were not understood in the West until the 1970s. I will discuss some of the properties of Islamic quasicrystalline tilings, and their relation to the Penrose tiling, construct nearly-perfect quasicrystalline patterns. These patterns have remarkable properties; they do not repeat periodically, and have special symmetry—and creation of increasingly complex periodic girih patterns, and by the 15th century, the tessellation approach was combined with self-similar transformations to zigzagging lines, and drafted directly with a straightedge and a compass. I discuss our recent findings that, by 1200 A. D., a conceptual breakthrough occurred. This result paves the way for a variety of investigations and theoretical predictions now varying both the hole doping x and J2. Other issues in the area of multifractals will also be addressed in this presentation, including the prediction of ferroelectricity in the spin zigzag E-type AF state.

First, the composite of two fractals is not generally scale invariant and exhibits complex multifractal scaling in the small flawed, and that fractal analysis as an authentication tool yields inconsistent and unreliable results. This work has also led to two new results in fractal analysis following the recent discovery of a cache of disputed Pollock paintings. I will demonstrate that this hypothesis of “Fractal Expressivism” is fundamentally characterized as fractal, and that fractal analysis can be used to authenticate works of unknown origin. This academic issue has become of more general interest issues in the area of multiferroics will also be addressed in this presentation, including the prediction of ferroelectricity in the spin zigzag E-type AF state.

Session W5 FPS: Physics Meets Art 401/402

11:15AM W5.00001 Quasicrystals in Medieval Islamic Architecture , PETER LU, Harvard University — The conventional view holds that girih (geometric star-and-polygon) patterns in medieval Islamic architecture were conceived by their designers as a network of zigzagging lines, and drafted directly with a straightedge and a compass. I discuss our recent findings that, by 1200 A. D., a conceptual breakthrough occurred in which girih patterns were conceived as tessellations of a special set of equilateral polygons (girih tiles) decorated with lines. These girih tiles enabled the creation of increasingly complex periodic girih patterns, and by the 15th century, the tessellation approach was combined with self-similar transformations to construct nearly-perfect quasicrystalline patterns. These patterns have remarkable properties; they do not repeat periodically, and have special symmetry—and were not understood in the West until the 1970s. I will discuss some of the properties of Islamic quasicrystalline tilings, and their relation to the Penrose tiling, perhaps the best known quasicrystal pattern.

11:51AM W5.00002 The Story of the Water Cube, DENIS WEAIRE, TCD, Dublin — The National Aquatics Center or “Water Cube,” constructed for the Beijing Olympics, is unusual in that its very structure has a physical significance. It consists of a massive framework of steel beams that are arranged as in the Weaire-Phelan structure of an ideal foam, with an outer facing of transparent “cushions.” Brilliantly conceived by Tristram Carfrae of the Arup Corporation, it makes a spectacular impression on those who enter. It provokes thoughts on aesthetics, order/disorder, optimisation, and the frequent recurrence of bubbles/foams in our literary and artistic culture. The story of the Water Cube will start in the nineteenth century, when William Thomson (Lord Kelvin) first posed the problem: what kind of foam of equal-sized bubbles minimises area (or energy)?

12:27PM W5.00003 The Drip Paintings of Jackson Pollock: Are They Really fractal?, KATHERINE JONES-SMITH, Case Western Reserve University — It has been claimed the drip paintings of late Abstract Expressionist painter Jackson Pollock can be usefully characterized as fractal, and that fractal analysis can be used to authenticate works of unknown origin. This academic issue has become of more general interest following the recent discovery of a cache of disputed Pollock paintings. I will demonstrate that this hypothesis of “Fractal Expressionsim” is fundamentally flawed, and that fractal analysis as an authentication tool yields inconsistent and unreliable results. This work has also led to two new results in fractal analysis of more general scientific significance. First, the composite of two fractals is not generally scale invariant and exhibits complex multifractal scaling in the small distance asymptotic limit. Second the statistics of box-counting and related staircases provide a new way to characterize geometry and distinguish fractals from Euclidean objects.

1:03PM W5.00004 Learning from Monet: A Fundamentally New Approach to Image Analysis1, CHARLES M. FALCO, University of Arizona — The hands and minds of artists are intimately involved in the creative process, intrinsically making paintings complex images to analyze. In spite of this difficulty, several years ago the painter David Hockney and I identified optical evidence within a number of paintings that demonstrated artists as early as Jan van Eyck (c1425) used optical projections as aids for producing portions of their images. In the course of making those discoveries, Hockney and I developed new insights that are now being applied in a fundamentally new approach to image analysis. Very recent results from this new approach include identifying from Impressionist paintings by Monet, Pissarro, Renoir and others the precise locations the artists stood when making a number of their paintings. The specific deviations we find when accurately comparing these examples with photographs taken from the same locations provide us with key insights into what the artists’ visual skills informed them were the ways to represent these two-dimensional images of three-dimensional scenes to viewers. As will be discussed, these results also have implications for improving the representation of certain scientific data. Acknowledgment: I am grateful to David Hockney for the many invaluable insights into imaging gained from him in our collaboration.

Session W6 GQI: Progress on Quantum Optics with Circuit Quantum Electrodynamics 406
et al. provides a complete description of the quantum state. We analyze the prepared states by mapping out the corresponding Wigner function, which is the phase-space equivalent to the density matrix and in the resonator [1]. Using a generalization of this scheme [2] we can now create arbitrary quantum states of the photon field with up to approximately 10 photons. In both proposals we borrow from inspiring quantum-optical tools and concepts, exploiting the good control over a superconducting phase qubit by using it to pump photons into a high-fidelity measurement may be achieved [2]. In this situation, i.e., in pure vacuum, we have resolved the renormalization of the qubit transition frequency - known as the Lamb shift - due to its non-resonant interaction with the cavity vacuum fluctuations [3].

1Work done in collaboration with Johannes Fink, Andreas Fragner, Alexandre Blais, Peter Leek and the ETH Quantum Device Team.

11:51AM W6.00002 Nonlinear response of the vacuum Rabi resonance, JENS KOCH, Yale University — On the level of single atoms and photons, the coupling between atoms and the electromagnetic field is typically very weak. By employing a cavity to confine the field, the strength of this interaction can be increased many orders of magnitude to a point where it dominates over any dissipative process. This strong-coupling regime of cavity quantum electrodynamics has been reached for real atoms in optical cavities, and for artificial atoms in circuit QED and quantum-dot systems. A signature of strong coupling is the splitting of the cavity transmission peak into a pair of resolvable peaks when a single resonant atom is placed inside the cavity – an effect known as vacuum Rabi splitting. The circuit QED architecture is ideally suited for going beyond this linear response effect. Here, we show that increasing the drive power results in two unique nonlinear features in the transmitted heterodyne signal: the supersplitting of each vacuum Rabi peak into a doublet, and the appearance of additional peaks with the characteristic √n spacing of the Jaynes-Cummings ladder. These constitute direct evidence for the coupling between the quantized microwave field and the anharmonic spectrum of a superconducting qubit acting as an artificial atom. Work done in collaboration with L.S. Bishop, J.M. Chow, A.A. Houck, M.H. Devoret, E. Thuneberg, S.M. Girvin, and R.J. Schoelkopf.

12:27PM W6.00003 Preparation of arbitrary quantum states in a microwave resonator, MAX HOFHEINZ, University of California, Santa Barbara — Two-level systems, or qubits, can be prepared in arbitrary quantum states with exquisite control, just using classical electrical signals. Achieving the same degree of control over harmonic resonators has remained elusive, due to their infinite number of equally spaced energy levels. Here we exploit the good control over a superconducting phase qubit by using it to pump photons into a high-Q coplanar waveguide resonator and, subsequently, to read out the resonator state. This scheme has previously allowed us to prepare and detect photon number states (Fock states) in the resonator [1]. Using a generalization of this scheme [2] we can now create arbitrary quantum states of the photon field with up to approximately 10 photons. We analyze the prepared states by mapping out the corresponding Wigner function, which is the phase-space equivalent to the density matrix and provides a complete description of the quantum state.

11:15AM W7.00001 Optimizing information flow in biological networks, WILLIAM BIALEK, Princeton University — The generation of physicists who turned to the phenomena of life in the 1930s realized that to understand these phenomena one would need to track not just the flow of energy (as in inanimate systems) but also the flow of information. It would take more than a decade before Shannon provided the tools to formalize this intuition, making precise the connection between entropy and information. Since Shannon, many investigators have explored the possibility that biological mechanisms are selected to maximize the efficiency with which information is transmitted or represented, subject to fundamental physical constraints.

I will survey these efforts, emphasizing that the same principles are being used in thinking about biological systems at very different levels of organization, from bacteria to brains. Although sometimes submerged under concerns about particular systems, the idea that information flow is optimized provides us with a candidate for a real theory of biological networks, rather than just a collection of parameterized models. I will try to explain why I think the time is right to focus on this grand theoretical goal, pointing to some key open problems and opportunities for connection to emerging experiments.

11:51AM W7.00002 Form, Function, and Information Processing in Stochastic Regulatory Networks, CHRIS WIGGINS, Department of Applied Physics and Applied Mathematics; Columbia University — The ability of a biological network to transduce signals, e.g., from chemical information about the abundance of small molecules into regulatory information about the rate of mRNA expression, is thwarted by numerous sources of noise. A great amount has been learned and conjectured in the last decade about the extent to which the form of a network — specified by the connectivity and sign of regulation — constrains or guides the networks function — the particular noisy input-output relation(s) the network is capable of executing. In parallel, a great amount of research has sought to elucidate the role of inescapable or ‘intrinsic’ noise arising from the finite copy number of the participating molecules, which sets physical limits on information processing in small cells. I’ll discuss how information theory may help illuminate these topics by providing a framework for quantifying function which does not rely on specifying the particular task to be performed a priori, as well as by providing a measure for the extent to which form follows function. En route I hope to show how stochastic chemical kinetics, modeled by the (linear) master equation describing the probability of copy counts for all reactants, benefits from the same spectral approaches fundamental to solving the (linear) diffusion equation.

12:27PM W7.00003 Decision boundaries for maximizing information transmission in neural circuits¹, TATYANA SHARPEE, The Salk Institute for Biological Studies — Everything we know about the world around us is represented in the nervous system in sequences of discrete electrical pulses termed spikes. One attractive theoretical idea, going back to 1950s, is that these representations are efficient in the sense of information theory. I will describe an approach for finding the optimal coupling strengths between different neurons that is based on a concept of a decision boundary [1]. In this framework, neural circuit responses are described by specifying for each neuron the decision boundary that separates multi-dimensional signals that elicit a spike in that neuron from those signals that do not elicit a spike. The shape and position of individual neurons’ boundaries determine the amount of mutual information that the neural circuit can transmit about the incoming signals. Correspondingly, the optimal configuration of the decision boundaries depends on the probability distribution of incoming signals. Signals typical of our natural sensory environment are known to be strongly correlated and to possess large-amplitude deviations that are often better described by an exponential rather than a Gaussian distribution. Considering exponentially distributed signals, we find that optimal decision boundaries of neurons are curved, and that they exhibit sharp discontinuities when decision boundaries of different neurons intersect. This, in turn, corresponds to non-zero coupling constants when these neural circuits are described using the pairwise maximum entropy models.

¹NIH/NIMH, Alfred P. Sloan Fellowship, Searle Foundation

1:03PM W7.00004 Information processing and signal integration in bacterial quorum sensing, PANKAJ MEHTA, Princeton University — Bacteria communicate with each other using secreted chemical signaling molecules called autoinducers (AIs) in a process known as quorum sensing. Quorum sensing enables bacteria to collectively regulate their behavior depending on the number and/or species of bacteria present. The quorum-sensing network of the marine-bacteria *Vibrio harveyi* consists of three AIs encoding distinct ecological information, each detected by its own histidine-kinase sensor protein. The sensor proteins all phosphorylate a common response regulator and transmit sensory information through a shared phosphorylase that regulates expression of downstream quorum-sensing genes. Despite detailed knowledge of the *Vibrio* quorum-sensing circuit, it is still unclear how and why bacteria integrate information from multiple input signals to coordinate collective behaviors. Here we develop a mathematical framework for analyzing signal integration based on Information Theory and use it to show that bacteria must tune the kinase activities of sensor proteins in order to transmit information from multiple inputs. This is demonstrated within a quantitative model that allows us to quantify how much *Vibrio’s* learn about individual inputs and explains experimentally measured input-output relations. Furthermore, we predicted and experimentally verified that bacteria manipulate the production rates of AIs in order to increase information transmission and argue that the quorum-sensing circuit is designed to coordinate a multi-cellular developmental program. Our results show that bacteria can successfully learn about multiple signals even when they are transmitted through a shared pathway and suggest that Information Theory may be a powerful tool for analyzing biological signaling networks.

1:39PM W7.00005 to be determined by you, BORIS SHRAIMAN, USCB — No abstract available.
11:51AM W8.00002 Novel Detector developments for the European XFEL. HEINZ GRAF, DESY-Hamburg — The source properties of the Novel XFEL to be built in Hamburg impose extremely demanding requirements for the X-ray detectors that will be used in the experiments. The high luminosity of European XFEL, with many more pulses per second as compared to the American and Japanese projects, is one of the strong points that for sure will be used to the advantage in the experiments. The time structure is however such that the pulses are not distributed uniformly in time but are delivered in bunch trains (with up to 3000 bunches in a train) of 0.6 msec followed by 99.4 msec with no beam. This means that up to 3000 images will have to be recorded during the bunch train of 0.6 msec. This can only be achieved by temporarily storing the images in the detector, and reading them out during the 99.4 msec intervals. Furthermore, for every pulse of less than a 100 fsec a complete image has to be recorded, one can not use photon counting (“all photons arrive at the same time”), and one has to use integrating detectors, that record the total deposited X-ray energy, but with sufficiently low noise, so that one is able to distinguish between 0, 1, 2, 3, ... photons. On top of this one also wants to be able to record up to 10^4 photons, meaning a true dynamic range of more than 10^4, which is far from trivial. I will show various experimental examples, illustrating the specific detector challenges that follow from the above requirements. I will also discuss one solution, currently under development, which is the Adaptive Gain Integration Pixel Detector (AGIPD) project (DESY, PSI, Uni-Bonn, Uni-Hamburg). This detector is based on a classical Hybrid pixel array detector with a dynamically switchable gain stage to cope with the dynamic range, and an analog pipeline to store the recorded images during the 0.6 msec bunch train. Two other projects, LPD, and DEPFET will also be mentioned briefly.

12:27PM W8.00003 Integrating Pixel Array Detector Development. 1. SOL GRUNER, Cornell University — X-ray experiments are very frequently detector limited at storage ring synchrotron radiation sources, and will be even more so at future x-ray free electron laser and energy recovery linac sources. Limitations most frequently arise from the inability of detectors to efficiently collect and process data at the rates at which the data can be generated. Two bump-bonded silicon pixel array detectors (PADs) are being developed at Cornell University that will greatly enhance data collection capabilities. In these PADs x-rays are converted to electrical signals in a pixilated layer of high resistivity silicon, each pixel of which is connected by a metal solder “bump” to a corresponding pixel in a CMOS silicon integrated circuit. Each CMOS pixel contains its own data handling and processing electronics. Since all pixels operate in parallel, the PAD is capable of handling extremely high data throughput. The PAD pixels feature integrating analog front-end electronics which allow extremely high instantaneous count-rates, yet sufficiently high signal-to-noise to be able to detect single x-ray photons. The first PAD is designed for coherent x-ray imaging experiments at the Linac Coherent Light Source (LCLS) at SLAC. This detector frames continuously at the LCLS rate of 120 Hz, where the data for each frame can arrive in femtoseconds. The second detector, a result of a collaboration with the Area Detector Systems Corporation, is designed for high throughput protein crystallography experiments. Both detectors are described, and test data is provided. The capabilities of the detectors suggest a variety of new applications, some of which will be discussed. 1Supported by DOE & NIH.

1:03PM W8.00004 CMOS Hybrid Pixel Detectors for Scientific, Industrial and Medical Applications. CHRISTIAN BROENNIMANN, DECTRIS Ltd — Crystallography is the principal technique for determining macromolecular structures at atomic resolution and uses advantageously the high intensity of 3rd generation synchrotron X-ray sources. Macromolecular crystallography experiments benefit from excellent beamline equipment, recent software advances and modern X-ray detectors. However, the latter do not take full advantage of the brightness of modern synchrotron sources. CMOS Hybrid pixel array detectors, originally developed for high energy physics experiments, meet these requirements. X-rays are recorded in single photon counting mode and data thus are stored digitally at the earliest possible stage. The lead role for several advantages over current detectors: No detector noise is added to the signal. Readout time is reduced to a few milliseconds. The counting rates are matched to beam intensities at protein crystallography beamlines at 3rd generation synchrotron. The detector is not sensitive to X-rays during readout; therefore no mechanical shutter is required. The detector has a very sharp point spread function (PSF) of one pixel, which allows better resolution of adjacent reflections. Low energy X-rays can be suppressed by the comparator At the Paul Scherrer Institute (PSI) in Switzerland the first and largest array based on this technology was constructed: The Pilatus 6M detector. The detector covers an area of 43.1 x 44.8 cm^2, has 6 million pixels and is read out noise free in 3.7 ms. Since June 2007 the detector is in routine operation at the beamline 6S of the Swiss Light Source (SLS). The company DETCRIS Ltd, has licensed the technology from PSI and is commercially offering the PILATUS detectors. Examples of the wide application range of the detectors will be shown.

11:15AM W9.00001 Depinning transition in failure of disordered materials. LAURENT PONSON, California Institute of Technology, Pasadena, US — Crack propagation is the fundamental process leading to material failure. However, its dynamics is far from being fully understood. In this work, we investigate both experimentally and theoretically the far-from-equilibrium propagation of a crack within a disordered brittle material. The variations of its growth velocity v with respect to the external driving force G are carefully measured on a brittle rock of average fracture energy (T). The crack dynamics is shown to display two regimes, well described by a sub-critical creep law v ∝ G^(μ−1) with μ ≃ 1 for G < G_c, at low velocities, and a critical behavior where v ∝ (G – G_c)^(θ) with θ ≃ 0.8 when G > G_c. We show that these variations, as well as the value of the exponents μ and θ, can be explained extending the continuum theory of Fracture Mechanics to inhomogeneous media. In particular, these two regimes are shown to be reminiscent of the dynamical critical transition underlying the failure of disordered brittle materials.

11:27AM W9.00002 Random Organization and Irreversibility at Plastic Depinning. CHARLES REICHARDT, CYNTHIA REICHARDT, Los Alamos National Laboratory — We provide evidence that plastic depinning falls into the same class of phenomena as the random organization which was recently studied for periodically driven particle systems by L. Corte et al. [Nature Phys. 4, 420 (2008)]. In the plastic flow system that we consider, the pinned regime corresponds to a quiescent state while the moving regime corresponds to a fluctuating state. Upon the sudden application of an external force, the system organizes into one of these two states and the time scale required to reach the final state diverges as a power law when approaching a nonequilibrium transition. We propose a simple experiment to test this transition in colloidal systems with random disorder and in superconducting vortex systems.

11:39AM W9.00003 Static Avalanche s in a Random Landscape. 1. A. ALAN MIDDLETON, Syracuse University, PIERRE LE DOUSSAL, KAY J. WIESE, CNRS-LPTENS — We study jumps or avalanches in a model of a d-dimensional elastic interface that is pinned by disorder and tied to a harmonic spring. The interface configuration is the most stable one, given the disorder and spring position: as the spring is moved, this most stable configuration undergoes discrete jumps or shocks. We carry out numerical simulations to study these shocks and find: (1) detailed qualitative and quantitative verification of the validity of the functional renormalization group analysis of such interfaces and (2) that the distribution of avalanche sizes is numerically consistent with our new calculation of the exact shape of the avalanche distribution, computed in an ε = 4 – d expansion. The results are quite similar to those seen for dynamic avalanches, where the drive pushes interface configurations between metastable (not globally stable) states. 1NSF DMR 0606424 and ANR 05-BLAN-0099-01
11:51AM W9.00004 A simple model for deformation in solids with universal predictions for stress-strain curves and slip avalanches  . KARIN, DAHMEN, Dept. of Physics, University of Illinois at Urbana Champaign, YEHUDA BEN-ZION, Earth Sciences, University of Southern California, JONATHAN UHL, KARIN DAHMEN COLLABORATION, YEHUDA BEN-ZION COLLABORATION — A basic model for deformation of solids with only one tuning parameter (weakening epsilon) is introduced. The model can reproduce observed stress-strain curves, acoustic emissions and related power spectra, event statistics, and geometrical properties of slip, with a continuous phase transition from brittle to ductile behavior. Exact universal predictions are extracted using mean field theory and renormalization group tools. The results agree with recent experimental observations and simulations of related models for dislocation dynamics, material damage, and earthquake statistics.

12:03PM W9.00005 Hysteresis loop area of the kinetic Ising model with next-nearest neighbor interaction , WILLIAM BAEZ, TRINANJAN DATTA, CHRISTIAN POPPELIERS, Augusta State University — We investigate the effects of the next-nearest neighbor interaction on the hysteresis loop area of the two-dimensional kinetic Ising model subject to a time dependent magnetic field. For the nearest neighbor model it is known that the loop area, $A(H_o, f)$, has a dispersion relationship given by $A(H_o, f) \propto H_o^{2/3} f^{1/3}$ in the low frequency limit, $f \rightarrow 0$, where $H_o$ is the external magnetic field amplitude. Using the Metropolis algorithm we explore the hysteresis dispersion in the low frequency limit for various external magnetic fields. We find that the hysteresis relationship changes, as compared to the nearest neighbor model, in the presence of next-nearest neighbor interaction.

12:15PM W9.00006 Decay of metastable states in the N-neighbor Ising model . RANJIT CHACKO, HARVEY GOULD, Clark University, W. KLEIN, Boston University — We study the decay of metastable states in the N-neighbor Ising model in which each spin equally interacts with all other spins. Previous work has shown that near the pseudospinodal in an Ising model with long-range interactions nucleation occurs when many clusters which span a correlation volume coalesce to form the nucleating droplet. By observing the decay of a metastable state in the N-neighbor Ising model we can study the effect of the pseudospinodal on nucleation in a model which does not possess a length scale. This study has implications for spin-crossover materials.

12:27PM W9.00007 Physical criteria for comparing length and time scales of coarsening models , BENJAMIN VOLLMAYR-LEE, Bucknell University — A variety of models have been introduced to study the dynamics of phase separation, ranging from sub-critical kinetic Ising models to phase-field models to Oono and Puri’s cell dynamical systems (CDS). These models have in common that at asymptotic late times the dynamics reduces to that of sharp interfaces driven by a surface tension. In practical terms, one is typically interested in simulating these models into the asymptotic late-time regime, but it is not clear how to compare the rates of approach to asymptopia. Additionally, while the sharp interface dynamics have a high degree of universality, it is not clear to what degree this applies to the sub-asymptotic dynamics. A scheme is presented to address these questions. Essentially, one first identifies the relevant parameters that determine the asymptotic dynamics and leading sub-asymptotic dynamics. From these, the appropriate dimensionless measures of effective convergence can be obtained. The technique will be illustrated by a comparison of CDH to the Cahn-Hilliard phase field model.

12:39PM W9.00008 Dynamics of Nucleation in the Ising model . SEUNGHWA RYU, Physics Department, Stanford University, WEI CAI, Mechanical Engineering Department, Stanford University — While several theories have been developed to describe the kinetics of first order phase transitions, the range of applicability of each theory is not fully understood due to uncertainties in experiments and numerical difficulties in rare event simulations. In this study, we compute the decay rate of meta-stable states of the Ising model to test the validity of several existing nucleation theories. We employ advanced sampling methods to compute the nucleation rate, which spans a range over ten orders of magnitude, as a function of temperature and external field. Investigation of the critical nuclei and the pre-exponential factor reveals that nucleation in the 2d Ising model is well described by the field-theoretic model of Langer (1969). However, discrepancies between theory and numerical results are observed in the 3d Ising model. This discrepancy points to the importance of the shape of the critical nuclei to the nucleation kinetics.

12:51PM W9.00009 Scaling of the Island Density, Size Distribution and Capture Numbers in 3D Nucleation and Growth 13. JOHN ROYSTON, JAQUEM AMAR, University of Toledo — The results of kinetic Monte Carlo (KMC) simulations of a model of the irreversible nucleation and growth of fractal islands in 3D are presented along with a comparison with rate-equation (RE) results and mean-field (MF) theory. In previous work for point-islands in 3D it was found that both the scaled island-size distribution (ISD) and capture-number distribution (CND) approach the MF prediction of a diverging ISD and size-independent CND in the limit of large $D/F$ (where $D$ is the monomer diffusion rate and $F$ is the deposition rate). In contrast, here we find that the divergence of the ISD with increasing $D/F$ is much weaker for the case of fractal islands while the scaled CND $C(s/S)$ (where $S$ is the average island size) is not constant but increases linearly with island size $s$. We also find that the exponent $\chi$ describing the dependence of the peak island-density on $D/F$ (e.g. $N_{pk} \sim (D/F)^{-\chi}$) deviates significantly from the standard prediction $\chi = 1/3$. Self-consistent RE results for the average island and monomer densities which give good agreement with simulations are also presented, along with an analytical expression for the exponent $\chi$.

1Supported by NSF DMR-0606307

1:03PM W9.00010 The effects of spatial symmetry breaking on unstable state evolution , RACHELE DOMINGUEZ, KIPTON BARROS, W. KLEIN, Boston University — We develop a theory that predicts two distinct stages for the early unstable kinetics of systems with spatial symmetry breaking transitions. In the first stage the kinetics is dominated by symmetry preserving dynamics which acts on a short time scale. In the second stage, which shares some characteristics with the Cahn-Hilliard-Cook theory, noise driven fluctuations break the symmetry of the initial phase on a time scale that is large compared to the first stage for systems with an effective long-range interaction. Our simulations of the initial evolution of a long-range antiferromagnetic Ising model quenched into an unstable region are consistent with our predictions.

1:15PM W9.00011 Liquid to solid nucleation through onion-structure droplets13 , KIPTON BARROS, WILLIAM KLEIN, Boston University — We start from a Landau-Ginzburg free energy and develop a theory of crystal nucleation for metastable liquids. Saddle points of the free energy represent nucleating droplets and are obtained analytically and numerically. We find nucleating droplets with hexagonal symmetry in two dimensions and bcc and icosahedral symmetries in three dimensions. Surprisingly, we also find nucleating droplets in three dimensions with a spherically symmetric structure resembling the layers of an onion. These onion-structure objects are the preferred nucleating droplets near the spinodal. We discuss recent experiments and simulations which are consistent with our predictions.

13Funded in part by NSF Grant No. DGE-0221680 and DOE Grant No. 2234-5.
1:27PM W9.00012 Dynamical non-ergodic scaling in continuous finite-order quantum phase transitions, SHUHA DENG, GERARDO ORTIZ, LORENZA VIOLA, Dartmouth College — We investigate the emergence of universal dynamical scaling in quantum critical spin systems adiabatically driven out of equilibrium, with emphasis on quench dynamics which involves non-isolated critical points (i.e., critical regions) and cannot be a priori described through standard scaling arguments nor time-dependent perturbative approaches. Comparing to the case of an isolated quantum critical point, we find that non-equilibrium scaling behavior of a large class of physical observables may still be explained in terms of equilibrium critical exponents. However, the latter are in general non-trivially path-dependent, and detailed knowledge about the time-dependent excitation process becomes essential. In particular, we show how multiple level crossings within a gapless phase may completely suppress excitation depending on the control path. Our results typify non-ergodic scaling in continuous finite-order quantum phase transitions.

1:39PM W9.00013 A deposition model with temperature dependent diffusion, YEN-LIANG CHOU, MICHEL PLEIMLING, Virginia Polytechnic Institute and State University — We study a deposition process where the deposited particles are allowed to hope to their neighboring sites with a probability that depends both on the temperature and on the height difference. Changing the temperature, the model evolves from the random deposition model with surface relaxation at zero temperature to the random deposition model at infinite temperature. A generalized dynamic scaling of the surface width as a function of the lattice size, the deposition time, and the temperature is given. The response to a sudden change in temperature is studied. Two types of quenching behavior are observed: a power law decay within the Edwards-Wilkinson regime and an exponential decay in the saturation regime.

1:51PM W9.00014 Hydrodynamic limit of a model of unstable diffusive interface growth, MATTEO NICOLI, Universidad Carlos III de Madrid, MARIO CASTRO, Universidad Pontificia Comillas de Madrid, RODOLFO CUERNO, Universidad Carlos III de Madrid — Recently we have proposed a stochastic moving boundary model to describe the morphological evolution of a large class of diffusive growth systems, with thin film production by Chemical Vapor Deposition and Electrochemical Deposition (ECD) as relevant physical examples. The model has a direct connection with measurable experimental parameters. In order to study the hydrodynamic limit of this model we have performed a small slopes expansion (SSE) that leads to an effective interfacial stochastic equation (ISE). In case of attachment kinetics much larger than the mean growth velocity the kinetic roughening exponents of this ISE are completely different from those of standard universality classes. This equation is a particular instance of a new class of nonlocal interface equations whose novel properties we have studied by numerical and RG techniques. In order to study the model beyond the SSE we have mapped it into an equivalent phase-field model. Numerical simulations of the latter show a remarkable quantitative agreement with ECD experiments.

2:03PM W9.00015 The Isothermal Dendritic Growth Experiment Archive, MATTHEW KOSS, College of the Holy Cross — The growth of dendrites is governed by the interplay between two simple and familiar processes—the irreversible diffusion of energy, and the reversible work done in the formation of new surface area. To advance our understanding of these processes, NASA sponsored a project that flew on the Space Shuttle Columbia in 1994, 1996, and 1997 to record and analyze benchmark data in an apparent-microgravity “laboratory.” In this laboratory, energy transfer by gravity driven convection was essentially eliminated and one could test independently, for the first time, both components of dendritic growth theory. The analysis of this data shows that although the diffusion of energy can be properly accounted for, the results from interfacial physics appear to be in disagreement and alternate models should receive increased attention. Unfortunately, currently and for the foreseeable future, there is no access or financial support to develop and conduct additional experiments of this type. However, the benchmark data of 35mm photonegatives, video, and all supporting instrument data are now available at the IDGE Archive at the College of the Holy Cross. This data may still have considerable relevance to researchers working specifically with dendritic growth, and more generally those working in the synthesis, growth & processing of materials, multiscale computational modeling, pattern formation, and systems far from equilibrium.

11:15AM W10.00001 First-principles theory of coloration of WO₃ upon charge insertion, YU XUE, PEIHONG ZHANG, Department of Physics, University at Buffalo, State University of New York, Buffalo, NY 14260, USA — Tungsten trioxide is one of the most extensively studied electrochromic materials. Here we report density functional theory (DFT) investigations of the coloration mechanism of WO₃ upon charge insertion. Our results explains very well the systematic change in color of Na₃WO₃ from blue to golden-yellow with increasing sodium concentration. We find that proper accounts for the free-carriers contribution to the optical response are critical for a quantitative understanding of the coloration mechanism in this system. We thank Dr. Yong Zhang for his helpful discussion. We thank Dr. M. D. Jones for his assistance in coding. We acknowledge the computational support provided by the Center for Computational Research at the University at Buffalo, SUNY.

11:27AM W10.00002 First principles studies of Ce and Eu-doped inorganic, ANDREW CANNING, ANURAG CHAUDHRY, ROSTYSLAV BOUTCHKO, STEPHEN DERENZO, Lawrence Berkeley National Laboratory — This work presents the results of first principles electronic structure calculations for europium and Ce doped inorganic compounds performed using the pseudopotential method based on the local spin density approximation (LSDA) and generalized gradient approximation+U (GGA+U) in density functional theory. The positions of the europium and cerium 4f and 5d states relative to the valence band maximum and conduction band minimum of the host material are determined. Qualitative predictions of the brightness of scintillation in the doped material is made based on the following criteria: (1) The size of the host material bandgap (2) The energy difference between the VBM (Valence Band Maximum) of the host material and the dopant 4f level (3) The energy difference between the occupied Eu or Ce 5d excited state and the host material CBM (Conduction Band Minimum) (4) The level of localization of the 5d excited state on the dopant atom. We have validated this theoretical approach on examples of known bright scintillators and non-activated scintillators. We have performed calculations on new Eu doped compounds to determine if they are candidates for Eu²⁺ activated scintillators

Electronic structure of the quasi-two-dimensional spin-gap system SrCu$_2$(BO$_3$)$_2$, ANDRES SAUL, CINaM/CNRS (Marseille, France), GUILLAUME RADTKE, IM2NP (Marseille, France), H. DABKOWSKA, B. GAULIN, G. BOTTON, McMaster University (Ontario, Canada) — During the last decade, a lot of theoretical and experimental work has been devoted to the study of the magnetoelectric coupling in quasi-two-dimensional (Q2D) layered systems. One of the most studied of such systems is SrCu$_2$(BO$_3$)$_2$, which is known to exhibit a rich variety of magnetic and electronic properties due to the presence of spin distortions. This compound is a prototypical example of a spin-gap system, where the magnetic excitations are suppressed below a certain temperature, leading to a gap in the excitation spectrum. In this talk, we will present the results of our recent calculations aimed at understanding the electronic and magnetic properties of SrCu$_2$(BO$_3$)$_2$, with a particular focus on the role of interlayer coupling. We will discuss the implications of our findings for the understanding of the magnetoelectric coupling in this and related systems.

PDMS-BaTiO$_3$, Composite with Mechanically Tunable Optical Properties, NASSER MOHAMED, MOISES HINOJOSA, VIRGILIO GONZALEZ, FIME-UANL — Novel composites that show visible light transmittance, mechanically tunable refractive index and good mechanical properties based on PDMS and BaTiO$_3$ (BT) nanoparticles (NP), were prepared in 2 steps. First, the NPs were obtained via mechanical milling; the BT was used as-purchased. Average particle sizes of ∼100nm were selected. Second, the NP were embedded into PDMS by in-situ polymerization. PDMS from Dow Corning (Silgard 184) was supplied as a kit containing 2 components: the Base and the Curing Agent. The BT content was varied up to 1.0wt%. Finally, thick films were prepared by solvent casting and cured in a vacuum furnace, where the trapped air and solvent were extracted. Weight content of the NP was examined. XRD and Raman confirmed the desired tetragonal phase of BT NP. Average particle size was determined by SEM, EDS maps revealed a homogeneous dispersion of the NP. UP-VIS analysis showed transmittances of ∼70%. The ellipsometry results revealed that the wt% of BT significantly influences the optical response of the composite when it is stressed, however the response is not linear.

Measuring Quantum Efficiency of Organic Dyes Encapsulated in Dielectric NanoSpheres, TIMOTHY RUSSIN, Department of Physics, The Pennsylvania State University, ERHAN ALTINOGLU, JAMES ADAIR, Department of Materials Science and Engineering, The Pennsylvania State University, PETER EKULUND, Department of Physics, Department of Materials Science and Engineering, The Pennsylvania State University — We present results of a fluorescent quantum efficiency (Φ) study on the encapsulation of the near infrared dye indocyanine green (ICG) in calcium phosphate (CP) nanoparticles (dia~50 nm). The quantum efficiency (Φ, described as the ratio of photons emitted to photons absorbed) provides a quantitative means of describing the fluorescence of an arbitrary molecule. However, standard quantum efficiency measurement techniques provide only Φ of the smallest fluorescing unit — in the case of a nanoparticle suspension, the nanoparticle itself. This presents a problem in accurately describing the quantum efficiency of fluorophores embedded in a nanoparticle. We have developed a method to determine the quantum efficiency of a constituent molecule embedded in such a nanoparticle, which provides a more meaningful comparison with the unencapsulated fluorophore. While applicable to generic systems, we present results obtained by our method for the ICG/CP nanoparticles in phosphate buffer solution, revealing a dramatic improvement in per-molecule Φ driven by encapsulation.

Dynamic mean-field analysis of the photo-induced insulator-metal transition in correlated electron systems — pump-probe spectroscopy, NAOTO TSUJI, TAKASHI OKA, HIDEO AOKI, Department of Physics, University of Tokyo — Recent pump-probe spectroscopy experiments have revealed that photo-excitation can trigger a ‘phase transition’ from an insulator to a metal in various strongly correlated materials. The transition, occurring inherently out of equilibrium, is distinct from conventional phase transitions. In order to identify the nature of the states emerging during the irradiation of an intense laser, we employ the dynamical mean-field theory combined with the Floquet technique for ac fields, which enables us to take account of both the electron correlation and the nonlinear electric-field effect, two essential ingredients in the photo-induced phenomenon. We apply the method to the Falicov-Kimball model, one of the simplest models of correlated electrons, coupled to an ac pump light. The derived optical conductivity spectrum exhibits a Drude-like peak in the low-energy region indicative of metallization. We have also obtained the nonequilibrium distribution of electrons, which turns out to very much deviate from the Fermi distribution, so that the phenomenon is distinct from the heating effect picture. Interestingly, a dip structure is found to emerge in the charge transfer peak, which is shown to come from the vertex correction. We also discuss the dependence of the optical conductivity on the photon energy of the pump light.

Group IIIA doping in $\alpha$-Fe$_2$O$_3$ for PEC hydrogen production, MUHAMMAD N. HUDA, ARON WALSH, YANPA YAN, SU-HUAI WEI, National Renewable Energy Laboratory, Golden, CO 80401; YONG-SHENG HU, ALAN KLEIMAN-SHWARSTEIN, ERIC MCFARLAND, Dept. of Chemical Engineering, University of California at Santa Barbara, CA 93106; MOWAFAK AL JASSIM, National Renewable Energy Laboratory, Golden, CO 80401 — Among iron oxides, $\alpha$-Fe$_2$O$_3$ is the most abundant on earth. Because it has a band gap of approximately 2 eV, it is stable and inexpensive to process, $\alpha$-Fe$_2$O$_3$ has been considered as a potential photoelectrocatalyst for solar driven photoelectrochemical (PEC) water splitting to make hydrogen. However, as $\alpha$-Fe$_2$O$_3$ is a charge-transfer type insulator, the poor conduction properties have limited its efficiency as a PEC material. We will present our study on the doping of group IIIA elements in $\alpha$-Fe$_2$O$_3$ to improve its performance. All the calculations were done with DFT+$U$. The main electronic features of $\alpha$-Fe$_2$O$_3$ remained almost unchanged for group IIIA doping. While for Al-doping, the band gap remained almost the same, for Ga and In substitution the band gap marginally increased. However, increased conduction and PEC efficiency has been experimentally reported for Al-doped $\alpha$-Fe$_2$O$_3$. It will be shown that the change in volume plays an important role in this behavior. A dramatic increase in photo-response cannot be expected for this type of doping in $\alpha$-Fe$_2$O$_3$.
12:51PM W10.00009 The band gap of ultra-thin amorphous and well-ordered Al$_2$O$_3$ films on CoAl(100)$^1$. VOLKER ROSE, Argonne National Laboratory, RENE FRANCHY$^2$. Research Center Julich — Understanding the insulating properties of thin oxide films is key to developing novel devices. In this work, the band gaps of ultra-thin amorphous and well-ordered alumina films on CoAl(100) were investigated by means of scanning tunneling spectroscopy (STS). The ordered intermetallic alloy CoNi(100) exhibits a magnetic surface, although the bulk is nonmagnetic. Such a material is extremely attractive for innovative technical applications. Utilizing selective oxidation, by which the oxidation of CoAl leads to surface segregation of the element with higher oxygen affinity, high-quality Al$_2$O$_3$ films are formed. Oxidation at 300 K leads to the growth of amorphous oxide, while well-ordered films result at elevated temperatures. In both cases, the self-limiting thickness of the oxide film amounts to around 1 nm. The analysis yields band gaps of 2.8 and 3.6 eV for amorphous and well-ordered Al$_2$O$_3$, respectively. The with respect to the bulk oxide reduced band gap can be explained by the appearance of defect induced states localized in the band gap.

1:03PM W10.00010 Spectroscopic analysis of ALD-coated 3D structures and origin of the Berreman effect. GIOVANNA SCAREL, JEONG-SEOK NA, KEVIN HYDE, GREGORY PARSONS, North Carolina State University, PARSONS GROUP TEAM — The Berreman effect sheds light on various phenomena in 2D systems. However, coatings of 3D systems in soft-lithography and photonic devices, or 3D fibers suggest that the Berreman effect in 3D structures could be different. Experimental and computational infrared spectroscopy studies of 3D structures conformally coated with Al$_2$O$_3$ and ZnO layers using atomic layer deposition support this conclusion. In 2D systems, defining $\theta_0$ the macroscopic incidence angle of the IR beam on a sample, the LO mode absorbance increases as $|\sin(\theta_0)|^2$ when $\theta_0$ becomes grazing. On the other hand, in 3D systems a linear combination of $|\sin(\theta_0)|^2$ with appropriate coefficients must be considered. Accounting for Snell’s law in the simulation model is essential to explain these results and the origin of the Berreman effect. We conclude that sample geometry determines infrared absorbance of LO modes versus $\theta$ and vice-versa.

Our results promise a new tool to investigate topography of insulating ionic oxide layers.

1:15PM W10.00011 Dielectric properties of solids in the regular and split charge equilibration formalisms. RAZVAN NISTOR, MARTIN MÜSER, University of Western Ontario — We investigate the generic dielectric properties of solids in which atomic charges are assigned within the split-charge equilibration (SQE) method, which contains the regular charge equilibration method as a limiting case. It is shown that the latter always mimics ideal conductors, while any positive bond hardness, which is introduced in the SQE method, turns the solid into a dielectric. Crystals with simple cubic and rocksalt structure are considered explicitly. For these symmetries we map the split-charge formalism onto a continuum model, which can be solved analytically, e.g., we provide simple analytical expressions for how the dielectric constant and penetration depth depend on atomic hardness, bond hardness, and lattice constant. This mapping may prove useful when having to solve the dielectric response of a heterogeneous system to external electrical fields not only on the atomic but also on a coarse-grained scale. Successful comparison of numerical data to analytical solutions is made, including those that contain discretization corrections to the continuum solution.

1:27PM W10.00012 Charge and Bonding States of Ag Atoms in Superionic Conductor $\alpha$-AgI. MASATO ITO, KAZUO TSUMURAYA, Meiji University, Japan — The fast migration mechanism of the cations in the superionic conductors has been little known up to now. In the case of $\alpha$-AgI, the charge states of the Ag atoms and the bonding states between Ag and I atoms during the migration remain to be explained. No explanation has also been given for the origin of both the positions and the asymmetric first peaks of the Ag-I and Ag-Ag pair distribution functions. We investigate the electronic states of AgI using the first principles electronic structure calculations. We use the Bader analysis to evaluate the charges that belong to each atom and obtain the ionicity of the atoms. The stability of the cation pairs in the conductor will be discussed using their binding energies.

1:39PM W10.00013 Multiplets and Crystal Fields: Systematics for X-Ray Spectroscopies. FRANCOIS VERNAY, BERNARD DELLEY, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland — Recently Soft X-ray spectroscopies such as XAS andRIXS, became tools of choice to investigate transition metal oxides. The current resolving power is such that it is nowadays possible to investigate multiparticle excitations like, for instance, bi-magnon dispersion throughout the entire Brillouin zone. Yet, these spectroscopies are strongly linked to local physics: the absorption of a photon and creation of a localized core-hole opens up a shell and therefore a multiplet structure becomes apparent in the spectra. From here we see that it becomes crucial, while interpreting the experimental data, to have a systematic, user-friendly and transparent way of computing the multiplet spectra in order to disentangle in the experiment the information arising from single-particle excitations from the information relevant to collective excitations. We present our approach for arbitrary core-valence multiplets arising from a single configuration. The method covers the full range LS-intermediate-jj and allows to introduce splitting by an arbitrary crystal field easily.

Session W11 DMP: Focus Session: Transport Properties of Nanostructures VI: Kondo Phenomena

11:15AM W11.00001 Very high Kondo temperature ($T_K \sim 80$ K) in single self-assembled InAs quantum dots coupled to metallic nanogap electrodes. KENJI SHIBATA, KAZUHIKO HIRAKAWA, IIS and INQIE, University of Tokyo — We have studied electron tunneling through single self-assembled InAs quantum dots (QDs) laterally coupled to metallic nanogap electrodes. Lateral electron tunneling structures were fabricated by forming nanogap metallic electrodes directly upon single self-assembled InAs QDs grown on GaAs surfaces. The n-type substrate was used as a backgate electrode. Although no intentional tunneling barriers were introduced, the fabricated samples worked as single electron transistors and exhibited Coulomb blockade effect. Furthermore, a clear spin-half Kondo effect was observed when strong coupling between the electrodes and the QDs was realized using a large QD with a diameter of $\sim 100$ nm. From the temperature dependence of the linear conductance at the Kondo valley, the Kondo temperature, $T_K$, was determined to be $\sim 81$ K. This is the highest $T_K$ ever reported for artificial semiconductor nanostructures. This high Kondo temperature is due to strong QD-electrode coupling and large charging/orbital-quantization energies in our self-assembled InAs QD structures.

11:27AM W11.00002 Reduced Kondo conductance in a quantum dot by a high-biased quantum point contact nearby

KENICHI HITACHI, Department of Physics, University of Tokyo, AKIRA OIWA, SEIGO TARUCHA, Department of Applied Physics, University of Tokyo — A quantum point contact (QPC) near a quantum dot (QD) can be used for detecting the charge state in a QD. Also a single spin in a QD can be monitored by pulsed gate operation. However it has been shown that applied QPC source-drain bias voltage induces undesirable charge and spin fluctuations in a QD, such as photon-assisted like tunneling in a Coulomb blockade regime or suppressing conductance at spin-half Kondo valley. In this experiment, we examined the influence of Kondo valley and inelastic cotunneling at Coulomb valley in detail. We found that decreasing conductance at Kondo valley can be explained by the increase of local temperature, which is estimated by the conductance at inelastic cotunneling. We predict that this local increase of temperature is caused by the back-action between a QD and a QPC. This gives an alternative explanation of suppressing conductance at Kondo valley, which was thought to be the effect of dephasing a spin singlet between the dot and the lead.

11:39AM W11.00003 A magnetic field-induced crossover to a non-universal regime in a Kondo dot

ANDREI KOGAN, TAI-MIN LIU, BRYAN HEMINGWAY, University of Cincinnati, STEVEN HERBERT, Xavier University, MICHAEL MELLOCH, Purdue University, UNIVERSITY OF CINCINNATI TEAM, XAVIER UNIVERSITY COLLABORATION, PURDUE UNIVERSITY COLLABORATION — We have measured the magnetic splitting, $\Delta_K$, of a Kondo peak in the differential conductance of a Single-Electron Transistor while tuning the Kondo temperature, $T_K$, along two different paths in the parameter space: varying the dot-lead coupling at a constant dot energy, and vice versa. At a high magnetic field, $B$, the changes of $\Delta_K$ with $T_K$ along both paths have opposite signs, suggesting that $\Delta_K$ is not a universal function of $T_K$. At low $B$, we observe a decrease in $\Delta_K$ with $T_K$ along both paths. Detailed $\Delta_K(B)$ data for two different $T_K$ show consistency for the splitting onset. Furthermore, we find $\Delta_K/\Delta < 1$ at low $B$ and $\Delta_K/\Delta > 1$ at high $B$, where $\Delta$ is the Zeeman energy of the bare spin. We discuss an approximate scaling of $\Delta_K$ with $B/T_K$ at low $B$ and compare the findings to previous measurements and theory.

$^3$The research is supported by NSF DMR award No. 0804199 and by University of Cincinnati.

11:51AM W11.00004 Correlated Wavefunction Description of Kondo States on Metal Surfaces

SAHAR SHARIFZADEH, Princeton University, Dept. of Electrical Engineering, PATRICK HÜANG, Physics and Life Sciences Directorate, Lawrence Livermore National Laboratory, EMILY A. CARTER, Princeton University, Dept. of Mechanical and Aerospace Engineering — At low temperatures, a variety of magnetic impurities adsorbed on metal surfaces form a Kondo state, where the conduction electrons are thought to screen out the spin on the impurity to yield a many-body spin singlet, based on analogy with bulk Kondo physics in which magnetic quenching is observed at low temperatures. In scanning tunneling spectroscopy (STS), this state manifests as a narrow resonance in the density of states at the Fermi level. However, qualitative differences in the Kondo resonance lineshape are seen between specific adatom-substrate systems, for reasons that are not understood. We present a many-body correlated wavefunction study of Co on transition metal surfaces. We apply an embedded configuration interaction (CI) approach, where a finite cluster containing the impurity is described by a many-body CI wavefunction, while the effects of the extended background are included via a periodic density functional theory-based embedding potential. We discuss the nature of the correlated wavefunction and impurity orbital structure on different surfaces, and discuss implications for the observed STS data.

12:03PM W11.00005 Kondo effect in single-molecule magnet transistors

GABRIEL GONZALEZ, MICHAEL LEIJENBERGER, NanoScience Technology Center, Univ Central Florida, EDUARDO MUCCIOLO, Department of Physics, Univ Central Florida — We present a careful and thorough microscopic derivation of the anisotropic Kondo Hamiltonian for single-molecule magnet (SMM) transistors. When the molecule is strongly coupled to metallic leads, we show that by applying a transverse magnetic field it is possible to topologically induce or quench the Kondo effect in the conductance of a SMM with either an integer or a half-integer spin $S=1/2$. This topological Kondo effect is due to the Berry-phase interference between multiple quantum tunneling paths of the spin. We calculate the renormalized Berry-phase oscillations of the two Kondo peaks as a function of a transverse magnetic field by means of the poor man’s scaling approach. We illustrate our findings with the SMM Ni4, which we propose as a possible candidate for the experimental observation of the conductance oscillations.

12:15PM W11.00006 Frequency-dependent Full Counting Statistics of Electron Transport in Double Quantum Dots

RAMON AGUADO, DAVID MARCOS, CSIC, CLIVE EMARY, TOBIAS BRANDES, Technische Universität Berlin — Full Counting Statistics is a powerful tool to study correlations in stochastic processes. It has been applied in the last years to characterize nanoscale transport. We present a technique that allows to calculate frequency dependent high-order correlators of the electronic current through an interacting nanostructure. We illustrate our technique by calculating the frequency-dependent shot noise (second order) and skewness (third order) of a double quantum dot. Our results demonstrate that the frequency- dependent skewness contains useful information about the interaction quantum dynamics of the nanostructure in bias voltage regimes where the second-order correlations are dominated by thermal fluctuations.

12:27PM W11.00007 Transport properties of a superconducting single-electron transistor coupled to a nanomechanical oscillator

VERENA KOERTING, T.L. SCHMIDT, C.B. DOIRON, C. BRUDER, Department of Physics, University of Basel, CH-4056 Basel, Switzerland, B. TRAUZETTEL, Institute for Theoretical Physics and Astrophysics, University of Würzburg, D-97074 Würzburg, Germany — Superconducting single-electron transistors (SSETs) are known to constitute a very sensitive probe for the position measurement of a nanomechanical resonator (NR) which can provide near quantum-limited accuracy. The laws of quantum mechanics, however, also require a backaction of the SSET on the resonator, which limits the sensitivity. Recent experiments have confirmed that the backaction gives rise to an effective thermal bath which has the potential to cool or drive the resonator. Our research attempts to gain a better understanding of this system by examining the action of the NR on the SSET. In particular, we investigate the effect on transport properties of the SSET. We focus on the double Josephson quasiparticle (DJQP) resonance where an especially strong backaction can be observed due to the tunneling of the two coherent Cooper pair tunneling events. We argue that a measurement of, for example the current, the charge noise and the shot noise (Fano factor) provides a direct way of gaining information on the state of the NR. In addition to an analytical discussion of the linear response regime we discuss results of higher order approximation schemes and a full numerical solution.

12:39PM W11.00008 Spin-dependent tunneling and the Kondo effect in quantum dots.* S. E. ULLOA, A. NGO, Ohio U, E. VERNEK, UFU-Brasil — Many-body effects have a significant role in electronic transport of nanoscale systems. Particular interesting systems are quantum dots coupled to electronic reservoirs via quantum point contacts. Due to strong spin-orbit interactions [1,2], quantum point contacts can exhibit spin dependent hybridization of the QD states, opening the possibility for generating spin-polarized transport. In this work we study electronic transport of a single level quantum dot coupled to polarizing quantum point contacts (QPCs) in both the Coulomb blockade and Kondo regimes. We study how QPC gate voltage dependence spin-polarized current is using scattering matrix methods and the equations-of-motion technique. We calculate the electronic Green’s function, conductance and spin polarization in different parameter regimes. Our results show that both Hubbard and Kondo regimes exhibit high spin-polarized conductance. We analyze how the spin-dependent hybridization of the QPC modifies the Kondo resonance, as well as the density of states of the system. These effects are controllable by lateral gate voltages applied on QPCs, as in recent experiments [2]. [1] A. Reynoso et al., Phys. Rev. B 75, 085321 (2007). [2] P. Debray et al., unpublished (2008). * Supported by NSF-DMR WNM.
Andreev transport through side-coupled double quantum dots, Yoichi TANAKA, Condensed Matter Theory Laboratory, RIKEN, Norio KAWAKAMI, Department of Physics, Kyoto University, Akira OGURI, Department of Material Science, Osaka City University — We study the transport through side-coupled double quantum dots, connected to normal and superconducting (SC) leads with a T-shape configuration, using the numerical renormalization group. We find that the Coulomb interaction in the side dot suppresses the destructive interference effect typical of the T-shape geometry, and enhances the conductance substantially in the Kondo regime. This behavior stands in stark contrast to a wide Kondo valley seen in the normal transport. Moreover, the SC proximity penetrating into the interfacial dot pushes the Kondo clouds, which screens the local moment in the side dot, towards the normal lead to make the singlet bond long. The conductance shows a peak of the unitary limit as the cloud expands. It is further elucidated that two separate Fano structures appear in the gate-voltage dependence of the Andreev transport, and the corresponding line shape is quite different from the Fano-Kondo plateau observed in the normal transport.

Zeeman vs resonance splitting effects in a double quantum dot system, N. SANDLER, Ohio U, E. VERNEK, UFU-Brasil, L.G.G.V. DIAS DA SILVA, ORNL-UT, R. INGERSENT, U Florida, S.E. ULLOA, Ohio U — Electron correlations in quantum dot (QD) systems have many intriguing consequences. At low temperatures, the coupling between confined and conduction electrons is known to realize the Kondo effect. This phenomenon exhibits new and interesting features when electrons in an interacting QD hybridize with a non-flat conduction band. For example, when the QD is side-connected to external leads via a second large (noninteracting) QD, the effective density of states coupling to the interacting QD can have a peak at or near the Fermi level. In this regime, interference between the many-body Kondo state in the interacting dot and the single-particle resonance on the other dot causes splitting of the Kondo resonance [1]. Here, we use the numerical renormalization group method to study this double-QD system in the presence of an external in-plane magnetic field. We explore the interplay between different energy scales and discuss the behavior of the Kondo resonance in the presence of competing interactions. The in-plane field suppresses the Kondo effect, although this requires a stronger field than for a single QD, and the conductance decreases with field in a non-universal fashion. [1] L. G. V. Dias da Silva et al., Phys. Rev. Lett. 97, 096603 (2006).

Shot noise in a Mn-doped quantum dot nanomagnet, L.D. CONTRERAS-PULIDO, ICM-CSIC, Spain, J. FERNANDEZ-ROSSIER, Universidad de Alicante, Spain, R. AGUADO, ICM-CSIC, Spain — A single-electron transistor (SET) based upon a II-IV semiconductor quantum dot doped with a single Mn ion behaves as a nanomagnet whose magnetic properties can be controlled electrically, and the effective exchange between the Mn and the carriers depends whether the SET is operated in the electron or the hole region. For holes, the Ising coupling for symmetric dots in absence of spin-flip Mn-hole exchange, results in Coulomb Blockade oscillations which depend on the spin state of the Mn atom [1]. We extended such analysis and studied finite-frequency shot noise through the SET [2]. Shot noise shows various regimes which, as a function of gate and bias voltages, reflect different magnetic configurations of the nanomagnet. We find super-Poissonian noise in a region of bias and gate voltages where the competing dynamics between slow and fast channels (corresponding to different orientations between the hole and the Mn ion) results in bunching. This behavior appears as a resonance around zero frequency, reflecting charge relaxation dynamics. We also discuss the role of transverse spin-flip terms. [1] J. Fernandez-Rossier and R. Aguado, Phys. Rev. Lett. 98, 106805 (2007) [2] D. Contreras-Pulido, J. Fernandez-Rossier and R. Aguado, in preparation

Kondo effects in triangular triple quantum dots, Akira OGURI, Takahide NUMATA, Yunori NISIKAWA, Osaka City University, A.C. HEWSON, Imperial College — We study the conductance through a triangular triple quantum dot, which is connected to two noninteracting leads, using the numerical renormalization group (NRG). It is found that the system shows a variety of Kondo effects depending on the filling of the triangle. The SU(4) Kondo effect occurs at half-filling, and a sharp conductance dip due to a phase lapse appears in the gate-voltage dependence. Furthermore, when four electrons occupy the three sites on average, a local S = 1 moment, which is caused by the Nagaoka mechanism, is induced along the triangle. The temperature dependence of the entropy and spin susceptibility of the triangle shows that this moment is screened by the conduction electrons via two separate stages at different temperatures. The two-terminal and four-terminal conductances show a clear difference at the gate voltages, where the SU(4) or the S = 1 Kondo effects occur [1]. We will also discuss effects of deformations of the triangular configuration, caused by the inhomogeneity in the inter-dot couplings and in the gate voltages.

Interference in triple quantum dot systems, George MARTINS, Oakland University, Edson VERNEK, Ohio University, Carlos BUSSER, Oakland University, Enrique ANDA, PUC - Rio - Brazil, Sergio ULLOA, Nancy SANDLER, Ohio University — Transport properties of an interacting triple quantum dot system coupled to three leads in a triangular geometry has been studied in the Kondo regime. Applying mean-field finite-U slave boson and embedded cluster approximations to the calculation of transport properties of this system unveils a set of very rich features associated to its particular symmetry. In the case where just two leads are present, interference effects between degenerate molecular levels are studied, as well as an S = 1 Kondo effect. The introduction of a third lead does not affect the coherence of propagating electrons, but rather results in an 'amplitude leakage' phenomenon, which alters the interference effects. There is a good overall agreement between the two techniques employed.

Bloch oscillations in lateral periodic nanostructure arrays, W. PAN, S.K. LYO, J.L. RENO, J.A. SIMMONS, Sandia National Labs, D. LI, S.R.J. BRUECK, CHTM, University of New Mexico — In a periodic structure of electron potential, under an external electric field E, if an electron can reach the boundary of the Brillouin zone (BZ) without being scattered, it undergoes Bragg reflection, passing back into the BZ on the opposite side. This results in a high frequency oscillation of electrons, i.e., Bloch oscillation (BO). Recently, BO has gained a renewed interest, as a Blochoscillator can be utilized as a frequency-tunable THz source. Work on BO has mainly been carried out in quantum well superlattices. On the other hand, a surface superlattices patterned into a two dimensional electron system has long been proposed as an alternative structure to generate BO. Here, we present our experimental results on the nonadiabatic differential conductance and Bloch oscillation induced edge magnetoplasma resonance in a series of lateral superlattices. Results from the so-called reversed Bloch oscillations measurements and bolometric measurements will also be presented and discussed. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin company, for the US Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000. The facilities of the NSF-sponsored NNIN node at UNM were used for the fabrication.

Thursday, March 19, 2009 11:15AM - 2:15PM – Session W12 DMP DCMP: Steps, Islands and Nanostructures
11:15AM W12.00001 Relaxation of Terrace-width Distributions: Novel Analysis and Features

T.L. EINSTEIN, Univ. of Maryland, College Park (UM), AMJI BH. HAMOUnda, UM & Univ. Monastir, Tunisia, A. PIMPINELLI, U.M & U.B.P.Clermont-2 & Science Attaque, French Consulate, Houston — We describe a Fokker-Planck scheme to describe the relaxation of the terrace-width distribution (TWD) on a vicinal surface toward the generalized Wigner form describing equilibrium. We performed KMC calculations on the standard minimal SOS model to show that the time constant gives physical information, in particular the energy barrier of the rate-determining process. For close-packed steps, this involves kink-antikink generation, breaking 3 rather than the expected 2 lateral bonds (the latter associated with equilibrium fluctuations). We discuss strengths and limitations of this FP procedure, higher moments of the distribution beyond the variance, and generalizations to other step orientations.

1Work at UM supported by the MRSEC, NSF Grant DMR 05-20471

11:27AM W12.00002 Nanowires of Terrace-width Distributions During Growth on Vicinals

AMJI BH. HAMOUnda, Univ. of Maryland, College Park (UM) & Univ. Monastir, Tunisia, A. PIMPINELLI, UM & U.B.P.Clermont-2 & Science Attaque, French Consulate, Houston, T.L. EINSTEIN, UM — Using kinetic Monte Carlo simulations for a generic minimal SOS model of vicinal surfaces, we compute the terrace-width distributions (TWDs) as a function of incident flux during homoepitaxial growth. We show that the distribution narrows markedly as though there were a flux-dependent repulsion between steps, until the step picture fails at high flux. Using a Fokker-Planck approach, we analyze the evolution and saturation of this narrowing. We compare with a 1D model and with simulations for narrowing due to an Ehrlich-Schwoebel barrier.

1Work at UM supported by the MRSEC, NSF Grant DMR 05-20471.

11:39AM W12.00003 Stability and mobility of vacancy nanoclusters on Cu(111) surface: An ab initio study

ALIREZA AKBARZADEH, ZHENGZHENG CHEN, NICHOLAS KIOUSSIS, California State University Northridge, Department of Physics & Astronomy, 18111 Northridge, CA 91330-8268 — We used ab initio calculations to study stability and mobility of vacancy nanoclusters on Cu(111) surface. We found that the formation energies for single vacancies in the vicinity of surface are ≈0.3 eV lower than that in bulk. Interestingly, calculations yield strongly bonded 1^2NN vacancy on the surface than in bulk. In addition a vacancy binds very strong on the surface, indicating that formation of loop-like vacancy nanoclusters are most energetically favored on the surface. These findings imply the ease of nucleation of vacancy nanoclusters on the surface. We also examined migration of mono-, di- and trivacancy on the surface. A zagzag motion for divacancy diffusion on the surface is predicted with the migration barrier higher on the surface than in the bulk due to larger binding energy and elastic contribution.

11:51AM W12.00004 Two-dimensional island ripening on the basal plane of ice

SHU NIE, NORM BARTEL, KONRAD THURMER, Sandia National Labs, SANDIA NATIONAL LABORATORIES TEAM — Despite the importance of ice surfaces to many natural phenomena there have been no accurate measurements of surface self-diffusion coefficients of ice. To provide this needed basic information, we applied the newly discovered capability of STM to image thick ice films on Pt [1], and tracked the evolution of 2-dimensional ice islands grown on the basal plane of ice. Uniform 5 nm thick ice films grown at 145 K were used as a template to study surface self-diffusion. By depositing a fraction of a monolayer of water onto these films at 115 K, we created arrays of two-dimensional islands with diameters of 5-10 nm. Remarkably, when annealed to temperatures between 115 and 135 K, these island arrays coarsened. By fitting the average island area to the $t^{2/3}$ growth law expected for diffusion-controlled ripening we extract an activation energy for surface self-diffusion of 0.4 ±0.1 eV, which is on the order of the energy of a hydrogen bond and much less than the value measured for bulk diffusion (0.7 eV) [2]. This work is supported by U. S. DOE, OBES, Division of Materials Sciences under contract DE-AC04-94AL8500. [1] K. Thürmer and N. C. Bartel, Phys. Rev. B 77, 195425 (2008). [2] D. E. Brown and S. M. George, J. Phys. Chem. 100, 15460 (1996).

12:03PM W12.00005 Ferromagnetic-Semiconductor Interfacial Order Suppression: Self-Assembled Fe$_x$Ga Island Structures on GaAs(001)

PHILIP RYAN, JONG WOO KIM, Ames Laboratory, JUSTIN SHAW, National Institute of Standards and Technology, CHARLES FALCO, University of Arizona, LAHSEN ASSOUFID, RICHARD ROSENBERG, DAVID KEAVNEY, Argonne National Laboratory, AMES LABORATORY TEAM, NIST COLLABORATION, UNIVERSITY OF ARIZONA COLLABORATION, ARGONNE NATIONAL LABORATORY COLLABORATION — The practical development of spintronics requires a new class of multifunctional microelectronic components, involving electronic device mechanisms dependent upon ferromagnetic materials. The Fe-GaAs(001) system has been extensively studied as the prototypical spin injection junction for spintronic device mechanisms. Increasing spin injection efficiency has been calculated to be dependent upon the structural order of an abrupt interfacial junction between a ferromagnet and semiconductor. Room temperature low coverage Fe deposition on GaAs(001) reveals the formation of fully strained, epitaxial Fe$_x$Ga domains. An iron interfacial layer adheres fully coherent to the buried substrate surface. The adlayer is mediated through the back-bonding of the Fe to substrate terminating As. This structural environment is tied to the suppression of interfacial order.

12:15PM W12.00006 Snow flake shaped gold nanostructures templated on graphene: an avenue to fabricate novel nano electronic devices

KABEER JASUJA, VIKAS BERRY, Kansas State University — Non spherical gold nanoparticles such as rods, multipods, polygons, cubes, stars and branched nanostructures have generated significant research attention in the past few years. Such anisotropic nano structures have been shown to exhibit size and shape dependent properties which are either significantly different or highly pronounced from their spherical counterparts. The unique properties of anisotropic nanostructures (such as localized surface plasmon resonance and surface enhanced fluorescence) make these ideal candidates for a broad range of emerging applications in photonics, opto-electronics, biomedical labeling, sensing and imaging. One of the foremost challenges in utilizing such properties is integrating the anisotropic gold nanostructures into devices which can justifiably tap these properties. Here we demonstrate a simple colloidal synthetic route that results in the formation of snow-flake shaped nanostructures of gold (Au SFs) templated on the nano-sheets of Graphene-oxide(GO). Graphene nanosheets have generated renewed interest in recent years due to their unique 2-dimensional nature and associated electronic, physical and chemical properties. An assembly of Au SFs supported on GO sheets will not only give way to the next generation electronic and optoelectronic nanodevices but will also find wide ranging applications in a number of industrially relevant reactions such as catalysis, fuel cell technology and pollution control.
12:27PM W12.00007 Large-area nanocrystal superlattice films by surface-tension mediated self-assembly. ANGANG DONG, CHRISTOPHER MURRAY, University of Pennsylvania — We report a facile and general approach based on the dynamic self-assembly of nanocrystals on the liquid/liquid interface to fabricate hierarchically ordered nanocrystal superlattices with thicknesses up to several centimeters. In addition to the close-packed ordering of nanocrystals at nanometer scale, the film exhibits exceptionally ordered stripe patterns at micrometer scale. The stripes are formed by the controlled, repetitive stick-slip motion of the liquid-liquid contact line. Both the film thickness and the stripe periodicity are tunable by changing the nanocrystal concentration. The final nanocrystal film, supported on the liquid surface, can be readily transferred to arbitrary substrates for device fabrication. The methodology reported here not only provides a simple and highly reproducible approach for production of large-area nanocrystal superlattice films, but also opens up a new avenue for lithography-free patterning of nanocrystal arrays for applications in optical, electronic, and magnetic devices.

12:39PM W12.00008 Mechanism of Asymmetric Growth of Wurtzite Nanostructures: A Case Study of CdSe Through Ab Initio Computations. GHANSHYAM PILANIA, RAMAMURTHY RAMPRASAD, University of Connecticut — An interesting and potentially useful phenomenon observed in wurtzite semiconductor nanocrystals is asymmetric anisotropic growth. This property has been exploited in the preferential creation of nanorods, nanoribbons and nanosaws over spherical nanocrystals. However, the details of the mechanism underlying this phenomenon of asymmetric anisotropic growth remain poorly understood. Here, we use CdSe as a prototypical wurtzite system, and oxygen as an agent that encourages asymmetric anisotropic growth. This study focus on the impact of the ordering of the surface energies of several polar and nonpolar surface facets as a function of (i) the chemical potential of Cd (i.e., precursor concentration), (ii) the presence of oxygen adsorbates, (iii) the binding modes of oxygen at the surface, and (iv) the density of oxygen adsorbates on the surfaces, using density functional theory (DFT). Our results show that by controlling the ordering of the surface energies (e.g., through proper choices of precursor concentration, temperature, and surfactants), novel growth modes such as asymmetric growth can be made possible.

12:51PM W12.00009 Ab Initio Study of the Effects of Surface Chemistry and Size on Xray Absorption Spectra of CdSe Nanoparticles. HEATHER WHITLEY, Lawrence Livermore National Laboratory, Livermore, CA 94551, DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA 94720, TADASHI OGITSU, ERIC SCHWEGLER, Lawrence Livermore National Laboratory, Livermore, CA 94551 — The specificity of their opto-electronic properties with respect to size, shape, and surface chemistry, as well as cost-effective sol-gel methods of synthesis, make CdSe nanoparticles a material of choice for use in novel opto-electronic devices, such as photovoltaics and field effect transistors. Developing methods by which these nanomaterials can be systematically engineered to meet specific device goals is largely dependent on understanding how surface passivation and reconstruction affect the properties of a given nanomaterial. Xray absorption spectroscopy (XAS) is an ideal method for structural analysis, but its application to studying nanomaterial surfaces is nontrivial due to the convolution of the absorption of surface atoms with those within the nanomaterial. We utilize ab initio methods to investigate the dependence of the Cd L-edge x-ray absorption cross-section on the size and passivation of Cd atoms both at the surface and within the core of CdSe nanomaterials. We aim to enable routine surface characterization of CdSe nanomaterials via XAS. Prepared by LLNL under Contract DE-AC52 07NA27344.

1:03PM W12.00010 Microwave induced in-situ deposition of Gold and Silver nanoparticles on chemically modified sheets of graphene: Avenue to build Graphene-metal interface. KABEER JASUSA, VIKAS BERRY, Kansas State University — In recent years there has been a great interest in the architecture of 2-D sheets of graphene which have been shown to display remarkable electronic, physical and chemical properties. An extremely high conductivity of graphene sheets along with the ease these can be prepared, has already made graphene as the material of choice for applications in several electronic, optoelectronic and biodevices. There is a great deal of interest in interfacing graphene sheets with other low dimensional nanostructures for building novel hybrids. Coupling such low dimensional materials at nano scale yield novel composites with interesting properties. In this study we synthesized nanoparticles of gold and silver on the sheets of graphene-oxide using a one step microwave heating method. Our results indicate that the sheets of chemically modified graphene act as excellent templates for in-situ formation of gold and silver nanoparticles. The advantage of this present synthetic route lies in not using the conventional low molecular weight stabilizing agents which can otherwise react with the graphene sheets leading to impurities. This simple processing approach opens up a new way to synthesize hybrid sheets of graphene decorated with gold and silver nanoparticles which can be used in developing novel catalysts and composites.

1:15PM W12.00011 Efficient sticking of surface-passivated Si nanospheres via phase-transition plasticity. TRAIAN DUMITRICA, MAYUR SURI, University of Minnesota — Large-scale atomistic simulations considering a 5 nm in radius H-passivated Si nanosphere that impacts with relatively low energies onto a H-passivated Si substrate reveal a transition between two fundamental collision modes. At impacting speeds of less than ~ 1000 m/s, particle-reflection dominates. At increased speeds the partial onset in the nanosphere of a β-tin phase on the approach followed by α-Si phase on the recoil is an efficient dissipative route that promotes particle-capture. In spite of significant deformation, the integrity of the deposited nanosphere is retained. Our result explains the efficient fabrication of nanoparticulate films by hypersonic impact, where the nanoparticle impact velocities equal 1000–2000 m/s.

1:27PM W12.00012 Electronic Nano-Structures as Ionic Barriers: A New Corrosion Prevention Concept. SREEYA SREEVATSA, Department of Applied Physics and the Electronic Imaging Center, HAIM GREBEL, Department of Electrical and Computer Engineering and the Electronic Imaging Center — Corrosion is a longstanding problem which costs the economy billions of dollars annually. The simplest way to prevent corrosion is to use paint thereby blocking diffusion of corrosive component towards the metallic surface. Here we consider a new concept - the electronic barrier – for corrosion prevention. The barrier is an electronic p-n junction made by topping one film of functionalized carbon nanotubes on another. The barrier is constructed such that the positive ions in the electrolyte are prohibited from reaching the metallic surface through electronic screening.

1:39PM W12.00013 Ion-beam-assisted nano-texturing of halite-structure thin films. VLADIMIR MATIAS, Los Alamos National Laboratory — We study biaxial crystalline texturing at early film growth in a variety of compounds during ion-beam-assisted deposition (IBAD). We have found that many different halite-structure compounds share the ion-beam texturing ability at nucleation and early film growth. This includes numerous oxides and nitrides. Fluorite-structure compounds also exhibit the possibility of fast IBAD texturing. For these materials IBAD texturing can be achieved within the first few nanometers of deposited material. We examine the detailed texture evolution for MgO. To perform these experiments we developed a unique experimental methodology based on linear combinatorial research. Three different texture development regions can be identified in MgO texture evolution. The first stage where biaxial texture first appears is during grain nucleation. With additional IBAD texture continues to improve by grain alignment up to a certain point. Further improvement in crystalline alignment can be achieved by a third stage of epitaxial overgrowth. We find that the IBAD texture development is very sensitive to the nucleation surface conditions, both chemical species and surface morphology. An in-plane texture of less than 0.5° and an out-of-plane texture of less than 1° are attainable in an artificially textured MgO layer on an amorphous substrate. This work is supported by the DOE Office of Electricity Delivery & Energy Reliability.
11:15AM W13.00001 Electronic structure of electron doped Ba$_2$Fe$_2$As$_2$ superconductors revealed by Angle Resolved Photoemission. P. VILMERCATI, I. VOBRONIK, M. UNNIKRISHNAN, A. FEDOROV, A. GOLDONI, G. PANACCIONE, A. SAFAFEFAT, R. JIN, M.A. MCGUIRE, B.C. SALES, D.J. SINGH, D. MANDRUS, N. MANNELLA — The electronic structure in the normal state of Co-doped Ba$_2$Fe$_2$As$_2$ superconductors has been measured by Angle Resolved photoemission (ARPES). Co doping on the Fe site results in electron doping [A. S. Sefat et al., Phys. Rev. Lett. 101, 117004 (2008)]. The data qualitatively reveal that Co-doping results in raising the chemical potential, as expected with electron doping. The Fermi surface topology and the possible relevance to the mechanism of spin fluctuation will also be discussed.

11:27AM W13.00002 ARPES Study of the Electronic Structure of the Fe Pnictides. MING YI, DONGHUI LU, RUIHUA HE. Stanford University, SUNG-KWAN MO. Advanced Light Source, LBNL, JAMES ANALYTIS, JUIN-HAW CHU, ANN ERICKSON, Stanford University, DAVID SINGH, Material Science and Technology Division, Oak Ridge National Lab, ZAHID HUSSAIN, Advanced Light Source, LBNL, TED GEBALLE, IAN FISHER, Stanford University, XINGJIANG ZHOU, G.F. CHEN, JIANLIN LUO, NANLIN WANG, Institute of Physics, Chinese Academy of Sciences — Recently superconductivity has been discovered in many iron pnictides when they are properly doped with charge carriers. Thus it is expected with electron doping. The Fermi surface topology and the possible relevance to the mechanism of spin fluctuation will also be discussed.

11:39AM W13.00003 Study of band structure and Fermi Surface of SrFe$_2$As$_2$ and BaFe$_2$As$_2$ by angle-resolved photoemission spectroscopy. MADHAB NEUPANE, Y.-M. XIU, Z. WANG, Boston College, P. RICHARD, S. SOUMA, WPI Research Center, Tohoku University, K. NAKAYAMA, Tohoku University, T. SUGAWARA, Tohoku University., T. ARAKANE, Y. SEKIBA, A. TAKAYAMA, T. SATO, T. TAKAHASHI, Tohoku University, X. DAI, Z. FANG, G.F. CHEN, J.L. LUO, J. BOWEN, N.L. WANG, H. DING, Institute of Physics, Chinese Academy of Sciences — Recently superconductivity has been discovered in many iron pnictides when they are properly doped with charge carriers. Thus it is important to understand the undoped parent compounds that also have a puzzling collinear antiferromagnetic ground state. We have performed a systematic angle-resolved photoemission study on some of the parent compounds, mostly on SrFe$_2$As$_2$ and BaFe$_2$As$_2$, to investigate their electronic structure and Fermi surface. We will report our experimental results and the comparisons to first-principle band calculations.

11:51AM W13.00004 Fermi surface and superconducting gap of Ba$_{1-x}$K$_x$Fe$_2$As$_2$ studied by high-resolution ARPES. K. NAKAYAMA, T. SATO, Y. SEKIBA, Tohoku University, P. RICHARD, S. SOUMA, WPI, Tohoku University, M. NEUPANE, Y.-M. XIU, Z. WANG, Boston College, X. DAI, Z. FANG, G. F. CHEN, J. L. LUO, N. L. WANG, H. DING, Chinese Academy of Sciences, T. TAKAHASHI, WPI, Tohoku University — The electronic states near the Fermi level are the key ingredient to understand the superconducting mechanism of iron-based superconductor. Although electrons in the iron orbitals have been found to play a key role to the occurrence of the superconductivity, the microscopic origin of high-$T_c$ superconductivity is still unclear. To address this important issue, we report our recent high-resolution ARPES results on hole-doped Ba$_{1-x}$K$_x$Fe$_2$As$_2$, and demonstrate the Fermi-surface-sheet and momentum dependence of the superconducting gap as well as the doping evolution of the Fermi surface and band structure.

12:03PM W13.00005 ARPES study of doping dependence of the superconducting gap in Ba$_{1-x}$K$_x$Fe$_2$As$_2$. Y.-M. XIU, M. NEUPANE, Department of Physics, Boston College, P. RICHARD, WPI Research Center, Advanced Institute for Material Research, Tohoku University, K. NAKAYAMA, Y. SEKIBA, Department of Physics, Tohoku University, T. QIAN, S. SOUMA, WPI Research Center, Advanced Institute for Material Research, Tohoku University, T. SATO, T. TAKAHASHI, Department of Physics, Tohoku University, H.-H. WEN, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Z. WANG, Department of Physics, Boston College, H. DING, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences — High transition temperature superconductivity has been discovered recently in many doped iron pnictides which join the cuprates in the family of high-$T_c$ superconductors. It is very important to understand the nature of the superconducting gap and its doping dependence, as in the case of the cuprates, in order to understand this new class of superconductors. A systematic angle-resolved photoemission spectroscopy (ARPES) study has been performed on the iron pnictide Ba$_{1-x}$K$_x$Fe$_2$As$_2$ at different K concentrations, to determine its doping dependence of the superconducting gap. We will report our ARPES results and their implications.
12:15PM W13.00006 Momentum dependence of superconducting gap, strong-coupling dispersion kink, and tightly bound Cooper pairs in the high-Tc (Sr,Ba)1-x(K,Na)xFe2As2 superconductors, LEWIS WRAY, DONG QIAN, DAVID HSIEH, YUQI XIA, ALI YAZDANI, N. PHUAN ONG, Princeton University, NANLIN WANG, Beijing National Laboratory for Condensed Matter Physics, M. ZAHID HASAN, Princeton University — We present a systematic angle-resolved photoemission spectroscopic study of the high-Tc superconductor class (Sr,Ba)1-x(K,Na)xFe2As2. By utilizing a photon-energy-modulation contrast and scattering geometry we report the Fermi surface and the momentum dependence of the superconducting gap, \( \Delta(T) \). A prominent quasiparticle dispersion kink reflecting strong scattering processes is observed in a binding-energy range of 25-55 meV in the superconducting state, and the coherence length or the extent of the Cooper pair wave function is found to be about 20 \( \AA \), which is uncharacteristic of a superconducting phase realized by the BCS-phonon-retardation mechanism. The observed 40-2.15 meV kink likely reflects contributions from the frustrated spin excitations in a J1-J2 magnetic background and scattering from the soft phonons. Results taken collectively provide direct clues to the nature of the pairing potential including an internal phase-shift factor in the superconducting order parameter which leads to a Brillouin zone node in a strong-coupling setting.

12:27PM W13.00007 Momentum dependence of the superconducting gap in NdFeAsO\(_{1−x}\)F\(_x\) single crystals measured by angle resolved photoemission spectroscopy, TAKESHI KONDO, A.F. SANTANDER-Syro, O. COPIE, CHANG LIU, M.E. TILLMAN, J. SCHMALIAN, S.L. Bud'ko, P.C. CANFIELD, A.D. Kaminiski, Nanlab and Dept. of Physics and Astronomy, Iowa State University — We use angle resolved photoemission spectroscopy (ARPES) to study the momentum dependence of the superconducting gap in NdFeAsO\(_{1−x}\)F\(_x\) single crystals. We find that the T' hole pocket is fully gapped below the superconducting transition temperature. The value of the superconducting gap is 15 ± 3 meV and its anisotropy around the hole pocket is smaller than 20% of this value. This is consistent with an isotropic or anisotropic s-wave symmetry of the order parameter or exotic d-wave symmetry with nodes located off the Fermi surface sheets. This is a significant departure from the situation in the cuprates, pointing to possibility that the superconductivity in the iron arsenic based system arises from a different mechanism.

12:39PM W13.00008 3D band structure determination of BaFe2As2, CaFe2As2 and SrFe2As2, QIANG WANG, ZHE SUN, Department of Physics, University of Colorado Boulder, FILIP RONNING, ERIC BAUER, Los Alamos National Laboratory, SUCHITRA SEBASTIAN, Cavendish Lab, Cambridge, UK, DANIEL DESSAU, Department of Physics and JILA, University of Colorado Boulder — The band structure of the parent compounds of iron-arsenic superconductors BaFe2As2, CaFe2As2 and SrFe2As2 are investigated by angle-resolved photoemission spectroscopy. The dispersion of predominant Fe 3d bands has been successfully resolved and compared with theoretical calculations. Although the overall band structure is in line with nonmagnetic DFT computations, the Fe 3d band dispersions strongly deviate from calculations, and the Fermi surface topology differs from theoretical results. These results suggest that some significant correlations have not been correctly involved in the current understanding of these new materials. The kz dependence of the Fermi surface structure has also been studied for these quasi-2D materials.

12:51PM W13.00009 Band Structure and Fermi Surface of Extremely Overdoped Iron-Based Superconductors, TAKAFUMI SATO, K. NAKAYAMA, Y. SEKIBA, Dep. Physics, Tohoku University, P. RICHARD, S. SOUMA, WPI, Tohoku University, Y.-M. XU, Boston College, G. F. CHEN, J. L. LUO, N. L. WANG, H. DING, Chinese Academy of Sciences, T. TAKAHASHI, WPI and Dep. Physics, Tohoku University — The discovery of superconductivity at 26 K in LaFeAsO\(_{1−x}\)F\(_x\) has triggered intensive researches on the high-temperature (\( T_c \)) superconductivity of iron pnictides and opened a new avenue for high-\( T_c \) material research beside cuprates. To elucidate the mechanism of high-\( T_c \) superconductivity in terms of the electronic structure, previous angle resolved photoemission spectroscopy (ARPES) studies have been performed on both hole and electron-doped compounds in the optimally- or non(under)-doped region. On the other hand, little is known about the electronic states in the overdoped region. We report ARPES measurements on heavily overdoped pnictides. Our results indicate that the electronic states around the M point play an important role in the high-\( T_c \) superconductivity of these materials and suggests that the interband scattering via the antiferromagnetic wave vector essentially controls the \( T_c \) value in the overdoped region.

1:03PM W13.00010 Electronic structure of electron-doped BaFe\(_2\)−\(_x\)Co\(_x\)As Superconductor class studied by ARPES, DONG QIAN, princeton university, N.L. WANG, Institute of Physics, Chinese Academy of Sciences, M.Z. HASAN, princeton university — State-of-art high resolution angle-resolved photoemission spectroscopic studies have been carried out on the electron doped BaFe\(_2\)−\(_x\)Co\(_x\)As Superconductor (Tc=26K). Electronic band structure, Fermi surface topology and superconducting gap evolution would be reported in this presentation. Nature of the spin sensitivity wave (SDW) state would be discussed from a band nesting point of view.

1:15PM W13.00011 Observation of an orbital selective electron-mode coupling in Fe-based high-Tc superconductors, PIERRE RICHARD, WPI, Tohoku University, T. SATO, K. NAKAYAMA, Dep. Physics, Tohoku University, S. SOUMA, WPI, Tohoku University, Y.-M. XU, Boston College, G.F. CHEN, J.L. LUO, N.L. WANG, H. DING, Chinese Academy of Sciences, T. TAKAHASHI, WPI and Dep. Physics, Tohoku University — The recent discovery of Fe-based superconductors with critical temperatures up to 56 K raises the prospect of unconventional superconducting pairing mechanism. While the electronic pairing in conventional superconductors is mediated by phonons, its nature in the Fe-based high-Tc superconductors is unknown. A direct signature of an electron-mode coupling is an anomaly in the electronic energy dispersion (kink). For example, previous angle-resolved photoelectron spectroscopy (ARPES) studies revealed a kink in cuprates, which is believed to be linked to the pairing. We report an ARPES observation of a kink around 25 meV in the dispersion of superconducting Ba\(_{0.6}\)K\(_{0.4}\)Fe\(_2\)As\(_2\) that nearly vanishes above \( T_c \). The energy scale of the related mode (13±2 meV) and its strong dependence on orbital and temperature indicates that it is unlikely related to phonons. Moreover, the momentum locations of the kink can be connected by the antiferromagnetic wavevector. Our results point towards an electronic origin of the mode and the superconducting pairing in the Fe-based superconductors, and strongly support the anti-phase s-wave pairing symmetry.

1:27PM W13.00012 Electronic properties of CaFe\(_2\)As\(_2\), CHIANG LIU, TAKESHI KONDO, ARI PALCZEWSKI, GERMAN SAMOYUK, YONGBIN LEE, NI NI, SERGEY BUD'KO, PAUL CANFIELD, ADAM KAMINSKI, Ames Laboratory and Iowa State University, AARON BOSTWICK, ELI ROTENBERG, Advanced Light Source, Berkeley National Laboratory — CaFe\(_2\)As\(_2\) is a parent compound of a new family of FeAs based high-Tc superconductors. It undergoes a first-order structural transition from low-\( T \) orthorhombic to high-\( T \) tetragonal phase [Ni et al., Phys. Rev. B 78, 014523]. Moderate pressure lowers the transition temperature, and turns on the superconductivity [Toriguchii et al., Phys. Rev. Lett. 101, 057006]. Study on its electronic properties is of crucial importance for understanding the pairing mechanism of the FeAs based superconductors. Here we present angle-resolved photoemission spectroscopy (ARPES) results on both the orthorhombic and the tetragonal phase of CaFe\(_2\)As\(_2\). In the orthorhombic phase, we find strong \( k_z \) dispersion on the Fermi surfaces, showing a three dimensional electronic structure. We also find dramatic difference of the Fermi surface structure between the orthorhombic and the tetragonal phase.
1.39PM W13.00013 Fermi surface of the parent compound of iron-based superconductor, T. SHIMOJIMA, ISSP U. Tokyo, Y. ISHIDA, RIKEN SPRing-8, N. KATAYAMA, K. OHGUSHI, K. ISHIZAKA, T. KISS, M. OKAWA, ISSP U. Tokyo, T. TOGASHI, RIKEN SPRing-8, X.-Y. WANG, C.-T. CHEN, CAS, S. WATANABE, ISSP U. Tokyo, T. OGUCHI, U. Hiroshima, S. SHIN, ISSP U. Tokyo — Fermi surface of the parent compound of iron-based superconductor BaFe2As2 is studied by angle-resolved photoemission spectroscopy using VUV-laser. This compound shows structural and magnetic phase transition around TN = 140 K [1]. We found the transformation of Fermi surface across TN. We will discuss its origin comparing with the first principle band calculation.

1.51PM W13.00014 APRES study of in-plane element substituted iron-based superconductors Ba(Fe1-xCo$_x$)$_2$As$_2$ and Ba(Fe1-xNi$_x$)$_2$As$_2$, JONATHAN BOWEN, Institute of Physics, Chinese Academy of Sciences, KENSEI TERASHIMA, PIERRE RICHARD, TAKAFUMI SATO, TAKASHI TAKAHASHI, Tohoku University, ZHUAN XU, Zhejiang University, HONG DING, Institute of Physics, Chinese Academy of Sciences — Much excitement has surrounded the recent discovery of the doped pnicnides which exhibit high temperature superconductivity. These new materials are generally grouped into either 1111 or 122 compounds by the stoichiometric formula of the parent compounds. Understanding how doping with different valence affects their superconducting properties is a vital element of working toward a complete picture of these interesting new compounds. To that end, we have conducted a high-resolution APRES study of two 122 compounds: Ba(Fe1-xCo$_x$)$_2$As$_2$ and Ba(Fe1-xNi$_x$)$_2$As$_2$ and will report our results.

11:15AM W14.00001 Clustering in a Dense, Freely-Falling Granular Stream, JOHN R. ROYER, SCOTT R. WAITUKAITIS, James Franck Institute, University of Chicago, DANIEL J. EVANS, HEINRICH M. JAEGER, James Franck Institute, University of Chicago — We investigate the breakup of a freely-falling granular stream into discrete, compact clusters of grains. This breakup, occurring for grain diameters less than about 200 microns falling out of a hopper opening, is reminiscent of the breakup of a liquid stream, though granular materials are generally thought of as lacking a surface tension. Our experiments employ high-speed video imaging in the co-moving frame, which allows us to track the onset of clustering and the subsequent cluster evolution in detail. Varying the material, size, roughness, and wetting properties of the grains as well as the surrounding gas pressure and the hopper opening diameter, we investigate the role of capillary, electrostatic and van der Waals forces in the clustering process. We find that the clustering provides a window to observe very weak cohesive forces between the grains which are masked in other experiments.

11:27AM W14.00002 Vector Force Measurements of a Dense Granular Flow, KEVIN FACTO, University of Massachusetts-Amherst, TOM SCHICKER, NARAYANAN MENON, University of Massachusetts-Amherst — We have made force measurements at the wall of a dense granular flow. The data was acquired with planar elements at rate of 800 Hz in all three spatial directions. The fluctuations in the forces were examined for a wide range of flow speeds. Correlations in the forces decay by the time the flow moves one ball diameter. The force along the flow direction is highly correlated with the force normal to the wall. For a given value of normal force, the force along the flow has a gaussian distribution about the tangential force that would be predicted from a constant friction angle.

11:39AM W14.00003 Space-Time Structure of Granular Flows in a Rough Vertical Channel, DONALD CANDELA, KEVIN FACTO, University of Massachusetts Amherst — We report measurements using PFG-NMR of the space and time structure of steady granular flows through a long vertical channel of circular cross section with roughened walls. The granular sample consisted of seeds approximately 400 μm in diameter, flowing through a 9.8 mm ID tube to which was adhered a monolayer of glass beads similar in diameter to the grains. Data was acquired from a region approximately 50 channel diameters higher than the aperture at the channel bottom used to control the flow rate. The mean velocity of the grains as well as the RMS fluctuations in the grain motion were measured as functions of the radial coordinate and for time intervals in the range 5-200 ms, for several different granular flow speeds. For some flow regimes the displacement distributions are distinctly non-Gaussian, at odds with a “molecular fluid” model of the granular medium. The time dependence of the fluctuation distribution provides clues to the mechanism by which the gravitational body force is transmitted to the channel walls.

11:51AM W14.00004 Vibrhology of Granular Matter, JOSHUA DIJKSMAN, GEERT WORTEL, MARTIN VAN HECKE, Leiden University — We show how weak agitations substantially modify the rheology of granular materials. We experimentally probe dry granular flows in a weakly vibrated split-bottom shear cell – the weak vibrations act as the agitation source. By tuning the applied stress and vibration strength, and monitoring the resulting strain, we uncover a rich phase diagram in which non-trivial transitions separate a jammed phase, a creep flow case, and a steady flow case.

12:03PM W14.00005 Shear zones at the walls of a 2D gravity-driven flow of grains, KELSEY HATTAM, NALINI EASWAR, Smith College, Northampton, MA, NARAYANAN MENON, University of Massachusetts, Amherst, MA — We study the flow of spherical grains under gravity in a vertical, straight-walled 2-dimensional hopper, where the flow velocity is controlled by a taper at the outlet. We perform these studies both for monodisperse steel spheres as well as for a bidisperse system of equal numbers of spheres with a ratio of diameters of 1.25. The monodisperse system shows crystalline order even in flow, whereas there is no obvious structural order in the bidisperse system. The velocity profile across the flow is profoundly different in the two systems: the wall shear zone in the monodisperse system extends only a few particle diameters, and there are only small velocity gradients in the bulk of the flow. In contrast to this nearly-plug-like flow, there are significantly broader shear zones in the disordered flow. We report these profiles as a function of the width of the hopper in order to study the scaling of the shear zone with the system size, and with the flow rate.

12:15PM W14.00006 A Void Diffusion Model of Granular Flow  JAYANTA RUDRA, PAUL VIETH, Oklahoma School of Science and Mathematics — In an earlier paper1 we derived a nonlinear diffusion equation to describe the dynamics in granular flow based on a Diffusion Void Model (DVM). The equation was successfully used to describe the flow of a homogeneous granular material through the hole of a container under gravity. It also properly described similar flow in the presence of a flat horizontal barrier placed above the hole. Recently, however, we have found that the above nonlinear equation does not lead to correct static equilibrium. For example, the stability of the free surface of a granular aggregate cannot be described by the equation. The equation also fails to describe, say, how an unstable vertical column of a granular material will change to a stable A-shaped pile at the angle of repose. In this paper work we derive an equation using an appropriate current density of voids that can explain all the observed dynamical characteristics of a simple granular state. 1 Jayanta K. Rudra and D. C. Hong, Phys. Rev. E47, R1459 (1993).

12:27PM W14.00007 The Role of Extensional Viscosity in Sedimentation of Dense Suspensions THEODORE BRZINSKI, DOUGLAS DURIAN, University of Pennsylvania — When two particles in a viscous fluid approach contact the motion of the interstitial fluid is dominated by extensional flows. We are interested in how the details of these flows influence the sedimentation of sense suspensions. To highlight the effects of extensional flows on particle motion we compare systems in which the fluids have the same shear viscosities, but drastically different extensional viscosities. We enhance the extensional viscosity by adding a flexible, high molecular weight polymer. In the case of a system without polymer there is a dense, static packing which grows from the bottom of the container, a region which remains at the initial grain density and settles at a constant velocity, and a clear supernatant at the top. In the polymeric fluid particles settle more slowly, and rather than sedimenting directly from the initial density to a static packing there is a long consolidation process during which the particle density increases at a constant rate.

12:39PM W14.00008 Local Rearrangements in a Dense Granular Medium During Steady and Oscillatory Shear STEVEN SLOBOTBACK, University of Maryland: College Park, KRISZTIAN RONASZEgli, Budapest University of Technology and Economics, WIM VAN SAARLOOS, Leiden University, WOLFGANG LOSERT, University of Maryland College Park — Cooperative motion is a hallmark of dense granular media. Using the laser sheet scanning method described in [1], we are able to track the motions of all particles in a dense packing of spheres in three dimensions. We analyze the motions of all particles within a split bottom shear cell. We study both steady and oscillatory shearing processes. We compare relative motions of neighboring particles using a measure, P(cos(α)), based on a measure originally used by Ellenbroek et al [1]. The angle, α, is the angle between the relative displacements of neighboring particles and their bond vectors. A pair of neighboring particles where cos(α)=0 is called a rolling contact. We find that particles in contact tend to roll past one another, which is consistent with the findings made by Ellenbroek et al for systems close to jamming and we also find that the number of rolling contacts drops at the onset of a shear reversal. [1] Ellenbroek et al, to appear in Phys Rev Lett [2] Ellenboek et al., Phys Rev Lett, 97 258001 (2006)

12:51PM W14.00009 Three-dimensional Order and Self-Diffusion in a Cyclically Sheared Granular System ANDREAEA PANAITEscu, ARSHAD KUDROLLI, Physics Department, Clark University — We investigate the structure and dynamics of a dense granular packing (consisting of one millimeter diameter spherical glass beads) undergoing cyclic shear flow obtained by smoothly deforming a parallellepped shaped cell. Using a fluorescent refractive index matched particle tracking technique, we obtain the three dimensional position of particles in the central region of the shear cell as a function of shear cycle. The granular packing is observed to evolve towards crystallization over thousands of shear cycles and the packing fraction is correspondingly observed to increase smoothly from loose packing fraction. We obtain the Voronoi cell volume distributions from the measured positions, and compare them with various models which predict a Gamma-distribution and help us define a regularity factor. Further, we discuss the measured radial distribution and the bond-order parameter Q6 which are widely used to quantify local order in spherical particle systems. We find that the initial self-diffusion of the particles is anisotropic with diffusion greater in the flow direction compared with the velocity gradient direction which in turn is greater than the vorticity direction.

