube complex, yielding circular dichroism. Symmetry breaking due to the Coulomb interaction and the ripples, both unavoidably present in the graphene sheet, will be briefly discussed. References: [1] I. F. Herbut, V. Juricic, and O. Vafek, arXiv:0707.4171.
11:39 AM J30.00003 Incommensurately Stacked Graphene Bi-Layer: A Raman Scattering Study\textsuperscript{1}. AWNISH GUPTA, Y. TANG, T. RUSSIN, V. CRESPI, P. EKLUND, Pennsylvania State University — We report results of Raman scattering studies of two novel graphene systems based on incommensurate stacking of sp\textsuperscript{2} carbon: (1) an incommensurate bi-layer (IBL) formed by folding a graphene sheet onto itself; (2) a graphene scroll formed by rolling up a graphene sheet via a shearing motion between scotch tape and substrate during the micro-mechanical cleaving process. In (1), we have a flat bi-layer system; in (2) it is a gently curved multilayer system — both should be incommensurate. Interestingly, although no significant D-band is observed in the parent graphene sheet, the incommensurate contact of the graphene sheet in (1) and (2) leads to strong D-band scattering near 1350 cm\textsuperscript{-1} using 514.5 nm excitation. The dispersion of the D-bands in (1) and (2) is significantly different: scroll (~38 cm\textsuperscript{-1}/eV) and IBL (~50 cm\textsuperscript{-1}/eV). A second Raman band is observed nearby at ~1384 cm\textsuperscript{-1} in both the IBL and the scroll. However, the ~1384 cm\textsuperscript{-1} band is non-dispersive in both cases and is much sharper in the IBL than in the scroll. Our data will be compared to theoretical calculations based on double-resonant (DR) scattering and the electronic states of an IBL.

\textsuperscript{1} NSF-ECS0609243

11:51 AM J30.00004 Anharmonic Effects in Raman Scattering Few-Layer Graphene System\textsuperscript{1}. TIMOTHY RUSSIN, Pennsylvania State University, AWNISH GUPTA, PETER EKLUND — Result of Raman scattering studies from supported and suspended n-layer graphene films (nGLs) are presented for the temperature range of ~190 to 500 °C. The samples were either supported directly on a Si/SiO\textsubscript{2} substrate or suspended over lithographically produced trenches; the measurements were performed in a N\textsubscript{2} atmosphere. For both supported and suspended films, the magnitude of the negative temperature coefficient of the G-band frequency (cm\textsuperscript{-1}/K) is found to decrease with increase in number of layers n in the nGL films (i.e., supported 1GL, 2GL and 5GL show ~0.10, ~0.13, and ~0.28 cm\textsuperscript{-1}/K, respectively.) The anharmonic coefficients are significantly higher than for highly oriented pyrolytic graphite (HOPG). Surprisingly, the G-band linewidth increases with temperature for the supported films and decreases with temperature for the suspended films. Furthermore, we see evidence for a permanent morphological change at ~300 °C for supported nGLs via new D-band and D’-band scattering. Unsupported films exhibit these changes at higher temperatures. The mechanism and details of the irreversible morphological change(s) is not yet known.

12:03 PM J30.00005 Tunneling spectroscopy of single- and double-layer graphene planar tunnel junctions. CONOR PULS, NEAL STALEY, YING LIU, Department of Physics, Pennsylvania State University — It is of fundamental as well as technological concern if there exists an energy gap in single- and double-layer graphene devices. Single-layer graphene is thought to be gapless while double-layer graphene features an energy gap tunable by controlling the charge difference between the two layers. Previously, scanning tunneling microscopy and spectroscopy studies have been employed to examine energy spectra of graphene films. This approach produces local charge inhomogeneity at the probe tip that could significantly alter the local density of states (DOS) in graphene. Planar tunnel junctions provide a probe of the DOS that should not induce such an inhomogeneity in the charge carrier density. We fabricated planar tunnel junctions on single- and double-layer graphene using an ultrathin quartz filament as a shadow mask over mechanically exfoliated graphene as an alternative to lithographic procedures so as to avoid possible contamination in a wet lithography process. We have measured tunneling spectra for both weakly and strongly disordered samples. For single-layer graphene, we observed an unexpected gap. For double-layer graphene, we found a gap and other features in the tunnel spectra by changing the back gate and tunnel junction bias voltages independently — thereby tuning the charge difference between the top and bottom layer — as well as varying magnetic field and temperature.

12:15 PM J30.00006 The G* (2450 cm\textsuperscript{-1}) Double Resonance Raman Peak in single-, few-layer graphene and DWNTs, ALFONSO REINA, HYUNGBIN SON, FEDERICO VILLALPANDO-PAEZ, HOOTAN FARHAT, JING KONG, MIT, MILDELD DRESSELHAUS, MATERIALS SCIENCE AND ENGINEERING TEAM, ELECTRICAL ENGINEERING AND COMPUTER SCIENCE TEAM, PHYSICS TEAM, IIC, BERKELEY TEAM — The dispersion and skewness of the 2450 cm\textsuperscript{-1} peak in the raman spectra of carbon structures was analyzed. The dispersion of this peak for graphene is smaller in extent and of opposite sign than that for the G* (~2700 cm\textsuperscript{-1}). This dispersion is independent on number of layers. The peak shows asymmetry (skewness) which increases with $E_{\text{laser}}$. The observations can be explained by viewing this double resonance process arising by the scattering with both an iT0 and a iLA phonon. The peak becomes more symmetric in DWNTs and it shows a stronger curvature dependence than the G* peak.

12:27 PM J30.00007 Probing Non-equilibrium Phonon Dynamics in Graphite by Time-Resolved Raman Spectroscopy, HUGEN YAN, Columbia University, DAOHUA SONG, KIN FAI MAK, IOANNIS CHATZAKIS, JANINA MAULTZSCH, TONY HEINZ — Time-resolved Raman spectroscopy has been applied to obtain direct information about phonon lifetimes in graphite. A non-equilibrium population of zone-center optical phonons was produced by the rapid relaxation of charge carriers following photoexcitation of the sample with a femtosecond laser pulse. The subsequent evolution of the phonon population was recorded using the strength of G-mode anti-Stokes Raman scattering from a time-delayed femtosecond probe pulse. A population lifetime for the G-mode phonons of approximately 2 ps was found. Analogous measurements of optical-phonon lifetimes were also conducted in few-layer graphene samples produced by mechanical exfoliation of bulk graphite. Results obtained for graphite and few-layer graphene will be compared with one another, as well as with earlier data on the lifetime of G-mode phonons in single-walled carbon nanotubes [1].

12:39 PM J30.00008 Transfer of Graphene to Alternative Substrates\textsuperscript{1}. TRACY MOORE, J.H. CHEN, D.R. HINES, E.D. WILLIAMS, University of Maryland, J. SIMSPON, A.R.H. WALKER, NIST — Graphene transport properties are limited by charge defects in SiO\textsubscript{2}, and by large charge density due strong interaction with SIC. We have investigated the transfer of graphene from one substrate to another using high pressures and temperatures to achieve control of the substrate interactions and thus their effects on graphene. The direct transfer from HOPG to alternative substrates PET and PMMA yields mostly multilayer, opaque graphite flakes. Raman signatures of the thinner, translucent flakes on PMMA can be clearly distinguished from the PMMA spectra and show a downshift in the G’ peak that occurs around 2700 cm\textsuperscript{-1} and a relative intensity of G to G’ peak of approximately one; characteristics of graphene spectra. In addition the transfer from SiO\textsubscript{2} to alternative substrates occurs readily for PET substrates, and infrequently for PMMA substrates with thicker flakes transferring more readily than thin flakes. Graphene transfer from 1) direct HOPG, 2) flakes on SiO\textsubscript{2}, and 3) the possibility of direct transfer from epitaxial graphene on SiC will be presented, along with the resulting device characteristics.

\textsuperscript{1} Supported by the Laboratory for Physical Sciences and NSF-MRSEC at UMD
12:51PM J30.00009 Gap and Impurity induced states on graphene layers, CHANYONG HWANG, DOHYUN LEE, WON DONG KIM, Korea Research Institute of Standards and Science, JUNGHWA YANG, JISANG HONG, Department of Physics, Pukyong National University — One of the interesting phenomena in graphene is the linear Fermi level crossing at the Dirac point. For the measurement of electronic structure, few layers of graphenes are formed on top of SiC substrate by thermal treatment. As the thickness of graphene layers increases, the formation of the gap near Dirac point is somewhat controversial. Recently this gap has been demonstrated to be tunable by the electric field. We have used angle-resolved photoemission spectroscopy and STM to characterize this gap state and actual morphology of the graphene layers to clarify this controversial issue. In addition, we have shown that the adatom carbon can play an important role in gap state. First principles calculation on this carbon adatom state will be discussed.

1:03PM J30.00010 Single Layer Graphene formation on Silicon Oxide surface(001), HEE SUNG CHOI, YOUNG-KYUN KWON, University of Massachusetts Lowell — Recently graphene is one of most interesting topics in physics and other research fields. For future nanoelectronics applications, graphene formation becomes an important issue. Here we present our theoretical study of how to make a graphene layer on silicon oxide surfaces. In this work, density functional theory calculations are used to determine atomic structures and energies for graphene formation from various carbon sources, such as anthracene, on silicon oxide. We will also present optimal graphene formation conditions obtained from our ab initio molecular dynamics simulations.

1:15PM J30.00011 Soldering to a single atomic layer, CAGLAR GIRIT, ALEX ZETTL, UC Berkeley, LBNL — The standard technique to make electrical contact to nanostructures is electron beam lithography. This method has several drawbacks including complexity, cost, and sample contamination. We present a simple technique to cleanly solder submicron sized, Ohmic contacts to nanostructures. To demonstrate, we contact graphene, a single atomic layer of carbon, and investigate low- and high-bias electronic transport. We set lower bounds on the current carrying capacity of graphene. A simple model allows us to obtain device characteristics such as mobility, minimum conductance, and contact resistance.

1:27PM J30.00012 Synthesis of Carbon Nanotubes by Rolling Up Patterned Graphene Nanoribbons Using Selective Atomic Adsorption1, DECAI YU, FENG LIU, University of Utah, LIU TEAM — We demonstrate a new method for synthesizing Carbon Nanotubes (CNTs), using first principles and classical molecular dynamics simulations. The single-walled nanotubes (SWNTs) are formed by rolling up graphene nanoribbons patterned on graphite films, through adsorption of atoms of varying coverage, which introduces an external stress to drive the folding process. The diameter and chirality of SWNTs can be a priori controlled by patterning graphene nanoribbons with predefined width and direction, so that the post-synthesis sorting process is eliminated. Our method allows potentially mass production of identical tubes and easy integration into device structures on a substrate.

1We acknowledge support from DOE.

1:39PM J30.00013 13C NMR studies on the organic zero-gap system, \( \theta-(BEDT-TTF)_2I_3 \) under pressure, KAZUYA MIYAGAWA, University of Tokyo and JST-CREST, MÔTOAI HIRAYAMA, University of Tokyo, MASAFUMI TAMURA, RIKEN, KAZUSHI KANODA, University of Tokyo and JST-CREST. — We present NMR data for the organic material, \( \theta-(BEDT-TTF)_2I_3 \) under pressure, which is a candidate for zero-gap conductor with cone-like dispersion. The quasi-two-dimensional organic conductor \( \alpha-(BEDT-TTF)_2I_3 \) is known to show peculiar behaviors under high pressure. The resistivity is insensitive to temperature, while the Hall coefficient is strongly dependent on temperature. The band calculation suggests that this system is in the zero gap state with a linear dispersion around the Fermi energy. While the \( \theta-(BEDT-TTF)_2I_3 \) is metallic under ambient pressure, above 5 kbar temperature dependences of resistivity and Hall coefficient are similar to those of \( \alpha-(BEDT-TTF)_2I_3 \). It is remarkable that the graphite like zero-gap state is realized in a bulk system. We have performed preliminary investigation into the magnetism of \( \theta-(BEDT-TTF)_2I_3 \) under 8 kbar by \(^{13}\)C NMR. The external field is applied to parallel to the conducting layer. In constant to the simple metallic behavior observed under ambient pressure (Korriga's relation holds), the Knight shift vanishes in proportion with temperature and 1/\( T \).

1:51PM J30.00014 UHV Growth of Graphene on SiC, PAUL CAMPBELL, GLENN JERNIGAN, KEITH PERKINS, BRENDÁ VANILÍN, RACHEL MYERS-WARD, KURT GASKILL, JAMES CULBERTSON, JEREMY ROBINSON, ERIC SNOW, Naval Research Laboratory — We report growth of graphene on Si- and C-face semi-insulating 6H SiC in UHV by thermal Si desorption/reconstruction of the remaining C. The SiC was etched in H₂ up to 1500 °C to smooth the surface. XPS shows the H₂-etched surfaces are covered by an oxide which desorbs at 1000 °C, resulting in a surface containing excess Si. At 1300 °C, the surface becomes stoichiometric in Si and C and a \( \sqrt{3} \times \sqrt{3} \) R30 LEED pattern is observed. At 1350 °C, we observe a 6/\( \sqrt{3} \) x 6/\( \sqrt{3} \) R30 LEED pattern when the graphene has formed, and a 1x1 LEED pattern for graphite films formed at temperatures greater than 1400 °C. Graphene layers were grown under a variety of temperatures and conditions and characterized using XPS, LEED, AFM, Raman spectroscopy, and Hall effect. Top-gated FETs were fabricated with a wide range of gate lengths (1-25 microns) and gate widths (2-130 microns), and transistor operation was obtained for both single and multiple graphene layers.

2:03PM J30.00015 UHV electron-probing of micro-mechanically cleaved Graphene on SiO₂, K.R. KNOX, S. WANG, P. KIM, R.M. OSGOOD, Columbia University, T.O. MENTES, M.A.N ORTI, A. LOCATELLI, Elettra Trieste Italy, D. CVETKO, A. MORGANTE, TASC-INFN Trieste Italy — While graphene’s distinctive Dirac-cone electronic structure and simple 2D atomic structure have attracted major interest in the physics community, the inherent limitations of isolated graphene samples mounted on an insulating substrates have made it difficult to study such systems with typical UHV probes such as photoemission and low energy electron diffraction (LEED). While most single layer graphene transport measurements are done on micro-mechanically extracted samples on SiO₂, all photoemission and LEED measurements of graphene performed so far have used films grown on SiC substrates. In this talk, we will discuss the first results of UHV probes carried out exfoliated graphene bonded to SiO₂. Using the high spatial resolution of the nanospectroscopy beamline at the ELETTRA synchrotron light source, we have been able to overcome the size limitations, which have prevented previous UHV study of this system. We will discuss the results of our X-ray photoemission (XPS), UV photoemission (UPS) and LEED measurements on single and multilayer graphene samples.

Morial Convention Center 223
11:15AM J31.00001 Atomic design of semiconductor nanostructures with optimal thermoelectric properties

GIULIA GALLI, University of California Davis — The search for novel materials with optimal thermoelectric properties (for either thermoelectric power generation or heat dissipation) is an active field of research. We present atomistic and ab-initio simulations of selected nanomaterials, aimed at predicting thermal conductivities and electronic transport properties, and ultimately at designing materials with optimal thermoelectric figure of merit. In particular we focus on carbon nanotubes [1], silicon wires [2] and nanoporous silicon [3] and we discuss both strategies and algorithms to optimize thermoelectric properties at the nanoscale.

1Supported by DARPA grant # W911NF-06-1-0175.

11:51AM J31.00002 Ab initio method for the electron-phonon scattering times in semiconducting nanomaterials

NATHALIE VAST, JELENA SJAKSTE, Ecole Polytechnique, Laboratoire des Solides Irradiés, CEA-DSM-DRECAM, CNRS, 91128 Palaiseau, France, VALERIY TYUTEREV, Tomsk State Pedagogical University, Tomsk, Russia — The interaction of excited electrons with phonons plays a central role for electronic and transport properties at the nanoscale. It is the dominant process limiting the excitation lifetime at medium excitation energies. Despite its importance, a reliable approach within ab initio methods for phonon interaction with excited carriers was still lacking. We present in this work our fully ab initio approach to calculate the electron-phonon scattering times for collisions of carriers in the conduction band with short-wavelength phonons. We apply it to the deexcitation of hot electrons in GaAs [1,2], and to the lifetime of the direct exciton in GaP and GaAs [2,3], all in excellent agreement with experiments. Finally, we discuss the effect of nanostructuring on the electron-phonon coupling constants in GaAs/AlAs superlattices.

12:03PM J31.00003 Quantum-size-induced phase transitions in quantum dots: Indirect-band gap GaAs nanoostructures

ALEX ZUNGER, JUN-WEI LUO, ALBERTO FRANCESCHETTI, National Renewable Energy Lab — Quantum nanostuctures are often advertised as having stronger absorption than the bulk material from which they are made, to the potential benefit of nanotechnology. However, nanostuctures made of direct gap materials such as GaAs can convert to indirect-gap, weakly-absorbing systems when the quantum size becomes small. This is the case for spherical GaAs dots of radius 15 Å or less (about 1000 atoms) embedded in a wide-gap matrix. The nature of the transition: Γ-to-X or Γ-to-L is however, controversial. The distinction can not be made on the basis of electronic structure techniques that misrepresent the magnitude of the various competing effective masses (e.g. DDA vs. GGA) or wavefunction coupling (e.g. tight-binding). Using a carefully fit screened pseudopotential method we show that the transition occurs from Γ to X, and, more importantly, that the transition involves a finite V (Γ-X) interband coupling, manifested as an “anti-crossing” between the confined electron states of GaAs as the dot size crosses 15 Å. The physics of this reciprocal-space Γ-X transition, as well as the real-space (type II) transition in GaAs/AlGaAs will be briefly discussed.

12:15PM J31.00004 Co-doping of Boron and Phosphorus in Silicon Nanoclusters

JAE-HYEON EOM, TZU-LIANG CHAN, JAMES R. CHELIKOWSKY, University of Texas at Austin — The effect of cluster size on the interaction between impurity atoms is studied using the first-principles calculations, i.e. pseudopotentials in real space. We calculate the stable configurations of B and P co-doped silicon nanoclusters as a function of size. We evaluate the evolution of interactions between impurity atoms by comparing the stable configurations. The evolution of photoluminescence is discussed.

12:27PM J31.00005 Quantum Confinement and Non-Magnetic-Doped Dilute Magnetic Semiconductors

HYUNWOOK KWAK, University of Minnesota, TZU-LIANG CHAN, JAMES R. CHELIKOWSKY, University of Texas — Dilute magnetic semiconductors are of interest for their unique magnetic properties and their promising role in development of “spintronic” semiconductor devices. Recently, a new dimension has been brought to this class of material by observing room temperature ferromagnetism in non-magnetic doped semiconductors and insulators. Using real-space pseudopotential applied to nitrogen-doped ZnO nanowires and nanocrystals, we report the theoretical evidence of magnetism in spatially confined non-magnetic doped semiconductor nanocrystals. Detailed electronic structures and magnetic properties are examined by comparing the total energy of different spin orderings and defect configurations. Besides the prediction of high Curie temperature, our results show that the ferromagnetic order becomes more stable when the nitrogen defects experience strong quantum confinement.

12:39PM J31.00006 Impurity Doping in PbSe Nanocrystals

STEVEN ERWIN, Naval Research Laboratory — We recently proposed that impurity doping in colloidal grown nanocrystals is controlled primarily by kinetics, rather than by thermodynamics. In this “trapped dopant” model, the diffusion of an impurity through a nanocrystal is negligible at colloidal growth temperatures. Therefore, an impurity can only be incorporated into a growing nanocrystal if it first adsorbs on the surface and is then overgrown. But this simple surface adsorption process is complicated by a competing “anti-crossing” between the confined electron states of GaAs as the dot size crosses 15 Å. The physics of this reciprocal-space Γ-X transition, as well as the real-space (type II) transition in GaAs/AlAs will be briefly discussed.

12:51PM J31.00007 Size Limits on Doping Phosphorous into Silicon Nanocrystals

TZU-LIANG CHAN, MURILLO L. TIAGO, University of Texas at Austin, EPFTHIMOS KAXIRAS, Harvard University, JAMES R. CHELIKOWSKY, University of Texas at Austin — The evolution of the semiconductor industry requires continued miniaturization. As this trend continues, devices will ultimately approach the nanometer-scale and it is expected that device construction based on macroscopic laws will start to fail. Using a real-space first-principles pseudopotential method, we study doping in the nano-regime using phosphorus-doped Si nanocrystals as the prototypical system. We simulate phosphorus-doped Si nanocrystals with diameter up to 6 nm and study the evolution of the defect state with the size of the nanocrystal. Our calculated size dependence of hyperfine splitting is in excellent agreement with experimental data. The effect of quantum confinement is also manifested in the higher binding energy of the dopant electron, we estimate that phosphorus in Si nanocrystals of less than 20 nm in diameter will not be a shallow donor. We also find that for Si nanocrystals smaller than 2 nm in diameter, the phosphorus atom will be energetically expelled to the surface, leading to a self-purification mechanism that hinders the incorporation of impurity atoms into nanocrystals.

1This work was supported in part by the National Science Foundation under DMR-0551195.
1:03PM J31.00008 Interface chemistry of silicon nanocrystals embedded in silica\(^1\). DUNDAR YILMAZ, CEYHUN BULUTAY, Bilkent University, TAHIR CAGIN, Texas A&M University — Molecular dynamics simulations of realistic-sized silicon nanocrystals (NCs) with the diameters in the range from 1 nm to 3 nm embedded in amorphous oxide are carried out till steady state conditions with the chemical environment described by the reactive force field model. We identify different types of three-coordinated oxygen (3cO) complexes, previously not noted, on the oxide interface. No double bonds were observed. We reveal that the interface bond topology evolves among different oxygen bridges through these 3cO complexes. The abundance and the charge distribution of each oxygen complex is determined as a function of the NC size as well as the transitions among them. The number of bridge bonds is observed to scale with surface area, thus the curvature has a small effect on the number of bridges. Among the three bonds of 3cO, the weaker bond is more susceptible to bond breaking which is also likely to take part in an optical activity through bond breaking and reformation. Our results indicate that the Si NC-oxide interface is more complicated than the previously proposed schemes which were based on solely double and bridge bonds.

1:15PM J31.00009 Structure and electronic properties of gold-tipped CdSe nanorods\(^1\). N. BARNETT, UZI LANDMAN, Georgia Institute of Technology — We investigate CdSe nanorods capped by gold contacts and passivated by phospho-organic molecules of varying chain length. The geometry is optimized and the electronic structure obtained using first-principles quantum mechanical methods. We discuss the formation of Schottky barriers, the development of interfacial dipoles, the presence and extent of gap states induced by the metallic contact and of states in the semiconductor energy gap associated with the passivant carbon chains.

\(^1\)Computations performed at the National Center for Computational Sciences

1:27PM J31.00010 Förster resonant energy transfer between CdSe nanocrystals: An empirical pseudopotential/transition density cube approach\(^2\). JOSHUA SCHRIER, LIN-WANG WANG, Lawrence Berkeley National Laboratory — We study the energy transfer between semiconductor nanocrystal dots and rods of CdSe using a semiempirical pseudopotential method (SEPM) description of the electronic structure of the nanocrystals, followed by evaluation of the Coulombic contribution to the energy transfer evaluated using the transition density cube (TDC) method. Our results are compared to the dipole-dipole theory of Förster to characterize the effects of nanocrystal shape, distance, and orientation. In agreement with previous effective-mass and tight-binding studies, we find that the coupling between spherical nanocrystals is well described by the Förster model. In contrast, we find that rod-shaped nanocrystals display more complicated behavior, which may be relevant to exciton migration in all-inorganic nanorod-based photovoltaic devices.

1:39PM J31.00011 Polar properties of ZnO nanostructures. GIANCARLO CICERO, Politecnico of Torino, Torino, Italy; CNR-IMEM, Parma, Italy, ANDREA FERRETTI, CNR-S3, Modena, Italy, ALESSANDRA CATELLANI, CNR-IMEM, Parma, Italy — The advent of all-inorganic nanorod-based photovoltaic devices critically enhances the role of surface and interface effects on bulk properties and determines the physical characteristics of the material: in particular, the understanding of the electronic properties of nanosized structures requires a proper accurate treatment. Here we report on first principles density functional calculations of the structural and electronic properties of the (1-100) “non-polar” surface of hexagonal zinc oxide (ZnO) and compare the results with those of ZnO nanowires grown along the [0001] direction and analogous exposed cuts, with a diameter range of about 9-23 Å. We discuss the formation of Schottky barriers, the development of interfacial dipoles, the presence and extent of gap states induced by the metallic contact and of states in the semiconductor energy gap associated with the passivant carbon chains.

1:51PM J31.00012 Softening of ultra-nanocrystalline diamond at small grain sizes, GEORGIOS KOPIDAKIS, Department of Materials Science and Technology, University of Crete, IOANNIS REMEDIAKIS, Department of Materials Science and Technology and Department of Physics, University of Crete, PANTELIS KELIRES, Department of Physics, University of Crete and Dept. of Mechanical Engineering and Materials Science and Engineering, Cyprus University of Technology — Ultra-nanocrystalline diamond is a polycrystalline material, having crystalline diamond grains of sizes in the nanometer regime. We study the structure and mechanical properties of this material as a function of the average grain size, employing atomistic simulations. Using the bulk and Young’s moduli as probes of stiffness, we observe softening of the material as the size of its grains decreases, similar to the reverse Hall-Petch effect observed for nanocrystalline metals. This softening is attributed to the enhanced fraction of interfacial atoms. The calculated scaling of the cohesive energy and bulk modulus with respect to average grain size agrees very well with this picture. Our results suggest that softening at very small grain sizes might be a generic property of nanocrystalline materials.

2:03PM J31.00013 A Molecular Dynamics Study of the Melting and Nucleation of Iron Nanoparticles YASUSHI SHIBUTA, TOSHIO SUZUKI, Department of Materials Engineering, The University of Tokyo — The melting and nucleation of iron nanoparticles were investigated by molecular dynamics simulation using a Finnis-Sinclair potential. The nanoparticle of the bcc single-crystal was uniformly melted from the surface at a melting point during heating, whereas a nucleus was generated near one side of an undercooled liquid droplet and the solidification spread toward another side at a lower temperature during cooling. The melting point and nucleation temperature decreased with particle radius. Moreover, the solid-liquid interfacial energy was estimated to be 0.101 J/m\(^2\) using a Gibbs-Thomson equation, which is of the same order as the experimental value based on Turnbull-Fusher’s classical nucleation theory.
11:15AM J32.00001 Spin-orbit damping in transition metals, KEITH GILMORE, National Institute of Standards and Technology — Magnetization dynamics are routinely described with the Landau-Lifshitz-Gilbert (LLG) equation. However, it is expected that the LLG equation fails to properly describe the large amplitude dynamics that occur during magnetization reversal. Improving switching speeds in nanoscale devices by tailoring materials requires both a qualitative understanding of the relaxation processes that contribute to damping and the ability to quantitatively calculate the resulting damping rates. We consider small amplitude LLG damping in transition metals as a prelude to approaching the more complicated mechanisms expected in complete reversal events. LLG damping rates in pure transition metal systems have been assessed using magnetization reversal data, including spin-pumping picture of the Gilbert damping. We also make contact with earlier theories of the transverse spin susceptibilities and with the conductivity, which can be calculated straightforwardly (no vertex corrections involved) leading to a Drude-like formula in which the inverses of the disorder and interaction scattering times enter in a simple additive form.

11:51AM J32.00002 Non-local damping effects in Py-Cu-FeMn trilayers, ERIC R.J. EDWARDS, LEI WEN, ZEENATH REDDY TADISINA, CLAUDIA K.A. MEWES, SUBHADRA GUPTA, TIM MEWES, Center for Materials for Information Technology, University of Alabama — We report a non-local enhancement of the Gilbert damping in Py-Cu-FeMn trilayers for in-plane ferromagnetic resonance measurements. We observe a 1/α dependence, t being the thickness of the permalloy, of the slope of the linewidth vs. frequency measurements indicating non-local contributions to the damping. In view of experimental verification of the adiabatic spin pump theory [1] in ferromagnetic heterostructures [2], these results suggest parallels in exchange biased systems. With the thickness of the non-magnetic layer, Cu, fixed below its spin-diffusion length, we understand this effect to be non-local resulting from the injection of spins by the precessing magnetization at the Py-Cu interface and subsequent scattering at the Cu-FeMn interface.

12:03PM J32.00003 Gilbert Damping in Single-Crystalline Ni/MgO(001)1, KEVIN J. SMITH, R. ALE LUKASZEW, ANNE REILLY, Department of Physics, College of William and Mary, GÜNTER LÜPKE, Department of Applied Science, College of William and Mary — The dynamical properties of Nickel and Nickel alloys are of great interest in spintronic applications, as these materials exhibit low coercivity and significant magnetoresistance, however, the interplay of the various damping mechanisms, such as two magnon scattering and local resonance, is not well understood. The frequency, ω, and Gilbert damping, α, behavior of uniform spin precession on Ni/MgO(001) are studied over a wide range of external field angles and magnitudes using the Time-Resolved Magneto-Optical Kerr effect (TR-MOKE). The damping parameter shows a strong dependence on the magnetocrystalline anisotropy, suggesting a tuneability of α over the range of 0.09 to 0.5. Two separate trends in α vs. ω are observed depending on the magnitude of the applied field when applied in-plane, indicating the presence of competing damping mechanisms. We further investigate these properties in measurements in which the external field is applied normal to the sample plane, thereby minimizing the role of two magnon scattering.

12:15PM J32.00004 Inhomogeneous Gilbert damping from disorder and electron-electron interactions1, Ewelina Hankiewicz, Fordham University, Giovanni Vignale, University of Missouri-Columbia, Yaroslav Tserkovnyak, University of California Los Angeles — We present a unified theory of Gilbert damping in itinerant ferromagnets at order α2 (α being the wave vector of the spin modulation) including electron-electron interactions and electron-impurity scattering – the idea being that these interactions are much stronger than the spin-orbit interaction, which controls the damping in the homogeneous case (α = 0). We show that Gilbert damping can be expressed in terms of the spin conductivity, which can be calculated straightforwardly (no vertex corrections involved) leading to a Drude-like formula in which the inverses of the disorder and interaction scattering times enter in a simple additive form. We also make contact with earlier theories of the transverse spin susceptibilities and with the spin-pumping picture of the Gilbert damping.

12:27PM J32.00005 FMR Investigations on Ni-Co thin films1, JUSTIN BAIZE, The University of Texas Pan American, STEVEN MICHALSKI, ROGER D. KIRBY, University of Nebraska Lincoln, MIRCEA CHIPARA, DAVID J. SELLMYER, University of Nebraska Lincoln — Magnetic interactions between thin films of Co and Ni spaced by a conducting, non-magnetic film (Pt) are analyzed by utilizing a Bruker ELEXYS-EPR spectrometer operating in the X-band (9 GHz). Ferromagnetic resonance spectra have been recorded at room temperature in the out-of-plane configuration, for different orientation of the external applied film relative to the plane of the sample. The effect of the metallic film (Pt) thickness on the interaction between Ni and Co is investigated. For most orientations, the ferromagnetic line of such multilayers is the result of a convolution between the lines of Ni and Co films and has been fitted by a superposition of two Lorentzian lines. The outcome of the interaction between the two magnetic layers on the position and the width of ferromagnetic resonance lines is analyzed in detail.

1ESR measurements were done within the laboratory of Professor A. Rajca from the Chemistry Department of the University of Nebraska Lincoln.

12:39PM J32.00006 Determination of ferromagnetic resonance of thin films with coplanar waveguide, XIN FAN1, TAKAIRO MORIYAMA, RONG CAO, JOHN XIAO — Determination of ferromagnetic resonance of thin films with coplanar waveguide X. Fan, T. Moriyama, R. Cao, John Q. Xiao Department of Physics and Astronomy, University of Delaware, Newark Delaware 19716 USA Recently, Coplanar Waveguide (CPW) has been applied to determine Ferromagnetic Resonance (FMR) of magnetic thin film due to its simple geometry and broadband nature. Compared to the conventional method using reflection in a resonant cavity, CPW should be interpreted by the transmission line theory, taking into account of both transmission and reflection. It has been shown that FMR linewidth extracted from S-matrix after four port calibration differs from that extracted from transmission only, which neglects the impedance mismatch effect. However, the four port calibration is rather complex and tedious. In this presentation, we introduce a new method to extract FMR spectrum without performing four port calibration. We use both transmission and reflection signals, and consider the impedance mismatch, We will demonstrate the difference between these two methods are negligibly small. 1. Y. Ding, T. J. Klemmer, T. 12:51PM J32.00007 Magnetostatic micro-resonators. ALEXANDER KOZHANOV, ZACH GRIFFITH, MARK RODWELL, JIM ALLEN, UCSB, Santa Barbara, CA, USA, DOK WON LEE, SHAN WANG, Stanford University, Stanford, CA, — AJEY JACOB, Intell, Inc., WIN COLLABORATION — Small scale magnetostatic wave devices are potentially important for on-chip filters for communication systems and more exotic gated spin wave devices. We describe experimental results that measure transmission and reflection resonances in micron size resonators coupled to coplanar waveguides. Ferromagnetic CoZrTa films were sputtered onto Si wafers covered by SiO2 and lithographically patterned into stripes and crosses of varying length and width. Magnetostatic waves were excited and detected by overlaying coupling loops patterned as shortened coplanar waveguides. Transmission and reflection S-parameters of fabricated structures were measured in the frequency range (0-50)GHz. Transmission and reflection resonances strongly dependent on the geometry of the ferromagnetic device and applied magnetic field are observed. The results are modeled as standing magneto static waves in micro-resonators. We discuss effect of biasing magnetic fields, approaches to enhanced coupling to the magnetostatic resonators, magnetostatic wave interferometers and magnetization controlled magnetostatic wave switching in junctions. This work is supported by the Nanoelectronics Research Initiative (NRI) - Western Institute of Nanoelectronics (WIN).

1:03PM J32.00008 Measurements of spin diffusion length in gold with point contact Andreev reflection spectroscopy MUHAMMAD FAIZ, RAGHAVA PANGULURI, Physics and Astronomy Department - Wayne State University, BAKLIN BALKE, SABINE WURMEHL, CLAUDIA FELSER, Johannes Gutenberg-Universitat, Germany, ANDRE PETUKHOV, Physics Department - South Dakota School of Mines and Technology, PO Box 4100, FI-02015 HUT, Finland — A family of inhomogeneous Hubbard models is shown to have multi-level spin-switching properties. The generic structure of the device is NNMMN/MMN, which defines a linear (quasi-0D) cluster, having open boundary conditions. Within the context of the Hubbard model, N refers to a nonmagnetic (U=0) atom and M is a magnetic atom having finite value of the Hubbard U. The model is solved by numerically exact diagonalization. Localized spin-switching is obtained as a function of the electron filling and is activated by application of an external magnetic field. Arbitrary numbers of nonmagnetic atoms at the edges of the chain, relative to the number of magnetic atoms in the system, lead to a range of spin-switching signals. One potential application to be demonstrated is that of a single minority spin-flip detector.

1:27PM J32.00010 Anisotropic spin exchange between electrons mediated by spin-orbit interaction SUHAS GANGADHARAIAH, JIANMIN SUN, OLEG STARYKH, University of Utah — It is well known that the exchange coupling between electrons in the presence of Rashba spin-orbit interaction (SOI) is anisotropic. In particular, due to the SOI, electron spins are not conserved during a tunneling process as a result anisotropic exchange terms of the Dzyaloshinkii-Moriya (DM) type are generated. In this talk, we re-visit and clarify the role of spin-orbit interaction in lowering the symmetry of the exchange coupling between spins. We point out that the exchange Hamiltonian, despite of its anisotropic appearance, retains spin-rotational (SU(2)) invariance to the second order in the spin-orbital coupling. We argue that spin-rotational symmetry is broken only in the fourth order in SOI coupling. To capture this, we calculate the exchange problem along the lines of the Heitler-London approach.

1:39PM J32.00011 Noise Spectrum Signature of Large Jumps in the Magnetization of a Finite System Near a Phase Transition ZHI CHEN, CLARE YU, University of California, Irvine — It is well known that a finite-size spin system can undergo thermally driven flips of the magnetization of the system as a whole. But what is an experimentally measurable signal of this? We show that the low frequency noise spectrum of the magnetization has a distinct signature of these total magnetization flips which as particularly evident just below the phase transition temperature. To see this, we studied the magnetization and energy spectra of the 2D Ising model by using Monte Carlo simulations. We find that at $T_C$ the noise power is a power law in the frequency where the power is given by the critical exponents. As the frequency decreases for a finite system just below $T_C$, the magnetization noise spectrum crosses over to $f^{-2}$. We show that this is due to large jumps in the entire magnetization. Finally at the lowest frequencies, the noise spectrum saturates at a frequency that depends on the system size. The method we used can be applied without much modification to quantify the contribution of jumps to the dynamics of other systems.

2:03PM J32.00013 The role of uncompensated spins in exchange biasing HANS J. HUG, Empa, Materials Science and Technology, Switzerland and Institute of Physics, University of Basel, Switzerland, IRIS SCHMID, PÉTER KAPPÉNBERGER, SARA ROMER, Empa, Materials Science and Technology, Switzerland — The origin of the exchange bias (EB) effect has been traced back to the existence of pinned uncompensated spins (UCS) in the antiferromagnet (AFM) or at its interface. However, the understanding of the underlying mechanism is still clouded by contradictory reports: For example, both a parallel as well as an antiparallel orientation of the UCS relative to the magnetization direction of the ferromagnet (FM) were reported for similar FM/AFM systems. Here different magnetization histories in magnetometry and high resolution magnetic force microscopy measurements are used advantageously to demonstrate the co-existence of pinned UCS that are parallel and antiparallel to the cooling field in metallic (IrMn) and oxidic (CoO) EB systems. We further conclude that the EB effect is mainly a result of pinned interfacial UCS, which are antiparallel to the FM spins. In further experiments, the distribution of density of the UCS were imaged on the length scales of single grains. A surprisingly strong fluctuation of the local UCS density (UCSD) was observed. A correlation between the UCSD and the local exchange field was performed. Clearly, a high UCSD results in a low local exchange bias field. Regions with an anti-ferromagnetic effect were found. Using grain-boundary engineering, exchange-biased materials without such regions could be fabricated that showed a substantially increased exchange bias effect.

11:15AM J33.00001 Ferromagnetism in Mn-implanted Ge and epitaxial GeC\(^x\). SAMARESH GUCHARIT, JOHN MARKERT, Department of Physics, The University of Texas at Austin, MUSTFA JAMIL, SANJAY BANERJEE, Department of ECE, The University of Texas at Austin — 20 keV energy Mn ions were implanted in two samples: 1) bulk Ge (100) and 2) a 250 nm thick epitaxial GeC film, grown on a Si (100) wafer. The GeC thin film was grown by UHV chemical vapor deposition using a mixture of germane (GeH\(_3\)) and methylgermane (CH\(_3\)GeH\(_3\)) gases and contains less than 1% carbon. X-ray diffraction data shows a single crystal phase for the GeC film, and the surface rms roughness is about 0.3 nm, measured with AFM. The Mn implant dose was 1.1 \times 10^{10}/cm\(^2\) at a temperature of 300°C for both samples. For this relatively low energy Mn ion implant, the range is about 17 nm and the straggles is about 9 nm. A SQUID magnetometer study shows ferromagnetism in both samples. While the Curie temperature for both samples is about 180 K, the in-plane saturated magnetic moment per unit area for the first sample is about 2.2 \times 10^{-5}emu/cm\(^2\) and that for the second sample is about 3.0 \times 10^{-5}emu/cm\(^2\). These results show clear enhancement of magnetic properties of the Mn-implanted GeC thin film over the identically implanted Ge layer due to the presence of a small amount of carbon.

\(1\)This work was supported by SWAN and NSF DMR 0605828.

11:27AM J33.00002 Influence of carrier type on the ferromagnetism in Ge\(_{1−x}\)Mn\(_x\) thin films. WENNING YIN, JIWEN LU, LI HE, JIAN YU, WENSIN FAN, ROBERT HÜLL, STUART WOLF, University of Virginia — We have been studying the magnetic and transport properties of Mn-doped Group IV semiconductors. Mn ions have been implanted into both boron doped P-type and phosphorus doped N type Ge thin films respectively. A ferromagnetic hysteresis loop has been observed in P-type samples at low temperatures and supermagnetism remains strong at 300 K. The P-type samples show much stronger ferromagnetism than N-type samples. At 5K, the ferromagnetic saturation moment (Ms) of 5% Mn-doped p-Ge sample is ~0.65 Bohr magneton per Mn, which is almost twice as much as that of the 5% Mn-doped n-Ge. Rapid thermal annealing has been used to reduce the ion implantation damage as well as to help Mn ions to incorporate into Ge lattice. In this talk we will present magnetic, transport and electron microscopy characterization of these samples. We are in the process of trying to understand the nature of the ferromagnetism in these films and its correlation to carrier type.

11:39AM J33.00003 Epitaxial Growth and Properties of Multilayers Containing (CoMn)\(_0.9\)Ge\(_0.9\) and Ge (001). LIANG HE, CHARLES MALMBERG, BRIAN COLLINS, FRANK TSUI, University of North Carolina at Chapel Hill — Epitaxial growth and magnetic and magnetotransport properties of superlattices containing Co and Mn codoped Ge magnetic semiconductor layers with Ge (001) interlayers have been studied. Layer-by-layer epitaxial growth has been observed during the deposition of the dopant magnetic semiconductor layers, i.e. (CoMn)\(_0.9\)Ge\(_0.9\), and that of the undoped Ge interlayers, as indicated by persistent oscillations in the intensity and width of reflection high energy electron diffraction. The superlattices exhibit a ferromagnetic transition near 100 K and superparamagnetism at higher temperatures, as determined by temperature and field dependent magnetic measurements using SQUID magnetometry. Magnetotransport properties indicate that the superlattices are p-type semiconductors with very large positive magnetoresistance (MR) and anomalous Hall effect (AHE). Conduction at low temperatures (\(< 100\) K) is dominated by variable range hopping in the impurity band. Below 100 K, the MR is found to scale with square of the magnetization, whereas the AHE exhibits a linear dependence on magnetization. Above 100 K, in the superparamagnetic regime the magnetotransport parameters scale with magnetic field.

11:51AM J33.00004 Different magnetic moment in Mn-doped amorphous group-IV semiconductors: a comparison study between Si and Ge matrices. LI ZENG, ERIK HELGREN, University of California, Berkeley, CINTHIA PIAMONTEZE, ELKE ARENHOLZ, ALS, Lawrence Berkeley Lab, Berkeley, CA, ADDISON HUEGEL, FRANCES HELLMAN, University of California, Berkeley — Mn-doped amorphous Si (\(\alpha\)-Si) and Ge (\(\alpha\)-Ge) are prepared by \(\gamma\)-beam co-evaporation for a wide range of concentrations (0.5–18 at.\%) to explore the Mn local moment in group-IV semiconductors. We find that Mn behaves quite differently in these two matrices: in \(\alpha\)-Si, the Mn local moment is quenched, even for the lowest doping (0.5 at.%), while in \(\alpha\)-Ge, a large Mn moment is observed, with a spin-glass ground state. X-ray absorption spectra (XAS) of \(\alpha\)-Mn\(_{2}\)Si\(_{1−2}\) have very broad L-edge absorption peaks which correlate with the quenched magnetic state. The quenched Mn moment in \(\alpha\)-Si is unexpected and can be understood by the formation of Anderson-localized itinerant states even on the insulating side of the metal-insulator transition. (\(\alpha\)-Si, \(\alpha\)-Ge) show atomic multiplicities. \(\alpha\)-Mn\(_{2}\)Si\(_{1−2}\) has positive magnetoresistance (MR) like typical non-magnetic doped systems, while \(\alpha\)-Mn\(_{2}\)Ge\(_{1−2}\) has negative MR, consistent with magnetization data.

12:03PM J33.00005 Magnetic Properties of Ge\(_{1−x}\)Mn\(_x\)Te Thin Films. JAMES R. ANDERSON, Dept. of Physics & Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD, W. KNOFF, MALGORZATA GORSKA, T. STORY, Institute of Physics, PAN, Al. Lotnikow 32/46, Warsaw, Poland, COSTEL R. ROTUNDU, Dept. of Physics & Center for Nanophysics and Advanced Materials, University of Maryland, College Park, MD — We have measured the magnetization of Ge\(_{1−x}\)Mn\(_x\)Te thin films with 0.08 < x < 0.19 at magnetic fields up to 7 T at temperatures from 2 to 385 K. The monocrystalline epitaxial layers of Ge\(_{1−x}\)Mn\(_x\)Te were grown on (111)-oriented BaF\(_2\) crystalline substrates in a home-built MBE system. The layer structure was rhombohedral, thickness in the range 0.5 – 1 micron, and hole carrier concentration of the order \(10^{21}\) cm\(^{-3}\). Magnetization measurements were made using a Quantum Design MPMS system. At low temperatures the samples were ferromagnetic. The ferromagnetic – paramagnetic transition was observed in various samples in a broad temperature range from 20 – 100 K. In some samples we have seen two peaks in the temperature dependence of the low-field magnetization. These peaks may be evident of two chemical phases or of an electronic phase separation. The origin of this effect is under investigation at the present time.

12:15PM J33.00006 Spin Engineering with Ion Implantation of Diamond Nitrogen-Vacancy Centers¹, G.D. FUCHS, F.J. HEREMANS, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation-University of California, Santa Barbara, CA, R. HANSON, Kavli Institute of Nanoscience - Delft Institute of Technology, A. BATRA, T. SCHENKEL, Lawrence Berkeley National Lab, S. SHIRVASTAVA, T. MUGATO, E. SIDERAS-HADDAD, University of Witwatersrand, Johannesburg, S. Africa — Nitrogen-vacancy (NV) defect centers in diamond exhibit long coherence times of spin states at room temperature. Individual NV centers can be optically initialized and read-out, making them attractive candidates for quantum information. By exploiting the interactions with naturally occurring, nearby spins, NV centers have been incorporated into two quantum bit (qubit) systems. Despite these successes, scaling NV qubit systems with naturally occurring spins is a challenge. Here we present an alternative approach where we deliberately place NV centers using spatial and energy selective ion-implantation of nitrogen into synthetic diamond samples with low nitrogen content. Since we use isotopically pure N-15 for implantation, we can distinguish the implanted NV centers from the naturally occurring N-14 centers by measuring the hyperfine splitting of the electron spin resonance peaks of individual NV centers.

¹Work supported by AFOSR, FCRP, and CNID.

12:27PM J33.00007 Electronic transport in nitrogen-rich diamond¹ , F.J. HEREMANS, G.D. FUCHS, C.F. WANG, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA, R. HANSON, Kavli Institute of Nanoscience, Delft University of Technology, The Netherlands — Electronic transport in carbon-based materials, including carbon nanotubes, graphene, and diamond, have been receiving significant attention as potential alternatives to silicon-based electronics. In particular, diamond’s excellent thermal properties provide a promising alternative in power-sensitive applications. Here we present studies of the photo-excited electronic transport in nitrogen-rich type IB diamonds. In addition to the study of the carrier dynamics within this system, we discuss a charge storage effect that may find potential application in charging-based memories. We find that the discharge curves follow a “stretched-exponential” form [1] with a fixed exponent, which does not depend on electrode spacing, voltage, and illumination intensity. These findings are discussed in the context of a transport mechanism in this nitrogen-rich diamond substrate.

¹This work was supported by AFOSR, FCRP, and CNID.

12:39PM J33.00008 Polarization-selective excitation of nitrogen vacancy centers in diamond . T. P. MAYER ALEGRE, Laboratorio Nacional de Luz Sincrotron, C. SANTORI, Hewlett-Packard Laboratories, G. MEDEIROS-RIBEIRO, Laboratorio Nacional de Luz Sincrotron, R. G. BEAUSOLEIL, Hewlett-Packard Laboratories — The nitrogen-vacancy (N-V) center in diamond is promising as an electron spin qubit due to its long-lived coherence and optical addressability. Nevertheless, some work remains in determining the detailed energy level structure. In particular, little emphasis has been put on the microwave polarization selection rules. In typical optically-detected magnetic resonance (ODMR) experiments, the microwave transitions are driven by linearly polarized fields. Thus the individual transitions can be selected only by applying a constant magnetic field to lift the degeneracy. Typically the magnetic field is applied along the quantization axis of the NV center to avoid mixing of the spin states. This applied magnetic field is in principle unnecessary with circularly polarized microwave excitation. Using a resonator designed to produce circularly polarized microwaves, we have investigated the polarization selection rules of the N- V center. We first apply this technique to N-V ensembles in [100] and [111]-oriented samples. Next, we demonstrate an imaging technique, based on optical polarization dependence, that allows rapid identification of the orientations of many single N-V centers. Finally, we test the microwave polarization selection rules of individual N-V centers of known orientation.

12:51PM J33.00009 Spin transport studies in high mobility organic semiconductor, Pentacene (C_{22}H_{14})¹ , J.H. SHIM, V. KARTHIK, J.S. MOODERA, MIT, MIT TEAM — Spin transport in organic semiconductors (OSs) is currently an attractive research area because these materials in general can have long spin coherence length due to weak spin-orbit scattering and hyperfine interaction. Charge and spin transport in OSs strongly depend on the intermolecular overlap of electronic wave functions and defects in OS which can be influenced by the thin film growth conditions. Here we chose OS, pentacene (C_{22}H_{14}), which is among the most promising materials due to its high mobility. From the measured temperature dependence of the conductance in Al/Pentacene/Co thin film tunnel junctions, different transport mechanisms were observed for pentacene barriers of various thicknesses. Thin, amorphous pentacene films were deposited with and without Al_{2}O_{3} seed layer at room temperature. Significant tunnel magnetoresistance (TMR) was observed at room temperature in junctions with Co and Fe electrodes and pentacene tunnel barrier. These results will be presented and discussed. Research supported by ONR and KIST-MIT programs.

¹Supported by U.S. DOE Office of Science under Contract No. DE-AC02-06CH11357.

1:03PM J33.00010 Is there really spin transport in AlQ3 spin-valves?¹ , J. SAMUEL JIANG, J.E. PEARSON, S.D. BADER, Argonne National Laboratory — There have been reports of GMR and extremely long spin relaxation in AlQ_{3}-based spin valves. However, it has also been suggested that direct tunneling through locally-thin regions of the Alq_{3} layer could be the magnetoresistance (MR) mechanism, i.e. the reported MR may be due to artifacts rather than spin transport via the molecular levels in AlQ_{3}. We present transport measurements on AlQ_{3}-based spin valves and unipolar devices where the Alq_{3} thickness is beyond the tunneling limit. The I-V characteristic is highly asymmetric and strongly temperature-dependent, different from the behaviors of devices where GMR has been reported. The charge transport in the Co/AlQ_{3}/Fe spin valves is by holes only and is injection-limited. More importantly, we observe no measurable MR in our non-tunneling Co/AlQ_{3} /Fe spin valves, or in Co/Al_{2}O_{3}/AlQ_{3}/Fe structures where spins can be injected via the AlQ_{3} barrier. These results indicate that spin transport in AlQ_{3} is unlikely.

¹Supported by U.S. DOE Office of Science under Contract No. DE-AC02-06CH11357.

1:15PM J33.00011 Inelastic tunneling spectroscopy study on organic semiconductor tunnel barriers with magnetic electrodes¹ , K.V. RAMAN, J.H. SHIM, J.S. MOODERA, MIT — Spin injection and transport through organic semiconductor (OS) is recently being researched extensively. Exploring the interfacial structural and chemical modifications in FM/OS/FM tunnel junctions can lead to a better understanding of spin injection and transport in OS. Inelastic tunneling spectroscopy (IETS), a high sensitivity technique, measures the vibrational and excitational modes of the molecules within a tunnel barrier, which are greatly influenced by any distortions in the molecules. These measurements are performed on thin films of OS, rubrene and pentacene, using Co/seed/OS/Pt and Al/seed/OS/Al junctions, all grown in-situ, for two different seed layers viz. AlQ_{3} and LIF. The IETS spectra matches well with the reported Raman and IR spectroscopy measurements performed for powder and bulk single crystal samples. In addition, the IETS spectra show weak signatures of the molecular distortions through modification of certain phonon peaks. Due to the amorphous nature of the films certain electronic states are also observed at higher bias voltages. The effect of vibrational modes on the spin conserved tunneling and the effect of different electrodes on the IETS spectra will also be presented and discussed.

¹Research supported by ONR and KIST-MIT programs.
1:27PM J33.00012 Spin transport studies through spin filter and organic semiconductor hybrid tunnel barriers. DEUNGJANG CHOI, Ewha University, TIFFANY SANTOS, Argonne National Lab, TAE HEE KIM, Ewha University, JAGADEESH MOODERA, Francis Bitter Magnet Lab, MIT — Spin polarized tunneling through a hybrid tunnel barrier of spin filter EuO magnetic semiconductor and an organic semiconductor Rubrene was investigated. With magnetic tunnel junction structures such as Co/Rubrene/EuO/Al or Cu we observed a magnetoresistance (MR) of up to 8.5%, whereas from the junction resistance versus temperature data, we deduced the capability to produce spin polarization (P) of up to 99%. Thus the observed low MR has been attributed to spin scattering by defects at various EuO and Rubrene interfaces and possible nonstoichiometry in EuO. With further optimization it should be possible to reach towards the expected large MR in such systems. Moreover, Rubrene which has a low barrier height also serves to magnetically decouple the ferromagnetic electrode from EuO, necessary for independent magnetic switching and reaching high MR. This study demonstrates the possibility of combining organic and spin filter materials as tunnel barriers.

1:39PM J33.00013 Quantitative analysis of molecular spintronics. ZHANYU NING, YU ZHU, JIAN WANG, HONG GUO, McGill University, HONG GUO TEAM, JIAN WANG TEAM — We report quantitative analysis of nonequilibrium spin injection from Ni contacts to octanethiol molecular spintronic system. Our calculation is based on carrying out density functional theory within the Keldysh nonequilibrium Green’s function formalism. The first principles results allow us to establish a clear physical picture on how spins are injected from the Ni contacts through the Ni-molecule linkage to the molecule, why tunnel magneto-resistance is rapidly reduced by the applied bias in an asymmetric manner, and to what extent ab initio transport theory can make quantitative comparisons to the corresponding experimental data. We found that extremely careful sampling of the two-dimensional Brillouin zone of Ni surface is crucial for accurate results.

1:51PM J33.00014 Hall conductivity and colossal magnetoresistance in FeSb2. RONGWEI HU, Condensed Matter Physics, Brookhaven National Laboratory, VESNA MITROVIC, Physics Department, Brown University, CEDOMIR PETROVIC, Condensed Matter Physics, Brookhaven National Laboratory — We report the anisotropic Hall conductivity and discuss mechanism of colossal magnetoresistance in Co doped FeSb2. The Hall conductivity is described in a multi-carrier picture, in which large carrier mobility was found in Co doped FeSb2.

2:03PM J33.00015 Electric field induced metal-insulator transition and colossal magnetoresistance in CdCr2S4. C.P. SUN, C.C. LIN, J.L. HER, S. TARAN, C.C. CHOU, C.L. CHAN, C.L. HUANG, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung 804, Taiwan — Multiferroic ordering existing in a single material is a recent hot topic in the field of condensed matter physics due to its potential application in device control. The chromium chalcogenide spinel CdCr2S4 is one of the attractive materials investigated by Hemberger et al. recently. Based on the electrical measurement, there is no discontinuity through the ferromagnetic ordering at TC ∼ 85K. [2] We measure the temperature dependent resistance under various electric fields to investigate the electrical properties of the present material. To our knowledge, we first observe the electric field induced metal-insulator transition in this material around TC. Moreover, a colossal magnetoresistance (CMR), which is comparable to that of manganese-based CMR material, is also observed near TC. The origin for these properties is discussed. [1] J. Hemberger, P. Lunkenheimer, R. Fichtl, H.-A. Krug von Nidda, V. Tsurkan, A. Loidl, Nature 434, 364 (2006). [2] P. K. Baltzer, H. W. Lehmann, and M. Robbins, Phys. Rev. Lett. 15, 493 (1965).
12:03PM J35.00003 Fullerene microcrystals under pressure¹, MURILO L. TIAGO, FERNANDO A. REBOREDO, Oak Ridge National Laboratory — Solid buckminsterfullerene ($C_{60}$) is known to be very soft, with a large number of crystalline phases that can be accessed by temperaturer or pressure. External pressure reduces the intermolecular distance, which affects the electronic structure in three ways: by increasing the overlap between molecular orbitals on neighbor molecules, by inducing additional chemical bonds between molecules, and by deforming the molecular structure. Having an exciton gap that is sensitive to pressure suggests that $C_{60}$ can be used as active element in an optical pressure gauge: a device that can detect pressure dynamically by measuring the emission from the ground state of the molecule. Spectroscopic single molecule studies provide insights into the many-body theory. We calculate the optical gap of solid $C_{60}$ and its pressure dependence. We also analyze the dependence of optical gap with deformations in the molecule. Our calculations are based on solving the Bethe-Salpeter for electron-hole excitations. The electron self-energy is calculated within the GW approximation. We use pseudopotential density-functional theory to determine the electronic structure of $C_{60}$ in its ground state.

¹Research supported by the Division of Materials Sciences and Engineering BES, U.S. DOE under grant ERKCS77.

12:15PM J35.00004 Nanowire waveguide made of extremely anisotropic metamaterials¹, Y.J. HUANG, W.T. LU, S. SRIDHAR, Department of Physics and Electronic Materials Research Institute, Northeastern University, Boston, MA 02115 — We consider wave propagation along a cylindrical fiber with anisotropic optical property. Exact solutions are obtained for all the modes. For extremely anisotropic cylinder where the transverse permittivity is positive, only transverse magnetic and hybrid modes will propagate on the waveguide. At a given frequency the waveguide support infinite number of eigenmodes. For the TM modes, there exists at most one forward wave. The rest of them are backward waves. These waveguides can be used as filter and phase shifter in integrated optical circuits.

12:27PM J35.00005 Doping Poly(p-phenylene vinylene) with Phosphomolybdate through Layer-by-Layer Fabrication for Optoelectronic Applications, CHRISS NELSON, BIN WANG, Lamar University — Poly(p-phenylene vinylene) (PPV) multilayers have been prepared from its cationic precursor via the layer-by-layer deposition. The photoluminescence (PL) and film thickness of the multilayers have been measured via fluorimetry and atomic force microscopy. The PL of the multilayers has been observed that is consistent with the literature results. When phosphomolybdate PMo12 is incorporated into the multilayer structure, PL quenching is detected that is proportional to the amount of PMo12 used. The quenching is interpreted as exciton diffusion through the polymer multilayers, followed by exciton dissociation at the polymer/PMo12 interface. We show that the modeling used for calculating the PL intensities derived from inorganic semiconductors is also applicable to conjugated polymers. According to the model, an exciton diffusion length is found to be 11.5±0.4 nm.

12:39PM J35.00006 Scattering studies of stacked polymer/liquid crystal composites, SAMEET SHRIYAN, KASHMA RAI, ADAM FONTECHIO, Drexel University — In this work we investigate light scattering from stacked polymer/liquid crystal composite films on several different substrates. Effect of different substrates such as glass, PET and PMMA coated with conductive layers such as Indium-Tin-Oxide (ITO) and PEDOT:PSS conducting polymer are analyzed using scattering and wavefront measurements. Scattering of light in both transmission and reflection mode is measured as a function of angle and its effect using different substrate layers coated with different conducting layers is analyzed. Shack Hartmann wavefront sensor is used to characterize the effect of various substrate and conducting layers on the transmitted wavefront quality in both transmission and reflection mode. Optimal stack length at which the scattering and wavefront degradations are at acceptable levels is derived from the scattering and wavefront measurements. Spectrometry results show notch formations at different wavelength and the effect on transmitted baseline reduction due to scattering using different substrates. SEM imaging shows the effect of different substrates and conducting layers on the formation and quality of gratings along with the LC droplet size which contributes to scattering. Optical path and stack length reduction of up to 45% for a stack of 10 layers is confirmed.

12:51PM J35.00007 Broadband Wavelength Spanning Holographic Polymer Dispersed Liquid Crystals, KASHMA RAI, SAMEET SHRIYAN, ADAM FONTECHIO, Drexel University — Broadened interaction wavelength of holographic polymer dispersed liquid crystals (HPDLCs) have extensive applications in beam steering for instrument clusters, hyperspectral imaging, wavelength filtering and construction of lightweight optics. A novel simultaneous time and spatial multiplexing formation configuration is proposed here, to increase narrow wavelength reflecting notch to broad range wavelength spanning device. HPDLC films have electro-optic controllability by applying field. No moving parts, light weight, small footprint compared to prisms and lenses, high color purity make the broadband wavelength HPDLCs desirable for the above applications. Varying the incident laser beam exposure angles using motorized rotating stage, during formation is the key step here for their formation in a single medium. The fabricated broadband wavelength sensitive HPDLCs are characterized for the uniformity of the reflected peak and electro optic response. Their output wavelength is analyzed using wavefront analysis technique.

1:03PM J35.00008 1.54 µm emitters based on monolithic integration of Er doped GaN with nitride emitters, RAJENDRA DAHAL, CRIS UGOLINI, ASHOK SEDHAIN, JINGYU LIN, HONGXING JIANG, Kansas State University, JOHN ZAVADA, US Army Research Office, North Carolina — Er doped III-nitride semiconductors have emerged as very promising materials for applications in photonics devices due to their novel optical and physical properties. Optoelectronic and photonic devices based on Er doped GaN are expected to meet the demand for next generation telecommunication devices due to efficient and temperature stable 1.54 µm emission from Er doped GaN. We report here on the successful fabrication of a chip size current injected 1.54 µm emitters based on monolithic integration of Er doped GaN epilayers with 365 nm nitride light-emitting diodes (LEDs). Er doped GaN and In$_{0.16}$Ga$_{0.84}$N epiayers were grown on sapphire substrates by metal organic chemical vapor deposition (MOCVD). The photoluminescence excitation (PLE) and absorption spectra of these epiayers were investigated to understand the 1.54 µm emission mechanism. A strong correlation between PLE and absorption spectra near the energy bandgap of host nitride epiayers suggest that band to band absorption and subsequent energy transfer to Er ion for 1.54 µm emission is a much more effective excitation mechanism compared to the direct absorption by Er ion. The success opens the possibility for next generation IR integrated photonic devices such as emitters, detectors, and optical amplifiers.

1:15PM J35.00009 Synthesis of Metal Silicides by Low Energy Ion Implantation, PRAKASH POUDEL, LEE MITCHELL, JIANYOU LI, BRIAN GORMAN, ARUP NEOGI, BIBHUDUTTA ROUT, JEROME DUGGAN, FLOYD MCDANIEL, University of North Texas — A 59keV Osmium beam was used to implant (5x10$^{16}$ atoms/cm$^2$) into p-type-Si (100). The implantation was performed with the ion source of a National Electrostatic Corp. 3 MV Tandem accelerator. The implanted sample was annealed at 650 °C in a gas mixture that was 4% H$_2$ – 96% Ar. Measurements showed that the samples contained a mixture of continuous polycrystalline osmium disilicide and a silicide layer. Rutherford Backscattering Analysis with 1.5 MeV Alpha particles was used to monitor the precipitate formation. Photoluminescence measurements were also performed to study possible applications of silicides in light emission.
1:27PM J35.00010 Sb-doped p-type ZnO and its application on light emitting devices1. SHENG CHU, LEELAPRASANNA J. LEELA, ZHENG YANG, JAE HONG LIM, LIN LI, JIANLIN LIU — Reliable Sb-doped p-type ZnO on silicon substrate was grown by molecular beam epitaxy. The hole concentrations up to \(10^{12}/\text{cm}^3\) were achieved by tuning the Sb cell temperature. The results from XPS and photoluminescence spectrum confirmed the theoretical prediction that the Sb doping mechanism in ZnO is the formation of complex shallow acceptor \(\mathrm{Sb}_{2n}+2\mathrm{Zn}_n\), with a low ionization energy of about 150meV. Then ZnO p-n homojunction light emitting diodes (LED) were fabricated based on the p-type Sb-doped layer, and the Ga-doped n-type ZnO layer. Low specific resistivity Au/NiO and Au/Ti contacts were deposited on top of the p-type and n-type layers, respectively, and the contacts were annealed to obtain ohmic conduction. Electroluminescence measurements were performed on the devices under different temperatures and injection currents. Strong near-band edge emissions were clearly observed at room and low temperatures. The device exhibited dominant UV peak at 3.31eV over the deep level emissions at 9K, which is the result from the large build in potential in the junction and the good film quality.

1Thanks the grant from CNID through DARPA and DMEA.

1:39PM J35.00011 2.4 \(\mu\)m GaInAsSb Mesa Photodiode Detectors: Leakage Currents and Ultimate Performance , JOHN PRINEAS, JEFF YAGER, Dept. Physics and Astronomy, University of Iowa, JON OLESBERG, Optical Science and Technology Center, University of Iowa, SHAHRAHM SEYDMOHAMADI, Dept. Physics and Astronomy, University of Iowa — Short-wave infrared photodiodes play an important role in areas such as molecular sensing, thermophotovoltaics, and astronomical study of galaxy, star, and planetary formation. Here we present results and analysis of uncoated, unpassivated, GaInAsSb mesa photodiodes. We have currently achieved room temperature peak specific detectivity \(D^*\approx6\times10^{10}\) Jones, dynamic resistance of 25 \(\Omega\)-cm\(^2\), and quantum efficiency of 50%. Devices are limited primarily by sidewall leakage currents, initially due to generation-recombination, and over time due to Ohmic leakage from buildup of sidewall oxides. Based on material parameters obtained in this as well as other studies, ultimate diode performance is predicted, and compared to extended-wave InGaAs/InP and HgCdTe detectors.

1:51PM J35.00012 Optically Active Erbium with Co-dopants in Silicon , S. ABEDRABBO, A. HADDAD, K. ALBATH, Q. YOUNIS, University of Jordan, A.T. FIORY, N.M. RAVIDRA, New Jersey Institute of Technology — Erbium impurity centers in silicon with strong optical emission properties in the near-Infrared are being sought for efficient silicon-based light sources because of the inherent advantages of integrating silicon photonics with VLSI technology. This work reports investigations of adding proper co-dopants to erbium in silicon through a cost-effective combination of techniques, comprising physical vapor co-deposition, implantation doping, ion beam mixing, and thermal annealing. Processed samples are characterized optically by photoluminescence and structurally by Rutherford backscattering.

2:03PM J35.00013 Characteristics of a Cr\(^{4+}\)-doped glass-ceramic; a new material for photonic devices , L.L. ISAACS, The City College of New York and the Graduate School of The City University of New York, New York, NY 10031, A.B. BYKOV, V. PETRICEVIC, I. POPOV, M. YU. SHARONOV, J. STEINER — The compound \(1.0(\text{Cr-doped } \text{Ca}_2\text{GeO}_4)-1.0(\text{Li}_2\text{O})-0.2(\text{Al}_2\text{O}_3)-0.5(\text{Bi}_2\text{O}_3)\), on quenching from the melt and subsequent heat treatment, yields a transparent glass-ceramic. The nanocrystallites formed by the ceramming procedure are distributed homogeneously in the bulk. Differential scanning calorimetry was used to determine the glass to crystal transformation temperature, \(T_g\), and its dependence on heating rate. The activation energy for the glass to crystallite nucleation is 62kJ/mol. The calculated Avrami exponent is 1, in agreement with scanning electron microscopy observations. X-ray diffraction data indicates that the structure of the nanocrystallites is that of distorted Cunyite (\(\text{Ca}_2\text{GeO}_4\)). Electron microscopy indicates that the crystallite sizes are less than \(1\mu\)m. The growth mode of the crystallites is “needle” like. The material exhibits broadband emission between 1050 to 1600 nm, with a maximum at \(\sim1260\) nm. The spectroscopic and optical properties indicate, that this material is a promising candidate for use in microelectronics, micro lasers and as fiber optic transmission lines.

Tuesday, March 11, 2008 11:15AM - 2:03PM — Session J36 DMP: Focus Session: Materials for Photovoltaics and Photocatalysis I — Morial Convention Center 228

11:15AM J36.00001 Polycrystalline TiO\(_2\) films with silver nanoclusters for photocatalysis . FRANK WOMACK, FEI WANG, ASOKA SEKHARAN, PHILLIP SPRUNGER, RICHARD KURTZ, Department of Physics and Astronomy, Louisiana State University — Metallic Ag nanoclusters nucleate on TiO\(_2\)(110) due to weak substrate interactions and the need to minimize their surface free energy. EELS results on single crystal TiO\(_2\) have shown that those nanoclusters have a distinct plasmon resonance at 3.7 eV which can be red-shifted when incorporated within a dielectric of titania. Polycrystalline oxides consist of mostly low surface free-energy faces and nanoclusters are expected to nucleate when dosed with Ag. We will present a combined synchrotron-based photoemission, Auger, and optical spectroscopy study of polycrystalline TiO\(_2\) films functionalized with Ag. We have made thin films of TiO\(_2\) by thermal evaporation of titanium followed by oxidation at elevated temperatures. Ag was then deposited via thermal evaporation of silver, and covered with additional layers of Ti that were subsequently oxidized and characterized with photoelectron and optical spectroscopies. We will discuss these data in the context of nanocluster formation vs bandgap doping.

11:27AM J36.00002 Buried silver nanoclusters on TiO\(_2\)(110) for photocatalysis . FEI WANG, FRANK WOMACK, ASOKA SEKHARAN, Department of Physics and Astronomy, Louisiana State University, BRENDAN WASTON, PHILLIP SPRUNGER, RICHARD KURTZ, Department of Physics and Astronomy, Louisiana State University, LSU CAMD COLLABORATION — Ag nanoclusters grown on TiO\(_2\)(110) can promote photochemistry by enhancing photoabsorption via their plasmon resonances. Overcoating the Ag clusters with a thin layer of titania red-shifts the plasmon to better match the solar spectrum and protects the nanoclusters from the environment. Our STM studies show that Ag clusters \(~5nm\) across and \(2nm\) high nucleate on the TiO\(_2\)(110) surface at room temperature. Photoemission performed at the LSU CAMD synchrotron shows that the clusters interact weakly with the substrate, although there is charge transfer from surface defects to the first nanoclusters that nucleate. EELS shows that the bare clusters exhibit a plasmon resonance located at 3.8 eV. Ti overgrowth and subsequent oxidation gives rise to new losses at about 1.5eV as observed in EELS. We will discuss our work at incorporating the nanoclusters within the titania matrix in light of their potential for producing hot electron-hole pairs for surface chemistry.
11:39AM  J36.00003  Epitaxial In$_2$O$_3$ and Sn-doped In$_2$O$_3$ thin films with (100) and (111) orientation$^1$, ERIE MORALES, Tulane University, MATTHIAS BATZILL, University of South Florida, ULRIKE DIEBOLD, Tulane University — In$_2$O$_3$ and Sn-doped In$_2$O$_3$ (Indium-Tin Oxide, ITO) have optical transparency and low electrical resistivity. Relatively little is known about their atomic-scale surface properties because of challenges in preparing single crystal samples. We have grown epitaxial In$_2$O$_3$ and ITO films on Yttrium Stabilized Zirconia. The (100) surface has polar character and the (111) orientation is non-polar. Films were prepared using oxygen-plasma assisted e-beam epitaxy under UHV conditions and the growth was monitored by RHEED. In-situ characterization with XPS, ARXPS, LEED and synchrotron-based UPS was used. In$_2$O$_3$ (100) facets while ITO(100) stays with a 1x1 termination and Sn segregates to surface. In$_2$O$_3$ and ITO (111) exhibit a 1x1 termination. On both orientations valence band maximum is 2.7 eV below the Fermi level. For the ITO films resonant photoemission measurements indicate a Sn-derived band gap state.

$^1$ NSF # CHE 0715576, CHE 010908

11:51AM  J36.00004  Epitaxial growth of In2O3(100) on Y-stabilised ZrO2(100) by O-plasma assisted molecular beam epitaxy: a study by HRTEM and XPS. ANNE BOURLANGE, DAVID PAYNE, RUSSELL EGDELL, JOHN FOORD, Dept. Chemistry, University of Oxford, OX1 3TA, PETER DOBSON, Begbroke Science park, University of Oxford OX5 1PF. JOHN HUTCHISON, Dept. Materials, University of Oxford OX1 3PH — Thin films of In2O3 have been grown on Y-stabilized ZrO2(100) by radiofrequency oxygen plasma assisted molecular beam epitaxy with a substrate temperature of 650 °C. Ordered epitaxial growth was confirmed by HRTEM and selected area electron diffraction taken across the interface between the substrate and the epilayer. Excellent crystalline order was preserved up to the surface of the films. The valence band onset in the X-ray photoemission spectra of the epitaxial films was found at 2.90 eV relative to the Fermi energy. The discrepancy between this value and the widely quoted value of 3.75 eV for the bandgap will be discussed in relation to recent theoretical work [1].

12:03PM  J36.00005  Radiation-induced defect formation and reactivity of model TiO2 capping layers with MMA: a comparison with Ru$^1$, THEODORE E. MADEY, BORIS V. YAKSHINSKIY, M. NEJIB HEDHILI, Physics Dept., Rutgers University, MANISH CHANDHOK, Intel Corp. — Our goal is to provide insights into surface processes that affect the reflectivity of TiO2- and Ru-capped multilayer mirrors used in EUV lithography by 13.5 nm (92 eV) photons. EUV-generated secondary electrons from the substrates cause surface reactions that lead to mirror contamination in background vacuum. In our experiments, low-energy electron beams mimic excitations initiated by EUV radiation. Oxygen vacancies are produced at energies above 25 eV. Carbon accumulation is measured on both Ru and TiO2 surfaces during 20 eV and 100 eV electron bombardment in methyl methacrylate vapor (MMA). The initial rates on the clean surfaces are very different: a C film grows more rapidly on TiO2 than on Ru. However, the limiting growth rates are the same for C thicknesses greater than ~1 to 1.5 nm, when MMA interacts with a C film. Irradiation of the C films in O2 gas has a mitigating effect.

$^1$Supported by Intel

12:15PM  J36.00006  In-situ vacuum studies of photocatalytic oxidation of isopropanol on nanometer thick TiO2 films grown on silicon , D. KAZAZIS, Brown Univ, Providence, RI, S. GUHA$^1$, N.A. BOJARCZUK, IBM T.J. Watson Research Center, Yorktown Heights, NY, H.-C. KIM, IBM Almaden Research Center, San Jose, CA, A. ZASLAVSKY, Brown Univ, Providence, RI — We report on measurements of the photocatalytic activity of ultra-thin TiO2 films grown on n and p type Si wafers. Using the oxidation of isopropanol to acetone as a model reaction, photocatalytic studies were carried out in-situ, in a high vacuum chamber equipped with leak valves for injecting isopropanol, oxygen and water vapor onto the TiO2 sample. The sample was irradiated through a quartz window with a UV strobe light source. The reaction was monitored with a line-of-sight mass spectrometer coupled to a lock-in amplifier tuned to the strobe frequency. We find that the photocatalytic efficiency is enhanced as the TiO2 thickness is reduced from 50nm to 2nm. We also find that the efficiency is enhanced by lowering the substrate Fermi level in going from n type to p type Si. The results strongly point to the hypothesis that only near surface electron-hole pair generation is relevant to the photocatalytic process; and that the reaction rate can be controlled by varying the substrate Fermi level which in turn changes the electrostatic potential variation within the heterostucture.

12:27PM  J36.00007  Generation of Organic Radicals During Photocatalysis on TiO2$^1$, MICHAEL HENDERSON, Pacific Northwest National Laboratory — It is well-known that water-related radicals (such as OH$^·$ species) are produced by charge transfer events at UV-irradiated TiO2 surfaces. In contrast, organic radicals are generally viewed as being formed by reactions with OH$^·$ groups and not by direct charge transfer events. Using rutile TiO2(110) as a model photocatalyst, we show that organic radicals are generated in single-step charge transfer events during photodecomposition of adsorbed carboxylates and ketones. Some organic radicals (e.g., methyl) are ejected from the surface and, in high surface area catalysts, experience reactions away from the surface of origin. Other radicals (e.g., ethyl and t-butyl) have limited ability to escape the surface of origin without capture and subsequent thermal reactions. Understanding the chemistry associated with organic radical formation on TiO2 opens the door for more detailed examinations of charge transfer dynamics and energy redistribution during photon-initiated reactions important to heterogeneous photocatalysis.

1:03PM  J36.00008  Photocatalytic reaction of catechol on rutile titanium oxide , PETER JACOBSON, CHUNDAO WANG, ULRIKE DIEBOLD, Tulane University — In an attempt to understand the fundamental aspects of photocatalysis we have studied the substituted benzene catechol on TiO2(110). Previous studies have given detailed information about the catechol bonding configuration letting our group focus on molecular level interactions with scanning tunneling microscopy and X ray photoelectron spectroscopy. Under UV exposure (248 nm) in an oxygen background, catechol is observed to degrade via oxidation. This oxidation process results in removal of roughly 10% of the initial monolayer. The removal of carbon from the TiO2 surface is shown to depend upon the background gas. Formation of a residual carbon layer is achieved by annealing the catechol monolayer to 600°C. This carbon layer is more difficult to remove by photocatalytic oxidation than a pristine catechol monolayer. Work supported by Intel Corporation.
1:15PM J36.00009 Water on anatase TiO2(101): a scanning tunneling microscopy study . Y.B. HE, O. DULUB, L.H. YING, U. DIEBOLD, Tulane University, C. DI VALENTIN, Universita degli Studi di Milano-Bicocca, Italy, A. TILOCCA, University College London, UK, A. SELLONI, Princeton University — The discovery of photochemical water splitting on TiO2 has motivated numerous studies of water on the surfaces of this important photocatalytic material. Previous temperature-programmed desorption and X-ray photoelectron spectroscopy studies of water on anatase TiO2(101), the most stable surface of the photocatalytically efficient anatase form, have revealed that water adsorbs molecularly on the surface in accordance with theoretical predictions. In the present study, we have employed low-temperature scanning tunneling microscopy to study water adsorption on anatase TiO2(101). We dose various amounts of water (0.2-1.8 Langmuir) at sample temperature T~130 K. Besides confirming that water favors molecular adsorption, atomically resolved STM images further reveal that water molecules adsorb at Ti5c sites forming preferentially one-dimensional chains with local doubling of the periodicity along the [010] direction. Near room temperature, the water molecules become mobile and hop between the Ti5c sites. Density Functional Theory calculations are underway to clarify the origin of the observed doubling of periodicity.

1:27PM J36.00010 Chemical Deposition and Photoactivity of Anatase and Rutile TiO2 Films on Si(111) . JOHN F. ANDERSON, University of Louisiana at Monroe, ERIE MORALES, ULRIKIE DIEBOLD, Tulane University — Dilute Aqueous Chemical Bath Deposition (CBD) from highly acidic (pH < 1) TiCl3 HCI solutions at room temperature and slightly higher (23°C – 40°C) produced thin titanium dioxide films on clean Si(111). We report initial results of X-ray Photoelectron Spectroscopy (XPS), Scanning Electron Microscopy (SEM), and X-ray Diffraction (XRD) measurements. The films thicknesses varied from 300 nm to ~ 1μm. It was found that the films required annealing to ensure adherence to the Si(111) substrate. XRD showed that the anatase and rutile structures were present in the TiO2 as a function of post-deposition annealing temperature. Additionally, photo decomposition results of methyl orange and methyl blue on TiO2/Si(111) system under UV light is observed and reported.

1:39PM J36.00011 Photoinduced Desorption of O2 and Photooxidation of Organics from TiO2(110) Surfaces . DAVID SPORLEDER, DANIEL WILSON, Stony Brook University, MICHAEL WHITE, Brookhaven National Lab and Stony Brook University — We present here, a study of photoinduced O2 desorption from, and reaction with coadsorbates on, a single crystal rutile TiO2(110) surface. Translational energy distributions of O2 desorbed with a photon excitation energy between 3.5 and 4.2 eV were measured using a pump-probe, time-of-flight (TOF) method. This method utilized a one-photon VUV ionization scheme for product detection that was developed in our lab. The translational energy distribution was found to be trimodal, indicating that different O2 species (i.e. O2 or O2−) or binding sites may play a role. It was found that the O2 translational energy distributions did not depend on the excitation energy over the range studied, which is consistent with a substrate mediated excitation mechanism involving hole capture. More recent experiments are exploring the mechanism for photooxidation of organic molecules. Specifically, we are determining translational energy distributions of small radicals originating from photoinduced fragmentation of simple ketones on a TiO2(110) surface.

1:51PM J36.00012 Influence of the Sensitizer Protonation and Adsorption Mode on the Efficiency of Dye-sensitized solar cells . ANNABELLA SELLONI, Princeton University, FILIPPO DE ANGELIS, SIMONA FANTACCI, Universita’ di Perugia, Italy, MOAMMHD NAZERUDDIN, MICHAEL GRAETZEL, Swiss Federal Institute of Technology, Lausanne, Switzerland — Dye sensitized solar cells (DSSCs) represent a promising approach to the direct conversion of light into electrical energy at low cost and with high efficiency. In these devices, a dye sensitizer absorbs the solar radiation and transfers the photoexcited electron to a nanostructured TiO2 electrode. We have studied the electronic structure of different Ru(II)-polypyridyl dyes adsorbed onto a model TiO2 nanoparticle by means of first principles Density Functional Theory calculations. Our results suggest that two different electron injection mechanisms (adiabatic and non-adiabatic) may be present in DSSCs employing dyes carrying a different number of protons. We also found that sensitizers with inequivalent pyridine ligands exert strong dipolar fields at the TiO2 surface, causing a conduction band down-shift and a reduction of the cell open circuit potential, thus resulting in a reduced DSSC efficiency.

Tuesday, March 11, 2008 11:15AM - 2:15PM Session J37 FIAP: QHE: Bilayers and Graphene Morial Convention Center 229

11:15AM J37.00001 Thin cylinder limit of Halperin bilayer quantum Hall states . ALEXANDER SEIDEL, Washington University in St. Louis, KUN YANG, National High Magnetic Field Laboratory, Florida State University — The traditional framework to study fractional quantum Hall states is based on Laughlin type wavefunctions and Chen-Simons field theories. Recently, a new framework has been proposed that puts stronger emphasis on the one-dimensional (1d) Hilbert space structure of Landau levels. One way to obtain this framework is by observing that states describing fractional quantum Hall liquids may be adiabatically evolved into simple one-dimensional charge-density-wave (CDW) patterns when the system is deformed, e.g., into a thin torus or cylinder. Many general properties of fractional quantum Hall systems are rooted in these CDW states, such as degeneracies and phase diagrams. In this talk, the thin cylinder limit of Halperin (m,m',n) bilayer quantum Hall states will be discussed. The corresponding CDW patterns are quite complicated for general (m,m',n), and can be worked out from a discrete version of the plasma analogy in a "squeezed space". The simpler cases map onto well-known spin-1/2 physics. This has some implications for a possible phase transition of the (331) state into the Moore-Read state.

11:27AM J37.00002 Metamorphism of quantum Hall bilayer state into a composite fermion metal . B. KARMAKAR, V. PELLEGRINI, NEST and Scuola Normale Superiore, Italy, A. PINCZUK, Columbia University, NY, L.N. PFEIFFER, K.W. WEST, Bell labs, Alcatel-Lucent NJ — In the regime of strong interlayer correlation and tunneling gap ∆_{SAS}>0, the quantum Hall (QH) ground state of bilayers at filling fraction νf=1 can be viewed as an excitonic insulator [1]. Here it will be shown that a phase transition occurs between this excitonic state and a composite-fermion metal state as ∆_{SAS} decreases [2,3]. The observations are based on inelastic light scattering of spin-wave (SW) mode at the Zeeman energy and spin-flip (SF) mode across ∆_{SAS}. These experiments show that the SF mode excitation collapses to the SW and disappears at a critical value of ∆_{SAS} while a low energy continuum of spin transitions below the SW mode appear. These transitions are interpreted as spin-flip SF excitations of the CF metal in which orientation of spin and CF Landau level index change simultaneously. Measurements of SW excitations at ∆_{SAS} will be also shown [4]. The behavior of the SW thermal activation gap as a function of the Zeeman energy suggests a subtle competition between interlayer correlation and spin effects in the broken-symmetry QH state at ∆_{SAS}≈0. [1] S. Luin, et al., PRL. 94, 146804 (2005); [2] S. Luin, et al., PRL. 97, 216802 (2006); [3] B. Karmarkar, et al., Solid State Comm. 143, 504 (2007); [4] B. Karmarkar, et al., work in progress.

11:39AM J37.00003 Evidence for a finite temperature phase transition in a bilayer quantum Hall system . A.R. CHAMPAGNE, J.P. EISENSTEIN, Caltech, L.N. PFEIFFER, K.W. WEST, Bell Labs — We study the Josephson-like interlayer tunneling signature of the quantum Hall bilayer excitonic state at total filling factor νf = 1 as a function of the layer separation, interlayer charge imbalance and temperature. The tunneling amplitude collapses to zero as either the temperature or interlayer spacing is increased. The interlayer tunneling amplitude dependences on the layer spacing at various temperatures are very similar, but the layer separations where the tunneling disappears scale linearly with temperature. Our results offer evidence [1] that a finite temperature phase transition separates the interlayer coherent phase from incoherent phases which lack strong interlayer correlations. The phase boundary is found to be re-entrant as a function of charge imbalance thus suggesting an intricate competition between the interlayer coherent phase and various independent layer states. This work was supported by the NSF and the DOE. [1] A.R. Champagne, J.P. Eisenstein, L.N. Pfeiffer, K.W. West, Cond-mat/0709.0718
is associated with the degeneracy of nearly degenerate Landau levels at the Dirac point compared to the four nearly degenerate levels which occur in an isolated layer. The additional degeneracy with a phonon mediated interlayer momentum transfer mechanism. Resonances are observed when the frequency of fields smaller than 1T. In addition to an unusual overall field dependence, we have discovered a series of oscillations in the drag resistivity which are periodic with the system in the quantum Hall state. We analyze the transport properties of bilayer Hall systems at total filling factor \( \nu = 1 \) in drag geometries as a function of interlayer bias, in the limit where the drag is sufficiently strong to form a transverse quantum Hall ferromagnet. We use a bosonic Chern-Simons model to describe the drag and drive layers, in qualitative agreement with experiment. We conclude with predictions for future experiments.

1US NSF under Grant Nos. MRSEC DMR-0800854, EPS-0720651 and DMR-0740433

12:15PM J37.00006 Non-perturbative approach to the quantum Hall bilayer. MILICA MILOVANOVIC, ZLATKO PAPIC, Institute of Physics, Belgrade — We study the disordering of the superfluid phase in the quantum Hall bilayer at the filling factor one with increasing distance between the layers. We find that the possibilities for ground state wave functions that describe the superfluid at an arbitrary distance fall into two universality classes. They correspond to (1) Berezinskii-Kosterlitz-Thouless (BKT) (2D XY) model of superfluid disordering in the presence of charged impurities and (2) \( \lambda \) transition (3D XY) model in a transverse invariant quantum Hall bilayer system. The BKT type of disordering likely ends with unbinding of charged pairs of neutral fermionic vortices (in a transition reminiscent of the one reported in Champagne et al.). In the transverse invariant system the ensuing quantum phase transition proceeds via condensation of loops of elementary charged vortices - merons into a topological phase associated with the toric code model.

12:27PM J37.00007 Phonon mediated resonances in bilayer magnetodrag. GOKUL GOPALAKRISHNAN, SANGHUN AN, DONGKYUN KO, YUKO SHIROYANAGI, THOMAS GRAMILA, The Ohio State University, Physics Dept., LOREN PFEIFFER, KEN WEST, Bell Labs, Lucent Technologies — The properties of the 2-dimensional electron gas (2DEG) have been studied extensively in the integer and fractional quantum Hall regimes. Much less is understood about the 2DEG at intermediate fields, where thermal fluctuations are comparable to the size of the Landau-level spacing. We have explored the electronic bilayer system with a magnetic field of up to 1T and 1.5K in fields smaller than 1T. In addition to an unusual overall field dependence, we have discovered a series of oscillations in the drag resistivity which are periodic in 1/8, but are distinct from variations in the density of states, as seen in Shubnikov-de Haas oscillations. These novel magnetodrag oscillations are consistent with a phonon mediated interlayer momentum transfer mechanism. Resonances are observed when the frequency of 2kF phonons matches an integer multiple of the cyclotron frequency, and they are suppressed as the densities of the two layers are mismatched.

12:39PM J37.00008 Unusual quantum Hall Ferromagnetism in Bilayer Graphene. BARLAS YAFIS, University of Texas at Austin, RENE COTE, Universite de Sherbrooke, ALLAN MACDONALD, University of Texas at Austin — Bilayer graphene has eight nearly degenerate Landau levels at the Dirac point compared to the four nearly degenerate levels which occur in an isolated layer. The additional degeneracy is associated with the degeneracy of \( n = 0 \) and \( n = 1 \) orbital Landau level states in the bilayer case and adds a Landau level pseudospin degree of freedom to the spin and valley pseudospins present in the single layer case. We predict broken symmetry states which lift the associated degeneracies with a Hunds rule which orders spin first, then valley, and finally the Landau-level pseudospin. It follows that a Landau level pseudospin orders at all odd total filling factors. We find unusual collective modes which are not gapped even though the system has uniaxial anisotropy, and a \( g^{1/2} \) dispersion at small \( g \) because the divergence of the pseudospin magnetization produces charges with long-range Coulomb interactions. Because of the charge carried by these collective modes, they are dipole active. We predict unusual intra-Landau-level contributions to the cyclotron resonance signal. We will also discuss unusual properties of the Skyrmions spin-textures of these quantum Hall ferromagnets.

12:51PM J37.00009 Symmetry Broken States of Dirac Fermions in Graphene with A Partially Filled High Landau Level. HAO WANG, D.N. SHENG, Department of Physics and Astronomy, California State University Northridge, F.D.M. HALDANE, Department of Physics, Princeton University — We report on numerical study of symmetry broken states of the Dirac electrons in partially filled N=3 Landau level (LL) in graphene. At half-filling, the static density-density correlation function displays sharp peaks at nonzero wavevector. Finite-size scaling shows that the peak value grows with electron number and diverges in the thermodynamic limit, indicating an instability toward a charge density wave. A weak disorder potential plays the role of selecting a symmetry broken stripe phase as the ground state from the nearly degenerated low-energy manifold. Such a quantum phase is experimentally observable through transport measurements. Associated with the special wavefunctions of the Dirac LL, both stripe and bubble phases become possible candidates for the ground state at lower filling numbers in the N=3 LL. We have also studied the ground state evolution and quantum phase transitions of the 2D electron gas at half-filled N=1 LL under an additional repulsive three-body interaction.

1:03PM J37.00010 Midgap states and the fractional quantum Hall regime in graphene quantum dots1. IGOR ROMANOVSKY, CONSTANTINE YANNOULEAS, UZI LANDMAN, School of Physics, Georgia Institute of Technology — Graphene quantum dots (QDs) with zigzag edges exhibit midgap single-particle states associated with such edges. At zero magnetic field (\( B \)), these states form a manifold of degenerate states similar to the lowest Landau level that forms in semiconductor QDs at high \( B \). It has been recently suggested that the midgap-state manifold in graphene dots can support correlated many-body states similar to the rotating-electron-molecule (REM) states (also referred to as rotating Wigner crystals) at high \( B \). Here, we will report systematic exact-diagonalization calculations for N = 1 - 10 QD electrons describing the REM states in graphene QDs. We anticipate that the graphene REM states exhibit for all N a single polygonal ring of localized electrons, in contrast to the multipolygonal ring configurations known from semiconductor QDs.

Coulomb interaction and Landau level spacing

And in the Hartree-Fock approximation, the ground state energy at half filling becomes nearly symmetric under rotations of the three-component vector (N1, N2, m), with the first two components representing the Neel order parameter orthogonal to and the third component the magnetization parallel with the external magnetic field. When the symmetry breaking effects arising from the lattice, Zeeman coupling, and higher Landau levels are included the system develops a quantum critical point at which the antiferromagnetic order disappears and the magnetization has a kink. The observed incompressible states at filling factor one are argued to arise due to a finite third component of the Neel order parameter at these electron densities. Recent experiments appear consistent with N1=N2=0, and N3 finite, at the filling factors zero and one, respectively.

The Neel order parameter at these electron densities. Recent experiments appear consistent with N1=N2=0, and N3 finite, at the filling factors zero and one, respectively.

### 1:27PM J37.00012 Phase Diagram for Quantum Hall States in Graphene

JIANHUI WANG, ANDREW IYENGAR, HERB FERTIG, Indiana University, LUIS BREY, CSIC-Madrid — We investigate integral and half-integral fillings (uniform and unidimensional stripe states respectively) for graphene using the Hartree-Fock approximation in the continuum limit. For fixed filling factor, the ratio between the scales of the Coulomb interaction and Landau level spacing g = (e^2/εL)/hνF is a field independent constant. However, when B decreases, the number of filled negative Landau levels increases, which surprisingly turns out to decrease the amount of Landau level mixing. The resulting states at fixed filling factor ν (for ν not too big) has very little Landau level mixing even at arbitrary weak magnetic fields. This means many different phases should emanate from the origin of the phase diagram when plotted in the B v.s. density plane, in contrast to regular 2 dimensional electron gas which has a Wigner crystal state in the vicinity of the same point. The stripe amplitudes scale roughly as B, so that the density waves "evaporate" continuously as B → 0. These results will be compared to those of tight binding calculations.

### 1:39PM J37.00013 Chirality Sum Rule in Graphene Multilayers

HONGKI MIN, ALLAN H. MACDONALD, The University of Texas at Austin — We show that the low energy electronic structure of arbitrarily stacked graphene multilayers with nearest-neighbor interlayer tunneling consists solely of chiral pseudospin doublets. Although the number of doublets in an N-layer system depends on the stacking sequence, the pseudospin chirality sum is always N. It follows that N-layer stacks always have N distinct Landau levels at E = 0 for each spin and valley, and that the quantized Hall conductivity σxy = ±(4e^2/ℏh)/N(2 + n) where n is a non-negative integer.

### 2:03PM J37.00015 Lattice-Induced Double-Valley Degeneracy Lifting in Graphene by a Magnetic Field

I.A. LUK'YANCHUK, University of Picardie, Amiens, 80039 France, A.M. BRATKOVSKY, Hewlett-Packard Labs, California 94304 — We show that the recently discovered double-valley splitting of the low-lying Landau level(s) in the Quantum Hall Effect in graphene can be explained as a perturbative orbital interaction of intra- and inter-valley microscopic orbital currents with a magnetic field. This effect is provided by the translationally-non-invariant terms corresponding to graphene's crystallographic honeycomb symmetry but do not exist in the relativistic theory of massless Dirac Fermions in Quantum Electrodynamics. We discuss recent data in view of these results [1]. [1] I.A. Luk'yanchuk and A.M. Bratkovsky, arXiv:0707.0466 (2007)

Tuesday, March 11, 2008 11:15AM - 2:15PM — Session J39 DMP GSNP: Focus Session: Friction and Contact Morial Convention Center 231

### 11:15AM J39.00001 A rigorous approach to the contact mechanics of rough, elastic solids

MARTIN MUSER, Univ Western Ontario — The basic ideas of a statistical field theory is presented, which allows one to calculate the displacement field and the pressure distribution P(r) in a contact formed by an elastic body and a rigid counter face of arbitrary topography. The theory is a cumulant expansion, which contains Persson’s contact mechanics theory as the leading-order term. The cumulant approach provides a framework which correction terms can now be systematically derived. Comparison is made to numerical data for surfaces that interact via exponentially repulsive forces.

### 11:27AM J39.00002 Molecular dynamics studies of contact mechanics: contact area and interfacial separation from small to full contact

CHUNYAN YANG, BO PERSSON, IFF, FZ-Juelich, D-52425, Germany — We report a molecular dynamics study of the contact between a rigid solid with a randomly rough surface and an elastic block with a flat surface. We study the contact area and the interfacial separation from small contact (low load) to full contact (high load). For small load the contact area varies linearly with the load and the interfacial separation depends logarithmically on the load [1-4]. For high load the contact area approaches to the nominal contact area (i.e., complete contact), and the interfacial separation approaches to zero. The present results may be very important for soft solids, e.g., rubber, or for very smooth surfaces, where complete contact can be reached at moderate high loads without plastic deformation of the solids.

11:51AM J39.00004 Local contact stress measurements at a rough interface, JULIEN SCHEIBERT, ALEXIS PREVOST, EYTAN KATZAV, MOHKTAR ADDA-BEDIA, GEORGES DEBRÉGEAS, LPS-ENS, CNRS-UMR 8550 Paris, France — An original MEMS-based force sensing device has been designed. It allows for spatially resolved measurements of both normal and tangential stress fields at the base of an elastomeric film in contact with a rigid substrate [1]. Model contact geometries involving a rough, nominally flat film pressed against smooth spherical and cylindrical glass substrates have been studied. In two different regimes, normal indentation and steady sliding. The measured stress profiles have been compared to calculations which assume a smooth contact obeying Amontons-Coulomb’s friction law. For the normal indentation a Finite Elements method was used, whereas for the sliding regime a semi-analytical model was developed. These direct comparisons showed that our device was accurate enough to discriminate between dry and lubricated contact conditions and evidenced load-dependent deviations from Amontons-Coulomb’s profiles. These deviations are qualitatively interpreted by taking into account the finite compliance of the contacting micro-asperities population. [1] J. Scheibert et al., arXiv:0711.117v1

12:03PM J39.00005 Friction induced displacement and stress fields within contacts with elastomers, ANTOINE CHATEAUMINOIS, CHRISTIAN FREIGNY, ESPCI, ESPCI TEAM — Friction is known to be associated with strongly heterogeneous stress and displacement fields within the contact zone. However, experimental approaches are often based on the measurement of friction forces (or mean shear stress), which makes difficult a detailed analysis of interface dynamics within sliding contacts. We have developed a new methodology for the determination of the interface shear stress distribution within macroscopic sliding contacts. It is based on an in situ measurement of the displacement field induced at the surface of highly deformable solids such as elastomers. An inversion of this field using contact mechanics models then provides the interface shear stress distribution. The experiments were carried out using two different contact configurations. The first one involves the linear sliding of a glass sphere on the elastomer substrate. The second one corresponds to an original torsional contact configuration which minimizes bulk viscoelastic dissipation during steady state sliding. Experimental distributions of frictional shear stress will be discussed in the light of theoretical models assuming either a constant interface shear stress (Tabor’s model) or a local Coulomb’s friction law.

12:15PM J39.00006 Optical measurements of pressure and displacement fields at a rough interface, ALEXIS PREVOST, JULIEN SCHEIBERT, GEORGES DEBRÉGEAS, LPS-ENS, CNRS-UMR 8550 Paris, France — We report on optical measurements of both pressure and displacement fields at the interface between a rough, nominally flat transparent elastomeric film and a smooth spherical glass lens. The multi-contact interface is imaged by transmission and the pressure field is deduced from the spatial distribution of the transmitted light. The displacement field is measured using Digital Image Correlation, focusing on a macroscopic scale. For normal loading, the mean surface pressure is measured using Hertz theory, as expected for a rough interface. A good quantitative agreement has been obtained within the statistical description of a rough sphere-on-plane contact by Greenwood and Tripp. When the interface is tangentially loaded below the macroscopic sliding threshold, analysis of the displacement field has shown a coexistence between an inner stuck region and an outer slipping annulus, as suggested by Catteneo and Mindlin. Quantitative comparison with this model yields a good overall agreement. However, small deviations are observed and can be related to the tangential compliance of the rough layer.

12:27PM J39.00007 Beller Lectureship Talk: Crack-like processes govern the onset of frictional motion, JAY FINEBERG, The Hebrew University — The dynamics of frictional slip have been studied for hundreds of years, yet many aspects of these everyday processes are not understood. One such aspect is the onset of slip. First described by Coulomb and Amontons as the transition from static to dynamic friction, the onset of frictional slip is central to fields as diverse as physics, tribology, the mechanics of earthquakes and fracture. We study the dynamics of how this transition takes place by performing real-time visualization of the true contact area which forms the interface separating two blocks of like material. The results show that the onset of frictional motion is driven by the interplay of three different types of coherent crack-like fronts, which propagate along the interface, reducing the contact area as they progress. Two of these, whose propagation speeds are, respectively, slightly below and significantly above the shear wave velocity, appear to be related to known propagation modes of shear cracks. The third type of front does not correspond to known fracture modes. It propagates over an order of magnitude more slowly, and is the most efficient of the three modes in reducing contact area along the interface. We first show that, at applied stresses that are well below the (Coulomb-Amontons) threshold for the onset of frictional motion, significant precursor activity occurs along the interface. This activity is comprised of propagating (subsonic) shear cracks which arrest before traversing the entire interface. In their wake, these “precursor” cracks systematically transform the initial spatially uniform contact area along the interface to a highly nonuniform one. Only at the transition to overall motion will these precursor cracks simultaneously excite, at their point of arrest, both the slow propagation modes and the intersonic ones. Until to this point, no overall frictional motion occurs. Frictional sliding only takes place when either the slow modes or additional shear cracks excited by the slow modes traverse the entire interface. These results suggest that to understand the transition to frictional motion, the dynamics of this entire chain of events must be taken into account.

1:03PM J39.00008 Precursor events and the onset of frictional sliding, ANDRÁS LIBAL, MARK ROBBINS, Johns Hopkins University — The precursor events leading to steady state sliding friction are investigated using a simple two-dimensional model of a rectangular block on a flat surface. As in experiments[1], a succession of cracks nucleates from the rear of the block. Each propagates rapidly and then arrests after a distance that scales with the height at which the lateral force is applied to the block. The propagation distance grows with each successive crack until a steady sliding state is attained. The distributions of local shear stress at the interface can be obtained directly in our simulations. The relation between this stress distribution, the static friction, the normal load, and the nucleation and propagation of successive cracks will be discussed. [1] S.M. Rubinstein, G. Cohen and J. Fineberg, PRL 98, 226103 (2007)
and we predict a melting temperature of about 6500 K at the core-mantle boundary. We will also present results on simulating the melting temperature of the GGA. Those systems which were too hot melted within 10 ps. Those which didn't remained with both solid and melt coexisting in the super-cell for over 25 ps.

We used 900 atoms (a 3x3x5 super-cell) with atoms in one half of the super-cell melted and the other half solid. Both halves are thermalised to the desired temperature, therefore, ab initio molecular dynamics simulations to predict its melting temperature throughout the Earth's mantle using the coexistence method. things as the crystallisation of the Earth's mantle from a magma ocean or the existence of melt in the current mantle, the melting temperature of the lower

lattice, as well as influences of the tip shape.

sliding: While some particles show finite friction increasing linearly with interface area, thus reinforcing Amontons’ law at the nanoscale, other particles assume a state of frictionless or ‘superlubric’ sliding. Additional experiments revealed a similar result even in air, which can be explained by contamination effects of the interface that alter the frictional properties.

Dragging shadows causes real friction: sliding Moiré’ patterns. A. VANOSSI, CNR-INFM S3 and Physics Dept., Modena National Laboratory, Italy, C. NEGRIT, N. MANINI, Physics Dept. and CNR-INFM, Milan University, Italy; SSISA and INFM-CNRR Democritos, Trieste, Italy, G.E. SANTORO, E. TOSATTI, SSISA, INFM-CNRR Democritos, and ICTP, Trieste, Italy — Surface Moire’ patterns are shadow-like modulations (kinks) which form at crystalline overlayers that are out of registry with their substrates. They were hardly considered in the context of friction so far, we here argue that they can be relevant. 1D model calculations suggest in fact that under the action of an external slider, the kinks are the real objects being rigidly dragged, as opposed to the real particles, which are not [1]. For a crystalline periodic slider, we predict peculiar phenomena on the fly caused by the pinning/depinning of the kink lattice to the slider, in full analogy with the well known real lattice static counterpart [2]. The frictional dissipation by a vibrating and/or sliding AFM probe should moreover be enhanced at the kinks, where atoms take poorly stable positions. Thus, AFM frictional maps [3] should reveal with much more contrast the Moire’ patterns than topographic maps of the same patterns. This concept is demonstrated by means of a simple model, which also provides a guide to the key parameters determining the enhancement. [1] A. Vanossi et al., PRL 97, 056101 (2006). [2] A. Vanossi et al., PRL 99, 206101 (2007). [3] C. Loppacher et al., PRB 62, 13674 (2000).

Contribution of Plowing to Nanotribology of Self-Assembled Monolayers. MICHAEL CHANDROSS, Sandia National Laboratories, CHRISTIAN LORENZ, King’s College, London, GARY GREST, Sandia National Laboratories, ERIN FLATER, Luther College, ROBERT CARPICK, University of Pennsylvania — Atomic force microscopy experiments and molecular dynamics (MD) simulations on self-assembled monolayer (SAM) systems have demonstrated that the nanotribology of these systems is dominated by a microscopic plowing mechanism. Due to relatively weak chain-to-chain interactions, compression only affects molecules directly under the probe tip, and not those outside the contact area. Under shear, the tip must plow into the molecules in front leading to frictional energy dissipation. We will present the results of coupled experiments and MD simulations of alkylsilane SAMs studying the plowing mechanism in detail. In particular, combinations of uncoated and SAM-coated substrates and tips are studied to probe the relationships between friction force and both contact area and applied load. As a SAM coating on the substrate (tip) is (is not) expected to result in plowing during shear, the contrast in these results, combined with detailed calculations using the MD results, will shed light on the complicated response of these systems. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy under Contract No. DE-AC04-94AL85000.

Accelerated Molecular Dynamics Simulation of AFM Experiments Using the Bond-Boost Method. WOO KYUN KIM, MICHAEL FALK, University of Michigan — We apply an accelerated molecular dynamics (MD) methodology to simulate the friction between a silicon tip and a silicon surface under perfect vacuum conditions. These simulations model recent Atomic Force Microscope (AFM) experiments which observed stick-slip motion and a lateral force showing dependence on temperature and sliding velocity. Our AFM models consist of crystalline silicon with an oxidized layer. We achieved the decrease in the simulated sliding velocity by several orders of magnitude compared with conventional MD simulations using the bond-boost method. This method is based on Voter’s hyper molecular dynamics scheme accelerating the process between slip events. The decrease in the sliding velocity makes it possible to simulate systems closer to the regime of the actual experiments. We compare the simulation results with the experimental data to elucidate the atomic level processes during sliding. We studied the effects of atomic mass transfer between the tip and the substrate on friction. Moreover, the dependence of friction on temperature and sliding velocity has been quantified, and compared with the modified Tomlinson model.

Measurement of lateral tip-sample forces in the attractive regime with picometer resolution in three dimensions. B.J. ALBERS, T.C. SCHWENDEMANN, M.Z. BAYKARA, N. PILLET, U.D. SCHWARZ, Department of Mechanical Engineering, Yale University, New Haven — Three-dimensional (3D) dynamic force spectroscopy, i.e., the acquisition of frequency shift vs. distance curves in a dense raster over a surface in order to recover the true tip-sample interaction forces with high local resolution, has so far suffered from relatively low resolution, as long-term drift stability has been a problem. Nevertheless, its promise to deliver not only the normal forces with atomic resolution, but also the lateral forces as well as the energy dissipated during an individual oscillation cycle makes it interesting for high-resolution nanotribology. Using our recently completed home-built low temperature, ultrahigh vacuum NC-AFM, we were able to map the full 3D force field over highly oriented pyrolytic graphite, which was chosen due to its qualities as a solid lubricant. Lateral forces have been measured quantitatively in a grid with spacing better than 6 pm in all three directions and pN resolution. We will discuss the distance-dependence of the static lateral forces, their local distributions with regard to the underlying lattice, as well as influences of the tip shape.

The melting curve of MgSiO3 perovskite from ab initio molecular dynamics using the coexistence method. JOHN BRODHOLT, Dept. of Earth Sciences, UCL — Despite its importance in understanding such things as the crystallisation of the Earth’s mantle from a magma ocean or the existence of melt in the current mantle, the melting temperature of the lower mantle phase MgSiO3 is poorly known. Estimates of its melting temperature at the core-mantle-boundary range from 5400 K to over 8000 K. We have used, therefore, ab initio molecular dynamics simulations to predict its melting temperature throughout the Earth’s mantle using the coexistence method. We used 900 atoms (a 3x3x5 super-cell) with atoms in one half of the super-cell melted and the other half solid. Both halves are thermalised to the desired temperature individually. We then turned off the thermalisation and allowed the system to evolve in an NV simulation, using DFT forces calculated within the GGA. Those systems which were too hot melted within 10 ps. Those which didn’t remained with both solid and melt coexisting in the super-cell for over 25 ps. These were plowed to either be on the melting curve of just below it. Our results agree well with the higher temperature melting curves found experimentally, and we predict a melting temperature of about 6500 K at the core-mantle boundary. We will also present results on simulating the melting temperature of the MgO-MgSiO3 binary.
11:51 AM J40.00002 First-Principles Molecular Dynamics of Melts in the MgO-SiO₂ System

BIJAYA KARKI, Louisiana State University, NICO DE KOKER, University of Michigan, D. BHATTARAI, Louisiana State University, LARS STIXRUDE, University of Michigan, DE KOKER COLLABORATION, STIXRUDE COLLABORATION — We have recently completed simulations of five melt compositions in the MgO-SiO₂ system within density functional theory. These results allow us to investigate the structural and thermodynamical, transport properties of melts along the MgO-SiO₂ join as a function of pressure. In particular, we have found that the mixing in MgO-SiO₂ system is significantly non-ideal at low pressures with negative excess volume and enthalpy of mixing. With increasing pressure, the volume of mixing decreases rapidly to a value close to zero at pressures above 50 GPa whereas the enthalpy of mixing remains negative. The radial distribution functions and coordination environments are found to show interesting changes with varying composition. Also, the effects of composition on diffusivity are shown to be substantial at low pressures whereas the effects are increasingly suppressed with increasing pressure.

12:03PM J40.00003 A New look into the spin transition in Fe₂O₃

DIPTA BHANU GHOSH, STEFANO DE GIRONCOLI, SISSA and DEMOCRITOS — The wide range of intriguing characteristics exhibited by Fe₂O₃ with pressure and temperature has renewed the attention of the scientific community in the last decade. Experimental and theoretical efforts are on to address and unravel the complexity of the system. The ambient pressure phase, hematite (α-Fe₂O₃), transforms to a new structure phase (HP1). That the HP1 phase is orthorhombic perovskite (Pbnm) or Rh₂O₃-II type (Pbcm) is still a debate and yet to be explored theoretically. On top of this ambiguous assignment of HP1, there has been a long-standing issue of an isostructural high spin (HS) to low spin (LS) transition. Experimental data till date are divided into two horizons—one assigning the spin transition in the hematite phase and the other in the HP1 phase. In this work, motivated by these exotic unresolved controversies of the system, we have tried to gain an insight of the system from first principles density functional calculations. Our results favor the Rh₂O₃-II type as the HP1 phase, in agreement with recent experiments. Also a (new) mechanism governing the HS to LS transition is proposed. This mechanism, we believe, might help in removing the boundary between the two horizons as mentioned above.

12:15PM J40.00004 Prediction of an ultrahigh-pressure form of Al₂O₃

KOICHIRO UMEMOTO, RENATA WENTZCOVITCH, Minnesota Supercomputing Institute and Department of Chemical Engineering and Materials Science, University of Minnesota — We predict by first principles a pressure induced phase transition in alumina at ~3.7 Mbar, relevant for interiors of the giant planets and terrestrial exoplanets, at room temperature from the Ca₃Al₂O₆-type polymorph to another with the U₃Si₂-type structure. This transformation should be important for the analysis of shock data in this pressure range, since alumina is used as window material. Our calculated compression curves agree with shock data excellently, indicating that the presence of two phase transitions (corundum–Rh₂O₃-II type and Rh₂O₃-II type–Ca₃Al₂O₆ type) had gone unnoticed in shock data. Our prediction suggests that the multi-Mbar crystal chemistry of planet-forming minerals might be related to that of the rare-earth sulfides.

12:27PM J40.00005 Models of Giant Planet Interiors Derived from First-Principles Simulation

BURKHARD MILITZER, UC Berkeley, JAN VORBERGER, University of Warwick, WILLIAM HUBBARD, University of Arizona — Our understanding of the interior of giant planets is based on the accurate characterization of hydrogen and helium at megabar pressures and temperatures of several thousands of Kelvin. Theoretical methods including first principles computer simulations have been the principal tool to predict high-pressure dense fluids because laboratory experiments cannot yet probe deep into Jupiter’s interior despite great progress in shock wave measurements with precompressed samples. Results from an extensive set of density-functional molecular dynamics simulations will be presented [J. Vorberger et al., “Hydrogen-Helium Mixtures in the Interiors of Giant Planets,” Phys. Rev. B 75 (2006) 024206]. A new and more accurate equation of state (EOS) will be derived that spans the interior of giant planets. Differences from the widely used Saumon-Chabrier-Van Horn (SCVH) EOS will be analyzed. An updated model for the interior of Jupiter will be introduced. Estimates for the heavy element enrichment as well as for the size of Jupiter’s core will be discussed and compared with previous models based on the SCVH EOS. This work is supported by NASA grants PGG04-0000-0116 and NAGS-13775 as well as NSF grant 0507321.

12:39PM J40.00006 Titan’s Interior Chemical Composition: Possible Important Phase Transitions

MICHAEL HOWARD, Lawrence Livermore National Laboratory, JOSEPH ZAUG, BISHUN KHARE, CHRISTOPHER MCKAY, NASA Ames — We study the interior composition of Titan using thermal chemical equilibrium calculations that are valid to high pressures and temperatures. The equations of state are based on exponential-6 fluid theory and have been validated against experimental data up to a few Mbars in pressure and approximately 20000K in temperature. In addition to CHNO molecules, we account for multi-phases of carbon, water and a variety of metals such as Al and Fe, and their oxides. With these fluid equations of state, chemical equilibrium is calculated for a set of product species. As the temperature and pressure evolves for increasing depth in the interior, the chemical equilibrium shifts. We assume that Titan is initially composed of comet material, which we assume to be solar, except for hydrogen, which we take to be depleted by a factor 1/1000. We find that a significant amount of nitrogen is in the form of N₂, rather than NH₃. Moreover, above 12 kbars, as is the interior pressure of Titan, a significant amount of the carbon is in the form of graphite, rather than CO₂ and CH₄. We discuss the implications of these results for understanding the atmospheric and surface composition of Titan.

12:51PM J40.00007 Extended-Solid Phases of Carbon Dioxide at High Pressures

VALENTIN IOTA, ZSOLT JENEI, JAE-HYUN KLEPEIS, Lawrence Livermore National Laboratory, CHOONG-SHIK YOO, Washington State University, Pullman, WILLIAM EVANS, Lawrence Livermore National Laboratory — At high pressures and temperatures, CO₂ transforms to a series of solid polymorphs with differing crystal structures, intermolecular interactions and chemical bonding. Among them are a number of covalent (extended) solid phases, with crystal structures analogous to SiO₂ polymorphs. Above 40GPa and 1500K CO₂ transforms to phase V, a network of corner sharing CO₂ tetrahedra — structurally similar to SiO₂ tridymite. At room temperatures, CO₂ forms a-carbonia, an amorphous extended-solid phase similar to silica glass. Recently, we reported another phase, with a structure resembling that of SiO₂ stishovite, formed by compressing associated phase II above 50GPa. Here, we present a systematic picture of the structural and bonding diagram of carbon dioxide, focusing on the relationship between its molecular and extended phases at high pressures and temperatures.

1This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
1:03PM J40.00008 High-pressure Neutron Powder Diffraction and Inelastic Neutron Scattering Studies on the Mineral Jarosite KFe$_3$(SO$_4$)$_2$(OH)$_6$. MONIKA HARTL, ALICE ACATRINEI, LUKE DAEMEN, HONGWU XU, Los Alamos National Laboratory, KIM TAIT, Royal Ontario Museum, YUEJIAN WANG, SVEN VOGEL, JIANZHONG ZHANG, YUSHENG ZHAO, Los Alamos National Laboratory — The mineral jarosite KFe$_3$(SO$_4$)$_2$(OH)$_6$ has been detected in rocks at the Meridiani Planum region of Mars [1 and cited therein]. Jarosite is typically formed in aqueous environments at acidic pH. It decomposes to ferric oxhydroxides in humid climate. This gives rise to the question under which conditions jarosite was formed on Mars and what it can tell us about the climatic cycles and the former presence of water on Mars. We are looking at the phases of jarosite at elevated temperature and pressure and were able to show the stability of jarosite up to 6 GPa at room temperature and up to 3 GPa at 300 °C using neutron powder diffraction. Furthermore, we used inelastic incoherent neutron scattering to look at the vibrational modes of the hydroxyl groups in jarosite at various temperatures between 10K and 200K. [1] A. Banin, Science 309 (2005) 888

1:15PM J40.00009 Lattice Dynamics and Thermal Equation of State of Platinum. TAO SUN, Dept. of Physics and Astronomy, Stony Brook University, KOICHIRO UMEMOTO, ZHONGQING WU, Dept. of Chemical Engineering and Materials Science, University of Minnesota, JINCHENG ZHENG, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory, RENATA WENTZCOVITCH, Dept. of Chemical Engineering and Materials Science, University of Minnesota — Platinum is widely used as a pressure calibration standard. However, the established thermal EOS has uncertainties, especially in the high P-T range. We use density functional theory to calculate the thermal equation of state of platinum, up to 550 GPa and 50,000 K. The static lattice energy is computed by using the LAPW method, with LDA, PBE, and the recently proposed WC functional. The electronic thermal free energy is evaluated using the Mermin functional. The vibrational part is computed within the quasi-harmonic approximation using density functional perturbation theory and pseudopotentials. Special attention is paid to the influence of the electronic temperature to the phonon frequencies. We find that in overall LDA results agree best with the experimental ones. To provide accurate thermal EOS for pressure calibration, we combine the computed temperature dependence of the Gibbs energy with the room temperature Gibbs free energy corrected by experiments. The resulting thermal EOS seems reasonably accurate and can be used as a reference for pressure calibration.

1:27PM J40.00010 Ultrafast shock wave propagation at high ambient pressure in a diamond anvil cell. MICHAEL ARMSTRONG, Lawrence Livermore National Lab, JONATHAN CROWHURST, JOSEPH ZAUG, WILLIAM HOWARD — The measurement and characterization of acoustic phenomena at high pressure is critical to the modeling of planetary dynamics, seismic events, and chemistry in extreme environments. Here we present the results of experiments using ultrafast laser excitation and detection of shock waves starting from high precompression (10s GPa) in a standard diamond anvil cell (DAC) with transient single shot shock pressures > 10 GPa. Using ultrafast interferometry, we directly detect surface motion with ~nm spatial resolution and ~ps time resolution. Such experiments enable examination of shock waves with significant strain starting at high ambient pressure using a convenient and relatively inexpensive apparatus. Ultrafast time resolution enables the observation of shock-induced chemistry on the scale of a picosecond shock rise. Furthermore, standard DACs can reach 100s GPa precompression, enabling the examination of phase transitions and chemical reactions starting from a wide range of thermodynamic initial conditions.

K1.00001 SUPERCONDUCTIVITY —

K1.00002 Crystal Structure and Superconductivity of FeSr$_2$(Y,Nd)(Cu,Zn)$_2$O$_{6-δ}$δ. WUERNISHA TUERXUN, International Center for Materials Nanoarchitechtonics (MANA), National Institute for Materials Science (NIMS), Japan, TAKASHI MOCHIKU, Superconducting Materials Center, NIMS, YOSHIKATA HATA, Department of Applied Physics, National Defense Academy, AKINORI HOSHIKAWA, Ibaraki University, YOSHITAKA MATSUSHITA, Quantum Beam Center, NIMS, HIROKI FUJII, Superconducting Materials Center, NIMS, HIROSHI YASUOKA, Department of Applied Physics, National Defense Academy, HIDEAKI KITAZAWA, (1) Quantum Beam Center, (2) MANA, NIMS — We have prepared the polycrystalline samples of FeSr$_2$Y$_{0.75}$Nd$_{0.25}$(Cu$_{1-x}$Zn$_x$)$_2$O$_{6-δ}$δ solid solution system ($x=0,0.01,0.02,0.05$) to investigate the Zn substitution effects. The DC magnetization measurement results showing the samples exhibiting decreased in $T_c$ while increasing the Zn content, $x$, and the superconductivity was disappeared around $x=0.05$. Crystal structure has been analyzed by using X-ray and neutron powder diffraction data. The relation between the superconductivity and crystal structure is discussed based on the experimental results.

K1.00003 DC Magnetization and Growth of Heavy-Fermion Superconductor CeCoIn$_3$ and CeIn$_3$ Crystal. TESFAYE GEBRE, National High Magnetic Field Laboratory, ERIC PALM, STANLEY TOZER, TIM MURPHEY, JU-HYUN PARK, NHMF, JASON COOLEY, Los Alamos National Laboratory — The superconducting and magnetic state in heavy-fermion intermetallic compounds provides a promising realm of materials to study quantum critical behavior. Single crystals of the heavy-fermion superconductors CeCoIn$_3$ and CeIn$_3$, synthesized from the pure material using an excess of indium, are typically grown by flux technique. The details of the flux-growth technique used to grow CeCoIn$_3$ and CeIn$_3$ and the result of DC magnetization and transport measurements performed in the temperature range 1.9K to 100K will be reported.

1Work was supported by DOE DE-FG52-06NA26193, NSF Cooperative Agreement No. DMR-0084173, and the State of Florida

K1.00004 Superconducting Properties of Al-Eu Alloys. J. P. BYCHOWSKI, A. ORLOV, G. SNIDER, S. T. RUGGIERO, University of Notre Dame — We discuss the superconducting properties of Al-Eu alloys with Eu concentrations in the range of 0-5000ppm. The electron-transport and tunneling properties are discussed in the context of Abrikosov-Gor’kov pair-breaking and Kaiser resonant-scattering theories. This complements previous work on the Al-Mn system.
K1.00005 New Superconducting Material: Mg$_2$SnX (X = C, B)\(^1\), ANTONIO JEFFERSON MACHADO, Departamento de Engenharia de Materiais - Escola de Engenharia de Lorena - USP, BRUNO DE GODOI CURATTI, AUSDINIR DANilo BORTOLOZO, CARLOS ALBERTO DOS SANTOS, DEMAR TEAM — In the Mg-Sn system, there is only one intermetallic phase of Mg$_2$Sn composition. This intermetallic phase crystallizes in a cubic symmetry with prototype CaF$_2$ structure, named anti-fluorite. About three years ago, our group reported the existence of superconductivity in the Mg$_2$Sn intermetallic phase with a superconducting critical temperature close to 35 K \([1]\). In this intermetallic phase the boron atoms occupy the interstitial sites available in the structure. This work shows that, besides boron atoms, carbon also can occupy the interstitial sites in the same structure and can also induce superconductivity in the system with high critical superconducting temperature. This conclusion is sustained by resistivity, magnetization, and X-ray diffraction measurements. This report is based upon work supported by FAPESP (2005/01257-9). \([1]\) B. Ferreira, C. M Franco, C. A. M. dos Santos, D. Rodrigues Jr., L. Ghivelder, and A. J. S. Machado; Phys. C 408- 410, 148 (2004)

\(^1\)This report is based upon work supported by FAPESP (2005/01257-9).

K1.00006 New superconductor of the M$_2$AX family with Ti$_2$GeC composition, , A.D. BORTOLOZO, O.H. SANT’ANNA, C.A.M. DOS SANTOS, A.J.S. MACHADO, Departamento de Engenharia de Materiais EEL USP - Lorena Brazil. Polo Urbo Industrial Gleba AI-6 P.O. BOX 116 12600-970. — In this work the Ti$_2$GeC phase is investigated by x-ray diffraction, magnetic and resistivity measurements. Polycrystalline samples with nominal compositions Ti$_2$GeC were prepared by solid state reaction. The samples were encapsulated under argon and heat-treated at 1100°C for 240 hours. X-ray powder diffractograms suggest that all peaks can be indexed with the hexagonal phase of Cr$_2$AlC prototype. The electrical resistance as a function of temperature for the Ti$_2$GeC reveals a standard metal like behavior when this material is cooled from the heat treatment under equilibrium conditions. However, magnetic measurements display diamagnetic behavior close to 9.5K. On the other hand, when the Ti$_2$GeC phase is submitted a rapid quenching the R(T,B) curve shows superconducting critical temperature close to 9.5K without applied magnetic field. The magnetoresistance data with applied magnetic field suggests bulk superconductivity. In spite of the great number of compounds which belong to this family, superconductivity has been reported for five cases. So, this work sustains the idea of the existence of a new class of superconducting materials that crystallizes in the Cr$_2$AlC prototype.

K1.00007 Search for Magnesium Diboride like Binary Superconductors\(^1\), O. PAUL ISIKAKU-IRONKWE, The Center for Superconductivity Technologies[TCST], Abuja FCT, NIGERIA — Efforts to create compounds iso-electronic and iso-structural with magnesium diboride and also superconducting have so far met with limited success. Doping the Mg-site or the B-site have also not yielded higher transition temperatures. They have either been non-superconducting or have lower transition temperatures, Tc. Searching for magnesium diboride-like compounds using the electronegativity of MgB$_2$ (1.7333) has yielded a rich family of potential superconductors. The search has been facilitated using the recently designed ElectroNegativity Spectrum Maps [ENSMaps] of binary systems A$_x$B$_{1-x}$. Here we display the potential families. Using the relationship between Tc and atomic mass, we estimate the transition temperatures of the most likely Mg$_2$-like binary superconductors. We also suggest materials that can be doped to give an electronegativity of 1.7333.

\(^1\)with research support from Mr. Ferguson Uzoma and Institute for Superconducting and Electronic Materials [ISEM], Wollongong NSW Australia

K1.00008 Study of the Pseudogap in Y$_1-x$Ca$_x$Ba$_2$Cu$_3$O$_{7-d}$ Superconductor, EDWIN HERRERA, HECTOR CASTRO — The generic phase diagram of doping vs. temperature for High Temperature Superconductors (HTSC) presents in the underdoped region a zone called Pseudogap (PG). The analysis of this region is very interesting since it is believed that it is deeply related, and therefore can help us understanding better the superconductive (SC) transition. Different theories exist up to now which try to explain the origin of the PG and its influence on the SC transition. Some of them see the PG as a precursor of the superconducting gap, while others see it as a competing phenomenon which retards the SC transition. In the present work we analyze resistivity measurements in bulk samples of the high temperature superconductor Y$_1-x$Ca$_x$Ba$_2$Cu$_3$O$_{7-d}$, for different concentrations of calcium (x) and oxygen (d), and its influence on the PG zone. We discuss our results on the light of some of these theories.

K1.00009 MaxEnt-MuSR study of GdBCO: potential precursor effects, J. WONG, T. SONGATIKAMS, R. NORRIS, C. BOEKEMA, San Jose State University, WISE@SJSU COLLABORATION — We analyze muon-spin resonance (muSR) data of underdoped (Tc = 81 K) and optimal doped (Tc = 93 K) superconducting GdBCO showing different precursor effects. \([1]\) Precursors refer to anomalous behavior seen just above Tc. Transverse field muSR data recorded at 1 kOe, RT, and 100 K were analyzed by Maximum Entropy. MaxEnt determines the frequency (i.e. magnetic field) distribution from the muSR time series. \([2]\) Two Lorentzians fit the frequency signals much better than two Gaussians, one Lorentzian, or one Gaussian. Thus, in GdBCO the muon probes dynamic fields, caused by muon motion and/or magnetic fluctuations. The number of Balmer (muon-stop) sites with magnetic field) distribution from the muSR time series. \([2]\) Two Lorentzians fit the frequency signals much better than two Gaussians, one Lorentzian, or one Gaussian. Thus, in GdBCO the muon probes dynamic fields, caused by muon motion and/or magnetic fluctuations. The number of Balmer (muon-stop) sites [1] has been confirmed. Zero-field muSR curve fitting studies [1] showed irregularities in asymmetry and muon-spin relaxation just above Tc. We apply MaxEnt to these ZF GdBCO data to search for magnetic precursor effects. Research is supported by DOE-LANL and WISE@SJSU. \([1]\) Dawson et al, J Appl Phys 64 (1988) 5809; \([2]\) Lee et al, J Appl Phys 95 (2004) 6906; also at scitation.aip.org.

K1.00010 The enhanced high Tc superconductivity by ordering dopant, CHANGQING JIN, Q.Q. LIU, W.B. GAO, H. YANG, L.X. YANG, Y. YU, R.C. YU, Institute of Physics, Chinese Academy of Science, China, S. UCHIDA, Department of Physics, University of Tokyo, Japan — We discuss the high pressure improvement on superconducting transition temperature (Tc) related to ordering apical oxygen layer of a high temperature superconductor (HTS). This study became available in the high pressure synthesized Sr$_2$Ti$_2$O$_7$ superconductor with K$_2$NiF$_4$ structure showing so far rarely formed partially occupied ?apical oxygen? which also act as the dopant of the HTS. The well-defined links between Tc and modulated structures suggests that optimizing the ordering at apical oxygen layer outside CuO$_2$ plane is a promising way to further enhance Tc.

K1.00011 Mo$_2$BC: Chemical and External Pressure Effects\(^1\), R. FALCONI, DACB-Universidad Juarez Autonoma de Tabasco, R. ESCAMILLA, R. ESCUDERO, IIM-Universidad Nacional Autonoma de Mexico — The intermetallic Mo$_2$BC is a superconductor with a Tc = 6.6 K and a crystalline face centered orthorhombic structure. Chemical pressure generated by changing the carbon concentration decreases Tc in a non monotonic rate. Complete elimination of carbon, changes the crystalline structure from orthorhombic to body centered tetragonal, and reducing Tc to about 5.8 K. At ambient pressure the compound presents a minimum in the resistivity at 50 K, which could be related to a Kondo anomaly. In polycrystalline samples we applied external pressures up to 4.8 GPa with a diamond anvil cell, which induced negative changes in the superconducting transition at a rate dTc/dP = - 0.03 K/GPa. These results will be discussed in terms of the electronic band structure.