1:03PM W14.00010 Dynamic effective mass of granular media DAVID JOHNSON, Schlumberger-Doll Research, ROHIT INGAL, JOHN VALENZA, CHAUR-JIAN HSU, NICOLAS GLAND, HERNAN MAKSE, SCHLUMBERGER-DOLL RESEARCH COLLABORATION, LEVICH INST. COLLABORATION — We report an experimental and theoretical investigation of the frequency-dependent effective mass, M(ω), of loose granular particles which occupy a rigid cavity to a filling fraction of 48%, the remaining volume being air of differing humidities. We demonstrate that this is a sensitive and direct way to measure those properties of the granular medium that are the cause of the changes in acoustic properties of structures containing grain-filled cavities. Specifically, we apply this understanding to the case of the flexural resonances of a rectangular bar with a grain-filled cavity within it. The dominant features of M(ω) are a sharp resonance and a broad background, which we analyze within the context of simple models. We find that: a) These systems may be understood in terms of a height-dependent and diameter-dependent effective sound speed (∼ 130 m/s) and an effective viscosity (∼ 2 × 10^4 Poise). b) The effective acoustic Janssen effect in the sense that, at any frequency, and depending on the method of sample preparation, approximately one-half of the effective mass is borne by the side walls of the cavity and one-half by the bottom. c) On a fundamental level, dissipation is dominated by adsorbed films of water at grain-grain contacts in our experiments.

1:15PM W14.00011 ABSTRACT WITHDRAWN —

1:27PM W14.00012 Visualization of displacement fields in sheared granular systems KINGA LORINCZ, PETER SCHALL, University of Amsterdam — The jamming transition, i.e. the transition in a granular system from rest to flow is a fundamental problem of great importance to the understanding of a wide class of disordered materials: grains, clay and glassy materials such as molecular glasses and gels. We visualize the particles in a sheared three-dimensional granular packing immersed in an index matching liquid using confocal microscopy and laser sheet imaging. These experimental methods allow for an accurate determination of the displacement field of the particles at the onset of flow.

11:15AM W15.00001 Assembly and melting of DNA nanotubes and tile lattices THOMAS SOBEY, STEPHAN RENNER, FRIEDRICH SIMMEL, Biomolecular Systems und Bioelectronics, Physics Department E14, Technical University Munich, 85748 Garching, Germany — Programmable molecular self-assembly using DNA is allowing the demonstration of increasingly novel nanoscale structures such as lattices and tiles. Understanding the assembly and melting pathways of these will allow us to develop more complex and/or stable structures, and potentially useful nanomaterials. We experimentally show differences in these pathways by correlating temperature-controlled UV absorption measurements with atomic force microscopy, fluorescence microscopy, and transmission electron microscopy measurements. The three-dimensional nanotubes assemble in several hierarchical steps but melt in a single step, and this contrast is proposed to arise from the fundamental distinction between three-dimensional closed tubes and two-dimensional open lattices.
11:27AM W15.00002 Response of a self-assembling to mechanical stress. YVES DUBIEF, University of Vermont, Mechanical Engineering and Material Science Program, ROSS PACKARD, University of Vermont, Material Science program, SREEDHAR MANCHU, LEONIE COWLEY, University of Vermont, Mechanical Engineering Program — Coarse-grained molecular dynamics is used to characterize the mechanical properties of a solution of phospholipids and polyelectrolytes under shear and compression. DPPC (1,2-Dipalmitoylphosphatidylcholine) and polyelectrolytes are coarse-grained using the MARTINI force field. Simulations are performed using both GROMACS and LAMMPS. In our simulation, the solution is confined by two rigid walls. The objective of this work is to study the influence of the electrostatic nature of the wall on the self-assembling structure of the solution and to define the rheological and structural response of the solution under shear and compression by moving one wall.

1The computational support of the Vermont Advanced Computing Center is gratefully acknowledged. Y. Dubief and S. Manchu also thank Vermont Epscor and NSF for their support.

11:39AM W15.00003 Self-assembling structures resulting from the presence of polyelectrolytes in a solution of phospholipids. ROSS PACKARD, YVES DUBIEF. University of Vermont — The objective of this study is the characterization of self-assembled structures formed by the combination of phospholipids and polyelectrolytes. Coarse-grained molecular dynamics is used to simulate solutions of DPPC (1,2-Dipalmitoylphosphatidylcholine) and polyelectrolytes in a three-dimensional domain. The MARTINI database defines the topology of coarse-grained macromolecules and water, and simulations are performed using GROMACS. The interaction between negatively charged polyelectrolytes and positively charged hydrophilic heads of DPPC causes the disruption of lipid bilayer membranes and vesicles. The study attempts to define the conditions necessary for the formation of vesicles or organized networks of lipid bilayers that encapsulate the polyelectrolytes. Such structures are expected to play an important role in biological fluids subject to large mechanical stress.

1The computational support of the Vermont Advanced Computing Center is gratefully acknowledged.

11:51AM W15.00004 Self-organized Gels in DNA/F-Actin mixtures without Crosslinkers. JOHN BUTLER, GHEE HWEI LAI, OLENA Z RBI, University of Illinois at Urbana-Champaign, IVAN SMALYUKH, University of Colorado at Boulder, THOMAS ANGELINI, Havard University, KIRSTIN PURDY, University of Illinois at Urbana-Champaign, RAMIN GOLESTANIAN, University of Sheffield, GERARD C. L. WONG, University of Illinois at Urbana-Champaign — Interactions between flexible chains and rigid rods govern a broad range of soft matter systems. As a model system of like-charged rigid rods and flexible chains, we examine mixtures of DNA and filamentous actin (F-actin). Confocal microscopy reveals the formation of elongated nematic F-actin domains reticulated via defect-free vertices into a network embedded in a mesh of random DNA. Synchrotron small-angle x-ray scattering (SAXS) indicates that the DNA mesh squeezes the F-actin domains into a nematic state with an inter-actin spacing that decreases with increasing DNA concentration. Salt strongly influences the domain sizes and transitions the system from a counterion-controlled regime to a depletion-controlled regime. Both mechanisms of which are entropic in origin.

12:03PM W15.00005 Modeling the hydrophobic effect by coupling solutes to a lattice gas. AMISH PATEL, DAVID CHANDLER, University of California, Berkeley — In problems of biological assembly, manifestation of the hydrophobic effect is complex depending on the size as well as the conformation of the solute. The solute disrupts the inherent structure of the solvent by causing an unbalancing of attractive interactions experienced by the solvent molecules. The extent of this disruption determines the relative ease with which the solute is solvated. The theory of Lucio, Chait, and Chandler (LCW) successfully describes this rich interplay between the solute and solvent structures by coarse-graining the solvent density and analytically integrating out solvent fluctuations on a length scale smaller than the coarse-graining length ($L_c$). Since the implementation of LCW theory can be computationally very demanding the coarse-grained solvent density was mapped onto a lattice gas by ten Wolde, Sun and Chandler. In this work, we further improve upon the theory by relaxing certain assumptions about the unbalancing of attractive interactions on length scales smaller than $L_c$. In addition to a brief overview of the theory, results obtained by application of the theory to several pertinent problems of hydrophobic assembly will be presented.

12:15PM W15.00006 Direct Measurement of Inter-filament Forces in Neurofilament Networks: Synchrotron X-ray Diffraction Study under Osmotic Pressure. R. BECK, J. DEEK, C.R. SAPINYA, UC Santa-Barbara — Neurofilaments (NFs) are the major protein constituents in neuronal processes (axons and dendrites) that impart mechanical stability and act as structural scaffolds. The filaments assemble from different subunit proteins (NF-L, NF-M, NF-H) to form a 10 nm diameter flexible polymer with radiating unstructured sidearms. Recent work showed that at high protein concentration, the NFs form a nematic hydrogel network with a well-defined interfilament spacing as can be measured by synchrotron small-angle x-ray scattering (SAXS) [1]. In order to directly elucidate the interfilament forces responsible for the mechanical properties of NFs hydrogel, we conducted a SAXS-osmotic study, which yielded pressure-distance curves at different subunit compositions and monovalent salts. We show that filaments composed with NF-L and NF-M strongly attract each other through their polyampholyte sidearms, in particular at high monovalent salt. However, filaments comprised of NF-L and NF-H, show a distinctly different pressure-distance dependency, with much larger interfilament spacing and weaker salt dependence. Supported by DOE DE-FG-02-06ER46314, NIH GM-59288, NSF DMR-0803103, and the Human Frontier Science Program organization. [1] J.B. Jones, C.R. Sapinya, Biophys. J. 95, 823 (2008)

12:27PM W15.00007 Flexible ferromagnetic filaments and the interface with biology. ANDREJS CEBERS, MIHAIdsl BELSOVS, KASPARS ERGLIS, University of Latvia — Flexible ferromagnetic filaments exist in Nature (magnetotactic bacteria use them for the navigation purposes in the magnetic field of the Earth) and may be synthesized artificially by linking the functionalized ferromagnetic particles by DNA fragments of definite length. Ferromagnetic filaments allow to mimic self-propulsion of microorganisms by using AC magnetic fields. It is investigated both theoretically and experimentally. The elastic properties of the filaments are studied by kinetics of their orientation in an AC magnetic field of enough high frequency and allow to describe the observed deformation of the filaments at reversal of the magnetic field. By numerical analysis the Floquet coefficients for the dynamics of ferromagnetic filaments are calculated and the existence of stationary oscillations of U-like shapes is confirmed. These shapes self-propel perpendicularly to the AC magnetic field.

1Supported by grant Y2-ZP10-100 of University of Latvia.

12:39PM W15.00008 Electrokinetic effects near a membrane. DAVID LACOSTE, CNRS- Paris — We discuss the electrostatic and electrokinetic contribution to the elastic moduli of a cell or artificial membrane placed in an electrolyte and driven by a DC electric field. The field drives ion currents across the membrane, through specific channels, pumps or natural pores. In steady state, charges accumulate in the Debye layers close to the membrane, modifying the membrane elastic moduli. We first study a model of a membrane of zero thickness, later generalizing this treatment to allow for a finite thickness and finite dielectric constant. Our results clarify and extend the results presented in [D. Lacoste, M. Cosentino Lagomarsino, and J. F. Joanny, Europhys. Lett., 77, 18006 (2007)], by providing a physical explanation for a destabilizing term proportional to $k_{\text{p}}^3$ in the fluctuation spectrum, which we relate to a nonlinear ($E^2$) electro-kinetic effect called induced-charge electro-osmosis (ICEO). Recent studies of ICEO have focused on electrodes and polarizable particles, where an applied bulk field is perturbed by capacitive charging of the double layer and drives flow along the field axis toward surface protrusions; we predict similar ICEO flows around driven membranes, due to curvature-induced tangential fields within a non-equilibrium double layer, which hydrodynamically enhance protrusions.
12:51PM W15.00009 Piezoelectricity of Fluid Lipid Lamellar Phases and Their Chirality Dependence . JOHN HARDEN, NICHOLAS DIORIO, Kent State Univ., ALEXANDER PETROV, Institute of Solid State Physics, Bulgarian Academy of Sciences, ANTAL JAKLI, Liquid Crystal Institute, Kent State Univ. — The effects of chirality of membrane-forming lipids, has been largely ignored at present. Here we demonstrate that the chirality of phospholipids makes fluid lipid bilayers piezoelectric. This implies that chiral lipids would play a central role in the functioning of cell membranes as active mechano-transducers. By periodically shearing and compressing nonequilibrium lamellar phases of left (L-alpha-Phosphatidylcholine), right (D-alpha-Phosphatidylcholine) and racemic (DL-alpha-Phosphatidylcholine) lipids, we induced a tilt of the molecules with respect to the bilayer's normal and produced an electric current perpendicular to the tilt plane with the chiral lipids but not with a racemic mixture. This effect occurs because the lipids form a SmA† phase liquid crystal structure of the bilayers. Under molecular tilt, a ferroelectric SmC* phase is formed, creating a polarization which is normal to the tilt plane. This coupling allows for a wide variety of sensory possibilities of cell membranes such as mechano-reception, magneto-sensitivity, as well as in-plane proton membrane transport and related phenomena like ATP-synthesis, soft molecular machine performance, etc.

1:03PM W15.00010 Biomotor-functionalized Nanowires for Nanobio-mechanical Applications , DONG SHIN CHOI, NANO Systems Institute, Seoul National University, KYUNG-EUN BYUN, Department of Physics and Astronomy, Seoul National University, EUNHEE CHO, MOON-SOOK LEE, Samsung Electronics Co. Ltd., SEUNGHUN HONG, Department of Physics and Astronomy, Seoul National University — Protein motors such as actomyosin have shown the possibility as a building block for bio-inspired nanomechanical applications such as protein motor-based nanoscale engines. For such applications, it is crucial to combine protein motors with inorganic nanostructure such as nanowires. However, it has been difficult to functionalize nanowires/nanotubes with biological motors due to the incompatibility of such nanostructures with biomotors. Herein, we present a method to functionalize nanowires with biomotors while maintaining their functionalities. Significantly, we successfully demonstrated various motility assays using biomotor-functionalized nanowires, such as the delivery of nanowires functionalized with actin filaments on solid substrates.

1:15PM W15.00011 Non-monotonic mobility vs. length dependence observed in electrophoretic separation of 25 bp DNA ladder in Pluronic gels . SEUNGYONG YOU, DAVID VAN WINKLE, Department of Physics and Center for Materials Research and Technology, Florida State University — We electrophoresed a double-stranded DNA ladder first in an agarose gel, then in gels of Pluronic F-127 at room temperature. The DNA ladder consisted of 19 discrete fragments ranging in length from 25 to 450 bp at 25 bp increments plus 500 bp. The DNA fragments were first separated in agarose gel and stacked normally with 25 bp having the highest mobility. A single lane of the separated DNA ladder in the agarose gel was inserted at the edge of a Pluronic gel slab. The DNA was electrophoresed from the agarose into the Pluronic gels perpendicular to the original separation axis. Mobilities of DNA fragments increased from 25 bp to 175 bp and then decreased from 175 bp to 500 bp. The 25 bp and 500 bp bands of the ladder had approximately the same mobility in several different Pluronic gel concentrations. Both were slower than most bands in between. The highest mobility fragments with length of 175 bp have 99.5 nm contour length which is about 3.5 times the diameter of a micelle (17 nm). This result suggests a crossover from chromatographic separation to electrophoretic separation for these short DNAs. This research is supported by the state of Florida (Martech) and Research Corporation.

1:27PM W15.00012 Partition function and space-filling fractal-like networks of branching tubes, SAMIR LIPOVACA — We may think of the probability in quantum mechanics as a sort of fluid that flows from one point to another continuously and without loss or gain. We will utilize this fluid idea and imagine that probability flows through a space-filling fractal-like networks of branching tubes similar to the networks of a general model for the origin of allometric scaling laws in biology. In the general model, scaling laws arise from the interplay between physical and geometric constraints. This model provides a complete analysis of scaling relations for mammalian circulatory systems that are in agreement with data. We will show that there is a connection between a quantum system in thermal equilibrium and space-filling fractal-like networks. The relationship will be revealed through the calculation of the total fluid (probability) network volume. We will show that this total volume is proportional to the partition function of the related quantum system.

1:39PM W15.00013 The impact of conformational fluctuations on self-assembly: Cooperative aggregation of archael chaperonin proteins1, STEPHEN WHITEHAM, Lawrence Berkeley National Laboratory, CARL ROGERS, ANDREA PASQUA, UC Berkeley, CHAD PAAVOLA, JONATHAN TRENT, NASA Ames Research Center, PHILLIP GEISSLER, UC Berkeley — Protein complexes called rosettasomes self-assemble in solution to form large-scale filamentous and planar structures. The relative abundance of these aggregates varies abruptly with environmental conditions and sample composition. Our simulations of a model of patchy nanoparticles can reproduce this sharp crossover, but only if particles are allowed to switch between two internal states favoring different geometries of local binding. These results demonstrate how local conformational adaptivity can fundamentally influence the cooperativity of pattern-forming dynamics.

Thursday, March 19, 2009 11:15AM - 2:03PM — Session W16 DAMOP: Bosons in Optical Lattices I 317

11:15AM W16.00001 Generic Phase Diagram for Bose-Einstein Condensation of Weakly Interacting Symmetric Bosonic Mixtures, A.B. KUKLOV, CSI, CUNY, T. BLANCHARD, ENS, Cachan, France, B.V. SVISTUNOV, UMASS, Amherst, USA, and Kurchatov Institute, Russia — Weakly interacting Bose gas represents strongly correlated classical field within a domain (determined by the gas parameter ) of its Bose-Einstein condensation (BEC) temperature Tc. Thus, N-component weakly interacting mixtures representing some symmetry can potentially exhibit rich phase diagram (PD). In particular, it can feature quasi-molecular phases preceding actual formation of the ODRO in the vicinity of Tc. However, realization of a specific part of the PD depends on details of interactions. As examples, we consider mixtures characterized by O(2)×O(2) symmetry (N = 2) and spin S = 1 with the symmetry reduced to U(1)×U(1) (N = 3). Monte Carlo simulations of these systems find a single line of the respective two- and three-component BEC transitions which has tricritical point separating II and I order transitions. No quasi-molecular phases have been found despite that naive mean field (with one loop correction) predicts it. We discuss how such phases can emerge above the actual N-component BEC transition. One suggestion relies on Feshbach resonance detuned into negative inter-specie scattering length even when the gas parameter remains small. We acknowledge support from NSF grants PHY 0653153, 0653183 and CUNY grant 80209-0914.

3We acknowledge funding from the US Department of Energy and BioSim European Union Network of Excellence.
11:27AM W16.00002 Universal state diagrams for harmonically trapped bosons in optical lattices. MARCOS RIGOL, Georgetown University, GEORGE G. BATROUNI, INLN, Universite de Nice-Sophia Antipolis, VALERY G. ROUSSEAU, Institut-Lorentz Universiteit Leiden, RICHARD T. SCALETTA, University of California. Davis — We use quantum Monte-Carlo simulations to obtain universal zero temperature state diagrams for strongly correlated lattice bosons in one and two dimensions under the influence of a harmonic confining potential. Since harmonic traps generate a coexistence of superfluid and Mott insulating domains, we use local quantities like the quantum fluctuations of the density and a local compressibility to identify the phases present in the inhomogeneous density profiles. We emphasize the use of the ‘characteristic density’ to produce a universal state diagram which is relevant to experimental optical lattice systems, regardless of the number of bosons or trap curvature. We show that the critical value of $U/t$ at which Mott insulating domains appear in the trap depends on the filling in the system, and it is in general greater than the value in the homogeneous system. Recent experimental results by Spielman et al. [Phys. Rev. Lett. 100, 120402 (2008)] are analyzed in the context of our two-dimensional state diagram, and shown to exhibit a value for the critical point in good agreement with simulations.

11:39AM W16.00003 Occupation Statistics of a Bose-Einstein Condensate in a Driven Double Well Potential. K. SMITH-MANNSSCHOTT, Wesleyan University, Middletown, CT; MPI for Dynamics and Self-Organization, Goettingen, Germany, M. CHUCHEM, Ben-Gurion University, Beer-Sheva, Israel, M. HILLER, Physikalisches Institut, Albert-Ludwigs-Universitaet, Hermann-Herder-Str. 3, Germany, T. KOTTOS, Wesleyan University, Middletown, CT; MPI for Dynamics and Self-Organization, Goettingen, Germany, D. COHEN, Ben-Gurion University, Beer-Sheva, Israel — We consider the occupation statistics $P_i(n)$ of a Bose-Einstein condensate consisting of $N$ particles loaded in a double-well trap with intersite coupling $K$. Two dynamical scenarios are investigated: a) wavepacket dynamics and b) linear variation of the bias between the onsite energies of the two wells. In the latter case, we resolve three different behaviors as we increase the driving rate for intermediate values of the interatomic interaction $K/N < U < NK$: quantum adiabatic, diabatic, and sudden regime. We find that during the adiabatic to diabatic crossover, many-body Landau-Zener transitions play a dominant role, resulting in oscillations of the second moment of the occupation statistics. In contrast, the crossover to the sudden regime is characterized by a broad distribution $P_i(t \to \infty)$ which is reflected in a global maximum of the second moment.

11:51AM W16.00004 Supersolidity of Cold Atomic Bose-Fermi mixtures in optical lattices. PETER P. ORTH, DORON L. BERGMAN, KARYN LE HUR, Yale University — An important possible mechanism for boson supersolidity in a Bose-Fermi mixture is the existence of a nested Fermi surface. Fermions then tend to exhibit a density wave at the nesting wavevector and imprint this order via boson-fermion interactions onto the bosons, which already support superfluidity. This coexistence of bosonic superfluidity and density wave order is a signature of the supersolid phase. We present new results concerning a cold mixture confined to a triangular optical lattice. For a fermionic density of $n_f = 3/4$ per lattice site, the Fermi surface exhibits both a van-Hove singularity and nesting. With a Landau-Ginzburg and a microscopic mean-field analysis, we predict the supersolid parametric regime in current experimental realizations of Bose-Fermi mixtures, and make comparisons with the square lattice geometry. We also discuss competing low-temperature phases such as a phase separated and a Mott insulating regime. Finally, we consider the case of spatially anisotropic hopping, which allows us to explore a quasi 1d regime of supersolidity.

12:03PM W16.00005 Magnetic phases of two-component lattice bosons at nonzero temperature. STEPHEN POWELL, University of Oxford — The realization of magnetically-ordered phases in optical lattices is set to be one of the next major experimental advances in the field of ultracold atoms. In the limit of strong repulsion and weak tunneling between lattice sites, perturbation theory predicts that two-component fermions form a Néel state with a two-sublattice structure, while bosons will tend to form a ferromagnetic insulator. This perturbative approach is, however, ill-suited for describing the physics above zero temperature and away from the strong-coupling limit. Here we address the phase diagram of two-component bosons at nonzero temperature using an approach that takes as its basis the standard mean-field theory for spinless bosons. This allows spin and charge excitations to be treated on an equal footing, and elucidates the competition between the possible magnetic and superfluid orders in the lattice.

12:15PM W16.00006 Ground State Phase Diagram of the Two-Component Bose-Hubbard Model. SEBNEM GUNES SOYLER, Department of Physics, University of Massachusetts, Amherst, BARBARA CAPOGROSSO-SANSONE, Institute for Theoretical Atomic, Molecular and Optical Physics, Harvard-Smithsonian Center of Astrophysics, NIKOLAY PROKOF’EV, BORIS SVISTUNOV, Department of Physics, University of Massachusetts, Amherst — We have performed path integral Monte Carlo simulations of the two-component hard-core Bose-Hubbard model on a square lattice at half-integral filling factor for each component. This system can be realized experimentally with heteronuclear bosonic mixtures in optical lattices with tunable interspecies interactions. Our results disagree with preexisting analytical treatments both quantitatively and qualitatively. We reveal the existence of an additional solid-superfluid phase for strong anisotropy between the hopping amplitudes which radically changes the topology of the ground-state phase diagram. The new phase is a direct consequence of effective interactions between “heavy” atoms mediated by the “light” superfluid component. Remarkably, mediated interactions are sign-alternating and thus lead to a rich variety of yet to be discovered quantum phases.

12:27PM W16.00007 Counterflow and paired superfluidity in one-dimensional Bose mixtures. ANZI HU, LUDWIG MATHEY, Joint Quantum Institute, University of Maryland and National Institute of Standard and Technology, Gaithersburg, MD 20899, IPPEI DANSHITA, Department of Physics, Faculty of Science, Tokyo University of Science, Shinjuku-ku, Tokyo 162-8601, Japan, CARL WILLIAMS, CHARLES CLARK, Joint Quantum Institute, University of Maryland and National Institute of Standard and Technology, Gaithersburg, MD 20899 — Experimental progress in recent years has made it possible to realize mixtures of cold atoms in optical lattices. In this talk, we present our work on two types of superfluidity in 1D Bose mixtures: the counterflow superfluid and the paired superfluid phase, each of which can coexist with charge-density wave order. We predict and identify these phases both with Luttinger liquid theory and with numerical simulations. Specifically, we show the phase diagram as a function of the filling fraction and the inter-species interaction. We address the question of realizability and detectability of these phases by adding a trap potential, and by calculating various quantities that can be measured in experiment.

12:39PM W16.00008 Determination of mixing or demixing state of a two-component BEC system. CHAO-CHUN HUANG, W. C. WU, National Taiwan Normal University — In a stable ultracold trapped two-component BEC system, it is shown that the condition $U_{12}U_{22} - U_{12}^2 > 0$ holds as long as the intra-species s-wave interactions $g_{11}$ and $g_{22}$ are both repulsive. Here $U_{ij} = g_{ij} \int |\Psi_i(r)|^2|\Psi_j(r)|^2$ with $\Psi_i(r)$ the wave function of species $i$. The condition is valid no matter the system is in a single-trap or in an optical lattice. Based on the variational approach, the condition has been applied to determine whether the system is in mixing or demixing state, both for the single-trap and optical-lattice cases. Phonon modes of the optical-lattice system are also shown to be intimately related to the above condition.

11:51AM W17.00001 Time dependent DMRG for spectral functions of Heisenberg chains
STEVEN WHITE, UC Irvine, IAN AFFLECK, University of British Columbia, RODRIGO PEREIRA, UC Santa Barbara — Recently developed real-time DMRG techniques allow the calculation of space and time dependent spin-spin correlation functions for spin chain systems. These correlation functions can be Fourier transformed to obtain momentum and frequency dependent spectral functions. The growth of entanglement in the simulation as a function of time prevents us from performing the calculation for long enough times. We have found that the long time behavior can be extrapolated using either of two different techniques, allowing us to obtain very high resolution spectra with very high accuracy. We demonstrate these techniques for the S=1/2 Heisenberg chain and the XXZ S=1/2 chain.

We thank NCSA for supercomputer times.
11:27AM W17.00002 High-threshold surface code quantum computing: threshold calculation¹
, PETER GROSZKOWSKI, AUSTIN FOWLER, Institute for Quantum Computing, University of Waterloo, ASHLEY M. STEPHENS, University of Melbourne — Surface codes are topological quantum error correcting codes. In such codes, information is encoded in a collection of physical qubits arranged on a lattice, with only nearest-neighbor interaction required for processing and readout. In this talk we present a detailed account of a numerical threshold calculation for a planar surface code with boundaries (arXiv:0803.0272). In the end we find a threshold value that’s approaching 1%.

1NSERC

11:39AM W17.00003 Error threshold in topological quantum-computing models with color codes
, HELMUT KATZGRABER, ETH Zurich, HECTOR BOMBIN, MIGUEL A. MARTIN-DELGADO, Departamento de Fisica Teorica I, Facultad de Ciencias Fisicas, Universidad Complutense de Madrid, Spain — Dealing with errors in quantum computing systems is possibly one of the hardest tasks when attempting to realize physical devices. By encoding the qubits in topological properties of a system, an inherent protection of the quantum states can be achieved. Traditional topologically-protected approaches are based on the braiding of quasiparticles. Recently, a braid-less implementation using brane-net condensates in 3-colexes has been proposed. In 2D it allows the transversal implementation of the whole Clifford group of quantum gates. In this work, we compute the error threshold for this topologically-protected quantum computing system in 2D, by means of mapping its error correction process onto a random 3-body Ising model on a triangular lattice. Errors manifest themselves as random perturbation of the plaquette interaction terms thus introducing frustration. Our results from Monte Carlo simulations suggest that these topological color codes are similarly robust to perturbations as the toric codes. Furthermore, they provide more computational capabilities and the possibility of having more qubits encoded in the quantum memory.

11:51AM W17.00004 Performing measurement based quantum computation on ground states¹
, ANDREW DOHERTY, University of Queensland, STEPHEN BARTLETT, University of Sydney — One of the most exciting developments in quantum computing in recent years has been the realisation that there exist states of quantum many-body systems that can serve as a universal resource for quantum computing, where computation proceeds solely through single-qubit measurements. Although currently only a few isolated examples of such universal resource states are known, we discuss the possibility that there exist models of interacting spin systems in which an ordered phase is characterized by the ability to perform measurement-based quantum computation (MBQC). To identify such phases, we propose to use nonlocal correlation functions that quantify the fidelity of quantum gates performed between well separated qubits. The quantum computing phase is then characterized by set of order parameters corresponding to a universal set of quantum gates. We investigate a simple spin-lattice system based on the cluster-state model for MBQC by using a series of dualities with better studied models. We demonstrate that the model possesses a zero temperature phase transition between a disordered phase and an ordered “cluster phase” in which it is possible to perform a large class of one and two qubit quantum gates.

12:03PM W17.00005 Operator Theoretic Quantum Fault Tolerance¹
, GERALD GILBERT, YAakov S. WEINSTEIN, MITRE Quantum Information Science Group, VANEET AGGARWAL, Dept. of Electrical Engineering, Princeton University, A. ROBERT CALDER-BANK, Depts. of Mathematics and Electrical Engineering, Princeton University — We outline the advantages of an operator approach to quantum fault tolerance. Operator quantum fault tolerance is based on an explicitly stated halting condition, exact solutions of quantum error correction code dynamics, and as accurate and realistic descriptions as possible of the error models. This allows the proper integration of error correction and concatenation strategies with the system dynamics so as to better allocate quantum computational resources such as qubits, quantum gates, and computation time for quantum circuit design. We demonstrate these characteristics of the operator approach with an example of an asymmetric error model.

12:15PM W17.00006 Parallel Environment for Quantum Computing¹
, FRANK TABAKIN, University of Pittsburgh, BRUNO JULIA DIAZ, Universitat de Barcelona — To facilitate numerical study of noise and decoherence in QC algorithms, and of the efficacy of error correction schemes, we have developed a Fortran 90 quantum computer simulator with parallel processing capabilities. It permits rapid evaluation of quantum algorithms for a large number of qubits and for various “noise” scenarios. State vectors are distributed over many processors, to employ a large number of qubits. Parallel processing is implemented by the Message-Passing Interface protocol. A description of how to spread the wave function components over many processors, along with how to efficiently describe the action of general one- and two-qubit operators on these state vectors will be delineated.

¹Supported NSF and PSC Grants.

12:27PM W17.00007 Relation of operator Schmidt decomposition and CNOT complexity¹
, MARK COFFEY, RON DEIOTTE, Colorado School of Mines — We consider two-qubit operators and provide a correspondence between their Schmidt number and controlled-NOT (CNOT) complexity, where the CNOT complexity is up to local unitary operations [1]. The results are obtained by complementary means, and a number of examples are given. Additionally, we present results for exact decompositions of two-qubit operators in terms of CNOT [2]. Instances of these results are applicable to superconducting-flux qubit and other systems. [1]M. W. Coffey and R. Deiotte, Quant. Info. Proc. 7, 117 (2008). [2]M. W. Coffey and R. Deiotte, preprint (2008).

12:39PM W17.00008 New Method for the Calculation of Qubit Decoherence in the Presence of 1/f Noise¹
, DONG ZHOU, ROBERT JOYNT, Physics Department, University of Wisconsin-Madison — We present a new mathematical method for the calculation of qubit decoherence subject to a broad range of colored noise. The time evolution of the qubit density matrix is governed by a non-Hermitian quasi-Hamiltonian, mapping the problem onto a system consisting of a spin-1 particle (the qubit) coupled to spin-1/2 particles (the fluctuators). The method gives non-perturbative results for the energy relaxation, free induction decay (FID) and spin echo pulse measurements. This extends the range of known results to strong coupling, beyond the range of validity of Redfield theory and the commonly-used Gaussian approximation. New functional forms are suggested to explain the recent experiments by Kakuyanagi (PRL 98, 047004 (2007)) and Yoshihara (PRL 97, 167001 (2006)) on qubit decoherence with 1/f noise.

¹Support: NSF-DMR-0325634.
12:03PM W18.00003 Velocity Dependency of Dragging Force and Wetting Properties of High Viscous Liquids Using Constant Diameter Nanoneedle-Tipped AFM Probes, MEHDI YAZDANPANAH, ElectroOptics Research Institute and Nanotechnology Center, University of Louisville, MAHDI HOSSEINI, SANTOSH PABBA, CHARLES WALTER, JAYAN HEWAPARAKRAMA, ROBERT COHN, ELECTROOPTICS RESEARCH INSTITUTE AND NANOTECHNOLOGY CENTER, UNIVERSITY OF LOUISVILLE TEAM — A high aspect ratio and constant diameter Ag₂Ga nanoneedle grown on an AFM cantilever was used to perform F-D experiments on four different molecular weights of PDMS surfaces. The needle is partially inserted into and retracted from the liquid surface in various scan speeds. The viscous drag force causes the cantilever to deflect and recorded as a function of vertical displacement of the needle for each scan speed. The viscosity of the liquid is calculated by fitting a model into experimental data. The results show that the viscosity has strong correlation with the scan speed. Due to simple geometry of the needles, F-D curves are also interpreted to study the wetting properties (i.e. dynamic contact angle, meniscus height) of the PDMS at different scan speeds. Also, F-D curves are interpreted for polymer fiber formation during the capillary thinning and meniscus stretching that shown a strong correlation between the fiber length and the stretching velocity.

12:15PM W18.00004 Mechanical Properties of Individual Microparticle , SARA HASHMI, ERIC DUFRESNE, Yale University — Microparticles are important materials for both basic science and engineering and have wide applications from the study of phase transitions to the delivery of drugs. The method for the preparation of monodisperse polymeric micro particles, that is dependent on high angle x-ray scattering (HAXS) and magnetic resonance imaging (MRI), has been developed. The Brownian motion of the microparticles in liquids was measured using a high-speed synchrotron x-ray system. The size and shape of the microparticles were determined by high resolution x-ray microscopy. The mechanical properties of the particles were studied using atomic force microscopy (AFM) and small angle neutron scattering (SANS). The mechanical properties of the microparticles were found to be dependent on the size and shape of the particles. The results of this study will be useful for the design and development of microparticle-based drug delivery systems.

12:27PM W18.00005 Intrinsically Disordered Titin PEVK as a Molecular Velcro: Salt-Bridge Dynamics and Elasticity , JEFFREY FORBES, WANXIA TSAI, NIAMS/NIH, RICHARD WITTEBORT, Univ. of Louisville, KUAN WANG, NIAMS/NIH — Titin is a giant modular protein (3-4 MDa) found in the muscle sarcomere, where the intrinsically disordered and elastic PEVK segment plays a major role in the passive tension of skeletal and heart tissues. We have proposed that salt-bridges play a central role in the elasticity of PEVK. The 50 kDa engineered PEVK polypeptide shows well-resolved NMR spectra at all concentrations. From long-range NOE’s, we observed stable K to E salt-bridges. Simulated annealing with NMR restraints yielded a manifold of structures for an exon 172 trimer. Steered molecular dynamics simulations were done to study how the manifold of salt-bridges evolves during the stretching experiment. Repeated SMD simulations at slow velocity (0.0005 nm/ps) showed force spectra consistent with experimental AFM for force experiments on the polypeptide. SMD shows that salt-bridges occur even at high degrees of stretch and that these short range interactions are in integral part of the mechanical properties of PEVK. We propose that the long-range, non-stereospecific nature of electrostatic interactions provide a facile mechanism to tether and untether the flexible chains, which is important to maintain the accessibility of protein-protein interaction to these nanogel-like proteins.

12:39PM W18.00006 Mechanical Signal Filtering by Viscoelastic Properties of Cuticle in a Wandering Spider , MICHAEL E. MCCONNEY, Georgia Institute of Technology, CLEMENS SCHABER, University of Vienna, MICHAEL JULIAN, California State University Stanislaus, JOSEPH A.C. HUMPHREY, University of Virginia, FRIEDRICH BARTH, University of Vienna, VLADIMIR V. TSUKRUK, Georgia Institute of Technology — As recently found, in mecha-sensors of wandering spiders (Cupiennius salei) viscoelastic materials are important in signal filtering. We used atomic force microscopy to probe the time dependent mechanical behavior of these materials in five animals. We measured Young’s modulus of the cuticle during the stretching experiment. Simulated annealing with NMR restraints yielded a manifold of structures for an exon 172 trimer. Steered molecular dynamics simulations were done to study how the manifold of salt-bridges evolves during the stretching experiment. Repeated SMD simulations at slow velocity (0.0005 nm/ps) showed force spectra consistent with experimental AFM for force experiments on the polypeptide. SMD shows that salt-bridges occur even at high degrees of stretch and that these short range interactions are in integral part of the mechanical properties of PEVK. We propose that the long-range, non-stereospecific nature of electrostatic interactions provide a facile mechanism to tether and untether the flexible chains, which is important to maintain the accessibility of protein-protein interaction to these nanogel-like proteins.

12:51PM W18.00007 Bacterial Cell Wall Peptidoglycan at Single Molecule Resolution , AHMED TOHAMI, University of Guelph, MANFRED JERICHOW, Dalhousie University, VALERIO MATIAS, Max Planck Institute, ANTHONY CLARKE, TERRY BEVERIDGE, JOHN DUTCHER, University of Guelph — The major structural component of bacterial cell walls is the peptidoglycan sacculus, which is one of nature’s strongest and largest macromolecules that maintains the large internal pressure within the cell while allowing the transport of molecules into and out of the cell and cell growth. The three-dimensional structure of this unique biopolymer is controversial, and two models have been proposed: the planar model, in which the glycan strands lie in the plane of the cell wall, and the wall model, in which the glycan strands lie perpendicular to the cell wall. We have used atomic force microscopy to investigate the high resolution structure of isolated, intact sacculi of Escherichia coli K12 bacteria. Atomic force microscopy single molecule force spectroscopy was performed on single sacculi exposed to the tAmiB enzyme which cleaves the peptide-glycan bonds. Surprisingly, the measurements revealed individual strands of up to 250 nm in length. This finding combined with high resolution AFM images recorded on hydrated sacculi provide evidence for the validity of the planar model for the peptidoglycan structure in Gram-negative bacteria.

1:03PM W18.00008 Unfolding polyelectrolytes in a strong DC electric field, HSIAO, KUN-MAO WU, Department of Engineering and System Science, National Tsing Hua University — The behavior of single polyelectrolytes in multivalent salt solutions under the action of an electric field is investigated by computer simulations. The variation of chain size against the strength of electric field displays a sigmoidal transition, which defines a critical field. Above the critical field, the chain is unfolded into a rodlike structure, aligned parallel to the field direction. We show that the electric field induces a significant decrease in stiffness of the cuticular material and therefore less efficient energy transmission due to viscoelastic effects, as the frequency dropped to around 10 Hz. The stimulus transmitting cuticular material is acting as a high-pass filter for the mechanical stimulus on its way to the strain receptors. The results of this study indicate that viscoelastic mechanical signal filtering is an important tool for arthropods to specifically respond to biologically relevant stimulus patterns.

1:15PM W18.00009 Liquid Drop Pinning on Micro-patterned Surfaces , AHMED SOHIMAN, YEVGENI KALININ, ROBIN BAUR, ROBERT THORNE, LASSP, Cornell University — Pinning of liquid drops on surfaces is important in many areas of biotechnology. Micro-patterned surfaces provide a way to control drop pinning, and to investigate the mechanisms of pinning on rough (sucurface). Continuous circular rings on silicon wafers produced by etching the interior and surrounding silicon are shown to dramatically increase contact pinning. The critical apparent contact angle increases and the lifetime of the contact line is much longer and well correlated with parameters that describe the ring geometry, such as ring-wall height and width, as well as ring surface energy (hydrophilicity / hydrophobicity). Micro-patterns of surfaces in this way can be used to improve drop pinning, shape reproducibility and imaging in high-throughput protein crystallization.
Analytes, including cholesterol and ethanol. Higher enzyme loading, diffusion effects dominate. As a biosensing platform, the system also has the potential to be adapted to detect other biologically relevant analytes, including cholesterol and ethanol.

The authors deeply appreciate the help of Nan-Rong Chiou and the support from the NSF under IGERT (0221678) and NSEC (EEC-0425626).

1:39PM W18.00011 Patterning of Ferritin Nanoparticles on Gold Posts of Silicon Substrate

YUNXIA HU, DIAN CHEN, SOOJIN PARK, TODD EMRICK, THOMAS RUSSELL, Dept. of Polymer Science and Engineering, University of Massachusetts Amherst, HITACHI COLLABORATION — Patterning and immobilizing protein nanoparticles with nanometer-scale control has been proven integral to a range of applications in the development of biochip arrays, biosensor and electronic devices. Protein nanoparticles, such as ferritin nanoparticles, have a uniform size distribution and shape that can be used to construct well-defined patterns with nanoscale features. Here, the gold posts on silicon were produced using block copolymer PS (47.6 kg/mol)-b-P4VP (20.9 kg/mol) (PDI: 1.14) as a template and then gold chloride solution was loaded into P4VP domain. After reducing gold salt into gold and removing the block copolymer using an oxygen plasma, producing a pattern of gold posts. Thiol modified horse spleen ferritin are anchored to silicon substrate by the binding of thiol and gold. Scanning electron microscopy (SEM) shows that the feature size of gold posts decreased from 30 nm to 13 nm after attached with modified ferritin nanoparticles, which is consistent with size of modified ferritin. Also XPS result shows nitrogen and ion elements on ferritin-attached gold posts, and the signal of gold was attenuated after ferritin attached.

This work was supported by MURI, DOE, and MRSEC.

1:51PM W18.00012 Rapid Hydrogel Microactuator Using Elastic Instability

HOWN LEE, CHUNG-GUANG XIA, NICHOLAS FANG, University of Illinois at Urbana-Champaign — Rapid Hydrogel Microactuator Using Elastic Instability Inspired by rapid movement of sensitive plants such as Venus flytrap [1], we present an innovative way to enhance actuation speed of hydrogel micro devices by exploiting elastic instability. In this work, hydrogel micro devices in doubly curved shape are designed and fabricated using projection micro-stereolithography [2], with embedded microfluidic channels on the surface. Local swelling of hydrogel around channels causes bending which subsequently induces stretching of the soft structure. Such coupling gives rise to elastic instability, the onset of which triggers rapid conversion of stored elastic energy into kinetic energy in fast motion. We further designed a set of devices with different dimensions, which leads to different coupling of elastic energy in bending and stretching [1]. Our experimental results verified the critical coupling parameter that triggers snap-buckling motion. Ongoing experiments are investigating the actuation speed as a function of coupling parameter. This novel approach promises new potential applications for hydrogel based devices in various fields of study including microfluidics, soft robotics, artificial muscle, and drug delivery. Reference [1] Forstre, Y., et al, Nature, 433, 421-425 (2005) [2] Sun, C., et al, Sensors and Actuators A, 121:1, 113-120 (2005)

2:03PM W18.00013 Effect of Single Bacterium Cell and DNA Attachment on the Electrical Properties of Chemically Modified Graphene Sheets

NIHAR MOHANTY, VIKAS BERRY, Kansas State University — Chemically modified graphene (CMG) sheets are expected to have a considerably different electrical sensitivity to molecular attachment than the pristine graphene sheets. Here we present the electrical-interfacing properties of (a) CMG’s hybrids with single bacterial cells, (b) CMG with DNA (single and double stranded) tethered on graphene-surface and (c) CMG with polyelectrolyte-layer assembled on surface. These hybrids function as: (a) single bacterium devices, (b) DNA hybridization sensor and (c) charge polarity sensitive chemical-detector, respectively. A single bacterium attachment leads to generation of ~1400 holes on a CMG while hybridization of ~4 DNA molecules on graphene-DNA-carpets lead to generation of one hole. Further explanation of the attachment-potential, system-reversibility and sensitivity will also be presented.

Thursday, March 19, 2009 11:15AM - 2:15PM — Session W19 DPOLY: The Physics of Polymer Nanocomposites: Grafting and Dispersion

11:15AM W19.00001 A theoretical study of polymer grafted nanoparticles as fillers in polymer nanocomposites

ARTHI JAYARAMAN, University of Colorado-Boulder, KENNETH SCHWEIZER, University of Illinois-Urbana — We have generalized the microscopic Polymer Reference Interaction Site Model (PRISM) theory to study the structure and phase behavior of polymer-tethered spherical nanoparticles (fillers) in a homopolymer matrix. In the absence of a polymer matrix, melts of polymer-tethered nanoparticles show strong concentration fluctuations indicative of aggregate formation and/or a tendency for microphase separation as the total packing fraction and/or nanoparticle attraction strength increase. In the presence of a polymer matrix there is competition between nanoparticle attractions, steric repulsion between grafted polymers, and polymer matrix induced depletion-like attraction. For single tethered particles, volume of the tether being equal to the volume of the nanoparticle, the apparent microphase spindal curve exhibits both dilution-like and depletion-like features, and a non-monotonic dependence on matrix chain length. As the particle size and tether length are increased, such that the total space filling volume of the tether continues to equal the nanoparticle volume, the shape of the microphase spindal curve remains unchanged, but the effect of matrix polymer chain length on the spindal temperature diminishes. The effect of various parameters on the spindal temperature will be presented.

11:27AM W19.00002 Highly-branched anisotropic hybrid nanoparticles at surfaces

VLADIMIR TSUKRUK, Georgia Tech — We present a brief overview of our recent studies on combined hybrid anisotropic structures composed of inorganic nanoparticles and highly branched molecular such as modified silsesquioxanes polyhedra cores (POSS) with mixed hydrophobic-hydrophilic tails and silver nanowires with functionalized star block copolymer with embedded gold nanoparticles (nanocobs). We demonstrate two-stage melting of that branched POSS and their ability to form monolayer and multilayered LB structures. On the other hand, we observed that silver-BCP-gold nanocobs display extremely bright Raman scattering caused by surface enhanced Raman effect with very different longitudinal and transversal optical properties as revealed by high-resolution confocal Raman microscopy. To study these hybrid nanostructures we applied combined AFM, SEM, TEM, XPS, SERS, UV-vis, and XR techniques.
11:39AM W19.00003 Particle Dynamics within Self-Assembling Polymer-Grafted Spherical Nanoparticles, PINAR AKCORA, University of Missouri, SANAT K. KUMAR, Columbia University, YU LI, BRIAN BENICEWICZ, University of South Carolina, SURESH NARAYANAN, Argonne National Laboratory, COLUMBIA UNIVERSITY COLLABORATION, ARGONNE NATIONAL LABORATORY COLLABORATION — We have recently shown that the self-assembly of polymer grafted spherical nanoparticles can be achieved by varying the brush grafting density and chain length. The mechanical behavior of these nanocomposites with various states of particle dispersion has been explored using x-ray photon correlation spectroscopy. Nanoscale and macroscopic dynamic measurements show that mechanical reinforcement results from the percolated and also strongly entangled brushes forming strong networks. Particle dynamics within various polymeric nanostructures will be discussed.

11:51AM W19.00004 Thermally Stable Au Nanoparticles via Photo-crosslinkable Polymeric Stabilizers, JOONA BANG, MISANG YOO, Korea University, BUMJOON J. KIM, KAIST — Polymer nanocomposites consisting of polymers and inorganic nanoparticles (NPs) have attracted many interest due to their applications such as solar cell, sensors, catalysts and ferroelectric devices. To integrate NPs into polymer matrix in the controlled manner, thiol-terminated stabilizers have been used to tune the surface property of NPs such as Au, Pt, CdSe, etc. However, a practical use of such particles in the nanocomposites is very limited by thermal instability even at ~90 °C, leading to the agglomeration of NPs. To impart the thermal stability of NPs, we modified Au NPs surface using UV-crosslinkable polymeric stabilizers. After UV-crosslinking, it was found that the Au NPs exhibit the excellent stability at high temperature (~180 °C) in both solution and thin-film states. Furthermore, we demonstrate that thermally stable Au NPs can be used as compatibilizers in PS/PMMA blends. The NPs at the PS/PMMA interface produced the dramatic reduction in the droplet size after 1 day of thermal annealing at 180 °C, in which the particle size is unchanged.

12:03PM W19.00005 Design of Polymer-Grafted Particles for Biocompatibility, DAVID TROMBLY, VENKAT GANESAN, Department of Chemical Engineering, University of Texas at Austin — Drug designers often coat drug particles with grafted polymers in order to introduce a net repulsion between the particles and blood proteins. This net repulsion results from the energy cost of compressing grafted chains on approach of proteins. It thus overcomes the Van Der Waals attraction between drug and protein which would otherwise cause particle-protein agglomeration and ultimately thrombosis. This study proposes to develop a fundamental understanding of the role of different features in controlling the efficacy of the grafted layers. We address this issue by developing a framework to predict the interactions between a polymer-coated spherical particle and a bare spherical particle. In order to fully capture the two-sphere system, a numerical solution of polymer mean field theory is used in a bispheerical coordinate system. Results for protein-particle interaction energies for different design parameters will be presented. For biological applications, polyethylene glycol is often used as the grafted polymer. The unique properties of this molecule will be accounted for using the n-cluster model.

12:15PM W19.00006 Synthesis of Polystyrene-Silica Composite Particles via One-Step Nanoparticle-Stabilized Emulsion Polymerization, LENORE DAI, HUAN MA, Department of Chemical Engineering, Arizona State University — Polystyrene-silica core-shell composite particles are prepared by one-step emulsion polymerization with a nonionic initiator V.A.-086, solely stabilized by silica nanoparticles. The silica nanoparticles are successfully incorporated into the shell, likely due to the fact that the nanoparticles are thermodynamically favorable to self-assemble and remain at the liquid-liquid interfaces during the emulsion polymerization. The silica content, determined by thermogravimetric analysis, is approximately 20 wt.%. However, we further explore the polymerization mechanism by studying the particle growth as a function of initiator concentration and reaction time: when the silica/monomer ratio is increased from 0.83 without reaction time decreases for a fixed monomer amount, probably due to a larger number of nuclei at the initial stage of polymerization. Further increasing the initiator/monomer ratio to 4.2 wt.%, which may be limited by the stabilization provided by a fixed concentration of silica nanoparticles. The surface coverage also changes with initiator concentration and reaction time although the underlying mechanism is not fully understood.

12:27PM W19.00007 Effects of Grafted Chain Density on Nanoparticle and Melt Structure, JOSHUA KALB, SANAT KUMAR, Columbia University, ROBERT S. HOY, University of California, Santa Barbara, GARY S. GREST, Sandia National Laboratories — Applications of nanoparticles have increased dramatically over the last few years with uses ranging from scratch proof glass to lubricants to fighting cancer. Grafting polymer chains to these systems further increases the range of their properties, but still much remains to understand about the behavior of ‘brush grafted nanoparticle’ systems, particularly in their interaction and entanglement with a polymer melt. Previous works on polymer brushes attached to a flat surface have demonstrated that entanglements between the attached chains and the polymer melt depend strongly on coverage and length of the attached chains. Allowing for a curved grafted nanoparticle surface allows for a wider range of interactions with the melt. Here we present molecular dynamics simulations of the structure of grafted nanoparticles and their entanglements with a highly entangled melt. Individual entanglements are identified using a modified version of primitive path analysis.

12:39PM W19.00008 Polyethylene/organically-modified layered-silicate nanocomposites with antimicrobial activity, P. SONGTIPYA, M.M. JIMENEZ-GASCO, E. MANIAS, Departments of Materials Sci & Eng and Plant Pathology, Penn State University — Despite the very intensive research on polymer nanocomposites, the opportunities for new functionalities possible by nanofillers still remain largely unexplored. Here, we present polyethylene/organoclay nanocomposites that exhibit strongly enhanced mechanical performance and, at the same time, also an antimicrobial activity originating from the organo-filler nature. Specifically, PE/organically-modified layered-silicate nanocomposites were prepared via melt-processing, and antimicrobial activity was designed by proper choice of their organic modification. Their antimicrobial activity was measured against three microorganisms: Penicillium roqueforti and Penicillium claviforme, and Fusarium graminearum. We study the changes in the mechanical properties of the nanocomposites, the decrease in the percolation threshold from the single to the multi-layered silicate nanocomposites, and the enhancement of the mechanical performance of the organo-clay nanocomposites.

12:51PM W19.00009 Modeling of block copolymer/nanoparticle nano-composites, MARCO PINNA, University of Central Lancashire, Preston, UK, IGNACIO PAGONABARRAGA, University of Barcelona, Spain, ANDREI ZVELINDOVSKY, University of Central Lancashire, Preston, UK — We develop a coarse grained simulation technique to study dynamics in soft nano-composites. The system consists of block copolymer melt with embedded nano-size particles. The time evolution of the system is described by a hybrid method combining a field based simulation for block copolymer component and a particle based method for nano-colloids. The block copolymer is modelled by cell dynamics simulation technique, and nano-particles are modelled as soft particles with prescribed density profile. A cross interaction term is controlling the interplay of dynamics of both components. The influence of nano-particles on block copolymer morphology is investigated.
further insight into the factors that determines the conformation of the PPEs. We have shown that short alkyl PPEs are fully stretched out. With increasing molecular weights they assume a worm like configuration. The current study provides further understanding of this behavior by studying the conformation of PPEs in toluene solutions. Toluene is a good solvent for the backbone and a poor solvent for the substituting side chains. Small angle neutron studies (PPEs) polymers, electro-active polymers, in dilute toluene solutions. The conformation of PPEs determines the conjugation of the polymer and their assembly para-polyphenyleneethylenes, SABINA MASKEY, FLINT PIERCE, DVORA PERAHIA, Clemson University, GARY GREST, Sandia National Laboratory — The interfacial region in polymer blends has been identified as a low viscosity region in which considerable slip can occur when the blend is subjected to shear forces. Here we use Molecular Dynamics simulations to establish the role that added nanoparticle fillers play in modifying the interfacial rheology. By choosing conditions under which the fillers are localized, either in the two phases or at the interface, we can look at the interplay between the decomposition of nanoparticles and the change in the interfacial slip behavior. We examine particle size, attraction between the particle and the polymer component, and the amount of filler in the material. Our studies are performed both above and below the point at which the filler particles form a transient network in the blend.

1:15PM W19.00011 Synthesis of composite polymer nanoparticles, EDWARD VAN KEUREN, MAKI NISHIDA, Georgetown University, Dept. of Physics — We have been developing composite nanoparticles using the reprecipitation method or miniumulsion polymerization. These methods enable the combination of multiple functional components, such as large metal or metal oxide clusters and molecular species such as fluorophores, into polymer nanoparticles. The incorporation of these into the polymer or monomer precursors requires a detailed understanding of the mutual solubility of the components. We present fluorescence correlation spectroscopy measurements of molecular solubility and results from dynamic light scattering, electron microscopy and Raman spectroscopy that reveal the morphology and composition of these particles.

1:27PM W19.00012 Relaxation behaviors of nanoparticles in polymer composites: influence of local frictions by polymer chains, BYEONGDU LEE, PAPPANANN THIYAGARAJAN, SURESH NARAYANAN, ALEC SANDY, VILAS POL, CHIEH-TSUNG LO, DAVID BOHNSACK, Argonne National Laboratory — The dynamics of Au nanoparticles (AuNP) tethered with thiol-terminated polystyrene (PS) in the composites with poly(styrene-b-2-vinylpyridine) diblock copolymers (PS-PVP) have been studied by x-ray photon correlation spectroscopy and small-angle x-ray scattering. Relaxation behaviors of nanoparticles located selectively in PS domain due to enthalpic interaction, interestingly, are not correlated with those of matrix polymer chains, i.e., their relaxation times are not dependent on the molecular weights of PS-PVP. They relax faster in PS-PVP than in PS homopolymer having the same molecular weight as the PS brush of PS-PVP. On the other hand, the influence of morphological structures of PS-PVP, however, is significant: AuNP moves faster in the lamellae phase than those in the cylinder phase.

1:39PM W19.00013 Nano-particle distribution in a polymer nano-composite, PANAGIOTIS MANIADIS, Theoretical Division and CNLS, Los Alamos National Lab, IOANNIS N. TSIMPANOGIANNIS, Environmental Research Laboratory, National Center for Scientific Research “Demokritos”, Greece, EDWARD M. KOBER, Institute of Multiscale Modeling and Simulations, Los Alamos National Lab, TURAB LOOKMAN, Theoretical Division, Los Alamos National Lab — We use the hybrid particle-Self Consistent Field calculation (hybrid particle-SCF) to study the distribution of particles in a multi-block copolymer nano-composite. Using the static approach, we first find the effective interaction potential between the nano-particles and the polymer. The interaction has an entropic and an enthalpic component. The dynamical simulation confirms that the distribution of particles has a maximum at the minima of the interaction potential. We also study the situation where the nano-particles are distributed in a blend of AB diblock and A homopolymer. In this case, for large homopolymer concentration (larger than 20%), an interface is created between components that are identical, but they come from different types of polymer chains (i.e. the AB diblock or the A homopolymer). We find that the interaction potential has a minimum in this A/A interface which is of pure entropic origin. Furthermore the dynamical simulation reveals that the distribution of nano-particles has a maximum in the area around this interface.

1:51PM W19.00014 Thermoresponsive Self-Assembling Nanocomposites, KARI THORKELSSON, YUE ZHAO, THOMAS SCHILLING, University of California, Berkeley, ALEXANDER MASTROIANNI, JOSEPH M. LUTHER, University of California, Berkeley, Lawrence Berkeley National Laboratory, YUE WU, University of California, Berkeley, A. PAUL ALIVISATOS, TING XU, University of California, Berkeley, Lawrence Berkeley National Laboratory — Nanoparticles have significant potential for use in fields including photovoltaics and memory storage, but to realize this potential, their distribution must be finely controlled. We present here a versatile method to achieve such control, using a diblock copolymer supramolecule composed of polystyrene-block-poly(4-vinylpyridine) (PS-b-P4VP) and 3-pentadecylphenol (PDP). The PDP hydrogen bonds to the P4VP block, forming a comb block. This change in morphology causes the PS-b-P4VP(PDP) supramolecule to force the nanoparticles into well-organized rows one nanoparticles thick at the center of the P4VP(PDP) domains. Furthermore, the morphology of the supramolecule-nanoparticle composite changes with temperature as hydrogen bonding is broken and the PDP becomes soluble in the PS block. This provides a useful path for the production of polymer-based thermoresponsive nanocomposites.

2:03PM W19.00015 Self-Assembly of Polymer-Decorated Nanoparticles in the Bulk and in a Nanometric Confined Region, DAMIEN MAILLARD, SANAT KUMAR, Department of Chemical Engineering, Columbia University, New York, NY, PINAR AKCORA, Department of Chemical Engineering, University of Missouri, Columbia, MO — As shown previously by simulation and TEM studies in the bulk, PS grafted nanoparticles when mixed a PS matrix self-assemble into a range of superstructures. These self-assembled structures can be regrouped into a phase diagram in which the leading parameters are the particles grafting density and the molecular weight ratio of the grafted and free matrix chains. Depending on those parameters the particles can be well dispersed or aggregated in a core-shell “onion” morphology or in one (strings), two (interconnected sheets) or three (spherical aggregates) dimensions. Here we consider the corresponding behavior in thin films (100 nm thick) using in-situ phase contrast AFM. In addition to yielding the morphologies, this protocol allows us directly visualize the aggregation process of the particles.

11:15AM W20.00001 Conformational Study of Di-Substituted para-polyphenyleneethylenes (PPE) in Dilute Solutions, SABINA MASKEY, FLINT PIERCE, DVORA PERAHIA, Clemson University, GARY GREST, Sandia National Lab — Molecular dynamics (MD) simulations have been used to study the conformation of highly rigid di-substituted para-polyphenyleneethylenes (PPEs) polymers, electro-active polymers, in dilute toluene solutions. The conformation of PPEs determines the conjugation of the polymer and their assembly mode which in turn affect the electro-optical properties. In solution, the conformation is determined by molecular parameters including the length of the polymer and the nature of the side chain, coupled with the interaction of the molecules. The present study investigates the effects of molecular weight and the nature of the side chain in toluene solutions. Toluene is a good solvent for the backbone and a poor solvent for the substituting side chains. Small angle neutron studies have shown that short alkyl PPEs are fully stretched out. With increasing molecular weights they assume a worm like configuration. The current study provides further insight into the factors that determines the conformation of the PPEs.
11:27AM W20.00002 Crystal and Rotator Phases of n-alkanes: a Molecular Dynamics Study
NATHANIEL WENTZEL, SCOTT T. MILNER, Pennsylvania State University — The odd n-alkanes exhibit a wide variety of solid phase behavior; experimentally observed phases include an orthorhombic crystal phase, in which the molecules show long range herringbone order, and rotator phases in which the molecules do not diffuse but display various degrees of disorder. The rotator phases are of interest because they are implicated in the nucleation of n-alkane and polyethylene crystals. C_{23} has been found experimentally to have two stable rotator phases, orthorhombic R_{II} and hexagonal R_{I}, at temperatures between the crystal and melt. The crystal-R_{II} and R_{II}-R_{I} phase transitions have been observed to be weakly first order. Simulations of C_{23} to date have found the R_{II} phase but not the R_{I} phase, and have not much characterized the phases or the transitions between them. We report our results for local order and pretransitional fluctuations of rotator phases, from our all-atom molecular dynamics simulations of thin layers of C_{23}. We also comment on how these properties relate to the experimentally observed phase transitions.

11:39AM W20.00003 Computational Modeling of Polymers and the Influence of Molecular Level Structural Features on Mechanical Properties
THOMAS CLANCY, SARAH-JANE FRANKLAND, National Institute of Aerospace — The role of molecular structure on the mechanical properties of polymer based materials is investigated through atomistic based molecular dynamics simulations. Models of crosslinked polymers were built with a range of moisture content in order to study the effect of environmental exposure on mechanical properties. Another key structural parameter, the degree of crosslinking, was also varied. The molecular structural features associated with these parameters are studied for their influence on the mechanical properties. The relative motion of crosslink points and the influence of penetrants such as water are investigated under deformation conditions. The mobility of penetrants within the polymer matrix is studied under equilibrium and deformation conditions in order to assess the role of these structural features on the mechanical properties as well as to assess the influence of deformation on diffusion rates.

11:51AM W20.00004 Hydrogen Bonding Structure in Hyperbranched Aliphatic Polymers Studied by MD Simulations
BRIAN OLSON, MUKUL KAUSHIK, SERGEI NAZARENKO, University of Southern Mississippi — Hyperbranched aliphatic polymers based on dimethoxy propionic acid (bis-MPA) as the repeating unit and ethoxylated pentaoxythanol as the tetrafunctional core gained widespread attention due to their unusual structure and properties. These globular macromolecules possess a large number of hydroxyl functional groups in particular on their periphery. These hydroxyl groups interact readily through hydrogen bonding (HB) and form clusters responsible for many physical properties of this system. The structure of these clusters however remains unclear. Therefore MD simulations have been used to elucidate the structure of these clusters. MD simulations revealed that peripheral hydroxyl groups form linear hydrogen bond clusters (strings) similar to those proposed in hydrofluoric acid (HF) but considerably shorter consisting of 4-10 hydroxyl groups per cluster. Simulations also led to prediction of WAXS pattern for these hyperbranched polymers in the bulk with the characteristic peak at 2θ = 30° due to O-O correlations similar to those in water. The predictions were in excellent agreement with the experimental WAXS data.

12:03PM W20.00005 Phases of functionalized polymer-inorganic composites in solution studied via molecular dynamics
JOSHUA ANDERSON, RASTKO SKNEPNEK, ALEX TRAVESSET, Iowa State University and Ames Laboratory — Using self-assembling polymer systems to direct the formation of inorganic crystals, polymer-inorganic composite materials offer new opportunities in materials design. Molecular dynamics simulations allow for an exploration of the wide range of phases in these systems. Amphiphilic ABA triblocks with A hydrophilic, B hydrophobic, and functional ends with an affinity to inorganic particles are modeled to capture the minimum physics needed to describe polymer-inorganic systems currently being investigated by experiment. A number of phases are formed in solution as the attraction strength between the inorganic particles and the affinity of those particles to the functional end beads of the polymer are varied. Some of the phases found include hexagonal, square columnar, lamellar, perforated lamellar, and the gyroid. Polymer stretching plays an important role in each of the phases found, with a characteristic multi-modal behavior in the polymer end to end distance distribution. In the gyroid phase, for instance, the peaks correspond to the polymers being in two preferred conformations: v-shaped with a small end to end distance and fully extended in a line with the largest possible end to end distance. At high interaction strengths, inorganic particles are found to crystallize and form plate-like structures.

12:15PM W20.00006 The effect of chain stiffness on the structure and phase behavior of diblock copolymer melts
G. LEUTY, MESFIN TSIGE, Southern Illinois University at Carbondale — In block copolymers the covalent bond joining the different immiscible block segments prevents the occurrence of macroscopic phase separation of the different components of a copolymer chain. Instead, the block segments give rise to well-organized periodic domain nanostructures whose size and shape mainly depend on the dimensions of the blocks and the segment-segment interaction parameters. Variations in the stiffness of the different block segments can directly affect the morphology of the system and may result in a very rich phase behavior. To the best of our knowledge, there is no theory at the atomic or molecular level that explains how variations in the stiffness of the different block segments can affect the dynamics and morphology of these systems. We have studied the microphase separation of symmetric diblock copolymers with variable block stiffness and different block chain length using coarse-grained molecular dynamics simulations. The morphology of the diblock systems we studied is found to be strongly dependent on the relative stiffness of the two block segments.

12:27PM W20.00007 Rigidity transition with increasing crosslinking of a single macromolecule
JIUJU LIU, PHILLIP DUXBURY, Michigan State University — A nano-particle can be formed by the intramolecular crosslinking of a polymer chain. In this process the rigidity of the system increases with the crosslinking density. We carried out extensive molecular dynamics simulations of the intramolecular crosslinking on six different models to study their rigidity transitions. It was found the crosslinking satisfiability of the system is greatly affected by its rigidity. A facile analysis of floppy modes of the system was employed to determine the rigidity transition threshold and a good agreement with simulation data was obtained.

12:39PM W20.00008 Spreading of Droplets on Viscous Polymer Liquids
FLINT PIERCE, DVORA PERAHIA, Clemson University, GARY GREST, Sandia National Laboratories — Significant strides have been made in understanding the spreading of liquid droplets on solid surfaces. However from biological complexes to polymeric interfaces, the surfaces are not ideal; explicitly, the surfaces may dynamically respond as spreading takes place and the droplets may partially penetrate. Molecular dynamic simulations were carried out to investigate the spreading of liquid droplets of short chains on films of viscous polymer melts. Unlike the spreading on solid surfaces, the droplets simultaneously spread and penetrate. The degree of penetration and the magnitude of damping from the film depend on the viscosity of the underlying liquid and the relative interaction of the two constituents. At the interface with viscous films a precursor foot spreads ahead of the droplet whereas on top of less viscous interfaces, the droplets penetrate while spreading with no precursor foot. A kinetic model described the spreading of shorter chain length droplets, while a hydrodynamic model better expresses the spreading of longer chain length liquid. Supported in part under DOE contract No. ER46456.
12:51PM W20.00009 Shear rate threshold for the onset of boundary slip in dense polymer films

Molecular dynamics simulations are carried out to investigate the dynamic behavior of the slip length in thin polymer films confined between atomically smooth surfaces. The polymer melt is modeled as a collection of bead-spring chains of 20 Lennard-Jones monomers interacting through the FENE potential. We found that at high melt densities and low shear rates the fluid velocity profiles acquire a pronounced curvature near the walls and the slip length is approximately equal to the thickness of the immobile boundary layer. The linearity of the fluid velocity profiles is restored at higher shear rates where the slip length increases rapidly as a function of shear rate. We will show that the friction coefficient at the interface between a polymer melt and a solid wall follows power law decay as a function of the slip velocity. At large slip velocities the friction coefficient is determined by the product of the value of surface induced peak in the structure factor and the contact density of the first fluid layer near the solid wall. A relation to recent slip flow experiments is discussed.

1:03PM W20.00010 Direct Numerical Evaluation of Plateau Modulus of Entangled Polymer Melts via Multi-Scale Molecular Dynamics (MD)

Plateau modulus and viscosity of entangled polymer melts can be calculated by off-diagonal elements of stress tensor, which are connected by the Green-Kubo relation and tube theory. However, direct numerical evaluation of plateau modulus via stress autocorrelation function (SAF) from MD simulation is a big challenge in a computational point of view due to the following reasons: strong fluctuations, long relaxation times and large spatial scales. In the present work, SAFs of entangled polymer melts are calculated by coarse-grained MD. We find that the use of time-averaged stress helps to reduce strong noise in SAF while capturing most local chain relaxations. Plateau values by SAF are compared with plateau values predicted from the entanglement length evaluated via primitive path analysis (PPA). The importance of well equilibrated melts for such an analysis is shortly discussed.

1:15PM W20.00011 Cole-Davidson Glassy Dynamics in Simple Chain Models

Cole-Davidson function was used to fit the response functions. For the systems studied, the Cole-Davidson function provided remarkably accurate fits (as compared to the transform of the Kohlrausch-Williams-Watts (KWW) function). The only appreciable deviations from the simulation results were in the high frequency limit and were due to ballistic, or free rotation, effects. The accuracy of the Cole-Davidson function appears to be the result of the transition in the time-domain from stretched exponential behavior at intermediate time to single exponential behavior at long time.

1:27PM W20.00012 Glass transition temperature of PIB, PDMS and PMMA from small-time simulations

Glass transition temperatures $T_g$ of poly(isobutylene), poly(dimethyl-siloxane), and poly(methyl methacrylate) from small-time atomistic molecular dynamics simulations. The different fragilities of these materials are reflected in the results of the simulations. One approach involved measurement of the apparent softening of the “cage” in which a monomer is bound, while another involved studying autocorrelation of a convolution of the velocity with a smoothing function in order to detect the frequency of escapes from the “cage.” To check the accuracy of the short-time methods, the $T_g$ of the polymers was also found using conventional diffusion simulations in which the rate of increase of the root mean squared displacement of an atom, monomer, or molecule is measured at very long times. The economical short-time simulations yielded results for $T_g$ that were identical to those of the computer-intensive long-time simulations.

Work supported by DOE Grant DE-FG02-05ER46244

1:39PM W20.00013 Translocation of a Polymer Through a Nanopore in the Presence of Obstacles

Translocation of a polymer through a nanopore is interesting both as a process of fundamental biological importance and as relevant to the development of next-generation DNA sequencing technology. Due to the time and length scale of typical systems and events, computer simulations are well suited to study this problem and have been used extensively to study different aspects of the translocation process. In this work, we present results from a system in which a polymer and a membrane containing a nanopore are placed in a medium containing obstacles. Using the Espresso Molecular Dynamics simulation package, simulations are performed in which the translocation events are driven by: i) an obstacle concentration gradient and ii) a varying amount of disorder. Results indicating the establishment of a preferential direction and assessing the impact of the system configuration on details such as the translocation time will be given.

1:51PM W20.00014 Role of RNA in the self-assembly of virus: A coarse-grained Brownian Dynamics study

Role of RNA in the self-assembly of virus: A coarse-grained Brownian Dynamics study

J.P. MAHALIK, MURUGAPPAN MUTHUKUMAR, University of Massachusetts — Assembly of a single viral capsid (icosahedral T1 type) was studied in the absence and presence of RNA. A coarse-grained rigid body model was used to represent the capsomer units and a flexible polyelectrolyte model was used to represent RNA. Brownian Dynamics simulation was used to study the assembly process. The rate of assembly was found to be enhanced in the presence of RNA. The free energy contribution of the RNA in the self-assembly process was computed using weighted histogram analysis method.

2:03PM W20.00015 Probability of adsorption of peptide (CR3-1, S2) chains on clay minerals by coarse-grained Monte Carlo simulation

Probability of adsorption of peptide (CR3-1, S2) chains on clay minerals by coarse-grained Monte Carlo simulation

RAS B. PANDEY, University of Southern Mississippi, HENDRIK HEINZ, University of Akron, BARRY L. FARMER, SHARON JONES, LAWRENCE F. DRUMMY, RAJESH R. NAIK, Air Force Research Laboratory, WPAFB — A coarse-grained description is used to study the structure and dynamics of peptide chains (CR3-1, S2) in presence of a clay surface on a cubic lattice. A peptide chain is represented by the specific sequence of amino acids. Specificity of residues is captured via an interaction matrix based on the insight gained from the atomistic simulation, i.e., each residue interacts with surrounding residues, solvent, and the clay surface with a unique interaction potential. We use a standard LJ potential with its coefficient controlled by the interaction matrix. Simulations are performed with a number of peptide chains. Along with the global energy and dynamics of peptides, we keep track of mobility, energy (total and adsorption), and correlation with the local structure from the density profiles of each residue. Based on the analysis of local and global quantities, we are able to assess the probability of adsorption of peptides to clay surface in agreement with experiment. The probability of adsorption of S2 is found to be much higher than that of CR3-1 in which S2 is anchored by Lysine. The procedure is complementary to biopanning experiments since it allows screening a large number of peptides (more than 10E+5) on the surface to estimate their binding potential.
11:15AM W21.00001 Temperature Dependence of the Minority Carrier Lifetime in n− Epilayers of 4H-SiC, Paul Klein, Naval Research Laboratory, Amitesh Shrivastava, Tangali Sudarshan, University of South Carolina—Controlling the lifetime of minority carriers in n− epilayers of 4H-SiC is of great current interest, as short lifetimes lead to a high forward voltage drop in high-voltage, bipolar switching devices. As such devices operate at elevated temperatures, the temperature dependence of the carrier lifetime is of particular interest. For materials where the lifetime is controlled by trapping at deep defects (e.g., Z1/2Z2), increasing the temperature results in the thermal emission of trapped carriers, leading to an increase in the carrier lifetime. In this work the temperature dependence of the carrier lifetime, measured by time-resolved photoluminescence decay at low injection, has been studied in a range of epitaxial layers. In addition to the classic temperature dependence, some samples exhibit a lifetime that decreases rapidly with temperature in a thermally activated manner. This behavior is believed to result from the fact that the deep defect concentration is too low in these samples to limit the lifetime, and that other processes have become dominant.

11:27AM W21.00002 Issues with Deep Defect Spectra in Electron Irradiated 4H-SiC, F. Yan, R.P. Devaty, W.J. Choyke, Univ. of Pittsburgh, T. Kimoto, Kyoto Univ., T. Ohshima, Japan Atomic Energy Agency, G. Pensl, Univ. of Erlangen—Recently, Steeds et al. [1] discussed deep levels induced by high fluence electron irradiation in 4H-SiC. We have also observed the particular triplet assigned to di-carbon antisites using both ion implantation and electron irradiation. Here we specifically address data obtained by 170 keV electron irradiation at a fluence of 5×10^16 cm^-2. We shall discuss details of the no phonon lines of the triplet as well as two sets of vibrational modes well beyond the highest energy of the SiC lattice spectrum. Theory suggests that one should observe four no phonon lines and groups of four lines for each observed localized mode. Our high resolution spectra reveal differences in the LVM spectra with respect to those reported by Steeds et al. We obtain strong spectra at a fluence of 5×10^16 cm^-2 whereas Steeds et al. report that they do not see the triplet in the irradiated area using greater than 10^19 cm^-2, but do see it beyond the periphery of the TEM beam. We can explain this in terms of the transverse straggling of the electrons in his TEM beam. Finally, we report the reappearance of this triplet due to an anneal at 1100°C after it had already annealed out at 1400°C. [1] J. W. Steeds et al., Phys. Rev. B 77, 195203 (2008).

11:39AM W21.00003 Charge transfer kinetics of carbon vacancy defect in 4H-SiC, J. Dashdorj, M.E. Zvanut, J.G. Harrison, Department of Physics, University of Alabama at Birmingham—There has been much detailed work aimed at understanding carbon vacancy related defects and their complexes in SiC, but there are no reports of charge transfer kinetics between the carbon vacancy and other defect centers. In this study, optical cross sections of the positively charged carbon vacancy, V^+, in high purity semi-insulating 4H-SiC were measured by time-dependent photo-electron paramagnetic resonance, EPR. The measurements were performed by a X-band EPR spectroscopy at 80 K. Selected photon energies used in this study were between 0.8 and 3.13 eV. A single defect model considering only capture and emission of electrons from V^+ was shown to fit well the measured data. The photon energy-dependence of the cross sections exhibit threshold value of 1.6 eV and peak value of 2.15 eV for the capture, and threshold value of 1.9 eV and peak value of 2.45 eV for the emission processes, respectively. In this talk, we will discuss the above results in terms of charge transfer mechanisms including the effects of the electronic density of states and participation of phonons.

11:51AM W21.00004 EPR Study of SiC Defects Related to N2 and O2 Annealing, Sarah Thomas, Mary Ellen Zvanut, University of Alabama at Birmingham—SiC is a promising replacement for Si in future high power, high temperature electronic devices. It is well known that the Si/SiO2 interface in MOSFETS has electronically active defects, and recent work has shown the same is true for SiC. Our research focuses on identifying the cause and location of defects in thermally treated SiC substrates using EPR at 9.8 GHz. Samples underwent isochronal anneals from 400 to 1000 °C in pure nitrogen and oxygen ambients. Room temperature EPR spectra showed two defects, defect A and defect B, with line-widths of 4G and 10G, respectively. The temperature dependence was similar for the N2 and O2 anneals until 800 °C, when the concentration of defect A, which stayed constant in N2, decreased in O2. In both ambients defect B was eliminated, and it was determined that this defect was due to cutting. That the amount of defect A decreased during the O2 anneals, but not during the N2 suggests that oxidation, perhaps through etching, removes the signal. During the talk we will compare the results of oxidation and reactive ion etching studies, as these will give a better understanding of the location of defect A.

12:03PM W21.00005 Pulsed ENDOR at 240 GHz of nitrogen centers in 4H-SiC: towards a detailed description of the wavefunction, Johan Van Tol, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32310, Mary Ellen Zvanut, Department of Physics, University of Alabama at Birmingham, Birmingham, AL 35294-1170—SiC is a very suitable semiconductor material for high power and high temperature applications. The electronic properties of many different defects and dopants in various polytypes have been studied by electron paramagnetic resonance (EPR), including various common nitrogen substitutional defects. In particular, high frequency EPR has proven very powerful in separating the EPR signals of different sites, while the nuclear transitions of hyperfine coupled 29Si and 13C that are observed by electron nuclear double resonance (ENDOR) can be well separated. Here we report on new data on the hexagonal nitrogen center in 4H-SiC, for which the hyperfine interaction with the surrounding silicon and carbon shells was measured by pulsed ENDOR at 240 GHz. While these measurements give precise values for the electron spin density on the surrounding atoms, the assignment of these densities to particular atomic sites has proven challenging. The multiplicity and structure of the conduction band in this indirect semiconductor complicates the analysis. We will discuss the observed results and propose a tentative assignment on the basis of the Kohn-Luttinger theory. Supported by the NSF through grants DMR-0654118 and NSF DMR-0520481.

12:15PM W21.00006 X-ray photoelectron spectroscopy of Ni doped boron carbides, Nina Hong, Physics & Astronomy University of Nebraska-Lincoln, ma. Langell, Chemistry University of Nebraska-Lincoln, S. Adenwalla, Physics & Astronomy University of Nebraska-Lincoln—Ni acts as an n-type dopant for semiconducting boron carbide (BC). A series of samples with increased Ni doping were grown on Si substrates using plasma enhanced chemical vapor deposition (PECVD) and characterized using X measurements and X-ray photoelectron spectroscopy (XPS). Increased Ni doping leads to a linear increase in Ni concentration as evidenced by the intensity of the Ni 2p photoemission peak relative to that of the B 1s peak; concomitantly, the XPS curves indicate that the BC becomes increasingly n doped. B1s peak shapes shows B-C and B-B bonding structure, and the C1s peak shows B-C and C-C bond chains in all samples. The overall binding energies for B and C are consistent with the results from sputter deposited stoichiometric B,C [1]; in these PECVD grown samples, however, the graphite peak commonly seen in the sputter deposited BC is absent. [1] I Jimenez, L. J. Terminello, et al. J. Elect. Spec. Relat. Phenom., 101-103, 611-615 (1999).

First-principles study of Oxygen vacancies in Mg,Zn\textsubscript{x}O alloys, ADISAK BOOCHUN, WALTER LAMBERT. Case Western Reserve University — A first-principles study of oxygen vacancies in Mg,Zn\textsubscript{x}O alloys has been carried out within the LDA+U + E\textsubscript{dd} FP-LMTO approach. Different types of oxygen vacancies are distinguished by their number of Mg and Zn nearest neighbors. We find that the energy of formation is lowest for oxygen vacancies surrounded by four Zn nearest neighbors. Because of the Boltzmann factor this implies that the probability of finding oxygen vacancies with one or more Mg as nearest neighbors is strongly suppressed. Unlike in pure ZnO and MgO, we do not find negative U behavior but this may in part be because of the small size of the supercell. The 2+/+ and +/0 transitions level gradually move to higher energy as the number of nearest neighbor Mg atoms increases. Defect levels in rocksalt MgO are also presented.

Cation dopant distributions in m-doped ZnO nanostructures and thin films: experiment and Monte Carlo simulations, T.C. DROUBAY, PACIFIC NORTHWEST NATIONAL LAB, D.J. KEAVNEY, S.M. HEALD, ARGON NATIONAL LAB, T.T. KASPAR, B.P. KASPAR, C.M. WANG, PACIFIC NORTHWEST NATIONAL LAB, C.A. JOHNSON, K.M. WHITAKER, D.R. GEMALINI, CHEMISTRY, UNIV. OF WASHINGTON, S.A. CHAMBERS, PACIFIC NORTHWEST NATIONAL LAB — Anion or cation doping at relatively high concentrations of several atomic percent is frequently suggested to realize synthetic materials with qualitatively new functionality. While the statistical probability of obtaining singles, dimers, and trimers has been determined for bulk lattices, these distributions are significantly altered in nanostructures and thin films due to the presence of under-coordinated surface sites. The dopant distributions in nanostructures and thin films of doped wurtzite ZnO have been determined from Monte Carlo simulations. Using empirical expressions derived from the MC simulations that accurately predict dopant bonding configurations as a function of surface-volume ratio and concentration, experimental results for epitaxial films of Mn-doped ZnO will be discussed. X-ray absorption and x-ray magnetic circular dichroism revealed that Mn(II) substituted for Zn in the Mn:ZnO films, which were deposited by PLD using targets created from Mn:ZnO nanoparticles. However, while substitutional, the Mn distribution is not stochastic but rather tends to segregate, yielding higher local concentrations than anticipated.

Weak localization effects in Al-doped ZnO films, PRIYA.V CHINTA*, Q.Y. CHEN*, O. LOZANO*, P.V. WADEKAR*, W.K. CHU, PACIFIC NORTHWEST NATIONAL LAB, D.J. KEAVNEY, S.M. HEALD, ARGON NATIONAL LAB, T.T. KASPAR, B.P. KASPAR, C.M. WANG, PACIFIC NORTHWEST NATIONAL LAB, C.A. JOHNSON, K.M. WHITAKER, D.R. GEMALINI, CHEMISTRY, UNIV. OF WASHINGTON, S.A. CHAMBERS, PACIFIC NORTHWEST NATIONAL LAB — Metal-semiconductor transitions (MST) at low temperatures were studied for Zn\textsubscript{1−x}Al\textsubscript{x}O thin films deposited by simultaneous RF magnetron sputtering of ZnO and Al onto (11-20)-oriented Al\textsubscript{2}O\textsubscript{3} substrates. The MST occurs at 100K, 102K and 260K for x = 2%, 3% and 10% of Al-doping, respectively. The samples display negative magnetoresistance at low temperatures with zero-field electrical resistivity as low as 3.3 × 10\textsuperscript{-4} Ω cm for x = 3%. The charge scattering mechanisms below the MST will be discussed in light of weak localization and coulomb interactions due to disorder in the system. *Also with Dept of Physics, NSYSU, Taiwan.

First-Principles Theoretical Analysis of Dopant Adsorption and Diffusion on Surfaces of II-VI Compound Semiconductor Nanocrystals, TEJINDER SINGH, J. T. MOUNTZIARIS, DIMITRIOS MAROUDAS, UNIVERSITY OF MASSACHUSETTS, AMHERST — We present a first-principles theoretical analysis of dopant adsorption, and diffusion on facets of II-VI semiconductor nanocrystal surfaces and discuss its implications for dopant incorporation into growing nanocrystals. We focus on ZnSe nanocrystals with diameters d ∼ 5 nm that have polyhedral shapes with well-defined facets. Using density functional theory calculations, we find that the binding energy for Mn adsorption onto various sites of the ZnSe(001)-(2×1) surface increases with increasing dopant surface concentration. This low binding energy at low dopant concentration provides an explanation for dopant diffusion during nanocrystal growth. In addition, we have analyzed several dopant migration pathways for Mn diffusion on the ZnSe(001)-(2×1) surface and calculated the corresponding activation barriers as a function of dopant surface concentration. We find that Mn atoms can migrate fast along the Se dimer rows. However, Mn migration to a trough site is governed by a high-barrier process that may lead to dopant incorporation into the ZnSe nanocrystal.

Effect of Oxygen Vacancies in In\textsubscript{2}O\textsubscript{3}, KALUM PALANDAGE, DEPARTMENT OF PHYSICS, UNIVERSITY OF CONNECTICUT, ADILGER KUSSOW, DEPARTMENT OF PHYSICS, UNIVERSITY OF MASSACHUSETTS LOWELL, ALKIM AKYURTLU, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING, UNIVERSITY OF MASSACHUSETTS LOWELL, GAYANATH FERNANDO, DEPARTMENT OF PHYSICS, UNIVERSITY OF CONNECTICUT — In order to assess the effect of oxygen vacancies on its electronic structure, we have calculated the band structure of In\textsubscript{2}O\textsubscript{3} (in the I\textsubscript{a}3 structure) with and without oxygen vacancies using density functional theory within the local density approximation. A 4 × 4 × 1 Monkhorst-Pack grid of k-points was used to sample the Brillouin zone while permitting full structural relaxation and self-consistency. A noticeable change that is observed is in the nature of the direct band gap of In\textsubscript{2}O\textsubscript{3} at the zone center, which becomes indirect with the addition of a single oxygen vacancy to an ideal 40-atom unit cell. There is also a clear tendency toward metallic behavior with the inclusion of a single oxygen vacancy, which appears to be independent of the location of the vacancy. In addition, spin-polarized calculations reveal negligible magnetic moments due to the introduction of these vacancies. The threshold vacancy concentration necessary for metallic behavior, our results from a symmetry analysis of the relevant valence and conduction band states, which are crucial for optical transitions, as well as effects due to Cr-doping will be presented.

Transport properties of transparent conducting oxide thin film, Nb:In\textsubscript{2}O\textsubscript{3}, O. LOZANO*, Q.Y. CHEN*, P.V. WADEKAR*, L.H. CHU, W.J. WIESUNDERA, WEI-KAN CHU, DEPARTMENT OF PHYSICS AND CENTER FOR NONSCIENCE AND NANOTECHNOLOGY, NATIONAL SUN YAT-SEN UNIVERSITY, KAOHSIUNG, TAIWAN, REPUBLIC OF CHINA, S.W. YEH, N.J. HO, DEPARTMENT OF MATERIALS AND OPTOELECTRONIC SCIENCES AND CENTER FOR NANOSCIENCE AND NANOTECHNOLOGY, NATIONAL SUN YAT-SEN UNIVERSITY, KAOHSIUNG, TAIWAN — Thin films of Nb-doped In\textsubscript{2}O\textsubscript{3} were deposited on YSZ(001) by magnetron co-sputtering. The well-oriented thin films were studied as a function of Nb concentration by optical absorption spectroscopy and magneto-optical transition measurement. The optical transparency in the visible and infrared spectral ranges is 97−99% while the electrical resistivity is about 0.4 mΩ·cm. The variation of these properties with respect to doping will be discussed in the context of scattering and optical transition mechanisms. *Also with Department of Physics and Center for Nanoscience and Nanotechnology, National Sun Yat-Sen University, Kaohsiung, Taiwan, Republic of China.

A First-Principle Density-Functional Theory of BxGa\textsubscript{1−x}BiyAs\textsubscript{1−y} Quaternary Alloys, ZUOZI CHEN, U.C. Berkeley and LBNL, LEI LIU, U.C. Berkeley, LBNL, and Nanyang Technical University, PETER Y. YU, U.C. Berkeley and LBNL, ZHI XUN MA, LBNL, S.S. MAO, U.C. Berkeley and LBNL, ZHILIAN WANG, LBNL, ZHUOZI CHEN, U.C. Berkeley and LBNL, LEI LIU, U.C. Berkeley, LBNL, and Nanyang Technical University, PETER Y. YU, U.C. Berkeley and LBNL, ZHI XUN MA, LBNL, S.S. MAO, U.C. Berkeley and LBNL — Both B and Bi are isovalent impurities in GaAs when they substitute for Ga and As, respectively, at low concentrations. At higher concentrations they can form alloys with GaAs. They have opposite effects on the host GaAs crystal in terms of the lattice constant and band gap. B is smaller than Ga and will increase the band gap of GaAs in addition to converting it from a direct band gap semiconductor into an indirect one. On the other hand, Bi is larger than As and will decrease the band gap of GaAs, turning it into a semi-metal at high concentration. In principle, by incorporating B and Bi into GaAs in appropriate concentration one can tune the band gap of the alloy over a large range of values from the far infra-red to the near uv. We have performed a first-principle density-functional calculation of the total energy, lattice parameters and the band gap of the cubic BxGa\textsubscript{1−x}BiyAs\textsubscript{1−y} alloy system. A generalized quasi-chemical approach is adopted to handle the disorder effects induced by alloying. The dependence of band gap energy surface Eg(x,y) of the quaternary alloy was also obtained. The restriction of a single oxygen vacancy, which appears to be independent of the location of the vacancy. In addition, spin-polarized calculations reveal negligible magnetic moments due to the introduction of these vacancies. The threshold vacancy concentration necessary for metallic behavior, our results from a symmetry analysis of the relevant valence and conduction band states, which are crucial for optical transitions, as well as effects due to Cr-doping will be presented.

Research supported by the U.S. Department of Energy, NNSA/NA-22, under Contract No. DE-AC02-05CH11231.

into regions more or less rich in the magnetic component, and that can be controlled by the growth parameters and co-doping with shallow donors and acceptors into the nitride matrix in a way giving rise either to a diluted random alloy or to ferromagnetic nanocrystals that aggregate by precipitation or by spinodal decomposition of a renormalization of extended states occurring if the impurities perturb strongly the crystal potential. We then show that the Fe ions are incorporated in the

formation on the Fe distribution at the nanoscale. In this talk, we first discuss our quantitative study of the exchange coupling between the spins S = 5/2 localized exhibiting spintronic functionalities has resulted in the discovery of a number of magnetically doped or nominally undoped wide-band gap semiconductors and

ductors. The case of (Ga,Fe)N

11:51AM W21.00004 Diffusion of point defects in CdTe

JOHN JAFFE, CHARLES HENAGER, Pacific Northwest National Lab — We have investigated the mobility of isolated native point defects in CdTe by first-principles calculations. Cd vacancies and interstitials, Te interstitials and Te-on-Cd antisites were considered. Diffusion barriers were found by the NEB (nudged- elastic-band) technique within the PAW-LDA method as implemented in the VASP code. Diffusion constants are estimated, and some implications for the growth of radiation detector material are suggested, especially in regard to the formation of Te precipitates. Comparisons to experimental and earlier theoretical studies are also provided.

11:15AM W22.00001 Nitrogen defects and ferromagnetism in Cr-doped AlN

BANG-GUI LIU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — It is believed that N defects play important roles in achieving high-temperature ferromagnetism in Cr-doped AlN. We use state-of-the-arts DFT method to investigate N defects and their effects on ferromagnetism of (Al,Cr)N with N vacancies \( V_N \). Our total-energy calculations show that the nearest Cr-Cr pair with the two spins in parallel is the most favorable and the nearest Cr-\( V_N \) pair makes a stable complex. Our formation energies indicate that \( V_N \) regions can be formed spontaneously under N-poor condition, or Cr-doped regions can be formed under N-rich condition. Hence real samples should be inhomogeneous. Both of the single Cr and \( V_N \) create filled electronic states in the semiconductor gap of AlN. N vacancies enhance the ferromagnetism by enlarging Cr moment, but reduce the ferromagnetic exchange constants between the spins in the nearest Cr-pair. These calculated results are in agreement with experimental observations and facts. Phys. Rev. B 78, 195206 (2008).

11:27AM W22.00002 Optical and magnetic properties of Tm-doped doped AlGaN alloys

N. NEPAL, S.M. BEDAIR, J.M. ZAVADA, Electrical and Computer Engineering, North Carolina State University, Raleigh, NC 27695 USA, N.A. EL-MASRY, Materials Science and Engineering, North Carolina State University, Raleigh, NC 27695 USA, D.S. LEE, A.J. STECKL, Electrical and Computer Engineering, Texas Tech University, Lubbock, Texas 79409, USA — Trivalent RE-ions in AlGaN alloys have been shown to emit narrow intra-4f transitions over the entire infra red to ultraviolet (UV) spectral range. Also, unpaired 4f-electrons of RE ions can align along an easy axis giving magnetic properties to these RE-doped semiconductors. Thulium is one of the RE elements which has an easy magnetic axis, and we study its optical and magnetic properties of Tm-doped Al\(_{x}\)Ga\(_{1-x}\)N \((0 \leq x \leq 1)\) alloy grown by solid-source molecular beam epitaxy. We present optical and magnetic properties of Tm-doped Al\(_{x}\)Ga\(_{1-x}\)N \((0 \leq x \leq 1)\) alloys.

11:39AM W22.00003 The Failure of LDA and GGA to describe Relative Stability, Electronic Structure and Magnetism of MnN and (Ga,Mn)N Alloys

JENNIFER CHAN, ZHE ZHOU, LIU HANNES RAEBIGER, STEPHAN LANY, ALEX ZUNGER, NREL, Golden, CO 80401 — Pure MnN and (Ga,Mn)N alloys are studied using \( \textit{ab initio} \) generalised gradient approximation +U (GGA+U) or hybrid-exchange density functional (B3LYP) methods which predict dramatically different electronic structure, magnetic behavior and relative stabilities compared to local-density calculations. A unique structural anomaly of MnN, in which local-density calculations fail to predict the experimentally observed rocksalt as the ground state, is resolved with GGA+U and B3LYP. The phase-separation of zinc-blende (Ga,Mn)N alloys is examined using a mixed-basis cluster expansion based on the corrected GGA total energies. The predicted asymmetric spinodal phase diagram indicates that (Ga,Mn)N precipitates contain \%50 Mn at typical growth temperatures. Thus, 100% pure MnN, that suppresses the Curie temperature, will not be formed. The Curie temperature for the \( x_{\textit{fit}}=50\% \) phase is estimated to be \( T_C=\sim 300 \text{ K} \) indicating that high \( T_C \) ferromagnetism in zinc-blende (Ga,Mn)N alloys is due to precipitates.

Session W22 GMAG DMP FIAP: Focus Session: Dilute Magnetic Nitride Semiconductors

Thursday, March 19, 2009 11:15AM - 1:51PM

11:51PM W21.00014 Diffusion of point defects in CdTe

JOHN JAFFE, CHARLES HENAGER, Pacific Northwest National Lab — We have investigated the mobility of isolated native point defects in CdTe by first-principles calculations. Cd vacancies and interstitials, Te interstitials and Te-on-Cd antisites were considered. Diffusion barriers were found by the NEB (nudged- elastic-band) technique within the PAW-LDA method as implemented in the VASP code. Diffusion constants are estimated, and some implications for the growth of radiation detector material are suggested, especially in regard to the formation of Te precipitates. Comparisons to experimental and earlier theoretical studies are also provided.

2:03PM W21.00015 Engineering Oxygen Vacancy Distribution by Exteranal Strain

DA-JUN SHU, SHU-TING GE, MU WANG, NAI-BEN MING, National Laboratory of Solid State Microstructures and Department of Physics, Nanjing University, Nanjing 210093, China — The most common defects on surfaces are transition metal oxides are oxygen vacancies, which play critical roles in applications such as heterogeneous catalysis, photoelectrolysis, biocompatibility, etc. If the nature and distribution of the oxygen vacancies can be controlled, the surface properties will then be modified for different applications. For this purpose, one needs to understand both the influence of oxygen vacancies on the surface properties and the responses of oxygen vacancies to different external fields. We have conducted comprehensive first principles calculations on the surface energy of strained rutile TiO2(110) with oxygen vacancies. The formation energy of each type of oxygen vacancy is calculated as a function of external strain. We find that the type of the most easily formed oxygen vacancy can be tuned by the strain and therefore suggest that the distribution of oxygen vacancies can be engineered by external strain, which helps to improve the applications of TiO2 surface where oxygen vacancies play important roles. The dependence of surface elastic properties on the type of oxygen vacancy is found to be responsible for the interplay between external strain and oxygen vacancies.

2:39PM W21.00016 Origin and control of ferromagnetism in magnetically doped semiconductors. The case of (Ga,Fe)N

ALBERTA BONANNI, Johannes Kepler University - Linz — The comprehensive search for materials exhibiting spintronic functionalities has resulted in the discovery of a number of magnetically doped or nominally undoped wide-band gap semiconductors and oxides showing ferromagnetic features persisting up to high temperatures. In order to shed light on the origin of the high-TC ferromagnetism in these materials systems, we have undertaken studies of MOVPE-grown (Ga,Fe)N, either undoped or co-doped with Si or Mg, combining the magnetic (SQUID and EPR), magnetoeoptical, and XANES investigation with a thorough structural and chemical characterization (SIMS, TEM, EDS, synchrotron XRD), that provides information on the Fe distribution at the nanoscale. In this talk, we first discuss our quantitative study of the exchange coupling between the spins \( s = 5/2 \) localized on the Fe ions and of the effective mass electrons. Our results point to an anomalous p-d exchange splitting of the valence band [1], that we explain in terms of a renormalization of extended states occurring if the impurities perturb strongly the crystal potential. We then show that the Fe ions are incorporated in the nitride matrix in a way giving rise either to a diluted random alloy or to ferromagnetic nanocrystals that aggregate by precipitation or by spinodal decomposition into regions more or less rich in the magnetic component, and that can be controlled by the growth parameters and co-doping with shallow donors and acceptors [2].

12:27PM W22.00005 Magnetic, structural and optical properties of Mn-based and Cr-based diluted magnetic semiconductors and alloys. A. ALSAAD, Jordan University of Science and Technology — We have implemented supercell approach by using local spin density functional theory for Mn-doped GaN, Mn-doped ScN and the linear muffin-tin orbital method to predict the structural and magnetic properties of these novel diluted magnetic semiconductors and their Ga$_{1-x}$Mn$_x$N and Sc$_{1-x}$Mn$_x$N alloys. The global energy minimum of MnN is obtained for zinc-blende structure. If the compound is compressed by 6 % the energy minimum corresponds to the NaCl structure in disagreement with the experimentally observed a slightly tetragonally distorted rocksalt structure, known as α phase. The rocksalt structure of CrN at about 8 % lattice expansion becomes stable in the ferromagnetic (FM) state and has a global minimum energy at a lattice constant of 3.9 Å. We have observed an isostructural phase transition for Sc$_{1-x}$Mn$_x$N alloys from zince-blende phase to hexagonal phase that occurs at a hydrostatic pressure of 17.5 GPa. Moreover, the structural and optical properties of single crystal CrN/ScN superlattices and C$_{1-y}$S$_y$N alloys are studied in details. We report an isostructural phase transition from wurzite (w-CrN) to hexagonal (h-ScN) at a hydrostatic pressure of 21 GPa. We have also used first-principles methods to study the electronic, optical and magnetic properties of MnN and MnAs compounds in the hypothetical cubic zinc-blende phase, a phase in which the two MnN and MnAs binaries have the same local environment as that they have in GaMnN and GaMnAs alloys. We show that MnN exhibits antiferromagnetic (AFM) ground state and MnAs adopts ferromagnetic (FM) ground state.

12:39PM W22.00006 Role of the Localized Defect States in the Unconventional Magnetism of GaN and ZnO. PRATIBHA DEV, PEIHONG ZHANG, Physics Department, University at Buffalo, Buffalo, NY 14260 — The cation defects -vacancies and the appropriate substitutionals - introduce localized defect states chiefly centered around the four surrounding anions in GaN and ZnO. This defect-induced magnetism in these otherwise nonmagnetic semiconductors is studied using ab-initio methods. The defects investigated include the cation vacancy, substitutional acceptors, and acceptor-like defect complexes. The defect states show two opposing attributes -one on one hand, they are strongly localized on the anions surrounding the defect site, leading to local magnetic moment formation, while on the other hand, the extended tails of their wavefunctions lead to the long-ranged exchange interaction between the local moments.

12:51PM W22.00007 Defect induced ferromagnetism in Gd doped GaN. CHANDRIMA MITRA, WALTER LAMBRECHT, Case Western Reserve University — We review various suggested mechanisms for the ferromagnetism in Gd-doped GaN using local spin density approximation supercell calculations. The spin splitting of the conduction band induced by the Gd s − f coupling is found to decrease linearly with Gd concentration and hence colossal magnetic moments cannot be explained by explaining this spin-split band with ionized donor electrons. Furthermore, we find the Gd-Gd interactions to be antiferromagnetic except in p-type material. Although, Ga vacancies can induce long range interactions and up to three Bohr magneton moments per vacancy in the neutral charge state, we note that these defects only are favorable to form in n-type materials and then should predominantly occur in a 3− charge state which has no magnetic moment. N-interstitials are likely to form in conjunction with N vacancies for mid gap Fermi levels consistent with the semi-insulating nature of the samples and have a magnetic moment for the corresponding charge state. We find that Gd in the presence of N interstitials alone prefer antiferromagnetic coupling but in the present of both N-interstitials and N vacancies prefer ferromagnetic coupling. We find that oxygen tends to segregate toward an interstitial site near the Gd and in that case can induce a strong ferromagnetic coupling between Gd.

1:03PM W22.00008 Ferromagnetism in GdN: an antiferromagnet in disguise. WALTER R. L. LAMBRECHT, CHANDRIMA MITRA, Case Western Reserve University — We analyze the exchange interactions in GdN and Gd pnictides GdX with X=P,As,Sb,Bi to the long-ranged exchange interaction between the local moments.

1:15PM W22.00009 Ferromagnetism and Photoluminescence in Rare-Earth doped GaN via Diffusion. M. OLIVER LUEN, N. NEPAL, S.M. BEDAIR, J.M. ZAVADA, Electrical and Computer Engineering, North Carolina State University, Raleigh, NC 27695 USA, EL EI BROWN, U. HOMMERICH, Department of Physics, Hampton University, Hampton, VA 23686 USA, P. FRAJTAG, N.A. EL-MASRY, Materials Science and Engineering, North Carolina State University, Raleigh, NC 27695 USA — Rare-earth doped GaN is attracting attention both as a diluted magnetic semiconductor (DMS) material and for optical devices useful in communications and multi-color semiconductor display technology. GaN’s large band gap (3.4 eV) gives rise to optical transparency over a wide spectral range, from the infrared (IR) to the ultraviolet. These properties make it an optimum host for the various emissions that are possible from rare-earth (RE) ions. Recently, rare-earth doped GaN also has demonstrated above room temperature ferromagnetism. In this study, we report the diffusion of RE (Nd, Sm, Gd and Er) into undoped, Mg-doped and Si-doped GaN templates. Room temperature optical and ferromagnetic properties were studied using photoluminescence (PL) and alternating gradient magnetometer, respectively. Ferromagnetic properties show a preference for undoped and n-type GaN. PL spectra exhibit RE ion inner shell transitions in the visible and infrared regions. The mechanisms for above room temperature ferromagnetism and emission intensity related to the RE concentration, is discussed.

1:27PM W22.00010 Dilute Magnetic and Electronic Properties of Mn$_{0.25}$Sc$_{0.75}$N/ScN(001)/MgO(001) Films Grown by Molecular Beam Epitaxy. COSTEL CONSTANTIN, Seton Hall University, KANGKANG WANG, ABHIJIT CHINCHORE, ARTHUR SMITH, Ohio University, HAN-JONG CHIA, JOHN MARKERT, University of Texas at Austin — In this study, we report the magnetic and electronic properties of Mn$_n$Sc$_{1-n}$N films grown by molecular beam epitaxy. Recently, theoretical calculations predicted a Curie temperature above 350 K for ScN films with up to 20% Mn impurity concentrations[1]. The magnetic hysteresis data suggests ferromagnetic behavior for Mn$_{0.03}$Sc$_{0.97}$N and Mn$_{0.15}$Sc$_{0.85}$N films with Curie temperatures of 383 K and 361 K, respectively. Furthermore, the measured electron concentrations for the Mn$_{0.03}$Sc$_{0.97}$N and Mn$_{0.15}$Sc$_{0.85}$N films are 6.51×10$^{19}$ cm$^{-3}$ and 6.17×10$^{19}$ cm$^{-3}$, respectively. These measured carrier concentration agree well with the prediction of Herwadkar et al. that ferromagnetism above room temperature in Mn$_{1-n}$Sc$_n$N should be possible by keeping the electron concentration below 10$^{20}$ cm$^{-3}$. This work is supported by: Seton Hall: University Research Council; Ohio University: DOE-BES Grant No. DE-FG02-06ER46317 and NSF Grant No. 0730257; and UT Austin: NSF Grant Nos. DMR-0605828 and DGE-0549417, Welch Foundation Grant No. F-1191. [1] A. Herwadkar (et al.), Phys. Rev. B 77, 134433 (2008).
11:15AM W23.00001 Pressure-induced structural transitions in the potential hydrogen storage compound NH$_3$BH$_3$ \(^{1}\). RAVHI KUMAR, HIPSEC, University of Nevada Las Vegas, JIANZHONG ZHANG, MONIKA HARTL, ZHUJUN LIN, SVEN VOGEL, LUKE DAEMEN, LANSCOE, ANDREW CORNELIUS, MALCOLM NICOI, HIPSEC, University of Nevada Las Vegas, YUSHEN ZHAO, LANSCOE — Ammonia borane has received much attention in recent years as it is reported to have up to 19.6 wt % of hydrogen \(^{1-2}\). Hydrogen is released in a three step process when heated above 100°C. To understand the structural stability of this compound under compression, we have performed high pressure angle dispersive x-ray diffraction experiments up to 27 GPa using synchrotron x-rays at HPCAT, Advanced Photon Source. Two successive pressure induced structural phase transitions were observed. The ambient tetragonal structure transforms to an orthorhombic structure around 1.2 GPa and then to another high pressure phase above 8 GPa. Complementary neutron diffraction experiments performed up to 5 GPa at LANSCOE are in good agreement with the x-ray results. The structural details of the high pressure phases will be presented.

\(^{1}\)This work was performed under the auspices of the U.S. Department of Energy jointly by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. The Advanced Light Source is supported by the Director, Office of Science, Office of Basic Energy.
12:27PM W23.00007 Quasi-isentropic Compression Waves Generated by Shock Waves into Sapphire

W. J. NELIS, Harvard University, G. I. KANELO, S. V. RAZORENOV, A. S. SAVINYKH, Institute for High Temperatures, A. M. RAJENDRAN, U. Mississippi — For sixty years it has tacitly been assumed that a shock wave incident on a material will propagate as a shock wave in that material. Between 15 and 80 GPa a shock wave cannot propagate in sapphire, the first material demonstrated not to have a Hugoniot. Wave profiles of sapphire crystals with three orientations and two thicknesses were measured at incident shock stresses of 14, 24 and 87 GPa. 14 GPa generates elastic shocks that are overdriven at ~90 GPa. Elastic-precursor decay occurs at 24 and 87 GPa. At 24 GPa all three orientations have plastic-compression waves with rise times of 200-300 ns. Long rise times are probably caused by strong bonds that break heterogeneously and statistically over a relatively long time interval. This slow damage-induced increase in pressure causes quasi-isentropic compression. Since the Hugoniot and isotherm of sapphire are essentially coincident up to 340 GPa, dissipative energy probably goes primarily into entropy of disordering the crystal rather than temperature.

1Work supported by USARO Grants W911NF0610517 and CRDF 1668.

12:39PM W23.00008 Micron scale simulations of a Kelvin-Helmholtz instability: a direct comparison between molecular dynamics and Navier-Stokes hydrodynamics.

VICTOR PARDO, DANIEL BALDOMIR, Applied Physics Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain, ARTURO MANUEL BANOBRE, Physical Chemistry Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain, ALBERTO PINEIRO, MOSEY, University of Kingston, YANG SONG, PETER NORTON, MARTIN MUESER, University of Western Ontario — In this study, we present X-ray diffraction data on zinc- and calcium phosphates. The experiments reveal that low-coordinated zinc phosphates are good anti-wear agents.

12:51PM W23.00009 Transition of deformation modes in Shocked Tantalum

LUKE HSIUING, Lawrence Livermore National Laboratory — Shock-induced twinning and α (bcc) → ω (hexagonal) phase transition in tantalum, which exhibits no clear solid-state phase transformation under hydrostatic pressure conditions, have been investigated. Since the domains of deformation twin and ω phase were frequently observed in experiments conducted at high pressure and small strain, we simulate shock wave propagation through dislocation-cell structures. It is suggested that the shock-induced shear transformations (twinning and phase transformation) occur as alternative deformation modes to accommodate insufficient dislocation flow resulting from the exhaustion of dislocation multiplication when dynamic recovery processes for dislocation annihilation and cell formation become largely suppressed under dynamic pressure conditions. A physical mechanism based upon the overlapping of closely spaced dislocation loops nucleated from a jogged screw dislocation is proposed to rationalize the shock-induced shear transformations. This work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

1:03PM W23.00010 Hydrogen at Extreme Conditions

SUBRAMANIAN NATARAJAN, ALEXANDER CONCHAROV, SOMAYAZULU MADDURY, RUSSELL HEMLEY, Geophysical Laboratory, Carnegie Institution of Washington, Washington DC 20015 — Vast regions of the P-T phase diagram of H₂, especially in the high P-T region, remain to be explored for melting behavior and exotic phenomena related to dissociation of the H₂ molecule, metallicity and superconductivity. In recent years, few experiments employing either laser-heating or resistive heating techniques in conjunction in situ spectroscopic experiments using Diamond Anvil Cells (DAC) have been reported attempting to address some of these. A key problem that faces experimenters is to confine the hot and reactive H₂ in the small DAC sample chamber at high pressures long enough to make meaningful measurements of physical properties. Recently, we have made considerable progress in confining hot and dense hydrogen while not compromising on the ability to make spectroscopic measurements using a complex sample assembly. With this, it has been possible to perform in situ Raman spectroscopy on H₂ and D₂ while simultaneously doing double-sided laser heating at P-T conditions of more than 1Mbar and 1500K. Typically, we are now able to perform laser heating and in situ Raman spectroscopy over several heating/cooling cycles without loss of H₂ in the Mbar range. Results of these experiments will be presented; along with details of the methodology we adopted to successfully confine hot and dense hydrogen.

1:15PM W23.00011 An accurate high pressure scale from quantum Monte Carlo

KENNETH ESLER, R.E. COHEN, Geophysical Laboratory, Carnegie Institution, BURKHARD MILITZER, Dept. of Astronomy, UC Berkeley, JEONGNIM KIM, University of Illinois at Urbana-Champaign, NCSA — We have developed a fundamental high-temperature and high-pressure scale based on cubic boron nitride (cBN) using a combination of Quantum Monte Carlo (QMC) for the static contribution along with density functional perturbation theory (DFPT) for the thermal pressure. The anharmonic Raman frequency was determined as a function of pressure by solving the Schroedinger equation for the vibrational well determined using QMC combination of Quantum Monte Carlo (QMC) for the static contribution along with density functional perturbation theory (DFPT) for the thermal pressure. The QMCPACK code. We include a novel correction based on all-electron wave functions to eliminate pseudopotential error.

1:27PM W23.00012 Softening of ultra-incompressible CrN at high pressure

FRANCISCO RIVADULLA, MANUEL BANOBRE, Physical Chemistry Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain, ALBERTO PINEIRO, TICTOR PARDO, DAVIEL BALDOMIR, Applied Physics Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain, ARTURO LOPEZ-QUINTELA, Physical Chemistry Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain, JOSE RIVAS, Applied Physics Department, University of Santiago de Compostela, 15782 Santiago de Compostela, Spain — We report a dramatic softening of CrN above 1.5 GPa, (the bulk modulus decreasing from K=4.0 GPa to 2.4 GPa) associated to a structural transition. From the structural and magnetic data under pressure, and ab-initio calculations we suggest that this effect is purely electronic, driven by the proximity of the ionic Cr-Cr bond to itinerant electron limit. Our results help to understand fundamental aspects of the chemical bond that gives superhard materials their superior mechanical properties, and could be useful to preserve the mechanical properties of CrN.

1:39PM W23.00013 Correlating cation coordination, stiffness, phase transition pressures, and smart materials behavior in metal phosphates

DMITRY SHAKHROVOSTOV, University of Western Ontario, NICHOLAS MOSEY, University of Kingston, YANG SONG, PETER NORTON, MARTIN MUESER, University of Western Ontario — In this study, we present X-ray diffraction data on zinc- and calcium phosphates. The experiments reveal that low-coordinated zinc phosphates are relatively soft at ambient conditions but stiffen dramatically with increasing pressure, p, exhibiting smart materials behavior, while high-coordinated zinc and calcium phosphates have higher initial bulk moduli and stiffen considerably less rapidly with increasing p. All systems amorphize when their bulk modulus reaches a value near 210 ± 40 GPa, where the precise value depends on chemical details, indicating that phosphate networks become unstable when their bulk modulus reaches that value. Our ab-initio simulations of zinc-α-phosphate support the idea that the elastic properties are controlled by the motion of rigid phosphate units, which becomes more hindered under densification, with or without increasing cation coordination. It is discussed how these results may explain why low-coordinated zinc phosphates are good anti-wear agents.
1:51PM W23.00014 Novel Numerical Computations for the Equation of State of Hard Particle Systems from Gaseous to Extreme High Densities, UDUZEI EDGAL, Old Dominion University — A special form of the “Reduced Monte Carlo Scheme” (RMCS) used for numerical computation of the EOS of the hard particle system (2D and 3D cases) will be discussed. A major advantage of the numerical scheme is that it does not lead to difficulties with meta-stable states as do traditional MC methods. In particular, RMCS calculations (in the special form) provide results from the lowest (fluid phase) to the highest (solid phase) densities which show a first order phase transition in the hard particle system.

2:03PM W23.00015 X-ray diffraction of electrodeposited nanocrystalline Ni under high-pressure, CHRISTIAN GRANT, Livermore National Laboratory, JONATHAN CROWHURST, TOM ARSENLIS, Lawrence Livermore National Laboratory, EDUARDO BRINGA, Instituto de Ciencias Basicas Universidad Nacional de Cuyo, MORRIS WANG, JAMES HAWRELIK, PETER PAUZAUSKIE, Lawrence Livermore National Laboratory, SIMON CLARK, Advanced Light Source, Lawrence Berkeley National Laboratory — We studied the compressibility of monolithic fully-dense electrodeposited nanocrystalline Ni (29 nm grain size) under both quasi-hydrostatic and non-hydrostatic conditions up to a nominal pressure of 50 GPa using angle-dispersive x-ray diffraction. We obtained an equation of state consistently and unambiguously from each measured reflection. The apparent bulk modulus measured under non-hydrostatic conditions is larger than that of the corresponding coarse grained-material under either type of compression, but is nearly the same when measured under quasi-hydrostatic conditions. Our results suggest that the strength, but not the bulk modulus, of 29 nm crystalline Ni is enhanced relative to its coarse-grained counterparts.

11:15AM W24.00001 Quantum Monte Carlo Studies of Interaction-Induced Localization in Quantum Dots and Wires, A. DEVIRM GÜÇÜL, Institute for Microstructural Sciences NRC, Ottawa and Duke University — We investigate interaction-induced localization of electrons in both quantum dots and inhomogeneous quantum wires using variational and diffusion quantum Monte Carlo methods. Quantum dots and wires are highly tunable systems that enable the study of the physics of strongly correlated electrons. With decreasing electronic interaction-induced localization of electrons in both quantum dots and inhomogeneous quantum wires using variational and diffusion quantum Monte Carlo methods. Quantum dots and wires are highly tunable systems that enable the study of the physics of strongly correlated electrons. With decreasing electronic interactions, electrons become stronger and electrons are expected to localize at their classical positions, as in Wigner crystallization in an infinite 2D system. (1) Dots: We show that the addition energy shows a clear progression from features associated with shell structure to those caused by commensurability of a Wigner density, interactions become stronger and electrons are expected to localize at their classical positions, as in Wigner crystallization in an infinite 2D system. (1) Wires: We study an inhomogeneous quasi-one-dimensional system—a wire with two regions, one at low density and the other high. We find that strong localization occurs in the low density quantum point contact region as the gate potential is increased. The nature of the transition from high to low density depends on the density gradient—if it is steep, a barrier develops between the two regions, causing Coulomb blockade effects. We find no evidence for ferromagnetic spin polarization for the range of parameters studied. The picture emerging here is in good agreement with the experimental measurements of tunneling between two wires. Collaborators: C. J. Umrigar (Cornell), Hong Jiang (Fritz Haber Institute), Amit Ghosal (IISER Calcutta), and H. U. Baranger (Duke).

12:03PM W24.00003 Iterative real-time path integral approach to nonequilibrium quantum transport, MICHAEL THORWART, Freiburg Institute for Advanced Studies, Univ. Freiburg, Germany, STEPHAN WEISS, Niels-Bohr-Institute, Univ. Copenhagen, Denmark, JENS ECKEL, REINHOLD EGGER, Institute for Theoretical Physics, Univ. Duesseldorf, Germany — We have developed a numerical approach to compute real-time path integral expressions for quantum transport problems out of equilibrium. The scheme is based on a deterministic iterative summation of the path integral (ISPI) for the generating function of the nonequilibrium current. Self-energies due to the leads, being non-local in time, are fully taken into account within a finite memory time, thereby including non-Markovian effects, and numerical results are extrapolated both to vanishing (Trotter) time discretization and to infinite memory time. This extrapolation scheme converges except at very low temperatures, and the results are then numerically exact. The method is applied to nonequilibrium transport through an Anderson dot. [1] S. Weiss, J. Eckel, M. Thorwart, and R. Egger, Phys. Rev. B 77, 195316 (2008).

12:15PM W24.00004 Time dependent transport in nanostructures1, KALMAN VARGA, Vanderbilt University — Using the Lagrange-function representation [1] we present time-dependent density functional calculations of the transport properties of nanostructures. To avoid the complications related to the semi-infinitive leads a complex absorbing potential (CAP) is added to the Hamiltonian [2,3]. This transformation leads to an effectively closed system which is computationally manageable. We will compare the results of the time dependent approach to those of time independent approaches for prototypical molecular devices such as benzene ring between gold electrodes and nanotubes.

1Supported by NSF ECS 0622146.
12:27PM W24.00005 Effective capacitance of small molecules and nanoscale devices in an electric circuit, XIAOGUANG ZHANG, Oak Ridge National Laboratory, JUN-QIANG LU, University of Puerto Rico-Mayaguez, SOKRATES PANTELIDES, Vanderbilt University — A quantum-mechanical-kinetic description of the capacitance of a molecule or nanodevice between two electrodes is complicated by the fact that one cannot unambiguously partition the electron density between the metal electrodes and the molecule or device. We introduce a procedure that leads to an unambiguous partitioning and to practical calculations using a linear response formalism for alternating current (AC) transport. The linear response theory is derived for a closed quantum system including the molecule and two electrodes with a finite length. The mutual capacitance between the two electrodes in the absence of a molecule or device is subtracted to obtain an effective capacitance for the molecule in the presence of the electrodes. Numerical calculations show that the effective capacitance converges with the increasing length of the electrodes. The converged results for small molecules of CO₂, CH₃, NH₃, H₂O, and benzene range from 0.18 to 2.832 (10⁻¹⁹ F).

1Work at CNMS at ORNL sponsored by Division of User Facilities, Office of Basic Energy Sciences, US Department of Energy.

12:39PM W24.00006 Theoretical Study of Electron Transport across Carbon Nanotube Junctions Decorated with Au Nanoparticles, KHOONGHONG KHOO, JAMES CHELIKOWSKY, University of Texas at Austin — In recent years, there has been extensive research on carbon nanotube networks owing to their potential for applications in transparent electronics, and several experimental studies have found that electrical conductivity across these networks can be increased by metal nanoparticle doping. To aid in understanding the mechanism of this conductance increase, we have performed first-principles calculations on nanotube junctions decorated with small Au nanoparticles. Our calculations show that the conductance of nanotube junctions is significantly increased by the introduction of odd-numbered Au nanoparticles, and electron transport is mediated by resonant tunneling through Au nanoparticle states. In addition, we find that interesting interference effects modulate conduction across doped nanotube junctions that connect near nanotube tips. This work was supported in part by NSF under DMR-0551195 and the U.S. Department of Energy under DE-FG02-06ER46286 and DE-FG02-06ER15760.

12:51PM W24.00007 Mechanism of Current-Induced Switching in Naphthalocyanine Molecular Device, TESFAYE ABTEW, NC State U. Raleigh NC, JERRY BERNHOLC, WENCHANG LU, NC State U. Raleigh NC and CSMD, ORNL, TN — Current-induced switching of inner cavity hydrogen atoms in a naphthalocyanine molecule has been reported experimentally [1]. The experiment shows a rotation of the lowest unoccupied molecular orbital (LUMO) image by 90° when the switching occurs. We study transport properties and energetics of a naphthalocyanine molecule sandwiched between gold leads using a parallel real space multigrid method. A non-equilibrium Green’s function formalism in a basis of optimized localized orbitals is employed to evaluate the current-voltage characteristics. Current-induced forces are evaluated and used to obtain bias-induced relaxations. The current-voltage characteristics indeed reveal contrasting high and low conductances depending on the orientation of the hydrogen atoms. However, a high energy barrier restrains the hydrogens from switching. We propose an alternative atomic configuration, which yields a much lower energy barrier for switching but still results in LUMO images that agree with the experimental results. [1] P. Liljeroth, J. Repp, and G. Meyer, Science 317, 1203 (2007).

1:03PM W24.00008 Negative differential resistance in molecular junctions: The effect of the electrodes electronic structure, NATALYA ZIMBOVSKAYA, University of Puerto Rico-Humacao, MARK PEDERSON, Naval Research Laboratory — We have carried out calculations of electron transport through a metal-molecule-metal junction with metal nanoclusters taking the part of electrodes. We show that negative differential resistance peaks could appear in the current-voltage curves. The peaks arise due to narrow features in the electron density of states of the metal clusters. The proposed analysis is based on the ab initio computations of the relevant wave functions and energies within the framework of the density functional theory using NRLMOL software package.

1 NZ acknowledges support from the ASEE and ONR Summer Faculty Research Program.

1:15PM W24.00009 Transport Properties of DNA Bases Placed in Graphene Nano-gap, CHRISTIAN WOLOWIEC, NICK KIOUSSIS, Department of Physics and Astronomy, California State University, Northridge, CA 91330, DMITRI NOVIKOV, Atomistic, Chief Technology Officer, Santa Clara, CA 95054 — There has been significant demand and research activity for the development of new DNA sequencing technologies employing transverse transport techniques. We present systematic first principles studies based on Density Functional Theory of the transport properties and current-voltage characteristics of nucleotide molecules of the DNA bases, placed in 1.2 nm gap formed between the zigzag edges of graphene-nano-electrodes. The linear dispersion of the graphene electrons and the local spin-polarization associated with the zigzag edges allow the exploration of both the charge- and spin-current signatures of the DNA bases to device properties. We present results in the tunneling regime of the charge- and spin-transport properties as the geometrical conformation of the bases is varied. Such signatures may be used experimentally for developing an efficient means of sequencing larger strands of DNA.

1:27PM W24.00010 Quantum mechanical pseudopotential atomistic simulations of nanosized CMOS devices, LIN-WANG WANG, Lawrence Berkeley National Laboratory, XIANG-WEI JIANG, HUI-XIONG DENG, Semiconductor Institute, Chinese Academy of Science — We have used empirical pseudopotential to calculate the electronic structures of million atom CMOS systems. This is done by using the linear combination of bulk band (LCBB) method. For a nonequilibrium CMOS system with an applied source-drain bias, we have devised three different ways to calculate the inverse carrier charge densities and the corresponding currents. The first is to use partition functions extended from source and drain using their respective Fermi energies. The second is to use a spatially dependent local quasi-Fermi energy, and the third is to calculate the current using Bardeen’s tunneling current formula. In this talk, we will compare the results of these three different methods. We will also compare the quantum mechanical results with classical simulation results. This work was supported by U.S. Department of Energy under Contract No. DE-AC02-05CH11231. It has also been supported by Chinese National Natural Science Foundation.

1:39PM W24.00011 Nagaoka instabilities and coherent pairing in various cluster topologies, ARMEN KOCHARIAN, California State University, Los Angeles, GYANATH FERNANDO, Department of Physics, University of Connecticut, KALUM PALANDAGE, JAMES DAVENPORT, Computational Science Center, Brookhaven National Laboratory — Electron pairing and formation of various types of magnetic correlations in the ensemble of small clusters of different geometries are studied with emphasis on tetrahedron, square pyramid, etc under variation of interaction strength, electron doping and temperature. These exact calculations of charge and spin collective excitations and pseudogaps yield intriguing insights into level crossing phenomena and spatial interference, providing a new route to superconductivity in inhomogeneous HTSC systems, different from the BCS scenario. Phase diagrams resemble a number of inhomogeneous, coherent and incoherent nanoscale phases seen recently in high Tc cuprates, manganites and CMR nanomaterials.

1:51PM W24.00012 Calculation of complex band structure for low symmetry lattices\textsuperscript{1}, MANOJ SRIVASTAVA, Department of Physics, University of Florida, XIAOGUANG ZHANG, Oak Ridge National Laboratory, HAI-PING CHENG, Department of Physics, University of Florida — Complex band structure calculation is an integral part of a first-principles plane-wave based quantum transport method. \textsuperscript{1} The direction of decay for the complex wave vectors is also the transport direction. The existing algorithm \cite{1} has the limitation that it only allows the transport direction along a lattice vector perpendicular to the basal plane formed by two other lattice vectors, e.g., the c-axis of a tetragonal lattice. We generalize this algorithm to nonorthogonal lattices with transport direction not aligned with any lattice vector. We show that this generalization leads to changes in the boundary conditions and the Schrödinger's equation projected to the transport direction. We present, as an example, the calculation of the complex band structure of fcc Cu along a direction perpendicular to the (111) basal plane. \cite{1} Hyoun Joon Choi and Jisoon Ihm, Phys. Rev. B 59, 2267 (1999).

2:03PM W24.00013 Reduced Bloch mode expansion for fast band structure calculations, MAHMOUD HUSSEIN, University of Colorado at Boulder — In this paper, we present reduced Bloch mode expansion for fast band structure calculations in lattice dynamics. The expansion employs a natural basis composed of a selected reduced set of Bloch eigenfunctions. The reduced basis is selected within the irreducible Brillouin zone at high symmetry points determined by the medium's crystal structure and group theory. At each of the reciprocal lattice section points, a number of Bloch eigenfunctions are used to accurately represent the dispersion relations. The resulting reduced Bloch mode expansion greatly improves both the memory and computational time required for band structure calculations.

11:15AM W25.00001 Atomically Flat Graphene on Mica Substrates, LI LUI, CHUN HUNG LUI, KIN FAI MAK, GEORGE FLYNN, TONY HEINZ, DEPARTMENT OF PHYSICS, COLUMBIA UNIVERSITY, NEW YORK, NY 10027 COLLABORATION, DEPARTMENT OF CHEMISTRY, COLUMBIA UNIVERSITY, NEW YORK, NY 10027 COLLABORATION — Much recent interest has focused on the question of the intrinsic flatness of monolayers of exfoliated graphene. In studies of both suspended graphene [Meyer et al, Nature 446 (2007)] and graphene deposited on SiO\textsubscript{2} substrates [Stolyarova et al, PNAS 104 (2007)], graphene monolayers exhibited clear variations in height. For suspended films, this variation was attributed to an intrinsic rippling instability [Meyer et al, Nature 446 (2007)]. In the case of graphene on SiO\textsubscript{2} substrates, the role of intrinsic and substrate-induced effects remained unclear because of the corrugation of the substrate. In this paper we present results of a detailed study of the morphology of exfoliated graphene monolayers deposited on the atomically flat terraces of cleaved mica surfaces. Using high-resolution atomic force microscopy (AFM), we demonstrate that graphene monolayers on mica, when measured with lateral spatial resolution of \(\sim\) 6nm, are flat to over micron lateral length scales to within the instrumental sensitivity of 50 pm. These results stand in sharp contrast to the behavior reported for both suspended graphene and graphene on SiO\textsubscript{2} substrates.

11:27AM W25.00002 Scattering in monolayer graphene on SiO\textsubscript{2} observed by STS, APARNA DESHPANDE, BRIAN LEROY, University of Arizona, WENZHONG BAO, FENG MIAO, CHUN NING LAU, University of California Riverside — The intrinsic ripples of graphene and its distinctive band structure make graphene a novel two-dimensional system of interest for the study of structural and electronic properties. To probe the influence of graphene structure on its electronic properties we have carried out scanning tunneling spectroscopy (STS) measurements on exfoliated graphene on SiO\textsubscript{2} with an ultra high vacuum scanning tunneling microscope (UHV STM) at 4.2 K. Atomically resolved local density of states (LDOS) images show an interference pattern due to scattering. 2D Fourier transforms of the LDOS maps reveal two types of scattering wave vectors corresponding to long range intravalley scattering and short range intervalley scattering. Interv valley scattering due to short range potential variations leads to a \(\sqrt{3}\times\sqrt{3}\) R30\textdegree interference pattern in the LDOS while intravalley scattering causes long range disorder in the LDOS images. Our measurements present a comprehensive picture of scattering mechanisms in exfoliated graphene and underline the contribution of random impurities, defects and SiO\textsubscript{2} morphology to the electronic properties of graphene.

11:39AM W25.00003 STM on Gate-Tunable Graphene, YUANBO ZHANG, Dept. of Physics, UC Berkeley — We have successfully performed atomically-resolved scanning tunneling microscopy and spectroscopy (STS) on mechanically exfoliated graphene samples having tunable back-gates. We have discovered that the tunneling spectra of graphene flakes display an unexpected gap-like feature that is pinned to the Fermi level for different gate voltages, and which coexists with another depression in density-of-states that moves with gate voltage. Extensive tests and careful analysis show that the gap-feature is due to phonon-assisted inelastic tunneling, and the depression directly marks the location of the graphene Dirac point. Using tunneling spectroscopy as a new tool, we further probe the local energetic variations of the graphene charge neutral point (Dirac point) to map out spatial electron density inhomogeneities in graphene. Such measurements are two orders of magnitude higher in resolution than previous experiments, and they can be directly correlated with nanometer scale topographic features. Based on our observation of energy-dependent periodic electronic interference patterns, our measurements also reveal the nature of impurity scattering of Dirac fermions in graphene. These results are significant for understanding the sources of electron density inhomogeneity and electron scattering in graphene, and the microscopic causes of graphene electron mobility.

12:15PM W25.00004 Effect of disorder on electron tunneling in graphene layers through potential barriers, VRINDA THAREJA, MANISH SHARMA, SANKALPA GHOSH, Indian Institute of Technology Delhi — Electrons at the fermi level in Graphene monolayer behave like massless Dirac fermions. Using a coherent potential approximation, we study the tunneling of such electrons through a double barrier potential in presence of disorder. We subsequently extend this study in the case of periodic lattice potentials. Our approach involves using the Green's function calculation and is particularly amenable to studying the effect of disorder, impurities and defects on electron propagation through Graphene.

12:27PM W25.00005 Scanning Gate Microscopy on Patterned Graphene Nanoribbons, ANDREI GARCIA, MARKUS KOENIG, KATHRYN TODD, DAVID GOLDBABER-GORDON, Stanford University — Graphene-based electronic devices are of interest due to the unique nature of the graphene band structure. Bulk graphene exhibits a gapless linear dispersion near the Fermi level. When graphene is etched to form a narrow ribbon a transport gap opens at the Dirac point. The origin of this transport gap in patterned graphene nanoribbons remains an unresolved problem. Two possible explanations for the origins of the gap are confinement in the direction perpendicular to the length of the ribbon and localization due to disorder along imperfectly formed ribbon edges. We explore the local properties of this gap in nanoribbons using a scanning gate microscope.
12:39PM W25.00006 Scanning tunneling microscopic (STM) studies of strain-induced local density of states modulations in single-layer graphene on SiO₂  A.P. LAI, M.L. TEAGUE, C.R. HUGHES, A.D. BEYER, N.-C. YEH, M.W. BOCKRATH, Phys. Dept, Caltech, Pasadena, CA, J. VELASCO, C.N. LAU, UC Riverside — We report strain-induced spatial modulations in the electronic density of states (DOS) of single-layer graphene on SiO₂. Spatially resolved topographic and spectroscopic measurements were performed simultaneously at 77 K and at pressures < 10⁻⁷ torr. Fourier transformation of local topography shows a distorted hexagon with lattice vectors ranging from a₀=3.0 ±0.2 Å to 2.1±0.2 Å as the result of surface corrugation from the roughness of the underlying substrate. A spatially varying strain map derived from local distortions of the lattice constants correlates well with the surface topography. Strained graphene, due to three dimensional surface corrugations of ± 5 Å over 10 nm lateral distance, show parabolic “U-shaped” conductance vs. biased voltage spectra rather than the Dirac-like “V-shaped” spectra. In contrast, for regions of relaxed graphene, Dirac-like spectra are recovered. The Dirac voltage, V_D, determined from the biased voltage of conductance minimum, appears to be position independent at V_D=36±5 meV, while the minimum conductance and the degree of derivation from the Dirac-like spectra at low energies appear to correlate directly with the topography. This work was supported by NSF/NRI under Caltech/CSEM.

12:51PM W25.00007 SPM measurements of graphene corrugation and spatial correlation  WILLIAM CULLEN, JIANHAO CHEN, University of Maryland, MASA ISHIGAMI, University of Central Florida, ELLLEN WILLIAMS, MICHAEL FUHRER, University of Maryland — In order to determine the effect of graphene corrugation on electronic transport, it is most important to know the spatial correlation properties of the corrugated graphene structure. In spite of much experimental effort, there is still contentious debate about the structure of graphene, both in supported and suspended geometries. It has frequently been asserted that a graphene monolayer exfoliated onto a SiO₂ substrate may display “intrinsic” corrugation — rippled structure which is not derived from the topography of the underlying substrate. Here, we report recent UHV NC-AFM and STM results which show that anomalous corrugation may be observed due to local interaction between the tip and the graphene monolayer. Our results show that non-perturbative NC-AFM measurement reveals a graphene topography which is as smooth as the underlying SiO₂, with height-height correlation exponent H=1. STM measurement of graphene, due to uncontrollable tip-sample forces, may exhibit anomalous corrugation depending on tip condition.

1Supported by a NRI supplement to the UMD-NSF-MBSEC grant #DMR 0520471.
2:03PM W25.00013 Enhancement of nearest neighbor spin-singlet correlations in d-wave SNS graphene Josephson junctions, ANNICA BLACK-SCHAFER, SEBASTIAN DONIACH, Stanford University — Using the self-consistent tight-binding Bogoliubov-de Gennes (BdG) formalism we investigate the effect of nearest neighbor spin-singlet bond (SB) correlations in a graphene SNS Josephson junction with d-wave superconducting contacts. All pi-bonded planar organic molecules, of which graphene is the infinite extension, show a preference for SB over polar configurations, as originally captured by Pauling’s idea of resonating valence bonds. At strong enough coupling and/or high doping levels, these correlations will give rise to a d-wave superconducting state. However, the estimated coupling strength in graphene would require a doping level not currently experimentally achievable by a gating bias. We demonstrate that by creating a graphene SNS Josephson junction with d-wave contacts, for example by depositing a high-Tc cuprate on top of the graphene, it should be possible to enhance the effect of the SB correlations and see clear signatures of d-wave pairing in proximity effect, superconducting decay length, and supercurrent.

Thursday, March 19, 2009 11:15AM - 2:15PM –
Session W26 DMP: Focus Session: Graphene XVI: Functionalization and Growth I

11:15AM W26.00001 Impact of Atomic Hydrogen Adsorption on Transport Properties of Graphene, JYOTTI KATOCH, Department of Physics, University of Central Florida, JIANHAO CHEN, Dept of Physics, Center for Nanophysics and Advanced Materials, and Materials Research Science and Engineering Center, Unive. of Maryland, College Park, MASA ISHIGAMI, Department of Physics, University of Central Florida — We have measured transport properties of graphene as a function of surface coverage by atomic hydrogen in ultra high vacuum. Hydrogen adsorption is reversible at moderate temperatures and alters electronic properties of graphene at atomic scale. We will discuss dependence of minimum conductivity and field-effect carrier mobility on the density of adsorbed hydrogen.

11:27AM W26.00002 Determination of the Crystallographic Orientation of Graphene by Raman Spectroscopy, MINGYUAN HUANG, Department of Mechanical Engineering, Columbia University, HUGEN YAN, Department of Physics and Electrical Engineering, Columbia University, CHANGYAO CHEN, Department of Mechanical Engineering, Columbia University, DAOHUA SONG, TONY HEINZ, Department of Physics and Electrical Engineering, Columbia University, JAMES HONE, Department of Mechanical Engineering, Columbia University — We present a systematic study of the Raman spectra of the G band in graphene monolayers under tunable uniaxial tensile stress. The G band splits into two distinct sub-bands; G+ and G−. The polarization dependence that reflects the angle between the axis of the stress and the underlying graphene crystal axes. Polarized Raman spectroscopy therefore constitutes a purely optical method for the determination of the crystallographic orientation of graphene.

11:39AM W26.00003 Growth and Characterization of CVD Graphene, ALFONSO REINA, XIAOTING JIA, JOHN HO, DANIEL NEZICH, HYUNGBIN SON, VLADIMIR BULOVIC, MILDRED S. DRESSELHAUS, JING KONG, Massachusetts Institute of Technology — Large-area (~cm²) graphene films are grown by ambient pressure chemical vapor deposition (CVD) on evaporated Ni films. We show that proper engineering of the Ni film properties, such as grain structure and surface roughness, and the use of ultra-diluted hydrocarbon flow yields films consisting of 1 to ~10 graphene layers in thickness. Furthermore, the produced graphene can be transferred, by wet-etching the underlying Ni, to a variety of substrates allowing graphene coverage over large areas on different materials such as glass, polymers or other semiconductors. Raman Spectroscopy, electron diffraction and transmission electron microscopy suggest disordered stacking of regions with multilayer graphene. Growth mechanisms will also be discussed. Opto-electronic properties and ambipolar transfer characteristics of the produced material is also demonstrated.

11:51AM W26.00004 Chemical exfoliation procedure for graphene deposition1, MICHELLE ZIMMERMANN, MAHITO YAMAMOTO, BRAD CONRAD, JIANHAO CHEN, ELLEN WILLIAMS, Department of Physics and University of Maryland Materials Research Science and Engineering Center, University of Maryland, College Park, MD 20742 — Mechanical exfoliation techniques for graphene production yield flakes which are too small and too rare for feasible large-scale experiments or commercial device fabrication. We present a systematic evaluation of the steps involved in chemical exfoliation of graphite to generate suspended graphene sheets. The approach is based on the solubilizing of a graphite intercalation compound in a polar solvent, analogous to solubilization of CNT salts [1] and recently reported for graphene [2]. A shift in the Raman G peak of graphite provides a metric of the degree of intercalation of lithium and naphthalene into graphite flakes. To optimize deposition onto SiO2 substrates, we compare drop casting, spin-coating and dip-coating, as well as the effects of different surface treatments (UV ozone, oxygen plasma, functionalization). [1] A. Pécaut, et al., J. Am. Chem. Soc. 127, 8 (2005). [2] C. Vallès, et al., J. Am. Chem. Soc. 130, 15802 (2008).

1Supported by NSF Grant No. DMR-080976 and UMD-NSF-MRSEC-SEF.

12:03PM W26.00005 Anomalously high conductivity in bromine-intercalated graphite, A.F. HEBARD, S. TONGAY, J. HVANG, D.B. TANNER, D. MASLOV, University of Florida — We have found that when graphite is intercalated with bromine, the ab-plane (~c-axis) conductivity sharply increases (decreases). Characterization of the Br intercalated samples by exposure time, weight uptake, sputter Auger spectroscopy and X-ray diffraction show a Br concentration that is uniformly distributed within a graphite host having an expanded interplanar spacing dc. The ab-plane conductivity is enhanced by several orders of magnitude in the temperature range from 300 K down to 1.7 K and shows no sign of saturation with increasing Br concentration. Hall measurements confirm a pronounced increase in the density of negative carriers consistent with an increased optical reflectivity (below 3000 cm⁻¹). The inferred plasma frequencies and extrapolated dc conductivities are consistent with the transport measurements. The diamagnetic susceptibility decreases with increasing Br concentration and follows a temperature dependence from which a Fermi energy that increases with increasing Br concentration is extracted. By increasing dc, the ab-plane conductivity of Br intercalated graphite begins to resemble the additive contributions of parallel connected doped graphene sheets and thus has implications for carbon based electronics.

12:15PM W26.00006 Influence of substrates on graphene layers: Raman study1, JORGE CAMACHO, LIYUAN ZHANG, TONY VALLA, IGOR ZALIZNYAK, Brookhaven National Laboratory — Electrical contacts and a substrate can significantly influence electronic and physical properties of graphene. Charge transfer, strain, introduction of various impurities and defects are some of the factors that can alter graphene properties. Therefore, the graphene has been considered in any real graphene-based device. Here we use Raman spectroscopy to study effects of different substrates and adsorbates on graphene Raman-active modes. We find that the intensity, frequency and line-width of some modes are very sensitive to the chemical environment of graphene sheets, reflecting the changes in interactions of these modes with charge carriers and degree of disorder introduced in the system.

Doping effect of electrode on Graphene\textsuperscript{1}, KEYU PI, KATHY MCCREARY, WEI HAN, YAN LI, WENZHONG BAO, CHUN NING LAU, ROLAND KAWAKAMI, University of California, Riverside. ROLAND, KAWAKAMI TEAM, CHUN-NING, LAU COLLABORATION — Graphene as a carrier tunable transport media has drawn a lot of interest since its discovery. It has recently been reported that invasive electrode contacts cause electron-hole asymmetry\textsuperscript{1} which will affect the transport properties. To study this effect, we developed an in-situ measurement system that combines Molecular Beam Epitaxy (MBE) with transport measurement. Fine control of the material deposition rate allows us to study the doping effect on graphene at the early stages of electrode formation.\textsuperscript{1}\textsuperscript{1} B. Huard et al., PRB. 78. 121402(R), 2008

We acknowledge the support of ONR, NSF and CNID.

Multi-layer graphene derived from graphite fluoride, S.H. CHENG, K. ZOU, A. GUPTA, H.R. GUTIERREZ, P. EKLUND, J.O. SOFO, J. ZHU, Department of Physics, The Pennsylvania State University, F. OKINO, Department of Chemistry, Faculty of Textile Science and Technology, Shinshu University — We produce multi-layer graphene through the reduction of graphene fluoride. Graphite fluoride (CF) is synthesized by reacting F\textsubscript{2} with graphite at 500 - 600°C. We obtain few-layer CF sheets through mechanical exfoliation and characterize their properties with electron diffraction, TEM, AFM, Raman and transport measurements. Electron diffraction spectra of fluorinated few-layer CF show the persistence of six-fold hexagonal symmetry and long-range in-plane crystalline order. Domains of varying thickness in both AFM and TEM measurements suggest an incomplete fluorination. Raman spectra of few-layer CF show the appearance of a D band (\textsim\sim 1350 cm\textsuperscript{-1}) as expected from sp\textsuperscript{2} bonding. Few-layer CF sheets are defluorinated in flowing H\textsubscript{2}/Ar (10%/90%) at 500 - 600°C. AFM studies of defluorinated CF show a pronounced decrease in roughness and thickness, suggesting the removal of fluorine. Raman spectra of defluorinated CF show a reduced background with an enhanced 2D peak (\textsim\sim 2700 cm\textsuperscript{-1}). We present transport measurements in field effect transistors fabricated from CF and defluorinated sheets and compare with that of pristine graphene and graphene-oxide reduced graphene.

Size Selection of Metal Nanoparticles on Few Layer Graphene\textsuperscript{1}, LUKE A. SOMERS, ZHENGTANG Luo, E.J. MELE, A.T. CHARLIE JOHNSON, University of Pennsylvania — We find layer number dependence in the size of metal nanoparticles grown on 1 to 10 layer graphene. Graphene is an attractive substrate for investigating and using nanoparticles due to its loose interaction with them. To preserve this condition it is ideal to grow particles in place rather than deposit them from solution. We find that annealing of evaporated metal nanoparticles on graphene and few layer graphene surfaces tightens their size distribution. The number of graphene layers changes the selected size. These results are in quantitative agreement with a model incorporating surface, bulk, and coulomb free energies.

This work was supported by the JSTO DTRA and the Army Research Office Grant # W911NF-06-1-0462.

Optimization of high quality epitaxial graphene growth on SiC, MING RUAN, MICHAEL SPRINKLE, YIKE HU, CLAIRE BERGER, WALTER DE HEER, Georgia Institute of Technology — We have developed an RF inductance furnace to grow epitaxial graphene(EG) of very high quality on SiC. EG has attracted much attention during the past years due to its potential as next generation material for electronic devices. The formation of graphene on silicon carbide by sublimation of Si is a complicated process that is not well understood yet. We present here our latest result on the growth of epitaxial graphene in low vacuum. The research is carried out for multilayer graphene growth on 4H SiC (000\textbar). Surface free energies of the monolayers and the SiO\textsubscript{2} (CF) is synthesized by reacting F\textsubscript{2} with graphite at 500 - 600°C. We obtain few-layer CF sheets through mechanical exfoliation and find that surface diffusion promotes a rough morphology. To reduce the mobility of surface atoms, the graphene surface is dressed by Ti atoms prior to MgO deposition. With as little as 0.5 ML monolayer of Ti, the MgO overlayer becomes atomically smooth. Single layer graphene on graphene by molecular beam epitaxy and find that surface diffusion promotes a rough morphology. To reduce the mobility of surface atoms, the graphene layers, such as MgO, are often used to minimize the conductivity mismatch between graphene and electronic contacts. We investigate the growth of MgO films on graphene by molecular beam epitaxy and find that surface diffusion promotes a rough morphology. To reduce the mobility of surface atoms, the graphene surface is dressed by Ti atoms prior to MgO deposition. With as little as 0.5 ML monolayer of Ti, the MgO overlayer becomes atomically smooth. Single layer graphene has been patterned into nanoscale devices to study the effect of the Ti dressing layer and MgO overlayer on the electronic and spintronic properties.

Size Selection of Metal Nanoparticles on Few Layer Graphene\textsuperscript{1}, LUKE A. SOMERS, ZHENGTANG Luo, E.J. MELE, A.T. CHARLIE JOHNSON, University of Pennsylvania — We find layer number dependence in the size of metal nanoparticles grown on 1 to 10 layer graphene. Graphene is an attractive substrate for investigating and using nanoparticles due to its loose interaction with them. To preserve this condition it is ideal to grow particles in place rather than deposit them from solution. We find that annealing of evaporated metal nanoparticles on graphene and few layer graphene surfaces tightens their size distribution. The number of graphene layers changes the selected size. These results are in quantitative agreement with a model incorporating surface, bulk, and coulomb free energies.

1:03PM W26.00010 Growth of atomically smooth MgO films on graphene by molecular beam epitaxy.\textsuperscript{1} — KATHLEEN MCCREARY, University of California, Riverside, WEI HAN, WEI-HUA WANG, KEYU PI, WENZHONG BAO, FENG MIAO, ROLAND KAWAKAMI, CHUN-NING LAU, UCR — Graphene has been the focus of many recent studies involving both electronic and spintronic devices due to its tunable charge carriers, high mobility, and possibility of long spin coherence lifetimes. To improve the spin injection into graphene spintronic devices, dielectric layers, such as MgO, are often used to minimize the conductivity mismatch between graphene and electronic contacts. We investigate the growth of MgO films on graphene by molecular beam epitaxy and find that surface diffusion promotes a rough morphology. To reduce the mobility of surface atoms, the graphene surface is dressed by Ti atoms prior to MgO deposition. With as little as 0.5 ML monolayer of Ti, the MgO overlayer becomes atomically smooth. Single layer graphene has been patterned into nanoscale devices to study the effect of the Ti dressing layer and MgO overlayer on the electronic and spintronic properties.

Growing Epitaxial Graphene on an Insulator by MBE, CHANDRA MOHAPATRA, JAMES ECKSTEIN, Department of Physics, University of Illinois Urbana Champaign, USA — We have used electron beam evaporation of solid carbon (C) to deposit graphene on MgO <111> at 850°C. The growth appears epitaxial as observed by in-situ RHEED which also reveals that the hot scattering surface transitions from an insulator to a conductor after deposition of 1 monolayer of C. Growth at higher temperatures gives better crystallinity. We further characterize the film by ex-situ Raman spectroscopy, AFM and transport. Raman reveals all the characteristic G, D and 2D peaks of graphene and the 2D peak can be fit to a single lorentzian typical for graphene. AFM pictures show that the surface consists of flat connected domains, which are uniform across the substrate. Electrical transport shows insulating behavior with resistance (R) varying as 1/T\textsuperscript{2}. This work was supported by the DOE BES at the F. Seitz Materials Research Laboratory at the University of Illinois, Urbana.

The effect of self-assembled monolayers on graphene conductivity and morphology, T. L. MOORE, J. H. CHEN, B. RIDDICK, E. D. WILLIAMS\textsuperscript{1}, University of Maryland, College Park — Graphene transport properties are limited by charge defects in SiO\textsubscript{2}, and by large charge density due to strong interaction with SiC. To modify these effects we have treated 300 nm SiO\textsubscript{2} with trichlorosilanes with different termination groups including pure and fluoro and amino-terminated hydrocarbons for use as substrates for mechanical exfoliation of graphene. XPS measurements verify the presence of the expected termination groups. AFM measurements reveal modified monolayer roughness and correlation lengths; for a fluorinated carbon chain the RMS roughness is 0.266 ± 0.017 nm and the correlation length is 10.2 ± 0.7 nm compared to 0.187 ± 0.011 nm and 19.8 ± 2.5 nm for SiO\textsubscript{2}. Surface free energies of the monolayers and the SiO\textsubscript{2} blank have been computed from static contact angle measurements and all decrease the SiO\textsubscript{2} surface free energy; for the fluorinated carbon chain monolayer a decrease of 20 mJ/m\textsuperscript{2} from SiO\textsubscript{2}. We will discuss the ease of exfoliation, and the morphology and conductivity of graphene on these monolayers.

\textsuperscript{1}Supported by the MRSEC University of Maryland.
The effect of SiO$_2$ surface states on the electronic characteristics of graphene FET devices

Jorge Sofo, Ning Shen, Hugo Romero, Peter Eklund, Dept. of Physics, Penn State — Electronic states localized at the surface of oxide semiconductors are a common cause of their low ionization potential. We study the properties of the SiO$_2$ surface states using density functional theory (DFT) and show that they strongly affect the intrinsic doping of graphene on oxidized silicon substrates. We present simple empirical model that it is parameterized from the DFT calculations. The model demonstrates that Dirac voltages as large as 50 V and intrinsic n-doping are produced by the presence of these surface states. We extend it to include the effect of other adsorbates, such as water, that modify the dielectric properties of the device.

Efficient manipulation of zigzag and armchair edges in graphene nanoribbons by joule heating

Xiaoting Jia, Mario Hofmann, Vincent Meunier, Bobby Sumpter, Jessica Campos-Delgado, Jose Romo-Herrera, Hyungbin Son, Ya-Ping Hsieh, Alfonso Reina, Jieing Kong, Mauricio Terrones, Mildred Dresselhaus — Edge study in graphene nanoribbons has attracted lots of interest in recent years, due to the different electronic properties of the ribbons arising from zigzag and armchair edges. Here we demonstrate and monitor an efficient crystallization process for graphite nanoribbon edges by Joule heating inside an integrated transmission electron microscope (TEM) equipped with a scanning tunneling stage STM (TEM-STM system). With this system we were able to produce for the first time atomically smooth zigzag or armchair edges from defective rough edges present in graphite nanoribbons, by applying a controlled voltage, while observing the structural behavior in-situ. Edge motion along certain preferred crystallographic orientations is observed, and the transformational effects of Joule heating and applied electric field are described. This work demonstrates both the possibility of self-eliminating lattice defects by applying a bias voltage, and an effective way to produce clean zigzag and armchair edges, which could be useful for both fundamental studies of edge reactivity, magnetism and the development of future electronics applications.

Functionalized Heterofullerenes for Hydrogen Storage

Puru Jena, Qian Wang, Virginia Commonwealth University, Qiang Sun, Peking University and Virginia Commonwealth University — Using density functional theory we show that Li decorated B doped heterofullerene (Li12C48B12) has the desired properties of a hydrogen storage material: (1) The Li atoms remain isolated. (2) Through charge transfer to electron deficient C48B12 heterofullerene, the Li atoms become positively charged. (3) Each Li atom is able to bind up to three H2 molecules which remain in molecular form, and the binding energies of successive H2 molecules are in the range of 0.135 to 0.172 eV/H2, suitable for ambient temperature storage; (4) The gravimetric density reaches the 9 wt.% limit necessary for applications in the mobile industry.

Can Silicon Carbide Nanotubes Be Effective Storage Medium for Hydrogen Storage

Souptik Mukherjee, Asok Ray, UTA — A systematic study of molecular hydrogen adsorption on three different atomic configurations of armchair SiCNTs has been performed. In the first stage of our study, first principles calculations using both density functional theory (DFT) and hybrid density functional theory (HDFT) as well as the finite cluster approximation have been performed to study the adsorption of molecular hydrogen on three types of armchair (9, 9) silicon carbide nanotubes. The distances of molecular hydrogen from the outer wall of the nanotubes have been optimized manually using the B3LYP and PW91 functionals and results have been compared in detail with published literature results. In the second part of our study, hydrogen molecule has been adsorbed from both inside as well as from the outer wall of nanotubes ranging from (3, 3) to (6, 6) for all three types. A detailed comparison of the binding energies, equilibrium positions and Mulliken charges has been performed for all three types of nanotubes and for all possible sites in those nanotubes. In the third phase, co-adsorption of two hydrogen molecules has been carried out. Possibilities of hydrogen storage have been explored in detail.

Nanostructured Adsorbents for Hydrogen Storage

Lin Simpson, National Renewable Energy Laboratory — To meet the DOE goals for hydrogen storage, NREL and our partners have focused development efforts on the use of nanomaterials with hydrogen binding energies between ~4 and 40 kJ/mol. The use of these types of materials enables hydrogen to be reversibly adsorption/desorption with moderate to low temperatures and pressures, and greatly simplifies the refueling/regeneration process. NREL is investigating multiple approaches to obtain high hydrogen sorption materials with the common goal of determining the underlying mechanisms and applying a fundamental basis to intelligently design advanced materials. NREL will provide detailed hydrogen capacity/performance and reproducible processing information for promising nanostructured materials. This will include detailing the potential for hydrogen storage by nanostructures, the effects of dopants, demonstrate materials with greater than 4 wt% hydrogen uptake, and discuss the potential to develop materials with 9 wt% or more hydrogen storage.

A comparative investigation of H$_2$ adsorption energy in Cd- and Zn-based metal organic framework-5

Pornjuk Srepusharawoot, Condensed Matter Theory Group, Dept. of Physics and Materials Science, Uppsala University, Sweden; Dept. of Physics, Khon Kaen University, Thailand. Carlos Moyses Araujo, Andeas Blomqvist, Ralph Scheicher, CMT Group, Uppsala; Rajeev Ahuja, CMT Group, Uppsala; Applied Materials Physics, Dept. of Materials and Engineering, Royal Institute of Technology (KTH), Stockholm, Sweden — Density functional theory has been used to study the physisorption energies of hydrogen at all possible adsorption sites near the metal oxide cluster in both Cd- and Zn-based Metal Organic Framework-5 (MOF-5). Three types of exchange-correlation functionals (LDA, GGA-PW91, and GGA-PBE) were compared. The binding for all adsorption sites in Cd-based MOF-5 was found to be generally stronger than in Zn-based MOF-5. In particular, the hydrogen adsorption energy at the secondary adsorption sites of Cd-based MOF-5 is increased by about 25% compared to Zn-based MOF-5. This result suggests that Cd-based MOF-5 might be better suited to store hydrogen at a given temperature than Zn-based MOF-5. See also: J. Chem. Phys. 129, 164104 (2008).
12:03PM W27.00005 Design of Multi-Decker Incorporated Metal Organic Frameworks for Hydrogen Storage. KIRAN BOGAVARAPU, McNeese State University, ANIL KANDALAM, McNeese State University — Metal Organic Frameworks (MOFs) are a new class of rationally designed microporous hybrid (organic-inorganic) materials. They have recently gained attention as potential hydrogen storage systems with gravimetric density meeting the DOE 2015 targets of 9 wt%. However, due to weak interaction between the molecular hydrogen and the host MOF (see figure), high pressures are required to reach the target storage levels. Recently, multi-decker organometallic complexes are shown to exhibit the ideal thermodynamics and kinetics for hydrogen storage. However, it is not clear if these multi-decker complexes can retain their hydrogen storage capability when assembled into a bulk-material. In this presentation, we investigate the hydrogen storage capability of a new class of materials by combining the strengths of MOFs and decker complexes. An ideal way to integrate these two systems is to incorporate the multi-deckers into the structural framework of MOFs. In these hybrid materials, the multi-decker units are expected to maintain their structural integrity and thereby retain the hydrogen storage capacity with an added advantage of being a part of stable porous MOF back-bone.

12:15PM W27.00006 Hydrogen Adsorption by High Surface Area Micro-porous Carbon Synthesized from Phenol-Formaldehyde. QINGYUAN HU,1 Purdue University, GREGORY P. MEISNER, GM Research and Development Center — A high surface area microporous carbon material can be synthesized by mixing the activation reagent potassium hydroxide into a carbon precursor solution of phenol-formaldehyde oligomers. Some polymerization of the carbon precursor occurs during the initial mixing, and further polymerization is completed by heating to 160°C. Carbonization and activation is accomplished by heating to 500°C - 900°C in an inert atmosphere. The porosity and surface area of the resulting carbon material depends predominantly on the amount of activation reagent added to the carbon precursor solution and the carbonization/activation temperature and time. Optimized synthesis conditions yield a microporous carbon with a very high BET specific surface area of nearly 3000 m²/g and a narrow pore size distribution. This new synthesis approach yields surface areas dramatically larger than those typically obtained by traditional chemical activation methods for porous carbon where solid carbon precursors are soaked in activation reagent solutions. Hydrogen adsorption up to 5.75 wt% at 77 K and above 20 bars hydrogen pressure is observed for this new microporous carbon material.

12:27PM W27.00007 Ab-initio study of hydrogen storage of Titanium-decorated organic systems with hydroxyl groups. MANH CUONG NGUYEN, JISOON IHM, Department of Physics and Astronomy, Seoul National University — Using first-principles calculation, we study hydrogen storage of Titanium-decorated organic systems with hydroxyl groups, such as propane-1,3-diol. The results show that Ti atom is bound selectively to hydroxyl groups with the binding energy of 3.0 eV. The first hydrogen molecule adsorbed on Ti is dissociated and then Ti can bind three hydrogen molecules in molecular form more with the binding energy suitable for reversible processes (adsorption and desorption) in hydrogen storage at ambient temperature and pressure. Using thermodynamics, the usable number of hydrogen molecules per Ti atom is almost three due to the proper binding energy of the last three hydrogen molecules on Ti. Based on this result, we can design organic systems with hydroxyl groups to store hydrogen with the reduction of the tendency of transition metal clustering. We also explain the mechanism of multi-container hydrogen adsorption on Ti by generalizing the Kubas model.

12:39PM W27.00008 First-principles study of dihydrogen interaction of porphyrin-like nitrogen-doped graphenes. WOON IH CHOI, National Renewable Energy Laboratory, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology, YONG-HYUN KIM, National Renewable Energy Laboratory — We have studied electronic structure and dihydrogen (H2) binding characteristics of porphyrin-like nitrogen-doped graphenes (PNGs) by performing first-principles total energy calculations based on the density functional theory. The stability of PNGs and the H2 binding ability of the PNG metal centers (Ca and 3d transition metals from Sc to Zn) have been analyzed within the generalized gradient approximation. We have found that Ca, Sc, Ti, Co, and Ni can be incorporated relatively easily into the nitrogen-doped graphenes, while V, Fe, Cu, and Zn are less likely to be. The PNGs can be used for active building blocks of hydrogen storing metal-organic frameworks. Due to the unique crystal field splitting of the planar PNGs, approaching dihydrogen exclusively interacts with the dz2 orbitals of the core metals. We also found that intra-/inter-orbital charge transfer plays a key role in the dihydrogen binding. Finally, we will discuss how such dihydrogen binding can be modified by external strain.

12:51PM W27.00009 Magnetic Properties of High-Surface-Area Carbons and Their Effect on Adsorbed Hydrogen. JIMMY ROMANOS, MATTHEW BECKNER, MICHAEL KRAUS, JACOB BURRESS, PETER PFEIFER, Dept. of Physics and Astronomy, Univ. of Missouri — We report the discovery that a large number of nanoporous carbon samples, made from corn cob and exhibiting high hydrogen storage capacities (Pfeifer et al, Mater. Res. Soc. Symp. Proc. 1041 R02-02 (2008)), show unexpected magnetic properties, due to iron impurities in the samples. Magnetization curves are consistent with ferromagnetic and/or super-paramagnetic behavior. Magnetic susceptibilities, saturation magnetizations, coercivities and remanence magnetizations, from measurements on a SQUID magnetometer, will be presented, and their temperature dependence will be discussed. Results will be presented regarding the presence of small iron clusters, magnetic properties of iron-leached samples, and hydrogen binding energies as a function of iron leaching. This material is based on work supported by the U.S. Department of Energy under Award No. DE-FG-08GO18142.

1:03PM W27.00010 Boron-Doped Carbon Nanospaces for High-Capacity Hydrogen Storage. MATTHEW BECKNER, JACOB BURRESS, CARLOS WEXLER, PETER PFEIFER, Dept. of Physics and Astronomy, Univ. of Missouri — The Alliance for Collaborative Research in Alternative Fuel Technology (ALL-CRAFT, http://all-craft.missouri.edu) has been optimizing high surface area (>3,000 m²/g) activated carbon nanospaces for high capacity hydrogen storage. Boron-doped samples have been produced using solid, liquid, and vapor phase boron doping. The boron-doped samples were shown by using x-ray diffraction and nitrogen adsorption that boron-doping increases the density functional theory results of nitrogen-doped graphenes, while V, Fe, Cu, and Zn are less likely to be. The PNGs can be used for active building blocks of hydrogen storing metal-organic frameworks. Due to the unique crystal field splitting of the planar PNGs, approaching dihydrogen exclusively interacts with the dz2 orbitals of the core metals. We also found that intra-/inter-orbital charge transfer plays a key role in the dihydrogen binding. Finally, we will discuss how such dihydrogen binding can be modified by external strain.

1:15PM W27.00011 Hierarchical Porous Structure of Engineered Carbon Nanospaces for Use in Hydrogen Storage. MICHAEL KRAUS, JACOB BURRESS, MATTHEW BECKNER, CARLOS WEXLER, PETER PFEIFER, Dept. of Physics and Astronomy, Univ. of Missouri — High-surface-area activated carbons are promising material for hydrogen storage. Mapping the pore structure at the nanometer scale is fundamental for the understanding of adsorptive properties. Structural analyses of pores in nanoporous carbons, using subcritical nitrogen adsorption, supercrITICAL methane adsorption, and small-angle x-ray scattering (SAXS), are presented. Adsorption isotherms provide pore-size distributions, while SAXS provides information about the spatial arrangement of pores. At large length scales, ~20-2000 nm, our samples exhibit an extended regime of surface fractal behavior with a fractal dimension of ~2.3, corresponding to a mild external roughness of the samples. At small length scales, the samples exhibit an abundance of pores 0.5-1.5 nm wide. An illustrative case exhibits cylindrical pores with average width of 0.9 nm and average length 1.6 nm, in excellent agreement with structural data inferred from adsorption isotherms. Comparison of pore data from SAXS and nitrogen isotherms will be compared with hydrogen uptake isotherms. This material is based on work supported by the U.S. Department of Energy under Award No. DE-FG-08GO18142. Use of the Advanced Photon Source was supported by the U.S. Department of Energy under Contract No. DE-AC02-06CH11357.
1:27PM W27.00012 Analysis of Hydrogen Adsorption in Engineered Carbon Nanospaces. JACOB BURRESS, MATTHEW BECKNER, NICK KÜLLMAN, RAINA CEPEL, CARLOS WEXLER, PETER PFEIFER, Dept. of Physics and Astronomy, University of Missouri — We present a survey of how appropriately engineered nanoporous carbons provide materials for reversible hydrogen storage, based on physisorption, with exceptional storage capacities (~80 g H2/kg carbon, ~50 g H2/liter carbon, at 50 bar and 77 K). The H2 gas-carbon surface interface physics was investigated using supercritical hydrogen isotherms. Experimental case studies, with surface areas as high as 3500 m2/g, in which 40% of all surface sites reside in pores of width ~0.7 nm and binding energy ~9 kJ/mol, and 60% of sites in pores of width >1.0 nm and binding energy ~5 kJ/mol, are also presented. We experimentally distinguish between mobile and local adsorption, how lateral dynamics affect the hydrogen storage capacity, and how the two situations are controlled by the vibrational frequencies of adsorbed hydrogen molecules parallel and perpendicular to the surface. In our samples, adsorption is mobile at 293 K, and localized at 77 K. These findings present evidence hydrogen storage capacities in nanoporous carbons can be increased, without any chemical surface functionalization, by more than a factor of two by suitable engineering of the nanopore space. This material is based on work supported by the U.S. Department of Energy under Award No. DE-FG02-07ER46411.

1:39PM W27.00013 Quantum energy levels of hydrogen adsorbed on nanoporous carbons: an intrinsic probe for pore structure, and improving Monte Carlo simulations of adsorption1. R. CEPEL, Univ. of Missouri, B. KUCHTA, Univ. de Provence, L. FIRLEJ, Univ. Montpellier 2, RAINA CEPEL, PETER PFEIFER, CARLOS WEXLER, University of Missouri — Carbons are one of potentially promising groups of materials for hydrogen storage by adsorption. However, the heat of hydrogen physisorption in such materials is low, in the range of about 4-8 kJ/mol which limits the total amount of hydrogen adsorbed at P = 100 bar to ~2 wt% at room temperature and about ~10 wt% at all conditions. To get better storage capacity, the adsorbing surfaces must be modified, either by substitution of some atoms in the all-carbon skeleton by other elements, or by doping/intercalation with other species. Here we analyze the variation of interaction energy between a molecule of hydrogen and graphene-based sorbents prepared as hypothetical modifications of the graphene layer. In particular, we show that partial substitution of carbons (for example, by boron) modifies both the symmetry of the energy landscape and strength of hydrogen physisorption. The effect of substituent extends over several sites of graphene lattice making the surface more heterogeneous.

1:51PM W27.00014 Structural and energetic factors in designing a perfect nano-porous sorbent for hydrogen storage1. BOGDAN KUCHTA, Université de Provence, LUCYNA FIRLEJ, Université Montpellier 2, RAINA CEPEL, PETER PFEIFER, CARLOS WEXLER, University of Missouri — Carbons are one of potentially promising groups of materials for hydrogen storage by adsorption. However, the heat of hydrogen physisorption in such materials is low, in the range of about 4-8 kJ/mol which limits the total amount of hydrogen adsorbed at P = 100 bar to ~2 wt% at room temperature and about ~10 wt% at all conditions. To get better storage capacity, the adsorbing surfaces must be modified, either by substitution of some atoms in the all-carbon skeleton by other elements, or by doping/intercalation with other species. Here we analyze the variation of interaction energy between a molecule of hydrogen and graphene-based sorbents prepared as hypothetical modifications of the graphene layer. In particular, we show that partial substitution of carbons (for example, by boron) modifies both the symmetry of the energy landscape and strength of hydrogen physisorption. The effect of substituent extends over several sites of graphene lattice making the surface more heterogeneous.

Thursday, March 19, 2009 11:15AM - 2:15PM - Session W28 FIAP DMP: Focus Session: Device Applications of Multiferroic Structures

11:15AM W28.00001 Multiferroic Microwave and Millimeter Wave Devices, GOPALAN SRINIVASAN, Oakland University — Layered composites of ferrites and ferroelectrics are magneto-electric (ME) multiferroics and are of interest for studies on the physics of ME interactions and for novel signal processing devices. There are two types of interactions. (i) ME coupling in bound ferrite-piezoelectrics: An electric field E applied to the composite produces a mechanical deformation in the piezoelectric phase that in turn is coupled to the ferrite, resulting in a shift in the ferromagnetic resonance field. The strength of the interactions is measured from the FMR shifts. (ii) ME interactions in unbound ferrite-ferroelectrics: This is a proximity effect in which hybrid spin-electromagnetic waves are formed. An electric field applied to the ferroelectric will result in a change in the permittivity and a shift in the hybrid modes. We performed studies on the nature of ME interactions at 1-110 GHz in bilayers of epitaxial yttrium iron garnet (YIG) films, single crystal spinel ferrites or hexagonal ferrites and single crystal lead magnesium niobate-lead titanate (PMN-PT) or polycrystalline lead zirconium titanate (PZT). A stripline structure or a cavity resonator was used. Electric fields effects were investigated on magnetostatic waves, uniform precession modes or hybrid modes in the ferrite. We found evidence for strong microwave ME coupling. The coupling strength has been found to be dependent on magnetic field orientation, the nature of piezo-electric coupling and volume for both phases [1]. The high frequency ME effect is of importance for dual electric and magnetic field tunable ferrite-piezoelectric devices. We will discuss the design and characterization of ME resonators, phase shifters, delay lines and filters [2]. The work is supported by grants from the Army Research Office and the office of Naval Research.

11:51AM W28.00002 Electric-field-induced magnetic domain wall motion in bilayer FeGa/BaTiO3 thin film structures1, JOHN CUMINGS, T. BRINTLINGER, S.-H. LIM, Y. QI, L. SALAMANCA-RIBA, I. TAKEUCHI, University of Maryland — We have studied electromechanical coupling induced magnetic domain motion in unclamped FeGa/BaTiO3 thin film bilayer structures. Magnetostriuctive FeGa layers were sputter-deposited on epitaxially grown BaTiO3 films on SrTiO3 substrates. Focused ion-beam milling was used to remove the substrate from underneath the BaTiO3 film, and electrodes were patterned in the metallic FeGa film to apply electric field across a patterned gap (1 micron). Lorentz microscopy was used to monitor the magnetic domains in FeGa, while electric field is applied to the piezoelectric BaTiO3. Lorentz microscopy allows direct and dynamic observation of magnetic domain motions. Reversible electric field induced magnetic domain motion was observed, and the results will be compared to micromagnetic simulations of the domain wall structure.

1 This work is funded by NSF MRSEC (DMR 0520471), ONR-MURI N000140610530 and ARO W911NF-07-1-0410.
12:03PM W28.00003 Ferroelectric control of magnetization in BiFeO3/CoFe heterostructures. MARTIN GAJEK, LANE MARTIN, JOHN HERON, JAN SEIDEL, University of California at Berkeley, CONCEPT GROUP BERKELEY TEAM — The cross coupling between ferroic order parameters in multiferroics opens an alternative for the control of magnetism in magnetoelectric devices by purely electrical means. We first report on the exchange coupling between BiFeO3, an antiferromagnetic ferroelectric, and CoFe. We then show that the domain structure of the ferromagnet can be changed by poling the ferroelectric layer. Finally, we will discuss the implementation of our findings into possible device schemes.

12:15PM W28.00004 Induced magnetization in ferroelectric-antiperovskite heterostructure. PAVEL LUKASHEV, RENAT SABIRIANOV, University of Nebraska, Omaha — We theoretically predict the linear magnetoelectric effect (ME) in ferroelectric-antiperovskite PbTiO3/Mn3GaN heterostructure. The effect is caused by the recently reported piezomagnetic nature of the Mn3GaN. Elastic deformations in the Mn3GaN are due to the surface strain and the soft mode atomic displacements from ferroelectric to the antiperovskite (AP) phase. Both mechanisms lower the symmetry of the AP component, which results in the induced magnetization. Reversal of the polarization direction in the ferroelectric phase results in the magnetization reversal in Mn3GaN, thus the observed effect is linear. We study few interface geometries to account for the electrostatic complementarity at the surface. Those interfaces, which are electrostatically incompatible exhibit strong tetragonal distortion of the cell. The induced magnetization depends on the termination of the components of the heterostructure, and ranges from 0.25 \( \mu_B \) to 0.6 \( \mu_B \) per unit cell of Mn3GaN. All calculations were performed by projector augmented wave method.

12:27PM W28.00005 Magnetoelectric Coupling in Complex Oxide Heterostructures. JASON HOFFMAN, CARLOS VAZ, Department of Applied Physics, Yale University, HAJO MOLEGRAAF, University of Twente, JEAN-MARC TRISCONE, University of Geneva, CHARLES AHN, Department of Applied Physics, Yale University — Current efforts to use materials with multifunctional capabilities have renewed interest in multiferroics, which display a coupling between ferroic order parameters. Engineered structures that combine dissimilar magnetic and ferroelectric systems epitaxially have been shown to exhibit enhanced magnetoelectric coupling. In this work, off-axis RF magnetron sputtering was used to deposit epitaxial ferroelectric Pb(Zr,Ti)O3 (PZT) / La0.6Sr0.4MnO3 (LSMO) heterostructures with high crystalline quality and atomically smooth surfaces. X-ray diffraction shows c-axis oriented growth of PZT, with a typical root-mean-square (RMS) surface roughness of 5Å. We employ magneto-optic Kerr effect (MOKE) magnetometry to study directly the local magnetic state of the LSMO as a function of the PZT polarization state. We demonstrate direct control of magnetism via applied electric fields, including on/off switching of magnetism. The coupling between magnetic and electric order parameters in ferroelectric / Sr-doped lanthanum manganite heterostructures is illustrated by hysteretic M-E (magnetization vs. electric field) loops, with a measured magnetoelastic susceptibility of \( a \sim 10 \text{ cm} / \text{kV}^{-1} \).

12:39PM W28.00006 GaMnAs-based hybrid multiferroic memory device. LEONID ROKHINSON, Purdue University — A rapidly developing field of spintronics is based on the premise that substituting charge with spin as a carrier of information can lead to new devices with lower power consumption, non-volatility and high operational speed. Despite efficient magnetization detection, magnetization manipulation is primarily performed by current-generated local magnetic fields and is very inefficient. Here we report a novel non-volatile hybrid multiferroic memory cell with electrostatic control of magnetization based on strain-coupled GaMnAs ferromagnetic semiconductor and a piezoelectric material. We use the crystalline anisotropy of GaMnAs to store information in the orientation of the magnetization along one of the two easy axes, which is monitored via transverse anisotropic magnetoresistance. The magnetization orientation is switched by applying voltage to the piezoelectric material and tuning magnetic anisotropy of GaMnAs via the resulting stress field.

1:15PM W28.00007 Exchange Coupling across BiFeO3/La0.7Sr0.3MnO3 Interface. PU YU, M. HUIJBEREN, M.B. HOLCOMB, C.H. YANG, Q. HE, Y. H. CHU, J. X. ZHANG, L. W. MARTIN, R. RAMESH, Department of Physics and Department of Materials Science and Engineering, University of California, Berkeley, PER-ANDERS GLANS, J. H. GUO, Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley — Controlling the magnetic state by using electric field is a central topic for spintronics and has piqued intense interest. The coupling of antiferromagnetic and ferroelectric order parameters of multiferroic BiFeO3 (BFO) provides a new approach to achieve this goal by using exchange coupling effect. Our previous studies have shown negative exchange bias between epitaxial ferromagnetic La0.6Sr0.4MnO3 (LSMO) and BFO heterostructures and magnetoelectric coupling at these interfaces. The coupling mechanism between these two materials is still a mystery due to the complexity of the G-type spin structure. In this work, by controlling the domain structures of BFO and studying the corresponding exchange coupling effect, the possible coupling mechanism of antiferromagnetic and ferromagnetic spin structures will be proposed. Additionally, the coupling of orbits across the interface will also be discussed, which will give us another possible clue to understand the spin coupling mechanism, since usually orbital and spin orders are coupled together.

1:27PM W28.00008 Electric field tuning of magnetic properties in FeGa films on ferroelastic Pb(Zr,Ti)O3 thin films probed by ferromagnetic resonance. ARUN LUYKX, SAMUEL LOFLAND, VARATHRAJAN ANBUSATHAIAH, VALANOKO NAGARAJAN, FRANISKA KARTAWIDJAJA, JOHN WANG, ICHIRO TAKEUCHI — In order to investigate the possibility of fabricating electric field tunable thin film magnetic devices using a ferroelastic transduction effect, we have patterned Fe80-Ga20 (FeGa) films sputter-deposited on PbZr0.3Ti0.7O3 (PZT(70/30)) / PbZr0.7Ti0.3O3 (PZT(70/30)) tetragonal/rhombohedral bilayers on Pt/Ti/SiO2/Si wafers. Previous piezoferroscopy microscopy studies have shown that the PZT bilayers exhibit presence of ferroelastic domains where the fraction of the local c/a domain ratio can be tuned by an applied electric field. The FeGa top layer was patterned into 20 \( \mu \text{m} \times 20 \mu \text{m} \) capacitor devices in order to apply electric field to the multilayers, and ferromagnetic resonance (FMR) measurements at 9.2 GHz were performed. Typically, a relatively sharp FMR signal observed before application of the electric field would get substantially broadened after initial application of +4 kV/cm. Angular dependent FMR indicates that magnetic anisotropy in the FeGa is indeed affected by application of electric field.

1:39PM W28.00009 Magnetoelectric/piezoelectric laminated structures for tunable remote contact-less magnetic sensing and energy harvesting. PETER FINKEL, Drexel University — We report a method for tunable, contact-less, magnetic field sensing using magnetoelectric coupling properties of the magnetoelectric/piezoelectric laminated composite structure. The magnetically tunable, flexural resonant mode in the bimorph FeNi36% (invar) / PVDF clamped cantilever has been investigated as a function of stress and external magnetic field using Doppler laser spectroscopy. Here we demonstrated that this bimorph structure can be used for low frequency contact-less detection of magnetic field fluctuation and magnetic field monitoring.
suggesting that the magnetic moments for the f-electrons play a significant role. and interband scattering to the Gilbert damping parameter. The Y/Ag/(Fe, Co) trilayers seems not to change the resonance linewidth from the bulk value, for Ag/TM/Ag, while Ni and Py in the trilayer films show equal or larger linewidths. We attribute this behavior to the relative contributions of intraband
magnetic properties of rare earth (Gd, Tb, Sm)/Ag/transition metal (Fe, Co, Ni and Py) trilayers by ferromagnetic resonance technique. We found that Fe

configurations by spin-polarized current.
Simulations show that these unusual features of spin torque dynamics are due to the second-order perpendicular magnetic anisotropy term at the Co/Pt
states. In the regime of current-driven persistent magnetization precession, we observe unusual non-monotonic dependence of the precession frequency on
current. However, we are currently not able to explain the asymmetry in the precession frequency observed for Ni/Pt. The dynamical coupling between
ferromagnets due to ST can induce dynamical states in magnetic multilayer nanopillars not accessible by any other techniques. For in-plane magnetic field, the predicted dynamical
regimes include elliptical, clamshell, and out-of-plane precession. The first two regimes have been demonstrated and extensively analyzed. However, the
out-of-plane precession has so far been elusive. Calculations [1] show that dynamical coupling between ferromagnets due to ST can result in suppression of
precession for one of the current polarities. We interpret our results in terms of the dynamical coupling between magnetic layers due to spin transfer, completely
suppressing precession of the thicker layer.

11:15AM W29.00001 Competition between orbital torques and spin polarization in controlling
FMRI linewidths
1
SEZEN DEMIRTAŞ, Department of Physics, University of Texas at Dallas, ALI R. KOYMEN, Department of Physics, University of Texas at Arlington, MYRON B. SALAMON, Department of Physics, University of Texas at Dallas — We have investigated temperature dependent dynamic
magnetic properties of rare earth (Gd, Tb, Sm)/Ag/transition metal (Fe, Co, Ni and Py) trilayers by ferromagnetic resonance technique. We found that Fe
and Co among TM (transition metals) show narrower magnetic resonance linewidths in rare earth (RE)/Ag/RE/Ag thin film trilayers compared to the values for Ag/Ag/Ag, while Ni and Pd in the trilayer films show equal or larger linewidths. We attribute this behavior to the relative contributions of intraband and interband scattering to the Gilbert damping parameter. The Y/Ag/(Fe, Co) trilayers seems not to change the resonance linewidth from the bulk value, suggesting that the magnetic moments for the f-electrons play a significant role.

11:27AM W29.00002 Current-induced dynamics in almost symmetric magnetic nanopillars
1
SERGEI URAZHDIN, WENG LIM, ANDREW HIGGINS, West Virginia University — Magnetic nanodevices usually include a free layer whose configuration can
be changed by spin-polarized current via the spin transfer (ST), and a fixed reference (polarizing) layer. The polarizer is usually made much larger than the
free layer to minimize the effects of ST. However, it is presently not known what makes a specific magnetic layer behave as a fixed polarizer or a free layer
driven by ST. Little is also known about the dynamics in bilayers with thin polarizers, where the effects of ST on both layers are significant. We will discuss our
spectroscopic measurements of current-induced dynamics in nanopillars with similar thicknesses of the extended polarizer and the nanopatterned free layer. We
demonstrate coherent out-of-plane precession for both polarities of current in symmetric devices. However, even slightly asymmetric devices exhibit a rapid suppression of
precession for one of the current polarities. We interpret our results in terms of the dynamical coupling between magnetic layers due to spin transfer, completely
suppressing precession of the thicker layer.

11:39AM W29.00003 Measurements of out-of-plane dynamics induced by spin transfer in magnetic
nanopillars
1
WENG LIM, West Virginia University, SERGEI URAZHDIN, West Virginia University — Current-induced spin transfer (ST) can induce dynamic states in magnetic multilayer nanopillars not accessible by any other techniques. For in-plane magnetic field, the predicted dynamical
regimes include elliptical, clamshell, and out-of-plane precession. The first two regimes have been demonstrated and extensively analyzed. However, the
out-of-plane precession has so far been elusive. Calculations [1] show that dynamical coupling between ferromagnets due to ST can result in suppression of
coherent out-of-plane precession in nanopillars with a patterned polarizing layer, which is the geometry studied so far. We will discuss our measurements of current-induced dynamics in nanopillars with extended polarizer, in which the decoherence caused by the coupling between magnetic layers is minimized. We
demonstrate coherent out-of-plane precession, whose dependence on current and the direction of the magnetic field is consistent with micromagnetic simulations. Most surprisingly, our data are asymmetric with respect to reversal of the magnetic field, which is explained by a combination of the Oersted field and sample shape imperfections. [1] S. Urazhdin, Phys. Rev. B 78, 060405(R) (2008).

11:51AM W29.00004 Spin Torque Dynamics of Nanomagnets with Weak Magnetic Anisotropy
HOANG YEN T. NGUYEN, XIAO CHENG, CARL BOONE, JIAN ZHU, ILYA KRIVOKROTTOV, Department of Physics and Astronomy, University of California, Irvine — We study switching and persistent precession of magnetization induced by spin transfer torque in Co(4 nm)/Cu(6 nm)/Co(0.7 nm)/Pt nanopillar spin
valves where perpendicular magnetic anisotropy at the Co/Pt interface nearly cancels the easy-plane shape anisotropy of the free Co layer. We find that in this
system with weak total magnetic anisotropy, spin torque can switch magnetization of the free layer between the in-plane and the out-of-plane static magnetic
states. In the regime of current-driven persistent magnetization precession, we observe unusual non-monotonic dependence of the precession frequency on
current. Simulations show that these unusual features of spin torque dynamics are due to the second-order perpendicular magnetic anisotropy term at the Co/Pt
interface. Our work demonstrates a method for controllable switching of magnetization of a nanomagnet between stable in-plane and out-of-plane magnetic
configurations by spin-polarized current.
12:03PM W29.00005 Slonczewski windmill with dissipation and asymmetry, YAROSLAW BAZALY, University of South Carolina — J. Slonczewski invented spin-transfer effect in layered systems in 1996. Among his first predictions was the regime of the "windmill motion" of a perfectly symmetric spin valve. In this regime magnetizations of the layers rotate in a fixed plane keeping the angle between them constant. Since "windmill" was predicted to happen in the case of zero magnetic anisotropy, while in most experimental setups the anisotropy is significant, the phenomenon was not a subject of much research. However, the behavior of the magnetically isotropic device is related to the interesting question of current-driven transitions between different exchange interaction, and layer asymmetry. It is shown that the windmill rotation is almost always destroyed by those effects, except for a narrow interval of electric current, determined by the parameters of the device.

12:15PM W29.00006 Spin-dependent tunneling effects in magnetic tunnel junctions, LI GAO, IBM Almaden Research Center — It has long been known that current extracted from magnetic electrodes through ultra thin oxide tunnel barriers is spin polarized. This current gives rise to two important properties: tunneling magnetoresistance (TMR) when the tunnel barrier is sandwiched between two thin magnetic electrodes and, spin momentum transfer, which can manipulate the magnetic state of the magnetic electrodes. In the first part of my talk I show how the structure of thin CoFe layers can be made amorphous by simply sandwiching them between two amorphous layers, one of them the tunnel barrier. No glass forming elements are needed. By slightly changing the thickness of these layers or by heating them above their glass transition temperature they become crystalline. Surprisingly, the TMR of the amorphous structure is significantly higher than of its crystalline counterpart. The tunneling anisotropic magnetoresistance, which has complex voltage dependence, is also discussed. In the second part of my talk I discuss the microwave emission spectrum from magnetic tunnel junctions induced by spin torque from spin polarized dc current passed through the device. We show that the spectrum is very sensitive to small variations in device structures, even in those devices which exhibit similarly high TMR (~120%) and which have similar resistance-area products (~4-10 Ωm²). We speculate that these variations are due to non-uniform spatial magnetic excitation arising from inhomogeneous current flow through the tunnel barrier. [In collaboration with Xing Jiang, M. Hayashi, Rai Moriya, Brian Hughes, Teya Topuria, Phil Rice, and Stuart S.P. Parkin]

12:15PM W29.00007 Frequency-doubling spin-torque microwave oscillator, GRAHAM ROWLANDS, ILYA KRIVOROTOV, University of California, Irvine — We describe a new type of spin torque oscillator with two free layers that is capable of emitting high microwave power (> 1 mW) at high frequency (> 50 GHz) in zero external field. This device has two perpendicular-anisotropy fixed ferromagnetic layers and two easy-plane free layers sandwiched between the fixed layers, with all of the magnetic layers separated from each other by non-magnetic spacers. We simulate current-driven magnetization dynamics in this structure in the macrospin approximation, taking into account spin-torque interactions between adjacent ferromagnetic layers. Our simulations show that for both fixed layers magnetized in the same direction perpendicular to the plane of the sample, spin-torque induces clockwise rotation of one of the layers and counterclockwise rotation of the other. This type of current-driven dynamics gives rise to large-amplitude microwave signal with the frequency that is the sum of the precession frequencies of the free layers. We study the effect of dipolar coupling, shape anisotropy and external field on the dynamics of this spin torque oscillator and determine the optimal device parameters for high-amplitude high-frequency microwave signal generation.

1:03PM W29.00008 Spectral Line Shape and Line Width of a Single-Mode Spin Torque Oscillator, ILYA KRIVOROTOV, CARL BOONE, JIAN ZHU, XIAO CHENG, Department of Physics and Astronomy, University of California, Irvine, JORDAN KATINE, JEFF CHILDRESS, Hitachi Global Storage Technologies — Spin torque auto-oscillators are strongly nonlinear dynamical systems that are highly susceptible to external perturbations such as spin-polarized current and temperature. To understand the effect of thermal fluctuations on the oscillator dynamics, we measure power spectrum of single-mode spin torque oscillators based on a GMR nanocontact to a permalloy nanowire. Our measurements reveal deviations of the power spectral line shape from a simple Lorentzian. These deviations can be understood in terms of dephasing induced by the oscillator amplitude fluctuations. The measured spectral line shape is in a good agreement with a recent analytic theory of spin torque oscillator dynamics at a non-zero temperature [1]. We show that precise measurements of the line shape give information on important oscillator parameters such as Gilbert damping in the large-amplitude regime of current-driven magnetization dynamics. [1] V. S. Tiberkevich, A. N. Slavin, J.-V. Kim, Phys. Rev. B 78, 092401 (2008).

1:15PM W29.00009 Time domain studies of aperiodicity in spin-torque driven vortex oscillations, VLAD PRIBIAG, B. WILLIAMS, A. STEHURA, D.C. RALPH, R.A. BUHRMAN, Cornell University, CORNELL TEAM — Previous studies of current-driven magnetic vortex oscillations in nanopillars [1] and point contact geometries [2] have been restricted to detection of the average envelope of the oscillations. In this talk we discuss aperiodic features of the vortex oscillations that were studied using single-shot time domain measurements of the oscillating GMR signal. These measurements reveal stochastic mode jumping at 10's of ms mean duty cycles between several closely spaced frequencies. The power spectrum of the time traces indicates that the shape and amplitude of the oscillation’s spectral peaks change abruptly as the function of time, corresponding to aperiodic modulation of these oscillations on the µs time scale. Due to the very narrow long-time linewidths of the oscillations it is possible to detect clearly these fine modulations of the peak shape, frequency and amplitude. From these studies of the spin-torque-driven vortex oscillator stability we seek to obtain insights for the design and fabrication of spin-torque oscillators with even narrower linewidths. [1] V.S. Pribiag et al., Nature Phys. 3, 498 (2007). [2] Q. Mistral et al., Phys. Rev. Lett. 100, 257201 (2008).

1:27PM W29.00010 The Role of Spin-Motive Forces in Spin-Valve Dynamics, JUN’ICHI IEDA, SADAMICHI MAEKAWA, Tohoku University; CREST-JST, STEWART E. BARNES, University of Miami — A spin-motive force (smf) is the counterpart of an electro-motive force, which couples to the spin rather than charge degrees of freedom of electrons. Here we discuss how smfs work in spin-valves. When the magnetization makes a sudden change, there often appears a large peak in dV/dl, i.e., a voltage jump that is better interpreted in terms of smfs. To see this, we model spin-valves using an equivalent circuit that involves magnetic dissipation represented by smfs as well as electric dissipation through ordinary resistors for both majority and minority currents. There are four possible conduction paths, e.g., the majority electrons hop to the majority band, or to the minority band and vice versa. The first path adds an up electron to the free layer and causes a rotation in a certain sense, while the second path adds a down electron and a rotation in the opposite sense. Since the rotations are in opposite senses so is the work done on the free layer and hence the smf. By solving the circuit problem and the Landau-Lifshitz equations supplemented with the Slonczewski torque-transfer term simultaneously we find the spin-transfer effect is dramatically modified by smfs. With the relevant parameters a stable large angle precession and a voltage signal are predicted.