\(^1\)Acknowledgements: (R. F.) Thanks SEP-Promepe 20050643 UJATAB-CA175.
K1.00012 Unconventional Metallic Phase of the Quasi Two-Dimensional Organic Superconductors. EDDY YUSUF, B.J. POWELL, R.H. MCKENZIE, Physics Department, University of Queensland, Brisbane 4072, QLD, Australia. — We show, by analyzing previously published nuclear magnetic resonance (NMR) data, that there are large antiferromagnetic fluctuations above $T_{\text{NMR}} \approx 50$ K in the metallic phase of $\kappa-(ET)_2X$ family of organic charge transfer salts. The proximity of the metallic phase to the antiferromagnetic Mott insulating phase and the d-wave superconductivity are thought to be the origin of the large antiferromagnetic fluctuations. The antiferromagnetic correlation lengths are estimated to be several lattice constants at $T_{\text{NMR}}$, which place the materials between the isotropic triangular lattice and the square lattice. For materials close to the Mott insulating phase the nuclear spin relaxation rate per unit temperature, Knight shift and Körringa ratio all decrease significantly with decreasing temperature below $T_{\text{NMR}}$, inconsistent with the renormalized Fermi liquid picture previously thought to be the correct description of the low temperature metallic phase in these materials. One plausible explanation is that a pseudogap, similar to that observed in the underdoped cuprate superconductors, opens up in the density of states below $T_{\text{NMR}}$. Such a pseudogap has recently been predicted to occur in the dimerised organic charge transfer salts materials by the resonating valence bond (RVB) theory.

K1.00013 Photoemission Spectroscopy on the System of Noncentrosymmetric Lithium Ternary Borides. RIKIYA YOSHIDA, IZUMI HASE, KOZO OKADA, HIROYUKI TAKEYA, KAZUTO HIYATA, TAKAYUKI MURO, HIROYUKI OKAZAKI, MITSUTOSHI TAJIMA, MASAKI HIRAI, YUJII MURAOKA, TAKAYOSHI YOKOYA, Okayama University — We performed x-ray photoemission spectroscopy at BL27SU of SPring-8 on polycrystalline samples of Li$_2$Pd$_3$S$_3$, Pd$_3$B$_2$ and Li$_2$Pd$_3$B$_2$ prepared by the arc melting method. We also employed a polycrystalline platinum plate commercially available for comparison. We also performed the calculation of valence band structure of Li$_2$Pd$_3$B$_2$ using full-potential augmented plane wave method with local density approximation. Our experimental data on the samples and the previous photoemission study on Li$_2$Pd$_3$B$_2$ support that electron correlations do not play an important role in them.

3The x-ray photoemission experiments were performed at SPring-8 under the proposal number of 2007B1519. One of the authors (R. Y.) thanks Grant-in-Aid for Attractive Education in Grant-in-Aid for Attractive Education in Graduate School.

K1.00015 Magneto-thermal instabilities in irradiated high density MgB$_2$ compound. E. VERDIN, Dpto. Fisica- U. Sonora, Mexico, A. DURAN, D.H. GALVAN, CCMC-UNAM, Mexico, E. IEM-UNAM, Mexico, M.B. MAPLE, DIP-PAP-U.C.-La joya-U.S.A., F. MORALES, R. ESCUDERO, IIM-UNAM, Mexico — The effects of irradiation with low dosages of $\gamma$-rays, protons and electrons on the magnetization and critical current density of MgB$_2$ bulk samples were studied. Magnetic susceptibility measurements present a transition temperature with diamagnetic signal at $\approx 38.5$ K. Magneto-thermal instabilities as flux jumps are observed in the magnetization hysteresis loops below 23 K, for all samples. The flux jump behavior is independent of the irradiation. The number of flux jumps decreases as the temperature increases. The magneto-thermal instabilities observed is a competing process between the Lorentz and pinning forces that depend on the bath temperature as well as on the defect density that influence the current density. The field dependence of the critical current density, $J_c$, was evaluated using the Bean’s model for different temperatures (from 2, 10, 15, and 20 K). The results show instabilities in the critical current, $J_c$, below 10 K as a consequence of the flux jumps events observed in the isothermal magnetization curves. In this presentation we will analyze the influence of the flux jumps on the critical currents densities.

K1.00016 Observed magnetism and its field dependence in c-axis-oriented YBCO vortex states. C. BOEKEMA, San Jose State University, C. TEICHGRAEBER, UC Berkeley, WISESJSU COLLABORATION — Muon-spin-resonance ($\mu$SR) data of c-axis-oriented YBCO [1} vortex states are analyzed to determine the field dependence of observed AF magnetism. Field distributions are obtained from $\mu$SR data using Maximum-Entropy (ME). We found [2} that well below $T_c$, YBCO vortex signals are best fitted by a Gaussian and a Lorentzian; the latter indicating AF in and near the vortex cores. The field dependence of the AF Lorentzian width is about linear. [2} ME-$\mu$SR analysis of c-axis-oriented YBCO data also suggests a field direction dependence, pointing toward 3-d magnetism. Our results show contraditions to curving fit and FFT results. [1} An LSCO neutron study agrees with AF 3-d field-induced AF. [3} An AF presence in and near vortex cores supports theories predicting a magnetic origin for cuprate superconductivity. [3, 4} Research supported by NSF-REU, DOE-LANL and WISE-SJSU. K1.00017 Magnetization, Creep, and Flux Pinning in YBa$_2$Cu$_3$O$_{7-x}$ Thin Films with Nanoscale Pinning. M.D. SUMPTON, Ohio State University, T.J. HAUGAN, P.N. BARNES, Air Force Research Laboratory, C. VARANASI, University of Dayton Research Inst. — Critical current and flux pinning have been studied for YBa$_2$Cu$_3$O$_{7-x}$ (YBCO) thin films with Y$_2$BaCuO$_5$ (211) precipitates introduced as layers and as random distributions. Magnetically determined critical current density ($J_c$) was fit to $J_c \propto B^{\alpha}$ and values of $\alpha$ were suppressed from the control sample values of $\alpha = 0.5$ to lower values for pinned samples, reaching as low as $\alpha = 0.2$ for the layer pinned 211 sample at low temperatures. $U/J$ vs $J$ curves were extracted from M-H measurements with various ramp rates, at temperatures from 4.2 K to 77 K for pinned and control samples. Direct magnetization decay measurements were made for the 211 layer pinned sample and good agreement was seen with ramp rate derived results. Values of $\mu \approx 0.6-0.8$ were seen for all samples, while $\mu \approx 0.4$ for control samples, 0.1 for layer pinned samples, and 0.0-0.4 for the random pinned samples. The values of $\mu$ and $\nu$ extracted were inconsistent with 2-D pinning behavior in all cases, even though the layer spacing in the layer pinned sample is smaller than the calculated collective correlation length. While the layer pinned sample is clearly in the collective pinning regime, the artificial defects in the random pinned sample may be in the isolated strong pinning regime.

K1.00018 Oxidation of MgB$_2$ Thin Films. J. READ, Cornell, Y. CUI, Penn State, B. MOECKLY, Superconductor Technologies, J. SHU, Cornell, X. XI, Penn State, R. BUHRMANN, Cornell — We report on x-ray photoelectron spectroscopy studies of the surface oxides of high quality MgB$_2$ thin films grown both by reactive evaporation [1] and by hybrid chemical physical vapor deposition [2]. Depending upon the treatment of the MgB$_2$ surface after deposition, the oxide can contain both magnesium and boron, with a substantial variation in the Mg:B ratio. Brief high temperature ($T \geq 400 {^\circ}C$) exposure of the MgB$_2$ surface to even near ultra-high-vacuum conditions, results in the formation of a thin mixed oxide (Mg$_x$B$_{1-x}$O$_y$) and subsurface layer of elemental B due to the greater reactivity of Mg. As a result of the higher mobility of the Mg cations, prolonged exposure to the background ambient additionally results in a progressively thicker MgO surface oxide layer, and in a larger elemental B subsurface component. The surface oxide formed at $\approx$38.5 K. Magneto-thermal instabilities as flux jumps are observed in the magnetization hysteresis loops below 23 K, for all samples. The results show instabilities in the critical current, $J_c$, below 10 K as a consequence of the flux jumps events observed in the isothermal magnetization curves. In this presentation we will analyze the influence of the flux jumps on the critical currents densities.
K1.00019 Deposition temperature dependence of YBCO transport properties, JIE WANG, J.H. KWON, J. YOON, H. WANG, Texas A&M University, T.J. HAUGAN, F.J. BACA, N.A. PIERCE, P.N. BARNES, Air Force Research Laboratory — In this paper, we report a strong correlation between the stacking fault (SF) density and the critical current density of YBa$_2$Cu$_3$O$_7$-(δ)YBCO thin films in an applied field (Jcin-field). High quality superconducting YBCO thin films (thickness ~300 - 350 nm) were deposited on SrTiO$_3$ (STO) and LaAlO$_3$ (LAO) substrates using a pulse laser deposition (PLD) technique. We found that the Jcin-field increases as the deposition temperature increases (775°C - 825°C) for the samples grown on both STO and LAO substrates. Detailed microstructural studies including cross-section transmission electron microscopy (TEM) and high resolution TEM were conducted for all the films deposited on STO substrates. The YBCO SF density increases from ~ 4.0 x10$^5$/cm to ~1.2 x10$^6$/cm as the deposition temperature increases from 775°C to 825°C. An interesting linear relation is observed between the SF density and the Jcin-field value, which suggests that the YBCO SF density plays an important role in the YBCO in-field transport performance.

K1.00020 Fluctuation Nernst-Ettingshausen Effect above Ordinary/Quantum Superconducting Transition, ANDREI SERGEEV, SUNY at Buffalo, MICHAEL REIZER, VLADIMIR MITIN, SUNY at Buffalo — A problem of the definition of the heat transferred in thermomagnetic phenomena has been well realized in the late sixties, but not solved up to date. Ignoring this problem, numerous recent theories grossly overestimate the thermomagnetic coefficients in strongly interacting systems. Here we develop a gauge-invariant microscopic approach, which shows that the heat transfer should include the energy of the interaction between electrons and a magnetic field. We also demonstrate that the surface currents induced by the magnetic field transfer the charge in the Nernst effect, but do not transfer the heat in the Ettingshausen effect. Only with these two modifications of the theory, the physically measurable thermomagnetic coefficients satisfy the Onsager relation. We critically revised the Gaussian fluctuation theory above the ordinary/quantum superconducting transition and show that the gauge invariance uniquely relates thermomagnetic phenomena in the Fermi liquid with the particle-hole asymmetry.

K1.00021 Flux-Flow noise in YBCO thin films in the normal region, transition and superconducting state, PAULA GIRALDO, HECTOR CASTRO — The dynamic of vortexes inside type II superconductor thin films in the mixed state, is that, under their critical temperature and immersed in a DC magnetic field below its critical value, can be studied by means of the measurement of flux-flow noise, before the transition, during it and in the superconducting state. We measure the fluctuation in the voltage signal in the pseudogap region for an YCaBaCuO thin film, and compare it with the response in the other two regions. The response for overdoped and underdoped samples is compared with the response of optimal doped samples.

K1.00022 Phase diagram and vortex dynamics in superconducting spherical nanoshells, JACQUES TEMPERE, TFVS, Universiteit Antwerpen, VLADIMIR GLADILIN, INPAC, Katholieke Universiteit Leuven, ISAAK SILVERA, Lyman Laboratory of Physics, Harvard University, JOZEF DEVREESE, TFVS, Universiteit Antwerpen, VICTOR MOSCHCHALOV, INPAC, Katholieke Universiteit Leuven — Curving a superconducting film into a spherical shell changes its vortex-related properties drastically due to topological constraints. The interplay between the Lorentz force due to an applied field and the vortex superflow will force vortices away from the equator (leaving an equatorial “Meissner band”) and towards the poles, where they may coalesce to form giant or ring-like vortexes. Using the time-dependent Ginzburg-Landau equations adapted for the spherical geometry, we derive the phase diagram and identify where, as a function of the applied magnetic field, the shell thickness and the shell radius, different vortex phases occur. We also examine the dynamics of the decay of giant and ring-like vortices into a vortex lattice, when the magnetic field is adapted so that a phase boundary is crossed. Moreover, we show that the vortex dynamics are insensitive to moderate imperfections in the shell: effects due to topological constraints can overcome the pinning potential due to imperfections. This robustness, together with the tunability of the phase diagram through a limited set of controllable parameters, makes superconducting nanoshells uniquely suited for the study of vortex states.

K1.00023 Out of equilibrium phase dynamics in ferromagnetic Josephson junctions, IVANA PETKOVIC, MARCO APRILI, Laboratoire de Physique des Solides, Univ. Paris-Sud, CNRS, UMR 8502, F-91405 Orsay Cedex, France — With a pump-probe measurement performed below 1K, we probe the switching mechanism of strongly underdamped ferromagnetic Josephson junctions in the classical limit. At equilibrium or for slow sweeps, we observe that the switching is governed by thermal fluctuations, as expected. When the sweep frequency is comparable to the inverse phase relaxation time, we observe premature switching due to phase bifurcation. From the frequency dependence of the switching probability we deduce the phase relaxation rate τ = 1/RC, where R is the quasiparticle resistance and C the junction capacitance. Moreover, we observe a peculiar scaling of the Fiske steps (resonances between the Josephson phase and the electromagnetic cavity modes) with the junction length: the resonance frequencies are not multiples of the inverse junction length, but present a finite offset. We attribute this offset to the high frequency ferromagnetic susceptibility.

K1.00024 Macroscopic quantum tunneling in a damped Josephson junction coupled to a nanomechanical resonator, JOSHUA SCHIFFRIN, Carnegie Mellon University, BRAD TREES, YASER HELAL, Ohio Wesleyan University, BRIAN SILLER, University of Illinois at Urbana-Champaign — Motivated by work in the field of quantum computation, we studied the tunneling rate in a damped Josephson junction (JJ) coupled to a nanomechanical resonator. The Josephson phase difference was treated as the coordinate of a particle trapped in a metastable cubic potential well, and the resonator was considered to be a simple harmonic oscillator. The damping on the system by the environment was modeled as two reservoirs of simple harmonic oscillators, one of which was coupled to the JJ, and the other coupled to the resonator. We found that damping the JJ suppresses the tunneling rate, a result already predicted by theory and verified by experiment for a single JJ. We also find that increasing the coupling strength between the JJ and the resonator suppresses the tunneling rate, while adding damping to the resonator actually enhances the tunneling rate. These results are important, as a full understanding of the tunneling rate’s dependence on system parameters is essential for the proper operation of quantum bits.

K1.00025 Suppression of quantum fluctuations in a Josephson junction coupled to a nanomechanical resonator, YASER HELAL, BRAD TREES, Ohio Wesleyan University, JOSHUA SCHIFFRIN, Carnegie Mellon University, BRIAN SILLER, University of Illinois at Urbana-Champaign — The quantum mechanical properties of a Josephson junction (JJ) in parallel with a nanomechanical resonator were studied. The JJ phase difference was treated as a “particle” trapped in a quadratic potential well, which was used to approximate the well-known tilted washboard potential of the junction. When coupled to the resonator, the square of the uncertainty in the position of the JJ “particle” was suppressed, i.e. quantum fluctuations of the JJ were reduced by the resonator. The uncertainty principle was obeyed by the system, in that the square of the uncertainty in the JJ’s momentum was enhanced with resonator coupling. We also included the effects of environmental damping. Damping the junction enhanced the suppression of quantum fluctuations beyond that due to resonator coupling alone. Damping the resonator, however, suppressed the effect of JJ-resonator coupling and thus resulted in less suppression of quantum fluctuations. Preliminary results for the effects on quantum fluctuations of a weak nonlinear term in the JJ’s potential energy have also been obtained.

Comparisons to experiment.

A new retrapping mechanism for fluxons, related to the coupling of the junctions in the array, has been identified. We present results from the simulations and determination of the transition rate of the fluxon from its pinned state to a running state. We simulate the classical RCSJ equations of motion for a 9-junction. Simulations of switching current measurements have been performed in order to support experimental work in our group. Switching current measurements allow incoherent electron charge pairing above $T_c$ and pair coherency with spin condensation below $T_c$. These ideas may also be linked to recent atomic scale tunneling experiments in La cuprates on nucleation of pairing pseudogaps and microscopic inhomogeneities in a real space.

KENNETH SEGALL, NIKHIL FERNANDES — We present a numerical study of the dynamics of fluxons trapped in a parallel array of Josephson junctions.

K1.00027 Exact thermodynamics of phase separation and pairings in Hubbard nanoclusters — ARMEN KOCHARIAN, Department of Physics and Astronomy, California State University Los Angeles, GAYANATH FERNANDO, TUN WANG, KALUM PALANDAGE, Department of Physics, University of Connecticut, JIM DAVENPORT, Computational Science Center, Brookhaven National Laboratory — The exact numerical diagonalization and thermodynamics in an ensemble of small Hubbard nanoclusters reveal intriguing insights into the phase separation, charge and spin pairings, Bose condensation and ferromagnetism in nanometer scale. The phase diagram off half filling strongly suggests the existence of electron pairing, superparamagnetism and saturated ferromagnetism in small nanoclusters driven by electron repulsion and doping. Rigorous criteria for the existence of charge and spin pairings in the ground state and corresponding crossovers at finite temperatures are formulated. The phase separation and electron pairing, monitored by a magnetic field and electron doping, surprisingly resemble phase diagrams in the family of doped high $T_c$ cuprates. Exact theory provides incoherent electron charge pairing above $T_c$, and pair coherency with spin condensation below $T_c$. These ideas may also be linked to recent atomic scale tunneling experiments in La cuprates on nucleation of pairing pseudogaps and microscopic inhomogeneities in a real space.

K1.00028 Ferromagnetic Pairing Ground States on Two-Coupled Chains — AKINORI TANAKA, Ariake National College of Technology — Recently, ferromagnetic superconductivity was discovered in ZrZn$_2$, UC$_2$Ge$_2$ and UB$_2$Ge$_2$. Microscopic explanation of this phenomenon is a challenge in theoretical physics, but the problem is rather subtle and difficult, since we have to treat rotational symmetry breaking of spin and electron-pair condensation simultaneously. At the present stage, it is expected that a simple concrete model exhibiting both ferromagnetism and electron-pair condensation, even if it has somewhat artificial aspects, will shed light on understanding of mechanisms of ferromagnetic superconductivity. Here we report an extended Hubbard model on two chains which has fully polarized pairing ground states. The Hamiltonian consists of intra-chain electron-hopping, on-site repulsion, inter-chain charge attraction and inter-chain ferromagnetic interaction terms. The following is shown in our model. In the case where the on-site repulsion term is vanishing, the model has degenerate ground states in which electrons form spin triplet pairs, and thus the ground states exhibit electron-pair condensation but do not exhibit ferromagnetism. When the on-site repulsion is added, the model has the unique (up to spin degeneracy) ground state in which ferromagnetism and electron-pair condensation coexist. We also present an extension of the model to higher dimensional cases.

K1.00029 Electron charge pairing and Nagaoka spin instabilities in nanoclusters — ARMEN KOCHARIAN, Department of Physics and Astronomy, California State University Los Angeles, GAYANATH FERNANDO, KALUM PALANDAGE, Department of Physics, University of Connecticut, JIM DAVENPORT, Computational Science Center, Brookhaven National Laboratory — The electron pairings and magnetism in various frustrated Hubbard clusters is studied systematically with emphasis on under doping, magnetic field and temperature. Small clusters provide insight into charge-spin separation and thermal condensation of electron charge and spin degrees [1]. The spin saturated phase in so called Nagaoka state is found equivalent to ferromagnetic Mott-Hubbard like insulator with spin pairing gap, while non maximum spin ground state is of BCS-like metallic origin with equal charge pairing and spin gaps. The calculated phase diagrams resemble a number of spatially inhomogeneous coherent and incoherent paired phases seen in nanometer scale in high $T_c$ cuprates, fullerene molecules, Co and Nb nanoparticles. [1] A. N. Kocharian, G. W. Fernando, K. Palandage, Tun Wang and J. W. Davenport, Phys. Rev. B 62, 8671 (2000).

K1.00030 Dynamic Response to On/Off Signals in Nano Junctions — ZHANYU NING, McGill University, YU ZHU, JOSEPH MACIEJKO, JIANG WANG, HONG GUO, HONG GUO TEAM, JIANG WANG TEAM — We report the implementation of the time-dependent nonequilibrium Keldysh Green’s function theorem (TD-NEGF). It provides a promising way to study the transient transport dynamics in nano devices by first principles calculation. Very importantly, we derive an efficient technique to overcome the singularity problem in the integration of spectrum function. The reliability of this method is carefully checked by a one-dimension chain model with the analytical solution. We then perform the ab-initio calculation in a realistic molecular junction (Al-Benzene-Al). The current dynamic response arises after applying an “upward” or “downward” step pulse, which predicts a characteristic timescale in transport dynamics of nano systems.

K1.00031 One-dimensional fermion pairing — RAFAEL MENDOZA, Posgrado en Ciencias Fisicas, UNAM, M. DE LLANO, Instituto de Investigaciones en Materiales, UNAM, M. FORTES, M.A. SOLIS, Instituto de Fisica, UNAM, Mexico — We study fermion pairing in a one-dimensional fermion gas at $T = 0$ interacting via a generalized two-body attractive, separable interaction [1] where the effective range was varied from zero (delta potential) to infinity. The binding energy of fermion pairs with zero center-of-mass momentum increases as a function of the interaction strength and decreases as a function of the interaction range for a given strength. Fermion pairs with finite, nonzero center-of-mass momentum have an energy dispersion relation that exhibits two excitation branches: One phonon-like for low momentum which, for weak coupling, can disappear before the second, roton-like excitation appears for values of the momentum larger than $2k_F$ and only above a minimum threshold interaction strength value. The interaction range has the effect of privileging the quadratic over the linear relation dispersion as it goes from short to long range. This study completes a trilogy initiated for 3D [2] and later for 2D [3].

K1.00033 Signatures of Kosterlitz-Thouless behavior in the superfluid density of anisotropic layered superconductors, LARA BENFATTO, Centro Fermi and University of Rome “La Sapienza”, CLAUDIO CASTELLANI, University of Rome “La Sapienza”, THIERRY GIAMARCHI, University of Geneva — In quasi-two-dimensional (2D) systems, as thin films of He or of superconductors, the superfluid transition is expected to be driven by phase fluctuations, according to the Kosterlitz and Thouless (KT) theory. However, signatures of KT vortex-antivortex phase fluctuations should be observable, at some energy scale $T_d$, also in strongly anisotropic layered superconductors, where quasi-2D behavior arises due to a small Josephson coupling between neighboring planes. While in the 2D case $T_d$ is uniquely identified by the KT temperature $T_{KT}$ where the universal jump of the superfluid density is observed, in the layered case such universality is lost. Here we show this effect by means of a renormalization-group analysis of a layered version of the sine-Gordon model, appropriate to describe the occurrence of KT physics in layered superconductors. We find that in the presence of a finite interlayer coupling $T_d$ is controlled by the vortex-core energy, and can be significantly larger than the 2D scale $T_{KT}$. When applied to the superfluid-density behavior in cuprate superconductors these results allows us to determine a non-trivial behavior of the vortex-core energy in these systems. L.Benfatto, C.Castellani and T.Giamarchi, Phys. Rev. Lett. 98, 117008 (2007).

K1.00034 Fermi surface arcs and the infrared conductivity of underdoped YBa$_2$Cu$_3$O$_{6.5}$, JUNGSEEK HWANG, University of Florida, JULES P CARBOTTE, THOMAS TIMUSK, McMaster University — Using recent finding, that the electronic states lost below the pseudogap energy ($\Delta$) are recovered in the energy region immediately above it, we analyze the in-plane far infrared conductivity data in underdoped ortho$\beta$YBa$_2$Cu$_3$O$_{y.5}$, and are able to find evidence for the opening of a pseudogap on part of the Fermi surface with the remaining ungaped piece proportional to the temperature. These results are similar to recent angle-resolved photoemission spectroscopy data in underdoped Bi$_2$Sr$_2$CaCu$_2$O$_{8-\delta}$.

1 This work has been supported by the Canadian Natural Science and Engineering Research Council (NSERC) and the Canadian Institute for Advanced Research (CIAR).

K1.00035 Ultrafast Carrier Dynamics of YBCO Films with Various In-plane Orientations Investigated by Pump-probe and Terahertz Spectroscopy, SHYH-SHIH PAI, ZEN-CHI LIN, PAO-AN LIN, CHENG-CHUNG CHI, INSTRUMENT TECHNOLOGY RESEARCH CENTER, NATIONAL APPLIED RESEARCH LABORATORIES, TAIWAN, ROC TEAM, INSTITUTE OF PHOTONICS TECHNOLOGIES, NATIONAL TSING HUA UNIVERSITY, TAIWAN, ROC TEAM, DEPARTMENT OF PHYSICS, NATIONAL TSING HUA UNIVERSITY, TAIWAN, ROC TEAM — In this study, we focus on the terahertz (THz) and optical responses of superconducting YBa$_2$Cu$_3$O$_{6-\delta}$ (YBCO) films with various in-plane orientations. We report results and analyses of THz time domain spectroscopy and time-resolved photoinduced reflectivity experiments on four in-plane oriented superconducting YBCO films grown on yttria-stabilized zirconia substrates. Our study of the transmissions of THz time domain spectroscopy indicates a higher value of conductivity at room temperature for the 0°-orientation films than the 45°-films. Using the optical pump-THz probe scheme, we observed combinations of positive and negative THz transmission transients relative to a thermal equilibrium level with different relaxation times of about 0.9 and 9.0 ps respectively for all samples containing 45°-domains. Possible physical mechanisms will be discussed.

K1.00036 Influence of oxygen orbitals on impurity states in superconducting cuprates, ALEXANDER KEMPER, HAI-PING CHENG, P.J. HIRSCHFELD, University of Florida — Recent STM studies have shown that the oxygen states play a hitherto unappreciated role in the inhomogeneous electronic structure of the CuO$_2$ plane. To gain some insight into these effects, we solve the Bogoliubov-de Gennes equations numerically for a 3-band Hubbard model with d-wave pair interaction. We consider the role of the various oxygen atomic orbitals in the in the formation of impurity bound states and magnetic moments in the presence of correlations described by the Hubbard U. Finally, we study the interference of many impurities.

3 This work was supported by DOE grants DE-FG02-97ER45600, DE-FG02-05ER46236 and DE-FG02-02ER45995 and by the University of Florida High Performance Computing center.

K1.00037 Nature of the superconductor-insulator transition in disordered thin films, YONATAN DUBI, Physics Department, University of California-San Diego, YIGAL MEIR, YSHAI AVISHAI, Department of Physics and The Ilse Katz Center for Meso- and Nano-Scale Science and Technology, Ben Gurion University, Beer Sheva 84105, Israel — Highly disordered superconducting (SC) thin films undergo a magnetic-field (B) driven superconductor-insulator transition (SIT) whose detailed nature is still not completely understood. Starting from a microscopic description, we analyze this SIT in disordered thin films, and demonstrate that disorder leads to the formation of islands where SC order is rather high. For weak disorder, increasing B eventually results in the vanishing of the SC order parameter, implying an insulating state. At higher disorder, however, increasing B suppresses correlations between phases of the SC order parameter in different islands, giving rise to a novel kind of SIT. One of the remarkable predictions of this study is that in the latter regime, there are still SC islands in the sample even on the insulating side. This outcome, which is consistent with pertinent experiments, explains the recently observed huge magneto-resistance peak in disordered thin films. It may also be relevant in attempts to explain the occurrence of pseudo-gap in under-doped high-Tc superconductors, which have recently been found to be intrinsically disordered.

K1.00038 Growth and properties of Wo3, NasWo3, and KxWo3 thin films, AKIO TSUKADA, SEUNG SAE HONG, RICHARD J. HAMMOND, THEODORE GEBALLE, MALCOLM BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University — We report optimization of thin-film growth conditions and films properties of Wo3, NasWo3, and KxWo3. Films are grown by pulse laser deposition and used as substrates are (100) LaAlO3 (a = 3.788 A) and (101) Y-ZrO2 (3.63 A). Growth temperature and oxygen pressure are varied from 600C to 300C and from 10 mTorr to 1000 mTorr, respectively. Wo3 are formed in monoclinic or tetragonal structure on LaAlO3 substrates. Films are insulators and temperature dependence of resistivity shows the variable range hopping with Coulomb interaction like behavior [resistivity is proportional to exp(1/T)^(1/2)]. On Y-ZrO2 substrates are (100) LaAlO3 (a = 3.788 A) and (111) Y-ZrO2 (3.63 A). Growth temperature and oxygen pressure are varied from 600C to 300C and from 10 mTorr to 1000 mTorr, respectively. Wo3 films are formed in monoclinic or tetragonal structure on LaAlO3 substrates. Films are insulators and temperature dependence of resistivity shows the variable range hopping with Coulomb interaction like behavior [resistivity is proportional to exp(1/T)^(1/2)]. Y-ZrO2 substrates are formed in mixed structure of hexagonal and tetragonal due to an epitaxial effect [(111) Y-ZrO2 substrate has hexagonal surface]. KxWo3 films are formed in mixed structure of hexagonal and tetragonal due to an epitaxial effect [(111) Y-ZrO2 substrate has hexagonal surface]. KxWo3 films are formed in hexagonal structure on both substrates. a- and c-axis oriented films are obtained on LaAlO3 and Y-ZrO2 substrates, respectively. KxWo3 films show superconductivity at Tc(onset) ~ 4 K and Tc(zero) ~ 2 K. This work is supported by Air Force Office of Scientific Research.

K1.00039 ABSTRACT HAS BEEN MOVED TO SESSION X11

K1.00040 Vortex phase diagram and electromagnetic anisotropy of cation composition controlled Bi2212 single crystals, JUN-ICHI SHIMOMURA, TAKANORI MAKISE, YOSHIKI KAGESHIMA, SHIGERU HIRIO, KOJI YASUDA, Department of Applied Chemistry, University of Tokyo — In the present study, vortex phase diagram and pinning properties of Bi2212 single crystals under H // c have been systematically studied as functions of cation and oxygen compositions, while these matters were well understood for slightly cation-nonstoichiometric samples almost ten years ago. We confirmed that cation stoichiometry largely affects vortex state and pinning strength. A particular crystal with a cation composition of nearly 2:2:1.2 “Bi2212” exhibited strong bulk pinning behaviors even in the high temperature region, resulting in disappearance of magnetic irreversible region below the first-order-transition (FOT) temperature of vortex state. In addition, entropy change of the vortex at FOT of “Bi2212” crystals was found to be apparently larger than that of conventional ones. On the contrary, Bi and Ca-rich and Sr-poor single crystals showed poor pinning behaviors with low irreversibility fields and critical current density. Systematic enhancement of in-plane anisotropy in resistivity, decreases in $\rho_c$ and increases of penetration depth with approaching the cation stoichiometric composition suggested that disordered crystal lattice due to partial substitutions of Bi and Ca for Sr-site, which is common for conventional Bi2212 single crystals, degraded superconducting properties of Bi2212.
**K1.00041** What is the vortex “transport entropy”?\(^1\) ANDREI SERGEEV, SUNY at Buffalo, MICHAEL REIZER, VLADIMIR MITIN, SUNY at Buffalo — Below the superconducting transition the large thermomagnetic effects in the type II superconductors are determined by magnetic vortices. These topological excitations are completely different from particle-hole excitations in the Fermi liquid and, therefore, the thermomagnetic effects do not require particle-hole asymmetry. Thermomagnetic effects in the vortex state are widely described in terms of the “transport entropy.” Despite of intensive theoretical and experimental investigations, this mysterious quantity is still in conflict with either the Onsager principle or the third law of thermodynamics [1]. We resolve this forty years enigma taking into account the magnetization current in the presence of the temperature gradient. Then contributions of superconducting currents of vortices are canceled in the Nernst effect, and, therefore, in agreement with the Onsager relation, both the Nernst and Ettingshausen phenomena originate solely from vortex cores. Finally, the transport entropy turns out to be by a factor of $4\ln(\lambda/\xi)$ smaller than that used in literature [1] ($\lambda$ is the magnetic field penetration depth, $\xi$ is the coherence length. For high-temperature cuprates this factor is $\sim 20$.

---

**K1.00042** Variational Monte-Carlo investigation of gossamer-superconductivity, SIEGFRIED GUERTLER, FU-CHUN ZHANG, The University of Hong Kong, Department of Physics — Motivated by the interesting superconducting properties in layered organic materials, and the proposed gossamer superconductivity in this context, we performed variational Monte-Carlo simulations. We investigate a previously proposed model-Hamiltonian of a Hubbard-model with additional anti-ferromagnetic coupling term. We work on a square lattice with additional diagonal bonds and with a wave-function with partly projected double-occupanted states. Further factors for anti-fermagnetic states are introduced in our wave-function.

**K1.00043** Superconducting Mechanism in multi-walled Carbon Nanotubes, YONG-JIHN KIM, University of Puerto Rico — Recently Japanese group led by Haruyama [1] reported the significant enhancement of superconductivity, i.e., $T_c=12K$, in end-bonded Multi-walled Carbon Nanotubes. We can explain the enhancement by the electron confinement in the lateral direction, i.e., between the inner and outer cylinders, because electron density correlation enhances the phonon-mediated superconductivity. In other words, superconductivity in the (multi-walled) Carbon Nanotubes is due to the electron-phonon interaction and $T_c$ is enhanced due to the density correlation caused by the confinement. First, we use simple concentric rings to estimate the $T_c$ enhancement using the BCS theory. Next, we use the tight-binding model to calculate the $T_c$ increase more accurately. In this context, this experimental result is very similar to the enhancement of $T_c=15K$ in 4 angstrom single-walled Carbon Nanotubes by Tang et al. [2]. [1] I. Takesue et al., Phys. Rev. Lett., Vol. 96, 057001 (2006). [2] Z. K. Tang et al., Science, Vol. 292, 2462 (2001).

**K1.00044** Theoretical Investigation of Fermion Pairing in Three-band Extended Hubbard Model, PARTHA GOSWAMI, University of Delhi — We analyze for fermion pairing the two-dimensional extended Hubbard model (or d-p model) on a square lattice by a slave-boson method reported in a previous work\(^1\). The onsite coulomb repulsion between Cu d holes is assumed to be strong. The nearest-neighbor interaction in momentum space $U_{kq}$, introduced additionally, for transition from a momentum q to k is assumed to be separable and is expanded in terms of basis functions corresponding to $d_{xy}$ and $d_{x^2−y^2}$. The possibility of a mixed (s-d)-wave symmetry also exists for the spin degeneracy $N>|\lambda\rangle$ if boson field fluctuations are taken into consideration. For the hole doping ($\delta > 0$) case, the additional holes are expected to occupy oxygen sites. This implies that the renormalized charge transfer gap $\Delta_{xy}$ tends towards zero for $\delta > 0$. We find the approximate Fermi liquid behavior for $\Delta_{xy}$ once the pure $d_{x^2−y^2}$ wave singlet superconducting instability sets in; otherwise non-Fermi liquid behavior is the prevalent one. The charge and the spin ordering gaps appear in the single-particle excitation spectrum when $d_{xy}$ component is taken into account. The latter is expected to lead to the spin-pseudo-gap phenomenon in cuprates.

---

**K1.00045** Electronic structure calculations for the fluctuating-bond model of high-temperature superconductivity, R. A. NISTOR, University of Western Ontario, D. M. NEWNS, C. C. TSUEI, G. J. MARTYNA, IBM T. J. Watson Research Center, M. H. MUSER, University of Western Ontario — High-temperature superconductors (HTS) have been intensely studied for the past 20 years due to their scientific and technological importance. The materials are characterized by square arrays of copper-oxygen-copper bonds. Although several salient features of HTS phenomena have been characterized, a working theory of the underlying physical processes in these materials has been lacking. Collaborators at IBM have recently proposed a model for HTS (Nature Physics 3, p. 184, 2007), involving a nonlinear coupling of the planar oxygen vibrations to the $d_{x^2−y^2}$ electrons on the copper. This interaction is modeled as a two-phonon coupling process in the resulting fluctuating-bond model (FBM). In the present work, we investigate the FBM theory by exploring the ability of the oxygens to buckle out of the straight Cu-O-Cu configuration by adjusting the charge on the copper atoms. The study is being conducted using Car-Parrinello simulations to investigate the electronic structure of the materials, and zero temperature single point DFT energy calculations to investigate the floppiness of the oxygen bonds. The aim is to justify, from first principles, the parameterization used in the FBM theory.

**K1.00046** Near-Zero Modes in Superconducting Graphene, POUYAN GHAEMI, FRANK WILCZEK, Massachusetts Institute of Technology — Vortices in the simplest superconducting state of graphene contain very low energy excitations, whose existence is connected to an index theorem that applies strictly to an approximate form of the relevant Bogoliubov-deGennes equations. When Zeeman interactions are taken into account, the zero modes required by the index theorem are (slightly) displaced. Thus the vortices acquire internal structure; the resulting “modicules” obey nonabelian quantum statistics.

**K1.00047** Do ‘magic’ Electronegativities exist for superconductivity?\(^3\) O. PAUL ISIKAKU-IRONKWE, The Center for Superconductivity Technologies[TCST], Abuja FCT, Nigeria — Studies have established a strong correlation between electronegativity and superconductivity. Here we examine the electronegativity values of many known binary superconducting systems[A15s, Y2C3, CaSi2, MgB2, ...] with high transition temperatures and use those[magic] values and their series to predict new superconducting materials. We also estimate the transition temperatures of the predicted compounds if they could be formed under pressure.

K1.00048 Bogoliubov angle and visualization of particle-hole mixture in1, ILYA GRIGORENKO, Los Alamos National Laboratory, KAZU FUJITA, JINHO LEE, ALFRED WANG, Cornell University, JIAN XIN ZHU, Los Alamos National Laboratory, J.C. DAVIS, Cornell University, HIROSHI EISAKI, Nanoelectronics Research Institute, AIST, Japan, S. UCHIDA, University of Tokyo, ALEXANDER BALATSKY, Los Alamos National Laboratory — Superconducting excitations — Bogoliubov quasiparticles — are the quantum mechanical mixture of negatively charged electron (−e) and positively charged hole (+e). Depending on the applied voltage bias in STM one can sample the particle and hole content of such a superconducting excitation. Recent Scanning Tunneling Microscope (STM) experiments offer a unique insight into the inner workings of the superconducting state of superconductors. We propose a new observable quantity for STM studies that is the manifestation of the particle-hole dualism of the quasiparticles. We call it a Bogoliubov angle. This angle measures the relative weight of particle and hole amplitude in the superconducting (Bogoliubov) quasiparticle. We argue that this quantity can be measured locally by comparing the ratio of tunneling currents at positive and negative biases. Bogoliubov angle allows one to visualize robustness of superconducting state locally. It may also allow one to measure the particle-hole admixture of excitations in normal state above critical temperature and thus to measure superconducting correlations in pseudogap state.

1Work supported by the BES and LDRD funds from U.S. Dept. of Energy at LANL under Contract No. DE-AC52-06NA25396 and from BNL under Contract No. DE-AC02-98CH18868.

K1.00049 ABSTRACT HAS BEEN MOVED TO SESSION W17 –

K1.00050 Electronegativity Spectrum Maps: A computational combinatorial materials synthesis and search tool, O. PAUL ISIKAKU-IRONKWE, The Center for Superconductivity Technologies (TCST), Abuja FCT, Nigeria — Using Pauling’s electronegativity scale of the elements from 0.7 to 4.0 we build a matrix of possible binary combinations in increments of 0.1 for binary systems _A_ _B_. We get a 34 x 34 spreadsheet of electronegativities. We call this an ElectroNegativity Spectrum Map (ENSMap). Each of the 1156 cells represents a possible combination of two electronegativities that could yield a binary compound. Using the correlation between electronegativity and superconductivity, we can identify from an ENSMap the electronegativities of known superconductors of a given binary class. We can also identify other electronegativity combinations that give the same electronegativity as a known superconductor. Here we show that ENSMAPS of binary systems can become a powerful computational combinatorial material synthesis tool and also a tool for searching for novel materials. We use ENSMaps to predict twenty new binary superconductors with high transition temperatures.

K1.00051 MAGNETISM (EXPERIMENT, THEORY, APPLICATIONS) –

K1.00052 Magnetic susceptibility and Mössbauer studies of [FeX_3](ClO_4)_2·H_2O with X = bpz, bpy, phen or ppy, J.C. HO, H.H. HAMDEH, R. KIRGAN, D.P. RILLEMA, Wichita State University — Magnetic studies have been made on several tris-chelated iron complex compounds [FeX_3](ClO_4)_2·H_2O with aromatic nitrogen heterocycle ligands X = bpz (2,2’-bipyrazine), bpy (2,2’-bipyridine), phen (1,10-phenanthroline) or ppy (2,2’,6,2’’-terpyridine). SQUID data (2-300 K and 0.01-1 T) yielded small effective magnetic moments, which are characteristic of low-spin Fe(II), in agreement with the isomer shift and quadrupole splitting values from Mössbauer measurements (4-300 K, 0-5 T). Meanwhile, apart from the expected diamagnetism, a positive term of temperature-independent paramagnetic susceptibility prevails in most cases.

K1.00053 Experimental Determination of Thermal Entanglement in Spin Clusters using Magnetic Susceptibility Measurements, R.S. SARTHOUR, A.M. SOUZA, Centro Brasileiro de Pesquisas Físicas, D.O. SOARES-PINTO, M.S. REIS, CICECO, Universidade de Aveiro, I.S. OLIVEIRA, Centro Brasileiro de Pesquisas Físicas — Until a few years ago, entanglement was not believed to exist beyond atomic scale, due to the large number of constituents of macroscopic objects. Surprisingly, it was theoretically demonstrated that entangled states can exist in solids at finite temperature. This phenomenon, referred to as “thermal entanglement”, is not an effect of the coupling between Mn-Mn ions, but it is a “universal” property of solids. Since then, a few experimental evidences have been confirmed reporting the presence of entanglement in solids state systems. The present work reports an experimental observation of thermal entanglement in a spin chain formed in the compound Na2CuSi3O14. The presence of entanglement was investigated through two measured quantities, an Entanglement Witness and the Entanglement of Formation, both derived from the magnetic susceptibility, determined experimentally. It was found that pairwise and tripartite entanglement exist below ~200 K and ~240 K, respectively. A theoretical study of entanglement evolution as a function of applied field and temperature is also presented.

K1.00054 Magnetic Structure and Magnetic Properties of CaMn2Sb2, A.L. LIMA SHARMA, Yeshiva University, A.M.S. GOMES, Universidade Federal do Rio de Janeiro, I.L. GONZALES, Pontificia Universidade Catolica do Rio de Janeiro — The AM2X2 ternary intermetallic (A = rare or alkaline earth, M = transition metal) compounds have revealed interesting magnetic properties due to the interplay between their magnetic sublattices. Pursuing the idea that the coupling between Mn-Mn ions can significantly affect electric transport properties, we investigated (Ca,Sr)Mn2Sb2 intermetallic compounds which presents two secondary magnetic transitions at 82K and 250K. Field dependent dc-magnetization curves for CaMn2Sb2 were obtained at two different temperatures, above and below 250K, show a relatively steep increase of the magnetization upon increasing the field to _H_ = 5 kOe, followed by a less steep and almost linear increase with the field and no tendency for saturation. The net macroscopic moment on the Mn at 300 K and 50 kOe is only a fraction of a Bohr magneton (ca. 0.15 _B_ / Mn), and evidently, a simple interpretation of its value in terms of localized high/low spin Mn_2+ _ions_ is unrealistic. The low moment can be viewed as a signature of the counterbalanced magnetic properties, which are dominated by the Eu-Eu superexchange coupling. The sharply defined Neel temperature increases with hydrostatic pressure ( _d_ _T_N_ / _d_ _P_ = +0.03 K/kbar at low pressures.)

K1.00055 Pressure Dependent Magnetism in Magnetically Ordered Interlanthanide Chalcogenides1, E.S. CHOI, Florida State University/NHMFL, R.P. GUERTIN, Tufts University, THOMAS ALBRECHT-SCHMITT, G.B. JIN, Auburn University — Several new interlanthanide chalcogenide compounds, Ln’/Ln”/Q (Ln’=light and Ln”=heavy lanthanide, Q=5 or Se) have been synthesized using a novel flux-growth technique, their complex structures determined, and their magnetic properties measured. The majority, with general formula Ln’Ln”Q_4_, are paramagnetic for _T_ > 2K, with effective moments consistent with the magnetic Ln constituents. Eu_2Ln_2Q_4_ (Ln’=Tb - Lu), which crystallize in the CaF_2O_4_-type three-dimensional channel structure, are all antiferromagnetic with _T_N_ ~ 3-5 K. The Ln constituent is geometrically frustrated and has secondary effects on the magnetic properties, which are obtained by the Eu-Eu superexchange coupling. The sharply defined Neel temperature increases with hydrostatic pressure to _P_~ 7 kbar for all EuLn_2Q_4_. (For example, for EuLu_2Se_4_, _dT_N_/dP = +0.03 K/kbar at low pressures.)

1Work supported by the US DOE through the EPSCoR program. NHMFL supported by NSF and the State of Florida.
K1.00056 Possible Exotic Magnetism in the Anti-Perovskite Nitride Cr$_3$PtN$^1$. J.R. THOMPSON, Univ Tennessee and Oak Ridge Natl Lab, M.P. BRADY, J.H. SCHNEIBEL, D.J. SINGH, E.A. PAYZANT, ORNL, J.W. SINCLAIR, A.P. SUBEDI, Univ Tennessee, A. MANIVANNAN, Natl Energy Tech Lab, M. SEEHRA, W VA Univ — Samples of the anti-Perovskite nitride Cr$_3$PtN were synthesized for bulk magnetism studies. X-ray diffraction confirmed the structure and several new phases within instrumental sensitivity ($\sim$-2.4 vol. %). Bulk magnetic properties were studied by SQUID magnetometry at $T = 5$-300 K in magnetic fields $H$ up to 6.5 T. Highly hysteretic ferromagnetism was found, with a Curie temperature $T_c \approx 110$ K. (Prior to nitriding, the Cr$_3$Pt starting material was paramagnetic.) At $5$ K, the coercive field $H_c$ is $\sim 2.3$ T. The curious and possibly exotic feature is that the saturation magnetic moment is small, 0.2 G-cm$^3$/gram: if the signal arises from bulk Cr$_3$PtN, the corresponding moment is only 0.1 $\mu_B$ per formula unit, which is quite small for a 100 K ferromagnetic. The saturation magnetization varies as $M_{sat} \sim (1/T)^{0.5}$ with critical exponent $\beta=0.40$. In isostuctural Pd-based Cr$_3$PtN (not single phase), no ferromagnetism was found above 5 K. DFT calculations of the band structure for the ideal anti-Perovskite compounds revealed a high electronic density of states $N(E_F)$ for Cr$_3$PtN and a somewhat lower value for Cr$_3$PdN.

$^1$Research sponsored by US DOE via the LDRP Program of ORNL.

K1.00057 Spin-reorientation transitions in Er, Tm and Yb orthoferrites: magnetic and structural properties. Y.A. BAZALIY, Leiden University, The Netherlands; University of South Carolina, Columbia, SC, USA; Institute of Magnetism, Kyiv, Ukraine, L. T. TSYMBAL, N. V. DERRKACHENKO, V. I. KAMENEV, O.Galkin Donets Physics and Technology Institute, National Academy of Science, Donets, Ukraine, G. N. KAKAZEI, Instituto de Ciencia de Materiales de Madrid, CSIC, Madrid, Spain; Institute of Magnetism, National Academy of Science, Kyiv, Ukraine, F. J. PALOMARES, and Structural characteristics of ErFeO$_3$, TmFeO$_3$ and YbFeO$_3$ single crystals were studied over a wide temperature range. Magnetic measurements found that the spin-reorientation transitions in all crystals are well described by the earlier proposed theory with no fitting parameters. Additionally, they have shown the absence of the magnetic compensation point in TmFeO$_3$, and a noticeable growth of the c-axis magnetization at low temperatures in TmFeO$_3$ and ErFeO$_3$. The X-ray measurements found no symmetry-lowering lattice distortions during the reorientation. Overall, the measurements cover a wide range of material parameters and demonstrate the generality of the modified mean field theory of the $\Gamma_3 \rightarrow \Gamma_{24} \rightarrow \Gamma_2$ orientation phase transitions in orthoferrites. // L. T. Tsymbal et al., J. Appl. Phys 101, 123919 (2007).

K1.00058 Magnetostatic Interactions in Partially Shielded Polyaniline-Ferromagnet Composite Nanowire Arrays. ADAM FRIEDMAN, DERRICK BRITTAIN, LATIKA MENON, Northeastern University Dept. of Physics — Ferromagnetic nanowires have remarkable magnetic properties including high coercivities and strong magnetic shape anisotropy. These unique properties have been theoretically studied and various models attribute the observed characteristics to inter- and intra-wire magnetostatic interactions, which are a function of the structure of the nanowires and their coupling with the applied magnetic field. In this study, we use porous alumina templates and electrodeposition to fabricate Fe, Ni, and Co nanowires, creating magnetically shielded ferromagnet structures. We measure the magnetic properties of these structures as a function of their diameter and temperature in order to better understand the magnetic interactions that arise in ferromagnetic nanowire arrays. By partially shielding the wires with PAni, we are able to better discern the effects of these interactions. Results will be presented and compared to theoretical models.

K1.00059 Dipolar effect in the standing spin waves of dot structures$^1$. C. YU, M. PECHAN, Department of Physics, Miami University of Ohio — Standing spin waves in dot structures are generally described by dipole-exchange mechanisms. In this work, the role of dipolar coupling has been probed via micromagnetic simulation of spin wave mode structure on a circular, permalloy dot, 200nm diameter, 40nm thickness containing a concentric gap (ring) void of magnetic material. This gap precludes exchange coupling between the inner dot and the outer ring of the overall ferromagnet structures. We measure the magnetic properties of these structures as a function of their diameter and temperature in order to better understand the magnetic interactions that arise in ferromagnetic nanowire arrays. By partially shielding the wires with PAni, we are able to better discern the effects of these interactions. Results will be presented and compared to theoretical models.

K1.00060 Absence of Hole Confinement in Transition Metal Oxides with Orbital Degeneracy$^3$. MARIA DAGOHER, University of Tennessee, KRZYSZTOF WOHLFELD, ANDRZEJ M. OLES, Jagiellonian University, ENRICO ARRIGONI, Graz University of Technology, PETER HORSCH, Max-Planck-Institut FKF — The compounds with orbital degrees of freedom exhibit many possible scenarios for hole propagation which in most cases lead to hole localization [1]. Here we investigate the spectral properties of a hole moving in a two-dimensional Hubbard model for strongly correlated $t_{2g}$ electrons. Although superexchange interactions are Ising-like, a quasi-one-dimensional coherent hole motion arises due to effective three-site terms. This mechanism is fundamentally different either from the hole motion via quantum fluctuations in the conventional spin model with SU(2) symmetry or from the $e_g$ orbital model [2]. The present orbital model describes also propagation of a hole in some $e_g$ compounds [3], and we argue that orbital degeneracy alone does not lead to hole self-localization. [1] J. Zaanen and A.M. Oleś, Phys. Rev. B 48, 7197 (1993). [2] J. van den Brink, P. Horsch, and A.M. Oleś, Phys. Rev. Lett. 85, 5174 (2000). [3] M. Daghofer, A.M. Oleś, and W. von der Linden, Phys. Rev. B 70, 184430 (2004).

$^3$We acknowledge support by Foundation for Polish Science (FNP), by the Polish Ministry of Science and Education Project No. N202 068 32/1481, and by the Austrian Science Fund (FWF Project P18505-N16).

K1.00061 Magnetic phase separation in LaMn$_{1-x}$Fe$_x$O$_{3+y}$, O.F. DE LIMA, Instituto de Fisica Gleb Wataghin, UNICAMP, Campinas, J.A.H. COAQUIRA, R.L. DE ALMEIDA, J.B. DE CARVALHO, S.K. MALIK, Centro Internacional de Fisica da Materia Condensada, UnB, Brasilia — We have investigated the LaMn$_{1-y}$Fe$_y$O$_{3+y}$ system in the whole composition range 0$\leq y \leq 1$, for polycrystalline samples prepared by solid state reaction in air. All samples show orthorhombic structure (space group Pnma). For $x=0$ the oxygen excess, estimated to be $y \approx 0.1$, produces vacancies in the La and Mn sites and generates a fraction around 20% of Mn$^{4+}$ ions (3t$_2g$) and 80% of the usual Mn$^{3+}$ ions (3t$_2g$, 1e$_g$), with possible double exchange interaction between them. The Fe-doping in this system is known to produce only stable Fe$^{3+}$ ions (3t$_2g$, 2e$_g$). We find an evolution from a fairly strong ferromagnetic (FM) behavior, with saturation magnetization (T=2K) $m_S \approx 4 \mu_B$ and Curie temperature $T_C \approx 160$ K, for $x=0$, to an antiferromagnetic (AFM) behavior, with $T_N=790$ K, for $x=1$. For intermediate Fe contents a mixed phase scenario occurs, with a gradual decrease (increase) of the FM (AFM) phase, accompanied by a systematic transition broadening for 0.2$<x<0.7$. A calculation based on the expected exchange interaction among the various magnetic-ion types, accounts very well for the $m_S$ dependence on Fe doping.

$^3$We acknowledge the Brazilian agencies FAPESP, CNPq and CAPES.
K1.00062 The Friedel-Anderson Impurity with Orbital Degeneracy. LIYE ZHANG, GERD BERGMANN, Univ. of Southern California — A recently developed compact solution for the non-degenerate Friedel-Anderson impurity is extended to impurities with orbital degeneracy. The singlet ground state is investigated for two and three orbits (corresponding to four and six d-states). The ground state energy and the multi-d-state occupations are calculated. The magnetic moment (above the Kondo temperature) is obtained in different regions of the parameter space of $V_{dd}$ (s-d-hopping matrix element), $E_g$ (d-state energy), $U$ and $U_d$ (Coulomb and exchange energies). The average d-state occupation can be adjusted to about one, two or three d-electrons. A comparison between different orbital degeneracy but the same d-state occupation is performed. The role of the Coulomb and the exchange interaction in the magnetic and singlet states is analyzed. The challenges for the treatment of a real d-impurity with five d-orbits is discussed.

K1.00063 Magnetic and charge correlations in the frustrated 2D Hubbard model1. MATTHEW ENJALRAN, Department of Physics, Southern CT State University, 501 Crescent St., New Haven, CT 06515 — The high temperature superconductors have motivated numerous theoretical studies of strongly correlated many-body systems for over two decades. The richness of the phase diagram of these materials belies their relatively simple quasi-two-dimensional structure of stacked CuO$_2$ planes, where copper ions form a square lattice. With the experimental observation of several complex phases, including superconductivity, in quasi-two-dimensional triangular lattice materials (e.g., Na$_x$CoO$_2$, $\delta$H$_2$O and $\kappa$-(ET)$_2$X) we now have material systems in which geometric frustration plays a prominent role. With this as our motivation, we investigate the 2D Hubbard model on a series of lattice geometries. The results show some interesting tendency towards new phases for the frustrated systems. We conclude with a discussion of the potential application of the constrained path quantum Monte Carlo (CPQMC) method to the study of frustrated 2D Fermi systems.

*K1.00064 Identification of Bosonic Mode in the Electron-Doped Superconductor Pr$_{1.05}$LaCu$_{12}$O$_{29.5}$, SHANKAR KUNWAR, FRANCIS NIESTEMSKI, SEN ZHOU, Department of Physics, Boston College, Chestnut Hill, MA, 02467, SHILIANG LEE, University of Tennessee, Knoxville, TN, 37996, HONG DING, ZIQIANG WANG, Department of Physics, Boston College, Chestnut Hill, MA, 02467, PENGCHENG DAI, University of Tennessee, Knoxville, TN, 37996, MADHAVAN VIDYA, Department of Physics, Boston College, Chestnut Hill, MA, 02467 — It is well known that in the superconducting state, the current carriers are the cooper pairs, where two electrons (fermions) get paired up by a mediator (glue) and behave as a single boson. In conventional superconductors, lattice vibrations (phonons) act as a glue to pair up the electrons, however, in high T$_c$ superconductors, the mechanism that binds these fermions together is still unclear. There are two principal contenders for the glue: phonons and the spin excitations. Using high resolution STM we have probed an electron-doped superconductor, Pr$_{1.05}$LaCu$_{12}$O$_{29.5}$, and identified a bosonic excitation at 10.5 ± 2 meV which could potentially act as the superconducting glue. The energy scale of this mode rules out an explanation in terms of the oxygen optical phonons confining the possibilities to spin excitations and the acoustic phonons. This finding potentially takes us one step closer to identifying the superconducting glue in High T$_c$ superconductors.

K1.00065 Investigating the Structure of La$_2$CuGa$_{12}$, Using Neutron Powder Diffraction. JASMINE MILLICAN, National Institute of Standards and Technology, JUNG YOUNG CHO, JULIA CHAN, Louisiana State University, JUDITH STALICK, National Institute of Standards and Technology — Single crystals of a new phase, La$_2$CuGa$_{12}$, have been synthesized using flux growth. Preliminary single crystal X-ray diffraction results suggest La$_2$CuGa$_{12}$ to be isostructural to Ce$_2$PdGa$_{12}$ and crystallize in the P$4$/nmb space group with lattice parameters of $a$ ~ 6.179 Å and $c$ ~ 15.384 Å. Residual electron density, which was observed in the Fourier difference map of the single crystal X-ray diffraction data, and the observation of satellite peaks in the data are indicative of the possibility of statistical disorder in La$_2$CuGa$_{12}$. In addition, unusual behavior of thermal parameters for an additional Ga position is observed in the X-ray diffraction data of La$_2$CuGa$_{12}$. Although a preliminary model has been constructed using single crystal X-ray diffraction experiments, due to the two electron difference between $^{67}$Ga and $^{61}$Ga, neutron powder diffraction experiments may be a more suitable probe in accurately determining the structure and site occupancy of the additional Ga atom in La$_2$CuGa$_{12}$. We have employed neutron powder diffraction (BT-1) to investigate the structure in the phase, La$_2$CuGa$_{12}$.

K1.00066 Synthesis and Characterization of High Quality Single Crystal CeCoIn$_5$, ABEBE KEBEDE. TERREL DIAL, NC A&T State University — The preliminary results on the structure and electronic properties of (Re, Ce)(Co, M)In$_5$ are presented. Here R = Pr and M = Fe. We present the results of our measurements of resistivity, specific heat and magnetization. This work is supported by the Department of Energy Grant # DE-F052-05NA27036.

K1.00067 Spin valve electrode for organic light emitting devices. LIANBIN NIU, YUNXIA GUAN, YUE REN, CHUNYANG KONG, YAN MA, YIPEING LIAN, YAN FANG, Department of Physics, Chongqing Normal University — Effects of spin filter on singlet and triplet exciton fractions in organic light-emitting devices (OLEDs) is attracting considerable attention nowadays. Electroluminescence in organic semiconductors strongly depends on the relative population of singlet and triplet excitonic states. Controlling the spin statistics by injecting and transporting carriers with defined spin orientation can amplify a chosen electronic transition increasing the device efficiency or changing the emission spectral band. A spin valve was used as hole injector, substituting the traditional indium tin oxide electrode. A comparison of electroluminescence and IV curves between similar devices with and without spin valve electrode is reported. The result shows that spin valve can successfully replace conventional electrode in OLEDs.

K1.00068 Nonlinear current-voltage characteristics of oxygen-deficient La$_{0.67}$Ca$_{0.33}$MnO$_{3-y}$ films1. SHIU-JEN LIU, Department of Materials Engineering, Mingchi University of Technology, J.Y. JUANG, Department of Electrophysics, National Chiao Tung University, J.Y. LIN, Institute of Physics, National Chiao Tung University, K.H. WU, T.M. UEN, Department of Electrophysics, National Chiao Tung University, Y.S. GOU, Department of Physics, National Taiwan Normal University — Two different types of nonlinear current-voltage characteristics are observed in oxygen-deficient La$_{0.67}$Ca$_{0.33}$MnO$_{3-y}$ (LCMO) films at temperatures below insulator-metal transition. The parabolic-like dynamic conductance $G(V)$, defined as $dI/dV$, curves near zero bias observed in highly oxygen-deficient LCMO films implies the contribution from the spin-dependent tunneling transport between ferromagnetic clusters with magnetic-disordered regions serving as tunneling barriers. On the other hand, for the slightly oxygen-deficient LCMO films, dips around zero bias were observed in nonlinear $G(V)$ curves and have been attributed to spin-flip scattering with oxygen vacancies serving as scattering centers.

1Supported by the National Science Council of Taiwan, under Grant No. NSC 95-2112-M-131-002-MY3
K1.00069 Anisotropies in Quaternary Intermetallic Compounds, W.C. LEE, Dept. of Physics, Sookmyung Women's Univ. Seoul 140-742, Korea — From the high-temperature series expansion of magnetic susceptibilities and the anisotropic Weiss temperatures, the first Stevens' parameter, $B_2^0$, and the magnetic exchange interaction constant $J_{1x}$ of each $R^3$ ions magnetic sublattice in quaternary intermetallic compounds, $R_{1}R_{2}B_{x}C_{y}(R=R_{tm}, R_{h}, D_{y}, T_{b})$ were obtained. The $R= Dy$ system shows the biggest $B_2^0$ value and the $R= Tb$ system does the smallest one. Also we have applied the anisotropic M(H) isotermers as a function of applied magnetic fields for H perpendicular and parallel to the c-axis for each compounds to check out our crystalline electric field (CEF) results obtained from the previous mentioned method by using the anisotropic Weiss temperatures. It turned out that most of the temperature dependence of magnetization curve M (T) for H perpendicular the c-axis at low temperature comes from the temperature dependent population of the singlet ground state in group L among groups L(low-lying levels of ground states), H(high levels of ground states), and M(first excited states).

K1.00070 Anisotropy in the magnetodielectric constant in orthorhombic HoMnO$_3$ thin film, SUNG HO LEE, BONG YEOL LEE, MIN HWAX JUNG, YOON HEE JONG, Pohang University of Science and Technology, Pohang, Korea — Epitaxial HoMnO$_3$ thin films in the metastable orthorhombic structure were successfully synthesized on SrTiO$_3$ substrates by pulsed laser deposition. The crystal structure, surface roughness, and surface morphology of the films were characterized by various tools such as X-ray diffraction, atomic force microscopy, scanning electron microscopy etc. Macroscopic physical properties were measured with a Quantum Design PPMS. It is found that an significant increase of the dielectric constant accompanies the onset of magnetic order at 45 K in the films. This then proves that there exists a magnetodielectric coupling in orthorhombic HoMnO$_3$. Anisotropy in the magnetodielectric constant was observed according to the direction for an external magnetic field. These behaviors will be compared to the cases of YmMnO$_3$ and BiMnO$_3$. Measurements of the reverse effect, that is, the variation of the magnetic susceptibility with an electric field, are being attempted.

K1.00071 ABSTRACT WITHDRAWN

K1.00072 Diffraction-induced magneto-optical enhancement in gyrotropic gratings, YUEHUI LU, MINHYUNG CHO, JINBAE KIM, GEONJOON LEE, YOUNGPAK LEE, q-Psi and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, Korea, — The spectra of diffrekted magneto-optical Kerr effect (D-MOKE), for polar magnetization in one-dimensional gyrotropic gratings, were presented by Antos et al. [Appl. Phys. Lett. 86, 231101 (2005)]. It was noted that the magnitude of Kerr rotation in the first-order diffraction was one order higher than that of the zeroth-order diffraction in most of the energy range. In this study, a rigorous coupled-wave approach, implemented as Airy-like internal series, was applied to investigate the diffraction-induced MO enhancement. The simulated spectra of D-MOKE are consistent with their experimental ones. Moreover, it was found that the magnitude ratio of the first-order Kerr rotation to the zeroth-order one was strongly dependent on the grating depth. In other words, D-MOKE can be effectively modulated by the groove depth. This theoretical approach is of great significance in designing and applying the diffracted MO elements.

K1.00073 Synthesis and magnetic properties of Zn$_{1-x}$Mn$_x$O/ZnO coaxial nanocable, D. WANG, S. PARK, Y. LEE, T. EOM, Y. LEE, q-Psi and BK21 Program Division of Advanced Research and Education in Physics, Hanyang University, Seoul, Korea — Zn$_{1-x}$Mn$_x$O/ZnO ($x=0.04$ and 0.20) coaxial nanocables were prepared by using an ultrahigh-vacuum radio-frequency magnetron sputtering system. The samples were characterized by scanning electron microscopy (SEM), x-ray diffraction (XRD), Rutherford backscattering and high-resolution transmission electron microscopy (HR-TEM), and with a superconducting quantum interference device magnetometer. The SEM images show that the morphology and the alignment of ZnO nanocables are maintained after the deposition of Zn$_{1-x}$Mn$_x$O layer, and the thickness of Zn$_{1-x}$Mn$_x$O layer is about 20 nm. The XRD analysis reveals that Mn is incorporated well into the wurtzite ZnO without forming Mn oxide. The HR-TEM image shows that both ZnO core layer and Zn$_{1-x}$Mn$_x$O shell layer are single crystalline and an excellent epitaxial growth has been achieved. The magnetic property measurement indicates that the Zn$_{0.96}$Mn$_{0.04}$/ZnO coaxial nanocable is in the ferromagnetic state at 300 K as well as at 10 K, while Zn$_{0.80}$Mn$_{0.20}$/ZnO is nonferromagnetic even at 10 K and the bare ZnO nanorod is diamagnetic. The aging effect of the magnetics for Zn$_{0.96}$Mn$_{0.04}$/ZnO coaxial nanocable was also investigated, and it was found that the aged sample showed a mixed magnetic phase of ferromagnetism and paramagnetism.

K1.00074 Enhanced magneto-optical effect in one-dimensional spin photonic crystals, J.B. KIM, J.Y. RHEE, BK21 Physics Research Division and Institute of Basic Sciences, Sungkyunkwan University, Suwon, Korea — Spin photonic crystals (SPCs) are very interesting for information technology which requires advanced solutions for heavy communication traffic, high-density storage, and high-speed computing. By using external magnetic field, for instance, the optical properties of SPCs can be tuned. By using the interference pattern of two femtosecond-laser beams, a selective-area annealing of the as-deposited Co$_2$Mn$_2$Si film was achieved and one-dimensional SPCs were fabricated. The atomic-force-microscopy results confirmed that regularly spaced alternating lines with a periodicity of 2 μm were produced, and the magnetic-force-microscopy studies revealed the same periodic patterns of magnetic domains. The longitudinal Kerr rotations of the p-polarized zeroth-order and first-order diffracted beams were measured. The longitudinal Kerr rotation of the first-order diffracted beam turns out to be nearly 28 times larger with respect to the zeroth-order one.

K1.00075 Size dependent magnetic properties of magnetite (Fe$_3$O$_4$) nanoparticles, SONGJIN JANG, SAVAS DELIKANLI, HAO ZENG, University at Buffalo-SUNY — Magnetism of magnetite (Fe$_3$O$_4$) nanoparticles was studied as a function of the particle size. Fe$_3$O$_4$ nanoparticles with different size from 3 nm to 10 nm were synthesized by high temperature organic solution phase method. Hysteresis loops of all the particles showed superparamagnetic behavior at room temperature. The blocking temperature ($T_B$) decreases with decreasing particle size. All hysteresis loops were fitted by the Langevin's function, where the saturation magnetization ($M_s$) was extracted. $M_s$ was further deduced by using the saturated moment and accurately measured mass of the particles. The two methods agree with each other excellently. $M_s$ decreases as the particle size is decreased, and is in general much smaller than that of bulk. $M_s$ shows a sharp drop with increasing temperature at low temperatures and deviates from the $T^{3/2}$-law. This behavior is attributed to competing ferromagnetic and antiferromagnetic exchange interactions which contribute differently at the surface and interior of the particles.

K1.00076 Ab initio study of the possibility of noncollinear magnetism in small Mn clusters, R.C. LONGO, MANUEL ALEMANY, Universidad de Santiago de Compostela, Spain, J. FERRER, Universidad de Oviedo, Spain, A. VEGA, Universidad de Valladolid, Spain, L. J. GALLEGO, Universidad de Santiago de Compostela, Spain — We investigated the possibility of noncollinear magnetism in small Mn$_n$ clusters ($n=2-6$) using the density-functional method SIESTA with the generalized gradient approximation (GGA) to exchange and correlation. The lowest-energy states identified were ferromagnetic for Mn$_2$ and Mn$_4$, and magnetically noncollinear for Mn$_3$, Mn$_5$, and most decidedly, Mn$_6$. These SIESTA/GGA results, which are compared with those of an earlier SIESTA study that used the local spin density approximation, are qualitatively in keeping with the result obtained by VASP/GGA calculations.

K1.0077 Microscopic simulation and a spin crossover transition. HAROLD O. JESCHKE, L. ANDREA SALGUERO, ROGER VALENTI, Institut fuer Theoretische Physik, Universitaet Frankfurt, Max-von-Laue-Str. 1, 60438 Frankfurt, Germany. BADIUR RAHMAN, TANUSRI SAHA-DASGUPTA, S.N. Bose National Centre for Basic Sciences, JD Block, Sector 3, Salt Lake City, Kolkata 700098, India, CHRISTIAN BUCHBAUM, VOLODYMIR PASHCHENKO, MARTIN U. SCHMIDT, Institut fuer Anorganische und Analytische Chemie, Universitaet Frankfurt, Max-von-Laue-Str. 7, 60438 Frankfurt, Germany. — In spin crossover materials, an abrupt phase transition between a low spin state and a high spin state can be driven by temperature, pressure or illumination. Of a special relevance are Fe(II) based coordination polymers where, in contrast to molecular systems, the phase transition shows a pronounced hysteresis which is desirable for technical applications. A satisfactory microscopic explanation of this large cooperative phenomenon has been sought for a long time. The lack of X-ray data has been one of the reasons for the absence of microscopic studies. In this work, we present an efficient route to prepare reliable model structures and within ab initio density functional theory analysis and effective model considerations we show that in polymeric spin crossover compounds magnetic crossover effects between high spin Fe(II) centres is as important as elastic couplings for explaining the considerable cooperativity and thus the width of the hysteresis.

K1.0078 Statistical mechanics and thermodynamics in anisotropic Heisenberg-like nanoclusters. ARMEN KOCHARIAN, Department of Physics and Astronomy, California State University, LEV ANANIKYAN, SERGEI POGHOSYAN, NERSES ANANIKYAN, Varennes Physics Institute. The single magnetic excitations thermal entanglements in nanoclusters are compared to the points are studied in small spin s = 1/2 and 1 in ferromagnetic and antiferromagnetic Heisenberg clusters. The grand canonical ensemble of Heisenberg clusters is also used for exact calculations of thermal properties, quantum and thermal entanglements of the spin lattice models in the presence of magnetic field and anisotropic field. We study the magnetic phase transitions and crossovers in clusters of various topologies driven by exchange interaction, external field and temperature. The comparison with the exact solution for the Heisenberg model in thermodynamic limit for the limiting cases is also provided. The small Ising and Heisenberg clusters are also used for comparison with the exact Bethe-ansatz solutions. These exact results in clusters give a novel insight into the properties of single molecule magnets, the dynamics of magnetization and can be useful for interpretation of the phase diagram in molecular nanomagnets and nanometer-sized magnetic particles. 

K1.0079 muSR in Ba$_2$CoO$_4$, PETER RUSSO, TRIUMF, JUN SUGIYAMA, Toyota CRDL, EDUARDO ANSALDO, TRIUMF, JESS BREWER, SCOTT STUBBS, UBC, KIM CHOW, University of Alberta, R. JIN, Oak Ridge, H. SHA, J. ZHANG, Florida International University. — A positive muon spin rotation and relaxation ($\mu$SR) experiment on the single crystal Ba$_2$CoO$_4$ indicates the existence of an antiferromagnetic (AF) transition occurring at $T_N$ $\sim$25 K. Weak transverse field measurements ($\mu$TF-$\mu$SR) show that the paramagnetic volume fraction of the sample decreases rapidly at the magnetic transition indicating a bulk effect. Zero field measurements (ZF-$\mu$SR) show the presence of a magnetically ordered state below $T_N$. The results are compared to recent magnetic susceptibility and neutron measurements. Although there are two possible AF spin structures proposed by recent neutron experiments, the $\mu$SR results clearly exclude AF order along the $c$-axis while supporting AF order in the ab plane.

K1.0080 Inelastic Neutron Scattering Excitations for a Spin $\frac{3}{2}$ Tetramer: Application to Magnetic Excitations in Na$_2$RuO$_4$. J. T. HARALDSEN, University of Tennessee, M.B. STONE, M.D. LUMSDEN, Oak Ridge National Laboratory, T. BARNES, University of Tennessee/Oak Ridge National Laboratory, R. JIN, Oak Ridge National Laboratory. — In an effort to explain the magnetic properties of such low-dimensional systems, $^{87}$Rb Nuclear Magnetic Resonance (NMR) experiments in a Na$_2$RbCu$_4$(AsO$_4$)$_2$Cl$_2$ system were performed. This novel two-dimensional (2D) cuprate contains layers of coupled CuO$_4$ tetramers. The spin exchange interactions are confined to 2D layers and the Cu are divalent, making the system an anisotropic, non-collinear AFM. In zero applied magnetic field, it orders antiferromagnetically via a second-order phase transition at $T_N$=15(1) K. The ordered state was characterized by $^{87}$Rb NMR, and a non-collinear rather than collinear arrangement of spins was suggested. New structural phase transition(s) around 74 and 110 K were also evidenced. We present a $\mu$SR study of this cuprate. The investigation of the spin dynamics (via the muon longitudinal relaxation rate $\lambda(T)$) in the temperature range 2<T<300K in zero-field, with particular attention to the order parameter below $T_N$ and around structural phase transitions at T$\sim$74K and T$\sim$110K is presented.

K1.0081 $\mu$SR study of spin dynamics and phase transition of the two-dimensional tetramer-cuprate Na$_2$RbCu$_4$AsO$_4$Cl$_2$. ANNAKI KRIISA, RAIVO STERN, National Institute of Chemical Physics and Biophysics, SHIOU-JHY HWU, WENDY QUEEN, Department of Chemistry, Clemson University, HUBERTUS LUETKENS, Laboratory for Muon-Spin Spectroscopy Paul Scherrer Institut — In an effort to explain the magnetic properties of such low-dimensional systems, $^{87}$Rb Nuclear Magnetic Resonance (NMR) experiments in a Na$_2$RbCu$_4$(AsO$_4$)$_2$Cl$_2$ system were performed. This novel two-dimensional (2D) cuprate contains layers of coupled CuO$_4$ tetramers. The spin exchange interactions are confined to 2D layers and the Cu are divalent, making the system an anisotropic, non-collinear AFM. In zero applied magnetic field, it orders antiferromagnetically via a second-order phase transition at $T_N$=15(1) K. The ordered state was characterized by $^{87}$Rb NMR, and a non-collinear rather than collinear arrangement of spins was suggested. New structural phase transition(s) around 74 and 110 K were also evidenced. We present a $\mu$SR study of this cuprate. The investigation of the spin dynamics (via the muon longitudinal relaxation rate $\lambda(T)$) in the temperature range 2<T<300K in zero-field, with particular attention to the order parameter below $T_N$ and around structural phase transitions at T$\sim$74K and T$\sim$110K is presented.

K1.0082 Spin dynamics of La$_{0.845}$Sr$_{0.155}$Mn$_{1-x}$M$_x$O$_3$ (M = Mn, Cu, Co) perovskites. MANH-HUONG PHAN, HARIHARAN SRIKANTH, University of South Florida, Tampa, FL 33620, THE-LONG PHAN, Micro- and Nano-Structures Group, H. H. W. Physics Lab, University of Bristol, Bristol BS8 1TL, UK. — Influence of the spin-lattice coupling on the magnetoresistance and magnetocaloric properties of La$_{0.845}$Sr$_{0.155}$Mn$_{1-x}$M$_x$O$_3$ (M = Cu, Co) perovskites has been investigated by means of electron spin resonance (ESR) spectroscopy. It was observed that asymmetrical ESR signals due to ferromagnetic correlations at temperatures T $<$ $T_{max}$, became Lorentzian at T $>$ $T_{max}$, where $T_{max}$, corresponds to the narrowest ESR linewidth. The temperature dependence of the ESR intensity, I(T), for the samples was well described by an expression of I(T) = I$_{0}$ $\exp$(E$_{g}$/k$_{B}$T). In the high temperature region, I(T) obeyed the Curie-Weiss law. The minimum linewidth, $\Delta$H$_{min}$, was determined to be 674, 890 and 750 Oe for La$_{0.845}$Sr$_{0.155}$Mn$_{0.98}$Co$_{0.02}$O$_3$ and La$_{0.845}$Sr$_{0.155}$Mn$_{0.98}$Cu$_{0.02}$O$_3$, respectively. This indicated an improvement of the spin-lattice coupling in samples with Cu or Co addition. The strongest spin-lattice coupling resulted in the largest magnetocaloric effect in La$_{0.845}$Sr$_{0.155}$Mn$_{0.98}$Cu$_{0.02}$O$_3$. The addition of Cu or Co in La$_{0.845}$Sr$_{0.155}$Mn$_{0.98}$O$_3$ reduced its ferromagnetism and conductivity. The mechanism of the spin-lattice coupling is discussed.

K1.0083 Competition between magnetic structures in the Fe-rich fcc FeNi alloys. IGOR ABRIKOSOV, ANDREAS KISSAVOS, FRANCOIS LIOT, BJORN ALLING, SERGEI SIMAK, Department of Physics, Chemistry and Biology, Linkoping University, Sweden, OLEG PEIL, ANDREI RUBAN, Applied Materials Physics, Royal Institute of Technology, Sweden. — We report on the results of a systematic ab initio study of the magnetic structure of Fe rich fcc FeNi binary alloys for Ni concentrations up to 50 at. %. Calculations are carried out within density functional theory using two complementary techniques, one based on the Exact Muffin-Tin Orbital theory within the coherent potential approximation and another one based on the Projector Augmented-Wave method. We observe that the evolution of the magnetic structure of the alloy with increasing Ni concentration is determined by a competition between a large number of magnetic states, collinear as well as non-collinear, all close in energy. We emphasize a series of transitions between these magnetic structures, in particular we have investigated a competition between disordered local moment configurations, spin spiral states, the double layer antiferromagnetic state, and the ferromagnetic phase, with a single spin flipped with respect to all others. We show that the latter should be particularly important for the understanding of the magnetic structure of the Invar alloys.
K1.00084 One-Dimensional Magnetic Chain Fragmentation in Ti/Ga Modified Multiferroic DyMn$_2$O$_5$. SUN-HEE KANG, HAI-JOON LEE, ILL-WON KIM, University of Ulsan, TAE-HWAN JANG, YOON-HEE JEONG, Pohang University of Science and Technology, TAE-YEONG KOO, Pohang Accelerator Laboratory, Pohang University of Science and Technology — We have studied the effect of Ga$^{3+}$ substitution into Mn$^{3+}$ site in DyMn$_2$O$_5$ on its multiferroic characteristics. Crystallographic structural, thermal, dielectric and magnetic properties are measured and discussed in terms of the dilution of magnetic Mn$^{3+}$ ions. Replacement of Mn$^{3+}$ ions with Ga$^{3+}$ changes the compound into a disordered multiferroic system and colossal magnetoelectric effect observed in DyMn$_2$O$_5$ disappears quickly below x<0.1 in DyMn$_{1-x}$Ga$_x$O$_5$. However as the content of Ga increases above x>0.1, a new type of ferroelectric transition identified by a peak in dielectric constant is evolved from the slowly varying dielectric background. Moreover remarkable enhancement of dielectric constant at ferroelectric transition temperature is continued even up to the solubility limit of Ga (x=0.2). This observation suggests a possible example of the channel for ferroelectricity in the disordered multiferroic system.

K1.00085 Maser Generation of Hypersound From Heat Through Adiabatic Demagnetization of a Paramagnetic Crystal. MICHAEL VAISFEL'D, Kingsborough College of CUNY — It has been shown in our earlier work on thermal masers [Sov. Phys. - JETP (USA), v. 57, No. 6, pg. 1263-9 (1983)] that the energy of thermal phonons of a crystal like La$_2$Mg$_3$(NO$_3$)$_2$·24H$_2$O (LaMN) doped with $^{16}$CO$^{3+}$ (ions A) and Ce$^{3+}$ (ions B) can be converted directly into the energy of coherent microwave radiation. Maser action has been observed at liquid helium temperatures in the 0.18-T static magnetic field after termination of the 1-T magnetic field pulse (which is applied for the adiabatic cooling of the electron spins 1/2 of the ions B). A partial population inversion is achieved in the system of hyperfine magnetic spin sublevels of the ions A as a result of the fast resonant thermal mixing between the nuclear spins I = 7/2 of the ions A and the cooled spins B. Our device acts as a quantum heat engine, without any microwave or optical pumping. Here we propose an analogous easily tunable pulsed phonon maser. The laser crystals of KY(WO$_4$)$_2$ [Eur. Phys. J. B 55, 388-395 (2007)] doped with $^{16}$E$^{3+}$ and $^{17}$I$^{3+}$ (I = 1/2) or $^{137}$I$^{3+}$ (I = 5/2) ions are proposed as working substances (instead of the crystal hydrate of LaMN:Ce$^{3+}$; $^{50}$Co$^{2+}$).

K1.00086 Magnetic and Structural Properties of Magnetite in Radicular Teeth of Chiton Acanthochiton Rubrolinestus. Y.N. HAN, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China, C.L. LIU, College of Chemistry-biology Science & Technology, YanTai University, Shandong 264005, China, L.D. YAO, Y. WANG, X.F. HAN, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, Beijing 100080, China — The major radular lateral teeth of Polyplacophora Chiton comprise a magnetic biomimetic cap. We have investigated the structure and magnetic properties of the biomimarized magnetite crystalites in mature teeth of Chiton Acanthochiton Rubrolinestus. From the measurement of magnetic properties of tooth particles using SQUID magnetometry we find that the saturation magnetization and the Verwey transition temperature ($T_v$) are 78.4 emu/g and 105 K, respectively. An in situ examination of the structure of magnetite-bearing region within individual tooth using the high resolution TEM, together with electron diffraction (ED) pattern and energy-dispersive X-ray (EDX) analyses indicates magnetite microcrystal form electron-dense polycrystalline sheets with typical length 800 nm and width 150 nm or so. These polycrystalline sheets are arranged regularly along the longitude direction of the tooth cutting surface. Furthermore, the microcrystallites in polycrystalline sheet take on the generally good crystallinity.

K1.00087 Heat diffusion in a classical Heisenberg chain. GONZALO GUTIERREZ, University of Chile, Chile. EDUARDO VALDEBENITO, University of Chile, SERGIO DAVIS, Royal Institute of Technology, Sweden — We study the heat transport in a one dimensional classical Heisenberg chain by means of spin dynamics simulation. The system consists of a $N=2000$ spins in the microcanonical ensemble, and the temperature is evaluated using the so-called configurational temperature formula. We thermalize the system to an equilibrium state at low temperature, and then we give a delta function energy packet in the middle of the chain. Studying both qualitatively and quantitatively the spreading of the delta, we characterize the diffusion of heat in the chain. In fact, calculating the second moment of the pulse, and using the relation

$$\langle \sigma(t)^2 \rangle = 2D\alpha^2, \quad (0 < \alpha < 2),$$

where $\sigma$ is the width of the pulse, $D$ is the diffusion constant and $\alpha$ is a parameter which consider the kind of diffusion. According our simulation, the heat in this system transports subdiffusively. This result imply that the system becomes a thermal insulator in the thermodynamic limit $N \rightarrow \infty$.

K1.00088 Magnetic properties of a mechanically alloyed metastable Cu$_{1-x}$Co$_x$ system. P. PRIETO, Excellence Center for Novel Materials, CENM, Cali - Colombia. D. REYES, A. CORTES, M. E. GOMEZ, W. LOPERA, Thin Film Group, Department of Physics, Universidad del Valle, AA. 25360, Cali - Colombia, M. LOPEZ, Departamento Ing. de Materiales, Universidad de Concepcion, Chile — We report a detailed study of the magnetic properties of Cu$_{1-x}$Co$_x$, with Co concentrations between 7 and 10 at% produced by mechanical alloying, through a reactive milling process by using a Retsch PM 400 planetary ball mill under argon atmosphere. We have magnetically characterized our samples by using a Vibrating Sample magnetometer, VSM, from Quantum Design. We conducted magnetization hysteresis loops at different temperatures from 5 to 300 K. We also measured magnetization as a function of temperature for samples with different milling times. We analyzed the dependence of the coercive field on temperature and found that when milling time increases from 80 to 100h, it reflects an increase in the coercive field from 425 to 525 Oe at 30K; that is the maximum coercive field observed on its multiferroic charateristics. Crystallographic structural, thermal, dielectric and magnetic properties are measured and discussed in terms of the dilution of magnetic Mn$^{3+}$ ions. Replacement of Mn$^{3+}$ ions with Ga$^{3+}$ changes the compound into a disordered multiferroic system and colossal magnetoelectric effect observed in DyMn$_2$O$_5$ disappears quickly below x<0.1 in DyMn$_{1-x}$Ga$_x$O$_5$. However as the content of Ga increases above x>0.1, a new type of ferroelectric transition identified by a peak in dielectric constant is evolved from the slowly varying dielectric background. Moreover remarkable enhancement of dielectric constant at ferroelectric transition temperature is continued even up to the solubility limit of Ga (x=0.2). This observation suggests a possible example of the channel for ferroelectricity in the disordered multiferroic system. K1.00089 Magnetic behavior of Mn$_{1-x}$Zn$_x$ Ferrite nanoparticles at low temperature. O. MARIN, D. REYES, Thin Films Group, Physics Department, Universidad del Valle, O. ALMANZA, Physics Department, Universidad Nacional de Colombia, P. PRIETO, Thin Films Group, Physics Department, Universidad del Valle, A. MENDOZA, Physics Department, Universidad Nacional de Colombia — We report on magnetic spin resonance and magnetization hysteresis loops of Mn$_{1-x}$Zn$_x$ Ferrite nanoparticles with sizes ranging from 20nm to 50nm obtained via microemulsions. The samples were evaluated by VSM technique ranging from 10K<300K at ZFC and FC. EPR measurements at T=180K were carried out in the 0 ≤ x ≤ 0.75 range. Experimental results for the peak-to-peak linewidth, $\Delta H_{pp}$, have been discussed by the existence of monodomain ferrimagnetic particles. The results indicate an increase of $\Delta H_{pp}$ by increasing the Zn concentration. The EPR signal shows a second EPR peak for x>0.5 at g=4.10 associated to local magnetic fields produced for Mn chains. The anisotropy constant was calculated by means of a genetic algorithm for parameter optimization of the Jiles-Atherton model.

This work was partially supported by COLCIENCIAS, under research Project No. 1106-05-11-458 Projects, and the Excellence Center for Novel Materials - CENM under COLCIENCIAS contract 043-2005.

K1.00090 ABSTRACT WITHDRAWN —
K1.00091 NMR and spin relaxation in systems with iron oxide nanoparticles . NATALIA NOGINOVA, TRACEE WEAVER, NSU, Norfolk, VA, ALEXANDR ANDREYEV, MARK FELCICIANO, OLHS, Virginia Beach, VA — Effect of the superparamagnetic nanoparticles to $^1$H NMR spectra and spin dynamics of the host systems have been studied in liquid (water and toluene), solid (polymer) and gelatin suspensions of $\gamma$-Fe$_2$O$_3$ nanoparticles. Significant broadening of $^1$H NMR spectra and growing relaxation rates were observed with increased concentration of nanoparticles in the liquid systems while the polymer systems demonstrate inhomogeneous broadening of the spectra and practically no dependence of $T_1$ upon the nanoparticle concentration. In gelatin solution, both effects were observed depending on the line position. We explain the experimental results taking into account predomination of self-diffusion as a source of the relaxation, with allowance made for the formation of magnetic aggregates.

1Research is supported by Fresno State CSM fund.

K1.00093 ABSTRACT HAS BEEN MOVED TO SESSION V32 —

K1.00094 Exchange biased anisotropic magnetoresistance in Co/CoO bilayer1, S. SAHOO, University of Nebraska-Lincoln, S. POLISETTY, YI WANG, T. MUKHERJEE, XI HE, CH. BINEK — We measured the anisotropic magnetoresistance of a Co(11nm)/CoO bilayer in exchange biased and unbiased states. The bilayer was fabricated on a-Al$_2$O$_3$ substrate maintained at 300°C by molecular beam epitaxy at a base pressure of 10$^{-11}$ mbar. θ-2θ X-ray diffraction scans reveal hcp (001) texture of the Co film. No peak associated with the naturally formed CoO top layer was identified. Small angle X-ray reflectivity scans yield the Co and CoO thicknesses as 11 and 2.4nm, respectively. Exchange bias was observed from field cooled magnetization measurements at various temperatures carried out in a closed cycle cryostat. Exchange bias varies quasi linearly with temperature and vanishes at the blocking temperature, $T_B$$=97K$. The latter is less than 2/3 of the bulk Neel temperature allowing to estimate the $T_0$ antiferromagnetic correlation length of Co to be 1.84 nm in accordance with the geometrical confinement.

1This work was supported by NSF through Career DMR-0547887, MRSEC DMR-0213808, and NRI.

K1.00095 Synthesis and characterization of iron nanoparticles by high-pressure sputtering. JEFFREY CARVELL, ELIJAH AIYETA, RIUHUA CHENG, Indiana University Purdue University Indianapolis — The study of magnetic nanoparticles is interesting because of its importance and applications in the production of nano-electromechanical systems (NEMS) and micro-electromechanical systems (MEMS). We use a sputtering technique to deposit iron nanoparticles on a silicon substrate. The nanoparticles are then analyzed using atomic force microscopy (AFM), x-ray diffraction, and superconducting quantum interference devices (SQUID). AFM data shows that the size of the particles depends on different deposition conditions. Then, x-ray diffraction data shows that the nanoparticles adopt the body-centered cubic crystal structure. Finally, SQUID measurements were performed to characterize the magnetic properties of the nanoparticles. Systematic change in the magnetic properties was observed for particles with different sizes. The results show that the size and magnetic properties could be tuned by changing the deposition conditions.

K1.00096 Magnetite-Alginate-AOT nanoparticles based drug delivery platform. R. REGMI, C. SU-DAKAR, A. DIXIT, R. NAIK, G. LAWES, Department of Physics and Astronomy, Wayne State University, U. TOTI, J. PANYAM, College of Pharmacy, University of Minnesota, R.P. VAISHNAVYA, Kettering University — Iron oxide having the magnetic structure is a widely used biomaterial, having applications ranging from cell separation and drug delivery to hyperthermia. In order to increase the efficacy of drug treatments, magnetite nanoparticles can be incorporated into a composite system with a surfactant-polymer nanoparticle, which can act as a platform for sustained and enhanced cellular delivery of water-soluble molecules. Here we report a composite formulation based on magnetite and Alginate-aerosol OT (AOT) nanoparticles formulated using an emulsion-cross-linking process loaded with Rhodamine 6G [1]. We prepared two set of nanoparticles by using Ca$^{2+}$ or Fe$^{3+}$ to cross-link the alginate polymer. Additionally, we added ∼8 nm diameter Fe$_3$O$_4$ magnetic nanoparticles prepared by a soft chemical method to these alginate-AOT nanoparticles. The resulting composites were superparamagnetic at room temperature, with a saturation magnetization of approximately 0.006 emu/g of solution. We will present detailed studies on the structural and magnetic properties of these samples. We will also discuss HPLC measurements on Rhodamine uploading in these composites. K1.00097 The importance of local band effects for ferromagnetism in hole doped La$_2$CuO$_4$. BERNARDO BARBIELLINI, Department of Physics, Northeastern University, Boston, Massachusetts 02115, USA, THOMAS JARLBORG, DPMC, University of Geneva, CH-1211 Geneva 4, Switzerland — Doping is of vital importance for cuprates, since only about 0.15 holes per Cu atom is sufficient to transform them from antiferromagnetic insulators to the best known superconductors. The doping is usually made through substitution of the ternary element (Sr for La etc.), and the effects are typically described by rigid band filling of the CuO band. However, results of band calculations for supercells of La$_{2-x}$Ba$_x$CuO$_4$ show that the rigid band model for doping is less adequate than what is commonly assumed. In particular, weak ferromagnetism (FM) can appear locally around $T_B$ and vanishes at the blocking temperature, $T_B$, because of its importance and applications in the production of nano-electromechanical systems (NEMS) and micro-electromechanical systems (MEMS). We use a sputtering technique to deposit iron nanoparticles on a silicon substrate. The nanoparticles are then analyzed using atomic force microscopy (AFM), x-ray diffraction, and superconducting quantum interference devices (SQUID). AFM data shows that the size of the particles depends on different deposition conditions. Then, x-ray diffraction data shows that the nanoparticles adopt the body-centered cubic crystal structure. Finally, SQUID measurements were performed to characterize the magnetic properties of the nanoparticles. Systematic change in the magnetic properties was observed for particles with different sizes. The results show that the size and magnetic properties could be tuned by changing the deposition conditions.

K1.00098 Tuning magnetic interaction in orthorhombic Neodymium-Yttrium-Manganites Nd$_{1-x}$Y$_x$MnO$_3$. SVEN LANDGESSELL, DIMITRI ARGYRIOU, NADIR ALIOUANE, Hahn-Meitner-Institut — By lowering the Mn-O-Mn bond angle in LnMnO$_3$ with Ln=La-Ho the Neel-temperature decreases and at $T_N$=Th the A-type antiferromagnet transforms to an incommensurate (IC) spin-spiral phase for $T_N$=Gd, Tb, Dy. The spin-spiral breaks both inversion and time reversal symmetry leading to a strong coupling between magnetism and ferroelectric polarization. We investigate the evolution of the magnetic and structural from the A-type phase to the IC spin spiral phase by systematically replacing neodymium by yttrium in NdMnO$_3$ resulting to a decrease of the tolerance factors to values similar to that for multiferroic TbMnO$_3$. One advantage of this approach is that the tolerance factor can be tuned and that neodymium and yttrium are not high neutron absorbing elements in sharp contrast to other rare earths like Gd, Dy and Eu. Compositions $x$=0.0 have been prepared, neutron and x-ray powder diffraction patterns were measured as well as the magnetic properties. It can be shown that by decreasing the tolerance factor that way, similar effects can be seen as with varying the ionic size of the rare earth ions. For example we found that between 0.4 $<$ $x$ $<$ 0.6 the incommensurate phase co-exists with the A-type antiferromagnetic phase and with $x$=0.6 and higher the system is only incommensurate and seemingly multiferroic.
K1.00099 Determination of Magnetic Directions in Multiferroic BiFeO$_3$ Thin Films, M.B. HOLCOMB, L.W. MARTIN, Y.H. CHU, UC Berkeley, A. SCHOLL, E. AREN HOLZ, Advanced Light Source, Lawrence Berkeley National Laboratory, S.Y. YANG, T. CONRY, Q. HE, R. RAMESH, UC Berkeley — BiFeO$_3$ (BFO), a ferroelectric and an antiferromagnet, is the only single phase room temperature multiferroic that is currently known. Multiferroics are interesting materials not only because of their exciting order parameters, but also for the potential for parameter coupling. In order to understand the magnetoelectric coupling, the individual order parameters must first be understood. A combination of in-plane and out-of-plane piezoresistance force microscopy (PFM) allows 3D mapping of the ferroelectric polarization directions in micron-sized regions of the films. The magnetic order of BFO was obtained by using x-ray linear and circular dichroism imaging using a photoelectron emission microscope (PEEM). Angle dependent structural measurements allow decoupling of the two order parameters, ferroelectric and magnetic, contributing to the photoemission signal. Careful analysis of linear and circular dichroism images at critical angles allows determination of magnetic directions in BiFeO$_3$. These studies reveal a strain-driven reduction in magnetic symmetry in thin films, leading to the formation of an easy magnetic axis as opposed to the observed easy plane for bulk films. This reduction along with the previous proof of FE-AM coupling allows electrical control of its magnetic axis.

K1.00100 Magnetization damping in epitaxial CrO$_2$ (110), HWACHOL LEE, KRISHNA CHETRY, CLAUDIA K.A. MEWES, ARUNAVA GUPTA, TIM MEWES, Center for Materials for Information Technology — Epitaxial CrO$_2$ thin films were grown on TiO$_2$ (110) substrates using chemical vapor deposition (CVD) using a CrO$_2$ precursor as described elsewhere [1]. In-plane angular dependent ferromagnetic resonance (FMR) measurements confirm a uniaxial in-plane anisotropy with the easy axis along the c-axis. Frequency dependent FMR measurements were carried out over a frequency range from 7-60 GHz along the easy axis of the film. The resonance field dependence on the microwave frequency is well described by the Kittel formula, enabling the determination of M$_c$ and γ of the films. The ferromagnetic resonance linewidth depends only weekly on the microwave frequency: the linewidth has a minimum around 20 GHz and increasing linearly for larger frequencies with a very small slope. Based on this we estimate the Gilbert damping constant (intrinsic) to be of the order 10$^{-4}$, i.e. very small. The main contribution to the magnetization relaxation is extrinsic in nature and can therefore be further optimized. References: [1]: X. W. Li, A. Gupta, and G. Xiao, Appl. Phys. Lett. 75, 713 (1999).

K1.00101 Magnetic Clustering and Possible Chemical Nonuniformity in Bi0.125Ca0.875MnO3, YUHAI QIN, TREVOR TYSON, New Jersey Institute of Technology — The manganite system Bi$_{3-x}$Ca$_x$MnO$_3$ possesses intriguing properties in the low bismuth doping region. In this electron doped region ($0.6<c<1$), a large ferromagnetic (FM) moment of $\sim 1.2$ Bohr magnetons per Mn site is found for $c<0.875$. However, the origin of this FM clustering configuration is still an open question. Chemical nonuniformity (Bi ion segregation) as a candidate interpretation has been explored with TEM/EDS, which can give a quantitative assessment of geometrical parameters, chemical composition and crystal structure of second phase particles. We have identified evidences for the possible Bi nonuniformity in nano-scale, which are consistent with the results from small-angle neutron scattering. This work is supported by NSF DMR-0512196.

K1.00102 ABSTRACT WITHDRAWN —

K1.00103 Zero and low field magnetization dynamics in tapered nanopillar spin valves caused by micromagnetic structure, P.M. BRAGANCA, O. OZATAY, O.J. LEE, D.C. RALPH, R.A. BUHRMAN, Cornell University — Exciting spin-torque driven magnetization dynamics in a uniformly magnetized nanomagnet typically requires large magnetic fields and electric currents, both of which are undesirable for practical applications. Here, we show that by combining an angled sidewall and a low saturation magnetization material, such as permalloy (Py), in a simple nanopillar spin valve structure, a micromagnetic configuration can be established which is conducive to spin-torque excitation of magnetization dynamics in the absence of an external magnetic field. As verified by micromagnetic simulations, these magnetization oscillations occur in both nanomagnet layers of the spin valve due to a substantial out of plane magnetization component that is located at and near the ends of the tapered elliptical disks. For magnetic fields close to zero, the resultant giant magnetoresistance spectra show oscillations with peak frequencies between 5.2-6.5 GHz, and minimum linewidths on the order of 50 MHz.

K1.00104 Non-Adiabatic Spin Transfer Torque in Realistic Materials, ION GARATE, ALLAN MACDONALD, University of Texas at Austin — The motion of simple domain walls and more complex magnetic textures in the presence of a transport current is sensitive to the size and sign of the non-adiabatic spin transfer torque coefficient $\beta$, even though this dimensionless coefficient is believed to typically have a small value. The ratio of $\beta$ to the Gilbert damping coefficient $\alpha$ is particularly important and has been variously estimated to be close to 0, close to 1, and large or small. By identifying $\beta$ as following from the influence of a transport current on $\alpha$, we derive concise analytical expressions for $\beta$ in real materials. When spin-orbit is included in the band structure, the damping has an intra-band contribution that is proportional to the square of the quasiparticle lifetime. We will discuss estimates for $\beta$ and for the $\alpha/\beta$ ratio in common magnetic materials.

K1.00105 Study of Fe/Cr Magnetic Multilayers and Periodic Arrays of Submicron Magnetic Dots by Vector Network Analyzer Technique, FARKHAD ALIEV, JUAN FRANCISCO SIERRA, AHMAD AWAD, VLADIMIR PRYADUN, Universidad Autonoma de Madrid, Spain, GLEB KAKAZEI, INSTITUTE OF MAGNETISM NASU, Kiev, Ukraine — Vector network analyzer (VNA) technique up to 8.5 GHz was applied to measure in-plane dynamic response in Fe/Cr magnetic multilayers and for the in-plane magnetized periodic arrays of Permalloy circular magnetic dots. In the antiferromagnetically coupled [Fe/Cr]$_n$, multilayers ($n=10,20,40$) we have investigated field dependence of the acoustic resonance in a wide range of temperatures between 300K down to 2K both for the low magnetic fields and close to the saturation field. FMR studies of the array of FeNi dots with diameter of 1 micron, the aspect ratio L/R=0.1 and with centre to centre distance varying between 1.2 to 2.5 micron allowed to resolve multiple FMR resonances as a function of magnetic field. We have found the main FMR linewidth to be dependent on the magnetic history. For the magnetic fields below 300 Oe, where magnetic vortex state forms, we have observed the field dependence of the radial modes ($f_r > 6$GHz) to show minima close to the zero magnetic field.

K1.00106 Ferromagnetic Resonance in Magnetic and Conducting Thin Films1, TOM GEORGE, University of Nebraska, Lincoln, JUSTIN BAIZE, MIRCEA CHIPARA, The University of Texas Pan American, RALPH SKOMSKI, DAVID J. SELLMYER, University of Nebraska, Lincoln — Ferromagnetic resonance provides unique information concerning both electronic spin orientation and their interactions. A model for the simulation of magnetic resonance line shape in metallic and magnetic thin films, developed within the thermodynamic approximation is presented. The proposed model includes the contribution of the Gilbert term to the precession of magnetic moments in external magnetic fields, the effect of shape anisotropy, of magnetocrystalline anisotropy, and allows for different textures. The main features of the ferromagnetic resonance line (line position, line width, line asymmetry, and line shape) are analyzed while taking into account the competition between magnetic and conducting features. The model allows a detailed analysis of the angular dependence of the ferromagnetic resonance line. It has been tested on a multilayer consisting of 60 bilayers (Fe 0.16 nm/Pt 0.18 nm).

1ESR measurements were done within the laboratory of Professor A. Rajca from the Chemistry Department of the University of Nebraska Lincoln.
K1.00107 Optical control of topological spin and charge transport in semiconductors, WANG YAO, ALLAN MACDONALD, QIAN NIU, The University of Texas at Austin — In n-doped semiconductors, the strong spin-orbit coupling in valance band can be utilized through the band renormalization by optical field off-resonantly coupled to the interband transitions. The adiabatic electronic ground state is thus reactively controlled by optical pulses, exhibiting an anomalous spin-dependent Hall conductivity. Light-matter interaction is exploited here in a unique way, i.e., light does not induce real excitations in the system but act as a control knob for switching on/off novel material properties, in contrast to most previous use of light. With the control by linearly polarized light, a pure spin Hall current of electrons can be driven by an in-plane DC electric field, which results in net spin accumulations at the edges of the optical excitation area. Effectively, one has created a spin battery powered by optical pulses together with DC electric field, or equivalently, an optically gated spin transistor. As conduction band spin-orbit coupling is not needed, the resultant electron spin accumulations can have long lifetime when control light is adiabatically switched off. In addition, circularly polarized light breaks the time reversal symmetry and can result in spin polarized anomalous Hall conductance.

K1.00108 Ultrafast Photoinduced Ferromagnetic Phase Enhancement in Ion Implanted GaMnAs, INGRID COTOROS, University of California at Berkeley, Berkeley CA 94720, JIGANG WANG, Lawrence Berkeley National Laboratory, Berkeley CA 94720, PETER STONE, OSCAR DUBON, DANIEL CHEMLA, University of California at Berkeley and Lawrence Berkeley National Laboratory, Berkeley CA 94720, MIKE D. COHEN, Department of Physics, MIT, 98 E. St., Cambridge, MA 02139, USA — First-principles relativistic band calculations for platinum, which is one of the most important materials for metallic SHE and spintronics. We find that intrinsic spin Hall conductivity (SHE) is as large as \( \sim 2000 \, h/e \, (\Omega \cdot cm)^{-1} \) at room temperature, and decreases down to \( \sim 200 \, h/e \, (\Omega \cdot cm)^{-1} \) at low temperature. It is due to the resonant contribution from the spin-orbit splitting of the doubly degenerated \( d \)-bands at high-symmetry \( L \) and \( X \) points near the Fermi level. By modeling these near-degeneracies by an effective Hamiltonian, we show that SHE has a peak near the Fermi energy and that the vertex correction due to impurity scattering vanishes. We therefore argue that the large SHE observed experimentally in platinum is of intrinsic nature. \[1\] G.Y. Guo, S. Murakami, T.-W. Chen, and N. Nagaosa, arXiv:cond-mat/07050409.

K1.00109 Intrinsic spin Hall effect in platinum metal, GUANG-YU GUO, Department of Physics, National Taiwan University, Taipei 106, Taiwan, SHUCHII MURAKAMI, Department of Physics, Tokyo Institute of Technology, Tokyo 152-8551, Japan, TSUNG-WEI CHEN, Department of Physics, National Taiwan University, Taipei 106, Taiwan, NAO TO NAGAO, Department of Applied Physics, University of Tokyo, 113-8656, Japan — Spin Hall effect (SHE) is studied with first-principles relativistic band calculations for platinum, which is one of the most important materials for metallic SHE and spintronics. We find that intrinsic spin Hall conductivity (SHE) is as large as \( \sim 2000 \, h/e \, (\Omega \cdot cm)^{-1} \) at room temperature, and decreases down to \( \sim 200 \, h/e \, (\Omega \cdot cm)^{-1} \) at low temperature. It is due to the resonant contribution from the spin-orbit splitting of the doubly degenerated \( d \)-bands at high-symmetry \( L \) and \( X \) points near the Fermi level. By modeling these near-degeneracies by an effective Hamiltonian, we show that SHE has a peak near the Fermi energy and that the vertex correction due to impurity scattering vanishes. We therefore argue that the large SHE observed experimentally in platinum is of intrinsic nature. \[1\] G.Y. Guo, S. Murakami, T.-W. Chen, and N. Nagaosa, arXiv:cond-mat/07050409.

K1.00110 First-principles Study on the Magnetic Interaction in ZnO-based Dilute Magnetic Semiconductors, MASAYUKI TOYODA, The Institute of Scientific and Industrial Research, Osaka University, HISAZUMI AKA, Graduate School of Science, Osaka University, KAZUNORI SATO, HIROSHI KATAYAMA-YOSHIDA, The Institute of Scientific and Industrial Research, Osaka University — Using first-principles calculations, we investigate the electronic structures and magnetic properties of dilute magnetic semiconductors (DMS). The electronic structures are calculated by using Korringa-Kohn-Rostoker method combined with the coherent potential approximation. Since the d electrons of the magnetic impurity in DMS are strongly localized, we apply self-interaction correction to the local density approximation for the exchange-correlation energy. From the first-principles results, we evaluate the magnetic exchange interaction \( J_{ij} \) between the pairs of magnetic impurities by using the Lichtenstein’s formula. We found that the magnetic interaction in ZnO-based DMS is basically antiferromagnetic without any additional carrier because of large energy gaps between the occupied and unoccupied d states. We will also discuss about the carrier dependence of the magnetic interaction in ZnO-based DMS.

K1.00111 Corresponds between Spin-Hall Effect and Ordinary Hall Effect, ROKSANA GOLIZADEH-MOJARAD, SUPRIYO DATTA, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN-47906, USA — The “spin-Hall effect” has recently attracted a lot of attention and a central question is whether the effect is due to the intrinsic spin-orbit interaction or due to spin-asymmetric scattering by extrinsic impurities. We shed light on this question using a new approach based on the non-equilibrium Green function (NEGF) formalism, which allows us to go continuously from the ballistic to the diffusive limit and we present approximate analytical expressions that describe our results fairly well. We establish a correspondence between Spin Hall effect and Ordinary Hall effect, since from our point of view these two effects are quite similar. Our model suggests that a spin accumulation proportional to the current should be observed in clean ballistic samples and we show how this spin accumulation evolves as momentum and/or spin relaxation processes are introduced in a controlled way. We further show good quantitative agreement with recent experimental observations in GaAs suggesting that this can be understood in terms of an intrinsic effect driven by the Rashba interaction, although experiments on ZnSe likely have a different origin.

K1.00112 Anisotropy, coercivity and thermal activation in \( L_{10} \)-FePt Nanoparticles, CHUANBING RONG, NARAYAN POUYDAL, J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019 — \( L_{10} \) FePt materials have attracted tremendous attention for their potential applications due to their high anisotropy and excellent mechanical properties. It is well known that the magnetization behavior of small particles is strongly affected by thermal fluctuation especially when the particle size is close to the critical size of superparamagnetic. In this work, the size effect on anisotropy constant \( K_u \), magnetic viscosity parameter \( S \), activation volume \( V_{ac} \), and coercivity \( H_c \) of the \( L_{10} \) FePt nanoparticles obtained by ion-beam sputtering have been investigated. The maximum field-dependent coercivity parameter \( S_{max} \) increases monotonously with temperature for the particles with size of 3 nm to 8 nm. Moreover, \( S_{max} \) of small particles is more sensitive to temperature than that of large particles. However, the temperature dependence of both \( S_{max} \) and \( V_{ac} \) of the 15 nm particles are different from those for 3-8 nm particles. Further analysis of relation between \( H_c \) and \( V_{ac} \) suggested that the 3-8 nm particles are ideal single-domain particles, while the 15 nm particles can not be well described as single-domain particles even the particle size is much smaller than the single-domain size.

K1.00113 Composition Dependent Properties in Disordered, Lower Dimensional Co/Ni Dichloride Monohydrate, G.C. DEFOITIS, E.S. VOS, A.H. HOPKINSON, W.M. MAY, T.M. OWENS, C.M. DAVIS, C.L. DESANTO, College of William and Mary — This new mixed magnet is composed of the lower dimensional insulators Co dichloride monohydrate and Ni dichloride monohydrate, both studied previously by us. The Co system is an antiferromagnetic singl band with an antiferromagnetic transition at 15.0 K and a spin glass transition at 8.4 K. The antiferromagnetic Ni system orders at 5.6 K. Both materials are characterized by ferromagnetic intrachain interactions and antiferromagnetic interchain interactions; an element of randomness is present in the Co system but not the Ni. Mixtures of these two components have been prepared and studied over a wide composition range. The variation in magnetic behavior with composition is not anticipated on the basis of pure component properties, e.g., the location of a susceptibility maximum and of a field induced transition. Irreversibility effects are present over a broad composition range. It seems likely that admixture of the two components enhances effects of disorder and frustration already present in the Co system, so that equilibrium behavior occurs even for Ni rich mixtures.

K1.00114 Generic and topological features of flat bands in tight binding hopping models, DORON BERGMAN, Yale University, CONGIUN WU, University of California, San Diego, LEON BALENTS, University of California, Santa Barbara — We study some generic features of flat bands, that appear in a number of tight binding hopping models. Such models have recently received some attention in the literature [1,2], with a number of suggested experimental realizations. In some models the flat band touches dispersing bands at a discrete set of high-symmetry points in the Brillouin zone. In other models, the flat band is gapped. A topological argument, crucially depending on the boundary conditions of the system, which explains why in some models the flat band is gapped, while in others it is not. The argument is based on the observation that in flat bands in addition to quasi-local eigenstates, there invariably exist states involving non-contractible loops. In those cases where the flat band touches a dispersive band, our argument also determines at which points in momentum space this occurs. [1] C. Wu, et al., Phys. Rev. Lett. 99, 070401 (2007) [2] J. Schulenburg, et al., Phys. Rev. Lett. 88, 167207 (2002)

K1.00115 Magnetic Behavior in Cobalt and Nickel Dibromide Hydrates1, G.C. DEFOTIS, C.M. DAVIS, C.L. DESANTO, College of William and Mary — The magnetism of 3d transition metal dibromide hydrates has been examined far less than for corresponding chlorides. Continued here is a program of examining the especially neglected monohydrate systems, by extending earlier studies of Co and Ni dichloride monohydrates to bromide counterparts. For comparison purposes the only lightly examined Co and Ni dibromide hydrate systems are also studied. Both Ni materials, dihydrate and monohydrate, show an antiferromagnetic susceptibility maximum at, surprisingly, virtually the same 6.0 K location. The maximum is broader and of lesser magnitude in the monohydrate, perhaps indicating lower dimensional character. Marked differences in magnetization isotherms as a function of temperature also distinguish these two materials. In Co dibromide dihydrate a susceptibility maximum occurs at 9.5 K, only about half the temperature of a similar feature in the corresponding chloroide. Yet in the monohydrate an enhanced susceptibility maximum appears at 15.9 K, remarkably close to such a feature in the corresponding chloride. And as in that system, nonequilibrium magnetic properties appear, suggesting that a significant degree of frustration is present.

K1.00116 Raman spectroscopy of multiferroic TbMnO3J, J. R. SIMPSON, A. R. HIGHT WALKER, NIST, Gaithersburg, MD 20899, R. VALDÉS AGUILAR, A. B. SUSHKOV, H. D. DREW, University of Maryland, College Park, MD 20742, S. PANKRATS, Y. J. CHOI, C. ZHANG, S.-W. CHEONG, Rutgers University, New Brunswick, NJ 08854 — Coupling between the lattice and magnetic degrees of freedom in TbMnO3 has been observed to produce magnetic excitations with electric dipole activity, or electromagnons. Recent reports of electromagnons in other multiferroic (113)-orthomanganites and related (125)-manganites indicate a complementary Raman study may provide additional insight into the importance of spin-lattice coupling. We present Raman spectra of single-crystal and polycrystalline TbMnO3 using a triple-grating spectrometer in a collinear backscattering configuration as a function of temperature (4 − 300 K) and polarization along various crystallographic axes. The absence of any observable low-frequency modes (intensity $\sim 1000$ times that of prominent Raman-active phonons) suggests a weak scattering cross-section for the electromagnon. Additionally, we discuss the temperature dependence of Raman-active phonons and compare with results from infrared measurements.

1Work supported, in part, by the NIST-NRC postdoctoral fellowship.

K1.00117 Magnetic behaviour of the Bi$_{1-x}$Sr$_x$Ir$_2$O$_7$ pyrochlore, CARLOS COSIO-CANESTEDO, OLIVER MARTINEZ-ANAYA, GUSTAVO TAVIZON, Facultad de Quimica, PABLO DE LA MORA, Facultad de Ciencias, FRANCISCO MORALES-LEAL, ROBERTO ESCUDERO, Instituto de Investigaciones en Materiales — Compounds of the Bi$_{1-x}$Sr$_x$Ir$_2$O$_7$ solid solution have been synthesized by the solid state reaction method. Structural modifications as well the valence states of Iridium have been studied as a function of the strontium content by Rietveld refinements and electrochemical analytical methods. Electrical properties of Bi$_{1-x}$Sr$_x$Ir$_2$O$_7$ show single phase and metallic behaviour in the whole range of compositions. Magnetically this system behaves as a Curie-Weiss paramagnet from 2-300 K. The magnetic moment suggests the presence of Ir$^{3+}$ valence state.

K1.00118 Invar effect and non-collinear magnetism in CuFe alloys, MARCUS EISENBACH, G. MALCOLM STOCKS, Oak Ridge National Laboratory, Oak Ridge, TN — The Invar effect has been observed in many Fe rich alloys, most famously Ni Invar. Generally the Invar behavior is associated with the strong coupling between the lattice and magnetic degrees of freedom, and therefore depends on the magnetic ordering in these alloys. Recent experimental works observed an Invar effect in fcc-CuFe solid solutions. [Gorria et al., PRB 69, 214421 (2004)] We investigate the magnetic states of fcc-CuFe solid solutions in the Invar regime and compare it with the order in low Fe concentration alloys, to establish the connection between the Invar effect and the magnetic order. To study this we employ the locally selfconsistent multiple scattering (LSMS) real space method for solving the LDA Kohn-Sham equation as well as its extension to fully relativistic calculations to investigate all effects leading to anisotropies and non collinear ordering of magnetic moments.

K1.00119 X-ray scattering study of the magnetic phase transitions in GdFe3(BO3)4, H. MO, C.S. NELSON, Brookhaven National Laboratory, Upton, NY 11973, L.N. BEZMATERIALYK, V.L. TEMEROV, Kirenskioe Institute of Physics, Russian Academy of Science, Akademgorodok, Krasnoyarsk, 660036 Russia — The rare earth iron borates have interesting magnetic properties due to the subtle interactions between the rare earth and the iron moments. Among these materials, GdFe3(BO3)4 has the most complex phase diagram as suggested by previous studies. [1,2] These studies suggest that iron moments order antiferromagnetically below $T_N \approx 36$ K and that there are several additional magnetic phase transitions below $T_N$. Yet whether and at what temperature the Gd moments order and the nature of the additional transitions, remain largely unknown. Using x-ray magnetic scattering, we have verified that the moments order antiferromagnetically with a propagation vector $(0 \ 0 \ 3/2)$. Large resonant scattering enhancements at the Gd $L_{11}$ and $L_{21}$ edges show unambiguously that Gd moments order at $T_N$. Both resonant and nonresonant scattering data exhibit a splitting of the magnetic peak along $c^*$ above $\sim 10$ K which indicates an incommensurate phase transition, with the incommensurability $\delta$ increasing continuously as a function of temperature ($\delta \sim 0.038$ near $T_N$). Use of the NSLS/BNL is supported by the U. S. DOE under Contract no. DE-AC02-98CH10886. [1] F.-Y. Chen et. al, PRB 73, 54435 (2006)

K1.00119 X-ray scattering study of the magnetic phase transitions in GdFe3(BO3)4, H. MO, C.S. NELSON, Brookhaven National Laboratory, Upton, NY 11973, L.N. BEZMATERNYKH, V.L. TEMEROV, Kirenskioe Institute of Physics, Russian Academy of Science, Akademgorodok, Krasnoyarsk, 660036 Russia — The rare earth iron borates have interesting magnetic properties due to the subtle interactions between the rare earth and the iron moments. K1.00120 Non-Collinear Magnetic Orderings in Mott Insulators, ALEXANDER BAZHAN1, P.L. Kapitza Institute for Physical Problems, RAS. — Non-collinear magnetic orderings of four Cu magnetic moments in Mott insulators R$_2$Cu$_2$O$_4$ (R = Nd, Pr) of I4/mmm symmetry and associated magnetic phase transitions are of interest in studies of transformations, when correlated electron-hole carriers are introduced in R$_2$-xCe$_x$Cu$_2$O$_4$. Orderings are determined by thermodynamic potential in representation by antiferromagnetic I$_1$, I$_2$, and magnetic m vectors, with orderings of I$_1$, I$_2$, vectors along [100], [010] axis, with values $I_1^2 = I_2^2 = 1/2$, $m^2 = 1$ [1], which can be presented as, $I_1 = 1/2$ A($I_1^2 + I_2^2$) + 1/2 A($I_1^2 - I_2^2$) + 1/4 $I_1^2$ + $I_2^2$ + 1/4 $I_1^2$ + 1/4 E ($I_1^2 - I_2^2$) + 1/4 a ($I_1^2 + I_2^2$) + 1/4 b ($I_1^2 + I_2^2$) + 1/4 c ($I_1^2 + I_2^2$) · m with $I_1 = 0$. Magnetic phase transitions, are concerned with change of I$_1$, I$_2$ values in fields ~H$_{-1}$, ~H$_{+1}$, where $I_1^2 = 0$, $I_2^2 = I_2^2$, when field is oriented along [100], [110] axis respectively, and next I$_2$ orientation to orthogonal to field direction in fields ~H$_{-1}$, ~H$_{+1}$, when field is along [110] axis. Fields H$_{-1}$, H$_{+1}$ are presented as, H$_{-1}$ = 2BE$_2$; H$_{+1}$ = H$_{+1}$, if H$_{+1}$ = b$_{+1}$BE$_1$, H$_0^2$ = -2H$_{+1}$H$_{-1}$ if H$_{+1}$ = b$_{+1}$BE$_1$. Formation of charge density waves of checkerboard structure can be detected by studies of transformation of magnetic phase transitions and fields in R$_2$-xCe$_x$Cu$_2$O$_4$. [1] A. N. Bazhan, AIP Proceedings 850 (2006) 1241

1 K1.00121 CHEMICAL PHYSICS —

K1.00122 CHEMICAL PHYSICS

K1.00122 An Explanation for the Very Low Friction of Polyelectrolyte Brushes, JEFFREY SOKOLOFF, Northeastern University — It is shown using a method based on the mean field theory of Miklavcic Marcella that it should be possible for osmotic pressure due to the counterions associated with the two polyelectrolyte polymer brush coated surfaces to support a reasonable load (i.e., about 10$^{15}$ Pa) with the brushes held sufficiently far apart to prevent entanglement of polymers belonging to the two brushes, thus avoiding what is believed to be the dominant mechanisms for static and dry friction. This is shown to be true even if the brushes are highly compressed, which is consistent with the observation by Raviv, et. al., that the friction for polyelectrolyte brush coated surfaces can be exceedingly low, even if the brushes are highly compressed.

K1.00124 Temperature Dependent Raman Intensities and Calculations of Chiral ketone Conformers, WATHEQ AL-BASHEER, The Hashemite University, Zarqa 13115, JUN LI, Pacific Northwest National Laboratory, Richland, WA 99352, ROBERT COMPTON, The University of Tennessee, Knoxville, TN 37996 — Vibrational Raman spectra for the C-H stretch region of 3-methylcyclopanetane (R3MCP) neat sample as a function of temperature variation will be presented and employed as a conformational analysis method. Probing the methyl group C-H stretch region (2850 – 3000 cm$^{-1}$) relative peak intensities of assigned conformers, is being manipulated to determine the conformer energy differences between equatorial methyl and axial methyl isomers. Raman spectroscopy performed under liquid nitrogen temperatures (LN) will also be presented as a preliminary tool to observe Raman vibrational modes at liquid nitrogen temperatures (~ 77 K), and to improve resolution and high signal to noise ratio. An observed few wavenumbers bathochromic (red) shift in Raman lines frequencies will be attributed to sample phase change. The validity of Density Functional Theory (DFT) calculations, of different levels basis sets, for R3MCP conformers Raman intensities and frequencies will be investigated and compared against experimental findings.

K1.00125 Optimum Atomic Ranges in Coupled Dipole Method, HYE-YOUNG KIM, ZACHARY BOND, Department of Chemistry and Physics, Southeastern Louisiana University, Hammond, LA — In recent years, the coupled dipole method (CDM) has been applied to calculate the van der Waals dispersion interaction (VDW) between dielectric nanoclusters. Similar self-consistent method has also been used to calculate the static polarizabilities, from which the fully-retarded VDW was calculated. The breakthrough in CDM is that it can calculate all n-body terms in VDW. This allows for significant improvement upon the usual 2-body description of VDW. As the size of nanoclusters close to the experimentally measurable size, however, solving for eigenvalues of a large matrix (with all n-body interactions) in CDM becomes non-trivial. Since each interaction term decreases as the separation distance becomes large, certain atomic ranges within which the VDW would converge is expected in large systems. Identifying this range will improve the efficiency of CDM. Here, we report the results of a systematic study on the optimized maximum atomic ranges in CDM for different shapes and sizes of clusters. REF: Langmuir 23, 1735 (2007).

K1.00126 Umbrella Sampling in the Long Range Ising Model, RANJIT CHACKO, HARVEY GOULD, Clark University, WILLIAM KLEIN — Umbrella sampling with the largest cluster size as the local order parameter has been used to study liquid to solid nucleation. In the absence of a rigorous definition of a solid-like cluster, an ad hoc definition of the clusters must be adopted. As a result it is not clear if the vanishing of the free energy barrier found by umbrella sampling should be interpreted in terms of a spinodal and how well the cluster found at the free energy maximum corresponds to the true nucleating droplet. To better understand umbrella sampling with a local order parameter we study nucleation in the long-range Ising model for which the cluster definition is given rigorously by a percolation mapping. We determine the free energy of the long-range Ising model as a function of the largest cluster size and the quench depth, and study the properties of the nucleating clusters as the spinodal is approached.

K1.00127 TOF MS Study of Photodissociation of Borazine at 193 nm, DACHUN HUANG, VLADIMIR MAKAROV, Univ of Puerto Rico, Dept of Chem, ARTURO HIDALGO, Univ of Puerto Rico, Dept of Phys, BRAD WEINER, Univ of Puerto Rico, Dept of Chem, GERARDO MORELL, Univ of Puerto Rico, Dept of Phys — Photofragmentation of borazine molecule has been investigated in a supersonic molecular beam condition (Ar + 1% borazine mixture) by using radiation of 193 nm (250 mJ/pulse). Fragments were photo ionized using another laser (193 nm, 3 mJ/pulse) and detected by a linear time-of-flight mass spectrometer. Both lasers passed through the work area of the TOF mass spectrometer at the same time. We found that the main channel of borazine photofragmentation is formation of B$_3$H$_4$ radical and hydrogen atom. The possible mechanism was proposed and discussed.
K1.00128 Single Pulse Time Resolved Four Wave Mixing. YEHIAM PRIOR, YURI PASKOVER, ILYA SH. AVERBUKH, Department of Chemical Physics, Weizmann Institute of Science, Rehovot, Israel 76100 — We present a new experimental technique for single-shot time resolved ultrafast Coherent Anti-Stokes Raman Spectroscopy (CARS), where we use the arrival time of pulses at the intersection of broad beams as controlled time delays. The three dimensional (Bovacs) phase-matching configuration allows unique mapping of two independent time delays (pump-Stokes and pump-probe) onto the geometrical axes of the interaction region. The signal emitted from each point of the beams’ intersection carries information on the molecular state at the particular time delay after the excitation, and thus the spatial profile of the CARS beam provides time resolved trace of the intra-molecular vibrational dynamics. We show that our technique allows for capturing of a few picoseconds of vibrational evolution by means of a single ultrashort pulse. Moreover, the ability to resolve two time delays between pulses enables us to study vibrational dynamics on the ground and the excited electronic states, as well as the correlation between the nuclear motions within these different vibrational potentials. The ability to record vibrational dynamics while the molecules freeze to the single molecule to a optical pulse allows for characterization of short living and unstable chemical species as transitional complexes of chemical reactions.

K1.00129 Spectroscopic characterization of the ionization energy, \( \Sigma^+_g \), \( (2)\Pi^+ \), and \( (3)\Pi \) states of Be \(_g\). JEREMY MERRITT, Department of Chemistry, Emory University, Atlanta GA 30322, VLADIMIR BONDBYBEY, Institut fur Physikalische und Theoretische Chemie der TU Munich, Garching, Germany, MICHAEL HEAVEN, Department of Chemistry, Emory University, Atlanta GA 30322 — Low-lying electronic states of beryllium dimer are investigated by laser induced fluorescence (LIF) and resonance enhanced multiphoton ionization (REMPI) spectroscopies. \( \text{Be}_2 \) is formed by pulsed laser ablation and free jet expansion into vacuum. Comparing 1+1 REMPI and LIF spectra for the \( \Sigma^+_g \) (v=0) \( \rightarrow \) \( \Pi^+_g \) (v) bands we find significant perturbations in the REMPI spectra, which are interpreted as autoionizing resonances in the ionization continuum. Photoionization efficiency (PIE) measurements yield an accurate value for the ionization energy, namely 7.40 eV, which is considerably larger than previous theoretical predictions. New CASSCF/MRCI calculations are presented which accurately reproduce the experimental IP. Rotationally resolved spectra for the \( (1)\Sigma^+_g \rightarrow (2)\Pi_1 \) and \( (1)\Sigma^+_g \rightarrow (3)\Pi \) band systems of \( \text{Be}_2 \) have also been measured for the first time providing further experimental benchmarks for recent ab initio calculations. PIE measurements are also used to accurately determine the \( \Sigma^+_g < \rightarrow (1)\Pi_1 \) interval.

K1.00130 Rovibrationally Inelastic Velocity-Dependent Cross Sections from Doppler Lineshapes. PAULA MATEI, STEVEN COPPAGE, BRIAN STEWART, Wesleyan University — We are studying rovibrationally inelastic processes in the Li\(_g\) (A) – noble gas system through a spectroscopic technique that employs the Doppler shift for velocity selection of the lithium molecules. Our goals are to look for experimental evidence of a novel vibrational transfer mechanism that involves impacts with the side of the molecule, and to investigate and compare different combinations of rotational and vibrational energy transfer. The experimental results will be compared with cross sections calculated from ab initio potential surfaces.