1:39PM W29.00011 Mutual phase-locking and frustration of interaction in arrays of interacting spin-torque nano-oscillators, ANDREI SLAVIN, VASIL TIBERKEVICH, Oakland University — We developed a perturbation theory describing collective dynamics of spin-torque nano-oscillator (STNO) arrays in a weak-coupling limit. In this limit each STNO is described by a single dynamical variable – effective phase φj, which satisfies the equation dφj/dt = ωj + ∑k λjk sin(φj - φk + βjk). Here ωj is the free-running (unperturbed) frequency of the j-th oscillator, λjk is the effective coupling amplitude of j-th and k-th oscillators, and βjk is the frustration angle of the oscillators’ interactions. The frustration angles βjk are determined by the intrinsic nonlinearities of STNO and by the delay of coupling signals. The frustration angles can be controlled by changing the distance between STNOs and/or by adding reactive elements to the STNO circuit. We have analyzed collective dynamics of STNO arrays in the case of global coupling, i.e. when coupling amplitudes and frustration angles for all STNOs are equal, λjk = λ, βjk = β. We have shown that STNO array mutually phase-locks only when cos(β) > 0. The critical coupling amplitude λc, at which phase-locking starts, has a minimum for cos(β) = 1 (i.e., for β = 2π), and increases with the decrease of cos(β). For cos(β) < 0 the mutual phase-locking of more than two STNOs is impossible, and the STNO array enters a frustrated state, in which the output power becomes vanishingly small due to the destructive interference between individual STNOs.

1:39PM W29.00012 Mutual phase-locking and frustration of interaction in arrays of interacting spin-torque nano-oscillators, ANDREI SLAVIN, VASIL TIBERKEVICH, Oakland University — We developed a perturbation theory describing collective dynamics of spin-torque nano-oscillator (STNO) arrays in a weak-coupling limit. In this limit each STNO is described by a single dynamical variable – effective phase φj, which satisfies the equation dφj/dt = ωj + ∑k λjk sin(φj - φk + βjk). Here ωj is the free-running (unperturbed) frequency of the j-th oscillator, λjk is the effective coupling amplitude of j-th and k-th oscillators, and βjk is the frustration angle of the oscillators’ interactions. The frustration angles βjk are determined by the intrinsic nonlinearities of STNO and by the delay of coupling signals. The frustration angles can be controlled by changing the distance between STNOs and/or by adding reactive elements to the STNO circuit. We have analyzed collective dynamics of STNO arrays in the case of global coupling, i.e. when coupling amplitudes and frustration angles for all STNOs are equal, λjk = λ, βjk = β. We have shown that STNO array mutually phase-locks only when cos(β) > 0. The critical coupling amplitude λc, at which phase-locking starts, has a minimum for cos(β) = 1 (i.e., for β = 2π), and increases with the decrease of cos(β). For cos(β) < 0 the mutual phase-locking of more than two STNOs is impossible, and the STNO array enters a frustrated state, in which the output power becomes vanishingly small due to the destructive interference between individual STNOs.
1:51PM W29.00012 Spin-torque-driven ferromagnetic resonance in a nonlinear regime\textsuperscript{1}, WENYU CHEN\textsuperscript{2}, G. DE LOUBENS\textsuperscript{3}, J.-M. L. BEAUJOUR, Dept. of Physics, NYU, J. Z. SUN, IBM T. J. Watson Research Center, A. D. KENT, Dept. of Physics, NYU — Spin-torque-driven ferromagnetic resonance (ST-FMR) is a quantitative tool for studying spin-transfer interactions in nanojunctions. Using this method we have studied Co/Cu/CoNi spin valves, in which the CoNi synthetic free layer has perpendicular magnetic anisotropy. Perpendicular field swept resonance lines were measured under a large amplitude GHz current excitation, which drove ST-FMR into a nonlinear regime and produced a large angle precession of the free layer magnetization. With increasing rf power, the resonance lines deviate from a Lorentzian shape and became asymmetric, with a lower resonance field and a larger linewidth. A non-hysteretic step jump in ST-FMR voltage signal was also observed at high powers. The comparison of the experimental results to the foldover and the nonlinear damping theories will be presented.

2:03PM W29.00013 Microwave oscillation generation in a Co/Cu/Co nano-contact without external magnetic field\textsuperscript{1}, KWUN HUNG CHEUNG, XIN XIAO, HONG WEN JIANG, UCLA Physics Department — Using spin-transfer-torque effect to generate microwave oscillation at zero magnetic-field is of recent interest. Here, we report the observation a resistive oscillation at microwave-frequencies ranging from 1.5 to 3 GHz in a nano-contact formed on a Co/Cu/Co tri-layer structure without any external field. The observed oscillation modes have frequencies that are much higher than that reported in other similar experimental systems [1,2]. We have studied the evolution of the oscillation as a function of the DC excitation current and the effect of a small in-plane field. Micromagnetic simulations support the notion that the oscillation is a result of the translational motion of a vortex-core underneath the nano-contact, due the competition of the circular Orstead field and the spin-transfer torque, both induced by the DC current passing through the nano-contact. The work was supported by the Western Institute of Nanoelectronics (WIN). [1] M. R. Pufall et al., Phys. Rev. B 75, 140404(R) (2007). [2] Q. Mishra et al., Phys. Rev Lett. 100, 257201 (2008).

Session W30 DMP GMAG: Focus Session: Ruthenates 334

11:15AM W30.00001 Ca\textsubscript{3}(Ru\textsubscript{1-x}Cr\textsubscript{x})\textsubscript{2}O\textsubscript{7}: A new paradigm for spin valves\textsuperscript{1}, GANG CAO, University of Kentucky — A spin valve is a device structure whose electrical resistance can be manipulated by controlling the relative spin alignment of adjacent metallic, magnetic layers separated by nonmagnetic insulating layers. The spin valve effect is a quantum phenomenon so far only realized in multilayer thin films or bulk.

\textsuperscript{1}In collaboration with V. Durairaj, S. Chikara, Dr. L. DeLong and Dr. P. Schlottmann. This work was supported by NSF through grant DMR-0552267

11:51AM W30.00002 Antiferromagnetism and bulk spin valve effect in Ca\textsubscript{3}(Ru\textsubscript{1-x}Ti\textsubscript{x})\textsubscript{2}O\textsubscript{7}. J. PENG, T.J. LIU, Z. QU, E. VEHSTEDT, B. QIAN, D. FOBES, Tulane University, L. SPINU, University of New Orleans, W. BAO, Los Alamos National Laboratory, Z.Q. MAO, Tulane University — Ca\textsubscript{3}Ru\textsubscript{2}O\textsubscript{7} has generated growing interest. It shows an antiferromagnetic (AFM) transition at \(T_N = 56\) K, followed by a metal-insulator (MI) transition at \(T_{M1} = 48\) K [1]. Giant magnetoresistance (GMR) across its metamagnetic transition is also observed. We have determined the magnetic structures of Ca\textsubscript{3}Ru\textsubscript{2}O\textsubscript{7} under magnetic fields using neutron scattering [2]. Our results demonstrate that the GMR in this material originates from a bulk spin-valve effect, and clarifies the origin for the puzzling observation that the GMR occurs under easy axis field alignment, while a colossal magnetoresistance appears with hard axis field alignment [1].

12:03PM W30.00003 Antiferromagnetic Metallic State And Spin Valve Effect in Doped (Ca\textsubscript{1-x}A\textsubscript{x})\textsubscript{3}Ru\textsubscript{2}O\textsubscript{7} (A = Sr, Ba) Single Crystals\textsuperscript{1}, S. CHIKARA, O.B. KORNETA, T.F. QI, S. PARKIN, G. CAO, Univ. of Kentucky, W.P. SONG, Inst. of Solid State Physics, Hefei 230031, P.R. China, W.P. CRUMMETT, Centre College, KY40422 — Bilayered Ca\textsubscript{3}Ru\textsubscript{2}O\textsubscript{7} is a highly anisotropic system [1] characterized by orbitally-driven colossal magnetoresistance\textsuperscript{2} and an unusual antiferromagnetic metallic (AFM-M) state [2]. We report transport and thermodynamic properties of (Ca\textsubscript{1-x}A\textsubscript{x})\textsubscript{3}Ru\textsubscript{2}O\textsubscript{7} (A = Sr, Ba) single crystals as a function of temperature and applied magnetic field. While Ba doping shows a far stronger impact, both Sr and Ba substitution for Ca induce a large array of interesting phenomena. Among them, a bulk spin-valve effect occurs in the AFM-M range, which is largely broadened due to the doping. This effect in bulk crystals is a novel phenomenon first observed in Ca\textsubscript{3}(Ru\textsubscript{1-x}Cr\textsubscript{x})\textsubscript{2}O\textsubscript{7} single crystals [3]. The spin-valve effect in (Ca\textsubscript{1-x}A\textsubscript{x})\textsubscript{3}Ru\textsubscript{2}O\textsubscript{7} single crystals opens new avenues to understand the underlying physics and realize the potential of spin valves in practical devices.

magnetic properties. The magnetic ground state ranges from an itinerant metamagnetic state

\( x < \), and finally to an antiferromagnetic (AFM) state

(0

Ru

et al. [1]. For nearly degenerate bands, spin-orbit coupling leads to a dramatic change of the Fermi surface warping. Above the transition field, under polar rotation we observe a first order phase transition in \( \rho_{xy} \) for angles close to the ab-plane clearly indicating a polarization of the \( 4d_{xy,yz} \) orbitals. Additionally, we have performed similar studies on \( \text{Sr}_{2-x} \text{Ru}_{2} \text{O}_{6} \), and have observed preliminary evidence of orbital-dependent magnetic correlations. This work is supported by the NSF under grant DMR-0645305, the DOE under DE-FG02-07ER46358.

12:39PM W30.00006 Electronic phase diagram in double layered ruthenates (\( \text{Sr}_{1-x}\text{Ca}_x\text{Ru}_2\text{O}_7 \)), Z.Q. MAO, Z. QU, PENG, T.J. LIU, D. FOBES, B. QIAN, Tulane University, L. SPINU, University of New Orleans — We previously established a magnetic phase diagram for (\( \text{Sr}_{1-x}\text{Ca}_x\text{Ru}_2\text{O}_7 \)) (0 \( x \leq 1 \)) using high quality single crystals grown by a floating-zone method [1]. This phase diagram exhibits rich magnetic properties. The magnetic ground state ranges from an itinerant metamagnetic state (0 \( x < 0.08 \)), to an unusual heavy-mass, nearly ferromagnetic (FM) state (0.08 \( x < 0.4 \)), and finally to an antiferromagnetic (AFM) state (0.4 \( x < 1 \)). In this talk we report the electronic properties of these magnetic states. We will show that the electronic and magnetic properties are strongly coupled in this system. The electronic ground state evolves from an AFM quasi-two-dimensional metal for \( x = 1.0 \), to an Anderson localized state for the AFM region 0.4 \( x < 1.0 \), and then to a weakly localized state, induced by magnetic scattering, for the nearly FM region 0.08 \( x < 0.4 \). When \( x \) approaches the critical composition 0.08, the localization weakens and non-Fermi liquid (FL) behavior occurs. The system eventually transforms into a FL ground state when the magnetic ground state switches to the itinerant metamagnetic state for \( x < 0.08 \). These results demonstrate the delicate balance among the charge, spin, lattice and orbital degrees of freedom in ruthenates.

12:51PM W30.00007 Inhomogeneous magnetic phases: a LOFF-like phase in \( \text{Sr}_2\text{Ru}_2\text{O}_7 \), ANDREW BERRIDGE, ANDREW GREEN, SANTIAGO GRIGERA, University of St Andrews, BEN SIMONS, University of Cambridge — The phase diagram of \( \text{SrRuO}_3 \) contains a metamagnetic transition that bifurcates to enclose an anomalous phase with intriguing properties - a large resistivity with anisotropy that breaks the crystal-lattice symmetry. We propose that this is a magnetic analogue of the spatially inhomogeneous superconducting Fulde-Ferrel-Larkin-Ovchinnikov state. We show - through a Ginsburg- Landau expansion where the magnetisation transverse to the applied field can become spatially inhomogeneous - that a Stoner model with electronic band dispersion can reproduce this phase diagram and transport behaviour.

1:03PM W30.00008 Crystal-Field Level Inversion in Lightly Mn-Doped \( \text{Sr}_2\text{Ru}_2\text{O}_7 \), MUHAMMED HOSSAIN, University of British Columbia (UBC), Z. HU, M.W. HAVERKORT, T. BURNUS, C.F. CHANG, S. KLEIN, Universität zu Köln, J.D. DENLINGER, Advanced Light Source, LBNL, H.-L. LIN, C.T. CHEN, NSPRC, Taiwan, B. MATTHEI, Y. KANEKO, Y. T. OKURA, S. SATOW, H. TAKAGI, University of Tokyo, Y. YOSHIDA, National Institute of Advanced Industrial Science and Technology (AIST), A. TANAKA, Hiroshima University, I.S. ELFIMOV, G.A. SAWATZKY, UBC, L.H. TENG, Universität zu Köln, A. DAMASCHELLI, UBC — \( \text{Sr}_2(\text{Ru}_{1-x}\text{Mn}_x)\text{O}_3 \), in which 4d-Ru is substituted by the more localized 3d-Mn, is studied by x-ray dichroism and spin-resolved density functional theory. We find that Mn impurities do not exhibit the same +4 valence of Ru, but act as +3 acceptors; the extra e\(_g\) electron occupies the in-plane 3d\(_{2z^2−r^2}\) orbital instead of the expected out-of-plane 3d\(_{xz, yz}\). We propose that the 3d-4d interplay, via the ligand oxygen orbitals, is responsible for this crystal-field level inversion and the material’s transition to an antiferromagnetic, possibly orbitally ordered, low-temperature state. Published: Phys. Rev. Lett. 101, 016404 (2008).

1:15PM W30.00009 Strong spin-orbit coupling effects on the Fermi surface of \( \text{Sr}_2\text{Ru}_2\text{O}_4 \) and \( \text{Sr}_2\text{Rh}_{0.4}\text{Ru}_{0.6} \), ANDREA DAMASCHELLI, University of British Columbia, MAURITS HAVERKORT, MPI Stuttgart, ILYA ELFIMOV, University of British Columbia, HAO TENG, University of Cologne, GEORGE SAWATZKY, University of British Columbia — We present a first-principle study of spin-orbit coupling effects on the Fermi surface of \( \text{Sr}_2\text{Ru}_2\text{O}_4 \) and \( \text{Sr}_2\text{Rh}_{0.4}\text{Ru}_{0.6} \) [1]. For nearly degenerate bands, spin-orbit coupling leads to a dramatic change of the Fermi surface with respect to non-relativistic calculations; as evidenced by the comparison with experiments on \( \text{Sr}_2\text{RhO}_4 \), it cannot be disregarded. For \( \text{Sr}_2\text{Ru}_2\text{O}_4 \), the Fermi surface modifications are so small that they are only barely observable in the material’s transition to an antiferromagnetic, possibly orbitally ordered, low-temperature state. Published: Phys. Rev. Lett. 101, 026406 (2008).

1:27PM W30.00010 Dimensionality and doping effect on the Core-level X-ray photoemission satellites in layered ruthenates,1 HAIZHONG GUO, YI LI, BIAO HU, RONGYING JIN, E.W. PLUMMER, JIANDI ZHANG, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, USA, D. URBINA, Department of Physics, FIU, Miami, FL 33199, USA, TIJJANG LIU, DAVID FOBES, ZHIQIANG MAO, Physics Department, Tulane University, New Orleans, LA 70118, USA — Core-level photoelectron spectra of the layered perovskite crystal \( \text{Sr}_{1+x}\text{Ru}_2\text{O}_{4+x/n} \) (\( n = 1, 2, \) and 3) and Mn-doped \( \text{Sr}_2\text{Ru}_2\text{O}_4 \) are investigated by x-ray photoemission spectroscopy (XPS) techniques. The 3d and Ru 3d core-level spectra exhibit a two-peak structure, screened and unscreened peaks, indicating strong correlation effects among Ru 4d electrons. However, there are little changes of the core-level satellite features with \( n \), suggesting the electron-electron correlation is mainly confined in the RuO\(_2\) plane. On the other hand, doping of Mn will drastically affect the core-level spectral weight, reflecting the doping-induced metal-to-insulator transition in the doped system. The position of Ru-core levels remain the same, thus, indicating no doping-induced change of Ru valence.

1:39PM W30.00011 Magnetic Ordering in Ba$_2$DyRuO$_6^{1}$, J. LAMSAL, Missouri University, W. YELON, Missouri University of Science and Technology. H. BLACKSTEAD, M. SMYLIE, University of Notre Dame, Q. CAI, Missouri University, W. JAMES, J. YANG, Missouri University of Science and Technology — Magnetization measurements and neutron diffraction (ND) studies have been carried out on the double perovskite rhenate, Ba$_2$DyRuO$_6$. The low field magnetization data indicate ordering around 50K, a sharp rise below 8K and a possible transition around 25K. Rietveld analysis of ND data confirms antiferromagnetic ordering at 48K. The temperature dependence of the Ru moment appears to follow a Brillouin type curve down to the lowest temperature accessible, (12K), and there is no evidence for a transition around 25K. In contrast, the Dy moment is found to be proportional to the square of the Ru moment, implying that the Ru moment is the primary order parameter and that Dy ordering is driven by the Ru-Dy coupling. The ND experiment could not reach the temperature at which the magnetization rises sharply (8K), but following similar arguments, we suggest that this point corresponds to the lowest temperature accessible, (12K), and there is no evidence for a transition around 25K. In contrast, the Dy moment is found to be proportional to the square of the Ru moment, implying that the Ru moment is the primary order parameter and that Dy ordering is driven by the Ru-Dy coupling. The ND experiment could not reach the temperature at which the magnetization rises sharply (8K), but following similar arguments, we suggest that this point corresponds to the lowest temperature accessible, (12K), and there is no evidence for a transition around 25K. In contrast, the Dy moment is found to be proportional to the square of the Ru moment, implying that the Ru moment is the primary order parameter and that Dy ordering is driven by the Ru-Dy coupling.

1:51PM W30.00012 Resistance noise in the bad metal SrRuO$_3^{1}$, FRANCOISE KIDWINGIRA, MICHAEL ROZLER, GERTJAN KOSTER, WOLTER SIEMONS, RIK GROENEN, MALCOLM BEASLEY, Geballe Laboratory for Advanced Materials, Stanford University — SrRuO$_3$ (SRO) is a strongly correlated electrons material with some interesting properties. It is an itinerant ferromagnet below 150K and it transitions from a bad metal at high temperature to a Fermi Liquid at low temperature. In SRO thin films, there is evidence that even a slight presence of Ru deficiencies increases the degree of electron correlations [1]. Using Scanning Tunneling Potentiometry [2], we have studied the local transport properties of this material. The measured resistance has a noise level well above Johnson noise that depends both on the method of synthesis and on the voltage across the sample. We will attempt to characterize these resistance fluctuations with respect to the various unusual properties of the material. [1] W. Siemons et. al., Phys. Rev. B 76, 075126 (2007) [2] M. Rozler and M. R. Beasley, Rev. Sci. Inst 79, 073904 (2008)

2:03PM W30.00013 Nyquist noise as probe of hot-electron effects in the ferromagnetic insulating state of manganites$^1$, SUDESHNA SAMANTA, ARUP K. RAYCHAUDHURI, S. N. Bose Centre, Block-JD, Sector-3, Salt-Lake, Kolkata-98, India — Hole-doped rare-earth manganites (like La$_{1-x}$Ca$_x$MnO$_3$) in the ferromagnetic insulating (FMI) state show large non-linear conductance. Such non-linear conductance can arise due to hot-electron effect which originates from decoupling of the electron and lattice temperatures at high power level. The non-linear conductance manifests as electro-resistivity or current induced resistance change. We report here low frequency temperature dependent noise measurement which allows us to estimate the electronic temperature by measuring Nyquist noise in contrast to 1/f noise in La$_{2-x}$Ca$_x$MnO$_3$ single crystals which has a distinct FMI state below 100K. The measurement was performed with low ac biasing current which was mixed with a high current density that leads to electron heating. We observed that in the insulating state, above a certain input d.c power, the Nyquist noise increases by a large extent and this is coupled to the onset of non-linear conduction as signalled by the power dependence of the differential conductance. The experiment establishes a direct link between hot-electron effect and non-linear conductance.

Thursday, March 19, 2009 11:15AM - 2:15PM — Session W31 DMP GMAG: Focus Session: Magnetic Nanoparticles and Nanowires 335

11:15AM W31.00001 Comparative studies of Co nanowires of different diameters electroplated into porous aluminum oxide membranes, ZUXIN YE, HAIDONG LIU, ZHIPING LUO, HAN-GIL LEE, WENHAO WU, D. G. NAUGLE, I. LYUKSYUTOV, Texas A & M University — The correlation between the structural and magnetic properties of template-electroplated Co nanowires has been investigated. Co nanowires of diameters either 65 or 200 nm were fabricated by electroplating Co into the pores of anodic aluminum oxide membranes. Strikingly different structures were observed in these two types of Co nanowires. The 65 nm-thick Co nanowires are composed of long Co single crystal segments with a hexagonal close-packed major phase, while the 200 nm-thick Co nanowires are composed of hexagonal close-packed and face center cubic Co single crystal segments. Correspondingly, different magnetic properties were revealed in these two types of Co nanowires. The 65 nm-thick Co nanowires have a magnetic hysteresis that is significantly larger than that of the 200 nm-thick Co nanowires. In contrast, the 200 nm-thick Co nanowires have large non-linear conductance which results from decoupling of the electron and lattice temperatures at high power level. The non-linear conductance manifests as electro-resistivity or current induced resistance change. We report here low frequency temperature dependent noise measurement which allows us to estimate the electronic temperature by measuring Nyquist noise in contrast to 1/f noise in La$_{2-x}$Ca$_x$MnO$_3$ single crystals which has a distinct FMI state below 100K. The measurement was performed with low ac biasing current which was mixed with a high current density that leads to electron heating. We observed that in the insulating state, above a certain input d.c power, the Nyquist noise increases by a large extent and this is coupled to the onset of non-linear conduction as signalled by the power dependence of the differential conductance. The experiment establishes a direct link between hot-electron effect and non-linear conductance.

11:27AM W31.00002 Self-Assembled Superparamagnetic Binary Nanoparticle Superlattices$^1$, J. CHEN, Dept Mat Sci & Engn, Univ Penn, X. YE, Dept Chem, Univ Penn, Y. ZHANG, Dept Mat Sci & Engn, Univ Penn, J.M. KIKKAWA, Dept Phys & Astron, Univ Penn, C.B. MURRAY, Dept Mat Sci & Engn, Dept Chem, Univ Penn — We report binary nanoparticle superlattices (BNSLs) composed of two different types of superparamagnetic nanoparticles (NPs). Since the magnetic properties of these NPs depend both on size and composition, two strategies are used to form BNSLs. First, we use different sizes of the same material (e.g. 10.5 nm and 5.6 nm diameter Fe$_3$O$_4$ NPs). Second, we use different materials, such as 14.2 nm Fe$_3$O$_4$ NPs and 6 nm FePt NPs, or 14.2 nm Fe$_3$O$_4$ NPs and 7.1 nm CoPt$_3$ NPs. We observe the formation of large scale BNSLs (up to several µm) due to the high uniformity of these nanoparticles. Using a serial tilting capability of our TEM tomography holder we confirm that the BNSLs are isochemical NaZn$_{13}$ and AlB$_2$ type structures, which are thermodynamically stable due to their high packing density. We further measured the magnetic properties of these BNSLs samples, and single component samples, by SQUID magnetometry. Dipolar and/or exchange coupling between two components is studied.

11:39AM W31.00003 Magnetic domain formation in monolayer nanoparticle films, BRIAN MARANVILLE, KATHRYN KRYCKA, JULIE BORCHERS, National Institute of Standards and Technology, CHARLES HOGG, SARA MAJETICH, Carnegie Mellon University, YUMI IJJIRI, Oberlin College — Self-assembled magnetic nanoparticle films offer promise as data storage media, but an understanding of the interactions is missing. Modified Langmuir-Blodgett methods were used to prepare monolayer films of 7 and 11 nm diameter Fe$_3$O$_4$ nanoparticles with large structural domains. Small-angle neutron scattering (SANS) shows a peak at a wavevector $Q$ corresponding to the particle size and spacing, and scattering at intermediate $Q$ indicating possible long-range correlations. We extend to lower $Q$ with off-specular neutron reflectivity, achieving high intensity by sacrificing resolution along on-plane direction $y$ while retaining high resolution in the other plane direction $x$ and the normal direction $z$. We measure in saturation and zero field to extract magnetic scattering. In high fields, the specular scattering ($Q_y = 0$) is increased, consistent with aligned moments. Preliminary results show weak magnetic scattering for nonzero $Q_z$. Since the maximal $Q_z$ roughly corresponds to the lowest $Q$ in SANS, the combination of these techniques allows us to quantify field-dependent magnetic domain size.
11:51AM W31.00004 Finite size effects and long wavelength magnetic structures in Mn$_3$O$_4$ nanoparticles, R. REGMI, R. TACKETT, G. LAWES, Department of Physics and Astronomy, Wayne State University — Mn$_3$O$_4$ (Hausmannite) having normal spinel structure with Mn$^{2+}$ ion at tetrahedral A site and Mn$^{3+}$ ion at octahedral B site orders ferromagnetically to Yafet-Kittel phase at 42K. The interplay between the different magnetic ions leads to additional magnetic transitions in bulk, including incommensurate and commensurate phases developing at 40K and 34K respectively. We have investigated the magnetic properties of Mn$_3$O$_4$ nanoparticles through both thermodynamic and magnetic studies. Both of these measurements observe only a single magnetic transition at 42K; the transitions at 40K and 34K appear to be completely suppressed. We motivate this suppression by comparing the long wavelength of the magnetic structure in the lower temperature phases with the particle size. These nanoparticles also exhibited superparamagnetic blocking near 40K and frequency dependent magnetic loss at 30K, which we attribute to surface spin effects.

12:03PM W31.00005 Fresnel Lorentz Microscopy Imaging of Domains in Fe3O4 Nanoparticle Arrays, S. A. MAJETICH, E. R. EVARTS, C. HOGG, Physics Department, Carnegie Mellon University, K. YAMAMOTO, T. HIRAYAMA, Japan Fine Ceramics Center — Fresnel Lorentz microscopy was used to study the magnetic domain structures of self-assembled nanoparticle arrays as a function of temperature, from 24 to 605 °C. 11 nm diameter Fe3O4 nanoparticles with an edge-to-edge spacing of 2.5 nm form magnetic domains through magnetostatic interactions alone. At room temperature stripe domains were evident in monolayer arrays. The average domain size in monolayer regions is larger than that in bilayers. Mean field theories predict a reduced stabilization energy for bilayers, relative to that for monolayers. The domain wall positions were fairly stable up to 500 °C, though the contrast in the walls diminished, indicating reduced magnetic order. Above 500 °C there were large temperature-dependent changes. The walls surrounding the smaller domains disappeared at lower temperatures than those of the larger domains. Some magnetic contrast was visible up to 575 °C, close to the Curie temperature of Fe3O4 (585 °C). Transmission electron microscopy after cooling showed that the particle shape and position in the ordered arrays had been preserved during the high temperature imaging experiments.

12:15PM W31.00006 Magnetic imaging of individual nanomagnets, B. KALISKY, J. R. KIRTLLEY, L. QIAN, N. KOSHNIC, Geballe Laboratory for Advanced Materials, Stanford University, M. E. HUBER, Department of Physics, University of Colorado Denver, K. A. MOLER, Geballe Laboratory for Advanced Materials, Stanford University — Characterization of nanomagnets is usually done in ensembles, which is problematic because their magnetic properties are inherently sensitive to small variations in volume, shape and structure. Our aim is to detect and characterize individual nanomagnets using scanning microscopy, which allows gathering statistics about the behavior of many individual particles under the same conditions. Scanning SQUID is a suitable tool for this challenge because it has sensitivity of ~800 spins. We built a scanning microscope for this purpose, which is intended to measure the nanomagnets up to their superparamagnetic state while keeping the SQUID superconducting. We will present on our preliminary efforts to measure FePt particles.

12:27PM W31.00007 FePt nanoparticles as high resolution magnetic force microscope (MFM) probes, LISA QIAN, Stanford University, JAEMIN KIM, Brown University, JOHN KIRTLLEY, BEENA KALISKY, Stanford University, SHOUHENG SUN, Brown University, KATHRYN MOLER, Stanford University — Current MFM probes are often fabricated by sputtering a magnetic thin film across the entirety of an atomic force microscope (AFM) cantilever, limiting their spatial imaging resolution to about 30nm. We report our progress on improving this resolution by using single crystal, high-coercivity ferromagnetic FePt nanoparticles as magnetic sensors for MFM. By attaching nanomagnets 5-10 nm in diameter to the end of a functionalized AFM tip, we have demonstrated that the FePt nanoparticles can be used to achieve atomic resolution in magnetic imaging. The FePt nanoparticles are fabricated by sputtering Fe and Pt onto a Si$_3$N$_4$ cantilever and etching it with a focused ion beam. The FePt nanoparticles are then functionalized with a thin layer of polymer to prevent degradation. The FePt nanoparticles are then attached to the AFM tip using a conductive adhesive.

12:39PM W31.00008 Mechanical Measurement of Magnetization Reversal in a Single Iron Filled Carbon Nanotube, PALASH BANERJEE, M. HERMAN, K.C. FONG, D.V. PELEKHOV, YU. OBUKHOV, P. CHRIS HAMMEL, Dept. of Physics, Ohio State University, 191 W. Woodruff Ave, Columbus OH 43210, F. WOLNY, U. WEISSKER, T. MÜHL, A. LEONHARDT, BERND BÜCHNER, Leibniz Institute for Solid State and Materials Research (IFW) Dresden, Helmholtzstrasse 20, D-01069 Dresden Germany — The hysteresis loop and switching behavior of an individual Fe-filled carbon nanotube (FeCNT) has been measured at low temperatures using cantilever magnetometry. From the magnetometry data, we are able to extract the total moment of the nanotube and the effective anisotropy field arising from the extreme aspect ratio of the nanotube (length ∼ 13 nm, diameter ∼ 25 nm). We have measured the FeCNT’s hysteresis loop and in a single step. These switching fields ($H_s = 2245$ G at 4.2 K) are characterized by a narrow distribution ($\sigma_{sw} \approx 1$ G) and their measured temperature dependence is consistent with a thermally activated process of magnetization reversal. This work was supported by the NSF Materials World Network grant DMR-0807093 and a NSF I2CAM Grant DMR-0645461. P.B. acknowledges support of the ICAM Branches Cost Sharing Fund for a postdoctoral fellowship.

1:03PM W31.00010 Functional nanocomposite polymer films with uniform magnetic nanoparticle dispersions, K. STOJAK, S. PAL, M.J. MINER, H. SRIKANTH, University of South Florida-Physics, S. SKIDMORE, J. WANG, T. WELLER, University of South Florida-Electrical Engineering — Magnetic nanoparticles embedded in polymer matrices are good examples of functional nanostructures with excellent potential in applications such as tunable microwave devices, EMI shielding, and flexible electronics. The challenge comes with evenly dispersing the nanoparticles once they are embedded in the polymer matrix. To avoid clustering of particles in the polymer nanocomposites and achieve excellent dispersion, competition between polymer-polymer and polymer-particle interactions must be balanced. In earlier work, we demonstrated the synthesis of 2 μm thick, spin-coated nanocomposite PMMA films with Fe$_3$O$_4$ (mean size 15nm) nanoparticles embedded that displayed superparamagnetic behavior. In this work we will report on the successful extension of this strategy to 20 μm thick films that are needed for microwave applications. In addition to Fe$_3$O$_4$, we have also functionalized the films with other ferrite nanoparticles. Magnetic characterization and microstructural studies of the polymer nanocomposites will be presented and discussed. Microwave response of these films using a coplanar waveguide fixture will also be reported.
1:15PM W31.00011 Effects of varying surfactant chain lengths on the magnetic, optical and hyperthermia properties of ferrofluids. CORNELIU RABLUI, PREM VAISHNAV, Kettering University, Flint, MI, RAJESH REGMI, CHANDRAN SUDAKAR, CORREY BLACK, GAVIN LAWES, RATNA NAIK, Wayne State University, Detroit, MI, MELISSA LAVOIE, Yale University, New Haven, CT, DAVID KAHN, Oakland University, Auburn Hills, MI — We report studies of the structural, magnetic, magneto-thermal and magneto-optic properties of dextran, oleic acid, lauric acid and myristic acid surfactated Fe$_3$O$_4$ nanoparticles of hydrodynamic sizes ranging from 32 nm to 92 nm. All the samples showed saturation magnetization of ~50 emu/g, significantly smaller than the bulk value for Fe$_3$O$_4$, together with superparamagnetic behavior. The ac magnetization measurements on the dextran coated nanoparticles showed frequency dependent blocking temperature, consistent with superparamagnetic blocking. The ferrofluid heating rates in a 250 Gauss, 100 kHz ac magnetic field varied with the chain lengths of the surfactants, with higher heating rates for longer chains. DC-magnetic-field-induced light scattering patterns produced by two orthogonal He-Ne laser beams passing through the ferrofluid sample revealed different optical signatures for different surfactants.

1:27PM W31.00012 Metallic Iron Nanoparticles for MRI Contrast Enhancement. HAFSA KHURSHID, MICHAEL BONDER, SRINIVASAN BALAKRISHNAN, University of DE, COSTAS HADJIPANAYIS, Emory University School of Medicine, GEORGE HADJIPANAYIS, University of DE — This study is focused on our chemically synthesized iron nanoparticles, coated with carboxyl-methyl terminated polyethylene glycol to make them biocompatible and water dispersible. The particles have an average size of 14 nm and a magnetization of 110 emu/g. TEM studies revealed their core shell structure with iron in the core and iron oxide in the shell. The effects of these nanoparticles on MRI contrast enhancement were studied in vitro using a clinical MRI scanner at a magnetic field of 1.5 T. Both the $r_1$ (1/T$_1$) and $r_2$ (1/T$_2$) were found to be significantly higher than those of iron oxide nanoparticles with a similar size. This behavior is attributed to their stronger magnetic susceptibility, leading to spin dephasing and shortening of T2 effects and thus darkening of the nanoparticles in the MRI contrast. These results suggested that the iron nanoparticles are expected to be more useful for MRI contrast enhancement and other biomedical applications than the currently used iron oxide nanoparticles.

1:39PM W31.00013 RIE-based Pattern Transfer Using Nanoparticle Arrays as Etch Masks. CHIP HOGG, SARA A. MAJETICH, JAMES A. BAIN, Carnegie Mellon University — Nanomasking is used to transfer the pattern of a self-assembled array of nanoparticles into an underlying thin film, for potential use as bit-patterned media. We have used this process to investigate the limits of pattern transfer, as a function of gap size in the pattern. Reactive Ion Etching (RIE) is our chosen process, since the gaseous reaction products and high chemical selectivity are ideal features for etching very small gaps. Interstitial surfactant is removed with an O$_2$ plasma, allowing the etchants to penetrate between the particles. Their pattern is transferred into an intermediate SiO$_2$ mask using a CH$_4$-based RIE. This patterned SiO$_2$ layer is finally used as a mask for the MeOH-based RIE which patterns the magnetic film. We present cross-sectional TEM characterization of the etch profiles, as well as magnetic characterization of the film before and after patterning.

1:51PM W31.00014 Magneto-Transport in quantum dot films. ALEXANDRE POURRET, PHILIPPE GUYOT-SIONNET, James Franck Institute, The University of Chicago — Colloidal semiconductor quantum dots are being studied intensely because of their tunable optical properties. Quantum dot solids (e.g. films) present further interesting possibilities for designing novel materials with control of the electronic properties at the nanometer scale. While neutral CdSe or CdSe/CdS nanocrystal films are quite insulating, photo excitation or doping the film electrochemically leads to higher conductivity. In this talk I will present photocconductivity and conductivity measurements of charged CdSe and CdSe/CdS nanocrystal films at low temperature under a magnetic field. The combination of electrochemistry and spectroscopy enables the precise control and detection of electrons injected into the quantum dot films. The temperature and electric field dependent conductivity is analyzed with the variable range hopping model of Efros and Shklovskii and the magneto-conductivity is discussed in terms of a spin-blockade.

2:03PM W31.00015 Surface and Size Manipulation of the Magnetic Properties of CdSe Quantum Dots. ROBERT MEULENBERG, Laboratory for Surface Science and Technology and Department of Physics and Astronomy, University of Maine, JONATHAN LEE, SCOTT MCCALL, LOUIS TERMINELLO, TONY VAN BUUREN, Lawrence Livermore National Laboratory — The appearance of magnetism in otherwise non-magnetic materials has recently been reported for a number of nanoscale materials. Coupled with the size-dependent optical and electronic properties of the nanocrystalline materials, this magnetic behavior opens the possibility for an extended range of technological applications. As such, identifying the origin of the magnetism is an extremely important goal, yet this remains the subject of some controversy in the literature. We report evidence that paramagnetism in CdSe QDs can be induced via manipulation of the particle size and surface ligands. Using SQUID magnetometry and x-ray absorption spectroscopy, we demonstrate that the paramagnetic behavior of the CdSe QDs can be varied by changing the ligand endgroup functionality of the passivating layer. Contrary to previous reports, no evidence for ferromagnetism was observed.

11:15AM W32.00001 The Ising model for the bcc, fcc and diamond lattices; a comparison. PER HÅKAN LUNDOW, KTH, KLAS MARKSTRÖM, Umeå University, ANDERS ROSENGREN, KTH — A large scale Monte Carlo simulation study of the Ising model for the simple cubic lattice was recently performed (Adv. Phys. 56, 653–755 (2007)). We have complemented that with a study of the bcc, fcc and diamond lattices. Both the canonical and microcanonical ensembles were employed. We present estimates of the critical temperature and other quantities in the critical region. An analysis of the critical behaviour suggests distinct high- and low-temperature exponents, especially for the specific heat, as was obtained also for the simple cubic lattice. This discrepancy is briefly discussed.

11:27AM W32.00002 Thermodynamicsof magnetic systems from first principles: gWL-LSMS 1, MARKUS EISENBACK, G. MALCOLM STOCKS, DON M. NICHOLSON, THOMAS SCHULTHES, Oak Ridge National Laboratory — Density Functional Calculations have proven to be a useful tool to study the ground state of many materials. For finite temperatures the situation is less ideal an one is often forced to rely on models with parameters either fitted to first principles or experimental results. This approach is especially unsatisfactory in inhomogeneous systems, nano particles or other systems where the model parameters should vary significantly from one site to another. Here we describe a possible solution to this problem by combining classical thermodynamic Monte Carlo calculations - The Wang-Landau method in this case [F Wang and DP Landau, PRL 86, 2050 (2001)] - with a first principles electronic structure calculation, specifically our locally selfconsistent multiple scattering code. The combined code shows superb scaling behavior on massively parallel computers and first tests on Fe systems provide a proof of principle.

11:39AM W32.00003 Quantum Monte Carlo calculates bulk properties and magnetic ordering in iron 1, WILLIAM D. PARKER, JOHN W. WILKINS, Ohio State University — Quantum Monte Carlo (QMC) models electronic systems with high accuracy but its computational demands limit wider use. Few QMC calculations exist for solid-state systems and none comparing the energetic ordering of different spin configurations (magnetic states). Density-functional calculations with generalized-gradient-approximation exchange-correlation give correct magnetic ordering and accurate lattice constants and bulk moduli for bcc iron. However, the predicted cohesive energy differs from experiment by 0.5-1.0 eV. QMC-calculated bulk elastic properties for pure iron in the bcc, hcp and fcc phases compare with properties in the ferromagnetic, antiferromagnetic and nonmagnetic spin configurations.

1The Ohio Supercomputing Center, NERSC and CCNI gave computational support. The DOE provided financial support(DE-FG02-99ER45795).

11:51AM W32.00004 Current-driven vortex oscillations in metallic nanocontacts, GINO HRKAC, University of Sheffield — In this paper, we performed full micromagnetism simulations of metallic nano-contacts from the TUNAMOS consortium, by solving the Landau Lifshitz Gilbert Slonctewski equation simultaneously with quasi-static Maxwell equations. We take into account the spatially inhomogeneous current distribution flowing through the magnetic free layer and consequently use the Oersted field generated by this current for the magnetization dynamics. The system we simulated was a 40nm-CoFe 2.5nm/Cu 3nm/NiFe 4nm stack. The saturation magnetization of the free layer is taken to be the same as the experimental value Ms = 1.1 T, and a GMR ratio of 1% is used. We account for the inhomogeneous current distribution flowing through the free layer by computing the local current density from the local angle between the free and fixed layer magnetizations. The Oersted field is computed with the Biot-Savart law from this current distribution [2], and an asymmetric Sloncetzewski term for the spin transfer is used [3]. We observe that the additional spin torque drives the vortex out of the contact area and towards a stable orbit around the contact. These simulations reveal that the oscillations observed are related to the large-amplitude translational motion of a magnetic vortex. In contrast to the nanopellar geometry in which the vortex core precesses within the confining part of the Oersted field [1], the dynamics here correspond to an orbital motion outside the contact region. This behavior can be likened to planetary orbital motion under the influence of a gravitational field; the spin-transfer torque leads to a centripetal motion of the vortex core, which is counterbalanced by the attractive potential provided by the Oersted field. Good quantitative agreement between the simulation and experimental frequencies is achieved [4].

12:27PM W32.00005 Monte Carlo simulation of incommensurate helical ordering in a frustrated FCC lattice of Heisenberg spins, SEONGWEON PARK, CH. M. SULLIVAN, G. SCHNEIDER, T.M. GIEBULTOWICZ, Oregon State University — The zinblende structure of MnSe can be stabilized in thin films and is expected to exhibit Type III FCC antiferromagnetic ordering. The expected magnetic order is indeed observed in MnSe/ZnSe superlattices where the MnSe layers experience compressive strain. However, in the MnSe/ZnTe system, in which MnSe layers experience tensile strain, the Mn spins form incommensurate helical structures [1]. Mean field theory can explain the basic mechanism leading to helical ordering but cannot explain details such as the temperature dependence of the pitch of the helical ordering. We report results of Monte Carlo simulations using classical 3D Heisenberg spins and “free” boundary conditions. The simulations were performed for a range of systems with different sizes (including “bulk” thickness) and exchange constants. The change of helical pitch with temperature is correctly reproduced in our results and our data indicate that it is at least partially a finite-thickness effect. We compare our results with earlier simulations using XY spins and “self-determined” boundary conditions [2].

12:39PM W32.00006 Dynamical magnetizations of nanomagnets with strong magnetic anisotropy, BANG-GUI LIU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We developed a non-equilibrium Monte Carlo method to investigate dynamical spins and magnetizations of nanomagnets with strong magnetic anisotropy and applied it to Co spin chains on Pt surface and a composite spin system (Phys. Rev. B 73, 174418; Phys. Rev. Lett. 96, 217201; Front. Phys. China 2, 424). Here we report on our exploration for universal dynamical magnetic properties of spin chains and single-layered nanomagnets with strong magnetic anisotropy. Furthermore, we investigate representative systems composed of sub-10nm nanomagnets with large uniaxial anisotropy for magnetic data storage, finding various magnetization memory effects and aging effects in such single systems of the interacting nanomagnets with the same easy axis, and study the exchange bias and training effect observed in composite films and heterostructures. This method is proved to be effective and reliable in simulating dynamical magnetism in nanomagnets with strong magnetic anisotropy.

13:51PM W32.00007 Tailoring Effective Exchange Interactions via Domain Walls in Coupled Heisenberg Rings, VANITA SRINIVASA, JEREMY LEVY, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260 — The nature of the exchange coupling variation in an antiferromagnetic spin-1/2 system can be used to tailor its ground-state properties. In particular, dimersed Heisenberg rings containing domain walls have localized states which can serve as “flying spin qubits” when the domain walls are moved (PRB 76, 094411 (2007)). We show theoretically that, when two of these rings are coupled, the movement of the domain walls leads to modulation of the effective exchange interaction between the qubits. Appropriately chosen configurations of domain walls can give rise to ferromagnetic effective exchange. We describe how these spin rings may be used as basic building blocks to construct quantum spin systems whose properties are tunable by virtue of the exchange variation within the rings.

1:03PM W32.00008 Electron magnetism of antiferromagnetic conductors,1, REVAZ RAMAZASHVILI, LPTMS, Orsay — Essential momentum dependence of the electron g-tensor in an antiferromagnet turns the common Zeeman term into a spin-orbit coupling. I will discuss some of the remarkable experimental consequences of this phenomenon. The predictions may be relevant to antiferromagnetic conductors from chromium to electron- and hole-doped cuprates, borocarbides, pnictides, organic and heavy fermion materials.

1I thank LPTMS for the kind hospitality, and IFRAF for generous support.

1:15PM W32.00009 On the Electric-Field-Controlled Surface Ferromagnetic Transition in Metals1, IGOR V. OVCHINNIKOV, KANG L. WANG, UCLA, E&E DEPT., DRL TEAM — It is widely believed that in metals, unlike in the dilute magnetic semiconductors, the control of the ferromagnetic ordering by an external voltage is hardly achievable. We compare the two materials and show that there is no obvious reason why metals are less preferable for this phenomenon. Similar effect in metals, however, has a different physical picture and should be identified as a voltage-induced surface ferromagnetic transition. We study its properties within the theory of the surface critical phenomena and discuss possible difficulties on the way to its experimental realization.

1:27PM W32.00010 Effect of fluctuations on effective Hamiltonians of anisotropic frustrated pyrochlore antiferromagnets,2, PAUL MCCLARTY, MICHEL GINGRAS, University of Waterloo — The rare earth pyrochlore magnets $\text{R}_2\text{Ti}_2\text{O}_7$ exhibit a wide range of puzzling features. $\text{R}_2\text{Ti}_2\text{O}_7$, a weakly Ising-like antiferromagnet, is a cooperative paramagnet down to, at least, 50 mK despite having a ~20 K Curie-Weiss temperature. $\text{Er}_2\text{Ti}_2\text{O}_7$, which has magnetic ions with a strong easy plane anisotropy, has a transition to an ordered phase but the origin of a long-range ordered state with discrete broken symmetry is not understood. Recent experimental work has also uncovered interesting field-induced phases in both of these materials. We construct effective Hamiltonians, derived from microscopic models, for these two frustrated antiferromagnets by considering the effects of quantum fluctuations out of the classical ground states of these models to assess the stability of these states, the nature of the excitations and possible mechanisms of degeneracy breaking.

1:39PM W32.00011 Ferromagnetic spin coupling as the origin of 0.7 anomaly in quantum point contacts1, KARAN ARYANPOUR, JONG E. HAN, Department of Physics, SUNY at Buffalo — We study one-dimensional itinerant electron models with ferromagnetic coupling to investigate the origin of 0.7 anomaly in quantum point contacts (QPC). Linear conductance calculations using the Kubo formula from the quantum Monte Carlo (QMC) technique for spin interactions of different spatial range suggest that 0.7 x $(2e^2/h)$ anomaly results from a strong interaction of low-density conduction electrons to ferromagnetic fluctuations formed across the potential barrier. The conductance plateau results due to the strong incoherent scattering at high enough temperatures when the electron traversal time through the gate voltage barrier matches the time-scale of dynamic ferromagnetic excitations (magnons). In addition, our model also captures the correct evolution of the anomalous plateau as a function of temperature and Zeeman magnetic field.

1:51PM W32.00012 Intrinsic Perturbation of the Landau Levels in Metals and Semiconductors at Low Temperatures, AYODEJI AWOBODE, University of Illinois at Urbana Champaign — The de Haas–van Alphen effect in non-superconducting metals and semiconductors at very low temperatures is proposed as a test of an intrinsic perturbative term which appears in the Landau equation sequel to the modification of the Pauli equation. Corrections to the frequency (or period) of the de Haas–van Alphen oscillation in metals is calculated and shown to depend on the Fermi energy and the measured anomalous part of the electron magnetic moment. Precision measurement of the magneto-optical properties which arise from the motion of electrons in binary semiconductors placed in a weak magnetic field is also proposed as a means of observing very small changes in the relationship between current I and magnetic field H derived from Ampere’s Law is $H = \frac{N I}{L}$, where $N I$ is magnetomotive force and $L$ is the length of the magnetic path. However, this formula fails to describe the variation in magnetic field with position. In fact H is usually inhomogeneous around a closed path unless special precautions have been taken to ensure uniformity. In order to describe the magnetic field around a closed circuit we have introduced extensions to the standard formula for a finite coil in a closed circuit. This includes parameters for location and shape of core to enhance the accuracy. This analytic model produces fast and accurate predictions for the variation of H with position. Results are comparable with FEM calculations that take much longer to generate.

2:03PM W32.00013 Variation of magnetic H field in closed loop magnetic circuits: problems with the standard equation, ESAINDANG UMENEI, EUGENE MELIKHOV, DAVID JILES, Wolfson Centre for Magnetics, Cardiff University, WOLFSOON CENTRE FOR MAGNETICS TEAM — We have developed a reliable method for calculating the variation of magnetic field H in closed circuits. This offers advantages over standard numerical Finite Element Modeling which requires meshing of the spatial domain. Such calculations can consume enormous computational resources and time. Analytical models work much faster but are only applicable in restricted cases. The well known “standard model” for the relationship between current I and magnetic field H derived from Ampere’s Law is $H = \frac{N I}{L}$, where $N I$ is magnetomotive force and $L$ is the length of the magnetic path. However, this formula fails to describe the variation in magnetic field with position. In fact H is usually inhomogeneous around a closed path unless special precautions have been taken to ensure uniformity. In order to describe the magnetic field around a closed circuit we have introduced extensions to the standard formula for a finite coil in a closed circuit. This includes parameters for location and shape of core to enhance the accuracy. This analytic model produces fast and accurate predictions for the variation of H with position. Results are comparable with FEM calculations that take much longer to generate.

Session W33 DCMP: Superconductor-Insulator Transitions 403

11:15AM W33.00001 Mott transition, magnetism and d-wave superconductivity on lattices with frustration1, A.M.-S. TREMBLAY, BUMSOO KYUNG, Universite de Sherbrooke — By tuning band parameters and choosing appropriate lattices, it is possible to frustrate antiferromagnetism to reveal the competing d-wave superconducting (d-SC) phase, the normal phase and the Mott insulating phase. We study the nature of the competition between these phases by using Cellular Dynamical Mean-Field Theory for the Hubbard model on the anisotropic triangular lattice and on the square lattice with second-neighbor hopping. The phase diagram in the $T = 0$ plane is drawn as a function of interaction strength $U/t$ and frustration $t'/t$. The critical interaction strength for the Mott transition is found as a function of frustration. At half-filling and for intermediate coupling we find that outside the Mott insulating phases, d-SC appears at an optimal level of frustration. We also identify spin fluctuations as the source of pair formation. We find that components of the spin susceptibility involved in binding are mostly centered in the quarter of the Brillouin zone closest to $(\pi, \pi)$. We conclude that retarded short-range spin fluctuations are crucial for d-SC even in the presence of frustration and that there are optimal values of frustration that favor d-SC.

11:27AM W33.00002 Superconductor-Metal-Insulator Phase Transition in Ta Films. YIZE LI, JONGSOO YOON. University of Virginia — We have reported the magnetically induced metallic phase in superconducting Ta films which intervenes the superconducting and insulating phases [1]. Recently, we studied the electronic transport properties of Ta film with various degrees of disorders which were controlled by film thickness. We found that as sample thickness decreases, the films undergo a superconductor-metal-insulator phase transition. Each phase exhibits distinct nonlinear current-voltage (I-V) characteristics, similar to those of magnetically induced superconductor-metal-insulator transition. We have measured the evolution of nonlinear I-V with changing magnetic field (B) and temperature (T), for representative samples with different degrees of disorders, which leads to the phase diagram in B-T-Disorder space. [2] Y.Qin et al., Phys. Rev. B 73, 100505(R) (2006).

11:39AM W33.00003 Dissipation-driven quantum phase transition in superconductor-graphene systems1 . ROMAN LUTCHYN, VICTOR GALITSKI, University of Maryland. GIL REFAEL, California Institute of Technology, SANKAR DAS SARMA, University of Maryland — We show that a system of Josephson junctions coupled via low-resistance tunneling contacts to graphene substrate(s) may effectively operate as a current switching device. The effect is based on the dissipation-driven superconductor-to-insulator quantum phase transition, which happens due to the interplay of the Josephson effect and Coulomb blockade. Coupling to a graphene substrate with gapless excitations further enhances charge fluctuations favoring superconductivity. The effect is shown to scale exponentially with the Fermi energy in graphene, which can be controlled by the gate voltage. We develop a theory, which quantitatively describes the quantum phase transition in a two-dimensional Josephson junction array, but it is expected to provide a reliable qualitative description for one-dimensional systems as well. We argue that the local effect of dissipation-induced enhancement of superconductivity is very robust and a similar sharp crossover should be present in finite Josephson junction chains.

11:51AM W33.00004 Superfluid response of a gated LaAlO3 / SrTiO3 heterostructure. SHASHANK MISRA, LUKAS URBAN, STEFAN THIEL, CHRISTOPH RICHTER, GERMAN HAMMERL, JOCHEN MANNHART, Universität Augsburg, ALI YAZDANI, Princeton University — Disordered two-dimensional superconductors undergo a quantum phase transition into an insulating phase, with an unusual intervening metallic phase, upon the introduction of sufficiently large amounts of disorder or the application of a sufficiently strong magnetic field. The LaAlO3 / SrTiO3 heterostructure, because it can be gated, provides a new opportunity: to see how two-dimensional superconductivity is destroyed continuously as a function of carrier concentration. We build on the electrical transport measurements in other works, which demonstrated the existence of a superconductor-insulator transition upon decreasing the carrier concentration, by using a two coil mutual inductance technique to measure the complex ac conductivity. We will track the superfluid density, which can be derived from the complex conductivity, throughout parts of the carrier concentration-temperature-magnetic field phase diagram, and make comparisons with data from the field-tuned superconductor-insulator transitions in MoGe and InOx. This work is supported by the DOE and the DFG via SFB484.

12:03PM W33.00005 Giant enhancement of superconductivity in ultrathin α-Pb films by a parallel magnetic field: effect of magnetic impurity. ASHWANI KUMAR, H. JEFFREY GARDNER, LIQUI YU, PENG XIONG, Department of Physics and MARTECH, Florida State University — An ultrathin superconductor containing paramagnetic impurities is predicted1,2 to exhibit enhancement of superconductivity (TC and IC) when subject to a parallel magnetic field. We have recently observed a pronounced enhancement of superconductivity in ultrathin homogeneous amorphous Pb films without any (intentionally added) magnetic impurities in the presence of a parallel magnetic field; the TC enhancement is as large as 13% and persists in field as high as 8 T. Our experiments are carried out in a modified dilution refrigerator capable of situ film growth, sample rotation, and incremental deposition of magnetic (Cr) impurities, which allows for a systematic, unambiguous elucidation of the effect of paramagnetic impurities on the field-enhancement of superconductivity. With increasing Cr density on a Pb film, the magnitude of the TC enhancement is progressively suppressed, contrary to the theoretical predictions. 1 Khartonov et al., JETP Lett. 82, 473 (2005). 2 Wei et al., Europhys. Lett. 75, 943 (2006).

12:15PM W33.00006 A direct transition between a Neel ordered Mott insulator and a dx2−y2 superconductor on the square lattice. YING RAN, ASHVIN VISHWANATH, DUNG-HAI LEE, UC Berkeley — In this paper we study a bandwidth-controlled direct, continuous, phase transition from a Mott insulator, with easy plane Neel order, to a fully gapped dx2−y2 superconductor with a doubled unit cell on the square lattice, a transition that is forbidden according to the Landau paradigm. This transition is made possible because the vortices of the antiferromagnet are charged and the vortices of the superconductor carry spins. These nontrivial vortex quantum numbers arise because the ordered phases are intimately related to a topological band insulator. We describe the lattice model as well as the effective field theory.

12:27PM W33.00007 Superconductor to Quantum Metal Transitions in Ultra Thin Films1 . YEN-HSIANG LIN, ALLEN M. GOLDMAN, University of Minnesota — Homogeneous films of amorphous bismuth have been continuously tuned from the superconducting state by increasing a perpendicular magnetic field. Electrical transport and Hall measurements show that the non-superconducting states of the films are quantum-corrected metals. In the vicinity of transition field, the resistance can be fit by an Arrhenius type of conduction at high temperatures but this form fails at lower temperatures where the resistance is a non-monotonic function of temperature. This suggests that a two-phase regime develops near criticality. Theories suggest that this is in the form of superconducting puddles embedded in a normal matrix1,2. 1B. Spivak, P. Oreo, and S. A. Kivelson, Phys. Rev. B 77, 214523 (2008) 2Y. Dubi, Y. Meir, and Y. Avishai, Nature 449, 876-880 (2007)

12:39PM W33.00008 The superconductor-insulator transition: is there a new insulating state? MAOZ OVADIA, BENJAMIN SACEPE, DAN SHAHAR, Weizmann Institute, Israel — We present nonlinear conductivity measurements on the insulating side of the superconductor-insulator transition in amorphous indium oxide. The results agree with previous data1,2, and show conductance jumps at well-defined voltage bias thresholds. The current in the sample changes by as much as a factor of 105 at the threshold, from our noise floor of 3×10−14A to over 10−8A. The jumps disappear above a magnetic-field- dependent temperature TC, which is 0.11K or lower. The threshold voltage changes from 20μV to over 0.2V (4 orders of magnitude) by application of a magnetic field. We ask whether a true zero conductance state exists in our samples. DC measurements reveal pseudo-exponential I-V characteristics, which can be extrapolated to find the high Ohmic resistance of these samples at low temperatures. The extrapolated R(T) curves typically show a sub-activated trend at low T. Our results suggest that our samples have zero conductance only at the absolute zero of temperature.

12:51PM W33.00009 Metal-insulator transition and superconductivity in the Mott insulator GaTa\textsubscript{2}Se\textsubscript{8} : towards a tuning of the Mott transition by electric pulses, E. JANOD, C. VALIU, IMN, V. DUBOST, INSP, B. CORRAZE, IMN, T. CREN, INSP, P. MOREAU, IMN, F. DÉBONTRIDDER, INSP, D. BRATHWAITE, CEA Grenoble, D. RODITCHDEV, INSP, L. CARIO, IMN, TEAM, INSP TEAM, CEA GRENoble TEAM — We have recently discovered the existence of a non-volatile electric-pulse-induced resistive switching (EPI-RS) in the spinel Mott insulator GaTa\textsubscript{2}Se\textsubscript{8} [1]. The origin of this effect is different from other EPI-RS mechanisms identified to date [2]. A granular superconducting state below $T_C = 5$ K, ascertainment by critical current and critical field data obtained on single crystals, appears in the EPI "metallic" state. This transition is reminiscent of the bulk superconductivity at 5-8 K obtained under pressure [3]. Interestingly, STM experiments have revealed a puzzling electromechanical coupling between the tip voltage and the GaTa\textsubscript{2}Se\textsubscript{8} sample surface. All these results may therefore indicate that, beside electronic doping and pressure, electric pulses, through an electrostrictive effect, could be a relevant parameter to tune the Mott metal-insulator transition. 1:03PM W33.00010 Enhanced Suppression of Superconductivity in Amorphous Films with Nanoscale Patterning, VADIM OGANESYAN, CUNY Staten Island, SHIVAJI SONDHI, Princeton University — We discuss the superconductor to normal phase transition in an array of small Josephson junctions driven by an applied current. The approach is a generalization of one previously used to treat the metastable superconducting state in an array of small Josephson junctions driven by an applied current. The approach is a generalization of one previously used to treat such an array at zero applied current. The array Hamiltonian is treated variationally using the Gibbs-Bogoliubov inequality, using a set of harmonic "phase phonons" as the variational state. We find that, for a given $J/U$, where $J$ and $U$ are the Josephson and charging energies, a superconducting (S) to insulating (I) transition occurs as a function of applied current, or by varying the direction of the applied current at fixed magnitude. The critical values of $J/U$ are calculated for a square, triangular, and simple cubic lattices of Josephson junctions as a function of bias current. The resulting critical $J/U$ is found to be non-monotonic with the film thickness. We have observed a pronounced enhancement of superconductivity in ultrathin 3-Pb films in the presence of a parallel magnetic field. We have measured the transition temperature of the superconducting critical temperature, $T_c(d_{xy})$, in amorphous Bi/Sb films patterned with a regular array of holes as well as nanoscale thickness variations. We find that the mean field $T_c$ is suppressed relative to simultaneously produced unstructured films of the same thickness. Surprisingly, however, the functional form for $T_c(d_{xy})$ remains unaffected. The role of the thickness variations in suppressing $T_c$ is compared to the role of the holes, through parameterization of the surface, as measured through AFM/SEM and a proximity effect calculation. These results suggest that these two nanoscale modifications suppress $T_c$ about equally and are consistent with $T_c$ being determined on a microscopic length scale.

1This work supported by the NSF through DMR-0203608 and No. DMR-0605797, by the AFRL, and by the ONR.

1:15PM W33.00011 Giant enhancement of superconductivity in ultrathin a-Pb films by a parallel magnetic field: effect of film thickness, H. J. GARDNER, L. YU, A. KUMAR, P. XIONG, Florida State University — We have measured the thickness dependence of the superconducting critical temperature, $T_c(d_{xy})$, in amorphous Bi/Sb films patterned with a regular array of holes as well as nanoscale thickness variations. We find that the mean field $T_c$ is suppressed relative to simultaneously produced unstructured films of the same thickness. Surprisingly, however, the functional form for $T_c(d_{xy})$ remains unaffected. The role of the thickness variations in suppressing $T_c$ is compared to the role of the holes, through parameterization of the surface, as measured through AFM/SEM and a proximity effect calculation. These results suggest that these two nanoscale modifications suppress $T_c$ about equally and are consistent with $T_c$ being determined on a microscopic length scale.

1:27PM W33.00012 Superconductor-insulator transitions in films patterned with a disordered nanohoneycomb hole array, H. Q. NGUYEN, S. M. HOLLEN, M. D. STEWART, JR., AIJUN YIN, J. M. SHAINLIN, J. M. XU, J. M. VALLES, JR., Brown University — On both sides of the Superconductor-Insulator Transition (SIT), ultrathin Bi films patterned with an ordered array of holes exhibit magnetoresistance (MR) oscillations with a period set by the superconducting flux quantum[1]. This observation implies that the insulating phase consists of localized Cooper pairs. To probe further this localized Cooper pair phase we have investigated samples patterned with disordered hole arrays. We have found that disorder reduces the number of MR oscillations and weakens the magnetic field tuned SIT. We will present these results and discuss their implications for the Cooper pair insulating phase.

1This work was supported by the NSF through No. DMR-0203608 and No. DMR-0605797, by the AFRL, and by the ONR.

1:39PM W33.00013 High field magnetoresistance peak near the superconductor-insulator transition in amorphous Bi films patterned with a nanohoneycomb array of holes, S. M. HOLLEN, H. Q. NGUYEN, M. D. STEWART, JR., J. M. SHAINLINE, AIJUN YIN, J. M. XU, J. M. VALLES, JR., Brown University — The spectacular magnetoresistance (MR) peak that appears on the insulating side of the Superconductor-Insulator Transition (SIT) in In Oxide films [1] has received much attention. It has been taken as a sign that Cooper pairs persist into their insulating phase. We have observed a similar MR peak in ultrathin amorphous Bi films patterned with a disordered nanohoneycomb array of holes. This peak increases in magnitude with decreasing thickness and moves to lower field with decreasing temperature. Most importantly, it coexists with MR oscillations at lower fields that reveal the presence of Cooper pairs [2]. We will present our latest investigations of this peak and contrast our results with the behavior of unpatterned amorphous film systems.

This work was supported by the NSF through No. DMR-0203608 and No. DMR-0605797, by the AFRL, and by the ONR.

1:51PM W33.00014 Superconductor-Insulator Phase Transitions in Current-Biased Arrays of Small Josephson Junctions, CHRISTOPHER PORTER, DAVID STROUD, The Ohio State University — We present a variational approach to treat the metastable superconducting state in an array of small Josephson junctions driven by an applied current. The approach is a generalization of one previously used to treat such an array at zero applied current. The array Hamiltonian is treated variationally using the Gibb's-Bogoliubov inequality, using a set of harmonic "phase phonons" as the variational state. We find that, for a given $J/U$, where $J$ and $U$ are the Josephson and charging energies, a superconducting (S) to insulating (I) transition occurs as a function of applied current, or by varying the direction of the applied current at fixed magnitude. The critical values of $J/U$ are calculated for a square, triangular, and simple cubic lattices of Josephson junctions as a function of bias current. The resulting critical $J/U$ is found to be highly sensitive to changes in bias current magnitude, and somewhat less sensitive to current direction, for all geometries studied.

[1] Work supported in part by NSF DMR04-13395

2:03PM W33.00015 Biot-Savart correlations in layered superconductors, KUMAR RAMAN, UC Riverside, VADIM OGANESEYAN, CUNY Staten Island, SHIVAJI SONDHI, Princeton University — We discuss the superconductor to normal phase transition in an infinite layered type-II superconductor in the limit where Josephson coupling between layers is negligible. We model each plane as a neutral gas of thermally excited pancake vortices and assume the Biot-Savart interaction between vortices is the dominant mechanism for coupling the layers. Using the real-space renormalization group, we demonstrate that the transition in this model is a Kosterlitz-Thouless transition driven by the unbinding of pancake vortices. We study the high temperature phase using a Debye-Huckel type mean field theory. We find that while the long range interaction leads to correlations between the planes, the screening within the individual layers is not significantly different from an isolated two-dimensional system. This overall picture places some claims expressed in the literature on a more secure analytical footing and also resolves some conflicting views. Experimental implications will be discussed.
temperatures, which depended upon the applied current. At this writing, the origin of the effect is unclear. This negative magnetoresistance can be as large as 50 percent even with applied field as low as few Oersted. This effect was found over a narrow range of temperatures, which depended upon the applied current. At this writing, the origin of the effect is unclear.

11:27AM W34.00002 ABSTRACT WITHDRAWN

11:39AM W34.00003 Electronic structure of quasi-one-dimensional edge-sharing cuprate LiCu$_2$O$_2$ single crystals measured by angle-resolved photoemission spectroscopy, K.-D. TSUEI, C.-M. CHENG, J.-Y. YUH, National Synchrotron Radiation Research Center, Hsinchu, Taiwan R.O.C., K.W. YEH, M.K. WU, Insitute of Physics, Academia Sinica, Taipei, Taiwan, R.O.C. — We have carried out a high resolution angle-resolved photoemission study on edge-sharing quasi-one-dimensional (1D) chain cuprate LiCu$_2$O$_2$ single crystals at room temperature. The low energy electron diffraction of cleaved (001) surfaces show a well ordered (2x1) pattern with single domain. Absence of photon energy dependence of high lying peaks just below the Fermi energy in the normal emission spectra suggests localization within the ab-pannar layers. One can identify three dispersive bands between 0.5 eV and 2 eV binding energies along the high symmetry directions along with the off-normal spectra. The highest energy peak is observed at the Y-point with a binding energy 0.55 eV bearing a d$_{xy}$ symmetry based on a polarization dependent selection rule, and can be associated with a hybridized state of primarily Cu 3d$_{xy}$ and O 2p orbitals, in agreement with a LDA band calculation. We observed no indication of a band maximum at half integral position along GY, predicted by a 1D $t-J$ model. Another peak at 1.3 eV shows a strong dispersion along GY, normal to the chain direction. Its identity will also be discussed.

11:51AM W34.00004 Synthesis and characterization of superconducting, single-crystal Al nanowires using template based electrodeposition. MEENAKSHI SINGH, JIAN WANG, MINGLIANG TIAN, Penn State University, ALEXIS PEREIRA, University of Puerto Rico Cayey, NITESH KUMAR, THOMAS MALLOUK, MOSES CHAN, Penn State University — Al nanowires (ANW) have been fabricated using template based electrodeposition at room temperature for the first time. An anhydrous electrolyte comprised of AlCl$_3$ and LiAlH$_4$ in tetrahydrofuran with a Pt anode and Ag cathode was used to electrodeposit Al in an anodic aluminum oxide template. X-ray diffraction and electron diffraction show that the ANW are single crystal with (110) as the growth direction. Transmission electron microscopy shows that the wires have uniform diameters with an oxidation layer a few nanometers thick around them. Four electrode transport measurements on a single 70 nm thick ANW have shown significant enhancement in the critical temperature and the critical field and decrease in the critical current density from the bulk value.

11:03PM W34.00005 Resistance in Superconducting Epitaxial Niobium Nanowires and Films, TIMOTHY MCARDLE, ALLISON DOVE, KEVIN INDERHEES, MITRABHANU SAHU, ALEXEY BEZRYADIN, PAUL GOLDBART, JAMES ECKSTEIN, Univ of Illinois, Urbana-Champaign — The thermally activated phase slip (TAPS) description of resistance in one-dimensional superconducting wires is unable to explain additional resistance observed in extremely narrow nanowires well below the critical temperature. We fabricate nanowires using electron beam lithography from single-crystal niobium films grown by ultra-high vacuum molecular beam epitaxy. Since the resulting wires are single crystal and homogenous, the role of disorder is reduced and neither weak links nor grains are present. The epitaxial films are 10 to 30 nm thick, while the finished wires range in length from 1 to 10 µm, and in width from 35 to 200 nm. Transport measurements on the nanowires of varying widths show a range of distinct temperature dependencies below the critical temperature that cannot be accounted for by the single exponential form of the TAPS model.

12:15PM W34.00006 Two superconducting transitions and periodic magnetoresistance oscillations in the crystalline Au nanowire with superconducting electrodes, JIAN WANG, CHUNTAI SHI, MINGLIANG TIAN, JAINENDRA JAIN, QI ZHANG, NITESH KUMAR, MEENAKSHI SINGH, THOMAS MALLOUK, MOSES CHAN, Penn State University — Transport measurements were made on individual crystalline Au nanowire with four focused ion beam (FIB) deposited tungsten (W) electrodes, which are superconducting below 5 K. It was found that the 1.2 microns long (between the inner edges of the two voltage electrodes) Au nanowire is superconducting. Instead of a single sharp drop to zero resistance as seen in usual superconductors, here the resistance drops in two steps. Below TC, with a magnetic field applied perpendicular to the axis of the nanowire, we found “magnetoresistance mini-gaps” in low field regime. In addition, clear periodic magnetoresistance oscillations in the superconducting to normal transition region were observed. All the 1 micron and 1.9 microns Au nanowires were also investigated to further reveal the anomalous superconductivity we found.

Work supported by NSF MRSEC program under grant DMR-0820404.

12:27PM W34.00007 Vortext blockade and conductance fluctuations of superconducting strips in magnetic fields, PAUL GOLDBART, University of Illinois at Urbana Champaign, GIL REFAEL, California Institute of Technology, DAVID PEEKER, Harvard University — Recent experiments on the conductance of a thin, narrow superconducting strip found periodic fluctuations as a function of the perpendicular magnetic field, with the period corresponding to approximately two flux quanta per strip area [1]. Using vortex-charge duality, we explore the possibility that the superconducting strip is the dual of a quantum dot, with vortices playing the role of the electrons, the magnetic field appearing as the gate voltage, and the applied current replacing the source-drain voltage. As with a quantum dot, extrema of the conductance are obtained when configurations with $n$ and $n+1$ vortices have equal energy; in the bias-current versus magnetic-field plane, the conductance displays blockade diamonds. Furthermore, we find that there is a simple relation between the linear-response conductance and the critical current, as they are both set by the barrier to vortex tunneling on to and off of the strip. [1] A. Johansson et al. Phys. Rev. Lett. 95, 116805 (2005).
12:39PM W34.00008 Tuning of the critical current of superconducting nanowires by application of voltage pulses, THOMAS AREF, ALEXEY BEZRYADIN, UIUC — The critical current of superconducting nanowires may depend on a number of factors such as dimensions of the nanowire, the wire’s normal resistance or the presence of magnetic impurities. Determining which factors are most important is key to developing a detailed understanding of the underlying physics of 1D superconductivity. It is experimentally difficult to alter and probe such properties in situ at cryogenic temperatures. We have developed a method for tuning the critical current of a nanowire in situ inside a helium cryostat by the application of short, high bias voltage pulses. These pulses alter the critical current of the nanowire in a controlled manner by annealing or electromigration. Thus, for a single nanowire, we can vary critical current and normal resistance in situ. This process may have applications in developing future superconducting nanowire circuitry such as qubits where precise control of the nanowire’s critical current is required. We also discuss the dependence of the critical current on the normal resistance of the wire and compare to existing theories.

12:51PM W34.00009 Flux-quantization effect in superconducting niobium loops1, SUHONG YU*, ZHILI XIAO*, ALEXANDRA IMRE, JIONG HUA*, ULRICH WELP, WAI-KWONG KWOK, Argonne National Lab, Northern Illinois University — Superconducting loops have periodic oscillation of critical temperature $T_c$ as a function of applied perpendicular magnetic field $H$. The corresponding periodicity is related to superconducting flux quantization, $h/2e$, due to size constraint. When the loop size shrinks, however, new phenomena can appear. For example, the oscillation can show a $h/e$ rather than $h/2e$ periodicity if the hole diameter is comparable to the superconducting coherence length. We present experimental investigation of flux-quantization effect in mesoscopic superconducting niobium loops. We developed a new approach to fabricate high quality loops by combining electron-beam lithography with focused-ion-beam (FIB) milling techniques. Periodic oscillations were observed in both the $H - T$ phase diagram and the magnetoresistance. Analysis of the data with various theories will be presented.

1:03PM W34.00010 Anisotropic magnetoresistance of a one-dimensional superconducting niobium strip1, JIONG HUA*, ZHILI XIAO*, ALEXANDRA IMRE, SUHONG YU*, UMESH PATEL*, LEO OCOLA, RALU DIVAN, ALEXEI KOSELEV, JOHN PEARSON, ULRICH WELP, WAI-KWONG KWOK, Argonne National Laboratory, Northern Illinois University — We investigated confinement effects on the resistive anisotropy of a superconducting niobium strip with a rectangular cross-section. When the strip’s transverse dimensions are comparable to the superconducting coherence length, we find the angle dependent magnetoresistances at a fixed temperature can be scaled as $R(\theta, H) = R(H/H_{c1})$, where $H_{c1} = H_{c1}(\cos^2\theta - \sin^2\theta)^{1/2}$ is the angular dependent critical field, $\gamma = w/d$ is the width to thickness ratio of the strip, and $H_{c1}$ is the out-plane critical field at $\theta = 0$. Our results can be understood in terms of the anisotropic diamagnetic energy of a one-dimensional superconductor in a magnetic field.

1:15PM W34.00011 Quasi-reentrant resistive behavior in Bi$_2$Sr$_2$CaCu$_2$O$_8$ whiskers1, SEVDA AVCI, Northern Illinois University, UMESH PATEL, SUHONG YU, Argonne National Laboratory, Northern Illinois University, ZHILI XIAO, RALU DIVAN, ULRICH WELP, WAI-KWONG KWOK, Argonne National Laboratory, MILIND KUNCHUR, University of South Carolina — BSCCO (2212) whiskers were fabricated via a melt-quench-growth method and their morphology was characterized with scanning/transmission electron microscopy and atomic force microscopy. Four-probe magneto-transport measurements were conducted as a function of temperature and current. In low magnetic fields and currents, the resistance decreases monotonically and vanishes at a temperature of $\sim 80$ K. However, at large currents and magnetic fields the resistance shows a non-monotonic dependence on temperature, even showing values that are higher than the normal state resistance for certain ranges of the parameters. We attribute the observed behavior to the brick-wall morphology of the whiskers leading to a competition between normal and superconductive tunnelings that is known to take place in granular superconductive systems.

1:27PM W34.00012 Quenching of Meissner Diamagnetism in Superconducting Nanocrystals, HELENA MOREIRA, IRENE RESA, BENOT MAHLER, BENOT DUBERTRET, HERVE AUBIN, CNRS — We developed a new chemical synthesis for the preparation of high quality monodisperse superconducting Lead (Pb) nanocrystals. They are obtained from the alcohol reduction of Lead carboxylates in a hot organic solution and lead to colloids stabilized and protected from oxidation by organic ligands. Large quantities of nanocrystals with tunable diameter (8 to 30 nm) can be obtained. This new method allows the study of the effects of quantum confinement on superfluid response with unprecedented size resolution. Magnetic susceptibility measurements show that the large critical field of the particles increases from 2 to 5 T as the diameter is reduced down to 16 nm. This critical field results from the competition between the kinetic energy for Cooper pairs and superfluid condensation energy. Below the diameter of 16 nm, no Meissner effect remains in the particles, but only the signature of residual superconducting fluctuations. Remarkably the size scale below which the superfluid response disappears (16 nm) is significantly larger than the value expected from Anderson criterion. This implies that, in the regime of quantum confinement, there are distinct size-scales for the formation of Cooper pairs and the establishment of the superfluid response.

1:39PM W34.00013 Thin Superconducting Rings and Cylinders in a Magnetic Field, ROBERT BEAIRD, DANIEL E. SHEEHY, ILYA VEKHTER, Louisiana State University — We examine the magnetic field dependence of the critical temperature ($T_c$) for a thin superconducting ring and thin-walled superconducting cylinder (of radius $R$), in the presence of a magnetic field ($B$). We include both the orbital effect and the Zeeman splitting of the quasiparticle state. We derive a Ginzburg-Landau free energy functional and allow for the appearance of the spatially-modulated (Fulde-Ferrell-Larkin- Ovchinnikov) state. We explore the competition between the orbital effect and Zeeman splitting as a function of the ratio of $R$ to the superconducting coherence length, the orientation of $B$ with respect to the plane of the ring, and the Maki parameter (the ratio of the orbital and paramagnetic critical fields). We focus on the interplay of the periodicity and the overall suppression of $T_c$ with applied $B$.

1:51PM W34.00014 Order and Creep in Flux Lattices and CDWs Pinned by Planar Defects, ALEKSANDRA PETKOVIC, THOMAS NATTERMANN, Institute of Theoretical Physics, University of Cologne, Zülpicher Str. 77, 50937 Köln, Germany — The influence of randomly distributed point impurities and planar defects on the order and transport in type-II superconductors and related systems is considered theoretically. For random planar defects of identical orientation the flux line lattice exhibits a new glassy phase with diverging shear and tilt modulus, a transverse Meissner effect, large sample to sample fluctuations of longitudinal magnetic susceptibility and an exponential decay of translational long range order. The flux creep resistivity for currents $J$ parallel to the defects is $\rho(J) \sim \exp(-(J_0/J)^{\mu}$ with $\mu = 3/2$. Strong disorder enforces an array of dislocations to relax shear strain.
have recently observed phonon spectral anomalies in Nb and Pb that correspond to Kohn anomalies in the Fermi surface, at energies matching the low T conducting layered cuprates. The pairing of oxygen holes into heavy bipolarons in the paramagnetic phase (current-carrier density collapse (CCDC)) explains edge, but propagate as the Bloch states above the mobility edge. I identify the Froehlich EPI as the most essential for pairing and phase separation in super-

Attractive electron correlations, caused by an almost unretarded EPI, are sufficient to overcome the direct inter-site Coulomb repulsion in these charge-transfer and phase separation in the Hubbard model with on-site repulsive electron-electron correlations. I argue that microscopic phase separations in cuprate super-
critical exponents in terms of the inter-chain couplings and interaction parameters of the model.

This is particularly relevant for stripe phases in High Temperature Superconductivity arising from the Josephson tunneling between neighboring stripes, and is essentially a problem of dimensional crossover. Using inter-chain Mean Field Theory, we present results for the gaps, critical temperatures, and couplings. This is particularly relevant for stripe phases in High Temperature Superconductivity arising from the Josephson tunneling between neighboring stripes, and is essentially a problem of dimensional crossover. Using inter-chain Mean Field Theory, we present results for the gaps, critical temperatures, and critical exponents in terms of the inter-chain couplings and interaction parameters of the model.

We consider the problem of competing orders in a stripe phase with a large spin gap. In developing the phase diagram, we discuss the phases arising from the stabilization of the Superconducting (SC) and Charge Density Wave (CDW) orders by inter-stripe couplings. This is particularly relevant for stripe phases in High Temperature Superconductivity arising from the Josephson tunneling between neighboring stripes, and is essentially a problem of dimensional crossover. Using inter-chain Mean Field Theory, we present results for the gaps, critical temperatures, and critical exponents in terms of the inter-chain couplings and interaction parameters of the model.

Coherent Lattice Vibrations, Kohn Anomalies, and Pseudogaps in Superconductors

ALAN M. KADIN, Princeton Junction, NJ — A recent analysis has proposed [1] that the superconducting state is associated with charge density standing waves at k=2k_F, coupled to coherent lattice vibrations at 2k_F-G, where G is a reciprocal lattice vector. Independently, Aynajian et al. [2] have recently observed phonon spectral anomalies in Nb and Pb that correspond to Kohn anomalies in the Fermi surface, at energies matching the low T energy gap 2\Delta(0). Since Kohn anomalies are also defined by k=2k_F-G, these observations appear consistent with [1]. This also suggests that Kohn anomalies and an associated pseudogap provide a universal precursor of the superconducting state. Further experiments are proposed that should provide direct evidence of the coherent lattice vibrations in the superconducting state of conventional electron-phonon superconductors, and of alternative coherent oscillations (spin waves, etc.) in unconventional materials.

Crossed Andreev reflection dominated subgap transport in normal metal/superconducting hybrid structures

ANDREAS KLEINE, ANDREAS BAUMGARTNER, JELENA TRBOVIC, CHRISTIAN SCHONENBERGER, Department of Physics, Univ. of Basel, NANOELECTRONICS GROUP AT BASEL TEAM — We report on a systematic study of the non-local Andreev process (also called cross Andreev reflection = CAR) in planar mesoscopic N-S devices that consist of a superconducting (S) Al wire with several normal metal (N) fingers contacting the superconductor via tunneling barriers. We measure the non-local voltage appearing at a N (detector) contact located outside the current path, while a bias current is driven from another N (injector) contact to the S wire. This non-local differential signal has been studied as a function of bias and temperature for several samples with different N-S contact transparencies. In addition to CAR, elastic co-tunneling (EC) and charge imbalance (CI) appears in the measurements. We observe a systematic dependence of the relative magnitude of CAR, EC and CI. Most strikingly, CAR can dominate the subgap transport for all energies below the superconducting gap for a certain kind of sample. If the tunneling resistance R_t is increased, EC starts to dominate over CAR. This contribution is limited to small subgap biases, whereas CAR remains dominating at higher subgap biases. This dependence is explained by Coulomb blockade that becomes more prominent for increasing R_t.

11:15AM W35.00001 Gap anisotropy and universal pairing scale in a spin fluctuation model for cuprates

ARTEM ABANOV, Texas A&M University, ANDREY CHUBUKOV, University of Wisconsin, MICHAEL NORMAN, Argonne National Laboratory — We consider the evolution of \Delta_{z,y,z} pairing, mediated by nearly critical spin fluctuations, with the coupling strength. We show that the onset temperature for pairing, T^\ast, smoothly evolves between weak and strong coupling, passing through a broad maximum at intermediate coupling. At strong coupling, T^\ast is of the order of the magnetic exchange energy J. We argue that for all couplings, pairing is confined to the vicinity of the Fermi surface. We also find that thermal spin fluctuations only modestly reduce T^\ast, even at criticality, but they substantially smooth the gap anisotropy. The latter evolves with coupling, being the largest at weak coupling.

11:27AM W35.00002 Magneto-oscillations in Underdoped Cuprates

CHANDRA VARMA, University of California, Riverside — The conventional interpretation of the recent magneto-oscillation experiments in underdoped Cuprates, requires that there be a state of altered translational symmetry in the pseudogap state which is not supported by structural and Angle Resolved Photoemission Spectroscopy (ARPES) experiments. I show that the observed oscillations may be reconciled with the conclusion arrived in ARPES experiments that the fermi-surface, suitably defined, has the shape of four arcs which shrink to four points as the temperature T approaches 0. Experiments, including infrared absorption in a magnetic field, are suggested to distinguish between such a state obtained by the conventional interpretation of the magneto-oscillations.

11:39AM W35.00003 Phase Diagrams for Stripe Phases with a Spin gap

AKBAR JAEFARI, SIDDHARTHA LAL, EDUARDO FRADKIN, University of Illinois — We consider the problem of competing orders in a stripe phase with a large spin gap. In developing the phase diagram, we discuss the phases arising from the stabilization of the Superconducting (SC) and Charge Density Wave (CDW) orders by inter-stripe couplings. This is particularly relevant for stripe phases in High Temperature Superconductivity arising from the Josephson tunneling between neighboring stripes, and is essentially a problem of dimensional crossover. Using inter-chain Mean Field Theory, we present results for the gaps, critical temperatures, and critical exponents in terms of the inter-chain couplings and interaction parameters of the model.

11:51AM W35.00004 Phase separation of electrons strongly coupled with phonons in cuprates and manganites

SASHA ALEXANDROV, Loughborough University — Recent advanced Monte Carlo simulations have not found superconductivity and phase separation in the Hubbard model with on-site repulsive electron-electron correlations. I argue that microscopic phase separations in cuprate superconductors and colossal magneto-resistance (CMR) manganites originate from a strong electron-phonon interaction (EPI) combined with unavoidable disorder. Attractive electron correlations, caused by an almost unretarded EPI, are sufficient to overcome the direct inter-site Coulomb repulsion in these charge-transfer Mott-Hubbard insulators, so that low energy physics is that of small polarons and small bipolarons. They form clusters localized by disorder below the mobility edge, but propagate as the Bloch states above the mobility edge. I identify the Froehlich EPI as the most essential for pairing and phase separation in superconducting layered cuprates. The pairing of oxygen holes into heavy bipolarons in the paramagnetic phase (current-carrier density collapse (CCDC)) explains also CMR and high and low-resistance phase coexistence near the ferromagnetic transition of doped manganites.

12:03PM W35.00005 Coherent Lattice Vibrations, Kohn Anomalies, and Pseudogaps in Superconductors

ALAN M. KADIN, Princeton Junction, NJ — A recent analysis has proposed [1] that the superconducting state is associated with charge density standing waves at k=2k_F, coupled to coherent lattice vibrations at 2k_F-G, where G is a reciprocal lattice vector. Independently, Aynajian et al. [2] have recently observed phonon spectral anomalies in Nb and Pb that correspond to Kohn anomalies in the Fermi surface, at energies matching the low T energy gap 2\Delta(0). Since Kohn anomalies are also defined by k=2k_F-G, these observations appear consistent with [1]. This also suggests that Kohn anomalies and an associated pseudogap provide a universal precursor of the superconducting state. Further experiments are proposed that should provide direct evidence of the coherent lattice vibrations in the superconducting state of conventional electron-phonon superconductors, and of alternative coherent oscillations (spin waves, etc.) in unconventional materials.

12:15PM W35.00006 Phase-fluctuations model for the pseudogap of high temperature superconductors

WONKEE KIM, YAN CHEN, C. S. TING — Within the phase fluctuation picture for the pseudogap state of a high-T_c superconductor, we incorporate the phase fluctuations generated by the classical XY model with the Bogoliubov-de Gennes formalism utilizing a field-theoretical method. This picture delineates the essential characteristics of spatially varying local order parameters observed in high-T_c superconductors above T_c. We also compute the local density of states near a non-magnetic impurity with a strong scattering potential. The resonance peak smoothly evolves as temperature increases through T_c without showing any sudden broadening, which is consistent with recent experimental findings.
12:27PM W35.00007 Antiferromagnetic to singlet transition in the quarter-filled band. R.T. CLAY, Mississippi State University, S. MAZUMDAR, University of Arizona — One of the greatest challenges in constructing a theory of superconductivity in the presence of strong electron-electron (e-e) interactions is to describe how a transition can occur from antiferromagnetic to singlet order. Transitions between antiferromagnetism (AFM) and singlet order are well known in several specific cases such as the spin-Peierls (SP) transition, dimerization in the presence of antiferromagnetic nearest neighbor and second neighbor couplings, and the nongapped singlet in the rectangular spin ladder. In all three examples, the transition is a consequence of confinement within a quasi-one-dimensional lattice. Similar AFM/singlet transitions have not been found in the two dimensional (2D) 1/2-filled band. We present evidence that an AFM/singlet transition can occur in a 2D 1/4-filled anisotropic triangular lattice. A key difference is that at 1/4 filling, inhomogeneity in the form of coexisting charge, bond, and spin orders occur due to e-e and electron-phonon interactions. We show that with increasing lattice frustration the ground state of the 1/4-filled band anisotropic triangular lattice changes from AFM to a charge-ordered state with local singlets. Our results have direct implications for the 1/4-filled organic superconductors as well as related inorganic materials such as Na$_2$CoO$_2$, LiTi$_2$O$_4$, CuRh$_2$S$_4$. Supported by DOE grant DE-FG02-06ER46315.

12:39PM W35.00008 Collective Fluctuations of the Loop-Current Phase in Cuprates, ARKADY SHEKHTER, VIVEK AJI, CHANDRA VARMA, UC Riverside — We have calculated the collective modes of the loop-current ordered phase observed in underdoped Cuprates. Besides the modes given by the fluctuations of the Ashkin- Teller model, we find that the current fluctuations introduce a mode whose properties are similar to that of electro-magnetic vector potentials. We calculate the coupling of such a mode to the Ashkin-Teller modes and to the Fermions. 

12:51PM W35.00009 Superconductivity in Spin-Chain Ladder Cuprate, SHIGERU KOIKEGAMI, Second Lab, LLC, TAKASHI YANAGISAWA, Nanoelectronics Research Institute, AIST — We study the superconductivity in the three-dimensional d-p model with the quasi-one-dimensional structure in which CuO$_2$-chain and Cu$_2$O$_2$-ladder are alternately stacked with each other. When we control the hole density on each Cu site in our model, we have two or three Fermi surfaces, on which the fully-gapped superconductivity develops. Both the inter-band nesting and the large density of states around Van Hove singularity points play essential roles to achieve the superconductivity, and these two factors can coexist easily owing to the electron transfer between chain and ladder.

1:03PM W35.00010 Superconducting Fluctuations in Strongly Correlated Electronic Systems, WILLIAM PUTIKKA, Physics Department, Ohio State University — Superfluid behavior is relatively common in strongly correlated fermion systems. This suggests there is a common reason for this behavior rooted in the strong correlations. I propose such a mechanism, developed in the context of the 2D t-J model, where $d_{x^2-y^2}$ superconducting fluctuations have recently been observed. The $d_{x^2-y^2}$ fluctuations are not due to antiferromagnetic fluctuations; the AF fluctuations compete with superconducting fluctuations. Pair fluctuations have their own, separate origin based in the strong correlations. If the on site repulsion is strong enough it can affect the electronic degrees of freedom while the entropy still dominates the free energy. This requires the entropy to be maximized under the constraint of no double occupancy, thereby rearranging the electronic degrees of freedom into separate spin and charge excitations. These excitations have different statistics and very different energy scales, allowing the charges to develop pair correlations before the spin degrees of freedom become coherent. Below the spin coherence temperature, the spins determine the symmetry of the pair wave function for the electronic pair fluctuations. The symmetry which best avoids the AF fluctuations on a square lattice is $d_{x^2-y^2}$.

1:15PM W35.00011 The quantum effective potential and the condensation of topological excitations in Josephson junction arrays, SAID SAKHI, College of Arts and Sciences, American University of Sharjah, PO Box 26666, Sharjah, UAE — I analyze the radiative corrections to the effective potential for an Abelian gauge theory relevant to Josephson junction arrays (JJA). This model consists of two disorder fields related to electric and magnetic charges coupled to topologically gauge fields described by Maxwell terms and a mixed Chern-Simons term. The symmetry of the ground state is studied through the effective potential which takes into account radiative corrections in the theory. Here zero condensation for the topological charge excitations describe [1] insulating phases of JJA, and nonzero condensates describe superconducting phases. The gauge fields contribution to the one-loop effective potential is evaluated and its effect on the spontaneous symmetry breaking is examined. Effects of dissipation driving coupling in JJA systems connected to a reservoir of gapless single-particle excitations are also studied. Coupling to gapless fermions is shown to induce radiative corrections in the effective potential which favor transitions between an insulating state and a superconducting state. [1] S. Sakh, Europhys. Lett. 73 (2), 267 (2006).

1:27PM W35.00012 Topological Confinement and Superconductivity, KHALED AL-HASSANIEH, CRISTIAN BATISTA, PINAKI SENGUPTA, Los Alamos National Laboratory, ADRIAN FEIGUIN, University of Maryland — We derive a Kondo Lattice model with a correlated conduction band from a two-band Hubbard Hamiltonian. This mapping allows us to describe the emergence of a robust pairing mechanism in a model that only contains repulsive interactions. The mechanism is due to topological confinement and results from the interplay between antiferromagnetism and delocalization. By using Density-Matrix-Renormalization Group (DMRG) we demonstrate that this mechanism leads to dominant superconducting correlations in a 1D-system. [1] K.A. Al-Hassanieh, C. Batista, P. Sengupta, and A. E. Feiguin, preprint arXiv:0808.3735.

1:39PM W35.00013 Vortex lattice structures of spin triplet superconductors, DANIEL AGTERBERG, University of Wisconsin - Milwaukee, SUK BUM CHUNG, Stanford University, EUN-AH KIM, Cornell University — Motivated by recent interest in spin triplet superconductors, we investigate the vortex lattice structures for this class of unconventional superconductors. We discuss how the order parameter symmetry can give rise to $U(1) \times U(1)$ symmetry in same sense as in spinor condensates, making the half-quantum vortex (1/2-qv) topologically stable. We then calculate the vortex lattice structure of 1/2-qv’s, with particular attention on the roles of the crystalline lattice, the Zeeman coupling, and Meissner screening, all absent in spinor condensates. Finally, we consider how spin-orbit coupling leads to a breakdown of the $U(1) \times U(1)$ symmetry and the fate of the 1/2-qv lattice. As examples, we consider models for spin-triplet superconductivity in Sr$_2$RuO$_4$ and more speculative spin-triplet models for Na$_2$CoO$_2$·yH$_2$O and Bechgaard salts.

1:51PM W35.00014 Strong coupling limit of superconductivity in anti-ferromagnetic phase: Extended hardcore boson picture of d-wave order and phase fluctuation, YUCEL YILDIRIM, WEI KU, Brookhaven National Laboratory — Strong coupling limit (local-pairing >> kinetic energy) of the superconductivity in High-Tc superconductors is investigated within the anti-ferromagnetic phase. An extended hardcore boson picture consisting of paired holes results from general considerations of paired fermions, in which directional near-neighbor occupations of bosons are forbidden. By use of Wannier function of the low-energy sector of the bosonic Hilbert space, our simple picture provides a natural separation of the phase of the superconducting order parameter into local and external ones. Within a realistic parameter range, the local structure is found to be of d-wave symmetry, driven by the kinetic energy. On the other hand, the genuine behavior of the superconductivity is controlled by the phase coherence of the external phase, which leads to experimentally observed linear reduction of super fluid density. Interestingly, due to the competition with p-wave symmetry, the effective mass of the boson is enormously enhanced from that of the Fermion, explaining the very small stiffness. Connections to recent observation of 4-period d-wave CDW in the "stripe" phase, and C2-symmetry bond-centered charge profile will also be addressed.
2:03PM W35.00015 A new method for solving the inhomogeneous Bogoliubov - de Gennes equations. LUCIAN COAVACI, MONA BERCIU, University of British Columbia, Vancouver, Canada — Inhomogeneities (surface, interfaces, impurities, etc.) in superconductors give rise to interesting phenomena, like broken time-reversal states, bound states near surfaces, etc. Numerical solutions of the self-consistent Bogoliubov-de Gennes mean field equations become computationally intensive for systems whose translational symmetry is broken. We propose a new method of solving the mean-field equations based on the Kernel Polynomial Method. We expand the Green’s functions in terms of Chebyshev polynomials and calculate the order parameters self-consistently. Because the most expensive operation is only the sparse matrix-vector multiplication, the benefits of this method are multiple: usage of large systems, easy implementation of symmetries, multiple bands. Although we apply this method to a specific example (formation of Andreev states in 2D superconductors), it is applicable to any mean-field calculation.

11:15AM W36.00001 Conductance of a fully equilibrated quantum wire1, TOBIAS MICKLITZ, JEROME RECH, K. A. MATVEEV, Argonne National Laboratory — We study electronic transport properties of a long weakly interacting homogeneous quantum wire, connected to non-interacting leads. From Galilean invariance of the system we infer that in a state with a finite electric current, the electrons reach thermal equilibrium in a frame moving with their drift velocity. At non-zero temperature the resulting distribution function inside the wire is slightly different from the distribution supplied by the leads. This gives rise to a small correction to the quantized value of conductance 2e2/h, which can be found by performing a careful analysis of the conservation laws. The correction is of the order of (∂E_F/∂T)^2 and does not depend on the details of the electron-electron interaction.

11:27AM W36.00002 Simulation of electron conduction in a prototypical three-terminal molecular transistor. HAIYING HE, RAVINDRA PANDEY, Department of Physics and Multi-Scale Technology Institute, Michigan Technological University, Houghton, MI 49931, SHASHI KARNA, US Army Research Laboratory, Weapons and Materials Research Directorate, ATTN: AMSRD-ARL-WM; Aberdeen Proving Ground, MD 21005-5069 — In a single molecule, electronic charge can be modulated either by electrical field or by chemical effects, thereby opening up the possibility of their use as active elements in electronic devices. In this talk, we present the results of a theoretical study on the electronic conduction of a novel, three-terminal molecular architecture, analogous to a heterojunction bipolar transistor. In this architecture, two diode arms consisting of donor-acceptor molecular wires fuse through a ring, while a gate modulating wire is a π-conjugated wire. The calculated results show the enhancement or depletion mode of a transistor by applying a gate field along the positive or negative direction. A small gate field is required to switch on the current in the proposed architecture. The changes in the electronic conduction can be attributed to the intrinsic dipolar molecular architecture in terms of the evolution of molecular wavefunctions, specifically the one associated with the terphenyl group of the modulating wire in the presence of the gate field.

11:39AM W36.00003 Synthesis and metal-to-semiconductor conversion of carbon nanotubes by light irradiation. LEWIS GOMEZ DE ARCO, AKSHAY KUMAR, YI ZHANG, KOUNGMIN RYU, ALEXANDER BADMAEV, CHONGWU ZHOU, Electrical Engineering - University of Southern California — We report on the synthesis of aligned nanotubes on Sapphire and quartz substrates, transfer, device fabrication and scalable light-to-semiconductor conversion of carbon nanotubes on field-effect transistor (CNTFET) channels by broadband light irradiation at environmental conditions. Inactivation of metallic nanotubes in the channels was achieved as a consequence of a light-assisted photochemical process that led to a controlled sp^2 to sp^3 transition in the nanotubes structure, and hence localization of π-electrons. Stronger gate bias dependence with improvements in the drain current On/Off ratio up to 10^5 was found in around 90 percent of the CNTFETs. The possibility of fabricating mostly semiconducting carbon nanotube transistors by simple light irradiation in air over entire wafers constitutes an important achievement in terms of assembly, integration and large scale fabrication of nanotube-based circuits.

11:51AM W36.00004 Spectroscopic and structural studies of L-arginine doped Potassium Dihydrogen Phosphate crystals3. JAYESH GOVANI, CRISTIAN BOTEZ, WILLIAM DURRER, FELICIA MANCIU, Physics Department, University of Texas at El Paso, TX 79968 — We report in this study the spectroscopic and structural characterization of standard and L-arginine doped potassium dihydrogen phosphate crystals synthesized by a solution growth technique. The infrared absorption and Raman results demonstrate chemical functionalization between the amino (NH叁) groups of the organic material and the phosphate units of the inorganic crystals. This affirmation, which also implies the achievement of successful doping, is supported by the existence of extra vibrational lines in the IR and Raman spectra of L-arginine doped potassium dihydrogen phosphate crystals; these vibrational lines exhibit shifting towards lower frequencies as compared with the characteristic bands of L-arginine. Incorporation of the amino acid into the structure of the inorganic material is revealed by X-ray diffraction results also, where the shifting of diffraction lines and the appearance of a new one are observed.

3This work was supported by the NSF-MRI grant # 0723115. The authors are thankful to Dr. Mihir Joshi from Saurashtra University, Rajkot 360005, India, for providing the samples.

12:03PM W36.00005 Heteroborane Analogs of Silicon clusters: Experimental and Theoretical Studies on Bi2Si14. KIRAN BOGGAVARAPU, McNeese State University, MILEY JACKSON, McNeese State University, XING LI, ANDREJ GRUBISIC, DI WANG, KIT BOWEN, Johns Hopkins University, ANIL KANDALAM, McNeese State University, HAO-PENG WANG, Johns Hopkins University — Despite numerous studies, silicon clusters continue to fascinate. Part of the intrigue comes from the fact that, unlike metallic clusters which have strongly delocalized electrons and prefer to follow simple electron counting rules such as those originating from Jellium models, there are no simple rules of thumb that can be used to understand the diverse structures of silicon clusters. However, over the last couple of decades, there have been attempts to connect the structure and bonding of silicon clusters to a large class of well-studied three dimensional boron hydride compounds, specifically boranes, BnHn叁. By equating the π-lone pair of divalent silicon to a B-H bond, it was shown that the frontier orbitals of both units are similar. Theoretical studies have concluded that the silicon clusters (Si2nmin) adopt similar structural patterns to those of boranes, when n = 5, 6, 7, 8, 10 and 13. The question then arises, whether neutral analogs of Si2nmin and neutral heteroboranes, X2Bi2BnHn (X = N, P, Sb, Bi), can be envisioned. Here, we present the scope and limitation such analogy based on our recent theoretical (DFT) and experimental (anion-photoelectron spectroscopy) studies on Bi2Si14 (n = 4-8). In particular, we show that both Bi2Si14 and Bi2Si18 adopt similar pentagonal bipyramidal (PBP) geometries and have analogous orbital energy patterns.
12:15PM W36.00006 In situ characterization of crystal structure and physical properties of individual nanostructures in as-fabricated devices. MARCEL LUCAS, School of Physics, Georgia Institute of Technology, ZHONG LIN WANG, School of Materials Science and Engineering, Georgia Institute of Technology, ELISA RIEDO, School of Physics, Georgia Institute of Technology — Nanostructures have potential applications as electronic components, catalysts, sensors, biomarkers, and energy harvesters. Control over their morphology and structure is essential, since their physical properties depend on their dimensions and crystallographic structure. Although in situ transmission electron microscopy can correlate the structure and physical properties of individual one-dimensional nanostructures, it usually damages the sample and is unable to recover the characterized nanostructure for next-step device fabrication and application. Here, we demonstrate a method combining atomic force microscopy and polarized Raman spectroscopy to characterize in situ the morphology, crystal structure and physical properties of individual nanostructures that can be as-fabricated devices without sample damage. Based on scanning probe microscopy, our method can be extended to study the electronic, mechanical, and tribological properties of inorganic/biological nanostructures.

12:27PM W36.00007 Simulating self-assembly of porphyrin nanorods. GREGORY K. GUTHE, ADAM V. SUBHAS, WALTER F. SMITH, JOSHUA SCHRIER, Haverford College — Diadid meso-tetra(4-sulfonatophenyl)porphine (TPPS4−) monomers have been shown to self assemble into nanorods with well-defined cross-section and intriguing photoelectronic properties. However, the structure and conduction mechanism of these nanorods is poorly understood, and questions remain about the aggregation process. Using density functional theory (DFT), we first obtain optimized geometries and atomic-charges for the monomers, which we then use for subsequent molecular dynamics (MD) simulations to observe the initial stages of the self-assembly process. This work uses the resources of the National Energy Research Scientific Computing Center. A.D. Schwab et al., J. Phys. Chem. B 107, 11339 (2003). A.D. Schwab et al., Nano Letters 4, 1261 (2004).

12:39PM W36.00008 Electric field directed growth of cuprous oxide nanostructures for photon sensing. SANGEETA SAHOO, SAROJ NAYAK, Rensselaer Polytechnic Institute, PULICKEL AJAYAN, Rice University — We demonstrate an electro-deposition technique to synthesize cuprous oxide nanomaterials in various types of nanostructural form at room temperature. We apply an electric field under deionized water on the top electrode with the conductive substrate made of Cu. Using this method, direct growth of nanostructures has been achieved on different types of substrates. We show that the structural evolution depends strongly on the electric potential between the electrodes and also on the type of substrates. We have studied the growth mechanism on flat Si substrate and on Transmission electron Microscopy grid. A variety of structures from simple one dimensional nanowires to different complex two and three dimensional structures are successfully grown directly on substrates with this method. Direct integration of these nanostructures on substrates paves the way to step ahead towards the fabrication of electronic devices. Taken together, this novel technique of Cu2O nanostructure production is highly reproducible, catalysts free, fast and a low cost simple process. In addition, the electrical characteristics indicates the usefulness of these structures for photo-sensing and optoelectronic applications.

12:51PM W36.00009 Ca1+xCoB1 and Ca1+xRuB4: New Borides with One-Dimensional Channel Structures. YUKARI KATSURA, HIRAKU OGINO, YUTAKA MATSUMURA, Department of Applied Chemistry, the University of Tokyo, KAZUMASA SUGIYAMA, TOETSU SHISHIDO, Institute for Materials Research, Tohoku University, SHIGERU HORII, JUN-ICHI SHIMOYA, KOJI KISHIO, Department of Applied Chemistry, the University of Tokyo — We discovered two novel borides Ca1+xCoB1 (x = 0.10) and Ca1+xRuB4 (x = 0.18) as the first members of Gd1−xFe2B2−x and Pr1−xRe2B2−x-type ternary borides with a divalent metal at the rare earth sites. In these compounds, tetrahedral chains of transition metals and boron form tetradimensional channel structures, which contain single atomic chains of Ca. These are composed of CoB4 and RuB4 sublattices, with common a-axis lengths and independent c-axis lengths. The two structural types are distinguished by configurations of the tetrahedral chains. Resistivity and magnetization measurements showed that these compounds are paramagnetic metals down to 2 K. Preliminary first-principle calculations indicated the presence of covalent bonds between transition metals and boron, and electrical conductivity originating from the d-bands of the transition metals.

1:03PM W36.00010 Photoluminescence Studies of Hydrogenated a-Silicon Carbide. SOMILKUMAR RATHI, Colorado School of Mines, FENG ZHU, MVSystems,Golden,CO, JOSHUA GALLON, BRIAN SIMMONDS, GEORGE RADZISZEWSKI, P. CRAIG TAYLOR, Colorado School of Mines — A series of PECVD grown silicon carbide samples differing in their carbon content was investigated by a near-IR FT-Photoluminescence (PL) technique. The goal of this study was to establish a correlation between carbon concentration in a-SiC and the observed luminescence signal. Variations in the observed temperature dependences of the PL signals in a-SiC are attributed to differences in the carbon content. The samples, initially kept at 18 K on a closed-cycle helium cryostat, were excited with Ar-ion laser light at 514.5 nm (with power ranging 5-30 mW; and a flume of 0.5 to 3 W/cm2), and the luminescence was recorded with an InGaAs detector over the range of 1.5 eV to 0.67 eV. There was no change in PL intensity below 50 K; above 50 K the intensity decayed logarithmically up to room temperature. The increase of carbon content caused an increase in the PL on the higher energy side of the emission peak (approximately centered at 1.29 eV; FWHM = 0.3 eV) with concurrent intensity decrease on the lower energy side.

1:15PM W36.00011 Electrical transport in YSi2 nanowires. V. IANCU, Department of Physics, University of Tennessee, P.R.C. KENT, T.-H. KIM, A.-P. LI, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, L.D. MENARD, J.M. RAMSEY, Department of Chemistry, University of North Carolina, Chapel Hill, H.H. WEITERING, University of Tennessee — When a small amount of yttrium is deposited onto Si, silicon islands in ultrathin films form. In subsequent metal deposition, the yttrium atoms self-assemble into highly uniform silicide nanowires with dimensions of the order of 4x1.1x1000 nm3. These YSi2 nanowires are among the thinnest silicide structures fabricated to date. Their electrical properties have been explored using a four-probe scanning tunneling microscope (STM). The wires exhibit ohmic conduction at room temperature but the conductance decreases at lower temperature. STS measurements [1] indicated a small gap opening at low temperature in the thinnest YSi2 wires, which appears to be associated with the charge-order fluctuations seen in STM. The YSi2 nanowires not only represent an interesting model system for exploring 1D quantum transport, but they can also be used as electronic/multicomponents in nanoscale electronic devices on silicon substrates. The research at Oak Ridge National Laboratory's Center for Nanophase Materials Sciences was sponsored by the National User Facilities Division, U.S. DOE. [1] C. Zeng et al. Nat. Mat. 7, 539 (2008)

1:27PM W36.00012 Gate-tunable magnetic exchange and giant g-factor fluctuations in InAs nanowire quantum dots. SZABOLCS CSONKA, LUKAS HOFSTETTER, FRANK FREITAG, STEFAN OBERHOLZER, CHRISTIAN SCHONENBERGER, Department of Physics, Univ. of Basel, THOMAS SAND JEPSEN, MARTIN AGASEN, JESPER NYCARD, Niels Bohr Institute, Copenhagen, NANOELECTRONICS GROUP AT BASEL TEAM, NANOSCALE QUANTUM ELECTRONICS GROUP AT THE NANO-SCIENCE CENTER TEAM — We use the spin-1/2 Kondo effect, which is observed in every other charge ground state with odd elec-trons, to measure the field-induced splitting of the spin-doublet, and hence the g-factor. We do this in hybrid quantum dots using both normal (N), ferromagnetic (F) and superconducting (S) contacts. Unlike to previous studies, the g-factors of neighboring states can vary a lot: g can scatter between 2 and 18 and can therefore be even larger than in the bulk (g ~ 15). We demonstrate further the electric gate tunability of the g-factor in a single charge state. When using F contacts, a zero-field splitting is induced. The proximity-induced exchange field has recently been measured for the first time by Hauptmann et al. (Nature Physics 4, (2008)) in carbon nanotubes. Here, we show the same effect in a semiconductor nanowire, demonstrating that this effect is universal. Employing a pair of S and F contacts, the proximity-induced exchange shows up as a minigap in superconducting spectroscopy.
There is a correlation between binding energy ($E_2$) and energy band gap ($E_g$) of TiO$_2$ nanowires. In general, $E_g$ increases with increasing $E_2$. In TiO$_2$ nanowires, both metallic and semiconductor nanowires are resulted. In this case, in addition to paramagnetic TiO$_2$ nanowires, there are also ferromagnetic ones. We have also studied the structural and electronic properties of bulk-like rutile (110) nanowires. There is a crossover in terms of energetics and bulk-like nanowires are more stable than the thin nanowires for larger radius wires after a critical diameter. These (110) rutile nanowires are all semiconductors.

We start, by way of first-principles calculations, the existence of a giant nonlinear flexoelectric effect in BN 2D strips. The induced polarization is quadratic in amplitude of atomic displacements $A$, yet the dipole moment per unit cell is about four times larger compared to PbZrTiO$_3$ [1]. The new effect may find a variety of practical applications and, in particular, as nanogenerators and tactile sensors powered by an ambient motion or agitation. BN material is inert and can be used in biological environment.

We have systematically investigated structural, electronic and magnetic properties of very thin TiO$_n$ ($x$=1,2) nanowires as well as bulk-like (110) rutile nanowires by using the first principles plane wave pseudopotential calculations based on density functional theory. A large number of different possible structures have been searched via total energy calculations in order to find the ground state structures of these nanowires. Three dimensional structures have been searched for both of the stoichiometries (i.e. $x$=1,2). The stability of TiO$_n$ nanowires enhances with its increasing radius, thus reaching sufficient coordination number of Ti and O atoms. All stoichiometric TiO$_2$ nanowires studied exhibit semiconducting behavior and have nonmagnetic ground state. There is a correlation between binding energy ($E_b$) and energy band gap ($E_g$) of TiO$_2$ nanowires. In general, $E_b$ increases with increasing $E_g$.
12:27PM W37.00007 Application of the Finite-Element Space-Time Algorithm to Bound States$^1$, CHARLES WEATHERFORD, Florida A&M University, ALBERT WYNN, DANIEL GEBREMEDHIN, XINGJUN ZHANG, Florida A&M University — The implementation of the Dirac representation is facilitated by the finite element space-time algorithm.$^1$ Multicenter integral computations are also facilitated by this same algorithm. The present work is the first application of this original algorithm to the computation of bound states of atoms and molecules. The Dirac representation is employed such that $H_0$ is the sum of the one-electron operators while the residual $H_1$ is the sum of the two-electron operators. Soft-Coulombic geminals are then used as the basis for the time-dependent calculation of a superposition of the bound-states. The eigenstates and eigenvalues are then extracted by filter-diagonalization. An addition theorem is given for the soft-coulombic geminals and the geminals are translated again using the space-time algorithm, so that multicenter integrals may be computed. Several small atoms and molecules are considered as an illustration of the method.$^1$

12:39PM W37.00008 Test of Current Variational Procedures for Electronic Structures and Properties of Molecular and Solid State Systems by application to Atomic Systems$^1$-H$^-$ Ion, HARI PAUDEL, ARCHANA DUBEY, UCF Orlando, R.H. SCHEICHER, Uppsala University, Sweden, S.R. BADU, R.H. PINK, T.P. DAS, SUNY Albany — Electronic properties of atomic systems are obtainable using Linked Cluster Many-Body Perturbation Theory (LCMBPT) with high accuracy and excellent agreement with experiment, using complete sets of states obtained by differential equation procedures$^1,2$. Unfortunately such procedures are not practicable for multi-center molecular and solid state problems and variational procedures have to be used for obtaining the occupied and excited one electron states to work on electronic properties of the latter systems. With the aim to assess the accuracies of the latter procedures with Gaussian basis states, like the first principles Hartree-Fock procedure together with many body perturbation theory, and density functional based procedures, we are testing them for both energy and wave function dependent properties of atoms. Results will be presented for H$^-$ ion, where Hartree-Fock theory predicts instability with respect to auto ionization to H atom and electron correlation effects obtained by the LCMBPT procedure$^3$ restore stability, providing nearly exact experimental affinity for H$^-$.$^1$[1] Alfred Owusu et al., Phys. Rev. A56, 305(1997)$^2$[2] T.Lee et al., Phys. Rev. A4 1410(1971)$^3$[3]C.M. Dutta et al., Phys. Rev. A2, 2289(1970)

12:51PM W37.00009 Computation of Nonlinear Impedance Spectra in Samaria Doped Ceria$^1$, FRANCESCO CIUCCI, California Institute of Technology — Samarium Doped Ceria (SDC) electrodes are currently of great interest for solid oxide fuel cells (SOFC) applications. For example, ceria-containing anodes can be operated directly on hydrocarbons without coking, and in addition can be used at lower temperatures than Ni/YSZ. In order to design, optimize, and characterize electrodes, it is very useful to have models to aid in interpreting experimental results. In this work, we present a non-linear, time-dependent model for the study of SDC. This model allows us to compute species concentrations, electric potential and currents under medium bias conditions. A regular perturbation of the drift diffusion equations and Poisson’s equation is used to derive the model for the behavior of bulk of the material. We also include the kinetics of reactions occurring at the SDC-gas surface where the SDC is exposed to a spatially uniform hydrogen-water-argon mixture at fixed total pressure. The numerical procedure allows for fast computations and for the direct determination of fast and rate limiting steps. Impedance spectra are computed in the 2D case and a quantitative comparison between experimental (symmetric cell) and numerical results is presented. Our model can be naturally extended to the non-symmetric case, i.e. the case under which the two sides of the SDC assembly are exposed to different atmospheres.

1:03PM W37.00010 An Analytical Approach to Computing Biomolecular Electrostatic Potential$^1$, ANDREW FENLEY, JOHN GORDON, ALEXEY ONUFRIEV, Virginia Tech — Analytical approximations to fundamental equations of continuum electrostatics on simple shapes can lead to computationally inexpensive prescriptions for calculating electrostatic properties of realistic molecules. Here, we derive a closed form, analytical approximation to the Poisson equation for an arbitrary distribution of point charges and a spherical dielectric boundary. The simple, parameter-free formula defines continuous electrostatic potential everywhere in space and is obtained from the exact infinite series (Kirkwood) solution by an approximate summation method that avoids truncating the infinite series. We show that keeping all the terms proves critical for the accuracy of this approximation, which is fully controllable for the sphere. We apply the approximation to 580 biomolecules under realistic solvation conditions, where the effects of mobile ions are included at the Debye-Hückel level. The accuracy of the approximation as applied to the biomolecules is assessed through comparisons with numerical Poisson-Boltzmann (NPB) reference solutions. For each structure, the deviation from the reference is computed for a large number of test points placed near the dielectric boundary (molecular surface). The accuracy of the approximation is within 1 kT per unit charge for 91.5% of the individual test points.

1:15PM W37.00011 Ab initio Study of Atomic and Molecular Polarizabilities$^1$, IGOR VASILIEV, New Mexico State University, JAMES R. CHELIKOWSKY, The University of Texas at Austin — We calculate the static electric dipole polarizabilities for a variety of atoms and molecules using a finite field method implemented in the framework of an ab initio density functional formalism. Our calculations employ several different representations of the exchange-correlation potential, including the local density approximation, generalized gradient approximation, and asymptotically correct functionals introduced by Leeuwen-Baerends$^1$ and Casida-Salahub$^2$. We observe that the computed values of polarizabilities are strongly influenced by the asymptotic behavior of the density functional exchange-correlation potential. The accuracy of theoretical atomic and molecular polarizabilities is substantially improved by the use of asymptotically correct exchange-correlation functionals. This result can be explained in terms of electronic excitation energies and the polarizability sum rule.

1:27PM W37.00012 Theoretical predictions of the impact of nuclear dynamics and environment on core-level spectra of organic molecules, DAVID PRENDERGAST, Molecular Foundry, Lawrence Berkeley National Laboratory, CRAIG SCHWARTZ, JANIEL UEJIO, RICHARD SAYKALLY, Chemical Sciences Division, Lawrence Berkeley National Laboratory — Core-level spectroscopy provides an element-specific probe of local electronic structure and bonding, but linking details of atomic structure to measured spectra relies heavily on accurate theoretical interpretation. We present first principles simulations of the x-ray absorption of a range of organic molecules both in isolation and aqueous solution, highlighting the spectral impact of internal nuclear motion as well as solvent interactions. Our approach uses density functional theory with explicit inclusion of the core-level excited state within a plane-wave supercell framework. Nuclear degrees of freedom are sampled using various molecular dynamics techniques. We indicate specific cases for molecules in their vibrational ground state at experimental conditions, where nuclear quantum effects must be included. Prepared by LBNL under Contract DE-AC02-05CH11231.
Efficient free energy calculations of quantum systems through computer simulations

Alex Antonelli, Universidade Estadual de Campinas, Rafael Ramirez, Carlos Herrero, Instituto de Ciencia de Materiales de Madrid, Eduardo Hernandez, Instituto de Ciencia de Materiales de Barcelona

In general, the classical limit is assumed in computer simulation calculations of free energy. This approximation, however, is not justifiable for a class of systems in which quantum contributions for the free energy cannot be neglected. The inclusion of quantum effects is important for the determination of reliable phase diagrams of these systems. In this work, we present a new methodology to compute the free energy of many-body quantum systems. This methodology results from the combination of the path integral formulation of statistical mechanics and efficient non-equilibrium methods to estimate free energy. Namely, the adiabatic switching and ensemble averaging methods. A quantum Einstein crystal is used as a model to show the accuracy and reliability the methodology. This new method is applied to the calculation of solid-liquid co-existence properties of neon. Our findings indicate that quantum contributions to properties such as, melting point, latent heat of fusion, entropy of fusion, and slope of melting line can be up to 10% of the calculated values using the classical approximation.

Applications of a novel QM/MM method incorporating a polarizable force field

Christopher Williams, John Herbert, Ohio State University

In conventional QM/MM methods the MM region is modeled by a force field that uses a set of point charges to represent the electrostatics. However, recently developed force fields use multipole expansions combined with polarizable sites to represent electrostatic interactions. A novel algorithm is presented to incorporate this class of force fields with a QM region by allowing the QM region and the MM region to share the same computational cell. This algorithm is implemented in the software package TINKER. The algorithm is general and can be used with a variety of QM methods including MP2 and DFT. Examples of both ground state and excited state calculations are presented, including the investigation of the effectiveness of many-body expansions in modeling the solvation of charged species and the effect of charged environments on biomolecules.

Numerical modeling of fast gate-coupled ion permeation in CIC channels

Mary H. Cheng, Department of Chemistry, University of Pittsburgh

We have developed a three dimensional Brownian dynamics (BD) and discrete-state model to couple ion permeation to the motion of a putative fast gate in the CIC channels. The model channel is designed so as to represent certain essential features of CIC chloride channel, in which a glutamate side chain moves from an open state to a closed state (blocking the channel pore at a position which also acts as a binding site for Cl	extsuperscript{−} ions moving through the channel). Both BD and the discrete-state model generate results in qualitative agreement with experimental observations and consistent with the foot-in-the-door mechanism. Furthermore, we have formulated a numerical approach to calculate the discrete rate constants in our model channel using BD. The discrete-state model with the rate constants solved via BD produces results consistent with the (continuous space) multi-ion BD simulations.

Modeling Ion Solvation and Transport through Chloride Transport Proteins

Thomas Beck, Univ. of Cincinnati

Ion channels and transporters are membrane proteins that selectively conduct ions either passively (channels) or actively using a chemical gradient of one ion (transporters). The H+/Cl	extsuperscript{−} transporter, first discovered in bacteria, has now been shown to also occur in animals and plants. This talk will discuss computational approaches aimed at understanding the ion transit pathways through the bacterial chloride transporter. A Monte Carlo method (TransPath) that uses the crystal structure as input and exhaustively searches the protein for open pore spaces and favorable electrostatic domains has been developed. The algorithm successfully predicted pathways for the motion of chloride ions and protons. In order to better understand the free energies along the predicted transport pathways, we have developed a new statistical mechanical approach for computing absolute solvation free energies in restricted environments based on a quasi-chemical approach. Anion free energy results employing the new method will be presented.

Snug-fit, fluctuations, and metal-ion hydration in the selectivity of potassium ion channels

Lawrence Pratt, Chemical and Biomolecular Engineering, Tulane University

On the basis of molecular simulation, an identification of a single dominating physical factor responsible for Na\textsuperscript{+}/K\textsuperscript{+} selectivity of the KcsA channel has been contentious. The potential distribution theorem and quasi-chemical theory cast new light on the factors responsible for Na\textsuperscript{+}/K\textsuperscript{+} selectivity. In that context, we argue that an alternative definite formulation of the molecular statistical thermodynamic problem can help in achieving a consensus view of selectivity. We summarize the necessary new theoretical ingredients and published numerical results in working toward that consensus view.

Conformation changes in the Glutamate receptor as studied by LRET

Vasanthi Jayaraman, University of Texas Health Science Center at Houston

Glutamate receptors are the primary mediators of excitatory neurotransmission in the mammalian central nervous system. Glutamate binding to an extracellular ligand binding domain initiates a series of conformational changes that results in the formation of cationic pathways in the channel. The potential distribution theorem and quasi-chemical theory cast new light on the factors responsible for Na\textsuperscript{+}/K\textsuperscript{+} selectivity. In that context, we argue that an alternative definite formulation of the molecular statistical thermodynamic problem can help in achieving a consensus view of selectivity. We summarize the necessary new theoretical ingredients and published numerical results in working toward that consensus view.

Electric and Molecular Characteristics of Ion Channels

Richard Desantis, APS

A galvanic cell’s electrolyte is an insulator. A conductive electrolyte would quickly discharge a dry cell’s voltage. Voltage-producing paths within an electrolyte can develop spontaneously. A voltage-producing path must bridge from the anode to the cathode, to export voltage out of the insulting electrolyte. Doubling cathode to anode distance does not decrease the cell’s fixed output voltage. The fixed voltage indicates superconductor-like behavior. Gaps between voltage-producing molecules would isolate the anode from the cathode, preventing superconductor-like behavior. Gating activity within membrane protein complexes can prevent or allow voltage-producing paths. A voltage-producing path is a single molecule containing both anode and cathode reactants. Only combined anode-cathode reactions within a single molecule can produce the cell’s fixed exterior voltage. While within the single molecule, atoms can relocate and react. In a lead acid cell, charging voltage raises the molecule’s energy state. The extra energy allows Pb and PbO2 to form during the molecule’s collapse. For discharging, an external circuit provides an outlet for the molecule’s voltage, which lowers the molecule’s energy state to a level that permits PbSO4 production.
that this lack of motion is not due to signal relay. Our results indicate that a quorum sensing mechanism exists which is closely coupled to chemotaxis.

of motion appears unaffected by the formation of streams. At large cell-cell distances cells do not form streams in response to externally applied chemical gradient. Analysis of cell tracks outside and within streams shows that cells do not speed up or slow down when moving as a group. PARENT, National Cancer Institute, NIH, COLIN MCCANN, University of Maryland and NCI — Cell migration up an external chemical gradient is a crucial based on live cell-imaging (J Neurosci. 2007, 27:507, Mol Biol Cell. 2005, 16:4243). We use this model to predict changes in axonal morphology upon local

axonal caliber and as a result, the kinetics of NF movement determines the overall shape of the axon. We developed a kinetic model for movement of NFs at the average slow rate of \(0.5\text{ mm/day}\). Characterized by bursts of movement and extended pauses in between. The local number of NFs determines the local shape, as well as the locations and intensities of certain intracellular signals. We found that when cells undergoing chemokinesis, random migration in response to a chemical signal, are directed off of a cliff, they do not fall off the cliff. Instead, they search for new attachment points, eventually change direction, and continue moving along the edge of the cliff. Both ridges and cliffs affect more than just the motion of a cell; they also affect its shape.

Dictyostelium discoideum

of cellular migration, an important physiological process that occurs in embryonic development, wound healing, and cancer metastasis. We study the motion of \(D.\) discoideum on surfaces with various topographies, particularly those that affect the direction of cellular migration. Topographical features, such as ridges and cliffs, were fabricated using multiphoton absorption polymerization. As the cells encountered these topographical features, we tracked their overall motions and shapes, as well as the locations and intensities of certain intracellular signals. We found that when cells undergoing chemokinesis, random migration in response to a chemical signal, encounter a ridge, they tend to move along that ridge, even if the ridge is shorter than the cell. When cells undergoing chemotaxis, directed migration in response to a chemical signal, are directed off of a cliff, they do not fall off the cliff. Instead, they search for new attachment points, eventually change direction, and continue moving along the edge of the cliff. Both ridges and cliffs affect more than just the motion of a cell; they also affect its shape.

11:27AM W39.00002 Cell migration on ridges and cliffs, MEGHAN DRISCOLL, University of Maryland, COLIN MCCANN, University of Maryland and the National Cancer Institute, National Institutes of Health, RAEL KOPACE, JOHN WATTS, University of Maryland, TESS HOMAN, University of Twente, WOLFGANG LOSERT, University of Maryland — The amoeba \(D.\) discoideum is a model system for the study of cellular migration, an important physiological process that occurs in embryonic development, wound healing, and cancer metastasis. We study the motion of \(D.\) discoideum on surfaces with various topographies, particularly those that affect the direction of cellular migration. 11:39AM W39.00003 ABSTRACT WRITTEN

11:51AM W39.00004 Mutational robustness emerges in a microscopic model of protein evolution¹, KONSTANTIN ZELDOVICH, University of Massachusetts Medical School, EUGENE SHAKHNOCVICH, Harvard University, Department of Chemistry and Chemical Biology — The ability to absorb mutations while retaining structure and function, or mutational robustness, is a remarkable property of natural proteins. We use a computational model of organic evolution [Zeldovich et al, PLOS Comp Biol 3(7):e139 (2007)], which explicitly couples protein physics and population dynamics, to study mutational robustness of evolved model proteins. We compare evolved sequences with the ones designed to fold into the same native structures and having the same thermodynamic stability, and find that evolved sequences are more robust against point mutations, being less likely to be destabilized, and more likely to increase stability upon a point mutation. These results point to sequence evolution as an important method of protein engineering if mutational robustness of the artificially developed proteins is desired. On the biological side, mutational robustness of proteins appears to be a natural consequence of the divergence-mutation- selection evolutionary process.

12:15PM W39.00006 Group behavior in cell migration¹, WOLFGANG LOSERT, University of Maryland, CAROLE PARENT, National Cancer Institute, NIH, COLIN MCCANN, University of Maryland and NCI — Cell migration up an external chemical gradient is a crucial element in many biological processes, such as embryogenesis and cancer metastasis. The aim of our study is to quantify chemotaxis of groups of cells. We find that at high cell densities (i.e. low cell-cell distances) cells migrate together in streams either spontaneously or in response to an externally applied chemical gradient. Analysis of cell tracks outside and within streams shows that cells do not speed up or slow down when moving as a group. In addition the persistence of motion appears unaffected by the formation of streams. At large cell-cell distances cells do not form streams in response to externally applied chemical gradients, and fewer cells move. At very low cell plating density cells are unable to respond to a chemical signal, even close to the signal source. We confirm that this lack of motion is not due to signal relay. Our results indicate that a quorum sensing mechanism exists which is closely coupled to chemotaxis.

1:27PM W39.00010 Effect of Recombination in the Evolutionary Dynamics of HIV under the Surveillance of Immune System. WEIQUN PENG, WENJING YANG, GUANYU WANG, The George Washington University — Human immunodeficiency virus (HIV) is a retrovirus that causes acquired immunodeficiency syndrome (AIDS), which has become one of the most destructive pandemics in history. The fact that HIV evolves very fast plays a central role in AIDS immunopathogenesis and the difficulty we face in finding a cure or a vaccine for AIDS. A distinguishing feature of HIV is its high frequency of recombination. The effect of recombination in the HIV evolution is not clear. We establish a mathematical model of the evolutionary dynamics. This model incorporates both point mutation and recombination for genetic diversity, and employs a fitness function developed by Wang and Deem (PRL 97, 188106, 2006) that accounts for the effect of immune system. Using this model, we explore the role of recombination in the battle between the virus population and the immune system, with a special focus on the condition under which recombination helps the virus population to escape from the immune system.

12:39PM W39.00008 A collective mechanism for phase variation in biofilms1. NICHOLAS CHIA, CARL WOESE, NIGEL GOLDFEN Feld — Understanding how microbes gather into biofilm communities and maintain diversity remains one of the central questions of microbiology, requiring an understanding of microbes as communal rather than individual organisms. Phase variation plays an integral role in the formation of diverse phenotypes within biofilms. We propose a collective mechanism for phase variation based on gene transfer agents, and apply the theory to predict the population structure and growth dynamics of a biofilm. Our results describe quantitatively recent experiments, with the only adjustable parameter being the rate of intercellular horizontal gene transfer. Our approach derives from a more general picture for the emergence of cooperation between microbes.

1:03PM W39.00010 λ-prophage induction modeled as a cooperative failure mode of lytic repression1, NICHOLAS CHIA, University of Illinois at Urbana-Champaign, IDO GOLDING, NIGEL GOLDFEN Feld — We analyze a system-level model for lytic repression of λ-phage in E. coli using reliability theory, showing that the repressor circuit comprises 4 redundant components whose failure mode is prophage induction. Our model reflects the specific biochemical mechanisms involved in regulation, including long-range cooperative binding, and its detailed predictions for prophage induction in E. coli under ultra-violet radiation are in good agreement with experimental data.

1:15PM W39.00011 Statistical Physics of Vaccine Design, MICHAEL DEEM, Rice University — I will define a new parameter to quantify the antigenic distance between two H3N2 influenza strains. I will use this parameter to measure antigenic distance between circulating H3N2 strains and the closest vaccine component of the influenza vaccine. For the data between 1971 and 2004, the measure of antigenic distance correlates better with efficacy in humans of the H3N2 influenza A annual vaccine than do current state of the art measures of antigenic distance such as phylegetic sequence analysis or ferret antisera inhibition assays. I suggest that this measure of antigenic distance can be used to guide the design of the annual flu vaccine. I will describe combining this measure of antigenic distance with a multiple-strain avian influenza transmission model to study the threat of simultaneous introduction of multiple avian influenza strains. For H3N2 influenza, the model is validated against observed viral fixation rates and epidemic progression rates from the World Health Organization FluNet - Global Influenza Surveillance Network. I find that a multiple-component avian influenza vaccine is helpful to control a simultaneous multiple introduction of bird-flu strains. I introduce Population at Risk (Par) to quantify the risk of a flu pandemic, and calculate by this metric the improvement that a multiple vaccine offers.

1:27PM W39.00012 Spatial coordination in membrane proximal signaling in T-cells. MAXIM N. ARTYOMOV, MIESZKO LIS, ARUP CHAKRABORTY, Massachusetts Institute of Technology — Membrane-proximal signaling initiates signaling networks of the T-cell which ultimately lead to the T-cell activation. Signal formation requires assembly of the several membrane proteins and successful cooperative interactions inside the complex. Diffusion and chemical reactions involved in the process are characterized by substantially different timescales. In this work we consider how the reaction-diffusion system described by the wide spectrum of timescales can be selective for the minute amounts of the signal (cognate peptide-MHC complex) over the large amounts of irrelevant targets (non-cognate peptide-MHC complex). Note that single distinction between relevant and irrelevant targets - the affinity to the T-cell receptor, is nonetheless sufficient to discriminate between two groups of targets. Moreover, proposed mechanism allows for signal cooperativity with non-cognate peptides amplifying the signal from cognate ones even though they can not signal by themselves. This kind of cooperativity has been observed in recent experiments.

1:39PM W39.00013 Digital signaling, signal filters and central tolerance in thymocytes, ASHOK PRASAD, MIT, JULIE ZIKHERMAN, UCSF, JAYAJIT DAS, OSU, JEROEN ROOSE, UCSF, ARTHUR WEISS, UCSF and HHI, ARUP CHAKRABORTY, MIT — T cells are characterized by the antigen binding receptors (TCR’s) they bear. TCR’s carried by immature T cells (thymocytes) are made in the thymus by a stochastic process, followed by testing against self-peptides. Thymocytes that do not respond too strongly die through apoptosis (negative selection). We present a new molecular explanation of this phenomenon via a computational model, which we also tested by experiments. We show that Ras activation in thymocytes is characterized by the presence of a digital molecular switch due to a positive feedback loop in a Ras-activating enzyme. We also show how an important adaptor protein, LAT, acts as a filter, sending weak TCR signals along a pathway that leads to Ras activation via a graded mechanism, and sending stronger signals along another path that activates Ras via the molecular switch. Our model yields a new mechanism for digital signaling of the Erk protein in mammalian cells, and has important implications for autoimmunity.

1:51PM W39.00014 A biophysical model of prokaryotic diversity in geothermal hot springs1. SUZANNE AMADOR KANE, ANNA KLALES, JAMES DUNCAN, ELIZABETH JANUS NETT, Physics Department, Haverford College, Haverford PA 19041 — Photosynthetic bacteria living in geothermal hot spring environments have surprisingly complex ecosystems with an unexpected level of genetic diversity. In particular, their thermal gradients support genetically distinct bacterial strains that differ in their preferred temperatures for reproduction and photosynthesis. Each region along the thermal gradient exhibits multiple strains of photosynthetic bacteria adapted to several distinct thermal optima, rather than the expected single thermal strain adapted to the local environmental temperature. Here we analyze microbiology data from several ecological studies to show that the thermal distribution field data exhibit several universal features independent of location and specific bacterial strain. These include the distribution of optimal temperatures of different thermal strains and the functional dependence of the net population density on temperature. We present a simple population dynamics model of these systems that explains the observed diversity of different strains of the photosynthetic bacteria, the observed thermal population distributions and certain features of population dynamics observed in laboratory studies of the same organisms.

2:03PM W30.00015 Understanding Original Antigenic Sin with a Dynamical System. KEYAO PAN, Dept of Bioengineering, Rice Univ, MICHAEL DEEM, Dept of Bioengineering and Physics & Astronomy, Rice Univ — Original antigenic sin is the phenomenon in which prior exposure to an antigen leads to a subsequent suboptimal immune response to a related antigen. Immune memory normally allows for an improved and rapid response to antigens and is the mechanism by which vaccination works. We here develop a dynamical system model of the mechanism of original antigenic sin, clarifying and explaining the detailed spin-glass treatment of original antigenic sin [1]. The dynamical system describes the virus load as it propagates through healthy and infected cells, the naive and memory B cell concentrations, and the affinity of the immune response. Explicit correspondences between the microscopic variables of the spin-glass model and the dynamical system model will be given. The dynamical system model reproduces the phenomenon of original antigenic sin, and describes how competition between different B-cells compromises the overall effect of the immune system. The trade off between the naive and memory immune responses as a function of antigenic distance between the initial and subsequent antigens is displayed. A suboptimal immune response, the original antigenic sin, is observed for intermediate antigenic distances. [1] Deem MW, Lee H-Y. Sequence space localization in the immune system response to vaccination and disease. Phys Rev Lett 2003;91:068101.

11:15AM W40.00000 Crowding Effects on the Unfolding of Ubiquitin1, DAVID PINCUS, Institute For Physical Science and Technology, University of Maryland, DEVARAJAN THIRUMALAI, Director, Biophysics Program, University of Maryland — Using a coarse-grained representation of polypeptide chains, we probed the mechanical stability of Ubiquitin (Ub) monomers and trimers ((Ub)) in the presence of monodisperse spherical crowding agents. Our findings indicate that crowding increases the volume fraction (φc)-dependent average force (⟨f(φc)⟩), relative to the value at φc = 0, needed to unfold Ub and the polypeptide. Furthermore, we found that average unfolding forces increase with decreasing crowder diameter (σc). The average unfolding force (f(φc)) depends on the ratio σc/σ, where D ∝ σc(σc/σ)2 with R Each being the radius of gyration of Ub (or (Ub)) in the unfolded state. Examination of the unfolding pathways shows that, relative to φc = 0, crowding promotes reassociation of ruptured secondary structural elements. Both the nature of the unfolding pathways (f(φc)) for (Ub) are altered in the presence of crowding particles with the effect being most dramatic for the subunit that unfolds last. We predict that (f(φc)) scales in a simple manner with φc.

11:27AM W40.00002 Electron Transfer in Myoglobin-based Single-Electron Transistors1, DEBIN LI, Dept. of Physics, West Virginia University, PETER GANNETT, Basic Pharmaceutical Sciences, West Virginia University, DAVID LEDERMAN, Dept. of Physics, West Virginia University — The mechanism of electron transfer by myoglobin was investigated using nanometer-gap platinum electrodes fabricated by breaking a small junction by electromigration at cryogenic temperatures. The experimental results suggest single electron transport behavior is mediated by resonance of the electronic levels of the heme group in a single myoglobin protein. Evidence for a two-step electron tunneling process, resulting from the structural relaxation of the protein with the addition of a single electron, was observed. Our experimental results show that the slow protein relaxation may result in resonant tunneling and the fast protein relaxation is the condition of two-step resonant tunneling behavior. The conformation and orientation of myoglobin in the gap of electrodes may significantly affect the conductance of these devices. The calculation for the conductance graph as a function of gate voltage and bias voltage was performed with the rate equations for electron tunneling via discrete quantum states and considering the two-step process. The results of calculation match those of our experiment.

11:39AM W40.00003 Surface-enhanced photocycle studied in a single photoreceptor protein molecule, KAAN KALKAN, AIHUA XIE, Oklahoma State University — Photoactive yellow protein (PYP) functions as a blue light sensor for bacterial vision (phototaxis). The photocycle of PYP is initiated by the absorption of a blue photon (absorption peak at 446 nm) by its para-coumaric acid (pCA) chromophore. The photon energy is stored in the pCA through photoisomerization which is subsequently transferred to the rest of the protein through a series of conformational states, finally leading to its partial unfolding (signaling). The present work captures the distinct conformational changes of PYP at the single molecule level, during the execution of its photocycle. In particular, the present work employs surface-enhanced Raman scattering (SERS) active substrates and non-resonant excitation at 514 nm. As we confirm with regular Raman spectroscopy, the photocycle of PYP cannot be excited under 514 nm irradiation. On the contrary, 514 nm photons can excite the photocycle when PYP is adsorbed on silver, as we evidence from single molecule as well as ensemble-averaged SERS. In this case, the optical absorption of PYP shows a dramatic broadening (full width at half maximum shifting from 0.4 to 0.9 eV) such that electronic excitation can occur significantly at 514 nm. Therefore, the origin of the observed “surface-enhanced photocycle” is understood to be of the same as “chemical enhancement” in SERS in view of the “adsorbate-induced resonance states model” (Persson, 1993).

11:51AM W40.00004 Rigidity effects and mechanical unfolding of proteins, OLEG VOROV, DENNIS LIVESAY, DONALD JACOBS, University of North Carolina, Charlotte — We describe a new method that shows promise for evaluating the partition function for a protein under an applied external force within a Distance Constraint Model (DCM). This approach is based on an approximate account for the rigidity effects due to hydrogen bond crosslinking using Maxwell constraint counting. Within a mean-field treatment, the free energy is estimated accurately over an ensemble of accessible conformations conditional upon the breaking of various weakest-link distance constraints, as they successively break due to a series of minu structural transitions. These calculations are performed using an exact transfer matrix approach combined with a combinatorial partitioning of the structure into different parts based on separating lines of unfolding pathways. The various shortest paths over an ensemble of structures that “crack” open in different ways are used to obtain the appropriate Boltzmann weight, related to the work done by the external pulling force. For structures with beta-hairpin geometry, all permutations of unfolding pathways are enumerated exactly. For a simple minimal DCM, results for extension-force curves agree markedly well with experiment.

12:03PM W40.00005 Physical Principles of Virus Templating through Single Molecule Dynamic Force Spectroscopy, RAYMOND FRIDDE, SELIM ELHADJ, GEORGE GILMER, ALEKSANDR NOY, LLLNL, JAMES DE YOREO, Molecular Foundry, LBNL — The use of macromolecular scaffolds for hierarchical organization of molecules and materials is a common strategy in living systems that leads to emergent behavior. One characteristic of this strategy is that it generates micron-scale structures from nm-scale building blocks, possessing high-density functionality, defined at angstrom-scales by active sites; a typical example being viral capsids. We are systematically determining the physical variables necessary to consistently pattern virus particles on to nanoscale templates. This presentation will focus on our theoretical and experimental findings regarding our Dynamic force spectroscopy (DFS) measurements; a technique in which fundamental parameters related to interaction potentials can be determined. Here we present a novel theory for determining kinetic desorption rates and equilibrium free energies using DFS in which two well-defined states exist. We compare the results with force spectra measured between individual MS2 virions and chemically modified AFM tips. We also investigate the effects of solution additives, such as PEG, on microscopic kinetics and free energies. Finally, we discuss the relation of single-molecule measurements with the ensemble, and show a connection between the two in the case of biomolecular dissociation.
12:15PM W40.00006 Probing Protein Folding Kinetics with High-resolution, Stabilized Optical Tweezers. WESLEY WONG, KEN HALVORSEN, Harvard University — Single-molecule techniques provide a powerful means of exploring molecular transitions such as the unfolding and refolding of a protein. However, the quantification of bi-directional transitions and near-equilibrium phenomena poses unique challenges, and is often limited by the detection resolution and long-term stability of the instrument. We have developed unique optical tweezers methods that address these problems, including an interference-based method for high-resolution 3D bead tracking (≈ 1 nm laterally, ≈ 0.3 nm vertically, at > 100 Hz), and a continuous autofocus system that stabilizes the trap height to within 1-2 nm long-term [1,2]. We have used our instruments to quantify the force-dependent unfolding and refolding kinetics of single protein domains (e.g. spectrin in collaboration with E. Evans). These single-molecule studies are presented, together with the accompanying probabilistic analysis that we have developed. References: 1. W.P. Wong, V. Heinrich, E. Evans, Mat. Res. Soc. Symp. Proc., 790, P5.1-P5.10 (2004). 2. V. Heinrich, W.P. Wong, K. Halvorsen, E. Evans, Langmuir, 24, 1194-1203 (2008).

12:27PM W40.00007 Electrostatic signatures of single protein dynamics for detection with carbon nanotube sensors. G. SCHNEIDER, L. PRISBREY, E. MINOT, Oregon State University — Observing single molecule dynamics in real time at atomic resolution is crucial to study enzyme function, which is closely linked to the intrinsic dynamics of the enzyme and molecular interactions between enzyme and substrate. At present, techniques such as nuclear magnetic resonance (NMR) and single molecule fluorescence energy transfer (FRET) are used together with computer simulations to study single molecule dynamics. Recent progress in point-functionalization of single wall carbon nanotube (CNT) opens the possibility of electronic detection of single molecule dynamics [2]. CNTs are ideal candidates for electronic sensing of single protein dynamics. Typical CNT diameters are 1-2 nm, comparable to both the size of proteins in solution and the electrostatic screening length in physiological solutions. CNT sensors based on point defects have potential advantages over FRET including better time resolution. We report results for the electrostatic signature of several proteins in solution, both in substrate free and bound forms, and discuss the potential for electronic detection of biologically relevant single protein dynamics using functionalized carbon nanotubes.

12:39PM W40.00008 Experimental Investigation of the Velocity Convergence of Jarzynski’s Equality Using Single-Molecule AFM Pulling of Titin I27. NOLAN HARRIS, CHING-HWA KIANG, Rice University, Physics and Astronomy Department, Houston, TX 77005 — Single molecule atomic force microscopy (AFM) of individual biomolecules allows one to observe high energy conformations and transitions between equilibrium states that are not otherwise observable. Jarzynski’s equality has been used to extract important equilibrium information, such as free energy surfaces, from these nonequilibrium AFM measurements. However, the convergence behavior of Jarzynski’s equality, i.e. the number of AFM trajectories required to adequately sample the nonequilibrium work distribution of a process, depends nontrivially on the AFM pulling schedule. Here we study the velocity dependent nature of Jarzynski’s equality in AFM experiments. We reconstructed the free energy surfaces for the forced unfolding of the I27 domain of human cardiac titin via AFM using different pulling velocities. We found that the number of experimental trajectories required for convergence of Jarzynski’s equality increases roughly exponentially as experimental pulling velocity is increased. We suggest optimal pulling velocities for pulling titin I27 and discuss the obstacles involved with using extreme pulling velocities.

12:51PM W40.00009 Real Time Single Molecule Imaging of Protein-Surface Interactions. SHANNON KIAN G. ZAREH, SHAWN H. DECENTZO, Y.M. WANG, Washington University in St.Louis, USA 63130 — We study the dynamics of the adsorption of protein to surfaces using real time Total Internal Reflection Fluorescence microscopy (TIRF). We have observed two mechanisms responsible for protein adsorption on surfaces: Reversible and Irreversible binding. The reversible binding occurs on the deposition step induced by the initial deposition flow, and the reversible binding is the equilibrium binding between the proteins and the surfaces. Our study has shown that the irreversible binding is the main contribution to the surface adsorption of proteins. We will discuss the energy for GFP and fused-silica surface interaction, and also a method to prevent protein adsorption onto surfaces.

1:03PM W40.00010 Single molecule image deconvolution. I. Standard deviation analysis of immobile fluorescent molecules. MICHAEL C. DESANTIS, SHAWN H. DECENTZO, Y.M. WANG, Washington University, St. Louis, MO — Single molecule fluorescence imaging has been a powerful technique in studying individual processes not accessible by bulk, ensemble-averaged measurements [1]. Improvements in image analysis are required for high temporal and spatial precision in the localization of single fluorescent molecules. We present the first thorough standard deviation analysis for point spread functions (PSFs) of single immobile fluorescent molecules. Using this new single molecule image deconvolution (SMID) method, we show that 3D localization of individual molecules with sub-nanometer precision can be achieved. We have derived an expression estimating the standard error of the PSF’s standard deviation, incorporating experimental effects of the number of collected photons, finite pixel size, and background noise. The localization precision obtained via this expression is approximately 1.5 times better than the current available methods. The use of SMID to extract subexposure dynamics of mobile molecules will also be discussed.

1:15PM W40.00011 Monte Carlo simulation of single-molecule trapping via electrophoresis. WILLIAM ROBINSON, LLOYD DAVIS, UTSI — For many biophysical studies, there is a need to observe a molecule for an extended duration without immobilizing it on a surface. The problem of trapping a single fluorescent molecule in solution is examined here via Monte Carlo numerical simulation. Optical forces are insufficient for trapping small molecules. Instead, trapping is executed by sensing the position and applying real-time feedback of flow to compensate diffusional displacement. Using a nanochannel as the volume of interest reduces the problem to one dimension, and with such a configuration the position of the molecule can be measured from its fluorescence in the presence of a two-focus irradiance pattern. The collected photons are analyzed by an algorithm developed previously. Two stable trajectories are obtained, indicating that the molecule is immobilized on a surface without photobleaching. Preliminary results and further applications will be presented.

1:27PM W40.00012 Sub-diffraction limit differentiation of single fluorophores using Single Molecule Image Deconvolution (SMID). SHAWN H. DECENTZO, MICHAEL C. DESANTIS, Y. M. WANG, Department of Physics Washington University, St. Louis Missouri, 63130 USA — In order to better understand biological systems, researchers demand new techniques and improvements in single molecule differentiation. We present a unique approach utilizing an analysis of the standard deviation of the Gaussian point spread function of single immobile fluorescent molecules. This technique, Single Molecule Image Deconvolution (SMID), is applicable to standard TIRF instrumentation and standard fluorophores. We demonstrate the method by measuring the separation of two Cy3 molecules attached to the ends of short double-stranded DNA immobilized on a surface without photobleaching. Preliminary results and further applications will be presented.
1:39PM W40.00013 Selection of optimal variants of Go-like models of proteins through studies of stretching, JOANNA SULKOWSKA, Center of Theoretical Biological Physics, Department of Physics, UCSD, and Institute of Physics Polish Academy of Science, Poland, MAREK CIEPLAK, Institute of Physics Polish Academy of Science, Al. Lotnikow 32/48, Warsaw, Poland — The Go-like models of proteins are constructed based on the knowledge of the native conformation. However, there are many possible choices of a Hamiltonian for which the ground state coincides with the native state. Here, we propose to use experimental data on protein stretching to determine what choices are most adequate physically. This criterion is motivated by the fact that stretching processes usually start with the native structure, in the vicinity of which the Go-like models should work the best. Our selection procedure is applied to 62 different versions of the Go model and is based on 28 proteins. We consider different potentials, contact maps, local stiffness energies, and energy scales — uniform and non-uniform. In the latter case, the strength of the nonuniformity was governed either by specificity or by properties related to positioning of the side groups. Among them there is the simplest variant: uniform couplings and no i + 2 contacts. This choice also leads to good folding properties in most cases. We elucidate relationship between the local stiffness described by a potential which involves local chirality and the one which involves dihedral and bond angles. The latter stiffness improves folding but there is little difference between them when it comes to stretching.

1:51PM W40.00014 Discontinuities at the DNA supercoiling transition, BRYAN DANIELS, SCOTT FORTH, MAXIM SHEININ, MICHELLE WANG, JAMES SETHNA, LASSP, Cornell University — While slowly turning the ends of a single molecule of DNA at constant applied force, a discontinuity was recently observed at the supercoiling transition, when a small plectoneme is suddenly formed. This can be understood as an abrupt transition into a phase in which stretched and plectonemic DNA coexist. We argue that there should be discontinuities in both the extension and the torque at the transition, and provide experimental evidence for both. To predict the sizes of these discontinuities and how they change with the overall length of DNA, we organize a theory for the coexisting plectonemic state in terms of four length-independent parameters. We also test plectoneme theories, including our own elastic rod simulation, finding discrepancies with experiment that can be understood in terms of the four coexisting state parameters.

2:03PM W40.00015 Pressure-driven single-file transport of DNA molecules along linear arrays of nanopits embedded in a slit-like nanochannel,1, JACKSON DEL BONIS-O’DONNELL, WALTER REISNER, Brown University, ANDERS KRISTENSEN, Technical University of Denmark, DEREK STEIN, Brown University — Due to the growth in nanobiofluidic technology for DNA manipulation and analysis, there is a growing interest in understanding the physics of DNA in nanoconfined environments. Using fluorescence video microscopy we study the transport of DNA in slit-like nanochannels with an embedded nanotopology consisting of linear arrays of nanopit structures. The nanopit structures are made via a two level fabrication process: (1) An e-beam lithography and etching step to make the nanopits followed by (2) a photolithography step to fabricate the slit. Under an applied pressure drop the DNA molecules are observed to move single-file down the nanopit array undergoing sequential pit-to-pit hops. We make systematic measurements of pressure dependent nanopit velocity. We observe two distinct transport regimes depending on whether the molecule configuration can occupy a single pit or must subdivide multiple pits. We interpret our results in terms of a simple scaling picture of the free energy of chains in the linear array.

Thursday, March 19, 2009 11:15AM - 1:51PM — Session W41 DCMP: Kondo Physics; Dynamical Mean-Field Theory 413

11:15AM W41.00001 The 2d Kondo effect in p-type Quantum Wells in GaAs, THEODORE CASTNER, University of Rochester — Two groups [Huang et al. [1] and Hamilton et al. [2]] have observed minima in the resistivity \( \rho(T) \) at very low T well below \( \rho_{\text{max}} \) at \( T_{\text{max}} \) in metallic samples (\( p > p_c \)). Minima in [1] were found at 32 mK for \( p \sim 2.1 \) mK, 25 mK for \( p \sim 1.76 \) mK, while no minimum was observed down to 0.5 mK for \( p \sim 1.24 \) mK. Both groups have interpreted their results in terms of a crossover to insulating (nonmetallic) behavior for \( T < T_{m} \) where \( dp/dT < 0 \). An alternative explanation arises from a 2d Kondo effect. Using the Hamann function [3] for the magnetic scattering contribution from localized magnetic moments and a term \( m(1/CT)F(p) \) from screening interactions one obtains an expression for \( T_{\text{m}}(p) \) which is very close to the Kondo temperature \( T_{K}(p) \) given by \( (E_{F}/k)\exp(-1/N(E_F)) \). The very strong p-dependence of \( T_{\text{m}}(p) \) and \( T_{K}(p) \) is dominated by \( N(E_F) \) which is shown to approach zero as \( p \) approaches \( p_c \) because of the pseudogap in the DOS. Good agreement is obtained \( T_{\text{m}}(p) \) for both [1] and [2]. The data in [1] supports metallic behavior down to 0.5 mK. The implications for a 2d MIT as a QPT are discussed.

11:27AM W41.00002 Quantum phase transition in the XY-anisotropic Bose-Fermi Kondo model, MENGXING CHENG, KEVIN INGERSENT, University of Florida — Using the numerical renormalization group, we study the quantum phase transition induced by dissipation in the XY-anisotropic Bose-Fermi Kondo model for a spin-one-half magnetic impurity coupled both to the on-site spin of a conduction electron band and, via its x and y spin components, to a bath of vector bosons. We focus on the case of a sub-Ohmic bath characterized by a power-law spectral exponent \( s < 1 \). Upon increasing the coupling of the impurity to the bosonic bath (at fixed fermionic coupling), the system exhibits a continuous quantum phase transition from a Kondo-screened ground state to a state in which the impurity moment is localized by the dissipation. We probe the quantum-critical behavior in the vicinity of this transition through the calculation of critical exponents describing the static and dynamical response to a local magnetic field both at absolute zero and at finite temperatures. Critical comparisons are made with analytical renormalization-group results obtained previously through expansion around the Ohmic case \( s = 1 \).

11:39AM W41.00003 ABSTRACT WITHDRAWN

11:51AM W41.00004 Validity of Equation-of-Motion Approach to Kondo Problem in the Large N limit, YUNONG QI, Texas Center for Superconductivity, University of Houston, JIAN-XIN ZHU, Theoretical Division, Los Alamos National Laboratory, CHIN-SEN TING, Texas Center for Superconductivity, University of Houston — The Anderson impurity model for Kondo problem is investigated for arbitrary orbit-spin degeneracy \( N \) of the magnetic impurity by the equation of motion method (EOM). By employing a new decoupling scheme, a set self-consistent equations for the one-particle Green function are derived and numerically solved in the large-\( N \) approximation. For the particle-hole symmetric Anderson model with finite Coulomb interaction \( U \), we show that the Kondo resonance at the impurity site exists for all \( N \geq 2 \). The approach removes the pathology in the standard EOM for \( N = 2 \), and has the same level of applicability as non-crossing approximation. For \( N = 2 \), an exchange field splits the Kondo resonance into only two peaks, consistent with the result from more rigorous numerical renormalization group (NRG) method. The temperature dependence of the Kondo resonance peak is also discussed.

1 We here should give special thanks to Shufeng Zhang and R. C Albers for useful discussions. This work was supported by the Robert Welch Foundation No. E-1146 at the University of Houston (Y.Q. and C.S.T.), by U.S. DOE under Contract No. DE-AC52-06NA25396.
12:03PM W41.00005 Evolution of a Large Fermi Surface in the Kondo Lattice  . JUNYA OTSUKI, Tohoku University, HIROAKI KUSUNOSE, Ehime University, YOSHIO KURAMOTO, Tohoku University — We investigate the Kondo lattice model with use of the continuous-time quantum Monte Carlo method, combined with the dynamical mean-field theory. The antiferromagnetic phase diagram is determined from a divergency of the corresponding susceptibility [1]. In the paramagnetic phase, crossover behavior is traced quantitatively to a heavy Fermi-liquid state from the local-moment state at high temperatures [2]. The momentum distribution in the low-temperature limit acquires a discontinuity at the location that involves the local-spin degrees of freedom. Even without the charge degrees of freedom for local electrons, the excitation spectra exhibit hybridized bands similar to those in the Anderson lattice. Temperature dependence in the zero-energy component of the self-energy is crucial in forming the Fermi-liquid state with the large Fermi surface. [1] J. Otsuki, H. Kusunose and Y. Kuramoto, arXiv:0808.3829; arXiv:0811.1102. [2] J. Otsuki, H. Kusunose and Y. Kuramoto, arXiv:0811.2613 to appear in Phys. Rev. Lett.

12:15PM W41.00006 A linear in $\beta$ solver for Cluster Dynamical Mean Field Theory . EHSAN KHATAMI, MARK JARRELL, University of Cincinnati, CHE-RUNG LEE, National Tsing Hua University, RICHARD SCALETTRAR, University of California, Davis — We develop a Quantum Monte Carlo (QMC) cluster solver for the Dynamical Cluster Approximation (DCA) which scales linearly in the inverse temperature, $\beta$, and has the same minus sign problem as conventional methods. Determinantal QMC (DQMC) used in this method is modified by adding non-interacting bands to mimic the coupling to the host. The DCA hybridization function is fitted to the non-interacting band parameters. We prove that the sign problem has the same statistics as in the Hirsch-Fye (HF) algorithm in the limit of a large number of bath bands ($N_b$). Whereas the HFQMC scales as $\beta^3$, this DQMC-based method scales linearly in $\beta$. We demonstrate rapid convergence of the sign to the HF result for different cluster sizes and model parameters as $N_b$ increases. We also present results for the convergence of other physical quantities to their HFQMC counterparts. This method can be used to solve other embedded cluster problems including those in Dynamical Mean Field Theory (DMFT), and cellular DMFT.

12:27PM W41.00007 The relationship between Hirsch-Fye and weak coupling diagrammatic Quantum Monte Carlo methods . KARLIS MIKELSONS, ALEXANDRU MACRIDIN, University Of Cincinnati, MARK JARRELL, Rutgers University — Two weak coupling Continuous Time Quantum Monte Carlo (CTQMC) methods are shown to be equivalent for Hubbard-like interactions. A relation between these CTQMC methods and the Hirsch-Fye Quantum Monte Carlo (HFQMC) method is established, identifying the latter as an approximation within CTQMC and providing a diagrammatic interpretation of HFQMC. Both HFQMC and CTQMC are shown to be equivalent when the number of time slices in HFQMC becomes infinite, implying the same degree of fermion sign problem in this limit.

12:39PM W41.00008 Cluster Dynamical Mean Field Theory of the Mott Transition . HYOWON PARK, KRISTJAN HAULE, GABRIEL KOTLIAR, Rutgers University — We address the nature of the Mott transition in the Hubbard model at half-filling using cluster dynamical mean field theory (DMFT). We compare cluster DMFT results with those of single site DMFT. We show that inclusion of the short range correlations on top of the on-site correlations does not change the order of the transition between the paramagnetic metal and the paramagnetic Mott insulator, which remains first order. However, the short range correlations reduce substantially the critical $U$ and modify the shape of the transition line. Moreover, they lead to very different physical properties of the metallic and insulating phases near the transition point. Approaching the transition from the metallic side, we find an anomalous metallic state with very low coherence scale. The insulating state is characterized by the narrow Mott gap with pronounced peaks at the gap edge.

12:51PM W41.00009 Nearly frozen Coulomb liquids . YOHANES PRAMUDYA, SERGEY PANKOV, Florida State University, National High Magnetic Field Laboratory, EFFRATIOS MANOUSAKIS, Florida State University, MARTECH, VLADIMIR DOBROSavljevic, Florida State University, National High Magnetic Field Laboratory — We show that very long range repulsive interactions of a generalized Coulomb-like form $V(R) \sim R^{-\alpha}$, with $\alpha < d$ (d-spatial dimensionality), typically introduce very strong frustration, resulting in extreme fragility of any charge-ordered state. An “almost frozen” liquid then survives in a broad dynamical range above the (very low) melting temperature $T_c$. Using a combination of extended dynamical mean-field theory [1] and Monte Carlo simulations we study classical lattice gas models with such long range interaction, focusing on the behavior at $T > T_c$. We find that a soft, temperature-dependent pseudo-gap emerges in this regime, reflecting strong short-range correlations that persist above the melting temperature. This “pseudo-gap” phase is characterized by unusual insulating-like, but very weakly temperature dependent transport, similar to experimental findings [2] in many low carrier density systems. [1] S.Pankov and V. Dobrosavljevic, Phys. Rev. Lett. 94, 046402 (2005). [2] K. Lai, W. Pan, D. C. Tsui, S. Lyon, M. Muhlbberger, and F. Schaffler, Phys. Rev. B 75, 033314 (2007).

1:03PM W41.00010 Quantum criticality out of equilibrium: Thermopower and shot noise in a ferromagnetic single electron transistor . JEDEDIAH PIXLEY, STEFAN KIRCHNER, QIMIAO SI, Rice University — The low-energy properties of a single electron transistor attached to ferromagnetic leads are described by the Bose-Fermi Anderson model. This model can undergo a continuous phase transition and it was shown in [1] that the transistor can be tuned through this quantum phase transition. The out-of-equilibrium scaling properties near the quantum critical point and in the adjacent phases of the spin and charge response and their fluctuation-dissipation ratios were recently studied in [2]. In this contribution, we study the thermopower and shot noise, which probe the quantum criticality in a way that goes beyond the current-voltage characteristics. The thermoelectric properties of a quantum dot in the Kondo regime can be directly measured [3]. Bulk thermopower measurements of heavy fermion compounds near their quantum critical point and in the adjacent phases of the spin and charge response and their fluctuation-dissipation ratios were recently presented (2005). We find an anomalous metallic state with very low coherence scale. The insulating state is characterized by the narrow Mott gap with pronounced peaks at the gap edge.

1:15PM W41.00011 Mottness scenario for non-Fermi liquid behavior in the periodic Anderson model within dynamical mean-field theory . GIOVANNI SORDI, ADRIANO AMARICCI, MARCELO ROZENBERG, Laboratoire de Physique des Solides, CNRS-UMR8502, Université de Paris-Sud, Orsay 91405, France — We study the Mott metal-insulator transition in the periodic Anderson model within dynamical mean-field theory (DMFT). Near the quantum transition, we find a non-Fermi liquid metallic state down to a vanishing temperature scale. We identify the origin of the non-Fermi liquid behavior as due to magnetic scattering of the doped carriers by the localized moments. The non-Fermi liquid state can be tuned by either doping or external magnetic field. Our results show that the coupling to spatial magnetic fluctuations (absent in DMFT) is not a prerequisite to realize a non-Fermi liquid scenario for heavy fermion systems. Refs: Phys. Rev. Lett. 99, 196403 (2007); Phys. Rev. Lett. 101, 146403 (2008).
1:27PM W41.00012 Percolation transition in nanowire magnetorheological fluids1. JOSH KARLI, DARIN ZIMMERMAN, JOSEPH FILER, RICHARD BELL. The Pennsylvania State University, Altoona, NORMAN WERELEY, The University of Maryland — We measure the yield stress of magnetorheological (MR) fluids that employ cobalt nanowires as the ferromagnetic component and observe a percolation transition in the yield stress at a critical value of the cobalt-nanowire volume fraction, \( p_c \). The critical volume fraction depends not only on the particle size and aspect ratio (as expected) but also on the external magnetic field applied to the MR-fluid sample. We fit the yield-stress data using McLachlan’s generalized effective medium (GEM) model to determine \( p_c \) and the percolation exponents \( x \) and \( t \) that describe the transition behavior below and above \( p_c \), respectively. The phase transition from low- to high-yield stress at low magnetic-particle volume fraction (< 1%) has potential application to the development of precision magnetic sensors and actuators.

1:39PM W41.00013 Anderson localization transition in thin films of gadolinium1. R. MISRA, A.F. HEBARD, K.A. MUTTALIB, University of Florida, Gainesville, FL-32611, USA, P. WOELFLE, ITKMI, University of Karlsruhe, Germany — In situ temperature-dependent transport studies have been performed on a series of gadolinium (Gd) films deposited onto sapphire substrates having sheet resistance \( R_0 \equiv R_{xx}(5K) \) varying over the range 4011 \( \Omega \) (∼35Å) to 132 KΩ (∼20 Å). The disorder strength, as measured by \( R_0 \), is sufficiently high so that quantum corrections to the classical Boltzmann conductivity are no longer observed. In this region of moderately strong disorder, we find a temperature-dependent conductivity of the form \( \sigma(T) = A + BT^p \) where \( A \) and \( B \) are disorder-dependent constants and \( p \) is a power with value 0.4. We find that \( A \) is proportional to \((1-R_0/R_c)^{-t} \) where the conductivity exponent \( s = -1 \) and the critical resistance \( R_c = 22.7 \Omega \). This change in sign of \( A \) with unity exponent at critical disorder describes the critical regime of an Anderson localization transition[1] with the temperature-dependent localization length sufficiently small so that the Gd films can be considered to be in the 3D regime, rather than the 2D regime where metallic behavior does not occur [2]. [1] Lee & Ramakrishnan, RMP 57, 287 (1985); Belitz & Kirkpatrick, RMP 66, 261 (1994) [2] Abrahams, Anderson, Licciardello & Ramakrishnan, PRL 42, 673 (1979)
4:18PM X1.00004 Effect of pair-breaking on superconductivity and on persistent currents well above the transition temperature, L. Bulaevskii (LANL), U. Welp, C. Kurter, K. Gray (MSD, ANL), L. Ozyuzer (Izmir Institute of Technology, Turkey), K. Kadowaki

We study the low temperature phase diagram of the vortex matter in the high-T_c superconductor Bi_2Sr_2CaCu_2O_8+δ. By employing vortex shaking the vortex system is relaxed towards the equilibrium state. We thus reveal a novel second-order glass transition, manifested by a sharp reversible kink in the measured local magnetization. The glass line bisects the first-order melting line close to its extremum below which disorder is dominant. Consequently, the phase diagram consists of four thermodynamic phases: At high fields, above the melting line, we find amorphous vortex glass and liquid phases; Surprisingly, at low fields the glass transition separates between a low-temperature Bragg glass and a thermally depinned variant of it - possibly a perfect lattice. Studying the oxygen doping dependence of the vortex phase diagram we unexpectedly find that the novel low-temperature glass transition, along which quenched disorder should play a dominant role, has the same anisotropy dependence as that of the high-temperature melting line, where disorder is negligible. Finally, we utilize an indirect measurement technique to reconstruct the low-temperature I-V characteristics in the region which is inaccessible by transport measurements. At high temperatures the bulk resistance is of a thermally activated flux flow with linear I-V both in the liquid phase above the melting line as well as below it within the ordered phase. At lower temperatures, on approaching the glass transition, the temperature dependence of the bulk resistance becomes much sharper. This deviation from a simple Arrhenius behavior tracks the glass line, and may signify criticality.

4:54PM X1.00005 Paramagnetic or diamagnetic persistent currents? A topological point of view, Xavier Waintal, SPEC, CEA Saclay — A persistent current flows at low temperatures in small conducting rings when they are threaded by a magnetic flux. I will discuss the sign of this persistent current (diamagnetic or paramagnetic response) in the special case of N electrons in a one dimensional ring. One dimension is very special in the sense that the sign of the persistent current is entirely controlled by the topology of the system. I will establish lower bounds for the free energy in the presence of arbitrary electron-electron interactions and external potentials. Those bounds are the counterparts of upper bounds derived by Leggett using another topological argument. Rings with odd (even) numbers of polarized electrons are always diamagnetic (paramagnetic).

The situation is more interesting with unpolarized electrons where Leggett upper bound breaks down: rings with N = 4n exhibit either paramagnetic behavior or a superconductor-like current-phase relation. The topological argument provides a rigorous justification for the phenomenological Huckle rule which states that cyclic molecules with 4n ± 2 electrons like benzene are aromatic while those with 4n electrons are not.

2:30PM X2.00001 Thermodynamics and Flow of the Vortex Matter at the Second-Order Glass Transition in Bi_2Sr_2CaCu_2O_8+x, HAIM BEIDENKOPF, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel — We study the low temperature phase diagram of the vortex matter in the high-T_c superconductor Bi_2Sr_2CaCu_2O_8. By employing vortex shaking the vortex system is relaxed towards the equilibrium state. We thus reveal a novel second-order glass transition, manifested by a sharp reversible kink in the measured local magnetization. The glass line bisects the first-order melting line close to its extremum below which disorder is dominant. Consequently, the phase diagram consists of four thermodynamic phases: At high fields, above the melting line, we find amorphous vortex glass and liquid phases; Surprisingly, at low fields the glass transition separates between a low-temperature Bragg glass and a thermally depinned variant of it - possibly a perfect lattice. Studying the oxygen doping dependence of the vortex phase diagram we unexpectedly find that the novel low-temperature glass transition, along which quenched disorder should play a dominant role, has the same anisotropy dependence as that of the high-temperature melting line, where disorder is negligible. Finally, we utilize an indirect measurement technique to reconstruct the low-temperature I-V characteristics in the region which is inaccessible by transport measurements. At high temperatures the bulk resistance is of a thermally activated flux flow with linear I-V both in the liquid phase above the melting line as well as below it within the ordered phase. At lower temperatures, on approaching the glass transition, the temperature dependence of the bulk resistance becomes much sharper. This deviation from a simple Arrhenius behavior tracks the glass line, and may signify criticality.

3:06PM X2.00002 Nanomechanics of Individual, Isolated Vortices in a Cuprate Superconductor, KATHRYN MOLER, Stanford University — No abstract available.

3:42PM X2.00003 Structure and stability of dynamic coherent states in intrinsic Josephson-junction stacks, ALEXEI KOSHELEV*, Materials Science Division, Argonne National Laboratory — Intrinsic Josephson-junction stacks are realized in mesas fabricated out of high-temperature superconductors. Phase oscillations in different junctions can be synchronized via coupling to the intrinsic cavity mode leading to powerful electromagnetic radiation in terahertz frequency range. As homogeneous oscillations do not couple directly to the cavity modes, the mechanism of mode excitations is a nontrivial issue. New inhomogeneous dynamic state providing such coupling has been demonstrated recently. In this state, the stack spontaneously splits into two subsystems with different phase-oscillation patterns. The phase shift between the oscillations in the two subsystems depends on the order parameter and on the external fields. The formation of this state can be used for efficient pumping of the energy into the cavity resonance. We will also discuss (i) stability of coherent states (ii) synchronization in inhomogeneous mesas, and (iii) mechanisms of damping of the resonance mode.

[4] In collaboration with L. Bulaevskii (LANL), U. Welp, C. Kurter, K. Gray (MSD, ANL), L. Ozyuzer (Izmir Institute of Technology, Turkey), K. Kadawaki (Tsukuba University, Japan)

This work was supported by the U. S. DOE, Office of Science, under contract # DE-AC02-06CH11357.
Radiation is the frequency, \( f \), of the radiation depends strongly on the shape and the size of the mesa. In the case of rectangular shape it follows the relation, \( f = c/(2\pi n) \), where \( c \) is the velocity of light in vacuum, \( n \) the refractivity of the superconductor and \( w \) the width of the mesa (shorter edge dimension), while it only depends on the radius \( a \) in the case of cylindrical mesa. Higher harmonics are also observed. Another stringent requirement for the radiation is the uc-Josephson effect, which must be fulfilled in each junction with the same frequency determined by the equation: \( fh = 2eV/n = 2e\nu_o \), where \( V \) is the voltage across the whole junction, \( N \) the number of junctions involved in the mesa, \( \nu_o \) the voltage appearing between each junctions, \( h \) the Planck constant, \( e \) the elementary charge. Since the radiation is monochromatic, \( \nu_o \) must be identical and synchronized coherently in all junctions in the mesa. A simple phenomenological interpretation of this synchronization is that it may occur due to the cavity resonance effect inside the mesa. The peculiar temperature dependence and the anisotropic directivity of radiation power observed experimentally may give a hint to understand the mechanism of such synchronized THz radiation from intrinsic Josephson junctions. We think that nonlinearity to be inherent in the Josephson junction as well as thermal nonequilibrium effect plays a crucial role for the synchronized THz oscillation. A more detailed view for the mechanism based on the experimental results will be presented.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X3 DCMP: Spin Hall and Quantum Spin Hall Effects 301/302

2:30PM X3.00001 Imaging electrical spin generation and spin Hall dynamics in semiconductors1, N.P. STERN2, Center for Spintronics and Quantum Computation, University of California, Santa Barbara, CA 93106 — The capability to generate and manipulate spin polarization through the spin-orbit interaction drives interest in all-electrical techniques to exploit electron spins for semiconductor spintronics. The spin Hall effect refers to the generation of a pure spin current transverse to a charge current, resulting in a spontaneous spin accumulation near sample boundaries without the need for magnetic fields or materials. Recent experiments toward imaging this electrically generated spin polarization with both spatially and temporally resolved Kerr rotation microscopy in bulk zincblende semiconductors are discussed. Both current-induced in-plane spin accumulation and out-of-plane spin accumulation from the spin Hall effect are observed in ZnSe up to room temperature3. In GaAs devices, spatially resolved measurements of steady-state spin Hall accumulation and associated modeling clarify the important role of drift and diffusion in transporting spins generated at sample boundaries to the device interior4. In these typical optical experiments, electrically-generated spin accumulation is measured using steady-state techniques that do not directly observe dynamics at timescales important for device operation. Here we discuss a time- and spatially-resolved measurement of the spin Hall effect using a pulsed current to drive spin accumulation5. The dynamical processes of spin accumulation and diffusion reveal spatially-dependent nanosecond timescales comparable to the electric-field dependent spin coherence time. A time-dependent decomposition analysis reconciles the observed spatial and temporal dynamics of spin accumulation from the spin Hall effect in one coherent picture.

3:06PM X3.00002 The quantum spin Hall effect and the topological magneto-electric effect . SHOUCHENG ZHANG, Stanford University — Search for topologically non-trivial states of matter has become a important goal for condensed matter physics. Recently, a new class of topological insulators has been proposed. These topological insulators have an insulating gap in the bulk, but have topologically protected edge states due to the time reversal symmetry. In two dimensions the edge states give rise to the quantum spin Hall (QSH) effect, in the absence of any external magnetic field. I shall review the theoretical prediction1 of the QSH state in HgTe/CdTe semiconductor quantum wells, and its recent experimental observation2. The QSH effect can be generalized to three dimensions as the topological magneto-electric effect (TME) of the topological insulators3. I shall also present realistic experimental proposals to observe fractional charge5, spin-charge separation and the deconfinement of the magnetic monopoles in these novel topological states of matter.

3:42PM X3.00003 Experimental observation of the quantum spin Hall state in HgTe quantum wells . LAURENS MOLENKAMP, Würzburg University — Spin-orbit interaction in semiconductors causes many interesting and potentially useful transport effects, such as e.g. the presently very topical spin-Hall effect1. So far no direct evidence for a ballistic, intrinsic SHE (i.e. resulting from the band structure) has been obtained by transport experiments. Here, we demonstrate that in specially designed nanostructures2, which are based on narrow gap HgTe type-III quantum wells, a detection of the spin signal is possible via non-local voltage measurements. Recently, it was pointed out that such HgTe quantum wells, that exhibit an inverted band structure where the ordering of electron- and hole-like states is interchanged, are topologically non-trivial insulators3, in which the quantum spin Hall insulator state4 should occur. In this novel quantum state of matter, a pair of spin polarized helical edge channels develops when the bulk of the material is insulating, leading to a quantized conductance. I will present transport data provide very direct evidence for the existence of this third quantum Hall effect: when the bulk of the material is insulating, we observe a quantized electric conductance5. Finally, we demonstrate how a combination of the techniques used in the above experiments allows us to verify that the transport in the quantum spin Hall insulator state indeed occurs through spin-polarized helical edge channels.

4:18PM X3.00004 Theory of Topological Insulators, LIANG FU, University of Pennsylvania — Topological insulators are materials with a bulk excitation gap generated by the spin orbit interaction, and which are different from conventional insulators. This distinction is characterized by $Z_2$ topological invariants, which characterize the ground state. In two dimensions a single $Z_2$ invariant describes the quantum spin Hall insulator phase. In three dimensions there are four $Z_2$ invariants, distinguishing “weak” (WTI) and “strong” (STI) topological insulators. The STI phase is characterized by the presence of unique gapless surface states whose Fermi surface encloses an odd number of 2D Dirac points. We will argue theoretically that the semiconducting alloy Bi$_{1-x}$Sb$_x$ is a strong topological insulator — a prediction that has recently been confirmed experimentally. We will next show that the proximity effect between this unique surface phase and an ordinary superconductor leads to a two dimensional state that resembles a spinless $p_+ + i p_-$ superconductor, but does not break time reversal symmetry. This state supports zero energy Majorana bound states at vortices, and may provide a new venue to realize proposals for topological quantum computing.

4:54PM X3.00005 Observation of a New Topological Phase of Quantum Matter: Quantum Hall-like Effect without Magnetic Field1. M. ZAHID HASAN, Department of Physics, Princeton University — Most quantum states of condensed-matter are categorized by the spontaneously broken symmetries. The remarkable discovery of charge quantum Hall effects (1980s) revealed that there exists an organizational principle of matter based not on the spontaneously broken symmetry but only on the topological distinctions in the presence of time-reversal symmetry breaking. In the past few years, theoretical developments suggest that new classes of topological states of matter might exist that are purely topological in nature in the sense that they do not break time-reversal symmetry hence can be realized without any applied magnetic field. Quantum Hall-like effects without magnetic field. In this presentation, I report a series of experimental results documenting and demonstrating the existence of such a topologically ordered time-reversal-invariant state of matter and discuss the exotic electromagnetic and spin properties this novel phase of quantum matter might exhibit and outline their potential use.

Thursday, March 19, 2009 2:30PM - 5:30PM – Session X4 DPOLY: Responsive Gels at Surfaces and in the Bulk 306/307

2:30PM X4.00001 Global Signaling of Localized Impact in Chemo-responsive Gels, ANNA BALAZS, University of Pittsburgh — A vital function performed by skin is to send a chemical alarm signal throughout the system in response to irritation or damage. Using our recently developed 3D model for chemo-responsive gels, we design a coating that can perform an analogous, biomimetic function. Our system consists of a polymer gel undergoing the Belousov-Zhabotinsky (BZ) reaction. We show that such coatings respond to a spatially localized mechanical force by exhibiting a range of signaling behavior. For example, an initially stationary gel can emit transient waves in response to a sufficiently weak, localized impact. A stronger localized impact, however, can generate a global signal, which encompasses both chemical waves and surface ripples that propagate across the entire sample. This complex dynamical response persists even after the force is lifted. Furthermore, the spatial patterns formed by these oscillating gels reveal the location and magnitude of the applied force. Our findings open up the possibility of harnessing BZ gels for a range of applications, such as creating sensors that transmit a global signal in response to a local mechanical impact.

3:06PM X4.00002 Volume-Phase Transitions and Swelling Instabilities in Surface-Tethered Responsive Gels, RYAN TOOMEY, University of South Florida — Responsive polymer hydrogels have opened exciting opportunities for breathable structures that adopt to environmental cues. Such structures can be designed from a variety of chemical motifs that endow specific response behavior at the material level. Moreover, mechanically pinning a responsive gel to a surface presents further opportunities for designing specific shape-volument transitions due to swelling-induced deformations that arise within confined structures. We present a simple technique for fabricating responsive polymer networks based on copolymers comprising the photocross reactive methacryloyloxybenzophenone (MaBP). This approach permits the synthesis of photo-cross-linkable polymers that are easily patterned with thicknesses down to 80 Angstroms. Using a combination of neutron reflection, QCM- D, and ATR-FTIR, we have mapped the volume-phase behavior of ultra-thin layers of responsive networks as a function of chemical functionality, cross-link density, and thickness. Interestingly enough, neutron reflection reveals diffuse interfaces at the periphery of surface-attached networks that grow with the degree of swelling, pointing to surface fluctuations that result from biaxial compression. Finally, confocal microscopy has been used to map three-dimensional swelling in patterned structures revealing swelling instabilities from surface undulations to macroscopic buckling depending on the aspect ratio of the pattern.

3:42PM X4.00003 Supramolecular Gels in the Bulk and at Surfaces1 , STEPHEN CRAIG, Duke University — Responsive gels might be broadly classified into two groups: those in which the material response is mediated by a phase transition involving the cooperative behavior of many molecules, or molecule moieties, together, and those in which the material response is dictated by the behavior of individual molecular components acting independently of each other. This talk will discuss the properties of supramolecular gels as a representative of the latter class of responsive materials. In the context of this talk, supramolecular gels are solvent-swollen polymer networks in which the connections between polymer chains that define the network are due to specific, directional, and reversible 1:1 interactions between molecular partners. In such cases, the properties of the network are responsive to the same stimuli that influence the reversible interaction between the molecular partners. The magnitude and sensitivity of stimulus-responsiveness in supramolecular gels is greatest in the vicinity of the gel point, and the characteristics of the sol-gel phase transition will be described for a family of coordinatively cross-linked poly(4-vinylpyridine) (PVP) organogels. It will be shown that the cross-linking interaction can have profound effects on the mechanical properties of similar, surface-bound networks prepared from end-grafted PVP.

1Support from NSF CHE-0646670 is gratefully acknowledged.

4:18PM X4.00004 Photoresponsive Polymers: Converting Light to Mechanical Work, RICHARD A. VAIA, Air Force Research Laboratory — The ability to remotely control the creation of mechanical work, rapidly, with high spatial precision, and over long distances, offers many intriguing possibilities. Whether driving direct conformational changes, initiating reversible chemical reactions to release stored strain, or converting the photon to a local temperature increase, combinations of photoactive units, nanoparticles, ordered mesophases and polymeric networks are providing an expansive array of photo-responsive polymer options. By combining these material responses with kinematic concepts, mechanical devices can be demonstrated that exhibiting tunable and controllable macroscopic deformation, high-frequency oscillation or directional motion. Specifically, we will discuss recent investigation of liquid crystal polymer networks containing main chain and pendant azobenzene moieties (azo-LCN) with modulus ~1.35GPa that are actuated at the absorptive overlap of the cis and trans confirmers (442 nm). Cantilevers and unconstrained beams of these azo-LCNs can be controlled by polarization angle of the source, as well as by a specific optical exposure history (on-off), with responses ranging from lateral motion to oscillations in excess of 30Hz. These phenomena reflect an underlying interaction between the mesophase order, the network architecture and kinematic constraints of the exposed material. In collaboration with Timothy Bunning, Timothy White, Hilmar Koerner, Air Force Research Laboratory; and Nelson Tabiryan, BEAM Co.

4:54PM X4.00005 3D Microfabrication of responsive protein gels, JASON SHEAR, The University of Texas at Austin — No abstract available.
2:30PM X5.00001 Collective dynamics of rigid and deformable self-propelled particles1, ARSHAD KUD RollI, Department of Physics, Clark University, Worcester, MA 01610 — We discuss a series of experiments with granular matter with novel shapes which self-organize upon excitation. Previously, we reported experiments with rigid rod shaped particles with asymmetric mass distributions which show directed motion on a vibrated plate [1]. Recognizing that such a system is a simple physical model of self-propelled particles, we discuss the observed collective behavior such as aggregation at the boundaries and swirling motion in the context of various minimal leaderless models of active living systems such as bacterial colonies and hoofed animal herds which show self-organization. We will introduce and discuss the dynamics of deformable shapes consisting of a head and a tail composed of a bead chain which is shown to undergo directed motion because of differential friction associated with the head and the body. [1]: “Swarming and swirling in self-propelled granular rods,” A. Kudrolli, G. Lumay, D. Volfson, and L. Tsimring, Phys. Rev. Lett. 100, 058001 (2008).

3:06PM X5.00002 Three dimensional reconstruction of starling flocks: an empirical investigation of collective animal behavior, IRENE GIARDINA, CNR-INFM — Bird flocking is a striking example of animal collective behaviour: thousands of birds gather above the roosting site, forming sharp-bordered flocks, which wheel and turn with remarkable coherence and synchronization. Despite an increasing theoretical interest, empirical investigations of collective motion have been limited so far by the difficulties of getting data on large systems. By means of stereoscopic photography and using statistical mechanics, optimization theory and computer vision techniques, we have measured for the first time the three-dimensional positions and trajectories of individual birds in groups of up to three thousands elements. This allowed us to analyze global morphological properties of the flocks, as well as structural and dynamical properties. Most notably, we investigated the nature of the inter-individual interaction. We found that the interaction between birds does not depend on their mutual metric distance, as most current models and theories assume, but rather on the topological distance (number of intermediate neighbors). In fact, we discovered that each individual interacts on average with a fixed number of neighbors (six-seven), rather than with all neighbors within a fixed metric distance. We argue that a topological interaction of this kind is indispensable to maintain flock’s cohesion against the large density changes caused by external perturbations, typically predation. More recently, we characterized the velocity field, and computed dynamical observables. We showed that flocks exhibit long range correlations, which are a signature of their remarkable collective behavior.

3:42PM X5.00003 Self Propelled Particles: from microdynamics to hydrodynamics1, APARNA BASKARAN, Syracuse University — In this talk I will illustrate the derivation of a unified continuum description of the large scale collective behavior of active matter from two specific physical microscopic dynamical models: stroke-averaged swimmers moving through a viscous fluid and self-propelled hard rods moving on a substrate. New results at large scales include a lowering of the density of the isotropic-nematic transition, an enhancement of longitudinal diffusion of the self-propelled orientable units, and a strong enhancement of boundary effects in confined self-propelled systems.

4:18PM X5.00004 Active biopolymer gels: from cells to tissues1, GIJSJE KOENDERINK, FOM Institute AMOLF — Living cells are active soft materials that are far out of thermodynamic equilibrium. They continuously use up chemical energy in order to generate forces that drive processes such as cell migration and division. Moreover, cells actively remodel their surrounding extracellular matrix (primarily collagen), so whole tissues can also be regarded as active soft materials. The aim of our research is to understand the physical mechanisms underlying the self-organization and mechanics of cells and tissues. To this end we use an experimental approach and study simplified model systems for the cytoskeleton (purified actin, tubulin, and accessory proteins) and for tissues (fibroblast-populated collagen and fibrin gels). We use microscopy and rheology to investigate the structure and mechanics on different length scales, from the single protein up to macroscopic level. I will discuss two examples of active mechanical behavior, namely in purified actin-myosin networks, and in purified fibrin matrices embedded with contractile fibroblasts. In both cases we observe active contraction and active stiffening. We quantify the active forces and examine how the structure and mechanics of the active gels depend on motor/cell density.

4:54PM X5.00005 Beller Lectureship Talk: Active response of biological cells to mechanical stress, SAMUEL SAFFRAN, Dept. Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel 76100 — Forces exerted by and on adherent cells are important for many physiological processes such as wound healing and tissue formation. In addition, recent experiments have shown that stem cell differentiation is controlled, at least in part, by the elasticity of the surrounding matrix. We present a simple and generic theoretical model for the active response of biological cells to mechanical stress. The theory includes cell activity and mechanical forces as well as random forces as factors that determine the polarizability that relates cell orientation to stress. This allows us to explain the puzzling observation of parallel (or sometimes random) alignment of cells for static and quasi-static stresses and of nearly perpendicular alignment for dynamically varying stresses. In addition, we predict the response of the cellular orientation to a sinusoidally varying applied stress as a function of frequency and compare the theory with recent experiments. The dependence of the cell orientation angle on the Poisson ratio of the surrounding material distinguishes cells whose activity is controlled by stress from those controlled by strain. We have extended the theory to generalize the treatment of elastic inclusions in solids to "living" inclusions (cells) whose active polarizability, analogous to the polarizability of non-living matter, results in the feedback of cellular forces that develop in response to matrix stresses. We use this to explain recent observations of the non-monotonic dependence of stress-fiber polarization in stem cells on matrix rigidity. These findings provide a mechanical correlate for the existence of an optimal substrate elasticity for cell differentiation and function.

Session X5 GSNP: Active Soft Matter: From Granular Rods to Flocks to Living Cells 401/402

Thursday, March 19, 2009 2:30PM - 5:30PM —
Session X6 DCOMP: Rahman Prize Lecture and Theory of Multiferroics 406
in vivo extrinsic and intrinsic nucleosome positioning signals. In order to see the relative importance of such signals for nucleosome positioning, currently available bioinformatics methods for predicting nucleosome positions are trained on sequence data and are thus unable to distinguish between long-range interactions. Hence, much of what we know about spin glasses and related systems comes from numerical simulations on simplified models. In this talk I will describe some of the challenges in performing reliable spin glass simulations. Then I will discuss several questions concerning phase transitions in spin glasses and related systems that have been addressed by simulations in recent years including (i) whether there is universality, (ii) whether there is a "vortex glass" transition in a disordered type-II superconductor in a magnetic field, (iii) whether "chiralities" play a crucial role in Heisenberg spin glasses, and (iv) whether there is a line of transitions (AT line) in a magnetic field.

3:06PM X6.00002 Superexchange-driven Magnetoelectricity in Magnetic Vortices, KRIS DELANEY, UCSC — We demonstrate that spins in topologically frustrated antiferromagnetic systems can form periodic arrays of magnetic vortices with symmetry allowing for a linear magnetoelectric response. Realization of this magnetic structure can be provided by transition-metal oxides with a layered Kagomé lattice. In such systems, an appropriately structured lattice leads to a microscopic coupling between spins and polar lattice distortions via Anderson superexchange, which has the potential to provide a large magnetoelectric response. In order to quantitatively probe the strength of the magnetoelectric coupling, we have performed density functional theory calculations in the presence of an applied electric field (using linear response) for hexagonal manganites. We demonstrate that the coupling is large and summarize the challenges for achieving such a response in real materials.

3:42PM X6.00003 First-Principles Approach to Lattice-Mediated Magnetoelectric Effects¹, JORGE IFÍGUEZ, Institut de Ciencia de Materiales de Barcelona (CSIC) — I will present a microscopic theory of the magnetoelectric response of an insulator, and derive from it an analytical expression for the lattice-mediated part of the effect. As I will show, such a result provides us with distinct hints at strategies to increase the magnitude of the response, as well as with a convenient method for performing first-principles calculations. I will illustrate the usefulness of the proposed approach with applications to Cr₂O₃, a model magnetoelectric crystal, and BiFeO₃ and related compounds, the best studied, and arguably most technologically promising, family of multiferroics. Ref.: J. Ifiguez, Phys. Rev. Lett. 111, 117201 (2008).

1Work funded by FP6-STRREP MaCoMuFi.