K1.00131 Saturated nucleate pool boiling of oxygen under magnetically-enhanced effective gravity\(^1\). T. A. CORCOVILOS\(^2\), M. E. TURK\(^3\), California Institute of Technology - Division of Physics, Math. and Astronomy, Pasadena, CA, USA, D. M. STRAYER, California Institute of Technology - Jet Propulsion Laboratory, Pasadena, CA, USA, N. N. ASPLUND, N.-C. YEH, California Institute of Technology - Division of Physics, Math. and Astronomy, Pasadena, CA, USA — We investigate the effect of enhancing gravity on saturated nucleate pool boiling of oxygen for effective gravities \( (g^e) \) of 1g, 6g, and 16g \( (g = 9.8 \text{ m s}^{-2}) \) at a saturation pressure of 760 torr and for heat fluxes of 10 \( \sim \) 3000 W m\(^{-2}\). The effective gravity on the oxygen is increased by applying a magnetic body force generated by a superconducting solenoid. We measure the heater temperature (expressed as a reduced superheat) as a function of heat flux and fit this data to a piecewise power-law/linear boiling curve. At low heat flux \( (\sim 100 \text{ W m}^{-2}) \) the superheat is proportional to the cube root of the heat flux. At higher heat fluxes, the superheat is a linear function of the heat flux. The value of the transition heat flux separating these two regions is proportional to \( \sqrt[3]{g^e} \), indicating a possible link to the critical heat flux.

K1.00132 Thermal Hysteresis in Magnetic Phases of Solid Oxygen. N. S. SULLIVAN, University of Florida, M. PILLA, Triquint Semiconductor Inc., J. A. HAMIDA, University of Florida — Measurements of the dielectric susceptibility of solid oxygen have been carried out in the temperature range 4.2 \( \sim \) 54 K. Relatively large hysteresis effects \( (~0.4\%) \) have been observed for the dielectric response in the \( \alpha \) and \( \beta \) phases on thermal cycling below 44 K. The temperature for the transition between the two-sublattice antiferromagnetic \( \alpha \) phase and the frustrated quasi-helical \( \beta \) phase is observed to be independent of the thermal cycles. The areas of the thermal hysteresis scale with the extent of the thermal excursion in the frustrated \( \alpha \) phase.

K1.00133 Does Hot Water Freeze Faster than Cold? Investigation of the Reproducibility and Causes of the Mpemba Effect. JOSEPH THOMAS, SUSAN LEHMAN, The College of Wooster — An investigation into the reproducibility and possible causes of the Mpemba effect has been performed. The Mpemba effect is the name given to the common observation by non-scientists that hot water appears to freeze faster than cold water.\(^1\) Previous scientific studies of this effect have found conflicting results. These discrepancies appear to be due in part to inconsistent definitions of freezing based on visual observation. We have investigated the Mpemba effect by continuously monitoring the temperature of a container of water to determine the amount of time needed for the water to turn completely to ice, as indicated by the temperature falling below 0 °C. We have successfully observed the effect repeatedly and have found it to be dependent on the sample’s temperature history rather than the sample temperature when placed into the freezer. Room temperature water which had been briefly heated to 100 °C then cooled froze approximately 50 % faster than room temperature water which had not been heated. The effect on the freezing time of increasing or decreasing the amount of dissolved gas in the water will also be discussed. 1. M. Jeng. Am. J. Phys. 74 514 (2006).

K1.00134 Surface roughness effects on superhydrophobicity. CHUNYANG YANG, UGO TARTAGLINO, BO PERSSON, IFF, FZ-Juelich, D-52425, Germany — Superhydrophobic surfaces, with liquid contact angle greater than 150 degree, have important practical applications ranging from self-cleaning window glasses, paints, and fabrics to low friction surfaces. Many biological surfaces, such as the lotus leaf, have hierarchically structured surface roughness which is optimized for superhydrophobicity through natural selection. Here we present a molecular dynamics study of liquid droplets in contact with self-affine fractal surfaces. Our results indicate that the contact angle for nanodroplets depends strongly on the root-mean-square (rms) surface roughness amplitude but is nearly independent of the fractal dimension of the surface\(^2\). References: [1] C. Yang, U. Tartaglino and B.N.J. Persson, Phys. Rev. Lett. 97, 116103 (2006) [2] C. Yang, U. Tartaglino and B.N.J. Persson, arXiv:0710.3264
K1.00135 Production of Polymer Core-Shell Colloids with High Uniformity via Coaxial Electrospay. YOUN KYUN HWANG, UNYONG JEONG, Department of Materials Science and Engineering, Yonsei University, Seoul — Although nanofibers fabricated by electrospinning have been attracting wide interest, the production of colloids by electrospaying has not much studied so far. We have developed a simple method for the production of core-shell colloids with high uniformity by means of the coaxial electrospay. Contrary to usual coaxial setup, the inner nozzle was set to touch the inside wall of the outer nozzle for reproducible production. A polymer solution for the core was introduced through the outer nozzle and another solution for the shell was provided through the inner nozzle. The structure of the colloids was dependent on the polymer concentration, relative feed ratio between the polymer solutions. Especially, core-shell structured colloids are our primary interest due to their promising uses in drug-delivery systems, cosmetics, and food industries. This talk will present the production of core-shell colloids consisting of two polymer components.

K1.00136 Janus particles at the planar water-oil interface. QIAN CHEN, SHAN JIANG, STEVE GRANICK, University of Illinois at Urbana-Champaign — Amphiphilic Janus particles (hydrophobic on one side, hydrophilic on the other) were placed at the planar water-oil interface at various surface coverage and found to self-assemble into two-dimensional crystals with long-range hexagonal order, which we studied by fluorescence and phase contrast microscopy. Surprising dependence is observed not only on the surface chemical makeup of the hydrophilic side but also on the Janus balance (i.e. the relative sizes of hydrophobic and hydrophilic portions), which is analogous to the HLB balance that characterizes molecular surfactants.

K1.00137 Ab Initio Simulations of Silica Alpha Quartz Surfaces and their Interaction with Water1, YUN-WEN CHEN, HAI-PING CHENG, Quantum Theory Project, Department of Physics, University of Florida — Two types of dry silica alpha quartz (0001) surfaces have been investigated through density functional calculations. One is the dense surface proposed by Rignanese et al. [1] that has 3-fold flower like six-member rings on the top and the three-member rings underneath. The other one is a newfound surface that has zigzag-shape six-member rings on the top and the three-member rings underneath. It is found that the new one is energetically more stable than the dense surface. The interactions of the surfaces with water molecules have also been concerned. Both of the surfaces have the similar hydrophilic properties. We report our results from MD simulations at a temperature of 300K.

1 Funded by NSF Grant 0403871

K1.00138 Molecular motion in alkylsilane self-assembled monolayers1, DERRICK STEVENS, North Carolina State University (NCSU), MARY SCOTT, LAURA GUY, JASON BOCHINSKI, LAURA CLARKE, NCSU — We have investigated intra-molecular rotation within polar-substituted alkylsilane self-assembled monolayers (SAMs) on fused silica, utilizing surface-sensitive dielectric spectrosopy. Both trichlorosilanes (which allow crosslinking within the SAM) and monochlorosilanes (attached only to the surface) are utilized to grow monolayer and submonolayer films. Dielectric loss spectra as a function of temperature have been obtained for SAMs with varying carbon chain length, surface coverage, and alkyl terminal group. As shown by ellipsometry, contact angle measurements, and AFM, monochlorosilanes form a more disordered monolayer than trichlorosilanes. This more disordered film may result in additional degrees of freedom within the monolayer, or in the language of phase transitions, a rotator phase. Issues such as uncontrolled vertical polymerization and film growth by island formation and their effect on rotational dynamics will be discussed.

1 Funded by NSF Grant 0403871

K1.00139 Photoemission and reaction study of mass-selected Pt clusters on TiO2(110) surface, NORITAKE ISOMURA, YOSHIHIDE WATANABE, Toyota Motor Corporation, Toyota Central R&D Labs., Inc. — Metal cluster ions were produced by a DC magnetron-sputter cluster ion source [1] with an ion funnel [2], the surface. Catalytic properties of mass-selected metal clusters on well-defined oxide surfaces have been investigated using the new ultra high vacuum cluster ion source. One is the dense surface proposed by Rignanese et al. [1] that has 3-fold flower like six-member rings on the top and the three-member rings underneath. The other one is a newfound surface that has zigzag-shape six-member rings on the top and the three-member rings underneath. It is found that the new one is energetically more stable than the dense surface. The interactions of the surfaces with water molecules have also been concerned. Both of the surfaces have the similar hydrophilic properties. We report our results from MD simulations at a temperature of 300K.

K1.00140 Structural and electronic properties of aluminum nanoclusters1, MRUDULA RAPARLA, TUNNA BARUAH, University of Texas at El Paso, RAJENDRA ZOPE, University of Texas at El Paso — The electronic properties of Al clusters containing up to 60 atoms are investigated using an all electron density functional theory using large polarized Gaussian basis sets with 39 Gaussians per atom (NRLMOL basis). We have performed an extensive search for the lowest energy isomers for clusters up to Al21. We build a database of candidate structures for the ground state using different strategies. First, a few structures are randomly generated and fully relaxed using planewave pseudopotential method. We also performed simulated annealing runs using ab initio molecular dynamics for clusters up to Al20. In three sets of simulated annealing runs the clusters were heated up to 900 and 1000K and were slowly cooled to 50K at different rates. After every half picosecond, the cluster was quenched. Additionally the best basin hopping geometries obtained using empirical embedded atom potential were also fully optimized. The process generates 40-50 structures for each size. All the structures are relaxed using empirical embedded atom potential. The calculated electron affinities and theoretical photoelectron binding energies are in very good agreement with experiment. Theoretical predictions for Zn, Ca and Cs anions display additional electron detachment binding energies that are not present in the published experimental data.

K1.00141 Density Functional Study of the Photodetachment Spectra of Zinc and Calcium Cluster Anions1, YAFEI DAI, E. BLAISTEN-BAROJAS, Computational Materials Science Center, George Mason University, Fairfax, VA — The structure and electronic states of zinc cluster anions Zn3 through Zn6 and calcium cluster anions from Ca2 through Ca19 were optimized within the hybrid density functional approach. Based on these results, the photodetachment spectra of Zn3 through Zn6 and of Ca3 through Ca4 anions were determined. Additionally, the electron affinity of Zn, (N up to 9) and of Ca (N up to 19) was calculated within the same approximation. Both the calculated electron affinities and theoretical photoelectron binding energies are in very good agreement with experiment. Theoretical predictions for Zn, Ca2 and Ca4 anions display additional electron detachment binding energies that are not present in the published experimental data.

K1.00142 Amorphous and crystallographic structures of TiO2(110) surfaces and their interaction with water, JUN-CHAI KIM, SANGHO JUNG, Department of Materials Science and Engineering, Ulsan National Institute of Science and Technology, Ulsan — The TiO2(110) surface is a model system for understanding the basic properties of amorphous titanium dioxide, the most important component of a number of chemical and physical systems such as catalysts, non-destructive diagnostics, and thin film solar cells. This talk will present the construction of a database of candidate structures for the ground state at various surface coverage using an all electron density functional theory. The database is then used to study the interaction between the water molecules and the TiO2(110) surface. The interaction energy profiles are calculated for various water molecules and the adsorption geometry is determined for each water molecule. The results are compared with the experimental data to evaluate the extent to which the theoretical predictions are in agreement with experiment.

K1.00143 Production of Polymer Core-Shell Colloids with High Uniformity via Coaxial Electrospay. YOUN KYUN HWANG, UNYONG JEONG, Department of Materials Science and Engineering, Yonsei University, Seoul — Although nanofibers fabricated by electrospinning have been attracting wide interest, the production of colloids by electrospaying has not much studied so far. We have developed a simple method for the production of core-shell colloids with high uniformity by means of the coaxial electrospay. Contrary to usual coaxial setup, the inner nozzle was set to touch the inside wall of the outer nozzle for reproducible production. A polymer solution for the core was introduced through the outer nozzle and another solution for the shell was provided through the inner nozzle. The structure of the colloids was dependent on the polymer concentration, relative feed ratio between the polymer solutions. Especially, core-shell structured colloids are our primary interest due to their promising uses in drug-delivery systems, cosmetics, and food industries. This talk will present the production of core-shell colloids consisting of two polymer components.

K1.00136 Janus particles at the planar water-oil interface. QIAN CHEN, SHAN JIANG, STEVE GRANICK, University of Illinois at Urbana-Champaign — Amphiphilic Janus particles (hydrophobic on one side, hydrophilic on the other) were placed at the planar water-oil interface at various surface coverage and found to self-assemble into two-dimensional crystals with long-range hexagonal order, which we studied by fluorescence and phase contrast microscopy. Surprising dependence is observed not only on the surface chemical makeup of the hydrophilic side but also on the Janus balance (i.e. the relative sizes of hydrophobic and hydrophilic portions), which is analogous to the HLB balance that characterizes molecular surfactants.

K1.00137 Ab Initio Simulations of Silica Alpha Quartz Surfaces and their Interaction with Water1, YUN-WEN CHEN, HAI-PING CHENG, Quantum Theory Project, Department of Physics, University of Florida — Two types of dry silica alpha quartz (0001) surfaces have been investigated through density functional calculations. One is the dense surface proposed by Rignanese et al. [1] that has 3-fold flower like six-member rings on the top and the three-member rings underneath. The other one is a newfound surface that has zigzag-shape six-member rings on the top and the three-member rings underneath. It is found that the new one is energetically more stable than the dense surface. The interactions of the surfaces with water molecules have also been concerned. Both of the surfaces have the similar hydrophilic properties. We report our results from MD simulations at a temperature of 300K.

K1.00142 Ligand-spacer controlled size selectivity of gold clusters1, GHAZAL SHAFAI, SAMPYOO HONG, TALAT RAHMAN, University of Central Florida, MASSIMO BERTINO, Virginia Commonwealth University — It has been observed in the experiment that the presence of diphosphine ligands with varying spacers (L1, L5, and L8) leads to the formation of Au clusters of characteristic size [1]. In particular, in the presence of L1, Au11 clusters are formed, while the presence of L5 leads to the formation of Au42, Au42, and Au14 clusters. We have carried out calculations based on the density functional theory in the projector augmented wave scheme (PAW) and the pseudopotential approach, to examine the effect of the diphosphine ligand spacer size on the stability of Au clusters containing 2 to 11 atoms through evaluations of the cluster total energy and proper corrections of spurious interactions between charged supercells. For example, to investigate the stability of Au11, we compare the total energy of Au11(X)2 and Au8(X)2 + Au4X4⁻ (X=L1, L3, or L5 ligands) and find that Au11 is indeed preferred by L1 rather than L5, in agreement with the experiment. The structural electronic changes brought about by the various local environments of these clusters are presented with full details. [1] Bertino et al. Phys. Chem. B Lett. 110, 21416 (2006)

K1.00143 An excitonic state-resolved approach to coherent phonons in quantum dots: generation and relaxation dynamics. RYAN COONEY, D.M. SAGAR, SAMUEL SEWALL, PATANJALI KAMBHAMPATI, McGill University — The strength of exciton-phonon couplings in quantum dots has remained controversial due in part to the complex eigenstate spectrum of electrons and holes in these systems. We recently implemented a combined time/frequency domain approach, towards exciton selective spectroscopy. This approach initially yielded a unified picture of the controversial mechanism of electron and hole relaxation dynamics in quantum dots. Recently, this approach yielded the first simultaneous observation of underdamped coherent optical and acoustic modes, thereby providing a direct measure of the controversy size dependent exciton-phonon coupling strengths for both modes. Pumping into higher excited states reveals that the Auger based electron relaxation process is vibrationally incoherent whereas non-adiabatic dynamics retain a memory of the vibrational coherence. Finally, phase and state-selective results reveal the electronic surface upon which the vibrational coherence is generated.

K1.00144 ABSTRACT WITHDRAWN

K1.00145 Photochemical Processing of Carbon Dioxide Ices and Simple Ice Mixtures1, T. RANDY DILLINGHAM, DAVID CORNELISON, Northern Arizona University — The investigation of the photochemical processes that can occur in carbon dioxide ices and ice mixtures have important applications in astrophysics, planetary astronomy, and atmospheric chemistry. In this investigation, carbon dioxide ices and ice mixtures are grown at various temperatures using a closed-cycle helium cryostat. The ices are irradiated with x-rays for periods of up to six hours. The chemical changes that occur during the processing are monitored using x-ray photoelectron spectroscopy and Fourier transform infrared spectroscopy. A quadrupole mass spectrometer is also used to study the gas phase species evoking from the ice surface during photoprocessing. The XPS, FTIR and mass spectrometer results are presented and correlated. It is noted that significant differences are observed, particularly for the time dependence of the evolution of the gas phase molecules, between ices grown at 77 K as compared to those grown at 20 K and at intermediate temperatures.

K1.00146 Single Electron Transport of Oligothiophene molecules1, TOSHIFUMI TERUI, National Institute of Information and Communications Technology, YUTA KO NOGUCHI, Center of Frontier Science, Chiba University, TAKUYA KATAYAMA, MICHI O MATSUSHITA, Grad. Sch. of Arts and Sci, University of Tokyo, RIEKO UEDA, National Institute of Information and Communications Technology, TADASHI SUGAWARA, Grad. Sch. of Arts and Sci, University of Tokyo — We examined the fabrication of single-electron transistors (SETs) with oligothiophene derivative or Au nanoparticle covered with oligothiophene as Coulomb island. The SET device was consists of a nanogap electrode, a molecular Coulomb island, and back gate electrode. The nanogap electrode was fabricated by the electromigration method. We could obtain the SET characteristics from the electron transport properties of both devices at 11 K. Spectra that owing to a molecule was obtained in the electric transport properties of these devices. Moreover, we could obtain the SET characteristics in some devices.

K1.00147 Characterization of hydroxyls on Si(001)-2×1:H2O using O 1s core-level spectroscopies and core-excited state DFT calculations, STEPHANE CARNIATO, Universite Pierre et Marie Curie, SYLVIE RANGAN, University of Texas at Dallas, JEAN-JACQUES GALLET, FRANCOIS ROCHET, GEORGES DUFOUR, FABRICE BOURNEL, Universite Pierre et Marie Curie, ALBERTO VERDINI, LUCA FLOREANO, TASC-INFN National Laboratory — The Si(001)-2×1 surface exposed to water molecules at room temperature has been chosen to single out the electron structure of the hydroxyl Si-OH, a surface species playing an important role in many technologically relevant processes. We confront here original core-electron spectroscopy DFT calculations to O 1s XPS (X-ray Photoelectron Spectroscopy) and NEXAFS (Near Edge Absorption Fine Structure) data. On various Si-OH environments (unpaired and paired hydroxyls), the impact of hydrogen bond on the calculated core-ionized and/or neutral core-excited states is examined, and compared to the limit case of the water dimer. The theoretical approach enables to label the main experimental NEXAFS transitions and to interpret their polarization-dependent dichroism. As water dissociation on the surface can go beyond the formation of hydroxyls, the vibrational coherence is generated.

K1.00148 Structure-Property Relations in beta-Hairpin Peptide Hydrogels, ROHAN HULE, DARRIN POCHAN, Materials Science and Engineering, University of Delaware — A de novo designed beta hairpin peptide, capable of undergoing intramolecular folding and consequent intermolecular self-assembly into a fibril-based network that forms a hydrogel, has been studied. A combination of SANS and cryo-TEM have been used to quantitatively investigate the nanofibrillar hydrogel network morphology. An increase in the peptide concentration resulted in a denser fibrillar network as revealed via a change in the high q mass fractal exponent from 2.5 to 3. This is accompanied by a decrease in the measured correlation length from 23 to 16 Angstroms, indicative of the increase in the number of crosslinks and a reduction in the interfibril distances in the proximity of individual crosslinking points. In the USANS regime, a slope of -4 is indicative of gel microporosity. These changes, both, at the network as well as the individual fibril length scales can be directly visualized in situ by cryo-TEM. Fibrillar nanostructure and the network morphology are directly related and can be used to tune the bulk hydrogel stiffness, as studied via oscillatory rheology. Knowledge of the precise nano-through microstructure can help in the formation of specific structure-property relationships in these novel peptide-based hydrogels.
K1.00149 Structured Hydrogels using Micelles as Templates, WONJOO LEE, PETER KOFINAS, ROBERT M. BRIBER, University of Maryland, College Park — Moleculearily imprinted polymers can be created by crosslinking polymers in the presence of molecular templates. If the pores generated after the removing of templates have almost the same size and shape as the template, the material has a potential to be used for separation, biosensor and drug delivery applications. In this work, micelles were used as the template as they can be easily removed from the hydrogel and a range of structures are accessible by combining a (linear) polyelectrolyte and an oppositely charged surfactant. Poly(2-(dimethylamino)ethyl methacrylate) (PDMAEMA) was synthesized and quaternized using methyl iodide. We have performed small angle neutron scattering (SANS) on solutions and hydrogels of PDMAEMA with sodium dodecyl sulfate (SDS) under different concentrations and crosslinking densities, and then performed the dynamic light scattering (DLS) and transmission electron microscopy (TEM). The results were confirmed by the SANS and DLS measurements. The PDMAEMA solution which contained SDS was dispersed as rod-like micelle-like structures coated with the SDS molecules. The micelle-like structures were associated along the polymer chain in a head-to-head structure consistent with what has been observed in the (uncharged) poly(ethylene oxide)/SDS system. Furthermore, we also show the interaction between PDMAEMA and micelles is strong enough to maintain the nanoscale structure formed along the PDMAEMA chain, even after crosslinking, leading to a structured hydrogel.

K1.00150 Controlled Charge-Flow in A Molecular Interferometer, SPIROS SKOURITSIS, Department of Physics, University of Cyprus, Nicosia 1678, Cyprus, DEQUAN XIAO, Department of Chemistry, Duke University, Durham, NC 27708, DAVID BERATAN, Department of Chemistry and Biochemistry, Duke University, Durham, NC 27708 — We describe an electron transfer molecule interferometer capable of controlling electron flow by inelastic tunneling manipulation. The molecule consists of electron donor and acceptor groups that are connected by a bridge. Upon photo-excitation of the molecule, an electron transfers from the donor to the acceptor group by tunneling through the bridge. The structure of the bridge is such that it provides interfering electron tunneling pathways. We show how to control interferences between the pathways by isotopic substitutions of pathway-specific bridge atoms. Such substitutions create pathway-localized bridge vibrations that can be selectively IR-excited during the electron transfer event. We suggest ways of experimentally controlling pathway interferences and electron transfer rates.

K1.00151 Single-crystalline rutile TiO$_2$ nanowires by mass selected Ni catalyst: Synthesis and electrical properties, MYUNG HWA KIM, CHRISTOPHER LARSON, JEONG MIN BACK, XIHONG CHEN, MARTIN MOSKOVITS, ALEC WODTKE, Department of Chemistry & Biochemistry, University of California at Santa Barbara — We present a novel method for growing high quality TiO$_2$ nanowires using mass-selected Ni clusters of nanometer sizes produced by magnetron sputtering and also show their electric field-effect functions. Single-crystalline TiO$_2$ nanowires (NWs) are grown by atmospheric pressure physical vapor deposition (APVVD) process, using TiO and Ti metal powders as a Ti source and Ni nanoparticles as a catalyst, respectively. For the TiO NWs growth, first, the Ti metal layer with a thickness of $\sim$50 nm was then deposited on the SiO$_2$/Si substrate by the e-beam evaporation technique and subsequently, the mass selected Ni clusters by using magnetron sputtering source combined with a quadrupole mass filter was deposited onto the Ti layer. APPVD growth was then performed in a horizontal quartz tube furnace at 800 °C–850°C by introducing high purity Ar carrier gas (99.999%) with the flow rate of 300 sccm for 2 hours. The $I-V$ curves are linear over the entire annealing temperature range at 200 °C–500°C, showing that the electrodes form good ohmic contacts with the nanowires. The $I$ vs $V$ curves for various values of $V_{SD}$ and gate dependent $I-V$ curves of a TiO$_2$ nanowire configured as a back-gated FET are also obtained and will be discussed.

K1.00152 Accurate electronic-structure description of Mn complexes: A GGA+U approach, ELISE Y. Li, Chemistry, Massachusetts Institute of Technology, HEATHER KULIK, NICOLA MARZARI, DMSE, Massachusetts Institute of Technology — Conventional density-functional approach often fail in offering an accurate description of the spin-resolved energetics in transition metals complexes. We will focus here on manganese (Mn) complexes, where Mn has the possibility to change its electronic configuration. Using an accurate method, we determine the electronic structure of these evolving complex (OEC) of photosystem II and the manganese catalysis (MC). We apply a self-consistent GGA + U approach [1], originally designed within the DFT framework for the treatment of strongly correlated materials, to describe the geometry, the electronic and the magnetic properties of various manganese oxide complexes, finding very good agreement with higher-order ab-initio calculations. By considering the different oxidation states of dinuclear systems containing the [Mn$_2$O$_2$]$^{2+}$ (n = 2, 3, 4) core, are investigated, in order to mimic the basic face unit of the OEC complex [1]. H. J. Kulik, M. Cococcioni, D. A. Scherlis, N. Marzari, Phys. Rev. Lett., 2006, 97, 103001

K1.00153 A density functional theory study of the benzene-water complex, SHEN LI, VALENTINO COOPER, Department of Physics and Astronomy, Rutgers, The State University of New Jersey, T. THONHAUSER, Department of Physics and Astronomy, Rutgers The State University of New Jersey and Department of Materials Science and Engineering, MIT, AARON PUDDER, Department of Physics and Astronomy, Rutgers, The State University of New Jersey and Lawrence Livermore National Laboratory, DAVID LANGRETH, Department of Physics and Astronomy, Rutgers, The State University of New Jersey — We calculated the intermolecular interaction of the benzene-water complex using real-space pseudopotential density functional theory with a van der Waals density functional (vdW-DF). Developed recently, vdw-DF has been applied to a number of van der Waals complexes with promising results. Our results for the intermolecular potential energy surface between benzene and a water molecule clearly show a stable configuration with the water molecule standing above the benzene with one or both of the H atoms pointing toward the benzene plane, as predicted by previous studies. However, when the water molecule is pulled outside the perimeter of the benzene ring, the configuration of the complex becomes unstable with the water molecule attaching in a saddle point configuration to the rim of the benzene with its O atom adjacent to a benzene H. The results for ground state structure are compared with available experiments and quantum chemical calculations.

K1.00154 First-principles study of the oxygen-reduction reaction on the Pt (100) surface, EUNJIA KIM, TAO PANG, Department of Physics and Astronomy, University of Nevada, Las Vegas — We have performed density-functional study of oxygen-reduction reaction on the Pt(100) surface. Equilibrium structures of oxygen on the surface are found and carefully analyzed. Our calculations show that oxygen molecules reside in the small terrace of the complete (100) surface. The adsorption of oxygen on Pt(100) is exothermic by $\sim$0.2 eV per oxygen atom. More oxygen molecules reaching the surface will continue to reduce but also drive the ones in the monolayer away from the surface, making the surface an effective catalyst. However, oxygen does not stack up into layers on the Pt(100) surface and therefore does not play a significant role in degrading the Pt (100) surface during any catalytic process there.

K1.00155 Chromium of Model Organic Aerosol$^1$, ANGELA RINCON, CALTECH, MARCELO GUZMAN, HARVARD UNIVERSITY, MICHAEL HOFFMANN, AGUSTIN COULISSI, CALTECH — The optical properties of the atmospheric aerosol play a fundamental role in the Earth’s radiative balance. Since more than half of the aerosol mass consists of complex organic matter that absorbs in the ultraviolet and visible regions of the spectrum, it is important to study the optical properties of the organic compounds. Here we report studies on the chromism vs. chemical composition of photolyzed (lamba longer than 305 nm) solutions of pyruvic acid, a widespread aerosol component, under a variety of experimental conditions that include substrate concentration, temperature and the presence of relevant spectator solutes, such ammonium sulfate. We use high resolution mass- and 13C NMR-spectrometries to track the oxidation state of the aerosol. First, we find that the aerosol undergoes a significant change in the UV-Vis spectrum when the aerosol is photolyzed with biologically active light of 212 nm. Subsequently, we study the effect of the aerosol’s chromism on its photobleaching properties. Since the chemical identity of the components of these mixtures does not change in these cycles, in which photobleached solutions gradually recover their yellow color in the dark with non-conventional kinetics typical of aggregation processes, we infer that visible absorptions likely involve the intermolecular coupling of carbonyl chromophores in supramolecular assemblies made possible by the polyfunctional nature of the products of pyruvic acid photolysis.

K1.00157 Spatially separating individual conformers of neutral (bio)molecules. JOCHEN KÜPPER, FRANK FILSINGER, UNDINE ERLÉKAM, GERT VON HELDEN, GERARD MEIJER, Fritz-Haber-Institut der MPG, Berlin, Germany — Large (bio)molecules exhibit multiple conformers (structural isomers), even under the cold conditions present in a supersonic jet. For various applications, i.e., scattering experiments, it would be highly desirable to prepare molecular packets of individual conformers. It is well-known that polar molecules can be manipulated using strong electric fields. Many techniques have been developed for the manipulation of small molecules in low-field-seeking quantum states. However, application of these techniques to large molecules is not straightforward, because, for larger molecules, all states are high-field seeking at the relevant electric field strengths. To manipulate the motion of large molecules one has to use Alternate Gradient (dynamic) focusing. This method has been successfully demonstrated in the Alternate Gradient deceleration of diatomic molecules. Using the same Alternate Gradient focusing principle, applying switched electric fields in a quadrupole guide, we have set up a new experiment to spatially separate individual conformers of large molecules. This experiment exploits the different mass-to-dipole $(m/q)$ ratios, similar to a quadrupole mass-to-charge $(m/q)$ filter for ions. In a proof-of-principle experiment, we have demonstrated the conformer selection of cis- and trans-3-aminophenol.

K1.00158 Spectroscopy of free radicals and radical containing entrance-channel complexes in superfluid helium nanodroplets. JEREMY MERRITT, Department of Chemistry, University of North Carolina - Chapel Hill, JOCHEN KÜPPER, Fritz-Haber-Institut der MPG, Faradayweg 4-6, 14195 Berlin, Germany, ROGER MILLER, Department of Chemistry, University of North Carolina - Chapel Hill — The unique properties of superfluid helium nanodroplets, namely their low temperature (0.4 K) and fast cooling rates ($10^{15}$ K$^{-1}$), provide novel opportunities for the formation and high-resolution study of metastable structures or molecular complexes containing free radicals. We discuss methods for the production of radicals and their applicability for embedding the radicals in helium nanodroplets. The spectroscopy of free radicals (i.e., $\text{C}_2\text{H}_4$) and of radical containing entrance-channel complexes, for example $\text{X}–\text{HY}$ ($\text{X}=\text{Cl, Br, I, CH}_3$, $\text{Y}=\text{F, CN}$), embedded in helium nanodroplets is detailed. The observed complexes provide new information on the potential energy surfaces of several fundamental chemical reactions and on the intermolecular interactions present in open-shell systems. Prospects for further experiments of radicals embedded in helium droplets are discussed.

K1.00159 Calculation of spin-orbit, static polarizabilities, and alignment of cold polar molecules. OLIVIER DULIEU, MIREILLE AYMAR, Laboratoire Aime Cotton, CNRS, Univ Paris-Sud Orsay, France, JOHANNES DEIGLMAYR, ROLAND WESTER, MATTHIAS WEIDEMÜLLER, Albert-Ludwigs-University Freiburg, Germany — Cold polar molecules offer exciting perspectives for studying strongly open-shell systems. Prospects for further experiments of radicals embedded in helium droplets are discussed.

K1.00160 Comparison of molecular energies calculation using simulated quantum algorithm and classical computer methods. JOSEPH LESNIAK, Department of Electrical and Computer Engineering, Wichita State University, ELIZABETH BEHRMAN, Department of Physics, Wichita State University, MELVIN ZANDLER, Department of Chemistry, Wichita State University, PREETHIKA KUMAR, Department of Electrical and Computer Engineering, Wichita State University — Very few quantum algorithms are currently usable today. When calculating molecular energies, using a quantum algorithm takes advantage of the quantum nature of the algorithm and calculation. A few small molecules have been used to show that this method is possible. This method will be applied to larger molecules and compared to classical computer methods.

K1.00161 SEMICONDUCTORS

K1.00162 Growth and characterizations of m-plane GaN and InN on gamma-LiAlO$_2$ substrate grown by plasma-assisted molecular beam epitaxy. LI-WEI TU, Z. L. LEE, Y. T. LIN, C. Y. HO, Y. L. CHENG, K. L. WU, Z. H. GONG, B. H. TSENG, M. C. CHOU, National Sun Yat-Sen University, Taiwan, Q. Y. CHEN$^1$, University of Houston, H. W. SEO, University of Arkansas, W. K. CHU, University of Houston — Non-polar nitrides are investigated in this report. Substrate used is gamma-phase LiAlO$_2$ (LAO) (100) grown by Czochralski pulling method. The in-plane lattice mismatch between the LAO (100) plane and the GaN (1-100) plane, is small with a lattice mismatch of $0.3\%$ and $[1120]$GaN$\parallel[001]$LAO $\sim 1.7\%$. M-plane GaN epilayer and InN were successfully grown by ultra-high vacuum plasma-assisted molecular beam epitaxy system. Extensive characterizations have been carried out which include x-ray diffraction theta-two-theta scan, rocking curve measurement, scanning electron microscopy, cathodoluminescence, photoluminescence, and Raman spectroscopy. Details will be presented.

$^1$current address: National Sun Yat-Sen University, Taiwan

K1.00163 AlGAN/GaN high electron mobility transistor grown on GaN template substrate by molecule beam epitaxy system$^1$. JENN-KAI TSAI, Center for General Education, National Formosa University, Hu-Wei, Yun-Lin, Taiwan 63208, R.O.C., Y. L. CHEN, M. H. GAU, W. Y. PANG, Y. C. HSU, IKAI LO, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China, C. H. HSIEH, Institute of Material Science and Engineering, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China — In this study, AlGAN/GaN high electron mobility transistor (HEMT) structure was grown on GaN template substrate by molecule beam epitaxy (MBE) equipped with an EPI UNI-Bulb nitrogen plasma source. The undoped GaN template substrate was grown on c-sapphire substrate assisted metal organic vapor phase epitaxy (MOVPE) using a 50 mTorr nitrogen plasma source. After growth of MOVPE and MBE, the samples are characterized by double crystal X-ray diffraction (XRD), transmission electron microscopy (TEM), field emission scanning electron microscopy (SEM), atomic force microscopy (AFM), and Hall effect measurements. We found that the RMS roughness of template substrate play the major role in got the high value of mobility on AlGAN/GaN HEMT. When the roughness was lower than 0.77 nm in a 25 $\mu$m x 25 $\mu$m area, the mobility of HEMT at the temperature of 77 K was over $10^{000}$ cm$^2$/Vs.

$^1$The authors would like to acknowledge Epistar corporation for supply GaN template substrates and financial support from the National Science Council of Republic of China.
The role of oxygen vacancies and defects on Lithium intercalation capacity of composite vanadium-titanium oxide thin films. M.B. SAHANA, C. SUDAKAR, C. THAPA, G. LAWES, K.R. PADMANABHAN, R. NAID, Dept. of Physics and Astronomy, Wayne State University, Detroit, MI 48201 USA, G. AUINER, Dept Electrical and Computer Engineering, Wayne State University, Detroit, MI 48202 USA, V.M. NAID, Dept of Natural Sciences, University of Michigan-Dearborn, Michigan 48128 — Composite films of vanadium-titanium oxide have been recognized as promising cathode materials for lithium ion batteries. While there is a consensus agreement that the cycling stability of the mixed V/Ti-oxide system is improved compared to V_2O_5 thin films, there are different findings on the Li+_ intercalation capacity of V_2O_5, PCCM Institute, Princeton University.

Fe-Doped SnO Powders Obtained By Sol-Gel Method, Mechanochemical Alloying, and Thermal Treatment. JAIME OSORIO, ANA CALLE, JAILES BELTRAN, LUIS SANCHEZ, Universidad de Antioquia, LILIANA TIRADO, Universidad del Quindio, KIYOSHI NOMURA, University of Tokyo, CESAR BARRERO, Universidad de Antioquia, ESTADO SOLIDO TEAM, OPTOELETRONICA TEAM, APPLIED CHEMISTRY SCHOOL OF ENGINEERING TEAM — The present work is aimed to investigate experimental conditions to obtain pure SnO_2 and FeSnO_2 powder by three methods: (1) sol-gel method, (2) mechanochemical alloying and (3) thermal treatment. In (1), different precursors were employed: mixtures of Sn^{4+} and Fe^{3+} or Sn^{2+} and Fe^{2+}. In (2), SnO_2 and α-Fe or α-FeO_2 were used as reactants. In (3), the Fe-doped SnO_2 were obtained by mechanochemical milling and thermal treatment. All samples were characterized by X-ray diffraction (XRD) using Rietveld refinement, Fourier-transformed infrared (FTIR) spectroscopy and room temperature 57Fe Mössbauer spectrometry (MS). The XRD patterns of samples prepared by (1) showed only peaks of SnO_2. The MS showed ferromagnetic and paramagnetic signals. The samples obtained by (2) showed XRD peaks due to SnO_2 (rutile). The MS revealed the presence of Fe^{2+} and Fe^{3+} states as well as α-Fe or α-FeO_2 due to the reactants. In the case of (3) was observed total incorporation of Fe^{3+} in the SnO_2 structure without presence of impurities.

ZnO films synthesized by thermal annealing of ZnSe/GaAs heterostructures. OLEG MAKSIMOV, Materials Research Institute, Pennsylvania State University — ZnO received much attention due to its potential application for the fabrication of ultraviolet light emitters and photodetectors. High crystalline quality films were grown using MBE, PLD, and CVD on Al_2O_3, GaN, SiC, and other substrates. However, further progress in this area is slowed down by the difficulties associated with doping ZnO p-type. Here, we report on the synthesis and doping of ZnO films using the annealing of MBE-grown ZnSe/GaAs heterostructures in the controlled environment. Se is displaced by oxygen through the reaction: 2ZnSe + 3O_2 → 2ZnO + 2SO_2. In addition, As migrating from the GaAs substrate into the ZnO layer, promotes p-type doping. While ZnGaO_2, ZnO_2, and other second phases form as the result of high temperature annealing (>700°C), stoichiometric ZnO films are obtained at moderate temperatures (~500°C). Films processed under optimized conditions exhibit sharp band edge excitations, narrow rocking curve, and are comparable with the ZnO films grown on the GaAs substrates. I would like to acknowledge support from the Office of Naval Research under grant N00014-06-1-1018.

CdTe films grown on Si, GaAs and Quartz substrates. Z.X. MA, KIN MAN YU, LBNL, LEI LIU, UCB, LAN WANG, DALE PERRY, WADEK WALKIEWICZ, LBNL, PETER YU, UC, LBNL, SAM MAO, LBNL — CdTe films of varying thickness were grown by the laser epitaxy technique on Si(001), GaAs(001), and quartz substrates. The quality of the resultant films was studied by x-ray diffraction and photoreflectance. Splitting of the valence band plus an increase in the band-gap were observed as the CdTe film thickness was decreased. To explain the observed band-gap narrowing, we would like to acknowledge support from the Office of Naval Research under grant N00014-06-1-1018.

Electrochemical capacitors and charge relaxation resistance of mesoscopic capacitors. FUMING XU, JIAN WANG, Department of Physics and the Center of Theoretical and Computational Physics, The University of Hong Kong, Hong Kong, China — We investigate numerically the transport properties of a mesoscopic capacitor which consists of a quantum dot connected via a single lead to an electron reservoir. The fluctuations and distributions of electrochemical capacitance C_q and charge relaxation resistance R_q have been studied. It shows that the distribution of electrochemical capacitance C_q at one conducting channel case in our numerical calculation is different from the former theoretical prediction obtained from the scattering matrix theory. The difference is due to the existence of neutral states which has been observed in a recent optical experiment.

Porous Silicon Structures under action microwave Radiation: Charge Carrier Heating Effects. EVGENIJUS SHATKOVSKIS, JONAS GRADASAKAS, ANTANAS CESNYS, Vilnius Gediminas Technical University — Porous silicon (por-Si) is one of modern nanomaterials, which is intensively investigated recently. The action of microwave radiation is only slightly investigated on por-Si. However, basically there are papers based on application of por-Si as substrates in microwave and opto-electronic interconnects. Action microwave radiation (MW) often manifests itself through effects of charge carrier heating in semiconductors. Since the energy quanta of MW radiation are too small to challenge any quantum jumps in common semiconductors, it is likely that carrier heating can be responsible for effects arising in por-Si under MW radiation also. This question is of interest for different contributions including information storage of electrical conductivity and electroactive force (emf) in por-Si structures under the action of 10 GHz frequency MW radiation pulses. Two-terminal por-Si containing structures were made by usual technology of electrochemical etching of p-type, 0, 4 Omh cm Si plates in the HF: Ethanol=1.2 electrolyte. It has been shown that experimentally observed decrease of the resistance of the samples and rise of emf can be explained both assuming concept of hole heating, by MW radiation in fractal-like percolation grid of por-Si structure.

Magnetization of Dirac electrons in Bismuth in the quantum limit. LU LI, JOSEPH CHECK-ELSKY, Department of Physics, Princeton University, Y. HOR, R. J. CAVA, Department of Chemistry, Princeton University, C. UHER, Department of Physics, University of Michigan, NAI PHUAN ONG, Department of Physics, Princeton University — In the semimetal Bi, the Fermi Surface (FS) is comprised of 3 Dirac-like electron pockets and a hole pocket. Accurate measurements of the magnetization M in Bi were previously limited to fields B < 2 T. Following the recent report of fractional filling in Bi by Behnia et al. (Science, 2007), we have performed extensive torque magnetization measurements in fields up to 33 T, in the geometry with H at angle θ to Z (trigonal axis). At small θ, we observe a set of quantum oscillations reflecting interference between hole and electron pockets. The pattern is highly sensitive to θ. We have mapped out the variation of the periods vs. θ and H in the quantum limit (m = 1 at 9 T), and beyond. We also observe oscillations above 9 T, which correspond to fractional filling ν = 2/3 and ν = 2/5. Other anomalous features at high fields will also be reported. Resarch supported by PCCM Institute, Princeton University.
K1.00171 Variational entropy and kinetics of hot electrons\(^1\). L. MEZA-MONTES, S. BALEON, J. L. CARRILLO, Instituto de Física B. Universidad Autónoma de Puebla, Apdo. Postal J-48, Puebla, C. P. 72570, Mexico — The carrier distribution function and the effective temperature of an electronic population, optically generated in a semiconductor, are obtained by means of a variational method. An expression for the rate of entropy increment during the cooling process of the plasma is derived. We apply this expression to study the transduction processes in quantum ratchets based on resonant tunneling systems. Additionally, the relation of this rate of entropy increment to a restricted formulation of a quantum H theorem is explored.

\(^1\)Partially supported by CONACyT and VIEP-BUAP.

K1.00172 Phase switching in a voltage-biased Aharonov-Bohm interferometer. VADIM PULLER, Department of Physics, Ben-Gurion University of the Negev, Beer Sheva 84105 Israel, YIGAL MEIR, Department of Physics and The Ilse Katz Center, Ben-Gurion University of the Negev, Beer Sheva 84105 Israel — Recent experiment [Sigrist et al., Phys. Rev. Lett. 98, 036805 (2007)] reported switches between 0 and \(\pi\) in the phase of Aharonov-Bohm oscillations of the two-terminal differential conductance through a two-dot ring with increasing voltage bias. Using a simple model, where one of the dots contains multiple interacting levels, these findings are explained as a result of transport through the interferometer being dominated at different biases by quantum dot levels of different “parity” (i.e. the sign of the overlap integral between the dot state and the states in the leads). The redistribution of electron population between different levels with bias leads to the fact that the number of switching events is not necessarily equal to the number of dot levels, in analogy with experiment. For the same reason switching does not always imply that the parity of levels is strictly alternating. Lastly, it is demonstrated that the correlation between the first switching of the phase and the onset of the inelastic cotunneling, as well as the sharp (rather than gradual) change of phase when switching occurs, give reasons to think that the present interpretation of the experiment is preferable to the one based on electrostatic AB effect.

K1.00173 Study of the 2DEG in InGaAs/AlInAs heterostructures by persistent photoconductivity effect. YU-CHI HSU, C.H. HSIEH, M.H. GAU, Y.L. CHEN, W.T. CHIU, C.C. YANG, J.Y. SU, IKAI LO, Department of Physics, Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China, J.K. TSAI, Center for general education, National Formosa University, Yunlin, Taiwan, Republic of China, F.S. CHAO, Department of computer Science and Electrical Engineering, Univ. of Maryland, Baltimore, MD20742, USA — The electronic properties of the two-dimensional electron gas (2DEG) in InGaAs/AlInAs heterostructures have been studied by Shubnikov-de Haas measurement at 0.3 K. After illuminating at 0.3 K, the carrier density of the sample increased from 2.3 \(10^{12}\) cm\(^{-2}\) to 2.5 \(10^{12}\) cm\(^{-2}\) and the mobility decreased slightly from 36200 cm\(^2\)/Vs to 34000 cm\(^2\)/Vs. In order to study the effect of the channel width on the 2DEG, we made the nanometer-scaled 2DEG channels were varied with different widths of 100 nm to 500 nm. The Sdh measurement was performed on these wires for the magnetic field up to 12 T at 0.3 K. We observed the persistent photoconductivity effect on these wires and the electronic properties of these wires are under investigation.

K1.00174 Magnetotransport study on the nanometer-scaled wires made of Al\(_{1-x}\)Ga\(_x\)N/GaN heterostructures. WEN-YUAN PANG, IKAI LO, YU-CHI HSU, YEN-LIANG CHEN, MING-HONG GAU, W.S. LIN, C.H. CHEN, J.C. CHIANG, Department of physics, National Sun Yat-sen University, Kaohsiung, Taiwan, Republic of China, JEN-KAI TSAI, Center for General Education, National Formosa University, Yunlin, Taiwan, Republic of China — The electronic characteristics of nano-wires made of high-mobility Al\(_{1-x}\)Ga\(_x\)N/GaN heterostructures have been studied. The Al\(_{1-x}\)Ga\(_x\)N/GaN samples were grown on GaN-template buffer layer by plasma-assisted molecular beam epitaxy. We obtained the mobility and carrier density of two-dimensional electron gas to be 9328 cm\(^2\)/Vs and 7.91x10\(^{12}\) cm\(^{-2}\) by conventional van der pauw Hall measurement at temperature of 300 K, respectively. We prepared the samples of field-effect-transistors and reduced the width of the conducting channel from 1\(\mu\)m to 100 nm by Focus Ion Beam. The Shubnikov-de Haas oscillations were observed by magneto-resistance measurement at 0.3 K and the electronic properties for the samples of different channel widths were under investigation.

K1.00175 Transport characterization in silicon nanowires\(^3\). DIDIER STIEVENARD, IEMN - Dpt ISEN, FRANCOIS VAURETTE, BRUNO GRANDIDIER, IEMN-Dpt ISEN, DOMINIQUE DEREMES, IEMN-DptISEN, JEAN-PHILIPPE NYS, IEMN-Dpt ISEN — In spite of the great technological interest associated with nanowires, there are only few direct electrical measurements of both the doping level and of the density of surface state. Moreover, the effect of the phonon surface scattering is not well known. We have studied the transport in silicon nanowires, fabricated using e-beam lithography and RIE etching on SOI substrate (thickness of silicon : 20 nm and P-type intentionally doped at 10\(^{18}\)cm\(^{-3}\)). The nanowire widths varies from 100 nm down to 10 nm. We can extract the intrinsic resistance of the nanowires, excluding the contacts resistances. We found resistances superior to theoretical resistances. We explain these higher resistances by surface defects on nanowires naturally oxidized and we are able to determine the depletion width due to surface defects, and to deduce the doping level and the density of surface states. We found a reasonable value of 1.10\(^{13}\) to 2.10\(^{13}\) defects/cm\(^2\), associated with a doping value of 5.10\(^{19}\) to 9.10\(^{19}\) cm\(^{-3}\). Studies of the transport in the range 80 to 300 K demonstrate that the resistance of the nanowires is mainly bound to phonon scattering localized on the surface (bulk contribution is negligible).

\(^3\)We would like to thank Jacques Gautier (CEA Grenoble) for the SOI substrates.

K1.00176 Study of the Mott-insulator TiOCl under pressure and doping. YUZHONG ZHANG, ROSER VALENTI, HARALD JESCHKE, Johann Wolfgang Goethe-Universität, Institut für Theoretische Physik, S. GLAWION, M. SCHLACHTER, K. GOß, M. SCHOLZ, M. SING, R. CLAESSEN, Experimentelle Physik 4, Am Hubland, University of Würzburg, D-97074 Würzburg, Germany — We discuss recent experiments of the Mott-insulator TiOCl under pressure and Na doping in the frame of Density Functional Theory (DFT) calculations where we employ Car-Parrinello molecular dynamics with Projected Augmented Wave (PAW) wavefunctions. For TiOCl under pressure a phase transition from insulator to metal is found as observed experimentally. For the doped system we have considered supercells of Na doped TiOCl and we propose possible effective models for the mechanism of doping.

K1.00177 Quantum Optics with Colloidal Nanocrystals in Solution. DAVID BUSSIAN, LANL, ANTON MALKO, University of Texas at Dallas, YONGFEN CHEN, JENNIFER HOLLINGSWORTH, HAN HTOON, VICTOR KLIMOV, LANL — Semiconductor nanocrystal quantum dots (NQDs) have been increasingly utilized in developing technologies such as lasers, light-emitting diodes, and bioimaging. Despite gaining popularity as labeling sources in bioimaging, no reliable method has been developed to characterize and identify single nanoparticles in solution, a requirement for efficient labeling at single-cell/single-NQD level. Here we present our recent results addressing the aggregation problem by combining FCS with photon pair correlation spectroscopy (PPCS). The combination of these two methods together with necessary theoretical treatment allows us to quantify, for the first time, the clustering degree of different nanocrystals in solution. The extent of aggregation in a sample can be straightforwardly determined by the deviation of occupation number between PPCS and FCS measurements. CdSe nanocrystals dispersed in organic solvents such as toluene or hexane have minimal clustering, usually less than 1.1 NQD/cluster and do not show considerable aggregation over time. To the contrary, commercially available water-soluble CdSe NQDs that are typically used for cell labeling show a tendency toward aggregation into small, 2-3 NQD clusters. In addition, the clustering degree of such dots increases over time rendering their use in single-dot labeling problematic.
K1.00178 Energy level shift due to the co-evaporated LiF in Alq3. KINWAN PARK, HUANGJUN DING, YONGLI GAO, FRANKY SO — Recently, one of us (FS) observed strong improvement in conductivity of LiF-doped tris (8-hydroxyquinoline) aluminum (Alq3). We have investigated the p-n doping of the organic material. The doping induces energy level shift in frontier orbitals for about 0.25 eV when the doping ratio by weight is 10%. Small amount of metal deposition (0.5 % of Al, Au) on LiF-doped Alq3 causes further shift, with Al the most (∼1 eV) and Au the least (0.3 eV). Further metal depositions reverse the shift for about 0.5 eV. These results suggest that the metal induced enhancement of n-doping in LiF-Alq3 contributes to the improvement in conductivity. After 1 to 2 Å, the properties of metals show up and the Energy levels converge.

K1.00179 Discontinuity of the dielectric function at Bragg reflexes. R. HAMBACH, C. GIORGETTI, F. SOTTILE, L. REINING, LSI, CEA-CNRS UMR 7642-Ecole Polytechnique, France and ETSF France. N. HIRAOKA, Y.Q. CAI, National Synchrotron Radiation Research Center, Hsinchu 30076, Taiwan. A.G. MARINOPoulos, Department of Physics and Astronomy, Vanderbilt University, Nashville, USA. F. BECHSTEEDT, IFTQ, Friedrich-Schiller Universitaet Jena, Germany. — As an example for layered materials, the loss function of graphite was studied for momentum transfers q beyond the first Brillouin zone. Surprisingly, near Bragg reflexes, the spectra are highly dependent on very small changes in q, which reminds the non-analyticity of the loss function in the optical limit (q → 0). The effect is investigated by means of first principle calculations within the random phase approximation (RPA) and is confirmed by inelastic x-ray spectroscopy (IXS) measurements. We find crystal local field effects to be crucial and propose a simple 2 × 2 model dielectric function for explanation.

K1.00180 Excitonic effects in optical absorption spectrum of CdSe/ZnSe core-shell Nanostuctures. KALUM PALANDAGE, GAYANATH FERNANDO, RAMPRI RAMPRASAD, University of Connecticut. JAMES DAVENPORT, Brookhaven National Lab — We have used a first principles, TDDFT method to study CdS (Type I) nanocrystal quantum dots and CdZnS core/shell (Type II) heteronanostructures with high accuracy. We have studied the existence of excitons and multi-excitons and the possibility of optical gain in these nanoclusters. The size dependence of the HOMO-LUMO gap, the electron-hole wave function overlap in the relevant states, coordination of atoms at the surface as well as the stability of such clusters will be presented in some detail.

K1.00181 Stark Shifts in the Mid-Infrared Absorption Edge of Type II Quantum Wells. JOHN LITTLE, KIMBERLEY OLIVER, WENDY SARNEY, STEFAN SVENSSON, Army Research Laboratory. FRED TOWNER, Maxion Technologies, QUANTUM DEVICES TEAM, MAXION TEAM — We have studied electric field induced (Stark) shifts in real-space indirect-mid-infrared transitions that occur in type II AIAs/InAs/GaSb quantum wells. Because of the spatial separation of the electron and hole wavefunctions, the potential drop between the layers dominates the shift in the absorption edge, and can result in either a red shift or a blue shift, depending on the ordering of the quantum wells within the intrinsic region of a p-n diode. Of particular interest is the case in which a reverse bias on the diode yields a blue shift in the absorption edge since this field tends to increase the overlap between the electron and hole wavefunctions, increasing the absorption strength. We will give the results of low temperature photocurrent spectroscopy on a series of samples with different layer ordering, degrees of confinement, and coupling between the wells.

K1.00182 Reflectance anisotropy spectroscopy of II-VI semiconductor surfaces. R. A. VAZQUEZ-NAVA, N. ARZATE, B. S. MENDOZA, Centro de Investigaciones en Optica — The spectroscopical reflectance anisotropy (RA) response of II-VI semiconductor surfaces, which exhibits different reconstructions are studied. We use, an ab initio pseudopotential calculation in the framework of the density functional theory and within the local density approximation (DFT-LDA) to obtain the relaxed atomic positions, and then we use a microscopic formulation based on a semi-empirical tight binding (SETB) approach which includes spin-orbit (SO) interactions[1] to obtain the RA spectra. We show RA spectrum of each surface reconstruction and compare our theoretical results with experimental. We find a good agreement between experimental and theoretical spectra.[1] R.A. Vázquez-Nava, B.S. Mendoza and C. Castillo, Phys. Rev. B 70, 165306 (2004).

K1.00183 Ultrafast nonlinear spectroscopy characterization of CdSe quantum dots. QIGUANG XU, SHENGMIN MA, BACHER TABIBI, JAETAE SEO, Hampton University. WILLIAM YU, Worcester Polytechnic Institute. HAMPTON UNIVERSITY COLLABORATION, WORCESTER POLYTECHNIC INSTITUTE COLLABORATION — Frequency degenerate and nondegenerate two-photon absorption spectra of direct band gap semiconductor quantum dot samples, such as CdSe and CdTe, have attracted great attention recently because of their potential applications in nonlinear photonic devices. In this work, we used the femtosecond time-resolved photon echo technique to characterize the third-order nonlinear optical properties of CdSe quantum dots in toluene. The quantum dots had an average size of about 3 nm and the lowest absorption peak at 559 nm. A femtosecond laser with 150 fs pulsewidth and 1 kHz repetition rate was used for the measurement. The copolarization hyperpolarizability at 775 nm was found to be about 1 x 10^-14 m^2/V^2 and the dephase time was shorter than the resolution limitation of our system at room temperature. This work at Hampton University was supported by Army Research Office (W911NF-07-1-0608) and National Science Foundation (HRD-074635, HRD-0630372, ESI-0426328/002, and EEC-0532472).

K1.00184 Direct bandgap of group IV semiconductors by uni-axial stress. FENG ZHANG, Department of Physics, Penn State University. PEIHONG ZHANG, Department of Physics, SUNY at Buffalo. VINCENT CRESPI — We theoretically examine the possibility of converting typical group IV semiconductors Si, SiGe (zinc blende), and Ge into direct bandgap materials by uniaxial stress along the (111)> and (100) directions. For silicon, the required tensile strain is too large to be practical. For SiGe and Ge along [111], the conduction band splitting at the L point lowers the required longitudinal strain along [111] to 7%. For SiGe, the required strain along [111] is 3% and 4% for GeSi and Ge, respectively. For Ge along [100], the position of the conduction band edge at the Γ point varies sub-linearly with strain; therefore strain along [100] is less efficient: GeSi is unlikely to achieve a direct gap by extension along [100] and Ge requires a 6% longitudinal strain. The full dependence of the indirect/direct transition on arbitrary combinations of uniaxial/hydrostatic tensile strain is given for both GeSi and Ge.

K1.00185 Quasi-particle spectra of various forms of crystalline Germanium Telluride. JINWOO KIM, Department of Physics, Pohang University of Science and Technology. GEUNSIK LEE, Department of Physics, University of Texas at Dallas. SEUNGHOO JHI, Department of Physics, Pohang University of Science and Technology — GeTe is known to undergo a very complex structural phase transition under pressure. Also it changes the phase upon heating from crystalline NaCl structure to amorphous phase. Several models were suggested for possible structural transition pathways such as Toledano, Modified Buerger and Watanabe model. We have investigated the dielectric function of GeTe at representative structural phases using the pseudopotential density functional method within the generalized gradient approximation. To calculate the quasiparticle spectra, we carried out the GW calculations. Semicore d-electrons of Te are found to be very critical for calculating correct transition pressures, and they are included explicitly as valence. These electrons affect the electronic structures through the p-d coupling, which is found non-negligible. Our results can help analyze experimental data and investigate the transition pathway of GeTe.
K1.00186 Spectroscopic characterization of Europium and Praseodymium doped Gallium Nitride powders. E. I. BROWN, OLUSOLA OYEBOOLA, UWE HOMMERICH, Hampton University, TAKAHIRO YAMADA, HIROSHI NABU, HISANORI YAMANE. Tohoku University, KENJI KOHIRO, YOSHIKO TSUCHIDA, Tsukuba Research Laboratory, JOHN ZAVADA, US Army Research Office — Rare earth (RE) doped GaN continues to be of interest for applications in display technology, solid-state light sources, and optical communications. Recently, RE doped GaN powders have been prepared using different methods including flux techniques and combustion synthesis. In this work, we report on the luminescent properties of Eu$^{3+}$ and Pr$^{3+}$ doped GaN powder prepared by a Na flux method for potential applications in light source development. Under above-gap pumping, GaN:Eu and GaN:Pr powders exhibited intense red emissions at $\sim$621 nm and $\sim$652 nm, which corresponds to the intra-4f RE$^{3+}$ transitions $^7$D$_0$ $\rightarrow$ $^7$F$_2$ and $^3$P$_0$ $\rightarrow$ $^3$F$_2$ states, respectively. A temperature dependent study of the red emission showed that the integrated PL intensity is quenched at room-temperature by $\sim$30% and $\sim$50% for Pr:GaN and Eu:GaN, respectively. More results of temperature dependent and time-resolved emission spectroscopy of Eu and Pr doped GaN powders will be presented at the conference.

K1.00187 Electronic structure and conduction-band mass of InN under pressure. NIELS E. CHRIS- TENSEN, Dept. of Physics and Astronomy, University of Aarhus, DK-8000 Aarhus, Denmark, IZA GORCZYCA, Inst. of High Pressure Physics, Polish Academy of Sciences, Warsaw, AXEL SVANE, Dept. of Physics and Astronomy, University of Aarhus, DK-8000 Aarhus C, Denmark — An initio calculations for n-type InN of the band structure and effective masses (optical- and curvature-) in the lowest conduction band as functions of applied pressure and varying electron concentration are presented. The calculations as well available experimental data demonstrate the strong non-parabolicity of the InN conduction band.

K1.00188 Temperature dependence of the InGaPN conduction band structure. K. L. LIN, T. S. WANG, J. S. HWANG — Material properties of III-N-V alloys, such as GaAsN, InGaAsN, and InGaPN, have been intensively studied, because a small amount of nitrogen (N) incorporation results in very large bandgap bowing and dramatic change in the band structure.1,2 Recently, temperature dependence of the parameters, i.e. the localized states energy $E_N$ introduced by an isolated N and the interaction potential $V$, of the band anticrossing (BAC) model in GaAsN epilayers has been reported.3 These properties have never been studied for InGaPN. In this work, temperature-dependent photoreflectance (PR) measurements are employed to characterize the conduction band structure of In$_{0.54}$Ga$_{0.46}$P$_1-y$N$_y$ ($y = 0$ and 0.02) grown on GaAs substrates. The band gap and the upper subband $E_+$ are observed in InGaPN as predicted by the BAC model. To investigate the energetic positions of the features in the PR spectra, a Kramers-Kronig analysis is proposed. Based on these PR data and the BAC model, we find $E_N$ = 2.054 eV and $V = 1.513$ eV at 293 K. With decreasing temperature, the energy of $E_N$ shifts significantly to higher energies. Simultaneously, the interaction potential $V$ between the N states and the host conduction band also rises to higher values. The thermal shifts of $E_N$ and $V$ are $dE_N/dT \approx -0.43$ meV/K and $dV/dT \approx -0.67$ meV/K, respectively. 1. APL 88, 031907 (2006). 2. APL 89, 192116 (2006). 3. APL 89, 202105 (2006).

K1.00189 Electron pairing in small Hubbard Clusters. KALUM PALANDAGE, GAYANATH FERNANDO, University of Connecticut, ARMEN KOCHARIAN, California State University, JAMES DAVENPORT, Brookhaven National Lab — Exact thermal studies of 4-site Hubbard Nanoclusters are carried out using the analytical eigenvalues. Electron pairing is seen when the on-site Coulomb interaction is smaller than a critical value Uc(T) in the repulsive Hubbard clusters which also show spin pairing at a lower temperature. Specific heat and probability calculations provide strong support for the existence of competing (paired and unpaired) phases near optimal doping. Attractive 4-site Hubbard model can be mapped on to the repulsive model and these studies can be used to understand ferroelectricity in certain metal clusters.

K1.00190 Dipole model for Non linear response of adsorbed overlayers1. R. A. VAQUEZ-NAVA, N. ARZATE, Centro de Investigaciones en Optica, J. E. MEJIA, Centro Universitario de los Lagos, U de G. Mexico, W. L. MOCHAN, Instituto de Ciencias Fisicas, UNAM, Mexico — We present theoretical calculations of second harmonic generation (SHG) from overlayers of alkali atoms adsorbed on a crystalline metallic surface. We assume that the overlay is formed by an ordered two-dimensional (2D) array of adatoms that respond to the local electric field like point-like harmonic oscillators. We consider overlayers with several rational coverages, assuming that the adsorbates occupy high symmetry sites which form a Bravais lattice that is commensurate with the substrate [1,2]. SHG spectra are obtained for the five 2D Bravais lattices. We found that SHG can be used to observe ordered phases when the ordered phase has a rectangular, centered-rectangular or oblique symmetry. [1] H. Arce, W. L. Mochan and G. Cocho, Surf. Sci. 294, 108 (1993). [2] H. Arce and W. L. Mochan, J. Phys.: Condens. Matter 5, A101 (1993).

K1.00191 Magneto-exciton transitions in laterally coupled quantum dots1. ZDENKA BARTEVIC, MONICA PACHECO, Depto. de Fisica, Universidad Tecnica Federico Santa Maria, CARLOS A. DUQUE, Instituto de Fisica, Universidad de Antioquia, LUIZ E. OLIVEIRA, Instituto de Fisica, Universidade Estadual de Campinas - UNICAMP — We present a study of the electronic and optical properties of laterally coupled quantum dots. The excitonic spectra of this system under the effects of an external magnetic field applied perpendicular to the plane of the dots is obtained, with the potential of every individual dot taken as the superposition of a quantum well potential along the axial direction with a lateral parabolic confinement potential, and the coupled two- dot system then modeled by a superposition of the potentials of each dot, with their minima at different positions and truncated at the intersection plane. The wave functions and eigenvalues are obtained in the effective-mass approximation by using an extended variational approach in which the magneto- exciton states are simultaneously obtained [1]. The allowed magneto-exciton transitions are investigated by using circularly polarized radiation in the plane perpendicular to the magnetic field. We present results on the excitonic absorption coefficient as a function of the photon energy for different geometric quantum-dot confinement and magnetic-field values. Reference: [1] Z. Barticic, M. Pacheco, C. A. Duque and L. E. Oliveira, Phys. Rev. B 68, 073132 (2003).

K1.00192 Anisotropy of plasmon spectrum due to joint Rashba and Dresselhaus spin-orbit interaction1. SAMVEL BADALYAN, Department of Radiophysics, Yerevan State University, 375025 Armenia and Department of Physics, University of Regensburg, 93040 Regensburg, Germany, ALEX MATOS-ABIAGUE, Department of Physics, University of Regensburg, 93040 Regensburg, Germany, GIOVANNI VIGNALE, Department of Physics and Astronomy, University of Missouri - Columbia, Missouri 65211, USA, JOARSLAV FABIAN, Department of Physics, University of Regensburg, 93040 Regensburg, Germany — We have investigated the combined effect of Rashba and Dresselhaus spin-orbit interaction (SOI) on the many-body polarization function of a two-dimensional electron system (2DES). The dielectric function of a 2DES is calculated within the random phase approximation and the plasmon energy spectrum as a function of the momentum magnitude for its different orientations is obtained. Our calculations show the peaked behavior of dynamical structure factor as a function of the polar angle of momentum. This strong peak corresponds to the plasmon, which is damped due to SOI. Thus, we have clearly demonstrated that due to the anisotropy of the spin-orbit interaction, the plasmons with the definite values of energy and momentum can be excited only in the certain direction.

K1.00193 A STM study on temperature-dependent adsorption of H₂O on Si(001)  
SANG-YONG YU, HANCHUL KIM, JA-YONG KOO, KRIS, KRIS TEAM — We studied the temperature dependence of water molecule adsorption on the Si(001)-2×1 surface by using Scanning Tunneling Microscopy. The water molecules are known to dissociate during the adsorption on Si(001) and form Si-H and Si-OH bonds. Recently, we demonstrated that they are two adsorption configurations: ID (inter-dimer) and OD (on-dimer). These two configurations show population ratio of n(ID)/n(OD) ~ 5 at Room Temperature. In order to understand the adsorption kinetics more thoroughly, we have measured n(ID)/n(OD) by varying the sample temperature from 300K to 870K. It is found that n(ID)/n(OD) show strong temperature dependence, and it even becomes smaller than 1. The cross-over temperature is at around 470K.

K1.00194 Phase Transition Plasticity Response in Uniaxially Compressed Silicon Nanospheres  
TRAIAN DUMITRICA, PAOLO VALENTINI, Department of Mechanical Engineering, University of Minnesota, WILLIAM W. GERBERICH, Department of Chemical Engineering and Materials Science, University of Minnesota — We present a microscopic description for the response of crystalline Si nanospheres up to 10 nm in radius for various uniaxial compression levels. The behavior at low compressions closely resembles the Hertzian predictions. At higher compressions the creation of a new beta-tin phase in the particle core leads to (i) volumetric changes (ii) an increase in elastic moduli, and (iii) significant hardening. Further, (iv) a reversible character of the transformation is obtained with molecular dynamics simulations. The agreement of (i)-(iv) with recent experimental findings [1] challenges the current exclusive view of a dislocation plasticity response in somewhat larger nanoparticles. The phase transition path should dominate in ultrasmall structures, where dislocation activity is prohibited. [1] W. W. Gerberich et al., J. Mech. Phys. Sol. 51, 979 (2003).

K1.00195 Friction measurements on InAs NWs by AFM manipulation  
HAKAN PETTERSSON, Halmstad University, Halmstad, Sweden, GABRIELA CONACHE, Halmstad University, Halmstad, Sweden, STRUAN GRAY, Lund University, Lund, Sweden, MICHAEL BORDAG, Leipzig University, Leipzig, Germany, ALINE RIBAYROL, LINUS FROBERG, LARS SAMUELSON, LARS MONTELIUS, Lund University, Lund, Sweden — We discuss a new approach to measure the friction force between elastically deformed nanowires and a surface. The wires are bent, using an AFM, into an equilibrium shape determined by elastic restoring forces within the wire and friction between the wire and the surface. From measurements of the radius of curvature of the bent wires, elasticity theory allows the friction force per unit length to be calculated. We have studied friction properties of InAs nanowires deposited on SiO₂, silanized SiO₂ and Si₃N₄ substrates. The wires were typically from 0.5 to a few microns long, with diameters varying between 20 and 80 nm. Manipulation is done in a ‘Retrace Lift’ mode, where feedback is turned off for the reverse scan and the tip follows a nominal path. The effective manipulation force during the reverse scan can be changed by varying an offset in the height of the tip over the surface. We will report on interesting static- and sliding friction experiments with nanowires on the different substrates, including how the friction force per unit length varies with the diameter of the wires.

K1.00196 First-Principles Theoretical Analysis of Dopant Diffusion on Surfaces of II-VI Compound Semiconductor Nanocrystals  
TEJINDER SINGH, T.J. MOUNTZIARIS, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — We present a detailed analysis of diffusion of dopants (e.g., Mn, Cu) on surfaces of ZnSe nanocrystals and discuss its implications for dopant incorporation into the growing nanocrystals. We focus on nanocrystals with diameters d ~ 5 nm that have polyhedral shapes with well-defined facets. Using first-principles density functional theory calculations, we have studied the dopant diffusion and adsorption mechanisms and obtained the energetics of various possible dopant diffusion pathways. ZnSe(001)-2×1 is found to be the energetically favorable surface for dopant binding, with multiple adsorption sites. Our results indicate that dopant atoms can migrate with low activation barriers along the Se dimer rows without substantial surface relaxation. Diffusion across the dimer rows is governed by a higher-barrier pathway, which can lead to dopant incorporation into the nanocrystal through strong bonding with the nanocrystal surface at the corresponding adsorption site in the trough between adjacent dimer rows.

K1.00197 Structural defects in SiC nanowires  
RENBING WU, FENG LIU, Department of Materials Science and Engineering, Zhejiang University — High-resolution transmission electron microscopy (HRTEM) and selected area electron diffraction (SAED) are used to investigate structural defects in zinc blende SiC nanowires produced by a vapor-solid (VS) mechanism. It is found that the defects exist as the stacking faults and twins including single twin, double twins, and quasiperiodic placement twins. The results indicate that the important role of defects in determining the morphologies and structures i.e. stacking faults result in formation of branches or junctions, while twins cause kinks, bamboo or a zigzag appearance. Based on the characterizations, the defects formation mechanism and the influence on the nanowire growth kinetics and behavior are also discussed.

K1.00198 Nonlinear modification of tunneling and conductivity in two-dimensional electron gas–impurity system in strong high-frequency electric fields  
DMITRY SOLENOV, VLADIMIR PRIVMAN, Department of Physics, Clarkson University, Potsdam, New York 13699-5820 — We investigate two-dimensional electron gas system coupled to adjacent impurity sites. When a high-frequency uniform electric field is applied perpendicular to the electron gas layer it significantly modifies electron correlations in the impurity–gas system. At strong magnitudes of external field the system enters nonlinear dynamical control regime, similar to double quantum dot structures. In contrast to the latter, coulomb activation of the impurity sites introduces strong scattering for conduction electrons that leads to nontrivial renormalization of the tunneling. Modification of tunneling rates as a function of the field amplitude is calculated. We show that for low enough temperatures this effect is manifested in nonlinear modification of tunneling and conductivity in two-dimensional electron gas–impurity system in strong high-frequency electric fields.

K1.00199 Influence of inactivated dopants clusters and post annealing on electrical and optical properties of indium tin oxide on plastic substrates  
TERRY ALFORD, HAUK HAN, School of Materials and Flexible Display Center at Arizona State University, JAY LEWIS, Center for Materials and Electronic Technologies, RTI International — Indium tin oxide (ITO) films have been introduced as a transparent electrode for large area electronics such like display and photovoltaics due to their high electrical conductivity coupled with high transmission. This study describes the influence of Sn defect clusters on the electrical and optical properties of the ITO films. Absorption coefficient analysis indicates that electrically inactive Sn clusters generate defect states within the band gap and strongly affect the electrical and optical properties of the ITO films. Electrical and optical properties of ITO films are enhanced by reduction of Sn defect clusters with activation of Sn dopants, upon heat treatment. To explain the enhanced carrier transport property, we propose the reaction model based on our Rutherford backscattering spectrometry (RBS), Hall measurement, and x-ray photoelectron spectroscopy (XPS) data. The proposed model describes Sn⁴⁺ ions forming a neutral defect complex with Sn⁵⁺ ions which may not contribute to electrical conductivity in the amorphous phase. These Sn defect clusters in the amorphous phase dissociate and could contribute to an increase in Sn⁴⁺ concentration in ITO films without changing oxygen contents.
**K1.00200** Hole mobility in Copper-doped CdTe films. Z.X. MA, KIN MAN YU, LBNL, LEI LIU, LBNL, UCB, LAN WANG, DALE PERRY, WALDEK WALUKIEWICZ, LBNL, PETER YU, UCB, LBNL, SAM MAO, LBNL — Copper-doped CdTe films have been grown by the laser epaaxy technique. X-ray diffraction, Rutherford backscattering, and photoflectance spectroscopy were utilized to characterize the CdTe/Cu films. Structural analysis suggests that the growth of CdTe/Cu on GaAs(100) is initiated along the (100) orientation, but changes to the (111) direction after the film thickness exceeds 400 nm. Hall effect measurements indicate that copper doping can achieve hole mobility over 150 cm²/Vs at room temperature. Changes in the hole effective mass and phonon spectra have been calculated to explain the enhanced hole mobility in Cu:CdTe.

1Supported by the U.S. Department of Energy, NNSS/NA-22, under contract No. DE-AC02-05CH11231.

**K1.00201** An experimental study on $\Gamma(2)$ modular symmetry in the quantum Hall system with a small spin-splitting, C.F. HUANG, CMS/ITRI, Y.H. CHANG, Dept. of Physics, NTU, H.H. CHENG, Z.P. YANG, Center for Condensed Matter Sciences, NTU, H.D. YEH, CMS/ITRI, C.H. HSU, C.-T. LIANG, Dept. of Physics, NTU, D.R. HANG, Dept. of Materials Science and Optoelectronic Engr., Natl. Sun Yat-sen Univ., H.H. LIN, Dept. of Elec. Engr., NTU — Magnetic-field-induced phase transitions are investigated by performing transport measurements on the two-dimensional (2D) electron system in an AlGaAs/GaAs heterostructure at low temperatures. [1] Both the semicircle law and universal two-parameter scaling are observed as the spin-splitting becomes resolved with increasing the magnetic field $B$ perpendicular to such a 2D system. The critical resistivities, however, are not of the expected universal values, and the modular symmetry is reduced from $\Gamma_0(2)$ to $\Gamma(2)$. On the other hand, $\Gamma_1(2)$ symmetry survives at lower $B$ where the spin-splitting is unresolved. Therefore, the reduction of the modular symmetry can be due to the resolved small spin-splitting as predicted by Dolan [2]. Such a small splitting not only reduces the modular symmetry, but also breaks the scaling on the longitudinal conductivity $\sigma_{xx}$ at higher temperatures. It is found that the scaling on the Hall conductivity $\sigma_{xy}$ is more robust than that on $\sigma_{xx}$ under a small spin gap. References [1] C. F. Huang, Y. H. Chang, H. H. Cheng, Z. P. Yang, H. D. Yeh, C. H. Hsu, C.-T. Liang, H. H. Lin, D. R. Hang, and H. H. Lin, J. Phys. Condens. Matt. 19, 026205 (2007).

**K1.00202** Probing insulator-quantum Hall transitions near the onset of Landau quantization in GaAs/AlGaAs heterostructures, KUANG YAO CHEN, National Taiwan University, Y.H. CHANG, C.-T. LIANG, National Taiwan University, N. AOKI, Y. OCHIAI, Chiba University, CHUN FENG HUANG, NML/CMS ITRI, LI-HUNG LIN, National Chiao Tung University, K. A. CHENG, Lung-Hwa University of Science and Technology, H.H. CHENG, H.H. LIN, National Taiwan University, JAU-YANG WU, SHENG-DI LIN, National Chiao Tung University — Magneto-transport measurements are performed on the two-dimensional GaAs electron systems (2DESs) to study the low-field insulator (I) and quantum Hall (QH) effect. With increasing the perpendicular magnetic field $B$, the 2DESs undergo direct I-QH transitions to enter QH liquids from the low-field insulators.

**K1.00203** Single-valley (110) and double-valley (001) AlAs quantum wells, DASGUPTA, A. FONTCUBERTA, M. BICHLER, G. ABSTREITER, Walter Schottky Institute, TU Munich, Germany, M. GRAYSON, Walter Schottky Institute, TU Munich, Germany & Dept. of Electrical Engineering and Computer Science, Northwestern University — Doubly-degenerate valley quantum number in (001)AlAs quantum wells (QWs) functions as pseudo-spin degree of freedom for understanding exchange interactions, and single valley anisotropic mass, if observed in high mobility (100)AlAs, could lead to interesting phases in quantum limit. We optimized growth of AlAs QWs [1], and grew (001) oriented double valley degenerate AlAs QW with density $n=2.4 \times 10^{11}$ cm$^{-2}$ and mobility $\mu=4.3 \times 10^2$ cm$^2$/Vs (330 mK), an improvement of almost an order of magnitude over published results. We also grew (110)oriented AlAs QW with $n=4.2 \times 10^{11}$ cm$^{-2}$ and $\mu=5.4 \times 10^4$ cm$^2$/Vs (330 mK). The (110)AlAs QW is predicted to occupy single valley, and anisotropic $\mu$ along two crystallographic directions of (100) & (1-10) may be expected. Experimentally, we observed $\mu$ anisotropy $\mu_{(100)}/\mu_{(1-10)}=1.5$ in dark (1.4 K) and strong odd-filling factor $S$Doh gaps, evidence consistent with single valley occupancy. We studied $\mu$ on both growth facets as function of temperature. The $\mu$ of (110)AlAs QWs is seen to saturates below the Fermi temperature but (001)AlAs QW does not saturate.

**K1.00204** ABSTRACT WITHDRAWN —

**K1.00205** Analysis of spin current shot noise from a quantum dot coupled to a quantized bosonic field, MARKO ZIVKOVIC, IVANA DJURIC, CHRISTOPHER SEARCH, Department of Physics and Engineering Physics, Stevens Institute of Technology, Castle Point on Hudson, Hoboken, NJ 07030 — We examine spin current generated by quantum dots coupled to quantized bosonic field. The dots are connected to normal leads at zero bias voltage across the dot. We model the dot as a two level spin system with one of the spin states lying below the Fermi level of the leads and the other above. Spin flips followed by subsequent tunnelling out into the leads generate a pure spin current in the absence of any charge current. The dot is coupled to a quantized bosonic field that influences the generation of spin current in one of two possible scenarios. First, we consider spin flips induced via Raman transitions in optical microcavity. Secondly, electron spin resonance via classical magnetic field induces spin flips in the presence of a quantized phonon field that modulates the energy levels of the dot. In the limit of strong Coulomb blockade our model is analogous to the Jaynes-Cummings model in quantum optics. In the case of optical cavity mediated spin flips, we show that the spin current is bistable for a coherently driven cavity and this bistability is clearly visible in the spin current shot noise. A comparison of spin current and shot noise for interactions with different bosonic fields is presented.

**K1.00206** Magneto-Dynamics of a Double Quantum Dot System, N.J.M. HORING, D. MIESSEIN, Stevens Inst. of Tech., L.Y. CHEN, University of Texas at San Antonio, QEPT TEAM — We have examined the microscopic dynamics of a double quantum dot system modeled by a potential having two three-dimensional Dirac functions of generally unequal strengths separated in position by $\vec{r}$:

$$V(\vec{r}) = -\alpha_1 \delta^{(3)}(\vec{r} - \vec{d}/2) - \alpha_2 \delta^{(3)}(\vec{r} + \vec{d}/2).$$

While these delta function potentials individually support a single energy level, the introduction of a strong magnetic field gives rise to Landau quantization and a plethora of energy levels. The relative magnitude of $\alpha_1/\alpha_2$ affects the bonding/antibonding character of the states, as well as the multiplicity of levels induced by magnetic quantization.
K1.00207 Magnetotransport Properties of Ferromagnetic Semiconducting Fe1−xCo2Si Alloy Nanowires: Building Blocks for Silicon Based Spintronics, SONG JIN, University of Wisconsin-Madison. Fe1−xCo2Si alloys were recently shown to be concentrated magnetic semiconductors and can be promising materials for spin injection into silicon not only because of its high spin polarization but also because of its CMOS compatibility. By developing a rational approach to synthesizing nanowires using single source precursors, we have realized a host of new transition metal silicide nanowires through chemical vapor deposition/transport. We have synthesized FeSi nanowires using Fe(SiCl3)2(CO)4 and CoSi nanowires using Co(SiCl3)(CO)4. Building on these initial successes, we synthesized magnetic semiconducting Fe1−xCo2Si alloys using mixed precursors. The as synthesized nanowires were characterized using high resolution transmission electron microscopy, energy dispersive X-ray spectroscopy, and X-ray absorption spectroscopy. The bulk Fe1−xCo2Si alloys were recently shown to be concentrated magnetic semiconductors and can be suitable materials for spin injection into silicon because of its CMOS compatibility. The interesting magnetic semiconducting behavior is shown using magnetotransport and X-ray magnetic circular dichroism revealing the interesting chemistry behind the magnetic properties. These novel magnetic semiconducting silicide nanowires are exploited as building blocks for silicon-based spintronic nanodevices.

K1.00208 Adsorption, Symmetry and Magnetic Properties in TM-GaN Nanocrystals, HE YAN DONG, KEMING FU, MING JIANG, Dept. of Physics, Yantai University, P.R. China. — Transition metal(TM)-doped dilute magnetic semiconductor nanocrystals are of interest for potential applications in spintronics due to their tunable properties. The interest of semiconductor nanocrystals depend on their size or shape, we present first-principles calculations for the electronic structure and magnetic properties of completely passivated, H-adSORBED and isolated Mn/Co-doped GaN nanocrystals with different point symmetry. A novel half-metallicity and magnetic metastability has been found. The multiple metastable spin states and spin-flip for metallic channel are demonstrated in these nanocrystals with the various H coverages and point groups symmetry. A detailed electronic structure analysis is given. Our calculated results imply a new type of half-metallic and spin-crossover nanomaterial.

K1.00209 Ab Initio Study of Magnetic Properties of Cr-doped Chalcopyrites: (BeSn, BeGe, MgGe)N2, J. RUFINUS, Widener University, Chester, PA 19013. J. L. DEWINTER, California Polytechnic State University, San Luis Obispo, CA 93407, — A Density Functional Theory within Generalized Gradient Approximation study of three thermodynamically stable Cr-doped (II-IV)-V2 chalcopyrites: (BeSn, BeGe, MgGe)N2 was performed. Since the chalcopyrites are ternary materials, there are possibilities of having ferromagnetic or antiferromagnetic configurations, depending on which metal was substituted by the dopant. The results show both BeSnN2 and BeGeN2 to be ferromagnetic independent of the substitution sites. On the other hand, MgGeN2 was found to be antiferromagnetic for CrAlP (Cr substitutes Mg site) and ferromagnetic for CrGe (Cr substitutes Ge site.)

K1.00210 Electron spin splitting effect in AlSb/InAs/AlSb quantum wells, MINUKIM, TAKAKIKOGA, Faculty of Engineering and Graduate School of Information Science and Technology, JUSST, Research Institute of Electrical Communication, Tohoku Univ., Japan. — We investigated the electron spin splitting effect in AlSb/InAs/AlSb quantum wells (QW) both experimentally and theoretically. Our experiment was performed on MBE grown high quality AlSb/InAs/AlSb QW samples with Mn potential symmetry was controlled by intentional/unintentional dopings near the QW layer, where we didn’t observe the beating pattern in the Shubnikov de Haas (SdH) oscillations experimentally. Although the presence of the beating pattern in the SdH oscillations can be considered as a side-evidence of the zero-field spin splitting in the pertinent 2DEG (two dimensional electron gas), the absence of it does not necessarily support the absence of the zero-field spin splitting. Our theoretical analysis including all the Rashba, Dresselhaus and Zeeman spin-splitting Hamiltonians revealed that the absence of the SdH oscillations itself is not inconsistent with the presence of the zero-field spin splitting in our specific samples. Considering the fact that SdH oscillations itself are not necessarily support the absence of the zero-field spin splitting.

K1.00211 Low-temperature spin dynamics of Mn-rich Mn(Ga)As nanoclusters embedded in a GaAs matrix, WEIZHU WANG, JIAJUN DENG, JUN LU, BAOQUAN SUN, JIANHUA ZHAO, State Key Laboratory for Superlattices and Microstructures, Institute of Semiconductors, Chinese Academy of Sciences — Recently, the composite systems of Mn-rich Mn(Ga)As nanoclusters embedded in GaAs matrices have received an increasing attention due to the large magneto-optical and magneto-resistance effects at room temperature which could be applied to spin-electronic devices. In this work, we report the low-temperature spin dynamic behaviours including memory effects and slow magnetic relaxation of such composite systems. The systems can be formed by in situ postgrowth annealing of (Ga,Mn)As films at 650 °C for 10 min because of spinodal decomposition. High-resolution TEM images show zincblende Mn-rich Mn(Ga)As nanoclusters with a diameter in the range of 10-20 nm embedded in a GaAs matrix. From zero-field cooled and field cooled measurements, we can observe a clear bifurcation of the two curves demonstrating the existence of the spin-glass-like phase below the blocking temperature in the systems with high Mn concentration. Memory effects and slow magnetic relaxation, the typical characteristics of spin-glass-like phases, are also detected, and the hierarchical model is confirmed to be in accordance with such low-temperature behaviours. On the other hand, for samples with low Mn content, ferromagnetic order remains up to 360K.

K1.00212 Proposal of Spin Interference Experiment Using GaAs/AlGaAs Heterostructures, KAZUAKI NISHIO, LI ZHANG, TAKAAKI KOGA, GSIST and CRIS (SOUSEI), Hokkaido University, Sapporo, Japan, and TOSHIYUKI KOBAYASHI, TATSUSHI AKAZAKI, NTT BRL, NTT Corporation, Atsugi, Japan. — We propose a spin interference (SI) experiment [1] using GaAs/AlGaAs system, where the zero-field spin-splitting (Δ0) is caused by the Dresselhaus term predominantly. GaAs/AlGaAs has the advantage in gating stability and long carrier mean free path relative to the other III-V materials, making it a standard semiconductor in mesoscopic physics experiment. It is shown theoretically as well as experimentally that values of Δ0 are generally smaller in GaAs/AlGaAs than in InGaAs/InAlAs. In the present work, however, we suggest that the gate-controllability of spins in GaAs/AlGaAs, Δ0 ≈ Δ0/h, being the relevant parameter, should also be as good as that in InGaAs/InAlAs based on our simulations, which makes the SI experiment possible even with GaAs/AlGaAs. We fabricated a series of quantum nanowires on GaAs/AlGaAs wafers with various wire widths. We discuss their transport properties and the prospective for the future SI experiment. [1] Koga et al., PRB 70, 161302(R) (2004); ibid. 74, 041302(R) (2006)

K1.00213 Electrical spin injection and detection by ballistic transport in MnAs / GaAs : MnAs spin–valve hybrid heterostructures. PHAM NAM HAI, YUSUKE SAKATA, MASAFUMI YOKOYAMA, Dep. of Electronic Eng., The Univ. of Tokyo, SHINOBU OHYA, MASAaki TANAKA, Dep. of Electronic Eng., The Univ. of Tokyo; JST — Electrical spin injection and detection by ballistic transport of spin-polarized carriers in ferromagnet (FM) / semiconductor (SC) / ferromagnet (FM) hybrid structures are key issues in semiconductor-based spintronics. By using ballistic transport of spin-polarized carriers, we can improve the spin injection / detection efficiency without using a high tunnel barrier at the FM/SC interface that decreases the current driving capability when used in active devices. In this paper, we report on the spin injection and detection by ballistic transport in perpendicular spin-valve hybrid heterostructures consisting of MnAs (20 nm) / GaAs (10 – 30 nm) / GaAs: MnAs (5 nm) grown by molecular beam epitaxy. The GaAs:MnAs layer contains ferromagnetic MnAs nanoclusters embedded in a GaAs matrix, and acts as a spin injector and a spin detector. Several % of spin-valve MR ratio was clearly observed up to 300 mV at temperature lower than 90 K. Considering the fact that all the junctions showed ohmic current-voltage characteristics, the spin-valve MR would be 10^{-6} for purely diffusive transport regime. Consequently, the spin-valve MR signal of several % is caused by the ballistic transport of spin-polarized carriers in the GaAs layer.

K1.00214 Observation of intrinsic spin-Hall effect in transport. EWELINA HANKIEWICZ, Fordham University, MARKUS KOENIG, ALENA NOVIK, Wuerzburg University, JAIRO SINtOVA, Texas A&M University, HARTMUT BtHMANN, LAURENS MOLENKAMP, Wuerzburg University — We study spin transport in n and p-doped mesoscopic H-bar structures fabricated from HgTe/HgCdTe quantum wells. In experiment the current is driven in one leg of H-bar structure while the second one is used to detect the voltage signal (similar to proposal presented in PRB 70, 241301(2004)). In p-doped samples, our data seem to confirm the existence of intrinsic spin-Hall effect. We also present the Landauer-Buttiker calculations with realistic parameters and details of band structure to verify experimental observation.

K1.00215 SOCIETY OF PHYSICS STUDENTS —

K1.00216 Crystal Growth of Quasi-One Dimensional SrNbO$_3$ and LaTiO$_3$$_{3,41}$. ANN DEML, University of Wisconsin-River Falls, C. A. M. DOS SANTOS, Escola de Engenharia de Lorena-USP, JOHN NEUMEIER, B. D. WHITE, Montana State University — Single crystals of SrNbO$_3$$_{4,1}$ and LaTiO$_3$$_{3,41}$ were grown in order to investigate the physical properties of these quasi-one dimensional conductors. Single crystals growth was accomplished with an optical image furnace; the synthesis was performed with X-ray powder diffraction. The resistivity and heat capacity of SrNbO$_3$$_{4,1}$ were measured in the temperature range 300 K $>$ T $>$ 0.3 K. SrNbO$_3$$_{4,1}$ was annealed to examine the influence of oxygen content on the electrical resistivity. The Debeye temperature and heat capacity coefficient of SrNbO$_3$$_{4,1}$ were found to be 458.5 $\pm$ 0.2 K and 0.77 $\pm$ 0.07 mJ/mol K respectively. 3This material is based upon work supported by the NSF (Grant Nos. DMR-0552458 (REU-Site) and DMR-0504799) and CAPES (Grant No. 0466/05-0).

K1.00217 Investigating the Diffusive Behavior of HPC with DLS and FPR: A Comparative Analysis of Experimental Method. RYAN MCDONOUGH, Cleveland State University, PAUL RUSSO, Louisiana State University, KIRIL STRELETZKY, Cleveland State University — The study of HPC (Hydroxy-propyl-cellulose) chains in aqueous solution through the experimental techniques of FPR (Fluorescence Photo-bleaching Recovery) and DLS (Dynamic Light Scattering) has shown empirical inconsistencies in observed polymer dynamics. The approach to analyzing the inconsistencies consisted of preparing fluorescein labeled and unlabeled HPC solutions at a range of concentrations from the same stock solution. Results from DLS have indicated the reliable presence of a slow mode of diffusion in both labeled and unlabeled samples. The slow mode appeared in FPR experiments, but not reproducibly. In addition, results from DLS on labeled and unlabeled HPC have found starting differences in line shape of correlation function indicating signal from an unknown mechanism. Future directions for this study include an investigation into the reasons behind the before mentioned inconsistencies and an analysis of HPC solutions with different fluorescent labels to further explore the nature of the slow diffusion mode if it is determined not to be an artifact from sample preparation, or an unknown aspect particular to DLS studies.

K1.00218 Investigation of the Oxidation Growth Kinetics of La$_{0.67}$Ba$_{0.33}$MnO$_3$ and LaMnO$_3$ Perovskite Films using Atomic Force Microscopy (AFM) lithography. MARC SCHNEIDER, MICHAEL EARLE, SANJAY ADHIKARI, MATT SNEIDER, KYLE HALL, RAJESwarI KOLAGANI, Towson University, DAVID SCHAEFER, Towson University — Manganese oxides doped with certain alkaline earth elements exhibit colossal magnetoresistance (CMR), which has great prospective applications in technological advancements. Our research is focused on the growth kinetics and electrical properties of LaMnO$_3$ and La$_{0.67}$Ba$_{0.33}$MnO$_3$. LaMnO$_3$, behaves as an anti-ferromagnetic and La$_{0.67}$Ba$_{0.33}$MnO$_3$ as a ferromagnetic material. The approach is based on a new way to generalize the so called “one way wave equation”. Our approach makes use some very simple,standard ideas from differential equations and the non-iterative solution of the Lippmann-Schwinger equation in quantum scattering. The importance of this new approach is that it corrects the usual approximation made in the one way wave equation so that the approach is equivalent to full solution of the two way acoustic scattering problem. However, because it is formulated so as to deal with coupled first order differential equations, it makes the problem appear to be one way. The initial conditions for the coupled first order differential equations need to satisfy the boundary conditions associated with waves that can travel two ways. The problem of evanescent waves is being treated using a projection operator technique patterned after an approach of H. Feshbach in nuclear physics. We are currently testing the method for several simple two dimensional acoustic models.

K1.00219 New Generalized Phase Shift Approach to Solve the Helomholtz Wave Equation. SAMEERA ABEBYKON, DONALD KOURI, University of Houston — A new method for solving the acoustic scattering wave equation in order to facilitate the exploration for production of oil and gas. The approach is based on a new way to generalize the so called “one way wave equation”. Our approach makes use some very simple,standard ideas from differential equations and the non-iterative solution of the Lippmann-Schwinger equation in quantum scattering. The importance of this new approach is that it corrects the usual approximation made in the one way wave equation so that the approach is equivalent to full solution of the two way acoustic scattering problem. However, because it is formulated so as to deal with coupled first order differential equations, it makes the problem appear to be one way. The initial conditions for the coupled first order differential equations need to satisfy the boundary conditions associated with waves that can travel two ways. The problem of evanescent waves is being treated using a projection operator technique patterned after an approach of H. Feshbach in nuclear physics. We are currently testing the method for several simple two dimensional acoustic models.

K1.00220 Characterization of 60 Hz environmental electromagnetic noise with a simple antenna. CHRISTOPHER HILL, RICHARD WILLIAMS, JOHN GAFFNEY, CHRISTOPHER SCHNEIDER, Southeastern Louisiana University, SATISH SHRESTHA, McNeese State University, SANICHIRO YOSHIDA, Southeastern Louisiana University, GIOVANNI SANTOSTASI, McNeese State University — The purpose of this project is to characterize environmental electromagnetic noise at 60Hz. We have constructed an antenna consisting of an LC circuit tuned around 60 Hz to detect the noise in the air, and made analyses in both the time and frequency domains. The data has shown considerable fluctuations in the peak frequency as well as the phase over any given period of time. Also, it has been found that the spectrum broadens depending on where the antenna is placed. We suspect that the broadening results from the superposition of seismic motion acting on the antenna to the electric signal. We are currently investigating if location and time of the day has any effect on the characteristics of the electromagnetic noise.
**K1.00221 Dynamics of a Planar Arm Model with Servo-regulated Viscoelastic Muscles in a Microgravity Environment**

JARED DURDEN\(^1\), Drury University Society of Physics Students — We constructed a mechanical arm model consisting of a rigid upper arm and forearm which simulates vertical planar arm motion with two degrees of freedom: shoulder rotation and elbow rotation. Computer controlled servo-motors effect rotation of the elbow and shoulder joints through tensions incited in elastic materials which represent muscles. We predicted and then observed vertical planar arm motion in the laboratory under normal Earth gravity conditions, and on NASAs Weightless Wonder in near zero gravity conditions. Because the arm only has two degrees of freedom we were able to simulate near zero gravity in the laboratory and predict the subsequent motion by operating it in the horizontal plane. We will discuss results of the actual observed motion in these three environments, and compare them to the motion predicted based on the equations of motion. We will also discuss how the project was developed physically, mathematically, and electronically.

**K1.00222 Why Not Solar Power?**

REEJU POKHAREL, PETER SHELDON, Randolph College (founded as Randolph-Macon Woman’s College) — Most of the world generally depends on energy sources such as fossil fuels and nuclear power to meet our energy consumption needs. As we all know, the excessive use of these resources has large environmental impacts, including displacing habitats, pollution, global warming, and scarcity of resources. Solar power is a clean energy source that has the potential to fulfill our energy needs while balancing the natural state of our environment. So why do we not power our houses with solar energy? I will give a general overview of the working principles of commercially available solar power, and examine the issues relating to why we should use it and why we currently do not.

**K1.00223 Ice Nucleation Near the Surfactant-Water Interface**

CALEB CARLIN, WILL CANTRELL, Dept. of Physics, MichiganTech University, CAROLINE TAYLOR, Dept. of Chemistry, MichiganTech University — Ice nucleation is a fundamental component of the atmospheric mechanisms driving the formation of clouds. Atmospheric nucleation occurs with a variety of compounds and conditions; but understanding the behavior of water is key in all cases. We have used multiscale molecular simulations to study heterogeneous nucleation in clouds, probing the influence of long-chain alcohols on the freezing of water droplets. Ice nucleation occurs at a finite distance from the heterogeneous surface, due to the disruption of the hydrogen bond network in response to the surfactant-water interface. The penetration depth of the disturbance is found to be dependent upon the chain length and surface organization, as well as the acidity of the terminal alcohol group.

**K1.00224 An Extended Hydrophobic Surface Submerged in Water: The Formation of a Depletion Layer**

COREY SHEMEhya, ADELE POYNOR, Allegheny College Physics Department — Hydrophobic literally means water hating. When small amounts of water come in contact with a hydrophobic surface, the water will minimize its contact area by forming a drop. What will happen when bulk water comes in contact with an extended hydrophobic surface? We have employed the surface sensitive technique of surface plasmon resonance to probe for the existence of a depletion region (an ultra-thin low-density region) at this boundary. We also explore the interaction of water and a mixed hydrophobic and hydrophilic surface and its effect on the formation of a depletion layer.

**K1.00225 ABSTRACT WITHDRAWN**

**K1.00226 PHYSICS EDUCATION**

**K1.00227 Physics Education for Blind Students: The Teachers’ Perspective**

AMAURI FERREIRA, Pontifícia Universidade Católica de Minas Gerais — We discuss the challenge high school teachers face when teaching physics to the blind. Using the oral history method, we interview physics teachers who have dealt with the inclusion of blind students in regular classrooms. Based on our study, we find that the performance of these students varies, depending on the studied subject. The narrative makes clear the teachers’ lack of preparation to deal with inclusion, and their search for alternative methods to improve blind students’ learning.

**K1.00228 Impact of Inquiry-Based Learning on Attitudes and Science Content Knowledge of Elementary School Teachers and Students\(^1\)**

PETER SHELDON, PEGGY SCHIMMOELLER, Randolph College (founded as Randolph-Macon Woman’s College) — We report on a research project studying the influence of hands-on and inquiry-based learning in K-8 classrooms. We designed learning experiences for teachers that included significant hands-on and inquiry-based lessons, and designed instruments to test attitudes and content knowledge. The lessons are meant to address topics of state and national learning standards. Teachers were invited to take part in a pilot program in the summer of 2006, and we hope to continue the project over the next few years. We will report on the activities developed, the attitudes toward and achievement in science, and any changes that were seen after learning science through active learning. Resources can be found on the project website, http://trst.randolphcollege.edu.

**K1.00229 Prospective Nanoscience Lessons for High School Classroom Activities**

JAETAE SEO, JAN MANQANA, COURTNEY DULA, OLIVIA KERWIN, JASMINE AUSTIN, THAMER KHASAWNEH, JENNIFER DO, LUIS GOITY, SEONGMIN MA, QIANGUANG YANG, BAGHER TABIBI, Hampton University, HAMPTON UNIVERSITY COLLABORATION, NORTHWESTERN UNIVERSITY COLLABORATION, PURDUE UNIVERSITY COLLABORATION — Workshops for learning and teaching in nanoscale science in the Hampton Roads area in Virginia have been provided for high school science teachers of 7-12th grade. Main objectives of the workshops are to enhance teachers’ awareness of the connections between nanoscience and the traditional sciences, and provide a collection of suitable classroom activities in nanoscience. Prospective nanoscience lessons for high school classroom activities have been introduced in summer 2007 and 08. The selected classroom lessons are surface area and volume, nanolight, solar cells, nanocard, allotropes of carbon, biosensors, DNA origami, ferrofluids, intermolecular forces, quantum dots, scanning probe microscopy, and space elevator. This work at Hampton University was supported by ARO (W911NF-07-1-0608) and NSF (HRD-0734635, HRD-0630372, and ESI-0426328/002).

**K1.00230 Modular Approach of Nanophysics for Undergraduate Science and Engineering Curriculum Development**

JAETAE SEO, EDMUND NDIP, JALE AKYURTULU, ATES AKYURTULU, Hampton University, HAMPTON UNIVERSITY COLLABORATION — Advances in nanoscience and nanotechnology are closely related with understanding nanoscale materials and their functionalization, which are still in their infancy. Further attention in the education of human-engineered nanoscale materials is needed before the beauty of nanoscience and nanotechnology becomes the reality of our modern life. The current urgent demand or existing challenge in nanoscience and nanotechnology is to educate, train, and prepare a new generation of skilled workers in nanoscience and nanotechnology. A modular approach of nanophysics for undergraduate curriculum development is introduced for educating students in multidisciplinary areas of science and engineering. The nanophysics educational modules are electronic dynamics and optical properties of semiconductor nanocrystals and nanomaterials. This work was supported by Army Research Office (W911NF-07-1-0608) and National Science Foundation (HRD-0734635, HRD-0630372, ESI-0426328/002, and EEC-0532472).
K1.00231 Quantum Mechanics Laboratories using Correlated Photons.\textsuperscript{1} , ENRIQUE GALVEZ, Colgate University — Progress in laboratory techniques with correlated photons has allowed the implementation of table-top experiments for teaching undergraduate quantum mechanics. The experiments that we have developed \textsuperscript{1} complement an undergraduate course on quantum mechanics. They use light at the quantum level to illustrate both fundamental and operational aspects of quantum mechanics. Laboratory experiments on interference of light with heralded photons, or with two correlated photons, going through an interferometer are vivid exercises on state superposition, state projection, and base rotation. Other experiments with entangled pairs address more fundamental aspects of quantum mechanics, including nonlocal correlations and violations of Bell Inequalities. \textsuperscript{[1]} E.J. Galvez et al., Am. J. Phys. 73, 127 (2005).

\textsuperscript{1} Funded by NSF grant DUE-0442882

K1.00232 Making the Nanoworld Accessible: Nanoscience Education Using Scanning Probe Methods\textsuperscript{1} , DANIEL KNORR, JASON KILLGORE, TOMOKO GRAY, DAVID GINGER, JOSEPH WEI, YEECHI CHEN, MEHMET SARIKAYA, HANSON FONG, TOM GRIFFITH, RENE OVERNEY — A partnership between researchers and educators at the University of Washington, North Seattle Community College and two companies, Nanosurf, AG and nanoScience Instruments has been forged to develop a nationally replicable model of a sustainable and up-to-date undergraduate teaching laboratory of scanning probe microscopy (SPM) methods applied to nanoscience and nanotechnology. Within this partnership a new paradigm of operating and maintaining a SPM laboratory has been developed that provides a truly hands-on experience in a classroom laboratory setting with a small student to instrument ratio involving a variety of SPM techniques and topics. To date, we have run a first successful undergraduate laboratory workshop, where students were able to have extensive hands-on experience on five SPM modes of operation including: electrostatic force microscopy involving photovoltaic polymeric materials, tunneling microscopy and the determination of the workfunction, and nanolithography using the dip-pen method.

K1.00233 Utilization of recycled neutron source to teach prompt gamma analysis activation-PGNA , CAMILO DELGADO-CORREAL, HECTOR MUNERA, university Nacional de Colombia — Neutron activation analysis based on prompt gamma ray emission has significantly developed during the past twenty years. The technique is particularly suited for the identification of low atomic number elements, as nitrogen that is a main component of drugs and explosives. Identification of these substances is important in the context of humanitarian demining, and in the control of illicit traffic of drugs and explosives. As a good example of recycling of radioactive sources, a $^{241}$Am-Be neutron source emitting $10^{7}$neutron/s, that was not longer in use for other purposes at Ingeominas, was used to build a neutron irradiator that can be used to teach prompt gamma ray analysis, and other nuclear techniques. We irradiated individual samples, each about 4 gram, of three different elements: nitrogen in urea, silicon in milled rock, and cadmium in cadmium oxide. The prompt gamma rays emitted in the nuclear reactions $^{112}$Cd (neutron,gamma) $^{113}$Cd, $^{29}$Si (neutron,gamma) $^{29}$Si and $^{14}$N (neutron,gamma) $^{15}$N were identified using a well-type NaI (Tl) detector, connected to a multi-channel analyzer.

K1.00234 Teaching Physics for Agronomy Students: Contextualizing Laboratory Classes \textsuperscript{1} , ANA LUCÍA NOGUEIRA, Universidade Estadual de Montes Claros, ADRIANA DICKMAN, Pontifícia Universidade Católica de Minas Gerais — In this paper we discuss a method of teaching physics to agronomy majors. We use laboratory classes to apply basic physics concepts to common situations in agronomy. As an example, we report a project developed by the students involving the construction of a device, frequently used on farms, to transport water without burning fuel or using electricity. We believe that contextualizing helps to improve physics classes and increase students’ motivation.

K1.00235 Measurement and simulation of AlSb/InAs triple barrier resonant tunneling diodes. NanoJapan program summer 2007\textsuperscript{1} , JEFFREY RUSSOM, KRISTJAN STONE, GSIST, Hokkaido University, Japan; Dept.of Physics and Astronomy, Rice University, TAKAAKI KOGA, GSIST and CRIS (Sousei), Hokkaido University, Japan; CREST, JST — Recently, Koga et al. \textsuperscript{1} proposed to make a spin filter out of only non-magnetic semiconductors. This spin filter consists of a triple barrier resonant tunneling structure (TB-RTS), and the Rashba spin-orbit coupling effect is utilized for matching the spin-dependent resonance levels, which would result in a high spin filtering efficiency. To test this theoretical idea, we obtained TB-RTS samples with InAs layers as quantum wells and AlSb layers as barriers from Tohoku University and studied their I-V characteristics. To understand the physics of our experimental $I – V$ curves obtained at 300, 77, and 4.2K, we also performed theoretical simulations. The authors acknowledge the growth of TB-RTS by Dr. K. Ohtani of Tohoku University. \textsuperscript{[1]} T. Koga, J. Nitta, H. Takayanagi and S. Datta, Phys. Rev. Lett. 88, 126601 (2002).

K1.00236 HISTORY OF PHYSICS —

K1.00237 Tracing the Rich History of Physics Research at NIST/NBS Through the Pages of the Journal of Research of the National Institute of Standards and Technology. SUSAN MAKAR, BARBARA SILCOX, National Institute of Standards and Technology — What do Edward B. Rosa, William W. Cobleantz, Ugo Fano, Charlotte E. Moore, William D. Phillips and Eric Cornell have in common? All are premier NBS/NIST physicists who published important research in the Journal of Research of the National Institute of Standards and Technology and the Journal’s precursors. The Journal of Research is the flagship publication of the National Institute of Standards and Technology, formerly the National Bureau of Standards. The Journal has been published under various titles and in various forms since 1904. This poster examines a sampling of the rich body of physics literature published in the Journal of Research since the early 1900s, and analyzes the impact this literature has had on the physics and scientific communities. From Edward B. Rosa’s paper, “The Absolute Measurement of Inductance” published in 1905, to the Journal’s 1996 Special Issue on Bose-Einstein condensation, the Journal of Research has been the venue for papers of some of the most influential American physicists of the twentieth century.

K1.00238 The Increasingly Disordered History of Entropy , CESAR RODRIGUEZ-ROSARIO, The University of Texas at Austin — The interpretation of irreversibility had played a significant part of philosophical debates, but it was not until Carnot and his son established entropy as part of the empirical science of engines that the issue reached practical importance. It also had to wait for Maxwell, Boltzmann, Gibbs and the birth of statistical mechanics that the concept of entropy was given a stronger theoretical basis, although the approximation it was based on is still a source of disagreement. This talk will focus on the debate from its early “demonic” times, past Szilard and Einstein building a refrigerator, to the role of von Neumann and Shannon in connecting the idea to information theory, without forgetting about the quantum mechanical master equations, all the way into its current use in quantum information theory.
K1.00239 The stolen brain of Einstein, KAVAN MODI, The University of Texas at Austin — Pathologist Thomas Stoltz Harvey performed an autopsy on Einstein after his death in 1955. During the autopsy Harvey removed Einstein’s brain, took pictures of it and then cut it into several pieces. A lot of scientific attention has been devoted to Einstein’ brain, and it still comes up once in a while. We’ve all heard something or other about Einstein’s brain, as it has become somewhat of a folk lore. What is less known is that Harvey in actuality did not have the permission to remove the brain. Only later pieces. A lot of scientific attention has been devoted to Einstein' brain, and it still comes up once in a while. We've all heard something or other about Einstein's

K1.00240 GENERAL THEORY INCLUDING SIMULATIONS OF MATTER AT EXTREME CONDITIONS; COMPUTATIONAL NANOSCIENCE; AND COMPUTATIONAL METHODS: MULTISCALE MODELING

K1.00241 Calculating cold curves for Equation of State using different types of Density Functional Theory codes, ANN E. MATTSSON, KYLE R. COCHRANE, JOHN H. CARPENTER, MICHAEL P. DESJARLAIS, Sandia National Laboratories, Albuquerque NM 87185 — With fast computers and improved radiation-hydrodynamics simulation techniques, increasingly complex high energy-density physics systems are investigated by modeling and simulation efforts, putting unprecedented strain on the underlying Equation of State (EOS) modeling. EOS models that have been adequate in the past can fail in unexpected ways. With the aim of improving the EOS, models are often fitted to calculated data in parts of the parameter space where little or no experimental data is available. One example is the compression part of the cold curve. We show that care needs to be taken in using Density Functional Theory (DFT) codes. While being perfectly adequate for calculations in many parts of the parameter space, approximations inherent to pseudo-potential codes can limit their applicability for large compressions. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

K1.00242 A Hybrid Density Functional Study of Zigzag SiC Nanotubes, KAZI ALAM, ASOK RAY — Using ab initio hybrid density functional theory based calculations, we report here the electronic and geometric structure properties of three different types of single-walled zigzag silicon carbide nanotubes from (3,0) to (11,0). Our calculations show type 1 structures to be most stable, with the cohesive energies of the newly proposed type 3 nanotubes intermediate between type 1 and type 2. For all nanotubes, Si atoms moved outward after relaxation making two concentric cylinders of Si and C atoms. The HOMO-LUMO (“band”) gaps for type 1 and type 2 nanotubes show an oscillatory pattern as the tube diameter increases but for type 3, the gap decreases monotonically with increasing tube diameter. All the tubes studied here appear to have triplet ground states except for type 1 (3, 0). It is expected that these tubes with significant surface reconstructions, varieties of band gaps, and magnetic properties would have interesting and important applications in the field of band gap engineering and molecular electronics.

K1.00243 Resonance modulations by tunable multi-level inter-dot coupling in a parallel quantum dot interferometer, YONG JOE, CHUNGHEE ROH, ERIC HEDIN, Ball State University, ARKADY SATANIN, Russian Academy of Science — We investigate the characteristics of resonance through parallel-coupled double quantum dots in an Aharonov-Bohm interferometer. In this system, we calculate the quantum transmission for different combinations of two-level inter-dot coupling by employing an exactly solvable tight-binding formalism. First, for the case that only one level in each dot participates in transport, we present contour plots of the transmission as a function of the energy level in each dot for different strengths of inter-dot coupling and magnetic flux. As the inter-dot coupling increases, an anti-crossing of resonances for a fixed magnetic flux appears due to the coalescence of two dots into one. In addition, a doubling of the periodicity in the transmission and the swing of the Fano resonance are also observed to be modulated by the magnetic flux. Second, for the case that two-levels in each dot contribute to the transport, an extra Fano resonance in the transmission appears by tuning the inter-dot coupling between the even–odd parity states. On the other hand, the inter-dot coupling of the odd-odd parity states gives rise to a collapse of the Fano dip in the transmission resonance. Finally, we discuss the resonance effect on the interplay between the two-level inter-dot coupling and magnetic flux.

K1.00244 Ab-Initio Molecular Dynamics Study of the Structural Stability of fcc-Carbon on Diamond, CHARLES CHIN-CANCHE, CESAR CAB, JORGE-ALEJANDRO TAPIA, Facultad de Ingenieria, Universidad Autonoma de Yucatan, GABRIEL MURRIETA, Facultad de Matematicas, Universidad Autonoma de Yucatan, ROMEO DE COSS, Departamento de Fisica Aplicada, Cineastav-Merida — The observation of a new carbon phase in thin films on diamond has been reported. High Resolution Electron Microscopy studies of the carbon thin films revealed a face-centered cubic (fcc) crystal structure with a lattice constant of 3.563 Å. It is interesting to note that this value is very close to that of carbon in the cubic diamond phase (3.567 Å), suggesting that the substrate is contributing to the stabilization of fcc-carbon. Thus, in the present work we have studied the structural stability of fcc-C on the surface (001) of diamond. We have used the Density Functional Theory and the Molecular Dynamics approach in the slab configuration. The calculations where performed with the pseudopotentials LCAO method (SIESTA code) and the Generalized Gradient Approximation (GGA) for the exchange-correlation potential. We have analyzed the changes in the atomic structure, density of states (LDOS), and the local orbital population. We found that the carbon layers in the fcc structure on diamond are unstable.

K1.00245 A coarse-grained model for simulations of graphite and carbon nanotubes, ALPER BULDUM, Department of Physics, The University of Akron, Akron, OH 44325, TOSHIIYUKI OHASHI, Honda Research Institute USA, Inc., Columbus, OH, 43212, LIMING DAI, Department of Chemical and Materials Engineering, University of Dayton — As multi-walled nanotubes in many experimental systems are quite large in diameter and in length and they consist billions of atoms, a new multi-scale modeling approach is necessary. This modeling approach can serve as a bridge between atomistic modeling and continuum modeling of multi-walled nanotubes. For graphite nanobeams and carbon nanotubes we present a new model which is based on the hexagonal symmetry of the graphite structure. This model is based on “N cell to one Cell” mapping of the graphite structure. N cells in the original atomic structure are equivalent to one cell in the hexagonal mesh model. The number N can be very large thus it is possible to model large multi-walled nanotubes and graphite nanobeams.
K.00246 Linking Quantum and Classical Descriptions: Hierarchical Development of Born-Oppenheimer-like Approximations. YING HU, Department of Physics and Astronomy, Vanderbilt University — The Born-Oppenheimer (BO) approximation is ubiquitous in quantum mechanical calculations of molecular wavefunctions. Here I report an extension of traditional BO approximation to a hierarchy of BO-like approximations which enables dynamic linking among distinct scales in complex crystals, from the quantum world to the macroscopic. At first, the usual BO approximation allows us to average out electrons to give descriptions of slow motion of nuclei. Then we describe an atom in crystals with two classes of independent variables corresponding to two distinct time scales: lattice deformation and relative atomic motion. We invoke a BO-like Ansatz as constraint to construct a ‘constrained distribution function’ so that phonons are averaged out from lattice deformation. To progress further, we use BO-like approximation to modify constraints so as to account for defects. The BO-like approximations is further extended from separating distinct time scales to different length scales. The ultimate hierarchy of BO-like approximations enables formulation of nonequilibrium multiscale statistical mechanics where electrons, phonons, defects and lattice deformation are dynamically coupled.

K.00247 Gas Adsorption Characterization of Rigid and Amorphous Polymers. GREGORY LARSEN, Penn State University, FLOR SIPERSTEIN, PETER BUDD, The University of Manchester, CORAY COLINA, Penn State University — Nanostructured materials have unusual mechanical, electrical and optical properties and are becoming increasingly important for energy storage. A variety of materials, such as zeolites, metal organic frameworks, covalent organic frameworks, activated carbons, and hypercrosslinked polymers, have recently been explored for energy storage. Polymers of Intrinsic Microporosity (PIMs) are macromolecules that form nanoporous materials (effective pore size <2 nm) that are rigid at a nanometer length scale due to the structure of the selected monomers, but can be flexible at a macroscopic scale and show swelling properties due to their polymeric nature. PIMs offer an interesting alternative to the materials mentioned above, as the functionality can be directly embedded in the material framework, allowing for intrinsic control in adsorptive properties by the PIM and flexibility in alternate adsorption applications such as CO2 sequestration. In this work, we present our recent efforts to study PIMs by MC simulations, and demonstrate the effects of box size and chain length on simulated measurements including pore size distribution and surface area.

K.00248 FLUIDS AND SOFT MATTER —

K.00249 Is the energy landscape of simple fluid a fractal?. GERARDO NAUMIS, Depto. de Física-Química, Instituto de Física, UNAM — The energy landscape of fluids is known to be very important close to a phase or glass transition. Real landscapes are fractal objects so one can ask if something similar happens with the structure of the phase space topology. Thus, a simple modification of the Monte-Carlo algorithm is proposed to explore the topography and the scaling of the energy landscape. We apply this idea to a simple hard-core fluid. The results for different packing fractions show a power law scaling of the landscape boundary, with a characteristic scale that separates the values of the scaling exponents. Finally, it is shown how the topology determines the freezing point of the system due to the increasing importance and complexity of the boundary.

K.00250 Ab initio molecular dynamics simulations of the static, dynamic and electronic properties of liquid lead1. L.J. GALLEGOS, MANUEL ALEMANY, R.C. LONGO, Universidad de Santiago de Compostela, Spain, D.J. GONZALEZ, L.E. GONZALEZ, Universidad de Valladolid, Spain, MURILO L. TIAGO, Oak Ridge National Laboratory, JAMES R. CHELIKOWSKY, University of Texas at Austin — We present results for a comprehensive study of the static, dynamic and electronic properties of liquid Pb near melting by means of 216-particle ab initio molecular dynamics simulations based on a real-space implementation of pseudopotentials constructed within density-functional theory. The predicted results and available experimental data are in very good agreement, which confirms the accuracy of this technique to achieve a reliable description of the behavior of liquid metals, including their dynamic properties. Although some of the computed properties of liquid Pb are similar to those of simple liquid metals, others differ markedly. Our results show that an appropriate description of liquid Pb requires the inclusion of relativistic effects in the determination of the pseudopotentials of Pb.

1 Work supported by the Spanish Ministry of Education and Science (Program Ramon y Cajal and Projects FIS2005-04239 and MAT2005-03415), by the NSF (Project DMR-0551195), by the DOD (Projects DE-FG02-06ER46286 and DE-FG02-06ER15760), and by CEGSA.

K.00251 Critical fluctuations and phase separation in pure fluid1, ANA OPRISAN, SORINEL OPRISAN, GREG SMITH, College of Charleston, JOHN HEGSETH, University of New Orleans — A series of experiments were performed in microgravity in order to study fluctuations and phase separation in pure fluids. These experiments were performed using Alice 2 apparatus containing an optical cell filled with sulfur hexafluoride (SF6) near critical point. Fluctuations of the intensity of the transmitted light through a cell containing the fluid under investigation appear as domains of different intensities. Critical fluctuation images are very sensitive to optical noise from the experimental system. Two different methods used in image processing were tested and the results in order to find the optimal filtering method. First method is based on an n-point filter to eliminate optical noise from images obtained in microgravity. The second method is based on wavelets threshold to eliminate optical noise. We also estimated the fractal dimension of the images. For the critical fluctuations the characteristic length of the fluctuations and the fractal structure factor were estimated. The temporal evolutions of concentration fluctuations were also analyzed and the correlation time was determined. The Schlieren technique was also used to image ultrasound beam incident on a corrugated water-brass interface and showed a backward displacement of the reflected beam at an angle of 22.5°, confirming the observations of Breazeale and Torbett [Appl. Phys. Lett. 29, 456 (1976)]. However, a new theory hypothesizes that this beam displacement results from excitation of a new type of leaky surface wave.

1 NASA-OBPs grant NAG3-2447, RGD grant -College of Charleston

K.00252 Imaging density fluctuations in liquids using Schlieren photographic technique, ANA OPRISAN, SORINEL OPRISAN, ALEM ABRAHA TEKLU, College of Charleston — Schlieren imaging method was used to visualize variations in the index of refraction or density of transparent liquid media. In one set of experiments, a colloidal suspension of silica and water was placed in a sample cell of 20 mm height. Schlieren method was used to visualize non equilibrium fluctuations caused by a concentration gradient. Using image processing techniques, the characteristic length of the fluctuations and the static structure factor were estimated. The temporal evolutions of concentration fluctuations were also analyzed and the correlation time was determined. The Schlieren technique was also used to image ultrasound beam incident on a corrugated water-brass interface and showed a backward displacement of the reflected beam at an angle of 22.5°, confirming the observations of Breazeale and Torbett [Appl. Phys. Lett. 29, 456 (1976)]. However, a new theory hypothesizes that this beam displacement results from excitation of a new type of leaky surface wave.

K.00253 Deep supercooling and relaxation processes in confined liquid crystals. FOAUD ALIEV, EDWIN ARROYO, SARMISTHA BASU, MANUELE RIVERA, University of Puerto Rico — Broadband dielectric and photon correlation spectroscopies has been applied for investigations of the dynamic behavior of liquid crystals (LCs) confined in porous matrices with random pores. We observed deep supercooling of LC in random pores. The relaxation times of the process due to the molecular reorientations in deeply supercooled state are slower than at the temperatures corresponding to nematic phase by a 5-6 orders of magnitude. This slowing down is accompanied by anomalous broadening of the dielectric spectra. The relaxation processes due to reorientation of molecules (of liquid crystals confined in narrow random pores) around their short axis is glass-like and the temperature dependence of relaxation times obeys Vogel-Fulcher law. Dynamics of director orientational fluctuations was also strongly affected by random confinement and these fluctuations were not frozen at temperatures much below bulk crystallization temperature. The small pore size (surface effects) and random pore structure (geometrical disorder) stimulate partial disorder (at least at long scales) and prevent crystallization. Therefore LC supercooled in small random pores has properties typical for glass forming liquids.
K1.00254 A study of electric field response by liquid crystal molecular dynamics algorithm. JONES TSZ-KAI WAN, Department of Physics, The Chinese University of Hong Kong — The response to an electric field of a liquid crystal cell is studied by the newly developed liquid crystal molecular dynamics (LCMD) algorithm. In contrast to the conventional conjugate gradient (CG) approach, which can only simulate the initial and final configurations of a LC cell under an applied electric field, the LCMD scheme can simulate intermediate configuration of the LC molecules. In addition, the electric field distribution within the LC cell at each time step is calculated directly. In this way, three cases will be presented: (i) LC molecules with spatial variation of polar angle, (ii) LC molecules with spatial variation of azimuthal angle and (iii) LC cells with nano-scale patterned substrates. The optical properties of the intermediate LC cell will also be presented.

K1.00255 Electro-optic properties of liquid crystal carbon nanotube composites. GEORGI GEORGIEV, Assumption College. YANIEL CARRERA, Tufts University. MARK CROWN, CHRISTOPHER ROCHELEAU, ZARNAB IFIHKAR, Assumption College. PEGGY CEBE, Tufts University. TUFTS UNIVERSITY COLLABORATION, ASSUMPTION COLLEGE COLLABORATION — We study the effects of carbon nanotubes on different properties of different liquid crystals: the elastic constant, Freedericksz transition, topological defect formation, interaction with external fields (i.e. electric). During our previous studies on the altitudinal angle of carbon nanotube doped liquid crystal electro-optic cells, we have measured a large shift of the transition voltage during Freedericksz transition. We are continuing our exploration on the physical properties of the liquid crystal nanocomposites. One of the most interesting questions is how different types of carbon nanotubes, conductive and semi-conductive affect the electrical properties of the liquid crystals. Our main tool is two dimensional microscopic transmission ellipsometry which provides information about the 3D orientation of the liquid crystalline entities.

K1.00256 Environmental Mode SEM Studies of Liquid Crystal Droplets. KASHMAI RAI, ADAM FOTEC-CHIO, Drexel University — An in-depth understanding of the liquid crystal nanometer scale structure of the holographic polymer dispersed liquid crystals (HPDLCs) is essential to optimally improve its diffraction efficiency. In this work the liquid crystal (LC) droplets are imaged for the first time in HPDLCs without LC removal using environmental mode SEM (ESEM). The field controllable HPDLCs have periodic layers of LC droplets and polymer matrix. Their applications include photonic crystals, optical pressure sensors, reconfigurable mirrors, wavelength filters and displays. Hi-vac mode SEM is a well-known technique used for high-resolution structural analysis of HPDLCs where the LC is removed prior to imaging. This results in the contractions and sometimes collapsing of grating structure. ESEM imaging aid in the study the LC microscopic structure without LC removal. A comparison of morphology features such as grating thickness, droplet structure is made between the images obtained by ESEM and hi-vac SEM.

K1.00257 Diffusion and micro-structure of dense liposome suspensions. YAN YU, Dept of Materials Science & Engineering, University of Illinois at Urbana-Champaign, STEPHEN M. ANTHONY, Dept of Chemistry, University of Illinois at Urbana-Champaign, SUNG CHUL BAE, STEVE GRANICK, Dept of Materials Science & Engineering, University of Illinois at Urbana-Champaign — Phospholipid vesicles can be stabilized against fusion, up to volume fraction around 80%, which is accomplished by studding the outer leaflet with charged nm-sized particles. The diffusion of such soft, flexible and hollow objects is revealed by single-particle tracking. Image analysis of time trajectories, obtained using epifluorescence imaging, was performed at sub-pixel resolution. This poster will reveal aspects of curiously heterogeneous dynamics and also quantification of microstructure in this system. Taken together, this system of charged, polydisperse, flexible objects displays rich dynamics that contrasts acutely with known behavior for hard-sphere dense particle systems.

K1.00258 Emulsions stabilized by Janus amphiphilic colloidal particles. SHAN JIANG, MITCH SCHULTZ, QIAN CHEN, JEFFREY MOORE, STEVE GRANICK, University of Illinois at Urbana-Champaign — Emulsions stabilized by amphiphilic colloidal particles were investigated by both theoretical calculation and experiments. The concept of Janus balance is defined as the dimensionless ratio of work to transfer an amphiphilic colloidal particle (a ‘Janus particle’) from the oil-water interface into the oil phase, normalized by the work needed to move it into the water phase. The calculation shows that the emulsion will be most stable when the Janus balance is unity. Experimentally, large quantities of Janus particles with different Janus balance were synthesized. The emulsion type and emulsion stability were investigated by using these particles to stabilize oil-water emulsions. It is found that Janus particles can stabilize emulsions for extended times. Finally, the emulsion type will be shown to depend on the geometry (Janus balance) of the Janus particles.

K1.00259 Flow-induced Shear of Colloidal Gels. TIFFANY SOO, GARY HUNTER, ERIC R. WEEKS, Emory University — We study colloidal gels as they break apart under shear. To make our colloidal gels, we add polyisocyanate polymer to PMMA colloids, inducing the depletion force. We then pump these colloidal gels through a capillary tube, and the resulting parabolic flow profile in the tube causes the gel to shear and break. We visualize this using confocal microscopy. We present two-dimensional and three-dimensional data from this experiment that has been analyzed through tracking individual particles and the movement of aggregates. We study the breaking points of the gel and characterize the structure of these points as a function of flow rate, volume fraction, and polymer concentration.

K1.00260 Effect of the polydispersion in the crystallization and micro-structure of the high charged colloids. EFRAIN URRUTIA-BÁÑUELOS, Universidad de Sonora, HELIM ARANDA-ESPINOZA, Department of Bioengineering University of Maryland, MARTIN CHASVEZ-PAEZ, Instituto de Fisica de la Universidad Autonoma de S.L.P. — In this work we investigate the effect of the polydispersion in the crystallization and micro-structure of the high charged colloids particles with tow and three different types and different concentrations of that types. This results were obtained by computer simulation, the particles interaction was modeled by a screened Coulomb potential. We used 4000 particles in our simulation cell to let them evolve from an initial random configuration, periodic boundary conditions was imposed to simulate the bulk. The temporal evolutions of the configuration show long-range self-ordering and a crystalline transition, the crystalline nucleation depend of the concentrations of different kinds as well as of types of particle. The common neighbor analysis (CNA) exhibits the competition of two micro-structures, icosahedral and bcc, in the equilibrium bcc crystalline order is dominant with relative abundance over the other micro-structures. 1. - U. Gasser, Eric R. Weeks et al, Science, 292 (250), 2001. 2. - Stefan Auer, Daan Frenkel, Letter of Nature, 400 (1020), 2001. 3. - J.P. Hoogenboom, et al, Phys. Rev. Letters, 89 (256104), 2002. 4. - M. Chávez-Pérez, E. Urrutia-Bañuelos and M. Medina –Noyola, Phys. Rev. E, 58 (681),1998 5. - Andrew S. Clarke and Hannes Jónsson, Phys. Rev. E, 47 (3975), 1993.