4:18PM X6.00004 First-principles Study of Improper Ferroelectricity in TbMnO₃, ANDREI MALASHYEVICh, Rutgers University — Perovskite TbMnO₃ at room temperature forms an orthorhombically distorted lattice with the Pnma space group. Below ~27 K the magnetic moments on the Mn atoms adopt an incommensurate cycloidal wave order, and simultaneously a polarization appears along the c direction. We present the results of our first-principles theoretical study of the magnetically induced polarization in TbMnO₃ with a commensurate cycloidal wave of Mn³⁺ moments with a wave-vector close to the experimental value.¹ The calculations are based on density-functional theory in the local-density approximation with the on-site Coulomb correction (LDA+U). The polarization is computed using the Berry-phase technique. We show, in particular, that the spin-orbit interaction is essential for the magnetoelectric coupling. We compute both the electronic and the lattice-mediated contributions to the polarization, and find that the latter is strongly dominant. We analyze the spin-orbit induced forces and lattice displacements from both atomic and mode-decomposition viewpoints, and show that a simple model based on nearest Mn-Mn neighbor Dzyaloshinskii-Moriya interactions is not able to account fully for the results. The direction and magnitude of our computed polarization are in good agreement with experiment. If time permits, calculations on other magnetically induced improper ferroelectrics will be discussed.

1Work supported by NSF grant DMR-0549198

4:54PM X6.00005 Density functional study of the spin exchange interactions, magnetic structures, and ferroelectric polarizations of multiferroics driven by magnetic order, MIKE WHANGBO, North Carolina State University — The electronic structures of magnetic insulators LiCuVO₄, LiCuO₂, TbMnO₃, Ca₃CoMnO₇, MnWO₄, CuFeO₂, Ba₂CoGe₂O₇ and CuBr were examined on the basis of first principles DFT+U+SOC calculations to evaluate their spin exchange parameters and account for their ordered magnetic structures. We then explored how the electric polarizations of these compounds are related to the magnetic ordering and spin-orbit coupling. In this talk results of our studies will be presented.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X7 DBP: DNA Loop Formation, Nucleosome Positioning and Transcriptional Regulation

2:30PM X7.00001 Statistical mechanics of chromatin: Inferring free energies of nucleosome formation from high-throughput data sets¹, ALEXANDRE MOROZOv, Department of Physics & Astronomy, Rutgers University — Formation of nucleosome core particles is a first step towards packaging genomic DNA into chromosomes in living cells. Nucleosomes are formed by wrapping 147 base pairs of DNA around a spool of eight histone proteins. It is reasonable to assume that formation of single nucleosomes in vitro is determined by DNA sequence alone: it costs less elastic energy to wrap a flexible DNA polymer around the histone octamer, and more if the polymer is rigid. However, it is unclear to which extent this effect is important in living cells. Cells have evolved chromatin remodeling enzymes that expend ATP to actively reposition nucleosomes. In addition, nucleosome positioning on long DNA sequences is affected by steric exclusion — many nucleosomes have to form simultaneously without overlap. Currently available bioinformatics methods for predicting nucleosome positions are trained on in vivo data sets and are thus unable to distinguish between extrinsic and intrinsic nucleosome positioning signals. In order to see the relative importance of such signals for nucleosome positioning in vivo, we have developed a model based on a large collection of DNA sequences from nucleosomes reconstituted in vitro by salt dialysis. We have used these data to infer the free energy of nucleosome formation at each position along the genome. The method uses an exact result from the statistical mechanics of classical 1D fluids to infer the free energy landscape from nucleosome occupancy. We will discuss the degree to which in vitro nucleosome occupancy profiles are predictive of in vivo nucleosome positions, and will estimate how many nucleosomes are sequence-specific and how many are positioned purely by steric exclusion. Our approach to nucleosome energetics should be applicable across multiple organisms and genomic regions.

3:06PM X7.00002 to be determined by you, LAURA FINZI, Emory University — No abstract available.
3:42PM X7.00003 Interconvertible Lac Repressor–DNA Loops Revealed by Single-Molecule Experiments, MARTIN GUTHOLD, Wake Forest University — At many promoters, transcription is regulated by simultaneous binding of a protein to multiple sites on DNA, but the structures and dynamics of such transcription factor-mediated DNA loops are poorly understood. We directly examined in vitro loop formation mediated by E. coli lactose repressor using single-molecule structural and kinetics methods. Small (150 bp) loops form quickly and stably, even with out-of-phase operator spacings. Unexpectedly, repeated spontaneous transitions between two distinct loop structures were observed in individual protein–DNA complexes. The results imply a dynamic equilibrium between a novel loop structure with the repressor in its crystallographic “V” conformation and a second structure with a more extended linear repressor conformation that substantially lessens the DNA bending strain. The ability to switch between different loop structures may help to explain how robust transcription regulation is maintained even though the mechanical work required to form a loop may change substantially with metabolic conditions.

4:18PM X7.00004 The Energy Landscape of Hyperstable LacI-DNA Loops, JASON KAHN, Chem. and Biochem., Univ. Maryland College Park — The Escherichia coli LacI protein represses transcription of the lac operon by blocking access to the promoter through binding at a promoter-proximal DNA operator. The affinity of tetrameric LacI (and therefore the repression efficiency) is enhanced by simultaneous binding to an auxiliary operator, forming a DNA loop. Hyperstable LacI-DNA loops were previously shown to be formed on DNA constructs that include a sequence-directed bend flanked by operators. Biochemical experiments showed that two such constructs (9C14 and 11C12) with different helical phasing between the operators and the DNA bend form different DNA loop shapes. The geometry and topology of the loops and the relevance of alternative conformations suggested by probable flexible linkers in LacI remain unclear. Bulk and single molecule fluorescence resonance energy transfer (SM-FRET, with D. English) experiments on a dual fluorophore-labeled 9C14-LacI loop demonstrate that it adopts a single, stable, rigid closed-form loop conformation. Here, we characterize the LacI-9C14 loop by SM-FRET as a function of inducer isopropyl-β-D-thiogalactoside (IPTG) concentration. Energy transfer measurements reveal partial but incomplete destabilization of loop formation by IPTG. Surprisingly, there is no change in the energy transfer efficiency of the remaining looped population. Models for the regulation of the lac operon often assume complete disruption of LacI-operator complexes upon inducer binding to LacI. Our work shows that even at saturating IPTG there is still a significant amount of LacI-DNA complexes in a looped state, in accord with previous in vivo experiments that show incomplete induction (with J. Maher). Finally, we will report progress on characterizing the “energy landscape” for DNA loop switching upon systematic variation of the DNA linkers between the operators and the bending locus. Rod mechanics simulations (with N. Perkins) provide testable predictions on loop stability, topology, and FRET.

4:54PM X7.00005 Mechanics of Protein-Mediated DNA Looping, JENS-CHRISTIAN MEINERS, University of Michigan — The formation of looped DNA-protein complexes in which a protein or protein assembly binds to multiple distant operator sites on the DNA is a common feature for many regulatory schemes on the transcriptional level. In a living cell, a multitude of mechanical forces and constraints act on these complexes, and it is imperative to understand their effects on biological function. For this aim, we study the lactose repressor as a model system for protein-mediated DNA looping in single-molecule experiments. Using a novel axial constant-force optical trapping scheme that allows us to manipulate sub-micron DNA fragments with well-controlled forces down to the 10 fN range, we show that mechanical tension in the substrate DNA of hundred femtonewton is sufficient to disrupt the loop formation process, which suggests that such mechanical tension may provide a mechanical pathway to controlling gene expression in vivo. From the force sensitivity of the loop formation process, we can also infer the topology of the looped complex; in our case an antiparallel conformation. In addition, we will present new tethered-particle microscopy data that shows lifetimes of the looped complexes that are two to three orders of magnitude shorter than those measured in biochemical competition assays and discuss possible interpretations, including the suggestion that operator binding of the lactose repressor tetramer leads to a destabilization of the dimer-dimer interface and that thus the loop breakdown process is mostly a dissociation of the tetramer into two dimers, instead, as widely assumed, an unbinding of the tetramer from the DNA.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X8 FHP: 50 Years of Anderson Localization 414/415

2:30PM X8.00001 Anderson localization in the seventies and beyond, DAVID THOULESS, University of Washington — Little attention was paid to Anderson’s challenging paper on localization for the first ten years, but from 1969 onwards it generated a lot of interest. Around that time a number of challenging questions were raised by the community, on matters such as the existence of a sharp distinction between localized and extended states, or between conductors and insulators. For some of these questions the answers are unambiguous. There certainly are energy ranges in which states are exponentially localized, in the presence of a static disordered potential. In a one-dimensionnal potential all states are localized. There is clear evidence, in three dimensions, for energy ranges in which states are extended and diffusive. Magnetic and spin-dependent interactions play an important part in reducing localization effects. For massive particles like electrons and atoms the lowest energy states are localized, but for massless particles like photons and acoustic phonons the lowest energy states are extended. In a one-dimensional disordered system all states are localized. Uncertainties remain. Scaling theory shows that in two-dimensional systems all states are weakly localized, and that there is no minimum metallic conductivity. The interplay between disorder and mutual interactions is still an area of uncertainty, which is very important for electronic systems. Optical and dilute atomic systems provide experimental tests which allow interaction to be much less important. The quantum Hall effect provided a system where states on the Fermi surface are localized, but non-dissipative currents flow in response to an electric field.

3:06PM X8.00002 Tests of Localization in Metals and Semiconductors, ROBERT DYNES, University of California San Diego — The metal-Insulator transition has been a subject of study for decades. It is now well known that entering the critical region of the transition the characteristics of a highly correlated system dominate. The dimensionality of the system is also very important. In this talk I will reminisce about the concepts and experiments to test models, explore systems, and investigate the role of dimensionality. Mott’s concept of a minimum metallic conductivity drove my own thinking until the landmark paper of Abrahams, Anderson, Licciardello and Ramankrishnan. A series of careful experiments testing the notions of weak localization followed this paper and provided critical tests of the concept. I will describe some of those experiments and the things we learned from this work.

3:42PM X8.00003 Anderson Localization of Light, MORDECHAI SEGEV, Technion - Israel Institute of Technology — Photonic lattices are excellent model systems for studying wave localization due to disorder. The recent progress on Anderson Localization of light will be reviewed, including the additional effects of nonlinearity, with an emphasis on the universal features common to all wave systems in nature.

4:18PM X8.00004 Anderson Localization and Mesoscopics, IGOR LERNER, University of Birmingham, B15 2TT, United Kingdom — I will review certain trends developed within the last thirty years of research on Anderson Localization with emphasis on the description of the Anderson transition in terms of the entire distribution function of the conductance mesoscopic fluctuations, and on the role of electron-electron interactions.
4:54PM X8.00005 Direct observation of Anderson localization of matter-waves in an optical disorder1, ALAIN ASPECT, Institut d’Optique and CNRS — In 1958, P.W. Anderson predicted the localization1 of electronic wave functions in disordered crystals, and the resulting absence of diffusion. It has been realized later that Anderson Localization is ubiquitous in wave physics2, and this has prompted an intense activity to observe it with light, microwaves, sound waves, and electron gases, but to our knowledge there was no direct observation of exponential spatial localization of matter-waves (electrons or others). We have observed directly3 exponential localization of the wave function of ultracold atoms released into a one-dimensional waveguide in the presence of a controlled disorder created by laser speckle. We will present this work, and the prospects of extending that experimental scheme to quantum gases in higher dimensions (2D and 3D), and with controlled interactions. We will also discuss its significance in the rapidly growing field of quantum simulators.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X9 GSNP: Focus Session: Jamming: Theory and Experiment II 303

2:30PM X9.00001 Jamming in Vibrated Granular Systems1, BRIAN UTTER, James Madison University — Granular materials exist all around us, from avalanches in nature to the mixing of pharmaceuticals, yet the behavior of these “fluids” is poorly understood. Their flow can be characterized by the continuous forming and breaking of a strong force network resisting flow. This jamming/unjamming behavior is typical of a variety of systems, including granular flows, and is influenced by factors such as grain packing fraction, applied shear stress, and the random kinetic energy of the particles. I’ll present experiments on quasi-static shear and free-surface granular flows under the influence of external vibrations. By using photoelastic grains, we are able to measure both particle trajectories and the local force network in these 2D flows. We find through particle tracking that dense granular flow is composed of comparable contributions from the mean flow, affine, and non-affine deformations. During shear, sufficient external vibration weakens the strong force network and reduces the amount of flow driven by interfaces. In a rotating drum geometry, large vibrations induce failure as might be expected, while small vibration leads to strengthening of the pile. The avalanching behavior is also strongly history dependent, as evident when the rotating drum is driven in an oscillatory motion, and we find that sufficient vibration erases the memory of the pile. These results point to the central role of the mobilization of friction in quasi-static granular flow.

3:06PM X9.00002 Scaling of Foam Flows near Jamming, MARTIN VAN HECKE, ERIK WOLDHUIS, BRIAN TIGHE, Leiden University, JORIS REMMERS, Eindhoven University, WIM VAN SAARLOOS, Leiden University — We probe the scaling behavior of flows near the jamming transition of soft, viscous discs in a variant of the well known bubble-model for foams, where we assume that the viscous forces between contacting bubbles scale with the relative velocity with an adjustable exponent α. This allows us to explore the non-trivial dependence of global flow exponents on the local exponent α. Even though we find that elastic stresses dominate the global stresses in the system, the exponent α which governs the sub-dominant viscous interactions still sets the global scaling exponents.

3:18PM X9.00003 ABSTRACT WITHDRAWN —

3:30PM X9.00004 Rheology of Soft Suspensions near Jamming1, KERSTIN NORDSTROM, EMLIE VERNEUIL, PAULO ARRATIA, University of Pennsylvania, JERRY GOLLUB, Haverford College, DOUGLAS DURIAN, University of Pennsylvania — The rheology of a suspension of soft colloidal particles is investigated using a pressure-driven flow in a deep 25 μm wide microchannel. The system is composed of N-isopropylacrylamide (NIPA) colloidal microgel particles, suspended in aqueous solution. NIPA is temperature-sensitive in that the hydrodynamic radius decreases rapidly with an adjustable exponent

α

. The largest event and number of events increase roughly linearly with the system width L for L varying from 25 to 400 particle diameters. Increasing

3:54PM X9.00006 Density of states in two-dimensional colloidal system, KE CHEN, ZEXIN ZHANG, PETER YUNKER, ARJUN YODH, Department of Physics and Astronomy, University of Pennsylvania — The vibrational density of states (VDOS) of particles in a two-dimensional binary colloidal system was investigated using video microscopy. Our ultimate goal is to explore how the VDOS varies near the jamming transition [1]. Various distributions of NIPA particles, whose diameters can be tuned by small temperature variations, were loaded into parallel-plate microscope cells, and their motions tracked with video microscopy. This approach permits in-situ observation over a wide range of particle packing fractions, from colloidal fluids to colloidal glasses. A search for excess VDOS at low frequencies in colloidal glass is ongoing. 1. N. Xu, M. Wyart, A. J. Liu, and S. R. Nagel, Phys. Rev. Lett. 98, 175502 (2007) This work is supported by NSF DMR-080488, MRSEC DMR-0520020.
4:06PM X9.00007 Applying the model of Soft Glassy Rheology to slowly driven dense granular matter\(^1\), DAPENG BI, BULBUL CHAKRABORTY, Brandeis University — In recent work by S. Henkes and B. Chakraborty (PRL 95, 198002 (2005)), a new statistical framework is proposed to describe static granular packings. In this framework, stress replaces energy as the conserved quantity and fluctuations in the stress are controlled by a quantity analogous to the thermodynamic temperature. We adapt this framework in the quasi-static limit and the model of Soft Glassy Rheology (P. Sollich, PRE 78, 2020 (1997)) to describe the rheological behavior of slowly driven dense granular matter. The model explains the experimental observation of R. P. Behringer et al. (Nature 421, 928 (2003)). We will describe ongoing efforts to apply this model to different scales of slowly driven granular media, and to relate the model to critical dynamics in other driven random media.

\(^1\)Work supported by NSF-DMR 0549762

4:18PM X9.00008 Theory of random packings, HERNAN MAKSE, City College of New York, CHAOMING SONG, PING WANG — We present a theory of random packings to describe the statistical mechanics of jammed matter with the aim of shedding light to the long-standing problem of order and long-range correlations in random jammed packings. We present a new statistical framework where state relations are determined by a conserved stress and fluctuations in the stress. We will compare our results to a number of systems for which we have high-quality measurements of their static and dynamical properties.

4:30PM X9.00009 Dense packings of hard tetrahedra, AMIR HAJI AKBAR, University of Michigan, Ann Arbor, XIAOYU ZHENG, Kent State University, ROLFE PETSCHER, Case Western Reserve University, PETER PALFFY-MUHORAY, Kent State University, SHARON GLOTZER, University of Michigan, Ann Arbor — The densest packing of tetrahedra remains an unsolved problem, and there has been much recent debate. We simulate dense packings of mathematically smooth, hard regular tetrahedra using NPT Monte Carlo simulations and determine the density-pressure equation of state. We find disordered packings with densities that significantly exceed the hard-sphere FCC packing density of 0.74084090. Our findings thus demonstrate that tetrahedra obey Ulam’s conjecture that spheres pack with a lower maximum packing density than any other hard convex object, despite recent conjecture to the contrary. The dense packings that we have found do not seem to be crystalline but are instead dense random packings. We show that the system is able to achieve such high packing densities by the local ordering of tetrahedra into certain favorable motifs, forming larger structures that pack efficiently but are overall jammed. We speculate that one or several denser crystalline packings exist.

4:42PM X9.00010 ABSTRACT WITHDRAWN

4:54PM X9.00011 Continuous Geometric Families of Mechanically Stable Particle Packings, GUOJIE GAO, Dept. of Mechanical Engineering, Yale University, JERZY BLAWZDZIEWICZ, COREY O’HERN, Dept. of Mechanical Engineering & Dept. of Physics, Yale University — We have performed numerical simulations of quasi-static shear flow of soft disks at zero pressure to generate mechanically stable (MS) packings as a function of applied shear stress/strain in small 2D systems ranging from 4 to 20 disks. In systems composed of frictionless disks, we find that at any given shear strain, there are a finite number of discrete MS packings characterized by the positions of all particles. In contrast, there are an infinite number of MS packings during continuous shear flow that form a finite geometric families (characterized by the network of interparticle contacts) as a function of shear strain. We count the number of geometric families and measure their length in strain as a function of system size. In particular, we will determine whether the MS packings at finite shear have different structural and mechanical properties from those at zero shear. We also study the effects of friction on MS particle packings. In contrast to frictionless MS packings, frictional packings form continuous geometric families even at a zero shear strain.

5:06PM X9.00012 Mechanically Stable Packings of Spherocylinders\(^1\), TIMOTHY GREEN, SCOTT FRANKLIN, RIT — Piles of long, thin rods are substantially more stable to perturbations than those of ordinary sand or rice. We generate 3d mechanically stable packings of spherocylinders by alternately enlarging particles (with an elastic repulsive interaction) and using a conjugate gradient minimization of the total elastic energy. The minimum stable packing is defined as the least dense packing for which the minimum energy is non-zero, and we investigate the average contact number, the spectrum of vibrational modes in the dynamical matrix, and other properties of this critical packing. We also test whether spherocylinders obey the isostatic conjecture, which states that the average contact number at ϕc is twice the number of degrees of freedom (for spherocylinders, 5). Spherocylinders’ straight edges, compared with the convex sides of ellipsoids, puts the isostatic conjecture in jeopardy, perhaps requiring a greater number of contacts to maintain stability.

\(^1\)Funded with support from the National Science Foundation (DMR-0706353)

5:18PM X9.00013 On the study of force-balance percolation, J. M. SCHWARZ, Syracuse University, M. JENG, Microsoft Corporation — We study models of percolation where there are constraints on the occupation of sites that mimic force-balance, i.e. for a site to be stable (remain occupied) requires occupied neighboring sites in all four compass directions in two dimensions. We prove rigorously that ϕc < 1 for the two-dimensional models studied. Numerical data indicate that the force-balance percolation transition is discontinuous with a growing crossover length, and the two-dimensional percolation model, but with the same underlying mechanisms causing the transition in both cases. In other words, force-balance percolation and jamming percolation may indeed belong to the same universality class. We find a lower bound for the correlation length in the connected phase and that the correlation function does not appear to be a power law at the transition. Finally, we study the dynamics of the culling procedure invoked to obtain the force-balance configurations and measure a dynamical exponent similar to that found in sandpile models.

Thursday, March 19, 2009 2:30PM - 5:18PM —
Session X10 DCMP: Insulators and Dielectrics: Defects, Structure, and Mechanical and Dynamical Properties 304

2:30PM X10.00001 Dynamics of implant damage as a precursor to nanocrystal nucleation, MATTHEW J. BECK, SOKRATES T. PANTELIDES, Vanderbilt University — Ion implantation into a-SiO\(_2\) leads to the self-assembly of metal or semiconductor nanocrystal arrays having applications in optical and non-volatile memory devices. The production of uniform arrays of similarly-sized nanocrystals within the a-SiO\(_2\) matrix has been shown to depend strongly on nucleation conditions. Here we report results of quantum mechanical calculations probing the atomic-scale dynamics in the first few nanoseconds following low-energy (RCP) and high-energy (RLP) implantation. We show that low-energy (with KE<100 eV) implants produce individual, isolated defects in the a-SiO\(_2\) structure, but rather produce nanoscale defect pockets. These defect pockets are sources for oxygen out-diffusion, and subsequently represent seed regions for nanocrystal nucleation.
JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The development of gate-stack structures for novel CMOS applications has

2:42PM X10.00002 Optical Emission from F2 (CN−) centers in CsCl1 JOSEPH WEST, Indiana State University, RICHARD DALLINGER, Wabash College, RYAN LIDSTER, Indiana State University — Strong, previously unreported, emission from at least two different excited electronic states of F2 (CN−) centers in CsCl has been measured following excitation at 532 nm, 514 nm and 568 nm. The temperature dependence of emission at 532 nm was obtained over the temperature range of 16K through 160K. No emission under excitation at 633 nm was detected. The presence of emission following excitation at the higher energies, but absent under 633 nm excitation, may suggest that the well-known energy transfer process from the electronic excited F-center states to the vibrational CN− energy levels in this system occurs from a single common relaxed excited electronic state associated with the absorption band at 633 nm.

1 Prepared by LLNL under Contract DE-AC52-07NA27344

2:54PM X10.00003 Ab-Initio investigation of defects in GaTe1, CEDRIC ROCHA LEAO, VINCENZO LORDI, Lawrence Livermore National Lab — Materials that are good candidates for room-temperature radiation detectors should ideally possess several characteristics that are somewhat contradictory. A higher mobility-lifetime product is required to maximize the collection of radiation generated charge, but a relatively large bandgap is desired to minimize thermal noise. High resistivity is usually also desired, to reduce background current which degrades the detection resolution. Furthermore, a high average atomic number increases absorption of high energy radiation. GaTe is attracting recent attention for the potential to satisfy many of these criteria, but its properties are still poorly understood. Like other III-VI compounds, GaTe is a layered material, but its unusual anisotropy in the atomic planes results in rather unique mechanical and electronic properties. In this talk, we discuss ab-initio calculations of the transport properties of GaTe with respect to its application to radiation detectors. Guided by very recent experimental results, we analyze the occurrence of native defects in this materials and possible compensating extrinsic defects, and their effects on the transport properties.

3:06PM X10.00004 Electronic properties of oxygen vacancy in HfO2 within GW calculations . EUN-AE CHOI, KEE JOO CHANG, Department of Physics, Korea Advanced Institute of Science and Technology, Daejon 305-701, Korea — Hafnia (HfO2) has attracted much attention as a high-k dielectric material, which substitutes for silicon gate oxide in nanoscale metal-oxide-semiconductor (MOS) devices. However, there remain several problems to be resolved in hafnia-based devices, such as flat band shift and threshold voltage instability. Oxygen vacancy, as the most common intrinsic defect, is regarded as a major cause of these problems. As previous calculations mostly rely on the local-density-functional approximation (LDA), the defect levels of oxygen vacancy are not accurately determined because of the LDA band gap problem. Here we perform GW calculations for the defect levels of oxygen vacancy in monoclinic HfO2. Our calculations show that the Fermi level pinning of p+-poly Si gate electrode is due to the change from oxygen vacancy to the electrode. In addition, the charge trap of oxygen vacancy can lead to the threshold voltage instability in both nMOS and pMOS devices. Finally, we suggest that oxygen vacancy may be a cause of the gate leakage current by the Poole-Frenkel conduction.

3:18PM X10.00005 DFT Energetics of Noble Gas Impurities and Schottky Defects in UO2 . ALEXANDER THOMPSON, CHRIS WOLVERTON, Northwestern University Materials Science and Engineering, RADIATION DAMAGE IN NUCLEAR FUEL FOR ADVANCED FUSION REACTORS. The choice of the k-Al2O3 phase is based on the similarity of its density to that of amorphous Al2O3. We analyze native point defects such as vacancies, self-interstitials, and antisites, as well as various relevant impurities. Our first-principles calculations are based on density functional theory (DFT). Hybrid functionals were utilized as a means of overcoming the band-gap problem. This approach allows us to accurately assess the positions of defect levels. We use calculated band offsets to make predictions about the location of these defect levels with respect to the band gap of relevant semiconductors used as channel materials. We will discuss which defects may impede the optimal performance of devices.

3:30PM X10.00006 Polarization Patterns In GeTe From Bulk To Ferroelectric Nanoclusters . ENGIN DURGUN, University of Liege, RIAD SHALTAF, XAVIER GONZE, University of Catholic Louvain, PHILIPPE GHOSEZ, JEAN-YVES RATY, University of Liege — In this study, we investigated the ferroelectric and structural properties of GeTe crystal and nanoclusters, an alternative type of ferroelectric material, up to 1500 atoms from first-principles calculations based on density functional theory (DFT). Firstly, the dynamical, dielectric and elastic properties of GeTe in ferroelectric phase have been investigated [1]. Next, we demonstrate, for the first time at the DFT level, the existence in the interior of sufficiently large dots of polarization vortices giving rise to a net and reversible toroidal moment of polarization (G) [2]. The amplitude of G decreases with the size of the system and is only slightly suppressed due to strain relief. (iv) For Ar, Kr, and Xe, the binding energy of a noble gas impurity with the SD is larger than the energy required to form a SD, thereby providing a strong favorable binding, due to the presence of emission following excitation at the higher energies, but absent under 633 nm excitation, may suggest that the well-known energy transfer process from the electronic excited F-center states to the vibrational CN− energy levels in this system occurs from a single common relaxed excited electronic state associated with the absorption band at 633 nm.

3:42PM X10.00007 First-principles study of point defects in k-Al2O3 . JUSTIN R. WEBER, ANDREW JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — The development of gate-stack structures for novel CMOS applications has stimulated interest in point defects that may occur in oxide dielectrics. We consider Al2O3 as a possible gate-stack material, and study defects in the low symmetry k-Al2O3 phase. The choice of the k-Al2O3 phase is based on the similarity of its density to that of amorphous Al2O3. We analyze native point defects such as vacancies, self-interstitials, and antisites, as well as various relevant impurities. Our first-principles calculations are based on density functional theory (DFT). Hybrid functionals were utilized as a means of overcoming the band-gap problem. This approach allows us to accurately assess the positions of defect levels. We use calculated band offsets to make predictions about the location of these defect levels with respect to the band gap of relevant semiconductors used as channel materials. We will discuss which defects may impede the optimal performance of devices.

3:54PM X10.00008 First-principles study on the electromigration of oxygen vacancy in metal oxides . SANG HO JEON, WON-JOON SON, BAE HO PARK, SEUNGWU HAN, DEPARTMENT OF PHYSICS, KONKUK UNIVERSITY TEAM, — The oxygen vacancy, which is a fundamental defect in oxides, plays a critical role in defining many electrical properties of oxides ranging from ionic conductivities to leakage behaviors. As such, to control the density and spatial distribution of the oxygen vacancy has often been an important goal in many researches on electronic devices, particularly for high-density devices, such as resistance-change random access memories (ReRAM). Despite its importance, the electromigration of oxygen vacancy has not been studied much from the microscopic point of view. In this presentation, we studied on the migration of the oxygen vacancy in metal oxides, such as MgO and TiO2. First, using the nudged elastic band (NEB) method, we estimated the migration barrier of charged oxygen vacancy under an external field. Then, we calculate the zone-center phonon modes of the bulk system to obtain the attempt frequency of the vacancy diffusion. Based on these results, we estimated the migration time of oxygen vacancy in metal oxide by using harmonic transition state theory, and it was in good agreement with the result of molecular dynamics (MD) calculation.
First-principles calculations of Ce activation in RE$_2$M$_2$O$_7$ (RE = La, Y; M = Ti, Zr, Hf). Anurag Chaudhry, Andrew Canning, Rostyslav Boutchkov, Stephen Derenzo, Niels Gronbech-Jensen — First-principles electronic structure calculations of Ce-doped La and Y compounds with composition RE$_2$M$_2$O$_7$ (RE = La, Y; M = Ti, Zr, Hf) are performed using the pseudopotential method based on the local density approximation in density functional theory. The positions of the 4f states relative to the valence band maximum and the position of the lowest 5d excited state relative to the conduction band minimum of the host material are determined. The prediction of Ce activation is based on the following criteria: (1) The energy difference between the occupied Ce 5d excited state (Ce$^{3+}$*) and the host material conduction band minimum (CBM) and (2) the degree of localization of the (Ce$^{3+}$*) excited state on the Ce atom. Our theoretical investigations indicate that Ce activation is not possible in these host materials.

Electric Field Induced Sub-Microsecond Resistive Switching, Nilanjan Das, Stephen Tsui, Ya-Qi Wang, Yuyi Xue, Ching-Wu Paul Chu, University of Houston — Electric field induced resistive switching in metal-oxide interfaces has attracted extensive recent interest. While many agree that lattice defects play a key role, details of the physical processes are far from clear. There is debate, for example, regarding whether the electromigration of pre-existing point defects or the field-created larger lattice-defects dominates the switch. We investigate several Ag-Pr$_{0.7}$Ca$_{0.3}$MnO$_3$ (PCMO) samples exhibiting either sub-microsecond fast switching or slow quasi-static DC switching. It is found that the carrier trapping potentials are very different for the pre-existing point defects associated with doping (and/or electromigration) and the defects responsible for the sub-μs fast-switching. Creation/removal of the defects with more severe lattice-distortions and spatial spreading (trapping potential $> 0.35$ eV), therefore, should be the dominating mechanism during sub-μs switching. On the other hand, the shallow defects (trapping potential $< < 0.2$ eV) associated with doping/annealing are most likely responsible for the resistance hysteresis (slow switch) during quasistatic voltage sweep.

Temperature dependence of Gigahertz-Range Ultra-High Frequency Micromechanical Resonators, Josef-Stefan Wenzler, Tyler Dunn, Diego Guerra, Pritiraj Mohanty — We report measurements of bulk mode resonators in the ultrahigh frequency range up to 4 GHz. The devices are fabricated with a stack of materials and actuated using piezoelectric technique. Typical dimensions of these resonators are 100 μm in length and width and 10 μm in thickness. The temperature dependence of mode frequencies and quality factor Q are investigated for temperatures ranging from 0.3 K – 400 K.

Temperature dependence of mechanical stiffness and dissipation in ultrananocrystalline diamond resonators, Vivekananda Adiga, University of Pennsylvania, Anirudha Sumant, Argonne National Laboratory, Sampa Suresh, Chris Guedmam, Innovative Micro Technology, Orlando Aucellio, Argonne National Laboratory, John Carlisle, Advanced Diamond Technologies, Robert Carpick, University of Pennsylvania — We have studied the mechanical softening and dissipation of ultrananocrystalline diamond (UNCD) resonators with temperature. Resonant excitation and ring down measurements were conducted under ultra high vacuum (UHV) conditions in a decoupled UHV atomic force microscope (AFM) to determine the Young’s Modulus and quality factor (Q) in UNCD cantilever structures. The temperature dependence of Young’s modulus revealed the characteristic Wachtman’s empirical relation. From this measurement the Debye temperature was estimated to be $\sim 1460$ K, significantly lower than Debye temperature of 1860 K for single crystal diamond. The quality factors of different resonators increased as the cantilevers were cooled from 300 K to 30 K and with the hydrogen termination of the cantilever surface. The results indicate that surface and bulk defects significantly contribute to the observed dissipation as well as the mechanical softening in UNCD resonators.

Evidence of universality in the dynamical response of micromechanical diamond resonators at millikelvin temperatures, Matthias Imboden, Pritiraj Mohanty, Boston University — We report Kelvin to millikelvin-temperature measurements of dissipation and frequency shift in megahertz-range resonators fabricated from ultrananocrystalline diamond. Frequency shift $\delta f/f_0$ and dissipation $Q^{-1}$ demonstrate temperature dependence in the millikelvin range similar to that predicted by the glass model of tunneling two level systems. The logarithmic temperature dependence $\delta f/f_0$ is in good agreement with such models, which include phonon relaxation and phonon resonant absorption. Dissipation shows a weak power law, $Q^{-1} \sim T^{1/3}$, followed by saturation at low temperature. A comparison of both the scaled frequency shift and dissipation in equivalent micromechanical structures made of single-crystal silicon and gallium arsenide indicates universality in the dynamical response.

Small to medium atomic size-mismatch leads to alloy phase-separation yet huge mismatch can lead to ordering, Xiwen Zhang, Giancarlo Trimarchi, Mayeul D’Avezac, Alex Zunger, National Renewable Energy Lab., Golden, CO 80401 — Most alkali halide alloys AX-BX (where A and B are alkali elements and X = F, Cl, Br, or I) are expected to have miscibility gaps (phase separation) which increases with the lattice mismatch. Even though LiO-RbX and LiX-CsX with lattice mismatches of 20 – 33% and 19 – 40% respectively might be expected to have pronounced miscibility gaps, they were experimentally found to have ordered structures. Here, we investigate the possible stabilization of ordered compounds with respect to random configurations. In the family of LiNaBr$_2$, LiKBr$_2$, LiRbBr$_2$, and LiCsBr$_2$, we find that as the lattice mismatch increases, the formation enthalpy of the random structure increases, (mainly due to the volume deformation), but the formation enthalpy of the ordered structure decreases becoming negative for the latter two. The ordered structures consist of distorted LiX$_4$ tetrahedral arranged in layers, with Rb (or Cs) sitting between layers at the center of the resulting triangular prism. We analyze the origin of ordering from the large local distortion induced by the huge lattice mismatch.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X11 DAMOP: Fermions in Optical Lattices II

Non-Equilibrium Enhancement of Superfluidity in a Trapped Fermi Gas, Andrew Robertson, Victor Galitski, University of Maryland, College Park — In 1970, Eliashberg showed that superconductivity could be stimulated by pushing the quasiparticle spectrum out of equilibrium and to higher energies using a periodic perturbation with a frequency of the order of the superconducting gap (Eliashberg, JETP Lett. 11, 114 (1970)). This effect has been observed in thin films (TM Klappen et al. JLTP 26, 3-4 (1977)). The theory of this gap enhancement can be mapped onto a cold Fermi gas. We present here the theoretical framework for describing the stimulation of the BCS order parameter in an interacting Fermi gas by means of a periodic perturbation.
2:42PM X11.00002 Realizing the Strongly Correlated \(d\)-Wave Mott-Insulator State in a Fermionic Cold-Atom Optical Lattice\(^1\). MICHAEL PETERSON, CHUANWEI ZHANG, SUMANTA TEWARI, SANKAR DAS SARMA, University of Maryland — We show that a new state of matter, the \(d\)-wave Mott-insulator state (\(d\)-Mott state) (introduced recently by [H. Yao, W. F. Tsai, and S. A. Kivelson, Phys. Rev. B 76, 161104 (2007)]), which is characterized by a nonzero expectation value of a local plaquette operator embedded in an insulating state, can be engineered using ultracold atomic fermions in two-dimensional double-well optical lattices. We characterize and analyze the parameter regime where the \(d\)-Mott state is stable. We predict the testable signatures of the state in the time-of-flight measurements.

2:54PM X11.00003 Spectral function of spinless fermions on a one-dimensional lattice. RODRIGO PEREIRA, KITP, STEVEN WHITE, UC Irvine, IAN AFFLECK, University of British Columbia — We study the spectral function of spinless fermions for an integrable lattice model away from half-filling. The sharp features of the spectral function at arbitrary momentum are argued to be power law singularities analogous to the x-ray edge singularity. Besides the singularity at the energy of the single-particle excitation, we find that at low fillings the spectral function can exhibit a second divergence associated with the formation of a \(p\)-wave antibound state. The predictions from the effective field theory are compared with numerical results from the time-dependent density matrix renormalization group.

3:06PM X11.00004 Superfluidity at the BEC-BCS crossover in two-dimensional Fermi gases with population and mass imbalance\(^1\). GARETH CONDUIT, University of Cambridge, PETER CONLON, University of Oxford, BEN SIMONS, University of Cambridge — We explore the zero-temperature phase behavior of a two-dimensional two-component atomic Fermi gas with population and mass imbalance in the regime of the BEC-BCS crossover. Working in the mean-field approximation, we show that the normal and homogeneous balanced superfluid phases are separated by an inhomogeneous superfluid phase of Fulde-Ferrel-Larkin-Ovchinnikov (FFLO) type. We obtain an analytical expression for the line of continuous transitions separating the normal and inhomogeneous FFLO phases. We further show that the transition from the FFLO phase to the homogeneous balanced superfluid is discontinuous leading to phase separation. If the species have different masses, the superfluid phase is favored when the lighter species is in excess. We explore the implications of these findings for the properties of the two-component Fermi gas in the atomic trap geometry. Finally, we compare and contrast our findings with the predicted phase behavior of the electron-hole bilayer system. [1] Phys. Rev. A 77, 053617 (2008)

3:18PM X11.00005 ABSTRACT WITHDRAWN —
4:18PM X11.00010 General Hubbard Model for Fermions in an Optical Lattice, JASON KESTNER, LUMING DUAN, FOCUS center and MCTP, Department of Physics, University of Michigan — For two-component fermions in an optical lattice, an effective general Hubbard model (GHM) with tunable on-site attraction/repulsion and occupation-dependent hopping rates emerges from very general arguments [1]. This model is quite interesting, containing as special cases both the t-J and the XXZ models. However, the experimental range of applicability and the connection between the model parameters and the actual experimental parameters must be determined explicitly. To this end, we have used a stochastic variational approach with correlated Gaussian wavepackets to numerically find the eigenstates of two atoms interacting in a 3D few-well lattice. By matching the variational spectrum of the GHM to the variational spectrum obtained, the validity of the model and the relationship between experimental and model parameters is determined. [1] L.-M. Duan, Euro. Phys. Lett. 81, 20001 (2008).

4:30PM X11.00011 ABSTRACT WITHDRAWN

4:42PM X11.00012 ABSTRACT WITHDRAWN

4:54PM X11.00013 Probing Nagaoka ferromagnetism in optical superlattices, JAVIER VON STECHER, JILA and Department of Physics, University of Colorado, Boulder, Colorado, EUGÈNE DEMLER, MIKAHIL LUKIN, Physics Department, Harvard University, Cambridge-MA, 20138, ANA MARIA REY, JILA and Department of Physics, University of Colorado, Boulder, Colorado — In 1966, Nagaoka predicted that interaction-induced ferromagnetism occurs in lattices with specific geometry when there is one electron fewer than in the half-filled system. Here, we describe a controllable method for observing Nagaoka Ferromagnetism in isolated quasiparticles (four lattice sites arranged in a square) created using optical superlattices. We next discuss the weakly coupled quasiparticles and suggest several approaches for creating systems exhibiting itinerant ferromagnetism.

5:06PM X11.00014 Competition between spin imbalance and mass imbalance in the 1D asymmetric Hubbard model, WEN-LONG LU, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong, ZHI-GUO WANG, Department of Physics, Tongji University, SHI-JIAN GU, HAI-QING LIN, The Chinese University of Hong Kong, Shatin, N.T., Hong Kong — In this talk, I will discuss the spin imbalance in the 1D asymmetric Hubbard model in the negative U region by the Bosonization method. A ground-state phase diagram has been obtained. We find that, unlike the $N_\uparrow = N_\downarrow$ case, there is no other phase transition in the ground state (always Singlet Superconducting) before it enters into the phase separation region, and the pairing correlation function is found to oscillate in real space (FFLO state). The maximum mode is only determined by difference of Fermi momenta, and the correlation exponent is determined by both the mass difference and spin polarization. $^1$This work is supported by HK RGC Grant 402107

5:18PM X11.00015 Spin-coherent and -incoherent Luttinger liquids in trapped ultracold atomic Fermi gases, PAATA KAKASHVILI, C. J. BOLECH, Rice University — Recent success in manipulating ultracold atomic systems allows to probe different strongly correlated regimes in one dimension. Experimentally, 1D tubes are defined by turning on a 2D optical lattice. Regimes such as the spin-coherent Luttinger liquid and the spin-incoherent Luttinger liquid can be realized by tuning the inter-atomic interaction strength and trap parameters. Due to the trap potential the density decreases near the edges of the tubes and the spin-incoherent regime is inevitably realized. In general, the spin-coherent Luttinger liquid regime in the center of the tube crosses over to its spin-incoherent counterpart at the edges. We identify the noise correlations of density fluctuations as a robust observable (uniquely suited in the context of trapped atomic gases) to discriminate between these two regimes. Finally, we address the concrete prospects of realizing and probing these phenomena experimentally using optical lattices.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X12 DMP DCMP: Structure and Morphology of Oxide Surfaces and Thin Films 308

2:30PM X12.00001 Finding stable α-quartz (0001) surface structures via simulations, YUN-WEN CHEN, CHAO CAO, HAI-PING CHENG, Department of Physics and Quantum Theory Project, University of Florida — Reconstruction of α-quartz (0001) surfaces is studied using combined classical molecular dynamics and density functional theory. Five reconstruction patterns are identified, including three (2 × 1) patterns and two (1 × 1) patterns. The energetically most stable surface structure is found to be a (2 × 1) reconstruction pattern, and several patterns can co-exist in a large scale surface. A combination of structures can explain the experimentally observed (2 × 2) diffraction pattern. $^1$Acknowledgement: this work is supported by the NSF under Grant No. DMR/ITR-0218957 and DMR-0804407.

2:42PM X12.00002 Investigation of stability issues of TCO barrier layers for CIGS devices during damp heat and dry heat exposures, RAJALAKSHMI SUNDARAMOORTHY, INGRID REPINS, DAVID ALBIN, JOHN PERN, XIANKAN LI, TIM GESSERT, THOMAS GENNETT, National Centre for Photovoltaics, National Renewable Energy Laboratory — The reliability of In$_2$O$_3$/SnO$_2$ (ITO) and In$_2$O$_3$/ZnO (IZO) as barrier layers for CuInGaSe$_2$ (CIGS) solar cells has been investigated. NREL’s high-efficiency CIGS devices are prepared using a three-stage process for the CIGS layer, and insulating ZnO and ZnO:Al as the (bi-layer) transparent conducting oxide (TCO) buffer and conducting layers, respectively. These CIGS devices are processed to explore the effectiveness of barrier layers of ITO and IZO sputtered at room temperature and at various temperatures. Devices are exposed to damp heat at 85°C and 85% relative humidity (RH) and dry heat conditions (85°C/∼0% RH). Some cells are also tested under 1-sun illumination and open-circuit voltage bias. Optical, electrical, structural, and imaging analyses are used to characterize the samples periodically before and after the exposures. Surface depth profiling and relative concentration of the elements present are analyzed using XPS. Results of these stability studies will be discussed. This abstract is subject to experimental verification using XPS.

2:54PM X12.00003 Scanning Tunneling Microscopy Study of a Vicinal Anatase TiO$_2$ Surface, SHAO-CHUN LI, OLGA DULUB, ULRRIKE DIEBOLD, Department of Physics, Tulane University, DEPARTMENT OF PHYSICS, TULANE UNIVERSITY COLLABORATION — Titanium dioxide finds versatile applications in various technical fields including gas sensing, coatings, pigments, heterogeneous catalysis, photocatalytic degradation of pollutants, and solar cells. TiO$_2$ is found in three main crystallographic phases: rutile, anatase and brookite. Rutile is the thermodynamically most stable form and is considered a model system for basic research. However, anatase TiO$_2$ is often considered to be catalytically more active than rutile for reasons not yet completely understood. In this work, using scanning tunneling microscopy (STM) and low energy electron diffraction (LEED), the structure of the anatase TiO$_2$(5 5T) surface, $\sim$10° vicinal to the $\sim$ lowest energy $\sim$ (101) plane, has been studied. The surface was found to facet into a structure composed of ridges with a uniform width of 5 lattice units. Based on atomically-resolved STM and electron counting rules, it is proposed that the sides of the ridges are parallel to (1 10) and (1 12) planes. These sides might be reconstructed to stabilize the microfaceted structure. Vapor-deposited gold shows pronounced clustering between the ridges, indicating a one-dimensional template effect of the vicinal surface, which supports denser and more uniformly sized Au clusters, as compared to the flat (101) surface.

4:30PM X12.00011 Tunable Metallicity at the Surface of La$_{5/8}$Ca$_{3/8}$MnO$_3$/SrTiO$_3$ Thin Films. KENJI FUCHIGAMI, Oak Ridge National Laboratory / The Univ. Tennessee, ZHENG GAI, Oak Ridge National Laboratory, THOMAS Z. WARD, Oak Ridge National Laboratory / The Univ. Tennessee, LIFENG YIN, PAUL SNIJDERS, Oak Ridge National Laboratory, WARD PLUMMER, The Univ. Tennessee, JIAN SHEN, Oak Ridge National Laboratory / The Univ. Tennessee — A series of in-situ STM studies of La$_{5/8}$Ca$_{3/8}$MnO$_3$(001) thin films reveals that the surface metallicity can be tuned by extrinsic oxygen doping at the surface. By in-situ annealing with or without oxygen, we can convert the surface back and forth between a ( Å2, x Å 2, Å45) reconstructed surface and a (1 x 1) surface. Electrical properties of the surfaces are investigated by scanning tunneling microscopy (STM). I–V curves clearly show that the oxygen doping renders the surface insulating while the (1 x 1) surface without the oxygen doping is metallic. Structural models and their correlation to the surface metallicity have been proposed.

4:42PM X12.00012 Surface properties of ultrathin ferroelectric films in external electric field. RENAT SABIRIANOV, University of Nebraska at Omaha, MINORU OTANI, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan, OSAMU SUGINO, University of Tokyo — The electric polarization of free standing ultrathin films of BaTiO$_3$ is analyzed using pseudopotential plane wave calculations within effective screening medium method. The polarization loop in asymmetrically terminated (Pb,Ba)TiO$_3$ film is biased, providing the existence of polarization without applied electric voltage across the film. We attribute the origin of bias to a creation of a bias field due to difference in surface work functions of TiO$_2$ and BaO terminations. These results in the formation of surface polarizations at each termination and inhomogeneous polarization profile across the thickness of the film. We show that the surface develops in-plane component of polarization in paraelectric state, and also in case of the ferroelectric films when the electric field applied perpendicularly to the plane of the film.

4:54PM X12.00013 Growth and Characterization of EuTiO$_3$ films on SrTiO$_3$ (001). H. Q. WANG, School of Applied and Engineering Physics, and Cornell Center for Materials Research (CCMR), J. D. FERGUSON, Department of Materials Science and Engineering, and CCMR, A. R. WOLL, School of Applied and Engineering Physics, and Cornell High Energy Synchrontron Source. D. A. MULLER, School of Applied and Engineering Physics, and CCMR, J. D. BROCK, School of Applied and Engineering Physics, and CCMR, Cornell University, Ithaca, New York, USA — Ferroelectric films display a variety of interesting physical properties, and their heteroepitaxial structures are of significant interest in oxide electronics. EuTiO$_3$ and SrTiO$_3$ are nearly perfectly lattice matched and have the same valence structure, and are therefore well suited as a model system for the study of ferroelectric interfaces. One outstanding question about such interfaces concerns the factors that determine and limit atomic and electronic abruptness. In this work, several monolayer thick EuTiO$_3$ films are grown on single-crystal SrTiO$_3$ (001) substrates using Pulsed Laser Deposition (PLD). The growth mechanisms are probed by the combination of synchrotron based in situ small x-ray scattering (SAXS) and in situ reflection high energy electron diffraction (RHEED). The atomic-scale interfacial properties are investigated by high resolution Scanning Transmission Electron Microscopy (STEM) and spatially resolved Electron Energy Loss Spectroscopy (EELS).

5:06PM X12.00014 Density functional calculations of the structure of near-surface oxygen vacancies and electron localization on CeO$_2$(111). M. VERONICA GANDUGLIA-PIROVANO, Humboldt-University Berlin, Unter den Linden 6, 10099 Berlin, Germany, JUAREZ L.F. DA SILVA, National Renewable Energy Laboratory, 1617 Cole Blvd., Golden, CO 80401, USA, JOACHIM SAUER, Humboldt-University Berlin, Unter den Linden 6, 10099 Berlin, Germany — The use of ceria as a key component in catalysts and as an electrolyte for solid oxide fuel cells relies on its notable capability of storing and releasing oxygen. This property results from the facility of both formation and healing of oxygen vacancies in ceria. Several studies have been reported in the last years for reduced CeO$_2$(111), however, one of the most topical issues surrounding oxygen vacancies on CeO$_2$(111), namely, the relative stability of surface and subsurface defects, is still under intense debate. Using density functional theory with the Heyd-Scuseria-Ernzerhof (HSE06) hybrid functional as well as the DFT+U approach, we find subsurface vacancies with 3×2 periodicity to be energetically more favorable by 0.45 (HSE06), 0.47 (PBE+U), and 0.22 eV (LDA+U). The excess-electrons localize not on Ce ions which are nearest neighbor to the defect as priory suggested, but instead on those that are next-nearest neighbors. The excess-electron distribution and the preference for subsurface vacancies are explained in terms of defect-induced lattice relaxation effects.

5:18PM X12.00015 Interface structure determination of crystalline oxides on silicon using synchrotron x-ray diffraction. F.J. WALKER, J.W. REINER, A.M. KOLPK, Y. SEGAL, Yale University, Z. ZHANG, Argonne National Laboratory, D. SU, Y. ZHU, Brookhaven National Laboratory, M.S. SAWICKI, C.C. BROADBRIDGE, Southern Connecticut State University, S. ISMAIL-BEIJI, C.H. AHN, Yale University — As electronic devices are reduced in size, well controlled atomically abrupt interfaces become increasingly important. This is especially true for field effect devices where the conducting channel is only a few atoms thick. Here we discuss the experimental determination of the atomic structure of an interface for a model system, crystalline oxides on silicon, which contains the essential elements of field effect devices. For both BaO/Si and SrTiO$_3$/Si structures, we use a combination of synchrotron x-ray scattering, Z-contrast transmission electron microscopy and density functional theory to determine the structure. The combination of these approaches has led to a unique detailed model of the interface. We have discovered features of these interfaces that emerge during growth that can be used to understand important elements of the measured electrical properties and microscopically identify sources of fixed charge, interface traps and field-dependent mobility.

2:30PM X13.0001 System-averaged exchange-correlation holes and self interaction in second-row atoms. ANTONIO C. CANCEIO, Ball State University — Recent work is presented on the theoretical calculation of system-averaged exchange and correlation holes (intracules) for a pseudopotential model of the valence shell for the second row atoms Mg through Ar. Exchange holes are obtained from numerical Fourier transform methods and correlation holes from variational quantum Monte Carlo calculations using the method of correlated estimates. We observe scaling behavior in both exchange and correlation, following the known scaling of the valence density across the row, once self-interaction effects are taken into account. The holes are compared to density-functional models including LDA, GGA and related SIC approaches. We note a sizeable error due to self-interaction occurs in the same-spin channel of the correlation hole which persists for the LDA and GGA even after standard self-interaction corrections are applied. The effects of this error and proposed corrections to it on the total exchange-correlation energy will be discussed.
2:42PM X13.00002 Constraint-based, Single-point Approximate Kinetic Energy Functionals
FRANK E. HARRIS, Physics, University of Utah, V. V. KARASIEV, Instituto Venezolano de Investigaciones Cientificas, R. S. JONES, Loyola College of Maryland, S. B. TRICKEY, QTP, University of Florida — We work toward the development of orbital-free density functionals for the Kohn-Sham kinetic energy $T_K$ of a quality suitable for the computation of quantum-mechanical forces in multi-scale molecular dynamics simulations. The functionals are based on constraints applicable to the Pauli potential $v_p = 8T_D/n$, where $T_D = T_v + T_w$ and $T_v$ is the von Weizsäcker kinetic-energy functional. We review our progress to date, and exhibit functionals that do not generate spurious singularities and that produce chemical bonding in semi-quantitative agreement with Kohn-Sham computations and relevant experiments.

1Supported by U.S. NSF Grants PHY-0601758 and DMR-0325553

2:54PM X13.00003 Functional minimization scheme for first-principles electronic structure calculations with bi-orthogonal interpolating wavelets, WILLIAM GARBER, WEI KU, JAMES DAVENPORT, DMITRI VOLIA1, Brookhaven National Laboratory — A new development of first-principles electronic method will be presented based on direct energy functional minimization and bi-orthogonal wavelet basis set. The employment of bi-orthogonal basis allows systematically controlled accuracy while benefiting from the compact support that allows O(N) algorithms. Furthermore, utilization of the interpolating nature of the wavelet, together with the effectiveness of multi-resolution of wavelet, enables very efficient calculation without compromising accuracy. By avoiding solving eigenvalue equation as in standard Kohn-Sham framework, the method is easily extended to parallel algorithms, and allows simple implementation of various non-local functionals. In case of crystals, our method gives directly solution as Wannier functions, further utilizing their sparseness. This new development is ideal for easy implementation and accurate systematic benchmarking of various modern functionals, and holds the potential to attack very large systems such as nano-materials.

3:06PM X13.00004 Quenched Lieb-Oxford Satisfaction and Improved Performance for PBE-type Functionals
S. B. TRICKEY, QTP, Univ. Florida, V. MEDEL, A. VELA, Cinvestav, Mexico City — Success for the orbital-free DFT approach to Born-Oppenheimer forces for first-principles molecular dynamics requires progress on orbital-free exchange-correlation (XC) functionals to go along with newly developed orbital-free kinetic energy functionals [V.V. Karasiev et al. arXiv 0809.4798, J. Comput.-Aided Mat.Des. 13, 111 (2006)]. We report on development and testing of a non-empirical X functional which generalizes PBE X. It satisfies a reduced Lieb-Oxford bound by quenching to homogeneous electron gas behavior for large values of the inhomogeneity $s \propto |\nabla n|/n^{1/3}$ on the grounds that large $s$ often corresponds (counter-intuitively) to small, smooth density. Used with the PBE C functional, our X functional reduces mean absolute errors for small molecules by 20% or more with respect to conventional PBE XC. Used with LYP C (a semi-empirical combination), the performance also is improved relative to PBE-LYP.

3:18PM X13.00005 On the performance of Thomas-Fermi in periodic two-dimensional systems
LAZARO CALDERIN, MALCOLM J. STOTT, Department of Physics, Queen’s University, Kingston K7L 3N6, Ontario, Canada — The largest missing piece of a completely orbital free Density Functional Theory is the kinetic energy functional $T_K[n]$, and approximations for this are of interest. One of these expands $T_K$ in terms of density gradients with the Thomas-Fermi functional as the first term. But in three-dimensions the expansion appears not to converge, and the sixth and higher order corrections diverge for localized systems. In contrast, a number of authors have shown that the density gradient corrections all vanish in two-dimensions, while numerical test revealed that, even when not exact, TF is a very good approximation. That has been shown for the case of an impurity in a otherwise two-dimensional uniform electron gas. In this work we explore the validity of TF and linear response theory for a periodic two-dimensional system, a system that is likely to be more widely applicable.

3:30PM X13.00006 Effect of disorder on the electronic properties of strongly correlated systems within the dynamical cluster approximation
UNJONG YU, ABDOLMAJID NILI, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University — We study the interplay of disorder and strong correlations on the electronic properties of highly correlated systems. We employ the dynamical cluster approximation (DCA) to include the effects of short-range correlations and alloy disorder beyond the coherent potential approximation (CPA). Our study focus on the double exchange model, relevant on the study of dilute magnetic semiconductors, and the periodic Anderson model to study heavy fermion compounds. We present results of several electronic properties as function of disorder strength, alloy concentration, and electron or hole doping.

3:42PM X13.00007 Basic Variables in Density Functional Theory in the Presence of a Magnetic Field
VIRAHT SAHNI, The Graduate Center CUNY, XIAOYIN PAN, Ningbo University — We have shown via a unitary or equivalently a gauge transformation that for a system of $N$ electrons in an external field $F = e\mathbf{A}/c$, the wave function $\Psi$ is in general a functional of the ground state density $\rho(\mathbf{r})$ and a gauge function $\alpha(\mathbf{R})$: $\mathbf{R} = \mathbf{r}_1, \ldots, \mathbf{r}_N$, i.e. $\Psi = \Psi[\rho, \alpha]$. The functions $\alpha(\mathbf{R})$ are arbitrary, the choice $\alpha(\mathbf{R}) = 0$ being equally valid. It is the presence of $\alpha(\mathbf{R})$ that ensures the wave function functional is gauge variant. Similarly, in the presence of a magnetic field $\mathbf{B}(\mathbf{r}) = \nabla \times \mathbf{A}(\mathbf{r})$, we show that in general the wave function is a functional of the density $\rho(\mathbf{r})$, the physical current density $\mathbf{j}(\mathbf{r})$, and a gauge function $\alpha(\mathbf{R})$: $\Psi = \Psi[\rho, \mathbf{j}(\mathbf{r}), \alpha]$. Again, the $\alpha(\mathbf{R})$ are arbitrary, the choice $\alpha(\mathbf{R}) = 0$ being valid. Hence, it is possible to construct a theory in which the basic variables are $\rho(\mathbf{r})$ and $\mathbf{j}(\mathbf{r})$. The generalized Hohenberg-Kohn theorems, as well as the equations for the noninteracting fermion Kohn-Sham system that reproduces the $\rho(\mathbf{r})$ and $\mathbf{j}(\mathbf{r})$ of the interacting system of electrons, are derived.

3:45PM X13.00008 Projector Augmented Wave database with automatic parameter optimization

R.J. Snow, University of California Davis, A.F. Wright, Sandia National Laboratory, C.Y. Fong, University of California Davis — Projector Augmented Wave (PAW) parameter sets, similar to pseudopotential parameters, can be constructed in many ways. Due to a non-local expansion of projectors, the PAW method can include parameters for each angular momentum channel separately. While this gives the flexibility to optimize projectors individually, it also creates an unfathomable parameter space for searching for good parameter sets. To automatically search for good PAW sets, log derivative derivatives were analyzed numerically for matching with AE log-derivatives. Log-derivative matching, total energy convergence, and self-consistency errors found in density functionals. Since the Projector Augmented Wave (PAW) formalism ensures accurate evaluation of interaction integrals by controlling the multipole moments, it is a natural choice for implementing OEP within an efficient pseudopotential-like scheme. We developed a frozen core approximation scheme for the atomic all-electron OEP formalism, partitioning the exchange potential into core and valence contributions. The corresponding valence exchange pseudopotential for PAW, $V^\text{val} (r)$, can be derived in a similar way so that for $r > R_c$, $V^\text{val} (r) = V^\text{val} (r)$.

We have investigated the behavior of PAW-OEP basis, projector, and pseudopotential functions for several elements throughout the periodic table. Supported by NSF Grants DMR-0405456, 0427055, and 0705239.

4:06PM X13.00009 A Projector Augmented Wave Formulation of the Optimized Effective Potential Formalism

Xiao Xu, N.A.W. Holzwarth, Wake Forest University — The optimized effective potential (OEP) or exact exchange (EXX) formalism has recently received renewed attention as a method which can improve the accuracy of density functional calculations by representing orbital-dependent potentials and avoiding self-interaction errors found in density functionals. Since the Projector Augmented Wave (PAW) formalism ensures accurate evaluation of interaction integrals by controlling the multipole moments, it is a natural choice for implementing OEP within an efficient pseudopotential-like scheme. We developed a frozen core approximation scheme for the atomic all-electron OEP formalism, partitioning the exchange potential into core and valence contributions. The corresponding valence exchange pseudopotential for PAW, $V^\text{val} (r)$, can be derived in a similar way so that for $r > R_c$, $V^\text{val} (r) = V^\text{val} (r)$.

We have investigated the behavior of PAW-OEP basis, projector, and pseudopotential functions for several elements throughout the periodic table.

4:18PM X13.00010 Density functional study of CO adsorption on d-metal surface using TPSS functional

Jianwei Sun, John Perdew, Department of Physics and Quantum Theory Group, Tulane University, New Orleans, Louisiana 70118 — Feibelman et al.[1] presented the puzzle of CO at the Pt(111) surface, showing that the LDA and Perdew-type GGA put the molecule at the wrong, high-coordination site. However, a recent study [2] showed that the BLYP yielded very satisfactory adsorption energies and the correct adsorption sites for CO adsorption at late 4d and 5d transition metal (111) surfaces, although at the price of large errors in the volume of the d metals. Since PBE and BLYP have similar accuracy, it seems the probable reason for the wrong adsorption site is due to the fact that the LDA and Perdew-type GGA’s are “jellium derived” and hence prefer a more delocalized bonding, rather than the fact that the LDA and GGA inaccurately describe the CO molecule’s chemical bond. TPSS meta-GGA is also “jellium derived”, but improves accuracy for molecules[4]. Therefore, as a possible candidate to identify the major reason for the wrong adsorption site, TPSS is used to calculate the adsorption energies and sites of CO on the d-metal surface in the more accurate geometric structure obtained by PBEsol[1]. 4:30PM X13.00011 Fully numerical all-electron solutions of the optimized effective potential equation for diatomic molecules

Adi Makmal, Weizmann Institute of Science, Israel, Stephan Kummel, University of Bayreuth, Germany, Leeor Kronik, Weizmann Institute of Science, Israel — We present an approach for fully numerical, all-electron solutions of the optimized effective potential equation within Kohn-Sham density functional theory for diatomic molecules. The approach is based on a real-space, prolate-spherical-coordinate grid for solving the all-electron Kohn-Sham equations and an iterative scheme for solving the optimized effective potential equation. The accuracy of this method is demonstrated by comparison with previously reported calculations and new benchmark fully numerical results for selected dimers are provided.

4:42PM X13.00012 Exchange Energy Density Functionals that reproduce the Linear Response Function of the Free Electron Gas

David García-Aldea, J.E. Alvelarlos, Dept. Física Fundamental, UNED — We present several nonlocal exchange energy density functionals that reproduce the linear response function of the free electron gas. These nonlocal functionals are constructed following a similar procedure used previously for nonlocal kinetic energy density functionals by Chacón-Alvarellos-Tarazona, García-González et al., Wang-Govind-Carter and García-Aldea-Alvelarlos. The exchange response function is not known but we have used the approximate response function developed by Utsumi and Ichimaru, even we must remark that the same ansatz can be used to reproduce any other response function with the same scaling properties. We have developed two families of new nonlocal functionals: one is constructed with a mathematical structure based on the LDA approximation — the Dirac functional for the exchange — and for the second one the structure of the second order gradient expansion approximation is took as a model. The functionals are constructed is such a way that they can be used in localized systems (using real space calculations) and in extended systems (using the momentum space, and achieving a quasilinear scaling with the system size if a constant reference electron density is defined).

4:54PM X13.00013 Non-local exchange-correlation term implemented into the density functional theory

Youky Ono, Center for Frontier Science, Chiba University, Koichi Kusakabe, Graduate School of Engineering Science, Osaka University, Takaishi Nakayama, Faculty of Science, Chiba University — The local density approximation (LDA) has serious limitation that this approximation cannot estimate the long-ranged (non-local) exchange-correlation interaction, as typified by the van der Waals (vdW) interaction. In this study we develop a method to calculate the vdW interaction based on the LDA together within the plasmon-pole approximation [1]. The computation code is developed as one of a module program of an existing first principle calculation package. Usefulness and efficiency of the method are confirmed by calculating the interaction energy of simple periodic systems. This method never relies on external parameters and/or on asymptotic model functions, and thus being applicable to any isolated 3 dimensional structures. [1] PRL 96, 073201 (2006), PRB 62, 6997 (2000), PRL 92, 246401 (2004).
When the average velocity verses mobility does not result in a Devil’s staircase, chaotic trajectories can be found.

In many instances, plotting the average velocity verses mobility results in a Devil’s staircase. When Devil’s staircases are seen, no chaotic behavior is present.

1. JAMES EAKINS, West Virginia University, JAMES VOPAL, West Liberty State College, BOYD EDWARDS, West Virginia University — Traveling-wave electrophoresis is a new method of separating charged analytes using a series of interlaced electrodes with time-varying electric potentials along a microchannel. This new representation allows for greatly reduced computation time and better description of the underlying mathematics is required in order to fully optimize this promising technology. As such, a new Fourier model of the electric potential inside the channel is introduced, along with preliminary computational results. This new representation allows for greatly reduced computation time and greater accuracy. Similarities and differences with other models are highlighted, as well as the dependence of the potential on the electrode and channel geometries. The movement of charged particles in response to the potential is examined, with several critical thresholds highlighted.

Funding from NSF grants DMR-0647763 and EPS-0554328, and a WVU Research Corporation grant.
4:06PM X14.00009 Ac electroosmotic flows above coplanar electrodes. YONG KWEON SUH, Department of Mechanical Engineering, Dong-A University — Interactive numerical method has been proposed to calculate the ac electroosmotic flows above a pair of coplanar electrodes. The thin electrical triple layer (ETL) has been modeled by an asymptotic theory developed by the authors. The model corresponds to a simple dynamic equation for the surface charge density representing the integrated charge over the inner layer. Interactive calculation of the dynamic equation and the Laplace equation for several ac frequency then yielded steady-state distribution of potential and the potential drop across the Stern and inner layers. The Smoluchowski’s slip velocity was then determined from those two set of data and used as the boundary condition for the calculation of the Stokes’ flow above the electrodes. We have shown that our solutions compared well with the experimental data reported in the literature. We investigated the effect of various parameters on the slip velocity distribution, such as the ac frequency, the electrode length, the effective Stern-layer thickness and the adsorption coefficients.

4:18PM X14.00010 Detection and electrokinetic trapping of single fluorescent molecules in fused silica nanochannels. BRIAN CANFIELD, XIAOXUAN LI, WILLIAM HOFMEISTER, LLOYD M. DAVIS, University of Tennessee Space Institute — We describe experimental detection and electrokinetic trapping of single, fluorescently-labeled proteins confined within ~100 nm fluidic channels fabricated in fused silica. Though difficult to fabricate, the fused silica environment yields lower autofluorescence than borosilicate glass, which is especially advantageous given the low light level from single molecules. The molecules are dispersed in a buffer solution at ultralow concentration (~10^-12 M) to provide single-molecule occupancy of the sub-femtoliter probe volume within the nanochannel. Fluorescence is excited and collected in a custom-built confocal microscope, using two temporally interleaved beams from a modelocked dye laser focused to adjacent spots along the nanochannel. Detection is accomplished with custom single-photon avalanche diodes for time-resolved single-photon counting, and by using this time stamp information, a field-programmable gate array circuit board controls the electrokinetic trapping by modulating an applied voltage. Fluorescence correlation spectroscopy is also used to monitor the transport of molecules along the nanochannel. Electrokinetic transport can thus be characterized from changes in the autocorrelation function with voltage modulation.

4:30PM X14.00011 Microfluidic device for the electrokinetic manipulation of single molecules. JASON KING, LLOYD DAVIS, BRIAN CANFIELD, WILLIAM HOFMEISTER, University of Tennessee Space Institute, PHILIP SAMPSON, Vanderbilt University — We are developing a microfluidic device for three-dimensional electrokinetic manipulation of single fluorescent molecules in solution. The device consists of electrode pairs deposited onto glass cover slips by ion milling of a nickel template and sputtering of the electrode material. By use of a double Mach-Zehnder interferometer configuration, 40 fs Ti:Sapphire laser pulses (repetition rate 76 MHz) are split into four temporally interleaved pulses (effective rate 304 MHz), which are then focused to the vertices of a tetrahedron (approximately one micron per side) within the central electrode region to generate two-photon-excited fluorescence from single molecules. The time stamp data from this four-focus probe, collected with a custom fast-timing single-photon avalanche diode, enables characterization of particle motion through fluorescence cross-correlation spectroscopy.

4:42PM X14.00012 Microfluidic Channels under Magnetohydrodynamic (MHD) Convection. YOGENDRA M. PANTA, HYUN W. KIM, Youngstown State University, SHIZHI QIAN, Old Dominion University — Magnetohydrodynamic (MHD) effects have been widely known since many years. MHD effects are used to propel, stir, and pump fluids in various fluid applications especially in the field of microfluidics. Orthogonally aligned electric flux density and magnetic flux density were applied to straight and torroidal micro-channels both aligned perpendicular to the desired direction of fluid flow. Microfluidic MHD channels in straight and torroidal shapes were fabricated from a thin brass sheet sandwiched between two polycarbonate sheets patterned with two platinum electrodes in the channel walls from inside. When a potential difference of low magnitude (~ 1 mV) is applied across the electrodes, a current density J transmitted through the electrolyte solution results. In the presence of a magnetic field B, the orthogonal interaction between the resulting current density J and the magnetic field B induces Lorentz forces F (=J x B) which induce and drive fluid motion in the channel. This effect was applied to propel and pump the fluid in presence of a current carrying species both in a straight and torroidal micro-channels. Flow velocities were obtained linearly increasing with the magnetic flux densities. A drop of dye was placed into the solution to trace the path of moving fluid under MHD convection.

4:54PM X14.00013 Cell and Colloidal Substrates for Dielectrophoretic Microfluidic Immunoassays. JILL MAZUR, ZACHARY GAGNON, HSUEH-CHIA CHANG, University of Notre Dame, Department of Chemical and Biomolecular Engineering — Dielectrophoresis (DEP) is a term commonly used to describe the field induced polarization and translational motion of a polarizable particle in a non-uniform AC field. The frequency at which the induced particle dipole goes to zero, known as the crossover frequency (cof), is highly dependent on the surface conductance of the particle. We have previously shown that DNA hybridization on the surface of a 100 nm functionalized silica particle leads to detectable surface conduction changes which make it possible to detect DNA hybridization reactions by simply measuring changes in particle suspension cof. In this work we present a similar detection scheme using novel colloidal and cell substrates as dielectrophoretic immunoensors. Aminated cell or nanocolloid surfaces are subjected to a polymer coating glutaraldehyde treatment followed by antibody coupling reaction for immunoassay based detection. By varying the polymer coating thickness on the colloidal or cell surface we demonstrate the ability to tune, stabilize the cell and colloid cof, and minimized non-specific adsorption of proteins. As such, a library of cof labeled colloids and cells are created and used for multiple antigen analysis. By measuring the colloid and cell specific DEP cof prior to and after antibody-antigen interaction we demonstrated the ability to perform rapid label free protein detection within a microfluidic device.
5:06PM X14.00014 AC Electrokinesis Cell Separation on a Microfluidic Device, ZACHARY GAGNON, University of Notre Dame, Dept. Chemical and Biomolecular Engineering, HSUEH-CHIA CHANG, University of Notre Dame, Department of Chemical and Biomolecular Engineering — Rapid cell separation and collection is demonstrated through the integration of electrokinetic pumps, dielectrophoretic (DEP) traps and field driven valves into a well designed microfluidic channel loop. We present the ground-up design and analysis of this fully functional microfluidic device for the rapid separation and collection of live and dead yeast cells and malaria red blood cells (RBCs) at low concentrations. DEP cell sorting and concentration schemes are based on the exploitation of cell specific DEP crossover frequencies (cof’s). A rigorous DEP study of yeast and RBCs is presented and used to determine optimal conditions for cell separation. By utilizing a glutaraldehyde crosslinking cell fixation reaction that is sensitive to cell membrane protein concentration, we demonstrate the ability to further amplify these differences between healthy and unhealthy cells as well as stabilize their DEP cof’s. Pumping is achieved with a new type of electrokinetic flow, AC electrothermal electro-osmosis (ETEO) and is shown to scale inversely with the field induced debye length and drive fluid velocities in excess of 6 mm/sec. The well characterized electrokinetic phenomena are integrated into a microchannel loop with a specifically designed electrode field penetration length for low concentration cell separation and concentration.

5:18PM X14.00015 Anomalous analyte dispersion at microchannel-nanocapillary membrane interfaces, JARROD SCHIFFBAUER, Physics Dept, West Virginia University, KATHLEEN KELLY, Chemistry Dept., West Virginia University, WILL BOOTH, Physics Dept., West Virginia University, JOSH FERNANDEZ, Chemical Engineering, Dept., West Virginia University, AARON TIMPERMAN, Chemistry Dept., West Virginia University, BOYD EDWARDS, Physics Dept. West Virginia University — The dispersion of a plug-like distribution of negatively charged fluorescent dye molecules inside a microchannel is studied by numerical analysis of a time-series of epifluorescence microscope images. The concentration is accomplished using a nanocapillary membrane (NCM) —based concentration device. Dispersion of the analyte after concentration is complete, i.e. after the applied voltage is removed, is of considerable technical interest as a limiting factor in the functionality of lab-on-a-chip concentration devices. Subsequent band-broadening is inconsistent with Taylor dispersion and is shown here to be influenced by the presence of charge-separation between the concentrated analyte and background buffer ions.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X15 DFD: Liquid Crystals II 316

2:30PM X15.00001 The Taming of the Screw: Nonlinear Interactions in Smectic Liquid Crystals, ELISABETTA MATSUMOTO, GARETH ALEXANDER, RANDALL KAMIEN, University of Pennsylvania — From the twist grain boundary phase to the smectic phases of bent core liquid crystals, beautiful and intricate textures composed of screw dislocations appear time and again in a wide variety of smectic systems; yet, little is known about the interactions of screw dislocations. The linear smectic free energy is not sufficient to describe the energetics of single screw dislocations, and superposition cannot shed light on the interaction of many such defects. The full rotationally invariant nonlinear smectic free energy provides insight into systems of multiple screw dislocations. Such nonlinear interactions allow us to begin to understand the stability of the bulk phases observed in both smectic A liquid crystals and their chiral smectic C* counterparts.

2:42PM X15.00002 Coalescence Dynamics Analysis Of Islands In Smectic A Freely Suspended Films1, ZOOM NGUYEN, University of Colorado, Boulder, CHEOL PARK, JOSEPH MACLENNAN, MATTHEW GLASER, NOEL CLARK — We explore the coalescence dynamics of circular islands in smectic A freely suspended liquid crystal films. The process typically has two distinct stages. First, when the islands make contact initially, the thinner island wraps around the thicker one. These dynamics are fast and determined by the line tensions of the islands and by the film’s viscosity. Then the region that used to be the thicker island expands and eventually covers the whole merged island. This process which is dependent on the permeation between layers in addition to the line tension and viscosity, is much slower. The shapes of the islands are extracted from high speed camera images and compared with model calculations.

5:06PM X15.00014 AC Electrokinesis Cell Separation on a Microfluidic Device, ZACHARY GAGNON, University of Notre Dame, Dept. Chemical and Biomolecular Engineering, HSUEH-CHIA CHANG, University of Notre Dame, Department of Chemical and Biomolecular Engineering — Rapid cell separation and collection is demonstrated through the integration of electrokinetic pumps, dielectrophoretic (DEP) traps and field driven valves into a well designed microfluidic channel loop. We present the ground-up design and analysis of this fully functional microfluidic device for the rapid separation and collection of live and dead yeast cells and malaria red blood cells (RBCs) at low concentrations. DEP cell sorting and concentration schemes are based on the exploitation of cell specific DEP crossover frequencies (cof’s). A rigorous DEP study of yeast and RBCs is presented and used to determine optimal conditions for cell separation. By utilizing a glutaraldehyde crosslinking cell fixation reaction that is sensitive to cell membrane protein concentration, we demonstrate the ability to further amplify these differences between healthy and unhealthy cells as well as stabilize their DEP cof’s. Pumping is achieved with a new type of electrokinetic flow, AC electrothermal electro-osmosis (ETEO) and is shown to scale inversely with the field induced debye length and drive fluid velocities in excess of 6 mm/sec. The well characterized electrokinetic phenomena are integrated into a microchannel loop with a specifically designed electrode field penetration length for low concentration cell separation and concentration.

2:30PM X15.00001 The Taming of the Screw: Nonlinear Interactions in Smectic Liquid Crystals, ELISABETTA MATSUMOTO, GARETH ALEXANDER, RANDALL KAMIEN, University of Pennsylvania — From the twist grain boundary phase to the smectic phases of bent core liquid crystals, beautiful and intricate textures composed of screw dislocations appear time and again in a wide variety of smectic systems; yet, little is known about the interactions of screw dislocations. The linear smectic free energy is not sufficient to describe the energetics of single screw dislocations, and superposition cannot shed light on the interaction of many such defects. The full rotationally invariant nonlinear smectic free energy provides insight into systems of multiple screw dislocations. Such nonlinear interactions allow us to begin to understand the stability of the bulk phases observed in both smectic A liquid crystals and their chiral smectic C* counterparts.

2:54PM X15.00003 Orientational fluctuation study in nematic liquid crystals by high speed micrograph, BEOM-JIN YOON, MIN SANG PARK, School of Polymer, Textile, and Fiber Engineering, Georgia Institute of Technology, JUNG O. PARK, School of Polymer, Textile, and Fiber Engineering, Center for Advanced Research on Optical Microscopy, Georgia Institute of Technology, MOHAN SRINIVASARAO1, School of Polymer, Textile, and Fiber Engineering, School of Chemistry and Biochemistry, Center for Advanced Research on Optical Microscopy — The orientational fluctuations in uniaxial and biaxial nematic liquid crystals were investigated with a polarized microscope and a high speed TV camera. Liquid crystals usually have fluctuations with respect to their director, even when the molecular axes tend to be aligned to each other. These fluctuations are sufficiently slow and large, have long wave length and increase with temperature. Herein, we describe our study on fluctuation dynamics by direct observations in real space, while it has been typically done by the photon scattering in reciprocal space. The twinkling of liquid crystals due to orientational fluctuations were observed with a high speed camera up to 500 frames/sec. The time correlation function of the intensity was computed via 2D spatial Fourier transform of each image and then the relaxation frequency was estimated from it. The elastic constant to the viscosity ratio was computed from the relaxation frequency. This approach provides facile route to analyze fluctuation dynamics in liquid crystals.

3:18PM X15.00005 Behavior of Focal Conic Defects in Shear Flow, SOURAV CHATTERJEE, SHELLEY ANNA, Carnegie Mellon University — The rheology of layered liquids is influenced to a large extent by defects present in the system, especially in small gaps. Toroidal focal conic defects are a common type of defect in small molecule layered liquids. We present a study of the influence of flow on focal conic defects in smectic liquid crystals, generated by antagonistic boundary condition at the surfaces. The defects are confined in gaps of the order of tens of microns and are subject to simple shear. The sizes of the focal conic defects vary with the gap size, and hence visual observations are made as to how the gap influences the dynamics of the focal conic defects in a shear flow. We also observe instabilities in initially defect free samples that lead to the creation of defects. The results offer insight into the complex relationship between defects and flow.

3:30PM X15.00006 Polarization current as evidence of local anticlinic correlations in de Vries smectics\(^1\), Z. V. SMITH, P. D. BEALE, R.-F. SHAO, L. WANG, D. M. WALBA, N. A. CLARK, M. A. GLASER, LCMRC, U. of Colorado, Boulder — Previous theoretical work on the electrooptic response of chiral de Vries SmA materials based on the electric field-induced reorientation of independent tilt domains [J. V. Selinger et al., Phys. Rev. E 64, 061705 (2001)] fails to account for the sigmoidal dependence of induced polarization (P) on field (E) seen in some materials. To account for this behavior, we model de Vries smectics as ensembles of small but finite anticlinic tilt domains. Within each domain, interlayer tilt coupling favors anticlinic interfaces, but the finite range of in-layer tilt correlations leads to thermally activated synclinic interfaces and a finite tilt correlation length along the layer normal. This model, equivalent to a generalized one-dimensional XY model in an external field with quadratic and quartic nearest-neighbor interactions, is studied by Monte Carlo simulation and transfer matrix methods. The model successfully reproduces the dependence of P on E for a specific material (W530), and yields physical parameters such as the in-layer correlation length and effective interlayer tilt coupling. The predicted anticlinic tilt correlations should be observable as diffuse superlattice reflections in polarized resonant x-ray scattering experiments.

4:20PM X15.00007 A one order parameter tensor description of biaxial nematic liquid crystals, XIAOYU ZHENG, Department of Mathematical Sciences, Kent State University, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — We present a simple one order parameter tensor mean field theory of biaxial nematic liquid crystals. We construct the free energy from molecular interactions, identify the components of the order parameter tensors, and obtain self-consistent equations, which are then solved numerically. The phase behavior is described via a 3D phase diagram. We discuss the connection between molecular properties and the coefficients in the Landau expansion.

4:40PM X15.00008 Elasticities and viscosities of a lyotropic chromonic nematic liquid crystal, KRISHNA NEUPANE, Kent State University, YURI NASTISHIN, Institute of Physical Optics, Lviv, Ukraine, ALAN BALDWIN, OLEG LAVRENTOVICH, SAMUEL SPRUNT, Kent State University — We have performed dynamic light scattering studies of the elastic moduli and viscosity coefficients in a uniformly aligned sample of a lyotropic chromonic nematic formed by 14 wt. % water solution of Disodium Cromoglycate \([1]\). These parameters show a significant anisotropy. In particular, the bend and splay moduli \(K_{11}\) and \(K_{13}\) are an order of magnitude higher than the twist modulus \(K_{22}\), and the ratio \(K_{13}/K_{11}\) shows an anomalous increase in temperature, which we attribute to the shortening of the aggregates. The bend viscosity is three orders of magnitude smaller than the splay and twist viscosities; all viscosity coefficients exhibit a strong temperature dependence.

4:06PM X15.00009 Reflection and transmission coefficients of a cholesteric liquid crystal film with a negative dielectric coefficient\(^1\), SABRINA RELAIX, WENYI CAO, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — A cholesteric liquid crystal (CLC) is a periodic dielectric structure where simple analytic solutions of Maxwell’s equations exist: light propagating along the helical axis has been first described by Mauguin in 1911 \([1]\), for wavelengths much smaller than the helical pitch, and was formulated more generally by de Vries in 1951 \([2]\). The analytical solutions are for bulk CLCs and do not describe the optical properties of a finite thickness CLC film. Recently, analytic expressions for the reflection and transmission coefficients of a CLC slab have been obtained by solving Maxwell’s equations and satisfying boundary conditions \([3,4]\), providing results for thick slabs which go beyond the limitation of numerical methods. We discuss how these results are modified when one of the dielectric coefficients is negative. We explore the connection with hyperbolic dispersion and negative index materials. \([1]\) C. Mauguin, Bull. Soc. Fr. Miner. Cristallogr. 34, 6 (1911) \([2]\) H. de Vries, Acta Crystallogr. 4, 219 (1951) \([3]\) W. Cao, Ph.D. dissertation, Chemical Physics, Kent State University (2005) (http://e-L.org) \([4]\) S. Relaix, W. Cao and P. Palffy-Muhoray, to be published

4:18PM X15.00010 Maier-Saupe Theory of Nematics in 4D, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University, XIAOYU ZHENG, Department of Mathematical Sciences, Kent State University — We extend the Maier-Saupe theory of nematics to 4 dimensions. We consider the interaction of cylindrically symmetric particles, and derive an effective single particle potential. Using this, we obtain the free energy and the self-consistent equation for the order parameter – a second rank traceless tensor. In 4D, the order parameter has three independent eigenvalues. We solve the self-consistent equation, and study the solutions as function of temperature. Our results give insight into the relation between orientational order parameters in different dimensions.

4:30PM X15.00011 Statistical mechanics of the flexoelectric effect in nematic liquid crystals\(^1\), SUBHAS DHAKAL, JONATHAN V. SELINGER, Kent State University — Flexoelectricity is the phenomenon in which polarization is induced by imposed deformations of the director field in nematic liquid crystals. Recent experiments \([1,2]\) have found that the flexoelectric effect is three orders of magnitude greater for bent-core liquid crystals than for conventional rod-like liquid crystals. To understand this experimental result, we develop a lattice model for the statistical mechanics of the flexoelectric effect. We perform Monte Carlo simulations and mean-field calculations to find the behavior as a function of interaction parameters, temperature, and applied electric field. The resulting phase diagram has four phases: isotropic, uniaxial nematic, biaxial nematic, and polar. In the uniaxial and biaxial nematic phases, there is a large splay or bend flexoelectric effect, which diverges as the system approaches the nematic-polar transition. This model may explain the large bend flexoelectric coefficient observed in bent-core liquid crystals, which have a tendency toward polar order. \([1]\) J. Harden, B. Mbanga, N. Eber, K. Fodor-Csorba, S. Sprunt, J. T. Glesson, and A. Jakli, Phys. Rev. Lett. 97, 157802 (2006). \([2]\) J. Harden, R. Teeling, J. T. Glesson, S. Sprunt, and A. Jakli, Phys. Rev. E 78, 031702 (2008).

4:42PM X15.00012 Aggregates in Chromonic Liquid Crystal Phases of Aqueous Solutions of Sunset Yellow*, LEELA JOSHI, SHIN-WOONG KANG, DENA MAE AGRA-KOULMAN, SATYENDRA KUMAR, Department of Physics, Kent State University — Molecules of dye Sunset Yellow consist of flat poly-aromatic core and hydrophilic groups at the periphery. In aqueous environments, they self-organize into columnar aggregates mainly via $\pi - \pi$ interactions between aromatic cores. At high concentrations, dye aggregates develop orientational and positional orders to form the nematic (N) and columnar (C) mesophases. Synchrotron x-ray scattering and optical polarizing microscopy were used to better understand the growth of aggregates and mesophase formation. Average column height and their spatial organization strongly depend on concentration, temperature, and pH value of the solution. The aggregate size decreases with temperature exhibiting an Arrhenius behavior with mesophase dependent activation energy. A dramatic decrease in the aggregate size upon addition of HCI highlights their sensitivity to electrostatic interactions. *Work supported by grant NSF/DMR-086991.

4:54PM X15.00013 Aggregation Properties of the Chromonic Liquid Crystal Benzopurpurin 4B, CHRISTOPHER MCKITTERICK, PETER COLLINGS, Swarthmore College — Benzopurpurin 4B (BPP) is a textile dye very similar to the common indicator Congo Red. As is true for all chromonics, the absorption spectrum is concentration dependent at low concentrations. To estimate a free energy change for aggregation, it is higher than has been determined for other systems. Unlike other recently investigated chromonic liquid crystals, BPP forms a liquid crystal phase at extremely low concentrations, about 0.5 wt%. Also unlike these other chromonic liquid crystals, the aggregation kinetics are exceedingly slow. X-ray diffraction and light scattering measurements indicate that the aggregates of BPP are much larger than for chromonic systems that form liquid crystals at higher concentrations. BPP aggregates can be imaged using confocal microscopy, revealing a layer distribution centered at 3 $\mu$m for a solution forced through a 0.2 $\mu$m filter. Over days, the aggregates lengthen to well over 10 $\mu$m. The diameter of the aggregate images is slightly greater than the diffusion limit of the microscope, placing an upper limit on the diameter of 0.14 $\mu$m. These dimensions are consistent with the light scattering results.

5:06PM X15.00014 Generalized Nemato-hydrodynamic Boundary Conditions with Application to Bistable Twisted Nematic Liquid Crystal Displays1, ANGBO FANG, Department of Physics, Hong Kong University of Science and Technology, TIEZHENQ QIAN, Department of Mathematics, Hong Kong University of Science and Technology, PING SHENG, Department of Physics and the Institute of Nano Science and Technology, Hong Kong University of Science and Technology — Parallel to the highly successful Ericksen-Leslie hydrodynamic theory for the bulk behavior of nematic liquid crystals (NLC), we derive a set of coupled hydrodynamic boundary conditions to describe the NLC dynamics near NLC-solid interfaces. In our boundary conditions, translational flux (flow slippage) and rotational flux (surface director relaxation) are coupled according to the Onsager variational principle of least energy dissipation. The application of our boundary conditions to the truly bistable $\pi$-twist NLC cell reveals that the thus far overlooked translation-rotation dissipative coupling at solid surfaces can accelerate surface director relaxation and enhance the flow rate. This can be utilized to improve the performance of electro-optical nematic devices by lowering the required switching voltages and reducing the switching times.

5:18PM X15.00015 Soft Micro- to Nanolithography Using Highly Periodic Smectic Liquid Crystal Defects, HEE-TAE JUNG, YUN HO KIM, Korea Advanced Institute of Science and Technology, DONG-KI YOON, Samsung Electronics, HYEON SU JEONG, Korea Advanced Institute of Science and Technology, ORGANIC OPTO-ELECTRONIC MATERIALS LAB, TEAM — Achieving perfect long-range order with soft building blocks at high speed and high resolution is one of the most exciting interdisciplinary research areas in current materials science and nano-biotechnology. Here, we have developed highly periodic patterns with sub-micrometer features over large-areas using toric focal conic domains (TFCDs) originating from smectic liquid crystal (LC). TFCDs are accomplished by precisely controlling the surface and interfacial properties of smectic LC. In order to apply the smectic liquid crystal defect arrays in lithography, the hexagonal arrays of domain patterns are used as molds for ultraviolet (UV) curable polymers, thereby providing LC defect stamps with high spatial resolution over large areas. Our method was further utilized to transfer patterns with sub-micrometer features from the polymer stamp surface to a secondary surface by microcontact printing ($\mu$-CP). The patterning method based on LC defects has significant advantages over existing lithographic approaches: 1) the masters and stamps are easy to fabricate, 2) the masters and stamps provide long-range surface ordering over large-areas, 3) the periodic arrays are formed quickly in several seconds, and 4) the stamps can generate feature sizes on the micrometer and submicrometer length scales, and 5) the methodology offers the possibility of controlling the array geometry by altering the geometry of the confining channels.

Thursday, March 19, 2009 2:30PM - 4:42PM
Session X16 DCMP: Liquid Helium 317

2:30PM X16.00001 Measurements of the Thermal Conductivity of Vycor Glass filled with Superfluid $^4$He1, WILLIAM TIERNAN, Mesa State College, Grand Junction, CO and Univ. of Mass. Amherst, MA, SILVIA IONSECU, MICHAEL RAY, ROBERT HALLOCK, Univ. of Mass. Amherst, MA — We report on experiments designed to measure the thermal conductivity of Vycor filled with superfluid $^4$He for temperatures in the range 1.2 - 2.0 K and pressures from 2 - 30 atm. The experimental apparatus, which consists of a rod of Vycor held in a stainless steel tube, will be described. We will report available results for the thermal conductivity as a function of temperature and pressure.

1 Supported by the NSF

2:42PM X16.00002 Phonon-roton modes, superfluidity and a Bose glass phase in nanoscale liquid $^4$He, JACQUES BOSSY, Institut Neel, CNRS-UJF, Grenoble, JONATHAN PEARCE, National Physical Laboratory, HELMUT SCHOBER, Institut Laue Langevin, Grenoble, HENRY GLYDE, university of Delaware — We present neutron scattering measurements of the elementary phonon-roton modes of liquid $^4$He confined in nanoporous media. The aim is to compare phonon-roton (P-R) and superfluid density measurements in helium at nanoscales and in disorder. A specific goal is to determine the relation between temperature and pressure in which well defined phonon-roton modes (and therefore BEC) exist and compare this with the superfluid phase region, i.e. with the superfluid-normal phase critical temperature $T_c$ and pressure $p_c$ in porous media. We find well defined P-R modes (BEC) extend to temperatures above $T_c$ (up to $T_s = 2.17$ K at SVP) and to pressures above $p_c$ (up to a pressure $p = 36.3-36.8$ bars at $T = 0$ but no modes above this pressure [1]). This suggests that there is a Bose glass phase consisting of local regions of BEC separated by normal liquid so that there is no phase coherence across the sample lying between the superfluid and normal liquid phase. The Bose glass phase spans the superfluid phase at all $p$ and $T$. We compare this phase diagram with other dirty Bose systems. [1] Bossy et al. Phys. Rev. Lett. 101, 025301 (2008), Phys. Rev. B (in press)(2008)
2:54PM X16.00003 Thin $^4$He films on Nano-porous Diblock Copolymer Substrates. John Cummins, Amherst, MA, Robert Hallock, Amherst, MA — In recent years diblock copolymer templates have been a focus of attention due to their potential uses in nano-scale systems. The ability to produce regular arrays of cylindrical pores has applications in areas such as the production of nanowires and magnetic storage. Porous polymer films made by diblock copolymer techniques provide an interesting substrate for helium. Previously studied porous geometries e.g. nucleopore, anopore, aerogel, vycor, and porous aluminia have provided interesting insights into capillary condensation, the Kosterlitz-Thouless transition and hysteresis. Here we report on the study of thin superfluid $^4$He films on diblock copolymer substrates by means of quartz crystal microbalance techniques.

3:06PM X16.00004 Evidence of a Proximity Effect in Liquid Helium. Mark O. Kimball, Justin K. Perron, Francis M. Gasparini, University at Buffalo, The State University of New York — We report measurements of the specific heat of helium confined to boxes connected via a 32 nm thick film. The spacing between the boxes is approximately 4 μm edge-to-edge. The specific heat is compared to a similar measurement of helium confined to the same size boxes where the spacing between boxes is 2 μm. Evidence of a coupling between the boxes in the tighter packed array is seen in a temperature region where the filling film is in the normal state. We also report measurements of the superfluid fraction of the film connecting the boxes in the present experiment. The superfluid state persists to higher temperatures than that expected on the basis of finite-size scaling for a 32 nm film. At the temperatures where the measurement of the film occurs, the helium in the boxes is already superfluid indicating, perhaps, the modification in behavior of a thin film in proximity to larger regions of superfluid.

3:18PM X16.00005 A Novel Method to Create Multielectron Bubbles. Jeiping Fang, Anatoly Dementyev, Harvard University, Jacques Tempere, Universiteit Antwerpen, Isac Silbera, Harvard University — A multielectron bubble (MEB) in liquid helium is a fascinating object with a spherical two-dimensional electron gas on its surface. Recent theoretical studies of MEBs discuss a plethora of new phenomena. We describe a novel way of creating MEBs and discuss possible ways of trapping them. An electrically heated tungsten filament submerged in superfluid helium is surrounded by a vapor sheath containing electrons due to thermionic emission. We were able to pull MEBs from the sheath by applying electric fields up to 15 kV/cm. The motion of MEBs was captured using a high-speed camera (6400 frames/sec). The trajectory of bubbles was clearly influenced by the electric field, which proved that bubbles were charged. In a separate experiment we measured the charge of such an MEB to be as high as 10$^{-5}$ C. We plan to trap MEBs using electromagnetic trap, which will enable extensive experimental studies of these elusive but exciting objects.

3:30PM X16.00006 Phase diagram for helium films on lithium substrates. E. Van Cleve, J. C. Burton, P. Tabor, University of California, Irvine — We have used an in situ cryogenic pulsed laser deposition system to deposit a lithium film onto a quartz crystal microbalance. Helium 4 adsorption isotherms were measured on a lithium substrate between 2K and 0.6K. Features of these isotherms such as superfluid mass decoupling and variations in the dissipation were used to construct a phase diagram for helium films including the KT line and the 2D liquid-vapor coexistence region. The liquid-vapor critical temperature is approximately 0.8K. The KT transition is anomalous inside the 2D liquid-vapor coexistence region, occurring at constant sub-monolayer coverage independent of temperature. No inert solid-like layers of helium form on lithium substrates, so superfluid films are in direct contact with the substrate. These results will be compared and contrasted with the behavior of helium on other intermediate strength substrates such as exfoliated graphite pre-plated with hydrogen, sodium and magnesium.

3:42PM X16.00007 Quantized vortices and superflow in arbitrary dimensions: Structure, energetics and dynamics. Florin Bora, Paul Goldbart, University of Illinois at Urbana-Champaign — The structure and energetics of superflow around quantized vortices, and the motion inherited by these vortices from this superflow, are explored for the superfluidity of helium-four in arbitrary dimensions. The vortices may be idealized as objects of co-dimension two, such as two-dimensional surfaces in the case of four-dimensional superfluidity. The energy of the superflow is found to take on a simple form for vortices that are smooth and asymptotically large, compared with the vortex core size. The motion of vortices is analyzed in general, as well as for the special cases of hyper-spherical and weakly distorted hyper-planar vortices. In all dimensions, vortex motion reflects vortex geometry. In dimension four and higher, this includes not only extrinsic but also intrinsic aspects of the vortex shape. For the generalizations of the vortex rings of three dimensional superfluidity, the energy-momentum relation is determined. Simple scaling arguments recover the essential features of these results, up to numerical and logarithmic factors.

3:54PM X16.00008 $^3$He Spin Pump. A. Yamaguchi, H. Ishimoto, Institute for Solid State Physics, University of Tokyo, H. Kojima, Rutgers University — The superfluid component of $^3$He A$_1$ phase is spin-polarized. The process of forcing the superfluid component through a spin filtering structure, in a manner of mechano-magnetic effect, can be used to increase the spin polarization beyond the equilibrium under a given applied magnetic field. We have constructed a test cell in which a glass capillary array acts as the spin (and entropy) filter and an electrostatically actuated diaphragm forces the superfluid flow through it. Preliminary results show that a maximum relative increase of polarization by 50% could be achieved. The maximum increase in polarization appears to be limited by the critical superfluid flow through the channels in the glass capillary array. The dependence of the observed effects on temperature, pressure and magnetic field will be presented.

4:06PM X16.00009 The Spin Diffusion Coefficient of Superfluid $^3$He in the A$_1$- phase. Ayodeji AwoBode, Anthony Leggett, University of Illinois at Urbana Champaign — Using the Boltzmann kinetic approach and perturbation theory, an approximate expression describing the variation with temperature of the spin diffusion coefficient in the A$_1$-phase of $^3$He is derived. It is observed that for temperatures close to the transition temperature $T_c$, the spin diffusion coefficient $D \sim (T_c - T)^{1/2} + \text{const}$. Comparison of the theoretical result with related experimental measurements is discussed.
in superconductors. For the B-like superfluid phase of\textsuperscript{3}He in 98\% porosity aerogel for several different pressures in zero magnetic field \cite{1}. It revealed and confirmed many interesting features directly associated with impurity scattering: collisional drag effect, absence of zero sound crossover and order parameter collective modes, and gapless superfluidity. In this work, we report an experimental effort to uncover the detailed gap structure that is expected to be significantly modified by the presence of impurity scattering. We conducted frequency dependent attenuation measurements, which might shed light on this problem as a tunneling experiment does in superconductors. For the B-like superfluid phase of\textsuperscript{3}He in 98\% aerogel, we report sound attenuation measurements performed between 14 and 33 bar, while using four frequencies between 3.7 and 11.2 MHz.

\textsuperscript{3}This work is supported by NSF through DMR-0239483 and 0803516 (YL), DMR-0701400 (MWM), DMR-0654118 (NHMFL), and the State of Florida.

4:30PM X16.00011 Superfluid \textsuperscript{3}He in Anisotropic Aerogels\textsuperscript{1}. JOHANNES POLLANEN, JOHN P. DAVIS, BENJAMIN REDDY, KENT R. SHIRER, HYOUNGSOON CHOI, WILLIAM J. GANNON, CHARLES A. COLLET, WILLIAM P. HALPERIN, Northwestern University — Anisotropic quasiparticle scattering has been predicted to modify the properties of superfluid\textsuperscript{3}He in high porosity silica aerogels\textsuperscript{2}. For example, anisotropic scattering produced by axial compression (or elongation) of the aerogel has been predicted to stabilize the axial (or polar) state of superfluid\textsuperscript{3}He. We have used a transverse acoustic interference method to determine the phase diagram of superfluid\textsuperscript{3}He in a 98\% porous silica aerogel subjected to 17\% axial compression. We have found that this uniform axial anisotropy does not increase the stable region of A-like phase but does inhibit the nucleation of the B-phase at low pressure. We have performed optical cross-polarization experiments\textsuperscript{3} to verify the presence and uniformity of the anisotropy in the aerogel samples. Additionally, we are performing nuclear magnetic resonance experiments on superfluid\textsuperscript{3}He in aerogels with anisotropy introduced with either axial or radial compression.

Thursday, March 19, 2009 2:30PM - 5:18PM –
Session X17 GQI: Semiconducting Qubits II 318

2:30PM X17.00001 Effect of Substrate Doping in Relaxed SiGe Buffers on Strained Si 2DEG Quantum Devices. KUN YAO, MIKHAIL GAEVSKI, Princeton University, ALEXANDER CHERNYSHOV, LEONID ROKHINSON, Purdue University, CURTIN MIKE, JI.SOO PARK, JAMES FIORENZA, ANTHONY LOCHTEFELD, AmberWave Systems, JAMES STURM, Princeton University — We describe the impact of Si substrate doping on the substrate leakage in strained Si two-dimensional electron gases (2DEG) on SiGe relaxed graded buffers and on quantum devices fabricated from the 2DEG. The best commercially available high quality SiGe relaxed buffers with 30\% Ge content, grown at temperature above 1000\°C, have very low threading dislocation density (<1E5cm\textsuperscript{-2}). Subsequent strained Si/SiGe heterostructures were grown at 625-700\°C in a rapid thermal chemical vapor deposition (RTCVD). However, it is shown that the substrate doping (Arsenic) contributes to leakage current origin in relaxed buffers at liquid helium temperatures if the starting Si substrate is heavily doped (~5E17cm\textsuperscript{-2}). The leakage can be attributed to enhanced dopant diffusion along misfit dislocations and high diffusion rate of As in SiGe. The leakage current makes side gating of nanostructures in the 2DEG impossible. With a lightly doped substrate, to avoid leakage the structure has a high quality 2DEG and successful side gating of a 2DEG quantum dot for a quantum point contact. This work is supported by the NSA under ARO contract number W911NF-05-1-0437.

2:42PM X17.00002 Robust Fabrication Techniques for Si/SiGe Quantum Dots. MINGYUN YUAN, FENG PAN, TIM GILHEART, JOEL STETTENHEIM, MUSTAFA BAL, Dartmouth College, D. E. SAVAGE, M. A. ERIKSSON, University of Wisconsin-Madison, A. J. RIMBERG, Dartmouth College — Si/SiGe quantum dots promise a long spin coherence time due to reduced electron-nuclear spin interaction. Nevertheless, successful device yield has been limited in this novel material system due to difficulties in producing reliable ohmic contacts and Schottky gates. We have successfully developed fabrication processes that produce robust ohmic contacts and non-leaky Schottky gates. The ohmic contacts typically have a two-probe resistance of a few tens of kilohms and the Schottky gates have no detectable leakage current up to an applied voltage of -5 V. In typical devices we are able to pinch off the quantum point contacts with a voltage range between -1.5 V to -4.5 V. Recent experimental results will be discussed. This work was supported by the NSF under Grant No. DMR-0804483 and 0803516 (YL), DMR-0701400 (MWM), DMR-0654118 (NHMFL), and the State of Florida.

2:54PM X17.00003 Effect of Intervalley Mixing on Qubit Operation in SiGe Quantum Dot Structures\textsuperscript{1}. A. A. KISELEV, R. S. ROSS, B. H. FONG, M. F. GYURE, HRL Laboratories, Malibu, CA 90265 — We analyze the effects of valley degeneracy and intervalley mixing on single- and multi-electron states in (001) SiGe heterostructures, including effect of interface steps and variations in interface quality. We focus on the structure of two-electron states in both single and double quantum dot structures in the presence of valley degeneracy in the host material and the oscillatory behavior of exchange coupling in the presence of nonplanar heterointerfaces. We present modeling and simulation results relevant to the design of SiGe based accumulation-mode quantum-dot structures, especially CI calculation in presence of the intervalley mixing.

\textsuperscript{1}Sponsored by United States Department of Defense. Approved for Public Release, Distribution Unlimited.

3:06PM X17.00004 Transport and charge sensing in Si/SiGe double-quantum dots. CHRISTIE SIMMONS, MADHU THALAKULAM, E. K. SACKMANN, B. J. VAN BAEL, D. E. SAVAGE, M. G. LAGALLY, R. JOYNT, M. FRIESEN, S. N. COPPERSMITH, M. A. ERIKSSON, University of Wisconsin - Madison — Gated quantum dots in Si/SiGe are of interest because spins in silicon are weakly coupled to the host material. We demonstrate that Coulomb blockade measurements through a single quantum dot are well correlated with charge sensing in a nearby quantum point contact. Charge sensing enables the determination of the absolute number of electrons in the system, and we present data demonstrating a one-electron single quantum dot. Incorporated with a double quantum dot, charge sensing can be used to probe the inter-dot motion of a single electron at fixed total charge in the double dot. The tunnel coupling between the two dots directly effects the charge localization and thus the sharpness of this inter-dot transition. Here we demonstrate gated electrical control of the exchange coupling and thus an important step towards qubit implementation – showing a smooth transition between two well-isolated dots, two dots so strongly coupled that they act as a single large quantum dot, and the intermediate regime.

3:18PM X17.00005 Quantum dot crossbar circuits. CHRISTINE R. NOGUERA, University of Wisconsin – Madison — Quantum dot crossbars are a scalable method for performing quantum logic gates using multiple qubits. Quantum dot crossbars can be made with thin silicon films using electron-beam lithography and selective-area growth. The quantum dots are spaced at a distance that limits parasitic interactions with the gates. To show that a quantum dot crossbar can be made with current technology, we present experiments on arrays of quantum dots fabricated in a patterned silicon film using an electron-beam writer. We also present a crossbar design that is scalable to large numbers of qubits.
3:18PM X17.00005 Transient and stationary leakage current through a double quantum dot in the Pauli spin blockade regime, FARZAD QASSEMI MALOOMEH, WILLIAM A. COISH, FRANK K. WILHELM, Institute for Quantum Computing and Physics Department, University of Waterloo — We have calculated stationary and transient leakage current through a double quantum dot in the Pauli spin blockade regime. Quite remarkably, even in systems with inhomogeneous hyperfine coupling, we find that the leakage current is often controlled by spin-flip cotunneling processes with the leads. Our calculations show that these processes can be suppressed for one of the spin-triplet states by applying a small magnetic field, allowing for the preparation of a pure spin triplet. We have also found the transient effective charge passing through the double dot between blocking events, which can be strongly modified due to the spin-flip cotunneling processes. These results may explain features observed in several experiments.

3:30PM X17.00006 ABSTRACT WITHDRAWN

3:42PM X17.00007 Energy Dependent Tunneling in a Silicon Double Quantum Dot, MARK FRIESEN, University of Wisconsin-Madison, C. B. SIMMONS, NAKUL SHAJI, R. H. BLICK, S. N. COPPERSMITH, M. A. ERIKSSON — We study transport currents in a few-electron Si/Ge double quantum dot. A detailed analysis is made of the recently discovered phenomenon of lifetime enhanced transport (LET), in which current may flow in a regime typically considered to be blocked. To understand this effect, a rate equation model is developed, including both singlet and triplet transport channels. Making use of a simple model of tunneling across a quantum barrier, we map out the energy dependence of the tunneling. This allows us to obtain quantitative estimates for the tunneling rates and transport currents throughout the reverse bias regime. We are then able to identify both resonant and non-resonant phenomena, and provide a physical understanding of the different blockade regimes. In particular, we provide detailed predictions for the conditions under which LET may be observed.

3:54PM X17.00008 Charge transport in silicon double quantum dots, TED THORBECK, JQI, NIST and U. of Maryland, NEIL ZIMMERMAN, NIST, AKIRA FUJIWARA, YUKINORI ONO, YASUO TAKAHASHI, HIROSHI INOKAWA, NTT Basic Research Laboratory — Double quantum dots are an essential component for many schemes of semiconductor quantum computation. We will present results for transport through a silicon double quantum dot system. Our devices are formed by mesa-etching an SOI wafer to form a nanowire, and then poly-silicon gates are deposited. A global gate is used to invert and local gates form tunnel barriers isolating quantum dots and controlling the potential of the dots. Because the coupling between the two dots is controllable, a transition from a single dot, to two coupled dots, to two uncoupled dots is observed. We will analyze the resulting honeycomb diagram. We also hope to present results in the few electron regime.

4:06PM X17.00009 Modeling of Accumulation-Mode Quantum Dot Structures for Quantum Information Processing1, R. S. ROSS, A.A. KISELEV, B.H. FONG, M.F. GYURE, HRL Laboratories, Malibu, CA 90265 — We present modeling and simulation results relevant to the design of SiGe and III-V based accumulation-mode quantum-dot structures for use as electron-spin-based qubits. We have developed a self-consistent real-space multi-electron simulation tool to efficiently explore and optimize these structures. Specific practical issues we address include the design of double-quantum-well heterostructures, enhancement-gate-electrode design and quantum-dot electronic structure with attention to the effects of electrostatic gate action. We examine the addition and excited-state spectra of single quantum dots (QDs), the exchange coupling of nearest-neighbor quantum dots and the vertical tunneling behavior of our accumulation-mode devices. We also present comparisons to recently obtained experimental results on addition spectra in accumulation-mode quantum dots and show that our models correctly capture the relevant behavior. In addition, we address the robustness of device designs with respect to randomly distributed discrete dopants using a semi-analytical model and full numerical simulation based on impurity-induced random potentials.

4:18PM X17.00010 Si double quantum dot spin qubit in a MOSFET structure, QUIZI LI, DAMITRICE CULCER, LUKASZ CYWINSKI, SANKAR DAS SARMA, University of Maryland, College Park — Motivated by recent experimental developments, we theoretically consider the prospects for creating spin qubits in a lateral double-dot structure fabricated in a Si MOSFET by lithographic patterning. We calculate tunnel coupling, exchange splitting, and other relevant qubit properties as functions of the double-dot structural parameters, i.e. dot separation, central barrier, detuning, etc. Our motivation is to obtain a detailed qualitative comparison between GaAs and Si double-dot systems to see whether a Si MOSFET double-dot structure is feasible as a spin qubit in real quantum computer architectures. We will discuss both regular single electron spin qubit and the successful (in GaAs quantum dots) singlet-triplet spin qubits.

4:30PM X17.00011 Accumulation-Mode Quantum-Dot Devices, MATTHEW BORESELLI, EDWARD CROKE, MARK GYURE, ROBERT HAYES, IVAN MILOSAVLEVIC, ADELE SCHMITZ, JEONG-SUN MOON, ANDREW HUNTER, HRL Laboratories, LLC. — We have developed a quantum-dot device based on a double-well heterostructure in which electrons are localized in the top, mostly empty small circular gate. Charge occupancy changes in the dot are monitored by measuring current confined to a narrow channel in the bottom well. In this design, dot occupancy is primarily controlled by a single gate and interacting dots can be straightforwardly fabricated. We have successfully fabricated and characterized single-dot of devices of this design in AlGaAs/InGaAs, and are extending the design to SiGe/Si heterostructures. We have measured charging spectra of III-V versions of the device down to zero electron occupancy. Charging spectra show enhanced stability for n=2, 6, 12, and 20 electrons. We have measured the tunneling times as a function of bias to map out excited states of a two-electron dot.

4:42PM X17.00012 Cross-correlation heterodyne detection part I: Measuring the vacuum fluctuations at microwave frequencies, MATTEO MARIANTONI, EDWIN P. MENZEL, M. A. ARAQUE CABALLERO, F. DEPPE, E. HOFFMANN, T. NIEMCZYK, A. MARX, R. GROSS, Walther-Meissner-Institut and TU Muenchen, Germany, E. SOLANO, Departamento de Quimica Fisica, Universidad del Pais Vasco / Euskal Herriko Unibertsitatea, Spain — In order to gain a profound insight into the fundamental properties of quantum electrodynamics (QED), studying the zero-point fluctuations of microwave radiation represents an important task. Here, we present a full experimental characterization of the vacuum fluctuations by measuring the Planck distribution of its noise power at microwave frequencies and very low temperatures. We observe a cross-over from thermal noise to vacuum quantum noise and quantify the level of vacuum fluctuations for a narrow frequency band centered around 5.85 GHz. We demonstrate the change of the vacuum fluctuations level with the center frequency. Finally, we perform a new type of heterodyne detection particularly suitable for circuit QED systems. It is based on a new, homodyne, cross-correlation method. The latter allows for the reconstruction of the entire covariance matrix of the vacuum. We acknowledge support from SFB631, NIM, EuroSQUIP, and the Ikerbasque Foundation.

In this contribution, we present our studies of Michelson and Fabry-Perot interferometers with WILDFEUER, LOUISIANA STATE UNIVERSITY, AARON J. PEARLMAN, JUN CHEN, Joint Quantum Institute, National Institute of Standards and Technology, and University of Maryland, JONATHAN P. DOWLING, Hearne Institute for Theoretical Physics, Louisiana State University, BATON ROUGE TEAM, Joint QUANTUM INSTITUTE, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY, AND UNIVERSITY OF MARYLAND TEAM — In this contribution, we present our studies of Michelson and Fabry-Perot interferometers with a photon-number resolving detector. We show experimentally that with a weak coherent light beam, the use of a photon-number resolving detector improves the interferometric resolution. We also discuss ways the sensitivity of interferometers can be further improved beyond the standard quantum limit by using nonclassical light and photon-number resolving detectors.

Thursday, March 19, 2009 2:30PM - 5:30PM – Session X18 DPOLY: Elastomers and Gels I

2:30PM X18.00001 Phase behavior of poly(ethylene oxide) in ethyl alcohol / water mixtures, S. H. SHIN, R. M. BRIBER, University at College Park, B. HAMMOURDA, D. L-T HO, National Institute of Standards and Technology — PEO in ethanol forms an opaque gel-like mixture with a partial crystalline structure. Addition of a small amount of water disrupts the gel: 5% PEO in ethanol with the addition of 4-10% water becomethan as an athermal polymer solution and the phase behavior changes from UCST to LCST rapidly as the fraction of water is increased. The observed origin of this unusual phase behavior comes from the formation of a hydration layer around the PEO chain. Two water molecules can hydrate one PEO monomer which is consistent with the suppression in the crystallization and change in the phase behavior observed by SANS. We measured the spinodal temperature and phase behavior of PEO solutions with different concentrations of PEO (2% PEO and 10% PEO) in the mixed water/ethanol solvent system to assess the role of hydration. The observed phase behavior is consistent with a hydration layer forming upon the addition of water and the system shifting from UCST to LCST behavior. The amount of water necessary to form a hydration layer around PEO chains varies in a self-consistent manner as the PEO concentration increases from 2 to 10%.

2:42PM X18.00002 pH-Responsive Swelling of PAMAM Dendrimer-Gels, RONALD HEDDEN, BURCU UNAL, Penn State University — End-linked hydrogels containing high mass fractions of amine-terminated poly(amideamine) (PAMAM) dendrimers are prepared by reaction of dendrimers with monodisperse, epoxide-terminated linear poly(ethylene glycol) chains. PAMAM dendrimers impart pH-dependent swelling characteristics to the gels, which absorb large amounts of water due to protonation of the dendrimers' amine groups under neutral or weakly acidic conditions. The equilibrium swelling of the gels passes through a maximum at pH of approximately 4.5, due to extensive protonation of the amine groups. Interestingly, the equilibrium swelling ratio is marked lower at both high external pH and low external pH. We model the swelling behavior by invoking the Donnan equilibrium theory, treating the gels as phantom networks that contain a high concentration of Lewis bases having pHb=3.5. The model captures the maximum in swelling near pH=4.5, though equilibrium swelling ratio is overpredicted in some cases. The collapse of the gels at both high and low external pH is explained in terms of the differential between the concentrations of mobile ions inside and outside the gel. We will discuss recent attempts to prepare stimuli-responsive gels based upon the remarkable swelling characteristics of PAMAM dendrimer-gels.

2:54PM X18.00003 Studies on shear-thinning and recovery properties of beta-hairpin peptide hydrogel, CONGQI YAN, RADHIKA NAGARKAR, JOEL SCHNEIDER, DARRIN POCHAN, University of Delaware — In solution, freely soluble, unfolded MAXI peptide ((VK)2-V(2)PPT-(VK)4-CO-NH2) undergoes a conformation change into a folded/hairpin by exposure to a folding stimulus, e.g. pH change, salt addition, or temperature rise. The consequent self-assembly leads to a stiff hydrogel stabilized by physical crosslinks between fibrillar nanostructures. When a proper shear stress is applied, the hydrogel shear-thins and flows. Moreover, as soon as the stress is ceased, the gel immediately reheals into a stiff solid and recovers its original mechanical strength quickly. This shear-thinning and rehealing property makes possible hydrogel delivery via syringe injection. In this work, Rheo-SANS was adopted to monitor the gel network morphology under shear flow. Also, rheological experiments were performed to measure the gel recovery after shear-thinning under various shear treatment conditions. Laser scanning confocal microscopy was used to observe the flow and velocity profile of the hydrogel through a channel. The results explain morphology changes of the gel network during shear-thinning and subsequent rehealing process. The fundamental gel shear-thinning and rehealing mechanisms will be discussed.

3:06PM X18.00004 Poly(Z-Lysine)-based Block Copolymer Organogels, SANDEEP S. NAIK, ADAM D. RICHARDSON, DANIEL A. SAVIN, School of Polymers and High Performance Materials, University of Southern Mississippi — A series of AB diblock copolymers consisting of poly(Lysine)(Z) (A = P(Lys(Z))) and poly(propylene oxide) or polyhedral oligomeric silsesquioxane (B = PPO, POSS) were synthesized and found to form stable, rigid organogels in THF and chloroform at room temperature. In these systems, the protecting group on the P(Lys) side-chains remains intact. As such, the secondary structure of the polypeptide chains retains helicity over a wide range of solution conditions. Gel formation in these systems results from the assembly of the solventphobic P(Lys(Z)) chains, which pack densely in an anti-parallel fashion, minimizing interfacial curvature. These gels all exhibited shear-thinning behavior, and as the temperature was heated to 350 K exhibited a gel-sol transition. The role of solvent polarity and molecular weight of the P(Lys(Z)) chains on the mechanical strength will be discussed.
3:18PM X18.00005 Anisotropic Poly(Vinyl Alcohol) Hydrogel: Connection Between Structure and Bulk Mechanical Properties1, STEPHEN HUDSON, JEFFREY HUTTER, LEONARDO MILLON, WANKEI WAN, The University of Western Ontario, Canada, MU-PING NIH, National Research Council Canada — Poly(vinyl alcohol) (PVA) hydrogels are formed from PVA solution by cross-linking of physical cross-links through freeze/thaw cycling. By choosing a suitable freeze/thaw protocol and applying a strain during thermal processing, gels with permanent, anisotropic bulk mechanical properties matching those of cardiovascular tissues can be made, making them useful for applications ranging from artificial heart valves to vascular grafts. We have performed small- and ultra-small-angle neutron scattering (SANS and USANS) measurements covering length scales from 2 nm to 10 µm, and modeled the structure as interconnected PVA blobs of size 20 to 50 nm arranged in fractal aggregates extending to at least 10 µm. Here, we discuss the relationship between the microstructure and bulk mechanical properties. Strength increases with the number of thermal cycles due to reinforcement of the small-scale gel phase, while anisotropy is due to elongation of the much larger fractal aggregates.

3:30PM X18.00006 Kinetics of phase separation of thermoreversible gels, FRANCISCO J. SOLIS, ASU West, CHRISTINE LEON, BRENT VERNON, Arizona State University — We study the kinetics of phase separation and thermoreversible gel formation of LCST-type polymers. A large number of NIPAM-based polymers exhibit transitions near room temperature from a liquid phase to a two-phase state. In the two-phase region of the phase diagram, a polymer dilute phase coexists with a gel. The corresponding shrinking transition for chemically-linked gels has been extensively studied in both its thermodynamic and kinetic aspects. We show that, in the thermoreversible case, the formation of the gel phase proceeds in a similar way. Upon entrance to the two-phase region, the gel volume follows a double exponential decay. The gel undergoes a fast shrinking associated with water ejection, followed by a slower reorganization regime.

3:42PM X18.00007 Structure and Rheology of Leucine Zipper Protein Hydrogels, B.D. OLSEN, J.A. KORNFIELD, D.A. TIRRELL, California Institute of Technology — Protein hydrogels from telechelic polymers physically crosslinked by the specific association of leucine zipper domains provide fundamental insight into polymer network structures due to the unparalleled control over molecular weight and network junction multiplicity. Two different leucine zippers are used to confer either tetrameric or pentameric end block association. By varying the length of the polyelectrolyte midblock, we show that the macroscopic and rheological properties of the hydrogels depend on both the polymer molecular weight and the aggregation state of the leucine zipper junctions. Cryo-TEM and negative staining are used together to visualize the gels, revealing heterogeneous structures. The gels are strongly shear thinning, and examination of Lissajous figures of stress vs. strain suggest a yielding mechanism. Under many conditions the gels can recover nearly their full strength less than a minute after the cessation of shear. These properties combined with the ease of biofunctionalization and pH and temperature responsive gelation transitions make the materials attractive for tissue engineering.

3:54PM X18.00008 Morphology of biaxially stretched triblock copolymer gels using SAXS, ARJUN KRISHNAN, TUSHAR GHOSH, RICHARD SPONTAK, North Carolina State University — Gels of styrenic triblock copolymers swollen by a low-volatility, midblock-selective oil behave as high-strain, low-field dielectric elastomers in the design of electroactive polymeric actuators. A standard configuration of such devices involves stretching, or “prestraining,” the elastomer film biaxially. However, little is known about the effect of biaxial prestrain on copolymer morphology. In this study, small-angle X-ray scattering (SAXS) is used to probe the nanostructure of gels composed of polystyrene-((ethylene-co-butylene)-(styrene) and mineral oil by systematically changing the concentration of polymer from 5 to 30 wt% and the biaxial prestrain from 0 to 300%. In the azimuthally integrated intensity profiles, the form factor due to scattering from polystyrene microdomains correlates strongly with polymer concentration and does not change with the applied prestrain, indicating that the polystyrene crosslinks remain as polystyrene spheres. The structure factor data correlates with prestrain, and is fitted using the Percus-Yevick approximation for interacting spheres. While a hard sphere interaction model is sufficient for unstrained gels, we resort to a square shoulder hard sphere potential for strained samples.

4:06PM X18.00009 Computer Simulation of a Switchable Metallo-Supramolecular Gel1, SHIHU WANG, ELENA DORIMONTOVA, Department of Macromolecular Science and Engineering, Case Western Reserve University — Using Monte Carlo simulation, we studied reversible metallo-supramolecular gel comprised of linear oligomers end-functionalized with ligands and metal ions that can form trans- or cis-ligand-metal complexes with a ratio up to 3:1. We found that cis-isomers exhibit a larger overall degree of association and higher average molecular weight compared to trans-isomers due to a larger fraction of 3:1 or 2:1 ligand-metal complexes. Furthermore the metallo-supramolecular gel formed by cis-isomers occurs within a wider range of metal-to-oligomer ratios at a lower oligomer concentration and exhibits a larger elastic modulus and a smaller mesh-size compared to gel formed by trans-isomers. We found that exchanging cis-to-trans-isomers leads to a monotonic change of the material properties for most cases except for the 2:1 ligand:metal ratio at which the mesh size exhibits a minimum due to the favorable formation of intra-molecular bonds by cis-isomers. These switchable properties suggest interesting application opportunities.

4:18PM X18.00010 Cavitational Rheology and Fracture Behavior of Polyacrylamide Hydrogels, SANTANU KUNDU, ALFRED CROSBY, University of Massachusetts- Amherst — Cavitational rheology is a new characterization technique for the measurement of mechanical properties on small length scales, e.g. 10-1000 µm, at any arbitrary location within a soft material. The technique involves growing a cavity at the tip of a syringe needle and monitoring the pressure of the cavity at the onset of instability. This critical pressure is directly related to the local modulus of the material. We used this technique to characterize the network mechanics of polyacrylamide hydrogel materials, a common material used in many biological applications. Gels with different moduli, which were obtained by varying initial monomer to water ratio, were investigated. As monomer concentration increased, a transition from stable cavity to fracture was observed. Applying scaling theory for gels, we modify the Lake-Thomas Theory for the fracture of crosslinked networks to relate the transition from cavitational to fracture in terms of molecular parameters. We anticipate this fundamental understanding of cavitational and fracture mechanism will be applicable to biological tissues, as well as the development of advanced soft materials.

4:30PM X18.00011 Dynamic display of biomolecular patterns through an elastic creasing instability of stimuli-responsive hydrogel surfaces, JUNGWOOK KIM, RYAN HAYWARD, University of Massachusetts, Amherst — Swelling a soft hydrogel film attached to a rigid substrate generates a lateral biaxial compressive stress within the gel. For sufficiently large stresses, the free surface of the gel undergoes a mechanical instability to form sharp creases on its surface. We have taken advantage of this process using temperature-responsive hydrogels to fabricate dynamic scaffolds that reversibly hide and display biomolecular patterns. Desired bioactive ligands are grafted to polyelectrolytes, which are then selectively deposited to pattern the hydrogel surface. The shapes of the patterns are directed by topographic features of the underlying substrate. At room temperature, the functionalized areas of the surface are hidden within creases, but as the temperature is raised, dehydration of the gel leads to unfolding of creases and exposure of the biomolecular patterns. By switching on and off the patterns, we could engineer dynamic interactions between our scaffolds and target objects such as microscopic beads or cells.
hard segments. Ionic conductivity measurements reveal that the through-plane conductivity increases by an order of magnitude upon stretching. The characteristic spacing between the pseudo-cylindrical aggregates increases with the molecular weight of the PDMS segments and the size of the hard charged segments, that include DABCO. X-ray scattering patterns were recorded at the small, intermediate and wide angle regions for both un-stretched and stretched films. Stretching induces orientation without changing the spacing in the morphology. The hard charged segments, that include DABCO, align in pseudo-cylindrical aggregates in the direction of the stretch and the PDMS soft segments remain amorphous. The orientation relative to the stretching direction suggests that the hard charged segments induce orientation without changing the spacing in the morphology. The stable bonds between the nanogels play an essential role by forming a backbone that provides a mechanical strength to the material. The simulations show that just a relatively small fraction of such labile bonds (roughly 15%) are needed to prevent the catastrophic failure of the sample. The findings provide guidelines for creating high-strength, self-healing materials.

5:06PM X18.0014 Effect of Confinement on the Dynamics of Three-Dimensional Chemo-responsive Gels, OLGA KUKSENOK, VICTOR V. YASHIN, ANNA C. BALAZS, Chemical Engineering Department, University of Pittsburgh — Chemo-responsive gels undergo the Belousov-Zhabotinsky (BZ) reaction could be ideal candidates for creating materials that can perform sustained mechanical work. We use theory and simulation to investigate the behavior of three-dimensional samples of BZ gels that are spatially confined in various geometric arrangements and show that the spatial confinement has a dramatic effect on the samples' dynamics. We first perform a linear stability analysis in two limiting cases, where a small sample is either completely free or attached at all the boundaries to fixed, hard walls. We find the critical reaction parameters at which the gels undergo a transition from a stationary steady state to an oscillatory regime in each of these cases. We then carry out corresponding computer simulations using our 3D gel lattice spring model and find an excellent agreement between the theory and simulations. Furthermore, we illustrate that the above analysis allows us to predict the behavior of larger samples that are confined in more complex spatial arrangements.

5:18PM X19.0015 Diffusion of molecular probes and proteins in hydrogels, RICCARDO RACCIS, ROBERT ROSKAMP, ANNETTE BRUNSEN, MAX PLANCK INSTITUTE FOR POLYMER RESEARCH, F.O.R.T.H. INSTITUTE OF ELECTRONIC STRUCTURE AND LASER TECHNOLOGY, WOLFGANG KNOLL, AUSTRIAN RESEARCH CENTERS, GEORGE FYTAS, MAX PLANCK INSTITUTE FOR POLYMER RESEARCH, F.O.R.T.H. INSTITUTE OF ELECTRONIC STRUCTURE AND LASER TECHNOLOGY — We employ fluorescence correlation spectroscopy to study the diffusion of molecular probes (Cy5) and dye-tagged proteins (Cy5-Ab-LlN21f, hydrodynamic radius 10nm and Alexa488-Streptavidin, 4nm) in surface-attached poly-N-isopropylacrylamide (PNIPAAm) gels. The diffusion process depends on the crosslinking density and the presence of electrostatic and steric interactions. The protein penetration into the hydrogel layer occurs close to the isoelectric point but the local probe concentration and diffusion rate diminish with increasing penetration depth. Mesh size characterization of the hydrogels is inferred from the diffusivity and the concentration profile of fluorescent probes with different size, with the molecular free dye diffusing deeper into the gel.

Thursday, March 19, 2009 2:30PM - 5:30PM Session X19 DPOLY: Charged and Ion-containing Polymers 320

2:30PM X19.0001 Molecular Weight and Charge Density Asymmetry in Polyelectrolyte Complexation, DEBRA AUDUS, GLENN FREDRICKSON, University of California, Santa Barbara, DOMINIJK DUECHS, Max Planck Institute, Mainz — We investigate the phase diagram of oppositely charged polymers in a good solvent using a field-theoretic model. Mean-field solutions fail to predict the experimentally observed macroscopic phase separation into a solvent-rich phase and a dense liquid aggregate of polymers - a “complex coacervate.” We therefore study the model within a one-loop approximation, which accounts for Gaussian fluctuations in electrostatic and chemical potentials. Our particular focus is the effect of molecular weight, ionic strength, and charge asymmetry on the phase envelope. A set of dimensionless parameters is identified that dictate the size and shape of the two-phase region. Our results should be helpful in guiding experimental studies of coacervation.

2:42PM X19.0002 PEG-based Sulfonated Ionomers Microphase Separate with Increasing Temperature, WENQIN WANG, Department of Materials Science and Engineering, University of Pennsylvania, GREGORY J. TUDRYN, RALPH H. COLBY, Department of Materials Science and Engineering, Pennsylvania State University, KAREN I. WINEY, Department of Materials Science and Engineering, University of Pennsylvania — A series of Li, Na, and Cs-neutralized sulfonated polymer ionomers with well-defined PEG spacer lengths have been investigated by in situ X-ray scattering over a wide temperature range. At room temperature, no “ionomer peak” at q ~1-5 nm^-1 was observed, due to the high dielectric constant of the polymer matrix. As the length of the PEG segment increases, the crystallization of PEG segments is evidenced by multiple crystalline reflection peaks. In addition, crystallization produces periodic low-angle peaks, indicating a layered structure. Scanning transmission electron microscopy will be employed to predict the behavior of larger samples that are confined in more complex spatial arrangements.

2:54PM X19.0003 Hierarchical Structures in PDMS-based Ammonium Ionomers, DAVID SALAS-DE LA CRUZ, University of Pennsylvania, SUDIPTO DAS, GARTH WILKES, Virginia Tech, KAREN WINEY, University of Pennsylvania — Ionomers are polymers with a charged entity in a backbone. Polyethylene (PE) and ionomers were synthesized from 6-monomer poly chloride and 1,4-diazabicyclo[2.2.2]octane (DABCO). X-ray scattering patterns were recorded at the small, intermediate and wide angle regions for both un-stretched and stretched films. Stretching induces orientation without changing the spacing in the morphology. The hard charged segments, that include DABCO, align in pseudo-cylindrical aggregates in the direction of the stretch and the PDMS soft segments remain amorphous. The orientation relative to the stretching direction suggests that the hard charged segments self assemble into anisotropic aggregates. This self-assembly arises from the hydrogen bonding of the urethane groups and ion sharing between Br^- and N+. The characteristic spacing between the pseudo-cylindrical aggregates increases with the molecular weight of the PDMS segments and the size of the hard segments. Ionic conductivity measurements reveal that the through-plane conductivity increases by an order of magnitude upon stretching.
Temperature and pH Responsive Chargeable Copolymers with Tunable LCSTs, KIATTIKHUN MANOKRUANG, EVANGELOS MANIAS, Materials Sci & Eng; Penn State University — A series of alternating copolymers, made of \( \alpha, \omega \)-polyethylene glycol oligomers (M\(_\text{w} \)= 400 or 900) alternating with 1,6-diamino-hexane-star-lysine, is presented. Specifically their aqueous phase behavior is outlined, exhibiting temperature-controlled solubility (LCST) and a pH-controlled transition (across the point where lysine is charged). The terpolymers are uncharged at low pH while they become charged (containing lysine anions) when the solution pH increases; the phase diagrams in the temperature and pH space are drawn, and the tunability of the critical points in water as it is controlled by the copolymer composition is discussed. These copolymers, due to their hydrophilic polyethylene-oxide comonomers, exhibit a genuine LCST, i.e., a bona fide first order thermodynamic transition, rather than the usual micellization related LCST of copolymers that contain hydrophobic blocks or grafts. This last point is demonstrated by comparisons against micelle-forming copolymers, consisting of hydrophobic and chargeable comonomers.

Ionic Conductivity of Poly(ethylene oxide)-Containing Block Copolymers at Order-Disorder and Order-Order Transitions, NISITA WANAKULE, UC Berkeley, ASHOUTOSH PANDAY, SCOTT MULLIN, NITASH BALSARA, UC Berkeley, Lawrence Berkeley National Labs — The order-disorder transition (ODT) and order-order transition (OOT) of block copolymers with lithium bis(trifluoromethanesulfonyl)imide (LiTFSI) salts are measured with a combination of small-angle x-ray scattering (SAXS) and birefringence. The block copolymers comprise of polyethylene oxide (PEO), a polymer with a higher dielectric constant that dissolves LiTFSI, and polystyrene (PS), a polymer with a lower dielectric constant that does not dissolve LiTFSI. Ionic conductivity of the block copolymers is measured through the observed ODT and OOT. The effect of morphology on the ionic conductivity will be presented and compared with literature results.

Origin of Lateral Nanoscale Heterogeneities in Weak Polyelectrolyte Brushes, YOU-YEON WON, KEVIN WITTE, JAEHYUN HUR, Purdue University — In this talk, we will first discuss experimental evidence of lateral nanoscale heterogeneities in a single-component weak polyelectrolyte brush system under zero to low salt conditions. Using an amphiphilic diblock copolymer, poly(2-(dimethylamino)ethyl methacrylate-b-n-butyl acrylate) (PDMAEMA-PnBA), for Langmuir film compression and Langmuir-Blodgett deposition on a hydrophobic substrate followed by fluid AFM imaging, we show the existence of regions of different brush heights, indicative of the thermodynamic instability (and resultant local clustering) of the PDMAEMA chains in the low-salt limit. Using SCF and scaling theories, we will also show that the lateral heterogeneities occur due to the combined effects of (i) the osmotic instability regulated by charge equilibrium and (ii) the hydrophobicity of the chains.

Counter-ion fluctuations in the presence of a spherical macromolecule, LEANDRO BOONZAEBER, KRISTIAN K. MUELLER-NEDEBOEK, Institute of Theoretical Physics, University of Stellenbosch, 7600 Matieland, South Africa, FREDERIK G. SCHOLTZ, National Institute for Theoretical Physics, Stellenbosch Institute for Advanced Study, 7600 Stellenbosch, South Africa — The effective interactions of charged macromolecules (e.g. polyelectrolytes) are still not fully understood. The role of counter-ion fluctuations, in the presence of these macromolecules, seems to be crucial in understanding these effective interactions. We consider a single charged spherical macromolecule, enclosed in a finite volume, in the presence of point-like counter-ions in an electrically neutral solution. Writing the partition function as a functional integral and only keeping terms up to quadratic order, we calculate the free energy in this approximation exactly.

Counterion Condensation and Collapse of Sodium Polystyrene Sulfonate in Water: A Molecular Dynamics Study, JAN-MICHAEL CARRILLO, ANDREY DOBRYNIN, University of Connecticut — Hydrophobic polyelectrolytes are known to form necklace-like structures of dense beads connected by strings of monomers. This structure appears as a result of optimization of electrostatic and short-range interactions. To elucidate the effect of counterion condensation on polyelectrolyte conformations we performed two sets of molecular dynamics simulations of sodium polystyrene sulfonate (NaPSS) chains with degree of polymerizations \( N=16, 32 \) and 64 and fraction of charged monomers \( f=0.25, 0.33, 0.5 \) and 1.0 in aqueous solutions; (1) water molecules were considered explicitly using TIP3P model and (2) water molecules were modeled as a dielectric continuum with dielectric constant 77.73. Our simulations showed that with increasing \( f \) a polyelectrolyte chain adopts an elongated conformation. The transition between collapsed and elongated states does not show any features of abrupt transition due to the fact that only relatively short chains were considered. Furthermore, even for our longest chains (\( N=64 \)) the necklace-like globule was not observed. Effect of the water-ion interactions on counterion condensation was analyzed by comparing the radial distribution function between the sulfonate groups and sodium counterions for chains with different \( f \). It was found that in simulations with explicit water ionized groups are located at the globular surface.
is also apparently important. Within the film (quantified by neutron reflectivity measurements) can have a large effect on the surface morphology diagram and the physics of glass-formation (flow coated versus spun cast films) so non-equilibrium effects evidently have a large effect on the surface pattern morphology. In particular, the residual solvent and we construct a surface morphology diagram as a function of hf and T. The surface morphology diagram is found to depend on the method of film formation cylinders oriented parallel to the substrate to a mixed or 'hybrid' state where the two orientations coexist (b) this hybrid morphology then transforms to cylinders with both blocks. Surface morphology transitions with increasing hf are observed in these model 'frustrated-interaction' films: (a) first, a transition occurs from increasing hf when the substrate interaction is highly selective for one of the blocks (PMMA) and the polymer-air interface has a nearly neutral interaction block-methyl methacrylate) (PS-b-PMMA). A transition from a perpendicular to a parallel cylinder orientation with respect to the substrate is observed upon the addition of external salts, the hydrodynamic radius of PSSNa was found to decrease with the increase of salt concentration, i.e., the chain contracts due to electrostatic screening and ion bridging effect. When the salt concentration increased beyond a certain value, the chains were observed to increase their dimension for a mono-, double- and triple-valent counterions. The experimental evidence shows the single chain behavior of re-entrant transition of polyelectrolytes.

1Project supported by National Natural Science Foundation of China (NSFC).

4:06PM X19.00014 Single chain contraction and re-expansion by counterions of polyelectrolytes 1. FENGXUANG JIA, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences, Beijing, China — We have studied the re-entrant transition of polyelectrolytes at single chain level. Diffusion rate of single chains of polystyrene sulfonate (PSSNa) has been investigated by fluorescence correlation spectroscopy under different counterion condition. Upon the addition of external salts, the hydrodynamic radius of PSSNa was found to decrease with the increase of salt concentration, i.e., the chain contracts due to electrostatic screening and ion bridging effect. When the salt concentration increased beyond a certain value, the chains were observed to increase their dimension for a mono-, double- and triple-valent counterions. The experimental evidence shows the single chain behavior of re-entrant transition of polyelectrolytes.

Thursday, March 19, 2009 2:30PM - 5:30PM – Session X20 DPOLY: Long Range Order in Polymer Structures and Morphologies

2:30PM X20.00001 Long range ordering in block copolymer thin films. CAROLINE ROSS, MIT — Thin films of microphase separated block copolymers, which can form patterns consisting of dense arrays of lines or dots, are attractive materials for self-assembled nanoscale lithography. The long range order of the block copolymer microdomains can be controlled by the use of chemical or topographical patterns. In this work, we discuss how Si-containing block copolymers, polystyrene-b-polyferrocenylidimethylsilane (PS-PFS) and polystyrene-b-polydimethylsiloxane (PS-PDMS), can be templated on substrates patterned with posts or steps. In the case of 40 nm period spherical morphology PS-PDMS, <20 nm diameter posts, which are coated with a grafted layer of PDMS homopolymer, define the locations of surrounding PDMS microdomains. The lattice spacing and orientation of the templated PDMS microdomain array can be predicted from the ratio between the post spacing and the equilibrium microdomain spacing. PFS spheres, formed from spherical-morphology PS-PFS, can be aligned within shallow trenches to form a close-packed array with row spacing determined by the trench width. We also show how 32 nm period cylindrical morphology PS-PDMS can be templated using topographical features. Templating using posts or linear substrate features gives arrays of straight parallel cylinders with controllable period and orientation, while templating in circular pits creates sharply curved, concentric toroidal structures. The overall morphology and period of the block copolymer microdomain arrays can be varied by solvent annealing in mixed solvent vapors, for example cylindrical-morphology PS-PDMS can form perforated lamellae by annealing in toluene plus heptane. These results will be discussed in the context of nanolithography, including examples of pattern transfer to form metal, oxide and polymer functional nanostructures. Bita et al, Science 321 939 (2008); Jung et al, Nano Letts. 7 2046 (2007); 8 2875 (2008).

3:06PM X20.00002 Surface Morphology Diagram for Cylinder-Forming Block Copolymer Thin Films. ALAMGIR KARIM, University of Akron, XIAOHUA ZHANG, JACK DOUGLAS, RONALD JONES, Polymers Division, NIST — We investigate the effect of annealing temperature (T) and film thickness (hf) on the surface morphology of flow coated films of a cylinder forming block copolymer, poly (styrene-block-methyl methacrylate) (PS-b-PMA). A transition from a perpendicular to a parallel cylinder orientation with respect to the substrate is observed upon increasing hf when the substrate interaction is highly selective for one of the blocks (PMMA) and the polymer-air interface has a nearly neutral interaction with both blocks. Surface morphology transitions with increasing hf are observed in these model ‘frustrated-interaction’ films: (a) first, a transition occurs from cylinders oriented parallel to the substrate to a mixed or ‘hybrid’ state where the two orientations coexist (b) this hybrid morphology then transforms to cylinders oriented perpendicularly to the polymer-air interface for larger hf. The characteristic values of hf defining these surface morphological transitions depend on T and we construct a surface morphology diagram as a function of hf and T. The surface morphology diagram is found to depend on the method of film formation (flow coated versus spin cast films) so non-equilibrium effects evidently have a large effect on the surface pattern morphology. In particular, the residual solvent within the film (quantified by neutron reflectivity measurements) can have a large effect on the surface morphology diagram and the physics of glass-formation is also apparently important.
3:18PM X20.00003 Practical Implementation of Order Parameter Calculation for Directed Assembly of Block Copolymer Thin Films.

The use of the Advanced Light Source, Berkeley National Laboratory, supported by the U.S. Department of Energy, Office routes to ultrahigh density, addressable systems. The sawtoothed substrate topography provides registered, directional guidance of the BCP self-assembly that is tolerant of surface defects, maintaining the application of these parameters and analyze with a high level of accuracy the translational and orientational parameters of the guiding pattern, the domains of a block copolymer directed to assemble on this pattern, as well as the underlying structure after lift-off. We observe that order can be preserved over a large area and can be retained in subsequent processing.

3:30PM X20.00004 Controlling the self-assembly of block copolymer materials in thin-films.

UNYONG JEONG, Dept. of Metallurgical Engineering, Yonsei University, TING XU, Dept. of Materials Science and Engineering, University of California, PARK, DONG HYUN LEE, BOKYUNG KIM, SUNG WOO HONG, JI XU, Dept. of Polymer Science and Engineering, University of Massachusetts Amherst, EUNGNAK HAN, Department of Materials Science & Engineering, University of Wisconsin-Madison, KARL STUEN, PAUL NEALEY, Department of Chemical & Biological Engineering, University of Wisconsin-Madison, PADMA GOPALAN, Department of Materials Science & Engineering, University of Wisconsin-Madison — We present a simple and efficient strategy towards surface modification for controlling the self-assembly of P(styrene-b-methylmethacrylate) diblock copolymer (BCP) in thin films. Photo-patternable, substrate-independent neutral surface was created to achieve vertical orientation of block copolymer (BCP) microdomains. A random copolymer of styrene (f= 0.58±0.03), methylmethacrylate (f= 0.41±0.06) and glycidyl methacrylate (f= 0.01±0.02) was synthesized. The copolymer uses photo-crosslinking reaction of epoxy groups by photoinitiator generator to formulate the neutral surface. Ultra-thin (2-6 nm) crosslinked film was created as a neutral interfacial layer between the block copolymer and the substrate. The composition of the copolymer was fine tuned to tailor the wetting behavior and hence the domain orientation (parallel or perpendicular to the substrate) in the self-assembled block copolymer film. The effectiveness of the new neutral polymer on a range of substrates such as glass and gold coated silicon wafer and for both symmetric and asymmetric BCPs is demonstrated.

3:42PM X20.00005 Shear Alignment and Realignment of Cylinder-Forming Block Copolymer Thin Films.

VINDHYA MISHRA, Materials Research Laboratory, University of California, Santa Barbara, EDWARD KRAMER, Department of Materials and Chemical Engineering, University of California Santa Barbara, SU-MI HUR, GLENN FREDRICKSON, Materials Research Laboratory, University of California, Santa Barbara, MICHAEL SPRUNG, Argonne National Lab, IL — In multilayer thin films of spherical morphology block copolymers, the surface layers prefer hexagonal symmetry while the inner layers prefer BCC. Thin films with spherical morphology of PS-b-P2VP blends with short homopolymer polystyrene (hPS) chains have an HCP structure up to a thickness n* at which there is a transition to a face centered orthorhombic structure. Using grazing incidence small angle X-ray scattering and transmission electron microscopy we show that that n* increases from 5 to 9 with increase in hPS from 0 to 12 vol%. For thicknesses just below n* the HCP and FCO structures coexist, but on long annealing HCP prevails. We hypothesize that the PS segregates to the interstices in the HCP structure reducing the stretching of the PS blocks and the free energy penalty of HCP versus BCC inner layers. Self consistent field theoretic simulations are being carried out to see if this idea is correct.

3:54PM X20.00006 Structural transition with thickness in films of poly-(styrene-2vinylpyridine) (PS-b-P2VP) diblock copolymer/homopolymer blends.

CHUANBING TANG, ERIN LENNON, MICHAEL DIMITRIOU, GLENN FREDRICKSON, EDWARD KRAMER, CRAIG HAWKER, Materials Research Laboratory, University of California, Santa Barbara — We present a modular and hierarchical self-assembling strategy for the generation of novel nanoscale patterns suitable for block copolymer lithography. Supramolecular block copolymers consisting of poly(ethylene oxide)-b-poly(styrene-4-vinylpyridine) and poly(styrene-2-vinylpyridine)-b-poly(methyl methacrylate) diblock copolymer blends with hydrogen-bonding interactions between the polystyrene majority segments were prepared by living free radical polymerization. By combining supramolecular assembly of H-bonding phenolic and pyridyl units with controlled phase separation of diblock copolymers, highly ordered square arrays were obtained. The compositions of H-bonding components were critical for generating both long range order and for controlling the spatial arrangement of ordered arrays. The utilization of these materials as lithographic masks was successful and allowed transfer of the polymeric template with high fidelity to silicon oxide substrates, leading to a highly ordered array of 20 nm cylindrical pores with a spacing of 50 nm. This modular blending approach to block copolymer resists demonstrates a new and powerful strategy for the fabrication of unique patterns for nanolithographic applications.

VINCENZO MEI, RICCARDO RUIZ, Hitachi Global Storage Technologies, San Jose Research Center, NICOLA FERRIER, Dept of Mech Engineering, University of California, Berkeley, THOMAS P. RUSSELL, Dept. of Polymer Science and Engineering, University of Massachusetts Amherst — We present a modular and hierarchical self-assembling strategy for the generation of novel nanoscale patterns suitable for block copolymer lithography. Supramolecular block copolymers consisting of poly(ethylene oxide)-b-poly(styrene-4-vinylpyridine) and poly(styrene-2-vinylpyridine)-b-poly(methyl methacrylate) diblock copolymer blends with hydrogen-bonding interactions between the polystyrene majority segments were prepared by living free radical polymerization. By combining supramolecular assembly of H-bonding phenolic and pyridyl units with controlled phase separation of diblock copolymers, highly ordered square arrays were obtained. The compositions of H-bonding components were critical for generating both long range order and for controlling the spatial arrangement of ordered arrays. The utilization of these materials as lithographic masks was successful and allowed transfer of the polymeric template with high fidelity to silicon oxide substrates, leading to a highly ordered array of 20 nm cylindrical pores with a spacing of 50 nm. This modular blending approach to block copolymer resists demonstrates a new and powerful strategy for the fabrication of unique patterns for nanolithographic applications.

4:18PM X20.00008 Macrosopic Addressable Arrays of Block Copolymer Microdomains.

The use of these materials as lithographic masks was successful and allowed transfer of the polymeric template with high fidelity to silicon oxide substrates, leading to a highly ordered array of 20 nm cylindrical pores with a spacing of 50 nm. This modular blending approach to block copolymer resists demonstrates a new and powerful strategy for the fabrication of unique patterns for nanolithographic applications.

4:30PM X20.00009 Self-Extinguishing Crystallization: Copolymer Behavior under Flow , DIANA SMIRNOVA, MEISAM HAJIMORAD, JULIA KORNFIELD, California Institute of Technology — It is known that short chain branches in copolymers act as crystal defects, resulting in materials with low crystallinity and poorly-defined morphology. We are interested in the behavior of copolymers under flow in the presence of species that readily form well-defined shish-kebab morphologies. Bimodal blends containing small concentrations of high molecular weight, high density polyethylene (HDPE, Mw = 526 kg/mol, Mw/Mn = 3) in an ethylene-co-hexene matrix (Mw = 50 kg/mol, Mw/Mn = 2, 5 mol % hexene) were studied via rheo-optical and rheo-xray techniques. HDPE concentrations were selected above and below the overlap concentration of 0.6%, but maintained below 1% such that the rheology of the blends was not significantly altered from that of the copolymer matrix. DSC traces were collected to ensure that co-crystallization between the two blend components occurs. Crystallization after shear quickly leveled off revealing a self-extinguishing behavior. The time frame for this extinction is coupled with a loss of anisotropy in scattering patterns indicating random crystallization uncorrelated with existing oriented structures.

4:42PM X20.00010 Quasicrystalline long-range order in an ABC star block copolymer , TOMONARI DOTERA, Department of Polymer Chemistry, Kyoto University, Japan — We report the formation of a dodecagonal quasicrystal (DDQC) in a lattice Monte Carlo simulation of a star-shaped three component polymeric alloy. We have observed a series of Archimedean and quasicrystalline phases (4.82 \rightarrow (3^2.4.3.4) \rightarrow DDQC - (4.6.12) with increase of one component of ABC star polymers. This phase behavior can be regarded as a transition from square tilting to triangle tilting via square-triangle tilting. The simulation is associated with the recent striking experimental manifestation of quasicrystalline order: A mesoscopic tiling pattern with twelvefold symmetry in a three-component star polymer system composed of polyisoprene, polystyrene, and poly (2-vinylpyridine). Since, the same kind of quasicrystalline structures have been found for metal alloys, chalcogenides, and liquid crystals, the present result confirms the universal nature of quasicrystalline long-range order over several hierarchical length scales.

5:06PM X20.00012 Ligand-induced order in Spotted vesicles and Striped micelles , DAVID CHRISTIAN, WOUTER ELLENBROEK, ANDREA LIU, DENNIS DISCHER, MRSEC, University of Pennsylvania — Thermoplastic Polyurethanes (TPU) are linear block copolymers typically constructed of statistically alternating soft (SS) and hard (HS) segments. Due to their numerous industrial applications these materials have received considerable attention. We have investigated the phase behavior and morphology of a set of high hard block content polyurethanes and varied the chain extender used. Using mainly calorimetry, scattering and microscopy techniques we were able to elucidate the origins of all the thermal events observed through differential scanning calorimetry. Correlating our thermodynamic work with our structural work we were able to propose a new morphological model of the structure and the phase behavior of high hard block content polyurethanes. We have shown that above 65% hard segment content the melt-quenched samples present a two-phase morphology one pure hard segment phase co-existing with a mixed phase with the same hard segment content of 65% for all samples. When annealed at high temperature the mixed phase undergoes phase separation resulting in the same phase-separated mesophase. Changing the chain extender has a significant impact on the phase behavior and morphology of these systems

5:18PM X20.00013 Electrospinning of semicrystalline polymer fibers , YING LIU, Stony Brook University, SHUANG CHEN, CHUNHUA LI, ELAINE DIMASI, Brookhaven National Laboratory, GAD MAROM, The Hebrew University of Jerusalem, MIIRIAM RAFAILOVICH — Electro spinning of polymeric fibers has been attracted increased interest in recent years. However, the research for ethylene-vinyl acetate (EVA) and linear polyethylene (PE) is still limited, due to their relatively poor solubility in conventional solvent systems at ambient temperature. In this study, EVA and PE fibers were electro spun with different fiber diameter when the electro spinning solution was kept at a temperature greater than that of the solidification temperature of the polymer solutions. The effects of the fiber physical dimension to its crystallization and mechanical properties were thus detected. The morphology of the fibers was measured by scanning electron microscope (SEM) and atomic force microscope (AFM). The shear modulation force microscopy technique (SMFM) was used to measure the melting point, Tm, which was found to increase with increased fiber diameter and crystallinity. AFM three-point bending test demonstrated that the Young’s modulus of the fibers drastically increased as fiber diameter decreased. Grazing-incidence small angle x-ray scattering (GISAX) showed that, compared to the bulk material, the crystallinity of the electro spun fibers had been changed.

Session X21 FLAP DCMP: Spectroscopic Studies of Semiconductor Structure and Their Growth

2:30PM X21.00001 Electronic structure of Na_xCoO_2 investigated by X-ray absorption spectroscopy with Ab initio calculation , PAO-AN LIN, JIUNN-YUAN LIN, BEN HSU, HORNG -TAY JENG, CHEN-SHIUNG HSUE, YIA-CHUNG CHANG — The soft X-ray absorption spectra (XAS) of Na_xCoO_2 revealed marked and puzzling polarization dependence. It can not be explained by the degeneracy of \( e_g \) states generally believed in Na_xCoO_2. We fabricated the thin films of \( x = 0.68 \) and \( x = 0.75 \) to investigate the polarization dependence of XAS. Within the first principles DFT calculations, we have explanations for this phenomenon. After the analysis of the DOS of Na_xCoO_2, we presume that the pre-edge peaks at 529 eV and 530 eV of Na_xCoO_2 O-K edge may be not solely due to the unoccupied states of Co3+ and Co4+ eg states, but also due to the spacial asymmetry in the occupied Co 3d orbitals. Due to the hybridization between Co 3d & O 2p orbitals, the \( p_{x,y} \) and \( p_z \) states will be non-degenerate.

2:42PM X21.00002 Investigations of individual quantum dots of InAsP in InP nano-wires. MATS-ERIK PISTOL, NIKLAS SKÖLD, KIMBERLEY DICK, Lund University, CRAIG PRORY, University of Iowa, JACOB WAGNER, Danish Technical University, LARS SAMUELSON, Lund University — We have grown InP quantum wires containing InAsP quantum dots by metal-organic vapor phase epitaxy. These structures were investigated by transmission electron microscope and photoluminescence spectroscopy and were modelled by six-band k-p theory. We observe sharp emission lines from excitons, bi-excitons and tri-excitons. When we observe tri-exciton emission we observe lines originating from the s-shell as well as from the p-shell. By changing the size of the dots we observe clear confinement effects. The wires have a wurtzite structure but were modelled (by necessity) using zinc-blende parameters. From the deviation between the theory and the experiments we can deduce rough values of the band-gap of the wurtzite InAs as well as the electron effective mass of wurtzite InAs.

2:54PM X21.00003 Size dependent exciton g-factor in self-assembled InAs/InP quantum dots. PAUL KOENRAAD, NIEK KLEEMANS, JOOST VAN BREE, MURAT BOZKURT, ANDREI SILOV, RICHARD NOTZEL, Eindhoven University of Technology, CRAIG PRORY, MICHAEL FLATTE, University of Iowa — We have studied the size dependence of the exciton g-factor in self-assembled InAs/InP quantum dots. Photoluminescence measurements on a large ensemble of these dots indicate a multimodal height distribution. Cross-sectional Scanning Tunneling Microscopy measurements have been performed and support the interpretation of the macro photoluminescence spectra. More than 160 individual quantum dots have systematically been investigated by analyzing single dot magnetoluminescence between 1200nm and 1600 nm. We demonstrate a strong dependence of the exciton g-factor on the height and diameter of the quantum dots, which eventually gives rise to a sign change of the g-factor. The observed correlation between exciton g-factor and the size of the dots is in good agreement with calculations. The results demonstrate that quantum dots emitting at 1.55 micrometer and showing no Zeeman splitting (g-factor = 0) can be constructed. This makes these dots interesting for quantum information processing at optical telecommunication wavelengths.

3:06PM X21.00004 Optical and Electrical Characterization of Melt-Grown Bulk Ternary In$_x$Ga$_{1-x}$As 1. J. WEI, S. GUHA, L. GONZALEZ, Air Force Research Laboratory, P. DUTTA, G. RAJAGOPPLAN, United Semiconductors, Y. K. YEÖ, R.L. HENGEHOLD, Air Force Institute of Technology — Recent crystal growth technology breakthroughs led to successful growth of good quality bulk melt-grown ternary In$_x$Ga$_{1-x}$As single crystals. However, these bulk materials have not been well investigated compared to the epitaxial layers grown on a binary compound semiconductor, GaAs. Therefore, the optical and electrical properties of the bulk grown In$_x$Ga$_{1-x}$As have been investigated systematically as a function of temperature and In mole fraction $x$. The results show that the refractive index increases linearly with temperature from 100 to 300 K and also with In composition $x$ from 0.0 to 0.9 for several IR wavelengths. Typical refractive index values are 3.388 and 3.376 for 4.6 and 10.6 $\mu$m, respectively, at 300 K for $x$=0.5. The results of Hall-effect measurements show that the electron concentrations increase monotonically with $x$, while the mobilities decrease as $x$ increases from 0.5 to 1.0. Typical electron concentration and mobility at 300 K are $1.3\times10^{16}$/cm$^3$ and 9.1$\times10^3$/cm$^2$/V S, respectively, at $x$=0.75.

3:18PM X21.00005 ABSTRACT WITHDRAWN —

3:30PM X21.00006 Structural, Optical and Electrical Properties of Sputtered InGaN Alloy Thin Films. MOHAMMAD EBDAH, DANIEL HOY, JOEL VAUGHN, MARTIN KORDESCH, Ohio University, DEPARTMENT OF PHYSICS TEAM — Amorphous and polycrystalline InGaN alloy thin films were successfully fabricated using rf sputtering technique with a sputtering targets of metal In and Ga in pure Nitrogen. Films were deposited on Si and quartz substrates, with the ratio of In to Ga being varied from 0 to 1 in the alloy. Growth under different sputtering conditions has been examined, such as different temperatures, pressures, and substrate-target distances. The corresponding obtained structures have been studied using the x-ray diffraction (XRD) and transmission electron microscope (TEM) techniques. The compositions have been verified by means of energy dispersive x-rays (EDX) spectroscopy and Rutherford back scattering (RBS). Multiple crystallographic phases have been investigated upon growth at different temperatures, and the existence of Gallium Nitride (GaN) and Indium Nitride (InN) phases were investigated. Hall effect measurements were made in 0.55 T magnetic field for characterizing the electrical resistivity at room temperature and 77 K, the free carrier concentration, and mobility. The optical bandgap and optical properties were studied by spectrophotometric and spectroscopic ellipsometric (SE) techniques.

3:42PM X21.00007 Atomic and electronic structure of AlN polar surfaces 1. MAOSHENG MIAO, ANDERSON JANOTTI, CHRIS VAN DE WALL, Materials Department, University of California, Santa Barbara — We studied the stability and electronic structure of AlN (0001) and (000-1) polar surfaces using first-principles DFT methods. A plane-wave basis set and PAW potentials are employed surface calculations. In order to correct the band gap of AlN, we applied the hybrid functional in the HSE [1] framework. Using this approach, we obtained a band gap of 6.1 eV, and lattice constants in excellent agreement with experimental values. Under Al-rich conditions, the Al adatom at T4 sites on the Al-terminated (0001) surface was found to be the most stable (2x2) reconstruction. This reconstruction is characterized by occupied surface states (Al dangling bonds) at 3.0 eV below the conduction-band minimum (CBM) and unoccupied surface states (Al dangling bonds) at 1.1 eV below the CBM. Under Al-poor conditions, the N adatom at the H3 site is the most stable reconstruction, with occupied N-Al bonding states at 4.2 eV and an unoccupied N-Al bonding state at 1.1 eV below the CBM. For the N-terminated (000-1) polar surface, the structure with an Al adlayer is the most stable under Al-rich conditions. The impact of the surface states on the properties of materials and devices will be discussed. [1] J. Heyd, G.E.Scuseria, and M. Ernzerhof, J. Chem. Phys. 118, 8207(2003).

3:54PM X21.00008 Micro-RDS to explore the spatial strain distribution in epitaxial AlN layers. CHUNHUA WANG, ZHIYU YANG, ZHIOQANG YAO, WENJUN ZHANG, DEPARTMENT OF PHYSICS, HONG KONG UNIVERSITY OF SCIENCE AND TECHNOLOGY TEAM, HONG KONG UNIVERSITY OF SCIENCE AND TECHNOLOGY, HONG KONG UNIVERSITY OF SCIENCE AND TECHNOLOGY TEAM — A non-destructive method to observe the spatial resolved strain distribution in the sub-micrometer scale has been developed. By using micro-RDS to obtain the RA distribution on AlN films grown on Si and sapphire substrates, combining with the relation of the strain and optical anisotropy, we reveal the local strain distribution in the sub-micrometer scale. Strain domains several micrometers in size have been observed in AlN films grown epitaxially on Si without the amorphous interface layer. Each domain consists of hundreds of AlN grains. In films with many defects or grown on sapphire substrate there are no domains of dominant sizes, and the average strain is about 6 times smaller than the ones without the interface layer. The magnitude of the strain agrees well with the experimental values from the established methods such as XRD, TEM and Raman scattering.

RAOUX, IBM Almaden Research Center, D.B. SHREKENHAMER, D.N. BASOV, UCSO, M.H. MUSER, U. of Western Ontario, D.M. NEWNS, IBM T. J. Watson Research Center — Phase change materials are materials that can be thermally interconverted between metallic (crystalline) and semiconducting (amorphous) phases. The interconversion process involves a change in local coordination number in some of the atomic constituents in these typically multicomponent materials. The electronic basis for the interconversion is still controversial. Here we report, in contrast to previous views, that the amorphization process is driven by an electronic reorganization in which lowering of the total energy by opening a Peierls-like gap drives the structural reorganization in the amorphous state, thereby explaining both the formation and semiconducting character of the amorphous phases. Our understanding of the process is based on phase transformation driven both thermally and by pressure, and in particular by analysis of long time...n...reorganization into the amorphous state, thereby explaining both the formation and semiconducting character of the amorphous phases. Our understanding of the process is based on phase transformation driven both thermally and by pressure, and in particular by analysis of long time...n...amorphization process. We demonstrate the equivalence of thermal and pressure-driven interconversions in a system where vacancies are either at very low levels or entirely absent. These discoveries open a new pressure-driven phase interconversion pathway.

4:42PM X21.00012 Structural, optical, and thermal stability properties of CdZnO thin films grown by molecular-beam epitaxy (MBE)1. ZHENG YANG, LIN LI, SHENG CHU, JIEYING KONG, JIALIN LIU, Quantum Structures of Laboratory, Department of Electrical Engineering, University of California, Riverside, California 92521 — CdZnO thin films with near-band-edge emission from violet (3.07 eV) to orange (2.04 eV) were grown using MBE. The CdZnO thin films evolve from pure wurzite (wz) structure to mixture of wz and rocksalt (rs) structures, and finally to pure rs structure, with increasing Cd concentration. Wz CdZnO shows a robust thermal stability than the rs CdZnO. The temperature dependence of the CdZnO bandgap shrinkage was investigated and analyzed based on the empirical Varshni and Bose-Einstein fitting of the...n...amorphization process. We demonstrate the equivalence of thermal and pressure-driven interconversions in a system where vacancies are either at very low levels or entirely absent. These discoveries open a new pressure-driven phase interconversion pathway.

4:54PM X21.00013 Electronic properties and stabilities of bulk, nano-cluster, and low-index surfaces of SnO in comparison with SnO2: application to high-temperature gas sensor. YUHUA DUAN, National Energy Technology Lab — High-temperature gas sensors to detect various components of the gas flow in gasification technologies are highly desired. As one kind of the wide band-gap oxide semiconductors, tin oxides (SnO2, SnO) are widely used as solid state sensor material, oxidation catalyst and transparent conductor. Due to the electronic structure and possibility of two different oxidation states of Sn1+ and Sn2+ and high thermal stability, tin oxides are very sensitive to oxidizing and reducing many kinds of gases, and therefore can be used to detect these gases with good sensitivity at high-temperature. In this study, based on density functional theory approach with an empirical correction of van der Waals interactions, the structural and electronic properties of the bulk, nano-cluster, and low-index surfaces of SnO2 and SnO are obtained. Our results indicate that the differences between SnO2 and SnO are significant and the controllable type of SnO2 nano-clusters have a great application in high-temperature sensor technology. In SnO, the van der Waals interactions play an important role and rule may lead to more active sites for interacting with other molecules. By investigating the interactions between gas molecules (such as CO2, H2O, C2H5, etc.) with the surfaces of SnO2 and SnO, the sensing mechanism of tin oxides will be explored.

5:06PM X21.00014 UV Induced Room Temperature Persistent Photocurrent in In2O3 Films. RAGHAVAN PANGULURI, A. DIXIT, C. SUDAKAR, P. KHAREL, PUSHKAL THAPA, Department of Physics and Astronomy, Wayne State University, Detroit, MI 48201, I.A. AVRUTSKY, Department of Electrical and Computer Engineering, Wayne State University, Detroit, MI 48201, ALEXANDER EFROS, Center for Computational Materials Science, Naval Research Laboratory, Washington DC 20375, R. NAIK, G. LAWES, B. NADGORNY, Department of Physics and Astronomy, Wayne State University, Detroit, MI 48201. We have investigated the effects of UV irradiation on the electrical and optical properties of In2O3 thin films. These films were grown on sapphire substrate by RF sputtering. Hall effect measurements carried out to measure the carrier concentrations, n, show n-type conduction, with n = 2 x 1016 cm−3. We find that UV illumination on In2O3 films leads to a dramatic increase in the charge carrier concentration, approximately one order of magnitude, and that these elevated carrier densities persist at room temperature on a timescale of days. Consequently, we observe distinct changes in the optical absorption spectra. Also, we studied the decay of the charge carrier density to the pre-illuminated state as a function of temperature. We will discuss possible mechanisms for persistent photocconductivity in these In2O3 thin films.
and devices, but more recently has been the subject of study as a rare-earth host. It is believed that Gd$_2$O$_3$ makes a good host for these dopants due to the similarity in ionic radii between the gadolinium ion and the rare-earth dopants. The reported long radiative lifetimes of rare earth dopants in this material make it interesting for optically pumped laser materials. In this study, europium-doped gadolinium oxide (Eu$_2$Gd$_2$O$_7$) polycrystalline thin films were deposited on sapphire substrates by pulsed laser deposition at 5 and 50 mTorr oxygen pressure. Changes in the crystal structure were observed by x-ray diffraction and photoluminescence. Low-temperature photoluminescence spectra of the $^5$D$_0-^7$F$_J$ transitions in the europium ion were recorded with high resolution. Because the $^5$D$_0-^7$F$_2$ transition in europium is not subject to fine structure splitting, it provides a useful mechanism for investigation of the local environment. The $^5$D$_0-^7$F$_2$ transition is of interest as it results in the most intense emission, making europium doped material useful for red light-emitting phosphors. Radiative lifetimes of the observed transitions are also reported.

2:42PM X22.00002 Transition metal-doped Sb$_2$Te$_3$ magnetic semiconductor thin films

1 CHANG-PENG LI, YI-JIUNN CHIEN, LYNN DAVIES ENDICOTT, CTRAD UHER, Physics Dept., Univ. Michigan — With the doping of vanadium in tetradymite-based Sb$_2$Te$_3$, magnetic semiconductor thin films Sb$_{2-x}$V$_x$Te$_3$ have been prepared on (0001) sapphire substrates by low-temperature molecular beam epitaxy. X-ray diffraction measurements and RHEED patterns confirm single-crystalline films growing along the c-axis direction. Magnetic and anomalous Hall measurements clearly show strong ferromagnetic ordering with the easy axis along c-axis direction up to Curie temperature, which increases nearly linearly with the content of V incorporated in the lattice. So far, a high Curie temperature of 213 K has been achieved for the composition of Sb$_{1.55}$V$_{0.45}$Te$_3$.

2:54PM X22.00003 MCD investigation on Mn doped CdSe Quantum Ribbons

KRITSANU TIVAKO-RAISATHORN, XINYU LIU, MARGARET DOBROWSOLKA, JACEK K. FURDYNA, University of Notre Dame, JUNG H. YU, JIN JOO, DONG W. LEE, JAE S. SON, TAEHWAN HYEON, JIWON PARK, YOUNG-WOON KIM, Seoul National University — We have successfully incorporated manganese ions into CdSe quantum ribbons with a thickness of 1.4 nm. The magnetic exchange interactions between the Mn ions are indeed present in the CdSe nanoribbons with Mn concentration ranging from 0.7 to 6.4%. The magnetic circular dichroism (MCD) spectra of Mn-doped CdSe quantum ribbons show that the Mn ions are indeed present in the CdSe nanoribbons.

3:06PM X22.00004 Fine Structure of PbSe Colloidal Nanostructures

J. G. TISCHLER, T. A. KENNEDY, E. R. GLASER, E. E. FOOS, T. J. ZEGA, R. M. STROUD, A. L. EFROS, S. C. ERWIN — Although much work has been done on PbSe nanocrystals in order to understand excited states, little is known of the ground state fine structure. Bulk PbSe is a semiconductor material with a direct band gap at the L point. The band structure at this symmetry point is four-fold degenerate for both electrons and light holes, and conduction and valence bands possess similar effective masses and g-factors. In this work, we synthesized high quality PbSe nanocrystals and characterized them using transmission electron microscopy and photoluminescence. Low-temperature photoluminescence spectra of the $^2$D$_0-^2$F$_J$ transitions in PbSe were recorded with high resolution. Because the $^2$D$_0-^2$F$_2$ transition is not subject to fine structure splitting, it provides a useful mechanism for investigation of the local environment. The $^2$D$_0-^2$F$_2$ transition is of interest as it results in the most intense emission, making PbSe doped material useful for red light-emitting phosphors. Radiative lifetimes of the observed transitions are also reported.

3:18PM X22.00005 Tunable magnetic exchange interactions in manganese-doped inverted core-shell ZnSe-CdSe nanocrystals

1 DAVID BUSSIAN, SCOTT CROOKER, MING YIN, Los Alamos National Lab, MARCIN BRYNDA, University of California-Davis, ALEXANDER EFROS, Naval Research Lab, VICTOR KLIMOVA, Los Alamos National Lab — Magnetic doping of semiconductor nanocrystals is pursued for applications in paramagnetic memory and spin-based electronics. A primary goal is to control interactions between carriers (electrons and holes) and the embedded magnetic atoms. We have demonstrated a tunable magnetic sp-d exchange interaction between electron-hole excitations and paramagnetic Mn$^{3+}$ ions using ‘inverted’ core-shell nanocrystals composed of Mn$^{3+}$-doped ZnSe cores overcoated with undoped shells of narrower-gap CdSe. Magnetic circular dichroism studies reveal giant Zeeman spin splittings of the band-edge exciton that are tunable in magnitude and sign. Effective exciton g-factors are controllably tuned from -200 to +30 at 1.6 K by increasing the CdSe shell thickness, demonstrating that strong quantum confinement and wavefunction engineering in heterostructured nanocrystals can be utilized to manipulate carrier-Mn$^{3+}$ wavefunction overlaps and the sp-d exchange parameters themselves. *D. Bussian et al., Nature Materials, in press.

3:30PM X22.00006 Observation of Exchange Enhanced Zeeman Splitting in (Zn,Mn)Se Nanowires. B. J. COOLEY, T. CLARK, B. LIU, C. EICHFELD, E. DICKEY, S. MOHNEY, N. SAMARTH, Materials Research Institute, Penn State University, S. A. CROOKER, National High Magnetic Field Lab, Los Alamos, C. E. PRYOR, M. E. FLATTE, Dept. of Physics, University of Iowa. — Magnetic semiconductor nanowires (NWs) are of potential interest as model systems for studying the physics of spin polarized 1D Fermi liquids. A high degree of spin polarization is anticipated from the spin-d exchange-enhanced Zeeman splitting of band edge states. Here, we report the vapor-liquid-solid growth of Mn-doped amorphous Si andGe matrices, in great contrast to the previous speculation that these two should behave very similar as the semiconductor host for transition metals. While we observed a large local moment of Mn in a-Ge, Mn moment is quenched in a-Si. The large difference of local magnetic moment of Mn in a-Si and a-Ge can be understood by the local atomic environment at the magnetic dopant sites, that is, the bond length and the coordination. Statistical DFT calculations shows that the magnetic dopant Mn with less coordination and large bond length hold large magnetic moment. Otherwise, the magnetic moment would be killed. In a-Ge, dopant Mn favours less coordination and large bond while more coordination and small bond length in a-Si, which result in the enhancement/quenchment of local magnetic moment Mn in a-Si/a-Ge.

The work is supported by DOE (Grant No. DEFG02-05ER46237). Calculations were performed on computers at NERSC.

4:06PM X22.00009 Magnetism of Mn doped in a-Si and a-Ge 1. JUEXIAN CAO — With experimental studies and density function theory calculations, we report on the properties of Mn-doped amorphous Si and Ge which are designed to understand the fundamentals of cooperative phenomena in highly correlated electronic and magnetic systems. We observed a striking difference in Mn local moment when doped in a-Si and a-Ge matrices, in great contrast to the previous speculation that these two should behave very similar as the semiconductor host for transition metals. While we observed a large local moment of Mn in a-Ge, Mn moment is quenched in a-Si. The large difference of local magnetic moment of Mn in a-Si and a-Ge can be understood by the local atomic environment at the magnetic dopant sites, that is, the bond length and the coordination. Statistical DFT calculations shows that the magnetic dopant Mn with less coordination and large bond length hold large magnetic moment. Otherwise, the magnetic moment would be killed. In a-Ge, dopant Mn favours less coordination and large bond while more coordination and small bond length in a-Si, which result in the enhancement/quenchment of local magnetic moment Mn in a-Si/a-Ge.

3:54PM X22.00008 Effects of defects on the half metallicity of a Mn/Si digital ferromagnetic heterostructure. MICHAEL SHAUGHNESSY, RYAN SNOW, CHING FONG, UC Davis — The effects of defects on the half-metallic properties of the Mn/Si digital ferromagnetic heterostructure (DFH) (PRL 96, 027211 (2006)) are investigated using a first principles density-functional theory approach. The half metallicity is retained when the Mn layer is recovered in quantum wells, in which the thickness of the Mn layer would be smaller than the region visited by the holes. [1] H. Boukari et al., Phys. Rev. Lett. 88, 207204 (2002); [2] D. Kechrakos et al., ibid 94, 127201 (2005).

4:30PM X22.00011 Ferromagnetic ordering of Mn-As co-doped Ge as diluted magnetic semiconductors studied within a Heisenberg model 1. HUA CHEN, U of Tennessee-Knoxville, WENGLUAN ZHU, ZHENYU ZHANG, U of Tennessee-Knoxville;Oak Ridge National Laboratory — To achieve room temperature ferromagnetism in group-IV-based diluted magnetic semiconductors, it is required to increase the concentration of magnetic dopant Mn in the host semiconductors. A recent theoretical study has suggested that the concentration of substitutional Mn in Ge can be greatly enhanced upon co-doping with As, an n-type electronic dopant [1]. Using Monte Carlo simulations based on a classical Heisenberg model with the magnetic coupling parameters calculated from first principles, we study the magnetic property of Mn and As co-doped Ge at low doping concentrations. The estimated Curie temperature increases almost linearly with increasing Mn doping concentration and reaches 264K at 5% Mn. In contrast, at the same doping level pure Mn doped Ge does not show any finite temperature ferromagnetic ordering. [1] W. G. Zhu, Z. Y. Zhang, and E. Kaxiras, Phys. Rev. Lett. 100, 027205 (2008).

1Supported by DMSE/BES of USDOE and USNSF.
The low temperature thermopower of the 2DES at the 2D system at $\nu$ schemes for detecting this degeneracy rely on interferometric braiding operations, it may also have thermodynamic implications. In particular, the entropy of the non-abelian Moore-Read paired composite fermion state. A key attribute of this state is its large degeneracy when quasiparticles are present. While most

...
The essence of the $\nu = 5/2$ fractional quantum Hall effect is believed to be well captured by the Moore-Read Pfaffian (or anti-Pfaffian) description. However, an important mystery regarding the formation of the Pfaffian state is the role of the three-body interaction Hamiltonian $H_3$ that produces the Pfaffian as an exact ground state and the concomitant particle-hole symmetry breaking. We show that a two-body interaction Hamiltonian $H_2$ constructed via particle-hole symmetrization of $H_3$ produces a ground state nearly exactly approximating the Pfaffian and anti-Pfaffian states, respectively, in the spherical geometry. More importantly, the ground state energy of $H_2$ is shown to exhibit a `Mexican-hat' structure as a function of particle number in the vicinity of half filling for a given flux indicating spontaneous particle-hole symmetry breaking.

3:18PM X23.00005 Jack Polynomials, W-algebras and application to Fractional Quantum Hall Effect

STEVEN H. SIMON, Oxford University, B. ANDREI BERNEVIG, Princeton University, VICTOR GURARIE, University of Colorado — We examine Jack symmetric functions and certain W-algebras as schemes for generating fractional quantum Hall wavefunctions. We add substantially to the evidence that the Ising anyons correspond to certain W-algebras, by calculating the central charge and scaling dimensions of some of the fields in both cases and showing that they match. Except for the Read-Rezayi series all of these Jack symmetric functions turn out to be nonunitary theories. We discuss the (perhaps optimistic) possibility that these approaches may have relevance to various physical quantum Hall systems. Open questions in the field, as well as why this is of importance to those concerned with real experiments, will also be discussed.

3:30PM X23.00006 Resources needed for performing Shor’s algorithm with Ising Anyons

MARA BARABAN, Yale University, STEVEN SIMON, Oxford University, NICK BONESTEEL, Florida State University — While Ising anyons, the presumed quasi-particles of the $\nu = 5/2$ fractional quantum Hall state, do obey non-Abelian statistics, their braid group is not sufficiently rich to support universal quantum computation (UQC). Recently, Bravyi [1] proposed a method for combining topological and non-topological operations that exploits the topological protection of the Ising anyons to allow for UQC even with very low accuracy non-topological operations. Starting from Bravyi’s proposal, we calculate the resources required to perform Shor’s algorithm. We find that when parallelization is included, the required number of qubits grows as the number of gates ($\sim N^3$, where $N$ is the length of the number to be factored using Shor’s algorithm) and that the total time required is nearly independent of $N$. Numerical work has further allowed us to determine how far apart the anyons must be in a realistic sample in order to perform topological operations. We thus estimate how large a coherent sample would be required for Ising anyons to successfully execute modular exponentiation. We compare our results to the requirements for performing Shor’s algorithm via fully topological quantum computation with Fibonacci anyons, the presumed quasiparticle excitation of the $\nu = 12/5$ fractional quantum Hall state. [1] S. Bravyi, Phys. Rev. A 73, 042313 (2006)
4:30PM X23.00011 Probing the neutral edge modes in transport across a point contact via thermal effects in the Read-Rezayi non-abelian quantum Hall states, EYTAN GROSFELD, University of Illinois, SOURIN DAS, Center for High Energy Physics, Indian Institute of Science, Bangalore, India — Non-abelian quantum Hall states are characterized by the existence of neutral gapless edge modes, whose structure is intricately related to the existence of bulk quasi-particle excitations obeying non-abelian statistics. Detecting the presence of these neutral modes is thus an important step towards establishing the non-abelian nature of these quantum Hall states. While it is hard to couple to the neutral modes using an electric field, they will directly couple to a temperature gradient and respond by contributing to the thermal current. By obtaining an expression for the thermal current through a quantum point contact, we demonstrate that a measurement of the thermal current will reveal the presence of the neutral modes. In addition, since thermal measurements are difficult to implement, we propose a setup which uses no external heaters and relies solely on noise measurements to detect thermal effects. The idea is to have two point contacts in series separated by a distance set by the thermal equilibration length of the charge mode. We show that by using the first point contact as a heating device, the excess charge noise measured at the second point contact carries a non-trivial signature of the presence of the neutral mode hence leading to its indirect detection.

4:42PM X23.00012 Charge-statistics separation and probing non-Abelian states for quantum Hall plateau at $\nu=5/2^*$, FEIFEI LI, DIMA FELDMAN, Department of Physics, Brown University, Providence, Rhode Island 02912, USA — Several states were proposed for quantum Hall plateau at $\nu=5/2$. We suggest a transport experiment that can distinguish six of the candidate states. The proposal involves measurements of current and shot noise in a geometry with three quantum point contacts. Unlike interference experiments, this approach can distinguish Pfaffian and anti-Pfaffian states as well as different states with identical Pfaffian or anti-Pfaffian statistics. Moreover, the transport is not sensitive to the fluctuations of the number of quasiparticles trapped in the system. [1] D. E. Feldman and Feifei Li, Phys. Rev. B 78, 161304(R) (2008).

4:54PM X23.00013 Quantum Hall hierarchy revisited, SUSANNE VIEFERS, JUHA SUORSA, University of Oslo, HANS HANSSON, MARIA HERMANNS, Stockholm University — Using techniques from conformal field theory, we construct explicit candidate wave functions for the entire Abelian quantum Hall hierarchy, i.e. quasihole- and quasielectron condensates, as well as mixtures of these. The formalism presented here, generalizes and unifies our previous techniques, which were only able to address quasielectron condensates. In the special cases of the positive and negative Jain sequences $\nu = n/(2np \pm 1)$, our method exactly reproduces Jain’s composite fermion wave functions. In general our results are consistent with Wen’s topological classification of FQH states.

5:06PM X23.00014 Non-Abelian quasielectrons, HANS HANSSON, MARIA HERMANNS, Stockholm University, SUSANNE VIEFERS, University of Oslo — Using methods from conformal field theory, we construct trial wave functions for quasielectron excitations in both Abelian and non-Abelian quantum Hall states. We briefly explain the underlying theory, and present analytical and numerical results for the case of two and four quasielectrons in the non-Abelian Moore-Read pfaffian state. Our methods generalize to other non-Abelian states, and can possibly also give a description of condensates of non-Abelian quasielectrons.

5:18PM X23.00015 Topological Entanglement Entropy of Realistic Quantum Hall States, BARRY FRIEDMAN, Department of Physics, Sam Houston State University, GREG LEVINE, Department of Physics and Astronomy, Hofstra University — The entanglement entropy for the incompressible states of a realistic quantum Hall system was studied by direct diagonalization for square clusters with periodic boundary conditions. The subdominant term to the area law, the topological entanglement entropy, was extracted for filling factors 1/3 and 5/2. The result for filling factor 1/3 is consistent with the topological entanglement entropy for the Laughlin wave function while the 5/2 filling factor exhibits a topological entanglement entropy consistent with the Moore-Read wave function. Preliminary results for the topological entanglement entropy for other incompressible states in the second Landau level will be discussed.

2:30PM X24.00001 "Developments in the application of borohydrides for hydrogen storage". ERIC MAUZOU, U of Missouri — No abstract available.

3:06PM X24.00002 First-Principles Determination of Crystal Structures, Phase Stability, and Reaction Thermodynamics in the Li-Mg-Al-H Hydrogen Storage System1, ALIREZA AKBARZADEH2, California State University Northridge, CHRIS WOLVERTON3, Northwestern University, VIDVUDS OZOLINS4, University of California Los Angeles — First-principles DFT calculations have been used to investigate the crystal structures, thermodynamic stability, and decomposition pathways of Li-Mg-Al-H hydrogen storage compounds. We find that the recently discovered LiMg(AlH4)3 compound is marginally stable with respect to decomposition into LiAlH4 and Mg(AlH4)2; however, we also find that LiMg(AlH4)3 is unstable with respect to H2 release and decomposes exothermically into LiMgAlH4, Al, and H2 in excellent agreement with measurements. Using ICSD crystal structures database, we predict that the hypothetical MgAlH4 compound should assume the orthorhombic BaGaF2 prototype structure. We also discuss that phonon vibrations have sizeable effects on the enthalpies and entropies of hydrogen release reactions of Li-Mg-Al-H compounds.

ACATRINEI, SAURABH KABRA, LUKE DAEMEN, LANCE-LEC, LANL, Los Alamos, NM 87545, USA — CuMg stoichiometry. NiMg$_2$x of formation of the hydride is related to that of the primary alloy, it was hypothesized that CuLi to the properties of the hydrogenated (and deuterated) CuLi$_2$NiMg−reason, much effort has been put toward lowering their thermal stability. One of the common routes taken to achieve this aim is to mix with other borohydrides to the Li-doped CuMg metal borohydrides, soft modes in LTI and in Mg-substituted CaMgNiH$_2$, are available in the published literature. We calculate the enthalpy of formation ∆H with density functional theory (DFT) for both using three different approximations for the exchange-correlation energy functional. Phonon spectra are calculated as well. DFT unequivocally identifies LTII as preferable since ∆H obtained for it is in better agreement with experiment and its phonon spectrum contains no anomalies. Structures approximating LTII derived from analyses of soft modes in LTI and in Mg-substituted CaMgNiH$_2$ are also discussed.

Mg$_2$NiH$_4$, JAN HERBST, LOUIS HECTOR, JR., GM R&D Center — Mg$_2$NiH$_4$ is a semiconductor and forms an ordered low temperature monoclinic phase and a disordered high temperature cubic modification. Two distinct structures for the monoclinic phase from neutron diffraction studies of the deuterated analog, which we designate as LTI and LTII, are present in the published literature. We calculate the enthalpy of formation ΔH with density functional theory (DFT) for both using three different approximations for the exchange-correlation energy functional. Phonon spectra are calculated as well. DFT unequivocally identifies LTII as preferable since ΔH obtained for it is in better agreement with experiment and its phonon spectrum contains no anomalies. Structures approximating LTII derived from analyses of soft modes in LTI and in Mg-substituted CaMgNiH$_2$ are also discussed.

Hydrogen Storage in Cu-Li-Mg Alloys, M. HELENA BRAGA$^2$, GEORGE CHERTKOV, ALICE Acatrinei, Saurabh Kabra, Luke Daemen, Lance-Lc, Lanl, Los Alamos, NM 87545, USA — CuMg does not form a hydride. However CuLi$_2$Mg$_2$−$_2$ (x ~ 0.11) has a hexagonal crystal structure (P6$_3$22), just like NiMg$_2$, a compound known for its hydrogen storage properties. A comparison between the phase diagrams of the systems Cu-Mg and Ni-Mg shows that these binary systems form compounds with similar stoichiometry. NiMg$_2$ is formed by peritectic reaction of the elements at 759 °C (1032 K) and CuMg$_2$ at 508 °C (841 K) by congruent melting. Since the energy of formation of the hydride is related to that of the primary alloy, it was hypothesized that CuLi$_2$Mg$_2$−$_2$...
4:42PM X24.00010 Hydrogen Desorption Behavior of Nickel-Chloride-Catalyzed Stoichiometric \text{Li,BN}_3\text{H}_{10}, FREDERICK PINKERTON, MARTIN MEYER, General Motors R&D Center — Li-B-N-H quaternary hydrides with the \(\alpha\)-phase crystal structure form over a range of compositions between Li\(_2\)BN\(_3\)H\(_4\) and Li\(_2\)BN\(_3\)H\(_{10}\) and have up to 11.9 wt\% hydrogen capacity. Previous work focused on the non-equilibrium Li\(_2\)BN\(_3\)H\(_4\) composition created by ball milling because it has maximum hydrogen release and minimum NH\(_3\) co-generation. Here we report the hydrogen and NH\(_3\) release characteristics of \(\alpha\)-phase material having the equilibrium Li\(_2\)BN\(_3\)H\(_{10}\) composition. In the absence of a dehydrogenation catalyst, H\(_2\) and NH\(_3\) were released simultaneously in roughly equal quantities by weight (or about 10\% NH\(_3\) by volume) at temperatures above 240 \(^\circ\)C. Adding Ni in the form of NiCl\(_2\) as a dehydrogenation catalyst reduced the H\(_2\) release temperature by 122 \(^\circ\)C. NH\(_3\) release, in contrast, still occurred only at the higher temperature. As a result, decomposition occurred in two steps separated in temperature, dominated by H\(_2\) gas at low temperature and NH\(_3\) at high temperature. The two gases clearly evolved in two distinct reactions that are coincident in uncatalyzed Li\(_2\)BN\(_3\)H\(_{10}\), but can be separated by a dehydrogenation catalyst. We expect that NH\(_3\) co-generation could be completely eliminated at sufficiently low dehydrogenation temperatures.

4:54PM X24.00011 Thermochemical Investigations of Nano-phase Ammonia Borane: Effect of Higher Loading, ABHI KARKAMKAR, Pacific Northwest National Laboratory, ASHLEY STOWE, TOM AUTREY — Chemical hydrogen storage materials that release H\(_2\) by thermolysis without generating CO\(_2\) offer an attractive option. The ammonia borane is an attractive compound containing more than 18 wt\% hydrogen. However, the kinetics of hydrogen release in not favorable in bulk materials where H\(_2\) is released at 114 \(^\circ\)C. We recently reported use of SBA-15 as scaffold material to form a nanophase ammonia borane species which liberated H\(_2\) at significantly lower temperatures. Hydrogen formation from bulk AB is slightly exothermic (-5 kcal/mol). The reaction enthalpy (\(\Delta H\)) for release of H\(_2\) from AB adsorbed into SBA-15 (1:1 w/w) was determined to be nearly thermoneutral—dramatically lower than the bulk material. Near thermoneutral reaction suggests that there would be less restrictive heat management issues, greater thermal stability and potentially a lower energy input requirement for regeneration of AB. One drawback which results for nano-phase AB is that while the hydrogen release properties are enhanced, the gravimetric hydrogen density is reduced by a 50\% for the 1 to 1 by mass ratio material. We here report on our efforts to increase the gravimetric hydrogen density of nano-phase AB by developing higher loading conditions of AB adsorbed into mesoporous silica (MCM-41).

5:06PM X24.00012 Hydrogen storage in ammonia borane: \textit{Ab initio} study of the de- and rehydrogenation mechanisms, KISEOK CHANG, DAVID TOMANEK, Michigan State University, EUNJU KIM, PHILIPPE F. WECK, University of Nevada Las Vegas — Using \textit{ab initio} density functional calculations, we study the microscopic mechanism of hydrogen release from ammonia borane (NH\(_3\)BH\(_3\)) and the reverse process leading to its subsequent recharging with hydrogen. Our total energy surfaces indicate the most favorable pathways to thermally convert the NH\(_3\)BH\(_3\) molecular solid to the energetically preferred polymer NH\(_3\)BH\(_2\) and molecular hydrogen. To prevent formation of undesirable side-products such as the cyclic compound borazine (N\(_3\)B\(_3\)H\(_6\)) or other complexes that would prevent subsequent rehydrogenation, we propose to enclose AB in narrow carbon nanotubes. In this constrained space, we investigate possible rehydrogenation pathways using atomic and molecular hydrogen as well as selected protonation agents.

\textbf{Thursday, March 19, 2009 2:30PM - 5:42PM — Session X25 DMP: Focus Session: Graphene XVII: p-n Junctions, Nanoribbons, and Quantum Dots 327}

2:30PM X24.00021 Theoretical investigations of deformed graphene nanoribbons, RICARDO KAGIMURA, MARIO S. C. MAZZONI, HELIO CHACHAM, Universidade Federal de Minas Gerais — Graphene nanoribbons (GNRs) have attracted considerable attention in the last two years. Recent experimental work [Science, 319, 1229 (2008)] has reported semiconducting GNRs with width of a few nanometers and suitable band gaps for electronic applications. One desirable aim in the investigation of GNRs is to control their electronic properties. It has been proposed, for instance, that chemical edge modifications or external strain can modify their electronic properties. In this work, we report density functional calculations, we study the microscopic mechanism of hydrogen release from ammonia borane (NH\(_3\)BH\(_3\)) and the reverse process leading to its subsequent recharging with hydrogen. Our total energy surfaces indicate the most favorable pathways to thermally convert the NH\(_3\)BH\(_3\) molecular solid to the energetically preferred polymer NH\(_3\)BH\(_2\) and molecular hydrogen. To prevent formation of undesirable side-products such as the cyclic compound borazine (N\(_3\)B\(_3\)H\(_6\)) or other complexes that would prevent subsequent rehydrogenation, we propose to enclose AB in narrow carbon nanotubes. In this constrained space, we investigate possible rehydrogenation pathways using atomic and molecular hydrogen as well as selected protonation agents.