K1.00261 Using DLS Spectroscopy and Optical Probe Diffusion to examine structure of Brij Micelles. KAREN WILLIAM, MIKE LEKAN, KIRIL STRELETZKY, Cleveland State University — We studied properties of Brij-35 surfactant micelles in solution using Dynamic Light Scattering (DLS) Spectroscopy and Optical Probe Diffusion method. Aqueous solutions of Brij-35 with concentrations ranging from 2 to 100g/L were prepared, both with and without polylysene latex probes of diameters 24, 50, 186, 282 and 792nm. Solutions were studied at four temperatures of 10, 25, 40 and 70°C with DLS to obtain micelle and probe diffusion coefficients (D_m, D_p). Using both diffusion coefficients we deduced micelle radius (a_m), micelle water content (δ), and number of surfactant molecules per micelle (N) using two different models. First, hard sphere model of micelles/probe interaction was used to analyze the data by two methods, after a_m was obtained from intercept of D_m(c). The first method uses the slope of D_m(c) and size of probes to determine N and δ. The second method uses the linear least-squares fit of D_m(c) for different probe sizes to determine N and δ. Both methods reveal that with increase in solution temperature a_m increases by 10%, N increases and δ decreases by a factor of 2. The second model treats micelles as core-shell particles with corona radius (a_c). This model used two different approaches based on linear least-squares fits of D_m(c) and D_p(c). We found a_c to be 4.45nm and a_m to be 1nm without relying on Stokes-Einstein equation. Results for N and δ were also consistent.
K1.00262 von Karman Vortex Streets Generated by Different Shaped Rods, ILDOO KIM, University of Pittsburgh, RORY CERBURSE, Purdue University, XIAO-LUN WU, University of Pittsburgh — von Karman vortex street is a pattern of vortices behind a bluff body in a uniform stream. Strouhal number St, a non-dimensional frequency of vortex shedding, depends on Reynolds number Re, however the precise relationship is not known although there were several proposals. To test these proposals and to investigate the nature of vortex shedding, we have generated von Karman vortex streets in two-dimensional soap film using conic bodies with different cross-sectional geometric shapes and orientations. We found that the structure-based St-Re relationship, St=1/(A+B/Re), is in good agreement with our experimental data using different shapes and orientations. Two coefficients A and B are functions of geometries and orientations of bluff bodies. Also, we found under certain conditions, two adjacent vortices merge into a big vortex downstream.

K1.00263 Electrostatic gyrokinetic turbulence, GABRIEL PLUNK, UCLA — A kinetic description of turbulence becomes necessary in cases where particle collisions are not strong enough to maintain a local Maxwellian velocity distribution over relevant dynamical timescales. This is often the case with plasmas. This type of turbulence can exhibit structure formation in phase space having, in general, double the dimensionality. We study a simple limit of the gyrokinetic equation where there are two spatial dimensions and one velocity dimension. Symmetries are exploited to find scaling laws using standard arguments from neutral fluid turbulence. A discussion of closure is presented with an emphasis on the relationship to Navier-Stokes turbulence and the kinetic extension of the Navier-Stokes equation, the Boltzmann equation.

K1.00264 Microfluidic cell electroporation using a mechanical valve, CHANG LU, JUN WANG, M. JANE STINE, Purdue University, West Lafayette, IN, BIOLOGICAL ENGINEERING TEAM — A microfluidic electroporation technique is demonstrated based on the operation of an elastomeric valve in a polydimethylsiloxane (PDMS) fabricated microchip and a common dc power supply. The pulse needed for permeabilization of the cell membrane is generated by temporarily interrupting the circuit using the valve. The electroperoxemabilization of suspended and adherent Chinese hamster ovary cells with green DNA dye SYTOX is demonstrated. The technique eliminates the cost and complexity associated with a pulse generator and microfabricated electrodes that are often involved in microscale electroporation devices. It also offers the potential of integrating electroporation as a unit operation in large-scale microfluidic systems with the increasing application of elastomeric valves in these systems.

K1.00265 Ionic currents through individual carbon nanotubes, CHRISTINE MEYER, MARC ZUDDAM, VISHAL MERANI, JEROEN DE GREBBER, CEES DEKKER, Kavli institute of nanoscience, Delft University of Technology, The Netherlands — The miniaturization from microfluidic to nanofluidic channels is a growing field of research. Many new effects are predicted and observed in nanochannels owing to the increased influence of surface interactions. One of the most intriguing features is the theoretical prediction by Hummer et al (2001) of an enhanced flow of aqueous solutions through hydrophobic carbon nanotubes. Experimental work has so far been done on membranes of carbon nanotubes (Hinds et al., Holt et al.). To the best of our knowledge, the experimental investigation of fluid flow through an individual single-wall carbon nanotube has not been conducted. We have developed a fabrication scheme that allows us to do measurements on such individual tubes. It is based on the use of a sacrificial layer etching process to fabricate connections to the nanotube. First measurements reveal that the ionic current through an individual 2 micron long single-wall nanotube is slightly smaller than expected from geometrical considerations. We hope to be able to present more extensive experimental data, e.g. on the variations between individual carbon nanotubes having the same nominal parameters.

K1.00266 Toward a Carbon Nanotube-Based Capillary Rheometer, NEAL SCRUGGS, JOSEPH ROBERTSON, JOHN KASIANOWICZ, KALMAN MIGLER, National Institute of Standards and Technology — Nanofluidic devices featuring multi-walled carbon nanotubes (MWNTs) as fluid channels are fabricated for the purpose of measuring the flow of individual, submicron objects (e.g. polymers, nanoparticles) in solution. (Sun, Crooks J. Am. Chem. Soc. 122, 12340, 2000) The MWNTs serve as conduits between two electrolyte reservoirs and the passage of an analyte through (MWNTs) as fluid channels are fabricated for the purpose of measuring the flow of individual, submicron objects (e.g. polymers, nanoparticles) in solution.

K1.00267 Sequential random packings1, PEDRO LIND, Institute for Computational Physics, Universitaet Stuttgart, Pfaffenwaldring 27, D-70569 Stuttgart, Germany — We introduce sequential random procedures to pack polydisperse particles, for both cases of spherical and ellipsoidal shape. In the case of spheres, we generalize the recent research of random space-filling bearings to a more realistic situation, where the spacing offset varies randomly during the space-filling procedure, and show that it reproduces well the size-distributions observed in recent studies of real fault gouges. In particular, we show that the fractal dimensions of random polydisperse bearings sweep predominantly the low range of values in the spectrum of fractal dimensions observed along real faults, which strengthen the evidence that polydisperse bearings may explain the occurrence of seismic gaps in nature. For ellipsoids we discuss the main difficulties in packing polydisperse ellipsoids sequentially and propose a procedure to overcome them, based in variational methods.

K1.00268 The stress dip under a granular semi-pile., TOM MULLIN, University of Manchester, IKER ZURIGUEL, University of Navarro — The origin of stress dip under the apex of a sandpile has stimulated significant debate within the scientific community. On the other hand, it is argued that a semi-pile built against a vertical wall is of more practical interest since it serves as a model of dams, dykes and embankments. Numerical results suggest that stress dip will not be a dip in this case. Here we show clear experimental evidence that the presence of the wall enhances the dip under the pile significantly. Moreover, our investigation provides insight into the influence of the wall on the force chains which appear to be a key element in the formation of the dip.

K1.00269 Discrete Element Modeling of Close Box Oscillation with Granular Particles: Force Laws and Energy Dissipation, XIANG-MING BAI, LEON KEER, JANE WANG, RANDALL SNURR, Northwestern University — Partially filled cavity particle dampers are widely used in aerospace applications. In comparison to the conventional viscous fluid based damping, the temperature-independent performance and design simplicity of particle dampers make them more attractive when the temperature varies significantly. Recently, the discrete element method (DEM) has been widely used to simulate the particle damper consisting of a cavity box. In order to truly represent the real damping system, the use of accurate force laws in the DEM simulation is critical. In this work, we use different force models in DEM simulation to investigate the damping behavior of a close oscillating box filled with glass and steel particles. The force models used in this work include linear, Hertz, inelastic, plastic, history-dependent, and history-independent models. We note that the damping is very sensitive to the shear force models, but insensitive to the normal force models. The underlying mechanism has been investigated. In order to investigate the optimum filled fraction of particles and help us design the dampers, various configurations of different filled fractions are simulated. The energy dissipation through collision and friction is also investigated in this damping device.
K1.00270 The Transition of Two-Dimensional Hard Spheres from Liquid to Solid Regimes Under Gravity Using a Global Equation of State. ALISON KOSER, PAUL QUINN, Kutztown University of Pennsylvania — In a previous paper, Hong started with the Enskog equation for hard spheres of mass $m$ and diameter $d$ under gravity, and derived an exact equation for an equilibrium density profile at a specific temperature $T$. [Physica A, 271, 192 (1999)] This leads to a transition between the liquid and the solid regime that is temperature dependent. The size of the solid regime can be predicted using the temperature of the system obtained from the density profile. In a previous paper, Luding derives a new global equation of state for hard spheres in two-dimensions under gravity. [Phys. Rev. E, 163(2001)] Using this equation, we obtain a more exact equation for an equilibrium density profile at a temperature $T$ in two-dimensions. We use this equation with MD simulated data to obtain relationships of the number of solid layers, the center of mass, and the fluctuations of the center of mass as a function of $T$.

K1.00271 ABSTRACT WITHDRAWN –

K1.00272 Solitary granular avalanches: stability, fingering and theoretical modeling. FLORENT MALLOGGI, BRUNO ANDREOTTI, ERIC CLEMENT, ESPCI - University of Paris 6, Paris, France, IGOR ARONSON, Argonne National Laboratory, USA, LEV TSIMRING, INS-University of San Diego, USA — Avalanching processes do not only occur in the air as we know of snow avalanches, mud flows and landslides. Such processes can be naturally found and studied also on a microscopic scale, such as they take place from turbidity currents to thick sediment waves. In this study, we report results on laboratory scale avalanche experiments taking place both in the air and under-water. In both cases a family of stable solitary erosion/deposition waves is observed [1]. At higher inclination angles, we show the existence of a long wavelength transverse instability followed by a coarsening and the onset of a fingering pattern. While the experiments strongly differ by the spatial and time scales, the agreement between the stability diagrams, the wavelengths selection and the avalanche morphology suggest a common erosion/deposition scenario. We also use these erosion/deposition waves to investigate the dynamics of granular flow and jamming in the frame work of the Partial Fluidization Theory (PFT) proposed by Aronson et al. to describe the dynamics of granular matter near jamming [2]. [1] F. Malloggi et al. Europhysics Letters, 2006, Erosion waves: Transverse instabilities and fingering, 75, 825-831 [2] I. S. Aranson et al. Transverse instability of avalanches in granular flows down an incline. Physical Review E, 2006, 73, 050302; I.S.Aronson et al., Non rheological properties of granular flows: exploring the near jamming limit, preprint (2007).

K1.00273 Examination of the Angle of Repose in a Vertically Vibrated Container of Granular Materials. CARL FAUST, PAUL QUINN, Kutztown University of Pennsylvania — Experiments are conducted using various granular materials subject to a vertical vibration. The angle of repose is studied while varying certain parameters of the system, such as vibration amplitude, vibration frequency, initial height, grain size, container size, and container shape. Empirical relationships are found for the angle of repose as a function of each of these variables. Precession of the angle of repose is also examined, particularly as a function of grain size.

K1.00274 Relative Permeabilities: a pore-level model study of the capillary number dependence. MARTIN FERER, GARY MASON, Physics, West Virginia University, GRANT BROMHAL, DUANE SMITH, U.S.; D. O. E.; National Energy Technology Laboratory — Relative permeabilities are widely used by the petroleum industry in reservoir simulations of recovery strategies. In recent years, pore-level modeling has been used to determine relative permeabilities at zero capillary number for a variety of more and more realistic model porous media. Unfortunately, these studies cannot address the issue of the observed capillary number dependence of the relative permeabilities. Several years ago, we presented a method for determining the relative permeabilities from pore-level modeling at general capillary number. We have used this method to determine the relative permeabilities at several capillary numbers and stable viscosity ratios. In addition, we have determined these relative permeabilities using one of the standard dynamic methods for determining relative permeabilities from core flood experiments. Our results from the two methods are compared with each other and with experimental results.

K1.00275 Analysis of Drop Oscillations Excited by an Electrical Point Force in AC EWOD. JUNG MIN OH, SUNG HEE KO, KWAN HYOUNG KANG, Dept. of Mech. Eng., POSTECH, San 31, Hyoja-dong, Pohang, South Korea — Recently, a few researchers have reported the oscillation of a sessile drop in AC EWOD (electrowetting on dielectrics), and some of its consequences. The drop oscillation problem in AC EWOD is associated with various applications based on electrowetting such as LOC (lab-on-a-chip), liquid lens, and electronic display. However, no theoretical analysis of the problem has been attempted yet. In the present paper, we propose a theoretical model to analyze the oscillation by applying the conventional method to analyze the drop oscillation. The domain perturbation method is used to derive the shape mode equations under the assumptions of weak viscous flow and small deformation. The Maxwell stress is exerted on the three-phase contact line of the droplet like a point force. The force is regarded as a delta function, and is decomposed into the driving forces of each shape mode. The theoretical results on the shape and the frequency responses are compared with experiments, which shows a qualitative agreement.

K1.00276 Apparent Slip at Hydrophilic Surface: Fluorescence Resonance Energy Transfer. CARL FAUST, PAUL QUINN, Kutztown University of Pennsylvania — Experiments are conducted using various granular materials subject to a vertical vibration. The angle of repose is studied while varying certain parameters of the system, such as vibration amplitude, vibration frequency, initial height, grain size, container size, and container shape. Empirical relationships are found for the angle of repose as a function of each of these variables. Precession of the angle of repose is also examined, particularly as a function of grain size.

K1.00277 Effect of surfactants on the film thickness in the drag-out coating problem. PRABIR DARIPA, Texas A&M University — In this paper, we give a simple proof of the thickening effect of surfactant on the thin film deposited when a flat plate is withdrawn from a liquid bath. This problem without the effect of surfactant was first considered in the seminal paper of Landau and Levich (1942). Our proof here is based on an asymptotic analysis of the lubrication model for the Navier-Stokes equations. Our result is consistent with the results obtained numerically and experimentally on similar problems by other investigators. We will discuss our result against the backdrop of these known numerical and experimental results. This result has been obtained in collaboration with Gulu Pasa.

K1.00278 Self-consistent fluid-plasma simulation in small spaces. MANISH JUGROOT, Royal Military College of Canada — There is a great interest in understanding fluids and plasmas in small spaces as the complexity of micro technology systems increases. A self-consistent model of charged and fluid particle dynamics is applied to atmospheric small space (200 μm) discharges in helium. Hydrodynamic transport equations of the self-consistent model are described with an emphasis on the different terms involved in the close coupling among the fluid species, charged species and the electric field. The discharges are studied from an initial cloud till the stages of charged particle over-amplification in small spaces where transients are particularly important. Gas heating, neutral depletion and electric field reversals are observed, highlighting the close interaction between fluid and charged species – both effects therefore characterize and govern the evolution of the small space discharge.
K1.00279 Relaxation Dynamics in Glass-Forming Hydrogen-Bonded Liquids, H.G.E. HENTSCHEL, Emory University, ITAMAR PROCACCIA, Weizmann Institute of Science — We will address the relaxation dynamics in hydrogen-bonded super-cooled liquids near (but above) the glass transition, measured via Broad-Band Dielectric Spectroscopy (BDS). We propose a theory based on decomposing the relaxation of the macroscopic dipole moment into contributions from hydrogen bonded clusters of molecules. We discuss the statistical mechanics of the super-cooled liquid and with a theoretical estimate of the relaxation time of each cluster we provide predictions for the real and imaginary part of the frequency dependent dielectric response. Using glycerol as a particular example we demonstrate quantitative correspondence between theory and experiments. The theory also demonstrates that the ε peak and the “excess wing” stem from the same physics in this material.

K1.00280 Breakdown of effective temperature agreement near jamming, ADAM ABATE, DOUG DURIAN, University of Pennsylvania — The jamming concept may unify a wide class of disparate phenomena. Central to this is the behavior of effective temperatures as a system falls out of equilibrium. We present experimental measurements of effective temperatures in a granular system as it is gradually brought close to jamming. One effective temperature is based on the Einstein relation and defined in terms of the ratio of diffusion to mobility of a heavy test particle dragged through the system. The others are measures from local single-particle observables: the granular temperature is the average kinetic energy of the grains; the thermostometer temperature is the average total mechanical energy of a weighted oscillator placed in the system. In thermal equilibrium and, surprisingly, when this non-equilibrium granular system is driven far from jamming, these effective temperatures agree. As jamming is approached, the Einstein temperature, which depends on system wide relaxation, systematically deviates from the other local measurements of effective temperature. The amount of deviation depends on the system’s proximity to jamming and results in qualitative scaling differences of the relaxation timescales. These results suggest that global packing constraints play an important role in the breakdown of the thermal analogy as granular materials jam.

K1.00281 Crystal growth kinetics exhibit a fragility-dependent decoupling from viscosity, MARK EDGER, University of Wisconsin-Madison, PETER HARROWELL, University of Sydney, LIAN YU, University of Wisconsin-Madison — We establish the temperature dependence of the kinetic coefficient associated with crystal growth into the supercooled liquid for 7 organic and 8 inorganic materials. We show that the kinetic coefficient for crystal growth scales with the shear viscosity raised to an exponent that depends systematically on the fragility of the liquid; fragility quantifies the deviation away from an Arrhenius temperature dependence for the viscosity. For strong liquids, the exponent is -1. The greater the fragility, the larger the deviation from -1. We argue that this breakdown in scaling between the crystal growth kinetics and the viscosity is a manifestation of heterogeneous dynamics in supercooled liquids.

K1.00282 Dynamics in depletion gels studied with X-ray photon correlation spectroscopy, ANDREI FLUERASU, ABDELLATIF MOUSSAID, European Synchrotron Radiation Facility — The slow, non-equilibrium, dynamics in low-concentration (particle volume fraction Φ ≈ 20 %) depletion gels consisting of colloid-polymer mixtures was studied using X-ray photon correlation spectroscopy. In some recent work (A. Flerasu et al. PRE 76, 010401(R), 2007) we have shown that towards full aging, the intermediate scattering functions are well described by compressed exponential decays, indicating a form of “jamming” in the system which occurs even on length scales smaller than the particle radius. Here we extend these results by probing samples with different interaction potentials (tuned by the polymer concentration) and by characterizing the dynamical heterogeneities in these soft gels. We will also show first results on the formation of the gels in shear flow that were obtained using a combination of X-ray, direct observation, and co-flow mixing techniques.

K1.00283 Exceptionally stable organic glasses: a molecular view of the glass-to-liquid transformation, STEPHEN SWALLEN, KENNETH KEARNS, MARK EDGER, University of Wisconsin-Madison — Exceptionally stable organic glasses have been prepared by physical vapor deposition. Substrate temperature and deposition rate have been found to determine the degree of stabilization. When optimized, these factors allow the production of films with very slow kinetics and up to 2% more dense than the ordinary glass. This is as dense as the estimated density of the equilibrium supercooled liquid at Tg – 50 K. Translational motion, density and surface mobility were measured in films vapor deposited at a range of temperatures from Tg down to Tg – 150 K. Stable films can be superheated well above Tg, and the very slow relaxation rates allow the investigation of the glass-to-liquid “melting” transition. Results suggest this process occurs by nucleation and growth, with regions of low viscosity liquid developing within the glassy matrix.

K1.00284 Unexpected long range order at the early stage of spinodal decomposition, LEOPOLDO R. GOMEZ, DANIEL A. VEGA, Department of Physics - Universidad Nacional del Sur - Argentina — During the early stage of spinodal decomposition most of the phase separating systems lead to the formation of incoherent structures with small-range orientational and translational order. In this work we found that in the region near below the spinodal line two-dimensional systems with competing interactions can form hexagonal structures with long-range order. As a consequence of the strong mode selectivity, a network of density scars with large density fluctuations is formed at the early stage of the process of phase separation. The points of ramification of this network of scars act like nucleation centers of a hexagonal phase and ultimately define the domain structure, correlation length and statistical properties of the topological defects.

K1.00285 Nonequilibrium Assembly of Polymers and Quantum Dots from a Confined Geometry, ZHIQUN LIN, SUCK WON HONG, JUN XU, MYUNGHWAN BYUN, Iowa State University — Dissipative structures, such as scanned probe microscopy. We will address the relaxation dynamics in hydrogen-bonded super-cooled liquids near (but above) the glass transition, measured via Broad-Band Dielectric Spectroscopy (BDS). We propose a theory based on decomposing the relaxation of the macroscopic dipole moment into contributions from hydrogen bonded clusters of molecules. We discuss the statistical mechanics of the super-cooled liquid and with a theoretical estimate of the relaxation time of each cluster we provide predictions for the real and imaginary part of the frequency dependent dielectric response. Using glycerol as a particular example we demonstrate quantitative correspondence between theory and experiments. The theory also demonstrates that the ε peak and the “excess wing” stem from the same physics in this material.

K1.00286 Quantitative analysis of buried structures in polymer, nanoparticles and their nanocomposites by GISAXS, ZHANG JIANG, XUEFA LI, DONG RYEOL LEE, MICHAEL SPRUNG, JIN WANG, X-ray Science Division, Argonne National Laboratory — Grazing incident small-angle x-ray scattering (GISAXS) is a powerful and rapidly developing technique for the characterization of nanoscopic morphology and structures at surfaces. However, due to complicated data analysis involving distorted wave Born approximation (DWBA), most of the quantitative analysis nowadays is carried out only on surface structures. When combined with x-ray resonant-enhanced geometry, GISAXS can be extended to measure the buried structures in 3D polymer, nanoparticles and their nanocomposite thin films. In the current work, a more comprehensive approach is developed in order to extract in-plane structures as well as their depth-dependence within thin films, which cannot be readily accessible using conventional techniques, such as scanned probe microscopy.

1 This work and the use of the Advanced Photon Source are supported by the U.S. Department of Energy, Office of Science, Office of Basic Energy Sciences, under Contract No. DE-AC02-06CH11357
K1.00287 Self-Assembled Arrays of Non-Coalescent Water Drops, VIVEK SHARMA, School of Polymer, Textile and Fiber Engineering, MOHAN SRINIVASARAO, School of Polymer, Textile and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology, Atlanta GA 30332 — Condensation figures form over polymer dissolved in volatile solvent exposed to a stream of moist air. These patterns are hexagonally symmetric and they comprise of non-coalescent and nearly monodisperse water drops. Typical condensation figures have a range of drop sizes, resulting from the nucleation, growth and coalescence of different generations of water drops. In this study, we image the pattern formation over evaporating polymer solutions. We observe that rafts of growing drops evolve into a highly organized two dimensional lattice, which eventually evaporate away as well, templating ordered arrays of holes in polymer films. We derive the analytical and modeling framework for determining the key kinetic parameters that control the typical length scales and timescales of droplet growth, non-coalescence and assembly.

K1.00288 Equilibrium Switching: Nucleosomes and Transmembrane Proteins, DAVID SCHWAB, KARIM WAHBA, ROBIN BRUINSMA, Dept. of Physics and Astronomy, UCLA — The problem of placing rods on a line is an old problem in statistical mechanics. It has recently found applications in biology in the context of nucleosome positioning and transmembrane helix prediction. In both of these problems, the underlying lattice possesses a heterogeneous energy landscape, making the problem nontrivial. We explain the relative ease of helix prediction over nucleosome positioning as due to the existence of “switching” regions, i.e. a ground state density profile that deviates from that formed by successively occupying the lowest available energy minima. We illustrate the concept with a simple disorder systems model that can be solved exactly and discuss the functional implications for both transmembrane proteins and nucleosomes.

K1.00289 Flow through a reconstituted marine quartz sediment by an interacting lattice gas simulation, ALLEN REED, Naval Research Laboratory, EDWARD BRAITHWAITE, JOE GETTRUST, Naval Research Laboratory, RAS PANDEY, Naval Research Laboratory and University of Southern Mississippi — Regions of a reconstituted cylinder of quartz sediment (5.9 cm diameter x 13 cm long) from the Northern Gulf of Mexico were sub-sampled as 6.5 mm diameter cylinders. Images of sub-samples were made from x-ray micro-focus computed tomography data at 11 micron resolution. Using a coarse-grained approximation, each sample image is represented by a cubic lattice (100³ voxels). Fluid, a pool of particles at the lattice base supplies fluid-particles flows against gravity to the sink at the top of the lattice. In addition to the concentration gradient, an external pressure bias, similar to a hydraulic head drives the mobile particles upward against gravity. Particles are allowed to execute stochastic motion by a Metropolis algorithm. The porous medium is generated by a random distribution of barriers on a three dimensional lattice with a slit across the center. Interacting particles enter the lattice from the source and execute their stochastic motion with the Metropolis algorithm, and are driven by their concentration gradient and a pressure bias against gravity. Density and mobility profiles of particles in steady-state are studied as a function of pressure bias. A large fraction of particles flows through the slit with a relatively uniform dispersion in the surrounding porous regions in absence of the bias. Increasing the bias introduces long-range correlations among the constituents resulting in larger density further away from the slit. Effects of the size of the slit’s width on the density profile of particles and their mobility are also examined.

K1.00290 Distribution of self-organizing driven particles and their mobility around a slit in porous media, JOE GETTRUST, Naval Research Laboratory, RAS PANDEY, University of Southern Mississippi — Self-organizing structures and mobility profiles of a mixture of immiscible driven particles (A, B with molecular weights $M_A$, $M_B$) through a porous medium are examined by an interacting lattice computer simulation. The porous medium is generated by a random distribution of barriers on a three dimensional lattice with a slit across the center. Interacting particles enter the lattice from the source and execute their stochastic motion with the Metropolis algorithm, and are driven by their concentration gradient and a pressure bias against gravity. Density and mobility profiles of particles in steady-state are studied as a function of pressure bias. A large fraction of particles flows through the slit with a relatively uniform dispersion in the surrounding porous regions in absence of the bias. Increasing the bias introduces long-range correlations among the constituents resulting in larger density further away from the slit. Effects of the size of the slit’s width on the density profile of particles and their mobility are also examined.

K1.00291 Pair diffusion in quasi-one- and quasi-two-dimensional binary colloid suspensions, Binhua Lin, David Valley, Stuart A. Rice, Hau My Ho, School of Polymer, Textile and Fiber Engineering, University of Southern Mississippi — We report the results of experimental determinations of the triplet correlation functions of quasi-one-dimensional (q1D) and quasi-two-dimensional (q2D) binary colloid suspensions. The new results extend the findings of similar studies of one-component q1D and q2D colloid suspensions. Our principal new finding is that the presence of the smaller diameter component can destroy the oscillatory structure of the separation dependence of the q2D relative pair diffusion coefficient of the large particles even though the oscillatory character of the large particle equilibrium pair correlation function remains prominent, and that no such effect occurs with the q1D suspension. An interpretation of these results is proposed.

K1.00292 Three-particle correlation functions of quasi-two dimensional one-component and binary colloid suspensions, Binhua Lin, Hau My Ho, Stuart A. Rice, University of Chicago — We report the results of experimental determinations of the triplet correlation functions of quasi-two-dimensional one-component and binary colloid suspensions in which the colloid-colloid interaction is short ranged. The suspensions studied range in density from modestly dilute to solid. The triplet correlation function of the one-component colloid system reveals extensive ordering deep in the liquid phase. At the same density the ordering of the larger diameter component in a binary colloid system is greatly diminished by a very small amount of the smaller diameter component. The possible utilization of information contained in the triplet correlation function in the theory of melting of a quasi-two-dimensional system is briefly discussed.

K1.00293 Rotational Diffusion of Colloidal Clusters, Jakub Otwinowski, Kazem Edmond, Ken Desmond, Eric R. Weeks, Emory University — We synthesize fluorescent PMMA particles and form them into clusters of several particles. We separate the clusters and make dilute suspensions of identical clusters in an index and density matched solvent. We scan the suspensions with a high-speed confocal microscope in 3D over time. For each cluster we determine the position and orientation with modified particle tracking software, and we follow the translational and rotational motion in time. The diffusion coefficients for translational and rotational motion agree with the Stokes-Einstein and the Stokes-Einstein-Debye relations.

K1.00294 DNA Linker Mediated Crystallization of Nanocolloids, Huiming Xiong, Brookhaven National Laboratory, Daniel Van der Lelei, Oleg Gang — Biofunctionalized nanocolloids offer a promising platform for creation of novel materials using bio-addressable interactions. Crystalline phases are of especial interest for the development of novel functional structures. We demonstrate that crystallization of nanocolloids can be achieved via hybridization of dispersed non-complementary single stranded DNA capped colloids with flexible single-stranded linker DNA. The crystalline structure belongs to body central cubic lattice and exhibits large thermal expansion. The evolution of the structure has been studied in details using in-situ small angle x-ray scattering. The formation of crystalline structures and reduced metastability are observed for systems with longer DNA linkers.

K1.00295 Translation-rotation coupling in concentrated colloidal suspensions, MINSU KIM, Physics, UIUC, STEPHEN ANTHONY, Chemistry, UIUC, STEVE GRANICK, material science and engineering, UIUC — Single-particle tracking has been used to contrast translational and rotational diffusion in monodisperse colloidal suspensions. Visualization of angular motion reveals that rotation has different properties from translation. Collective motions of particles lead to subdiffusive rotation. Deviations from Fickian motion increase as the volume fraction increases above 50%. Translational and rotational coupling of a single particle is measured directly for the first time and its dependence on the volume fraction is discussed.

K1.00296 Large Scale Computer Simulation of Erythrocyte Membranes with Explicit Cytoskeleton†, CAMERON HARVEY, JOEL REVALEE, MOHAMED LARADJI, University of Memphis, P.B SUNIL KUMAR, IIT-Madras, Chennai, India — The erythrocyte membrane is composed essentially of a self-assembled lipid bilayer and a polymerized protein meshwork, referred to as the cytoskeleton. For the erythrocyte, the polymer meshwork is composed of spectrin and anchored to the bilayer through specialized proteins. In this investigation we extended a coarse-grained model of self-assembled lipid membranes, recently developed by us, to account for the cytoskeleton. Simulation of bilayer patches, with dimensions about 0.5 μm × 0.5 μm, were performed to investigate the effects of the cytoskeleton on the membrane elastic properties. The bending modulus and surface tension are extracted from the spectra of the out-of-plane thermal undulations of the membrane. Using Monte Carlo, we also extracted the compression and shear moduli. Preliminary findings suggest a measurable effect in thermal undulations resulting from the introduction of the cytoskeleton.

K1.00297 QUANTUM INFORMATION, CONCEPTS, AND COMPUTATION II —

K1.00298 ABSTRACT WITHDRAWN —

K1.00299 Transconductance of a double quantum dot system coupled to a microcavity, VIJAY KASISOMAYAJULA, PETER BONANNO, ONOFRIO RUSSO, New Jersey Institute of Technology — The transconductance of a double quantum dot system in the coulomb blockade regime for single spin 1/2 electrons on each dot mutually coupled by an exchange interaction has been studied. We investigate the effect of this system when coupled to a microcavity and determine conditions for the external potential on each of the dots. The significant peaking in the transconductance as found without cavity mode coupling, is due to a large degree on the potential of each dot. The electron spins on each of the quantum dots are responsible for the strong mutual interaction but, also these spins result in only weak coupling to the adjacent leads. The weak Kondo condition, however is responsible for the enhanced transconductance. The addition of the dominant modes of a strongly coupled microcavity and its effect on the transconductance are discussed for differing potentials and spacing between the dots, and for some conditions result in an enhanced transconductance. L. V. Koerten, P. Wolfe, PRL 99, 036807(2007)

K1.00300 The role of state preparation in quantum process tomography, KAVAN MODI, AKI-MENG KUAH, CESAR RODRIGUEZ-ROSAIRO, GEORGE SUDARSHAN, The University of Texas at Austin — We study the effects of preparation of input states in a quantum tomography experiment. We study two preparation procedures, stochastic preparation and preparation by measurements. It turns out that the stochastic preparation procedure yields linear process maps, while the results obtained from an open system that is initially prepared using von Neumann measurements is shown to be non-linear, and can only be consistently described by a bilinear process map. A new process tomography recipe is derived for preparation by measurement for qubits. The difference between preparing states for an experiment by measurement and by stochastic process is analyzed.

K1.00301 Quantifying the role of interference in quantum information processing, DANIEL BRAUN, BERTRAND GEORGET, LUDOVIC ARNAUD, University Paul Sabatier Toulouse — We present a quantitative measure of interference, applicable to any quantum mechanical process in a finite dimensional Hilbert space, and use it to examine the role that interference plays in various quantum algorithms and other quantum information theoretical tasks. We present results for the amount of interference in both Grover’s search and Shor’s factoring algorithms, and on how interference correlates with success probability in the case of disturbances of these algorithms through static or random unitary errors, or decoherence through bit-flips and spin flips [1]. We have also studied the statistics of interference in random quantum algorithms, both using well known random matrix ensembles (CUE, the circular unitary ensemble, and HOE, the Haar orthogonal ensemble), as well as recently introduced random circuit ensembles. We show that interference distributions in the random circuit ensembles converge rapidly (i.e. exponentially, or even in a Gaussian fashion) towards the universal interference distributions of CUE and HOE, which predict close to maximum interference with very high probability for a randomly picked quantum algorithm [2].

K1.00302 Resonant activation and multi-junction switching characteristics of Bi-2212 intrinsic Josephson junctions, NOBUHIRO KITABATAKE, RIEC, Tohoku Univ., KUNIHIRO INOMATA, RIKEN, SHIGEO SATO, RIEC, Tohoku Univ., MITSUNAGA KINJO, Department of Electrical and Electronic Engineering, Univ. of the Ryukyus, HUBING WANG, TAKESHI HATANO, NIMS, KOJI NAKAJIMA, RIEC, Tohoku Univ. — Bi-2212 intrinsic Josephson junctions (IJJs) are expected to be applied to a superconducting qubit. We have studied quantum behavior of two different types of Bi-2212 IJJs, one is fabricated by FIB etching [2,3] and the other is fabricated by Double Side Etching Method (DSEM) [4]. In this report, we show their multi-junction switching properties with or without microwave irradiation. The experimental results indicate that the couplings between junctions change according to the sample fabrication process. [1] K.Inomata et al., Phys. Rev. Lett. 95, 107005 (2005) [2] S.-J.Kim et al., Appl. Phys. Lett. 74,1156 (1999) [3] Yu.I.Latyshev et. al., JETP Lett. 69, 84 (1999) [4] H.B.Wang et al., Appl. Phys. Lett. 78, 4010 (2001)

K1.00303 Macroscopic Resonant Tunneling Above the Crossover Temperature in a rf SQUID†, LUIGI LONGOBARDI, DOUGLAS BENNETT, VIJAY PATEL, JAMES LÜKENS, Stony Brook University, Department of Physics and Astronomy — We report studies of macroscopic resonant tunneling (MRT) between fluxoid states in an rf-SQUID qubit as function of temperature. The measured tunneling rates as a function of bias exhibit evidence of energy level quantization up to a temperature (900 mK) well above the crossover temperature (Tc) between the quantum and the thermal regime. The data agree with the level structure calculated using independently measured circuit parameters. The MRT is a useful probe of decoherence-inducing noise in the rf SQUID since the measurements are much simpler and give values for flux noise equal to those obtained from Tz.

†This work has been supported in part by NSF and by AFOSR and NSA through a DURINT program.

K1.00304 Universal quantum degeneracy point for solid-state qubits†, L. TIAN, Department of Applied Physics and E. L. GinZton Laboratory, Stanford University, Stanford, CA 94305 — When operated at the quantum degeneracy point, the so called “sweet spot”, solid-state qubits can be protected from the first order decoherence of low-frequency noise in the off-diagonal coupling. Here, we show that a quantum degeneracy point can also be found for low-frequency noise in the diagonal coupling in an encoded-qubit scheme. We also study the protocols for implementing one and two bit quantum logic gates and the effects of circuit imperfection on this scheme. A practical system to realize this scheme with superconducting qubits is then presented.

†This work is supported by the Karel Urbanek Fellowship and the SORST program of JST.
K1.00305 SURFACES, INTERFACES AND THIN FILMS —

K1.00306 Diffusion Prefactors and Vibrational Entropic Contributions for small Cu and Ag clusters on Cu(111) and Ag(111) 1. HANHAND YILDIRIM, ABDKADER KARA, TALAT S. RAHMAN, Department of Physics, University of Central Florida — In examination of the diffusion energetics and dynamics of small 2D Ag and Cu clusters on Ag(111) and Cu(111) we found the results for the 7-atom cluster to be particularly interesting. In particular the diffusion pre-exponential factor for the Cu clusters on Ag(111) is found to be one order of magnitude larger than that for the homo-systems; Cu cluster on Cu(111) and Ag cluster on Ag(111). Analysis of the vibrational entropic contributions to the system free energy points to the subtle differences in the three cases and the significant contribution of the substrate atoms that lie in the vicinity of the diffusing islands. We trace the differences in the results for the 7-atom cluster from those for smaller sized ones to the nature of the cluster-substrate interactions. The vibrational dynamics and energetics of the systems are obtained using ab initio electronic structure calculations (density functional theory) and compared to those obtained using many body interaction potentials.

K1.00307 Magnetic studies on thin films of iron oxides, JAYA OSORIO, JUAN URIBE, CESAR BARRER, DORIS GIRATA, ALVARO MORALES, Universidad de Antioquia, AXEL HOFFMANN, Argonne National Laboratory, RAMON GANCEDO, CSIC, ESTADO SOLIDO TEAM, MATERIALS SCIENCE DIVISION TEAM, INSTITUTO ROCASOLANO TEAM — We have grown hematite (α-Fe₂O₃) thin films on stainless steel and silicon dioxide (SiO₂) substrates and magnetite (Fe₃O₄) thin films on silicon substrates by RF magnetron sputtering process. Conversion Electron Mössbauer (CEM) spectra of these films exhibit hyperfine parameter values which are characteristic of these iron oxides. Magnetization measurements parallel to the plane of the film as a function of temperature, M(T), were done at a constant field of 1 kOe to α-Fe₂O₃ films and at 200 Oe to Fe₃O₄ films. The M(T) curve of the α-Fe₂O₃ film showed a linear increasing of magnetization from 5 K to 160 K, related with the Morin transition. While the temperature of the Fe₃O₄ film is decreased, a sharp decrease in magnetization is observed at 123 K, associated to the Verwey transition. We carried out measurements of magnetization as a function of applied magnetic field, the loops of α-Fe₂O₃ film exhibits hysteresis which is related to their weakly ferromagnetic behavior and the loops of the Fe₃O₄ film at 300 and 110 K show a magnetic value around 5 memu at 3 Koe in the curves.

K1.00308 Far-from-equilibrium Ag-Cu thin-films on Cu(100) and Ag(100) substrates, ANTONIO CADILHE, T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA; GCCP-Centro de Fisica da Universidade do Minho, 4710 Braga, Portugal, NUNO A.M. ARAUJO, GCCP-Centro de Fisica da Universidade do Minho, 4710 Braga, Portugal; T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, A.F. VOTER, T-12 Group, MS B268, Los Alamos National Laboratory, Los Alamos, NM 87545, USA — We study the dynamics of multilayer, heteroepitaxial deposition of mixed incoming fluxes of Ag and Cu atoms and the corresponding post-deposition relaxation on Ag (100) and Cu (100) substrates. To this end, we carried out extensive temperature accelerated dynamics (TAD) simulations at different substrate temperatures to characterize the morphology of the resulting films. Depending on the flux of impinging atoms, the number of layers, and the substrate temperature, the system can exhibit kinetically trapped, far-from-equilibrium configurations. Complex multi-adatom moves, not usually accounted for in regular Monte Carlo simulations, have a non-trivial relevance in the dynamics.

K1.00309 Chemical and structural dynamical equilibrium in bimetallic nanoclusters, JÉRÔME CREUZE, LEMHE/ICMOMO, UMR 8182, Université Paris Sud-XI, Bat. 410, F91405 Orsay cedex, France, LAURE DELFOUR, BERNARD LEGRAND, SRMP-DMN, CEA Saclay, F91191 Gif-Sur-Yvette cedex, France — Coupling the surface and finite-system thermodynamics is a challenging key point in modeling bimetallic clusters. This is particularly crucial when the alloy surfaces undergo first-order phase transitions. In this context, we have investigated the segregation of Ag atoms in the substructures (Ag₇O₇) and Ag₃O₃ by using N-body interaction potentials and the Monte Carlo method. The (111) and (100) surfaces of Cu-Ag alloys are known to exhibit first-order phase transitions coupling a jump in the surface concentration and structural rearrangements. For the Wulff polyhedron of 405 atoms, these phase transitions are replaced by a dynamical equilibrium (DE) in phase space. For the (100) facets, this DE affects both the composition and the structure of the facets. Furthermore, all the (100) facets are correlated during the DE, due to atomic relaxations which affect also the core region of the nanocluster. For the (111) facets, the DE concerns only the composition of the facets, the atomic structure remaining unchanged. Consequently, the (111) facets are not correlated each other, indicating that pure Ag and pure Cu (111) facets can be observed in a given nanocluster. These simulations allow us to propose a surface phase diagram for the studied Wulff polyhedron.

K1.00310 Mechano-Chemical Stability of Gold Nanoparticles Coated with Alkanethiolate SAMs1, BRIAN HENZ, U.S. Army Research Laboratory, TAKUMI HAWA, MICHAEL ZACHARIAH, University of Maryland and National Institute of Standards and Technology — Molecular dynamics simulations are used to probe the structure and stability of alkanethiolate self-assembled monolayers (SAMs) on gold nanoparticles. We have observed that the surface of gold nanoparticles become highly corrugated by the adsorption of the SAMs. Furthermore, as the temperature is increased, the SAMs dissolve into the gold nanoparticle, creating a liquid mixture at temperatures much lower than the melting temperature of the gold nanoparticle. By analyzing the mechanical and chemical properties of gold nanoparticles at temperatures below the melting point of gold, with different SAM chain lengths and surface coverage properties, we have determined that the system is metastable. The model and computational results that provide support for this hypothesis are presented.

K1.00311 Morphology and Growth Dynamics of Buckling Polymer Surfaces, DEREK BREID, Dept. of Polymer Science and Engineering - University of Massachusetts, ALFRED CROSBY, Dept. of Polymer Science and Engineering, University of Massachusetts — Surface buckling is an expected response of a polymer surface when an applied in-plane stress exceeds a material-defined critical stress. This onset of a prescribed surface structure has been gaining increasing attention over the last decade towards applications as diverse as enhanced adhesion and flexible circuitry. However, the majority of research has been performed for systems subjected to stresses well above their critical buckling stress. Here, we highlight recent experiments that characterize the buckle morphology and dynamic buckling behavior of an oxidized PDMS surface swollen with solvent vapor. At low stresses, we observe the spontaneous formation of hexagonally packed microlens arrays not predicted by current buckling theory. These structures coalesce at higher stresses into predicted morphologies. This understanding provides new routes for the controlled formation of surface patterns with complex arrangements and geometries.
K1.00312 Preparation and Characterization of Ta$_2$O$_5$–CeO$_2$ Films, DURSEN SAYGIN HINCZEWSKI, Istanbul Technical University, I.T.U., KENAN KOC, Yildiz Technical Univ., IDRIS SORAR, I.T.U., MICHAEL HINCZEWSKI, TUBITAK Bosphorus Univ, Feza Gursey Institute, FATMA Z. TEPEHAN, I.T.U., GALIP G. TEPEHAN, Kadir Has Univ. — Ta$_2$O$_5$ films have been widely studied due to their chemical and thermal stability, high dielectric constant and refractive index. It is known, for certain composites of Ta$_2$O$_5$–TiO$_2$, Ta$_2$O$_5$–Al$_2$O$_3$, and Ta$_2$O$_5$–ZrO$_2$ polycrystalline ceramics, that there is a significant increase in the dielectric constant compared to pure Ta$_2$O$_5$; this has stimulated research of doped thin films of Ta$_2$O$_5$. In this study [1], the sol-gel spin coating method has been used to make Ta$_2$O$_5$–CeO$_2$ thin films. These films have been prepared in various composition ratios to observe changes in their surface morphology, optical and structural properties. Reflectance and transmittance spectra were collected in the spectral range of 300-1000 nm, and were accurately fit using the Tauc-Lorentz model. Film thicknesses, refractive indices, absorption coefficients, and optical band gaps were extracted from the theoretical fit. The highest refractive index value was found at 5% CeO$_2$-doping. The structure of the films was characterized by XRD and FTIR spectrometry, while the surface morphology was examined through AFM. [1] D. Saygin-Hinczewski, K. Koc, I. Sorar, M. Hinczewski, F.Z. Tepehan, and G.G. Tepehan, Sol. Energy Mater. Sol. Cells 91, 1726 (2007).

K1.00313 On x-ray scattering by solitons in systems of adsorbed atoms, IRINA BARIAKHTAR, Boston College, VICTOR BARYAKHTAR, Institute of Magnetism, Ukraine — The cross section for scattering of x-rays by solitons is calculated. The authors consider solitons corresponding to the formation of a kink in a system of adatoms on the surface of a substrate, or a crowdion in a chain of adatoms in crystals described by the sine-Gordon equation, and also solitons in a bound electron-phonon quasi-one-dimensional molecular chain. It is shown that study of the x-ray scattering provides for the possibility to gather information on the static and dynamic properties of the solitons.

K1.00314 On electromagnetic wave propagation in systems of adsorbed monolayers, IRINA BARIAKHTAR, Boston College, VALERI LOZOVSKI, National University of Kiev, Ukraine — Taking into account the discrete nature of the adsorbed layer, the authors study electromagnetic waves in the system of insulating substrate with the monolayer of adsorbed molecules. Calculated are the dispersion relations of the excitations with s- and p- polarizations localized at the adsorbed layer. To obtain the linear response of such systems, Green’s function approach was undertaken. The susceptibility tensor of the system is expressed in terms of Green’s function, and the pole structure of the susceptibility is investigated.

K1.00315 Complex electronic interference effects in Ag films on Ge(111), YANG LIU, NATHAN SPEER, University of Illinois at Urbana-Champaign, SHU TANG, National Tsing Hua University, THOMAS MILLER, TAI CHIANG, University of Illinois at Urbana-Champaign — We have performed a 3-D mapping by angle-resolved photoemission of the electronic structure of atomically uniform Ag thin films grown on Ge(111). Electrons in the Ag film with energies within the absolute gap of Ge are fully confined, forming quantum well states, while electrons with energies outside this gap form quantum well resonances. In addition to these features, our results show complex interference patterns from which can be attributed to umklapp processes at the interface. The lattice mismatch between Ag and Ge creates an incommensurate interface, which introduces multiple periodicities, resulting in a rich electronic structure. We have performed a detailed numerical analysis of the experimental results, and the interaction parameters, related to the interfacial potential modulation, are extracted.

K1.00316 Effects of Energetic Particles on Friction Behavior of Diamond-like Carbon, KE WANG, HONG LIANG, Texas A&M University, JEAN MICHEL MARTIN, THIERRY LE M OGNE, — This research investigates the failure mechanisms of damages induced by interactions of energetic particles and a diamond-like carbon (DLC) film. Experimental approaches include using an ultra-high vacuum tribometer with attached spectroscopic analysis techniques to generate those particles and conduct in-situ tribological testing. Analytically, using multiple-peaks deconvolution to analyze carbon 1s X-ray photoelectron spectroscopy (XPS) results, the bonding information of C atoms on the surface of DLC film has been extracted. Comparing with friction test results, it is found that the frictional behavior of DLC film (after the reaction with energetic particles) strongly depends on the ratio between sp3 and sp2 hybridization of C atoms on the surface.

K1.00317 Nonextensivity in Magnetic Systems, IVAN OLIVEIRA, DIOGO PINTO SOARES, ROBERTO SARTHOUR, Brazilian Center for Research in Physics, MARIO REIS, Ciceco - Aveiro University — Nonextensive statistics has been successfully applied to different areas of physics, whenever long-range correlations, fractality, inhomogeneity or long memory time are present. Nonextensive thermodynamics is derived from the definition of nonextensive entropy: \[ S_q = k \left( 1 - \sum_i p_i^q \right)/(q-1) \], where \( p_i \) are probabilities and \( q \) is the so-called entropic index. From this definition one obtains the q-density matrix, \( \rho^q \), and, from it, thermodynamically related quantities. In condensed matter, strong correlated systems are good candidates to be studied in the nonextensive approach. The paper is an overview of the results obtained in this field of research. A variety of inhomogeneous media using the nonextensive approach.

K1.00318 Low temperature metamagnetic transitions in single crystal ErNi$_2$B$_2$C: torque magnetometry study, DONALD NAUGLE, K.D.D. RATHNAYAKA, Texas A&M University, BORIS BELEVTSOEV, B. Verkin Institute for Low Temperature Physics and Engineering, SUNG-IK LEE, Pohang University of Science and Technology — The phase diagram of metamagnetic transitions in single-crystal rare-earth nickel borocarbide ErNi$_2$B$_2$C has been determined at 1.9 K with a Quantum Design torque magnetometer. The critical fields of the transitions depend crucially on the angle between applied field and the easy axis [100] in the a-b-plane. Torque measurements have been made while sweeping the magnitude of the magnetic field at a constant angular direction (parallel to basal tetragonal a-b-planes) over an angular range greater than two quadrants. Sequences of metamagnetic transitions with increasing field differ for the fields along (or close enough to) the easy [100] axis from those near the hard [110] axis. These torque measurements reveal new metamagnetic states in ErNi$_2$B$_2$C which were not apparent in previous longitudinal-magnetization and neutron studies. Their nature is considered and clarified. In the low-field range influences of superconductivity are observed and interpreted. 

K1.00319 Phase diagram of Na$_1$-xCaxV2O4 compounds synthesized at high pressure, TAMAS VARGA, JOHN MITCHELL, Argonne Natl Lab, KAZUNARI YAMAURA, DAVID MANDRUS, Oak Ridge Natl Lab, JUN WANG, Argonne Natl Lab — Ambient pressure CaV2O4 and high-pressure Na$_1$V2O4 crystalize in the CaFe2O4 structure type containing double chains of edge-sharing VO6 octahedra. Recent measurements on Na$_2$V2O4 reveal low-dimensional metallicity and evidence of half-metallic ferromagnetism. In contrast, Ca$_2$V2O4 is an antiferromagnetic insulator. To explore the evolution of these ground-state behaviors, we have prepared a series of Ca-doped Na$_2$V2O4 compounds with the formula Na$_{1-x}$CaxV2O4 (x=0-1) using high-pressure synthesis. The lattice parameters of Na$_{1-x}$CaxV2O4 samples change with nominal x according to Vegard’s law. The metallic state in Na$_2$V2O4 is dramatically altered by Ca doping. Samples with higher Ca concentrations (x=0.6-0.8) exhibit a metal-insulator transition around 150 K. Samples at the Na end (x=0-0.2) show a broad antiferromagnetic transition in the 120-160 K range in accordance with earlier reports. With increased Ca doping, the antiferromagnetic transition is suppressed to ∼70 K at the Ca-endmember. Transport measurements show an insulator-metal transition at x∼0.4. Comparison to existing studies at the Ca- and Na-rich ends will be discussed along with a schematic (T-x) phase diagram for the Na$_{1-x}$CaxV2O4.
This work was supported in part by National Natural Science Foundation of China (Grant No.50272009, 50572024), and NSF-PREM program (Grant No. 0351449).
K1.00328 Structural and physical properties of Fe-doped LiMn\textsubscript{2}O\textsubscript{4} oxides\textsuperscript{1}, YANG LI, Department of Engineering Science and Materials, University of Puerto Rico at Mayaguez, PR 00681, USA, BOYU MA, NING CHEN, YANG LIU, WEIPENG WANG, AIHUA WANG, XINGQIAO MA, GUOHUI CAO, Department of Physics, University of Science and Technology Beijing, 100083, China — A joint experimental and theoretical study of the physical property and electronic structures in Fe-doped LiMn\textsubscript{2}O\textsubscript{4} has been performed. The samples with pure phase are prepared by the solid reaction. The X-ray diffraction refinement and SEM analysis show that Fe enters lattice to occupy Mn site. The physical property measurements indicate that Fe doping results in modification of microstructure. The physical properties heavily depend on Fe-doping concentration. The first-principles simulations show that charge ordering and magnetic ordering occur in Fe-doped samples. The electron increasing in the system results in carrier concentration changing.

\textsuperscript{1}This work was supported in part by National Natural Science Foundation of Beijing (Grant No. 1072007), and National Science Foundation PREM program (Grant No. 0351449)

K1.00329 Small Angle X-ray Scattering of Self-assembling Systems Composed of Phosphocholine Lipids and Dendrimers, DEREK DORMAN, PAUL RUSSO, Louisiana State University — Polypropyleneimine tetraamine (DAB-Am) and 1-directional arboral dendrimers have been studied in different molar concentrations with 1,2-Dioleoyl-sn-Glycero-3-phosphocholine (DOPC). One-directional arborals are amphiphilic dendrimers with hydrophilic head group composed of 9 hydroxyl groups and a short alkyl chain for the hydrophobic tail. Film and liposome shell thickness was determined using small angle x-ray scattering beamline at the Center for Advanced Microstructures and Devices at Louisiana State University.

K1.00330 Conformational Space of Hydroxyacetone Studied by Matrix-Isolation FTIR Spectroscopy and Quantum Chemical Methods\textsuperscript{1}, A. SHARMA, I. REVA, R. FAUSTO, University of Coimbra, Portugal — The matrix-isolation FTIR spectrum of hydroxyacetone monomers isolated in Ar matrix at 12K was studied. Interpretation of the experiment was aided by MP2 and DFT calculations at the 6-311++G(d,p) level. A 2D potential energy surface, in the space of OCCO and HOCC dihedral angles, revealed 4 non-equivalent minima, C\textsubscript{c}, T\textsubscript{g}, T\textsubscript{t} and C\textsubscript{t}. The energy barriers for T\textsubscript{g}→T\textsubscript{t} and C\textsubscript{t}→C\textsubscript{c} conversions (0.7 kJ/mol both) were found to be below the zero-point vibrational level associated with the isomerization coordinate of the higher energy form in each pair (T\textsubscript{g} and C\textsubscript{t}). Then, only C\textsubscript{c} and T\textsubscript{t} forms have physical meaning. In accord with the relative energy calculated for T\textsubscript{t} (>11 kJ/mol), its estimated population in gas phase at 298K is only 1%. Indeed, only C\textsubscript{c} form was experimentally detected. Its characterization included the full interpretation of the vibrational spectrum and the calculation of the NMR spectra of the compound in different media.

\textsuperscript{1}This work was supported by Portuguese Science Foundation (FCT) Grant n SFRH/BPD/31840/2006 and Research Projects POCI/QUI/58937/2004 and POCI/QUI/59019/2004.

K1.00331 Synthesis and characterization of size-selected Ag nanoparticles with icosahedral shape\textsuperscript{1}, MIGUEL GRACIA-PINILLA, EDUARDO PEREZ-TIJERINA, SERGIO MEJIA-ROSALES, Universidad Autonoma de Nuevo Leon, MIGUEL JOSE-YACAMAN, University of Texas at Austin — We report the synthesis of Ag nanoparticles, produced by the technique of Inert Gas Aggregation, which allows a very precise selection of the nanoparticle sizes and deviations. We found the optimal experimental conditions to synthesize nanoparticles of six different sizes: 1.3±0.24, 1.7±0.35, 2.5±0.44, 3.7±0.41, 4.5±0.88, and 5.5±0.24 nm. With this, we were able to investigate the dependence of the size of the nanoparticles on the synthesis parameters. Our data suggest that the aggregation of clusters (dimers, trimers, etc) inside of the nanocluster source is the predominant physical mechanism for the formation of the nanoparticles. In order to preserve their structural and morphological properties, the impact energy of the clusters landing into the substrate was controlled; the acceleration energy of the nanoparticles was around 0.1 eV/atom, assuring a deposition in a soft landing fashion. HRTEM and HAADF-STEM images showed that the particles were icosahedral.

\textsuperscript{1}This work was supported by CONACYT, (scholarship 207569).

K1.00332 Directed polymer in random media with a defect, JIN MIN KIM, JAE HWAN LEE, Soongsil University — We investigate a directed polymer in random media with an attractive defect at the center of the one dimensional substrate. Without the defect, end to end distance $\Delta x \sim x^{1/2}$ with $x = 2/3$ which is related to the value of the dynamic exponent in Kardar-Parisi-Zhang equation. When the defect strength $\epsilon$ is weak, its contribution to $\Delta x$ is negligible. If $\epsilon > \epsilon_c$, then $\Delta x$ becomes constant. This kind of transition is related to a queuing phenomena in the asymmetric simple exclusion process. Various critical exponents near the transition point are also discussed.

K1.00333 Thermal conductivity measurements of Bi\textsubscript{2}Te\textsubscript{3} nanowire arrays in anodic aluminum oxide template by 3$\omega$ method, PING-CHUNG LEE, CHENG-LUNG CHEN, MIN-NAN OU, YANG-YUAN CHEN, Institute of Physics, Academia Sinica — Bismuth telluride is a thermoelectric material which is famous for its high figure of merit $ZT \sim 1$. Theoretical predictions propose that the thermoelectric properties of nanowires could be greatly enhanced compared to its bulk form. We have prepared Anodic Aluminum Oxide (AAO) templates with 60 nm pore diameter, 80 $\mu$m thick and ~30% porosity, and synthesized bismuth telluride nanowire arrays into the AAO template by electrodeposition. The modified version of the 3$\omega$ slope method [1] was employed to measure the anisotropic thermal conductivity of the nanowire array in AAO template. This report presents the temperature dependent cross-plane (parallel to nanochannel) and in-plane (perpendicular to nanochannel) thermal conductivity of the nanowires. And estimate the thermal conductivity of bismuth telluride nanowire specifically by using a nanowire filling factor of ~30% in a temperature range of 80-300 K.

K1.00334 Theoretical Study on F atom diffusion on Si(111) surface, NARA JUN, National Institute for Materials Science and Institute of Industrial Science, University of Tokyo, YUSUKE ASARI, National Institute for Materials Science, TAKAHIRO OHNO, National Institute for Materials Science and Institute of Industrial Science, University of Tokyo — We studied diffusion mechanisms of fluorine atom adsorbed on Si(111) surface in a low coverage regime by means of the first-principles density functional calculation. Recent experiments found that the diffusion frequency of the fluorine atoms on Si(111)-(7x7) surface is very low and interestingly it is enhanced after the deposition of silicon atoms on the surface. While this measurement strongly suggests that the diffusing extra silicon atoms assist the fluorine migration, the mechanism has not been understood yet. We found that it is hard for F atoms to hop between surface Si atoms directly because of the strong Si-F bonding. Instead we suggest the SiF complex diffusion model, in which SiF bond is kept during diffusion. This model is also understood as the Si atom diffusion with carrying the F atom. This model, in which the activation energy is calculated to be 1.34 eV, can explain the experiment very well. This work was partly supported by RSS21 project in IT program and a Grant-in-Aid for Scientific Research (No.17064017) of MEXT of the Japanese Government.
A setup for simultaneously measuring the thermopower and electrical conductivity of \(\mu\text{m}\)-thickness specimens, CHIH-TING CHEN, Institute of Physics, Academia Sinica, P.C. LEE, Y.Y. CHEN, SERGEY HARUTYUNYAN, INSTITUTE OF PHYSICS, ACADÉMIA SINICA TEAM — We report the concept and configuration of our new setup for measurement of thermopower and electrical conductivity for \(\mu\text{m}\)-thickness specimens, especially for thermoelectric materials. It is very difficult and tedious to accurately measure the thermopower for specimens with thickness less than \(\sim 100 \mu\text{m}\) due to the limitations of smallest size \(\sim 25 \mu\text{m}\) of thermocouples. Such are obvious when applied to the measurement of nanowire arrays and multilayer. In order to resolve these difficulties, we developed a new setup with integration of Pt-film thermometers and electrical electrodes on two sapphire chips used to clamp specimens with thickness \(\geq 40 \mu\text{m}\) and cross section \(2 \times 3 \text{ mm}^2\). Use this setup the thermopower and electrical conductivity can be measured simultaneously for temperature range 20-400 K. The advantages of the setup are (1) accuracy: the real temperatures of both sides of the sample can be obtained. (2) convenience for loading samples: just assemble the sample between the two microchips and make sure of a good thermal and electrical contacts. A Bi\(_2\)Te\(_3\) nanowire array in AAO template was tested, the thermopower \(\sim 50\text{\mu V}/\text{K}\) was measured for diameter \(60 \mu\text{m}\) of nanowires.

**K1.00336** SNS-Magnetism Reflectometer Initial Measurements, H. AMBAYE, R. GOYETTE, Oak Ridge National Lab-SNS, G. FELCHER, Argonne National Lab, A. PARIZZI, Oak Ridge National Lab-SNS, F. KLOSE, ANSTO — The SNS Magnetism Reflectometer is one of the first three operational SNS instruments. Its construction was completed in May 2006 and the first data sets were collected in July 2006, shortly after passing the instrument readiness safety review. The beamline commissioning proceeds in parallel to the power ramp up of the SNS accelerator. While the initial reflectivity measurements were taken with only 250 Watts of proton power, by mid November 2006 proton power had already increased to 60 kW, making the SNS the most intense pulsed neutron source on a per pulse basis and in August 2007 by running at 185kW became the most intense source in the world. In this presentation, initial commissioning results for the Magnetism Reflectometer, in particular beam intensity/divergence measurements, tests of the polarized neutron equipment (super mirror polarizer, large spin flippers) as well as transmission measurements of the bandwidth limiting chopper systems and some science reflectivity measurements will be presented. Reflectivity data for magnetic MgO and Si3Na/Mn multilayer will be discussed in this presentation. The magnetic MgO:N(2.2%) is a system that is doped with 2.2% Nitrogen there by introducing a local magnetic moment of about 8emu/cc. The SNS Magnetism Reflectometer on beamline 4A shares a common primary beam port and shutter with the SNS Liquids Reflectometer (BL4B) from which it is separated by 4.8˚ in horizontal angle. Individual secondary shutters allow operating the two instruments independently.

**K1.00337** Magnetic resonance force microscopy with two-dimensional spatial encoding, KAI W. EBERHARDT, URBAN MEIER, ANDREAS HUNKELER, BEAT H. MEIER, ETH Zurich — We demonstrate a novel method of creating Magnetic Resonance Force Microscopy (MRFM) images that eliminates the need to scan the probe-sample distance. Conventionally, scanning a magnetic tip over the sample in at least two dimensions is required for imaging with MRFM. At each position the signal from a different slice of the sample is acquired, where the slice is defined by the rf field and the ferromagnetic gradient tip geometry. An image can be reconstructed by deconvolving the shape of the slice from the data. The new method we demonstrate keeps the sample-tip distance constant and resolves the signal origin by spatial encoding with rf pulses. For spatial encoding in one dimension rf pulses are applied with a gradient field coil. These pulses produce a Fourier-encoding in the longitudinal magnetization. In the second dimension Hadamard encoding [1] is employed. 2D images of a patterned (NH\(_4\))\(_2\)SO\(_4\) crystal sample are reconstructed from the known field distributions with a resolution of 1 \(\mu\text{m}\) at room temperature. [1] K. W. Eberhardt et al., Phys. Rev. B 76: 180405 (2007)

**K1.00338** Optical and Transport Study of Nanocomposite Film of Polymer and PbS Quantum Dots, JIAN ZHANG, XIAOMEI JIANG, Department of Physics, University of South Florida — Optical studies have been done with nanocomposite of conjugated polymers with colloidal lead sulfide PbS quantum dots (QDs). Partial quenching of polymer photoluminescence by PbSe QDs showed the co-existence of energy and charge transfer within this system. Further investigation by means of cw spectroscopy (including photoluminescence action spectroscopy, photo-induced absorption spectroscopy and photoluminescence quantum efficiency) have been rendered for comprehensive study regarding photogenerated charge transfer. Transient transport and time of flight measurements have been employed to conduct mobility and recombination rate study of the same film. The size dependent optoelectronic properties were observed and explained by model fittings. Life time and activation energies were drawn from the fittings. Study also shows improvement on both optical absorption and charge transfer properties with QDs being treated with post-synthesis ligands exchange.

**K1.00339** Multiscale modeling of early stage growth of CNTs produced by a catalytic CVD process, JAMES ELLIOTT, University of Cambridge, YASUSHI SHIBUTA, University of Tokyo — The catalytic chemical vapour deposition process is a widely used method for the production of single and multi-wall carbon nanotubes (CNTs), but there remain many uncertainties concerning the precise synthesis mechanisms and the properties of the CNTs that can be produced. Hence, we have developed a parameterized mesoscale model to simulate the early stages of growth of CNTs, and used this to establish a connection between the carbon-catalyst interaction energy, carbon deposition rate and catalyst particle shape and size and the type of CNT produced. The interaction energies for the various components of the model were determined using molecular dynamics simulations [1] using potential functions previously derived from density functional calculations [2] for cobalt, iron and nickel catalyst particles interacting with carbon. We present results from simulations for the different surface energies of the carbon mesh on various metal nanoparticles, and also influence of additives, such as sulfur or oxygen, on the graphitization ability of transition metals via semi-empirical molecular orbital calculations. [1] Y. Shibuta, J.A. Elliott, Chem. Phys. Lett., 427, 365-370 (2006). [2] Y. Shibuta and S. Maruyama, Comp. Mater. Sci., 39, 842-848 (2007).

**K1.00340** Investigation of a potential force-generation machinery driven by a cytoskeletal Walker-type ATPase in prokaryotic cells, ANDREAS ERBE, SING-YI HOU, CHEN-YUN CHEN, YI-LIH LIN, JIE-PAN SHEN, LI-JING LIN, CHIA-FU CHOU, YU-LING SHIH, Academia Sinica — Cytoskeletal proteins are often involved in generating mechanical force to drive various cellular processes. A subgroup of the Walker-type ATPases acts as cytoskeletal proteins that show highly dynamic behavior in bacterial cells. One of the most prominent examples is MinD that works with other cellular components to prevent cell division at unwanted polar sites through cycles of pole-to-pole oscillation in E. coli cells. We use fluorescence microscopy techniques to study the process of MinD assembly and disassembly on a lipid bilayer membrane surface and any possible change of membrane properties caused by MinD association with the membrane. To form a supported bilayer membrane, vesicles of the polar or total extract of E. coli membrane or synthetic lipids of defined composition are adsorbed to a treated glass coverslip. Ca\(^{2+}\) is added to enable vesicle fusion to form a continuous bilayer on a glass surface. Formation of a bilayer is examined using fluorescence recovery after photobleaching. The results on the protein assembly on membranes present an important step in understanding the intermediate stages that occur during the dynamic movement of MinD in cells.

**K1.00341** Resistive Small-World Networks, ALICE KOLAKOWSKA, Florida Institute of Technology — The focus of this study is small-world network where there are at least two network paths between any two nodes and the edges have uniform Ohmic resistance. Assuming that signals can locally propagate along the edges between nearest-neighbor nodes due to only potential difference between the nodes, the question being asked is about the global propagation of signals through the network. Simulations demonstrate that the average equivalent resistance of random conductive network follows the average geodesic path but only for highly-connected networks. One physical realization of this situation are conduction paths observed during electrical breakdown.

Session L1 APS DAMOP: Nobel Prize Session followed by Onsager Prize Session Morial Convention Center LaLouisiane AB

2:30PM L1.00001 Recent developments and perspective in spintronics, A. FERT, UMR CNRS/Thales, 91767 Palaiseau and Université Paris-Sud, 91405 Orsay, France — Recent developments and perspective in spintronics: A. Fert, UMR CNRS/Thales, 91767 Palaiseau and Université Paris-Sud, 91405 Orsay, France After an introduction on the fundamentals of spin transport and the discovery of GMR, I will focus on the most recent developments in spintronics. I will first describe the field of the spin transfer phenomena by reviewing experimental results on magnetic switching and generation of microwave oscillations by spin transfer. The synchronization and phase locking of a collection of STOs (Spin Transfer Oscillators) is an example of new important problem raised by the experiments of spin transfer. I will present data on the synchronization of electrically connected STO. I will then continue the review with results on spintronics with semiconductors, molecular spintronics and spin Hall effect.

3:06PM L1.00002 From spinwaves to Giant Magnetoresistance (GMR) and beyond, PETER GRUENBERG1. Institut fuer Festkoerperforschung Forschungszentrum Juelich — Standing spinwaves and surface waves in layered magnetic structures can be used for the detection and quantitative evaluation of interlayer exchange coupling (IEC). Using this method antiferromagnetic IEC has been found in Fe/Cr/Fe layered structures. This was applied to switch the alignment of the magnetizations of the Fe films in an external field from antiparallel to parallel whereby the Giant Magnetoresistance (GMR) effect was discovered. Currently the interest focuses on “Current Induced Magnetic Switching” (CIMS) which can be understood as inverse GMR effect. For all three effects, IEC, GMR and CIMS there are many interesting applications.

1Presented as Nobel lecture in Stockholm on 8th December, 2007

3:42PM L1.00003 Lars Onsager Prize Talk: Quantum fluids: from liquid helium to cold atoms, CHRISTOPHER PETHICK, Nordita and University of Copenhagen — The study of quantum liquids has led to ideas and concepts of broad applicability. I shall illustrate this by examples from the physics of liquid helium-3, heavy-fermion compounds, quark-gluon plasmas and cold atomic gases.

4:18PM L1.00004 Lars Onsager Prize Talk: Stepping through forty years of quantum fluids, GORDON BAYM, University of Illinois at Urbana-Champaign — This talk will trace milestones in quantum fluids from dilute solutions of He-3 in He-4, to superfluids in neutron stars, to cold atoms.

4:54PM L1.00005 Lars Onsager Prize Talk: A New Challenge for Cold Atom Physics: Achieving the Strongly Correlated Regimes for Cold Atoms in Optical Lattices, TIN-LUN (JASON) HO, The Ohio State University — Cold atoms in optical lattices show great promise to generate a whole host of new strongly correlated states and to emulate many theoretical models for strongly interacting electronic systems. However, to reach these strongly correlated regimes, we need to reach unprecedented low temperatures within current experimental settings. To achieve this, it is necessary to remove considerable amount of entropy from the system. Here, we point out a general principle for removing entropies of quantum gases in optical lattices which will allow one to reach some extraordinarily low temperature scales.

Session L2 DCMP DMP: The Physics of Next Generation Photovoltaics Morial Convention Center LaLouisiane C

2:30PM L2.00001 Nano-Structured Silicon Thin Films for Photovoltaic Applications, P. CRAIG TAYLOR, Colorado School of Mines — The current technology for thin-film silicon photovoltaic panels is based on hydrogenated amorphous silicon and related alloys, such as silicon-germanium and silicon-carbon. Currently there is great interest in using some form of thin-film silicon that includes nano-structured components. This interest is driven in part by the potential for decreased cost, increased efficiency, and increased stability. Also driving this interest is the abundance of silicon as an element and its lack of toxicity. I will review various structures that have been suggested, and discuss recent results on inhomogeneous films of hydrogenated amorphous silicon that contain nanocrystalline inclusions. In particular, I will describe the mechanisms for optical absorption, carrier transport and the role of defects.
mechanisms at electrochemical interfaces; an efficiency and reliability with industrial credibility have been demonstrated and verified, and a significant role in production. G24 Innovations PLC in Wales is commissioning a manufacturing plant, and Dyesol PLC in Australia is making available the required materials certified, and a stability of over 14,000 hours under accelerated testing with continuous simulated AM1.5 illumination was recently reported. In consequence and frequently a nanodispersed Pt precipitated from hexachloride solution is employed. It is by now evident that the achievement of an industrially-competitive dye—semiconductor bond. A wide range of organic systems were therefore investigated, with the present favored formulation being based on imidazole salts. The iodine/iodide system, with the advantage that the ions, both oxidized and reduced are relatively small, and therefore mobile in the supporting electrolyte. Energy therefore a sophisticated molecular engineering product. The electrolyte is also an optimized electrochemical system. The basic redox behavior is provided by the modified by substitution with thiocyanide groups. Chemisorptive attachment of the dye to the metal oxide surface is obtained by carboxyl groups attached properties expected. A ruthenium-pyridyl complex provides the chromophore of the dye, with the HOMO-LUMO gap, and thence the absorption spectrum bring convenient thin-film process such as screen printing or tape casting. The preferred dye system is inspired by the natural processes involving chlorophyll, the can be determined by hydrothermal processing of a precursor sol, and the film can be deposited on a transparent conducting oxide (TCO) substrate by any photoelectrochemical applications is titanium dioxide in the anatase crystal structure. The size of the nanocrystals making up the semiconductor photoanode also a highly-disordered, even porous, semiconductor structure is acceptable, enabling surface adsorption of a sufficient concentration of the dye to permit total absorption of incident light of photon energy greater than the HOMO-LUMO gap of the dye molecule. The accepted wide-band semiconductor for photovoltaic applications is titanium dioxide in the anatase crystal structure. The size of the nanocrystals making up the semiconductor photoanode can be determined by hydrothermal processing of a precursor sol, and the film can be deposited on a transparent conducting oxide (TCO) substrate by any convenient thin-film process such as screen printing or tape casting. The preferred dye system is inspired by the natural processes involving chlorophyll, the coloring material in plants on which all earthly life depends. Chlorophyll is an organometallic dye, with a metal ion, Mg, within a porphyrin cage of nitrogen atoms. The synthetic chemist of course can select any convenient metal within the periodic table, and experience shows that ruthenium has the optimal properties expected. A ruthenium-pyridyl complex provides the chromophore of the dye, with the HOMO-LUMO gap, and thence the absorption spectrum bring modified by substitution with thiocyanide groups. Chemisorptive attachment of the dye to the metal oxide surface is obtained by carboxyl groups attached to the pyridyl components. The energetics of the dye is that the LUMO level is just above the conduction band edge of the semiconductor, enabling relaxation by electron injection as required. A satisfactory electroactive dye structure, with good attachment properties and a wide optical absorption spectrum is therefore a sophisticated molecular engineering product. The electrolyte is also an optimized electrochemical system. The basic redox behavior is provided by the iodine/iodide system, with the advantage that the ions, both oxidized and reduced are relatively small, and therefore mobile in the supporting electrolyte. Energy losses due to slow diffusion is minimized. Early experiments used aqueous electrolytes, though with limited cell lifetime due to hydrolysis of the chemisorptive dye—semiconductor bond. A wide range of organic systems were therefore investigated, with the present favored formulation being based on imidazole salts. These have the additional advantage of low vapour pressure, thereby avoiding as a photovoltaic system the mid—day sun illumination may reach 80 °C or higher. Low losses at the cathode counter electrode are also a requirement for cell efficiency. The cathode is not necessarily transparent, and prototype cells on thin metal foils have been produced. However a TCO on glass or polymer counter electrode is widely used. In either case suitable electrolytically behavior is required and frequently a nanodispersed Pt precipitated from hexachloride solution is employed. It is by now evident that the achievement of an industrially-competitive sensitized photoelectrochemical solar cell is the result of the optimization of several components, associated obviously with their effective synergy. Each change of a single component has repercussions on the choice and performance of others. However as already mentioned an efficiency of over 11% has now been certified, and a stability of over 14,000 hours under accelerated testing of continuous simulated AM1.5 illumination was recently reported. In consequence there is increasing confidence on the part of industry. Several licensees of EPFL patents on dye—sensitized photo voltaic cells are now preparing for large-scale production. Dyesol PLC in Wales is commissioning a manufacturing plant, and Dyesol PLC in Australia is making available the required materials on an industrial scale. In conclusion, then, it can be stated that the DSC system is much more than a fascinating scientific artifact illustrating charge-transfer mechanisms at electrochemical interfaces; an efficiency and reliability with industrial credibility have been demonstrated and verified, and a significant role in competition with other photosystems can be foreseen.
2:30PM L3.00001 The Disordered Kinetics of Earth’s Carbon Cycle

Discussed at a simple box model of soil-vegetation-atmosphere interactions that we recently introduced to study the insulation of summer droughts at continental midlatitudes (D’Andrea et al, GRL 2006, Baudena et al, AWR 2007). I show that the model possesses multiple equilibria and that, for the same synoptic forcing, soil moisture at the beginning of summer and vegetation cover play a primary role in determining which equilibrium will be reached. We also observe a difference in the drought climatologies associated especially with the dynamics of natural vegetation, capable of adapting to the prevailing soil moisture conditions, and with cultivated vegetation such as eggplant, that cannot spontaneously modify its areal extent. I conclude with some speculations on a conceptual model of the interaction between vegetation and climate at global scale. The results discussed in this talk are the product of joint work with Fabio D’Andrea (ENS, Paris) and Mara Baudena (ISAC-CNR).

3:06PM L3.00002 The Quantum and Fluid Mechanics of Global Warming

Support in part by NSF grant no. DMR-0605619.

3:42PM L3.00003 Geostrophic Turbulence and the stability of Ocean models

ANNALISA BRACCO, Georgia Tech — Despite multiple efforts, predictions of climate change remain uncertain. Where precision is an issue (e.g., in a climate forecast), only ensembles of simulations made across model families which differ for parameterizations, discrete algorithms and parameter choices allow an estimate of the level of uncertainty. Is this the best we can do? Or is it at least conceptually possible to reduce these uncertainties? Focusing on ocean models in idealized domains we describe chaotic space-time patterns and equilibrium distributions that mimic nature. Using the Navier-Stokes equations for barotropic flows as a zero-order approximation of analogous flow pattern, we then investigate if it is possible, in this overly-simplified set-up, for which smooth-solutions exist, to bound the uncertainty associated with the numerical domain discretization (i.e. with the limitation imposed by the Reynolds number range we can explore). To do so we analyze a series of stationary barotropic turbulence simulations spanning a range of Reynolds number of 10^3.

4:18PM L3.00004 Heat waves, climate change and eggplant harvests - simple models of climate systems

ANTONELLO PROVENZALE, ISAC-CNR, Torino, Italy — I discuss a simple box model of soil-vegetation-atmosphere interactions that we recently introduced to study the insulation of summer droughts at continental midlatitudes (D’Andrea et al, GRL 2006, Baudena et al, AWR 2007). I show that the model possesses multiple equilibria and that, for the same synoptic forcing, soil moisture at the beginning of summer and vegetation cover play a primary role in determining which equilibrium will be reached. We also observe a difference in the drought climatologies associated especially with the dynamics of natural vegetation, capable of adapting to the prevailing soil moisture conditions, and with cultivated vegetation such as eggplant, that cannot spontaneously modify its areal extent. I conclude with some speculations on a conceptual model of the interaction between vegetation and climate at global scale. The results discussed in this talk are the product of joint work with Fabio D’Andrea (ENS, Paris) and Mara Baudena (ISAC-CNR).

4:54PM L3.00005 Physical Problems in Modeling the Global Ocean

STEPHEN GRIFFIES, NOAA/Geophysical Fluid Dynamics Lab — Understanding and modeling the physical ocean circulation is of primary importance for both enhancing the science of the ocean, and for providing rational projections of future climate. This talk aims to outline fundamental physical and numerical aspects of ocean climate modeling. We highlight features associated with representing elements of the continuum ocean fluid using a discrete model lattice. A major challenge of this representation includes the parameterization of scales which are unresolved by the simulation. This subgrid-scale problem is ubiquitous in computational fluid dynamics, and forms a major focus of ongoing research and development with ocean climate models. Another challenge involves developing robust numerical methods whose truncation errors do not adversely corrupt the quasi-ideal nature of much of the ocean circulation outside of boundary layers. Progress has been made on both fronts, with improvements arising from better understanding of the ocean, smarter methods used to simulate the ocean, and enhancements in computational power.

Tuesday, March 11, 2008 2:30PM - 4:54PM Session L4 DCMP: Bosonic Modes in HTSC

2:30PM L4.00001 STM Observation of a Bosonic Mode in the Electron-Doped Superconductor

2\text{0}_{0.88}\text{LaCe}_{0.12}\text{CuO}_{4-\delta} \text{, VIDYA MADHAVAN, Boston College — Information on bosonic excitations in high temperature superconductors is part of a critical dataset that is necessary to decipher the physics of the pairing mechanism in these materials. In this talk, I will discuss our recent STM investigations of the electron-doped cuprate superconductor 2\text{0}_{0.88}\text{LaCe}_{0.12}\text{CuO}_{4-\delta} (PLCCO) (T_c = 24 K). Our spectra reveal superconducting gaps with coherence peaks that disappear above T_c. In addition, multiple step/peak-like features are observed outside the gap. Such features in STM spectra are suggestive of bosonic excitations that couple strongly to the electrons. Analysis of the data indicates that the observed (bosonic) mode energy in PLCCO lies at 10.5 \pm 2.5 meV which is much lower than the bosonic mode observed in hole-doped BSCCO. The energy scale of our mode is the same as the magnetic resonance mode (spin-excitations) in PLCCO measured by inelastic neutron scattering but is also consistent with a low energy acoustic mode. Additionally, I will show that both the local mode energy and the intensity reveal correlations with the local gap energy scale. The sensitivity of the mode intensity to the energy scale of the onset of the continuum of excitations (\Delta) may indicate an electronic origin rather than phonons. This work was done in collaboration with F. C. Nietsenski, S. Kunwar, S. Zhou, Shiliang Li, H. Ding, Ziqiang Wang, and Pengcheng Dai.
3:06PM L4.00002 Bosonic self energy spectrum of high temperature superconductors from optical spectroscopy1. THOMAS TIMUSK, McMaster University — We address the problem of extracting the bosonic spectral function in high temperature superconductors using optical spectroscopy. Last year, we succeeded in inverting the optical spectra of the cuprates and extract the quantity, analogous to the electron-phonon spectral density $\alpha^2 F(\omega)$ in the conventional superconductors, for YBCO Ortho II system. We used the highly ordered crystals grown by Hardy, Bonn and Liang and compared our results with magnetic neutron spectra on samples from the same source measured by Stock et al. There was excellent agreement between the results of the two sets of spectroscopies. Since then we have refined our inversion technique and have been able to make a similar comparison for the LSCO system with new neutron scattering data from Vignolle et al. This magnetic spectrum, together with our Eliashberg inversion, accounts in a straightforward way for the lower $T_c$ of LSCO as compared to other cuprates. We also offer a detailed prediction of the evolution of the magnetic excitation spectrum with temperature and doping for the highly studied system Bi-2212, a material were neutron scattering data are very hard to get. Our data show that the bosonic self energy function evolves continuously from the broad background.

1Work done in collaboration with Jungseok Hwang, Jules Carbotte and Ewald Schachinger

3:42PM L4.00003 Visualizing pair formation in $Bi_2Sr_2CaCu_2O_{x=2.5}$. ABHAY PASUPATHY, Princeton University Physics Dept. — Unlike traditional superconductors, the density of states (DOS) of the high-Tc superconductor $Bi_2Sr_2CaCu_2O_{x=2.5}$ shows large nanoscale variations that have been detected using scanning tunneling microscopy (STM) [1,2]. Such variations are seen in the low temperature superconducting gap [1] and in features associated with the coupling of pairs to boson modes [2]. In order to understand these variations in the spectra, we perform atomic resolution STM measurements of $Bi_2Sr_2CaCu_2O_{x=2.5}$ as a function of temperature [3]. Using newly developed experimental techniques, we measure the evolution of the DOS from low temperature ($T<<Tc$) to temperatures where all gaps in the spectrum have disappeared ($T>T^*$). Such measurements show that the pairing gap nucleates in nanoscale regions at temperatures between $Tc$ and $T^*$. By normalizing the low temperature DOS ($T<<(Tc)$ to the DOS at high temperature, we are able to fit the superconducting DOS to the d-wave BCS form. We find that the experimental spectrum deviates from a simple d-wave fit indicating a strong coupling between electrons and bosonic modes. We will discuss the temperature evolution of these as well as other features in the DOS, and correlate such measurements with the inhomogeneity seen in the gap magnitude at low temperature.

Work in collaboration with Kenjiro Gomes, Aakash Pushp, Colin Parker, Shimpei Ono, Genda Gu, Yoichi Ando and Ali Yazdani.

3:48PM L4.00004 Evolution of the gaps through the cuprate phase-diagram. ALAIN SACUTO, University Denis Diderot- Paris 7 — The actual physical origin of the gap at the antinodes, and a clear identification of the superconducting gap are fundamental open issues in the physics of high-Tc superconductors. Here, we present an electronic Raman scattering study of single layer cuprates, as a function of both doping level and temperature. We examine both the evolution of the gaps close to the nodes and at the antinodes in the normal and superconducting sates. On the deeply over-doped side, we show that the anti-nodal gap is a true superconducting gap. In contrast, on the under-doped side, our results reveal the existence of a break point close to optimal doping below which the anti-nodal gap is gradually disconnected from superconductivity. The nature of both the superconducting and normal state is distinctly different on each side of this break point and will be discussed.

Tuesday, March 11, 2008 2:30PM - 5:30PM – Session L5 DCMP: Phase Transitions in Disordered Magnets

2:30PM L5.00001 Dilute anisotropic dipolar systems as random field Ising ferromagnets, MOSHE SCHECHTER, University of British Columbia — We have shown the equivalence, at low energies, of dilute anisotropic dipolar magnets to the Ising model in the presence of an effective randomly longitudional field and an effective transverse field, both of which are independently tunable. In the ferromagnetic (FM) regime, these systems constitute the first realization of the classical, as well as quantum, random field Ising model in a FM system, allowing, in particular, the application of a longitudinal field conjugate to the FM order parameter. In the spin-glass regime [2,3] we elucidate the role of both the hyperfine interactions, which couple the system to a spin bath and change the low-energy degrees of freedom, and the off-diagonal terms of the dipolar interactions, which lead to the effective random field. This resolves long standing questions regarding quantum spin glasses in general, and the quantum phase transition between the spin glass and paramagnetic phases in particular.

1. LiHo$_2$Y$_{1-x}$F$_3$ as a random field Ising ferromagnet, M. Schechter, Cond-mat/0611063.

3:06PM L5.00002 A ferromagnet in a continuously tuneable random field1. D.M. SILEVITCH, James Franck Institute/University of Chicago — The Random-Field Ising Model (RFIM) has been extensively studied as a model system for understanding the effects of disorder in magnets. Since the late 1970s, there has been a particular focus on realizations of the RFIM in site-diluted antiferromagnets. We observe random-field effects in the dilute dipole-coupled ferromagnet LiHo$_2$Y$_{1-x}$F$_3$. In the presence of a magnetic field transverse to the Ising axis ($H_z$), the behavior of LiHo$_2$Y$_{1-x}$F$_3$ becomes increasingly dominated by the influence of random-field terms in the effective Hamiltonian. This is seen experimentally in the shape of the ferromagnetic-paramagnetic phase boundary and in changes to the critical exponents near the classical critical point. We find that above the classical critical point the magnetic susceptibility diverges as $H_z \to 0$, and that the susceptibility both above and below the classical critical point can be collapsed onto a single universal curve using a modified Curie law which explicitly incorporates random-field contributions. The discovery of a ferromagnetic realization of the RFIM opens the door to investigation of the random-field problem with the wide variety of techniques available for probing ferromagnets, including the ability to examine both the statics and dynamics of the random-field problem. It also allows studying the effects of controlled amounts of randomness on the dynamics of domain pinning and the energetics of domain reversal.

1Performed in collaboration with D. Bitko, J. Brooke, S. Ghosh, G. Aeppli, and T.F. Rosenbaum. The work in Chicago was supported by NSF and DOE BES, while work in London was supported by the UK EPSRC and a Wolfson-Royal Society Research Merit Award.
3:42PM L5.00003 Activated quantum criticality of complex systems, BERNARD BARBARA, CNRS, Institut Néel, Grenoble — Magnetization measurements performed on single crystals of Ho$_{x}$Y$_{1-x}$LiF$_4$ with $x \approx 16.5\%$ and 4.5\% show the same behavior for both compositions: (i) absence of divergence of the non-linear susceptibility in a transverse field (ii) same absence of divergence in zero field. These results are in sharp contrast with earlier studies of Ho$_{x}$Y$_{1-x}$LiF$_4$. In (i) the observed lack divergence results from the presence of random fields induced by the applied transverse field (no spin-glass phase transition, as predicted by Schechter, Laflorencie and Stamp). In (ii) its results from important slowing down of the dynamics due to huge energy barriers. Excellent fits for the linear and non-linear susceptibilities with $\ln(M) = -T / (H, T)$ ($\Gamma$ is a functional form), suggesting the possibility of a dynamical phase transition involving thermally activated tunneling states. This model may also be useful for more general quantum dynamics of complex systems at finite temperatures. Scaling of non-linear susceptibility in MnCu and GdAl spin-glasses, Barbara, A. P. Malozemoff, and Y. Imry, PRL, 7, 1852 (1981).

Nuclear spin driven quantum relaxation in LiHo$_{0.002}$Y$_{0.998}$F$_{4}$, R. Giraud, W. Wernsdorfer, A. M. Tkachuk, D. Mailly, and B. Barbara, PRL, 87, 057203 (2001).

Significance of the hyperfine interactions in the phase diagram of LiHo$_{x}$Y$_{1-x}$F$_4$, M. Schechter and P. C.E. Stamp, PRL, 95, 267208 (2005).

3:42PM L6.00003 Use of X-ray absorption spectroscopy in the search for the best LIGO mirror coatings1. STEPHEN C. MCGUIRE, Southern University and A&M College — The Laser Interferometer Gravitational-wave Observatory (LIGO) seeks to improve its sensitivity for gravity-wave detection by a factor of ten during the next phase of operation. Advanced LIGO. In order to achieve this goal it is necessary to design and fabricate test mass mirrors that help minimize the noise in the interferometers and in doing so maximize gravity-wave detection capability. In this talk we will present recent results from our program of X-ray absorption spectroscopy measurements to obtain detailed chemical composition and structure of titania (TiO2)-doped tantala (Ta2O5) multilayers fabricated via ion beam sputtering on SiO2 substrates. Our investigations focus on how the microscopic features of the coatings influence their macroscopic mechanical loss properties. Our goal is to obtain correlations between chemical imurities and/or dopants and the optical and mechanical loss characteristics of these multilayer coatings. To examine our samples we use synchrotron-based X-ray absorption Spectroscopy (XAS) techniques including Extended X-ray Absorption Fine Structure (EXAFS), X-ray Absorption Near Edge Structure (XANES) and X-ray Fluorescence (XRF). We present chemical and structural data obtained at the titanium K-edge and tantalum L2,3-edge as well as relative elemental distribution information (Ti/Ta, Fe/Ta, and Cr/Ta) obtained via XRF. Following a brief description of the LIGO experiment, our program of research in optical materials for use in advanced versions of the interferometer will be described.

4:18PM L6.00004 A Mathematical Solution to the Theoretical Band Gap Underestimation: Predictive Calculations of Properties of Semiconductors1. DIOLA BAGAYOKO, Southern University and A&M College — Most density functional theory (DFT) calculations find band gaps that are 30-50 percent smaller than the experimental ones, as illustrated in this presentation that recalls some popular explanations of this band gap problem, i.e., self-interaction effects and derivative discontinuities of the exchange correlation energy. A survey of the increasingly numerous approaches aimed at resolving the theoretical underestimation follows these explanations. These approaches include the Green function and screened Coulomb approximation (GWA), time dependent density functional theory (TDDFT), the exact exchange and screened exchange methods, and the use of local density approximation (LDA) potentials plus additional potentials located at atomic sites. Using the Rayleigh theorem, we describe a basis set and variational effect inherently associated with calculations that employ a linear combination of atomic orbitals (LCAO) in a variational approach of the Rayleigh-Ritz type. This description concomitantly shows a source of large underestimation errors in calculated band gaps, i.e., an often dramatic lowering of some unoccupied energies on account of the Rayleigh theorem as opposed to the Hamiltonian. We present the Bagayoko, Zhao, and Williams (BZW) method [Phys. Rev. B 60, 1563 (1999); PRB 74, 245214 (2006); and PRB 76, 037101 (2007)] that follows from the description of the aforementioned effect and that leads (a) to DFT and LDA calculated band gaps of semiconductors in agreement with experiment and (b) theoretical predictions of band gaps that are confirmed by experiment. Unlike most calculations, BZW computations solve, self-consistently, a system of two coupled equations. DFT-BZW calculated mass and optical properties (dielectric functions) also agree with measurements. We illustrate ten years of success of the BZW method with its results for GaN, C, Si, 3C-SiC, 4H-SiC, ZnO, AlN, CaF2, ZnSe, w-InN, InAs, and AlN. We conclude with a request to revisit beliefs relative to actual limitations of DFT and of schemes purporting to correct it or to go beyond it.

1Work funded in part by the Department of the Navy, Office of Naval Research (ONR, Award Nos. N00014-05-1-0830 and N00014-05-1-0009), NASA (NNG 05G146G), and the National Science Foundation (NSF, Award No. HRD 0503362).

4:54PM L6.00005 New Possibilities for Understanding Complex Metal Hydrides via Synchrotron X-ray Studies1. TABETHA DOBBINS, Grambling State University and Louisiana Tech University — Ultrasmall-angle x-ray scattering (USAXS) and X-ray absorption spectroscopy (XAS) are used for the study of chemical and morphological changes in metal hydride powder (e.g. NaAlH4) both before and after transition metal salt catalytic dopant additions by high energy ball milling. The variation in surface fractal dimension and particle size with milling time and dopant content were tracked. These studies show that dopant content level (e.g. 2 mol % and 4 mol %) and dopant type (i.e. TiCl2, TiCl3, VC3, and ZrCl4) markedly affects NaAlH4 powder particle surface area (determined using USAXS surface fractal dimension). As well, the chemical reaction between the catalyst and hydride powder was further elucidated using XAS. Ti-metal reacts with the Al desorption product (NaAlH4) to form TiAlx product phases. These studies were able to link powder particle surface area to catalytic doping and were able to link dopant chemical state with dehydrogenation reactant and product phases.

Tuesday, March 11, 2008 2:30PM - 5:30PM –
Session L7 DBP GSNP: Multiscale Phenomena in Biological Physics Morial Convention Center R05

2:30PM L7.00001 Self assembly of natural and synthetic membranes using coarse grain models , MICHAEL L. KLEIN, University of Pennsylvania — The talk will review recent work by the Klein group in deriving force fields for natural and synthetic membrane forming systems. Molecular dynamics studies of the self-assembly will be presented for both types of systems.

3:06PM L7.00002 Bridging time-scale gaps via reaction path optimization , JHIH-WEI CHU, Department of Chemical Engineering, University of California, Berkeley — In this talk I will present a series of new computational methodologies that can be applied to systematically investigate the mechanism, free energy profiles, and rates of large-scale conformational changes of biomolecules. First, we enhance the efficiency of reaction path optimization methods, which use a series of duplicated systems, or replicas, to represent a discrete path by using holonomic constraints instead of reparametrization or using penalty potential functions that measure its next phase of operation. Advanced LIGO. In order to achieve this goal it is necessary to design and fabricate test mass mirrors that help minimize the noise in the interferometers and in doing so maximize gravity-wave detection capability. In this talk we will present recent results from our program of X-ray absorption spectroscopy measurements to obtain detailed chemical composition and structure of titania (TiO2)-doped tantala (Ta2O5) multilayers fabricated via ion beam sputtering on SiO2 substrates. Our investigations focus on how the microscopic features of the coatings influence their macroscopic mechanical loss properties. Our goal is to obtain correlations between chemical imurities and/or dopants and the optical and mechanical loss characteristics of these multilayer coatings. To examine our samples we use synchrotron-based X-ray absorption Spectroscopy (XAS) techniques including Extended X-ray Absorption Fine Structure (EXAFS), X-ray Absorption Near Edge Structure (XANES) and X-ray Fluorescence (XRF). We present chemical and structural data obtained at the titanium K-edge and tantalum L2,3-edge as well as relative elemental distribution information (Ti/Ta, Fe/Ta, and Cr/Ta) obtained via XRF. Following a brief description of the LIGO experiment, our program of research in optical materials for use in advanced versions of the interferometer will be described.

3:42PM L7.00003 A Novel Empirical Potential Function and A Monte Carlo Sampling Technique , JIANPENG MA, Baylor College of Medicine — In protein folding study, two major issues are effective potential function and powerful sampling technique. In this meeting, recent results in both directions will be presented. In terms of potential function, we have developed an orientation-dependent statistical all-atom potential derived from side-chain packing. Test of the new potential on decoy set recognition indicates that it outperforms all the known statistical potential functions in the literature. Applications of this potential in substantially improving side-chain modeling will also be discussed. In terms of sampling technique, I will discuss some new results of a novel Monte Carlo sampling technique that performs simulation via direct computation of partition functions. The results will be compared with those of the well-known Wang-Landau sampling scheme. Application of this new MC method in studying protein folding will also be discussed.

1Work supported by National Science Foundation Grants No(s). PHY-0101177 and PHY-0701652.
J. C. Crocker and D. G. Grier, analyzed. The interaction between two isolated droplets was calculated from their trajectories through the Markovian dynamics extrapolation method developed. The dynamics of droplets at interface were imaged using optical microscopy, from which the droplets' motions were tracked and droplets eliminated surface roughness and thus reduced the complexity of the system. We captured micron-sized oil droplets at water-air interface and measured attraction, but the possibility remains that attraction arises from an irregular contact line on the particles' surfaces. Replacing the solid particles with liquid 1 long-range attraction among microparticles at fluid interfaces. Recent theoretical work represents the simplest system which can capture one of the relevant components of multi-body interactions, the fact that while two particles can freely rotate anisotropy of MOON (Modulated Optical Nanoprobes) particles to simultaneously measure their translation and rotation in an optical microscope. This system — Three colloidal particles were placed in small corrals and the strong correlations between their translation and rotation were quantified using the optical — A large variety of nanoparticles holds extraordinary promises for practical applications, e.g., in catalysis and materials science. For these and other applications it is necessary to assemble the nanoparticles to yield supra-molecular aggregates of desired morphology. We are interested in the self-assembly of spherical colloids (i.e., nanoparticles) induced by interactions that become anisotropic because of entropic effects. Thus short polymer brushes are grafted on restricted regions of the spherical nanoparticles considered (e.g., the equatorial plane). Monte Carlo simulations were conducted to assess the properties of the self-assembled nanostructures as a function of the length of the brushes and of the strength of the particle-particle attraction. Depending on the specific solution conditions (particle-particle dispersive attractions, as well as length and density of the grafted polymer brushes) it is possible to obtain uniform dispersions, irregular aggregates, spherulites, one-dimensional wires, and two-dimensional colloidal sheets. We will discuss whether or not the effective colloid-colloid pair interactions at infinite-dilute conditions (i.e., the potential of mean force) can be used to predict the emerging behavior of the colloidal nanoparticles at larger concentrations.

2:42PM L9.00002 Emerging Structures for Colloidal Brushes: from Dispersions and Agglomerates to Spherulites, Wires, and beyond. ALBERTO STRIOLO, University of Oklahoma — A large variety of nanoparticles holds extraordinary promises for practical applications, e.g., in catalysis and materials science. For these and other applications it is necessary to assemble the nanoparticles to yield supra-molecular aggregates of desired morphology. We are interested in the self-assembly of spherical colloids (i.e., nanoparticles) induced by interactions that become anisotropic because of entropic effects. Thus short polymer brushes are grafted on restricted regions of the spherical nanoparticles considered (e.g., the equatorial plane). Monte Carlo simulations were conducted to assess the properties of the self-assembled nanostructures as a function of the length of the brushes and of the strength of the particle-particle attraction. Depending on the specific solution conditions (particle-particle dispersive attractions, as well as length and density of the grafted polymer brushes) it is possible to obtain uniform dispersions, irregular aggregates, spherulites, one-dimensional wires, and two-dimensional colloidal sheets. We will discuss whether or not the effective colloid-colloid pair interactions at infinite-dilute conditions (i.e., the potential of mean force) can be used to predict the emerging behavior of the colloidal nanoparticles at larger concentrations.

2:54PM L9.00003 Roughness-controlled depletion interactions for controlling colloidal self-assembly. KUN ZHAO, Dept. of Chemistry, University of California- Los Angeles, THOMAS G. MASON, Deps. of Physics and Chemistry, University of California- Los Angeles — The surfaces of colloidal particles resulting from many new fabrication methods are not molecularly smooth, so understanding how the surface roughness affects the depletion attraction is very important. We show that the depletion attraction between custom-shaped microscale platelets can be suppressed when the nanoscale surface asperity heights become larger than the depletion agent. In the opposite limit, the attraction re-appears and columnar stacks of platelets are formed. Exploiting this, we selectively increase the site-specific roughness on only one side of the platelets to direct the mass-production of a single desired assembly, a pure dimer phase. Furthermore, we model the interaction between flat plates coated by hemispheres having controlled sizes and densities relative to those of a spherical depletion agent. Overall, these studies provide significant insight into attractive bonds between particles that retain lubrication, and they provide a basis through which more complex assemblies can be made.

3:06PM L9.00004 Corralled Colloids in Four Dimensions. STEPHEN ANTHONY, Department of Chemistry, University of Illinois, MINSU KIM, Department of Physics, University of Illinois, STEVE GRANICK, Department of Materials Science and Engineering, University of Illinois — Three colloidal particles were placed in small corrals and the strong correlations between their translation and rotation were quantified using the optical anisotropy of MOON (Modulated Optical Nanoprobes) particles to simultaneously measure their translation and rotation in an optical microscope. This system represents the simplest system which can capture one of the relevant components of multi-body interactions, the fact that while two particles can freely rotate together (like gears), once a third particle (or gear) is added there is no universally favorable set of rotations. This single multi-body system provides a paradigm of how rotation influences translation and vice-versa.

3:18PM L9.00005 Interactions among microdroplets at the water-air interface. CHUAN ZENG, Department of Physics, University of Massachusetts Amherst, ANTHONY D. DINSMORE — There has been a great mystery concerning the origin of measured long-range attraction among microparticles at fluid interfaces. Recent theoretical work showed that electrostatic interactions should not lead to long-range attraction, but the possibility remains that attraction arises from an irregular contact line on the particles' surfaces. Replacing the solid particles with liquid droplets eliminated surface roughness and thus reduced the complexity of the system. We captured micron-sized oil droplets at water-air interface and measured the interaction between them. The dynamics of droplets at interface were imaged using optical microscopy, from which the droplets' motions were tracked and analyzed. The interaction between two isolated droplets was calculated from their trajectories through the Markovian dynamics extrapolation method developed by J. C. Crocker and D. G. Grier. We acknowledge support from NASA through the Fluid Physics program (NRA 02-OBPR-03-C) and from the NSF-supported MRSEC on Polymers (DME-0213695).

3:30PM L9.00006 Geometrical frustration in colloidal “antiferromagnet”¹, YILONG HAN, Hong Kong University of Science and Technology, YAIR SHOKEF, AHMED ALSAYED, PETER YUNKER, TOM LUBENSKY, ARJUN YODH, University of Pennsylvania — We report experiments about a self-organized colloidal system that exhibits geometrical frustration similar to that of antiferromagnetic Ising spins on a triangular lattice. Novel thermally sensitive microgel NIPA (N-isopropyl acrylamide) spheres are close packed between two parallel flat walls with a vertical separation of about 1.5-particle diameters. The particles form an approximate in-plane triangular lattice. Neighboring particles tend to push each other toward opposite walls leading to out-of-plane local up and down buckling. We tune the strength of such effective antiferromagnetic interactions by varying temperature-tunable diameter of spheres. “Spin” flipping was directly visualized with video microscopy. We investigated the static structures, the dynamics of particles with different degrees of frustration and the degenerated ground state. This experiment is the first dynamic measurement in a geometrical frustrated system at single-particle resolution.

3:42PM L9.00007 Correlated Motion of Ellipsoids Diffusing in 3D, KENNETH DESMOND, ERIC R. WEEKS, Emory University — Currently the hydrodynamic interaction between two ellipsoids in a fluid is not well understood. By observing the Brownian motion of micron sized ellipsoids suspended in a fluid using confocal microscopy, we directly measure these interactions. The ellipsoids exhibit both translational and rotational diffusion. The motion of an ellipsoid induces a flow field, which couples the motion of other ellipsoids with the first one. In our experiments we measure the translational and rotational diffusion of polystyrene ellipsoids suspended in a water glycerol mixture in three dimensions, and examine the spatial correlations between the rotational and translational motion of pairs of ellipsoids. Rotational motions set up a dipolar flow field, and thus the resulting correlations decay quicker than the correlations caused by translations.

3:54PM L9.00008 Simulating Collective Dynamics of Confined Colloids¹, JONATHAN K. WHITMER, ERIK LUITJEN, University of Illinois at Urbana-Champaign — We investigate the dynamical behavior of colloidal particles under confinement, by means of computer simulations that explicitly account for hydrodynamic interactions. Even under dilute conditions, long-range solvent-mediated coupling of the translational and rotational degrees of freedom influences the relative motion of colloidal particles. These effects on the collective dynamics are often ignored in simulations. Our calculations utilize the hybrid Stochastic Rotation Dynamics/Molecular Dynamics method [A. Malevanets and R. Kapral, J. Chem. Phys. 112, 7260 (2000)] to incorporate both hydrodynamic and Brownian forces exerted on colloids by the solvent. The computational results are compared to recent experiments on few-body colloidal systems where the particle number is limited through confinement in a cylindrical trap.

¹This work is supported by the National Science Foundation through Grant No. DMR-0346914.

4:06PM L9.00009 Stripes and their zigzagging in buckled hard spheres, YAIR SHOKEF, University of Pennsylvania, YILONG HAN, Hong Kong University of Science and Technology, AHMED ALSAYED, PETER YUNKER, TOM LUBENSKY, ARJUN YODH, University of Pennsylvania — We use a hard sphere model to describe recent experiments on buckled colloidal monolayers. Our detailed Monte Carlo simulations exhibit the behavior, observed experimentally, of antiferromagnetic order and the formation of stripes that randomly zigzag around the system. Using free volume calculations, we deduce the strength of the effective antiferromagnetic interactions between neighboring particles. We furthermore explain how the geometrical frustration is partially removed by collective effects arising from sphere packing. We show how lattice distortions enable striped configurations to pack better than disordered ground states of the simple antiferromagnetic Ising model and that zigzagging of these stripes does not affect the free volume of the system.

4:18PM L9.00010 Breakdown of Pairwise Additivity in Colloidal Electrostatics¹, SUNIL SAINIS, Yale University, Mechanical Engineering Department, ERIC DUFRESNE, Yale University, Departments of Mechanical Engineering, Chemical Engineering and Physics — Predictions of the structure and stability of charged colloidal suspensions typically assume pairwise additive forces. We directly measure electrostatic forces in small clusters of two to seven particles in a nonpolar solvent. We find that electrostatic interactions are not pairwise additive when the particle separations are much smaller than the screening length.

¹Yale University, Sandia NINE, Cabot Corp.

4:30PM L9.00011 Mystery on Charge Asymmetry: Anionic Macroions in Periodic Lattices Held by Hydrated Cations and Not vice versa¹, WILLIAM KUNG, MONICA OLVERA DE LA CRUZ, Northwestern University — We propose a mean-field analytical model to account for the observed asymmetry in the ability to form long-range attraction by the negatively charged colloidal particles and not their equivalently charged positive counterpart. We conjecture that this asymmetry is due to solvation effects, and we phenomenologically capture its physics by considering the relative strength of this water-induced short-range repulsion between the different charge species. We then apply our model to the colloidal system of negatively charged disks that are neutralized by a sea of counterions and strongly absorbed to an interface in a compressible binary system. We demonstrate the resulting coexistence between a dilute isotropic ionic phase and a condensed hexagonal lattice phase as a function of density and interaction strength.

¹ACS-PCF Grant 44645-AC7.

4:42PM L9.00012 Charged colloids in low polar solvents, ANDREW HOLLINGSWORTH, MIRJAM LEUNISSEN, WILLIAM IRVINE, PAUL CHAIKIN, New York University, ALFONS VAN BLAADEREN, Utrecht University — In a low polar environment, sterically-stabilized poly(methyl methacrylate) spheres become positively charged and exhibit extraordinary long-range repulsive interactions. Confocal microscopy shows that they can form low density, body centered cubic crystals with lattice constants up to 40 microns. We attribute this behavior to the cyclohexyl bromide (CHB) in which the colloidal particles are suspended. CHB is a desirable solvent due to its density matching capability; however, it is difficult to purify. Trace amounts of the hydrogen halide resulting from the hydrolysis of CHB apparently interact with the stabilizer layer, imparting charge to the colloids. Surprisingly, water can also be used to deionize the organic solvent, depending on the relative amounts of the two fluids. The addition of quaternary ammonium salts was used to screen charge (reducing long range particle interaction). Ionic strengths were computed using ionic association theory; in turn, particle charge and surface potentials were estimated from electrokinetic measurements.
4:54PM L9.00013 Direct measurements of the pair potentials of colloids with light scattering and optical traps, KISUN YOON, SEAS, Harvard University, VINOTHAN MANOHARAN, Department of Physics, SEAS, Harvard University — We present a methodology of directly measuring the pair potentials of colloids. We take snapshots of the thermal fluctuation of a pair of colloidal particles in equilibrium. The probability distribution of the separation distance obtained from the snapshots should follow the Boltzmann distribution because the separation distance of the particle pair is the only independent variable necessary to describe the effective free energy of a macrostate of the colloidal particle pair in equilibrium. The measurement of the pair potentials can be achieved by appropriately subtracting the unwanted potentials due to optical traps and optically induced interactions from the effective free energy. Accurate measurement of the separation distance between colloidal particles has critical importance in measuring colloidal interactions. Conventional Video Microscopy used for separation distance measurement is significantly restricted due to the two-dimensional nature of the measurement. Furthermore, the measurement is seriously distorted when the two particles are nearly in contact because of the diffraction of light and multiple scattering effect. We introduce a new technique to accurately measure the separation distances using light scattering. This light scattering technique can measure the separation distance in 3D and appropriately considers the multiple scattering effect.

5:06PM L9.00014 Concentration Gradients in Mixed Magnetic and Nonmagnetic Colloidal Suspensions, RANDALL ERB, BENJAMIN YELLEN, Duke University — The ability to form concentration gradients in mixed magnetic/nonmagnetic colloidal suspensions using magnetic field gradients has many practical applications in the fields of biosensors and life science diagnostics. Previously, we developed and experimentally confirmed a self-consistent model describing the local distribution of magnetic nanoparticles exposed to a magnetic field gradient. Here, we have derived an analytic expression to describe the local concentration of nonmagnetic colloids which are also affected by field gradients when inside magnetic colloidal suspensions. The model calculates the force on particles as a function of local magnetic particle concentration, and solves for the equilibrium distribution of particles through the drift-diffusion equations. We investigate the ability to concentrate and deplete nonmagnetic particles from specific regions of a substrate, such as nearby patterned micro-magnets on a substrate. Also, we have qualitative experimental results to support our expression. Our results show that nonmagnetic particles which are 5-10 times larger than the magnetic nanoparticles can be effectively concentrated or depleted at specified regions of the substrate.

5:18PM L9.00015 Interactions and self assembly of two heterogeneously charged surfaces, ROBERT BREWSTER, Dept. of Materials And Interfaces, Weizmann Institute of Science, PHILIP PINCUS, Dept. of Physics, SAMUEL SAFRAN, Dept. of Materials And Interfaces, Weizmann Institute of Science — Recent experiments1,2 have measured attractive interactions between two surfaces that each bear two molecular species with opposite charge. Theoretical considerations predict equilibrium finite-sized domains of each species, consistent with experiment. These domains, whose observed sizes are typically tens of nanometers, are the result of a balance between the line tension, which prefers macroscopic separation, and the electrostatics, which prefers mixing. Additionally, two such surfaces show a long range attraction. We present a theoretical model that predicts the domain size, phase behavior and forces for two such interacting surfaces.

Tuesday, March 11, 2008 2:30PM - 5:30PM —
Session L10 DMP: Focus Session: Electronic and Vortex Mechanisms for Higher Performing Superconductors Morial Convention Center RO8

2:30PM L10.00001 Exploring the limits of critical currents in superconductors, ALEX GUREVICH, National High Magnetic Field Laboratory, Tallahassee, FL 32310 — Mechanisms, which determine the ultimate limit of the critical current density \( J_c(T, B) \) in superconductors are discussed. The talk is mostly focused on the extreme strong pinning limit of highly deformed vortex segments, the role of anisotropy, current-blocking effects of pinning centers and grain boundaries, thermal fluctuations of vortices in high-\( T_c \) superconductors. In particular, the design of optimum pinning nanostructures, which produce the maximum \( J_c \), is addressed. The results are applied to YBCO thick-film coated conductors with insulating nanoprecipitates, for which several groups have reported very high \( J_c \), values, up to 12-20 % of the depairing current density. Requirements for a putative room-temperature superconductor to be useful in high-field applications are discussed.

3:06PM L10.00002 Current density in YBCO-based Tapes Studied over 8 Decades of Dissipation1, J.R. THOMPSON, Univ Tennessee & Oak Ridge Natl Lab, OZGUR POLAT, Univ. Tennessee, D.K. CHRISTEN, ORNL, D. KUMAR, NC A&T Univ, P.M. MARTIN, ORNL, J.W. SINCLAIR, Univ. Tennessee — Many applications of superconductors require conduction of high density electric currents in a magnetic field, with minimal dissipation. We investigated the dependence of current density \( J \) on electric field \( E \) due to motion of deformed vortices, over a range of \( 10^8 \) in \( E \). The materials are pre-commercial YBa\(_2\)Cu\(_3\)O\(_y\)-\( \gamma \) coated conductors (3.5\( \mu \)m) on buffered Hastelloy substrates prepared by SuperPower, Inc. Experimental methods include conventional 4-probe electrical transport at the highest \( E \) fields; inductive measurements of magnetic moment \( m \sim J \) using a swept magnetic field \( dH/dt \sim E \) at lower \( E \) fields; and time dependent “flux creep” measurement where \( dm/dt \sim E \). At \( T \approx 77 \) K, a power law variation \( E \sim J^\alpha \) is found. The resulting \( E(J) \) dependencies become steeper, i.e., the characteristic \( \alpha \) value increases, as \( J \) is reduced, reflecting a diverging activation energy for vortex movement. The inductive studies are easily extended to lower temperatures and a wide range of magnetic fields. Implications for applications will be discussed.

1 Research sponsored by DOE, Division of Materials Sciences and Engineering, and Office of Electricity Delivery and Energy Reliability.

3:18PM L10.00003 Isotropic critical currents in anisotropic superconductors: a simple physical model1, D.K. CHRISTEN, Y.L. ZUEV, S. WEE, A. GOYAL, S.W. COOK, Oak Ridge National Laboratory — Critical current densities, \( J_c \), that are nearly independent of magnetic field orientation can be observed in intrinsically anisotropic high-temperature superconductors that have specific, very strong flux pinning nanostructure. The phenomenon is observed to occur at specific temperature dependent fields, \( H^*(T) \). The possibility of such isotropic behavior can be described by a simple physical model based on the orientation dependence of the irreversibility field \( H_i(T, \theta) \) and the power-law decay exponent \( \alpha(\theta) \), where \( J_c \propto H_i^{\alpha(\theta)} \) in the intermediate field regime. An analysis will be discussed that elucidates necessary conditions for occurrence of the effect, and provides possible predictive tools for tailoring of \( H^*(T) \) to practical fields and temperatures by means of defect engineering.

1 Research sponsored by the U.S. Department of Energy - Office of Electricity Delivery and Energy Reliability and the Office of Science, Division of Materials Sciences and Engineering
3:30PM L10.00004 Exploring the limits to vortex pinning in superconductors\textsuperscript{1}, LEONARDO CIVALE, Los Alamos National Laboratory — Vortices in type II superconductors sit on a potential energy landscape created by material inhomogeneities. In the presence of an electrical current these inhomogeneities produce a restoring force that precludes vortex motion, thus allowing dissipation-free transport, as long as the current density does not exceed the critical current density $J_c$. Based on present theoretical understanding, by introducing the appropriate type of pinning centers it should be possible to attain $J_c$ values (for low vortex densities) as large as the physical limit determined by the depairing current density $J_0$. However, after decades of large efforts and resources dedicated to pinning enhancement (which has obvious technological relevance) we are far below that limit. Presently, the largest $J_c/J_0$ ratios have been obtained for very thin epitaxial $YBa_2Cu_3O_7$ films and are ~0.3, slightly higher than in the conventional superconductor Nb-Ti ($J_c/J_0 \sim 0.25$). I will analyze the possible reasons for this limitation and discuss possible ways to circumvent it. I will particularly focus on the influence of thermal fluctuations, which promote some level of vortex motion even below $J_c$, resulting in a temporal decay of the supercurrents and consequently lower $J_c$ values as determined by standard experimental techniques. Based on general principles, I will discuss what pinning performance we may expect in yet-to-be-discovered superconductors with high $T_c$.

4:06PM L10.00005 Magnetic field and temperature specific isotropic critical currents in strong-pinning high-temperature superconductors\textsuperscript{1}, Y.L. ZUEV, D.K. CHRISTEN, S.H. WEE, A. GOYAL, S.W. COOK, Oak Ridge National Laboratory — We report the observation of a unique temperature-dependent magnetic field, $H^*(T)$, at which the critical current of ($R$)BaCuO ($R$=rare earth) films with strong c-axis pinning can be nearly isotropic. That is, $J_c(\theta, H^*) \approx$ constant over nearly the entire interval of sample orientation from $H||c$ to $H||ab$ (in the full Lorentz force configuration). The phenomenon is observed in classes of HTS coatings that contain self-assembled, strongly pinning columnar stacks of second-phase precipitates, BaZrO$_3$, oriented near the $c$ axis, and appears to originate from the combination of and offsetting effects of material anisotropies. Systematics of this behavior will be explored and several important control parameters will be identified.

\textsuperscript{1}Research sponsored by the U.S. Department of Energy - Office of Electricity Delivery and Energy Reliability and by the Office of Science, Division of Materials Sciences and Engineering.

4:18PM L10.00006 AC losses in multifilamentary YBCO thin films, RAN YANG, ANDREA LUCARELLI, GUNTER LUEPKE, College of William and Mary, TIMOTHY HAUGAN, PAUL BARNES, AFRL Propulsion Directorate — Striation of superconducting tape allows the reduction of hysteresis losses. We studied the effect of an ac current as a function of the frequency and of a static magnetic field on the flux behavior in multifilamentary $YBa_2Cu_3O_7$ (YBCO) thin films. The current density, the magnetic and electric field profiles are determined quantitatively during the cycle. The shielding and transport current distribution in the filaments are affected by hysteresis and inductive effects that depend on the number and the distribution of the filaments. Time resolved magneto-optical imaging measurements reveal a cross-talk between adjacent conducting filaments that affects the overall hysteresis losses. This new, quantitative and fast method allows us to determine a of dynamic parameters, such as mapping the transport current density and electric field distribution during the ac cycle, that are important for practical superconducting applications and complementary to conventional transport measurement techniques.

4:30PM L10.00007 Evaluation of YBCO to 45T over wide temperature range, ZHIJUN CHEN, FUMITAKE KAMETANI, DAVID LARBALESTIER, Florida State University — The ability to tune the vortex pinning of YBCO in coated conductor form is both an enormous benefit to future superconducting materials applications and a challenge to understanding the properties over a broad range on particular samples. We have been doing such characterizations in support of the design of 30 T magnets. In recent work we have mapped the $J_c$ to fields of 35T at temperatures down to 4K and measured the angular dependent $J_c$ in similar fields. We see that it is possible to enhance $H_{c1}^*$ by about 15% as compared to standard YBCO at 55K, when a high density of RE$_2$O$_3$ nanoprecipitates is formed in the microstructure. These precipitate arrays produce $J_c$ of 50 MA/cm$^2$ almost 20% of the deparing current density.

4:42PM L10.00008 Vortex phases and dynamics in $YBa_2Cu_3O_7$+$BaZrO_3$ films as a function of angle and field up to 50 Tesla, S.A. BAILY, B. MAIOROV, H. ZHOU, S.R. FOLTYN, T.G. HOLESINGER, Q.X. JIA, LEONARDO CIVALE, Superconductivity Technology Center, LANL, Los Alamos, NM, F.F. BALAKIREV, M. JAIME, National High Magnetic Field Laboratory, LANL, Los Alamos, NM — Studying the vortex solid-liquid transition (nematic-0) in high $T_c$ superconductors is scientifically and technologically relevant. We have used low current transport measurements to study the melting line of $YBa_2Cu_3O_7$ films with and without $BaZrO_3$ additions in fields up to 50 T. Samples with mostly extended particle defects, mostly columnar defects, or a mixture of both will be compared. Plain $YBa_2Cu_3O_7$ shows correlated pinning along the crystalline axes and the emergence of a smectic phase when field is aligned with the a-b plane. Inclusion of $BaZrO_3$ not only alters the angular dependence of the irreversibility line indicating the stronger influence of c-axis correlated pinning, but also affects dissipation in the vortex-liquid state over the entire angular range. We will discuss the results in terms of vortex pinning, the corresponding types of phase transitions, micro-structural analysis, and information obtained from critical current measurements.

4:54PM L10.00009 Vortex pinning landscape in MOD-TFA YBCO nanostructured films, J. GUTIERREZ, T. PUIG, A. POMAR, X. OBRADORS, ICMAB-CSIC — A methodology of general validity to study vortex pinning in YBCO based on $J_c$ transport measurements is described. It permits to identify, separate and quantify three basic vortex pinning contributions associated to anisotropic-strong, isotropic-strong and isotropic-weak pinning centers. Thereof, the corresponding vortex pinning phase diagrams are built up. This methodology is applied to the new solution-derived YBCO nanostructured films, including controlled interfacial pinning by the growth of nanostructured templates by means of self-assembled processes [1] and YBCO-$BaZrO_3$ nanocomposites prepared by modified solution precursors. The application of the methodology and comparison with a standard solution-derived YBCO film [2], allows us to identify the nature and the effect of the additional pinning centers induced. The nanostructured templates films show c-axis pinning strongly increased, controlling most of the pinning phase diagram. On the other hand, the nanocomposites have achieved so far, the highest pinning properties in HTS-superconductors [3], being the isotropic-strong defects contribution the origin of their unique properties. 5:06PM L10.00010 Flux dynamics in a two-band superconductor with delocalized electric fields. MILIND N. KUNCHUR, JAMES KNIGHT, Dept. of Physics & Astronomy, University of South Carolina — In conventional flux flow, vortex dissipation is localized to the vicinity of the vortex core leading to a viscous coefficient $\eta$ that is independent of flux density $B$ and a flux-flow resistance $R_f$ becomes independent of $B$, as observed in disordered magnesium diboride. Such an intrinsically field indifferent mixed-state response makes this system especially suited for magnetic-field induced switching.

Work supported by U. S. Department of Energy under grant no. DE-FG02-99ER45763.

5:18PM L10.00011 In-Field Critical Current by Correlated Anti-Pins in Type-II Superconductors. ERIC J. OSWALD, JOSE P. RODRIGUEZ, Physics & Astronomy, California State University at Los Angeles — The critical current shown by films of YBa$_2$Cu$_{3-x}$O$_y$ that contain naturally occurring linear pinning centers aligned parallel to the c-axis decays with increasing magnetic field that is also aligned in parallel as an inverse-square-root power law. Recent theoretical work based on 2D collective pinning of the vortex lattice by such material line defects recovers this dependence on magnetic field in the weak-pinning limit[1]. It further predicts an in-field critical current for correlated antipins that decays with magnetic field more slowly, as an inverse power law characterized by an exponent below 1/2. We test these predictions by performing Langevin dynamics simulations of the corresponding 2D vortex lattice driven by the Lorentz force. Long-range logarithmic interactions between vortices are assumed, while (anti)pinning centers are arranged in a "liquid" fashion. We find indeed that collective pinning by antipins result in a significant critical current. More detailed comparisons with theory in relation to the power-law decay with magnetic field will be made.

Tuesday, March 11, 2008 2:30PM - 5:30PM — Session L11 DCMP: Superconductivity: Transport and Fermi Pockets Morial Convention Center R09

2:30PM L11.00001 Low Temperature Thermal Conductivity in Cuprate Superconductors Amidst Coexisting Charge Order: Part II - Effect of Self-Consistent Disorder and Vertex Corrections. PHILIP SCHIFF, ADAM DURST, Stony Brook University — As in Part I, we consider a d-wave superconductor (dSC) in which the superconductivity coexists with charge density wave (CDW) order of wavevector $(\pi,0)$. Here we discuss two significant improvements to the calculation of the low temperature thermal conductivity. First, rather than taking the 4-by-4 self-energy matrix to be a scalar and a constant, independent of the CDW order parameter, we compute it from an impurity density and scattering potential, within the self-consistent Born approximation. We find that self-consistency requires two off-diagonal terms in the self-energy matrix, in addition to the diagonal term. Furthermore, we find that these off-diagonal terms dominate in the clean limit. Second, we include ladder corrections to the bare vertex, as required to satisfy Ward identities. We compute their contribution, which is verified to be small in the low impurity density limit. However, the contribution of the off-diagonal terms in the self-energy matrix is found to be quite important, significantly reducing the critical value of the CDW order parameter beyond which the thermal conductivity vanishes. Results are used to identify signatures of the effect of charge order on quasiparticle transport in the underdoped cuprates.

2:42PM L11.00002 Low Temperature Thermal Conductivity in Cuprate Superconductors Amidst Coexisting Charge Order: Part I - Bare Bubble Calculation. ADAM DURST, Stony Brook University, SUBIR SACHDEV, Harvard University — We consider a d-wave superconductor (dSC) in which the superconductivity coexists with charge density wave (CDW) order of wavevector $(\pi,0)$. While the nodes of the quasiparticle energy spectrum survive the onset of charge order, there exists a critical value of the CDW order parameter beyond which the quasiparticle spectrum becomes fully gapped. We perform a linear response Kubo formula calculation of thermal conductivity in the low temperature (universal) limit, where a simplified model of disorder has been employed and vertex corrections have been neglected. Effects of self-consistent disorder and vertex corrections are discussed in a separate talk — Part II. Results reveal the dependence of thermal transport on increasing CDW order parameter up to the critical value at which the quasiparticle spectrum becomes fully gapped and thermal conductivity vanishes. In addition to numerical results, closed-form expressions are obtained in the clean limit for the special case of isotropic Dirac nodes.

2:54PM L11.00003 Thermal and electrical transport in a random dissipative quantum system controlled by an infinite randomness critical point. ADRIAN DEL MAESTRO, BERND ROSENOW, MARKUS MUELLER, SUBIR SACHDEV, Harvard University — The complicated interplay between quantum fluctuations and disorder in the vicinity of a quantum phase transition can have drastic effects and lead to exotic Griffiths phases and the flow to infinite randomness. We present a study of a dissipative Hertz-like theory in the presence of quenched disorder which may describe the quantum phase transition between a superconductor and metal in ultra narrow metallic wires tuned by an external source of pair-breaking. By finding a numerical solution to the large-N self-consistency equations for real-space chains we are able to directly compute the finite temperature thermal and electrical correlating through the quantum critical regime. From an analysis of the typical and average correlation functions we find evidence for dynamically activated scaling in accord with recent strong disorder real space renormalization group calculations.

3:06PM L11.00004 Theory of the Marginal Fermi liquid. ARKADY SHEETER, CHANDRAVARMA, UC Riverside — Marginal Fermi liquid is a successful phenomenological description of the strange metallic phase of cuprates near optimal doping. We cast the theory into the standard microscopic form for interacting fermions, employing particle-hole scattering and (singular) Landau parameters. We calculate the density-density correlation function and demonstrate its standard relation to the conductivity through the continuity equation. Internal consistency of the theory is ensured by showing that the relevant conservation laws are obeyed. The relation to the kinetic equation is established.

A.S. is partially supported by I2CAM award from NSF Grant DMR # 0645461.

3:18PM L11.00005 The effect of electron pockets on the quasiparticle interference patterns in cuprate. KANGJUN SEO, JIANGPING HU, Purdue University — We study the hole/electron pockets in the d-density wave and the spin density wave states. While the hole/electron pockets can be seen in the presence of the DDW and the SDW orders, the shape, locations, and the number of the Fermi pockets are different, depending on the band structures and the wavevectors of the order parameters. We calculate the local density of states in the presence and the absence of the electron pockets in the DDW and SDW states. We find that the quasiparticle scattering interference patterns by the single impurity are dramatically affected in the presence of the DDW and SDW order in comparison with one without the electron pockets.
3:30PM L11.00006 Quantum oscillations and Fermi surface in underdoped YBa$_2$Cu$_3$O$_{6.5}$, N. DOIRON-LEYRAUD, Universite de Sherbrooke, CYRIL PROUST, LNCP Toulouse, DAVID LEBOEUF, Universite de Sherbrooke, JULIEN LEVALLOIS, LNCP Toulouse, JEAN-BAPTISTE BONNEMAISON, Universite de Sherbrooke, RUIXING LIANG, DOUG BONN, WALTER HARDY, University of British Columbia and CIAR, LOUIS TAILLEFER, Universite de Sherbrooke and CIAR — We report quantum oscillations in the transport properties of YBa$_2$Cu$_3$O$_{6.5}$ at 10% doping, showing that a well-defined Fermi surface with closed orbits is a fundamental property of underdoped cuprates. In contrast with the large Fermi surface seen on the overdoped side, we observe a very small orbit whose area is only 1.9% of the Brillouin zone. Such a small Fermi surface does not come from the band structure of YBa$_2$Cu$_3$O$_{6.5}$ and is most likely the result of a reconstruction.

3:42PM L11.00007 Shubnikov-de Haas oscillations in YBa$_2$Cu$_3$O$_y$, A. F. BANGURA, J. D. FLETCHER, A. CARRINGTON, P. J. HEARD, N.E. HUSSEY, (Bristol), J. LEVALLOIS, M. NARDONNE, B. VIGNOLLE, C. PROUST, (LNCP, Toulouse), N. DOIRON-LEYRAUD, D. LEBOEUF, T. TAILLEFER, (Sherbrooke), S. ADACHI, (ISTEC, Tokyo) — The recent report of quantum oscillations in the single-chain underdoped cuprate YBa$_2$Cu$_3$O$_{6.5}$ - ortho II (hole doping $p < 0.10$) points to the possibility that the underlying electronic structure in the underdoped region of the cuprate phase diagram contains Fermi surface pocket(s), at odds with results from ARPES experiments. In this talk I will describe our observation of quantum oscillations in the Hall resistivity $\rho_{xy}$ of the stoichiometric double-chain cuprate YBa$_2$Cu$_3$O$_y$ (hole doping $p < 0.14$), in pulsed magnetic fields up to 62T. Our results show that both the area of the quasiparticle orbit and the cyclotron effective mass of YBa$_2$Cu$_3$O$_6$ are larger than those measured for YBa$_2$Cu$_3$O$_{6.5}$ - ortho II. The observed negative Hall coefficient and the failure of LDA bandstructure calculations to account for the oscillations suggests a non-trivial origin. However, clear evidence of quantum oscillations in materials with such different levels of doping and of the details of the transport properties of the two compounds, allows us to conclude that small Fermi surface pocket(s) are a generic feature of the underdoped side of the Yttrium-based cuprate phase diagram and are associated with the CuO$_2$ planes.

3:54PM L11.00008 Electron pockets in the Fermi surface of hole-doped high-Tc superconductors, DAVID LEBOEUF, NICOLAS DOIRON-LEYRAUD, JULIEN LEVALLOIS, RAMZY DAOU, B. BONNEMAISON, NIGEL HUSSEY, LUIS BALICAS, BRAD RAMSHAW, RUIXING LIANG, DOUG BONN, WALTER HARDY, S. ADACHI, CYRIL PROUST, LOUIS TAILLEFER — The Fermi surface of the electronic states in the underdoped YBCO materials YBa$_2$Cu$_3$O$_y$ and YBa$_2$Cu$_4$O$_8$ was recently shown to include small pockets, in contrast with the large cylinder that characterizes the overdoped regime, pointing to a topological change in the Fermi surface. Here we report the observation of a negative Hall resistance in the magnetic-field-induced normal state of YBa$_2$Cu$_3$O$_y$ and YBa$_2$Cu$_4$O$_8$, which reveals that these pockets are electron-like rather than hole-like. We propose that these electron pockets most probably arise from a reconstruction of the Fermi surface caused by the onset of a density-wave phase, as is thought to occur in the electron-doped copper oxides near the onset of antiferromagnetic order.

4:06PM L11.00009 Evidence of Fermi surface reconstruction and the formation of small hole pockets in underdoped La$_{2-x}$Sr$_x$CuO$_4$: Far Infrared Hall measurements, D.C. SCHMADEL, G.S. JENKINS, H.D. DREW, CNAM, University of Maryland at College Park, I. TSUKADA, T. ANDO, Materials Science Research Laboratory, CRIEPI, Tokyo, Japan — The Hall effect in La$_{2-x}$Sr$_x$CuO$_4$ films is measured from 3 to 100 meV as a function of temperature from 5K to 300K and carrier doping ranging from severely underdoped ($x = 0.03$) to optimal doped ($x = 0.15$). The behavior of the infrared Hall angle with temperature and frequency is found to be consistent with a simple extended Drude model at all dopings. A significant reduction of the Hall mass is observed when the hole doping level is reduced from optimal doping, which is consistent with a drastic reduction of the Fermi surface volume. These results are similar to earlier mid-IR Hall measurements obtained in underdoped YBCO. [1] and are related to the recent observation of quantum oscillations reported in YBCO. [2]

The authors acknowledge support of the NSF through grants DMR-0303112.

4:18PM L11.00010 Evidence of Fermi surface reconstruction in Pr$_{2-x}$Ce$_x$CuO$_4$: Far IR Hall measurements in electron doped cuprates, G.S. JENKINS, D.C. SCHMADEL, P. BACH, R.L. GREENE, H.D. DREW, University of Maryland at College Park, CNAM, UNIVERSITY OF MARYLAND AT COLLEGE PARK — The Hall Effect is measured at far infrared frequencies (24-85 1/cm) in Pr$_{2-x}$Ce$_x$CuO$_4$ films as a function of temperature from 5K to 300K and electron doping levels ranging from severely underdoped ($x = 0.10$) to overdoped ($x = 0.19$). In underdoped PCCO, the doping and temperature dependence of the complex Hall angle is found to be consistent with a simple Drude model with an associated reduction of the Hall mass in comparison with optimal doping. The mass reduction is consistent with Fermi surface reconstruction and the formation of small electron pockets. In overdoped PCCO, evidence for both electron and hole contributions to $\sigma_{xy}$ is observed even at low temperatures, a contradictitious result compared with the DC Hall Effect in PCCO as well as the behavior observed in IR Hall measurements in La$_{2-x}$Sr$_x$CuO$_4$. These data suggest interactions through the exchange of incoherent zone corner magnons.

The work was supported by NSF grants DMR-0303112 and DMR-0653535.

4:30PM L11.00011 Disorder and the Metal-Insulator Crossover in Pr$_{2-x}$Ce$_x$CuO$_{1-y}$, P. L. BACH, W. YU, J. S. HIGGINS, H. XU, R. L. GREENE, CNAM, Department of Physics, University of Maryland, B. WEAVER, Naval Research Laboratory — One of the outstanding issues in the electron doped cuprates is the role that oxygenation plays in the superconductivity and normal state properties. Oxygen addition can be considered both a doping and a disordering process. To disentangle these two effects, disorder can be introduced by irradiating the samples without altering doping. We report transport studies on optimal and underdoped Pr$_{2-x}$Ce$_x$CuO$_{1-y}$ films subject to proton irradiation and oxygenation. We establish a correlation between the static AFM and the metal-insulator crossover. Our separation of the disorder and doping effects also shed light on oxygen reduction effects in electron-doped cuprates. Supported by NSF grant DMR-0653535.

4:42PM L11.00012 Doping dependence of the dynamic critical exponent in Pr$_{2-x}$Ce$_x$CuO$_4$, M.C. SULLIVAN, J. SOUSA, M. SALVAGGIO, Department of Physics, Ithaca College, Ithaca NY, R.L. GREENE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland. College Park — Scaling analysis of voltage vs. current isotherms is a favorite tool to study the normal-superconducting phase transition in cuprate superconductors. This measurement has never been performed on the electron-doped cuprate superconductor Pr$_{2-x}$Ce$_x$CuO$_4$, despite unusual behaviors which may alter this phase transition and yield interesting results (behaviors such as the extended doping range of the antiferromagnetic phase and the quantum critical point). This is perhaps due to the lack of consensus regarding the analysis of voltage vs. current isotherms, due in part to finite-thickness effects even in thick ($d \approx 3000\AA$) films. If finite-thickness effects are taken into consideration, we can find the dynamic critical exponent $z$ in our Pr$_{2-x}$Ce$_x$CuO$_4$ films. We present our results of the dynamic critical scaling exponent $z$ as a function of doping.

Supported by NSF grant DMR-0706557.

4:54PM L11.00013 Thermal and electrical transport in the cuprate superconductor Nd-LSCO. 
LOUIS TAILLEFER, R. DAOU, S.Y. LI, DAVID LEBOEUF, OLIVIER CYR-CHONIERE, University of Sherbrooke, J.-Q. YAN, J.-S. ZHOU, J.B. GOODENOUGH, University of Texas at Austin — We present a study of the thermal and electrical transport properties of the cuprate superconductor Nd-LSCO in a wide range of doping from x=0.12 to x=0.25. The behavior of the thermal conductivity in the zero temperature limit allows us to access the quasi-particle transport in both the superconducting and normal state. The impact of stripe order on quasiparticle transport is discussed.

5:06PM L11.00014 Measurements of the Hall Effect and Resistivity in La_{2-x}Sr_{x}CuO_{4+δ} with Ultrafine Stoichiometry Resolution, $\delta x \sim 2.5 \times 10^{-4}$. JEFFREY CLAYHOLD, BRYAN KERNS, MICHAEL SCHROER, DAVID RENCH, Physics Department, Miami University, GENNADY LOGVENOV, ANTHONY BOLLINGER, IVAN BOZOVIC, Brookhaven National Laboratory — Recent reports of sharp changes of transport properties with small variations of stoichiometry in cuprate superconductors have motivated us to look for similar behavior in optimally- and over-doped La_{2-x}Sr_{x}CuO_{4+δ}, using a recently completed system for creating and measuring samples with ultrafine stoichiometry resolution. The data are from MBE films grown with a linear stoichiometry gradient and were taken with a characterization system that can measure both the Hall effect and resistivity simultaneously at 31 different locations on the film. We will show new data for x ranging from 0.15 to 0.30.

5:18PM L11.00015 Magnetotransport and noise in lightly doped La_{2−x}Sr_{x}CuO_{4} and La_{2}Cu_{1−x}Li_{x}O_{4}. IVANA RAICIEVIC, Dept. of Physics and National High Magnetic Field Laboratory (NHMFL), Florida State Univ. (FSU), DRAGANA POPOVIC, NHMFL/FSU, CHRISTOS PANAGOPoulos, Cavendish Laboratory, Univ. of Cambridge, TAKAO SASAGAWA, Materials and Structures Laboratory, Tokyo Institute of Technology — We report a detailed comparative study of magnetotransport and noise in high quality single crystals of La_{2-x}Sr_{x}CuO_{4} (LSCO) and La_{2}Cu_{1-x}Li_{x}O_{4} (x = 0.03) at temperatures 0.100 < T(K) < 150 and fields 0 < B(T) < 18 parallel and perpendicular to the c-axis. Our results demonstrate that, in both materials at low T, the positive magnetoresistance (MR) exhibits signatures of glassiness, such as hysteretic behavior and memory. At such low T < T_{sg} (T_{sg} = spin glass transition temperature), the resistance noise data reveal other glassy features, such as slowing down of the charge dynamics and the onset of cooperativity at T is reduced. The crossover to negative MR takes place at higher T and B in all samples and for both B orientations. However, for B || c, a steep decrease in MR is observed only in La_{2}Cu_{1-x}Li_{x}O_{4} at high T, as the system enters the Néel state, similar to the result obtained on antiferromagnetic LSCO with x = 0.01 [1]. [1] Supported by NSF DMR-0403491, NHMFL via NSF Grant DMR-0084173, and The Royal Society.

2:30PM L12.00001 Phonon Anomalies in α-uranium. XIADONG YANG, PETER RISEBOROUGH, Temple University — The temperature-dependence of the phonon spectrum of α-uranium has recently been measured by Manley et al. [1] using inelastic neutron scattering and x-ray scattering techniques. Although there is scant evidence of anharmonic interactions, the phonons were reported to show some softening of the optic modes at the zone boundary. The same group of authors later reported that an extra mode was observed to form at a temperature above 450 K [2]. The existence of the proposed new mode is inconsistent with the usual theory of harmonic phonons, as applied to a structure composed of a monoclinic Bravais lattice with a two-atom basis. We investigate the effect that the f electron-phonon interaction has on the phonon spectrum and its role on the possible formation of a breathing mode of mixed electronic and phonon character.

Work supported by the US Department of Energy, Office of Basic Energy Sciences.

2:42PM L12.00002 Phonon Spectra and Lattice Thermal Conductivity of UO2 and PuO2. QUAN YIN, SERGEY SAVRASOV, University of California, Davis — Electronic structure, phonon spectrum and lattice thermal conductivity of UO2 and PuO2 are studied using a combination of Density Functional Theory within Local Density Approximation and Dynamical Mean Field Theory (LDA+DMFT). UO2 and PuO2 are mixed oxides fuel (MOX) used in modern thermal reactors. Both oxides are Mott-insulators with strongly correlated 5f electrons, showing very similar electronic structures and phonon dispersions. The calculated phonon dispersion for UO2 is generally consistent with experiment and we give prediction and PuO2 are mixed oxides fuel (MOX) used in modern thermal reactors. Both oxides are Mott-insulators with strongly correlated 5f electrons, showing very similar electronic structures and phonon dispersions. The calculated phonon dispersion for UO2 is generally consistent with experiment and we give prediction when the proposed experiment is consistent with the usual theory of harmonic phonons, as applied to a structure composed of a monoclinic Bravais lattice with a two-atom basis. We investigate the effect that the f electron-phonon interaction has on the phonon spectrum and its role on the possible formation of a breathing mode of mixed electronic and phonon character.

2:54PM L12.00003 Spectral Properties of Plutonium and its Compounds. JIAN-XIN ZHU, Los Alamos National Laboratory, A.K. MCMAHAN, Lawrence Livermore National Laboratory, M.D. JONES, University at Buffalo, SUNY, T. DURAKIEWICZ, J.J. JOYCE, J.M. WILLS, R.C. ALBERS, Los Alamos National Laboratory — By combining the local density approximation (LDA) with dynamical mean field theory (DMFT), we analyze the spectral properties of plutonium and its compounds. The LDA Hamiltonian is extracted either from a tight-binding fit to full-potential linearized augmented plane-wave calculations, or directly from the full-potential linearized muffin tin orbitals calculations. The DMFT equations are solved by the exact quantum Monte Carlo method complemented with the Hubbard-I approximation. We compare the f electron behaviors in Pu elemental solid and compounds. The theoretical results will also be discussed in the context of photoemission spectroscopy data.

3:06PM L12.00004 Crossover from non-Fermi liquid to Fermi liquid behavior: Amplitude of de Haas-van Alphen oscillations. PEDRO SCHLOTTMANN, Florida State University — Deviations from Landau’s Fermi liquid behavior in numerous U, Ce and Yb based heavy fermion systems are known as non-Fermi liquid behavior and are frequently attributed to a quantum critical point (QCP). A nested Fermi surface together with the remaining interaction between carriers after the heavy bands are formed may give rise to itinerant antiferromagnetism. We consider an electron pocket and a hole pocket, with Fermi momenta $k_{F1}$ and $k_{F2}$, respectively. The order can be suppressed by increasing the mismatch of the Fermi momenta and a QCP is obtained as $T_{N} \rightarrow 0$. For the tuned QCP the specific heat over $T$ increases as the logarithm of the temperature as $T$ is lowered [1] and the linewidth of the quasi-particles is linear in $T$ and $\omega$. [2] The numerical results display a crossover from non-Fermi liquid ($\sim T$) to Fermi liquid ($\sim T^{2}$) behavior. [2] Using the quasi-particle linewidth the temperature dependence of the amplitude of the de Haas-van Alphen oscillations (corresponding to the pocket frequencies) is computed.

3:06PM L12.00004 Crossover from non-Fermi liquid to Fermi liquid behavior: Amplitude of de Haas-van Alphen oscillations. Although ferromagnetic ordering does occur in some materials, such as CeRu2Ge2. Extending a previously developed framework [1] for the antiferromagnetic Kondo lattice, we now consider the case where the magnitude of the antiferromagnetic Kondo coupling is small compared to the ferromagnetic RKKY interactions. The magnetic orderings in spin waves and conduction electrons are relevant, resulting in a change in the form of the QNLsM in the appropriate energy and momentum range. At the lowest energies, a gap in the continuum of excitations renders the Kondo coupling irrelevant. We conclude that a ferromagnetic state with a "small" Fermi surface (where local moments are not included in the Fermi volume) is stable. Finally, we discuss how the lack of Kondo screening in magnetic materials is reflected in magnetic properties. We show that, in some cases, spin symmetry breaking does not lead to a reduction of spin symmetry, further emphasizing the need to go beyond the conventional order parameter to characterize these magnetic quantum phases. [1] S. J. Yamamoto and Q. Si, Phys. Rev. Lett. 99, 016401 (2007)

3:42PM L12.00007 Study of the gap formation in Kondo insulators. M. A. MAJIDI, University of North Dakota, K. MIKELSONS, A. MACRIDIN, University of Cincinnati, J. MORENO, University of North Dakota, M. JARRELL, University of Cincinnati — Motivated by recent experimental measurements of the temperature-dependent gap formation in the Kondo insulator SmB6 (Matsunami et al.) we investigate the periodic Anderson Model at half-filling and in the strong-coupling regime. We solve this model in three dimensions using the Dynamical Cluster Approximation to incorporate non-local correlations and the Maximum Entropy Method to derive the spectral functions. We calculate the temperature dependence of the insulating gap and the screened moment, and discuss how the appearance of the gap is related with the lattice Kondo screening.

3:54PM L12.00008 Is FeSi a Kondo Insulator? JAN KUNES, University of Augsburg, VLADIMIR I. ANISIMOVA, Institute of Metal Physics, Yekaterinburg — Using combination of a simple model of local bandstructure and quantum Monte-Carlo technique we show that 3d 'Kondo insulators' such as FeSi and FeSb differ in many respects from classical f-electron based Kondo insulators. In particular we show that hybridization between narrow f-band and a broad conduction band typical for f-electron compounds is not a necessary condition for observation of the typical Kondo insulator behavior of susceptibility and dc as well as ac conductivity. The difference between FeSi and f-electron Kondo insulators becomes apparent when doped, while the former exhibits enhanced susceptibility leading to a Stoner-like ferromagnetic instability the latter are usually characterized by competition between the Kondo screening and local moment magnetism with RKKY inter-site coupling.

4:06PM L12.00009 A Phenomenological Theory of Quantum Tricritical Point: Applications to a Heavy-Fermion Compound YbRh2Si2. TAKAHIRO MISAWA, Department Applied Physics, Univ. of Tokyo, YOUHEI YAMAJI, MASATOSHI IMADA — We construct a phenomenological theory of quantum tricritical point (QTPC) of itinerant antiferromagnets by extending the self-consistent renormalization theory. We have shown that a novel non-Fermi liquid behavior comes out at the QTPC where a continuous phase transition changes into a first-order one at zero temperature. In contrast to the conventional quantum criticality proposed by Moriya, Hertz and Millis, a remarkable feature of the QTPC is the divergence of the ferromagnetic susceptibility at the antiferromagnetic phase transition under the magnetic field. In a heavy-fermion compound YbRh2Si2, enhancement of the ferromagnetic susceptibility near the antiferromagnetic quantum critical point has been an unsolved puzzle. We have shown that the quantum tricriticality naturally explains this puzzling enhancement. In particular, singularities of ferromagnetic susceptibility and the magnetization curve near the QTPC are well consistent with the experimental results.

4:18PM L12.00010 Two Channel Kondo Effect and Superconductivity in Pu and Np compounds. REBECCA FLINT, MAXIM DZERO, PIERS COLEMAN, Rutgers University — Recently, superconductivity has been observed in two heavy fermion compounds, PuCoGa4 and NpPdAl2, which transition directly from unquenched spins into the superconducting state, without passing through an intermediate heavy fermi liquid state. These two compounds can be modeled with the two channel Kondo model, where the two channels derive from virtual valence fluctuations of different crystal symmetries. The electron-spin scattering develops an Andreev component, creating a composite bound state of a spin-flip and a triplet pair of electrons. This process can be examined in a controlled fashion with symplectic N, with the maximum transition temperature occurring when the two channels have equal strengths. We will also discuss the effect of Pu doping on the superconducting transition temperature of NpPdAl2.

4:30PM L12.00011 Fermionic quantum criticality and the fractal nodal surface. FRANK KRUGER, JAN ZAANEN, Institut-Lorentz, Leiden University — Normal metals are characterized by a degeneracy scale imposed by Fermi-Dirac statistics: the Fermi energy. This paradigm breaks down in the high-Tc and heavy-fermion compounds where one encounters metallic states with scale invariant quantum dynamics. A theoretical understanding of these quantum critical states is lacking because the fermionic minus signs render the path integral non-probablistic. We demonstrate that within the constraint-path-integral formalism scale invariance and Fermi-Dirac statistics can be reconciled. The latter is translated into a geometrical constraint structure. We prove that this "nodal hypersurface" encodes the scales of the Fermi liquid and turns fractal when the system becomes quantum critical. To illustrate this we calculate nodal surfaces and electron momentum distributions of Feynman backflow wave functions and indeed find that with increasing backflow strength the quasiparticle mass gradually increases, to diverge when the nodal structure becomes fractal. This explains precisely the puzzling behaviors observed in the heavy-fermion intermetallics.

4:42PM L12.00012 Non-linear Sigma Model of Kondo Lattice in Antiferromagnetic Regime. TZEN ONG, Stanford University, B. A. JONES, IBM Almaden Research Center — We analyze the antiferromagnetic transition in heavy fermion compounds in two dimensions, which is studied in this paper, to be in the antiferromagnetic regime, with a Heisenberg coupling (Jzz) that is larger than the Kondo coupling (JK). The Heisenberg terms are mapped onto a non-linear sigma model, and the fermions are then formally integrated out to obtain an effective theory for the Neel field. We then study the evolution of the Heisenberg and Kondo couplings under perturbative RG, and calculate the critical exponents at the phase transition. Preliminary results indicate the possibility of a quantum phase transition from an AFM to a helical phase with anisotropy in the time-like direction.
Derivation and study of the Fermi-Majorana bi-resonant level model. C. J. BOLECH, Rice University, A. IUCCI, University of Geneva — We review the mapping of the anisotropic two-channel Anderson impurity model to a Fermi-Majorana bi-resonant level model. The correspondence is rigorously proved by using bosonization and explicitly constructing the new fermionic fields and Klein factors in terms of the original ones. We also demonstrate that the fixed points associated to the solvable manifold of the new model are renormalization-group stable and generic, and therefore representative of the physics of the original isotropic model. The simplicity of the mapped model allows for the computation of the full set of thermodynamic quantities as well as the identification of the different physical energy scales. In the absence of external fields the impurity physics is of non-Fermi liquid type. As expected, an arbitrarily small external field breaks some of the symmetries and introduces an extra energy scale below which the system flows to a local Fermi-liquid fixed point.

Tuesday, March 11, 2008 2:30PM - 5:18PM –
Session L13 DCOMP: Ground State Density Functional Theory: Theory Development

2:30PM L13.00001 Strictly correlated electrons in density-functional theory: A general formulation with applications to spherical densities, MICHAELA SEIDL, Institute of Theoretical Physics, University of Regensburg, Germany — We reformulate the strong-interaction limit of electronic density functional theory in terms of a classical problem with a degenerate minimum. This allows us to clarify many aspects of this limit, and to write a general solution which is explicitly calculated for spherical densities. We then compare our results with previous approximate solutions and discuss the implications for density functional theory.

2:42PM L13.00002 Spherically and system-averaged pair densities in the strong-interaction limit of density functional theory, PAOLO GORI-GIORGI, ANDREAS SAVIN, Laboratoire Chimie Théorique, CNRS and University Paris VI, Paris, France, MICHAELA SEIDL, Institute of Theoretical Physics, University of Regensburg, Regensburg, Germany — The spherically and system-averaged pair density (also known in chemistry as intracule density) plays a central role in the construction and understanding of exchange-correlation energy functionals in density functional theory. We have calculated the intracule density for several atoms in the strong-interaction limit of density functional theory. Comparison of our results with the same quantities calculated in the opposite limit, the non-interacting Kohn-Sham system, provides useful insight on the nature of electronic correlation in density functional theory.

2:54PM L13.00003 Internally Consistent Local Approximation to Density Functional Theory, ANTONIOS GONIS, Lawrence Livermore National Laboratory, DON M. NICHOLSON, G. MALCOLM STOCKS, Oak Ridge National Laboratory — We propose a new non-local functional for the implementation of density functional theory (DFT) within a local approximation. This functional is obtained through the replacement of the conventional form $T_\alpha = \frac{1}{2} \int \frac{d\mathbf{r}'}{n_\alpha} \int \frac{d\mathbf{r}_1}{n_\alpha} \frac{n_\alpha(\mathbf{r}_1 + \mathbf{r}_2 - \mathbf{r}')}{n_\alpha(\mathbf{r}_1) n_\alpha(\mathbf{r}_2)}$ to represent the kinetic and Coulomb energy of a non-interacting system with the expression $T_\alpha = \frac{1}{2} \int \frac{d\mathbf{r}_1}{n_\alpha(\mathbf{r}_1)} \int \frac{d\mathbf{r}_2}{n_\alpha(\mathbf{r}_2)} n_\alpha(\mathbf{r}_1 + \mathbf{r}_2 - \mathbf{r}')$, where $n_\alpha(\mathbf{r})$ is the two-particle density formed from the non-interacting wave function, and $n_\alpha(\mathbf{r})$ is the single-particle density. Based on this new functional we develop a local approximation and show that it is self-interaction free and also leads to energies that form an upper bound to the exact ground-state energy. We provide a brief comparison with the conventional Kohn-Sham local density approximation and some of the schemes introduced to correct for the presence of self-interaction in the conventional formalism, and comment on our immediate plans for future development.

3:18PM L13.00005 The Role of Quantum Stress in Descriptive Chemistry, ILYA TOKATLY, Lehrstuhl für Theoretische Festkörperphysik, Universität Erlangen-Nürnberg, Germany, GIOVANNI VIGNALE, University of Missouri-Columbia, JIANMIN TAO, Los Alamos National Laboratory — We show that key concepts of descriptive chemistry, such as atomic shells, bonding electron pairs and lone electron pairs, may be described in terms of quantum stress focusing, i.e. the spontaneous formation of closed surfaces upon which the electronic pressure has an extremum. This description subsumes previous mathematical constructs, such as the Laplacian of the density and the electron localization function, and provides a new tool for visualizing chemical structure. We also show that the full anisotropic stress tensor can be easily calculated from density functional theory.

3:30PM L13.00006 Semiclassical Approaches in Density Functional Theory, PETER ELLIOTT, ATTILA CANGI, DONGHYUNG LEE, KIERON BURKE, University of California, Irvine — We discuss the use of semiclassical methods in understanding, and improving, density functional theory (DFT). It has been found[1] that semiclassical approaches can explain many features of modern exchange-correlation approximations, such as the local density approximation or generalized gradient approximations. In this work, we continue this line of inquiry, showing how semiclassical approximations may be used to construct a form for the non-interacting kinetic energy density. A semiclassical approximation to the Green’s function is made[2], which, when integrated appropriately, yields leading corrections to the Thomas-Fermi result. It can be regarded as a functional of the potential. We test this approximation for various 1D systems confined within a box and present the results. This, coupled with the corresponding form of the density[2], could provide an orbital-free DFT which would allow more complex systems to be studied.

3:42PM L13.00007 Correlation Energy of 3D Spin-Polarized Electron Gas: A Single Interpolation Between High- and Low-Density Limits. JIAWEI SUN, JOHN PERDEW, Department of Physics and Quantum Theory Group, Tulane University, MICHAEL SEIDL, Department of Physics, University of Regensburg. — We present an analytic model for the correlation energy per electron \( N_e \left( \varepsilon \right) \) in the three-dimensional (3D) uniform electron gas, covering the full range \( 0 \leq \varepsilon \leq \infty \) and \( 0 \leq \zeta \leq 1 \) of the density parameter \( r_s \) and the relative spin polarization \( \zeta \). An interpolation is made between the exactly known high-density (\( r_s \to 0 \)) and low-density (\( r_s \to \infty \)) limits, using a formula which (unlike previous ones) has the right analytic structures in both limits. We find that there is almost enough information available from these limits to determine the correlation energy over the full range. By minimal fitting to numerical quantum Monte Carlo data, we predict the value of \( b_1(\zeta) \) at \( \zeta = 0 \) close to the theoretical value [1], where \( b_1(\zeta) \) is the coefficient of the \( r_s \) term in the high-density expansion. The model finds correlation energies for the unpolared \( (\zeta = 0) \) and fully polarized \( (\zeta = 1) \) cases in excellent agreement with Monte Carlo data.

3:54PM L13.00008 Semiclasiﬁc Origin of Density Functionals. ATTILA CANGI, PETER ELLIOTT, DONGHYUN LEE, KIERON BURKE, University of California, Irvine. — We use methods of semiclassical physics [1] to study the basic ingredients of DFT in terms of an asymptotic expansion in powers of the particle number. As an example we derive an approximate many-particle density [2] of a general potential in a one-dimensional system with hard walls. If the Fermi wave number lies above the maximum of the potential, we obtain densities very close to the exact answer, even for a small particle number. Density oscillations due to the effect of the boundaries are also present.

4:06PM L13.00009 Construction of an analytic exchange-correlation hole for the Penderwe-Burke-Ernzerhof GGA. MATTHIAS ERNZERHOF, Department of Chemistry, University of Montreal, HILKE BAHMANN, Department of Chemistry, University of Wuerzburg. — The Perdew-Burke-Ernzerhof (PBE) [1] approximation to the exchange-correlation energy is employed as a starting point for the construction of an approximate, spherically averaged exchange-correlation hole. In a first step, we develop a new model for the PBE exchange hole. This model satisfies the homogeneous electron gas limit; it is normalized and yields the correct small-gradient limit in the system average. A correlation factor [2], i.e., a function multiplying the exchange hole, is proposed that turns the exchange into an exchange-correlation hole. The correlation factor has a simple form and its parameters are determined through a number of known conditions that are satisfied by a PBE exchange-correlation hole. The homogeneous-electron-gas limit of the new hole model is compared to the LSD hole [3].

4:18PM L13.00010 Orbital-free Kinetic Energy Density Functional of GGA Type with Positive-definite, Finite Pauli Potentials. S.B. TRICKEY, QTP, Univ. Florida, V.V. KARASIEV, Instituto Venezolano de Investigaciones Cientificas, R.S. JONES, Physics, Loyola College of Maryland, FRANK HARRIS, Physics, Univ. Utah. — A reliable, orbital-free expression for the Kohn-Sham kinetic energy functional \( T_{KS} \) would provide Born-Oppenheimer forces of first-principle many-particle density [2] of general potential in a one-dimensional system with hard walls. If the Fermi wave number lies above the maximum of the potential, we obtain densities very close to the exact answer, even for a small particle number. Density oscillations due to the effect of the boundaries are also present. Illustrative results will be reported.

1Work supported in part by US NSF ITR Grant DMR-0325553.

4:30PM L13.00011 Exact condition on the non-interacting kinetic energy for real matter. DONGHYUN LEE, KIERON BURKE, University of California, Irvine. — From the analysis of the asymptotic expansion [1,2] for the total energies of neutral atoms, we suggest a modified gradient expansion approximation to the kinetic energy which satisfies the exact asymptotic condition as the number of electrons \( N \to \infty \). The resulting function determines the small gradient limit of any generalized gradient approximation, and conflicts with the standard gradient expansion. We apply this new functional to the atoms up to \( Z \to 88 \) in comparison with the 2nd and 4th gradient expansion approximations. We also give a modern, highly accurate parametrization of the Thomas-Fermi density of neutral atoms.

4:42PM L13.00012 Construction of Wave Function Functionals. MARLINA SLAMET, Sacred Heart University, XIAO-YIN PAN, Ningbo University, VIRAHT SAHNI. The Graduate School, CUNY. — We recently proposed [1] expanding the space of variations in calculations of the energy by considering the approximate wave function \( \Psi = \Phi_0 \) of a function of \( \Phi_0 \), rather than a function. A constrained search is first performed over all functions \( \Phi_0 \) that satisfy a physical constraint or leads to a known value of an observable. A rigorous upper bound to the energy is then obtained via the variational principle. In this paper we apply this idea to the ground state of the He atom by constructing \( \Phi_0 \) that reproduce the exact expectations of the Hermitian single- and two-particle operators \( W = \sum_i r_i^2, n = -2, -1, 1, 2, W = \sum_i \delta(r_i); W_1 = |r_1 - r_2^2|, m = -1, -2, 1, 2 \). The functional \( \Phi_0 \) are of the form \( \Psi_0 = \Phi_0 - f(\chi) \), where \( f(\chi) \) is a prefactor and \( f(\chi) \) a correlation factor. The \( \Psi_0(\chi) \) lead to the exact expectation value of \( W \); (ii) are automatically normalized; and (iii) provide a rigorous upper bound to the energy. [1] X.-Y. Pan, et al, PRA 72, 032505 (2005).

4:54PM L13.00013 LDA+DMFT Charge self-consistency applied to Yb valence transition. ERIK R. YLVISAKER, W. E. PICKETT, UC Davis, A. K. MCMANAHAN, LLNL. — Ytterbium metal, in a pressure range of 0 to 34 GPa, is known to undergo a gradual transition from a \( v^3 f^{14} \) state to a \( v^3 f^{14} \) state where \( v \) and \( f \) represent valence (spd) and d-orbital occupations, respectively. We present, first, conventional LDA+DMFT studies of this transition using both the Hirsch-Fye QMC and Hubbard I atomic solvers. This application of DMFT to the correlated f-orbitals gives reasonable agreement with the experimental transition. However, the neglect of charge self-consistency is questionable for a valence transition where the concentration of valence electrons changes. Therefore we generalize the procedure and compare and contrast LDA+DMFT results (transition pressure, energy and equation of state) with and without charge self-consistency for Yb using the Hubbard I impurity solver.
5:06PM L13.00014 Fock exchange in FLAPW method. TATSUYA SHISHIDOU, TAMIO OGUCHI, Hiroshima University — Fock exchange potential has distinct features which cannot be seen in the LDA exchange potential. (i) It is self-interaction free potential and (ii) nonlocal potential and thus state-dependent potential. With appropriate correlation effects added, these two features may produce significantly improved results over the conventional LDA results, as one can witness in the GW calculations. Massidda et al. (1993) proposed a way to calculate Fock exchange potential of extended solids within the FLAPW method. Their idea was to apply Weinert’s Poisson solver to infinite lattice summation as is done for the Hartree potential calculation. Due to the long range nature of Coulomb interaction, one encounters singularity problem in this process. They handled it by simply extending Gygi’s prescription (1986), which was originally developed for the norm-conserving pseudopotential framework. In this paper, we present our formula in calculating Fock exchange matrix of solids based on the FLAPW method. Following Massidda’s idea, we use Weinert’s Poisson solver. However, in treating the Coulomb singularity, we have developed a more accurate way: the occupied eigenfunctions in Fock operator are expanded up to the second order in terms of \( q \) vector based on the \( k \cdot p \) perturbation theory, whereas Gygi’s way corresponds to the zeroth order expansion. With this higher order expansion, one can achieve faster convergence for the Brillouin zone integration appearing in the Fock operator.

Tuesday, March 11, 2008 2:30PM - 5:30PM —
Session L14 GQI: Focus Session: Foundations of Quantum Theory II Morial Convention Center 205

2:30PM L14.00001 General probabilistic theories for quantum foundations and quantum information. JONATHAN BARRETT, University of Cambridge — Is there any reason why the universe should obey the laws of quantum theory, as opposed to any other possible theory? Is quantum theory special in any way? The best way to address these questions is to view quantum theory as just one point in an entire space of possible theories, and to compare and contrast quantum theory with its rivals. As the success of quantum information theory makes clear, one means by which different theories may be compared and contrasted is via their information processing capabilities. To this end, following early work of Mackey, Ludwig and others, I show how to write down essentially arbitrary probabilistic models, based on the conditions that state spaces are convex and that separated systems cannot be used for instantaneous signalling. Both the classical and quantum theories are special cases. With a focus on information processing, I then describe (i) some features of quantum theory that one might have expected to be uniquely quantum, but turn out to be highly generic, and (ii) some features that do mark quantum theory as special. Some of this is work done in collaboration with Howard Barnum, Matthew Leifer and Alexander Wilce.

3:06PM L14.00002 Fully epistemic toy theory\(^1\), MICHAEL SKOTINIOITIS, AIDAN ROY, BARRY C. SANDERS, Institute for Quantum Information Science, University of Calgary — The Spekkens toy model is an interesting example of how to modify classical physics in order to perform several quantum information processing tasks. Spekkens’ toy model has four axioms concerning toy states, valid operations, measurements, and composition of single toy systems. Motivated by the empirical indistinguishability of epistemic vs. ontic states in the toy universe, we show that relaxing valid operations to mappings of epistemic rather than ontic states preserves the features of the toy model. Similarly we show that relaxing the axiom regarding the composition of single toy systems also preserves the toy model. Relaxing both axioms simultaneously, however, breaks the correspondence of the toy model with quantum theory because the tensor product composition rule is violated, but these two relaxations together produce a group of operations on epistemic states that is isomorphic to the projected extended Clifford Group.

3:18PM L14.00003 Tensor products and teleportation protocols for abstract state spaces. ALEXANDER WILCE, Susquehanna University — In a well-known generalization of classical probability theory, arbitrary compact convex sets serve as abstract “state spaces” for (hypothetical) physical systems, with classical systems corresponding to simplices and quantum systems, to state spaces of \( C^* \)-algebras. One can define natural tensor products for abstract state spaces, modeling composite systems subject to a no-signaling condition. Remarkably, many basic quantum-information-theoretic phenomena, including the no-cloning and no-broadcasting theorems, already appear at this level of generality. However, the existence of a teleportation protocol is a strong constraint, moving us closer to quantum theory. In this talk, after a brief summary of the framework, I will outline what we currently understand about teleportation in this setting. This represents recent and ongoing joint work with Howard Barnum, Jonathan Barrett and Matthew Leifer.

3:30PM L14.00004 The Density Matrix and the Interpretation of Quantum Theory. OWEN MARONEY, Perimeter Institute for Theoretical Physics — Can a density matrix be regarded as a description of the physically real properties of an individual system? If so, it may be possible to attribute the same objective significance to statistical mechanical properties, such as entropy or temperature, as to properties such as mass or energy. Non-linear modifications to unitary evolution can be proposed, based upon this idea, to account for thermodynamic irreversibility. Traditional approaches to interpreting quantum phenomena assume that an individual system is described by a pure state, with density matrices arising only through a statistical mixture or through tracing out entangled degrees of freedom. We discuss how treating the density matrix as fundamental can affect the viability of some of these interpretations, and how the thermodynamically motivated non-linearities do not, in themselves, help in solving the quantum measurement problem.

3:42PM L14.00005 An Approach to Quantum State Pooling from Quantum Conditional Independence\(^1\), MATTHEW LEIFER, University of Waterloo — In approaches to quantum theory in which the quantum state is taken to represent an agent’s belief, knowledge or information about a physical system, it is legitimate for different agents to assign different states to one and the same physical system. The question then arises of what state they should assign if they get together and share their information about the system. This is the problem of quantum state pooling. The classical counterpart of this problem for probability distributions only has a unique solution under additional assumptions about how the data are collected, such as conditional independence constraints. Recently, Spekkens and Wiseman found a quantum pooling rule analogous to the classical one, which is valid if the differing state assignments arise from making indirect measurements on special classes of tripartite quantum state. We show that this pooling rule applies to a much wider class of tripartite states, and that its validity rests on quantum analogs of conditional independence recently studied by one of the authors, as well as a generalization of the notion of a sufficient statistic to the quantum case. Work done in collaboration with Robert Spekkens, University of Cambridge.

\(^1\) ML was supported in part by grant RFP-06-006 from The Foundational Questions Institute (fqxi.org).

4:18PM L14.00006 New results in the category-theoretic approach to foundations of quantum physics. BOB COECKE, Oxford University — We report on some recent results in the category theoretic approach quantum physics, which aims to provide an operational foundation, a logical axiomatics as well as a purely diagrammatic language for it. Firstly, we were able to unify several measurement-based quantum computational schemes; in particular, the categorical language is sufficient to provide proofs of universality for each of these. Secondly, we have a manner to abstractly generate arbitrary multi-partite entangled states; hence equipping multi-partite entanglement with a formal interpretation in terms of information-flow. Also, we axiomatised Spekkens’ model in purely category-theoretic terms; its quantum-like behaviors are now consequences merely of abstract category-theoretic structure.
4:30PM L14.00007 Graphical Calculi and Mutually Unbiased Embeddings of Classical Logic

1This work supported by EPSRC Postdoctoral Research Fellowship EP/E045006/01.

4:42PM L14.00008 Basing quantum theory on information processing

HOWARD BARNUM, Los Alamos National Laboratory — I consider information-based derivations of the quantum formalism, in a framework encompassing quantum and classical theory and a broad spectrum of theories serving as foils to them. The most ambitious hope for such a derivation is a role analogous to Einstein’s development of the dynamics and kinetics of macroscopic bodies, and later of their gravitational interactions, on the basis of simple principles with clear operational meanings and experimental consequences. Short of this, it could still provide a principled understanding of the features of quantum mechanics that account for its greater-than-classical information-processing power, helping guide the search for new quantum algorithms and protocols. I summarize the convex operational framework for theories, and discuss information-processing in theories therein. Results include the fact that information that can be obtained without disturbance is inherently classical, generalized no-cloning and no-broadcasting theorems, exponentially secure bit commitment in all non-classical theories without entanglement, properties of theories that allow teleportation, and properties of theories that allow “remote steering” of ensembles using entanglement. Joint work with collaborators including Jonathan Barrett, Matthew Leifer, Alexander Wilce, Oscar Dahlsten, and Ben Toner.

Supported by the US DOE through the LDRD program at LANL.

5:45PM L14.00009 Quantum mechanics and the nature of the second law of thermodynamics

IAN T. DURHAM, Saint Anselm College — The second law of thermodynamics is inherently a classical law, though quantum analogues have been suggested. What are these quantum analogues and what is their relation to the classical version of the second law? In particular, what can Bell’s inequalities tell us about this relation? This continues ongoing work, some of which has been presented at previous APS meetings, and makes a stronger argument on the thermodynamic nature of Bell’s inequalities.

5:06PM L14.00010 Many worlds and the appearance of probability in quantum mechanics

ROBERT A. VAN WESEP — The theory of measurement has posed a conceptual problem since the beginning of quantum mechanics (QM). On the one hand, the quantum theory of measuring systems says that when a system measures the value of a quantity \( A \) associated with a system \( \mathcal{S} \), the state of the compound system \( \mathcal{S}\mathcal{O} \) following the measurement is a superposition of pure product states, one for each eigenvalue of \( A \). On the other hand, one’s subjective experience (as the observer \( \mathcal{O} \)) is that this statevector “collapses” nondeterministically to a pure state with probability given by the Born rule. The Copenhagen interpretation (CI) says that this collapse actually occurs. The many-worlds view (MW) is that it doesn’t. The defects of CI are obvious: there is no way to say which interactions are measurements to which the interpretation applies, and there is no way to describe the process of collapse that it calls for. MW, on the other hand, does not seem able to incorporate the Born rule. If this were true, it would rule out MW as a description of reality. We show that it is not true, in the strongest possible way: the Born rule is actually a derivable consequence of the quantum theory of measurement as long as we accept the theory as is, i.e., as long as we accept MW[1]. The proof uses the strong law of large numbers, which is the link between the abstract notion of probability and the concrete properties of sequences of observations.

5:18PM L14.00011 Quantum catalysis of information

KOJI AZUMA, Department of Materials Engineering Science, Osaka University, MASATO KOASHI, NOBUYUKI IMOTO, Department of Materials Engineering Science, Osaka University; CREST — In quantum information science, it has been long believed that no one can access quantum information in a system without disturbing it. In fact, the belief has been corroborated by several no-go theorems such as the no-cloning theorem and the no-deleting theorem. Here, however, we show that the belief is incorrect, by exhibiting a novel process, ‘quantum catalysis of information’, in which, without receiving any disturbance, a system certainly exchanges a type of information that cannot be transmitted without quantum communication channel.

Tuesday, March 11, 2008 2:30PM - 5:18PM
Session L15 GQI: Focus Session: Progress toward Scalable Quantum Information Processing
Morial Convention Center 207

2:30PM L15.00001 Ensemble encoding of quantum registers: it’s easy if you can count to one

KLAUS MOLMER, Lundbeck Foundation Theoretical Center for Quantum Systems Research, University of Aarhus — We present a new encoding of qubits in multi-bit registers which makes use of the collective population of a set of internal states of an ensemble of identical quantum systems. This establishes a linear rather than exponential relationship between the number of bits and the internal state Hilbert space dimension of our basic physical system. The key requirement of our proposal is that we can count to one and restrict the collective populations to the values zero and unity. We propose physical implementations and recipes for one- and two-bit gates with ground state atoms interacting via Rydberg excited states, offering up to 14 bits in a small cloud of cesium atoms, and with polar molecules interacting via a stripline cavity field and a Cooper pair box, offering even larger register sizes.

In collaboration with Etienne Brion, Imperial College; Line Hjortshøj Pedersen, University of Aarhus; Mark Saffman, University of Wisconsin; and Karl Tordrup, University of Aarhus.
3:06PM L15.00002 Progress toward scalable optical quantum computing1. PAUL KWIAT, University of Illinois at Urbana-Champaign — Quantum computing holds great promise for solving certain problems which would be intractable using classical computing architectures. Compared to other carriers of other quantum information (e.g., ions, spins, or superconductors) photons have the simultaneous advantage and disadvantage of interacting with the environment and each other only weakly. They are thus relatively immune to decoherence, but it is difficult to achieve the required qubit-qubit interactions. Fortunately, in 2001 Knill, Laflamme, and Milburn proposed a scheme that was scalable at least in principle, if not in practice (too many resources per gate were required). Since then, the ideas were merged with those of “one-way quantum computing” to realize a scalable approach based on “cluster states”, with much more modest though still very challenging – resource requirements. Here I will describe some of the challenges and recent successes, both in implementing the necessary resources (i.e., high-efficiency detectors, single- and entangled-photon sources, and fast logic), and in applying these to realize some basic quantum computing primitives (single- and two-qubit gates and some simple algorithms).

1This work was supported by the IARPA QCCM project “Optical Quantum Computing”

3:42PM L15.00003 Experimental demonstration of decoherence-free one-way quantum information processing, ROBERT PREVEDEL, Faculty of Physics, University of Vienna, MARK S. TAME, The Queen’s University, Belfast, ANDRÉ STEFANOV, IQOOI, Austrian Academy of Science, MAURO PATERNOSTRO, MYUNGSHIK KIM, The Queen’s University, Belfast, ANTON ZEILINGER, Faculty of Physics, University of Vienna and IQOOI, Austrian Academy of Science — In recent years, one-way quantum computing has become an exciting alternative to existing proposals for quantum computers. In this specific model, coherent quantum information processing (QIP) is accomplished via a sequence of single-qubit measurements applied to an entangled resource known as cluster state. However, there has so far been no experimental realization of noise-resilient quantum computation in the one-way model. Here we report the experimental demonstration of a one-way quantum processor reliably operating under the effects of decoherence. Information is protected by a properly designed decoherence-free subspace in which the cluster states reside. We demonstrate our scheme in an all-optical setup by encoding the information into the polarization of states of four photons. A one-way information-transfer protocol is performed with the photons exposed to severe symmetric phase damping noise. Remarkable protection of information is accomplished, delivering nearly ideal computational outcomes.

3:54PM L15.00004 Entangling the optical frequency comb into multiple continuous-variable cluster states1. OLIVIER PFISTER, HUSSAIN ZAIDI, University of Virginia, NICOLAS MENICUCCI, Princeton University and the University of Queensland, STEVEN FLAMMIA, Perimeter Institute for Theoretical Physics, RUSSELL BLOOMER, MATTHEW PYSHER, University of Virginia — A single multimode optical parametric oscillator (OPO) can be designed so that its nonlinear gain medium (typically a two-photon parametric amplifier) generates a particular network of entangling interactions between the eigenmodes of its optical cavity. We show how this can be formulated using nonstandard graph states and how these are related to the usual graph states, an example of which is the cluster state for one-way quantum computing. We also report on the progress of our very compact experimental implementation, in a single OPO with a single pump field, of a parallel quantum register comprising several independent quadripartite cluster states.  

1NCM acknowledges support from the U.S. Dept. of Defense and the National Science Foundation, STF from ONR Grant No. N00014-07-1-0304, and HZ, RB, MP, and OP from NSF Grants No. PHY-0555522 and No. CCF-0622100.

4:06PM L15.00005 Experimental Teleportation-Based Quantum Gate, KAI CHEN, ALEXANDER GOEBEL, CLAUDIA WAGENKNICHT, YU-AO CHEN, JIAN-WEI PAN, PHYSIKALISCHES INSTITUT, RUPRECHT-KARLS-UNIVERSITÄT HEIDELBERG, GERMANY, TEAM, HEFEI NATIONAL LABORATORY FOR PHYSICAL SCIENCES AT MICROSCALE AND DEPARTMENT OF MODERN PHYSICS, USTC TEAM — For large scale quantum computation, the major challenge for entangled qubits is the environment-induced interaction between them. Teleportation-based scheme offers an alternative way for scalable quantum computing. Most attractively, this architecture allows for realizations of universal quantum gates in a fault-tolerant manner as shown by Gottesman and Chuang, and in fact serves as an important basis for measurement-based quantum computing. We report a proof-in-principle experimental implementation of this architecture by demonstrating a teleportation based two-qubit CNOT (controlled NOT) gate through linear optics with 6-photon scheme. By preparation of high-fidelity four-photon cluster states and applying two Bell state measurements with the photons of our very compact experimental implementation, in a single OPO with a single pump field, of a parallel quantum register comprising several independent quadripartite cluster states.

4:18PM L15.00006 Generation arbitrary permutation symmetric state with projection, FANGWEN SUN, Optical Nanostructures Laboratory, Columbia University, New York, NY 10027, CHEE HAE WONG, OPTICAL NANOSTRUCTURES LABORATORY, COLUMBIA UNIVERSITY, NEW YORK, NY 10027 TEAM — We proposed a scheme to generate arbitrary permutation symmetric multi-partite state. The system contains N equally single quantum particles (We use atoms for these particles) which may interact with single photon to generate entanglement between them. This entanglement can be obtained by the transition from three-level \( \lambda \) atom’s exited state to different low levels and emitting corresponding polarized photon, or by inputting a single-photon to a trapped atom to gain different phase shift . After preparing N photon-atom entangled states, the N photons are combined into same path mode to erase the Welcher-Weg information. By postselection \( (N-k) \) photons in one polarization state and \( (N+k) \) photons in its orthogonal polarization state with N-fold coincidence counts, we can generate the atom Dicke state \( \left\{ \frac{N-k}{N+k} \right\} \). Moreover, the arbitrary superposition of these Dicke states can be generated by constructing corresponding projection measurements, which includes multi-atom GHZ state. Based on the discussion on the entanglement between different degrees of freedom, we will show that the projection measurement can also be constructed in the far-field region without combining all photons in one path mode.

4:30PM L15.00007 Single photon Mach-Zehnder interferometer for quantum networks based on the Single Photon Faraday Effect: principle and applications, HUBERT SEIGNEUR, CREOL, University of Central Florida, MICHAEL LEUENBERGER, NanoScience Technology Center and Dept. of Physics, University of Central Florida, WINSTON SCHEFFIELD, CREOL, University of Central Florida — Combining the recent progress in semiconductor nanostructures along with the versatility of photonic crystals in confining and manipulating light, quantum networks allow for the prospect of an integrated and low power quantum technology. Within quantum networks, which consist of a system of waveguides and nanocavities with embedded quantum dots, it has been demonstrated in theory that many-qubit states stored in electron spins could be teleported from one quantum dot to another via a single photon using the Single Photon Faraday Effect. However, in addition to being able to transfer quantum information from one location to another, quantum networks need added functionality such as (1) controlling the flow of the quantum information and (2) performing specific operations on qubits that can be easily integrated. In this paper, we show how in principle a single photon Mach-Zehnder interferometer, which uses the concept of the single photon Faraday Effect to manipulate the geometrical phase of a single photon, can be operated both as a switch to control the flow of quantum information inside the quantum network and as various single qubit quantum gates to perform operations on a single photon. Our proposed Mach-Zehnder interferometer can be fully integrated as part of a quantum network on a chip.
4:42PM L15.00008 High threshold 2D nearest neighbor quantum computation. , AUSTIN FOWLER, PETER GROSZKOWSKI, Institute for Quantum Computing, Waterloo; ROBERT RAUSSENDORF, University of British Columbia — We describe a quantum computation scheme on a 2D nearest neighbor coupled square lattice of qubits that requires relatively few physical qubits per logical qubit, permits logical operations between arbitrarily distant logical qubits in almost constant time and has a physical gate threshold error rate of almost 1%. To the best of our knowledge, no other quantum computation scheme simultaneously possesses all of these desirable properties.

4:54PM L15.00009 A Universal Operator Theoretic Framework for Quantum Fault Tolerance. , GERALD GILBERT, MITRE Quantum Information Science Group; ROBERT CALDERBANK, VANEET AGGARWAL, Princeton University; MICHAEL HAMRICK, YAAKOV WEINSTEIN, MITRE Quantum Information Science Group — We introduce a universal operator theoretic framework for quantum fault tolerance. This incorporates a top-down approach that implements a system-level criterion based on specification of the full system dynamics, applied at every level of error correction concatenation. This leads to more accurate determinations of error thresholds than could previously be obtained. The basis for the approach is the Quantum Computer Condition (QCC), an inequality governing the evolution of a quantum computer. In addition to more accurate determination of error threshold values, we show that the QCC provides a means to systematically determine optimality (or non-optimality) of different choices of error correction coding and error avoidance strategies. This is possible because, as we show, all known coding schemes are actually special cases of the QCC. We demonstrate this by introducing a new, operator theoretic form of entanglement assisted quantum error correction.

5:06PM L15.00010 Structure and quantum-dynamics relationship in spin networks , LUIS CAJAMARCA, LUIS QUIROGA, Universidad de los Andes — We report on the relationship of the spin dynamics with the quantum network topology. The network consists of N-1 spins-1/2 arranged along a circle, also referred to as a ring, equidistant to a central spin (Heisenberg star or ring topology). Every spin along the ring interacts with its first neighbors by means of a constant coupling J1, as well as with the central spin by means of a constant coupling J1. Both couplings are of antiferromagnetic nature and the competition among these incorporates the well known magnetic frustration behavior, which is characteristic of this type of systems. A full analysis of the quantum system's dynamics is carried out for the two limiting cases of coupling constants. We analyze the ground state transitions of the system as well as correlations between any pair of spins including the temperature dependence. The time evolution of the central spin is also analyzed for a given preparation state of the whole spin network. Finally, an stochastic element is incorporated into the system by disconnecting the central spin with any spin along the ring in a random manner. Such dynamics is referred to as dilution and allows us to describe how quantum quantities, such as spin coherences, entanglement and general quantum correlations, depend on the different path topologies between the considered spins (classical structural quantities). Extensions to more complex network topologies are also addressed.

Session L16 DBP: Focus Session: Brownian Motors Morial Convention Center 208

2:30PM L16.00001 Stochastic path integrals and geometric theory of mesoscopic stochastic pumps and reversible ratchets. , ILYA NEMENMAN, LANL — A variety of stochastic systems, from enzyme kinetics to epidemiology, exhibit pump-like behaviors, where adiabatic changes of parameters result in a nonzero directed current through the system. Using the stochastic path integral technique from mesoscopic physics, we have been able to relate these and similar phenomena to geometric effects in mesoscopic stochastic kinetics and construct their unifying theory. In the talk, this methodology will be demonstrated on three examples: (1) an adiabatic pump effect in the evolution of a Michaelis-Menten enzyme, treated as a classical two-state stochastic system; (2) a reversible ratchet; and (3) a related novel phenomenon in a previously unexplored domain, namely the SIS epidemiological model. In all of these examples, pump-like currents follow from very similar geometric phase contributions to the effective action.

3:06PM L16.00002 ABSTRACTS WITHDRAWN –

3:18PM L16.00003 Failure of Overdamped Models for Buttiker-Landauer Heat Engine: Molecular Dynamics Simulation , RONALD BENJAMIN, RYOICHI KAWAI, University of Alabama at Birmingham — A spatially inhomogeneous temperature profile in presence of a periodic potential leads to directed current of Brownian particles, commonly known as Buttiker-Landauer ratchet. Under a small external load the system can do work as a heat engine. Overdamped models, neglecting inertial effect (m = 0), predict that the engine can reach Carnot efficiency. On the other hand, the overdamped limit (m → 0) predicts the opposite due to the kinetic energy contribution to the heat transfer, suggesting that m = 0 is mathematically a singular point. A phenomenological argument predicts that the heat from the hot to the cold reservoir diverges as 1/√m [1,2]. We confirmed this singular behavior by Molecular Dynamics (MD) simulation and also by numerically solving the corresponding inertial Langevin equation. We obtain good agreement between the MD simulation and the inertial Langevin equation whereas the solution of the overdamped Langevin equation qualitatively disagrees with them. We also confirmed, from the numerical simulation, that the efficiency of the engine does not reach the Carnot limit.

3:30PM L16.00004 Modeling an efficient Brownian heat engine , MESFIN ASFAW TAYE, National Central University Jongli, 32054 Taiwan — We investigate the effect of subdividing the ratchet potential on the performance of a tiny Brownian heat engine that modeled as a Brownian particle hopping in a viscous medium in a sawtooth potential (with or without load) assisted by alternately placed hot and cold heat baths along its path. We obtain analytic expression for the steady state current. The expressions for velocity, efficiency and coefficient of performance of refrigerator are reported for different number of barrier subdivisions. We find that the velocity, the efficiency and the coefficient of performance of the refrigerator maximize as the number of barrier subdivisions increase.

3:42PM L16.00005 Trajectories of a Brownian Motor, DEAN ASTUMIAN, University of Maine — Many bio-molecular motors are dimers that move by a “hand-over-hand” mechanism along polar bio-polymeric tracks. Examples include kinesin, that “walks” on microtubule and myosin V that “walks” on actin. These molecular motors share two important symmetries. Typically the motor dimers have approximate mirror symmetry, and their tracks have translational, but not mirror, symmetry. Here we use a trajectory approach to analyze a minimal model for a generic dimeric motor that moves on a polymer track incorporating these two symmetry features. The analysis focuses on the relative probabilities of forward, reverse, backward, backward reverse trajectories and provides an experimentally accessible measure of the relative importance of a “Brownian motor” vs. “Power stroke” mechanism. Reciprocal relations, similar to those derived for the linear regime by Onsager for the fluxes (generalized velocities), hold for arbitrary magnitude forces (i.e., far from the linear regime) for the net probabilities for stepping and for chemical reaction.

4:18PM L16.00006 ABSTRACT WITHDRAWN —

4:30PM L16.00007 Nonequilibrium Fluctuations and Mechanochemical Couplings of a Molecular Motor, ANDY LAU, Florida Atlantic University, DAVID LACOSTE, ESPCI, KIRONE MALICK, CEA Saclay — We investigate theoretically the non-equilibrium features of a single processive motor operating far from equilibrium using an extension of the two-state model introduced by Kafri et al [Biophys. J. 86, 3373 (2004)]. By including an important variable, namely, the number of ATP consumed, we construct a thermodynamic framework, which allows us to characterize the ATP consumption rate of a motor, its run length, and its thermodynamic efficiency. Additionally, with the aid of the Fluctuation Theorem, we analyze the violations of Einstein and Onsager relations as functions of generalized forces. Our main results are (i) one of the Einstein relations holds near stalling, (ii) the degree by which the Onsager symmetry is broken is largely determined by the underlying asymmetry of the substrate, (iii) kinesin’s maximum efficiency and its maximum violation of Onsager symmetry occur roughly at the same energy scale, corresponding to that of an ATP hydrolysis (~ 20 k_BT).

4:42PM L16.00008 Influence of non-conservative optical forces on the dynamics of optically trapped colloidal spheres: The fountain of probability, BO SUN, YOHAI ROICHMAN, ALLAN STOLARSKI, DAVID G. GRIER, Center for Soft Matter Research, New York University — We demonstrate both experimentally and theoretically that a colloidal sphere trapped in an optical tweezer does not come to equilibrium, but rather reaches a steady state in which its probability flux traces out a toroidal vortex. This non-equilibrium behavior can be ascribed to non-conservative optical forces and constitutes a particularly simple thermal ratchet. We briefly discuss ramifications of this effect for previous experiments in which optical tweezers have been treated as conservative potential energy wells.

4:54PM L16.00009 Anomalous single-particle diffusion in a tilted washboard potential, KE XIAO, YAEEL ROICHMAN, Center for Soft Matter Research of New York University, SANGHYUK LEE, University of California, Berkeley, DAVID GRIER, Center for Soft Matter Research of New York University — A corrugated optical vortex acts as a tilted washboard potential for micrometer-scale colloidal particles. A single particle circulating around a corrugated optical vortex undergoes normal diffusion in the limit of strong driving and high temperatures. In the opposite limit, a particle becomes localized. When the effective barrier height is comparable to the thermal energy scale, the particle switches intermittently between stationary and running states. This intermittent switching results in a giant enhancement of the particle’s effective self-diffusion coefficient, which has been predicted theoretically and demonstrated experimentally. The observed enhancement is at least one order of magnitude larger than predicted. Simulations of this system reveal that, contrary to predictions, the single particle undergoes anomalous diffusion, and that this explains the unexpectedly large enhancement of the thermally driven fluctuations. In particular, we show that giant diffusivity arises from the competition between sticking and running states, and can be related to the anomalous diffusion characteristics. We show that the system crosses over from superdiffusive behavior to subdiffusion as the driving increases relative to the barrier height, in agreement with experiments.

5:06PM L16.00010 New Proposed Mechanism for Actin-Polymerization-Mediated Propulsion, KUN-CHUN LEE, ANDREA LIU, University of Pennsylvania, Department of Physics and Astronomy — An important component of the cellular cytoskeleton is F-actin, a biopolymer whose non-equilibrium self-assembly is key to the process of cell crawling. We have reported previously how the polymerization and branching of F-actin near the cell membrane drives cell crawling using a physically-consistent Brownian Dynamics model. Here we show that the creation of new polymerizing filaments by the branching process leads to a steady-state concentration profile of actin away from the moving surface. This non-equilibrium concentration profile is associated with an osmotic pressure profile. The gradient of the osmotic pressure, evaluated at the surface, is the force density on the actin. This force pushes actin backwards, away from the surface. By Newton’s third law, this force has a reaction force on the disk; this is the force pushing the disk forwards.

5:18PM L16.00011 Stochastic Regulation of Actin Bundles Growth Dynamics, PAVEL ZHURAVLEV, YUEHENG LAN, GAREGIN PAPOIAN, Department of Chemistry, The University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-3290 — Actin polymerization in living cells exemplifies biological dynamical processes where mechanics is intrinsically coupled to chemistry. Modeling the dynamics of biochemical reaction networks may by itself be challenging, because ordinary chemical kinetics is often inapplicable when a small copy number of individual proteins are involved. Instead, to treat large fluctuations, the reaction dynamics should be computed with stochastic methods. We have developed an extensible mechano-chemical model describing the dynamics of actin bundle growth and retraction, where all reaction and diffusion processes are treated stochastically. We have applied our computational algorithm to study the dynamics of filopodia, where polymerization rate at the tip is coupled to the membrane force and fluctuations. Our approach allows to investigate how a particular regulatory protein, participating in the relevant signaling network, influences the distribution of filaments in the bundle, growth and retraction rates and other dynamical characteristics. Among these proteins, the most interesting are capping proteins (that block polymerization), formins (that promote polymerization), fascins (that connect the filaments in the bundle together) and myosins (molecular motors that have been observed in filopodia and may participate in active transport to the tip).
The search for supersolidity was given impetus by recent experiments in which solid helium appeared to decouple from a torsional oscillator, but other phenomena which characterize superflow have not yet been observed. Both experiments and theory indicate that defects are involved in supersolidity and these should also affect the solid’s mechanical behavior. We have measured the shear modulus of solid helium at extremely low frequencies and strains, using a new method, and observe anomalous stiffening at temperatures below 200 mK. It has the same dependence on temperature, measurement amplitude, \(^4\text{He}\) impurity concentration and annealing as the torsional oscillator decoupling. This elastic behavior is explained in terms of a dislocation network which is pinned by \(^3\text{He}\) at the lowest temperatures but becomes mobile above 100 mK. Moving dislocations appear eliminate the decoupling and disrupt possible supersolidity.

This research was supported by grants from NSERC Canada and the University of Alberta.

The shear modulus of solid \(^4\text{He}\) increases substantially in the temperature range below 200 mK where torsional oscillator measurements showed mass decoupling apparently associated with supersolidity. The amount of helium which decoupled depended on the oscillator amplitude, which was interpreted in terms of a supersolid critical velocity of order 10 microns/second. We observed a similar amplitude dependence in our shear modulus anomaly - the stiffening at low temperatures decreased above a critical drive level. By varying the measurement frequency (from 20 to 2000 Hz) and by changing the sample’s dimensions, we conclude that the amplitude dependence we see is a function of the stress or displacement in the solid helium rather than the velocity. This contrasts with recent torsional oscillator measurements in which the amplitude dependence scaled with sample velocity. However, the amplitude dependence in our modulus measurements begins at stresses comparable to those in torsional oscillators and at low temperatures it shows hysteretic behavior similar to that seen in torsional oscillators.

This research was supported by grants from NSERC Canada and the University of Alberta.

The shear modulus of solid \(^4\text{He}\) has been investigated as a function of stress or displacement in the solid helium. If we exclude supersolidity, we find the inferred increase in the shear modulus is necessary to account for typical frequency shifts in TO studies is significantly larger than that reported in Ref. [1] and nearly unphysical. Experiments are in progress to understand the connection between NCRI and the increased shear modulus. [1] J. Day and J. R. Beamish, arXiv:0709.4666v1 (2007).

This work is supported by NSF under grant DMR-0706339.

We have constructed a compound torsional oscillator which could be operated at two resonant modes (the first at 496 and the second at 1172 Hz). This device allowed us to study the non-classical rotation inertia of the identical solid \(^4\text{He}\) at the two oscillator modes driven separately. We present here recent studies of NCRI when the two modes are simultaneously excited. The idea was to drive the first mode at high amplitude and to detect its effect on NCRI fraction by the second mode. We expected that when the solid \(^4\text{He}\) was driven at high amplitudes with the first mode to produce significant reduction in NCRI fraction, the same reduction would be measured with the second mode driven simultaneously at very low amplitude. On the contrary, the observed reduction in NCRI fraction by the second mode was much smaller than that expected from the first mode. If the driver/detector roles of the first and second modes were reversed, the amount of reduction of NCRI fraction detected and induced by a high drive amplitude of the second mode became greater in the first mode driven at a low amplitude. The critical drive amplitude effects of NCRI induced in one mode are not entirely “seen” by the other mode in our oscillator.

This work is supported by NSF grant DMR-0706339.

3:42PM L17.00007 Torsional oscillator and synchrotron x-ray experiments on solid helium in aerogel, J. WEST, M.H.W. CHAN, Dept. of Physics, the Penn State University, University Park, Pennsylvania 16802, N. MULDERS, Dept. of Physics and Astronomy, University of Delaware, Newark, Delaware 19716, C.N. KODDITUWAKKI, C.L. BURNS, Dept. of Physics, Western Michigan University, Kalamazoo, Michigan 49008, L.B. LURIO, Dept. of Physics, Northern Illinois University, Dekalb, Illinois 60155 — A number of Torsional Oscillator experiments have shown that the Non Classical Rotational Inertia fraction in solid $^4$He is strongly dependent on sample preparation. Samples presumed to be the most pristine show the smallest fraction, rapidly quenched samples a much larger one. On the assumption that samples grown in a strongly disordered environment would similarly show a large NCRIff, we have made T.O. measurements on solid samples grown in 95% porous silica aerogel. Contrary to expectation, these samples show a behavior that is very similar to high purity samples grown from the superfluid phase. Subsequent x-ray diffraction experiments show that the solid grown in aerogel is highly polycrystalline, with a hcp crystal structure (as in bulk) and a crystallite size of approximately 100 nm. X-ray diffraction experiments were performed at the Advanced Photon Source, Argonne national laboratory. This work was supported through NSF DMR-0706339 (MHW) and DE-FG01-05ER05-02 (CAB).

3:54PM L17.00008 Non-classical response of solid helium confined in Vycor glass$^1$, DUK YOUNG KIM, CSQR and Department of Physics, KAIST, R.O.K., HYUNG CHAN KIM, Research and development division,NFRC, R.O.K., EUNSEONG KIM, CSQR and Department of Physics, KAIST, R.O.K., KAIST TEAM, NFRC COLLABORATION — The non-classical rotational inertia of solid $^4$He was observed by a series of torsional oscillator experiments$^1$. Probable heat capacity signature of the supersolid transition which coincides with the non-classical mass decoupling is also observed$^2$. Recent torsional oscillator experiments suggest that disorder and the orientation of a helium crystal may play an important role in the appearance of non-classical rotational inertia. Accordingly, the investigation on the role of defects and crystal orientation may provide crucial clues to understand supersolidity. Solid helium confined in porous media cannot possess well-defined crystal orientation and is likely heavily populated with defects. Here we will present the pressure dependence of the non-classical rotational inertia in solid helium confined in Vycor glass by torsional oscillator techniques. $^1$ E. Kim and M. H. W. Chan, Science 305, 1941 (2004); Nature 425, 227 (2004); J. Low Temp. Phys. 138, 859 (2005); Phys. Rev. Lett. 97, 115302 (2006). $^2$ X. Lin, A. C. Clark, M. H. W. Chan, Nature 449, 1025 (2007).

4:06PM L17.00009 Torsional oscillators and the entropy dilemma of solid $^4$He, M.J. GRAF, A.V. BALATSKY, I. GRIGORENKO, S.A. TRUGMAN, (LANL), Z. NUSSINOV, (WUSTL) — Solid $^4$He is viewed as a nearly perfect Debye solid. Yet, recent calorimetry measurements by Chan’s group (JLTP 138 (2005) 853 and Nature 449 (2007) 1025) indicate that at low temperatures the specific heat has both cubic and linear contributions. These features appear in the same temperature range where measurements of the torsional oscillator period suggest a supersolid transition. We analyze (Phys. Rev. B 76 (2007) 094501) the heat and compare the measured with the estimated entropy for a proposed supersolid transition with 1% superfluid fraction and find that the observed entropy is too small. We suggest that the low-temperature linear term in the specific heat is due to a glassy state that develops below such a mixture of tunneling systems in the crystal. We propose that dislocation related defects produce those tunneling systems. Further, we argue (Phys. Rev. B 76 (2007) 014530) that the reported mass decoupling is consistent with an increase in the oscillator frequency as expected for a glass-like transition. The glass model offers an alternate interpretation of the torsional oscillator experiments in contrast to the supersolid nonclassical rotational inertia (NCRI) scenario.

4:18PM L17.00010 The excitation spectrum of solid $^4$He$^1$, JOHN GOODKIND, University of California, San Diego, ELIZABETH BLACKBURN, SUNIL SINHA, COLLIN BROHOLM, JOHN COPLEY — Speculation about a possible Bose condensation in solid $^4$He has existed for decades and has recently been further stimulated by the discovery of an acoustic anomaly and a decrease in the moment of inertia at temperatures below 200 mK. The excitation spectrum played an important role in understanding the properties of superfluid liquid helium so that, if there is such a condensation in solid $^4$He, the spectrum might also confirm it and aid in understanding it. We have measured the excitation spectrum of solid $^4$He by neutron scattering using the Disc Chopper Spectrometer at NIST. We have identified a sharp line in the spectrum as vacancy wave excitations. The dispersion relation for these excitations has a minimum energy of 1 meV and is quadratic. This vacancy mode intersects the longitudinal phonon mode at 1.1 meV and the two become degenerate at higher energies. The degenerate mode has a linear dispersion law with smaller slope than the longitudinal acoustic mode at lower energies. No change in the spectrum was observed below 200 mK. The spectrum has strong similarities to the spectrum in superfluid liquid helium.

4:30PM L17.00011 Torsion Oscillator Studies of Solid Helium-4$^1$, ETHAN PRATT, BENJAMIN HUNT, Cornell University, MINORU YAMASHITA, Cornell University and Kyoto University, J.C. SEAMUS DAVIS, Cornell University — We will present results of torsion oscillator experiments on solid helium-4 below 300 mK.

This work was supported NSF grant 0434801.

4:42PM L17.00012 Pairing states for the ring exchange t-J model, MING LOU, MICHAEL MA, University of Cincinnati, FU-CHUN ZHANG, University of Hong Kong — Multiple spin interactions, introduced by ring exchange process, are important for many systems, including solid $^3$He and High Tc cuprates. In high Tc cuprates, the dominant term is the 2-spin antiferromagnetic interaction, which leads to d-wave singlet pairing upon doping. In solid $^3$He, on the other hand, the 4-spin interaction plays an important role, and it’s interesting to determine how the Cooper pairing state may differs from that of cuprates. In this work, we apply the renormalized mean-field theory$^1$ to a modified t-J model, where the J term includes the 4-spin interaction introduced by the ring exchange. Our result shows that a mixed state of singlet and triplet pairing optimizes the energy. At half filling, the pairing state is unphysical, due to the fact that there is no double occupancy. Upon doping or with intrinsic vacancies, the paring state becomes physical. Such a mechanism may introduce supersolidity in bulk solid $^3$He and solid $^3$He absorbed on a substrate at very low temperature. $^1$ F.C. Zhang, C. Gros, T.M. Rice and H. Shiba, Supercond. Sci. Technol. 1 36 (1988).

Tuesday, March 11, 2008 2:30PM - 5:42PM
Session L18 DPOLY: Focus Session: John H. Dillon Medal Symposium
Morial Convention Center 210

2:30PM L18.00001 John H. Dillon Medal Talk: Polymer Droplets, KARI DALNOKI-VERESS, McMaster University — The simplicity of a liquid droplet, say a dew drop on spider silk, is both esthetically beautiful and scientifically intriguing. The interplay of surface energies, thermal motion, and confinement of the liquid, especially on small length scales can reveal interesting physics. Droplets are an ideal confining geometry because the length scales can be easily controlled and it is possible to arrange the system such that each droplet acts as an independent experiment. The talk will focus on some recent examples where we have used the droplet geometry to learn about material properties. It will become apparent in the presentation that the deviations from the "expected" behaviour in confined systems are far from subtle!
Lett. 71, 938 (2005)). Our results allow to understand the large deviation from the Manning law observed in these experiments.

Our predictions are in very good agreement with the recent experimental measurements of the effective charge by Essafi et al. (Europhys. Lett. 70, 938). This allows us to calculate the effective electric charge of the pearl as a function of the structure reminiscent of the Rayleigh instability of a charged droplet. Using a Poisson-Boltzmann approach, we calculate the counterion distribution around a given pearl assuming the latter to be penetrable for the counterions. This allows us to calculate the effective electric charge of the pearl as a function of the structure reminiscent of the Rayleigh instability of a charged droplet.

3:30PM L18.00004 Comparison of surface mobility of polymeric and low molecular weight glass-formers. MARK EDIGER, STEPHEN SWALLEN, KEN KEARNS, University of Wisconsin-Madison — The last ten years has seen considerable effort to understand dynamics at the surface of polymer melts and glasses. For comparison, we present data on two low molecular weight glass formers: trisnaphthylbenzene (TNB) and indomethacin (IMC). Neutron reflectivity provides direct information about mobility in the top several nanometers of TNB glasses. Two other measurements (surface crystal growth rates and the enthalpy of glasses prepared by vapor deposition) offer indirect information on surface mobility for IMC and TNB. These measurements indicate that surface dynamics at Tg are 2-5 orders of magnitude faster than bulk dynamics. The temperature dependence of the surface relaxation process is weak below the bulk Tg, in qualitative agreement with recent measurements on polymer surfaces in this regime.

4:2PM L18.00005 Modeling Solvent Evaporation from Glass-Forming Polymer Films by MD Simulations, JORG BASCHNAGEL, SIMONE PETER, HENDRIK MEYER, Institut Charles Sadron, Strasbourg — By means of molecular-dynamics simulations we study solvent evaporation from glass-forming, free-standing and supported polymer films. Polymers are represented by a commonly employed bead-spring model, solvent molecules are modeled as Lennard-Jones particles, and polymer-solvent interactions are tuned such that good-solvent conditions are realized. We start the simulations from a dense solution with a solvent content of 20% and explore the evaporation process for temperatures T above and below the glass transition temperature Tg of the pure polymer film. At all T we observe the formation of a polymer-rich crust at the free surface upon solvent evaporation. For T > Tg we can reproduce the simulation results (reduction of film thickness with time, solvent and polymer density profiles, etc.) by a Fickian diffusion model with a constant diffusion coefficient. For T < Tg deviations from Fickian diffusion are observed. We suggest that these deviations may be rationalized by a diffusion coefficient of the solvent, which depends on film composition and distance from the free surface. We attempt to compare our results to recent experiments.

5:4PM L18.00006 Studies of Glassy Colloidal Systems Under Shear, MICHAEL MASSA, CHANJOONG KIM, DAVID WEITZ, HSEAAS, Harvard University — In analogy with the glass transition of polymer (and other molecular) liquids, colloidal suspensions can undergo dynamic arrest to form a glassy state, when the system is concentrated beyond a critical volume fraction. However, in contrast to their molecular counterparts, studies of the glass transition in colloidal systems are facilitated by their natural length- and time-scales, which make it possible to directly visualize the behavoir of the individual constituent particles. Using confocal microscopy, we follow the dynamics of colloidal suspensions near the glass transition, and in particular, their reaction to an imposed deformation. We investigate the evolution from a quiescent solid to a shear melted liquid, to elucidate the nature of the structural rearrangements that govern the properties of glassy materials.

6:06PM L18.00007 Growth and Stability of Polymer Surface Wrinkles, ALFRED CROSBY, University of Massachusetts — For certain materials and geometries, the surface of a polymer film will wrinkle upon the application of a critical in-plane stress due to surface tension. The resulting morphology minimizes the in-plane strains and the system energy by locally bending the surface plane. This process and morphology have been studied at an increasing rate over the last decade and demonstrated in applications ranging from materials metrology to adhesion control. In general, the knowledge and use of this phenomenon has been developed for conditions that far exceed the point of initiation, under static equilibrium. In this presentation, we highlight recent experiments that explore the growth and morphological transitions of surface wrinkles. We quantify the growth mechanism under different conditions of mechanical constraint and demonstrate a unique ability to stabilize a wide variety of unique, non-predicted, surface wrinkle morphologies.

4:18PM L18.00008 Toughening Mechanisms in Polymer Gels, HUGH BROWN, University of Wollongong — I will describe a simple model that accounts for the very high toughness of double network gels. The model is based on the assumption that the first, stiff network will break up forming multiple cracks when the stress is above a defined value. These cracks are held together by the second network. A multiply cracked damage zone will form round any macroscopic crack in the material causing energy dissipation and shielding the second network. The toughness enhancement by this process is estimated to be about x40. Other techniques of gel toughening will then be discussed.

4:30PM L18.00009 Theory of polymer crystallization, M. MUTHUKUMAR, UMMASS, Amherst — We will present new conceptual arguments for the spontaneous selection of very small lamellar thicknesses and their melting behavior.

4:42PM L18.00010 On the effective charge of hydrophobic polyelectrolytes, ELIE RAPHAEL, UMR CNRS Gulliver 7083, ESPCI, 10 rue Vauquelin, 75005 Paris, France, ALEXEI CHEPELIANSKII, Laboratoire de Physique des Solides, UMR CNRS, 8502, Bat. 510, Universite Paris-Sud, 91405 Orsay, France, FARSHID MOHAMMAD-RAFIEE, Institute for Advanced Studies in Basic Sciences (IASBS), Zanjan 45195, P.O. Box 45195-1159, Iran — In this paper we analyze the behavior of hydrophobic polyelectrolytes. It has been proposed that this system adopts a pearl-necklace structure reminiscent of the Rayleigh instability of a charged droplet. Using a Poisson-Boltzmann approach, we calculate the counterion distribution around a given pearl assuming the latter to be penetrable for the counterions. This allows us to calculate the effective electric charge of the pearl as a function of the chemical charge. Our predictions are in very good agreement with the recent experimental measurements of the effective charge by Essafi et al. (Europhys. Lett. 71, 938 (2005)). Our results allow to understand the large deviation from the Manning law observed in these experiments.
4:54PM L18.00011 Disentanglement in thin polymer films, HENDRIK MEYER, ULP Institut Charles Sadron, CNRS UPR22, Strasbourg, France — Molecular dynamics simulations of thin polymer films confined between structureless walls show accelerated in-plane dynamics with decreasing film thickness. Using the primitive path analysis (PPA) introduced by Everaers et al. [Science 303 (2004) 823] for chain length up to N = 1024, we can show that the entanglement density decreases with decreasing film thickness. However, the effect becomes pronounced only for films thinner than the bulk radius of gyration where also the chain structure becomes modified by the confinement [1]. The PPA algorithm can be modified to estimate the contribution of self-entanglements. The latter become more important for thinner films, however, they do not counterbalance the global decrease of entanglements. [1] H. Meyer et al. Eur. Phys. J. Sp.Top. 141 (2007) 167.

5:06PM L18.00012 Complex Structural Packing of ABC Triblock Copolymers Solvent Annealed at High Humidity, CHUANBING TANG, University of California Santa Barbara, JOONA BANG, Korea University, GILA STEIN, GLENN FREDICKSON, CRAIG HAWKER, EDWARD KRAMER, University of California Santa Barbara, MICHAEL SPRUNG, JIN WANG, Argonne National Laboratory — The use of ABC triblock copolymers to obtain industrially relevant morphologies for block copolymer lithography has been investigated. Nanoporous thin films of poly(ethylene oxide)-poly(methyl methacrylate)-polystyrene triblock copolymer spheres were prepared by solvent annealing under controlled humidity followed by UV degradation and acid washing. Ordered half spheres at the surface that template ordering of spheres below the surface in thin films were formed as a result of the interaction between the highly hydrophilic PEO segments and water vapor in the chamber. The spherical block copolymer domains exhibit complex packing behavior on the surface and in the interior which is dependent on film thickness. Half sphere “monolayer” and half sphere plus whole sphere “bilayer” formed in thin films were shown to have hexagonal lattice symmetry. For half sphere plus two whole sphere “trilayers”, the coexistence of regions of hexagonal and square packing was observed by TEM, SFM, SEM and GISAXS. Square packing was consistent with a surface truncated unit cell of a body-centered cubic lattice with the (100) plane parallel to the surface.

5:18PM L18.00013 High resolution structure of bacterial cell sacculi, JOHN DUTCHER, AHMED TOUHAMI, VALERIO MATIAS, ANTHONY CLARKE, University of Guelph, MANFRED JERICHO, Dalhousie University, TERRY BEVERIDGE, University of Guelph — The major structural component of bacterial cell walls is the peptidoglycan sacculus, which is one of nature’s strongest and largest macromolecules that allows the cell to maintain a large internal pressure while allowing the transport of molecules into and out of the cell and cell growth. The three-dimensional structure of this unique biopolymer is controversial, and two models have been proposed: the planar model, in which the glycan strands lie in the plane of the cell surface, and the scaffold model, in which the glycan strands lie perpendicular to the cell surface. In this study we have used atomic force microscopy (AFM) to investigate the high resolution structure of isolated, intact sacculi of both Gram-positive and Gram-negative bacterial cells. We have observed a sponge-like structure for both types of sacculi with pore diameters between 5 to 15 nm. Our data for Gram-positive sacculi provide evidence for the validity of the scaffold model, whereas our data for Gram-negative sacculi indicate an orientation along the short axis of the cell which is consistent with the planar model. To further elucidate the structure, we have exposed sacculi to the tAmiB enzyme which cleaves peptide-peptide bonds.

5:30PM L18.00014 Mechanical Response of Lipid Multilayers From Micro- and Nanoparticle Embedment, GREGORY MCKENNA, Texas Tech University, KIRTHI DESHPANDE, Texas Tech University — We have used atomic force microscopy (AFM) to image micro- to nano-meter sized particles embedded into lipid multilayer films prepared by a spin coating technique. The lipid investigated was 1,2-dipalmitoyl-Sn-glycerol-3-phosphotidylcholine (DPPC). Gold, silica and polystyrene were used for the embedding particles. Particle diameters ranged from 50 to 300 nm and all tests were performed at atmospheric conditions and ambient temperature. Film thickness was approximately 87 nm based on AFM determination. We used the elastic analysis for contact between a rigid sphere and elastic substrate with the work of adhesion wA acting as the force on the sphere to determine the shear modulus G in terms of wA, the particle radius and the height of the sphere that remains above the surface. From the AFM height measurements, we find that the shear modulus for the DPPC falls in the range from 3 to 30 MPa, but seems independent of particle type and particle size. The potential for the particle embedment method for mechanical property determination of soft materials will be discussed.

Tuesday, March 11, 2008 2:30PM - 5:06PM — Session L19 DMP: Focus Session: Dopants and Defects in Semiconductors II, Morial Convention Center 211

2:30PM L19.00001 Highly Enriched 28Si – A New Testbed for Impurity and Defect Structure, MIKE THEWALT, Simon Fraser University — We have recently found that many optical transitions in Si, including those of shallow impurity bound excitons, and the electronic ground state to excited state transitions of shallow donors and acceptors, are remarkably sharper in highly enriched 28 Si than in natural Si, due to the removal of inhomogeneous isotope broadening. This work is now being extended to deeper defects, many of which have been studied for decades. We will show that high resolution spectroscopy in highly enriched Si exhibits transitions which are sharper than in natural Si by a factor of 10. Isotopic substitutions for hydrogen and nitrogen result in the expected frequency shifts, thereby providing an unambiguous identification of these complexes. The N-H stretches are stable up to ~700 °C. The introduction of neutral N-H complexes could prove useful in achieving reliable p-type conductivity in ZnO.

This work was supported by the National Science Foundation (DMR-0704163).

3:06PM L19.00002 Nitrogen-hydrogen complexes in ZnO: A possible route toward p-type conductivity, M.D. MCCLUSKEY, Washington State University, S.J. JOKELA, University of Georgia — Zinc oxide (ZnO) is a wide band gap II-VI semiconductor with optical, electrical, and mechanical applications. The lack of reliable p-type doping, however, has prevented it from competing with other semiconductors such as GaN. In this talk, I describe the successful incorporation of nitrogen-hydrogen (N-H) complexes in ZnO during chemical vapor transport (CVD) growth, using ammonia as an ambient. The N-H bond-stretching mode gives rise to an infrared (IR) absorption peak at 3150 ± 6 cm⁻¹. Isotopic substitutions for hydrogen and nitrogen result in the expected frequency shifts, thereby providing an unambiguous identification of these complexes. The N-H complexes are stable up to ~700 °C. The introduction of neutral N-H complexes could prove useful in achieving reliable p-type conductivity in ZnO.
3:18PM L19.00003 Vibrational lifetimes of O-H stretch modes in MgO and ZnO, ERIK SPAHR, GUNTER LUPKE, College of William and Mary, NORMAN TOLK, Vanderbilt University, LEONARD FELDMAN, Rutgers University — Hydrogen is an important and omnipresent impurity in a wide class of oxides. A more complete understanding of the role of hydrogen in wide-bandgap oxides such as MgO and ZnO is crucial for further development of oxide-based optoelectronics. We have measured for the first time the vibrational lifetime of the O-H stretch mode associated with the Mg$^{2+}$ vacancy in MgO for the charge state, $V_{OH}^-$, and the neutral state, $V_{OH}^0$, using picosecond transient bleaching spectroscopy. For the $V_{OH}$ center we find the lifetime (~11 ps) is longer than for the charged defect state (~5 ps). These lifetimes are almost an order of magnitude shorter than in ionic semiconductors Si and Ge [1].

3:30PM L19.00004 Carrier Dynamics and Photoexcited Emission Efficiency of ZnO:Zn Phosphor Powders, JOHN V. FOREMAN, HENRY O. EVERITT, Dept. of Physics, Duke University, Durham, NC 27708 and U.S. Army Aviation and Missile RDEC, Redstone Arsenal, AL 35898, JIE LIU, Dept. of Chemistry, Duke University, Durham, NC 27708 — The undoped and Ga-doped ZnO thin films were grown on sapphire using molecular-beam epitaxy (MBE) system. The samples of electron concentrations ranging from $1.4 \times 10^{19}$ to $3.4 \times 10^{19}$ cm$^{-3}$ were grown and studied. The RT PL peaks show a monoton red shift from 3.280 to 3.229 eV with the increase of electron concentration, which is attributed to the band-gap narrowing effect. The red-shifted peak values have been fitted. The evolution of the LT PL spectra were studied and discussed. The free exciton emission at 3.371 eV, the first Ga-level-related peak at 3.313-3.321 eV, and the second Ga-level-related peak at 3.359 eV (assigned as the Ga $D^X$ peak) are competing with each other in the LT PL spectra. These three kinds of peaks are dominating in the lightly (or undoped), mediate, and heavily doped ZnO:Ga samples, respectively. From the experiments, we conclude that there are two Ga levels in ZnO. In the lightly doped sample, the Ga atoms contribute to the first Ga level around 3.352 eV. When the Ga incorporation reaches some critical amount, Ga atoms form the second Ga level in ZnO at 3.359 eV.

3:42PM L19.00005 Study of the carrier concentration dependent photoluminescence of Ga-doped ZnO thin films grown by molecular-beam epitaxy, ZHENGYANG, LEELAPRASANNA MANDALAPU, JILIN LIU, Quantum Structures Laboratory, Dept. of Electrical Engineering, University of California, Riverside — The undoped and Ga-doped ZnO thin films were grown using molecular-beam epitaxy (MBE) system. The samples of electron concentrations ranging from $1.4 \times 10^{19}$ to $3.4 \times 10^{19}$ cm$^{-3}$ were grown and studied. The free exciton emission at 3.371 eV, the first Ga-level-related peak at 3.313-3.321 eV, and the second Ga-level-related peak at 3.359 eV (assigned as the Ga $D^X$ peak) are competing with each other in the LT PL spectra. These three kinds of peaks are dominating in the lightly (or undoped), mediate, and heavily doped ZnO:Ga samples, respectively. From the experiments, we conclude that there are two Ga levels in ZnO. In the lightly doped sample, the Ga atoms contribute to the first Ga level around 3.352 eV. When the Ga incorporation reaches some critical amount, Ga atoms form the second Ga level in ZnO at 3.359 eV.

3:54PM L19.00006 Zinc Vacancy induced magnetism in ZnO thin films and nanowires, QIAN WANG, Virginia Commonwealth University, QIANG SUN, Peking University, PURU JENA, Virginia Commonwealth University — Extensive theoretical studies based on first-principles have been carried out for the mechanism of magnetism in ZnO thin films and nanowires. It has been identified that the observed magnetism is introduced by Zn vacancy and is affected by its concentration. The main source of the magnetic moment comes from the unpaired 2p$^-$ electrons in oxygen sites around the Zn vacancy, instead of Zn 3d electrons. Moreover, Zn vacancy is more energetically favorable to reside on the surface, and its formation energy is found to be less than that of oxygen vacancy that does not introduce any magnetism. These findings suggest that the main vacancy species is Zn vacancy as expected by experiments. The present theoretical study not only provides some deep understandings for the experimentally observed magnetism in un-doped ZnO samples, but also suggests that introducing Zn vacancy is a natural and an effective way to fabricate magnetic ZnO structure for bio-magnetic applications.

4:06PM L19.00007 Magnetism of Undoped and Co-Doped TiO$_2$ Clusters, X. WEI, R. SKOMSKI, M. SCHUBERT, D. SELLMYER, Nebraska Center for Materials and Nanoscience, University of Nebraska — TiO$_2$ is a widely used optically active material, and transition-metal doped TiO$_2$ has attracted much attention in spintronics. Recently, it has been argued that ferromagnetism is a universal feature of nanoparticles of nonmagnetic oxides, and our focus is on doped and undoped TiO$_2$ nanoclusters. The clusters are examined with TEM, AFM, MFM, and hysteresis loops and zero field cooled magnetization curves were measured by SQUID magnetometry. Both doped and undoped films display hysteresis and magnetic order in the investigated temperature range of 50K to 400K. The ordering temperature is above 400 K, and both magnetization and coercivity are enhanced in the out-of-plane direction. Undoped TiO$_2$ particles exhibit a nominal moment of about 0.2 $\mu_B$ per surface atom. Small Co concentrations have little effect on the magnetism of the particles. Higher Co doping percentages, about 5%, yield prototropic (clockwise) loops, indicating the formation of CoO. It has been suggested that the magnetic moment of 'nonmagnetic' oxide thin films is a surface effect, and the comparison of different particle sizes yields a similar picture for our particles. Our renormalization-group modeling assumes indirect exchange interactions between scarce magnetic moments and yields a logarithmic dependence of the ordering temperature on the particle size - This research is supported by NSF MRSEC and NCMN.

4:18PM L19.00008 First-principles determination of the electronic structure of native point defects and impurities in rutile TiO$_2$. JUN HE, Argonne National Laboratory, SUSAN SINNOTT, University of Florida — Density-functional theory calculations are used to determine the electronic structures of native point defects (Ti interstitials and O vacancies) and dopants (Al and Nb) in rutile TiO$_2$. The calculated densities of states (DOS) show that in pristine and defective structures that contain charged Ti interstitials or O vacancies, the lower conduction bands of the defective structures are shifted up in energy relative to the perfect structure. This shift leads to a broader lower conduction band that more readily promotes the formation of shallow donor levels. This effect is more pronounced in the case of Ti interstitials. We also find that the charge state of the Ti interstitial influences the extent of orbital overlap. The case of Al dopants is much more complex since Al can either be a donor or an acceptor. In the case of Al and Nb substitutional defects, the calculated DOS is similar to the DOS of the pristine structure.

4:30PM L19.00009 Group III-A Acceptor-Hydrogen interactions in SnO$_2$, JOEL VARLEY, Physics Department, University of California, Santa Barbara, CA 93106, ANDERSON JANOTTI, ABHISHEK SINGH, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106 — Using first-principles calculations we investigate the role of hydrogen in the passivation of p-type dopants in SnO$_2$. We focus on group III-A elements, including Al, Ga, and In and investigate the stability of these impurities when substituting Sn under hydrogen-free and hydrogen-rich conditions. Hydrogen effectively passivates the acceptors and removes their electrical activity. Based on calculated binding and migration energies we discuss conditions under which hydrogen can be removed and acceptor activation can take place. We also calculate the stretch-mode vibrational frequencies associated with the hydrogen-impurity complexes, providing a signature for experimental identification in vibrational spectroscopy. We conclude that the group III-A elements studied are suitably shallow acceptors for p-type doping and that the presence of interstitial H will not impede, and potentially enhance, p-type doping of SnO$_2$.

4:42PM L19.00010 Investigation of Electroluminescent Degradation in doped ZnS phosphors1, FRANK BRIDGES, JACOB STANLEY, YU JIANG, LAUREL RUHLEN, JOHN WILLY, SUE CARTER, Physics Dept. UCSC Santa Cruz 95064 — We present optical and EXAFS data on a series of ZnS samples doped with Cu, Mn and Cl. These materials (30 micron particles) have a strong electroluminescence (EL) when subjected to a 100V square-wave voltage. At 100 Hz, the luminescence decays significantly in a 20 hr period. We show that this degradation can partially be reversed by annealing the sample and that this can be repeated several times. In addition the EL emission centers reoccur at the same points in the 30 micron particles after the anneal. The optimum annealing temperature is about 180°C, but varies slightly for different wavelengths. Surprisingly an anneal at somewhat higher temperatures (240°C) dramatically reduces the EL intensity. The EXAFS studies show that the local structure about Cu continues to look like Cu2 for “as made”, EL degraded, rejuvenated samples (annealing at 180°C), and thermally degraded samples (annealed at 240°C). This means that most of the Cu is in the relatively inert CuS precipitates, and does not change significantly with EL degradation or annealing. Thus the EL active sites must be dilute. We discuss some possible models.

4:54PM L19.00011 Theoretical Study of native defects in CdGeAs2, TULA R PAUDEL, Department of Physics, Case Western Reserve University, WALTER R.L. LAMBRECHT, Department of Physics Case Western Reserve University — First-principles results are presented for various native defects viz. : V_{Cu}, V_{Ge}, V_{As}, Cd_{As}, Ge_{Cd}, Ge_{As}, Ge_{As}, and As_{Cd}, in CdGeAs2 under different growth conditions. The defects were calculated by constructing a 64 atom supercell in the full potential linearized muffin-tin orbital implementation of the density functional theory under the local density approximation (LDA). Calculations of the energy of formation show that antisites should be the most abundant type of defect. The LDA band gap is adjusted to experimental band gap by introducing a non-local orbital dependent constant potential shift to the s-orbitals of Cd and Ge and d-orbitals of Cd within the LSDA+U approach. The defect transition levels for different charge states are calculated. The calculations support the earlier suggestion that Ge_{As} is a shallow acceptor. The calculated transition levels are found to be significantly different form corresponding defects levels of ZnGeP2. The defect levels are interpreted in a simple molecular-orbital theory and compared with the available experimental data.

Session L20 DMP: Focus Session: Self-Assembled Organic Overlayers Morial Convention Center 212

2:30PM L20.00001 Self-assembly at the liquid/solid interface: from patterns to function, STEVEN DE FEYTER, K.U.Leuven — Self-assembly - the spontaneous organization of molecules into stable, structurally well-defined aggregates - has been put forward as a possible paradigm for generating nanoscale templates under ambient conditions. A very convenient method for the formation of extended two-dimensional (2D) networks is physisorption at the liquid-solid interface. The preparation is relatively simple and scanning tunneling microscopy (STM) allows a detailed investigation of the structural aspects of the 2D patterns. A deep understanding and control of the spatial orientation and packing of molecules in self-assembled systems is indispensable for the development of future nanodevices. We have developed hydrophobic - hydrophilic nanopatterns at electirfied surfaces via the self-assembly of amphiphilic molecules. For this purpose we selected 5-hexadecyloxysphotic acid: this neutral amphiphile forms hydrogen-bonded rows that are commensurate with the Au(111) surface. Based on the successful adsorption of these amphiphiles, multicomponent architectures have been realized at these electirfied surfaces as the result of the potential directed assembly of charged and non-charged molecular systems. Following a slightly different approach, nanoporous two-dimensional networks were formed at the interface between an organic liquid and highly oriented pyrolytic graphite. Pore sizes of more than 5 nm in diameter can be realized. As an alternative approach to make nanoporous two-dimensional networks, molecular defined shape-persistent two-dimensional oligomers, such as molecular spiked wheels, are used.

3:06PM L20.00002 Stress-Induced Striped Domains at the C60-Pentacene Interface*, DANIEL DOUGHERTY, National Institute of Standards and Technology, WEI JIN, Department of Chemistry and Biochemistry and Materials Research Science and Engineering Center University of Maryland at College Park, WILLIAM CULLEN, Department of Physics and Materials Research Science and Engineering Center University of Maryland at College Park, GREGORY DUTTON, JANICE REUTT-ROBEY, Department of Chemistry and Biochemistry and Materials Research Science and Engineering Center University of Maryland at College Park, STEVEN ROBEY, National Institute of Standards and Technology — Cd60:pentacene heterojunctions have been recently employed in functional organic photovoltaic devices [1]. In order to develop a detailed structural understanding of these junctions, we have made STM observations of the growth of pentacene on top of a monolayer film of C60 on Ag(111). We observe pattern formation in the first pentacene layer due to the tensile stress arising from interactions with the underlying C60. The stress results in a striped pattern of alternating commensurate and incommensurate domains of pentacene with respect to the C60 monolayer. The incommensurate domains appear as bright regions 3.6 ± 0.6 nm in width and are discussed using a 1D Frenkel-Kontorova model. *Supported by the NIST Center of Nanomanufacturing and Metrology and the University of Maryland MRSEC via DMR-05-20471 [1] Yoo et al., Appl. Phys. Lett. 85, 5472 (2004).

3:18PM L20.00003 The growth mechanism of Pentacene-C60 heteroepitaxial films, A. AL-MABBOO, J.T. SADOWSKI, Y. FUJIKAWA, T. SAKURALI, Institute for Materials Research, Tohoku University — Pentacene (Pn) and fullerene (C60) are of great interest among organic semiconductors as they show highest field-effect hole and electron mobilities respectively. The absorption peak in Pn crystal is located close to maximum of solar visible spectra, making a bipolar Pn-C60 diode promising for solar cell application. In order to improve its efficiency to satisfy the requirement for practical application, an in-depth understanding of Pn-C60 interface formation is necessary for further optimization. We shall discuss the growth mechanism of Pn-C60 heteroepitaxial films on Bi(0001)/Si(111) substrate studied by real time low-energy electron microscopy and complementary scanning tunneling microscopy. A competitive growth between a thin-film phase of Pn having standing-up orientation and a phase with laying-down orientation has been observed. The growth of laying-down phase is suppressed gradually with increasing film thickness. The nucleation of this phase is also suppressed with increasing temperature and the standing up phase without co-presence of laying down phase is achievable at ~75°C.

3:30PM L20.00004 Self-Limiting C60-Pentacene Network on Ag(111)1, WEI JIN, University of Maryland, DANIEL DOUGHERTY, National Institute of Standards & Technology, GREGORY DUTTON, WILLIAM CULLEN, University of Maryland, STEVEN ROBEY, National Institute of Standards & Technology, JANICE REUTT-ROBEY, University of Maryland — During Scanning Tunneling Microscopy investigations of C60:Pentacene (Pc) interfaces on Ag(111), we identified a new network structure. This binary arrangement forms readily by sequential deposition: Pc, of 0.3 mL coverage, is first evaporated onto the Ag(111), forming a 2-D grid. Subsequent C60 deposition produces a network, consisting of chains of close-packed C60 molecules, spaced by C60 molecules. The characteristic 1 x 2.5 nm2 pores are sized to accommodate Pc molecules. Spontaneous formation of this structure from an initial Pc coverage ranging from 0.6 to 0.6 mL, indicates a self-limiting assembly process. Drawing upon topographic and Z(V) measurements, we propose a structural model and describe molecular mechanisms that could cause this self-limiting behavior.

1Supported by the Dept. of Commerce through the NIST Center of Nanomanufacturing and Metrology and the NSF-funded MRSEC via DMR-05-20471.
3:42PM L20.00005 Guest-host interaction of C_{60} adsorbed on an ordered layer of phthalocyanine derivatives, TOMAS SAMUELY, MEIKE STOEHR, NIKOLAI WINTJES, University of Basel (Switzerland), THOMAS A. JUNG, Paul Scherrer Institute (Switzerland), MARCO HAAS, SHI-XIA LIU, SILVIO DECURTINS, University of Bern (Switzerland) — Symmetrically substituted phthalocyanines (Pcs) with eight peripheral di-(tert-butyl)phenoxy (DTPO) groups self-organize on noble metal substrates. The rotational degrees of freedom, specific for the DTPO substituents, allow a bowl-like conformation of the Pc derivatives and thus, hosting of the C_{60} molecules in two clearly distinguishable binding sites. Moreover, controlled manipulation of the C_{60} by the STP enables switching from one site to the other. Since Pcs are well-known electron donors and C_{60} molecules are good acceptors, it can be conceived as a system with two morphologically different donor-acceptor complexes, individually addressable by an STP tip. Preliminary STS analysis shows vast differences in the electronic properties. Exploration of such a system is of great interest because of its similarity to fundamental biological processes (photosynthesis, respiration), as well as its potential application in energy storage, conversion, nanoelectronics, etc.

3:54PM L20.00006 Scanning Tunneling Microscopy Investigation of Ordered Iron Phthalocyanine Molecules on Ag(111), KEN PARK, KEDAR MANANDHAR, Baylor University, S. MA, JAN HRBEK, Brookhaven National Laboratory — A well-ordered, molecular thin films (about 0.5 monolayers) of iron phthalocyanine (FePc) on Ag(111) has been investigated using a scanning tunneling microscopy. The room temperature deposition, followed by 30 minutes annealing up to 475 K results in well-ordered islands of FePc molecules which form a two-dimensional, oblique lattice. The overlay lattice vectors a, and b, are 16.2 Å each with the angle of 80° between the lattice vectors. The FePc overlay lattice is commensurate to the substrate lattice with the relationship of a = 6a - b and b, = a + 6b, with a and b, are the Ag(111) lattice vectors. Furthermore, FePc molecules at the opposite corners within the unit cell align their isodole rings at each other, significantly increasing the nearest and the next-nearest neighbor distances in the overlay. The commensurate overlay lattice structure and the distinct molecular orientation within the unit cell are attributed to the molecule-surface interaction via the Fe 3d_{x^2−y^2} and Ag 4d_{x^2−y^2} orbitals.

4:06PM L20.00007 Self-assembly of functionalized fullerenes on strained metallic interfaces, BOGDAN DIACONESCU, MIKAEL JAZDZYK, GLEN MILLER, KARSTEN POHL, University of New Hampshire — The process of growing ordered arrays of molecules or nanometer sized clusters with tailorable properties on the dislocation networks of strained metallic thin films requires a detailed understanding of the nucleation processes and film-molecule and intermolecular interactions. We compare two different self-assembly mechanisms of functionalized fullerenes on strained metal films of Ag on Ru(0001). We found that by controlling the molecular coverage and/or the strain in the thin film, various interactions can dominate the self-assembly process, thus resulting in a richness of structures with controllable properties. At low molecular coverage on 1 monolayer Ag films on Ru(0001), ordered triangular arrays of clusters, 4.9 nm apart, with a tunable number of molecules can be grown. This process is driven by strain relaxation in the metal film, as confirmed by 2D Frenkel-Kontorova models, and was found to be a general one working for various functionalized molecules. At higher molecular coverage and different Ag film thickness, the intermolecular interaction becomes dominant and the symmetry and unit cell size of the self-assembled monolayer are a consequence of the molecular structure and functionality. Both these processes are generally applicable to many functionalized C_{60} molecules thus opening avenues towards complex self-organized structures based on lock and key type approach.

4:18PM L20.00008 Morphology of thin organic semiconductor layers on vicinal (0001) sapphire surface, GVIDIO BRATINA, PRIMOŽ REBERNIK RIBIC, University of Nova Gorica — Morphology of pentacene, 3,4,9,10-perylenetetracarboxylic dianhydride (PTCDTA), rubrene, and N,N′-diphenyl-N,N′-bis(3-methylphenyl)-1,1′-diphenyl-4,4′-diamine (TIPD) layers grown on vicinal (0001) sapphire surface was examined by non-contact atomic force microscopy ex situ. The layer thickness ranged from a submonolayer coverage to up to four molecular layers. Pentacene molecules on the terraces in a layer-plus-island growth mode. PTCDTA nucleates randomly at room temperature, while at 135°C and low coverage the molecules aggregate at the steps. At increased coverage the island growth proceeds in the directions determined by the intermolecular interactions and not along the steps. Rubrene and TIPD nucleate in 3D islands that evolve over time by ripening. TIPD nucleates along the steps and also ripening proceeds along the steps. The rate of ripening of rubrene islands is one order of magnitude slower than the rate of ripening of TPD. We associate this difference to the wealth of rotational degrees of freedom in TPD molecules as opposed to only twisting degree of the tetracene backbone in rubrene.

4:30PM L20.00009 Organic Vapor-Liquid-Solid Deposition for Controlled Growth of Organic Semiconductor Films, DAVID PATRICK, BRAD JOHNSON, Western Washington University — Thin films of low molecular weight organic semiconductors (OS) are drawing much attention for their potential use in a range of different applications. Because the optical and electronic properties of OS films are extremely sensitive to structural imperfections, domain size, and crystallographic orientation, preparation of high quality thin films with controlled microstructure under technologically favorable conditions has long been a bottleneck toward practical applications and better controlled fundamental studies. Here we describe an approach for fabricating OS films that comes close to achieving these demanding objectives. The main advance is the combined use of atmospheric pressure chemical vapor deposition (APCVD) and capillary liquid injection (LC) solvent, which is applied as a thin coating onto a supporting substrate, providing an organized fluid environment in which OS crystals nucleate and grow. The technique produces relatively large crystals, enables control over crystallographic orientation, growth habit, and size, and involves near ambient conditions compatible with a variety of substrates and inexpensive processing conditions. Results will be presented for the model compounds tetracene and pentacene.

4:42PM L20.00010 Structure and adsorption mechanisms of thiol self-assembled monolayers on GaAs (001) surfaces, OLEKSANDR VOZNYY, JAN J. DUBOWSKI, University of Sherbrooke — Self-assembly of organic molecules on solid substrates attracts a lot of interest from both fundamental and practical perspectives. Particularly, alkanethiol SAMs on GaAs surfaces can be used, e.g., for surface passivation, bio- and chemical sensing, molecular electronics and nanolithography. However, the progress of the investigation of this material system is hindered by problems of reproducibility of SAMs growth due to insufficient understanding of the deposition process on the atomic level and a lack of experimental characterization techniques. In this work, we present the results of ab initio modeling of thiol SAMs on GaAs (001) surface which helps to resolve the SAM structure, chemistry of bonding to substrate, adsorption kinetics and energetics. We also compare the GaAs case to a prototypical system of thiols on Au and discuss differences the semiconductor surface brings to the process.

4:54PM L20.00011 Self-assembly of long chain alkane and their derivatives on graphite, YANG YANG, SAVAS BERBER, DAVID TOMÁNEK, Michigan State University, JUN-FU LIU, GLEN P. MILLER, University of New Hampshire — We combine scanning tunneling microscopy (STM) measurements with ab initio calculations to study the self-assembly of long chain alkane and related alcohol and carboxylic acid molecules on graphite. For each system, we identify the optimum adsorption geometry and explain the energetic origin of the domain formation observed in the STM images. Our results for the hierarchy of adsorbate-adsorbate and adsorbate-substrate interactions provide a quantitative basis to understand the ordering of long chain alkane in self-assembled monolayers and ways to modify it using alcohol and acid functional groups. Supported by NSF NIRT grant ECS-0506309 and NSF NSEC grant EEC-425826.
5:06PM L20.00012 Theoretical Modelling of Self-Assembly of Molecular Networks, MANUEL MURA, NATALIA MARTSINOVICH, LEV KANTOROVICH, King's College — The phenomenon of self-assembly of atomic and molecular superstructures on crystal surfaces has attracted an increasing interest in nanotechnology. Self-organised nano-templates where the self-assembled monolayer traps other molecules with selected functional properties, can be used as building blocks for larger nanoscale structures. These superstructures can form chiral domains ranging from 1D chains to 2D monolayers. In particular, there have been many scanning tunneling microscopy (STM) studies of self-assembly of melanine, perylene tetra-carboxylic di-imide (PTCDI) or perylene tetra-carboxylic di-anhydride (PTCDA) molecules on the Au(111). STM images of these networks do not reveal the exact details of the intermolecular bonding and process of network growth. It is therefore the task of theory to determine the exact atomic structure of these networks. We present a theoretical study of self-assembly of molecular networks on different molecules by using a systematic approach to build molecular superstructures. The energies of these structures are calculated using the density-functional theory SIESTA code. The theoretically predicted monolayer structures are in very good agreement with the results of STM measurements.

5:18PM L20.00013 Polymerization of a perylene derivative on a metal surface, MANFRED MATENA, JORGE LOBO-CHECA, MEIKE STOEHR, University of Basel, Switzerland, KATHRIN MUELLER, THOMAS A. JUNG, Paul-Scherrer-Institute, Switzerland, TILL RIEHM, LUTZ H. GADE, University of Heidelberg, Germany — By utilizing the concepts of supramolecular chemistry, impressive results for molecular self-assembly on surfaces have been achieved. Mostly, non-covalent interactions like metal coordination, hydrogen bonding or dipolar coupling are exploited to create supramolecular patterns. One approach to influence these structures relies mainly on the sophisticated design of the molecular functional groups. Thus it makes use of properties already inherent to the molecules. In our work we have chosen a different concept. A thermally-induced surface-assisted reaction was used to modify the endgroups of a perylene derivative (TAPP) and thereby, the molecular interactions are altered. TAPP was found to form a closed-packed assembly on Cu(111), whereas the molecular interactions are based upon vdW-forces. After annealing at 150 °C, a rectangular network is obtained which is commensurate to the underlying Cu surface. In this case the organic molecules coordinate to Cu atoms through the lone pairs of their nitrogen atoms.

Tuesday, March 11, 2008 2:30PM - 4:30PM — Session L21 DCP: Focus Session: Clusters, Cluster Assemblies, Nanoscale Materials V Morial Convention Center 213

2:30PM L21.00001 Ab Initio Simulations of Nano-Diamond Surface Reconstruction, WILLIAM MATTSON, RADHAKRISHNAN BALU, US Army Research Laboratory — We have simulated with in the Density Functional Theory (DFT) spherically cut nano-diamonds from bulk diamond at ambient conditions. The 2.6 nanometer diameter sphere is then allowed to relax at 250K and surface reconstruction is observed. Four hemispherical fullerene like regions form on the surface and while the interior maintains the diamond structure, it undergoes compression equivalent to over 30GPa in the bulk. Results of dynamic shearing will be presented.

2:42PM L21.00002 TiO₂ nanocrystals prepared by ferrocene/cobalt catalyst agents¹, M.E. GOMÉZ, J.C. CAICEDO, G. ZAMBRANO, Thin Film Group, Department of Physics, Universidad del Valle, A. A. 25360 Cali, Colombia, A.M. LAZAR, D. CHAUMONT, LRRS and FR 2604 Université de Bourgogne 21078 Dijon, France, Y. LACROUTE, M. SACILOTTI, CMN and LPUB. UFR Sc. Techn. FR 2604 Université de Bourgogne, 9 avenue A. Savary, BP 47870, 21078 Dijon Cedex, France — We present the growth and characterization of TiO₂ nanocrystals. Nanostructured growth is obtained in a low-pressure CVD system by using an organometallic precursor Ti(OCH₃)₄ as both the Ti and O source catalyzed by both ferrocene (an organometallic precursor) and cobalt metallic clusters prepared by the microwave-assisted polyol method. Two kinds of TiO₂ structures were obtained in the cobalt clusters: a) pine-tree like (with short-leaf structure) and b) long-leaf structures as large as a few micrometers in size and both under 10-nm in thickness. Long-leaf TiO₂ structures were grown at cobalt grain boundaries. For the growth conditions utilized, the TiO₂ structures are composed of both anatase and rutile crystallographic phases.

¹This work was accomplished under contract project title FILIMON35 n ANR-05-NANO-016-03 France, and the Excellence Center for Novel Materials - CENM contract 043-2005 with COLCIENCIAS, Colombia.

2:54PM L21.00003 Metal cluster anions produced by attachment of slow electrons: Evaporative cooling, cluster energetics, and restructuring of the abundance spectra¹, VITALY KRESIN, ROMAN RABINOVITCH, CHUNLEI XIA, University of Southern California — Metal clusters are able to attach low-energy electrons with very large cross sections by capturing them in a strong long-range polarization potential. But little information has been available about the last stage of the collision process: what happens to the energy deposited by the captured electron, and are the cluster size distributions modified? We have carried out measurements of the mass spectra of negative sodium cluster ions born in the electron-cluster interaction region. Importantly, the arrangement allowed us to monitor the parent and the daughter cluster beams simultaneously. It is found that the electron affinity energy is quickly thermalized and is sufficient to cause rapid evaporative cooling. As a result, the magic numbers shift from Naₙ to Naₙ⁻. And a host of other significant changes in the abundance structure are observed, compared to the parent cluster beam. These are well reproduced by a detailed analysis based on the evaporation cascade model, and yield new information about cluster binding energies.

¹Supported by NSF

3:06PM L21.00004 Anion Photoelectron Spectroscopy and Density Functional Investigation of Diniobium-Carbon Clusters¹, P.A. CLAYBORNE, Virginia Commonwealth University, K.L. KNAPPENBERGER, JR., University of California, Berkeley and Lawrence Berkeley National Laboratory, J.U. REVELES, Virginia Commonwealth University, M.A. SOBHY, C.E. JONES, JR., U.U. GUPTA, I. IORDANOV, J. SOFO, A.W. CASTLEMAN, JR., Pennsylvania State University, S.N. KHANNA, Virginia Commonwealth University — Experimental photoelectron and computational results show diniobium-carbon (Nb₂C₄) clusters to coexist in multiple structural isomers: three-dimensional geometries, planar rings and linear chains. Three-dimensional clusters having up to five carbons are formed preferentially with Nb-Nb bonding, whereas only Nb-C bonding is observed experimentally at six carbons. Clusters consisting of an odd number of atoms are also observed with linear geometries. The larger binary clusters (n ≥ 7) display properties similar to pure carbon clusters. We provide evidence for niobium substitution of carbon atoms.

¹The authors gratefully acknowledge support from the US Air Force Office of Scientific Research, Grant FA9550-04-1-0066 and FA9550-05-1-0186 and from the Department of the Army through MURI Grant # W911NF-06-1-0280.
3:18PM L21.00005 Towards Artificial Molecules: Metallodielectric Clusters. VINOTHAN MANOHARAN, JONATHAN FAN, Harvard University, SEAS — Recent advances in the synthesis of metallic colloids have allowed for an explosion in research into their optical properties. It is now possible to synthesize solid metallic colloids, core-shell colloids that mix different metals, and core shell colloids of metallodielectrics. In this talk I propose a mechanism for further exploring the optical properties of such materials by producing clusters of metallodielectric colloids and studying the relationship between the structure and composition of a colloidal cluster and its optical response. To this end, we synthesized a number of solutions, each of clusters consisting of a different average number of colloids. By doing this, we hope to study the effects of different dielectrics and near neighbor interactions on the plasmonic resonances of the metallic shells in the colloid. In the future, we hope to produce and study high yield, pure samples, both in solution and as photonic crystals. All of these options provide new ways of producing specific optical resonances that can be used in sensors, spectroscopy, optical triggers, and many other applications.

3:30PM L21.00006 Quantum transport in molecular electronic devices described with complex source and sink potentials. ALFARO, MARTIN JUAREZ FLORES, ANDREAS KOSTER, CINVESTAV, Departamento de Quimica, MARCELA BELTRAN, UNAM, J. ULISES REVELES, GWINN, DIRK BOUWMEESTER, DEBORAH FYGENSON, University of California Santa Barbara — We synthesize fluorescent clusters of silver atoms on metallodielectric colloids and studying the relationship between the structure and composition of a colloidal cluster and its optical response. To this end, we synthesized a number of solutions, each of clusters consisting of a different average number of colloids. By doing this, we hope to study the effects of different dielectrics and near neighbor interactions on the plasmonic resonances of the metallic shells in the colloid. In the future, we hope to produce and study high yield, pure samples, both in solution and as photonic crystals. All of these options provide new ways of producing specific optical resonances that can be used in sensors, spectroscopy, optical triggers, and many other applications.

3:42PM L21.00007 Charge carrier solvation on a polymer chain revealed in ab initio computations. MICHAEL MAYO, YURI GARTSTEIN, The University of Texas at Dallas, Richardson, Texas, USA — When an excess charge carrier (electron or hole) is added to a semiconducting polymer chain in vacuum, it is well known that the carrier may self-trap into a polaronic state accompanied by a self-consistent localized bond alternation pattern. A different mechanism of self-localization is a solvation of the charge carrier expected to take place when the polymer chain is immersed in a polar medium (such as a common solvent) - in this case a self-consistent pattern of the orientational polarization is formed around a localized charge. The goal of our study is to identify this solvation effect within ab initio computations. Using long carbon atom chains (both hydrogen terminated and rings) as model systems, we employ the hybrid B3LYP density functional within the DFT and the Polarizable Continuum Model to find the resulting electronic level structure and atomic charge densities. Our results clearly show trends towards excess charge self-localization due to the solvation. We suggest that this effect may be of importance for various semiconductor nanostructures in polar environments.

3:54PM L21.00008 Nanotubes in polar environments: Solvated charge carriers and their dynamics. GREGORY USSERT, YURI GARTSTEIN, Dept. of Physics, Univ. of Texas at Dallas, Richardson, TX, USA — Excess charge carriers on semiconducting nanotubes immersed in sluggish polar environments (such as common solvents) can undergo self-localization into polaronic states whose properties are profoundly different from the free band states. We explore such solvated states within the adiabatic continuum framework using a simplified picture of an electron or a hole confined to a cylindrical surface in the 3D polar medium. At the static level, the binding energy of a polaron is evaluated and found to be a sizable fraction (~0.3) of the corresponding Wannier-Mott exciton binding energy, which is expected to substantially decrease the thermal activation energy for the exciton dissociation. We discuss the diffusion and mobility of polarons caused by the dielectric fluctuations of the medium and applied electric fields, as well as the local dielectric relaxation modes in the vicinity of the polaron. We also discuss the electronic (optical) transitions between the localized electronic states within a self-consistent potential well due to the orientational polarization pattern.

4:06PM L21.00009 Fluorescent silver atom clusters in DNA hairpin loops. PATRICK O’NEILL, ELISABETH GWINN, DIRK BOUWMEESTER, DEBORAH FYGENSON, University of California Santa Barbara — We synthesize fluorescent clusters of silver atoms on DNA hairpins, and systematically vary the loop region to examine the effects of DNA sequence and structure on the optical properties and chemical stability of the Ag clusters. We find that these novel fluorophores only form on the single stranded hairpin loop, have Stoke’s shifts ranging from 60nm to 120nm and can be tuned to emit at wavelengths ranging from 525nm to 670nm. Furthermore, certain DNA geometries support strong excitation of visible fluorescence by the Ag clusters. We find that these novel fluorophores only form on the single stranded hairpin loop, have Stoke’s shifts ranging from 60nm to 120nm and can be tuned to emit at wavelengths ranging from 525nm to 670nm. Furthermore, certain DNA geometries support strong excitation of visible fluorescence by the Ag clusters.

Tuesday, March 11, 2008 2:30PM - 5:30PM — Session L22 DPOLY: Confinement-Induced Structures in Block Copolymers Morial Convention Center 214

2:30PM L22.00001 Dillon Symposium Break —
curvature influences the defect density in the formed structure.

In particular, the distribution of characteristic morphologies and structure dimensions for a given fiber diameter are characterized. Key novel aspects of this work include sampling of thermal fluctuations in full three dimension, rather than finding minimum energy surfaces and extensive comparison to experimental data on electrospun block copolymer–polymer fibers. Two methodological innovations are also introduced. First, an unprecedentedly precise estimate of Flory $\chi$ parameters for the model allows a quantitative comparison to field theoretic models. Second, a novel reflective boundary model allows common boundary artifacts in total density to be effectively eliminated, even for fibers with of dimensions comparable to single chains.

Complex Morphologies of Symmetric Diblock Copolymers under Nano-Confinement

By employing a bond fluctuation lattice Monte Carlo simulation, block copolymers confined in nano-cylindrical cavities are studied. The effects of preference of the surface for segments and incompatibility between different blocks as well as the symmetry of the chains and the ratio of cavity diameters to the lamellae period of copolymers in the bulk $(D/L_0)$ are investigated in detail. Numerous novel morphologies such as complicated helical structures, plate morphologies with fins and dendrites etc are presented in this work. Some phase diagrams regarding above parameters are provided in order to understand the transitions between structures. Additionally, the orientation parameters indicating the alignments of the polymer chains were calculated and correlated with the morphologies. The simulation results are compared with experimental results qualitatively.

Morphologies of a diblock copolymer melt confined in a spherical nanopore

We systematically investigate the microdomain morphologies that self-assemble in a diblock copolymer melt confined in a spherical nanopore, using real-space self-consistent mean-field theory. Near the surface of the nanopore we find that perforated-layer structures form, with four-, five-, and six-fold coordinated pores, for melts that form the cylindrical phase in the bulk. Simultaneously, spherical domains, toroidal domains, or small networks form in the centre of the pore. We vary the diameter of the pore and accurately locate the diameters where phase transitions between these morphologies occur. The effect of confinement on melts that form spherical microdomains in the bulk is also examined. We find that convergence to regular structures is complicated by the formation of defects, and we develop techniques to eliminate these defects. Methods to distinguish the various morphologies will also be discussed.

Spherical nano-shells of block copolymers

We study the self-assembled morphologies of symmetric diblock copolymers under planner and cylindrical confinement by homogeneous surface(s). The SCF equations are solved with high accuracy in real space, without a priori knowledge of the possible morphologies. Effects of surface preference and film thickness / pore diameter are investigated in detail. In addition to simple morphologies (i.e., surface parallel and perpendicular lamellae), complex morphologies are found in both cases and their stable regions are determined. Our SCF calculations also reveal the formation mechanism of these complex morphologies.

Water permeable nanotubes from amphiphilic block copolymers

By employing a bond fluctuation lattice Monte Carlo simulation, block copolymers confined in nano-cylindrical cavities are studied. The effects of preference of the surface for segments and incompatibility between different blocks as well as the symmetry of the chains and the ratio of cavity diameters to the lamellae period of copolymers in the bulk $(D/L_0)$ are investigated in detail. Numerous novel morphologies such as complicated helical structures, plate morphologies with fins and dendrites etc are presented in this work. Some phase diagrams regarding above parameters are provided in order to understand the transitions between structures. Additionally, the orientation parameters indicating the alignments of the polymer chains were calculated and correlated with the morphologies. The simulation results are compared with experimental results qualitatively.

Effect of curvature on equilibrium and non-equilibrium properties of a 2D smectic phase

We study the Otha-Kawasaki model for diblock copolymers equilibrium and non-equilibrium features of two dimensional smectic phases on curved sinusoidal substrates. At low curvatures defect free patterns are found to be stable. In agreement with theoretical predictions of Vitelli and Nelson [], at high curvatures topological defects are observed in the ground state. In this regime positive (negative) disclinations are located in regions of positive (negative) curvature. The configurations formed by stripes aligned with the lines of longitude are found to be unstable, while the equilibrium state is formed by the stripes aligned with the parallels. General features of smectic phases on curved backgrounds are discussed by a Frank elastic free energy in the one constant approximation.

Phase Transitions in block copolymers under external electric field and in confinements

We describe dynamics of phase transitions of various block copolymer morphologies (lamellae, hexagonally packed cylinders, spheres, gyroid, hexagonally perforated lamellae) under an applied electric field. Second example illustrates kinetics of surface phase transitions in confined systems (thin films).
5:06PM L22.00012 Crystalline Dichloblock Copolymers of Linear Polyethylene - Hydrogenated Polynorbornene, RICHARD REGISTER, SASHA MYERS, SHENG LI, Princeton University — The melt and solid-state morphologies of linear polyethylene (LPE) - hydrogenated polynorbornene (hPN) dichloblock copolymers, and their crystallization behavior, were explored over a range of block ratios and diblock molecular weights. LPE and hPN are both highly-crystalline polymers, with similar melting points, so the final structure can potentially be dictated by the melt structure, or by crystallization of either block. For diblocks with molecular weights of 50 kg/mol, symmetric copolymers exhibited lamellar microphase-separated melts, while diblocks with 20 or 80% LPE were homogeneous, indicating a modest LPE-hPN interaction energy density of approximately 1 J/cc. For the relatively slow crystallizations which can be conducted isothermally, hPN appears to always crystallize first; the two crystallization processes can be resolved by time-resolved DSC and x-ray diffraction at small undercoolings. However, the LPE block has a stronger temperature dependence of its crystallization rate, implying that LPE would crystallize first at deep undercoolings. Up to the highest diblock molecular weights explored (100 kg/mol), crystallization “breaks out” from the melt mesophase to form spherulites defined by the hPN block; subsequent crystallization of the LPE within these spherulites is apparent from a change in optical texture.

5:18PM L22.00013 Deformation-induced structure changes in olefin block copolymer, FENG ZUO, YIMIN MAO, JONGKAH KHEUM, CHRISTIAN EGGGER, BENJAMIN HSIAO, Stony Brook University, HONGYU CHEN, DEBIE CHIU, SHIH-YAW LAI, The Dow Chemical Company — Uniaxial tensile deformation was applied on two olefin block copolymer (OBC) samples to investigate the structure, morphology and orientation development using in-situ small-angle X-ray scattering and wide-angle X-ray diffraction techniques. Two samples have similar molecular characteristics but different chain architectures due to the different content of chain shuttling agent in production. The samples behave alike at room temperature, but the difference becomes distinct at high temperatures, such as fracture strain and crystal orientation. As more chain shuttling agents was used, the more frequently the growing chains transferred between catalysts; shorter block segments are formed. The OBC sample with a 40/60 block ratio has a film thickness of approximately 100 nm. The BCP self assembles into a variety of ordered structures with a period of 100 nm domains. The BCP self assembles into a variety of ordered structures with a period of 200 nm in thickness confining a block copolymer (BCP) to ~100 nm domains. The BCP self assembles into a variety of ordered structures with a period of ~200 nm. A lamellar-in-lamellar structure was achieved and by varying the BCP structure more complex cylinder-in-lamellar and sphere-in-lamellar structures are envisioned. The HP and BCP phase separation/crystallization dichotomy during the formation of hierarchical dielectric mirrors will be discussed.

Tuesday, March 11, 2008 2:30PM - 5:18PM — Session L23 DMP: Focus Session: Probing and Modifying Materials with Lasers II Morial Convention Center 215

2:30PM L23.00001 Femtosecond laser structuring in dielectrics, Saulius Juodkazis, RIES, Hokkaido Univ. — Three-dimensional (3D) structuring of glasses, crystals, and polymers by tightly focused femtosecond laser pulses is a promising technique for microfluidic, micro-optical, photonic crystal and micro-mechanical applications [1-4]. The 3D laser micro-structuring of resists is demonstrated by direct laser writing [1] and holographic recording using phase control of interfering pulses [2]. Tightly focused laser pulses can reach dielectric breakdown irradiance without self-focusing when sub-1 ps pulses are used for laser-structuring inside dielectrics. The limiting case of microstructuring, a void recording, can be achieved [3]. The mechanism of void formation has been explained as a result of dielectric breakdown and micro-explosion. The absorption is localized within a skin depth of tens-of-nanometers in the plasma at the focus. This defines an ultimate localization of the energy delivery by a laser pulse. The absorbance reaches 0.6 in a fully ionized solid state density breakdown plasma. The high temperature and pressure buildup is large enough to generate a shock wave (strong micro-explosion). For example, a single 100 nJ laser pulse forms a void under tight focusing conditions even in the high strength sapphire (Young modulus of 400 GPa). It is considered that material fails upon compression rather than tension for which the mechanical failure threshold is by an order of magnitude smaller. This scenario of breakdown by compression is corroborated by numerical modeling of the strong explosion at our experimental conditions. Modification of materials by tightly focused femtosecond pulses opens new material processing routes for inert dielectrics [4] and can possibly be used for creation of novel high-temperature and pressure phases inside the volume of irradiated samples. These regions with altered nano-structure have different chemical properties as was found in silica glass, quartz, and sapphire by wet etching of the “shocked” regions in aqueous solution of hydrofluoric acid. Current challenges of structural characterization of micrometer-sized volumes of nano-structures materials are discussed. The achievable resolution limits and potential of the fabricated 3D patterns in photonics, micro-fluidics, and sensor applications will be presented. [1] K. K. Seet et al., Adv. Mat. 17, 541, 2005. [2] T. Kondo, et al., New J. Phys. 8, 250, 2006. [3] S. Juodkazis, et al., Phys. Rev. Lett. 96 166101 2006. [4] S. Juodkazis, et al., Adv. Mater. 18 1361 2006.

3:06PM L23.00002 Mechanisms of nanoparticles size reduction by laser irradiation, ALEXANDER Pyatenko, MUNEHIRO Yamaguchi, Masaaki Suzuki, AIST — Size reduction of nanoparticles after laser irradiation is well known phenomenon. Two different mechanisms of size reduction have been proposed: 1) the photoionization of electrons from a particle into a solution which caused ionization and Coulomb explosion of the ionized particle. 2) a simple heating-melting-evaporation mechanism. In this report we show that the different mechanisms are working under different experimental conditions, and give the criterion for their applicability. The main experimental parameter responsible for such criterion is the laser energy flow density, \( I_0 = E/\tau \), where \( E \) and \( \tau \) are the laser pulse energy and duration, and \( S \) is the laser beam cross section. We calculated the critical value for this parameter in case of spherical silver and gold particles. When this parameter exceeds the value of about 10^{10} W/cm^2, the electron ejection can be started. For nanosecond lasers such energy flow density values can be achieved only with beam focusing, but for pico and especially femto lasers this condition can be realized in different experimental arrangements. When \( I_0 \) is smaller than the critical value, the particle heating-melting-evaporation mechanism is responsible for particle size reduction.
3:18PM L23.00003 Novel Nanostructured Materials and Properties by Pulsed Laser Deposition, JAGDISH NARAYAN, COPINATH TRICHI, North Carolina State University — Pulsed laser deposition has been used to create novel nanostructured materials either as layered or nanodot structure. By controlling thin-film growth kinetics during island growth, we are able to create three-dimensional self-assembled nanodot structures of Ni and ordered L10 FePt in a given matrix. Epitaxial growth and Integration of Ni and FePt on Si(100) substrate was achieved via domain matching epitaxy which facilitated epitaxial growth across the misfit scale. Magnetic properties can be varied by controlling the orientation and coercivity higher than 1.2 Tesla achieved. These results on ordered L10 FePt will be compared with those Ni with practical implications of information storage (1,2). (1) H. Zhou, D. Kumar, A. Krots, A. Tiwari, J. Narayan, J. Appl. Phys. 94, 4841 (2003). (2) G.R. Trickey, D. Chakrabarti, J. Narayan, J. T. Prater, J. Phys. D: Appl. Phys 40, 7273 (2007).

3:30PM L23.00004 A study of photoemission using CW and pulsed UV light sources to probe surface slip band structure evolution of single crystal aluminum1, MINGDONG CAI, University of Houston, STEPHEN LANGFORD, J. THOMAS DICKINSON, Washington State University — We report measurements of photoelectron emission from high-purity single crystal aluminum during uniaxial tensile deformation. A 248 nm pulsed excimer laser was used as a light source and the generated photoemission data was compared with that using a filtered mercury lamp. Time-of-flight curves of photoelectrons generated by pulsed excimer laser irradiation were observed showing a two peaked structure. These two peaks correspond to photoelectrons of two energy levels. It was also found that real time total photoelectron charge increases linearly with strain; and the increment is heterogeneous. Photoemission using low-energy photons is sensitive to changes in surface morphology accompanying deformation, including slip line and band formation. The discontinuity in photoelectron intensity and the heterogeneous surface slip band structure prove the production of fresh surface area is not continuous, which is predicted by a recent dislocation dynamics theory based on percolation process. Except for differences in instrumentation and data analysis, the photoemission data from a filtered mercury lamp and from the excimer laser are comparable. Current studies extend the application of the excimer laser into surface dynamics analysis.1 This work was supported by the Department of Energy under Grant DE-FG03-02ER45088.

3:42PM L23.00005 Self-Positioning Optically Trapped Microspheres For Nanoscale Laser Direct Write, CRAIG ARNOLD, EUAN MCLEOD, Princeton University — We present a novel method of near-field laser direct-write patterning by incorporating self-positioning optical manipulation of polystyrene microsphere combined with pulsed laser processing. A 532 or 1064 nm CW laser optically traps a water-dispersed microsphere against a polymer substrate using a 2-dimensional Bessel beam trap. The optical scattering force due to the Bessel beam in the propagation direction is balanced by the repulsive interaction near the surface thereby creating an equilibrium spacing between the two, regardless of large scale surface features. A pulsed nanosecond 355 nm laser directed down the same beam path, is then used to ablate or modify the surface below the microsphere. While the pulsed laser has a large spot diameter, the intensity required for material modification is only achieved directly below the sphere due to focusing and near-field enhancement. Using an x-y translation stage, we demonstrate the ability to move the substrate while keeping the bead fixed in the optical trap, but allowing it to maintain its position above the surface. Direct-write nanoscale features are thereby enabled through this process. Characterization of the resulting structures along with advantages and limitations of this technique will be discussed.

3:54PM L23.00006 2D patterned GaN$_{x}$As$_{1-x}$ Quantum structures using Ion Implantation and Pulsed Laser Melting, TAESEOK KIM, MICHAEL J. AZIZ, VENKATESH NARAYANAMURTI, School of Engineering and Applied Sciences, Harvard University — We will present two dimensionally patterned GaN$_{x}$As$_{1-x}$ nanostructures fabricated in a GaAs matrix using nitrogen implantation followed by pulsed laser melting and rapid thermal annealing (RTA). The arbitrarily patterned GaN$_{x}$As$_{1-x}$ regions are investigated by ballistic electron emission microscopy (BEEM), a three terminal scanning tunneling microscopy technique. BEEM can image both the surface topography and the local hot electron transport. By analyzing BEEM images, we are able to study the surface features for metal blackening and characterized the spectral responses of the black metals from UV to IR. The black metals promise potential for a variety of technologically important applications.

4:06PM L23.00007 Femtosecond laser-induced black metals, ANATOLIY VOROBYEV, CHUNLEI GUO, University of Rochester — Metals are one of the most commonly used materials in everyday life. One of the intrinsic properties of nearly all metals is that they are highly reflective for electromagnetic waves. Recently, by treating metal surfaces with high-intensity femtosecond laser pulses, we turned highly reflective metals highly absorptive and created, for the first time, “black metals”. We also investigated the surface features for metal blackening and characterized the spectral responses of the black metals from UV to IR. The black metals promise potential for a variety of technologically important applications.

4:18PM L23.00008 Cooling rates and mechanisms of resolidification in short pulse laser processing of metal targets1, LEONID ZHIGILEI, ZHIBIN LIN, WILLIAM DUFF, University of Virginia, DMITRIY IVANOV, Technical University of Kaiserslautern — Short-pulse laser irradiation of a metal target can create conditions for generation of non-equilibrium phases and unusual microstructure in the surface region of the irradiated target. The shallow melt depths produced by the short pulse laser irradiation and the high thermal conductivity of metals can result in very high cooling rates, strong undercooling and rapid resolidification. In this work, the melting and resolidification processes occurring under conditions of extreme heating and cooling rates are investigated in large-scale molecular dynamics simulations. The kinetics of the resolidification process and the microstructure of the surface region are found to be defined by a competition between the epitaxial regrowth of the substrate and nucleation of crystallites within the undercooled melt region. The dependence of the final microstructure of the surface region on the irradiation conditions is discussed.

1Financial support of this work is provided by the National Science Foundation, Grant No. CTS-0348503.

4:30PM L23.00009 Modeling of early-stage plasma during femtosecond laser ablation of metals, ZHAOYANG CHEN, SAMUEL MAO, UC Berkeley — We developed a model of early-stage plasma induced by intense femtosecond laser ablation of metals in an ambient gas. We consider a 100 fs FWHM, 800 nm wavelength laser pulse irradiating a copper target in 1 atm nitrogen environment. Electron and lattice temperature of laser-irradiated target were calculated based on a two-temperature model, with surface electron emission due to thermonic and photoelectric effects utilized as the boundary condition for plasma initiation. Plasma development was calculated based on conservation laws for electrons, ions, as well as atoms from ambient gas. Inverse Bremsstrahlung laser absorption by electrons and electron impact ionization were found to be responsible for plasma development, and the simulation results yielded the laser intensity threshold for femtosecond laser-induced plasma formation.
4:42PM L23.00010 Laser-Ablation Deposited Hafnium-Oxide Films for Triple Point Cathodes, RONALD GILGENBACH, NICHOLAS JORDAN, Y.Y. LAU, DAVID FRENCH, P. PENCVANICH, BRAD HOFF, MICHAEL ATZMON, University of Michigan — The triple-point is defined as the interface between metal, dielectric and vacuum; it provides a copious source of electrons for cold-cathodes. Pulsed-laser-deposition has been utilized to fabricate triple-point cathodes consisting of hafnium-oxide film-islands deposited over metal substrates. A 600 mJ, 20 ns KrF laser ablates a solid target of hafnium metal in a background gas of 20 percent O2 and 80 percent Ar at 100 mTorr at 10-15 ps. Contact lithography is employed to fabricate arrays of Hf-oxide islands on substrates to maximize the area of triple points for electron emission. For materials analysis, the films are deposited on a Si substrate. Plume plasma diagnostics include gated optical emission spectroscopy; neutral and singly-ionized hafnium have been measured. Hafnium-oxide film diagnostics include XEDS, SEM, TEM, profilometry, ellipsometry and x-ray diffraction (XRD). Hafnium-oxide deposition rates are about 0.06 nm/pulse. Cathode experimental current results will be presented at -300 kV.

4:54PM L23.00011 Growth control of GaAs nanowires using pulsed laser deposition with arsenic over-pressure, X.W. ZHAO, A.J. HAUSER, T. R. LEMBERGER, F.Y. YANG, Department of Physics, the Ohio State University — Using pulsed laser ablation with arsenic over-pressure, the growth conditions for GaAs nanowires (NWs) catalyzed by gold nanoparticles have been systematically investigated. The single-crystal structure and geometry of the NWs have been characterized for various growth conditions. Arsenic over-pressure with As2 molecules was introduced into the system by thermal decomposition of polycrystalline GaAs to control the stoichometry and shape of the NWs during growth. GaAs NWs exhibit a variety of geometries under varying arsenic over-pressures. Without As2 over-pressure, branched growth of GaAs with uncontrollable size and geometry was observed due to the decomposition of GaAs NWs, producing metallic Ga which serves as catalysts for the branched growth of GaAs on the nanowire surfaces. Under optimal As2 over-pressure, at substrate temperature of 570 °C, single-crystal GaAs NWs with uniform diameter of ~50 nm, small diameter distribution, length over 20 micrometers, and thin surface oxide layer of ~0.5 nm were obtained. X-ray diffraction results confirm the zinc-blende crystal structure of the GaAs NWs. A preliminary electrical characterization gives a linear J-V curve with a reasonable resistance, which leads to more thorough electrical characterization on GaAs NWs and device fabrication.

Tuesday, March 11, 2008 2:30PM - 5:30PM – Session L24 DMP: Focus Session: Transport in Nanostructures IV: 2DES, Dots, and QPCs

Morial Convention Center 216

2:30PM L24.00001 Coulomb and Spin Blockade transport through molecules and quantum dots, BHASKARAN MURALIDHARAN, Purdue University, OWEN MILLER, University of Virginia, AVIK GHOSH, Univeristy of Virginia, SUPRIYO DATTA, Purdue University — In this talk we address some common theoretical grounds between molecular electronics and quantum-dot transport. Here, we focus on how theoretical models based on Coulomb Blockade (CB) theory can be successfully applied in order to theoretically interpret various notable transport experiments in both molecular electronics and quantum dot transport. We first show that, a majority of low-temperature molecular experiments can be explained easily, using a simplified CB theory. In the later part, we focus on how the many-body excitation spectrum of the molecule/quantum dot plays a significant role, in many other experiments. This includes, not-so-commonly observed transport effects such as Negative Differential Resistance (NDR) and bi-stability, resulting from asymmetry within the molecule or within the quantum dot array.

2:42PM L24.00002 Influence of coherent level mixing on the resonant currents at anti-crossings between two single particle levels of a vertical quantum dot, C. PAYETTE, D.G. AUSTING, NRC, McGill University (Canada), G. YU, J.A. GUPTA, NRC (Canada), S.V. NAIR, University of Toronto (Canada), B. PARTOENS, Universiteit Antwerpen (Belgium), S. AMADA, ICORP-JST (Japan), Y. TAKURA, NTT-BRL (Japan), S. TARUCHA, ICORP-JST, University of Tokyo (Japan) — We study single electron resonant tunneling through weakly coupled vertical quantum dot molecules. Using the ground state of one of the constituent dots as an energy filter, we can probe the single particle energy spectrum of the other dot. Overall, the spectra are well modeled by assuming the dots are either circular or elliptical and parabolic, except in the regions where two or more single particle states approach each other. In these regions, we observe pronounced level mixing behavior. Here, we focus on the numerous two level anti-crossings, examining the conditions which lead to either simple transfer of the resonant current strengths between the two branches or concurrent enhancement and suppression of the resonant current in the two branches. We show that both types of behavior can be understood using a simple coherent level mixing model.

2:54PM L24.00003 Electron-Phonon Kinetics and Transport in 2D Structures of Reduced Electron Concentrations, ANDREI SERGEEV, SUNY at Buffalo, MICHAEL REIZER, VLADIMIR MITIN, SUNY at Buffalo — Usually, screening of the electron-phonon (e-ph) interaction is considered in linear approximation. In this case in 2D systems, the Debye screening radius \( r_D \) is independent on the electron concentration, \( n \). The linear approximation ignores the discreteness of the electron charge and it is not applicable for diluted systems. Here we show that the screening radius for e-ph interaction is in fact

\[
\max(r_D, n^{-1/2})
\]

For this reason, e-ph interaction is drastically enhanced in the diluted systems. In particular, a value of the deformation potential is increased by a factor of

\[
\frac{n^{1/2}}{r_D} \approx R_0/a_0 = r_s.
\]

The suggested approach explains puzzling data [1], which demonstrate that the deformation potential between holes and phonons in dilute 2D GaAs is twenty times stronger than expected from the theory. Strong coupling increases all e-ph phenomena. Using the Keldysh diagrammatic technique, we calculate kinetic and transport characteristics for diluted 2D systems. [1] X.P.A. Gao et al, Phys. Rev Lett. 94, 086402 (2005).

3:06PM L24.00004 Novel measurement techniques for probing quantum point contacts1 — LINDSAY MOORE, Stanford University — Conductance measurements of quantum point contacts (QPCs) reveal an anomalous plateau at roughly 0.7 x 2e^2/h, when the mode occupation is just short of making a fully transmitting 1D channel available. Past experiments have built a consensus that this so-called “0.7 structure” is related to electron spin and electron-electron interaction, but the detailed description remains controversial. We have performed measurements on two new kinds of devices which give new insight into the interactions of electrons in these clean quasi-one dimensional systems. One device allows us to measure the compressibility of the electrons in a QPC for the first several conduction modes. Comparison with density functional calculations give new information about the relative importance of interactions (including exchange) as the density in the QPC is depleted. The second device allows us to measure the local density of states (DOS) in the QPC as we tunnel directly into the constriction. Deviations from the 1D DOS would help to develop a more complete picture of the transport through a QPC. We acknowledge support from the ONR Young Investigator Program, Award No. N00014-01-1-0569 and a Research Corporation Research Innovation Award, No. R1260.

3:42PM L24.00005 Ballistic hole transport and the 0.7 anomaly in p-type GaAs quantum wires — A.R. HAMILTON, School of Physics, University of New South Wales, Sydney, NSW 2052, Australia, R. DANNEAU, UNSW and Low Temperature Laboratory, Helsinki University of Technology, Espoo, Finland, O. KLOCHAN, W.R. CLARKE, L.H. HO, A.P. MICOLICH, M.Y. SIMMONS, School of Physics, University of New South Wales, Sydney, NSW 2052, Australia, M. PEPPER, D.A. RITCHIE, Cavendish Laboratory, University of Cambridge, Cambridge CB3 0HE, U.K. — Studying the spin degree of freedom of charge carriers in semiconductors is an area of significant current interest. Although spin-orbit coupling is extremely strong in p-type semiconductors such as GaAs, to date there have been only a limited number of experiments on holes in p-GaAs nanostructures. We have fabricated extremely high quality 1D hole quantum wires that show up to 10 extremely clean and stable quantized conductance plateaus at B=0 [1]. In contrast to 1D electrons, we observe an extreme anisotropy of the Zeeman spin splitting of the 1D energy levels depending on whether the magnetic field is parallel or perpendicular to the quantum wire [2]. We use this anisotropy to show that the 0.7 feature and zero bias anomaly are both spin related in hole quantum wires [3]. [1] O. Klocham et al, APL 89, 092105 (2006); R. Danneau et al, ibid 88, 012107 (2006). [2] R. Danneauet al, PRL 97, 026403 (2006). [3] R. Danneau et al, PRL in press.

3:54PM L24.00006 Elementary Events of Electron Transfer in a Voltage-Driven Quantum Point Contact — MIHAJLO VANEVIC, YULI NAZAROV, WOLFGANG BELZIG, Universitat Basel — We find that the statistics of electron transfer in a coherent quantum point contact driven by an arbitrary time-dependent voltage is composed of elementary events of two kinds: unidirectional one-electron transfers determining the average current and bidirectional two-electron processes contributing to the noise only. This result pertains at vanishing temperature while the extended Keldysh-Green’s function formalism in use also enables the systematic calculation of the higher-order current correlators at finite temperatures.

4:06PM L24.00007 Zeeman splitting and subband spacing in ballistic Ga0.25In0.75As/InP quantum point contacts — THEODORE MARTIN, A. SZORKOVSKZY, University of New South Wales, C.A. MARLOW, University of Oregon, L. SAMUELSON, Lund University, H. LINKE, University of Oregon, R.P. TAYLOR, University of Canterbury, A.P. MICOLICH, A.R. HAMILTON, University of New South Wales — Spin-resolved transport in low-dimensional, solid state systems is a leading area of research at the nanoscale, due to potential device applications. This project extends our work in the quantization of such devices using the spin-orbit coupling to generate a well-resolved energy level spectrum and a large splitting of the spin-degeneracy. Here we investigate the transport properties of a ballistic quantum point contact (QPC) etched into a high indium content strained GaInAs/InP heterostructure, a system with strong spin-orbit coupling and large 1D subband spacings. We have measured the 1D subband spacing using two independent methods, and find it to be ~10 meV, with a very steep confining potential. We also present data studying the Zeeman splitting of the 1D subbands for different magnetic field orientations.

4:18PM L24.00008 Magnetococonductance of interacting electrons in quantum wires in the integer quantum Hall regime — IGOR ZOZOLENKOV, SIARHEI HNATSENKA, Linkoping University — We present systematic quantitative description of the magnetococonductance of the split-gate quantum wires. Accounting for the exchange and correlation interactions within the spin density function theory (DFT) leads to the lifting of the spin degeneracy and formation of the spin-resolved plateaus at odd values of e^2/h. We show that the width of the odd conductance steps in the spin DFT calculations is equal to the width of the transition intervals between the conductance steps for the spinless Hartree electrons. A detailed analysis of the structure of compressible/incompressible strips and the evolution of the Hartree and the spin-DFT subband structure provides an explanation of this finding. Our spin-DFT calculations reproduce not only qualitatively, but rather quantitatively all the features in the magnetoconductance observed in the experiment [1] including the unexpected effect of the collapse of the odd conductance plateaux at lower fields.

4:30PM L24.00009 The Virtual Scanning Tunneling Microscope: A Novel Probe Technique for Imaging Two-Dimensional Electron Systems — ADAM SCIAMBI, DAVID GOLDBERGER-GORDON, Stanford University, SETH BANK1, ARTHUR GOSSMARK, University of California, Santa Barbara — We propose a novel probe technique, the virtual scanning tunneling microscope (VSTM), which will provide both spatial and spectroscopic information about two-dimensional electron systems (2DESs) in semiconductor heterostructures. The VSTM’s innovation is the addition of a second ‘probe’ 2DES separated by a low barrier from the sample 2DES below. Simulations show that a positively-biased tip held above the sample surface can greatly diminish the interlayer barrier and induce tunable tunneling between the two 2DESes. If the tip is scanned, the tunneling region will follow below, acting as a virtual tip while screening the true tip from the sample 2DES. This probe technique is motivated by interesting local 2DES physics that can only be studied indirectly because of the depth of 2DESes; we describe a range of predicted spatially-organized phases of 2D electrons which could be accessed with this new probe. We follow with experimental results showing induced tunneling in a GaAs/AlGaAs bilayer 2DES sample, which we characterize thoroughly and use to tunnel into a quantum Hall liquid.

4:42PM L24.00010 Virtual Scanning Tunneling Microscope: Modeling Interlayer Tunneling Between Two-Dimensional Electron Systems in the Ballistic Regime — KATHERINE LUNA, EUN-AH KIM, PAUL ORETO, STEVEN KIVELSON, Stanford University — We study a theoretical model for the virtual scanning tunneling microscope (VSTM), which is a proposal to use interlayer tunneling in a bilayer system as a way to probe two-dimensional electron systems (2DES) in semiconductor heterostructures. We moderate the bi-layer in the presence of weak tunneling between the layers using an analog of the spin-boson model. Previously, such a system was modeled in the diffusive regime by Levitov and Shytov [1], and they predicted a zero-bias anomaly, where the tunneling conductance vanishes singularly near zero-bias as a result of Coulomb blocking. Motivated by the availability of high mobility samples and the goal of using VSTM to probe the physics of clean 2DES dominated by interactions, we focus on tunneling in the ballistic regime. We find the absence of a zero-bias anomaly due to extremely efficient screening in the ballistic regime. We discuss the implications of our results on ongoing experimental efforts. [1] S. Levitov and A.V. Shytov. JETP Lett. 66, 214 (1997).
enhance the formation of lamellar structure consisting of the alpha-form of isotactic polypropylene (iPP) crystal. At low temperature (e.g., polymer in melts, the confinement to the layers results in an enhanced gamma form where hydrogen bonds form in between parallel nylon 6 chains dominate. Interface with the clay particles, the polymer chains orient perpendicular to the interface. While the alpha crystalline form dominated the structure of the polymer in the nano-particle. The structural evolution as a result in alternating layers of nylon and nylon/clay regions forming two distinct interfaces, that with the nanocomposites made by chaotic flow. 

Optical, and electrical applications. Single crystal lattice, tethering them to both surfaces. This control over the 2D assembly of these materials allows us to study materials for various biological, optical, and electrical applications.

5:06PM L25.00002 Polymer Single Crystals as 2D Templates. STEPHEN CHENG, RYAN VAN HORN, WENBIN ZHANG, University of Akron — Polymer single crystals grown from dilute solution provide a novel approach to studying polymer physics. Because these crystals are lamellar in shape, their fold surfaces provide a platform from which to study two-dimensionally ordered structures. By coupling other polymers (forming multiblock copolymers) or inorganic particles (forming organic/inorganic hybrids) to the crystallizable block, it is possible to analyze the inherent physics of confining this assembly to 2D space and to provide an opportunity to use the crystal as a template. These non-crystallizable components are excluded from the single crystal lattice, tethering them to both surfaces. This control over the 2D assembly of these materials allows us to study materials for various biological, optical, and electrical applications.

3:06PM L25.00002 Polymer Single Crystals as 2D Templates. STEPHEN CHENG, RYAN VAN HORN, WENBIN ZHANG, University of Akron — Polymer single crystals grown from dilute solution provide a novel approach to studying polymer physics. Because these crystals are lamellar in shape, their fold surfaces provide a platform from which to study two-dimensionally ordered structures. By coupling other polymers (forming multiblock copolymers) or inorganic particles (forming organic/inorganic hybrids) to the crystallizable block, it is possible to analyze the inherent physics of confining this assembly to 2D space and to provide an opportunity to use the crystal as a template. These non-crystallizable components are excluded from the single crystal lattice, tethering them to both surfaces. This control over the 2D assembly of these materials allows us to study materials for various biological, optical, and electrical applications.

3:18PM L25.00003 Interfacial and confinement effects to the structure of nylon 6 /clay nanocomposites made by chaotic flow. DILRU RATNAWEERA, DVORA PERAHIA, CHAITRA MAHESHA, DAVID ZUMBRUNNEN, Clemson University, MARK KAMPF, Appelton — The structure of polymers within nanocomposites is strongly affected by the confinement of the polymer to the interface with the nanoparticles and the method of blending. In nanocomposites of Nylon 6 and clay particles are made by chaotic blending, the strength of the chaotic flow affects the internal structure on multiple length scales, where the local structure is determined by the interfacial effects between the polymer and the nano-particle. The structural evolution as a results in alternating layers of nylon and nylon/clay regions forming two distinct interfaces, that with the clay and that of the pure nylon and the composite. The structure has been studied by X-ray, AFM and TEM at different chaotic blending strengths. At the interface with the clay particles, the polymer chains orient perpendicular to the interface. While the alpha crystalline form dominated the structure of the polymer in melts, the confinement to the layers results in an enhanced gamma form where hydrogen bonds form in between parallel nylon 6 chains dominate.

3:30PM L25.00004 WAXS investigations on Polyethylene – Carbon Nanofibers Composites. BRIAN JONES, University of Nebraska, Lincoln, JIANHUA LI, Rigaku Americas, TX, ROGELIO BENITEZ, KAREN LOZANO, MORCEA CHIPARA, ALIN CRISTIAN CHIPARA, MAGDALENA DOGNA CHIPARA, The University of Texas Pan American, DAVID J. SELLMYER, University of Nebraska, Lincoln — Nanocomposites have been obtained by high-shear mixing of isotactic polyethylene with various amounts of purified nanofiller (vapor grown carbon nanofibers type PR-24AG from Pyrograf Products, Inc) by utilizing a HAAKE Rheomix at 65 rpm and 180 °C for 9 min followed by an additional mixing at 90 rpm for 5 min. Composites loaded with various amount of vapor grown carbon nanofibers have been prepared. Various spectroscopic techniques have been used to assess the interactions between the polymeric matrix and carbon nanofibers. Wide angle X - Ray scattering investigations focused on the effect of carbon nanofibers on the crystalline phases of polypropylene and on the overall crystallinity degree of the polymeric matrix. This research aims at a better understanding of the nature and structure of the polymer – carbon nanofibers interface.

3:42PM L25.00005 Crystallization of Propylene-Hexene Random Copolymer. YIMIN MAO, FENG ZUO, JONGKAHK KEUM, BENJAMIN HSIAO, Department of Chemistry, Stony Brook University, Stony Brook, NY 11794-3400 — Time resolved small- and wide-angle x-ray scattering (SAXS/WAXS) were used to study the crystallization behavior of propylene-hexene random copolymer containing non-crystallizable hexene segments and crystallizable propylene segments. It was found that the copolymer would follow two crystallization paths depending on temperature, resulting in two distinct crystalline structures. At high crystallization temperatures (e.g. 100°C), the combined effects of phase separation and high chain mobility greatly enhance the formation of lamellar structure consisting of the alpha-form of isotactic polypropylene (iPP) crystal. At low temperature (e.g. 40°C), the lack of phase separation and the low chain mobility mainly result in the formation of fringe-micelle structure also with the alpha-form of iPP.

3:54PM L25.00006 Probing the crystallisation of polyethylene confined to a system of droplets. JESSICA CARVALHO, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University — We present results on the crystallisation of polyethylene (PE) confined to a system of dewetted droplets. With the droplet system, we have access to a large ensemble of small. isolated volumes of crystallisable material, allowing for a direct measurement of nucleation rates. In our previous work with dewetted droplets of poly(ethylene oxide), we were able to demonstrate that long chains showed the same nucleation behaviour as chains roughly an order of magnitude shorter[1]. In contrast to this, it has been shown that for systems of n-alkanes molecular weight plays a role[2]. By investigating a wide range in molecular weight, the dependence of nucleation on molecular weight will be addressed in PE. [1] M.V. Massa et al., Phys. Rev. Lett. 97, 247802 (2006). [2] H. Kraack et al., Macromolecules, 33, 6174 (2000).
4:06PM L25.00007 Crystalline Morphology of Propylene 1-Octene Random Copolymers¹. KEEsu JEOu, RUFUINA G. ALAmO, Department of Chemical and Biomedical Engineering, FAMU-FSU College of Engineering — The morphology of isotactic propylene 1-octene random copolymers has been studied by AFM, DSC, WAXS, and FTIR in an octene range of 10-20 mol %. Different morphologies were observed below and above 15 mol %. The morphological components in the higher count copolymers are not of the lamellae-type, thicker than lamellae observed below 15 mol %, connected and isotropic in their orientation. Their global morphology is developed via nucleation and growth (NG) of spherulitic aggregates. The evolution of heat of fusion with time is also sigmoidal shape, typical of NG-type crystalization mechanism. WAXS diffractograms for the higher count copolymers are devoid of crystalline reflections, except for small and broad peaks suggesting mesomorphic-like structures, which by FTIR show small contents of the 840 cm⁻¹, 12 and higher units regularity bands, and hence formed of short helical sequences. The PO morphology is additionally compared with copolymers with ethylene, 1-butene and 1-hexene counts at matched contents.

4:18PM L25.00008 Tailoring the Properties of Poly(ethylene terephthalate) without Addition of Fillers via Solid-State Shear Pulverization. CYNTHIA PIERRE, KOSMAS KASIMATIS, JOHN TORKELSON, Northwestern University — We demonstrate the ability to very strongly tune the physical and mechanical properties of poly(ethylene terephthalate) (PET) by changing the processing conditions of neat PET during solid-state shear pulverization without addition of any fillers or nucleating agents. Using differential scanning calorimetry, we observe a roughly factor of 3 increase in crystallinity of PET that has been pulverized and subsequently melted relative to the unprocessed PET. We also observe a dramatic increase in the rate of crystallization of the pulverized samples. Rheological characterization has demonstrated an increase in viscosity of the pulverized material, which can be ascribed to branching in the pulverized product. We also observe significant reductions in the oxygen permeability of the PET with pulverization as well as enhancements in mechanical properties that are commensurate with the modified crystallization properties of the pulverized PET.

4:30PM L25.00009 Crystallization of Bromine Substituted Polyethylene with Precise Placement or Random Distribution¹. R.G. ALAMO, K. JEOU, R.L. SMITH, FAMU-FSU College of Engineering, E. BOZ, K.B. WAGENER, Dept. of Chemistry, University of Florida — The crystalline properties of a series of bromine containing polyethylene (PEs) with either a random or an exact placement of the Br atom on each and every 21st, 19th, 15th and 9th backbone carbon have been studied by DSC, NMR, Raman spectroscopy, WAXS and SAXS. Taking into account a larger strain due to the size of the Br atom, the crystallization behavior is analogous to Cl substituted PEs. While all precision Br-PEs crystallize as homopolymers as demonstrated by 1. DMDAS solid-state ¹³C NMR spectra; 2. development of relatively large crystal thickness, and 3. sharp crystallization and melting peaks, the development of the crystalline state in random analogues is led by selection of most crystalline sequences indicated by broad thermal transitions, and lower crystallinities. WAXS patterns are unique for each type of substitution. For precision Br-PEs WAXS contain reflections corresponding to planes containing the Br atoms which are tilted 35° in reference to the chain axis. Due to the accommodation of the large Br atom, the crystals of all precisely substituted Br-PEs studied are deformationally disordered as observed by their Raman and NMR spectra. In contrast, crystals from random analogues display negligible conformational disorder.

4:42PM L25.00010 Molecular and Crystalline Microstructure of Ferroelectric Poly(vinylidene fluoride-co-trifluoroethylene) Ultrathin Films on Bare and Self-Assembled Monolayer-Modified Au Substrates. YOUN JUNG PARK, SEOK JU KANG, Yonsei University, BERNARD LOTZ, ANNETTE THIERRY, Institut Charles Sadron, CHEOLMIN PARK, Yonsei University — There has been much interest in polymorphic crystal structures and ferroelectric properties in polymer materials, as one way of an application for organic memory device. We investigate the molecular and microdomain structure of Poly vinylidene fluoride-co-trifluoroethylene (P(VDF-TrFE)) thin films spin-coated on bare and self-assembled monolayers (SAMs)-modified Au substrates. The two types of films display similar crystalline morphologies with edge-on needlelike crystalline microdomains. They have, however, a different structure depending on the substrate. When the films are deposited on a bare Au surface, the films preferentially have a (110) contact plane with the substrate but a (100) contact plane when deposited on the Au surface modified by SAMs. The polar b-axis, along which the ferroelectric polarization is oriented, is therefore tilted to the film (and substrate) surface normal at 30 and 90°, respectively. In particular, the orientation of the polar b-axis tilted at some 90° to the normal of the polymer films on a CH₃ terminated SAM modified Au surface explains the smaller remanent polarization at low initial electrical bias.

4:54PM L25.00011 Chirality Information Transfer in Poly(Lactides): From Main-Chain Chirality to Lamella Curvature. ROBERT EMERY PRUD’HOMME, DAMIEN MAILLARD, University of Montreal — The behaviour of ultrathin polymer films is very different from that in the bulk phase. In this work, the crystallization of poly(D-lactide) (PDLa) and poly(L-lactide) (PLLa) was followed using in situ atomic force microscopy over a broad range of temperatures and thicknesses. Using a forced nucleation technique, edge-on lamellae were observed, showing a curvature which can be related to the polymer chirality. In the case of PLLA, the lamellae are S-shaped, contrary to the PDLa lamellae which are Z-shaped. This behaviour was also observed on TEM pictures of PLLA and PDLA films crystallized in the same conditions without any external nucleation. For the first time, a relationship has been established between the molecular chirality of poly(lactide)s and their macroscopic behaviour. Moreover, the rotating direction of those lamellae can be directly linked with the sense of twisting of the poly(lactide)s lamellae in banded spherulites. Those observations can lead to a model to where the curved crystals in ultrathin films can be considered as half-lamellae, which, when associated together, give twisted complete lamellae.

5:06PM L25.00012 Effects of Vitamin E on the Oxidative Reaction of Free Radicals in Ultra-High Molecular Weight Polyethylene. BENJAMIN WALTERS, MUHAMMAD JAHAN, The Univ. of Memphis, Phys Dept. — Free radicals in gamma- or x-irradiated ultra-high molecular weight polyethylene (UHMWPE) are investigated as a function of vitamin E (alpha-tocopherol (α-T)). α-T is mixed with UHMWPE (GUR 1020) powder (e-PE) before (premix) or after (post-mix) irradiation. Pre-mix powder is also compression-molded (CM) to solid pucks (1" thick and 2.5" dia.) at 200°C under constant force of 20-40 kN. Free radicals are detected using an X-band electron spin resonance (ESR) spectrometer, and oxidation index (OI) (1720 cm⁻¹) by FTIR technique. As expected, no measurable OI is detected by FTIR and thus e-PE suffers no loss in its mechanical properties. ESR data, however, suggest that α-T quenches polyethylene radicals during and/or immediately after irradiation, but it does not have any effect on the long-term oxidative reaction. The difference between the pre- and post-mix powder is apparent only at the initial stage, and the terminal oxygen-induced radicals (OIR) are produced in all irradiated samples. Both pre- and post-mix powders are found to have equal amount of residual α-T radical (tocophereryl).
is difficult. Limit the number of control electrodes due to the constraints of size, decoherence and cross-talk, and where complex temporal variation of the control voltages of the ‘quantum wire’ and the system’s symmetries are explored. It may also be relevant for gate-controlled solid-state systems where it is desirable or necessary to show how such minimal control could significantly improve information processing in terms of speed, fidelity and transfer efficiency. The scheme presented has efficient execution of a range of useful QIP tasks. We show that it is in principle possible to achieve global control with a single, simple, fixed, local actuator, and most restricted candidate systems where only a single energy transition can be controlled by a piecewise-constant field, and show that even this is sufficient for viable control solution. Normal optimization problems in virtually any area of engineering and science typically have landscape topologies that remain a mystery. Quantum mechanics appears out to be quite special in that the topology of quantum control landscapes can be established generically based on minimal physical assumptions. Various features of these landscapes will be discussed and illustrated for circumstances where the controls are either an external field or the time independent portions of the Hamiltonian; the latter circumstance corresponds to subjecting the material or molecules to systematic variation and hence viewed in the context of being controls. Both theoretical and experimental findings on control landscapes and their consequences will be discussed, including issues of robustness to noise, search algorithm efficiency, existence of multiple control solutions, prospects for identifying reduced sets of control variables, simultaneous control of multiple quantum systems (optimal dynamic discrimination (ODD)), and mechanism analysis.

 Seeking the best control over a posed quantum dynamic objective entails climbing over the associated control landscape, which is defined as the quantum mechanical observable as a function of the controls. The topology and general structure of quantum control landscapes as input output maps dictate the final attainable yield, the efficiency of the search for an effective control, the possible existence of multiple dynamically equivalent controls, and the robustness of any viable control solution. Normal optimization problems in virtually any area of engineering and science typically have landscape topologies that remain a mystery. Quantum mechanics appears out to be quite special in that the topology of quantum control landscapes can be established generically based on minimal physical assumptions. Various features of these landscapes will be discussed and illustrated for circumstances where the controls are either an external field or the time independent portions of the Hamiltonian; the latter circumstance corresponds to subjecting the material or molecules to systematic variation and hence viewed in the context of being controls. Both theoretical and experimental findings on control landscapes and their consequences will be discussed, including issues of robustness to noise, search algorithm efficiency, existence of multiple control solutions, prospects for identifying reduced sets of control variables, simultaneous control of multiple quantum systems (optimal dynamic discrimination (ODD)), and mechanism analysis.

 Seeking the best control over a posed quantum dynamic objective entails climbing over the associated control landscape, which is defined as the quantum mechanical observable as a function of the controls. The topology and general structure of quantum control landscapes as input output maps dictate the final attainable yield, the efficiency of the search for an effective control, the possible existence of multiple dynamically equivalent controls, and the robustness of any viable control solution. Normal optimization problems in virtually any area of engineering and science typically have landscape topologies that remain a mystery. Quantum mechanics appears out to be quite special in that the topology of quantum control landscapes can be established generically based on minimal physical assumptions. Tuesday, March 11, 2008 2:30PM - 5:18PM - Session L26 DCP: Focus Session: Quantum Control II

Morial Convention Center 218

2:30PM L26.00001 Hiking Over Quantum Control Landscapes, HERSCHEL RABITZ, Princeton University — Seeking the best control over a posed quantum dynamic objective entails climbing over the associated control landscape, which is defined as the quantum mechanical observable as a function of the controls. The topology and general structure of quantum control landscapes as input output maps dictate the final attainable yield, the efficiency of the search for an effective control, the possible existence of multiple dynamically equivalent controls, and the robustness of any viable control solution. Normal optimization problems in virtually any area of engineering and science typically have landscape topologies that remain a mystery. Quantum mechanics appears out to be quite special in that the topology of quantum control landscapes can be established generically based on minimal physical assumptions. Various features of these landscapes will be discussed and illustrated for circumstances where the controls are either an external field or the time independent portions of the Hamiltonian; the latter circumstance corresponds to subjecting the material or molecules to systematic variation and hence viewed in the context of being controls. Both theoretical and experimental findings on control landscapes and their consequences will be discussed, including issues of robustness to noise, search algorithm efficiency, existence of multiple control solutions, prospects for identifying reduced sets of control variables, simultaneous control of multiple quantum systems (optimal dynamic discrimination (ODD)), and mechanism analysis.

3:06PM L26.00002 Non-resonant, non-perturbative Dynamic Stark Control of Quantum Dynamics, ALBERT STOLOW, National Research Council — One of the most important non-resonant interactions is the dynamic Stark effect. In the non-resonant but non-hamiltonizing limit, an effective Hamiltonian can be constructed based upon a hierarchy of approximations (the Born-Oppenheimer Approximation, Slowly Varying Envelope Approximation, the Rotating Wave Approximation). In this situation, the effective Hamiltonian contains first order (dipole) and second order (polarizability) matter-field interactions which can lead to significant yet reversible changes to the molecular Hamiltonian. The first order term leads to a fast evolution which follows each optical cycle. The second order term causes an evolution which follows, by contrast, the envelope of the laser pulse. We discuss the use of the non-resonant second order Dynamic Stark Effect as a tool for controlling quantum systems without any net absorption of light. We illustrate this by examples chosen from problems in: (i) Control of branching ratios during non-adiabatic photodissociation; (ii) Control of 3D field free molecular frame alignment of asymmetric tops.

3:42PM L26.00003 Controlling and Understanding Laser Filamentation in the Solution and Gas Phase Molecular Systems, ROBERT J. LEVIS, Temple University — The process of laser filamentation is highly nonlinear, yet amenable to control using laser pulse shaping techniques. Investigations of our ability to control the spatial position of a filament in a water tank and measurements of the forward and back scattered amplified spontaneous emission (resulting from the strong field excitation in the resulting plasma) will be presented. Our time resolved measurements of the dynamics of the filamentation process in various gases will also be reviewed. Finally, a model of the plasma formation will be presented.

4:18PM L26.00004 New Developments in Quantum Control: Phase Space Learning Algorithms and Uncontrollable Quantum Systems, DAVID J. TANNOR, Department of Chemical Physics, Weizmann Institute of Science — This talk has two parts. The first deals with a new representation of shaped ultrafast laser pulses based on a von Neumann time-frequency lattice. We show that a pulse defined in terms of an amplitude and a phase at N frequency points can be represented on the von Neumann lattice using √N points in frequency and √N in time without loss of information. The transformation from the frequency (or time) representation to the von Neumann representation is one-to-one and therefore invertible. We discuss three possible applications of the von Neumann representation of pulses: 1) for cleaning and interpreting complex pulses; 2) for performing systematic scans of the effect of timing and frequency on molecular control; 3) as genes to be used in mutations and crossover in evolutionary algorithms. The second part of the talk deals with the classification of uncontrollable quantum systems. It is well-known that for a quantum system to be controllable the Lie algebra spanned by iterated commutators of H0 and H1 must span the full space of the dynamical algebra. We pose the following questions: When a system is not completely controllable, can we classify different families of uncontrollable systems? If so, can we associate these different types of mathematical structures with different underlying physics (for example, dark states or generalized entangled states)? We show that uncontrollable quantum systems fall into two categories: reducible and irreducible. The former is associated with dark states and the latter with generalized entangled states. Based on Lie subalgebras we give a complete characterization of irreducible uncontrollable systems for systems up to 9 levels. Finally, we show that an earlier intuitive concept of connectivity only incompletely captures this Lie algebraic structure of uncontrollable systems.

4:54PM L26.00005 Quantum information processing with a minimal control, PETER PEMBERTON-ROSS, SONIA SCHIRMER, DAMTP, University of Cambridge, IVAN PULLEN — Various physical and practical constraints limit the amount and type of control we have in quantum information processing systems, leading to complicated or unreliable implementations. To try and circumvent these problems, we take the most restricted candidate systems where only a single energy transition can be controlled by a piecewise-constant field, and show that even this is sufficient for efficient execution of a range of useful QIP tasks. We show that it is in principle possible to achieve global control with a single, simple, fixed, local actuator, and show how such minimal control could significantly improve information processing in terms of speed, fidelity and transfer efficiency. The scheme presented has a natural application to spin-chain systems, where only one interaction between two spins can be controlled, and the effects of the position of the controller in the ‘quantum wire’ and the system’s symmetries are explored. It may also be relevant for gate-controlled solid-state systems where it is desirable or necessary to limit the number of control electrodes due to the constraints of size, decoherence and cross-talk, and where complex temporal variation of the control voltages is difficult.
A Simulation of Strong-Field Attosecond Electron Dynamics: Effects of Pulse Shape

Tuesday, March 11, 2008 2:30PM - 5:30PM — Session L27 GMAG: Focus Session: Low-dimensional Spin Systems

Morial Convention Center 219

2:30PM L27.00001 Specific heat and magnetoelectric effect of the S=1/2 spin-ladder compound (CH$_3$)$_2$CHNH$_3$CuCl$_3$ , YOUNGHAK KIM, YASUO YOSHIDA, YASUMASA TAKANO, University of Florida, HIROYUKY TSUJII, Kanazawa University, KEISHI KANADA, TAKEHIRO SAITO, AKIRA OOSAWA, TAKAYUKI GOTO, Sophia University — As the complexity of systems increases from atoms to molecules, the exploration of non-adiabatic electron dynamics in strong fields requires a leap in understanding and in the principles of description. Recently, a time-dependent Hartree-Fock approach (TDHF) was developed to study the dynamics of individual electrons in multielectron systems. We have used this TDHF approach to numerically simulate the non-adiabatic electron dynamics of a few small molecules and polyacenes using basis sets ranging from AUG-cc-pVTZ for smaller molecules to 6-31G(d,p) for larger molecules. The electric field was applied in the direction of the long molecular axis and the attosecond response of the electrons during and after the laser pulse has been obtained. To determine the effects of ionization, electron dynamics for both neutrals and ions was also simulated. As a function of pulse shape, there are significant differences in the excitation spectrum and volume for each molecule.

2:42PM L27.00002 Neutron scattering study of strong- and weakly-coupled, spin-1/2 spin-ladders , BELLA LAKE, S. NOTBOHM, D.A. TENNANT, Hahn-Meitner Institut, T.G. PERRING, C.D. FROST, R.I. BEWLEY, P. MANUEL, K.P. SCHMIDT, G.S. UHRIG, P. RIBEIRO, C. SEKAR, R. KLINKELER, C. HESS, G. KRABBES — This presentation will discuss two-leg spin-ladders where the magnetic ions have spin-1/2 moments and antiferromagnetic exchange interactions. In the limit of strong rung coupling, the magnetic spectrum is dominated by the gapped magnon mode of an antiferromagnetic dimer, introduction of leg coupling modulates this mode. In the limit of weak rung coupling the excitations are similar to the multi-spinon continuum of the one-dimensional, spin-1/2, Heisenberg antiferromagnet, although the gap remains in the presence of infinitesimal rung coupling. Cyclic exchange interactions are often found in spin-ladders and reduce the gap size. Inelastic neutron scattering measurements will be presented for two ladders. La$_2$Sr$_{10}$Cu$_{24}$O$_{41}$ has strong rung coupling and excitations consisting of a gapped one-magnon mode and a two-magnon continuum. In contrast CaCu$_2$O$_3$ has a weak rung interaction and a substantial cyclic exchange which drives the system gapless and quantum critical. The excitations are similar to a multi-spinon continuum of a spin-1/2 chain, however the presence of rung coupling is revealed by a modulation parallel the rung at low energies.

3:06PM L27.00004 Magnetic and transport properties of the mixed valent vanadium oxides LuV$_4$O$_8$ and YV$_4$O$_8$ — S. DAS, A. NIAZI, D.C. JOHNSTON, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, IA 50011 — Mixed valent vanadium oxides have been subjects of wide interest owing to their exotic properties such as heavy fermion behavior below 10 K in spinel LuV$_4$O$_8$, isomorphous phase transition and charge ordering in YbV$_4$O$_8$, LuV$_4$O$_8$ (L = Y, Lu) crystallize in a structure similar to that of orthorhombic CaFe$_2$O$_4$, containing four inequivalent V sites arranged in zig-zag chains. The formal oxidation state of V in these compounds is 3.25. In this study, the magnetic and transport properties of these LuV$_4$O$_8$ compounds are reported. The magnetic susceptibility indicates two possible structural phase transitions in YbV$_4$O$_8$ in the temperature (T) range 70–90 K. Anomalies in the heat capacity are also seen in this temperature range. The zero- field-cooled/field-cooled magnetic susceptibilities show possible canted antiferromagnetic ordering in both YbV$_4$O$_8$ and LuV$_4$O$_8$ for T < 50 K. For LuV$_4$O$_8$, the dc electrical resistivity of a sintered pellet measured using a standard four-probe technique shows a strong increase at T < 100 K. Supported by the USDOE under Contract No. DE-AC02-07CH11358.

3:18PM L27.00005 Single Crystal Growth and Characterization of Quasi 1-D, Magnon BEC Candidate Pb$_2$V$_3$O$_9$ , BENJAMIN CONNER, NHMFL/FSU, WANG ZHANG, NHMFL, CHRISTOPHER WIEBE, NHMFL/FSU, LUIS BALICAS, YOUNG-JUNG JO, NHMFL — Recent success in the floating zone growth of single crystal Pb$_2$V$_3$O$_9$ will be highlighted. Pb$_2$V$_3$O$_9$ has been studied as part of the class of antiferromagnetic 1D spin 1/2 dimer compounds that are believed to be driven through a phase transition to a BEC state with applied magnetic field. Magnetic susceptibility and specific heat measurements will be discussed.

3:30PM L27.00006 Magnetic structure of frustrated Haldane chain compound Ca$_2$V$_4$O$_7$ , B. LAKE, Hahn-Meitner Institut, O. PIPER, A. DAVOLD-LADINE, M. REEHUIS, K. PROKES, M. EINERLE, A. NIAZI, J.Q. YAN, D.C. JOHNSTON — While the Haldane chain, (Heisenberg spin-1 chain with nearest neighbor antiferromagnet interactions) has been much studied and shown to have gapped magnon excitations, the effect of frustration and single ion-anisotropy has not been investigated experimentally. Theory suggests that frustration can enhance the multi-particle spectrum and the combination of frustration and anisotropy can drive the system into a gapless chiral phase. Ca$_2$V$_4$O$_7$ is a candidate for such a system. This compound consists of two inequivalent one-dimensional chains consisting of spin-1 V$^{3+}$ ions which have antiferromagnetic first and second neighbour interactions. Interchain coupling gives rise to long-range order below $T_g$ = 71K. Neutron diffraction measurements will be described. They reveal collinear spin order within the chains and canting between chains, with the average spin direction along the $b$ axis. The ordered spin moment was also measured and found to be 1 $\mu_B$ per Vanadyl; this reduction of 50% from full spin ordering suggests loss of moment due to quantum fluctuations. Finally, preliminary inelastic neutron scattering reveals a gap due to single-ion anisotropy. In addition a steep dispersion along the $c$ (chain) direction and much weaker dispersions along $a$ and $b$ confirm the one-dimensional nature of Ca$_2$V$_4$O$_7$. Supported by the USDOE under Contract No. DE-AC02-07CH11358.
The local density of states of a finite quantum wire: New insights from DMRG and bosonization

We consider interacting fermions on a finite one-dimensional lattice. By using an adapted DMRG algorithm we are able to calculate the energy and spatially resolved local density of states (LDOS) for the lattice model directly without using time-dependent correlations. We compare to analytic expressions for individual energy levels in systems with open boundary conditions from Luttinger Liquid theory. In this way, a detailed understanding of the LDOS for each individual energy level can be obtained in both fermionic and bosonic pictures. Certain degeneracies of the Luttinger Liquid spectrum are lifted in the lattice model by band curvature and interaction effects, leading to a large number of states and energy levels in the LDOS. The standing waves in the LDOS reveal the collective bosonic excitations explicitly.

Real-time dynamics of spinons and holons in one-dimensional correlated electron systems

In the antiferromagnetic spin-liquid spin-wave stiffness and the Isinglike ferromagnetic excitation spectrum gap, exhibiting the spin-wave to spinon crossover. In the group theory, throughout the entire temperature and anisotropy ranges in both ferromagnetic and antiferromagnetic regions. We obtain, for all anisotropies, the in-plane interaction $s_{i}^z s_{j}^z + s_{i}^x s_{j}^x$ induces an antiferromagnetic correlation in the out-of-plane $s_{i}^y$ component. Conversely, an antiferromagnetic $s_{i}^z s_{j}^z$ interaction induces an correlation in the $s_{i}^x$ component. As another purely quantum effect, (i) in the antiferromagnet, the value of the specific heat peak is insensitive to anisotropy and the temperature of the specific heat peak decreases from the isotropic (Heisenberg) with introduction of either type (Ising or XY) anisotropy; (ii) in complete contrast, in the ferromagnet, the value and temperature of the specific heat peak increase with either type of anisotropy.

Excitation Spectrum Gap and Spin-Wave Stiffness of XXZ Heisenberg Chains: Global Renormalization-Group Calculation

The anisotropic XXZ spin-$\frac{1}{2}$ Heisenberg chain is studied using renormalization-group theory, throughout the entire anisotropy ranges in both ferromagnetic and antiferromagnetic regions. We obtain, for all anisotropies, the in-plane interaction $s_{i}^z s_{j}^z$ + $s_{i}^x s_{j}^x$ induces an antiferromagnetic correlation in the out-of-plane $s_{i}^y$ component. Conversely, an antiferromagnetic $s_{i}^z s_{j}^z$ interaction induces an correlation in the $s_{i}^x$ component. As another purely quantum effect, (i) in the antiferromagnet, the value of the specific heat peak is insensitive to anisotropy and the temperature of the specific heat peak decreases from the isotropic (Heisenberg) with introduction of either type (Ising or XY) anisotropy; (ii) in complete contrast, in the ferromagnet, the value and temperature of the specific heat peak increase with either type of anisotropy.

4:18PM L27.00010 Dispersive excitations in the $S = 1$ antiferromagnet $Ba_3MnO_6$

We study the full Raman intensity for the Heisenberg $S = 1/2$ antiferromagnet on the triangular lattice by simultaneously considering the effects of the renormalization of the spectrum by $1/S$ correlations, and the final state magnon-magnon interactions. The analysis of the Raman intensity without final state interactions shows, that it has two peaks, corresponding to two maxima of the bare magnon spectrum $E_k$. Then we calculate Raman intensity with the renormalized spectrum. We obtain that at the energy at which the renormalized dispersion has a plateau, and, therefore, density of states is large, the Raman intensity is strongly enhanced. We also derive explicit expressions for the vertex functions of order $1/S$, and calculate Raman intensity including $1/S$ self-energy and the vertex corrections on equal footing. The vertex corrections is calculated by a summation of ladder diagrams with magnon-magnon interactions. Once interactions are included, the peak smears out and shifts to lower energies.

techniques have the potential for enabling quantum computing applications such as coupling several qubits via a quantum bus interactions in circuit quantum electrodynamics (QED) experiments \[1\].

We have used the stochastic series expansion quantum Monte Carlo method \[1\] and used the results to interpret our experimental data. For example, copper pyrazine diazide, CuPz(N\(_2\)), has a primary exchange of 15.5 K and an anisotropy parameter \(\alpha = 0.4\). The stronger exchange is due to the superexchange pathway through the pyrazine molecule and the weaker corresponds to the azide bridges. \[1\] A. Sandvik, PRB 59, R14157 (1999).

### 5:18PM L27.00015 Magnetic and Thermal Properties of the Spin \(S = 1/2\) Zig-Zag Spin Chain Compound In\(_2\)VO\(_5\) \(*\). YOGESH SINGH, DAVID JOHNSTON, Ames Laboratory — The structure of In\(_2\)VO\(_5\) consists of zig-zag V\(^{4+}\) (spin \(S = 1/2\)) chains along the \(b\)-axis. Prior to our work, there were two theoretical reports on this material.\[1,2\] One report suggested that the nearest-neighbor and next-nearest-neighbor interactions between the V\(^{4+}\) moments would be anti-ferromagnetic and frustrated,\[1\] while the second report suggested that both these interactions should be ferromagnetic.\[2\] An experimental study of the physical properties of this material had not been reported. We measured magnetic susceptibility \(\chi\), ac susceptibility \(\chi_{ac}\) and specific heat \(C\) versus temperature \(T\) on In\(_2\)VO\(_5\) and \(\chi\) and \(C\) versus \(T\) on the isostructural, nonmagnetic compound In\(_2\)TiO\(_3\). The \(\chi(T)\) data for In\(_2\)VO\(_5\) showed that the dominant magnetic exchange between the V\(^{4+}\) moments was ferromagnetic above 150 K. However, the \(\chi(T)\) and the frequency dependence of the \(\chi_{ac}(T)\) data indicate that below 3 K the system is in a spin-glass state indicating the presence of disorder and frustrated interactions at these temperatures. Our \(C\) and entropy \(S\) data suggest that there may be a structural change below 140 K in In\(_2\)VO\(_5\) which could possibly change the interactions between the V\(^{4+}\) moments.

**Tuesday, March 11, 2008 2:30PM - 5:30PM – Session L28 DCMP: Material Issues for Superconducting Qubits** Morial Convention Center 220

### 2:30PM L28.00001 Fabrication and Characterisation of Superconducting Coplanar Waveguide Resonators for Circuit QED Applications. MARTIN GÖPPLE, Department of Physics, ETH Zurich, ROB SCHOELKOPF, Department of Applied Physics and Physics, Yale University, ANDREAS WALLRAFF, Department of Physics, ETH Zurich, ETH QUANTUM DEVICE TEAM, YALE CIRCUIT QED TEAM — Superconducting thin film microwave cavities have gained great interest in recent years for studying qubit-photon or qubit-photon-qubit interactions in circuit quantum electrodynamics (QED) experiments \[1,2\]. Thin film cavities made by using standard optical lithography and microfabrication techniques have the potential for enabling quantum computing applications such as coupling several qubits via a quantum bus \[2\]. In order to specifically design circuit QED systems the cavity parameters such as resonance frequency and quality factor, determined by the input and output coupling strength need to be precisely controlled. We have fabricated niobium and aluminum resonators on Si, Si/SiO\(_2\) and Al\(_2\)O\(_3\) substrates. Resonators with quality factors up to several hundred thousands have been characterized. Furthermore, the effect of external parameters such as temperature and drive power have been investigated. The measured frequency dependent transmission of the cavities is found to be in good agreement with analytical circuit models.

1. Supported by the USDOE under Contract No. DE-AC02-07CH11358.

### 2:42PM L28.00002 Materials for superconducting qubits: Measurements of dielectric loss at low temperatures. AARON O’CONNELL, M. ANSMANN, R.C. BIALCZAK, R. MCDERMOTT, M. HOFHEINZ, N. KATZ, E. LUCERO, M. NEELEY, H. WANG, E.M. WEIG, J.M. MARTINIS, A.N. CLELAND, UC Santa Barbara — The energy relaxation time \(T_1\) of the Josephson phase qubit is significantly impacted by the microwave loss in the dielectric materials used in fabrication. This loss mechanism is most likely due to the qubit coupling to a ferromagnetic bath of two-level defect states embedded in the dielectrics. At high temperatures or high excitation voltages, these states can become saturated, so that the low loss tangents reported in the literature do not accurately represent the material performance at low temperatures and very small excitation energies. We have probed the microwave (\(~\)6 GHz) loss tangents of a number of common thin-film dielectrics at \(~\)100mK, using very low excitation voltages, in order to obtain values for the loss tangents relevant to quantum computation. We present these loss tangent data, and illustrate a technique to extract material values from measurements of the quality factors of coplanar waveguide resonators.

### 2:54PM L28.00003 Multi-level Spectroscopy of Microstates Coupled to a dc SQUID Phase Qubit. TOM VALLEAU, ROB BUTCHER, BRIAN KEITH, CHRISTOPHER LANDEE, MARK TURNBULL, Clark University, ANDERS SANDVIK, Boston University — Rectangular antiferromagnets are two-dimensional systems with inequivalent exchange strengths \((J', J)\) along the two principle axes with \(J' > J\). Our results are consistent with experimental conclusions that the critical flux \(J_c\) is much larger than the critical flux \(J_c\) for a one-dimensional system. For example, compound VO\(_2\) is frustrated at high temperatures, while the second report suggested that both \(J\) and \(J'\) are frustrated.

\[1\] A. Sandvik, PRB 59, R14157 (1999).

**3:06PM L28.00004 Effect of Two Level System Saturation on Charge Noise in Josephson Junction Quibts. MAGDALENA CONSTANTIN, CLARE YU, University of California, Irvine, JOHN MARTINIS, University of California, Santa Barbara — It is not widely appreciated that two-level systems in small qubits can easily be strongly saturated when the applied electromagnetic flux \(J\) is much larger than the critical flux \(J_c\). We show that charge noise \(S_Q\) in Josephson qubits can be produced by fluctuating two-level systems with electric dipole moments in the substrate using the standard flat density of states. At high frequencies the frequency and temperature behavior of the charge noise depends on the ratio \(J_c/J_d\). Our results are consistent with experimental conclusions that \(S_Q \sim 1/f\) at low frequencies and \(S_Q \sim f\) at high frequencies.
3:18PM L28.00005 Crystalline Josephson phase qubits with improved performance. JEFFREY KLINE, SEONGSHIK OH, National Institute of Standards and Technology. HAOHUA WANG, JOHN MARTINIS, U.C. Santa Barbara, DAVID PAPPAS, National Institute of Standards and Technology — One of the greatest challenges in the development of a practical solid-state quantum computer is to overcome decoherence due to coupling between the environment and the qubit. Superconducting quantum computers based on Josephson phase qubits are susceptible to decoherence due to charge noise in both the tunnel barrier and crossover insulators. We have demonstrated that the usage of crystalline tunnel barriers greatly reduce the density of spurious charge fluctuators in the tunnel barrier when compared to the ubiquitous amorphous barrier. However, a performance gain in coherence time was not realized due to decoherence in the crossover insulator. In the latest generation of devices, we have optimized both the tunnel barrier and crossover insulator materials. Low temperature measurements performed on a large area (50 μm²) device yielded a coherence time of 500 ns which is tied for the Josephson phase qubit world record. We expect increased performance in future generation devices where small area (13 μm²) junctions will be used.

3:30PM L28.00006 1/f Flux Noise in Josephson Phase Qubits1, ROBERT MCDERMOTT, UW-Madison Dept. of Physics, RADEK BIALCZAK, MÁRKUS ANSMANN, MAX HOFHEINZ, NADAV KATZ, ERIK LUCERO, MATTHEW NEELEY, AARON O’CONNELL, HAOHUA WANG, ANDREW CLELAND, JOHN MARTINIS, UCSB Dept. of Physics — We present the results of a novel measurement in a Josephson phase qubit which uses the resonant response of the qubit to directly measure the spectrum of low-frequency noise. This general method can be applied to any qubit system. By alternating the sense of the qubit bias, we show that the noise is predominantly flux-like, as opposed to a critical-current noise. The magnitude of the noise is compatible with previous measurements of excess low-frequency flux noise in SQUIDs cooled to millikelvin temperatures. We present the results of calculations of flux noise from paramagnetic defects in the native oxides of the superconductors, and show that the measured flux noise cannot be explained by the standard model of two-level state defects.

3:42PM L28.00007 Measurements of Decoherence in rf SQUID Qubits1, DOUGLAS BENNETT, LUIGI LONGOBARDI, VIJAY PATEL, DMITRI AVERIN, JAMES LUKENS, Stony Brook University, Department of Physics and Astronomy — We report measurements of coherence times of an rf SQUID qubit using pulsed microwaves and rapid flux pulses. The modified rf SQUID has independent, in situ, controls for the relative positions of levels in different fluxoid wells and the barrier height between the wells. The decay of coherent oscillations is dominated by the lifetime of the excited state and low frequency flux noise. The low frequency flux noise is observed using microwave spectroscopy and resonant tunneling between fluxoid states in addition to the decay of coherent oscillations. These measurements are useful for evaluating the various insulating layers which are believed to be an important source of 1/f noise in many superconducting qubits.

3:54PM L28.00008 Josephson junction microscope for probing and quantum manipulation of low-frequency fluctuators1, LIN TIAN, Department of Applied Physics and E. L. Ginzton Laboratory, Stanford University, Stanford, CA 94305, RAYMOND SIMMONDS, National Institute of Standards and Technology, 325 Broadway, Boulder, Colorado 80305-3328 — The high-Q harmonic oscillator mode of a Josephson junction can be used as a novel probe of spurious two-level systems (TLSs) inside the amorphous oxide tunnel barrier of the junction. In particular, we show that spectroscopic transmission measurements of the junction oscillator mode can reveal how the coupling magnitude between the junction and the TLSs varies with an external magnetic field applied in the plane of the tunnel barrier. The proposed experiments offer the possibility of clearly resolving the underlying coupling mechanism for these spurious TLSs, an important decoherence source limiting the quality of superconducting quantum devices. Meanwhile, quantum manipulation of the TLSs via the junction oscillator mode can also be achieved. L. Tian and R. W. Simmonds, Phys. Rev. Lett. 99, 137002 (2007).

4:06PM L28.00009 Low-frequency Flux Noise in SQUIDs and Superconducting Qubits, STEVEN SEnDELBACH, DAVID HOVER, ACHIM KITTEL, MICHAEL MUECK, ROBERT MCDERMOTT, UW-MADISON DEPARTMENT OF PHYSICS COLLABORATION, INSTITUT FÜR ANGEWANDTE PHYSIK, JUSTUS-LEIBIG-UNIVERSITÄT GIEBEN COLLABORATION — Superconducting qubits are a leading candidate for scalable quantum information processing. In order to realize the full potential of these qubits, it is necessary to develop a more complete understanding of the microscopic physics that governs dissipation and dephasing of the quantum state. In the case of the Josephson phase and flux qubits, the dominant dephasing mechanism is an apparent low-frequency magnetic flux noise with a 1/f spectrum. The origin of this excess noise is not understood. We report the results of SQUID measurements that explore the dependence of the excess low-frequency flux noise on SQUID inductance, geometry, materials, and temperature. We discuss contributions to the measured noise from temperature fluctuations, trapped vortices in the superconducting films, and surface magnetic states in the native oxides of the superconductors. We discuss implications of our measurements for qubit dephasing.

4:18PM L28.00010 Small shadow evaporated junctions for superconducting phase qubits, F. ALTOMARE, M.S. ALLMAN, K. CICAK, M.A. SILLANPÄÄ1, J.D. WHITTAKER, R.W. SIMMONDS, National Institute of Standards and Technology, Boulder, CO 80305 USA — One of the biggest problems facing the fabrication of quantum computers based on superconducting qubits is the short coherence time of the quantum states. This is due to interaction of qubits with both the environment and defects (two level systems-TLS) in the Josephson junction (JJ). Because of the large JJ area, this problem is particularly obvious in phase qubits where it has been shown that TLS greatly affect the coherence time. One way to overcome this problem is to reduce the size of the JJ thus reducing the number of TLS. We will discuss the results of our approach to this solution, namely using shadow evaporated JJ (< 1μm²) and low-loss capacitor, and the results of our experiments on coupled qubits.

4:30PM L28.00011 Investigating two-level systems in the Josephson tunnel barrier1, JOSHUA STRONG, NIST, FABIO ALTOMARE, RAYMOND SIMMONDS — The presence of two-level system defects within the Josephson tunnel barrier has been made apparent in the spectroscopy of superconducting phase quantum bits. Here, we present a different circuit—a tunable harmonic resonator based on the Josephson inductance— which is better suited to the study of these two-level systems. A typical circuit is tunable over a gigahertz range and behaves linearly at sufficiently low drive amplitudes. We use this circuit to investigate the properties of individual defects, extracting parameters such as strength of coupling to the resonator, etc. The sea of two-level systems also has a bulk effect, causing a degradation in the quality factor of the resonator. This means that the Josephson tunnel barrier has a non-zero loss tangent in the microwave regime.

4:42PM L28.00012 Probing dissipation from vortices with superconducting microwave resonators. C. SONG, T.W. HEITMANN, M.P. DEFOE, K. YU, B.L.T. PLOURDE, Syracuse University; R. MCDERMOTT, University of Wisconsin — One potential source of dissipation in superconducting films comes from vortices trapped in the thin films. We present a design for a system of microwave resonators for studying the loss contributed by trapped flux over the frequency range from 2 - 12 GHz. This consists of a multiplexed set of superconducting resonators with a wide range of lengths that are capacitively coupled to a common superconducting feed-line. By cooling the resonators in different magnetic fields, it is possible to probe the loss from vortices as a function of field and frequency, at least at the discrete frequencies of the resonators in our set.

4:54PM L28.00013 Decoherence in Superconducting Qubits from Surface Magnetic States, DAVID HOVER, STEVEN Sendelbach, UW-Madison Department of Physics, ACHIM KITTEL, Institut für Angewandte Physik, MICHAEL MUECK, Justus-Leibig-Universität Gießen, ROBERT MCDERMOTT, UW-Madison Department of Physics, UW-MADISON DEPARTMENT OF PHYSICS COLLABORATION, INSTITUT FÜR ANGEWANDTE PHYSIK COLLABORATION, JUSTUS-LEIBIG-UNIVERSITÄT GIEBEN COLLABORATION — Unpaired spins in amorphous surface oxides can act as a source of decoherence in superconducting and other solid-state qubits. A density of surface spins can give rise to low-frequency magnetic flux noise, which in turn leads to dephasing of the qubit state. In addition, magnetic surface states can couple to high-frequency resonant magnetic fields, and thereby contribute to energy relaxation of the qubit. We present the results of low-frequency measurements of the nonlinear and imaginary spin susceptibility of surface magnetic states in superconducting devices at millikelvin temperatures. In addition, we describe high-frequency magnetic resonance measurements that directly probe the surface spin density of states. We present calculations that connect the measurement results to qubit energy relaxation and dephasing times.

5:06PM L28.00014 Measurement of low frequency flux noise in superconducting flux qubits1. WEI QIU, BO MAO, Department of Physics and Astronomy, University of Kansas, Lawrence, KS 66045, YANG YU, Department of Physics, Nanjing University, Nanjing 210093, China, SHAOXIONG LI, SIYUAN HAN, Department of Physics and Astronomy, University of Kansas, Lawrence, KS 66045, DEPARTMENT OF ELECTRONICS SCIENCE AND ENGINEERING, NANJING UNIVERSITY COLLABORATION — The development of superconducting quantum interference device (SQUID) technology has been impeded significantly in the last several years by excessive low frequency flux noise which has become the dominant decoherence mechanism in several experiments. We measured the low frequency flux noise in SQUIDs with inductance ranging from about 30 pH to 1 nH. We found that for the Nb SQUIDs fabricated with the same process the measured rms low frequency flux noise has a linear dependence on the inductance of the SQUIDs. Implications of the result on material, design, fabrication of flux qubit will be discussed.

5:18PM L28.00015 Measurement of Spin Susceptibility of Thin Films and Nano-Scale Structures, JULIE BERT, HENDRIK BLUHM, NICHOLAS KOSHNICK, Stanford University; MARTIN HUBER, University of Colorado Denver, KATHRYN MOLER, Stanford University — We report measurements of a spin-like paramagnetic susceptibility signal from high purity metallic and insulating thin films. The measurements were performed using a Superconducting Quantum Interference Device (SQUID) in a scanning microscope. By using the SQUID to scan areas of the sample both near and far from the metallic films, we found a paramagnetic susceptibility associated with both Au and AlOx films that was ten times larger than could be explained by the concentration of impurity spins expected for 6N gold. The 1/T temperature dependence and the paramagnetic sign indicate that the susceptibility signal is caused by localized spins that are at most weakly coupled to each other and to the conduction electrons. Moreover, the signal exhibits a measurable out of phase response which can be related to 1/f noise due to fluctuating spins [Koch, Divincenzo, and Clarke, Phys. Rev. Lett. 98, 267003 (2007)]. These results demonstrate the utility of scanning SQUID based susceptibility measurements for characterizing spin related effects. Further applications of this technique may include probing 1/f noise origins in superconducting devices as well as imaging magnetic structures such as nanomagnets.

Session L29 DMP: Focus Session: Carbon Nanotubes and Related Materials VIII: Electronic Structure of Graphene, Morial Convention Center 221

2:30PM L29.00001 Electronic Structure and Morphology of Graphene Layers on SiC, TAI SUKE OHTA, Lawrence Berkeley National Laboratory/Fritz Haber Institute — Recent years have witnessed the discovery and the unique electronic properties of graphene, a sheet of carbon atoms arranged in a honeycomb lattice. The unique linear dispersion relation of charge carriers near the Fermi level ("Dirac fermions") lead to exciting transport properties, such as an unusual quantum Hall effect, and have aroused scientific and technological interests. On the way towards graphene-based electronics, a knowledge of the electronic band structure and the morphology of epitaxial graphene films on silicon carbide substrates is imperative. We have studied the evolution of the occupied band structure and the morphology of graphene layers on silicon carbide by systematically increasing the layer thickness. Using angle-resolved photoemission spectroscopy (ARPES), we examine this unique 2D system in its development from single layer to multilayers, by characteristic changes in the π band, the highest occupied state, and the dispersion relation in the out-of-plane electron wave vector in particular. The evolution of the film morphology is evaluated by the combination of low-energy electron microscopy and ARPES. By exploiting the sensitivity of graphene’s electronic states to the charge carrier concentration, changes in the on-site Coulomb potential leading to a change of π and π* bands can be examined using ARPES. We demonstrate that, in a graphene bilayer, the gap between π and π* bands can be controlled by selectively adjusting relative carrier concentrations, which suggests a possible application of the graphene bilayer for switching functions in electronic devices. This work was done in collaboration with A. Bostwick, J. L. McChesney, and E. Rotenberg at Advanced Light Source, Lawrence Berkeley National Laboratory, K. Horn at Fritz-Haber-Institut, K. V. Emteev and Th. Seyller at Lehrstuhl für Technische Physik, Universität Erlangen-Nürnberg, and F. El Gabaly and A. K. Schmidt at National Center for Electron Microscopy, Lawrence Berkeley National Laboratory.

3:06PM L28.00002 Tailoring electronic properties in coated graphene, BRUNOUCHOA, C.-Y. LIN, N.M.R. PERES, J.M.B. LOPES DOS SANTOS, A.H. CÁSTRO NETO, Boston University — Graphene is a single layer carbon material whose unique properties in transport are tied to its peculiar Fermi surface, which is made out of six points at the corners of the Brillouin zone where the conduction and valence bands touch. Due to the vanishing density of states at these points, the low energy excitations are made of massless Dirac fermions, with several anomalous properties in transport. We propose that some of the unique properties of graphene can be tailored by the chemical adsorption of impurity atoms on its surface. If on one hand the impurities atoms are good charge donors and can be used to control the number of charge carriers in graphene, transition metals have a more covalent character and can be used to induce magnetism. We show that despite pure graphene cannot be magnetized, the hybridization of the carbon orbitals with non-magnetic d orbitals can generate strong itinerant magneticity in graphene coated with transition metal atoms. On the other hand, if an isolated impurity atom is able to form a stable localized level under hybridization with the bath of electrons in graphene, we show that the suppression of the density of states at the localized level can strongly favor the formation of a local magnetic moment at the impurity. We propose that the local magnetization of the impurity can be controlled by the application of an external gate voltage.
WALTER DE HEER, Georgia Institute of Technology — Graphite oxide is a layered semiconducting material that is produced from graphite or graphene by LI, XIAOSONG WU, Georgia Institute of Technology, CLAIRE BERGER, Georgia Institute of Technology - USA; CNRS - Institut Neel, Grenoble - France, ∼

For the bi-layer, a strong absorption peak was seen at 0.37eV. The absorption spectrum of tri-layer graphene was found to be well represented by the sum of those

HEINZ, Columbia University — Absorption spectra in the infrared range (0.3 – 1 eV) were measured for large-area, single-crystal mono-, bi- and tri-layer

Multi-layer Graphene Samples

 layers in the Visible and Near-Infrared

energy distribution, how they are modified by the application of external electric fields, and differences with respect to the polarity of the fields. The calculated results will be compared to the electronic and structural properties observed in scanning tunneling microscopy experiments.

Columbia University — Single-crystal mono- and multi-layer graphene samples were prepared by mechanical exfoliation on quartz substrates. The absorption spectra of samples of 1 – 3 monolayer thickness were measured in the optical and near-infrared range. The absorption coefficient was found to be largely independent of photon energy and linear in the number of graphene layers. Such absorption measurements can thus be used to determine the thickness of mesoscopic graphite to monolayer accuracy, as already demonstrated in the context of Rayleigh scattering [Casiraghi et al. Nano Letters 2007]. By analysis of the optical transmission problem for a thin film at the air-quartz interface, we deduced an absorption of 2.3% per layer. The magnitude of the monolayer absorption agrees with the value of $\pi \alpha$, where $\alpha$ is the fine-structure constant, and corresponds the result obtained from a tight-binding model of the graphene electronic structure [Gusynin et al. PRL 2006]. The predicted (and measured) optical absorption, we note, is equivalent to a constant optical conductance of $\sigma_{xx} = 6.09 \times 10^{-5} \Omega^{-1}$.

4:06PM L29.00007 Experimental Measurement of Ultrafast Carrier Dynamics in Mono- and Multi-layer Graphene Samples , DAOHUA SONG, KIN FAI MAK, YANG WU, CHUN HUNG LUI, Columbia University, MATTHEW SFEIR, Brookhaven National Laboratory, SAMI ROSENBLATT, HUGEN YAN, JANINA MAULTZSCH , TONY HEINZ, Columbia University — The ultrafast dynamics of charge carriers in mono- and multi-layer graphene was investigated by femtosecond transient reflectivity measurements. The experiments were performed using 100-fs optical pump pulses at a wavelength of 400 nm and probe pulses at a wavelength of 800 nm. We observed a transient response on the time scale of several picoseconds. For bulk graphite, a decay time of $\sim$ 3 ps was found; for thin graphene multilayer samples, a reduced decay time was observed, dropping ultimately to $\sim$ 1 ps for a single graphene layer. The reflectivity transients can be understood in terms of coupling of the photo-generated electronic excitations to optical phonons, and the subsequent loss of energy from this sub-system. The possible role of graphene interactions with the quartz substrate and the effect of the graphene electronic specific heat on the decay rate will be discussed.

4:18PM L29.00008 Exposure of Epitaxial Graphene on SiC(0001) to Atomic Hydrogen1. NATHAN GUISINGER, National Institute of Standards and Technology, GREG RUTTER, Georgia Institute of Technology, JASON CRAIN, National Institute of Standards and Technology — Graphite films on SiC exhibit coherent transport properties that suggest the potential for novel carbon-based nanoelectronics applications. Recent studies suggest that the role of the interface between single layer graphene and silicon-terminated SiC can strongly influence the electronic properties of the graphene overlay. In this study, we have exposed the graphiteized SiC to atomic hydrogen in an effort to passivate dangling bonds at the interface. We have used scanning tunneling microscopy to investigate the interface surface structure following exposure to atomic hydrogen for a range of sample temperatures. Initial results indicate that regions of clean SiC were successfully passivated with atomic hydrogen below 400 °C, while the underlying interface of the graphitized regions appear to be unchanged for all temperatures studied. The threshold temperature for passivating clean SiC suggest that the passivated dangling bonds are primarily from Si atoms that are present within the SiC surface reconstruction. Although the hydrogen does not appear to penetrate below the graphene layer, initial results suggest that it does adsorb to the graphene.

4:30PM L29.00009 Characterization of Epitaxial Graphene Oxide , FAN MING, MICHAEL SPRINKLE, XUEBIN LI, XIAOSONG WU, Georgia Institute of Technology, CLAIRE BERGER, Georgia Institute of Technology - USA; CNRS - Institut Neel, Grenoble - France, WALTER DE HEER, Georgia Institute of Technology — Graphite oxide is a layered semiconducting material that is produced from graphite or graphene by chemical oxidation. The material is characterized by various probes such as transport, Raman spectroscopy and optical absorption spectroscopy. Here we present the properties of graphite oxide, which is chemically converted from epitaxial graphene directly on silicon carbide chips. The absorption spectrum indicates a large band gap and the Raman spectrum shows a pronounced D line while the 2D line is absent.
Depto de Física - UFMG — The authors introduce a geometry for ultrathin Au and Ag wires that is analyzed in terms of an interplay between geometric and electronic structure effects. Conductivity of individual graphene oxide sheets on silica/silicon substrate were measured with a 4-electrode configuration at room temperature. The conductance was found to be in the range of 500 to 1000 S/cm.

5:45PM L29.00011 Electrical conductivity of graphene oxide sheets and networks of such sheets1. Supported by the NASA through the University Research, Engineering, and Technology Institute on Bio-inspired Materials (BiMat) and by the DARPA Center on Nanoscale Science and Technology for Integrated Micro/Nano-Electromechanical Transducers (IMINT).

5:06PM L29.00012 The epitaxial graphene-graphene oxide junction, a key step towards epitaxial graphene electronics. We report on a theoretical study of the influence of electron-electron interactions on the one-particle Green’s function of a doped graphene sheet based on the random-phase-approximation and on graphene’s massless Dirac equation continuum model. We find that the presence of Schottky barriers, due to the band gap in GO, is essential to obtaining a high conductance.

5:18PM L29.00013 Plasmons and The Spectral Function of Graphene. We acknowledge support from the Brazilian agencies: FAPEMIG, CAPES, CNPq, and Instituto do Milênio de Nanotecnologia/MCT.

2:30PM L30.00001 Surface scattering in metallic nanowires. We study the dynamical motion of the atoms in the wire. Soft phonon modes were studied. It has been found that the lowest phonon states are associated with motions of atom in the middle of the chain. Atomic motion of this mode was studied by solving the nuclear wavefunction of the wire.

2:42PM L30.00002 Phonon mode and Breakdown of a Au nanowire between electrodes. We report on a theoretical study of the influence of electron-electron interactions on the one-particle Green’s function of a doped graphene sheet based on the random-phase-approximation and on graphene’s massless Dirac equation continuum model. We find that the presence of Schottky barriers, due to the band gap in GO, is essential to obtaining a high conductance.

2:54PM L30.00003 Semiconducting chains of gold and silver1. We acknowledge support from the Brazilian agencies: FAPEMIG, CAPES, CNPq, and Instituto do Milênio de Nanotecnologia/MCT.
3:06PM L30.00004 Bonding, Conductance and Magnetization of Oxygenated Au Nanowires

Chun Zhang, Robert Barnett, Uzi Landman, School of Physics, Georgia Institute of Technology — Spin-density-functional calculations of tip-suspended gold chains, with molecular oxygen, or dissociated oxygen atoms, incorporated in them, reveal structural transitions for varying lengths. The nanowires exhibit enhanced strength for both oxygen incorporation modes, and upon stretching tip atoms join the wire. With incorporated molecular oxygen the wire conductance is about 1(2e2/h), transforming to an isolating state beyond a critical length. The nanowire conductance with embedded oxygen atoms is low, 0.2 (2e2/h), and it develops magnetic moments localized on the oxygen and the neighboring Au atoms. *Physical Review Letters* (in press)

3:18PM L30.00005 ABSTRACT WITHDRAWN

3:30PM L30.00006 Superconductivity and metal-insulator transition in Bi nanowires.1

Mingliang Tian, Jian Wang, Nitesh Kumar, Qi Zhang, Thomas Malouk, Jianendra Jain, Moses H.W. Chan, Center for Nanoscience, Penn State University — Semi-metallic bismuth has long been a prototype system for quantum transport and finite-size effect studies, due to its long electron mean-free path, low carrier density and small carrier mass. We found Bi nanowires (NWs) of less than 100 nm diameter can be superconducting, metallic and insulating closely depending on the details of their microstructures, morphology and surface condition. For granular Bi NWs with grains showing (001) preferred orientation, the NWs are superconducting with Tc’s of 7.2 and 8.3 K. Without (001) preferred orientation, the NWs show superresistive behavior. For single-crystalline Bi NWs, when the wires are embedded inside anodized aluminum oxide (AAO) membrane, insulating behavior is found below 1.0 K with low excitation current but metallic at a higher bias current. However, this metallic state can be tuned into isolating again by an applied magnetic field. We have also made measurements on an individual single-crystalline Bi NWs released from the AAO, an thin oxide layer is found on the wire surface. Interestingly, the wire was found to be superconducting below 1.5 K.

3:42PM L30.00007 Evolution of Integer Quantized Conductance in Gold Nanowires.

Yoshihiko Kuriu, Dept. Cond. Matt. Physics, Tokyo Institute of Technology, Yoshifumi Oshima, Dept. Materials Science & Engineering, Tokyo Institute of Technology, Japan; Tokai University, Japan, K. Takayanagi, Mechanical Engineering Research Laboratory, Japan. — In the metallic regime, the conductance was quantized in units of the conductance quantum $G_0 = 2e^2/h$. The quantized conductance $G_n$, $n = 0, 1, 2, 3, \ldots$ was measured when the nanowires were contacted by submicron electrodes from above. By employing 4- and 2-probe configurations, not only the intrinsic electrical resistivities of the individual nanowires were measured, but also the electronic contact resistances, $R_c(T)$, have been determined. Several models are available for $R_c(T)$, including the thermal-activation model, the thermal-activation model involving three activation energies, and the thermal-activation model involving two activation energies.

3:54PM L30.00008 Intrinsic Electrical-Transport Properties of Single ZnO Nanowires.

S.P. Chiueh, Y.H. Lin, J.J. Lin, Institute of Physics, National Chiao Tung University, Taiwan, W.B. Jian, Department of Electrophysics, National Chiao Tung University, Taiwan, Z.Y. Wu, F.R. Chen, J.J. Kai, Department of Engineering and System Science, National Tsing Hua University, Taiwan. — Single-crystalline zinc oxide (ZnO) nanowires (NWs) were synthesized by the thermal evaporation method. The intrinsic electrical-transport properties of ZnO NWs were studied by carrying out four-probe measurements on individual NWs. The electrodes were made by the standard electron-beam lithography technique. The current-voltage characteristics and the zero-bias resistivities, $\rho(T)$, were measured over a wide range of temperatures between 0.25 and 300 K. We found that, in many cases, the temperature behavior of $\rho$ could be well-described by the thermal-activation model involving three activation energies ($E_1$, $E_2$, and $E_3$). Our values of $E_1$ (approximately, several tenths meV) and $E_2$ (approximately, several meV) were extracted from the $\rho(T)$ data. The $E_3$ (approximately, thousands meV) value was determined by fitting the $\rho(T)$ in the intermediate temperature regime with the thermal-activation model involving two activation energies. The $E_3$ value was found to agree well with the current understanding of the rutile material within the framework of the Boltzmann transport theory. On the other hand, we found that, for high-resistance contacts, $R_c$ increases rapidly with decreasing temperature and finally saturates at liquid-helium temperatures. This behavior of $R_c$ can be satisfactorily explained in terms of the “thermally fluctuation-induced tunneling” conduction through a microscopic junction incidentally formed at the interface between the electrode and the NW.

4:06PM L30.00009 Electrical-transport studies of individual RuO2 nanowires and their nanowire contacts.

Y.H. Lin, Institute of Physics, National Chiao Tung University, Taiwan, K.J. Lin, F.R. Chen, J.J. Kai, Department of Engineering and System Science, National Tsing Hua University, Taiwan. — Single-crystalline RuO2 nanowires (NWs) have been prepared by the thermal evaporation method. The conductance of gold junction was measured by employing a four-probe configuration. The conductance histogram exhibits the quantized conductance $G_n$, $n = 0, 1, 2, 3, \ldots$. The conductance $G_n$ was measured when the NWs were contacted by submicron electrodes from above. By employing 4- and 2-probe configurations, not only the intrinsic electrical resistivities of the individual nanowires were measured, but also the electronic contact resistances, $R_c(T)$, have been determined. Our measured resistivity behavior of the NWs is found to agree well with the current understanding of this rutile material within the framework of the Boltzmann transport theory. On the other hand, we found that, for high-resistance contacts, $R_c$ increases rapidly with decreasing temperature and finally saturates at liquid-helium temperatures. This behavior of $R_c$ can be satisfactorily explained in terms of the “thermally fluctuation-induced tunneling” conduction through a microscopic junction incidentally formed at the interface between the electrode and the NW.

Wen-Hao Wu, Hai-Dong Liu, Zuxin Ye, Zhiping Luo, K. D. D. Rathanayaka, Texas A & M University — We report an anomalous proximity effect observed in single-crystal nanowires of Zn, Sn, and Pb of length up to 60 μm. These nanowires were electrochemically deposited into the pores of anodic aluminum oxide membranes and polycarbonate membranes. Using an in situ self-contacting method, single nanowires were electrically contacted on both ends to a pair of macroscopic film electrodes of Au, Sn, and Pb. The conductance and the superconducting transition temperature were measured by employing a four-probe configuration. The conductance of the nanowires was found to be quantized in units of the conductance quantum $G_0 = 2e^2/h$. The $C_0$ and $C_1$ conductance peaks in the vicinity of $C_0(=2e^2/h)$ were observed at lower temperatures, while simultaneously acquiring transmission electron microscope images. The conductance histogram exhibits the quantized conductance $G_n$, $n = 0, 1, 2, 3, \ldots$. The conductance $G_n$ was measured when the NWs were contacted by submicron electrodes from above. By employing 4- and 2-probe configurations, not only the intrinsic electrical resistivities of the individual nanowires were measured, but also the electronic contact resistances, $R_c(T)$, have been determined. Our measured resistivity behavior of the NWs is found to agree well with the current understanding of this rutile material within the framework of the Boltzmann transport theory. On the other hand, we found that, for high-resistance contacts, $R_c$ increases rapidly with decreasing temperature and finally saturates at liquid-helium temperatures. This behavior of $R_c$ can be satisfactorily explained in terms of the “thermally fluctuation-induced tunneling” conduction through a microscopic junction incidentally formed at the interface between the electrode and the NW.

4:30PM L30.00011 Electronic Transport of TiO$_2$ Nanowire Devices. Geetha Dholakia, Elore/NASA Ames Research Center, STEVEN KUO, NASA Ames Research Center, San Jose State University. Emily Allen, Dept. of Materials Engineering, San Jose State University — Titanium dioxide (TiO$_2$) is a wide band-gap semiconductor with applications in photovoltaics and sensing. Large scale integration of nanowires onto functional devices requires new techniques to manipulate them at the nanoscale. Currently engineering strategies for efficient assembly of nanoscale objects is very limited. Here we report the use of dielectrophoresis to assemble TiO$_2$ nanowires onto devices. We use a sol-gel template based synthesis of TiO$_2$ nanowires. The nanowires have a typical diameter of 100-150 nm and a length of 3-10 µm. Devices for two probe and four probe measurements were fabricated by standard lithography. AC dielectrophoresis was used to assemble the TiO$_2$ nanowires on devices. A dielectrophoretic translational force and a torque aligns the nanowires onto the devices. FIB assisted platinum deposition on the aligned TiO$_2$ nanowires ensures ohmic contacts. Two probe room temperature I-V measurements show a resistivity of 0.22 Ω-cm, which is comparable to 0.26 Ω-cm for a thin film1. Temperature dependent transport measurements are being pursued. We have demonstrated an efficient method of assembling and fabricating nanowire device structures. T. Miyata et. al. Thin Solid Films, 496, 136 (2006).

4:42PM L30.00012 Conductivity of MgZnO nanoparticles as a function of gas exposure and temperature. Chris Berven, Joseph Dick, Leah Bergman, Jesse Huso, John Morrison, University of Idaho — Changes in the current-voltage (I-V) characteristics of Mg$_{x}$Zn$_{1-x}$O ($x \approx 0.15$) nanoparticles as a function of gas exposure and temperature are reported. The nanoparticles were prepared using wet chemical techniques on insulating thermally grown SiO$_2$ substrates. We find that the photoconductivity is not sensitive to the value of the gate voltage applied to the underlying silicon, but only to changes in the energetic and spatial position of individual defects in semiconductor nanoelectronic devices.

5:06PM L30.00014 Remarkable Effects of Gating on the Photoconductivity of Porphyrin Nanorods. C. K. Riley, X. Huang, W. F. Smith, Haverford College, D. E. Johnston, A. T. Johnson, Univ. of Pennsylvania — Tetrakis(4-sulfonatophenyl) porphine self assembles into well-defined nanorods with intriguing photoelectronic properties. For example, when light is applied, the conductivity immediately jumps up from zero, then grows further over several hours. This may be due to a light-induced structural change. In recent experiments, we imaged the nanorods with AFM while measuring the photoconductivity; we observed no change in morphology. We also deposited nanorods onto oxidized silicon substrates. Contact to the nanoparticle film was made by gold wires laid across about 2 mm apart. The experiments were performed in a custom-built environmental chamber with the ability to evacuate or introduce various gases. For these experiments, the temperature was tuned over a range of about 300 K to 420 K. Our measurements showed a possible history-dependant behavior in changes of the conductance of the nanoparticle film. When the device was heated to ~120 K in vacuum or in an Ar the current increased by the same amount. When repeated with H$_2$, the current increase was less. Initially, the effect was quite pronounced with a relative change by a factor of 20. With repetitions of the experiments, the same effect was observed but to a lesser degree suggesting a saturation phenomena. When the experiment was modified so that the H$_2$ gas was introduced at a high temperature to an evacuated chamber the current dropped but not by the same degree as before. A similar response to exposure to H$_2$ was found for exposure to O$_2$. Possible explanations for the observations will be presented.

5:18PM L30.00015 Adsorption Kinetics of Alkanes on Purified HiPco Nanotubes. Dinesh Rawat, Murat Bulut, Aldo Migone, Southern Illinois University, Carbondale, IL-62901, USA — We present results for the adsorption kinetics of methane, ethane and butane on purified HiPco SWNTs. We studied the adsorption kinetics by monitoring the evolution of the gas pressure with time from the instant at which a dose of adsorbate is added to the sample, until the moment at which equilibrium is reached. The waiting times for comparable coverages increase with increasing alkane chain length. For methane and ethane, the equilibration time decreases with increasing fractional coverage. For the butane, on the other hand, the kinetic measurements display a reverse trend: the equilibration times increase with increasing fractional coverage. We speculate that this observed increase in the waiting time is due to a possible reorientation of adsorbed molecules in the film. The observed differences in adsorption kinetics suggest the possibility of using adsorption as a means to achieve the separation of gaseous alkane mixtures.

Tuesday, March 11, 2008 2:30PM - 5:30PM — Session L31 DCMP: Graphene: Atomic Structure and Lattice Properties

2:30PM L31.00001 Nano-Engineering Defect Structures on Graphene1. Mark Lusk, Lincoln Carr, Department of Physics, Colorado School of Mines — We present a new way of nano-engineering graphene using defect domains. These regions have ring structures that depart from the usual honeycomb lattice, though each carbon atom still has three nearest neighbors. A set of stable domain structures is identified using density functional theory (DFT), including blisters, ridges, ribbons, and meta-crystals. All such structures are made solely out of carbon; the smallest encompasses just 16 atoms. Blisters, ridges and meta-crystals rise up out of the sheet, while ribbons remain flat. In the vicinity of vacancies, the reaction barriers to formation are sufficiently low that such defects could be synthesized through the thermally activated restructuring of coalesced adatoms. These defect domains may offer technological applications associated with the confinement and transport of charge.

2:42PM L31.00002 Solid State Zwitterions realized on carbon graphenic surface. Zhaohui Huang, Vincent Crespi, Dept. of Physics, Penn State Univ. — Zwitterions are single molecular species that combine anionic and cationic groups. Here we consider the prospects for introducing the concept of a zwitterion into the solid state, by combining geometrically incompatible anionic and cationic moieties within a single extended structural element whose covalent rigidity frustrates the close approach of the anionic and cationic regions. Specifically, first principles computations for anionic and cationic groups such as NH$_3$ and CO$_2$ covalently attached to a graphenic surface via linker elements demonstrate long-range charge transfer, the hallmark of a zwitterion, while maintaining overall structural integrity.

2:54PM L31.00003 Atomic structure of corrugated graphene. YOU LIN, XIANG GU, IVAN OLEYNIK, University of South Florida, CARTER WHITE, Naval Research Laboratory — Following its successful isolation, there has been intense interest in a single sheet of graphite, known as graphene, due to its fundamental physical properties as well as its promising applications in nanoelectronic devices. Recent experimental studies of graphene, freely suspended on nanofabricated scaffolding, found appreciable deviations from a perfect two-dimensional crystalline structure [1]. In this presentation, we discuss results of atomistic modeling of graphene with the occurrence of possible corrugated structures examined under the influence of several factors including sample size and temperature. [1] J.C. Meyer, et al, Nature 446, 60 (2007).

3:06PM L31.00004 Ab initio study on atomic and electronic structures of epitaxial graphene. SEUNGCHUL KIM, JISOOON IHPM, Department of Physics and Astronomy, Seoul National University, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University, YOUNG-WOO SON, Department of Physics, Konkuk University — Recently, lots of efforts have been devoted to the growth of epitaxial graphene and its geometric and electronic structure measurements. Several models for the interface structure have been suggested but never been successful in explaining the observations from various experiments. Using density functional theory (DFT) calculations, we find an interface atomic structure of graphene on hexagonal silicon carbide which agrees well with the low energy electron diffraction (LEED), scanning tunneling microscopy (STM), as well as angle resolved photo emission spectroscopy (ARPES). Our results clearly resolve the disagreement between \(6 \times 6\) periodic pattern from STM measurements and the \(6\sqrt{3} \times 6\sqrt{3}\) from the LEED measurements. Furthermore, we also investigate the origin of the gap opening at the Dirac point in the present geometry.

3:18PM L31.00005 Phonon dispersions and vibrational properties of monolayer, bilayer, and trilayer graphene\(^1\). JIA-AN YAN, W. Y. RUAN, M. Y. CHOU, School of Physics, Georgia Institute of Technology, GEORGIA INSTITUTE OF TECHNOLOGY — The phonon dispersions of monolayer and few-layer graphene (AB bilayer, ABA and ABC trilayers) are investigated using the density-functional perturbation theory (DFPT). Compared with the monolayer, the optical phonon \(E_{a2g}\) mode at \(n\) splits into two and three doubly degenerate branches for bilayer and trilayer graphene, respectively, due to the weak interlayer coupling. These modes are of various mode symmetry and exhibit different sensitivity to either Raman or infrared (IR) measurements (or both), and therefore the combination of Raman and IR measurements of the zone-center optical modes should give a clear identification of the layer number as well as the stacking geometry. The splitting is found to be \(5 \text{ cm}^{-1}\) for bilayer and \(2 \text{ cm}^{-1}\) for trilayer graphene. The interlayer coupling is estimated to be about \(2 \text{ cm}^{-1}\). We found that the highest optical modes at \(K\) upshift by about \(12 \text{ cm}^{-1}\) for bilayer and \(18 \text{ cm}^{-1}\) for trilayer relative to monolayer graphene. The atomic displacements of these optical eigenmodes are analyzed.

3:30PM L31.00006 Structural study of the phase evolution of 6H-SiC(0001) by low energy electron microscopy. JIEBING SUN, KARSTEN POHL, University of New Hampshire, RUDOLF M. TROMP, JAMES B. HANNON, IBM T. J. Watson Research Center — The surface phase transition of Si-terminated 6H-SiC(0001) upon heat treatment is studied by low energy electron microscopy (LEEM). Bright and dark field imaging demonstrates a direct in situ observation of the surface phase evolution, transitions in a sequence from \(1 \times 1, 3 \times 3, \sqrt{3} \times \sqrt{3}/\sqrt{6}\) to the graphene phase due to gradually increasing the temperature. Intensity vs. voltage (IV) spectra extracted from single domain diffraction images is used to determine the local surface structure and chemical stoichiometry. Preliminary results from a quantitative dynamical analysis of the LEEM-IV curves show a Si-depleted \(1 \times 1\) structure and an adatom-trimer-adlayer structure on \(3 \times 3\) reconstruction. Ongoing work on the structure of the \(\sqrt{3} \times \sqrt{3}/\sqrt{6}\) and \(6 \times 6\) phases is aimed to unraveling the initial growth mechanism of graphene on SiC.

3:42PM L31.00007 The Initiation of Graphene Growth on SiC(0001)-6H. JAMES HANNON, RUDOLF TROMP, IBM Research Division — We have studied the evolution of surface morphology on SiC(0001)-6H during annealing at temperatures up to 1250 C using low-energy electron microscopy (LEEM). Surface roughness is dominated by the formation of deep pits or canyons. We show that the canyons form because of the stability of the \(6 \times 6\) phase, which pins atomic steps during the decomposition of SiC. The density of pits is ultimately determined by how the \(6 \times 6\) phase nucleates. Graphene forms preferentially in these pits, where the step density is highest.

3:54PM L31.00008 Imaging the interface states of epitaxial graphene layers on 6H-SiC. G. SUN, Y. QI, M. WEINERT, L. LI — Single and bi-layer graphene were epitaxially grown on both the Si- and C-terminations of 6H-SiC. The energy dependence and spatial distribution of their local density of states were investigated using scanning tunneling microscopy and spectroscopy. Of particular interest is the r\(3\)x\(3\) reconstructed interface state. Atomically resolved topographs and dI/dV images show clear differences between the single and bi-layer graphene at different length scales. These results will be compared to the electronic and structural properties obtained by first principles calculations.

4:06PM L31.00009 Interface Studies of Graphene layers on SiC thin films and bulk SiC(0001). ANNA SANDIN, J.L. TEDESCO, NC State University, R.J. NEMANICH, Arizona State University, J.E. MILLAN, J. HASS, Georgia Institute of Technology, F. VARCHON, Institut Neel/CNRS, W.A. DEHEER, C. BERGER, P.N. FIRST, Georgia Institute of Technology, L. MAGAUD, Institut Neel/CNRS, E.H. CONRAD, Georgia Institute of Technology — We present x-ray diffraction experiments showing that multilayer graphene grown on 4H-SiC(0001) (C-face) consists of a high density of rotational stacking faults. The existence of these faults explains why multilayer graphene is electronically similar to an isolated graphene sheet [1]. The faults present themselves as graphite rods rotated through a series of commensurate graphene/SiC angles relative to the SiC rods and as rods shifted due to compressed graphene at the fault boundaries. By analyzing the intensity modulations of these different rods, it is possible to extract information on the distributions of these faults in the film. We will present results from calculations of different models for the fault distribution and compare them against x-ray data for graphene films of different thicknesses. [1] J. Hass, F. Varchon, J. E. Millan-Otoya, M. Sprinkle, W.A.de Heer, C. Berger, P.N. First, L. Magaud, E.H. Conrad (to be published) http://arxiv.org/abs/0706.2134.
4:30PM L31.00011 Dispersive Raman Scattering from $n=1$-4 Graphene Layers (nGLs)  
Peter Eklund, Pennsylvania State University, Awnish Gupta, PSU — We present new Raman scattering results from nGLs ($n=1, 2, 3, 4$) in the range of 100 - 4500 cm$^{-1}$. Dispersive behavior of Raman peaks was probed at room temperature with 7 laser lines from 1.5-2.7 eV. In addition to the five Raman peaks reported previously, we report on the behavior of five new weaker features that appear in graphene (514.5 nm excitation) at $\sim$1882 cm$^{-1}$($\sim$125 cm$^{-1}$/eV), $\sim$2035 cm$^{-1}$($\sim$177 cm$^{-1}$/eV), $\sim$2218 cm$^{-1}$($\sim$43 cm$^{-1}$/eV), $\sim$3174 cm$^{-1}$($\sim$40 cm$^{-1}$/eV) and $\sim$4069 cm$^{-1}$($\sim$35 cm$^{-1}$/eV). The value in ( ) is the respective band dispersion, or shift with peak position per eV change in the excitation energy. The band dispersion is connected with the ratio of the phonon to Fermi velocity and stems from the double resonance (DR) scattering. New Raman bands that are only observed for nGLs ($n > 1$) are found at $\sim$1510 cm$^{-1}$($\sim$16 cm$^{-1}$/eV) and 1737 cm$^{-1}$ ($\sim$10 cm$^{-1}$/eV). The identities of the new peaks will be discussed based on DR scattering and the phonon dispersion curve of graphene.

4:42PM L31.00012 The Thickness Dependence of the Graphene Oxidation  
Liu Liu, Sunmin Ryu, NSEC & Department of Chemistry, Columbia University, Michelle Tomask, NSEC, Columbia University, Elena Stolyarova, Michael Steigerwald, NSEC & Department of Chemistry, Columbia University, Mark Hysbertsen, Center for Functional Nanomaterials, Brookhaven National Laboratory, Louis Brus, George Flynn$^1$, NSEC & Department of Chemistry, Columbia University — Single-, double-, and triple-layer graphene sheets were heated in an oxygen atmosphere at various temperatures generating nano-sized holes in the sheets. Both AFM topography and Raman spectroscopy indicate that the oxidative reactivity of single-layer sheets is greater than that of thicker sheets. The distribution of hole sizes and STM topography studies suggest that the oxidation reaction is initiated at the pristine carbon surface. Vertical etching of carbon atoms from the graphene surface occurred at a much lower temperature than that from a highly oriented, multi-layer pyrolytic graphite crystal. The mechanism for this thickness dependence of reactivity will be discussed.

4:54PM L31.00013 UHV STM/STS and AFM study of oxidized graphene sheets  
Deepak Pandey, Birck Nano Technology Center, Purdue University, Richard Piner. The University of Texas at Austin, Ronald Reifenberger, Birck Nano Technology Center, Purdue University — Exfoliated oxidized graphene sheets, suspended in an aqueous solution, were deposited on freshly cleaned HOPG and studied by ambient AFM and UHV STM. The AFM images revealed oxidized graphene sheets with a lateral dimension of $\sim$5-10 µm. The oxidized graphene sheets exhibited different thicknesses and were found to conformally coat the HOPG substrate. Wrinkles and folds induced by the deposition process were clearly observed. Phase imaging and lateral force microscopy showed distinct contrast between the oxidized graphene and the underlying HOPG substrate. The UHV STM studies of oxidized graphene revealed atomic scale periodicity showing a 0.26 nm x 0.42 nm unit cell over small areas. This periodicity is identified with oxygen atoms bound to the oxidized graphene sheet. I(V) data were taken from oxidized graphene sheets and compared to similar data obtained from bulk HOPG. The dI/dV data from oxidized graphene reveals a reduced density of electron states within ±0.1 V around zero bias.

5:06PM L31.00014 Scanning Tunneling Spectroscopy (STS) studies of graphene films on an insulating substrate  
Elena Stolyarova, Li Liu, Columbia University, Mark Hysbertsen, Brookhaven National Laboratory, Philip Kim, Tony Heinz, George Flynn, Columbia University, Center for Functional Nanomaterials, BNL Team, Center for Electron Transport in Molecular Nanostructures, Columbia University Team, Department of Chemistry, Columbia University Team — Scanning Tunneling Spectroscopy has been utilized to study the differences between the electronic structure of a three-dimensional graphite crystal and its two-dimensional building block, graphene. Single and few-layer graphene samples were isolated on a non-conductive silicon dioxide substrate and contacted at the edges with a gold electrode. For single layer flakes current-voltage dependent I(V) curves, recorded at 4.6 K under Ultra-high Vacuum (UHV) conditions, show no additional features for states far from the Fermi energy that might be considered characteristic of a weak interaction between graphene and the substrate. No significant spatial inhomogeneity of local sample properties was observed. Evolution of spectroscopic curves as a function of graphene layers will be discussed.

5:18PM L31.00015 Generation of atomic scale defects in graphene by high-energy positive-ion bombardment  
Danail Stolyarov, Brookhaven National Laboratory, Elena Stolyarova, George Flynn, Columbia University, Karl Kusche, Igor Pavlishin, Igor Poporelsky, Brookhaven National Laboratory, Peter Shkolkovskii, Stony Brook University, Vitaly Yakimenko, Brookhaven National Laboratory — We have demonstrated controllable defect generation in graphene (a single layer of a graphite crystal) and in few atomic layer thick graphite films. Graphene flakes deposited on a silicon dioxide substrate by mechanical exfoliation were bombarded by a collimated high-energy (1 MeV) particle beam consisting of protons and positively charged ions. This beam was produced by Target Normal Sheath Acceleration (TNSA) upon irradiation of a metal foil with a terawatt CO2 laser pulse. Ions and protons with different mass and energy were separated by a permanent magnet installed between the laser target and the sample. After the exposure the graphene flakes were examined by Atomic Force Microscopy (AFM) and Scanning Tunneling Microscopy (STM). Irradiation of graphene films with both protons and positive ions results in the formation of atomic-scale defects without mesoscopic damage to the film. The density of observed defects depends strongly on the number of atomic layers. This method can be used to modify single chemical bonds in graphene films and to engineer carbon based devices and sensors with tailored properties.

Tuesday, March 11, 2008 2:30PM - 5:30PM –
Session L32 GMAG DMP FLAP: Focus Session: Spin Transfer Torque II
Morial Convention Center 225

2:30PM L32.00001 Time-Resolved X-ray Microscopy for Direct Observation of Spin-Torque and Oersted-Field Driven Vortex Gyration  
M. Bolte, G. Meier, L. Bocklage, A. Drews, B. Krueger, University of Hamburg, Germany, T. Tyliszczak, ALS, LBL, Berkeley, CA, A. Vansteenkiste, B. Van Waeyenberge, Ghent University, Belgium, K.-W. Chou, H. Stoll, Max-Planck-Institute for Metal Research, Stuttgart, Germany — Due to their symmetry, magnetic vortices are ideal candidates for studying the influence of the spin-transfer torque on the local magnetization. The out-of-plane magnetization with a laser induced azimuthal chirality a chirality-dependent phase shift of $\phi_0$ is observed that is attributed to Oersted fields from the spin-polarized current. An analytical model estimates corresponding field strengths of $\mu_0 H \sim 10^{-10}$ A/m. This study confirms our assumption that Oersted fields from spin-polarized currents cannot be neglected in spin-torque experiments and shows the sensitivity of the measurement technique.
2:42PM L32.00002 Time-resolved X-ray Imaging of Spin-Torque-Induced Vortex Oscillation

XIAOWEI YU, Stanford University, VLAD PRIBIAG, Cornell University, YVES ACREMANN, Stanford Synchrotron Radiation Laboratory, VENKATESH CHEMBROLOU, Stanford University, ASHWIN TULAPURKAR, Stanford Synchrotron Radiation Laboratory, TOLEK TYLISZCZAK, Advanced Light Source, ZHIPAN LI, ROBERT BUHRMAN, Cornell University, JOACHIM STOHR, Stanford Synchrotron Radiation Laboratory, HANS SIEGMANN, PULSE Center, Stanford Linear Accelerator Center — Recent transport measurements demonstrated a persistent oscillation of a magnetic vortex isolated in a nanoscale spin-valve structure driven by STT. This vortex precession is inferred from the giant magnetoresistance (GMR) signal, which depends on the relative average magnetization of the two magnetic layers. Here, we report spatially resolved measurements of the vortex oscillation driven by spin-transfer torque by using advanced x-ray imaging technique. The microwave-frequency vortex oscillation is synchronized to the fast x-ray pulses. Motion images with 70ps time resolution and 30nm spatial resolution reveal the complicated dynamics underlying the previously observed oscillating GMR signal. [1] V. S. Pribiag, I. N. Krivorotov, G. D. Fuchs, P. M. Braganca, O. Ozatay, J. C. Sankey, D. C. Ralph, and R. A. Buhrman, Nature Physics 3, 498 (2007)

2:54PM L32.00003 Spin-current induced magnetic excitations in single magnetic layer nanopillars1

BERND BESCHOTEN, NICOLAS MÜSCENS, MARK WEIDENBACH, EVA MAYNICKE, COEN SMITS, II. Physikalisches Institut, RWTH Aachen, MATTHIAS BÜCKINS, JOACHIM MAYER, Gemeinschaftslabor für Elektronenmikroskopie, RWTH Aachen, GERNOT GÜNTHERODT, II. Physikalisches Institut, RWTH Aachen — We investigate current-induced spin-wave excitations in Cu/Co/Cu single magnetic layer nanopillars with asymmetric Cu leads by means of transport and microwave probes at room temperature. The thin film stack is deposited by MBE in prefabricated nanostencil masks with lateral dimensions below 100 nm. At high current densities, we observe narrow excitations (bandwidth ~ 100 MHz) and higher harmonics for magnetic fields perpendicular to the layers. The frequency increases with increasing current and magnetic field, which indicates an out-of-plane precessional mode as found in bilayer systems (e.g., Kiselev et al., PRL 93, 036601(2004)). Furthermore, we observe frequency jumps as a function of both current and magnetic field, which might originate from transitions between different localized nonlinear spin-wave modes.

3:06PM L32.00004 Large angle out of plane steady precession induced by spin-transfer with perpendicular to plane polarizer. Dimtri Houssameddine, Spintec - CE/A/CNRS — The dynamics of a ferromagnetic system is characterized by a conservative precession torque, as well as a non-conservative damping torque. The damping torque is responsible for the realignment of the magnetization with the equilibrium direction after excitation. Recently, it has been shown that the damping torque can be compensated by a spin transfer torque that is due to the interaction between a spin polarized current and the local magnetization. This additional spin transfer torque can lead to auto-oscillations of the magnetization close to constant energy trajectories. The potential exploitation of such large angle auto-oscillations for tunable microwave devices is currently driving many research efforts. For an in-plane magnetized thin film with uniaxial anisotropy, two types of constant energy trajectories exist which are commonly called in-plane precession (IPP), where the magnetization oscillates around the in-plane energy minimum, and out of plane precession (OPP) where the magnetization oscillates around the out of plane energy maximum [1]. IPP and OPP oscillations differ substantially in their dependence of frequency and amplitude as a function of current and/or applied bias field. In many experiments so far, IPP precessions have been obtained at the threshold current using in-plane magnetized spin valve structures. However, from an applications point of view it will be of interest to excite OPP oscillations since they will lead to a larger output signal than IPP oscillations. Here, we will present experimental evidence of large angle OPP oscillations using a spin torque oscillator that contains a perpendicularly magnetized polarizing layer and an in-plane magnetized analyzing layer in addition to a planar free layer [2]. We will show that OPP oscillations are induced at the threshold current for moderate current densities of 9*10^7 A/cm^2. The experimental current-field state diagram as well as the dependence of the frequency vs. current and applied bias field is in good qualitative agreement with macrospin and micromagnetic simulations. Furthermore, due to the perpendicular nature of OPP oscillations, they allow a direct comparison of the OPP and IPP precession amplitudes. [1] A. N. Slavin, V. S. Tyberkevich Phys. Rev. B 72, 94428 (2005) [2] Houssameddine et al, Nature Materials 6, 441 (2007)

3:42PM L32.00005 Current-Induced Magnetization Switching with a Spin-Polarized Scanning Tunneling Microscope. MATTHIAS BODE, Argonne National Laboratory, STEFAN KRAUSE, University of Hamburg, LUIS BERBIL-BAUTISTA, University of California at Berkeley, GABRIELA HERZOG, WOLFGANG GUNTHERODT, University of Hamburg — The understanding of current-induced magnetization switching is in the focus of many ongoing investigations since switching the magnetization by the injection of a spin-polarized current rather than by magnetic fields may open the gateway for new data storage technologies at much higher bit densities. We show how individual superparamagnetic Fe nanoislands with typical sizes of 100 atoms can be addressed and locally switched using a magnetic scanning probe tip. We demonstrate current-induced magnetization reversal across a vacuum barrier and combine it with the ultimate resolution of spin-polarized tunneling microscopy. This technique allows us to control the nanoscale distance and quantity three fundamental contributions that are involved in magnetization switching, i.e. current-induced spin torque, heating the island by the tunneling current, and Oersted field effects.

3:54PM L32.00006 Current-Induced Magnetoresistance in Antiferromagnetic Spin Valves1

WEI, University of Texas at Austin, A. SHARMA, J. BASS, Michigan State University, M. TSOI, University of Texas at Austin — Influence of the magnetic state of a ferromagnet (F) on its electronic transport properties has been found in various phenomena, including giant magnetoresistance (GMR) in magnetic multilayers, where the relative orientation of the magnetic moments of F-layers affects the current flow. MacDonald and co-workers recently predicted that a corresponding effect - antiferromagnetic GMR (AGMR) - should exist in structures where F-layers are replaced by antiferromagnets (AFM). To test this prediction, we measured the (closely) current-perpendicular to plane (CPP) magnetoresistance (MR) of three types of AFM spin-valve multilayers: (I) AFM/N/AFM, (II) F/AFM/N/AFM, and (III) F/AFM/N/AFM/F, with a non-magnetic (N) layer between the two AFM layers. We saw no MR in samples of type I or II at any current density j, or of type III when j was small. But large enough j ~ 10^3 A/m^2 applied to type III multilayers gave small positive MRs (largest resistance at high field). As these MRs are inverted from the usual GMR of the F-layers, they must be due to the AFM layers, and thus be an AGMR. We will describe how this AGMR varied with applied current j and AFM layer thickness [arXiv:0711.0059].

4:06PM L32.00007 RF Assisted Spin Transfer Switching in Nanopillar Spin-Valves. S.H. FLOREZ, J.A. KATINE, M. CAREY, L. FOLKS, O. OZATAY, B.D. TERRIS, Hitachi Global Storage Technologies, San Jose Research Center, 3403 Yerba Buena Road, San Jose CA 95135 — We study at low temperature spin transfer torque (STT) driven free-layer magnetization reversal in current perpendicular to plane (CPP) spin valves with in-plane magnetization. The precessional frequencies of the direct current driven pre-switching modes were measured. Based on this characterization we compare the pre-switching and switching behavior, when driven by direct currents only and in the presence of an additional rf current bias. We find interesting rf induced dynamics such as frequency locking as well as effects on the critical switching boundary. These effects appear for applied frequencies close to the dc-only driven pre-switching resonance frequencies. In particular, we observe a reduction in the critical current for switching when applying rf with frequencies slightly below this range. Macrospin simulations (using Slonczewski STT) reproduce well our experimental data and serve as a basis for the development of a phenomenological model that describes the observed behavior.

\(^1\)Research supported in part by NSF grant DMR-05-01013.
2:30PM L33.00001 Ultrafast coherent optical manipulation of a single electron spin in a quantum dot. M.H. MIKKELSEN, J. BEREZOVSKY, N.G. STOLTZ, L.A. COLDREN, D.D. AWSCHALOM, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — A key ingredient for spin-based quantum information processing is the coherent rotation of a spin state on timescales much faster than the spin coherence time. By applying off-resonant, picosecond-scale optical pulses, we demonstrate the coherent rotation of a single electron spin in a GaAs quantum dot (QD) through arbitrary angles up to \( \pi \) rad. We directly observe this spin manipulation using time-resolved Kerr rotation spectroscopy at \( T = 10K \). Measurements of the spin rotation as a function of laser detuning and intensity confirm that the optical Stark effect is the operative mechanism and the results are well-predicted by a model including the electron-nuclear spin interaction. Using short tipping pulses and QDs with long spin coherence times, this technique enables one to perform a large number of operations within the coherence time.

We acknowledge support from NSF and AFOSR.

2:42PM L33.00002 Coherent Population Trapping of an Electron Spin in a Singly-Charged Quantum Dot. XIAODONG XU, BO SUN, PAUL R. BERMAN, DUNCAN G. STEEL, The Physics Department, The Univ. of Michigan, ALLAN S. BRACKER, DAN GAMMON, Naval Research Lab. LU J. SHAM, The Physics Department, The Univ. of California, San Diego — When two radiation fields drive coupled transitions in a three-level lambda system, a steady-state coherent superposition of the ground states can be formed in which the system is totally decoupled from the applied fields, a process that is sometimes referred to as coherent population trapping (CPT). Here we report the demonstration of the CPT of an electron spin in a singly-charged quantum dot. By applying a magnetic field in the Voigt geometry, we create a three-level lambda system, formed by two Zeeman sublevels of an electron spin and an intermediate trion state. As we tune the driving and probe fields to the two-photon Raman resonance, we observe a pronounced dip in the probe absorption spectrum, indicating the CPT of the electron spin. An arbitrary superposition of the electron spin states can be prepared by varying the ratio of the Rabi frequencies between the driving and probe fields. This work shows that spin based semiconductor quantum dot systems can exhibit the same interesting quantum behavior that has been found in simple atom-field systems.

This work was supported in part by U.S. ARO, AFOSR, ONR, NSA/LPS, and FOCUS-NSF.

2:54PM L33.00003 Spin polarized current generation from quantum dots without magnetic fields. JACOB J. KRICH, BERTRAND I. HALPERIN, Harvard University — An unpolarized charge current passing through a chaotic quantum dot with strong spin-orbit coupling can produce a spin polarized exit current without magnetic fields or ferromagnets. If there is only one channel in the output lead, no spin polarization can be produced. We use random matrix theory to estimate the typical spin polarization as a function of the number of channels in each lead, finding rms spin polarizations up to 45% with one input channel and two output channels. Finite temperature and dephasing both suppress the effect, and we include dephasing effects using a new variation of the third lead model.

This work has been supported in part by NSF grants PHY-06-46094 and DMR-05-41988 and the Fannie and John Hertz Foundation.

3:06PM L33.00004 The role of electron-hole exchange in the spin mixing of excited-shell excitons in quantum dots. STEFAN C. BADESCU, THOMAS L. REINECKE, U.S. Naval Research Laboratory — In semiconductor quantum dots (QDs) the long-range electron-hole exchange is known to lift the spin degeneracy of ground orbital state excitons for small lateral asymmetries. In the context of solid-state quantum computing recent developments in optical manipulation of spin involve the excited shells of charged excitons in single and coupled QDs. We demonstrate here that this electron-hole exchange is important in the mixing of spin states of excitons in higher shells in QDs, e.g., the p-shell exciton. In contrast to the ground states, no lateral asymmetry is necessary for simultaneous reversal of an electron and a hole spin in these excited shells. For charged excitons, this interaction competes with the asymmetric exchange between electrons or between holes. We discuss the optical selection rules and the role of dephasing from phonons for the dynamics of excited excitons. We conclude that the e-h exchange is an important factor in designing logical gates with excited states.

This work is supported by the Office of Naval Research.

3:18PM L33.00005 Theoretical Study of Dynamical Nuclear Spin polarization in Semiconductor Quantum Dots. CHIA-WEI HUANG, XUEDONG HU, University at Buffalo, The State University of New York — Dynamical nuclear spin polarization (DSP) can be achieved optically in a semiconductor quantum dot (QD) via the hyperfine interaction between the optical oriented electron and nuclear spins. Here we explore several mechanisms, combined with the hyperfine interaction, to investigate how efficiently they can transfer the electron spin polarization to nuclei. Specifically, to ensure energy conservation during the spin transfer, we consider both a combination of electron spin-orbit and electron-phonon interactions, and cotunneling processes. Based on these interactions we evaluate the buildup time for DSP in a semiconductor QD. Our results show that the DSP buildup time of spin-orbit associated with the hyperfine interaction, accompanied by phonon emission, is of the order of seconds. This is much longer than that of the recent experimental findings. [1] The calculated nuclear spin polarization rate also shows a different Zeeman-energy-dependence from what is observed experimentally. [1] We thus conclude that hyperfine interaction combined with electron level broadening due to cotunneling processes between the QD and the nearby reservoir is more likely to be responsible for the fast buildup of nuclear polarization in experiments. [1] We have studied the emission spectra from InAs quantum dots as a function of carrier spin polarization; experiment and theory. [1] I. KHAN, T. ALI, M. YASAR, A. PETROU, SUNY at Buffalo, G. KIOSEOGLOU, C.H. LI, A.T. HANIBICKI, B.T. JONKER, Naval Research Laboratory, Washington DC, M. KORKUSINSKI, P. HAWRYLAK, Institute for Microstructural Sciences NRC, Ottawa — We have studied the emission spectra from InAs quantum dots (QDs) under the following conditions: a) recombination of spin-polarized electrons with unpolarized holes; b) recombination of spin-polarized electrons with spin-polarized holes. In the first experiment (a), we recorded the electroluminescence from Fe/GaAs n-i-p spin-LEDs which incorporate a single layer of InAs QDs at the center of the intrinsic region of the device. In the second experiment (b), we studied the photoluminescence spectra from a similar undoped heterostructure using optical pumping. In both experiments, in addition to the typical shell structure of the emission spectra, new polarization maxima are observed on the high and low energy sides of the shell emission features as a result of the imbalance between the two spin populations of the carriers. These results are compared with a calculation for the case of two and six electron-hole occupancy of the QDs.

1 Work at SUNY was supported by ONR and NSF.
3:42PM L33.00007 Determination of spin polarization in InAs/GaAs self-assembled quantum dots, F. G. C. HERNANDEZ, T. P. MAYER ALEGRE, G. MEDEIROS-RIBEIRO, Laboratorio Nacional de Luz Sincrotron — The electronic spin in a quantum dot (QD) has been proposed as a candidate two-level system for qubit implementation in a quantum information processing scheme (QIP). For semiconductor quantum dots, the optical transition selection rules provide a natural tool for a direct and quantitative measurement of the electronic spin polarization. In contrast to the optical scheme, electrical readout of the electronic spins orientation do not require any knowledge of hole polarization. Here we perform magneto-capacitance spectroscopy measurements of QDs embedded in a Metal-Insulator-Semiconductor (MIS) capacitor structure. A statistical approach for the population of the spin levels allows one to study the spin orientation in the limit of comparable magnetic and thermal energies. The amount of polarization was inferred by measuring the addition energies of electrons sequentially loaded in QDs. In this experiment, we found an electron spin polarization higher than 50% for $B_{\text{eff}} = 4T$. Finally, by including the g-tensor anisotropy the angular dependence of spin polarization with the magnetic field $B$ orientation and strength could be explained.

3:54PM L33.00008 Non-volatile spin bistability based on ferromagnet-semiconductor quantum dot hybrid nanostructure1, YURIY SEMENOV, HANI ENAYA, North Carolina State University, JOHN ZAVADA, U.S. Army Research Office, KI WOOK KIM, North Carolina State University — Electrical manipulation of a memory cell based on bistability effect in a nanostructure consisting of a semiconductor quantum dot (QD) adjoining on opposite sides with a dielectric ferromagnetic layer (DFL) and a reservoir of itinerant holes is investigated theoretically. The operating principle is based on the interplay between the exchange field of the holes $B_h$ acting on the magnetization vector of the DFL at perpendicular to the structure plane and the anisotropy field $B_a$ which aligns $M$ along the plane. At low hole population of the QD ($B_h < B_a$), $M$ is still in plane direction (first stable state “0”). If an applied bias populates the QD sufficiently ($B_h > B_a$), the subsequent $M$ rotation will decrease the hole energy in the QD; hence the high hole population state is sustained (second stable state “1”) under a fixed electro-chemical potential set by the reservoir even after bias is removed. The analysis of bit retention time of the proposed memory demonstrates the feasibility of the device with lateral QD size at least 30 nm under room temperature operation. Another advantage is the extremely small dissipative energy for Write/Erase operations.

4:06PM L33.00009 Method for Full Bloch-Sphere Control of a Localized Spin in a Quantum Dot via a Single Electrical Gate, JOSEPH PINGENOT, CRAIG E. PRYOR, MICHAEL E. FLATTE, Department of Physics and Astronomy and Optical Science and Technology Center, University of Iowa — Manipulating individual spins in solids requires quickly and coherently reorienting localized spins while leaving neighboring spins unaffected. Difficulties confining oscillating magnetic fields have motivated alternate approaches that use electric fields to change the local magnetic environment, including moving an electron within a hyperfine field gradient or fringe-field gradient. Higher temperatures require spins to be localized in much smaller quantum dots, where these techniques are less effective. In contrast, g-tensor manipulation techniques[1] couple an electric field to the spin via the spin-orbit interaction, and should be scalable to small dots with large confinement. Here we calculate the g-tensor of a single electron in a small quantum dot and show the symmetry of its electric field dependence permits full Bloch sphere control of the spin using an electric field applied in a single direction. We find the spin manipulation frequency of an InAs/GaAs QD in 1 Tesla exceeds 150 MHz. We acknowledge support of an ONR MURI and an NSF NIRT. [1] Kato et al. Nature 299, 1201 (2003)

4:18PM L33.00010 Enhancement of spin lifetime in quantum well lasers using interface fluctuation quantum dots, RYAN WOODWORTH, Pennsylvania State University, ARI MIZE, Science Applications International Corporation, RUSKO RUSKOV, Ames National Laboratory, GERALD MAHAN, Pennsylvania State University — Research on semiconductor heterostructures provides many insights into the next generation of optoelectronic devices. In particular, the gain of a microdisk laser seems to be enhanced by the presence of a long-lived optical cavity mode. Here we analyze a recent experiment using GaAs-AlGaAs microdisks with interface fluctuation quantum dots. A numerical simulation shows enhancement of spin dephasing time in the conduction band due to exchange scattering and D’yakonov-Perel coupling. Possible applications to quantum computing are discussed.

4:30PM L33.00011 Piezomagnetic quantum dots1, Ramin ABOULFATH, SUNY Buffalo; University of Texas, Dallas, A.G. PETUKHOV, South Dakota School of Mines and Technology, Rapid City, IGOR ZUTIC, SUNY Buffalo — We study the influence of deformations on magnetic ordering in quantum dots doped with magnetic impurities. The reduction of symmetry and the associated deformation from circular to elliptical quantum confinement lead to the formation of piezomagnetic quantum dotsp. The strength of elliptical deformation can be controlled by the gate voltage to change the magnitude of magnetization, at a fixed number of carriers and in the absence of applied magnetic field. We reveal a reentrant magnetic ordering with the increase of elliptical deformation and suggest that the piezomagnetic quantum dots can be used as nanoscale magnetic switches. Finally, we discuss thermodynamic stability of piezomagnetism in such quantum dots.

Session L35 FIAP: Optoelectronic Devices and Applications Morial Convention Center 227

2:30PM L35.00001 High Efficiency Quantum Cascade Lasers1, MATTHEW ESCARRA, ANTHONY HOFFMAN, SCOTT HOWARD, KAILE FRANZ, AISHWARYA SRIDHAR, CLAIRE GMACHL, Princeton University — Quantum cascade (QC) lasers have proven to be of great interest as powerful and versatile mid-infrared light sources. However, improvement in the wall-plug efficiency of these sources at room temperature and under continuous wave operation is critical to their development across a broad range of sensing applications. The internal, current, voltage, and optical efficiencies all must be maximized. Several different approaches must be taken. We will focus primarily on several QC laser designs with low voltage defect. Low voltage defect quantum designs with heterogenous injector regions have shown efficiencies as high as 13.9% from a single facet in 80K, pulsed operation. Performance at high temperatures can be improved by better confinement of electrons in the upper laser level. The addition of high-reflection and anti-reflection coatings to opposing facets has greatly improved the optical efficiency. Temperature performance can also be improved through InP lateral regrowth, epitope side down mounting, and electroplated gold top contacts.

This work is supported in part by DARPA-EMIL and MIRTHE (NSF-ERC).
2:42PM L35.00002 High-speed wavelength conversion in quantum-dot and quantum-well semiconductor optical amplifiers. DAVID NIELSEN, S. L. CHUANG, University of Illinois at Urbana-Champaign, N. J. KIM, D. LEE, Chongnam National University, S. H. PYUN, W. G. JEONG, Sungkyunkwan University, C. Y. CHEN, T. S. LAY, National Sun Yat-Sen University — All-optical wavelength conversion is an important technology for advanced wavelength division multiplexed networks. The carrier localization available in quantum dots, due to the relatively slow carrier capture and escape times compared to intersubband relaxation in quantum wells, makes it possible to achieve efficient wavelength conversion through the non-linear optical process of four-wave mixing due to enhanced spectral hole burning. To examine the various carrier dynamics we experimentally investigate four-wave mixing in both quantum-dot and quantum-well optical amplifiers. Our results show superior conversion efficiency in a quantum-dot device compared to a quantum well device with identical gain at pump-probe detunings between 100 GHz and 1 THz, and a small-signal modulation bandwidth > 25 GHz. Cross-gain modulation measurements were performed as well and show a much smaller bandwidth of 1 GHz indicating that four-wave mixing is superior for high-speed signals.

2:54PM L35.00003 Magnetic field controlled sub-THz emission in Quantum Cascade Lasers. A. WADE, G. FEDOROV, D. SMIRNOV, NNMFL, S. KUMAR, Q. HU, MIT, Dept of EE and CS, B.S. WILLIAMS, Univ. of California at LA, Dept of EE — We report on the observation of strong multi-wavelength terahertz (THz) radiation in GaAs/AIGAs based Quantum Cascade Lasers (QCL). The QCL was measured in a strong magnetic field, up to 31 T, applied parallel to the growth axis. The lasing intensity exhibits oscillations due to magnetophoton resonance and Landau Level interaction resulting in a strong increase in the optical power and reduction of the current threshold. By applying the appropriate magnetic field and bias, lasing emission is obtained between 3.27 to 2.61 and 1.53 to 0.68 THz. This demonstrates that a magnetic field offers the unprecedented possibility to control the QCL emission frequency and achieve lasing action as low as 0.68 THz.

3:06PM L35.00004 Effect of Waveguide Side-Wall Roughness on Quantum Cascade Laser Performance. FATIMA TOOR, HAO LIU, Princeton University, DEBORAH SIVCO, Alcatel-Lucent, CLAIRE GMACHL, Princeton University — Waveguide loss in optical devices can be attributed to two main factors, intrinsic material loss (e.g. free carrier absorption) and scattering loss from imperfections (e.g. fabrication errors). To-date most work for determining the waveguide loss of quantum cascade lasers (QCLs) is concentrated on determining the intrinsic material loss, but there is very little research work done on determining the effect of fabrication errors such as side-wall roughness on QCL performance. Here, we report on an experimental and modeling study to determine the effect of side-wall roughness on QCL laser performance. The work involved designing and fabricating waveguides with different amounts of side-wall roughness. Measurements were then taken to determine the effect of waveguide side-wall roughness on laser performance parameters like threshold current density and slope efficiency.

3:18PM L35.00005 Optical coherence imaging using the phase coherent photorefractive effect in ZnSe quantum wells. A. KABIR, M. AJWARD, S. TRIPATHY, H.P. WAGNER, Department of Physics, University of Cincinnati, OH 45221, U.S.A. — We have performed depth-resolved optical coherence imaging (OCI) of both stationary and moving objects using the exciton resonant phase coherent photorefractive (PCP) effect in ZnSe quantum wells (QWs). PCP QWs operate without electrical contacts thus avoiding elaborate sample processing and avoiding sample destruction due to Joule heating. In addition, the PCP effect exploits the coherence of excitons in OCI experiments thus enabling 3D images of reflecting objects with a depth resolution of ∼2 µm using 90 fs pulses. Due to the high diffraction efficiency of η ∼ 10~4 in our PCP ZnSe QWs we are able to record still images at very low intensities (∼500 µW/cm~2). The OCI movies of moving objects were recorded using a camcorder with frame rates of 60 and 180 Hz. The shortest possible time resolution in these experiments is determined by the decay time of the PCP electron grating being in the 10~6 range.

3:42PM L35.00007 High precision frequency characterization of THz quantum cascade lasers by heterodyne mixing. MARK LEE, MICHAEL WANKE, MAYTEET LERTTAMRAB, ERIK YOUNG, ALBERT GRINE, JOHN RENO, Sandia National Laboratories, ROBERT DENGLER, PETER SIEGEL, Jet Propulsion Laboratory - Cal Tech — Terahertz quantum cascade lasers (QCLs) have been used together with a monolithic planar Schottky diode receiver to study the heterodyne mixing between dual internal modes of a QCL and between a single mode of a QCL and a known molecular line from a molecular gas laser. Dual mode mixing using a single QCL shows that the intrinsic linewidth of a free-running QCL is < 30 kHz. Both a grating and distributed feedback grating QCLs were mixed against known molecular gas laser lines. Resulting difference frequency spectra gave a high precision measurement of a QCL’s absolute frequency against known references. Unusual slow transient turn-on behavior was also observed in a pulsed standard QCL. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

3:54PM L35.00008 Electric Field and Polarization Dependent Spatial Fringe-Patterns in Electro-optic Crystals. RANDALL HINTON, ANTHONY GARZARELLA, DONG HO WU, Naval Research Laboratory/ Temple University — Electro-optic (EO) crystals, such as LiNbO3, are being widely used for high speed optical communication applications, which exploit their fast EO modulation capability. This EO modulation capability is also being used for the detection of an electric field over an extremely broad frequency band, namely DC through THz. It is known that most of EO crystals exhibit the photorefractive, pyroelectric, piezo and photo-electric effects. While considered as parasitic effects and detrimental for most EO applications, our experimental results seem to suggest that some of these effects can increase the effective EO responsivity. To understand how these effects influence the EO responsivity we have carried out systematic investigations with LiNbO3 and Sr0.75Ba0.25Nb2O6 crystals. When a linearly polarized laser beam (628 nm) passes through the crystal, to which an external low frequency AC field is applied, we observed a periodic interference pattern, which was dynamically modulated by the AC field. We also found that the interference pattern was produced by the reflected beam from the crystal’s front and back surfaces. The patterns and dynamic modulation behaviors of the transmitted and reflected beams were noticeably different from each other. We will discuss the implications of these experimental results to the EO responsivity.
4:06PM L35.00009 A MHz-Rate High-Power UV Laser Source for High-Speed Planar Laser-Induced Fluorescence Spectroscopy, MIKHAEL N. SLIPCHENKO, JOSEPH D. MILLER, TERRENCE R. MEYER, Department of Mechanical Engineering, Iowa State University, Ames IA 50011; NAIEO JIANG, WALTER R. LEMPERT, Departments of Mechanical Engineering and Chemistry, The Ohio State University, Columbus, OH 43202, JAMES R. GORD, Air Force Research Laboratory, Propulsion Directorate, Wright-Patterson AFB, OH 45433 — We report on producing MHz-rate pulse burst tunable high energy UV radiation and its application to high-speed temperature measurements of combustion based on planar laser-induced fluorescence (PLIF) spectroscopy. The laser system consists of a narrowband high-speed tunable seeded OPO pumped by harmonics of a MHz-rate pulse-burst pump laser. The pump laser utilizes an AOM-based pulse slicer followed by a 5-stage Nd:YAG amplifier. The pump laser produces 4 bursts per second with a burst duration as long as 1.5 ms and total burst power up to 2 J. Each burst consists of 5 to 100 pulses with each pulse duration variable between 6 to 50 ns. The custom OPO produces up to 5 mJ per pulse in the range from 220 to 315 nm for exciting electronic transitions of species such as nitric oxide and the hydroxyl radical. The laser system performance is tested in well characterized flames and pulse-burst PLIF results are presented.

4:18PM L35.00010 Theory of THz rectification at a gate controlled Shottky barrier in a FET based plasmonic detector, G.R. AIizin, J. MIKALOPAS, CUNY, New York, G.C. DYER, UC Santa Barbara, E.A. SHANER, M.C. WANKE, Sandia National Laboratories, S.J. ALLEN, UC Santa Barbara — We present a theory of the resonant THz photoresponse in a grating gated FET with a gate controlled Shottky barrier [1]. We use theoretical modeling to show that the potential barrier induced in the 2D FET channel by an isolated gate finger, biased to pinch off, yields the Shottky-like I – V characteristics of the FET. The gate coupling causes an external THz radiation to the plasmon excitations in the 2D electron channel. We calculate the photoresponse signal resulting from the THz rectification at the Schottky barrier and demonstrate that it has resonant peaks at plasmon frequencies. The results obtained are consistent with recent measurements [2]. This work is supported by ARO (Grant # W911NF-05-1-0031) and The University at Buffalo NSF NIRT (Grant # ECS0609146 ). Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000. 1. E.A. Shaner et al, Appl. Phys. Lett., 90, 181127 (2007). 2. G. Dyer et al, this meeting presentation.

4:30PM L35.00011 Control of exciton fluxes, ALEX HIGH, AARON HAMMACK, E.E. NOVITSKAYA, LEONID BUTOV, University of California at San Diego, MICAH HANSON, ARTHUR GOSSARD, University of California at Santa Barbara — We present proof of principle for control of excitonic fluxes by gate in mesoscopic devices. Since excitons are bosonic particles, control of exciton fluxes can extend mesoscopics, the field which electron transport in transport provides. Also, as are coupled to light, the control of exciton fluxes may lead to development of new optoelectronic devices. The demonstrated devices as a directional switch, star switch, and flux merger.

4:42PM L35.00012 Experimental Studies of Alignment Tolerance and High Temperature Performance of A Fabry-Perot Interferometric Pressure Sensor, IVAN PADRON, ANTHONY FIORY, NUGGEHALLI RAVIDNRA, New Jersey Institute of Technology — Fabry-Perot interferometry is one of the most reliable of the several optical techniques that can be utilized to facilitate the fabrication of an optical sensor. Devices based on this technique can provide high degree of sensitivity, versatility and immunity to environmental noise. The Fabry-Perot Interferometric Sensor (FPIS), to be discussed in this presentation, consists of a Fabry-Perot cavity formed between two bonded surfaces: a corrugated diaphragm with a center rigid body (or boss) which deflects under internal pressure and keeps a high alignment tolerance and a glass surface with an optical fiber insert. The Fabry-Perot cavity and optical fiber have been used as the sensing element and interconnect, respectively. The Fabry-Perot cavity has been fabricated using the MEMS technology. Micromachining techniques make Fabry-Perot sensors very attractive by reducing the size and cost of the sensing element.

4:54PM L35.00013 Growth and properties of wide band gap II-VI multi-quantum well structures for mid-infrared quantum cascade lasers, WILLIAM CHARLES, The City College of New York, KALE FRANZ, Princeton University, AIDONG SHEN, MARIA TAMARGO, The City College of New York, CLAIRE GMACHL, Princeton University — Mid-infrared emission based on intersubband transitions has been recently very actively pursued for the fabrication of quantum cascade lasers (QCLs) operating in that wavelength range. Highly efficient, ultra fast lasing can be achieved from engineered structures in which the emission wavelength is determined by the precisely controlled multi-layered structure rather than the specific materials of choice. However, operation at wavelengths shorter than 3.5 μm is limited by the conduction band offset of the materials currently available. To address this limitation, we have begun to explore wide band gap II-VI ZnCdMgSe materials grown lattice matched to InP substrates for these applications. Recently, we reported the growth and characterization of multi-quantum well structures that exhibit absorption in the 3-5 μm region. We have designed a structure consisting of the active/injector regions of a QCL and fabricated electroluminescent devices. Electroluminescence emission at 4.7 μm has been observed in these structures, suggesting that these materials hold great promise for the fabrication of short wavelength mid-IR QCLs. This work is supported by NSF Grant No. EEC-0540832 (MIRTHE-ERC).

5:06PM L35.00014 Behavior of laser diodes in the small particle number quantum limit, KAUSHIK ROY CHAUDHURY, ANTHONY F.J. LEVI — We use master equations to model the steady-state and transient response of a laser diode in the small particle number quantum limit. In scaled laser diodes n electrons and s photons are correlated such that <ns> may not be factorized and there are significant differences in behavior compared to predictions of continuum mean-field theory. Quantization of photon number is found to suppress lasing threshold and create a non-Poisson probability distribution for n discrete electrons and s discrete photons. The same correlation effect dampens the transient dynamic response of laser emission. The predictions of conventional mean-field and Langevin theory are recovered in the large particle number limit.
Understanding Atomistic Mechanisms for Reversible Hydrogen Storage in Metal Hydrides: Application to Alane Formation on Ti Doped Al Surfaces

We describe a density functional kinetic Monte Carlo approach enabling us to study and simulate the steady-state situation of dissociative adsorption of hydrogen along with diffusion and reaction of Al and H atoms leading towards the formation of alane species on Ti-doped Al surfaces. In the first step, density functional theory is used in conjunction with the nudged elastic band/drag method to obtain the energetics of the relevant atomistic processes of Al and H diffusion and their reactions on Al surfaces with different concentration of dopant Ti atoms. Subsequently, the kinetic Monte Carlo method is employed, which accounts for the spatial distribution, fluctuations, and evolution of chemical species at Ti-doped Al surfaces under steady-state conditions. This DFT-based KMC approach provides an insight into the kinetics of alanes at technologically relevant pressure and temperature conditions. Our computed production rates of AlH3 on Al surfaces are in agreement with experimental data. We also obtained temperature programmed desorption spectra of different alane species, which is agreeing well with experiments.

3:06PM L36.00002 Density Functional Theory Based Kinetic Monte Carlo Approach for Understanding Atomistic Mechanisms for Reversible Hydrogen Storage in Metal Hydrides: Application to Alane Formation on Ti Doped Al Surfaces1, A. KARIM, J. MUCKERMAN, P. SUTTER, E. MULLER, BNL — We describe a density functional kinetic Monte Carlo approach enabling us to study and simulate the steady-state situation of dissociative adsorption of hydrogen along with diffusion and reaction of Al and H atoms leading towards the formation of alane species on Ti-doped Al surfaces. In the first step, density functional theory is used in conjunction with the nudged elastic band/drag method to obtain the energetics of the relevant atomistic processes of Al and H diffusion and their reactions on Al surfaces with different concentration of dopant Ti atoms. Subsequently, the kinetic Monte Carlo method is employed, which accounts for the spatial distribution, fluctuations, and evolution of chemical species at Ti-doped Al surfaces under steady-state conditions. This DFT-based KMC approach provides an insight into the kinetics of alanes at technologically relevant pressure and temperature conditions. Our computed production rates of AlH3 on Al surfaces are in agreement with experimental data. We also obtained temperature programmed desorption spectra of different alane species, which is agreeing well with experiments.

3:18PM L36.00003 Alanes formation on the Al(111) surface, SYLVIE RANGAN, JEAN-FRANCOIS VEYAN, YVES J. CHABAL, University of Texas at Dallas, SANTANU CHAUDHURI, Washington State University, JAMES T. MUCKERMAN, Brookhaven National Laboratory — Alane clusters (AlH3) are believed to be the ubiquitous intermediates in hydrogen storage reactions for a wide variety of alanates (LiAlH4, NaAlH4) currently considered for hydrogen storage. The formation and behavior of alanates at surfaces appear to control and limit the efficiency of hydrogen storage. In particular, hydrogen adsorption on the Al(111) surface leads to the coexistence of several adsorbed species, the concentration of which is affected by the step density, the surface coverage and the temperature. We combine density functional theory (DFT) and surface infra-red (IR) absorption spectroscopy to uncover the mechanisms for alane formation on Al(111) surfaces. At low coverage, DFT predicts a two-fold bridge site adsorption for atomic hydrogen, consistent with previous Electron Energy Loss Spectroscopy measurements. At higher coverage, the formation of small chemisorbed AlH3 occurs at the step edges. With increasing coverage AlH3 is extracted from the step edge and becomes highly mobile on the terraces in a weakly bound state. This mobility is the key factor leading to the growth of larger alanates through AlH3 oligomerization. For these large alanates, previous Thermal Programmed Desorption studies are discussed and compared to the thermal stability observed in IR.

3:30PM L36.00004 Watching the dehydrogenation of alane (AlH3) in a TEM, SHANE BEATTIE, TERRY HUMPHRIES, LOUISE WEAVER, SEAN MCGRADY, University of New Brunswick — Alane (AlH3) is a promising candidate for on-board hydrogen storage applications. Its theoretical gravimetric capacity is 10.1 percent and decomposition is achieved with modest heating (60-200 deg C). We studied the dehydrogenation of alane, insitu, in a TEM. Alane powder was loaded into the TEM and heated at 80 deg C. We were able to watch the dehydrogenation of the alane to aluminum. Electron diffraction and dark field images are used to show how and where the aluminum crystallites grow. Although crystalline aluminum phases were successfully identified, some of the sample remained amorphous. We will discuss the nature of the amorphous material and present images clearly identifying the nature of the aluminum crystallites.

3:42PM L36.00005 Hydrogen Multicenter Bonds on Small Metal Clusters1, P. TARAKESHWAR, T.J. DHILIP KUMAR, N. BALAKRISHNAN, Department of Chemistry, University of Nevada Las Vegas, 4505 Maryland Parkway, Las Vegas, NV 89114, USA — We investigate the saturation of hydrogen on metal clusters employing ab initio calculations. Our calculations reveal that energetically the most preferred configuration of the hydrogen saturated metal clusters exhibit hydrogen multicenter bonds. The strength of these hydrogen multicenter bonds can be modulated either by changing the extent of hydrogen saturation or using different metal clusters. In the context of hydrogen storage materials, our calculations indicate that early first-row transition metals have the best propensity to form hydrogen multicenter bonds. The relevance of this work in the context of hydrogenation and dehydrogenation kinetics of complex metal hydrides will be discussed.

3:54PM L36.00006 The absorption of hydrogen by Nb thin films capped with Pd studied by transmission of visible light1, J. I. AVILA, A. L. CABRERA, Facultad de Fisica, Pontificia Universidad Catolica de Chile, G. B. CABRERA, DAVID LEDERMAN, Department of Physics, West Virginia University, Morgantown — Samples of Nb films with thickness between 2.5 to 14 nm were deposited on glass and capped by a continuous 6 nm Pd film in a sputtering system. The light transmission and reflection, in the visible range (400 to 1000 nm), were measured when the sample was exposed to different hydrogen pressure up to 75 Torr. Experiment on continuous pure Pd film and Nb film were done for comparison. The relative change in transmission for Nb at 74 Torr of hydrogen is about 5 percent but the saturation occurs after 2500 s. A sample of 14 nm Nb capped by Pd showed a 2 percent increase in transmission at the same pressure but the saturation time is reduced to 50 s, same as pure Pd. Change in the kinetics of hydrogen absorption by Nb capped with Pd indicates that the rate limiting step in the absorption process by pure Nb is located on the Nb surface.

4:06PM L36.00007 Theoretical Analysis on X-ray Absorption Spectra of Ti compounds as Catalysts in Lithium Amide-Imide reactions, TAKAO TSUMUYARA, TATSUYA SHISHIDOU, TAMIO OGUCHI, Hiroshima University — Solid-state storage is conceptually efficient approach for on-board vehicular hydrogen storage. In this context, light-element materials such as lithium amide LiNH$_2$ and lithium imide Li$_2$NH have been attracted much attention due to their high gravimetric densities of hydrogen. Recently, various transition-metal compounds have been examined with ball-milling technique for exploring catalysts to improve the hydrogen storage and desorption kinetics, and it is found that a small amount (1mol%) of titanium compounds revealed a superior effect in hydrogen desorption reaction LiNH$_2$ + LiH $\rightarrow$ Li$_2$NH + H$_2$ [1]. However, these catalysts mechanism and role of Ti in the reaction remain unanswered. Isobe et al. have carried out measurements of X-ray absorption spectroscopy(XAS) at Ti K-edge to see the electronic states of Ti recently [2]. In this paper, we calculate the electronic structure of Ti metal and its compounds, and obtained theoretical spectra to compare with the measured spectra by using first-principles calculations based on the all-electron FLAPW method. We discuss chemical bonding and local geometry of catalytically active states in the reaction. [1] T. Ichikawa, S. Isobe, N. Hanada and H. Fujii, J. of Alloys and Comp. 365, 271 (2004). [2] S. Isobe, T. Ichikawa, Y. Kojima and H. Fujii, J. of Alloys and Comp. 446-447, 360 (2007).

Tuesday, March 11, 2008 2:30PM - 5:18PM — Session L37 DCMP: Semiconductors II: Structure and Phase Diagrams Morial Convention Center 229

2:30PM L37.00001 First-Principles epitaxial phase-diagram, short-range order, microstructure and electronic properties of (In,Ga)N zincblende alloys on GaN$^1$, ZHE LIU, PAULO PIQUINI, ALEX ZUNGER, National Renewable Energy Lab., Golden, CO 80401 — A first-principle total energy cluster expansion method is developed to study thermodynamic properties of epitaxial semiconductor alloys coherent to substrate (i.e., $<critical$ $thickness$ $h_c$), in which coherent strain energy as a function of atomic configuration is explicitly described. The search for epitaxial ground state structures of (In,Ga)N alloy grown on GaN (001) substrate concludes that epitaxial strain suppresses phase separation, which is normally observed for bulk (In,Ga)N alloy and relaxed films. Two (102) superlattices: (InN)$_2$/(GaN)$_2$ and (InN)$_3$/(GaN)$_3$, are determined to be the epitaxial ground state structures. Composition-temperature phase diagram calculated by Monte Carlo method shows that homogeneous solid solution phase is thermodynamically stable at typical growth temperature of blue and green LED by MBE and MOCD (x/ln~0.20~0.30 and $h_c$ ~10~30nm). Such calculated phase diagram can be used to understand the controversy regarding atomic microstructures in (In,Ga)N quantum well devices. Short-range-ordering of the solid solution phase and its influence on the electronic properties are also discussed.

2:42PM L37.00002 First principles and valence force field study of III-V quaternary alloys$^1$, KOUSHIK BISWAS, ALBERTO FRANCESCHETTI, STEPHAN LANY, National Renewable Energy Laboratory — We report on the elastic properties and formation energies of Ga$_x$In$_{1-x}$P$_y$N$_{1-y}$-quaternary alloys using first principles and valence force field (VFF) calculations. The elastic constants of the binary compounds (GaP, InP, GaN, and InN) were calculated using the local density approximation (LDA). The resulting VFF parameters, $\alpha$ (bond stretching) and $\beta$ (bond angle bending) were used within the Keating model to calculate the formation energies of GaNP, GaN, InP, and GaPN ordered structures. We found that the VFF formation energies of phosphide-nitride alloys (e.g. GaPN) were not in very good agreement with the LDA formation energies. Conventionally, the bond bending parameter $\beta$ for a ternary alloy is chosen as the arithmetic mean of the binary constituents. To improve the accuracy of the VFF model, we lifted such restriction on the $\beta$-parameter and we also introduced the parameter $\sigma$ (bond length-bond angle interaction). The VFF parameters $\alpha$, $\beta$, and $\sigma$ were fitted to the LDA-calculated formation energies of a large number of ternary ordered structures and were used to calculate the formation energy of the Ga$_x$In$_{1-x}$P$_y$N$_{1-y}$-quaternary alloy.

2:54PM L37.00003 First Principles Phase Diagram Calculation For Al$_x$Ga$_{1-x}$N, JEREMY NICKLAS, JOHN WILKINS, Ohio State University — First principles phase diagram calculations were performed for the wurtzite and zincblende structures of the quasibinary system AI$_2$Ga-N. The cluster expansion method using the code ATAT was performed without and with excess vibrational contributions to the free energy, $F_{vib}$. The ab initio calculations were performed with VASP using the PAW pseudopotentials with PBE for the exchange and correlation energies. Preliminary results show miscibility gaps for both structures with a decrease in the consolute points, $(X_C, T_C)$, when including $F_{vib}$. The wurtzite structure is predicted to be approximately symmetric while the zincblende is predicted to be quite assymmetric.

3:06PM L37.00004 Simulation studies of GST phase change alloys, GLENN MARTYNA, IBM Research — In order to help drive post-Moore’s Law technology development, switching processes involving novel materials, in particular, GeSbTe (GST) alloys are being investigated for use in memory and eFuse applications. An anneal/quench thermal process crystallizes/amororphizes a GST alloy which then has a low/high resistance and thereby forms a readable/writeable bit; for example, a “one” might be the low resistance, conducting crystalline state and a “zero” might be the high resistance, glassy state. There are many open questions about the precise nature of the structural transitions and the coupling to electronic structure changes. Computational and experimental studies of the effect of pressure on the GST materials were initiated in order to probe the physics behind the thermal switching process. A new pathway to reversible phase change involving pressure-induced structural metal insulator transitions was discovered. In a binary GS system, a room-temperature, direct, pressure-induced transformation from the high resistance amorphous phase to the low resistance crystalline phase was observed experimentally while the reverse process under tensile load was demonstrated via ab initio MD simulations performed on IBM’s Blue Gene/L enabled by massively parallel software. Pressure induced transformations of the ternary material GST-225 (Ge$_2$Sb$_2$Te$_5$) were, also, examined In the talk, the behavior of the two systems will be compared and insight into the nature of the phase change given.

3:18PM L37.00005 Local structure and Phase transition of (GeTe)$_n$(Sb$_2$Te$_3$)$_m$ pseudo-binary system for the phase-change memory, JINO IM, JAE-HYEON EOM, JISUON IHM, Department of Physics and Astronomy, Seoul National University, Seoul, Korea — A theoretical investigation on the local structure and phase transition between the crystalline and the amorphous phase of (GeTe)$_n$(Sb$_2$Te$_3$)$_m$ pseudo-binary system(GST) for the phase-change memory is presented. Based on the study of the coordination number for the amorphous phase of GST, the local structure of the amorphous phase of the GST is shown to be composed of the stibnite-like building block for the Sb$_2$Te$_3$ and chain-like building block for the GeTe. The phase transition between the crystalline and the amorphous phase of GST is explained by relative repositioning of these building blocks. Density functional total energy minimization calculations show that the crystallization energy and the volume change in transition also agree with experimental data.
3:30PM L37.00006 Raman scattering studies of Ge-Sb-Te nanoparticles\(^1\). CHRISTINE KIM, HAE-YOUNG SHIN, AH REUM JEONG, WILLIAM JO, SEOKHYUN YOON, Department of Physics and Division of Nano Sciences, Ewha Womans University, Seoul 120-750, Korea — We have measured Raman scattering spectra of Ge-Sb-Te (GST) nanoparticles which are synthesized by a pulsed laser ablation method. The nanoparticles were grown under different growth conditions such as temperatures and/or pressures. Our measurements could provide information towards the optimal growth conditions for better crystalline quality of the GST nanoparticles. We have also measured nitrogen-doped GST nanoparticles. Comparison between Raman responses of nitrogen- doped- and undoped-GST nanoparticles will be presented. Our results suggest that Raman scattering spectroscopy can be used to study phases and phase changes through local structural information in the GST nanoparticles, which are being developed for low-power non-volatile memory applications.

3:42PM L37.00007 Theory of unsaturated silicon lattices\(^1\), FENG ZHANG, DAVID STUCKE, DRAGAN STOJKOVIC, VINCENT CRESPI — Several molecules are known to contain stable silicon double or triple bonds that are sterically protected by bulky side groups. Through first-principles computation, we demonstrate that well-defined \(\pi\) bonds can also be formed in two prototypical crystalline Si structures: Schwarzite Si-168 and dilated diamond. The sp\(^2\)-bonded Si-168 is thermodynamically preferred over diamond silicon at a modest negative pressure of -2.5 GPa. Ab-initio molecular dynamics simulations of Si-168 at 1000 K reveal significant thermal stability. Si-168 is metallic in density functional theory, but with distinct \(\pi\)-like and \(\pi^*\)-like valence and conduction band complexes just above and below the Fermi energy. A bandgap buried in the valence band but close to the Fermi level can be accessed via hole doping in semiconducting Si\(_{14}\)B\(_2\). A less-stable crystalline system with a silicon-silicon triple bond is also examined: a rare-gas intercalated open framework on a doped diamond lattice.

3:54PM L37.00008 Phase diagram of silicon using a DFT-based neural network potential. OLIVIERO ANDREUSSI, Scuola Normale Superiore di Pisa, Italy & DMSE, Massachusetts Institute of Technology, USA. JOERG BEHLER, Ruhr-Universitaet Bochum, Germany, MICHELE PARRINELLO, ETH Zurich, Switzerland — The phase diagram of silicon is computed by means of Classical Molecular Dynamics. A variety of Ge nanostructures formed on intact Si(111) have been observed. However, the fine structures of the atomic arrangements in the Ge nanostructures have remained elusive. We performed scanning tunneling microscopy observations and first-principle calculations for investigating the fine structures of the Ge nanostructures on the Si(111)-7\times7 surface. We obtained atomic structures of the nanostructures formed with a certain process involving deposition at temperature of 423 K and annealing at 550 K. We found that Ge nanocluster, located predominately in the faulted half unit cells of the Si(111)-7\times7 surface, contained approximately six Ge atoms with three bonded center Si adatoms. We also observed that the obtained nanostructures were stable up to 600 K.

3:46PM L37.00009 Fine Structures of Ge Nanoclusters on Si(111): STM Observations and First-Principles Theory\(^1\), A.S. RAO, University of Tulsa, H.F. MA, M.C. XU, D.X. SHI, H.J. GAO, Chinese Academy of Sciences, R. GUDIPATI, H.L. DANG, SANJU WANG, University of Tulsa — Germanium-based nanoclusters grown on silicon substrates have potential applications in optoelectronics and nanotechnology. A variety of Ge nanostructures formed on intact Si(111) have been observed. However, the fine structures of the atomic arrangements in the Ge nanostructures have remained elusive. We performed scanning tunneling microscopy observations and first-principle calculations for investigating the fine structures of the Ge nanoclusters on the Si(111)-7\times7 surface. We obtained atomic structures of the nanostructures formed with a certain process involving deposition at temperature of 423 K and annealing at 550 K. 4:06PM L37.00010 Damping of high amplitude phonons in bismuth: classical and quantum mechanical simulations. EAMONN MURRAY, Rutgers University, AARON HURLEY, University College Cork, Ireland, DAVID PRENDERGAST, Lawrence Berkeley Laboratory, TADASHI OGITSU, Lawrence Livermore National Laboratory, DAVID FRITZ, Stanford Linear Accelerator Center, DAVID REIS, University of Michigan, STEPHEN FAHY, University College Cork, Ireland — Using both classical and quantum mechanical simulations together with first-principles results, we investigate the damping mechanism of high amplitude excitations in the \(A\text{g}\) phonon mode in bismuth. Pump-probe experiments using ultrafast lasers can generate and measure large amplitude coherent oscillations of the \(A\text{g}\) phonon mode in bismuth. A substantial reduction in the lifetime of the phonon is observed when higher amplitude oscillations are produced. With third-order couplings obtained from first-principles calculations we calculate the rate of energy loss from the \(A\text{g}\) mode over several picoseconds. We find that as the highly excited \(A\text{g}\) mode decays, it produces highly excited modes in relatively small regions of the Brillouin Zone, leading to an increase in the decay rate into these modes. We show how this can greatly affect the observed lifetime of the high amplitude excitation of the \(A\text{g}\) mode.

4:30PM L37.00011 Structure of Bi\(_2\)Sr\(_2\)CaCu\(_2\)O\(_{6+\delta}\) supermodulation from ab initio calculations\(^1\). Y. HE, Quantum Theory Project, U. Florida, S. GRASER, P.J. HIRSCHFELD, H.-P. CHENG, Physics Dept., U. Florida — We present results of density functional theory (DFT) calculation of the structural supermodulation in Bi\(_2\)Sr\(_2\)CaCu\(_2\)O\(_{6+\delta}\), structure, and show that the supermodulation is indeed a spontaneous symmetry breaking of the nominal crystal symmetry, rather than a phenomenon driven by interstitial O dopants. The structure obtained is in excellent quantitative agreement with recent x-ray studies, and reproduces several qualitative aspects of scanning tunnelling microscopy (STM) experiments as well. The primary structural modulation affecting the CuO\(_2\) plane is found to be a buckling wave of tilted CuO\(_2\) half-octahedra, with maximum tilt angle near the phase of the supermodulation where recent STM experiments have discovered an enhancement of the superconducting gap. We argue that the tilting of the half-octahedra and concommitant planar buckling are directly modulating the superconducting pair interaction.

4:42PM L37.00012 Discovery of Dynamics of Jahn-Teller Effect. DAN LIU — Taking \(S=1/2\) NaSi\(_7\)O\(_{26}\), as example, we discovered the dynamics of the Jahn-Teller effect of solids by extending the molecular frontier orbital theory from chemistry to solid state physics. At the orbital and spin levels, the dynamics of the Jahn-Teller effect is exposed to spin flipping and spontaneous orbital transition that is driven by the spin-orbital coupling to keep the angle momentum reservation. The orbital transition leads to a dramatic structural change, i.e., the JT distortion. In analogue to the single-triplet intersystem crossing of photochemistry, the JT effect is a non-adiabatic process, associated with the first-order phase transition. The JT effect agrees well with the low-dimensional, \(S=1\) Haldane gap on the basis of the antimagrine Heisenberg model, if emphasizing that the \(S=1\) parameter of Haldane gap indicates the parallel spins of neighboring orbitals, rather than the on-site parallel spins. We provide insight to understanding of the unusual structural, magnetic properties of \(S=1/2\) NaTi\(_3\)S\(_6\), as well as the \(S=1\)LiV\(_2\)O\(_4\) and \(S=3/2\) LiCrGe\(_2\)O\(_6\).
4:54PM L37.00013 Dynamics of A-B transition of the DNA double helices, HOA WANG, THOMAS CHEATHAM, PETER GANNETT, JAMES LEWIS, Department of Physics, West Virginia University, Morgantown, WV 26506 — The conformational transitions of DNA and the sensitivity of DNA structure to the surrounding environment are very relevant to its chemical and biological function and potential applications in nano-technology. Different conformations of DNA, even with the same sequence, exhibit different electronic structures, resulting in different conduction properties. We present theoretical work on the dynamical features of electronic states in the A-B transition of a model DNA duplex of \( d(C\overline{G}GCGCGG)_{2} \) (10 base-pairs, 628 atoms) as the molecule undergoes conformational changes and thermal fluctuations at room temperature. We couple state-of-the-art empirical force field molecular dynamics (MD) simulations with an \textit{ab-initio} electronic structure method based on density-functional theory, called FIREBALL. For the A-B transition, we calculated the effects of conformational change on the electronic structure for each snapshot obtained from nanosecond MD simulations.

5:06PM L37.00014 Mechanism of GeSbTe phase change materials: an \textit{ab initio} molecular dynamics study\(^1\), JEAN-YVES RATY, CÉLINE OTJACQUES, JEAN-PIERRE GASPARD, University of Liège, Belgium, CHRISTOPHE BICHARA, CRMCN, University Aix-Marseille, France — Among phase change materials, Ge2Sb2Te5 (225) is one of the most successfully used in applications. Accepted models are based on EXAFS spectra and simulate a complete reorganization of bonds during amorphization, with Ge changing from sixfold to tetrahedral coordination. We perform \textit{ab initio} MD simulations of the (225), (124) and (415) liquid alloys. We show that the crystalline, liquid and amorphous structure of these systems are similar, with very little sp3 hybridization around Ge atoms and a majority of p-sigma bonds. Using a set of quenched liquid configurations we reproduce the EXAFS measurements on the (225) composition and explain how the static Debye Waller factor due to the vacancies in the crystal phase leads to a cancellation of individual neighbors contribution to the EXAFS signal while in the amorphous, a larger coherence occurs, enhancing the EXAFS signal. The computed electrical conductivities of the three phases (cubic solid, liquid and amorphous) prove to be very different, accordingly with the experiment.

\(^1\)We acknowledge support from the FNRS, the FAME NoE, and the Clusters and Wires IAP project.

Session L39 GSNP DMP: Focus Session: Deformation and Fracture Morial Convention Center 231

2:30PM L39.00001 Strain localization as a mechanism for dynamic weakening in amorphous solids, M. LISA MANNING, JAMES S. LANCER, JEAN M. CARLSON, University of California Santa Barbara — Solids such as foams, colloids, amorphous metals and granular fault gouge are composed of particles in closely-packed, non-crystalline configurations, and small-scale mechanisms for deformation in these materials are less well-understood than those in liquids or crystals. I will discuss a mesoscopic model for these disordered solids, the theory of Shear Transformation Zones (STZs), and show that it captures macroscopic features seen in experiments as well as interesting internal dynamics such as shear banding. An important component of this model is the effective temperature, which describes the statistical distributions of particle configurations and governs plastic deformation. Shear banding occurs due to a "frozen"-time instability in the effective temperature field, and one can determine a condition for shear banding based on the initial conditions alone. I will discuss how the STZ formulation can be used as a continuum model for fault gouge and includes a mechanism by which the system can dynamically weaken.

2:42PM L39.00002 What is the structure of a polymer glass after plastic deformation?, HELENE MONTES, FRANCOIS LEQUEUX, ESPCI, PPMD, CHRISTIANE ALBA-SIMIONESCO, LCP, Orsay, FREDERIQUE CASARAS, UMR 5254, Pau, PPMD, ESPCI TEAM, LCP, ORSAY TEAM — We aim to study the effect of plastic deformation on the structure of a glassy polymer. Using neutrons scattering on a large range of length scales, and comparing samples deformed below and above \( T_g \), we show that: 1) The deformation is extremely homogeneous (or affine) for length scales above the entanglement distance 2) The crossover length scale between affine and non affine deformation is about half the one of the entanglements, and is independent of temperature below the glass transition 3) The arrangement of the polymer chain is distorted by plastic deformation at the atomic scale. We then discuss these results and compare them to the results of the simulation of Hoy and Robbins (J. Polym. Sci., 44 (2006), 3487). As a conclusion we see that the entanglements are responsible for the very homogeneous deformations, forcing the individual plastic events to propagate in the sample following the tension of the chains. Thus we conclude that the physics of the plastic deformation of polymer glasses are very different from the one of other glasses.

2:54PM L39.00003 Depinning transition in failure of disordered brittle materials\(^1\), LAURENT PONSON, California Institute of Technology, FEDERAL UNIVERSITY OF RIO DE JANEIRO COLLABORATION — Crack propagation is the fundamental process leading to material failure. However, its dynamics is far from being fully understood. In this work, we investigate both experimentally and theoretically the growth velocity \( v \) of a crack propagating in brittle materials in the limit of low velocities compared to the sound speed. The variations of \( v \) with respect to the external loading \( K_I \) are carefully measured on two kinds of brittle rocks over various orders of magnitude. The crack dynamics is shown to display two regimes, well described by a sub-critical creep law \( v \sim e^{-(K_I-K_{0})^\mu} \) with \( \mu \geq 1 \) for \( K_I < K_c \), at low velocities, and a critical behavior where \( v \sim (K_I-K_c)^\theta \), with \( \theta \approx 0.8 \) when \( K_I > K_c \). We show that these variations, as well as the value of the exponents \( \mu \) and \( \theta \), can be explained extending the theoretical framework of Linear Elastic Fracture Mechanics to inhomogeneous media. In particular, these two regimes are shown to be reminiscent of the dynamical critical transition underlying the failure of disordered brittle materials.

\(^1\)The author would like to thank Dr. Guilherme Cordeiro and Ashutosh Bindal for their help in the experiments. Financial support from the French Ministry of Foreign Affairs through the Lavoisier Program is acknowledged.

3:06PM L39.00004 Role of microstructural heterogeneities on rupture of polycrystalline materials, PHILLIP DUXBURY, Michigan State University — Grain boundary networks are the dominant heterogeneity in many polycrystalline materials, and their performance may be dramatically improved by increasing the fraction of boundaries which have either low grain boundary energy or which are special boundaries, such as coincident site lattice boundaries. Significant improvement in properties such as corrosion resistance, critical current in superconductors and mechanical strength and toughness occur, provided special percolating grain or grain boundary structures can be engineered. Nevertheless, grain boundary network correlations constrain the extent to which property improvements can be achieved. A common deleterious effect is that degraded boundaries have a tendency to cluster in linear chains leading to unexpected reductions in performance. After an introduction to the area, scaling laws and the results of large scale simulations of percolation, critical manifolds and rupture in polycrystals will be presented. In particular, deleterious effects due to grain boundary correlations will be elucidated and strategies for their mitigation will be discussed.
3:42PM L39.00005 Phase field modeling of liquid metal embrittlement$^{1}$, ROBERT SPATSCHEK, NAN WANG, ALAIN KARMA, Physics Dept. and CIRCS, Northeastern University — Liquid metal embrittlement (LME) is a phenomenon whereby a liquid metal in contact with another, higher-melting-point polycrystalline metal, rapidly penetrates from the surface along grain boundaries. This phenomenon is known to be greatly accelerated by the application of tensile stress, resulting in the rapid propagation of intergranular cracks in normally ductile materials. Although this phenomenon has been known for a long time, it still lacks a convincing physical explanation. In particular, the relationship of LME to conventional fracture mechanics remains unclear. We investigate LME using a phenomenological three-order-parameter phase field model that describes both the short scale physics of crystal decohesion and macroscopic linear elasticity. The model reproduces expected macroscopic properties for well separated crack surfaces and additionally introduces short scale modifications for liquid layer thicknesses in the nanometric range, which depend on the interfacial and grain boundary energy as well as elastic effects. The results shed light on the relative importance of capillary phenomena and stress in the kinetics of LME.

3:54PM L39.00006 Atomic simulation studies of plastic deformation and dislocation patterning as a function of temperature$^{1}$, N. SCOTT WEINGARTEN, Physics Dept., Catholic Univ., ROBIN SELINGER, Liquid Crystal Institute, Kent State Univ. — The mechanical properties of crystalline solids depend sensitively on the mechanisms controlling dislocation nucleation, motion, and patterning. To explore the role of thermal activation in these processes, we carry out atomistic Monte Carlo simulation studies of plastic deformation of 2-d single crystals at a range of temperatures. We find that at intermediate temperatures, dislocations readily coalesce to form tilt boundaries, while at high temperature, the defects remain disordered in a gas-like phase, suggesting the possibility of an order-disorder phase transition. Conversely, near $T = 0$, dislocation mobility is too low to produce patterning on short time scales, again producing disordered structures. We study also the response of a polycrystalline solid under pure compression and look at the resulting distribution of stresses. We find that the defect-rich grain boundary regions bear higher stresses than those in the bulk, in agreement with Mughrabi’s two-component composite theory. Results are compared with recent experiments by L. E. Levine et al.

4:06PM L39.00007 Novel plastic processes in nanoindented stepped Au surfaces, VIOLETA NAVARRO, OSCAR RODRIGUEZ DE LA FUENTE, ARANTAZU MASCARAUDE, JUAN MANUEL ROJO, Univ. Complutense of Madrid, 28040 — While much work has been done recently on defect nucleation during plastic processes, mechanical properties of real surfaces have been seldom studied atomistically. Defect nucleation is well known to be critical in the mechanical behaviour of materials$^{[1]}$. But the role that surface defects play on the earliest stages of plasticity still needs to be elucidated. We approach realistic surfaces by using vicinal surfaces with a high step density. Nanoindentation with AFM and atomistic simulations have been performed on the Au(788) surface$^{[2]}$. Force vs penetration curves show a hertzian initial stage and a later incipient plastic regime when dislocations are nucleated. Between these two regimes we report a novel one, in which dislocations nucleate at the steps but no pop-ins are visible. This novel regime is to a large extent reversible in the sense that defects disappear when the tip is retracted$^{[2]}$. Heterogeneous dislocation nucleation is catalyzed by the presence of the surface steps.

$^{[2]}$V. Navarro et al. Submitted

4:18PM L39.00008 Hysteresis in Kinking Nonlinear Elastic Solids and the Preisach-Mayergoz Model, PETER FINKEL, AICUO ZHOU, Drexel University, GARY FRIEDMAN, Drexel University, MICHEL BARSOUM, Drexel University — We show that the stress-induced, dislocation-based, elastic kypic loops of kinking nonlinear elastic solids – polycrystalline cobalt, Ti3SiC2 and a 10 vol. % porous Ti2AlC - obey the scalar Preisach-Mayergoz phenomenological model because they exhibit wipe-out and congruency, two necessary and sufficient tenets of the model. We also present experimental proof of the applicability of the model for the prediction of the response of these materials to complex stress histories.

4:30PM L39.00009 Strain Relaxation through Structural Phase Transition in Ultrathin Films of FCC Metals, KEDARNATH KOLLURI, M. RAUF GUNGOR, DIMITRIOS MAROUDAS, University of Massachusetts, Amherst — We report a computational analysis of atomistic mechanisms of relaxation of biaxially applied tensile strain over a broad range of strain levels, ε, in freestanding ultra-thin Cu films based on iso-thermal-iso-strain large-scale molecular-dynamics simulations. Our analysis reveals that for ε < 10%, plastic deformation occurs through ductile void growth and dislocation nucleation and glide from the thin-film surfaces. For ε > 10%, strain relaxation is dominated by the nucleation of a high density of dislocations at the film’s surface, leading to a martensitic transformation of the thin film from an fcc to a hcp lattice structure. The hcp phase nucleates at the surface of the thin film and propagates into the film due to the glide of dislocations; in this process, the relative atomic slips have magnitudes identical to those observed in Bain transformations. Furthermore, mechanical analysis according to generalized stability criteria shows that the observed phase transition is consistent with the onset of a shearing instability of the thin film.

4:42PM L39.00010 Mechanical Properties and Fracture of Electrochemically Deposited CdSe Nanocrystal Films, SHENGGuo JIA, SARBABIT BANERJEE, DONGyun Lee, JOZe BEvK, JEFFREY KYsAR, IRVING HERMAN, Materials Research Science and Engineering Center, Columbia University — The fracture, strain, and stress of electrochemically deposited (EPD) CdSe nanocrystal films are studied as a function of the film thickness, nanocrystal size, and drying method. Fracture results from the film stress that develops with the loss of residual solvent after EPD, when the film exceeds a threshold thickness. Generational crack formation and a preferred direction for film drying are observed in real time. The elastic modulus and hardness of films of 3.2 nm CdSe nanocrystals are studied as a function of the film thickness, nanocrystal size, and drying method. For ε < 10%, plastic deformation occurs through ductile void growth and dislocation nucleation and glide from the thin-film surfaces. For ε > 10%, strain relaxation is dominated by the nucleation of a high density of dislocations at the film’s surface, leading to a martensitic transformation of the thin film from an fcc to a hcp lattice structure. The hcp phase nucleates at the surface of the thin film and propagates into the film due to the glide of dislocations; in this process, the relative atomic slips have magnitudes identical to those observed in Bain transformations. Furthermore, mechanical analysis according to generalized stability criteria shows that the observed phase transition is consistent with the onset of a shearing instability of the thin film.

4:54PM L39.00011 Current-induced Stabilization of Surface Morphology in Stressed Solids, VIVEK TOMAR, M. RAUF GUNGOR, DIMITRIOS MAROUDAS, University of Massachusetts Amherst — We report results on the surface morphological evolution of a conducting crystalline solid under the simultaneous action of an electric field and mechanical stress based on a fully nonlinear model and combining linear stability theory with self-consistent dynamical numerical simulations. Surface diffusional anisotropy is taken into account in the analysis. We address the evolution of a conducting crystalline solid under the simultaneous action of an electric field and mechanical stress based on a fully nonlinear model and combining linear stability theory with self-consistent dynamical numerical simulations. Surface diffusional anisotropy is taken into account in the analysis. and finally allowed to release isentropically. Here, we will discuss the details of the experiments and error analysis in deriving the yield strength of aluminum.

The aluminum samples were initially shocked to a fixed state on the Hugoniot, then quasi-isentropically compressed, to achieve a state of fixed entropy. The phase diagram. We employed these advances in recent tailored dynamic experiments to gain insight into the yield strength of aluminum along "hot" isentropes.

The formulation can be used in analyzing deformation mechanisms associated with defects involving heterogeneous fields at the nanoscale and macroscale, and in studying nanoscale processes where nonlocality is important.

3:30PM L40.00006 Violation of the London law and Onsager–Feynman quantization in multi-component superconductors, EGOR BABAЕV, University of Massachusetts Amherst, NEIL W. ASHCROFT, Cornell University — Non-classical response to rotation is a hallmark of quantum ordered states such as superconductors and superfluids. The rotational responses of all currently known single-component ‘super’ states of matter (superconductors, superfluids and supersolids) are largely described by two fundamental principles and fall into two categories according to whether the systems are composed of charged or neutral particles: the London law relating the angular velocity to a subsequently established magnetic field and the Onsager–Feynman quantization of superfluid velocity. These laws are theoretically shown to be violated in a two-component superconductor such as the projected liquid metallic states of hydrogen and deuterium at high pressures. The rotational responses of liquid metallic hydrogen or deuterium identify them as a new class of dissipationless states; they also directly point to a particular experimental route for verification of their existence.

3:42PM L40.00007 Ab-initio study on the crystal structure and the superconductivity of calcium in phase IV and $\gamma$, TAKAHIRO ISHIKAWA, HITOSE NAGARA, KOICHI KUSAKABE, Graduate School of Engineering Science, Osaka University, NAOSHI SUZUKI, Department of Pure and Applied Physics, Kansai University — Calcium shows interesting structural phase transitions and the superconductivity under high pressure. Structural transformations from the simple cubic structure (Ca-III) to a complex structure (Ca-IV) at 133GPa and from Ca-IV to another complex one (Ca-V) at 139GPa have been reported, but their structures have not been identified. The pressure-induced superconducting transition has been observed in Ca-III, and the superconducting transition temperature $T_c$ dramatically increases at the transition from Ca-III to Ca-IV and reaches to 25K, which is the highest $T_c$ in an element, at 161GPa in Ca-V. We explored the structures of Ca-IV and Ca-V via the metadynamics simulation based on the density functional theory and obtained two new structures: A helical structure and a zigzag structure. From comparison of the $x$-ray diffraction patterns we identified that the helical structure and the zigzag structure are candidate structures of Ca-IV and Ca-V, respectively. For the zigzag structure of Ca-V we calculated Tc using the Allen-Dynes formula. We assumed the effective screened Coulomb repulsion constant $\mu^*$ to be 0.1. We obtained $T_c=18.19$K at 140GPa, and the estimated values of $T_c$ are high and are close to the experimental values of Ca-V.

3:54PM L40.00008 Pressure-induced insulator-metal and structural transitions of BaBiO$_3$ from first principles LDA+$U$, DAVIDE CERESOLI, SISSA, Trieste, ERIO TOSATTI, SISSA and ICTP, Trieste — At zero pressure and temperature BaBiO$_3$ is an insulator with a structural dimerization, equivalent to a static valence disproportionation of the two Bi ions per cell from 4+ to 3+/5+. Under pressure one would expect an insulator-metal transition and the eventual disappearance of the dimerization. Moreover, the metallic phase should be superconducting, in analogy the metal doped Ba$_{1-x}$K$_{x}$BiO$_3$ compounds. To date, there are no accurate ab initio predictions under pressure, essentially because LDA or GGA fail to stabilize an insulating phase with the correct distortion and electronic gap. We carried out first principles LDA+$U$ calculations by determining the effective Hubbard U self-consistently at every pressure, and that the presence of U is mandatory for a correct description of the zero-pressure state. Upon increasing pressure, we found an insulator to metal transition at $\sim 20$ GPa. By further increasing the pressure, we predict the appearance of a superconducting phase, characterized by quantum melting of the weakly dimerized CDW lattice. The dimerization tendency and superconductivity are expected to weaken only at much higher pressures, presently under investigation.

4:06PM L40.00009 High pressure magnetic phase transitions in the quasi-2D ferromagnet, CeCrSb$_3$ investigated using designer diamond anvils, D.D. JACKSON, S.K. MCCALL, S.T. WEIR, Lawrence Livermore National Laboratory, A.B. KARKI, D.P. YOUNG, Louisiana State University, W. QIU, Y.K. VOHRA, University of Alabama, Birmingham — Pressure tuning magnetic phase transitions is a powerful method of discovering new physical properties of materials. At ambient pressure, CeCrSb$_3$ undergoes ferromagnetic ordering at 115 K due to the Cr ions, followed by a gradual ferromagnetic alignment of the Ce moments between 48 and 18 K. The evolution of these magnetic transitions was investigated via ac magnetic susceptibility to pressures of 20 GPa using designer diamond anvils. The ferromagnetic ordering due to the Cr ions decreases at a rate of $d T_c / d P = -1.75$ K/GPa, while the onset of the Ce ferromagnetic ordered phase increases at a rate of $d T_c / d P = 3.6$ K/GPa, followed by a sharp drop at $P_t = 11$ GPa. In addition, the electrical resistivity reveals that a possible superconducting phase is found between 11 GPa $< P < 16$ GPa below $T_t$ $\approx 3$ K.

4:18PM L40.00010 Zirconium Hydride: Structural Integrity at High-Pressures - A Synchrotron X-Ray Diffraction Study, PATRICIA E. KALITA, A. CORNELIUS, Department of Physics, University of Nevada Las Vegas, NV, USA, S. SINOGEIKIN, Geophysical Lab, Carnegie Institution of Washington, Washington DC, USA, A. MARTIN, Department of Physics, Xavier University of Louisiana, New Orleans, LA, USA, T. HARTMANN, Institute of Nuclear Science & Engineering, Idaho State University, Idaho Falls, ID 83401, USA, K.E. LIPINSKA-KALITA, Dept. of Chemistry, University of Nevada Las Vegas, NV, USA — Metal hydrides are of great interest not only from the fundamental research point of view but also because of their many technological applications, including hydrogen storage. Here we present our most recent studies in situ, high-pressure, angle-dispersive, synchrotron x-ray diffraction studies of zirconium hydride. We investigate the effects of hydrostatic and non-hydrostatic conditions. We also show the results of structural refinements as well as the bulk modulus of ZrH$_2$. *Work at UNLV is supported by DOE award No. DEFG36-07NA27344.

4:30PM L40.00011 Structural changes in borohydride hydrogen storage materials, RAVHI KUMAR, HiPSEC, Dep.Physics, University of Nevada Las Vegas, NV 89154, ANDREW CORNELIUS, HiPSEC, Department of Physics and Astronomy, University of Nevada Las Vegas, NV 89154, MALCOLM NICOL, HiPSEC, Department of Physics and Astronomy, University of Nevada Las Vegas, NV 89154 — Angle dispersive powder x-ray diffraction and Raman experiments were performed on ABH$_4$ ($A = K, Rb$) at high pressures up to 27 GPa. We demonstrate that KBH$_4$ exhibits structural phase transitions from the ambient $\alpha$-KBH$_4$ phase (cubic Fm-3m) to $\beta$-KBH$_4$ (tetragonal-P421c) at 3.8 GPa and to $\gamma$-KBH$_4$ phase (orthorhombic-Pnma) at 6.8 GPa which is similar to the phase transition sequence observed for NaBH$_4$ earlier [1]. However, RbBH$_4$ undergoes two successive pressure induced structural transitions from the ambient $\beta$-KBH$_4$ phase to an orthorhombic Pnma phase around 2.9 GPa and then to a monoclinic phase above 8 GPa. The high pressure monoclinic phase is found to be stable up to 27 GPa. The experimental results reveal the phase transition sequence exhibited by RbBH$_4$ is different from the pressure induced changes observed in similar cubic compounds NaBH$_4$ and KHBH$_4$. The results further show that both the transition pressure and the structural ordering at high pressures are influenced by the atomic size of the alkali cation in these compounds. [1]. R.S. Kumar and Andrew L. Cornelius, App.Phys.Lett., 2005, 87, 261916.

Session P1 DCMP: Is There Pairing Glue in Cuprate Superconductors?

Wednesday, March 12, 2008 8:00AM - 11:00AM  
Session P1 DCMP: Is There Pairing Glue in Cuprate Superconductors?  
LaLouisiane AB

8:00AM P1.00001 The Question of Pairing Glue in the Cuprate Superconductors1, DOUGLAS SCALAPINO, UCSB — The Hubbard and t-J models exhibit many of the properties which are observed in the cuprate superconductors. Thus they provide a framework for addressing the question of whether one should expect to find a “pairing glue” in the cuprates. This question is basically a question regarding the dynamics of the pairing interaction. If the dynamics of the pairing interaction arises from virtual states, whose energies correspond to the Mott gap, and give rise to the exchange coupling J, the interaction is instantaneous on the relative time scales of interest. In this case one would not speak of a pairing glue. However, if the energies correspond to the spectrum seen in the dynamic spin susceptibility, then the interaction is retarded and one could speak of a spin-fluctuation glue which mediates the d-wave pairing interaction. We will review results from recent numerical calculations which provide insight into this question.

1Supported by NSF-DMR 0528969.

8:36AM P1.00002 Strongly Correlated d-wave Superconductivity: a CDMFT Perspective1, GABRIEL KOTLIAR, Rutgers University — We examine the impact of the proximity to a Mott insulating state on the superconducting properties of model new crystal structures previously unknown for these materials, of [0001] direction or uniaxial tension along the [110] direction, causes a transformation to a five-fold coordinated unbounded wurtzite structure which we named HX. On the other hand, uniaxial tension along the [0001] direction causes the materials to transform into a body-centered-tetragonal structure which we named BCT-4. The critical equilibrium transformation stresses for these transformations are obtained and their correlation with the ionicity of the materials is analyzed.

1Currently at CWRU, Cleveland, OH 44106.
9:12AM P1.00003 The Fluctuating Bond Model, a Glue for Cuprate Superconductivity? 1. DENNIS NEWNS, IBM T.J. Watson Research Center — Twenty years of research have yet to produce a consensus on the origin of high temperature superconductivity (HTS). The mechanism of HTS - which originates in the CuO₂ plane, common to all HTS families - can be constrained by some key experimental facts regarding superconducting and pseudogap behaviors. Superconductivity, involving a Tc of order 100K, exhibits an unusual d-wave superconducting gap, with Fermi liquid nodal excitations, and an anomalous doping-dependent oxygen isotope shift. A "pseudogap," also with d-symmetry, leads to a dip in the density of states below a characteristic temperature scale T*, which has a negative isotope shift; we associate the pseudogap with the recently observed spatially inhomogeneous (nanometer-scale) C₄ symmetry breaking. The isotope shifts and other evidence imply a key role for oxygen vibrations, but conventional BCS single-phonon coupling is essential for this purpose, and by the on-site Coulomb interaction U. In a novel approach, we introduce a model based on a strong, local, nonlinear interaction between electrons within the Cu-O-Cu bond in the CuO₂ plane, and the oxygen vibrational degrees of freedom, termed the Fluctuating Bond Model (FBM) [D.M. Newns and C.C. Tsuei, Nature Physics 3, 184 (2007)]. In mean field the model predicts a phase manifesting broken C₄ symmetry, with a d-type pseudogap, and an upper phase boundary in temperature, with a negative isotope shift, which we identify with T*. An intrinsic d-wave pairing tendency is found, leading to a transition temperature dome and an anomalous isotope shift similar to that found experimentally. The softening in the oxygen vibrational frequency below Tc, seen in Raman and neutron spectra, has a natural explanation in the FBM. Recent ab initio calculations have been implemented which provide microscopic support for the model.

1Work done with C.C. Tsuei.

9:48AM P1.00004 The Normal State Pseudogap in Underdoped Cuprates: Precursor Pairing vs. Competing Order? 1, MOHIT RANDERIA, The Ohio State University — The "pseudogap" in the normal state of underdoped High Tc cuprates refers to a set phenomenon associated with the loss of low energy spectral weight in various spectroscopies, starting at a temperature T*(x), much higher than Tc(x), and with a completely different doping dependence. Understanding the unusual phenomena in the pseudogap regime, which lies between the Mott insulator and the optimally doped superconductor, is an important challenge for any theory of high Tc superconductivity. I will first review some of the main experimental facts about the pseudogap, focusing in particular on recent angle-resolved photoemission (ARPES) data. I will then critically examine which aspects of the data can be qualitatively understood in terms of theories of precursor pairing or those based on a competing order parameter.

10:24AM P1.00005 Two-Dimensional Hubbard Model and High-Tc Superconductivity 1. MASATOSHI IMADA, University of Tokyo — No abstract available.

Wednesday, March 12, 2008 8:00AM - 9:48AM — Session P2 DCMP: Controlling Electron Spins: Propagation and Dynamics Morial Convention Center LaLouisiane C

8:00AM P2.00001 An Exact SU(2) Symmetry and Persistent Spin Helix in a Spin-Orbit Coupled System 1. B. ANDREI BERNEVIG, Princeton University — Spin-orbit coupled systems generally break the spin rotation symmetry. However, for a model with equal Rashba and Dresselhaus coupling constant (the ReD model), and for the [110] Dresselhaus model, a new type of SU(2) spin rotation symmetry is discovered. This symmetry is robust against spin-independent disorder and interactions, and is generated by operators whose wavevector depends on the coupling strength. It renders the spin lifetime infinite at this wavevector, giving rise to a Persistent Spin Helix (PSH). We obtain the spin fluctuation dynamics at, and away, from the symmetry point, and suggest experiments to observe the PSH. Recent experimental efforts have already discovered signs of the Persistent Spin Helix. Although reaching the Rashba equal to Dresselhaus point is difficult, the Persistent Spin Helix manifests itself in a long-lived spin-density wave even from this point, making its discovery especially suitable for optical techniques such as transient spin-grating spectroscopy. The SU(2) symmetric point allows one to obtain the exact analytic transport equations from the diffusive to the ballistic regime, which has previously been accessible only through numerical work.

8:36AM P2.00002 Evidence for a persistent spin helix in a 2-dimensional electron gas 1. JAKE D. KORALEK, LBNL and UC Berkeley — Using time-resolved transient spin-grating spectroscopy we uncover strong evidence for the existence of a persistent spin helix (PSH) in a 2-dimensional electron gas. The PSH is a collective helical spin excitation that persists far beyond the lifetime of its individual constituent spins when the Rashba (α) and Dresselhaus (β) spin-orbit coupling terms are comparable. The helix is predicted to have an infinite lifetime when they are exactly equal. These effects have great potential for application to spintronics where they would allow rapid control of the spin lifetime over several orders of magnitude in systems with both high electron density and high mobility. The transient spin-grating technique is ideally suited for study of the PSH as it can directly measure the dynamics of optically generated spin excitations of variable spatial periodicity. This is accomplished by interfering two non-collinear, orthogonally polarized pulses from a Ti:Sapphire laser at the surface of the sample. Through the optical orientation effect in GaAs, this generates a spin excitation which varies periodically in space between up and down spins at a wavelength determined by the angle between the interfering pulses. We tune the spin-orbit coupling in our GaAs based quantum wells through asymmetric modulation doping, which has allowed us to increase a to be comparable to β. In these systems we find that spin-gratings with periodicity comparable to that of the PSH can live several orders of magnitude longer than the individual spin lifetime as measured by time-resolved Faraday rotation. We study this over a wide range of parameter space, systematically varying doping asymmetry, well width, and disorder. We find that the lifetime of the PSH in these samples is ultimately limited by the spatial disorder in the Rashba strength, and by a novel relaxation mechanism based on phonon-induced Rashba coupling. Supported by DMSE office of BES-DGE, NSF, MARCO, ASEE and CNID.

1In collaboration with C.P. Weber and J. Orenstein, LBNL and UC Berkeley, S. Mack and D.D. Awschalom, CSQC and UC Santa Barbara.
change, mechanics will also consider briefly the influence of diffusion on aggregation properties. Our understanding of dynamical properties close to the sol-gel transition is lower as another important concept also introduced by de Gennes concerning the possibility of observation of classical exponents in the case of vulcanization. We made by de Gennes and Stauffer. We will discuss some recent experiments showing the relevance of percolation in the description of the sol-gel transition, as because both excluded volume interactions and loops were neglected. An important progress was made when an analogy between percolation and gelation was proposed as the basis of micro-actuation and artificial muscles, both heat and light-driven. In 1969, de Gennes already described ideal networks heated through Morial Convention Center 206.

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P3 DPOLY: Simple Views on Bulk Polymers: Symposium Honoring P G de Gennes

8:00AM P3.00001 How Polymer Physics Was Born, PHILIP PINCUS, Physics Department, UCSB — We review the physics of some of de Gennes’ principal contributions to fundamental aspects of polymer solution science. These include critical phenomena views on interacting polymers, reptation, polyelectrolytes, and gels.

8:36AM P3.00002 Polyelectrolyte Solutions, RALPH H. COLBY, Materials Science and Engineering, Penn State University — Pierre-Gilles de Gennes once described polyelectrolytes as the “least understood form of condensed matter”. In this talk, I will describe the state of the polyelectrolyte field before and after de Gennes’ seminal contributions published 1976-1980. De Gennes clearly explained why electrostatic interactions only stretch the polyelectrolyte chains on intermediate scales in semidilute solution (between the electrostatic blob size and the correlation length) and why the scattering function has a peak corresponding to the correlation length (the distance to the next chain). Despite many other ideas being suggested since then, the simple de Gennes scaling picture of polyelectrolyte conformation in solution has stood the test of time. How that model is used today, including consequences for dynamics in polyelectrolyte solutions, and what questions remain, will clarify the importance of de Gennes’ ideas.

9:12AM P3.00003 Block Copolymers, LUDVIK LEIBLER, Matière Molle et Chimie, UMR 7167 CNRS/ESPCI, ESPCI, 10 rue Vauquelin, 75005 PARIS, France — In 1969 (Rep. Prog. Phys. 32, 187(1969)) de Gennes proposed a simple way to understand and describe mesophase organization of block copolymers in what we now call the strong segregation limit. The following year he showed how self-consistent methods due to Edwards can be applied to understand subtle correlation effects in polymer melts (J. Physique 31, 235(1970)) and established theoretical framework for quantitative interpretation of scattering experiments and of what we call now weak segregation regime of block copolymers. This was the basis of the theory of order-disorder transition in multiblock copolymers that he published in 1980 (Faraday Transactions). In this pioneering work he also discussed the role of blocks’ polydispersity. Eventually, as early as in 1977 de Gennes realized that block copolymers “are most promising systems for deeper understanding of lyophilic phase diagrams” (in Suppl. Solid State Phys Ed. Ehrenreich 1977) and this vision led not only to some very interesting theories of block copolymer solutions, but also to some very quantitative model of membranes and interfaces elasticity and to a very influential theory of microemulsions (J. Phys. Chem. 86, 2294(1982)). Since 1980 tens of thousands of papers dealing with block copolymers were published, but it should be stressed that in seventies it has been a very unknown area. Clearly de Gennes’ visionary block copolymer research has had a very important impact in the field. I will illustrate using several examples from very different areas how de Gennes’ deep understanding of block copolymers and the theoretical methods he introduced influenced both theory and experiments and I will also show how they are relevant for many present and future industrial applications.

9:48AM P3.00004 Percolation and Gelation, MOHAMED DAOUD, CEA Saclay — The sol-gel transition, as well as the vulcanization of Polymers chains, was described long ago by Flory, Stockmayer, Zimm within mean field approximation. This however had strong limitations because both excluded volume interactions and loops were neglected. An important progress was made when an analogy between percolation and gelation was made by de Gennes and Stauffer. We will discuss some recent experiments showing the relevance of percolation in the description of the sol-gel transition, as well as another important concept also introduced by de Gennes concerning the possibility of observation of classical exponents in the case of vulcanization. We will also consider briefly the influence of diffusion on aggregation properties. Our understanding of dynamical properties close to the sol-gel transition is lower than that of the static ones. Some analogies were given by de Gennes to describe various hydrodynamic limits, but the experimental results still lead to some discussions. Finally, we will mention some generalizations and open questions.

10:24AM P3.00005 Liquid Crystalline Polymers and Networks — orientation, molecular shape change, mechanics, MARK WARNER, University of Cambridge — In a prescient paper of 1969, Pierre-Gilles de Gennes envisaged both liquid crystal polymers and elastomers. 10 years later, these systems were realised. After 25 years, monodomain elastomers were prepared and displayed phenomena he had predicted: rods incorporated into polymers induce liquid crystallinity in polymer melts and elastomers; orientational order causes shape changes in the backbone of such polymers; mechanical ramifications follow in networks, e.g. spontaneous elongations and contractions on changing order. The latter are proposed as the basis of micro-actuation and artificial muscles, both heat and light-driven. In 1969, de Gennes already described ideal networks heated through the nematic-isotropic transition losing all their order by mechanical relaxation. It is not obvious, but is true in theory and largely in experiment, even in highly non-ideal networks. He also envisaged that a cholesteric network, where there is a topological memory of chirality imprinted by crosslinking chains in a twisted state, chirality cannot relax away on entering the isotropic phase, even in systems without molecular chirality (for instance those crosslinked in the presence of chiral solvent that is subsequently exchanged away). His chiral elastomers have found application as mechanically-tunable, rubber lasers. De Gennes also constructed the first continuum elastic theories of nematic elastomers (1982), though distortions are generally very large. His elasticity has informed non-linear elasticity that works even at large amplitudes. I shall describe de Gennes’ many contributions, and the current state of a field that has since yielded still more remarkable phenomena.

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P4 GSNP: Fluctuations and Rare Events in Physical, Chemical, and Biological Systems

Morial Convention Center 206
8:00AM P4.00001 Rare events and phase transitions in reaction-diffusion systems

ALEX KAMENEV, University of Minnesota — I shall discuss a way to evaluate tails of the probability distribution functions in stochastic reaction-diffusion models. The method is based on the semi-classical treatment of a proper "quantum" field theory, which may be associated with reaction-diffusion systems. The same set of ideas may be applied to a classification of non-equilibrium phase transitions, taking place in these models. V. Elgart and A. Kamenev, Classification of phase transitions in reaction–diffusion systems, Phys. Rev. E 74, 041101 (2006). V. Elgart and A. Kamenev, Rare Events Statistics in Reaction–Diffusion Systems, Phys. Rev. E 70, 041106 (2004).

8:36AM P4.00002 Switching and phase transitions in a parametrically-excited cold atom trap

WONHO JHE, Seoul National University — Stochastic dynamics of cold atoms in a modulated magneto-optical atom trap was investigated. The studies focused on the phenomenon related to switching between the parametrically excited period-2 states. The rates of single-atom activated transitions were analyzed. When the atom density was increased, there were observed Ising-class phase transitions where the symmetric population of period-2 states was spontaneously broken [1,2]. Anomalous fluctuations in the decay of the unstable state were investigated [3].

This work was supported by the Creative Research Initiative of Korea.

9:12AM P4.00003 Activation barrier scaling and switching path distribution in a micromechanical parametric oscillator

H.B. CHAN, University of Florida — Parametrically modulated systems develop multiple coexisting states under sufficiently large drive. In the presence of fluctuations, the system can occasionally overcome the activation barrier and switch from one state to the other, resulting in the phase of oscillation slipping by \( \pi \). We study noise-induced switching in a parametrically-driven micromechanical torsional oscillator. Certain properties of the switching are generic to bistable systems, while others are specific to nonequilibrium systems that lack detailed balance. For instance, close to the bifurcation points, the activation barrier for switching is expected to display system-independent scaling. By measuring the rate of random transitions at different fluctuation intensities, we deduce the activation barrier as a function of frequency detuning from the bifurcation points and measure a critical exponent that is in good agreement with theoretical predictions. We also measure the escape trajectories followed by the oscillator, confirming the notion that they form narrow tubes in phase space centered at the most probable escape path. The uphill section of this path is found to be distinct from its time-reversed downhill section, an important property for systems far from thermal equilibrium. Near the saddle point the velocity is significantly diminished and the motion becomes diffusive, leading to strong broadening and increase in height of the probability distribution. Apart from fundamental interest, the sharp change in the oscillation amplitude near the subcritical bifurcation point can provide accurate determination of device parameters.

BARUCH MEERSON, Hebrew University of Jerusalem — Statistics of rare events, or large deviations, in chemical reactions and systems of birth-death type have attracted a great deal of interest in many areas of science including cell biochemistry, astrochemistry, epidemiology, population biology, etc. Large deviations become of vital importance when discrete (non-continuum) nature of a population of "particles" (molecules, bacteria, cells, animals or even humans) and stochastic character of interactions can drive the population to extinction. I will briefly review the novel spectral method [1-3] for calculating the extreme statistics of a broad class of birth-death processes and reactions involving a single species. The spectral method combines the probability generating function formalism with the Sturm-Liouville theory of linear differential operators. It involves a controlled perturbative treatment based on a natural large parameter of the problem: the different fluctuation intensities, we deduce the activation barrier as a function of frequency detuning from the bifurcation points, the activation barrier for switching is expected to display system-independent scaling. By measuring the rate of random transitions at different fluctuation intensities, we deduce the activation barrier as a function of frequency detuning from the bifurcation points and measure a critical exponent that is in good agreement with theoretical predictions. We also measure the escape trajectories followed by the oscillator, confirming the notion that they form narrow tubes in phase space centered at the most probable escape path. The uphill section of this path is found to be distinct from its time-reversed downhill section, an important property for systems far from thermal equilibrium. Near the saddle point the velocity is significantly diminished and the motion becomes diffusive, leading to strong broadening and increase in height of the probability distribution. Apart from fundamental interest, the sharp change in the oscillation amplitude near the subcritical bifurcation point can provide accurate determination of device parameters.

This work was partially supported by awards NSF DEB-0328267 and NSF/NIH DMS/NIGMS-0342388.

10:24AM P4.00005 Strong Fluctuations and Cycling in Biological Systems

TIMOTHY NEWMAN, Arizona State University — In this talk I describe a mechanism for generating cycles in a large class of "mesoscale" biological populations (meaning populations composed of thousands to tens of thousands of units). Cycles are caused by a resonant amplification of the system dynamics triggered by internal noise. I will discuss this mechanism in the context of two classes of simple systems: ecological (e.g. predator-prey, host-pathogen) and biochemical (e.g. small gene regulation networks, modules of metabolic processes). [Predator-Prey Cycles from Resonant Amplification of Demographic Stochasticity, A. J. McKane and T. J. Newman, Physical Review Letters 94, 218102 (2005); Amplified Biochemical Oscillations in Cellular Systems, A. J. McKane, J. Nagy, T. J. Newman, and M. Stefanini, Journal of Statistical Physics 128, 165-191 (2007)].

Wednesday, March 12, 2008 8:00AM - 11:00AM – Session P5 GQI: Quantum Information Meets Gravitation Morial Convention Center R01

8:00AM P5.00001 Quantum Computational Complexity in the Presence of Closed Timelike Curves

DAVE BACON, University of Washington — What are the consequences of modifying the laws of physics for the theory of computation? Considering this question in the context of quantum theory has led to a seemingly new class of computing devices known as quantum computers. In this talk I will discuss how modifying computation (in a quantum or classical context) to allow for closed timelike curves leads to a new model of computation. In particular I will discuss how such a model of computation with closed timelike curves can be formulated, whether it can be made robust to noise, and how recent results of Aaronson and Watrous show that this model is no more than the well studied complexity class PSPACE. Consequences of these results on foundational issues in quantum theory will also be discussed.
8:36AM P5.00002 Black holes as mirrors: quantum information in random subsystems, JOHN PRESKILL, Caltech — We study information retrieval from evaporating black holes, assuming that the internal dynamics of a black hole is unitary and rapidly mixing, and assuming that the retriever has unlimited control over the emitted Hawking radiation. If the evaporation of the black hole has already proceeded past the “half-way” point, where half of the initial entropy has been radiated away, then additional quantum information deposited in the black hole is revealed in the Hawking radiation very rapidly. Information deposited prior to the half-way point remains concealed until the half-way point, and then emerges quickly. These conclusions hold because typical local quantum circuits are efficient encoders for quantum error-correcting codes that nearly achieve the capacity of the quantum erasure channel. Our estimate of a black hole’s information retention time, based on speculative dynamical assumptions, is just barely compatible with the black hole complementarity hypothesis. This is joint work with Patrick Hayden.

9:12AM P5.00003 Entanglement in non-inertial frames and curved spacetime, IVETTE Fuentes-Schuller, University of Potsdam, Germany — The insight that the world is fundamentally quantum mechanical inspired the development of quantum information theory. However, the world is not only quantum but also relativistic, and indeed many implementations of quantum information tasks involve truly relativistic systems. In this talk I consider relativistic effects on entanglement in flat and curved spacetimes. I will emphasize the qualitative differences to a non-relativistic treatment, and demonstrate that a thorough understanding of quantum information theory requires taking relativity into account. The exploitation of such relativistic effects will likely play an increasing role in the future development of quantum information theory. The relevance of these results extends beyond pure quantum information theory, and applications to foundational questions in cosmology and black hole physics will be presented.

9:48AM P5.00004 Spin-induced non-geodesic motion, Wigner rotation and EPR correlations of massive spin-1/2 particles in a gravitational field1, PAUL M. ALSING, University of New Mexico — We investigate in a covariant manner, the spin-induced non-geodesic motion of massive spin-1/2 particles in an arbitrary gravitational field for trajectories that are initially geodesic when spin is ignored. Using the WKB approximation for the wave function in an arbitrary curved spacetime, we compute the $O(\hbar)$ correction to the Wigner rotation of the spin-1/2 particle, whose $O(1)$ contribution is zero on timelike geodesics. We consider specific examples in the Schwarzschild metric for motions in the equatorial plane for (i) particles falling in from spatial infinity with non-zero angular momentum and (ii) circular geodesic orbits. For the latter case we consider the Bell inequalities for a perfectly anti-correlated EPR entangled pair of spins as the separate qubits traverse the circular geodesic in opposite directions.

1 In collaboration with G.J. Stephenson Jr., University of New Mexico and Patrick Kilian, Universitat Wuerzburg, Germany.

10:24AM P5.00005 Quantum Graphity: a model of emergent locality, FOTINI MARKOPOULOU, Perimeter Institute for Theoretical Physics — Quantum graphity is a background independent condensed matter model for emergent locality, spatial geometry and matter in quantum gravity. The states of the system are given by bosonic degrees of freedom on a dynamical graph on N vertices (that is, changing in time). At high energy, the graph is the complete graph on N vertices and the physics is invariant under the full symmetric group acting on the vertices and highly non-local. We find evidence that the model has a phase, in which the ground state breaks the permutation symmetry to translations and discrete rotations. In this phase the system is ordered, low-dimensional and local. Consideration of the free energy associated with the dominant terms in the dynamics shows that the ground state is thermodynamically stable under local perturbations. The model gives rise to an emergent U(1) gauge theory in the ground state by the string-net condensation mechanism of Levin and Wen. We will reformulate the model in graph-theoretic terms and compare its dynamics to some common graph processes.

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P6 DFD: Fluid Dynamics and Biology Morial Convention Center RO4

8:00AM P6.00001 Depolymerization-driven flow and the crawling of nematode sperm, CHARLES WOLGEMUTH, UCONN Health Center — Cell crawling motility is integral in many biological and biomedical processes, such as wound healing, cancer metastasis, and morphogenesis. A complete understanding of the mechanics by which cells crawl is still lacking, but it is known to entail at least three separate physical processes: (i) cytoskeletal extension at the front of the cell; (ii) adhesion to the substrate at the cell front and release at the rear; and (iii) advance of the cell body. In most cells, the cytoskeletal network is composed of actin. The mechanism by which force is generated to drive translocation of the cell body is still debated. Originally, this force was attributed to an actomyosin system similar to muscle. However, nematode sperm utilize a cytoskeleton composed of a network of Major Sperm Protein (MSP) that forms non-polar filaments for which molecular motors have not been identified. The motility of these cells still exhibits all three fundamental processes required for standard crawling motility. Experiments suggest that depolymerization of the cytoskeletal network is the force-producing mechanism for pulling up the rear. In this talk I will present a mechanical model that describes how depolymerization of the cytoskeleton can drive motility. This model accounts for both cytoskeletal displacements and cytosolic (the fluid component of the cell) flow. The model accurately fits in vitro data using nematode sperm extracts where depolymerization induces contraction of MSP polymer bundles. Application of this model to cell crawling produces testable predictions about how the size and shape of a cell affect crawling speed. Experiments using Caenorhabditis elegans sperm show good agreement with the model predictions. Interestingly, the model requires that cells are anisotropically elastic, being more stiff in the direction of motion perpendicular to it. A simple physical picture can account for this anisotropy. The model also predicts that cell speed increases with anisotropy and with depolymerization rate.

8:36AM P6.00002 Optimizing Low Reynolds Number Locomotion, ANETTE HOSOI, MIT — In this talk I will discuss optimal stroke patterns for low Reynolds number linked swimmers. We begin by optimizing stroke patterns for Purcell’s 3-link swimmer modeled as a jointed chain of three slender links moving in an inertialless flow. The swimmer is optimized for efficiency and speed and we are able to attain significant increases is efficiency over those previously suggested by authors who only consider geometric design rather than kinematic criteria. We then go on to investigate unflagellate and biflagellate organisms and compare the optimized results to biological data from spermatozoa and chlamydomonas.
On ultracold Fermions and Bose-Fermi mixtures in optical lattices will be presented. A "Coulomb-blockade" type tunnelling resonance one can count atoms one by one to determine their number statistics in the lattice potential. Finally, latest such superexchange interactions for the investigation of dynamical behaviour in quantum spin systems and for quantum information processing will be outlined.

In optical superlattices in an antiferromagnetically ordered state, we are able to observe a coherent superexchange mediated spin dynamics down to coupling measurement of such superexchange interactions with ultracold atoms in optical lattices. After preparing a spin-mixture of ultracold atoms with the help of magnetism in strongly correlated electronic media and are believed to play a major role in high-Tc superconducting materials. We report on the first direct realization of super-exchange interactions in ultra-cold atoms. The many-body dynamics arising from the coherent coupling between singlet-triplet pairs in adjacent double-wells will be also discussed. In particular, we will describe how it can lead to the formation of frustrated spin states with a high degree of density fluctuations, which appear to be driven by the active stress instability.

**Life in a drop of Ocean: microfluidic insights into microbial ecology**

ROMAN STOCKER, Civil and Environmental Engineering - MIT — Bacteria are the most abundant and successful form of life on Earth. Their physico-chemical interactions with their fluid environment are surprisingly complex and have enormous implications, which we can only hope to grasp if we learn to study microorganisms within realistic microenvironments. Microfluidics for the first time enables us to create microhabitats, including chemical and fluid mechanical landscapes, while visualizing bacterial behavior at a single-cell resolution. Here I focus on the application of microfluidics to gain insight in the life of marine bacteria. In their quest for nutrients, marine bacteria often experience the Ocean as a desert, where rare and ephemeral nutrient patches represent transient resource oases. In this patchy seascape, swimming and chemotaxis represent critical assets, but effective patch utilization is constrained by energetic requirements. And then there are predators and viruses... These interactions form the basis of the ‘microbial loop’, the ensemble of microbial processes known to directly impact the productivity of marine ecosystems and the rates of carbon turnover in the Ocean. I will show how fundamental new insight on selected aspects of microbial life in a drop of Ocean can be achieved by a combination of microfluidic experiments and theoretical modeling.

**Optimal flexibility in flapping appendages**

SILAS ALBEN, Georgia Institute of Technology — When oscillated in a fluid, appendages such as insect wings and fish fins can produce large thrust forces while undergoing considerable bending. Can we understand these bending patterns by comparing them with the patterns which produce maximum thrust, or a given thrust at maximum efficiency? We present a general model for how flexible surfaces produce vorticity and bend actively and passively in a fluid. We solve the model numerically, and discuss results for moderate deflections (relevant for large thrust), and for small deflections (relevant for high efficiency). We’ll then consider how a fish-fin-like structure might be designed for optimal performance.

---

**Repulsively bound atom pairs in an optical lattice**

JOHANNES HECKER DENSCHLAG, Experimentalphysik, Universitaet Innsbruck — Three dimensional optical lattices represent an interesting environment for fundamental research with ultracold atoms. We have observed novel kind of stable bound state of two atoms which is based on repulsion rather than attraction between the particles [1]. We will explain how these lattice-induced repulsively bound pairs can be used to study strongly correlated condensed matter physics. [1] K. Winkler et al., Nature 441, 853 (2006).

---

**Critical velocity for superfluid flow across the BEC-BCS crossover**

DANIEL MILLER, Massachusetts Institute of Technology — Critical velocities have been observed in an ultracold superfluid Fermi gas throughout the BEC-BCS crossover. A pronounced peak of the critical velocity at unitarity demonstrates that superfluidity is most robust for resonant atomic interactions. Critical velocities were determined from the abrupt onset of dissipation when the velocity of a moving one-dimensional optical lattice was varied. The dependence of the critical velocity on lattice depth and on the inhomogeneous density profile was studied.

---

**Towards Quantum Magnetism with Ultracold Quantum Gases in Optical Lattices**

IMMANUEL BLOCH, Johannes Gutenberg Universität Mainz — Quantum mechanical superexchange interactions form the basis of quantum magnetism in strongly correlated electronic media and are believed to play a major role in high-Tc superconducting materials. We report on the first direct measurement of such superexchange interactions with ultracold atoms in optical lattices. After preparing a spin-mixture of ultracold atoms with the help of optical superlattices in an antiferromagnetically ordered state, we are able to observe a coherent superexchange mediated spin dynamics down to coupling energies as low as 5 Hz. Furthermore, it is shown how these superexchange interactions can be fully controlled in magnitude and sign. The prospects of using such superexchange interactions for the investigation of dynamical behaviour in quantum spin systems and for quantum information processing will be outlined in the talk. In addition we present results on the dynamical resolved co-tunnelling of repulsively bound atom pairs in optical superlattices and show how by using "Coulomb-blockade" type tunnelling resonance one can count atoms one by one to determine their number statistics in the lattice potential. Finally, latest results on ultracold Fermions and Bose-Fermi mixtures in optical lattices will be presented.

---

**Probing and controlling quantum magnetism with ultra-cold atoms**

ANA MARIA REY, ITAMP — By loading spinor atoms in optical lattices it is now possible to experimentally implement quantum spin models. These systems allow the investigation of quantum magnetism in strongly correlated systems within a controlled environment. In this talk we will describe a novel approach to prepare, detect and control superexchange interactions in ultra-cold spinor atoms in optical superlattices [1]. Recently this approach was used for the first experimental realization of super-exchange interactions in ultra-cold atoms [2]. The many-body dynamics arising from the coherent coupling between singlet-triplet pairs in adjacent double-wells will be also discussed. In particular, we will describe how it can lead to the formation of frustrated spin states with a high degree of multi-particle entanglement. Finally, we will present an extension of this approach to prepare and detect d-wave pairing in an array of coupled plaquettes.

10:24AM P7.00005 Heteronuclear Molecules in a 3D Optical Lattice. CHRISTIAN OSPELKAUS, National Institute of Standards and Technology, 325 Broadway, Boulder, CO 80305, USA and Institut fuer Laser-Physik, Universitaet Hamburg, Germany — The production of ultracold polar molecular samples is a long standing goal of AMO and ultracold physics. The interest is motivated by novel quantum gases with anisotropic interactions between these polar molecules, by applications in quantum computation and simulation which benefit from the long-range interaction as well as by perspectives of measuring a T-violating permanent electric dipole moment of the electron in such a polar molecular system. While a lot of work has been done on direct cooling of polar molecules, a second proposed route to the production of ultracold polar molecules starts with ultracold atomic samples, where tremendous progress has been made in recent years, and assembles an ultracold atom mixture into weakly bound heteronuclear Feshbach molecules. These could then be transferred into the absolute internal molecular ground state using coherent Raman schemes. As a crucial step in this approach, we report where tremendous progress has been made in recent years, and assembles an ultracold atom mixture into weakly bound heteronuclear Feshbach molecules. The molecules are associated from a quantum degenerate mixture of fermionic $^{85}$Rb and bosonic $^{133}$Rb atoms loaded into a 3D optical lattice. The binding energy of the heteronuclear molecules is precisely determined by rf spectroscopy and compared to a theoretical model based on a pseudopotential approach. We also characterize both the lifetime of the sample and the efficiency of rf association; comparison to the pseudopotential model results in excellent agreement.

Wednesday, March 12, 2008 8:00AM - 11:00AM – Session P8 DFD: Glassy Dynamics Morial Convention Center R06

8:00AM P8.00001 Nonlinear Dynamics Near the Jamming Transition. EDWARD J BANIGAN, Dept of Physics and Astronomy, Univ of Pennsylvania, DAVID A EGOLF, Department of Physics, Georgetown University — How dynamical behaviors and static measures are related near the jamming transition remains an open question. In simulations of a two-dimensional sheared granular cell, we have calculated mathematical quantities that characterize the underlying nonlinear dynamics near the jamming transition. We find that the Lyapunov exponents and vectors characterizing the most important dynamical modes correlate well in space and time to localized events that alter the physical characteristics of the system. For example, the Lyapunov exponents and vectors highlight areas in which particles are involved in cooperative rearrangement or the formation or destruction of stress chains. In at least some cases, the behavior of the dynamical quantities appears to indicate future position or stress rearrangements. In addition, we report measurements of a dynamical time scale and a dynamical length scale that diverge as the system jams, suggesting an intriguing connection between the jamming transition and a transition between chaotic and non-chaotic dynamical states.

8:12AM P8.00002 Probing Cooperative Motion in Super-Cooled Colloidal Suspensions. PRASAD SARANGAPANI, Y. ELAINE ZHU, University of Notre Dame, Department of Chemical and Biomolecular Engineering, 182 Fitzpatrick Hall, Notre Dame, IN 46556 — The physics of the glass transition remains inadequately understood despite its broad technological relevance. The anomalous divergence of viscosity without apparent structural change as a liquid is cooled has been attributed to the existence of growing dynamic length scales of “cooperatively rearranging regions” (CRR). In this work, we use ultra-fast fluorescence correlation spectroscopy (FCS) combined with high-speed imaging to determine the CRR sizes by measuring single-particle dynamics of tracer nano-particle embedded in super-cooled “hard-sphere” colloidal suspensions. Fluorescent poly-(methyl methacrylate) (PMMA) tracer particles of radii ranging from $r = 0.1-0.4 \mu m$, mixed with plain PMMA particles of radius, $r = 0.6 \mu m$ and bulk volume fraction, $\phi = 0.38-0.58$, serve as excellent probes for changes in the energy barrier landscape of the suspensions of increasing volume fraction and are sensitive to the creation and annihilation of isosahedral order in metastable colloidal fluids. We also find that the correlation length, determined by fluctuation-dissipation relations from the measured auto-correlation functions, shows a dramatic increase in the super-cooled regime until it diverges at $\phi = 0.58$.

8:24AM P8.00003 Structural relaxation in sheared two-dimensional foams. MATTHIAS MOBIUS, GJS KATGERT, MARTIN VAN HECKE, University of Leiden — Athermal and disordered systems at rest, such as foams and granular media, are stuck in a metastable configuration. Upon shear the system unjams and complex vortex-like rearrangements ensue that are correlated in time and space. In our experiment we investigate what the typical time scales of these structural relaxations are as a function of the local shear rate in a two-dimensional, disordered foam that is linearly sheared. After an initial super-diffusive regime, the bubbles become diffusive at later times. This transition is reflected in the statistics of the bubble displacements, which are initially strongly correlated and non-Gaussian but eventually become Gaussian. We find that the relaxation time decreases with shear rate. For large shear rates the dependence follows a power law with an exponent significantly different from -1.

8:36AM P8.00004 From spontaneous to induced dynamic fluctuations: Granular packings as an experimental probe. FREDERIC LECHENAULT, North Carolina State University, OLIVIER DAUCHOT, SPEC, CEA France, GIULIO BIROLI, SPHT, CEA France, JEAN-PHILIPPE BOUCHAUD, Science & Finance, Capital Fund Management — We track the motion of a horizontally vibrated amorphous assembly of bidisperse hard disks, for densities ranging across the jamming transition. The spatial extension of dynamical heterogeneities and the associated relaxation time are found to exhibit critical behavior. Moreover, a dynamical fluctuation inequality relating the dynamical susceptibility $\chi_d$ and the response of the dynamics to a change in density is tested. As the diffusion length is found to rescale these quantities, the dependencies of the inequality on length and time scales as well as density can be evaluated independently. Surprisingly, the lower bound is found to reproduce the non-monotonic behavior of $\chi_d$ in time, which reveals an intimate link between dynamical heterogeneity and marginal super diffusion. Finally, the bound is shown to be tight and to mimic the anomalous features of the dynamical susceptibility across the transition.

8:48AM P8.00005 Influence of the microstructure on jammed packings of spheres. ERIC CORWIN, MAXIME CLUSEL, ALEXANDER SIEMENS, JASNA BRUJIC, New York University — Jammed matter is by definition impenetrable to light, such that little is known about the geometry of jammed systems. Using confocal microscopy to image an emulsion in 3D, we use the enhanced fluorescence at the droplet contacts to determine the contact network inside this model frictionless system. This enables the experimental determination of the average coordination number $< Z >$, which agrees with the isostatic predicted value of $< Z > \approx 6$ [1]. Furthermore, we measure the distribution of coordination numbers within the jammed packings close to the isostatic limit. We show that the distribution of sizes of the droplets strongly influences the coordination number distribution, as well as the volume fraction at which the system becomes jammed. This may have important consequences on the stress propagation properties of the material as a whole. [1] J. Brujic et al., Phys. Rev. Lett. 98, 248001 (2007)

9:00AM P8.00006 Mode-coupling and generalized mode-coupling theory: a diagrammatic approach. GRZEGORZ SZAMEL, Department of Chemistry, Colorado State University — We present a diagrammatic approach to the dynamics of interacting Brownian particles. Within this approach, the time-dependent density correlation function is represented by a series of diagrams with three and four leg vertices. We analyze the structure of this series and obtain a diagrammatic interpretation of reducible and irreducible memory functions. The one-loop self-consistent approximation for the latter function coincides with mode-coupling approximation for Brownian systems that was derived previously using a projection operator approach. Finally, we investigate the diagrammatic interpretation of a generalized mode-coupling theory.
9:12AM P8.00007 Percolating Clusters in Systems of Gapped Rigid Rings, Christopher Lasota, Ariel Helper, Kenyon College — We have examined the behavior of kinetically agitated collections of rigid rings with angular gaps in them. For small gap angles, large clusters form readily and are sufficiently tangled so that they may be raised vertically under gravitational stresses without decomposing. Using gravity as a stressor under semi-static conditions, we have measured average cluster size as a function of the gap angle and witness what appears to be a second order percolation phase transition. The critical gap angle depends somewhat on the relative thickness of the ring material compared to the ring diameter. Although friction is necessary for the formation of clusters, it appears that cluster formation is dominated by geometry effects.

9:24AM P8.00008 Jamming transition in a temperature-sensitive 2D colloidal suspension, Zheng Zhang, Daniel T. N. Chen, Arjun G. Yodh, University of Pennsylvania, Kevin B. Aptowicz, West Chester University, Piotr Habdas, Saint Josephs University — We experimentally investigate the jamming transition of a 2D colloidal system. The system consists of a bidisperse mixture of thermo-responsive microgel particles confined between two glass slides, with a thickness of roughly the diameter of the larger particle. The packing density of the system is tuned by changing the temperature. A range of packing densities, both below and above the jamming transition is studied. We use video microscopy and particle tracking techniques to characterize the motion of the particles. On approaching the jamming transition the motion becomes slower and more heterogeneous. We characterize the jamming transition in terms of both structure (pair correlation function) and dynamics (mean square displacement, non-Gaussian parameter, four-point susceptibility). To our knowledge this study provides the first experimental evidence for the jamming transition in a 2D colloidal system.

9:36AM P8.00009 Exact Enumeration of Jammed States for Confined Hard Discs, S.S. Ashwin, Department of Chemistry, University of Saskatchewan, Richard K. Bowles, Department of Chemistry, University of Saskatchewan — Enumeration of jammed states of particle systems interacting with hard potentials such as hard discs and hard spheres is a long-standing problem which holds the key to understanding the nature of glassy dynamics and the question of the possibility of an ideal glass transition in these systems. A simple model consisting of hard discs (of diameter \( \sigma \)) trapped between two hard lines separated by a distance \( \beta ! \) exhibits slow relaxation and heterogeneous dynamics characteristic of glassy systems. We map the locally jammed structures in this model to tiles and pose the problem of enumeration of jammed states for the case \( H < 2\sigma \), as a tiling problem on a subset of a plane. Further on applying constraints for collective jamming on the arrangement of the tiles, we exactly enumerate the entire jamming landscape of the system and explore how this landscape is connected to the thermodynamics and dynamics of the glassy system.

We would like to thank NSERC and CFI for funding.

9:48AM P8.00010 Heterogeneities in granular dynamics, Anita Mehta, S. N. Bose National Centre for Basic Sciences, Calcutta, India — The absence of Brownian motion in granular media is a source of much complexity; among these is the presence of heterogeneity, whether static or dynamic, within a given system. Such strong heterogeneities can exist as a function of depth in a box of grains; this is the system we study here. We present results from three-dimensional, cooperative and stochastic Monte Carlo shaking simulations of spheres on heterogeneous density fluctuations. These are justaposed with results obtained from a theoretical model of a column of grains under gravity; frustrations via competing local fields is included in our model, while the effect of gravity is to slow down the dynamics of successively deeper layers. The combined conclusions suggest that the dynamics of a real granular column can be divided into different phases — ballistic, logarithmic, activated and glassy — as a function of depth. The nature of the ground states and their retrieval, in the glassy phase, shows clear evidence of intrinsic states, which lie below a band of approximately degenerate ground states. In the other three phases, by contrast, the system jams into a state chosen randomly from this upper band of metastable states.

10:00AM P8.00011 Confocal Microscopy of Shear-Induced Dynamics in Jammed Emulsions, Joaquim Clara-Rahola, Eric R. Weeks, Emory University - Physics Department — Emulsions are liquid droplets suspended in a second continuous fluid. We study polydisperse decane-in-water emulsions at droplet volume fractions of about 0.8. At such concentrations emulsions are jammed and the system exhibits the properties of a solid. Droplet rearrangements due to Brownian motion are limited in this jammed material. Thus, to induce droplet displacements at a length scale above a particle diameter, an oscillating strain is applied. We use confocal microscopy to track the trajectories of the droplets in real time and space. By taking advantage of this technique we quantify the affine and non-affine motion of the droplets due to the shear. Moreover, we study elastic and plastic droplet reconstructions as well as the spatial extent of the rearrangements when the droplet volume fraction and polydispersity are varied.

Swiss National Foundation

10:12AM P8.00012 Vacancy diffusion in a triangular lattice model, M. Jeng, M. Bowick, Syracuse University, W. Krauth, Laboratoire de Physique Statistique, Ecole Normale Superieure, J. M. Schwarz, X. Xing, Syracuse University — We study vacancy diffusion in the classical triangular lattice dimer model, subject to the kinetic constraint that dimers can only translate, but not rotate. A single vacancy—i.e. a monomer—in an otherwise fully packed lattice, is always localized in a tree-like structure. The distribution of tree sizes is asymptotically exponential and has an average of \( \langle s \rangle = 0.01 \). A connected pair of monomers has a finite probability of being delocalized. When delocalized, the diffusion is anomalous: \( \langle \tau^2 \rangle \propto t^\beta \), with \( \beta = 0.46 \pm 0.05 \). The same diffusion law is also exhibited by clusters of three or four monomers. It is found that both swap motions (translations of dimers transverse to their axes) and glide motions (translations of dimers parallel to their axes) are essential for the large-scale diffusion of monomers.

10:24AM P8.00013 Studying microscopic rearrangements in a sheared supercooled colloidal liquid, Dandan Chen, Denis Semwogerere, Joaquim Clara-Rahola, Eric R. Weeks, Emory University — Shearing induces complex microstructure changes inside an amorphous material, which is related to interesting phenomena like shear thickening and shear thinning. We use a colloidal suspension to simulate amorphous materials, and we study how shearing changes this structure using fast confocal microscopy. Many experiments and simulations have found macro-stress fluctuations in sheared dense jammed suspensions. However, the micro-rearrangements of the particles while being sheared are not very clear. We study the non-affine motion of the colloids, finding the particles move in groups, and characterize these groups for different shearing rates.

10:36AM P8.00014 Temperature control of attractive interactions in colloids, Peter Schall, University of Amsterdam, Zhbing Hu, University of North Texas — Attractive colloidal systems have attracted increasing interest recently: They exhibit phase behavior with solid, liquid, and gas phases, and various metastable states, ranging from gel-like to glassy. These colloidal systems offer a convenient way to investigate important phenomena such as phase separation and kinetic arrest. The most prominent colloidal systems are colloidal-polymer mixtures, in which the attractive strength is fixed by the concentration of the added polymer. We present a colloidal system that allows variation of the attractive potential with external control: a binary liquid solvent gives rise to temperature-dependent particle attractions close to the demixing temperature of the liquid mixture. This allows us to use temperature control to induce transitions from gas to liquid to solid, or to metastable gel-like or glassy states. Variation of the heating rate allows us to investigate the kinetics of these transitions. In this talk, I will focus on a novel system, in which close index- and density matching of the solvent and the particles is possible; this enables us to study bulk processes with temperature control.
Wednesday, March 12, 2008 8:00AM - 10:48AM –
Session P9 DFD: Microfluidic and Nanofluidic Devices
Morial Convention Center RO7

8:00AM P9.00001 Microfluidic Fabrication of Bio-compatible Vesicles by Self-assembly in Double Emulsions, HO CHEUNG SHUM, Harvard School of Engineering and Applied Sciences, Harvard University, JINWOONG KIM, Amore Pacific Co. R&D Center, DAEYEON LEE, Harvard School of Engineering and Applied Sciences, Harvard University, DAVID WEITZ, Harvard School of Engineering and Applied Sciences, and Department of Physics, Harvard University — Vesicles are compartments surrounded by bilayered membranes of amphiphilic molecules such as diblock copolymers and phospholipids. To minimize the exposure of their hydrophobic part to water, amphiphilic molecules self-assemble into aggregates of different structures. When the hydrophobic to hydrophilic ratio is close to unity, amphiphiles self assemble into bilayers, which tend to fold themselves into vesicles. These vesicles are useful for encapsulating and transporting actives such as drugs, flavor, and fragrance. To solve the problems of low encapsulation efficiency and large vesicle size distributions afforded by traditional techniques to create vesicles, we engineer a novel route to generate vesicles using monodisperse double emulsions prepared in microfluidics as templates. The double emulsion-to-vesicle transition exhibits different behaviors depending on the properties of the amphiphilic molecules such as the hydrophobic-to-hydrophilic ratio. Using this technique, we have fabricated both bio-compatible diblock copolymer vesicles, also known as polymersomes, and also lipid vesicles with high encapsulation efficiency.

8:12AM P9.00002 Glass Coating for PDMS Microfluidic Channels by Sol-Gel Methods, THAO DO, ADAM ABATE, DAVID WEITZ, Harvard University — Soft lithography in polydimethylsiloxane (PDMS) allows one to fabricate complex microfluidic devices easily and at low cost. However, PDMS swells in the presence of many organic solvents, which can significantly degrade the performance of PDMS microfluidic devices. We present a method to coat PDMS channels with a glass-like layer using sol-gel chemistry. As a demonstration of chemical resistance, we flow toluene and aqueous Rhodamine B through coated PDMS channels. Toluene is an organic solvent that significantly swells PDMS in a matter of seconds. Rhodamine B is an organic fluorescent molecule that leaches into PDMS and can therefore be used as a fluorescent probe. Indeed, the coating suppresses swelling of the channels when exposed to toluene; it also prevents leaching of Rhodamine B into PDMS channels. In addition, the channels can be functionalized with silanes to precisely control surface properties. We exploit the high chemical resistance and precise surface functionalization of the coating to produce both direct toluene-in-water and inverted water-in-toluene emulsions in coated, functionalized, PDMS microfluidic channels. This combines the ease of fabrication afforded by soft-lithography with the precision control afforded by sol-gel glass.

8:24AM P9.00003 Fluid Flow and Heat Transfer in a Dual-wet Micro Heat Pipe, JIN ZHANG, STEPHEN WATSON, HARRIS WONG, Louisiana State University — Micro heat pipes have been used to cool micro electronic devices, but their heat transfer coefficients are low compared with those of conventional heat pipes. In this talk, a dual-wet pipe is proposed as a model to study heat transfer in micro heat pipes. The dual-wet pipe has a long and narrow cavity. The bottom-half of the horizontal pipe is made of a wetting material and holds a wetting liquid, whereas the top-half is made of a non-wetting material and is filled with the vapor. As one end of the pipe is heated, the liquid evaporates and increases the vapor pressure. The higher pressure drives the vapor to the cold end where the vapor condenses and releases the latent heat. The condensate moves along the bottom half of the pipe back to the hot end to complete the cycle. Hence, the heat pipe is driven by the difference in equilibrium vapor pressure between the hot and cold ends, and not by the liquid-vapor interfacial curvature as is commonly believed. Our analysis provides an explanation for the comparatively low effective thermal conductivity in micro heat pipes [1].

8:36AM P9.00004 Measuring velocity profiles and nanoparticle interactions between 20 and 300 nm from surfaces, PATRICK TABELING, CEDRIC BOUZIGUES, ESPCI, MICROFLUIDICS TEAM — The observation of flows at a nanometric scale is crucial for understanding phenomena involving interactions between liquids and solid surfaces, such as slippage and electro-osmosis. Here we report a new method based on nanoparticle imaging by total internal reflection fluorescence, allowing the first observation of water flows between 20 and 300 nm from surfaces. We probed the energy landscape, leading to first local measurements of the Debye length and surface/nanoparticle interactions; and provide an unambiguous determination with 10 nm accuracy of the slip length for different surfaces - wetting, non-wetting, hard, soft. These results represent an improvement of one order of magnitude compared to the state of the art. In addition to investigating locally energetic and electrostatic properties of the wall/liquid system, this Letter lays down the foundations of a technique that can foster the development of nanofluidics: Imaging of Nanoparticles for Energy Landscape and Speed flow measurements (INES).

8:48AM P9.00005 Poisson-Nernst-Planck model of ion current rectification through a nanofluidic diode, DRAGOS CONSTANTIN, ZUZANNA SIWY, University of California, Irvine — We have investigated ion current rectification properties of a recently prepared bipolar nanofluidic diode. This device is based on a single conically shaped nanopore in a polymer film whose pore walls contain a sharp boundary between positively and negatively charged regions. A semiquantitative model that employs Poisson and Nernst-Planck equations predicts current-voltage curves as well as ionic concentrations and electric potential distributions in this system. We show that under certain conditions the rectification degree, defined as a ratio of currents recorded at the same voltage but opposite polarities, can reach values of over 1000 at a voltage range (-2V, +2V). The role of thickness and position of the transition zone on the ion current rectification is discussed as well. We also show that the rectification degree scales with the applied voltage.

9:00AM P9.00006 Non-reflecting boundary conditions for fluctuating hydrodynamics of compressible fluids, RAFAEL DELGADO-BUSCALIONI, Universidad Autonoma de Madrid, ANNE DEJOAN, CIEMAT, Madrid — Many important phenomena in microfluidics involve propagation of fast sound waves. Computational modeling of such problems requires a way to evacuate the reflected waves out of the computational box. However, a way to construct open boundary conditions for Fluctuating Hydrodynamics (FH) is lacking in the literature. This work presents open boundary conditions for fluctuating hydrodynamics solvers based on the Navier-Stokes Landau-Lifshitz equations. The objectives are i) ensure robust non-reflecting boundary conditions and ii) keep thermodynamic consistency for total mass fluctuation, i.e. agreement with the grand canonical ensemble. We show that by ensuring the fluctuation-dissipation balance for the total mass, one also gets the correct equilibrium power spectra of local mass and momentum at each point of the computational box. We consider real compressible fluids (argon and water) under isothermal condition and present results for the equilibrium and several out-of-equilibrium states involving generation of sound waves.

9:12AM P9.00007 ABSTRACT WITHDRAWN —
9:24AM P9.00008 Liquid precursor films spreading on chemically patterned substrates. ANTONIO CHECCO, Condensed Matter Physics and Materials Science Dept, Brookhaven National Laboratory — We study the spreading of nonvolatile liquid squalane on chemically patterned nanostrayps by using non-contact Atomic Force Microscopy (NC-AFM). The substrates are octadecyltrichlorosilane(OTS)-coated silicon wafers chemically patterned on multiple length-scales using a combination of UV and AFM oxidative lithographies. This process allows us to locally convert the terminal methyl groups of the OTS surface (non-wettable) into carboxylic acid groups (wettable) without affecting considerably the substrate roughness (<0.3nm rms). The patterned regions are shaped as a network of large (nm-sized) wettability lines connected to smaller and larger (mm-sized) lines. Liquid squalane spreads across this "microfluidic network" starting from the large lines eventually reaching the nanolines (50 to 500 nm-wide). NC-AFM is used to image the morphology of the liquid as it spreads across the nanolines. We find that the liquid thickness on the nanolines grows with time (up to ~10 nm) according to a power-law with exponent ~1. These preliminary results suggest that the spreading dynamics of laterally-confined liquids slightly differs, as expected, from the one of laterally homogeneous precursor films. We compare our findings to recent theoretical predictions of confined liquid flow and also discuss its relevance to nanofluidics.

1Supported by U.S. DOE under contract No. DE-AC02-98CH10886

9:36AM P9.00009 Velocity Dependent Selectivity of Deterministic Lateral Displacement Arrays. JASON PUCHALLA, KEITH MORTON, ROBERT AUSTIN, Princeton University — Deterministic lateral displacement (DLD) has been demonstrated as a promising microfluidic method to circumvent diffusive dispersion while separating small particles based on size. At low average flow velocity, steric repulsion and diffusion seem sufficient to describe particle behavior and array separation characteristics. However, at higher but still laminar flow velocities, particle behavior changes drastically. We have investigated this regime using a silicon DLD array. We present how the local disruption of fluid flow about a moving particle and the effects inertial forces can alter DLD behavior and can be exploited for selective sorting.

9:48AM P9.00010 Fluctuation effects and evolution in bacterial populations on a chip. JAAN MANNIK, JUAN E. KEYMER, CEEES DEKKER, Delft University of Technology — Fluctuation effects are ubiquitous in physics. Relatively little is known about what role these effects play in systems involving biological organisms. How do random fluctuations originating from the environment and from the biological organisms themselves affect the population dynamics and evolution? Here, we address this question using an experimental approach where we grow a large number of independent E. coli populations on a microfluidic silicon chip designed to evolve the body size distribution. We provide the same environmental conditions for different parental populations and follow their evolution in real time measuring number of bacteria in different colonies. We analyze fluctuations in these numbers and how the body size distribution of bacteria changes.

10:00AM P9.00011 Modelling colloidal dynamics in complex systems. CHRISTOPHER SMITH, COLIN DENNISTON, University of Western Ontario — We present a lattice Boltzmann method for dealing with solid moving boundaries in a fluid. A novel method is introduced to introduce a solid surface onto the fluid mesh. We show that for a single particle in a chute with Stokes flow, the quantitatively correct Stokes drag is obtained. Comparing two scenarios at the same Reynolds number, where the wall induces the flow or where the particle is moving, we show there is little discernible difference in the force measured. Next, we have a system with two particles and show we get quantitative agreement for the interaction between the two particles measured by our algorithm and the interaction expected according to the Rotne-Prager (RP) tensor or the Oseen tensor, in the regimes in which they are expected to be accurate. Moving away from irrotational flow, for a cylinder in a two dimensional chute the Reynolds number of the flow is increased further into the laminar region and we show the formation of eddies shedding off the solid surface. We incorporate this new algorithm into liquid crystals simulations to look at novel colloidal interactions through topological defects.

10:12AM P9.00012 Experimental and Theoretical Studies of Electroosmotic Membrane Micropumps. ZULI XU, JIA NYING MIAO, NING WANG, PING SHENG, Department of Physics and Institute of Nano Science and Technology, Hong Kong University of Science and Technology, Clear Water Bay, Hong Kong, China — Electroosmotic (EO) effect means fluid flow (through a porous medium) induced by an applied electric field. EO pumps have the advantages of no moving parts and easily-controlled accurate flow rate at low applied voltages. We have fabricated nano-channel EO membrane pumps using anodized aluminum oxide (AAO) as the template [1]. The diameter of the uniform-sized nanochannels can range from 60-300nm, with a membrane thickness of 30-100 microns. The EO effect is enhanced by coating the nanochannels with silica. By using de-ionized water, the nanopump performance is shown to agree reasonably well with the theoretical model, with factors such as the ratio of the double layer thickness to channel diameter, channel geometry, and treatment of the AAO membranes playing important roles. With silica coating to the nanochannels, the nanopump can produce a maximum pressure of 1 atm and a maximum flow rate of 86,000µL/min-cm2 under an applied field of 0.94 V/m. Besides DI water, the micropumps have also been tested to work well with salt, acid or base solution. [1] J.Y. Miao, Z.L. Xu, X.Y. Zhang, N. Wang, Z.Y. Yang, P. Sheng, submitted to Advanced Materials (Appeared online: 10.1002/adma.200700767).

10:24AM P9.00013 Investigation and Characterisation of Resealable Nanopores in an Elastomeric Membrane. GEOFF WILLMOTT, Industrial Research Limited — Experimental and theoretical work relating to the development of resealable synthetic nanopores will be presented. The nanopores, which are roughly conical, are formed by puncturing a relatively thick (~250 µm) elastomeric membrane with an STM tip. The aperture can be closed and the size can be dynamically controlled by stretching the elastomer [1]. Use of this technology presents a collection of interesting physical problems, covering topics that include the failure and mechanical properties of the elastomer, flow of ionic current through the aperture and particle sensing using the resistive pulse technique. Synthetic nanopores have potential applications in many fields, but especially relating to nanoscale sensing and diagnostic devices, and replication of ion channels in living cells. [1] S. J. Sowerby, M. F. Broom, G. B. Petersen, Dynamically Resealable Nanometre-Scale Apertures for Molecular Sensing, Sensors and Actuators B: Chemical 123 (1), pp. 325-330 (2007)

10:36AM P9.00014 The physics of densely-packed emulsions. DONALD M. AUBRECHT, Harvard University, DAVID F. MARRAN, DARREN R. LINK, RainDance Technologies, Inc., DAVID A. WEITZ, Harvard University — One strategy for microfluidic lab-on-a-chip applications is to use water droplets as tiny reaction vessels in a carrier stream of oil. As biochemical and cell-based experiments often require control over events that take place over a wide range of time scales, strategies need to be developed to ensure adequate timing without limiting droplet throughput. In general, longer time scales can be achieved by using longer channels or more densely packed droplets. Long channels become increasingly impractical at high throughputs for times exceeding tens of minutes, thus motivating work with densely packed droplets. Dense packing of droplets can be achieved by generating droplets on-chip, collecting them off-chip to allow the oil to drain, and re-injecting them back on-chip as a packed emulsion. This strategy is limited in that it only provides access to time scales in excess of hours. Moderate time scales can be accessed by removing carrier oil from the flow without removing the droplets. Here we present some of the physical principles governing how this can be implemented and discuss the flow of the resulting dense collections of droplets through microchannels.

Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P10 DCMP: Superconducting Nanostructures | Morial Convention Center RO8
8:00AM P10.00001 Microwave Response in Short Superconducting Nanowires, ROBERT DINSMORE, MYUNG-HO BAE, ALEXEY BEZRYADIN, University of Illinois at Urbana-Champaign — Short superconducting nanowires, of length L~100 nm, have been exposed to microwave radiation (MWR) giving rise to phase slip centers that do not appear in DC measurements, without MWR. For frequencies in the 100-1000 MHz range multiple voltage jumps are observed indicating multiple phase slip centers. Each such voltage plateau is characterized by a small differential resistance, of the order of 10-20 Ohms. In this frequency range zero crossing plateaus were also observed. For frequencies from 2 to 9 GHz, MWR had a synchronization effect on the superconducting phase rotation. Resonances are observed for integer and half integer orders, similar to the original observation of Anderson and Dayem on much larger superconducting bridges [1]. [1] Anderson and Dayem, Phys. Rev. Lett. 13, p.195 (1964)

8:12AM P10.00002 Resistance in One-Dimensional Superconducting Epitaxial Niobium Nanowires, TIMOTHY MCARDLE, KEVIN INDERHEES, PAUL WELANDER, ALLISON DOVE, JAMES ECKSTEIN, Univ of Illinois Urbana-Champaign — Thermally activated phase slips cause resistance in one-dimensional superconducting wires near the critical temperature. However, this description of a thermally activated process is not able to explain additional resistance observed in extremely narrow nanowires well below Tc. We fabricate nanowires using electron beam lithography from single-crystal niobium films grown by ultra-high vacuum molecular beam epitaxy. Since the films are single crystal, the role of disorder is reduced and neither weak links nor grains are present. The films are 10 to 20 nm thick, have transition temperatures ranging from 7.2 to 9.2 K, and residual resistance ratios of 5 to 10, typical for ultra-thin single-crystal niobium films. The wires are 10 μm long and range in width from 35 to 200 nm. Transport measurements on the nanowires show two distinct regions of temperature dependence below Tc. This work was supported by the DOE BES at the F. Seitz Materials Research Laboratory at the University of Illinois, Urbana.

8:24AM P10.00003 Magnetoresistance and Critical Current Oscillations in Superconducting NbSe2 and NbN Nanowires, U. PATEL, Z.L. XIAO, J. HUA, Argonne National Laboratory and Northern Illinois University, R. DIVIAN, U. WELP, W.K. KWOK, Argonne National Laboratory — Magnetoresistances and critical currents of superconducting NbSe2 and NbN nanowires with cross-section dimensions from 300 nm to 2 μm were studied as a function of magnetic field. Sample specific oscillations were found with respect to applied magnetic field. The oscillations were completely reproducible, symmetric with respect to the direction of the field and independent of the field sweep direction. They disappeared at high fields, temperatures or currents. The oscillations were periodic in nature with superposition of more than one frequency as revealed in Fast Fourier Transform of the oscillations. The frequencies of oscillations were independent of temperature and current. Details about the transport measurements of resistance and critical current and origin of such oscillations will be discussed.

8:36AM P10.00004 “Giant” strengthening of superconducting pairing in small metallic nanoparticles: high Tc state, VLADIMIR KRESIN, Lawrence Berkeley Laboratory, YURIU OVCHENNIKOV, Landau Institute of Theoretical Physics, BAOPENG CAO, MARTIN JARROLD, Indiana University, Bloomington — The study focuses on metallic nanoclusters containing N~10^2-10^3 free carriers (e.g., Ga_{52}, Al_{25}). The delocalized cluster electrons form energy shells similar to those in atoms or nuclei. Under special conditions, superconducting pairing in such nanoclusters can become very strong, and they form a new family of high temperature superconductors. For realistic sets of parameters one can expect a high value of Tc (150 K) as well as strong modification of the energy spectrum. In principle, it is possible to raise Tc up to room temperature. Specific experiments aimed at detecting the phenomenon of pair correlation in nanoclusters can be proposed: spectroscopy, magnetic, and thermodynamic properties. Transition to the superconducting state of the cluster is accompanied by the peak in its heat capacity. The phenomenon is promising for the creation of high Tc superconducting tunneling networks, and hence macroscopic superconductivity.

8:48AM P10.00005 Evidence for High Tc Superconducting Transitions in Isolated Al_{45} and Al_{47} Nanoclusters, MARTIN JARROLD, BAOPENG CAO, COLLEEN NEAL, ANNE STARACE, Indiana University, YURIU OVCHENNIKOV, Landau Institute for Theoretical Physics, VLADIMIR KRESIN, Lawrence Berkeley Laboratory — Heat capacities measured for Al_{45} and Al_{47} nanoclusters have reproducible peaks at ~ 200 K. The data were obtained using a multi-collision dissociation method [1] allowing us to perform measurements for isolated nanoclusters. The peaks are observed for selected Al clusters only. These peaks are consistent with theoretical predictions that some clusters with highly degenerate electronic states near the Fermi level will undergo a transition into a high Tc superconducting state [2]. An analysis based on a theoretical treatment of pairing in Al_{45} and Al_{47} agrees well with the experimental data in both the value of the critical temperature and in the size and width of the peaks in the heat capacity. The observed value of Tc exceeds those found in bulk systems. [1] G.Breaux, C.Neal, B.Cao, M.Jarrod, Phys. Rev. Lett. 94, 173401 (2005) [2] V.Z.Kresin, Yu.Ovcchinnikov, Phys. Rev. B 74, 024514 (2006)

9:00AM P10.00006 Quantum confinement effects on superconducting properties of Lead nanocrystals, HERVE AUBIN, CNRS-ESPCI, HELENA MOREIRA, UPM6, BENOIT MAHLER, ESPCI, BENOIT DUBERTRET, CNRS-ESPCI — We developed a new chemical synthesis method for producing large quantities of monodispersed lead (Pb) nanocrystals. They are obtained from the alcohol reduction of a mixture of two lead carboxylates with alkyl chains of different lengths, dissolved in a high temperature solvent. The nanocrystals obtained are monodispersed particules are obtained when nucleation and growth occur at distincts temperatures, possibly as a consequence of different reactivities of the reagents. The delocalized cluster electrons form energy shells similar to those in atoms or nuclei. Under special conditions, superconducting pairing in such nanoclusters can become very strong, and they form a new family of high temperature superconductors. For realistic sets of parameters one can expect a high value of Tc (150 K) as well as strong modification of the energy spectrum. In principle, it is possible to raise Tc up to room temperature. Specific experiments aimed at detecting the phenomenon of pair correlation in nanoclusters can be proposed: spectroscopy, magnetic, and thermodynamic properties. Transition to the superconducting state of the cluster is accompanied by the peak in its heat capacity. The phenomenon is promising for the creation of high Tc superconducting tunneling networks, and hence macroscopic superconductivity.

9:12AM P10.00007 Superconductivity of nano-size Pb Islands studied by low-temperature scanning tunneling microscopy / spectroscopy, TAKAHIRO NISHIO, TOSHU ATSUMI, ANTSUHI NOMURA, KOUSUKE MIYACHI, TOYOAKI EGUCHI, YUKIO HASEGAWA, Inst. Solid State Phys., Univ. Tokyo, HIDEAKI SAKATA, Tokyo Univ. of Science — Nano-size superconducting materials, whose dimensions are comparable with or smaller than their coherent length / penetration depth, behave differently from bulk superconductors. By forming structures using lithographic methods various unique properties of mesoscopic superconductors have been elucidated. Since these studies, however, measure electrical conductance and / or magnetization, details inside the superconductors cannot be directly probed. In this study we investigated superconductivity inside superconductors by directly measuring the superconducting gaps over ultra thin Pb island structures using a LT-STM at 2.0 K [1]. The obtained tunneling spectra exhibit an increment of zero bias conductance (ZBC) with a magnetic field and its dependence on the lateral size of the islands. Moreover, from spatial mappings of ZBC, the island size dependence and spatial variation of superconductivity inside of each island are visualized. We found that the number of vortices piercing the islands before breakdown of superconductivity depends on the lateral size of the islands. Details of the size-dependent critical fields are discussed at the presentation. [1] Nishio et al., APL 88, 113115 ’06, JAP 46, L880 ’07.
9:24AM P10.00008 Flux jump in superconducting Pb networks at fractional numbers of the matching fields, TAKEKAZU ISHIDA, YOSHIKAZU MATSUSHIMA, MAKOTO SHIMIZU, Osaka Prefecture University, MASAHIKO HAYASHI, Akita University, HIROMICHI EBISAWA, Tohoku University, MASARU KATO, Osaka Prefecture University, OSAMU SATO, Osaka Prefectural College of Technology, NEYAGAWA, KAZUO SATO, TSUTOMU YOTSUYA, Technology Research Institute of Osaka Prefecture — The extended Little-Parks effect of superconducting network is known as a periodic Tc variation as a function of magnetic field. Superconducting Pb honeycomb networks of matching field 0.106 G and triangular microhole lattice of Pb of matching field 0.425 G have been fabricated by the combined techniques of the electron beam lithography and a lift-off process of evaporated Pb films. The application of magnetic field corresponds to the vortex doping into networks. We measured the magnetization of the networks systematically by using a SQUID magnetometer. We found that flux jump appears rather periodically as a function of magnetic field. Flux jumps may be induced by a periodic decrease in the critical current density of the network. To the authors’ knowledge, this is for the first time to observe the extended Little-Parks effect appeared in flux jumps. We also discuss the anomalous matching effect.

9:36AM P10.00009 Switching Current Distributions of Superconducting Nanowires: Evidence for Individual Quantum Phase Slips, MITRABHANU SAHU, MYUNG-HO BAE, UIUC, ANDREY ROGACHEV, University of Utah, DAVID PEKKER, Harvard University, NAYANA SHAH, UIUC, TZU-CHIEH WEI, University of Waterloo, PAUL GOLDBART, ALEXEY BEZRYADIN, UIUC — Phase slip fluctuations cause premature stochastic switching of the state of a current biased quasi-one-dimensional nanowire from superconducting to normal at sub-critical currents. Here, we report on measurement of the distributions of switching currents performed on amorphous superconducting MoGe/Co21 nanowires over a range of temperatures. The measured widths of the switching current distributions are observed to increase with decreasing temperature. We explain this counterintuitive result by considering a microscopic stochastic model of heating caused by each phase slip event. The measured rates of escape from the superconducting state agree well with the predictions of the stochastic model under the assumption of phase slippage by thermal activation at relatively high temperatures and macroscopic quantum tunneling at sufficiently low temperatures. We identify and explore a region in which a single quantum phase slip is all that is necessary to trigger switching from the superconducting to the normal state.

9:48AM P10.00010 Theory of superconductive-resistive switching in nanowires due to heating by stochastic phase slips, NAYANA SHAH, University of Illinois at Urbana-Champaign, DAVID PEKKER, Harvard University, PAUL GOLDBART, University of Illinois at Urbana-Champaign — We study the stochastic dynamics of superconductive-to-resistive switching in hysteretic current-biased superconducting nanowires undergoing phase-slip fluctuations. We assume that the hysteresis is thermal in nature, and postulate that the mechanism for the switching is thermal runaway, i.e. random sequences of stochastic phase slips, closely spaced in time, that heat the nanowire. Thus, via the master-equation formalism, we obtain the distribution of currents at which switching occurs. If switching were caused by single, thermally-activated phase-slip events then this distribution would narrow as the temperature is reduced. However, at higher temperatures we find that several phase-slip events are typically necessary for inducing switching, and this results in an initial broadening of the distribution upon cooling. Quite generally, we predict that at low temperatures thermal runaway is caused by a single phase-slip event. Thus, measurements of switching-current distributions in this regime are a direct probe of this basic collective process. In particular, this regime could yield observations of individual quantum phase slips in nanowires.

10:00AM P10.00011 Anisotropic Superconductivity in MoGe - Permalloy Bilayers1, GORAN KARAPETROV, Argonne National Lab, A. BELKIN, ANL and Illinois Institute of Technology, V. NOVOSAD, M. IAVARONE, J. FEDOR, Argonne National Lab, A. TRONCALLI, Austin College, J. PEARSON, W.K. KWOK, Argonne National Lab — We studied the magnetico-transport properties of superconductor-ferromagnet MoGe/Permalloy bilayers. The ferromagnet with stripe domain structure induces in-plane anisotropy in superconducting order parameter. Superconducting phase diagram shows that near the S-N phase boundary the superconductivity is localized in narrow mesoscopic channels just above the magnetic domain walls. We determined the scaling phase diagram, which shows that even in wider samples the PSS contribution dominates over vortices in a substantial region of current/temperature variations [1]. The above fluctuations generated by topological excitations also provide a noise limit to superconducting detectors operating in a resistive state, e.g. for dark counts in single-photon detectors. [1] M. Bell et al., Phys. Rev. B 76, 094521 (2007).

10:12AM P10.00012 Superconductor-Ferromagnet Bilayers: Influence of Magnetic Domain Structure on Vortex Dynamics1, ANDREY BELKIN, Argonne National Laboratory and Illinois Institute of Technology, V. NOVOSAD, M. IAVARONE, J. PEARSON, W.K. KWOK, G. KARAPETROV, Argonne National Laboratory — We investigate the influence of orientation of stripe-like domain structure in ferromagnetic films on vortex dynamics in superconductor-ferromagnet bilayers. We measure transport properties in different external magnetic fields applied perpendicular to the surface of the bilayers. Parameters of superconductor-ferromagnet bilayers are such that domain period is much bigger than the superconducting coherence length but much smaller than the effective penetration depth. Prominent dissimilarity of critical currents of two studied bilayers runs systematically by using a SQUID magnetometer. We found that flux jump appears rather periodically as a function of magnetic field. Flux jumps may be induced by a periodic decrease in the critical current density of the network. To the authors’ knowledge, this is for the first time to observe the extended Little-Parks effect appeared in flux jumps. We also discuss the anomalous matching effect.

10:24AM P10.00013 Topological excitations in superconducting nanostripes: Resistive States and Noise1, MATT BELL, ANDREI SERGEEY, VLADIMIR MITIN, ALEKSANDR VEREVKIN, SUNY at Buffalo — We investigate competition between one- and two-dimensional topological excitations - phase slips and vortices - in formation of resistive states and noise generation in ultrathin superconducting Bi2122Nanostripes in a wide temperature range below the mean-field transition temperature Tc0. The widths w = 100 nm of our ultrathin Bi2122 nanostructures are substantially larger than the Ginzburg-Landau coherence length ξ = 4nm and the fluctuation resistivity above Tc0 has a two-dimensional character. However, our data shows that the resistivity below Tc0 is produced by one-dimensional excitations, - thermally activated phase slip strips (PSSs) overlapping the sample cross-section. We determine the scaling phase diagram, which shows that even in wider samples the PSS contribution dominates over vortices in a substantial region of current/temperature variations [1]. The above fluctuations generated by topological excitations also provide a noise limit to superconducting detectors operating in a resistive state, e.g. for dark counts in single-photon detectors. [1] M. Bell et al., Phys. Rev. B 76, 094521 (2007).

10:36AM P10.00014 Nonlinearities and Parametric Amplification of Superconducting Coplanar Waveguide Resonators1, DAVID HAVILAND, ERIK THOLÉN, ADEM ERGUL, Royal Institute of Technology KTH, NANOSTRUCTURE PHYSICS KTH TEAM — We have experimentally studied the nonlinear properties of superconducting coplanar stripline resonators fabricated from Al and Nb films with small transverse dimensions (gap size 1 µm). Magnetic field penetration into the superconductor causes a current-dependant kinetic inductance, which gives an ideal Kerr nonlinearity. When the nonlinear oscillator is pumped very near its dynamic instability, it can be used to realize parametric amplification. We have achieved a gain of ~22.4 dB in a 5.8 GHz resonator cooled to 450 mK [E. Tholén et. al. Appl. Phys. Lett. 90, 253509 (2007)]. Parametric deamplification or squeezing of a signal has also been verified with squeezing of 30 dB. The later effect is interesting because it can be used to generate squeezed vacuum states of the electromagnetic field. We have modeled the data using a theory developed by Yurke and Buks [I. Lightwave Technol. 24, 6054 (2006)]. Excellent fit of the model to the measured data can be achieved over a wide range of pump power, and the strength of the nonlinear terms can be obtained with high accuracy.

10:48AM P10.00015 Observation of Nonlocal Coherence Between Normal Metals Coupled by a Superconductor1, PAUL CADDEN-ZIMANSKY, JIAN WEI, VENKAT CHANDRASEKHAR, Northwestern University — In conventional superconductors the effective size of the constituent Cooper pairs can approach several hundred nanometers, a length scale accessible by nanolithographic techniques. By placing two normal metals on a superconductor within a coherence length of each other, it has been predicted that the quasiparticles in the separate metals can be coherently coupled by the Cooper pairs through the nonlocal processes of Elastic Cotunneling and Crossed Andreev Reflection. We present experimental observations of coherent, nonlocal thermoelectric effects between normal metals coupled to a superconductor by using a hybrid normal-superconductor interferometer. The sign of the observed thermoelectric voltage can be switched using an external field, indicating that the voltage is dynamically driven by a persistent current induced in the interferometer.

1Supported by NSF Grant No. DMR-06-04601

Wednesday, March 12, 2008 8:00AM - 10:24AM —
Session P11 DMP: Focus Session: MgB2-like: Disorder in Novel Superconductors Morial Convention Center R09

8:00AM P11.00001 Penetration depth study of Li, C and Li+C doped MgB2 single crystals, CATALIN MARTIN, MATTHEW VANNETTE, RUSLAN PROZOROV, Ames Laboratory, Ames, IA 50011, J. KARPINSKI, N. ZHIKADLO, R. KHASANOV, Laboratory for Solid State Physics, ETH, 8093 Zurich, Switzerland — Magnetic penetration depth was studied in single crystals of MgB2, pure and doped with Li, C and Li+C. At zero applied field London penetration depth is measured and superfluid density, n_s, can be evaluated. We analyze effect of the dopings on n_s, thus on the superconducting gaps. In the vortex state, Campbell penetration depth is measured and it provides information about true critical current unaffected by the magnetic relaxation. In particular, penetration depth in vortex state becomes strongly irreversible, and we show that C doping enhances the irreversibility region, whereas the substitution with Li does not affect the results. They are discussed in terms of two-gap nature of MgB2.

1Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358.

8:12AM P11.00002 Nano-scale TiB2 Precipitates in MgB2 Superconducting Wire1, D.K. FINNEMORE, M.E. TILLMAN, P.C. CANFIELD, S.L. BUD’KO, Y.Q. WU, M.J. KRAMER , Ames Lab / Iowa State University, J.V. MARZIK, Specialty Materials, Inc., Lowell, MA, M. RINDFLEISCH , Hyper Tech Research Inc., Columbus, OH , S.T. HANNAHS, NHMFL, Tallahassee, FL — Superconducting MgB2 wire containing uniformly dispersed, nano-scale TiB2 precipitates has been produced using a plasma synthesis method to make the starting Ti doped B powder. A powder-in-tube method is used for making the wire. Sub-micrometer size MgB2 grains are decorated with a random dispersal of 5 to 20 nm precipitates. The superconducting properties are reported for a family of powder-in-tube wires fabricated with pure boron, carbon doped boron, and titanium doped boron. The particle size of the doped boron powder, of 50 to 100 nm, permits low reaction temperatures and short reaction times. The sign of the observed thermoelectric voltage can be switched using an external field, indicating that the voltage is dynamically driven by a persistent current induced in the interferometer.

8:24AM P11.00003 Properties of Carbon Doped MgB2 Films by HPCVD Using TMB, WENQING DAI, R.H.T. WILKE, KE CHEN, QI LI, XIAOXING XI1, Department of Physics, The Pennsylvania State University, University Park, Pennsylvania, USA — Carbon-doping is an effective way to enhance the upper critical field of MgB2. Our previous carbon-alloyed MgB2 films using (MeCp)2Mg as the carbon source show dramatically increased Hc2 values to over 60 T at low temperatures. Structure analyses of these films indicate that only part of the carbon is doped into the MgB2 lattice and the rest forms highly resistive foreign phases in the grain boundaries. To fabricate more homogeneously carbon doped thin films, gaseous trimethylboron (TMB) was used as the carbon source. The normal state resistivity of carbon doped films using TMB increases much more slowly with carbon concentration, demonstrating a better connection between the MgB2 grains. However the relatively high growth temperature, required to decompose TMB, limits the film thickness in the original Hybrid Physical-Chemical Vapor Deposition (HPCVD) setup. A hot wire is then installed in the HPCVD system to help decompose TMB while the substrate and Mg bulk source are kept at relatively low temperature. Initial results of these films will be presented.

1Also with Department of Materials Science and Engineering, The Pennsylvania State University, University Park, Pennsylvania, USA

8:36AM P11.00004 Inhomogeneous Nanoscale Disorder in Doped Magnesium Diboride1, PAUL VOYLES, University of Wisconsin, Madison — Using TEM and STEM imaging and microanalysis, we have shown that doped MgB2 has a variety of forms of disorder at a length scale of 5-50 nm. In [0001]-normal, carbon-doped HPCVD thin films, there is a thin, amorphous, C-rich layer which separates domains of lightly carbon-doped MgB2. Carbon also causes significant spread in the local in-plane orientation and c-axis direction of the MgB2. We also observed disorder in the orientation of small MgB2 domains in oxygen-doped thin films grown by MBE. Both of types of films show dramatic enhancement in the upper critical magnetic field compared to pure MgB2, with extrapolated Hc2(0 K) reaching 65-70 T for some samples. The origin of this increase may be in the observed disorder, particularly in confinement of the superconducting MgB2 domains by non-superconducting second phase layers.

1This work was supported by the NSF FRG on Magnesium Diboride, DMR-0514592.
9:12AM P11.00005 The Ca and Yb Isotope Effect in Superconducting Ca and YbC12

DAVID HINKS, DAN ROSENMANN, HELMUT CLAUS, Argonne National Laboratory — The isotope effect \((\alpha = -\log T_c/\log M)\) where \(M\) is the isotope mass and \(T_c\) is the transition temperature \((300 \text{K})\) is a measure of the phonon contribution to the superconductivity. We have measured both the Ca and the Yb isotope effect in intercalated highly orientated pyrolytic graphic (HOPG) by vapor phase transport of the isotopes. We find a large and, within the experimental error, equal \(\alpha\) for each element, \(0.36(4)\) and \(0.40(4)\) for Yb and Ca, respectively. The value for Ca is larger then theoretically predicted indicating a stronger electron-phonon coupling.

3Work supported by DOE Office of Science under Contract No. DE-AC02-06CH11357.

9:24AM P11.00006 Crystal Structures and Physical Properties of One-Dimensional Borides

A11+MFe4B12 \((A = \text{Ca, Y; La; } M = \text{Fe, Co, Ru})\), YUKARI KATSURA, HIRAKU OGINO, YUTAKA MATSUMURA, SHIGERU HORII, JUN-ICHI SHIMOYAMA, KOHIJI KISHIO, Dept. of Applied Chemistry, Univ. of Tokyo — We investigated crystal structures and physical properties of La11+Fe4B12 (\(\varepsilon \approx 0.06\)) and three new borides Y11+Fe4B12 (\(\varepsilon \approx 0.16\)), CaCo4B12 and Ca11+Ru4B12 (\(\varepsilon \approx 0.13\)). Poly crystalline bulk samples were obtained by reacting metal boride precursors (FeB, CoB, RuB) with La, Y and La metals. Microstructure were analyzed using a SEM with an EDX. Crystal structures were analyzed through XRD and Rietveld analysis of powder XRD patterns. Electrical resistivity and magnetization measurements were carried out from 1.8 to 300 K. We found that all these compounds belong to the same structural family as RE11+Fe4B12 (RE = La-Tm): a tetragonal lattice composed of one-dimensional channels of FeB and single atomic chains of RE. Incommensurate structures along c-axis were observed in La11+Fe4B12, Y11+Fe4B12 and Ca11+Ru4B12. The La11+Fe4B12 bulks exhibited type-II superconductivity below 6.0 K, although this might be due to the superconductivity of dirty \(\beta\)-La remaining in the bulks. The other new borides did not show superconductivity down to 1.8 K.

9:36AM P11.00007 Observation of a new phase in the Li-B system.

EDUARD GALSTYAN, YUYI XUE, YANYI SUN, IRENE RUSAKOVA, TsSUH and Department of Physics, University of Houston, NING WANG, Department of Physics, The Hong Kong University of Science and Technology, KAREN MKHOYAN, Department of Applied and Engineering Physics, Cornell University, CHING-WU CHU, TsSUH, The Hong Kong University of Science and Technology, Lawrence Berkeley National Laboratory — The simple compounds of boron and light elements have attracted interest since the unexpected discovery of high temperature phonon-coupled superconductivity (SC) in MgB2. The numerous theoretical works show that the Li-B system has electronic features similar to those in MgB2 and compounds in the system are expected to be superconducting. In fact, there were early reports of Li-B compounds. Although the small Li-size suggests a rich phase diagram, the previous investigations discovered only one stable compound over a broad initial stoichiometry. The extreme reactivity and hydrolyses of Li in air may be partially responsible for this. We were able to synthesize a new Li-B pure phase that belongs to hexagonal symmetry through a new synthesis procedure. We report on the structural, magnetic, and electron energy loss spectra (EELS) analyses of this compound. Despite the similarity with the electronic structure of MgB2, the Li-B system has not yet shown the existence of SC.

9:48AM P11.00008 Superconductivity in heavily boron-doped single crystalline and nanocrystalline diamond thin films

P. ACHATZ, C. MARCENAT, CEA Grenoble/DRFMC/SPSMS, France, E. BUSTARRET, T. KLEIN, CNRS Grenoble/Institut Niel, France, O.A. WILLIAMS, Institut for Materials Research, Belgium, J.A. GARRIDO, M. STUTZMANN, WSI TUM, Germany — Our results show that the critical boron concentration \(n_B\) for single crystalline diamond (scd) and nanocrystalline diamond (ncd) thin films is the same for the normal to superconducting and for the non-metal to metal transitions, on the order of 5 \times 10^{20} \text{ cm}^{-3}, in agreement with estimates derived from various theoretical approaches. In scd material, a variable range hopping behaviour was clearly observed on the insulating side of the transition, and, as expected, the characteristic temperature \(T_H\) tended toward zero at the transition. On the metallic side, the zero temperature conductivity \(\sigma_0\) scaled with \((n_B/n_c \sim 1)^{\nu} \approx 1\). The critical temperature \(T_c\) remained high in the vicinity of the metal-non metal transition, and it was rather found to scale with \((n_B/n_c \sim 1)^{3/2}\). These results led us to propose that the electron-phonon coupling parameter \(\lambda\) remains large down to \(n_B/n_c \approx 1\), and to examine the metal-insulator transition and the parameter set \((\lambda, \mu)\) in terms of scaling laws.

Low temperature magnetotransport measurements and the possible occurrence of a superconductor-insulator transition in heavily boron-doped ncd will be discussed.

10:00AM P11.00009 Tracing the evolution of two energy gaps of MgB2 with increasing disorder

MAURICIO ESCOBAR M., YONG-JIHN KIM, University of Puerto Rico — Previously we have determined the phonon-mediated matrix elements for MgB2 using the two band model and the scattered states. We noticed that, in the dirty limit, where the resistance ratio is about 3, the impurity scattering does not reduce the matrix elements much due to the Cooper pair size effect, whereas, in the weak localization limit, where the resistance ratio is less than 3, all the matrix elements are decreasing significantly due to weak localization. Now we calculate numerically the matrix elements and solve the gap equations with increasing disorder. We determine when the two energy gaps merge into one common energy gap and compare our calculations with experiments. We also calculate the transition temperature, \(T_c\), as a function of the resistance ratio.

10:12AM P11.00010 Magnetic field-tuned superconductor-insulator transition in quenched-condensed ultrathin Be films

ZUXIN YE, WENHAO WU, Texas A & M University — We quenched condensed ultrathin Be films onto glass slides inside a dilution refrigerator with the substrates held near 10 K. The films were first tuned from insulating to superconducting by increasing the thickness in fine steps. The thickness-tuned transition occurs at a normal state sheet resistance \(R_N \sim 13 \text{ k-Ohm measured at } 10 \text{ K.}\) For superconducting films of various thickness, the field-tuned superconductor-insulator transition was then investigated. Remarkably, the critical resistance of the field-tuned transition was found to be \(R_C = \sim 4/6\), independent of the thickness of films of \(R_N\) ranging from 11 to 6 k-Ohm, critical temperature \(T_c\) ranging from 1.3 to 5.2 K, and critical field \(B_C\) ranging from 1 to 8 T. This result is a strong evidence for a duality quantum phase transition from a vortex glass in the superconducting state to a Bose glass in the field-induced insulating state. For thicker films with \(R_N < 5 \text{ k-Ohm, the critical resistance no longer remained at } h/4e^2\) but was nearly equal to \(R_N\). This observation suggested that these thick films were no longer in the vicinity of the quantum critical point.

Session P12 GFC: Skutterudites and Other Heavy Fermions Morial Convention Center 203

8:00AM P12.00001 Metal-insulator and metal-metal behavior in filled-skutterudites

LING YANG, SHAN-WEN TSAI, Department of Physics & Astronomy, UC Riverside — Filled-skutterudites compounds are of the form \(LT_{2.1}X_{12}\), where \(L\) stands for Lanthanide, \(T\) stands for transition metal and \(X\) stands for Pnictogen. They show many unusual properties, and are also important due to their thermo electric properties. Here we focus on the metal-insulator and metal-metal behavior observed in \(PrRu_2P_{12}\) and \(PrOs_2P_{12}\) compounds. We propose a simple model where the positions of the L atoms in different minima inside the cage, and a phase transition occurs when the temperature is lowered. The nature of the transition depends on the density of carriers.
Andreev spectroscopy study of multigap pairing in PrOs$_4$Sb$_{12}$. C.S. Turel, J.Y.T. Wei, University of Toronto, B. Djurkovic, J.B. Kycia, University of Waterloo, W.M. Yuhasz, R. Baumbach, M.B. Maple, University of California at San Diego — The recent discovery of superconductivity in the filled skutterudite heavy fermion material PrOs$_4$Sb$_{12}$ has generated widespread interest. Different experimental studies have reported various field- vs-temperature phase diagrams, with mixed evidence for nodes in the pairing gap. Some experiments have also indicated the presence of multiple gaps, suggesting that the pairing involves multiple bands or multiple order parameters. We present Andreev spectroscopy data, down to 80 mK and up to 2.5 T, taken using ballistic point contacts made with Pt-Ir tips on single crystals of Pr(Os$_{1-y}$Ru$_y$)$_4$Sb$_{12}$. We observed distinct spectral evidence for gap nodes. We also observed multiple spectral features arising from Ru-doping. We interpret the evolution of these spectral features within the scenario of multigap pairing.

Defects and broken time-reversal symmetry in superconducting Pr(Os$_4$Ru$_4$)$_4$Sb$_{12}$. D.E. MacLaughlin, LEI SHU, U. Calif., Riverside, A.D. Hillier, ISIS, Rutherford Appleton Lab., O.O. Bernal, Calif. State U., Los Angeles, Y. Aoki, D. Kikuchi, H. Sato, Y. TunaShima, T.A. Sayles, T. Yanagisawa, W.M. Yuhasz, M.B. Maple, U. Calif., San Diego — Muon spin relaxation studies of a spontaneous local field $H_L$ in a powder sample of PrOs$_4$Sb$_{12}$, previously observed in the superconducting state of PrOs$_4$Sb$_{12}$ and attributed to broken time-reversal symmetry, have been extended to PrRu$_4$Sb$_{12}$ and PrOs$_4$Ru$_4$Sb$_{12}$ by means of quasielastic muon spin relaxation with $H_L > 0.1 T$. The effect is reduced by a factor of 2 in PrRu$_4$Sb$_{12}$, and in PrOs$_4$Ru$_4$Sb$_{12}$ it is strongly suppressed but remains observable for $x \leq 0.2$. In powder samples prepared by solid state reaction, however, no field is observed for $x = 0.1$ or 0.2. Muon spin relaxation due to dynamic $^{141}$Pr nuclear spin fluctuations is reduced in the powders. Both results can be understood if the density of microscopic defects is smaller in the powders: defects increase muon spin relaxation by $^{141}$Pr spins, and supercurrents associated with defects are predicted to create spontaneous fields in TRS-breaking superconductors. Our results are strong experimental evidence for this prediction.

Multi-symmetry and Multi-band Superconductivity in Superconducting Filled-skutterudites. R.W. Hill, University of Waterloo, Canada, S.H. Li, Universite de Sherbrooke, Canada, M.B. Maple, University of California, San Diego, L. Taillefer, Universite de Sherbrooke, Canada — Thermal conductivity measurements were performed on single crystal samples of the superconducting filled skutterudite compounds PrOs$_4$Sb$_{12}$ and PrRu$_4$Sb$_{12}$ both as a function of temperature and magnetic field applied perpendicular to the heat current. In zero magnetic field, the low temperature electronic thermal conductivity of PrRu$_4$Sb$_{12}$ vanishes at low temperatures, consistent with a fully-gapped Fermi surface. For PrOs$_4$Sb$_{12}$, however, we do not find clear evidence for residual electronic conduction as the temperature tends to zero Kelvin which is consistent with the presence of nodes in the superconducting energy gap. The field dependence of the electronic conductivity for both compounds shows a rapid rise immediately above $H_T$, and a significant structure over the entire vortex state. For both compounds, superconducting properties imply a $d$-wave state and significant structure over the entire vortex state. In the fully gapped superconductor PrRu$_4$Sb$_{12}$, this is interpreted in terms of multi-band effects. In PrOs$_4$Sb$_{12}$, we consider the Doppler shift of nodal quasiparticles at low fields and multiband effects at higher fields.

High-field de Haas-van Alphen investigation of the filled skutterudite compound NdOs$_4$Sb$_{12}$. P.-C. Ho, Physics/CSU-Fresno, J. Singleton, NHML/LANL, M.B. Maple, Physics/UCSD, P. Goddard, Physics/Oxford U., T. Yanagisawa, Nagita U., Japan — The filled skutterudite compound NdOs$_4$Sb$_{12}$ displays mean-field type ferromagnetism with a Curie temperature of $0.9\text{K}$. The spontaneous magnetization of this compound is $0.75\text{K}$ at $T = 0$. The magnetization is strongly suppressed but remains observable for $x \leq 0.2$. In powder samples prepared by solid state reaction, however, no field is observed for $x = 0.1$ or 0.2. Muon spin relaxation due to dynamic $^{141}$Pr nuclear spin fluctuations is reduced in the powders. Both results can be understood if the density of microscopic defects is smaller in the powders: defects increase muon spin relaxation by $^{141}$Pr spins, and supercurrents associated with defects are predicted to create spontaneous fields in TRS-breaking superconductors. Our results are strong experimental evidence for this prediction.

Non-Fermi liquid behavior in the filled skutterudite compound CeRu$_4$As$_{12}$. R. Baumbach, Physics and IPAPS, UCSD, P.-C. Ho, CSU Fresno, T. Sayles, M.B. Maple, Physics and IPAPS, UCSD, R. Vawreyk, T. Cichorek, A. Pietraszko, Z. Henkie, Low T and Struct, Polish Acad. of Sci. — The filled skutterudite compounds of the form MT$_2$X$_{12}$ (M = alkali metal, alkaline earth, lanthanide, actinide, T = Fe, Ru, Os and X = P, As, Sb) exhibit a wealth of strongly correlated electron phenomena. The CeT$_2$X$_{12}$ subclass is interesting since it includes the only filled skutterudite known to show non-Fermi liquid (NFL) behavior. CeRu$_4$As$_{12}$, in addition to various semiconductors where the gap-size is controlled by the lattice constant. We present electronic resistivity, specific heat, and magnetic susceptibility measurements for the new compound, CeRu$_4$As$_{12}$, which reveals NFL T-dependences at low T, i.e., $\rho(T) \sim T^{1-\delta}$ and weak power law or logarithmic divergences in $C(T)/T$ and $\chi(T)$. Measurements also show that the T-dependence of the thermoelectric power $S(T)$ deviates from that in other Ce systems. The NFL behavior appears to be associated with a nonmagnetic or weakly magnetic ground state, as revealed by magnetization M(H,T) measurements.

Non-Fermi liquid behavior in the filled skutterudite compound CeRu$_4$As$_{12}$. R. Baumbach, Physics and IPAPS, UCSD, P.-C. Ho, CSU Fresno, T. Sayles, M.B. Maple, Physics and IPAPS, UCSD, R. Vawreyk, T. Cichorek, A. Pietraszko, Z. Henkie, Low T and Struct, Polish Acad. of Sci. — The filled skutterudite compounds of the form MT$_2$X$_{12}$ (M = alkali metal, alkaline earth, lanthanide, actinide, T = Fe, Ru, Os and X = P, As, Sb) exhibit a wealth of strongly correlated electron phenomena. The CeT$_2$X$_{12}$ subclass is interesting since it includes the only filled skutterudite known to show non-Fermi liquid (NFL) behavior. CeRu$_4$As$_{12}$, in addition to various semiconductors where the gap-size is controlled by the lattice constant. We present electronic resistivity, specific heat, and magnetic susceptibility measurements for the new compound, CeRu$_4$As$_{12}$, which reveals NFL T-dependences at low T, i.e., $\rho(T) \sim T^{1-\delta}$ and weak power law or logarithmic divergences in $C(T)/T$ and $\chi(T)$. Measurements also show that the T-dependence of the thermoelectric power $S(T)$ deviates from that in other Ce systems. The NFL behavior appears to be associated with a nonmagnetic or weakly magnetic ground state, as revealed by magnetization M(H,T) measurements.

Low-temperature thermal and transport properties of single-crystalline Ce$_4$Pt$_2$Sn$_{25}$. Nobuyuki Kurita, Han-Oh Lee, Yoshifumi Tokiwa, Eric Bauer, Joe Thompson, Los Alamos National Laboratory, Zachary Fisk, Department of Physics, University of California Davis, PEI-Chun Ho, M. Brian Maple, Department of Physics and Institute for Pure and Applied Physical Sciences, University of California-San Diego, Roman Movshovich, Los Alamos National Laboratory — Low-temperature specific heat $C(T)$ and electrical resistivity $\rho(T)$ measurements have been performed on a flux-grown single-crystalline Ce$_4$Pt$_2$Sn$_{25}$ which has a body-centered cubic structure. As temperature decreased, $C(T)$ increased and showed a huge jump $(\Delta C/T \sim 43 J/mole-K^2-Ce)$ at $T \sim 0.2 K$, probably due to a magnetic ordering. The entropy gain connected with the ordering reaches a half of $C(T)$ at $T = 0.2 K$. Corresponding to the degeneracy of the fundamental crystal-field doublet. On the other hand, $\rho(T)$ showed metallic behavior and decreased rapidly around the ordering temperature with a clear kink. We will also discuss the results of external-field effect on this compound.

9:24AM P12.00008 Magnetodynamics of Heavy Fermion YbCo$_2$Zn$_{20}$ and YbFe$_2$Zn$_{20}$, A.D. CHRISTIANSON, Oak Ridge National Laboratory, Oak Ridge 37831, TN USA, E.A. GOREMYCHKIN, Argonne National Laboratory, Argonne, IL 60439, USA, MICHAEL M. KOZÁ, Institut Laue-Langevin, FR-38042 Grenoble, France, J.L. ZARESTKY, Ames Laboratory, Iowa State University, Ames, Iowa 50011, USA, C.H. WANG, University of California, Irvine, California 92697, USA, A.I. KOLESNIKOV, Argonne National Laboratory, Argonne, IL 60439, USA, N. NI, S. JIA, E.D. MUN, S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory and Department of Physics, Iowa State University, Ames, Iowa 50011, USA — We have performed inelastic neutron scattering experiments on the recently discovered heavy Fermion systems YbCo$_2$Zn$_{20}$ and YbFe$_2$Zn$_{20}$. The magnetic excitation spectrum demonstrates that YbCo$_2$Zn$_{20}$ exhibits crystal field dynamics with an overall splitting of 2.72 meV. Despite this, the splitting between the ground state and first excited state is large enough such that the large low temperature electronic specific heat is not due to crystal field entropy and hence YbCo$_2$Zn$_{20}$ is a truly heavy Fermion material. YbFe$_2$Zn$_{20}$ exhibits significantly different spin dynamics. At 200 K the scattering is quasilastic and as the temperature is lowered the spectral weight is progressively shifted to finite energy transfers. This temperature dependence is characteristic of an intermediate valence system with an unusually low Kondo temperature of ~50 K.

9:36AM P12.00009 High field de Haas-van Alphen measurements of RT$_2$Zn$_{20}$ (R=Yb and Lu,T=Fe, Co and Rh)¹, N. NI, S. JIA, Ames Lab / Iowa State University, N. HARRISON, NMFL / Los Alamos, NM, G.D. SAMOLYUK, S.L. BUD’KO, P.C. CANFIELD, Ames Lab / Iowa State University — The de Haas-van Alphen (dHvA) effect in heavy fermion compounds YbFe$_2$Zn$_{20}$, YbCo$_2$Zn$_{20}$ and YbRh$_2$Zn$_{20}$, as well as the nonmagnetic compounds LuFe$_2$Zn$_{20}$, LuCo$_2$Zn$_{20}$ and LuRh$_2$Zn$_{20}$ have been observed in pulsed fields up to 55 T directed along [110] and in the temperature range 0.4K to 12K. The cyclotron effective masses of YbT$_2$Zn$_{20}$ (T=Fe,Co and Rh) range from 1.8m$_e$ to 2.8m$_e$. Self-consistent tight binding linear muffin-tin orbital method in the atomic sphere approximation (TB-LMTO-ASA) has been used to construct Fermi surfaces of LuT$_2$Zn$_{20}$ (T=Fe, Co and Rh). The calculated dHvA frequencies show good agreement with the experiments.

9:48AM P12.00010 Induced Phase Separation in GdBaCo$_2$Fe$_{2}$O$_{5.5-δ}$ by Fe Doping², YAN-KUN TANG, C.C. ALMASAN, Department of Physics, Kent State University, Kent, Ohio 44242, USA — A detailed magnetic study has been carried out for the Fe doped GdBaCo$_{2-δ}$Fe$_{2}$O$_{5.5-δ}$ (x = 0.02, 0.05, 0.10, and 0.20) cobaltites. Fe doping enhances the high temperature ferromagnetism present in the Fe-free samples and it induces a second ferromagnetic order, which develops at a lower T. Also, the spin-state transition temperature shifts to higher T with increasing the Fe content. Phase separation in two magnetic phases, namely, Fe-rich and Fe-free regions, provides a phenomenological interpretation of these magnetic behaviors. The Fe-rich regions are responsible for the second ferromagnetic order present at lower T. The shift of the low temperature M(T) peak related to this second ferromagnetic order is due to the decrease in the oxygen content in the Fe-rich regions with increasing Fe doping and the presence of the antiferromagnetic Fe-Co superexchange interaction in these regions. The high temperature M(T) peak (corresponding to the Fe-free regions) and the spin-state transition temperature shift to higher temperatures with Fe doping because of the slight compression of the Fe-free regions with Fe doping.

10:00AM P12.00011 Quantum Critical Phenomena in Ni$_3$Al$_{1-x}$Ga$_x$ Alloys³, M.H. FANG, Zhejiang University (ZJU) and Tulane University (TU), J.H. YANG, Z.A. XU, JZU, B. CHEN, Y. ITOH, K. YOSHIMURA, Kyoto University, Z.Q. MAO, TU — Considerable study has been devoted to quantum phase transitions (QPTs), which are believed to be a key concept for understanding the physics of strongly correlated electrons. In this talk we report on observation of quantum critical phenomena in Ni$_3$Al$_{1-x}$Ga$_x$ alloys. Ni$_3$Al is a ferromagnetic metal with T$_c$ = 41.5K. With Ga substitution for Al, T$_c$ and the spontaneous magnetic moment are gradually suppressed down to zero near the critical composition of $x_c$ ~ 0.4. We found that near the critical composition the magnetization as a function of magnetic field M(H) and the magnetic susceptibility as a function of temperature $\chi(T)$ both obey the scaling laws theoretically expected for QPTs, i.e., $M(H) \propto H^{1/3}$ and $\chi^{-1} \propto T^{4/3}$. In addition, we observed that near $x_c$ the derivative derived from the Arrott plots, i.e., $\gamma=d(M^2)/d(H/M)$ value exhibits a remarkable peak at about 2-3 T. This peak enhances with decreasing temperature. In terms of a recent theory, we argue that $\gamma$ reflects characteristics of spin excitation spectrum near QPTs.

10:12AM P12.00012 Physical properties of new ternary U compounds U$_3$Bi$_4$M$_3$ (M = Rh, Ni), TOMASZ KLIMCUK, HAN-OH LEE, FILIP RONNING, ERIC BAUER, TOMASZ DURAKIEWICZ, HEATHER VOLZ, JOE THOMPSON, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — A common belief has been that only Sb and Sn can form the U$_3$X$_4$M$_3$ structure. We have observed that also Bi can stabilize the structure as Ce$_3$P$_2$Bi$_4$, the well known Kondo insulator. Resistivity and photoemission spectroscopy measurements on U$_3$Bi$_4$N$_3$ indicate the presence of a charge gap, suggesting that it might be a Kondo insulator. However, the nonmagnetic reference compound Th$_3$Bi$_4$N$_3$ is a semiconductor, and, consequently, U$_3$Bi$_4$N$_3$ is rather a band insulator, similar to U$_3$Sb$_4$N$_3$. On the other hand, replacing Ni with Rh, which has one less electron than Ni, to form U$_3$Bi$_4$Rh$_3$ produces a metallic resistivity and modestly large electronic specific heat coefficient ($\gamma(0.4K) = 200 mJ/mol-U K^2$), characteristic of a Kondo-lattice system. Details of specific heat, magnetic susceptibility and electrical resistivity measurements on these single crystals will be discussed.

10:24AM P12.00013 Electronic and magnetic properties of single-crystalline UNi$_5$Sb$_2$,², B.K. DAVIS, M. S. TORIKACHVILI, Dep. of Physics, San Diego State U., E. D. MUN, J. C. FREDERICK, G. J. MILLER, S. THIMMAIAH, S. L. BUD’KO, P. C. CANFIELD, Ameslab and Iowa State U., G. M. SCHMIEDEHOFF, Dep. of Physics, Occidental C. — We studied the electronic and magnetic properties of antiferromagnetic UNi$_5$Sb$_2$ ($T_N \approx 161 K$) by means of measurements of magnetic susceptibility, thermal expansion, and electrical resistivity ($\rho$) at ambient pressure, and $\rho$ under hydrostatic pressures up to 20 kbar, in the temperature range from 1.9 to 300 K. The value of $\rho(T)/T$ changes drastically from positive below $T_N$ to negative above it, reflecting the loss of spin-disorder scattering in the ordered phase. Two small features in the $\rho$ vs $T$ data centered near 40 and 85 K, which are quite hysteresis in temperature, correlate well in temperature with features in the magnetic susceptibility, and thermal expansion. The effect of pressure is to suppress the amplitude of the small features in $\rho$ vs $T$ at lower temperatures, and to raise $T_N$ at the rate of $\approx 0.76 K/kbar$.

1Supported in part by NSF Grant 0120967 (YT) through the STC MDITR and DOE Grants DE-FG02-04ER15999 (FV) and DE-FG03-97ER45623 (JJR).

9:12AM P13.00007 Time-dependent density-functional approach for exciton binding energies\textsuperscript{1}, VOLODYMYR TURKOWSKI, CARSTEN A. ULLRICH, Department of Physics and Astronomy, University of Missouri, Columbia, MO 65211 — We use TDDFT to study ultrafast electron dynamics and excitonic effects in insulators and semiconductors. Within a two-band approximation of the linearized semiconductor Bloch equations, we derive a TDDFT version of the Wannier equation for excitonic wave functions and binding energies. The TDDFT Wannier equation produces in principle the exact excitonic spectrum. However, this puts stringent requirements on the exchange-correlation (XC) kernel. We analyze various XC kernels that lead to bound excitonic states, and propose new model XC kernels designed to reproduce experimental exciton spectra.

\textsuperscript{1}This work is supported by NSF Grant DMR-0553485.

9:24AM P13.00008 Autoionizing Resonances in TDDFT\textsuperscript{1}, HARSHANI WIJEWARDANE, AUGUST KRUEGER, GABRIELLA MULLADY, NEENA MAITRA, Hunter College of the City University of New York — In an independent-particle picture such as the Kohn-Sham system, bound states with an energy above one of the occupied orbital ionizations are truly bound. When interaction is accounted for, configuration coupling turns the bound state into an autoionizing resonance. In exact TDDFT, it is the exchange-correlation kernel that mixes the ionized and bound state, creating a Fano resonance profile. Although autoionization peaks arising from single excitations have been accurately captured with the available functional approximations, resonances arising from double excitations lying in the continuum are missing. By studying a simple model system, we uncover the features of the exact exchange-correlation kernel that are needed to capture the lifetimes and line shapes of these resonances accurately.

9:48AM P13.00010 Adiabatic connection fluctuation dissipation theorem density functionals beyond the random phase approximation, FILIPP FURCHE, University of California, Irvine — The random phase approximation (RPA) is an increasingly popular starting point for the construction of improved correlation energy functionals. As opposed to semi-local approximations, RPA-based functionals do not suffer from Coulomb self-interaction and naturally include van der Waals interactions; the price is higher computational cost. To compete with traditional correlated wavefunction methods, it is necessary to go beyond the bare RPA. I will analyze successes and failures of recent attempts to do so [1,2], and outline promising future directions. 

10:00AM P13.00011 New Perspectives on the Fundamental Theorem of Density Functional Theory\textsuperscript{1}, VIRAHT SAHNI, The Graduate School, CUNY, XIAO-YIN PAN, Ningbo University — The fundamental theorem of time-dependent/time-independent DFT due to Runge-Gross(RG)/Hohenberg-Kohn(HK) proves the bijectivity between the density $\rho(r)$ and the Hamiltonian $H(t)/H$ to within a function $C(t)/constant C$, and wave function $\Psi(t)/\Psi$. (Implicit in the RG theorem is that the initial condition $\Psi(t_0)$ is fixed.) As such in DFT the wave function is considered solely a functional of the density. Since the density is gauge invariant, the wave function as a functional of the density is also gauge invariant. However, it is well known that the Hamiltonian and wave function are gauge variant. There is, therefore, an inherent inconsistency in the RG/HK theorem. We resolve this inconsistency of the theorem via a unitary or equivalently a gauge transformation. As a consequence we generalize the theorem to external potentials that include the momentum operator and a curl-free vector potential operator. The RG/HK theorems then each constitute a special case of this generalization.

10:12AM P13.00012 Photo-excited dynamics of CH$_2$N$_2$; time-dependent density functional theory, HOSIK LEE, NEC Corp., YOSHIYUKI MIYAMOTO, NANO ELECTRONICS RESEARCH LABORATORIES, NEC CORPORATION TEAM, CREST, JAPAN SCIENCE AND TECHNOLOGY AGENCY TEAM — A highly reactive organic molecule carbene has been an important subject in organic chemistry in several decades. The carbene which is formulated by R$_1$R$_2$C: shows high yield and lesser or no side products during its reaction [1]. By using ultra-fast (sub-pico second) laser flash photolysis(LFP) technique to its precursor diazirine or diazomethane, the highly reactive short-living (~100 fs) carbene can be conveniently prepared and used for production. In this study, photo-excited dynamics of diazirine and diazomethane will be shown within the scheme of the first principles time-dependent density functional calculations. With quite good agreements to experimental photo-excitation spectra, our preliminary calculation results show different phases of molecular motion which hardly is achieved with thermal effect. Temperature-induced kinetic effect in the photo-excited dynamics also is discussed.

10:24AM P13.00013 Time dependent density functional study of enhanced field emission from carbon nanotubes, JOSEPH DRISCOLL, KALMAN VARGA, Vanderbilt University, Nashville — We have calculated the field emission current of carbon nanotubes in real-time and real-space using the Lagrange- function basis [1] combined with efficient time-propagating schemes. Experimental studies reported orders of magnitude increase of field emission current from Cesium deposited carbon nanotubes [2]. We have studied the increase of field emission current due to the deposition of different atoms (Cesium, Gold, Tungsten, etc.) on capped carbon nanotube tips. The theoretical results are in good agreement with the experimental findings. This work was supported by NSF grant ECS 0522146.

Center 205

8:00AM P14.00001 High-Bandwidth Atomic Force Microscopy Reveals A Mechanical spike Accompanying the Action Potential in mammalian Nerve Terminals1, BRIAN M. SALZBERG, University of Pennsylvania School of Medicine — Information transfer from neuron to neuron within nervous systems occurs when the action potential arrives at a nerve terminal and initiates the release of a chemical messenger (neurotransmitter). In the mammalian neurohypophysis (posterior pituitary), large and rapid changes in light scattering accompany secretion of transmitter-like neuropeptides. In the mouse, these intrinsic optical signals are intimately related to the arrival of the action potential (E-wave) and the release of arginine vasopressin and oxytocin (S-wave). We have used a high bandwidth (20 kHz) atomic force microscope (AFM) to demonstrate that these light scattering signals are associated with changes in nerve terminal volume, detected as nanometer-scale movements of a cantilever positioning on top of the neurohypophysis. This method can be applied to any nervous system and may provide new insights into the mechanism(s) by which excitation is coupled to secretion at nerve terminals.

8:36AM P14.00002 Studying Chemical Reactions, One Bond at a Time, with Single Molecule AFM Techniques, JULIO M. FERNANDEZ, Department of Biological Sciences, Columbia University, New York, NY 10027, USA — The mechanisms by which mechanical forces regulate the kinetics of a chemical reaction are unknown. In my lecture I will demonstrate how we use single molecule force-clamp spectroscopy and protein engineering to study the effect of force on the kinetics of thiol/disulfide exchange. Reduction of disulfide bond via the disulfide/disulfide exchange chemical reaction is crucial in regulating protein function and is of common occurrence in mechanically stressed proteins. While reduction is thought to proceed through a substitution nucleophilic bimolecular (SN2) reaction, the role of a mechanical force in modulating this chemical reaction is unknown. We apply a constant stretching force to single engineered disulfide bonds and measure their rate of reduction by dithiothreitol (DTT). We find that while the reduction rate is linearly dependent on the concentration of DTT, it is exponentially dependent on the applied force, increasing 10-fold over a 300 pN range. This result predicts that the disulfide bond lengths by 0.34 Å at the transition state of the thiol/disulfide exchange reaction. In addition to DTT, we also study the reduction of the engineered disulfide bond by the E. coli enzyme thioredoxin (Trx). Thioredoxins are enzymes that catalyze disulfide bond reduction in all organisms. As before, we apply a mechanical force in the range of 25-450 pN to the engineered disulfide bond substrate and monitor the reduction of these bonds by individual enzymes. In sharp contrast with the data obtained with DTT, we now observe two alternative forms of the catalytic reaction, the first requiring a reorientation of the substrate disulfide bond, causing a shortening of the substrate polypeptide by 0.76±0.07 Å, and the second elongating the substrate disulfide bond by 0.21±0.01 Å. These results support the view that the Trx active site regulates the geometry of the participating sulfur atoms, with sub-Ångström precision, in order to achieve efficient catalysis. Single molecule atomic force microscopy (AFM) techniques, as shown here, can probe dynamic rearrangements within an enzyme’s active site which cannot be resolved with any other current structural biological technique. Furthermore, our work at the single bond level directly demonstrates that thiol/disulfide exchange in proteins is a force-dependent chemical reaction. Our findings suggest that mechanical force plays a role in disulfide reduction in vivo, a property which has never been explored by traditional biochemistry.

9:12AM P14.00003 Imaging and Beyond with High Speed AFM, PAUL HANSMA, University of California at Santa Barbara — It is now possible to perform AFM experiments at speeds of up to 600 lines per second over scan ranges exceeding 10 microns. For a 100 x 100 pixel image this gives frame rates of 60 frames/second: faster than video rate. This has required small cantilevers, new scanners, new high voltage amplifiers, and a new scan control system. The small cantilevers are from SCL Sensor-Tech (Deutsch-Wagram, Austria). The new scanner is based on a sophisticated system of flexures that constrain the motion of each separate piezo stack to one dimension in a three-dimensional scanner. It has a scan range of 15 microns and a lowest resonance frequency of about 27 kHz. The new high voltage amplifier, built in collaboration with TechProject (Vienna, Austria), can deliver up to 8 amps over the entire output range from 0 to 150 volts with the challenge of having the piezo as a capacitive load. The new scanner is based around a commercially available DAQ board in a Windows environment. One of the major challenges is now to move beyond imaging to Force-Volume imaging, which involves taking an array of force curves over a sample and then reconstructing a zero force image as well as a map of local mechanical properties.

9:48AM P14.00004 AFM probes with integrated electrostatic actuators for fast, quantitative imaging and force spectroscopy, LEVENT DEGERTEKIN, Georgia Institute of Technology — In this talk, we summarize our efforts in developing novel AFM probes (FIRAT) with integrated sensing and actuation. These probes exploit recent advances in microscale sensor technology and open up the design space for AFM applications including fast imaging, quantitative material characterization and single molecular mechanics measurements. For fast imaging applications in air, probes with aluminum force sensing structures are surface micromachined on quartz substrates. Using 0.7-0.8µm thick, 40µm x 60µm clamped-clamped beams over 2.8µm of air gap, probes with resonance frequencies in the order of 1MHz and Q in the 5-15 range are obtained. These probes are actuated directly by electrostatic forces applied to the mechanical structure by rigid electrodes on the substrate shaped as optical diffraction gratings, enabling imaging bandwidths in the order of 100kHz. The integrated grating interferometer provides 10fm/√Hz level displacement sensitivity down to 3Hz. The surface micromachining approach used for probe fabrication lets one to precisely control the probe dynamics and overcome the difficulties associated with regular AFM cantilevers for applications such as time resolved interaction force (TRIF) measurements. Using FIRAT probes with over damped dynamics, clean TRIF signals are obtained while imaging the surface at regular speeds. This enables us to use a simple model to invert quantitative mechanical properties of a variety of polymers. For measurements on single molecules, membrane type FIRAT probes suitable for in liquid operation have been developed. These probes are made of dielectric materials with embedded actuation electrodes. Used only as actuators or both actuators and force sensors, these devices are shown to enable parallel force spectroscopy measurements. We also show that the spring constant of these probes can be electrically reduced to achieve higher force sensitivity while not affecting its noise performance and discuss the effect of hydrodynamic forces in these membrane type probes as compared to cantilever type probes for fast force spectroscopy measurements.

8:00AM P15.00001 Quantum non-demolition measurement of a superconducting two-level system. ADRIAN LUPASCU, Kavli Institute of NanoScience, Delft University of Technology, The Netherlands — In quantum mechanics, measurement can be understood as the interplay between extraction of information and disturbance of the state of the measured system. For projective measurements this disturbance is minimized: the post-measurement state is fully correlated to the indication of the detector. Quantum non-demolition (QND) detection is a strategy used to implement a projective measurement, which relies on a specific type of interaction between the measured system and the detector. In our experiments we apply these principles to the measurement of a superconducting flux qubit, which is an artificial two-level system built using mesoscopic Josephson junctions. Our detection method relies on probing the response of a hysteretic non-linear resonator coupled to the qubit. This setup allows for very efficient detection of the state of our system, with a measured contrast of 85%. The large correlations between the results of two consecutive measurements demonstrate the QND nature of this method. This result establishes the validity of a QND strategy for projective measurement of superconducting qubits and has implications for quantum information processing.

8:36AM P15.00002 Tunneling of a modulated oscillator: quantum interference in the classically forbidden region. MICHAEL MARTHALER, MARK DYKMAN, Michigan State University — We describe a new coherent quantum effect in periodically modulated systems. It occurs in a modulated nonlinear oscillator and has no analog in two-level systems. The effect consists in oscillations and sign change, with the varying modulation frequency, of the tunnel splitting of the symmetric and antisymmetric time-periodic states. These states are formed by period-2 oscillator states, which classically have the same amplitudes and opposite phases. The effect is due to the wave function oscillations and the related interference in the classically forbidden region of the oscillator phase space. The tunnel splitting oscillations emerge already in the “ground state” of the oscillator Hamiltonian in the rotating frame. The WKB analysis in the rotating wave approximation is in excellent agreement with the numerical results. The tunnel splitting oscillations persist in the parameter range where the rotation wave approximation becomes inapplicable. The effect occurs in the parameter range accessible with currently available Josephson junction-based systems.

9:00AM P15.00004 Measurement induced heat bath and decay rates in circuit QED. MAXIME BOISSONNEAULT, Université de Sherbrooke, JAY GAMBITTA, IQC, University of Waterloo, ALEXANDRE BLAIS, Université de Sherbrooke, YALE CIRCUIT QED TEAM — In circuit QED, a superconducting qubit is fabricated inside a high quality superconducting coplanar resonator. This system allows for strong interaction of the artificial atom with the photon field [1]. In the dispersive regime, where the detuning between the qubit and the resonator frequency is large with respect to their coupling, the physics of this system is understood in terms of Lamb and Stark shifts. However, as the coupling strength or the number of photons in the resonator increases, this description breaks down. In this talk, we will explain that, when taking into account higher order corrections to the dispersive approximation, measurement photons act as a heat bath inducing incoherent relaxation and excitation of the qubit. We will discuss how this can decrease achievable signal-to-noise ratio and may reduce the QND aspect of the measurement. [1] A. Wallraff, et al., Nature 431, 162 (2004)

9:12AM P15.00005 Single shot readout in a circuit QED system. ANDREW HOUCK, Yale University, ALEXANDRE BLAIS, Université de Sherbrooke, STEVEN GRIVIN, ROBERT SCHOELKOPF, Yale University — In the dispersive limit of circuit QED, measurement-induced decoherence can be used for quantum non-demolition measurements of the state of a superconducting qubit. Here, we present an optimization of the measurement of a transmon qubit, including a new understanding of how measurement affects the rate of demolition. Both cavity and qubit parameters were optimized to maximize signal to noise without introducing substantial new channels for decoherence. Single shot readout fidelities of over 70% have been achieved, and greater than 90% fidelity should be possible with presently achievable coherence times. This opens up the possibility of observing quantum jumps in the state of the qubit. Work done in collaboration with the Yale circuit QED team.
9:24AM P15.00006 Dissipation and cooling of a nanomechanical oscillator coupled to a Cooper pair box1, RAKESH TIWARI, D. STROUD, Department of Physics, The Ohio State University — We calculate the dynamics of a nanomechanical oscillator (NMO) coupled capacitively to a Cooper pair box (CPB), by solving a stochastic Schrodinger equation with two Lindblad operators. Both the NMO and the CPB are assumed dissipative. We show numerically that, if the CPB decay time is smaller than the NMO decay time, the coupled NMO will lose energy faster, and the coupled CPB more slowly, than the uncoupled NMO and CPB. We find that both of these effects are largest if 3 times the NMO frequency equals the energy splitting of the CPB. Thus we show that an NMO can be cooled to low temperatures much more efficiently by coupling the NMO to a CPB.

9:36AM P15.00007 Microwave Reflectometry Measurements of Flux States of a dc SQUID Phase Qubit1, B. K. COOPER, R. M. LEWIS, S. K. DUTTA, T. A. PALOMAKI, ANTHONY PRZYBYSZ, H. KWON, HANHEE PAIK, J. R. ANDERSON, C. J. LOBB, F. C. WELLSTOOD — We performed measurements of a 2-junction niobium circuit in a dc-SQUID configuration, with near zero current bias and flux bias close to half a flux quantum. Because of the large self-inductance, the potential of an intrinsic phase qubit has several minima. In order to perform quantum operations from a single well, a technique using low-frequency microwaves is presented. Due to the large self-inductance, the potential of an intrinsic phase qubit has several minima. In order to perform quantum operations from a single well, a technique using low-frequency microwaves is presented.

A single well, a technique using low-frequency microwaves is presented. In order to perform quantum operations from a single well, a technique using low-frequency microwaves is presented.

The utility of this measurement for qubit state readout is discussed.

The utility of this measurement for qubit state readout is discussed.

Our device is a Nb/AlOx/Nb SQUID fabricated by Hypres with loop inductance of 1.3 nH and symmetric junction critical currents of approximately 5 µA. The SQUID is current and flux biased, with one junction used as the qubit and the other used to provide isolation. The isolation junction is shunted by a large capacitor to depress its plasma frequency to about 1.5 GHz. This frequency can be shifted by flux-induced circulating current in the SQUID loop, allowing us to determine which flux state we are in by making reflectometry measurements of the resonant behavior of the isolation junction. The utility of this measurement for qubit state readout is discussed.

The utility of this measurement for qubit state readout is discussed.

We will discuss how the measurement performance depends on biasing parameters of each junction.

We will discuss how the measurement performance depends on biasing parameters of each junction.

9:48AM P15.00008 Measurements of a dc-SQUID phase qubit using rf-reflectometry1, R.M. LEWIS, University of Maryland, B.K. COOPER, S.K. DUTTA, T. A. PALOMAKI, HANHEE PAIK, A. PRZYBYSZ, H. KWN, J. R. ANDERSON, C. J. LOBB, F. C. WELLSTOOD — We performed measurements of a Nb/AlOx/Nb dc-SQUID phase qubit at 100 mK by monitoring the plasma frequency, fp, of the readout/isolation junction. This qubit contains two Josephson junctions (JJs) separated by a 1.3 nH inductance; one JJ operates as a pure phase qubit, the second JJ isolates and reads out the qubit junction. When driving the isolation junction at 1.5 GHz near fp, current fluctuations in the SQUID loop cause fluctuations in fp, which appear in the sidebands of the reflected microwave power. At 100 mK we find an effective flux noise, Sθ2/2 of 50 µµ0/Hz1/2 at 1 Hz. The measurement bandwidth is about 10 MHz, the upper limit being set by the Q of the readout junction. We will discuss how the measurement performance depends on biasing parameters of each junction.

10:00AM P15.00009 DC SQUID Phase Qubit with LC Filter, HYEOKSHIN KWON, A.J. PRZYBYSZ, HANHEE PAIK, R. M. LEWIS, T. A. PALOMAKI, S.K. DUTTA, B.K. COOPER, J.R. ANDERSON, C.J. LOBB, F.C. WELLSTOOD, University of Maryland, College Park — We investigate the use of an inductor-capacitor (LC) network to increase the isolation of a dc SQUID phase qubit from its current bias leads and thereby increase the dissipation time T2 and coherence time T1. One junction in the SQUID acts as an ideal phase qubit while the second junction and the SQUID loop inductance act as a broadband filter to isolate the first junction from the current bias leads. The LC-isolation network provides an additional isolation factor and allows flexibility in the choice of SQUID parameters. In addition to increasing the isolation from the leads, our design minimizes the effects of dielectric loss and two-level systems by using a relatively small Josephson junction, building the devices from Al/AlOx/Al on sapphire, and only using insulating layers (SiNx) in external capacitors for the readout junction and LC network. *Funding provided by JQI, CNAM and the DOD.

10:12AM P15.00010 Strong tunable coupling between a charge qubit and a phase qubit1, AURELIEN FAY, EMILE HOSKINSON, FLORENT LECOCQ, LAURENT LEVY, Institut Neel, CNRS-UJF, FRANK HEKKING, LPMMC, CNRS-UJF, WIEBKE GUICHARD, OLIVIER BUISSON, Institut Neel, CNRS-UJF. — We have studied the quantum dynamics of a superconducting circuit based on a dc-SQUID coupled to a highly asymmetric Cooper pair transistor (ACPT). The dc-SQUID is a phase qubit controlled by a bias current and magnetic field. The ACPT is a charge qubit controlled by a bias current, magnetic flux and gate voltage. We have measured by microwave spectroscopy the lowest quantum levels of the coupled circuit as function of applied flux, bias current and gate voltage. Quantum state measurements of the phase and charge qubit are achieved by a nanosecond flux pulse applied to the dc-SQUID. Our circuit enables the independent manipulation of each qubit as well as the entanglement of the quantum states of the two circuits. We observe avoided level crossings between the two qubits when they are put in resonance. The coupling strength is measured over a large frequency range and varies from 100MHz to 1.3GHz. We succeed to realize a tunable coupling between the charge and the phase qubit. The measured tunable coupling strength is well explained by a combination of a capacitive and a Josephson coupling between the two qubits.

10:24AM P15.00011 Superconducting phase qubit in a “camel” potential1, EMILE HOSKINSON, FLORENT LECOCQ, AURÉLIEN FAY, NICOLAS DIDIER, Institut Neel and LPMMC, CNRS-UJF, Grenoble, France, RALF DOLATA, ALEXANDER ZORIN, PTB, Braunschweig, Germany, FRANK HEKKING, WIEBKE GUICHARD, OLIVIER BUISSON, Institut Neel, CNRS-UJF, Grenoble, France — A prototypical phase qubit consists of a single current biased Josephson junction, in which the dynamics of the phase across the junction is analogous to a quantum particle trapped in a quadratic-cubic potential. We demonstrate a phase qubit in a double barrier quadratic-quartic “camel” potential. This potential is formed by a 2-junction niobium circuit in a dc-SQUID configuration, with near zero current bias and flux bias close to half a flux quantum. Because of the symmetry of the potential, the qubit is predicted to be optimally insensitive to current fluctuations. We perform a nanosecond single shot measurement by applying a flux pulse which reduces the height of the two potential barriers, allowing the excited state of the qubit to escape by two independent paths to an adjacent flux state of the dc-SQUID. We find Rabi oscillation, Ramsey oscillation, and energy relaxation decay times on the order of 60 ns, 20 ns, and 100 ns, respectively. Via spectroscopy, we show that the effects of current noise are rendered negligible in this circuit.

1Supported by the EU through the EuroSQIP project.

10:36AM P15.00012 Properties of a High-Tc Intrinsic Phase Qubit, X. Y. JIN, J. LISENFELD, Y. KOVAL, A. V. USTINOV, P. MÜLLER, Physics Department, Universität Erlangen-Nürnberg, Erwin-Rommel-Str. 1, D-91058, Erlangen, Germany — We discuss the properties of high-Tc intrinsic phase qubits. An intrinsic phase qubit is a superconducting ring made of a Bi2Sr2CaCu2O8+δ single crystal, intercepted by two intrinsic Josephson junction stacks. As a stack consists of many intrinsic Josephson junctions, an intrinsic phase qubit can be regarded as a multi-junction system, i.e. a system of many degrees of freedom in phase space. However, I-V characteristics and switching current distributions of our samples show that an intrinsic phase qubit behaves like a system with only two degrees of freedom, independent of the number of junctions in the stacks, as long as the two stacks are uniform. Due to the large self-inductance, the potential of an intrinsic phase qubit has several minima. In order to perform quantum operations from a single well, a technique using low-frequency microwaves is presented.
Performing a linear stability analysis of the actin velocity due to perturbations of the fragment boundary, we find that as the dimensionless profile is radial and is imposed by mass conservation for constant polymer density. The radius of the fragment is fixed by conservation of total monomer and start moving. In the stationary state in our model, actin polymerizes at the fragment edge and depolymerizes uniformly in the bulk. The initial velocity lies is sufficiently strong. The motivation for this work are the experiments of Verkhovsky et al. (Verkhovsky et al, Curr. Biol., 9: 11-20 (1999)) in which flat, circular, stationary cell fragments on a substrate, containing only actin and myosin motors, can either spontaneously or under applied force change shape and start moving. In the stationary state in our model, actin polymerizes at the fragment edge and depolymerizes uniformly in the bulk. The initial velocity profile is radial and is imposed by mass conservation for constant polymer density. The radius of the fragment is fixed by conservation of total—monomer and filamentous—actin. Performing a linear stability analysis of the actin velocity due to perturbations of the fragment boundary, we find that as the dimensionless parameter $\frac{\xi R_0^2}{\eta} \rightarrow 0$, where $\xi$ is the actin-substrate friction, $\eta$ is the viscosity, and $R_0$ is the initial fragment radius, the perturbed velocity obeys a Darcy Law, and combined with the force-free condition at the fragment boundary, this leads identically to a viscous fingering instability. This asymptotic limit should be achievable since $R_0$ can be tuned by making a fragment with enough actin.

The interaction between severing and annealing in disassembling a model lamellipodial actin network. The network is treated as a periodic array of crosslinked actin filaments which sever randomly. The lamellipodial actin density drops abruptly as a function of distance from the membrane in the absence of annealing. When annealing is included, the drop is more gradual, and at a critical value of the annealing rate the thickness becomes infinite. It is shown that lamellipodial disassembly is controlled by two characteristic times: the time that a single subunit remains in the network, and the time that it takes for actin polymerized at the membrane to move to the edge of the lamellipodium.

The stochastic dynamics of filopodial growth. We have investigated the length distribution of individual filaments in a growing filopodium and studied how it depends on various physical parameters. The distribution of filament lengths turned out to be narrow, which we explained by the negative feedback created by the membrane load and monomeric G-actin gradient. We also discovered that filopodial growth is strongly diminished upon increasing retrograde flow, suggesting that regulating the retrograde flow rate would be a highly efficient way to control filopodial extension dynamics. The filopodial length increases as the membrane fluctuations decrease, which we attributed to the unequal loading of the membrane force among individual filaments, which, in turn, results in larger average polymerization rates. We also observed significant diffusional noise of G-actin monomers, which leads to smaller G-actin flux along the filopodial tube compared with the prediction using the diffusion equation.

Mechanics of Lamellipodia. The actin cytoskeleton is a morphologically-complex assembly of cross-linked F-actin filaments. The cytoskeleton provides rigidity for the cell within appropriate time scales so that it can change its shape to, for example, crawl along surfaces. In addition to cross-linking proteins, many other proteins are involved in the assembly of the actin cytoskeleton such as branching proteins, capping proteins, and severing proteins. Presumably these proteins work cooperatively toward the dynamic formation of rigidity. We will initially focus on the role of branching proteins. The F-actin filaments in lamellipodia—protrusions of the mobile edge of a crawling cell—have some overall orientation due to the branching. Branched filaments emerge at a 70 degree angle from the mother filament’s growing end. This overall orientation is modelled as an anisotropy in an effective medium theory determining the cytoskeleton’s elasticity in the static regime. The potential for a splay rigid phase, in addition to a rigid phase, is also investigated.

9:24AM P16.00006 Nonlinear elasticity of composite networks of stiff biopolymers with flexible linkers. CHASE BROEDERSZ, Vrije Universiteit, C. STORM, Vrije Universiteit and Universiteit Leiden, F. C. MACKINTOSH, Vrije Universiteit — Motivated by recent experiments showing novel rheological properties of biopolymer networks, we develop an effective medium theory for rigid filaments cross-linked by flexible linkers. Specifically, we treat such a network as a collection of randomly oriented stiff polymers mechanically connected by highly compliant cross-linkers to an elastic continuum, which effectively represents the surrounding network. For cross-links with a finite compliance, we find a smooth cross-over between two distinct elastic regimes. Starting from a linear elastic regime dominated by cross-link elasticity, the network begins to stiffen significantly as the cross-links reach full compliance. We extend this model to a self-consistent one, in which the effective medium reflects the non-linear elastic properties of the cross-linked network. This model yields a cross-over to a nonlinear regime that is consistent with recent experimental studies of the cellular cytoskeletal polymer F-actin with filamin cross-links. 

9:36AM P16.00007 Effects of Osmotic Force and Torque on Microtubule Bundling and Pattern Formation. YONGXING GUO, YIFENG LIU, Physics Department, Brown Univ., RUDOLF OLDENBOURG, Marine Biological Laboratory, JAY TANG, JAMES VALLES, Physics Department, Brown Univ. — We report the effect of Polyethylene Glycol (PEG, MW=35kd) on microtubule bundling and pattern formation. Without PEG, polymerizing microtubule (MT) solutions of a few mg/ml [1,2] can spontaneously form striated birefringence patterns through MT alignment, bundling and buckling in coordination. With PEG, bundles become more distinct and the birefringence pattern weakens. Using quantitative birefringence measurements, the average number of MTs in the cross section of a bundle induced by 1% w/w PEG 35kd is determined to be around 26, with a wide spread in size. The amplitude of the buckling is reduced with increased PEG concentration. At sufficiently high PEG concentration (0.5% w/w), the pattern is totally suppressed and the sample contracts laterally during the development of a microtubule bundle network. We propose that the decrease of the buckling amplitude is due to the depletion of the dispersed MT network, which is essential for the pattern formation. We attribute the anisotropic contraction to an osmotic torque that drives bundles that cross to align. [1] Y. Liu, et al, PNAS 103, 10654 (2006). [2] Y. Guo, et al, PRL 98, 198103 (2007). 9:48AM P16.00008 Buckling and force propagation in intracellular microtubules. MOUMITA DAS, Vrije Universiteit, ALEX J. LEVINE, University of California, Los Angeles, F. C. MACKINTOSH, Vrije Universiteit — Motivated by recent experiments [1] showing the buckling of microtubules in cells, we study theoretically the mechanical response of, and force propagation along elastic filaments embedded in a non-linear elastic medium. We find that embedded microtubules buckle when their compressive load exceeds a critical value \( f_c \), which is two orders of magnitude larger than for an isolated MT as found earlier [1], and that the resulting deformation is restricted to a penetration depth that depends on both the non-linear material properties of the surrounding cytoskeleton, as well as the direct coupling of the microtubule to the cytoskeleton possibly through MT-associating proteins (MAPs). The deformation amplitude depends on the applied load \( f > f_c \), as \( (f-f_c)^{1/2} \). This work shows how the range of compressive force transmission by microtubules can be as large as tens of microns, and is governed by the mechanical coupling to the surrounding cytoskeleton.

10:00AM P16.00009 Hydrodynamic tether extrusion from “gelly” vesicles. KARINE GUEVORKIAN, SEBASTIEN KREMER, FRANCOISE BROCHARD-WYART, Institut Curie — Extrusion of cell tethers requires the detachment of the plasma membrane and GPI used to probe the forces generated by membrane-cytoskeleton adhesion. We have studied the hydrodynamic extrusion of tethers from red blood cells [1] and developed a theoretical model based on permeation of lipids through the network of membrane proteins linked to the cytoskeleton [2]. Our aim here is to probe the model on biomimetic systems, namely lipid vesicles filled with artificial cytoskeleton made of synthetic or biological gels, where we can adjust the membrane-cytoskeleton coupling. The properties of tubes extruded from these “gelly” vesicles will be compared to simple vesicles on one hand, and to red blood cells or human carcinoma BON cells on the other. [1] N. Borghi et al, Biophys. J. 93 (2007) [2] F. Brochard-Wyart, et al, Proc. Natl. Acad. Sci. USA, 103 (2006)

10:12AM P16.00010 Living Microlens Arrays. JESSICA ZIMBERLIN, PATRICIA WADSWORTH, ALFRED CROSBY, University of Massachusetts — Using the properties of living cells and early tissue formation, we define adaptable surface structures of three-dimensional, hexagonal arrays of microchannels. These “living” microchannels are achieved by growing a monolayer cell sheet on a thin film of poly(ethylene) [PS] attached to a substrate of crosslinked poly(dimethyl siloxane) [PDMS] microwells. The contractile nature of the cells attached to the surface and the compliance of the PDMS surface geometry allows the PS thin film to buckle, forming arrays of convex microchannels. The curvature of the microchannels is related to the strain applied by monolayer cell sheets to the PS surface. We use this measurement to differentiate the strains applied by two different cell types and relate these strains to differences in the intercellular coupling of the different cell types. We also show that by adding different chemical triggers to the system, the contractile nature of the cells changes, modifying the focal length of the microchannels. This design introduces a new paradigm for advanced materials and offers great promise for a range of applications.

10:24AM P16.00011 Local viscoelasticity of the surfaces of individual Gram-negative bacterial cells measured using atomic force microscopy. VIRGINIA VADILLO-RODRIGUEZ, TERRY BEVERIDGE, JOHN DUTCHER, University of Guelph — The cell wall of Gram-negative bacteria performs many important biological functions: it plays a structural role, it allows the selective movement of molecules across itself, and it allows for growth and division. These functions not only suggest that the cell wall is dynamic, but that its mechanical properties are very important. We have used a novel, AFM-based approach to probe the mechanical properties of single bacterial cells by applying a constant compressive force to the cell under physiological conditions while measuring the time-dependent displacement (creep) of the AFM tip due to the viscoelastic properties of the cell. For these experiments, we chose a representative Gram-negative bacterium, E. coli (E. coli) PA01, and we used AFM tips of different size and geometry. We find that the cell response is well described by a three element mechanical model with an effective cell spring constant \( k \) and an effective time constant \( \tau \) for the creep motion. Adding glutaraldehyde, which increases the covalent bonding of the cell surface, produced a significant increase in \( k \) and a significant decrease in \( \tau \).

10:36AM P16.00012 Stall Force and Response of Lung Cilia. RICHARD SUPERFINE, DAVID HILL, VINAY SWAMINATHAN, E. TIMOTHY O’BRIEN, University of North Carolina, RIC BOUCHER, BRIAN BUTTON, ASHLEY ESTES — We report on the response of lung cilia to applied forces. We have applied magnetic forces to magnetic beads attached to individual human lung cilia in cell cultures. Our magnetic system is capable of generating large forces (~1 nanoNewton on 1 micron beads) with a 3kHz bandwidth. We record the cilium beat motion using video microscopy to record beat frequency and amplitude as a function of applied force. We present three major findings. First, the stall force is approximately 150 pN. Second the frequency is unchanged by the application of forces up to the stall point. Third, the speed of the beat motion slows down according to the diminution of the beat amplitude while maintaining a constant frequency and the speed of the motion is the same whether the beat direction is in the same direction as the applied force or against the applied force.
8:00AM P17.00001 Simulating the Melting Transition of Helium in Two Dimensions . KEOLA WIERSCHEM, MARTECH & Dept. of Physics, Florida State University, EFSTRATIOS MANOUSAKIS, MARTECH & Dept. of Physics, Florida State University, and Dept. of Physics, University of Athens, Greece — We study the melting behavior of $^4\text{He}$ in two dimensions with the path integral Monte Carlo method. Systems of helium atoms are simulated in a periodic cell designed to accommodate a triangular solid. We calculate the translational and orientational order parameters, as well as the defect fraction. Defects are defined as atoms with more or less than six neighbors; the nearest neighbor network is found through Delaunay triangulation. Two dimensional melting is a defect-mediated phase transition, thus, defects will proliferate as the solid is melted. Additionally, melting is expected to occur via a two-stage process, with transitions for both translational and orientational order. At high number density (0.0846 Å$^{-2}$), we have seen a single transition (within the accuracy of our simulations). We are currently working to observe the melting transition at lower densities.

8:12AM P17.00002 Lithium, magnesium and sodium $^4\text{He}$ adsorption experiments performed below 1K. ELI VAN CLEVE, PETER TABOREK, JAMES RUTLEDGE, University of California, Irvine — We have constructed a $^4\text{He}$ optical cryostat and used a previously developed technique of Cryogenic Pulsed Laser Deposition (CPLD) (1), to deposit films of sodium, lithium and magnesium onto the surfaces of quartz crystal microbalances at cryogenic temperatures. The elements in the first and second column of the periodic table interact weakly with adsorbed helium. Theoretical calculations predict that helium will wet all the elements lighter than rubidium, but solid-like layers will not form, so liquid and superfluid films can exist at sub-monolayer coverage. We will present vapor pressure isotherms on Li, Mg and Na substrates in the temperature range 0.5K -1.3K and discuss the wetting and superfluid onset behavior. We will also present in-situ optical work function measurements of the metallic films, and discuss the relation between work function and wettabillity. (1) E. Van Cleve, P. Taborek, J.E. Rutledge JLTP online

8:24AM P17.00003 Third Sound Propagation in Superfluid $^4\text{He}$ Films Adsorbed on Nanotube Bundles . SONNY VO, TIM HSIEH, JOHN SCHULMAN, GARY A. WILLIAMS, UCLA — We have observed the propagation of third sound waves in thin superfluid $^4\text{He}$ films adsorbed on carbon nanotube bundles. The nanotubes are sprayed onto a plexiglass substrate, forming a tangle of interconnected bundles that is about 15 μm thick and 2.5 cm square, with an average bundle diameter of about 4 nm. A heater and bolometer at opposite corners allow detection of resonant third sound modes, and the third sound speed is deduced from the resonant frequencies. The helium adsorption is greatly affected by the surface tension forces generated by the high curvature of the nanotubes, and the film thickness on the tubes remains very thin compared to the thickness in flat regions of the cell. As helium is metered into the cell at 1.3 K the Kosterlitz-Thouless transition on the nanotubes is observed as the onset of the third sound signal, and then with increasing film thickness the third sound velocity decreases. The velocity appears to be dropping towards zero at a finite film thickness. In flat regions of the tube, in qualitative agreement with a surface-tension instability predicted for cylindrical geometries by Cole and Saam [Phys. Rev. Lett., 32, 985 (1974)].

3Work supported by the NSF, DMR 05-48521. We thank D. Hecht and G. Gruner for preparing the nanotubes.

8:36AM P17.00004 Bose-Einstein Coherence in Two Dimensional Superfluid $^4\text{He}$ . SOULEYMANE DIALLO, University of Delaware, JONATHAN PEARCE, National Physical laboratory, UK, RICHARD AZUAH, NIST Center for Neutron Research, JON TAYLOR, Rutherford Appleton Laboratory, HENRY CLEVE, University of Delaware — We present high-resolution measurements of the momentum distribution of atoms in liquid $^4\text{He}$ films adsorbed in nanoporous MCM-41, with 45 Å mean pore diameter. The measurements were performed at temperatures $T = 0.3$ K and $T = 2.3$ K and saturated vapor pressure (SVP) in the wavevectors range $32 < Q < 29$ Å$^{-1}$ using the MARI time-of-flight (TOF) chopper spectrometer at the ISIS spallation neutron source. The main goal is to determine whether there is a Bose-Einstein condensate (or coherence) in a finite-size two dimensional (2D) Bose fluid at low temperatures. It is also to investigate the 2D-3D dimensional crossover in the condensate properties. We find clear evidence of a condensate parameter, $n_0$, at $T = 0.3$ K in the films investigated. In the thinnest film (~approximately one atomic layer thick), the observed condensate fraction is greater than but consistent with the bulk superfluid 4He value of 7.25% within precision; i.e. $n_0 = (9.34 \pm 3.84)\%$. As more $^4\text{He}$ is adsorbed in the substrate pores, $n_0$ appears to decrease below the bulk value, possibly due to the disorder introduced by the confining media; i.e. $n_0 = (2.45 \pm 2.54)\%$ near full pore filling.

8:48AM P17.00005 Dynamics of one and two dimensional solid $^4\text{He}$ adsorbed on nanotubes . BJORN FAK, CEA, DRFMC Grenoble, France, SOULEYMANE DIALLO, University of Delaware, MARK ADAMS, Rutherford Appleton Laboratory, UK, OSCAR VILCHES, University of Washington, HELMUT SCHOBER, Institut Laue Langevin, Grenoble, France, HENRY GLYDE, University of Delaware — In a previous experiment[1], we showed that one dimensional (1D) solid helium can be created on the surface of nanotube bundles. Specifically, when $^4\text{He}$ is first adsorbed on nanotubes, it forms a 1D linear solid along the grooves between two nanotubes on the bundle surface with lattice parameter, $a_1 = 3.40 \pm 0.02$ Å. When more helium is added, 2D solid helium covers the whole bundle surface. We have now determined the vibrational dynamics of these 1D and 2D solids, the dynamic structure factor, $S(Q,\omega)$. From the inelastic intensity integrated over all $\omega$ we obtain the MS amplitude of vibration along 1D chain ($u_2$) = 0.28 Å$^2$ for Lindemann ratio $\gamma = ((u_2)^2/\langle u_2^2 \rangle/\langle u_2^2 \rangle) = 0.15$ which is less than the bulk solid value near melting. The vibrational density states (DOS) of the 2D solid shows a gap at $\omega = 0.75$ meV indicating a commensurate solid as found for $^3\text{He}$ and $^3\text{He}$ on graphite surfaces. In contrast the 1D DOS shows little or no gap and the DOS goes uniformly to zero as $\omega \rightarrow 0$. [1] Pearce et al. Phys. Rev. Lett. 95, 185302 (2005).

9:00AM P17.00006 100-fold reduction of 2D spin-polarized hydrogen gas’s clock-shifts explained . KADEN R.A. HAZZARD, ERICH J. MUELLER, Cornell University — Recent experiments have observed that when two-dimensional spin-polarized hydrogen is adsorbed on a superfluid helium film, the density dependent shift of the 1S-2S spectral line (clock shift) is 100 times smaller than expected [1]. By studying the theory of interactions between hydrogen atoms and helium films, we show that when helium-mediated hydrogen-hydrogen interactions dramatically reduce the clock shift. The mediated potential is sensitive to experimental parameters, such as temperature and $^3\text{He}$ concentration. This explains another mysterious experimental result: we find that increasing $^3\text{He}$ concentration increases the clock-shift, as observed. In contrast, the naive picture which neglects mediated interactions predicts the clock-shift to decrease with $^3\text{He}$ concentration due to deconfinement of the hydrogen gas. [1] J. Ahokas, J. Järvinen, and S. Vasiliev, Phys. Rev. Lett. 98, 43004 (2007).
9:12AM P17.00007 Bound spin waves in the ferromagnetic layer of $^3$He on highly oriented graphite\textsuperscript{1}, LEI GUO, JINSHAN ZHANG, C.M. GOULD, H.M. BOZLER, Univ. of Southern California — The second monolayer of $^3$He on graphites such as Grafoil becomes highly ordered at millidegree temperatures. This system is a good model for nanoscale two-dimensional magnetism because of the large number of separated two-dimensional planes. Motivated by our interest in increasing the structural coherence of the graphite samples that we study, we have used exfoliated ZYX grade graphite as a substrate for our recent experiments. Much of the general picture of finite temperature ordering with ZYX is similar to Grafoil. However, as a byproduct of our increased structural coherence, we have observed several distinct resonances in the ordered spin system. This result is surprising because the structural size of platelets of graphite is not controlled. Nevertheless, the separation of the resonances is consistent with bound two-dimensional spin waves with length scales consistent with the average sizes of the graphite platelets. We will present our analysis of the temperature dependence of the spin wave modes.

9:24AM P17.00008 Spin Pumping in Superfluid $^3$He in High Magnetic Field\textsuperscript{1}. H. KOJIMA, Rutgers University, K. SUZUKI, Y. AOKI, A. YAMAGUCHI, H. ISHIMOTO, ISSP. U. of Tokyo — The spin flow dynamics in superfluid $^3$He $A_1$ phase in magnetic field has been studied up to 13 tesla. The apparatus consists of a large reservoir of $A_1$ phase in which a small enclosed chamber with a built-in differential pressure sensor is immersed. The chamber is connected to the reservoir via a superleak channel. The channel is fabricated from Macor parts such that the residual heat leak is much reduced from those in our experiments. Our focus is on the measurement of relaxation of the induced pressure subsequent to either magnetically induced spin-polarized superflow or by electrostatic spin pumping. In general, both methods of measurement show that the relaxation time $\tau$ of the induced pressure tends to vanish smoothly as the transition temperature $T_\lambda$ is approached. However, the observed dependence of $\tau$ on magnetic field is different. The measured $\tau$ by the field gradient method continues to increase up to 8 tesla. On the other hand, $\tau$ measured by the spin pumping method tends to saturate to a constant between 5 and 13 tesla. The discrepancy is unexpected and not yet understood.

\textsuperscript{1}Research supported in part by the U.S. NSF grant DMR-0704120, JSPS and MEXT of Japan.

9:36AM P17.00009 Discovery of a New Excited Pair State in Superfluid $^3$He\textsuperscript{1}, JOHN P. DAVIS, JOHANNES POLLANEN, HYOJUNGSOON CHOI, JAMES A. SAULS, WILLIAM P. HALPERIN, Northwestern University — In superfluid $^3$He, the order parameter collective modes correspond to excited states of the $^3$He Cooper pairs and are classified by their total angular momentum, $J = L + S$. Many of these modes with $J \leq 2$ have been experimentally observed through longitudinal sound measurements or NMR. As a result of coupling to the collective mode with $J = 2$ and $m_J = \pm 1$ there is an enhanced restoring force for transverse sound in pairs. $^3$He-$B$. Previously, we have used the interference of transverse sound waves to study this collective mode. Recently we have discovered a new coupling to transverse sound near the pair-breaking threshold with the classic signatures of a collective mode. Application of a magnetic field results in circular acoustic birefringence and a new acoustic Faraday effect, from which we extract the corresponding Verdet constant. Selection rules for the coupling to transverse sound and acoustic birefringence require this mode to have $J \geq 4$, suggesting that this mode is most likely the $J = 4$ ($m_J = \pm 1$) mode resulting from an attractive $f$-wave pairing interaction in this $p$-wave superfluid.

\textsuperscript{1}We acknowledge support from the NSF. DMR-0703656.

9:48AM P17.00010 Direct Sound Propagation in Superfluid $^3$He-A in 98% Aerogel\textsuperscript{1}, B. H. MOON, N. MASUHARA, P. BHUPATHI, M. GONZALEZ, M. W. MEISEL, Y. LEE, NHMFL and Dept. of Phys. Univ. of Florida, Gainesville, FL 32611, N. MULDERS, Dept. of Phys and Astronomy, University of Delaware, Newark, DE 19716 — Liquid $^3$He impregnated in high porosity aerogel has been studied extensively in recent years since its unique structure provides static impurities in this system. The fragile nature of $p$-wave Cooper pairs against impurity was clearly demonstrated by the significant depression of the superfluid transition. The scattering off the aerogel also significantly modifies the low energy excitation by inducing impurity bound states inside the gap. Recent ultrasound attenuation measurements performed in the $B$-like phase of superfluid $^3$He in 98% porosity aerogel revealed many interesting features and provided strong experimental evidence of gapless superfluidity. We conducted high frequency sound propagation measurements at 6.22 MHz in the $A$-like phase of superfluid $^3$He. The $A$-like phase is stabilized by magnetic fields (up to 4 kG) applied perpendicular to the direction of sound propagation. We present our preliminary results of ultrasound attenuation down to the zero temperature limit at 29 bar and the field dependent A-B transition identified by the jump in attenuation.

\textsuperscript{1}Supported by NSF DMR-0239483 (YL) and DMR-0701400 (MWM).

10:00AM P17.00011 Effect of Global Anisotropy on Superfluid $^3$He in Compressed Aerogels\textsuperscript{1}, P. BHUPATHI, B. H. MOON, M. GONZALEZ, Y. LEE, Department of Physics, University of Florida, Gainesville, FL 32611-8440, N. MULDERS, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716 — The importance of anisotropic scattering on the superfluid phases of $^3$He has been addressed recently and experiments using uniaxially distorted aerogel have been proposed in order to elucidate the influence of global anisotropy on the A-B transition\textsuperscript{2}. We performed high frequency transverse acoustic impedance measurements on superfluid $^3$He confined in 98% porosity aerogel at 29 bar. The aerogel cylinder is compressed along the symmetry axis to generate global anisotropy. With 10% axial compression, our measurements reveal that the A-like to B-like transition is absent on cooling down to $\sim 350 \mu K$ in the absence of magnetic field and in magnetic fields up to 3 KG. This behavior is in contrast to that in uncompressed aerogels, in which the supercooled A-like to B-like transitions have been identified by various experimental techniques. Our results are consistent with the theoretical prediction by Aoyama and Ikeda.

\textsuperscript{1}This work is supported by NSF grant no. DMR-0239483 (Y.L).

10:12AM P17.00012 Low field NMR in aerogel-confined superfluid $^3$He\textsuperscript{1}. YULIANG DU, H.M. BOZLER, C.M. GOULD, Univ. of Southern California — The superfluid phases of bulk liquid $^3$He were convincingly identified through their longitudinal and transverse NMR spectra. The order parameters of the superfluid phases of $^3$He confined within aerogel have generally been assumed to be identical to those in bulk liquid. While that identification has not been contradicted by experimental data, it has not yet been tested as carefully as in bulk. Fomin has suggested that the A-like phase in aerogel could be an axiplanar state, distinct from the bulk axial state. We have tested the identification by studying low-field NMR which is more sensitive to the distinction between the candidate states. Using the dc SQUID based NMR detection system developed in our laboratory over many years we have studied both longitudinal and transverse resonance spectra in 99.5% porosity aerogel in magnetic fields of 1-4 mT, an order of magnitude lower than previous NMR work. Our work shows qualitative features similar to those found in higher magnetic fields. While we were unable to resolve the longitudinal resonance, transverse resonance measurements exhibit a characteristic field- and temperature-dependence.

10:24AM P17.00013 Dynamics of Quantum Vortices, LARA THOMPSON, UBC, PHILIP STAMP, UBC, PITT —
Quantized vortices exist in systems ranging from low-T magnets, to superfluids and superconductors; however, their dynamics remain controversial. Even the existence of a force acting transverse to the motion (like a Lorentz force) relative to thermal quasiparticles has been widely debated. Quite remarkably, it remains unresolved just what forces act on a quantum vortex. From an influence functional calculation, we show that the expected log divergent mass generalizes to a frequency dependent mass and damping, which, in time, manifest as memory dependent damping forces, acting both longitudinal and transverse to current motion. Based on our numerical simulations to directly estimate this force, we predict the existence of new, previously unconsidered unsuppressed quantum vortices within disc and insulating magnets, we are able to find the various forces, including those resulting from vortex-magnon interactions, and derive their dynamics. In contrast to superfluids and superconductors, an experimental test in insulating magnets should be possible using existing methods.

Wednesday, March 12, 2008 8:00AM - 11:00AM —
Session P18 DPOLY: Polymer Nanocomposites — Morial Convention Center 210

8:00AM P18.00001 Disordered nanoparticle interfaces for defect-tolerance in the self-assembly of block-copolymers, KEVIN YAGER, ALAMGIR KARIM, Polymers Division, National Institute of Standards and Technology, ERIC AMIS, Materials Science and Engineering Laboratory, National Institute of Standards and Technology — Directed self-assembly is a promising route to controlling the nanostructure and surface properties of coatings. We describe a general and robust strategy for controlling the self-assembly of thin films by tuning the film-substrate interaction, using an inherently defective nanoparticle layer. These tunable surfaces exhibit hierarchical and controllable roughness via spin-coating conditions (20 nm silica nanoparticle solutions), and tunable surface energy via selective oxidation. Independent manipulation of these parameters enables control of self-assembled order for coatings cast on these tunable substrates. In particular, we demonstrate control of the orientation of lamellae in poly(3,4-dianilinestyrene-block-methyl methacrylate), with expression of the vertical lamellae orientation under certain conditions. Moreover we demonstrate that the lamellae orientation depends upon film thickness in a periodic manner in the range from 30 nm to 240 nm, which provides insights into the fundamental driving forces in this self-assembly. The proposed assembly orientations are compared with theory and validated by complementary neutron reflectivity and small-angle neutron scattering measurements.

8:12AM P18.00002 Anisotropic Self-Assembly of Spherical Nanoparticles in Polymer Composites, PINAR AKCORA, SANAT K. KUMAR, Columbia University, YU LI, BRIAN BENICEWICZ, LINDA S. SCHADLER, Rensselaer Polytechnic Institute, DEVIRM ACEHAN, New York University, JACK F. DOUGLAS, National Institute of Standard and Technology, COLUMBIA UNIVERSITY COLLABORATION, RPI COLLABORATION, NYU COLLABORATION, NIST COLLABORATION — I will present our recent experimental findings on the organization of isotropic polymer grafted particles forming anisotropic three dimensional structures. Earlier studies have shown that particle shape and anisotropic particle interactions determine the self-assembly process. It has been also shown that isotropic particles can form string like colloidal assemblies within monolayers at two-dimensions but at high particle loadings. Here, I will present the three dimensional sheet structures formed by mixing spherical nanoparticles that are grafted uniformly with long polymers and dispersed in the same homopolymer matrices at relatively low loadings. The molecular origin of this anisotropic organization is the combined short ranged repulsive forces and longer ranged attraction interaction between the particles that is also supported through theory and numerical simulations. The self-assembly of isotropic nanoparticles into anisotropic structures within polymer melts has profound application potentials in improving the electrical and mechanical properties of composite materials.

8:24AM P18.00003 Enthalpic Relaxation of Silica-Polyvinyl Acetate Nanocomposites, SAMUEL AMANUEL, Department of Physics and Astronomy, Union College, Schenectady, NY 12308, SANFORD STEINSTEIN, Department of Materials Science and Engineering, Rensselaer Polytechnic Institute, Troy, NY 12180 — While the effects of nanoparticle size and surface treatment on the glass transition temperature have received well-deserved attention, their effects on other physical parameters associated with the glass transition have received less interest. In order to understand how the incorporation of nanoparticles affects the enthalpic relaxations associated with the glass transition, Differential Scanning Calorimeter (DSC) measurements were carried out on silica-polyvinyl acetate nanocomposites with respect to filler content, annealing temperature and annealing period. As expected, longer annealing periods below the glass transition temperature result in an increase of the subsequent enthalpic relaxations. However, the presence of filler substantially reduces the enthalpic relaxation relative to that of the neat polymer. Even after corrections to account for filler weight, the enthalpic relaxations still decrease monotonically with increasing filler content. The underlying enthalpic relaxations and the effects suppressed by the fillers are specific to the annealing temperature. These results suggest a significant alteration of the physical state of the matrix material by the presence of the filler particles.

8:36AM P18.00004 Particle structuring in stretched soft/hard nanocomposite, YANN LE DIAGON, UPME, STEPHANIE MALLARINO, CHRISTIAN FREITIGNY, CNRS, PPMD TEAM — The deformation mechanisms of nanocomposites made of disordered rigid inclusions imbedded in a soft matrix are rather complex as the local geometry and mechanical responses are very intricate. Atomic force microscopy (AFM) is used to analyze the surface of a model elastomer submitted to uniaxial traction. Since the sample contains monodisperse spherical rigid inclusions, images easily yield statistical data on the positions of the fillers. As expected, it is observed that the displacement field is affine at large scales. At short range, important deviations are observed. Two factors present the characteristic “butterfly” patterns, similar to the neutron scattering patterns obtained on many deformed heterogeneous materials. We show that mechanical confinement of the inter-particular matrix regions must be taken into account in order to explain the results. Finally AFM images reveal higher order correlations: Fillers are observed to be arranged along lines which are roughly perpendicular to the stretching direction. Such a characteristic organization seems to be characteristic of the soft/hard disordered systems.

8:48AM P18.00005 Particle inclusion effect on the rheological properties of polymeric materials, GREGORY TOEPPEPERWEIN, GEORGE PAPAKONSTANTOPOULOS, JUAN DE PABLO, University of Wisconsin — Recently developed algorithms have permitted the extraction of the primitive path and the entanglement length, Ne, from simulations of polymer melts. Experimental studies on the effect of the addition of nanoparticles to a polymer melt have revealed that nanoparticles can alter the plateau modulus and subsequently the entanglement length of the polymer. We use simulations to directly estimate the entanglement length of nanocomposite systems to study the effect of spherical and anisotropic nanoparticles on the entanglement length of a polymer matrix. In this work we present a systematic study of the effects of particle-particle interactions, particle size, aspect ratio and volume fraction. Advanced Monte Carlo techniques involving chain connectivity algorithms are used to create statistically independent configurations. Attractive, neutral and repulsive polymer particle interaction are considered. Furthermore, we examine the effect of different assumptions on the calculation of Ne.

9:00AM P18.00006 Dimensional Analysis of Percolation Theory: Applications to Polymer Composites, DERRICK STEVENS, Dept. of Physics, North Carolina State University (NCSU), TORISSA HOFFMAN, Dept. of Physics, NCSU, RUSSELL GORGA, Dept. of Textiles Engineering, Chemistry and Science, NCSU, LAURA CLARK, Dept. of Physics, NCSU — Percolation theory is well known to describe functional phenomena in polymer composites such as electrical conductivity, when combining a conducting particle and insulating matrix. Nanostructured composites can, however, present unique morphologies that are not easily described by the typical one, two, or three-dimensional viewpoint. One example is random mats of polymer/carbon nanotube (or silver nanoparticle) composite nanofibers. With this motivation, Monte Carlo simulations were developed to investigate various effects within such a fibrous geometry, including changes to the critical volume fraction due to the dimensionality: particle aspect ratio, relative size of particle and fiber (or film), sample size, continuous vs. porous structure. From these simulations a model was developed to predict the percolation threshold based on the dimensionality of the system. The results of these simulations and the derived model will be presented.
A hybrid particle-field (HPF) simulation method for polymer-nanoparticle composites, DOMINIK DUECHS, UC Santa Barbara, SCOTT SIDES, Tech-X Corp., GLENN FREDRICKSON, UC Santa Barbara — A hybrid particle-field (HPF) simulation method for composite systems of polymers and sets of movable particles is presented. The particles are implemented as cavities in an otherwise flat density profile of the polymeric background (corresponding to overall incompressibility), enabling a common treatment of both components in the general framework of well-known self-consistent field theory (SCFT). The particle movements are controlled by force-biased and, where applicable, torque-biased propagation schemes. Particles and polymers interact via local contact interactions originating at the particle surfaces. Simulations with orientationally homogeneous spheres as well as with spheres possessing two distinct sets of interaction parameters on their two hemispheres are compared to experimental results.

Responsive Assemblies: Gold Nanoparticles with Mixed Ligands in Microphase Separated Block Copolymers, JINBO HE, ELIZABETH GLOGOWSKI, QIFANG LI, TODD EMRICK, THOMAS RUSSELL, Department of Polymer Science and Engineering, University of Massachusetts, Amherst, XUEFA LI, JIN WANG, Advanced Photon Source, Argonne National Laboratory, Argonne — A simple method for controlling the spatial distribution of gold nanoparticles in a polystyrene-block-poly (2-vinylpyridine) (PS-b-P2VP) diblock copolymer is shown. By varying the ligand functionality of the gold nanoparticles, as well as the processing and annealing conditions, the distribution of gold nanoparticles in the microdomains of the diblock copolymer was controlled and altered. In addition, the presence of nanoparticles was also found to affect the diblock copolymer morphology. Subsequent thermal annealing causes a coarsening of the nanoparticles, and a sequestration of the nanoparticles to the P2VP microdomain. Further heating leads to an expulsion of the particles from the microdomains, a modification of the interfacial interactions, and a reorientation of the copolymer morphology.

Physical Characterization of Hierarchically Structured Nanocomposites, ROSS BEHLING, ERIC COCHRAN, Iowa State University — In this contribution we present various aspects of the thermodynamics of self assembly in block copolymer / layered silicate nanocomposites (BCLPLs). Hierarchically structured BCLPLs were prepared using an in situ atom transfer radical polymerization (ATRP) approach. The three part synthesis of the materials included an ion exchange functionalization of the clays, sonication during styrene (St) polymerization, and 103˚C for the St. This is a significant Tg enhancement for atactic tBA (Tg = 42˚C) and is attributed to the chain extension which occurs in the confined microscopy (SEM) and transmission electron microscopy (TEM).
Using x-ray photon correlation spectroscopy, we have studied slow, wave vector and temperature dependent microrheology of nano particles embedded in a soft glassy matrix with unique viscoelastic properties. The measurements were done for a polymer matrix (PMMA) using gold nanoparticles as probe. The intensity autocorrelation function exhibits a cross-over from compressed to stretched relaxation behavior on cooling from above the glass transition temperature ($T_g$) of PMMA. Although stretched exponential relaxation is expected in the glassy state one would expect simple exponential relaxation above the $T_g$. We also find that the relaxation time ($\tau_g$) of PMMA follows $\tau \sim q^{-1}$ dependence indicating super-diffusive motion of nanoparticles. Interestingly, we have also observed subtle effects like length scale dependence of the stretching exponent. This points to the importance of the nanoparticles in modifying the viscoelastic property of the polymer matrix and highlights the strength of this technique in extracting their micro-rheological properties.

Wednesday, March 12, 2008 8:00AM - 11:00AM
Session P20 DMP: Focus Session: Engineering Interfaces for New Materials I: Internal Interfaces
Morial Convention Center 212

8:00AM P20.00001 Segregation Effects at Internal Interfaces in Alloys: Atom-Probe Tomographic Experiments and Simulations
DAVID SEIDMAN, Northwestern University — This talk first focuses on experimental studies of solute segregation effects on an atomic scale of solute segregation at grain boundaries (GBs) and heterophase interfaces employing atom-probe field-ion microscopy and three-dimensional atom-probe tomography; both instruments provide a spatial resolution of ca. 0.2 nm in direct space. It is demonstrated that the Gibbsian interfacial excess of solute at an internal interface depends on its five macroscopic degrees of freedom (DOFs), which is consistent with J. Cahn’s local phase rules for GBs and heterophase interfaces. Experimental data is presented for GBs in metallic alloys (e.g. Fe-Si, Al-Sc-Mg, Ni-Al-Cr alloys), and metal silicide/silicon and indium arsenide heterophase interfaces. Secondly, atomic-scale simulations will be presented of GB segregation in binary metallic alloys described by embedded-atom method potentials employing Metropolis algorithm Monte Carlo simulations, which further demonstrate the intimate relationships between GB structure, on an atomic scale, and the Gibbsian interfacial excess of solute. It is also shown how the microscopic DOFs of a GB affect the Gibbsian interfacial excess of solute. Additionally, the results of atom-probe tomographic studies of segregation effects at heterophase interfaces between the gamma (f.c.c.) and gamma prime (L1_2) structure heterophase interfaces in Ni-Al-Cr alloys are discussed and compared in detail with the results of lattice kinetic Monte Carlo (LKMC) simulations, which involves a vacancy mediated diffusion mechanism. The LKMC simulation allow us to explain the role of vacancy-solute binding energies on the observed concentration profiles of Ni, Al, and Cr between the gamma and gamma prime phases. These detailed experimental and simulation studies of segregation effects result in a relatively new atomistic picture of segregation at internal interfaces that differs from the conventional wisdoms found in the literature concerning segregation.

8:36AM P20.00002 Interface structure and radiation damage resistance in Cu-Nb multilayer nanocomposites
MICHAEL DEMKOWICZ, RICHARD HOAGLAND, JOHN HIRTH, Los Alamos National Laboratory — We use atomistic simulations to show that misfit dislocations in Cu-Nb interfaces can shift location between two adjacent planes by forming pairs of extended jogs, a mechanism that involves removal or insertion of atoms. Different jog combinations give rise to interface structures with unlike densities but nearly degenerate energies, making Cu-Nb interfaces virtually inexhaustible sinks for irradiation-induced point defects and catalysts for efficient Frankel pair recombination.

8:48AM P20.00003 Threshold Shear Stresses at Aluminum-Silicon interfaces
ALICE NOREYAN, University of Windsor. YUE QI, General Motors, VESSELIN STOILOV, University of Windsor — The critical shear stress at Cu-Nb interfaces can shift location between two adjacent planes by forming pairs of extended jogs, a mechanism that involves removal or insertion of atoms. Different jog combinations give rise to interface structures with unlike densities but nearly degenerate energies, making Cu-Nb interfaces virtually inexhaustible sinks for irradiation-induced point defects and catalysts for efficient Frankel pair recombination.

9:00AM P20.00004 The strength characterization of Al/Si interfaces with a hybrid nanoindentation/FEM method
SHUMAN XIA, Division of Engineering, Brown University. YUE QI, THOMAS A. PERRY, GM Research & Development Center, KYUNG-SUK KIM, Division of Engineering, Brown University — The mechanical property characterization of the reinforcement/matrix interface in a metal matrix composite (MMC) is entailed for tailoring the interface in the microstructure design of the composite. In this work we developed a hybrid method to characterize the interface strength of an MMC, combining a nanoindentation experiment and a finite element analysis. The nanoindentation experiment was carried out by indenting individual reinforcement particles on a free surface with a nanoindenter. The dependence of indentation response on the interface properties was systematically studied through the finite element analysis with cohesive zone modeling of the interface failure. The interface strength could then be extracted from the comparison between the experimental and FEM results. With this method, the shear strength of an Al/Si interface was measured approximately 240MPa which compares well with the lower bound of an atomistic simulation with a modified EAM potential. The intrinsic fracture toughness of the interface crack tip surrounded by densely populated dislocations was measured 0.25 J/m2. We also studied the effect of the strontium modification on the interface strength with this hybrid method.

9:12AM P20.00005 Atomic Resolution Study of the Interfacial Bonding at Si₃N₄/CeO₂₋δ Grain Boundaries¹. ROBERT F. KLIE, WERONIKA WALKOSZ, SERDAR OGUT, University of Illinois at Chicago, A. BORISEVICH, PAUL F. BECHER, STEVE J. PENNYCOOK, JUAN C. IDROBO, Materials Science and Technology Division, Oak Ridge National Laboratory — Using a combination of atomic resolution Z-contrast imaging and electron energy-loss spectroscopy (EELS) in the scanning transmission electron microscope, we examine the atomic and electronic structures at the interface between Si₃N₄ (10T0) and CeO₂₋δ inter-granular film (IGF). Ce atoms are observed to segregate to the interface in a two-layer periodic arrangement, which is significantly different compared to the structure observed in a previous study. Our EELS experiments show that (i) oxygen is present at the interface in direct contact with the terminating Si₃N₄ open-ring structures, (ii) the Ce valence state changes from +3 to +4 in going from the interface into the IGF, and (iii) while the N concentration decreases away from the Si₃N₄ grains into the IGF, the Si concentration remains uniform across the whole width of the IGF. Possible reasons for these observed structural and electronic variations at the interface and their implications for future studies on Si₃N₄/rare-earth oxide interfaces are briefly discussed.

9:24AM P20.00006 The Influences of different cathode materials on Tris-(8-Hydroxyquinoline)- Aluminum Doped with CsNO₃ in Organic Light emitting Devices. MEI-HSIN CHEN, YIN-JULI LU, CHUNG-CHIH WU, CHIH-I WU, Graduate Institute of Photonics and Optoelectronics — This paper presents the investigations of interfacial interactions and electron-injection mechanisms between cesium nitrate (CsNO₃) and different cathode materials. By using ultraviolet and x-ray photoemission spectroscopy, the properties of electronic structures and the interfacial chemistry are studied. According to our results, there exists a phenomenon of electron exchange at the interface results in changes of Aluminum 2s core level binding energy by 1 eV when aluminum was deposited on CsNO₃. This means electrons transfer from cathode materials to the surface of CsNO₃, forming a strong dipolar field at the interface and reduction of the electron injection barrier. But, in contract, there exists nearly no reaction between CsNO₃ and silver cathode. The evidences show that CsNO₃ is more effective only with aluminum cathode due to a reaction between Aluminum, Cesium and Nitrogen atoms.

9:36AM P20.00007 Atomic-resolution study of cobalt valence and spin-state transitions in Ca₃Co₄O₉ using in-situ scanning transmission electron microscopy. GUANG YANG, YUAN ZHAO, ROBERT KLIE, Department of Physics, University of Illinois at Chicago — The misfit-layered Ca₃Co₄O₉ (CCO) has been of great interest due to its high thermo-electric power and thermal stability. The CCO structure consists of five layers: three rock salt-type layers Ca₃Co₂O₆ are sandwiched between two CdI₂-type Co₂O₆ layers along the c-direction. The presence of different Co valence states is assumed to account for the thermal stability of CCO, and the abrupt changes of electrical resistivity at 420K is believed to be due to a Co spin-state transition. Here, we combine scanning transmission electron microscopy (STEM) with electron energy loss spectroscopy (EELS) to study the atomic and electronic structure of CCO. Using atomic-column resolved EELS, the Co valence states in the different layers are quantified and significant charge transfer from CoO₆ to Ca₂Co₂O₆ is measured. The effects of the potential spin-state transition at 420K on the local structure will be studied by in-situ heating experiments. We will show how atomic-resolution Z-contrast imaging in combination with EELS and in-situ experiments can be utilized to understand the effects of interfacial charge transfer and spin-state transitions in complex oxide materials.

9:48AM P20.00008 The Classical Size Effect: Impact of Grain Boundaries on Resistivity in Encapsulated Cu Thin Films¹. TIK SUN, BO YAO, ANDREW WARREN, KEVIN COFFEY, University of Central Florida, VINEET KUMAR, KATAYUN BARMAK, Carnegie Mellon University — Surface and grain boundary electron scattering contribute significantly to resistivity as the dimensions of polycrystalline metallic conductors are reduced to, and below, the electron mean free path. A methodology is developed to independently evaluate surface and grain boundary scattering in encapsulated polycrystalline Cu thin films, with thicknesses in the range of 27-165 nm. The film resistivity, measured at both room temperature and at 4K, is compared for samples having different grain sizes (as determined from 400 to 1,500 grains per sample) and film thicknesses. The experimental data is compared to models of surface and grain boundary scattering in thin films. The resistivity contribution from grain boundary scattering is found to be significantly greater than that of surface scattering in Cu thin films which allows a quantitative measurement of the parameters for the Mayadas-Shatzkes model. It is also found that the Ta barrier layer prohibits grain growth which explains the higher resistivities observed in encapsulated Cu samples with Ta barrier layers.

¹This research is supported by the SRC, Task 1292-008 and the MRSEC under NSF DMR-0520425.

10:00AM P20.00009 Resistivity induced by electron-grain boundary scattering on thin gold films deposited on mica substrates under high vacuum. RAUL C. MUNOZ, RICARDO HENRIQUEZ, PABLO LEIVA, SIMON OYARZUN, MARCO A. SUAREZ, PAULA MANRIQUE, SIMON SILVA, GERMAN KREMER, LUIS MORAGA, Department of Physics, University of Chile — We report measurements of the room temperature resistivity and of the grain size distribution on a family of gold films deposited onto mica substrates under high vacuum. The films are of approximately the same thickness (100 nm ± 10%), deposited at the same rate (3 nm/min), varying both the temperature of the substrate and the annealing temperature (if any) between −170 °C and +270 °C. The grain distribution was measured with a Scanning Tunneling Microscope. The average grain size decreases from approximately 200 nm to a few nm, when the temperature of the substrate decreases from +270 °C to −170 °C during evaporation. The monotonic decrease in grain size leads to a monotonic increase in resistivity of almost one order of magnitude. The resistivity of the film evaporated with the substrate held at +270 °C and annealed for one hour at +270 °C after evaporation, exhibits a room temperature resistivity only a few percent larger than crystalline gold. Research funded by FONDECYT 1040723.

10:12AM P20.00010 The effect of hydrogen content on intrinsic stress in nanocrystalline diamond (NCD) coatings. HAI BO GUO, University of South Carolina, YUE QI, XINGCHENG XIAO, General Motors R&D, ABHISHEK KOTHARI, BRIAN W. SHELDON, Brown University, MATERIALS AND PROCESSES LAB, GENERAL MOTORS R&D & COLLABORATION, UNIVERSITY OF SOUTH CAROLINA COLLABORATION, BROWN UNIVERSITY COLLABORATION — The stress control is critical to ensure the reliability of nanocrystalline diamond (NCD) coatings. We found the intrinsic stress in NCD is tensile at deposition temperature above 700°C. Decreasing the deposition temperature decreases this tensile stress, and eventually leads to compressive stresses. The stress evolution appears to be largely dictated by grain boundary formation and hydrogen incorporation, which involves absorption, desorption, and recombination kinetics on diamond surfaces. The competition between these reactions indicates that the hydrogen coverage at interfaces should increase with decreasing growth temperature. This is consistent with Raman spectra and elastic recoil detection. To understand hydrogen effects, density functional theory (DFT) is used to model the coalescence of two diamond grains that approach each other to form a grain boundary. The two surfaces exhibit attractive forces when hydrogen coverage is less than 75%, and repulsive forces when all the surface bonds are hydrogen terminated (100% hydrogen coverage). In this way, differences in the hydrogen coverage can explain the observed transition from tensile to compressive intrinsic stress as the growth temperature decreases.
10:24AM P20.00011 Super Hard Cubic Phases of Period VI Transition Metal Nitrides: A First Principles Investigation 1, S.V. KHARE, Department of Physics, University of Toledo, S.K.R. PATIL, Department of MIME, University of Toledo, N.M. MANGALE, Department of EECS, University of Toledo, S. MARSILLAC, Department of Physics, University of Toledo — We report a systematic study of mechanical and electronic properties of 32 cubic phases of nitrides of the transition metals M (M = Hf, Ta, W, Re, Os, Ir, Pt, Au), in zinc-blende, rocksalt, pyrite, and fluorite structure using ab initio computations. Our results reveal that MN2 (M = W, Re, Os, Ir, Pt, Au) in pyrite phase, have a bulk moduli greater than 330 GPa, MN2 (M = Re, Os, Ir) in fluorite phase have a bulk moduli greater than 350 GPa and TaN in rocksalt phase has a bulk modulus of 380 GPa making them candidates for super hard materials. Based on the bulk and shear modulus for stable phases, potential hard coating materials for cutting tools have been identified. Structural stability of stable binding phases has been obtained by linked to a transition chain. The high values of bulk moduli are attributed to strong bonding of transition metal d-orbitals with nitrogen p-orbitals. The trend in the bulk modulus is related to the valence electron density of these materials.

1We thank Wright Patterson Air Force Base and Ohio Board of Regents for supporting this work.

10:36AM P20.00012 Coherent atomic motion in nano-crystal film 1, JUNJIE LI, XUAN WANG, SHOUHUA NIE, RICHARD CLINITE, JIANMING CAO, Physics Department and National High Magnetic Field Laboratory, Florida State University — We report a theoretical study of the structural dynamics in metallic film in response to ultrafast laser heating. A two-dimensional model using a harmonic approximation is used to simulate the lattice dynamics. We examine the response of the adatom. The linear arrangement of favorable binding sites induces the self-organization of Au atoms into chains. For every ad-chain, the number of neighbors is increased by 1 and the distance between neighboring adatoms is increased by a constant value. The adatom-atom interaction in a metal film is considered in order to determine the modes of lattice motions. Moreover, a large projection of coherent lattice oscillation in the in-plane direction is found, which was previously thought to be very small and was neglected in one-dimensional models. The simulation agrees well with our femtosecond electron diffraction measurements.

1Physics Department and National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32310

10:48AM P20.00013 Tuning physical properties by assembling subnanometer inorganic and organic units, YONG ZHANG, P.A. PARILLA, S.P. AHRENKIEL, A. MASCARENHAS, NREL, Z. ISLAM, Y. REN, P.L. LEE, APS/ANL, M.J. MCNEVIN, UC. Boulder, I. NAUMOV, H.X. FU, U. Arkansas, X.Y. HUANG, J. LI, Rutgers U. — Designing inorganic-organic hybrid materials in a nanoscopic scale allows taking the full advantage of the two worlds, which has recently been demonstrated in a new family of hybrid crystalline materials that are the fully ordered assemblies of sub-nanometer scale inorganic units (e.g., few monolayer-thick slab, single atomic chain) and organic molecules[1]. They have been shown to exhibit a number of unique properties that are not readily available in either of the components or their nanostructures: for instance, strongly enhanced exciton-polariton absorption and exciton binding energy[2], a massive bandgap blue shift (~2 eV) from that of the bulk inorganic semiconductor[3], and fine-tuning of thermal expansion and achieving zero-thermal-expansion[4]. They have great potential for applications in areas including transparent conductors, thermoelectric materials, UV optoelectronic devices, because of their unusual electronic, vibrational and optical properties and the flexibility in tailoring the material properties adapting to the specific application requirements. Wednesday, March 12, 2008 8:00AM - 11:00AM — Session P21 DCP: Focus Session: Fundamental Issues in Catalysis | Morial Convention Center 213

8:00AM P21.00001 The role of hot electrons in catalysis science, GABOR A. SOMORJAI, Department of Chemistry, University of California Berkeley — One long-standing observation in the field of heterogeneous catalysis is that the activity and selectivity in certain reactions is dramatically affected by the oxide onto which the metal nanoparticles are deposited, even though the oxide itself is not active in catalysis. Recently, studies which detected hot electron formation at metal surfaces helped to explain these curious findings. Pulse probe experiments have detected hot electron formation within femtoseconds when photons are incident on a metal surface. Experiments indicate that the mean free path of these hot electrons is on the order of 5 nm, which is in the range of the size of catalytic nanoparticles. Further studies indicate that exothermic catalytic reactions can also produce hot electrons readily, for example CO oxidation or the reaction of hydrogen and oxygen to form water. We have constructed a “catalytic nanodiode” in our laboratory whereby we carry out catalytic reactions at high and continuous turnover and, using a Schottky barrier, collect hot electrons. Simultaneous measurement of turnover frequency and hot electron current during CO oxidation has shown that the hot electron current and the turnover rate for the reaction are correlated. This implies that the catalytic activity at the oxide-metal interface in certain catalytic reactions is associated with the hot electron flow.

8:36AM P21.00002 CO oxidation over noble metals: The continuum from ultrahigh vacuum to atmospheric pressures, DAVID GOODMAN, Texas A&M University — Catalytic oxidation of CO has been investigated for many decades by numerous researchers and is considered to be one of the best understood catalytic reactions. Because of its importance in pollution control, fuel cells, etc., this reaction has received considerable attention for fundamental and practical reasons. Removal of CO from automobile exhaust is accomplished by catalytic converters using supported Pt-group metals of Pt, Pd and Rh catalysts. The catalytically removal of traces of CO from H2 by Pt-group metals to the few ppm level is required for efficient operation in fuel cells. Efforts in our laboratory have addressed the adsorption of CO and the kinetics of CO-oxidation on single crystals and supported metal catalysts over a wide temperature (400–650 K) and pressure (1–10 bar) range. Two active phases, CO-dominated and O-dominated, have been identified for which the mechanisms for CO catalytic oxidation are entirely different. The highly active phase formed in oxygen-rich crystals and supported metal catalysts over a wide temperature (400–650 K) and pressure (1–10 bar) range. Two active phases, CO-dominated and O-dominated, have been identified for which the mechanisms for CO catalytic oxidation are entirely different. 9:12AM P21.00003 Gold atoms, chains and islands on oxide films: looking at orbitals and counting electrons, HAJO FREUND, Fritz Haber Institute of the Max Planck Society — Low-temperature STM measurements combined with DFT calculations are employed to analyze the adsorption of gold on alumina/NiAl(110). The binding of Au monomers involves breaking of an oxide Al-O bond below the adatom and stabilizing the hence under-coordinated O ion by forming a new bond to an Al atom in the NiAl. The adsorption implies negative charging of the adatom. The linear arrangement of favorable binding sites induces the self-organization of Au atoms into chains. For every ad-chain, the number of electrons, in particular of transfer-electrons from the support, is determined by analyzing the node structure of its HOMO.

9:48AM P21.00004 Theoretical Insights into C1 Surface Chemistry, MATTHEW NEUROCK, University of Virginia — Reforming and partial oxidation of methane as well as other C1 fuels are important processes in the production of hydrogen and synthesis gas and will likely play important roles future energy strategies. Herein we use theory and simulation to examine the reactivity of methane, methanol and dimethylether with CO2, H2O, or O2 supported transition metals. We systematically probe the elementary C-H bond activation as well as the oxidation pathways involved in both reforming as the oxidation of methane and other C1 intermediates over well defined transition metal surfaces, metal alloys and metal nanoparticles. The calculations demonstrate well-established trends in C-H bond activation as the result of changes in the metal, the activating molecule (methane, methanol, and DME) as well as the reaction conditions. The reaction conditions ultimately dictate the surface coverage of carbon and oxygen which have important consequences on the surface reactivity. The theoretical and simulation results are compared with well defined experiments carried out at Berkeley over supported particles.
10:24AM P21.00005 Atomic ordering periodicity and catalytic properties of nanoparticles. VALERI PETKOV, Central Michigan University — Often nanosized particles of crystals are catalytically very active while the corresponding crystals are not. A typical example is gold. The enhanced catalytic performance of nanosized particles, however, does not come merely from their greatly enhanced surface-to-volume ratio. We would like to draw attention to the often overlooked fact that nanosized particles of crystals do not necessarily possess the periodic 3D structure of their bulk counterparts, and this too may impact their catalytic properties substantially. In particular, nanoparticles that do not have a periodic 3D structure may not contain in a well-defined, faceted shape, i.e. may be not terminated by well-defined (usually high energy) atomic planes, as crystalline objects of the same size would be. Hence, nanoparticles may be catalytically more (or less) active than “nanized” crystals. Results from recent structure studies (synchrotron XRD and computer simulations) on 1 – 5 nm Ru, Au and Pt particles will be presented as evidence.

10:36AM P21.00006 First-principles investigation of Ag-Cu alloy surfaces in an oxidizing environment. SIMONE PICCININ, CATHERINE STAMPFL, The School of Physics, The University of Sydney, Australia, MATTHIAS SCHAFFLER, Fritz-Haber-Institut der Max-Planck-Gesellschaft, Germany — By means of density-functional theory, together with concepts from atomistic thermodynamics, we present a theoretical procedure for describing the structure and stoichiometry of a binary alloy in contact with a surrounding gas phase environment. We apply the approach to the Ag-Cu alloy in an oxygen atmosphere, for which recent results report a superior selectivity for ethylene epoxidation compared to pure silver, the predominant catalyst for this reaction. We first show that the presence of oxygen leads to copper segregation to the surface. Then, considering the surface free energy as a function of the surface Cu composition, we construct the “convex hull”. By including the dependence of the surface free energy of the oxygen chemical potential, we determine the phase diagram of the alloy as a function of temperature, pressure, and Cu surface content. We predict that for conditions typical of the epoxidation reaction, a number of structures can be present on the surface of the alloy including the clean silver surface, thin copper-oxide-like structures, and thick copper oxides. These findings are consistent with, and help explain the recent experimental results. We envisage this approach will be useful and generally applicable for the study of other alloys in contact with a gas or liquid phase.

10:48AM P21.00007 The Cu/ZnO(0001) Surface under Oxidative and Reducing Conditions: A First-principles Study. KAWATU CHUAISIRIPATTANA, OLIVER WARSCHKOW, University of Sydney, School of Physics, BERNARD DELLEY, Paul Scherrer Institut, Villigen Switzerland, CATHERINE STAMPFL, University of Sydney, School of Physics — The Cu/ZnO(0001) surface is widely used as a catalyst for the production of H₂-gas from methanol and is thus of considerable relevance to the emergent hydrogen economy. A key to the further development of this catalyst system is the understanding of the relation between surface structure and function versus environmental conditions such as copper content and state of surface oxidation. Towards this goal, we use density functional theory within the framework of ab initio atomistic thermodynamics to conduct a detailed study of conceivable surface structures under variety of Cu exposures. This produces a surface phase diagram that reveals several distinct regimes of surface reconstruction under oxygen-rich and poor conditions. We correlate our findings with experimental studies, including recent scanning tunneling microscopy results by Dulub et al [1].

8:00AM P22.00001 High Performance Solution Processable TFTs. DAVID GUNDLACH, NIST — Organic-based electronic devices offer the potential to significantly impact the functionality and pervasiveness of large-area electronics. We report on soluble acene-based organic thin film transistors (OTFTs) where the microstructure of as-cast films can be precisely controlled via interfacial chemistry. Chemically tailoring the source/drain contact interface is a novel route to self-patterning of soluble small molecule organic semiconductors and enables the growth of highly ordered regions along opposing contact edges which extend into the transistor channel. The unique film forming properties of soluble fluorinated anthradithiophenes allows us to fabricate high performance OTFTs, OTFT circuits, and to deterministically study the influence of the film microstructure on the electrical characteristics of devices. Most recently we have grown single crystals of soluble fluorinated anthradithiophenes by vapor transport method allowing us to probe deeper into their intrinsic properties and determine the potential and limitations of this promising family of oligomers for use in organic-based electronic devices. 8:36AM P22.00002 Solution-Processible Thin Film Transistors Using Surface-modified BaTiO³/Polymer Nanocomposites as Gate Insulators. PHILSEOK KIM, Georgia Institute of Technology, XIAOHONG ZHANG, PETER HOTCHKISS, BENOIT DOMERQ, SIMON JONES, SETH MARDER, BERNARD KIPPELEN, JOSEPH PERRY — Polymer/ceramic nanocomposites (NC) can exhibit high k and easily processible materials suitable for gate insulators in organic field-effect transistors (OFET). To obtain high k NCs, high volume fractions (>30 %) of dielectric nanoparticles (NP) are needed. However, due to NP agglomeration at such high volume fractions, poor quality films with high leakage current are obtained. Recently, we have reported that phosphonic acids can strongly bind to BaTiO₃ (BT) NPs and provide enhanced dispersability of NPs in polymer hosts allowing increased volume loading. We report the use of phosphonic acid-modified BT NPs (30–50 nm in poly(4- vinyl phenol) (PVP, k = 3.9) as gate insulators in OFET, which can be readily processed to high quality thin films by simple solution techniques. BT NPs modified with a phosphonic acid bearing a hydrophilic group afforded high quality NC thin films at high loading (up to 75 wt. %) in PVP. Bottom-gate pentacene OFET devices were fabricated on the NC gate insulators. The improved film quality and increased capacitance density (~50 nF/cm², k ~14) were reflected in a low threshold voltage (~1.1 V), a high on/off ratio (~2×10⁶) and ~10⁵ fold decrease in leakage current as compared to that of unmodified BT.

8:48AM P22.00003 Evolution of the Unoccupied States in Alikali metal doped Copper-Phthalocyanine. HUANJUN DING, KIWAN PARK, YONGLI GAO, University of Rochester — The evolution of both the occupied and unoccupied states for Cs and Na-doped Copper-Phthalocyanine (CuPc) has been investigated with photoemission and inverse photoemission spectroscopy (IPES). From the IPES measurement, it is observed that, as the alkali doping ratio increases, the lowest unoccupied molecular orbital (LUMO) of CuPc shifts toward the Fermi level, and the shift becomes saturated when the LUMO edge is aligned with the Fermi level. After the saturation, the LUMO intensity decreases monotonically, while a gap state grows in the valence spectra. The evolution of the LUMO gives direct evidence for the origin of the doping-induced gap state in CuPc molecules. The intensity of the LUMO, as well as the gap state, for high Cs doping ratios clearly suggests that multiply charged CuPc species are formed in the doped film.
selectivity/sensitivity can be enhanced by incorporating organic receptors. Significant dipole moments such as ketones and alcohols. We will describe the physics of operation of such sensors in various modes and also outline how the integration of organic and inorganic oxides such as SnO₂/xerogel can be achieved using a variety of techniques. The films were grown in-situ, using organic molecular beam deposition. The C and N K-edge spectra display similarities with those from other metal-Pcs, while the O K-edge and Ti L-edge spectra support the premise that the titanyl species are spatially isolated. Good agreement is found between a calculation of the partial density of states and the measured spectra. The Ti L-edge spectra display marked differences with previous reports. Two energy-loss features are reported from resonant x-ray inelastic scattering of the Ti L-edge associated with Ti 3d-O 2p and Ti 3d-N 2p charge transfer transitions. Our measurements will be discussed in the context of earlier soft x-ray studies of TiO₂, with particular attention paid to issues of contamination and beam damage.

9:12AM P22.00005 Charge transport mechanisms in phthalocyanine thin films. CORNELIU COLENSIUC, AMOS SHARONI, IVAN K. SCHULLER, Department of Physics, University of California San Diego, La Jolla, CA 92033 — Devices consisting of phthalocyanine thin films sandwiched between gold electrodes were fabricated by organic molecular beam deposition. Samples with different organic layer thicknesses were deposited on sapphire substrates in-situ, using a shadow mask and a mobile sample holder controlled manually. The structural asymmetry of the devices determined by the different metal-organic interfaces is reflected in the I-V curves at positive and negative voltages. The logarithmic scale I-V plots can be fitted with linear functions of different slopes corresponding to different conduction regimes. At low temperatures a transition from the ohmic regime to a slope two space charge limited conduction mechanism is followed at higher voltages by a high slope linear dependence that tends to saturate when the voltage reaches maximum values. At higher temperatures the intermediary space charge limited regime disappears and the transition is from ohmic to high slope space charge limited. Traps with different energy and energy distribution determine the different conduction regimes. Shallow traps located at discrete energy levels control the transport at intermediate voltages while exponentially distributed traps determine the high voltage behavior. Work supported by AFOSR-MURI.

9:24AM P22.00006 Soft X-Ray Spectroscopic Studies of the Electronic Structure of Aluminum tris-8-hydroxyquinoline (Alq₃). A. DEMASI, L.F.J. PIPER, Y. ZHANG, I. REID, S. WANG, K.E. SMITH, Boston University, J. DONNES, Macquarie University, N. PELTEKIS, C. MCGUINNESS, Trinity College Dublin, A. MATSUURA, In-Q-Tel — The valence and core level electronic structure of the organic semiconductor aluminum tris-8-hydroxyquinoline (Alq₃) has been measured using synchrotron radiation-excited resonant x-ray emission spectroscopy (RXES), and x-ray photoelectron spectroscopy (XPS). Samples were in the form of thin films, grown in-situ in an organic molecular beam deposition chamber attached to the spectrometer system. The films were found to be highly sensitive to photon induced beam damage, but this problem could be alleviated by continuous translation of the films during measurement. Our RXES measurements are compared to the results of density functional theory (DFT) calculations. The DFT calculated C, N and O partial densities of states are found to agree very well with the corresponding emission spectra. Our measurements will be discussed in the context of earlier soft x-ray studies of Alq₃, with particular attention paid to issues of beam damage.

9:36AM P22.00007 High Carrier Density and High Hole Mobilities of Ion Gel Gated Polymer Thin-Film Transistors. JIYOUN LEE, C. DANIEL FRIEBIE,1 Department of Chemical Engineering and Materials Science, University of Minnesota, TIMOTHY P. LODGE, Departments of Chemistry and Chemical Engineering and Materials Science, University of Minnesota — We report the comprehensive study of a highly conductive polymer thin-film transistors (IG-PTFT), in which POT-12 was used as the active ion gel comprising a polymeric network swollen with an ionic liquid as the gate dielectric. The high capacitance of ion gels (>10 μF/cm²) can induce a very large hole density (~2 x 10¹⁴ charges/cm²) in the channel of polymer semiconductor layers in IG-PTFTs, leading to low operation voltages, high hole mobilities of > 1 cm²/Vs, and high ON currents. High ionic conductivities of ion gels (> 1 mS/cm) enable fast response time (~1.5 ms at 80 % ON/OFF) of IG-PTFTs. Temperature dependent measurements were carried out with IG-PTFTs. In the high temperature range (310 K ~ 360 K), the device showed faster response time and little hysteresis due to increasing ionic conductivity with the operating temperature. At low temperature (20 K ~ 185 K) where the ions are immobile, high ON currents between source and drain can be maintained with weak temperature dependence. Overall, the results demonstrate that the IG-PTFTs offer opportunities to probe transport of high 2-D charge carrier densities in semiconductors.

9:48AM P22.00008 Ionic-doping-induced nonvolatile switching in conductive polymer/inorganic complex for nonvolatile memory. QIANXI LAI, YONG CHEN, Department of Mechanical & Aerospace Engineering, University of California-Los Angeles — Organic nonvolatile memories have received extensive attention in recent years due to their low cost and high scalability. We have studied the nonvolatile switching property of a metal/conductive polymer (MEHPPV)/metal system which is induced by ionic doping under electric field. The switching phenomenon have been observed both in devices doped by electrochemical doping in liquid solution (TBAl) and in devices integrated with a solid electrolyte (RbAg4I5) in the device structure. The device can be switched from its high-resistance state (OFF) to its low resistance state (ON) by a threshold voltage with appropriate polarity and vice versa. The switching on/off ratio is more than 3 orders of magnitude with a switching time as short as 1us and the switching is reversible and repeatable. The resistance change is attributed to the reversible p-type doping of MEH-PPV by injecting/extracting iodide anions into/from the conductive polymer under the voltage bias above certain threshold amplitude. The results of Capacitance-Voltage (CV) measurements also indicated the ion migration in the polymer under the electric field.

10:00AM P22.00009 Chemical Vapor Sensing Using Dual Channel Hybrid Organic/Inorganic Field-Effect Transistors. SHANNON LEWIS, The University of Texas at Austin, SEBASTIAN SCHOEFER, The University of Texas at Austin, DEEPAK SHARMA, ANANTH DODABALAPUR, The University of Texas at Austin — We have developed a field-effect chemical sensing device architecture in which two semiconducting channels are employed, one of which is exposed to the analyte and is chemically sensitive. The second channel (usually silicon) is used for signal transduction/amplification. Such sensors work can work in many device modes including one that can be described as a “chemical memory mode”. For the chemically sensitive channel, several classes of materials can be employed including small molecule organic semiconductors, conjugated polymers, and inorganic oxides such as SnO₂. With organic semiconductor channels, it is possible to demonstrate charge trapping of volatile organic molecules with significant dipole moments such as ketones and alcohols. We will describe the physics of operation of such sensors in various modes and also outline how the selectivity/sensitivity can be enhanced by incorporating organic receptors.
10:12AM P22.00010 Correlation of microstructure and magnetotransport in organic semiconductor spin valve structures†. Y. LIU, J. GORHAM, T. LEE, H. FAIRBROTHER, H. E. KATZ, D. H. REICH, The Johns Hopkins University, S. WASTON, J. BORCHERS, NIST — Magnetic/electric devices based on organic semiconductors (OSC) hold promise due to the long spin relaxation time and the ability to tune relevant properties such as interface barriers. However, it is unclear to date whether magnetotransport effects observed in these systems is due to tunneling, or whether spin-coherent diffusive transport is also possible. We have studied magnetotransport in Co/OsC/Fe trilayer junctions, with 50 to 150 nm thick OSC layer, where tunneling would not be expected. Positive magnetoresistance (MR) is observed at T = 4.2 K for several OSCs and it persists up to T = 290 K for two systems: tris(8-hydroxyquinoline) Aluminum (III) (Alq3) and copper phthalocyanine (CuPc). In order to probe the origins of MR, we have done structural studies on Co/Alq3/Fe trilayer films by x-ray reflectivity and Auger depth profiling. The results indicate well-defined layers with modest interface roughness (3-5 nm) between the Alq3 and the surrounding FM layers. While these results rule out large-scale intermixing of Co or Fe into the OSC, they do not as yet rule out the existence of local defects, such as pinholes, in the OSC layers that could enable tunneling to occur.

10:24AM P22.00011 EPR Studies of Highly Interconnected Nanostructured Polyaniline Network†. OLUDUROTIMI O. ADETUNJI, N.-R. CHIOU, N.P. RAJU, A.J. EPSTEIN, Department of Physics, The Ohio State University, Columbus, OH 43210-1117 — We present temperature-dependent X-band electron paramagnetic resonance susceptibility and linewidth studies of nanostructured polyaniline doped with perchloric acid (PANN/HClO4). From analysis of the EPR data we determine that network has both Pauli- and Curie-like susceptibility with X’ of ~2 x 10^-5 emu/mole-2-ring repeat unit and a localized spin density of ~1 spin per 400 2-ring repeat units and exhibits a Lorentzian-like lineshape. The EPR linewidth from 100 K to room temperature exhibits two different linear regimes, where the linewidth increases linearly with increase in temperature. We will discuss the role of Korrina relaxation in determining the high temperature linewidth. We will consider the roles of disorder, localization and interfiber contact within the nanostructure network.

10:36AM P22.00012 Capacitance-voltage characterization of polythiophene-based field-effect transistors. BEHRANG HAMADANI, NIST, IAIN MCCULLOCH, Imperial College, MARTIN HEENEY, Queen Mary University of London, DAVID GUNDLACH, NIST, NIST COLLABORATION, IMPERIAL COLLEGE COLLABORATION — We report on frequency-dependent capacitance-voltage characteristics of organic field-effect transistors based on (2,5-bis(3-tetradecylthiophen-2-yl)thieno[3,2-b]thiophene) as the active polymer layer. The gate voltage and frequency behavior of the devices with the polymer spun on treated and untreated oxide gate dielectric are explored. The high quality of the devices (contact and channel properties) allows the use of traditional CV modeling to accurately describe the electronic characteristics of the intrinsic channel. The findings from this study provide new insight into charge trapping and transport in the field-accumulated channel of organic field-effect devices.