2:42PM X25.00002 Quantum Dot Behavior in Graphene Nanoconstrictions, KATHRYN TODD, HUNG-TAO CHOU, SAMI AMASHA, PATRICK GALLAGHER, DAVID GOLDBABER-GORDON, Stanford University — Graphene nanoribbons have been proposed as novel high-frequency transistors due to their high mobility and transport gap that scales inversely with width. In order to understand the origin of the transport gap in long nanoribbons, we measure transport through short side-gated nanoconstrictions. Unlike in long (\(\geq 250\) nm) nanoribbons, we measure transport through multiple quantum dots in series, shorter (\(\leq 60\) nm) constrictions display behavior characteristic of single and double quantum dots. We find that dot size scales with constrictions width. In the narrowest short constrictions, high on/off ratios are achievable, while in wider (\(\geq 35\) nm) constrictions we observe quantum dot behavior overlaid on a highly conducting background. We hypothesize that the metal side gates in close proximity to our short constrictions suppress the importance of edge disorder, and compare constrictions fabricated with and without metal side gates. We propose a model where transport occurs through quantum dots nucleated by disordered background potential in the presence of a confinement gap.

2:54PM X25.00003 Interaction effects in graphene p-n junctions, LINGFENG MATTHEW ZHANG, University of California, San Diego — We review our recent analytical and numerical studies of a new class of graphene devices: lateral p-n junctions. Such structures are realized experimentally by modulating the electron density in graphene samples with external gates. Our theory describes the charge density distribution, the electric field profile, and the resistance of such p-n junctions. The proper treatment of the electrostatic screening beyond the linear order is crucial for obtaining correct results for all these quantities. In particular, the electric field at the interface of the electron and hole regions is strongly enhanced due to limited screening capacity of Dirac vacuum. This nonlinear screening effect can significantly reduce the junction resistance. It is necessary to include it in order to obtain a good agreement with the experiments. More subtle interaction effects such as the Bragg reflection of quasiparticles on Friedel oscillations near the p-n interface are also discussed.

3:30PM X25.00004 Effect of Shape on Electronic and Magnetic Properties of Graphene Nanoribbons (GNRs) | ALBERT K. DEARDEN, PHILIP SHEMELLA, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute. Troy, NY. PULICKEL M. AJAYAN, Dept. of Mechanical Engineering & Materials Science, Rice University, Houston, TX. SARIOJ K. NAYAK, Department of Physics, Applied Physics, & Astronomy, Rensselaer Polytechnic Institute. Troy, NY. We have studied electronic and magnetic properties of graphene nanostructures with different shapes. In particular, we have studied both zigzag and armchair graphene nanoribbons (GNR) of triangular shape using density functional method. We find electronic and magnetic properties of triangular structures are drastically different from their rectangular counterparts and our results suggest that, in addition to size effect, shape of the structure has a large impact on the underlying electronic properties of GNRs. We will compare our results with available experiments.

3:42PM X25.00005 Probing the transport gap in edge disordered graphene nanoribbons | MELINDA HAN, PHILIP KIM, Columbia University. We present experimental studies on the detailed nature of the transport gap observed in etched graphene nanoribbons. Temperature dependent measurements of electronic transport in the “gapped” region of suppressed conductance suggest transport via localized states or charge islands, giving rise to separate energy scales for hopping conductance and the transport gap. Distinct temperature regimes with different exponential temperature dependences are observed, with a crossover temperature dependent on ribbon width. A transition to “bulk” graphene electronic behavior is observed for wider ribbons, and the size of the transport gap shows a length dependence consistent with conduction due to hopping.

3:54PM X25.00006 Role of edge states in graphene nano-ribbons: - DFT studies | SUMIT SAXENA, TREVOR A. TYSON, Dept. of Physics, New Jersey Institute of technology. Newark, NJ. We present first principle calculations to study the effect of edge states in graphene nano-ribbons. Spin restricted calculations for graphene nano-ribbons were performed using ground state density functional theory. The plot of electron localization function corresponding to the edge dangling bonds has revealed highly reactive edge states in graphene nano-ribbons. The reactivity of the graphene nano-ribbons with respect to the edge structure is discussed. This study has been supplemented by band structure studies in armchair and zigzag edged graphene nano-ribbon systems. This work is supported in part by NSF DMR-0512196.

4:06PM X25.00007 Electronic properties of Graphene quantum dots | PAWEL HAWRYLAK, Institute for Microstructural Sciences NRC, Ottawa, PAWEL POTASZ, Wroclaw University of Technology, Poland. We study electronic properties of Graphene quantum dots in magnetic fields. Graphene quantum dots are atomically thick nanometer-scale islands constructed by connecting benzene molecules. Quantum dots with triangular and hexagonal shape have shown to have different edge properties [1,2], and triangular zig-zag structures have recently attracted attention due to their half-filled zero-energy edge states. In this work, we investigate electronic and magnetic properties of triangular and hexagonal shaped islands. We study the effect of first and second nearest neighbour interactions, magnetic field and the number of atoms on the single-particle properties using a tight-binding model. We then use configuration interaction method to study the effect of electron-electron interactions on the ground state properties including magnetization, excitation spectra, and their effect on Coulomb blockade and tunneling through graphene islands. [1] J. Fernandez-Rossier and J.J. Palacios, Phys.Rev.Lett. 99, 177204 (2007); [2] M. Ezawa, Phys.Rev.B, 77, 155411 (2008).

4:18PM X25.00008 Charge transport in ballistic multipe probe bilayer graphene dots,1 | IGOR ROMANOVSKY, CONSTANTINE YANNOUTEAS, UZI LANDMAN, Georgia Institute of Technology. Atlanta, GA 30332. We present a numerical analysis of the transport properties of the bilayer graphene quantum dots attached to multiple leads. In the framework of the tight binding model and using the nonequilibrium Green’s function technique, we study numerically effects due to: magnetic fields, bias voltage between the layers, geometrical shape, and the arrangement of the attachments of the leads to the device. The results are compared to those obtained for similar quantum dot structures made from a graphene monolayer.1Supported by the US D.O.E. (FG05-86ER-45234)

4:30PM X25.00009 Graphene Josephson Qubit | COLIN BENJAMIN, JIANNIS K. PACHOS, School of Physics & Astronomy, University of Leeds. Leeds, UK. We propose to combine the advantages of graphene, such as easy tunability and long coherence times, with Josephson physics to manufacture qubits. These qubits can either be built around a 0 and π junction and controlled by external flux or a d-wave Josephson junction can itself be tuned via a gate voltage to create superpositions between macroscopically degenerate states. We show that ferromagnets are not required for realizing π junction in graphene, thus considerably simplifying its physical implementation. We demonstrate that one qubit gates, such as arbitrary phase rotations and the exchange gate, can be implemented easily.

4:42PM X25.00010 Quantum Transport in Graphene pnp Junctions with Contactless Top Gates | JAIRO VELASCO JR., GANG LIU, WENZHONG BAO, CHUN NING LAU, University of California at Riverside. We show that graphene offers the unique opportunity to explore relativistic physics in a condensed matter system. One such example is the phenomenon of Klein tunneling in graphene pnp junctions. By using a contactless top gate, we are able to fabricate very high quality pnp junctions, and perform electrical transport spectroscopy measurements in zero and finite magnetic fields. We observe oscillations in conductance of the pnp junction and changes in magnetoresistance. Latest experimental progress and comparison with theoretical predictions will be discussed.

4:54PM X25.00011 Systematic study of the transport gap and localization in graphene nanoribbons of varying lengths | PATRICK GALLAGHER, KATHRYN TODD, DAVID GOLDHABER-GORDON, Stanford University. Recent studies of very short graphene nanoconstrictions[1] have found that short constrictions lack the large transport gap displayed by longer nanoribbons, implying that localization behavior plays a critical role in the transport gap. We present transport measurements on graphene nanoribbons of constant width and varying length and report on gap characteristics and Coulomb blockade behavior. We discuss the relevant theoretical models and compare their predictions to our data.

5:06PM X25.00012 Signatures of classical chaos in gate-defined graphene quantum dots | JENS H. BARDAKRSON, Laboratory of Atomic and Solid State Physics, Cornell University. Ithaca, NY 14853-2501, USA. M. TITOV, School of Engineering & Physical Sciences, Heriot-Watt University, Edinburgh EH14 4AS, UK. We have studied electronic and magnetic properties of graphene nanostructures with different shapes. In particular, we have studied both zigzag and armchair graphene nanoribbons (GNR) of triangular shape using density functional method. We find electronic and magnetic properties of triangular structures are drastically different from their rectangular counterparts and our results suggest that, in addition to size effect, shape of the structure has a large impact on the underlying electronic properties of GNRs. We will compare our results with available experiments.
5:18PM X25.00013 Quantum Hall Effect in Two-Terminal Graphene Devices. JAMES WILLIAMS, Harvard University, DIMA ABANIN1, Massachusetts Institute of Technology, LEONARDO DICARLO2, Harvard University, LEONID LEVITOV, Massachusetts Institute of Technology, CHARLES MARCUS, Harvard University — We report on transport measurements in the quantum Hall regime of two-terminal single and bilayer graphene devices. The mixture of the longitudinal and transverse conductivities in the two-terminal geometry results in departures from the expected conductance values on the Hall plateaus and are found to be device-dependence dependent. The experimental results are compared to theory and discrepancies are discussed. Research supported in part by INDEX, an NRI Center, and by the Harvard NSEC.

5:30PM X25.00014 New Computational Approach to Electron Transport in Irregular Graphene Nanostructures. DOUGLAS MASON, ERIC HELLER, Physics Dept., Harvard University, Cambridge, MA, DAVID PRENDERGAST, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA — For novel graphene devices of nanoscale-to-macroscopic scale, many aspects of their transport properties are not easily understood due to difficulties in fabricating devices with regular edges. Here we develop a framework to efficiently calculate and potentially screen electronic transport properties of arbitrary nanoscale graphene device structures. A generalization of the established recursive Green’s function method is presented, providing access to arbitrary device and lead geometries with substantial computer-time savings. Using single-orbit nearest-neighbor tight-binding models and the Green’s function-landauer scattering formalism, we will explore the transmission function of irregular two-dimensional graphene-based nanostructures with arbitrary lead orientation. Prepared by LBNL under contract DE-AC02-05CH11231 and supported by the U.S. Dept. of Energy Computer Science Graduate Fellowship under grant DE-FG02-97ER25308.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X26 DCMP: Nanowire & Nanotube Synthesis and Properties 328

2:30PM X26.00001 Aligned Gallium Nitride Nanowire Growth by Chemical Beam Epitaxy Method. RYAN MUNDEN, App Phys, Yale Univ, ALEKSANDAR VACIC, ERIK CASTIGLIONE, WEIHUA GUAN, Elect Eng Yale Univ., CHRISTINE BROADBRIDGE, Physics, Southern CT State Univ, MARK REED, EE/AP Yale University — Gallium Nitride (GaN) Nanowires (NWs) have successfully been grown via a chemical beam epitaxy method. Source gases of Trimethylgallium (TMGa) and Ammonia (NH3) are impinged directly onto a hot growth substrate (∼800 °C) in high vacuum (∼1x10^-8 torr, base; ∼1x10^-5 torr, growth). A thin metal film acts as catalyst, but NWs were also grown without catalyst. By this method NWs have been grown on silicon, alumina, sapphire, and GaN-film substrates. NWs grown on GaN films grow aligned to the growth substrate, perpendicular to the c-plane GaN film surface. Wires aligned to the GaN a-planes can also be observed. NWs have been studied by SEM, TEM, and electrical characterization. NW widths are ∼2.5 micron with diameters of ∼25 nm. NWs are uniform, straight, and aligned with the substrate over large areas. However closer inspection of the NWs by TEM shows that the NWs are often polycrystalline in nature. There are distinct segments “stacked” into a nanowire leading to noticeable diameter variations on the nanoscale. Diameter modulation can be enhanced through choice of growth substrate, temperature, and pulsing of the TMGa source.

2:42PM X26.00002 Temperature Evolution of Gallium Nitride Nanowire Vapor-solid Growth Matrix. K. MCELROY, Michigan State University, B.W. JACOBS, Sandia National Laboratories, CA, T.R. BIELER, M.A. CRIMP, V.M. AYRES, Michigan State University — Recent results indicate that vapor-solid growth mechanisms can yield semiconductor nanowires with high crystallinity. In the present experiments, gallium nitride nanowire growth is initiated following formation of a microcrystalline growth matrix. A change in nanowire orientation from wurtzite (zinc-blende) directions at 850 °C and 950 °C to the wurtzite [0001] direction at 1000 °C is observed. The change in nanowire orientation is correlated with changes in the growth matrix. Investigations of the evolution of the growth matrix as a function of temperature using x-ray diffraction with orientation analysis, atomic fore microscopy, high-resolution transmission electron microscopy (HRTEM) and scanning electron microscopy (SEM) are presented.

2:54PM X26.00003 Interaction between the boron nitride nanotube and biological molecules. CHIH-KAI YANG, Chang Gung University — By calculating the interaction between boron nitride nanotubes (BNNT) and a variety of biological molecules, including amino acids and nitrogenous bases that are part of a nucleotide, using density functional theory, we conclude that there is no bonding or chemical adsorption between the wide band-gap BNNT and the biological molecules considered. This weak interaction suggests that BNNTs may be used as a safe nanoscale channel for transporting biological molecules.

3:06PM X26.00004 Formation of Silicon Carbide Y Junctions by the Coalescence of Catalysts. ZHENYU LIU, JUDITH C. YANG, Department of Mechanical Engineering and Materials Science, University of Pittsburgh, Pittsburgh, 15261 PA, USA; V. SROT, PETER A. VAN AKEN, M. RÜHLE, Max-Planck-Institute for Materials Research, Heisenbergstrasse 3, D-70569, Germany — We previously reported the formation of crystalline SiC nanocones by the released ion catalytic procedure, where the initially carbon-encapsulated iron nanoparticles escape from their carbon shells and agglomerate while catalyzing 1D SiC growth. Here we show that the coalescence of the iron nanoparticles can lead to Y junctions. Y junctions where the SiC branches are either parallel or inclined with respect to each other have been observed by scanning electron microscopy (SEM) and high resolution transmission electron microscopy (HRTEM). The microstructure of the resulting products is analyzed by various techniques, including X-ray diffraction (XRD), energy dispersive X-ray spectroscopy (EDS) as well as electron energy loss spectroscopy (EELS). The Y junction with two parallel branches of various diameters suggests that the Y junction can be induced by the growth kinetics attributed to the diameter dependence, such as by the Gibbs-Thomson or surface tension effect. The proposed formation mechanism of Y junctions by the coalescence of catalyst droplets is a promising method to the construction of heterostructure nanowire devices.

3:18PM X26.00005 Quantum Confinement in PbS nanowire. SUBHASISH MANDAL, RANJIT PATI, Michigan Technological University, Houghton, MI 49931 — One dimensional nanowires have become leading candidates in building nano sensor, nano transistor, optoelectronic devices and logic circuit. In the last several years, PbS nanowire has drawn considerable interest for its potential applications in optical switch and solar cell. Controlled synthesis of PbS nanowire with diameter ranging from 1.2 nm to 20 nm have been reported with the photo luminescence study revealing wide band gap behavior for the nanowire. This offers exciting opportunities to study theoretically quantum confinement effect in PbS Nanowire. We report first principles density functional calculations of the electronic properties of PbS nanowire as a function of diameter. Our calculation shows, by varying the diameter of the nanowire from ∼1.17 nm to ∼3.64 nm, the energy band gap is found to change from 1.55 eV to 0.93 eV, substantially higher than the band gap observed for the PbS bulk confirming the role of quantum confinement.
3:30PM X26.00006 Toward complex nanostructures: lead chalcogenide nanoparticles, nanowires, and more 1, WEON-KYU KOH1, DAVID K. KIM2, CHERIE R. KAGAN3, CHRISTOPHER B. MURRAY4. University of Pennsylvania — Lead chalcogenides have been shown to be interesting semiconductor materials due to their small bandgaps and large Bohr radii. Based on lead chalcogenide nanoparticles as building blocks, we studied anisotropic growth of their nanowires and other structures. Growth mechanism of those structures is believed to oriented attachment which is mainly driven by dipole moment; in addition the role of surfactant is also important due to their dynamic binding on the nanoparticle surface. As-synthesized nanoparticles and nanowires were characterized using electron microscopy, X-ray diffraction, optical and electrical measurement. Our initial results open up new opportunities for photovoltaic device, sensor, and other application using those unique structures.

3:42PM X26.00007 Optimal Annealing Conditions, Mechanism, and Applications for the Crystallization of Titania Nanotubes Powders Obtained by Anodization, EUGEN PANAITESCU, LATIKA MENON, Northeastern University, Physics Department — Titanium oxide nanotubes have drawn recent interest due to their possible application in photocatalysis, water splitting and photovoltaics, as they combine the wide gap semiconductor properties of the material with the high surface per unit volume of the nanostructures. Amorphous ordered titania nanotubes arrays can be obtained by anodization of titanium foils, and our group developed a method of ultrafast synthesis of powders containing such nanotubes bundles. Crystallization can be achieved by annealing, and we investigated the influence of annealing parameters using differential scanning calorimetry coupled with spectroscopy and imaging techniques such as SEM, TEM and XRD. Our extensive study revealed the optimal parameters for crystallization without structural damage at the nanoscale, which can occur for temperatures as low as 270 degrees Celsius. Mechanistic explanations and numerical studies offered us a theoretical insight on the phase transition process. Further employing of our crystalline powders in dye sensitized solar cells revealed efficiency results superior to those previously reported for crystallization at higher temperatures and annealing rates.

3:54PM X26.00008 Controlled Attachment of Gold Nanoparticles on Ordered Titania Nanotube Arrays. MOHAMED ABDIELMOULA, EUGEN PANAITESCU, Physics Department, Northeastern University, CHRISTIAAN RICHTER, Yale University, LAURA LEWIS, Department of Chemical Engineering, Northeastern University, LATIKA MENON, Physics Department, Northeastern University — Gold nanoparticles have been deposited on electrochemically synthesized high-aspect ratio Titania nanotubes. Titania nanotubes with very long aspect ratio as long as 50microns are synthesized by means of electrochemical anodization of titanium foils in chlorine containing electrolytes. The tube dimensions (diameter, wall thickness and length) of the tubes can be controlled in our fabrication process. The gold particles are deposited on the tubes by means of a modified deposition-precipitation method in HAuCl4 solution under controlled concentration of the solution. We show that by adjusting the fabrication conditions, we can obtain a high deposition density of the gold particles over the nanotube surface (over 90% coverage percentage ) and also have good control over the size of the gold nanoparticles (<5 nm). We show that there is an increase in particle size upon increasing the deposition period. The samples have been characterized by means of scanning and transmission electron microscopy. The optical and preliminary catalytic properties of such gold-supported Titania nanotubes will also be reported.

4:06PM X26.00009 Novel Fabrication and Enhanced Photosensitivity of Selenium Filament Arrays by Optical-Fiber Thermal Drawing, DAO SHENG DENG, N. ORF, A. ABOURADDY, Y. FINK, Massachusetts Institute of Technology — Structures with high aspect ratio and nanometer cross-sectional dimensions have been the subject of recent studies. These nanometer-scale wire structures are typically processed through a bottom-up approach that yields limited wire lengths lacking global orientation and presenting challenges to handling and electrical contacting. Here, we report a novel physical phenomenon in which a cylindrical shell undergoing a scaling process evolves into an ordered array of filaments upon reaching a characteristic thickness. We propose a fluid front instability mechanism to account for the observed phenomena. The fleeting evolution of fluid breakup from a thin film to a filament array is captured in the frozen state by a thermal drawing process which results in extended lengths of solid sub-100nm filaments encapsulated within a polymer fiber. Furthermore, we demonstrate that the electrical connectivity of centimeter-long filament arrays to external circuitry is readily achieved by contacting the fiber ends, allowing one to study their electrical and optoelectronic properties. Enhanced photosensitivity of filaments is observed compared to a selenium film. This approach offers unique opportunities for fabrication of nanometer scale devices of unprecedented lengths allowing simplified access and connectivity.

4:18PM X26.00010 Self-assembled Au nanorods - polymer composites, HEUNG-SHIK PARK, OLEG LAVERNTOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, ASHISH AGARWAL, NICHOLAS KOTOV, Department of Chemical Engineering, University of Michigan — The unique optoelectronic properties of the anisotropic metallic nanorods (NRs) are of great interest because of their potential applications in biological sensing, solar energy conversion, cloaking devices, etc. In order to utilize NRs, tuning their properties and immobilizing NRs into polymer matrix are essential. We present a simple and universal process for formation of self-assembled nanorods polymer composite. This approach is based on the anisotropic electrostatic interaction between aggregates of chromonic molecules and NRs that lead to either end-to-end or side-by-side assembly of NRs. We discuss encapsulation of these structures with polymer matrices.

4:30PM X26.00011 Focused Ion Beam Treatment of ZnO Nanowires, GAGIK SHMAVONYAN, State Engineering University of Armenia — We investigated vapour-liquid-solid-grown ZnO nanowires (NWs) on a Si substrate by SEM. SEM investigations show that there are single NWs and ensembles of NWs, among which we found straight and bend, perfect and non-perfect NWs, as well as NWs with clean surfaces and surfaces with the dark spots and features. After focused ion beam polishing we found that every NW has a clean homogeneous surface, which allow us to conclude that all those dark spots and surface features of the NWs really are just surface features. The focused ion beam milling gives information of the deeper interior of the NWs, i.e. buried structures within the NWs and whether those structures are propagating within the NWs. But also here we found that there are no buried structures inside the NWs and the dark spots and features are not propagating within the NWs, which leads to the result that the NWs are totally homogeneous. The sizes of the NWs were determined: the length is about 2-24 μm, and the width and height are about 200-500 nm.

1Author thanks Prof. Dr. Jens Falta and his group at the University of Bremen, Germany.
4:42PM X26.00012 Controlled Growth of Zinc Oxide Nanostructures for Applications, ABHISHEK PRASAD, ARCHANA PANDEY, YOKE KHIN YAP, Michigan Technological University — Zinc Oxide (ZnO) has proven to be a versatile functional material with promising properties. Here we discuss about the controlled growth and applications of various ZnO nanostructures including novel ZnO nanotubes (NTs) and nanosquids (NSqs). We use a conventional thermal CVD technique for the synthesis of ZnO nanostructures. We found that ZnO nanowires, nanobelts and nanocoms can be readily obtained by applying appropriate gas flow rates and growth temperatures. ZnO NTs and NSqs can be formed on the substrates when appropriate cooling rate was applied. These nanostructures were characterized using XRD, HRTEM, FESEM, Raman spectroscopy, and photoluminescence. Results show that ZnO nanostructures were single crystals in wurtzite structure. Among these ZnO NWs were found to be excellent electron field emitters and field effect transistors.

4:54PM X26.00013 CO Gas Sensing with ZnO Nanowire Mat, SIRISHA CHAVA, CHRISTINE BERVEN, University of Idaho, DAQUING ZHANG, California State University — We report the electrical properties of a gas sensor constructed from mats of ZnO nanowires grown on sapphire substrate that shows a reversible response which is unique to CO exposure. The sensor is a two terminal design, where the terminals consist of two 25 µm diameter gold wires laid parallel on the nanowire mat. The individual nanowires have an average diameter of 50 nm with lengths of about 10 µm. The nanowire mat is about 20 µm thick and extends over an area of about 1 cm2. When exposed to Ar, CO2 or H2 no significant changes in the current-voltage behavior of the mat are observed. CO exposure results in approximately a three-fold increase in current. The response is reversible after evacuation. Typical currents when exposed to pure CO under room temperature without prior introduction to any other gas are in the range of 40 nA compared to non-exposed 15 nA. Growth technique of nanowires and comparative work will be discussed.

5:06PM X26.00014 Transparent Thin Film Transistors based on Pristine and Doped Indium Oxide Nanowires, PO-CHIANG CHEN, GUOZHEN SHEN, SAOWALAK SUKCHAROENCHOKE, CHONGWU ZHOU, University of Southern California, UNIVERSITY OF SOUTHERN CALIFORNIA TEAM — The key to the realization of transparent electronics is the development of transparent thin film transistors (TTFT) with good device performance, in terms of high device mobility, low temperature fabrication, and optical transparency. We present our work on the fabrication of high performance TTFTs using both pristine In2O3 nanowires and doped In2O3 nanowires. In2O3 nanowire TTFTs were made on glass and PET substrates with Al2O3 as gate insulator and ITO source/drain electrodes. These devices showed a transparency of about 80% and n-type transistor performance. The device characteristics exhibit a subthreshold slope of 0.2 V/dec, a current on/off ratio of 106, and a field-effect mobility of 514 cm2/V−1S−1. We also fabricated TTFTs wbuilt on Arsenic-doped In2O3 nanowires with a field-effect mobility of 1,183.8 cm2/V−1S−1 without any post-treatments. In addition, we integrated TTFTs with organic light emitting diode (OLED) to make an active matrix organic light emitting diode (AMOLED) display, and thus made an animation by controlling the OLED light output.

5:18PM X26.00015 Studies of Surface Exciton Polaritons in Nano-Materials by Electron Energy-Loss Spectroscopy, C.H. CHEN, Center for Condensed Matter Sciences, National Taiwan University, C.T. WU, Department of Materials Science and Engineering, National Taiwan University, M.W. CHU, L.C. CHEN, Center for Condensed Matter Sciences, National Taiwan University, C.W. CHEN, Department of Materials Science and Engineering, National Taiwan University, K.H. CHEN, Institute of Atomic and Molecular Sciences, Academia Sinica, Taiwan — Surface plasmon polaritons (SPPs), which normally occur in the optically metallic spectral regime, are collective charge density oscillations of conduction electrons at the surface of metals. In sharp contrast to SPPs, the excitations of surface exciton polaritons (SEPs), which are collective oscillations of delocalized excitons at the surface of semiconductors or insulators, have been shown to be correlated with distinct excitonic onsets (interband transitions) in these materials. Using electron energy-loss spectroscopy (EELS) with a 2-A electron probe in the near-field geometry and energy-filtered spectral imaging in real space, we have unambiguously demonstrated the existence of the SEP excitations on the surfaces of GaN and ZnO nanorods at energies near the interband transitions.

Thursday, March 19, 2009 2:30PM - 5:30PM – Session X27-FlAP: Optoelectronic Devices and Applications 329

2:30PM X27.00001 Optical Fiber Tapers for Characterization of Novel Photonic Crystal Devices, JENNA HAGEMEIER, Physics Department, University of California, Santa Barbara, JAN GUDAT, Huygens Laboratory, University of Leiden, The Netherlands, SUSANNA THON, Physics Department, University of California, Santa Barbara, DIRK BOUWMEESTER, Physics Department, University of California, Santa Barbara and Huygens Laboratory, University of Leiden, The Netherlands — Optical fiber tapers are a useful tool for near-field spectroscopy of solid state devices. There are advantages to using fiber tapers rather than other waveguides because they can be moved spatially with respect to the device being studied, a single taper can be used for both pumping and data collection, and they can be used to probe bare cavities. The experimental procedures and challenges for building these microl-scale tapers will be discussed, as well as their uses for probing new kinds of photonic crystal cavities.

2:42PM X27.00002 Temporal Wavelength Multiplexing of a Quantum Cascade Laser, FATIMA TOOR, AMIRALI SHANECHI, JIANXIN CHEN, CLAIRE GMACHL, Electrical Engineering, Princeton University — Quantum cascade (QC) laser based sensor systems in the mid-infrared wavelength range (3-30 µm) have applications in environmental, industrial and medical trace gas sensing. QC laser-based spectroscopic techniques have been developed by several research groups. However, more research work is needed to make these techniques more compact and field deployable. One approach to compactness is to have spectral versatility from a single device. Here we report work on a QC laser based system that is both temporally and wavelength multiplexed, that is, it can emit two different wavelengths at two alternate time slots. A bi-directional and multi-wavelength QC laser source that emits at 10.2 µm wavelength for positive polarity current and 8.6 µm for negative polarity current is used. A system is designed so that a single pulsed current source is the input to a pulse-alternator circuit that flips the polarity of every other pulse. The output of the circuit is connected to the bi-directional and multi-wavelength QC laser to emit two different wavelengths for alternate pulses. Contributions by Gary Shu at the beginning of the work are acknowledged.

3:06PM X27.00004 Electrically Pumped Quantum Post Vertical Cavity Surface Emitting Lasers, HYOCHUL KIM, MATTHEW RAKHER, DIRK BOUWMEESTER, Physics Department, University of California Santa Barbara, PIERRE PETROFF, Materials Science Department, University of California Santa Barbara — Quantum dot (QD) lasers based on high quality, small mode volume microcavities have shown low lasing current threshold. A novel MBE grown self assembled nanostructure, the quantum post (QP) is also a very good candidate as a gain medium for low threshold lasing. As opposed to the QD laser, the delta function density of states in the QP is associated with multiple vertically and laterally confined states. In addition, QPs have a large carrier capture cross section. We demonstrate very low threshold electrically pumped lasing in oxide apertured vertical cavity surface emitting lasers (VCSELs) with QPs as the active medium and compare their characteristics with similar structure with QDs as the active gain medium.

3:18PM X27.00005 In situ Contact Resistance Evaluation of 2.6-2.9 THz Quantum Cascade Lasers, NEELIMA CHANDRAYAN, KRONTIP TREMKIOA, JIN LI, XIFENG QIAN, SHIVASHANKAR VANGALA, WILLIAM GOODHUE, Photonics Center, Dept. of Physics, UMass Lowell, ANDRIY DANYLOV, JERRY WALDMAN, ROBERT GILES, Sub-millimeter Wave Technology Lab, Dept. of Physics, UMass Lowell, WILLIAM NIXON, U.S. Army National Ground Intelligence Center — The fabrication of THz Quantum Cascade Lasers (QCL) requires a strong understanding of the two electrical contacts of the device. Contact resistance as well as contact/semiconductor interdiffusion properties must be designed to minimize series resistance, free carrier absorption, and e-e scattering. Here, in situ measurement of contact resistance using Transmission Line Measurement (TLM) pads has been implemented in the fabrication of 2.6-2.9 THz quantum cascade lasers. The measurement of contact resistances as part of device processing also verifies the correct etch depth of laser structure, uniformity of the etching, and the ohmic nature of the contacts. For example, the procedure has been used to successfully fabricate 2.93 THz lasers with 5 mW of continuous wave output power.

3:30PM X27.00006 Magnetic Field Assisted sub-THz Quantum Cascade Lasers, A. WADE, Y. KIM, D. SMIRNOV, National High Magnetic Field Laboratory, S. KUMAR, Q. HU, Massachusetts Institute of Technology, B.S. WILLIAMS, University of California, Los Angeles, J. RENO, Sandia National Labs — In THz QCLs radiative transitions take place between closely-spaced 2D electronic subbands (1THz ~ 4meV) of a multi-QW semiconductor system. THz quantum cascade lasers now cover the frequency range from 1.2 THz to 5 THz, though cryogenic cooling is still required. Further progress towards the realization of devices emitting at longer wavelengths (sub-THz QCLs) and higher temperatures may be realized in a system with additional lateral confinement. Here we use strong magnetic fields to achieve quasi-0D confinement in THz QCL based on the resonance phonon design. We studied two designs: (a) 2-well injector/2 well active region, emitting at 3 THz at B=0; and (b) 1-well injector/3-well active region, emitting at 2 THz at B=0. T by applying the appropriate electrical bias and strong magnetic fields, we achieved laser emission at 0.8-0.9 THz at B=16 T [1], and 0.6 THz at B=17 T, from devices a and b respectively. The ability to achieve sub-THz lasing is due to magnetic field enhanced population inversion in a quasi-0D QCL.

3:42PM X27.00007 Conducting a wide-range single-transverse mode operation in a commercial multi-mode VCSEL by beam-profile transferred optical feedback1, CHUAN-PI HSU, TSU-CHIANG YEN, Department of Physics, National Sun Yat-sen University, DA-LONG CHENG, Department of Computer and Communication, SHU-TE UNIVERSITY, WANG-CHUANG KUO, Department of Physics, National Sun Yat-sen University — In this research, a beam-profile transferred optical feedback (BTOF) method was employed to conduct a wide range single-transverse mode operation of a commercial multi-mode VCSEL. In BTOF, a spatial modulation optical system was used to reconfigure the spatial distribution of the feedback beam, and to control the laser’s transverse mode. Experimental results indicated that, over a range of about 8.7 times of the laser’s threshold current, BTOF could conduct the laser to output a single-transverse mode with high spectral purity and low intensity noise. While, without optical feedback, the solitary laser exhibited a multi-mode output with a complicated variation in mode distribution as the laser’s current was tuned. More special features of BTOF will be presented in the report.

Supported by NSC of R.O.C. under grand No. NSC 96-2112-M-110-008-MY2

3:54PM X27.00008 Single mode operation in ultra-short cavity Quantum Cascade lasers1, RICHARD CENDEJAS, Princeton University, WENDY SANCHEZ-VAYNSHTEYN, City University of New York, DONGXIA QU, CLAIRE GMACHL, Princeton University — Single-mode continuous wave operation of a A=5.3 μm Quantum Cascade laser (QCL) is achieved through the systematic shortening of the cavity length of ridge-waveguide QCLs with wavelength of emitting from 800 to 1000 μm. Increasing mirror loss was mitigated with highly reflective metallic facet coatings. With smaller cavity lengths, the power consumption of an ultra-short cavity QCL of 110 μm is ~250 mW at 80K, or about 20 times lower than conventional QCLs. Shortening the cavity length increases the free spectral range of the longitudinal modes placing the side modes at the edge of the gain profile, thus deliberately reducing the number of lasing modes until single-mode operation is achieved. The dominant mode is placed on the gain peak via temperature tuning, increasing the gain margin between the dominant and side modes, further increasing the single-mode current range. Amplified spontaneous emission spectra at various temperatures show that an initial gain margin increase from 1.5:1 to 2:1 doubles the single-mode current range. Ultra-short cavity QCLs with lengths of 110 μm are shown to operate single mode with the best device having a 10 cm⁻¹ single-mode continuous tuning.

Work supported in part by MIRTHE NSF-ERC

4:06PM X27.00009 Correlated Photon Noise at Threshold of an Interband Cascade Laser, PATRICK FOLKES, Army Research Laboratory — We report the observation of correlated photon fluctuations at threshold of an interband cascade laser at 30 K and 100 K. Away from threshold, the laser exhibits a frequency-independent photon noise spectral density. The correlated photon noise is manifested by fluctuations in the low-frequency photon noise spectral density at certain frequencies over a narrow range of current near threshold. Concurrently, we observe the emergence and growth of the lasing mode over the same current range. The data indicates that the correlated photon noise is caused by the onset of laser coherence.
4:18PM X27.00010 Effect of free carrier absorption on the efficiency of nitride devices.
EMMANOUL KIOUPAKIS, University of California, Santa Barbara, ANDRE SCHLEIFE, IFTO, Friedrich-Schiller-Universitaet Jena, PATRICK RINKE, University of California, Santa Barbara, FRIEDHELM BECHSTEDT, IFTO, Friedrich-Schiller-Universitaet Jena, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — Indium gallium nitride alloys are successfully being used in the fabrication of optoelectronic devices, such as light emitting and laser diodes, in the green to ultraviolet part of the optical spectrum. The wider application of these devices, however, is limited by their reduced efficiency in the green part of the spectrum. Several mechanisms have been suggested as the cause of this efficiency loss, such as Auger recombination and free carrier absorption. We use the band structure and density-matrix elements from highly accurate many-body perturbation theory calculations in the GW approach (P. Rinke et al., Phys. Rev. B77, 075202 (2008)) to determine the optical absorption coefficient due to free carriers in InGaN. From this we obtain the corresponding photon mean free path and examine the role of free carrier absorption as a possible energy loss mechanism at high carrier concentrations. The computed values indicate that the effect is weak in light emitting diodes but it may become relevant for laser devices that operate at higher current densities.

4:30PM X27.00011 Light Emission Polarization Properties of a-plane InGaN/GaN Quantum Wells.
HUNG-HSUN HUANG, YUH-RENN WU, Graduate Institute of Photonics and Optoelectronics, National Taiwan University — This paper discusses the optical characteristics for nonpolar a-plane InGaN/GaN quantum wells (QWs) with different indium compositions, QW well widths, and injection carrier densities. We compared it with the results of the conventional c-plane QWs and analyzed the characteristics of optical anisotropy polarization in (110)-oriented wurzite a-plane InGaN-based QWs. A self-consistent Poisson, Schrodinger, and many-body-perturbation theory calculations (density-functional and many-body-perturbation theory), in which individual loss processes can explicitly be isolated, that Auger recombination is a key loss mechanism in wurzite InGaN. Auger recombination had previously been proposed by Shen et al. [1] as a loss mechanism in optically pumped InGaN LED devices, but it is difficult to discriminate between different radiationless processes experimentally. We examine two different mechanisms — inter- and intra-band recombination — that affect different parts of the spectrum. In the blue to green spectral region and at room temperature the Auger coefficient can be as large as 2x10^{-10} cm^2/s -1 and in the infrared even larger. Since Auger recombination scales with the cubic power of the free-carrier concentration it becomes an important non-radiative loss mechanism at high current densities. [1] Shen et al., Appl. Phys. Lett. 91, 141101 (2007).

4:42PM X27.00012 Auger recombination rates in nitrides from first principles.
PATRICK RINKE, KRIS T. DELANEY, CHRIS G. VAN DE WALLE, University of California at Santa Barbara, CA 93106 — Indium gallium nitride (InGaN) alloys are successfully being used for light emitting and laser diodes in the green to ultraviolet part of the spectrum, but increases in internal quantum efficiency (IQE) are still required to allow broader applications. The IQE of InGaN devices is limited by loss mechanisms that, at high drive currents (i.e., high carrier concentrations) lead to a decrease in IQE, a phenomenon commonly referred to as "efficiency droop". We demonstrate by means of rigorous first-principles calculations (density-functional and many-body-perturbation theory), in which individual loss processes can explicitly be isolated, that Auger recombination is a key loss mechanism in wurtzite InGaN. Auger recombination has previously been proposed by Shen et al. [1] as a loss mechanism in optically pumped InGaN LED devices, but it is difficult to discriminate between different radiationless processes experimentally. We examine two different mechanisms — inter- and intra-band recombination — that affect different parts of the spectrum. In the blue to green spectral region and at room temperature the Auger coefficient can be as large as 2x10^{-10} cm^2/s -1 and in the infrared even larger. Since Auger recombination scales with the cubic power of the free-carrier concentration it becomes an important non-radiative loss mechanism at high current densities. [1] Shen et al., Appl. Phys. Lett. 91, 141101 (2007).

4:54PM X27.00013 Enhancement of terahertz output power in terahertz parametric oscillator with recycled pump beam.
DONG HO WU1, Naval Research Laboratory, TOMOFUMI IKARI2, Temple University — In the terahertz parametric technique the pump beam is used only once, and then dumped, regardless that the dumped pump beam still has substantial laser energy. So the energy efficiency of the technique is low. This paper reports a new parametric technique in which we recycle the pump beam (instead of dumping it) in order to increase the efficiency and enhance the terahertz beam output. Our experiments, in which we used a doped LiNbO3 crystal with 5% MgO, indicate that the terahertz beam output increases almost five times magnitude for a terahertz parametric oscillator with recycled pump beam.

5:06PM X27.00014 Electro-optic sensors for high power microwave measurements.
ANTHONY GARZARELLA, DONG HO WU, Naval Research Lab — Nonperturbative measurements of high power microwave fields utilizing electro-optic (EO) field sensors are described. Conventional metallic-based field probes (such as dipole antennas) perturb the very fields they measure and typically saturate for field strengths exceeding ~1000 V/m. EO sensors are all-dielectric, have large intrinsic bandwidths (DC to THz), and measure the true waveform of the field noninvasively. Nonlinear EO crystals such as Lithium Niobate or Potassium Dideuterium Phosphate have half-wave retardation fields of the order 10^9 V/m, making them ideal for high power microwave applications. Initial field tests with our EO sensors revealed several sources of noise and instability which are normally not encountered in laboratory settings. In this presentation, we describe a newly-designed EO sensor and how it is configured to address the noise issues in high power microwave field tests. Using this improved sensor configuration, electric field measurements in the near and far field regions of a radiating microwave horn antenna are presented.

ALEX NEMIROSKI, KEITH BROWN, DAVID ISSADORE, ROBERT WESTERVETL, Harvard University School of Engineering and Applied Science, CHRIS THOMPSON, KEITH OBSTEIN, Harvard University Medical School, MICHAEL LAINE, Soltegic, LLC. — We have built a miniature wireless biosensor with fluorescence detection capability that explores the miniaturization limit for a self-powered sensor device assembled from the latest off-the-shelf technology. The device is intended as a remote medical sensor to be inserted endoscopically and remains in a patient’s gastrointestinal tract for a period of weeks, recording and transmitting data as necessary. A sensing network may be formed by using multiple such devices within the patient, routing information to an external receiver that communicates through existing mobilephone networks to relay data remotely. By using a monolithic IC chip with integrated processor, memory, and 2.4 GHz radio, combined with a photonic sensor and miniature battery, we have developed a fully functional computing device in a form factor compatible with insertion through the narrowest endoscopic channels (less than 3mm x 3mm x 20mm). We envision similar devices with various types of sensors to be used in many different areas of the human body.
2:30PM X28.00001 Quantitative investigation of magnetoelectric coupling in various forms of multiferroics, KEE HOON KIM, Seoul National University — Magnetoelectric susceptibility (MES) is probably the most direct way of estimating the magnitude of magnetoelectric coupling in many forms of multiferroic materials. However, the MES has been found in numerous existing magnetoelectric materials in broad field, frequency, and temperature ranges and their MES values have been tabulated [1]. With growing interest worldwide toward applications of magnetoelectric for novel memory and sensor devices, however, there have been ever-increasing demands to measure quantitatively the MES of multiferroic thin films. Yet, the measurements of thin film MES become challenging in spite of its large MES value because the magnetoelectric voltages, proportional to the film thickness, usually get too small to be measured reliably. Herein, we introduce a highly sensitive magnetoelectric susceptometer that can detect the charge variation down to \(\sim 10^{-17} \text{C}\) in a few gauss oscillating magnetic field. Using this specific setup, we could measure the MES of multiferroic thin films or single crystals with unprecedented accuracy and sensitivity in cryogenic (down to 2 K) and magnetic field (up to 9 T) environments. In this talk, we summarize a number of key results based on this technique; (1) MES of a 300 nm BiFeO\(_3\)-CoFe\(_2\)O\(_4\) nanopillar structure as well as that of a 250 nm BiFeO\(_3\) film and of a BiFeO\(_3\) single crystal. (2) MES of (Pb,Zr)TiO\(_3\)-NiFe\(_2\)O\(_4\) nanocomposite films, and (3) temperature- and field-dependent MES in representative multiferroic crystals/films including TbMn\(_2\)O\(_4\), GaFeO\(_3\), and Cr\(_2\)O\(_3\). In particular, we demonstrate that the MES of the film with the nanopillar structure is enhanced by approximately one order of magnitude reaching \(210^{12} \text{V/(Oe cm)}\) at room temperature, compared with those of a pure BiFeO\(_3\) film and a single crystal. Furthermore, based on detailed field and temperature dependent MES studies, we show that magnetoelectric coupling in TbMn\(_2\)O\(_4\) has been mediated and amplified by the large magnetoelastic effect. [1] G. A. Smolenskii and I. E. Chupis, Sov. Phys. Usp. 25, 475 (1982); F. W. Hehl et al. Phys. Rev. A 77, 022106 (2008).

3:06PM X28.00002 Magnetoelectric effects induced by domain walls, ANDREA SCARAMUCCI, University of Groningen, THOMAS KAPLAN, Michigan State University, MAXIM MOSTOVOY, University of Groningen — We explore the possibility to observe high-temperature multiferroic behavior in thin films of ordinary ferrimagnets. In thin films magnetostatic interactions induce periodic stripe domain patterns. We show that stripe domain patterns, stabilized by magneto-dipolar interactions, have ferroelectric properties similar to those of magnetic spirals in bulk materials. We studied behavior of domain patterns and the induced electric polarization in applied magnetic and electric fields using mean field approximation and Monte Carlo simulations. We find a sharp increase in dielectric constant and ferroelectric polarization at the critical field, induced by both magnetic and electric field. We studied the domain walls in conical spiral multiferros, where magnetization \(M\) consists with the electric polarization \(P\) induced by the cylindrical spiral. The structure of these domain walls explains the conservation of \(P \times M\) recently observed in CoCr\(_2\)O\(_4\) as well as the magnetic field dependence of the polarization vector \(P\) in ZnCr\(_2\)Se\(_4\).

3:18PM X28.00003 Large electric polarization in high pressure synthesized orthorhombic manganites \(\text{RMn}_\text{O}_3\) (\(R=\text{Ho, Tm, Yb, and Lu}\)) by using the double-wave PE loop measurements, Y.S. CHAI, Y.S. OH, N. MANIVANNAN, Y.S. YANG, KEE HOON KIM, XMPL, Seoul National University, S.M. FENG, L.J. WANG, C.Q. JIN, Institute of Physics, Chinese Academy of Science — The magnitude of electric polarization via the conventional pyroelectric current and/or PE loop measurements often is ambiguous due to resistive components of the sample. To avoid this, a new technique called the double-wave method has been developed [1], in which only hysteretic PE components can be measured. Using this technique, we have measured the ferroelectric polarization of the orthorhombic \(\text{RMn}_\text{O}_3\) (\(R=\text{Ho, Tm, Yb, and Lu}\)) synthesized at high pressure. Large remnant polarization \(P_r\) up to 920 \(\mu\text{C/cm}^2\) is observed at 10 K for LuMn\(_3\)O\(_7\). Furthermore, the \(P\) vs. temperature data from the PE loop has shown consistency with that measured through the pyroelectric current measurements, supporting a theoretical prediction of large polarization in the \(E\)-type spin structure in this system [2]. We also discuss the influence of thermal histories on the ferroelectric domain dynamics and possible internal bias field effects originating from oxygen vacancies in \(\text{RMn}_\text{O}_3\). [1] M. Fukunaga, et al. J. Phys. Soc. Jpn. 77, 064706 (2008). [2] I. A. Sergienko, et al. Phys. Rev. Lett., 97, 227204 (2006).

3:30PM X28.00004 Chemical engineering of the critical magnetic field for switching ferroelectricity in multiferroic hexaferrites, SAE HWAN CHUN, YISHENG CHAI, SO YOUNG HAM, DEEPSHIKA JAIWAL-NAGAR, DONG HAK NAM, YOON SEOK OH, INGUY KIM, BEOM SUNG LEE, KEE HOON KIM, FPRD, Department of Physics and Astronomy, Seoul National University, Seoul 151-747, Korea, KYUNG TAE KO, JAE HOON PARK, Department of Physics, POSTECH, Pohang 790-784, Korea, JAE-HO CHUNG, Department of Physics, Physics Korea, Seoul 136-713, Korea — Multiferroics wherein the magnetic and ferroelectric order parameters coexist with their large cross-coupling effects have promising application potentials for multifunctional devices. To realize various technical exploitations, not only the capability of switching ferroelectricity with low magnetic field but also the tunability of the critical magnetic field \((H_c)\) for the switching is essential. Herein, we report our discovery of a novel chemical route to engineer \(H_c\) in a low field regime in the multiferroic hexaferrite system and discuss its mechanism.

3:42PM X28.00005 Ferroelectric and magnetic properties of multiferroic BaCoF\(_3\) thin films, TRENT JOHNSON, FELIO PEREZ, DAVID LEDERMAN, West Virginia University — Thin films of BaCoF\(_3\) have been successfully fabricated by molecular beam epitaxy and e beam technique on sapphire substrate (110), with a buffer layer of palladium grown using sputtering dc in argon atmosphere. Here we investigated the structural, morphological and ferroelectric properties were analyzed by means of various characterization techniques. The x-ray patterns showed that the films were oriented, but RHEED showed that the films were polycrystalline in the plane. AFM images showed a relatively granular surface. Measurements of the dielectric polarization showed that the films were ferroelectric at room temperature. The effect of magnetic fields on the ferroelectric properties at cryogenic temperatures will be described.

This work is supported by National Science Foundation (grant EPS-0314742) and the WVNano Initiative at West Virginia University.

3:54PM X28.00006 All thin film magnetoelectric magnetic field sensors, PENG ZHAO, University of Maryland, College Park — We have fabricated prototype ac magnetic field sensors operating at room temperature based on all thin film ME devices showing strong magnetoelectric (ME) coupling. The ME layers consist of a sol-gel derived Pb\((\text{Zr}_{0.52}\text{Ti}_{0.48})\)TiO\(_3\) (PZT) film and a dc magnetron sputter deposited magnetostrictive Fe\(_{72}\)Ga\(_{28}\) (FeGa) film. The bilayer structures are prepared on micromachined Si wafers, and the laser cutting technique is used to release and isolate the cantilevers for optimization of the sensor performance. The PZT layer and the FeGa layer couple via the piezoelectric \(d_{33}\) mode and the corresponding ME coupling coefficient is as high as \(\pm 2\text{ V/} (\text{Oe cm})\) for a lateral dimension of 1 mm\(^2\) device at the mechanical resonant frequency of 333 Hz of a Si cantilever. The soft magnetic FeGa film requires dc bias magnetic field of around 90 Oe to operate the thin film ME device. The coupling between the PZT and the FeGa films is remarkably improved by depositing a 40 nm thick Pt intermediate layer. The clamping effect on the ME coupling is dramatically reduced by back-etching the Si cantilever down to 35 \(\mu\)m thick. The present work indicates presence of robust ME coupling in microfabricated multilayer thin film ME devices.

This work is done with collaboration with Zhenli Zhao, Richard Suchoski, Scott Mathews, Chen Gao, Manfred Wuttig, and Ichiro Takeuchi. This work is funded by NSF, Mosaic at UMD and ARO.
4:30PM X28.00007 Magnetic anisotropy modulation of magnetite in Fe$_3$O$_4$/BaTiO$_3$(100) epitaxial structures. CARLOS A.F. VAZ, JASON HOFFMAN, AGHAM POSADAS, CHARLES AHN, Yale University and Center for Research on Interface Structures and Phenomena (CRISP) — Temperature dependent magnetometry and transport measurements on epitaxial Fe$_3$O$_4$ films grown on BaTiO$_3$(100) single crystals by molecular beam epitaxy show a series of discontinuities that are attributed to changes in the magnetic anisotropy induced by strain in the different crystal phases of BaTiO$_3$. High resolution x-ray diffraction measurements show that the magnetite film is under tensile strain at room temperature, which is ascribed to the lattice expansion of BaTiO$_3$ at the cubic to tetragonal transition, indicating that the magnetite film is relaxed at the growth temperature. From the magnetization versus temperature curves, the variation in the magnetic anisotropy is determined and compared with numerical estimates for the magnetoelastic anisotropies. In particular, the tensile strain in the Fe$_3$O$_4$ films is shown to give rise to a strong perpendicular magnetic anisotropy, as observed experimentally. These results demonstrate the possibility of using the piezoelectric response of BaTiO$_3$ to modulate the magnetic anisotropy of magnetite films.

4:42PM X28.00008 Enhanced power output from a magnetically coupled piezoelectric cantilever. JI-TZUOH LIN, University of Louisville, BARCLAY LEE, DuPont Manual High School, BRUCE ALPHENAAR, University of Louisville, WALTER JONES, DEIRDRE ALPHENAAR, Gencsape, Inc. — Piezoelectric cantilevers have been widely studied for energy scavenging applications, but suffer from poor output power outside of a narrow frequency range near the cantilever resonance. Here, we demonstrate how power output can be enhanced by applying a simple passive external force. A symmetrical and repulsive magnetic force is applied to a piezoelectric cantilever beam to compensate the cantilever spring force. The raised and compensated spring potential introduced by the magnetic coupling is found to broaden the frequency response without altering the resonant frequency or introducing damping at resonance. Furthermore, the modified cantilever responds chaotically outside of the resonant frequency, causing increased voltage output across a large spectral region. The total voltage output across the spectrum increases between 31% and 87%. Model calculations support these results.

4:54PM X28.00009 Quantitative determination of the enhanced magnetoelectric. YOUNG HOON KIM, Dept. of Physics and Astronomy, Seoul National University, STEVEN P. CRANE, R. RAMESH, University of California, Berkeley, SEONGSU LEE, S-W. CHEONG, Rutgers University — With growing interest worldwide toward applications of multiferroic materials for novel memory and magnetic sensor devices, there have been numerous efforts to synthesize multiferroic thin films with large magnetoelectric coupling. Yet, quantitative information on the strain in the different crystal phases of BaTiO$_3$ is still lacking because it is difficult to measure a reduced magnetoelectric signal due to a tiny thickness. In the present work, we have determined quantitative MES for a 300 nm BiFeO$_3$/CoFe$_2$O$_4$ nanostructure, 250 nm BiFeO$_3$ film, and BiFeO$_3$ single crystal with our highly sensitive magnetoelectric susceptometer operating in cryogenic (down to 2 K) and high magnetic field, $H$, (up to 9 T) environments. We find that the MES of the BiFeO$_3$/CoFe$_2$O$_4$ nanostructure shows a typical anti-symmetric shape with DC magnetic field up to 340 K, as expected in the magnetoelectric coupling mediated by strain between piezoelectric and magnetostrictive materials. At room temperature, the transverse MES of the nanostructure shows a maximum of $2 \times 10^{-10}$ V/m at low $H = 6$ kOe. Our results also demonstrate that the MES value of the nanopillar structured film is enhanced by approximately one order of magnitude than that of pure 250 nm BiFeO$_3$ film and BiFeO$_3$ single crystal.

5:06PM X28.00010 Epitaxial complex oxide tunnel barriers. JUNWOO SON, POUYA MOATAKEF, JOEL CAGNON, SUSANNE STEMMER, University of California, Santa Barbara — Tunnel junctions with complex oxide thin film barriers are of interest for studies of the critical thickness of ferroelectricity, of phonon modes in ultrathin films and of traps in inelastic tunneling spectroscopy. We show that high-quality epitaxial SrTiO$_3$ and BaTiO$_3$ tunnel barriers can be grown on Pt bottom electrodes. Coherent, epitaxial Pt films with roughness of less than a unit cell were grown on (001) SrTiO$_3$ to serve as bottom electrodes for epitaxial SrTiO$_3$ and BaTiO$_3$ tunnel barriers. All interfaces were atomically abrupt as confirmed by atomic resolution Z-contrast imaging. The IV characteristics were non-linear, demonstrating good insulating properties. For the SrTiO$_3$ barriers and voltage sweeps up to $\pm 0.5$ V, the measured tunnel current was independent of the sweep direction. At low biases, dynamic conductance curves showed a symmetrical parabolic shape around the origin in both resistance states. At high bias, deviation from the ideal tunnel behavior was observed. A large increase of the tunnel conductance occurred above a minimum positive bias. A dramatic decrease of tunnel conductance occurred for a large negative bias, indicating bipolar switching. We show the contributions to the resistive switching. Phonon modes and traps are determined using inelastic tunneling spectroscopy with both paraelectric and ferroelectric tunnel barriers.

Thursday, March 19, 2009 2:30PM - 5:18PM — Session X29 GMAG DMP FLAP: Focus Session: Current Induced Dynamics in Magnetic Tunnel Junctions and Spin Waves

2:30PM X29.00001 Influence of electron-magnon scattering on spin transfer torque in magnetic tunnel junctions. AURELIEN MANCHON, SHUFENG ZHANG, University of Arizona — Manipulating the magnetization direction using spin transfer torque in magnetic tunnel junctions (MTJs) has been one of the most important challenges in spin electronics for the past five years. Elastic tunneling theories show that the torque possesses two components, one being mainly linear in bias voltage whereas the other shows a quadratic bias dependence. These theoretical results have been recently confirmed by “spin-diode” experiments [1]. However, the validity of the elastic tunneling has been questioned by two experimental studies [2]. These studies show that the bias dependence of the out-of-plane torque can be dramatically different from the elastic quadratic dependence. Using the Transfer Hamiltonian formalism, we study the influence of interfacial electron-magnon scattering on the bias dependence of the spin transfer torque. We show that the bias dependence can strongly affect the bias dependence of the spin transfer torque in agreement with the recent experimental studies [2]. [1] J. C. Slonczewski, J. Phys. Condens. Matter 11, A509-11 (1999). [2] S. Petit, et al., Phys. Rev. Lett. 98, 077203 (2007); Z. Li, et al., Phys. Rev. Lett. 100, 246602 (2008).

2:42PM X29.00002 Macrospin model of incubation delay due to field-like spin transfer torque. SAMIR GARZON, YAROSLAV BAZALY, RICHARD A. WEBB, University of South Carolina, MARK COVINGTON, SHEHZAAD KAKA, Seagate Research, THOMAS M. CRAWFORD, University of South Carolina — While extensive measurements have tested the validity and limitations of the macrospin model with Slonczewski’s spin transfer torque in metallic spin valves, recent experiments with magnetic tunnel junctions (MTJs) have reported an additional “field-like” or “perpendicular” spin torque. The observed field-like torques generally agree with theoretical predictions, but some controversies remain: frequency domain measurements at low voltages and switching current measurements at large voltages report contradictory signs for the field-like term. Here we show that the absence of pre-switching oscillations (“incubation delay”) reported in magnetic tunnel junctions can be explained within the macrospin model by a sizable field-like component of the spin-transfer torque. Furthermore, we propose that measurements of the voltage dependence of the tunnel junction switching time in the presence of external easy axis magnetic fields can be used to determine the magnitude and voltage dependence of the field-like torque over a broad range of voltages.

d\tau was initially reported by two groups. After the correction is applied, we measure consistent values of \( dV/dI \) of the spin torque. In the case of an applied field along the easy axis, which can be attributed to the differences in the precession axis and switching barriers as well as effects of thermal fluctuations. We will also report results of single-shot transport measurements in the regime of spin-torque-driven steady-state precession.

3:06PM X29.00004 Bias and Angular Dependence of Spin-Transfer Torque in Magnetic Tunnel Junctions, C. Wang, Y.-T. Cui, R.A. Buhrman, D.C. Ralph, Cornell University, Ithaca, NY 14853, DANIELE MAURI, JORDAN A. KATINE, Hitachi Global Storage Technologies, San Jose Research Center, San Jose, CA 95135 — We present single-shot time domain resistance measurements of spin-transfer-driven dynamics in CoFeB/MgO/CoFeB tunnel junctions. In the regime of thermally-activated current-driven switching, we have sufficient sensitivity to resolve the pattern of resistance oscillations caused by the magnetic dynamics leading up to switching. When an in-plane hard-axis magnetic field is applied, within a short interval before the switching instant the resistance oscillations show a steadily-increasing amplitude, qualitatively consistent with expectations for large-angle precession in a single macrospin model, although the oscillation amplitude can vary between individual switching events. Moreover, the oscillation rate is observed to be absent in the case of an applied field along the easy axis, which can be attributed to the differences in the precession axis and switching barriers as well as effects of thermal fluctuations. We will also report results of single-shot transport measurements in the regime of spin-torque-driven steady-state precession.

3:18PM X29.00005 Effect of asymmetry on the bias dependence of spin torque in magnetic tunnel junctions, N. KIOUSSIS, Y.-H. TANG, ALAN KALITSOV, California State University, Northridge — The switching of magnetic states in magnetic tunnel junctions (MTJ) by spin-polarized current via the spin torque has been the subject of intensive theoretical and experimental researches. One outstanding question which remains unresolved and controversial is the bias dependence of field-like spin torque, \( T_{\text{per}} \), parallel to the plane of the two magnetizations. In this study, we show that bias behavior of \( T_{\text{per}} \) can change dramatically with the asymmetry in the ferromagnetic electrodes from purely quadratic with negative curvature in agreement with Kubota’s experimental results [1], to linear with sign reverse with bias in agreement of Li’s observation [2], and finally to quadratic but with positive curvature in agreement with Sankey’s experiments [3]. These results suggest that the asymmetry due to the amorphous alloys may cause the discrepancy in the bias dependence of \( T_{\text{per}} \) in experimental findings [1-3]. Moreover, our results have important practical applications for MRAM devices, since the magnetic configurations of MTJ can be tuned by external bias and without the application of external magnetic field. This work is supported by NSF PREM Grant No. DMR-0011656. [1] J. Kubota et al., Nature Phys. 4, 37 (2008) [2] Z. Li et al., Phys. Rev. Lett. 100, 246602 (2008) [3] J. C. Sankey et al., Nature Phys. 4, 67 (2008).

3:30PM X29.00006 Voltage dependence properties of ballistic spin currents and spin torques in magnetic tunnel junctions, MAIRBEK CHSHIEV, SPINTEC, CEA/CNRS, Grenoble, France / MINT Center, University of Alabama, AL, USA — Interest in spintronics [1] has been strongly accentuated by the discovery of current induced magnetization switching caused by spin transfer torques (STT) [2]. Among the most favorable candidate systems for the realization of STT-based spintronic devices are epitaxial magnetic tunnel junctions (MTJ) [3]. Here we present a systematic study of voltage-induced STT in MTJs and provide an insight into the nature of its voltage behavior by investigating the properties of membrane spin currents [4,5]. We demonstrate that the band filling has a dramatic impact on voltage dependence properties of both STT components, tunnel magnetoresistance (TMR) as well as on equilibrium interlayer exchange coupling [5]. Both in-plane (Slonczewski) and perpendicular-to-plane (field-like) STT components demonstrate a wide range of nontrivial behavior as a function of applied voltage [4,5]. The explanation is given in terms of the spin and charge current dependence on the interplay between evanescent states in the insulator and the Fermi surfaces of the ferromagnetic electrodes comprising the MTJ [5]. In particular we show that in ballistic regime the field-like torque is an even parity function of applied voltage while the parallel torque may exhibit a range of behavior [4,5]. Recent experiments [6] are in agreement with these predictions. Calculations are based on the non-equilibrium Green functions technique.

4:06PM X29.00007 Excitation of magnetization dynamics in patterned thin films using surface acoustic waves, A. BARUTH, S. ADENWALLA, University of Nebraska - Lincoln — The investigation of magnetization dynamics often involves the application of magnetic field or light pulses on very short time scales. Here we outline an alternative method that utilizes the changes in magnetic anisotropy associated with magneto-elastic strain. Surface Acoustic Wave (SAW) transducers are readily available at high frequencies (>10GHz), and provide an ideal method for straining thin film magnetic elements. SAWs propagate across a piezoelectric substrate, alternately compressing and expanding the surface with a wavelength on the order of a few millimeters. The periodicity of the interdigital transducer (IDT) that produces the SAW. Patterning thin film magnetic nanostructures at a spacing identical to the SAW wavelength ensures that all elements will be in phase as the SAW passes through. Passage of the SAW through a magnetic element leads to expansion and compression along the SAW propagation direction dynamically altering the easy axis of magnetization at ultra high frequencies. The subsequent dynamics can be probed using the Kerr effect. Using an IDT of 100 fingers operating at 87.2 MHz with realistic insertion losses, an array of 30 mm thick, 10x20pm2 rectangular Co bars require voltages of ~3.3V to fully switch the magnetization from the easy to hard axis without the application of an external field. Funded by NSF-MRSEC DMR-0820521.

4:18PM X29.00008 Spin Wave Quantization by the Stripe Domain Structures in a Continuous Film, CHUN-YEOL YOU, SEUNG-SOEK HA, JUNGBUM YOON, SUKMOCK LEE, Dept. of Phys. Inha University, MYUNG-HWA JUNG, Dept. of Phys. Sogang Univ., YOUNG KEUN KIM, Deparment of Materials Science and Engineering, Korea University — Abnormal field dependence and dispersion relations of spin wave excitations in the Brillouin light scattering were observed in a continuous CoFeSiB film. The observed spectra are similar to spin wave quantization in laterally-confined magnetic structures such as arrays of magnetic nanowires. In the array of nanowires, the propagating spin wave formed a standing wave due to the reflection from the geometrical confinement, boundaries of the nanowire, and the spin wave exciting modes are quantized. In our observation, the possible reflection source in the continuous CoFeSiB film is the regular stripe domain boundaries, domain walls. As evidence, we observed very regular stripe domain structures by magnetic force microscopy. In the low field region (11 kOe), the regular stripe domain patterns are formed and additional spin wave excitations are observed, while in the large field region, it behaves as usual continuous film. We believe that the regular domain wall acts as a scattering source of the spin wave, and it causes spin wave mode quantization.
range, 0.04 likely due to strong electron correlation effects. The various contributions to the heat capacity provide a detailed picture of the evolution of the phase-separated observations include a discontinuity in Debye temperature accompanying the percolation-type insulator-metal transition and a large electron mass enhancement, \( T \leq 1 \).

Mitchell (Argonne National Lab). Work supported by DoE and NSF.

are not required to explain the physical properties of these cobaltites. Co-authors: C. He, S. El-Khatib, J. Wu, (UMN), J.W. Lynn (NIST), H. Zheng, J.F. MITCHELL, University of California, Los Angeles, AJEY JACOB, Intel — To date, the spin-wave logic devices are seen promising for parallel data processing at high speed (Appl. Phys. Lett. 87, 153501 (2005), and Superlattices and Microstructures 38, 184 (2005)). However, there is no power gain with the current spin-wave logic devices, and the spin-wave cannot propagate a long distance because of the spin-wave dumping effect. All those will prevent the spin-wave devices from real applications. Here we report a spin-wave amplifier with a power gain that is controlled by the pumping power level. At the pumping power of 16 dBm at 2.6 GHz, the power gain is 6.4 dB and the frequency is 1.3 GHz. The amplifier is made from a permalloy film with its thickness of 25 nm. The signal input, pump wave input, and signal output are simple microstrip lines, thus the device structure is simple.

Quantitative characterization of a thin ferromagnetic film by pi-MFM and FMRM: Y. OUKHOV, I.H. LEE, D.V. PELEKHOV, Ohio State University, E. NAZARETSKI, Los Alamos National Lab, P. BANERJEE, P.C. HAMME, Ohio State University — We present a theoretical analysis of two new methods for high resolution magnetic characterization of magnetic materials. These two, probe-induced (pi) Magnetic Force Microscopy and Ferromagnetic Resonance Force Microscopy are related in exploiting the modification of sample properties by the magnetic field of the probe to enable new imaging capabilities. Our analytic theory enables quantitative modeling of signals obtained in these two microcopy methods, and so allows us to extract parameters describing the magnetic properties of ferromagnetic films. We compare our theory with experimental data and find excellent agreement. More detailed experimental data will be presented in an accompanying talk. Our methodology allows detailed local characterization of ferromagnetic films in complementary MFM and MRFM experiments.

Thursday, March 19, 2009 2:30PM - 5:18PM – Session X30 DMP GMAG: Focus Session: Cobaltites 334

Doping fluctuation-driven magneto-electronic phase separation in La\(_{1-x}\)Sr\(_x\)CoO\(_3\) single crystals, CHRIS LEIGHTON, University of Minnesota — The doped perovskite cobaltites, in particular La\(_{1-x}\)Sr\(_x\)CoO\(_3\) (LSCO), have emerged as productive systems for the study of the magneto-electronic phase separation phenomenon widely observed in complex oxide materials. It is now well established that this system phase separates into hole-rich ferromagnetic clusters embedded in a hole-poor non-ferromagnetic insulating matrix at low doping. These clusters percolate at a critical doping value near \( x = 0.17 \) leading to a crossover from short- to long-range ferromagnetic order and a simultaneous insulator-metal transition. In this work we have used multiple complementary experimental probes (e.g. small-angle neutron scattering (SANS), heat capacity, and magnetotransport) to establish that high quality single crystals actually exhibit magnetic phase separation only over a well-defined doping range, 0.04 < \( x \) < 0.22. We further show that these limits can be perfectly reproduced by simple statistical simulations where the existence of local ferromagnetism is driven solely by the inevitable local compositional fluctuations that are present at such small length scales. These length scales are defined by the mean cluster size which is determined directly by SANS. The same simulations also reproduce the doping dependence of both the observed magnetic phase fractions and SANS intensity. A remarkable consequence of this analysis is that it suggests that the magnetic phase diagram measured on macroscopic specimens is applicable even at length scales as small as 1 nm. Most importantly, it is clear from this work that models based on true electronic phase separation are not required to explain the physical properties of these cobaltites. Co-authors: C. He, S. El-Khatib, J. Wu, (UMN), J.W. Lynn (NIST), H. Zheng, J.F. Mitchell (Argonne National Lab). Work supported by DoE and NSF.

Heat capacity study of magneto-electronic phase separation in La\(_{1-x}\)Sr\(_x\)CoO\(_3\) single crystals, C. HE, University of Minnesota, S. EISENBERG, C. JAN, University of Minnesota, H. ZHENG, J.F. MITCHELL, Argonne National Laboratory, J.W. LYNN, National Institute for Standards and Technology, C. LEIGHTON, University of Minnesota — We present an investigation of the specific heat (0.35 K < \( T \) < 270 K) and ordinary Hall effect (300 K) in La\(_{1-x}\)Sr\(_x\)CoO\(_3\) single crystals (0.00 < \( x \) < 0.30). The data reveal new information on the nature of the percolation transition, the crystal and electronic structure, and the magneto-electronic phase separation. The observations include a discontinuity in Debye temperature accompanying the percolation-type insulator-metal transition and a large electron mass enhancement, likely due to strong electron correlation effects. The various contributions to the heat capacity provide a detailed picture of the evolution of the phase-separated state with doping. Most importantly, this provides strong evidence for the anticipated result that the phase separation is restricted to a well-defined doping range, 0.04 < \( x \) < 0.22, in close agreement with recent small-angle neutron scattering.

Work supported by DoE and NSF.
Cobaltites, JUAN YU, DESPINA LOUCA, University of Virginia, DANIEL PHELAN, KEISUKE TOMIYASU, KAZUMASA HORIGANE, KAZUYOSHI YAMADA — The doping of holes into the non-magnetic Mott insulator, LaCoO$_3$, induces a magnetic inhomogeneous state resulting from competing magnetic phases. Elastic neutron scattering measurements on Ca, Sr, and Ba doped single crystals showed that phase competition is strongly dependent on the tolerance factor, $t$. When $t$ is small as in La$_{1-x}$Ca$_x$CoO$_3$, only a ferromagnetic (FM) phase is present. As $t$ gets large as in La$_{1-x}$Ba$_x$CoO$_3$, an incommensurate (IC) phase coexists with the FM phase. The IC phase becomes commensurate and as strong as the FM phase by $x \approx 0.18$, with a very long correlation length. This is in stark contrast to La$_{1-x}$Sr$_x$CoO$_3$, where the IC phase remains short-range and with its intensity reduced when the system orders ferromagnetically. Our observation shows that increasing $t$ enhances the presence of two phases and favors the growth of nanoscale spin-ordered superstructures. The subtle lattice changes brought about by changing $t$ have a direct effect on the Co-O hybridization that in turn affects the magnetic interactions. Double exchange interactions between Co$^{2+}$ and Co$^{4+}$ result in FM correlations while the superexchange between Co$^{2+}$ ions result in antiferromagnetic correlations giving rise to the second phase. This may be mediated by a Jahn-Teller mechanism that sets in at high temperatures.

Incommensurate charge and spin ordering in doped layered Co perovskite oxides: small-polaron charge glass, I. ZALIZNYAK, CMPMSD, Brookhaven National Laboratory, N. SAKIYAMA, ISSP, University of Tokyo, S.-H. LEE, University of Virginia, Y. MITSUI, H. YOSHIZAWA, ISSP, University of Tokyo — Using neutron diffraction, we have investigated two families of cobalt-based layered perovskite oxides, Pr$_2$-$_x$Ca$_x$CoO$_3$ ($0.39 < x < 0.73$) and La$_2$-$_x$Sr$_x$CoO$_3$ ($x = 0.5, 0.61$), which are relatives of high-Tc cuprate superconductors. In the range of heavy doping, $0.5 < x < 0.75$, we have discovered the doping-dependent incommensurate short-range ordering of charges and magnetic moments, whose scattering signatures look somewhat similar to those previously found in cuprates and nickelates. The average incommensurability of charge order (CO) propagation vector, $Q = (\epsilon_c, 0, 0)$, scales roughly linearly with doping and is proportional to the concentration of Co$^{2+}$ ions, $\epsilon_c \sim (1-x)$. CO exists already at room temperature and shows no change on cooling. In cobaltites, CO can be understood as a glassy state formed by nano-scale patches of commensurate small-polaron superlattices, whose average period is determined by the doping, $x$, but the long-range coherence is frustrated by the charge neutrality requirement. The magnetic spin order on cobaltites only develops at low $T < 40$ K. Its period is roughly twice that of CO, indicating dominant antiferromagnetic correlation between the nearest Co$^{2+}$ spins.

Core level line shape analysis of LaCoO$_3$, E. M. PAISLEY, J. STANLEY, J. HINTON, N. SUNDARAM, UC Santa Cruz, B. S. MUN, A. BOSTWICK, E. ROTENBERG, ALS, LBNL, J. F. MITCHELL, Argonne National Laboratory, D. P. BELANGER, G.-H. GWEON, UC Santa Cruz — The spin state of LaCoO$_3$ is a topic of high interest lately. Here we investigate the electronic structure of LaCoO$_3$ using core level and valence band photoemission spectroscopy. We compare the competing spin models in the literature by using our data obtained as a function of incident photon energy and temperature. Using line shape simulation of the Co 3s core level spectroscopy data and the Co 2p core level spectroscopy data, we address the issue of extracting the spin state information of the ground state from the photoemission data.

Spin Glass Behavior in the new cobaltite series (BaSr)$_{1-x}$La$_x$CoO$_{15}$, OVIDIU GARLEA, RONGYING JIN, RADU C. STOICEA, Oak Ridge Natl. Lab., HAO SHA, Florida International University, JIANDI ZHANG, Florida International University and Louisiana State University — We report on the structural and magnetic properties of a new class of cobaltites with the chemical formula (BaSr)$_{1-x}$La$_x$CoO$_{15}$. These compounds crystallize in a hexagonal structure, where Co ions occupy two different sites with octahedral and tetrahedral oxygen environments. Four Co ions of the unit cell define the vertices of a tetrahedron and their mutual antiferromagnetic superexchange interactions are topologically frustrated. Partial substitution of Sr and Ba atoms for La allows one to adjust the degree of Co valence mixing and finely tune their magnetic interactions. A strong irreversibility between FC and ZFC magnetizations and the absence of magnetic reflections in the neutron diffraction patterns suggest a spin glass-like ground state for all the compositions.

Competition between Jahn-Teller instability and uniaxial magnetism in Ca$_2$CoMoO$_6$ (M = Mn, Co, Rh), YUEMEI ZHANG, Department of Chemistry, North Carolina State University, Raleigh, NC 27695-8204, HONGJUN XIANG, National Renewable Energy Laboratory, 1617 Cole Blvd., Golden, CO 80401, ERJUN KAN, Department of Chemistry, North Carolina State University, Raleigh, NC 27695-8204, A. Various magnetic ground states linked to sodium ordering pattern via controlled cooling in Na$_2$CoO$_2$ ($x \approx 0.75-0.85$), J. KANTER, W. WITTWER, T. SCHULZE, P. HAEFLIGER, S. PETTITJEAN, Laboratory for Solid State Physics, ETH Zurich, Switzerland, D. SHEPTYAKOV, CH. NIEDERMAYER, Laboratory for Neutron Scattering, PSI Villigen, Switzerland, K. MATTENCBERGER, B. BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — Detailed characterization is presented of a recently found link between the low temperature magnetic properties of Na$_2$CoO$_2$ and a sodium rearrangement process at the onset of sodium mobility around 200 K. Switching between different sodium ordering patterns is possible by adjusting the cooling speed, due to the long time constant of the sodium rearrangement. The various magnetic states (with $T_c$ of 6, 15 and 22 K) are characterized by transport, magnetization, specific heat and thermal expansion measurements and linked to the sodium ordering process. The magnetic field dependence of the transition temperatures and the magnetic anisotropy were studied in detail. Muon Spin Rotation experiments confirmed the true bulk character of the magnetic transitions and locally probed the different phases. Single crystal diffraction data links the different magnetic ground states to structural changes.
4:42PM X30.00010 A quantum Monte Carlo study of magnetism in the frustrated Hubbard model1, MATTHEW ENJALRAN, Department of Physics, Southern CT State University, New Haven, Connecticut — Motivated by the observation of complex phases in materials with quasi-two-dimensional triangular lattice structures, Na$_2$CoO$_2$ · yH$_2$O and κ-(ET)$_2$X, where nearest neighbor interactions are frustrated, we investigate the magnetic correlations in the 2D Hubbard model using constrained path quantum Monte Carlo. In order to develop our understanding of the effect of geometric frustration on the magnetic correlations in an itinerant electron model, we report results for the square and triangular lattice geometries at half-filling.

4:54PM X30.00011 Does disorder destroy e$_g$ pockets in Na$_{0.3}$CoO$_2$? A new ab initio method for disorder1, TOM BERLIN, DIMITRI VOLJA, WEI KU, Brookhaven National Laboratory/ Stony Brook University — Hydrated Na$_{0.3}$CoO$_2$ shows interesting superconductivity[1], with evidence of a nodal order parameter[2]. One possible origin of the nodal structure is f-wave pairing[3] due to the six e$_g$ pockets predicted by the local density approximation[4]. However, ARPES experiments[5] showed no sign of these hole pockets. In this talk, we will investigate a recent proposal[6] of destruction of the e$_g$ pockets due to disorder. An affordable ab initio Wannier function based method will be presented that takes into account spatial distributions of disorder, beyond existing mean-field approximations (e.g. VCA, CPA). We also use our Wannier functions to analyse the crystal field splitting, the sign of which critically determines the role of correlation in DMFT.

5:06PM X30.00012 Novel electronic states in the sodium rich phases of cobaltates Na$_x$CoO$_2$. MENG GAO, ZIQIANG WANG, Boston College — The cobaltates display many unusual properties in the sodium rich regime. We study the effects of strong local and finite range correlation and the sodium dopant order within the framework of an extended Hubbard model on the triangular lattice. We find that despite the proximity to the band insulating state at $x = 1$, the interplay of strong electronic correlation and sodium order leads to the formation of various unconventional inhomogeneous electronic states. We compare these findings to recent experimental observations around $x = 0.84$.

Session X31 DMP GMAG: Focus Session: Magnetic Nanostructures: Domain Walls, Reversal, Oscillators 335

2:30PM X31.00001 Reversal mechanisms and defects in perpendicularly magnetized nanostructures. JUSTIN SHAW, NIST — The problem of switching field distributions (SFDs) is currently plaguing developing technologies which rely on uniform arrays of magnetic nanostructures such as bit patterned media, magnetic random access memory (MRAM) and spin-torque oscillators. Most of these technologies are shifting towards the use of perpendicularly magnetized materials due to the increased device performance and thermal stability that can be achieved. SFDs in such perpendicularly magnetized nanostructures can result from dot-to-dot interactions and size distribution, but is largely dominated by material defects [1- 4]. Such defects can arise from both the material deposition process, and post-deposition processing that occurs during nanofabrication. By comparing nanostructures fabricated by deposition on pre-patterned wafers to those fabricated by ion milling of continuous films, we show that the anisotropy of the edge region can be greatly different in each case. The size, temperature, and angular dependences of the reversal field indicate that the reversal mechanism also differs. In contrast to fabrication induced defects, microstructural variations manifest themselves as a random distribution of local anisotropies. We studied the anisotropy distribution in patterned elements by imaging the localized reversal of low anisotropy regions and mapping these sites as a function of applied field using MFM imaging and TEM. In addition, we used simulations to show the effect a small localized region of lower anisotropy material (such as a grain) has on the reversal field of the entire nanostructure. We find that the reversal field depends on both the relative anisotropy of the defect to the film, as well as, the location of the defect within the structure.

3:06PM X31.00002 Controlling Double Vortex States in Low-Dimensional Dipolar Systems, SERGEY PROSANDEEV, Research Assistant Professor, LAURENT BELLAICHE, 21-st century Professor in Nanotechnology, PHYSICS DEPARTMENT, UNIVERSITY OF ARKANSAS TEAM — The reversal process of the chirality of each opposite vortex belonging to a double vortex state in ferromagnetic hysterons, via the application of in-plane magnetic fields, is reported [1]. Simulations reveal that such a process involves the formation of four intermediate states, including original ones. Hysteresis loops can occur only in a counterclockwise fashion because of one of these intermediate states. Double vortex states can also be controlled by electric fields in ferroelectric nanostructures of different shapes, but with some key differences with respect to the ferromagnetic case.

3:18PM X31.00003 Magnetic domain wall shift registers for data storage applications, DAN READ, Imperial College London, L. O'BRIEN, H.T. ZENG, E.R. LEWIS, D. PETIT, J. SAMPAIO, L. THEVENARD, R.P. 3:30PM X31.00004 Ratchet Effects and Domain Wall Energy Landscapes in Amorphous Magnetic Films with 2D Arrays of Asymmetric Holes. J.I. MARTIN, A. ALLIA, I. SOBRADO, A. PEREZ-JUNQUERA, G. RODRIGUEZ-RODRIGUEZ, M. VELEZ, J.M. ALAMEDA, U. Oviedo-CINN, Oviedo, Spain, V.I. MARCONI, U. Nacional de Cordoba, Argentina, A.B. KOLTON, C. Atomico Bariloche, Argentina, J.M.R. PARRONDO, U. Complutense, Madrid, Spain — The driven motion of domain walls in extended magnetic films patterned with 2D arrays of asymmetric holes has been found to be subject to two different crossed ratchet effects [1] which results in an inversion of the sign of domain wall motion rectification as a function of the applied magnetic field. This effect can be understood in terms of the competition between drive, elasticity and asymmetric pinning as revealed by a simple model. In order to optimize the asymmetric hole design, the relevant energy landscapes for domain wall motion across the array of asymmetric holes have been calculated by micromagnetic simulations as a function of array geometrical characteristics. The effects of a transverse magnetic field on these two crossed ratchet effects will also be discussed in terms of the decrease in domain wall energy per unit area and of the modifications in the magnetostatic barriers for domain wall pinning at the asymmetric inclusions. Work supported by Spanish MICINN [1].

3:42PM X31.00005 Magnetic Frustration in Nanowires: Domino Effect, SAMIR LOUNIS, PETER H. DEDERICHS, STEFAN BLÜGEL, Institut fur Festkörperforschung and Institute for Advanced Simulation, Forschungszentrum Julich, D-52425 Julich, Germany, STEFAN BLÜGEL TEAM. — The parity of the number of atoms in finite antiferromagnetic nanowires deposited on ferromagnetic substrates is shown to be crucial in predicting whether the magnetic ground state is non-collinear or collinear [1]. Using the full-potential Korringa-Kohn-Rostoker method for non-collinear magnetism [2] and a Heisenberg model we show that the magnetic structure of the whole nanowires dramatically changes if a single adatom is added. Infinite and finite nanochains with even number of adatoms are always magnetically non-collinear while odd number of atoms in the wire lead under given conditions to a collinear ferrimagnetic ground state. This unexpected nano-effect, which resembles a domino-effect, occurs only for wires at finite lengths. [1] S. Lounis, P. H. Dederichs, S. Blgel, Phys. Rev. Lett. 101, 107204 (2008). [2] S. Lounis, Ph. Mavropoulos, P. H. Dederichs, S. Blgel, Phys. Rev. B 72 224437 (2005).

4:06PM X31.00007 Magnetic and mechanical characterizations of ultra-high frequency nano-electromechanical systems (NEMS). JOE LOSBY, N. LIU, Department of Physics, University of Alberta, C. HOLT, Department of Chemical and Materials Engineering, University of Alberta, D. MITLIN, Department of Chemical and Materials Engineering, University of Alberta and National Institute of Nanotechnology, A.E. FRASER, V. SAUER, W.K. HIEBERT, National Institute of Nanotechnology, M.R. FREEMAN, Department of Physics, University of Alberta and National Institute of Nanotechnology — Recent efforts in our group involve time-domain studies of the motion of silicon NEMS and spin dynamics in nanometer-scale permalloy elements. Transduction of microwave frequency (> 1 GHz) cantilevers, and time domain coherent control (“unringing”) of nanoscale resonators have been demonstrated. For the next stage of this work, we have fabricated permalloy NEMS cantilevers and doubly clamped beams in order to begin exploration of magnetomechanical dynamics in ferromagnetic nanostructures. The magnetization of these resonators is probed using time-resolved magneto-optical Kerr effect microscopy, while stroboscopic optical interferometry is used for the detection of vibrational modes. 1. Sydora, and M.R. Freeman, Phys. Rev. B. 77. 174410 (2008).

4:18PM X31.00008 Synchronization of spin-torque oscillators via phase-shift control, JOHAN ÅKERMANN, Göteborg University and Royal Institute of Technology — The Spin Torque Oscillator (STO) shows great promise as a frequency generating device at microwave frequencies. However its very limited output power has to be significantly improved for any realistic application. One possibility is the synchronization of two or more STOs to both increase the microwave power and further increase Q. We have recently demonstrated an intrinsic preferred phase shift between an STO and an injected RF current [1, 2]. This phase shift has direct implications for current-mediated synchronization of serially connected STOs [3]. It is exactly at this phase shift where the multi-STO synchronized state develops the highest robustness and by tuning the total circuit I-V phase shift, synchronization can be enhanced by close to 2 orders of magnitude. Since our initial work, we have now determined both the phase shift and the enhancement factor in all types of STOs (standard, perpendicular [4], wavy torque [5], tilted polarizer [6]). More recently we have also found that the perpendicular torque synchronization can be enhanced by close to 2 orders of magnitude. Since our initial work, we have now determined both the phase shift and the enhancement factor in all types of STOs (standard, perpendicular [4], wavy torque [5], tilted polarizer [6]). More recently we have also found that the perpendicular torque synchronization can be enhanced by close to 2 orders of magnitude. 4:54PM X31.00009 Microwave Emitting Nanomagnet Oscillator: Strongly coupled spin-photon modes, Ö.Ö. SOYKAL, M.E. FLATTE, Optical Science and Technology Center and Department of Physics and Astronomy, University of Iowa — We describe a microwave emitting nanomagnet oscillator confined in a high Q-cavity. The precession of the magnetization of a typical Fe nanomagnet of 100 nm in radius, possessing roughly $10^{10}$ spins and described as a macrospin, is tuned to be in resonance with a microwave cavity of 1 mm in volume with an applied magnetic field. The Hamiltonian of the spin-cavity system is quantized in a fully quantum treatment. Due to the very large number of coherently-oriented spins, the interaction Hamiltonian of the spin-cavity system contains magnet-microwave mode coupling terms that exceed several GHz. Coherent coupling of the microwave field with nanomagnet spins is analyzed in terms of the coherent states of the spin-cavity system, which are characterized by large oscillations in the nanomagnet spin and cavity photon number, as well as by exceptionally long dephasing times. Therefore, the nanomagnet-cavity system is predicted to have distinguishable large total spin, long coherence times, and high power output. This may serve as an efficient means of transferring information between a magnetic and a photonic system.

2:30PM X32.00001 A Spin-Orbital Singlet and Quantum Critical Point on the Diamond Lattice: FeSc$_2$S$_4$, GANG CHEN, UCSB, LEON BALENTS, ANDREAS SCHNEDER, Kavli Institute for Theoretical Physics, UCSB — We present a theory of spin and orbital physics in the A-site spinel compound FeSc$_2$S$_4$, which experimentally exhibits a broad “spin-orbital liquid” (SOS) regime. A spin-orbital Hamiltonian is derived from a combination of microscopic consideration and symmetry analysis. We demonstrate a keen competition between spin-orbit interactions, which favor formation of a local “Spin-Orbital Singlet”, and exchange, which favors magnetic and orbital ordering. Separating the SOS from the ordered state is a quantum critical point (QCP). We argue that FeSc$_2$S$_4$ is close to this QCP on the SOS side. The full phase diagram of the model includes a commensurate-incommensurate transition within the ordered phase. A variety of comparison to and suggestion for experiments are discussed.

2:42PM X32.00002 Quantum Critical Phenomena near Stoner Transition in Two Coupled Quantum Dots with Spin-Orbit Coupling, OLEKSANDR ZELYAK, GANPATHY MURTHY, University of Kentucky — We consider a system of two coupled quantum dots. Both the dots and connecting region are assumed to be in universal crossover regimes between Gaussian orthogonal and symplectic ensembles. Using a diagrammatic approach appropriate for energy separations much larger than the level spacing, we obtain the ensemble-averaged one- and two-particle Green’s functions. The diffusion and Cooperon parts of the two-particle Green’s function are described by separate scaling functions. We then use this information to investigate a model of interacting system in which one dot has Stoner exchange interaction, while the other is non-interacting but contains spin-orbit coupling.

3:06PM X32.00004 Cross-over of universality class in the Ising chain frustrated by long-range interactions, ALESSANDRO VINDIGNI, ETH Zurich, FABIO CINTI, University of Florence, OLIVER PORTMANN, DANilo PEScia, ETH Zurich — We investigate a spin chain in which the ferromagnetic nearest-neighbor exchange interaction $J$ competes with a long-range antiferromagnetic interaction of strength $g$ decaying spatially as $1/r^z$. For $\alpha$ smaller than a certain threshold $\bar{\alpha}$ (with $\bar{\alpha} > 2$), the long-range interaction is able to avoid the global phase separation — the uniformly magnetized state favored by the exchange interaction — even at $T = 0$. The ground state then consists of an ordered sequence of segments with equal length and alternating magnetization, resulting in a superlattice of magnetic domains. A memory of this periodic spin profile is retained at finite $T$ in the two-point correlation function, which oscillates as well but with a temperature-dependent period. Such an oscillation is then exponentially damped over a spatial scale, the correlation length, which diverges asymptotically, roughly, as the inverse of $T$. This suggests that the long-range interaction drives the Ising chain to acquire a universality class consistent with an underlying continuous symmetry. The $\epsilon T$-temperature dependence of the correlation length and the uniform ferromagnetic ground state, characteristic of the $g = 0$ discrete Ising symmetry, are recovered for $\alpha > \bar{\alpha}$.

3:18PM X32.00005 ABSTRACT WITHDRAWN

3:30PM X32.00006 Nature of topological quantum phase transition in chiral spin liquid, SUK BUM CHUNG, HONG YAO, Stanford University, EUN-AH KIM, Cornell University, STEVEN KIVELSON, Stanford University — How to best characterize and detect topological order, which is not associated with any local broken symmetry is one of central questions in the field of topological phases. While the ground state degeneracy that depends on the topology of the manifold the system is defined in has been a successful theoretical indicator of topological order, this concept is applicable only at $T = 0$ and not accessible experimentally. Another important indicator has been topological entanglement entropy. However, topological entanglement entropy at $T = 0$ can be the same for two distinct topological phases. Here we study an exactly solvable model first introduced in Ref.[1], motivated by the fact that the existence of topological quantum phase transition is known and the full spectrum is available. We examine the nature of Abelian to non-Abelian topological quantum phase transition by studying the expectation value of global flux which shows an abrupt jump at the critical point. We discuss the phase diagram of this quantum phase transition in terms of the global flux and entanglement entropy and discuss to what extent the existence of topologically ordered ground state with non-Abelian excitations is revealed at finite temperature. [1] H. Yao and S.A. Kivelson, PRL 99 247203 (2007).

3:42PM X32.00007 Scaling in modulated systems and reentrance of order, OLIVER PORTMANN, ALESSANDRO VINDIGNI, DANilo PEScia, ETH Zurich — Ultrathin ferromagnetic iron films exhibit a peculiar reentrance of order[1] A less symmetric pattern (stripes) that is present at lower temperatures reoccurs at higher temperatures after a more symmetric intermediate state (labyrinth). We obtain a good qualitative understanding of the system by analytically reducing this problem in two spatial dimensions to an effectively one-dimensional problem that retains important properties of the original system even in the presence of small deviations from mono-dimensionally modulated order. As revealed by a scaling analysis, this system is characterized by a highly anomalous temperature dependence of an elastic constant. This finding is corroborated by mean-field calculations. By means of the scaling analysis, we can relate this experimentally inaccessible elastic constant to experimentally measurable quantities. Comparison with experiment suggests that the driving force for the reentrance of order is indeed the strongly anomalous behavior of this elastic constant.

2 Orthorhombic SrRuO$_3$, JINGUANG CHENG, JIANSHI ZHOU, JOHN GOODENOUGH, TMI, University of Texas at Austin — SrRuO$_3$ is a metallic ferromagnet with $T_c \approx 160$ K where mean-field (MF) critical behavior has been observed. [1] Recently, we have shown that cubic BaRuO$_3$, which changes the bond angle $\angle$Ru-O-Ru changes the bond angle $\angle$Ru-O-Ru$_3$ versus $\sigma^2$, and introduces an A-cation size variance $\sigma^2$. The partial chemical substitution by either smaller Ca$^{2+}$ or larger Ba$^{2+}$ in Sr$_{1-x}$A$_x$RuO$_3$, which changes the bond angle $\angle$Ru-O-Ru$_3$ introduces an A-cation size variance $\sigma^2$, and $\langle r^2 \rangle$, causes a clear deviation from the MF behavior. In order to distinguish effects of $\angle$Ru-O-Ru versus $\sigma^2$, we have synthesized Sr$_{1-x}$Ca$_{0.5}$Ba$_{0.5}$RuO$_3$ under 1000°C and 10 GPa in a Walker-type multianvil; these samples have the same average $\angle$Ru-O-Ru$_3$, but a different $\sigma^2$. All samples exhibit perfect MF critical behaviors, which indicates that the peculiar bond angle $\angle$Ru-O-Ru$_3$ plays an essential role in determining the MF critical behavior of SrRuO$_3$.

3:54PM X32.00008 Generalized Onsager cavity field method for magnets with local spin fluctuations, JAMES GLASBRENNER, ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, University of Nebraska - Lincoln — The Onsager cavity field method is extended to magnets described by a classical spin fluctuation model which interpolates between the limits of localized and itinerant magnetism and captures the qualitative features of itinerant thermodynamics. We find that both the interatomic exchange coupling and the on-site interaction are renormalized by short-range order. In the localized (Heisenberg) limit Onsager’s approximation is recovered, but in itinerant systems it is essential to include both corrections, for in this case a simple subtraction of only the Onsager reaction field leads to poor results. The generalized Onsager method is compared with the results obtained through mean-field and Monte Carlo methods. It is found that for close-packed lattices with nearest-neighbor exchange there is excellent agreement between the generalized Onsager method and Monte Carlo for any degree of itineracy, and offers a significant improvement over the mean-field approximation in predicting the Curie temperature [1]. 4:06PM X32.00009 Spin Rotation Technique for Non-Collinear Magnetic Systems: Application to the Generalized Villain Model, J.T. HARALDSEN, R.S. FISHMAN, Oak Ridge National Laboratory — This work develops a new generalized technique for determining the static and dynamic properties of any non-collinear magnetic system. By rotating the spin operators in the local spin reference frame, we evaluate the zeroth, first, and second order terms in a Holstein-Primakoff expansion, and through a Green’s functions approach, we determine the structure factor intensities for the spin-wave frequencies. To demonstrate this technique, we examine the spin-wave dynamics of the generalized Villain model with a varying interchain interaction. The new interchain coupling expands the overall phase diagram with the realization of two separate spin configurations. The rotational Holstein-Primakoff expansion provides both analytical and numerical results for the spin dynamics and intensities of these phases. Research sponsored by the Division of Materials Sciences and Engineering, U.S. Department of Energy under contract with UT-Battelle, LLC.

4:18PM X32.00010 Edge States of Quantum Antiferromagnets, JOSÉ HOYOS, S. CHANDRASEKHARAN, H. U. BARANGER, Duke University — We investigate the edge states of spin systems in the Affleck-Kennedy-Lieb-Tasaki (AKLT) phase. Edges of correlated systems may show novel lower dimensional physics (as in quantum Hall edge states) and have recently garnered increasing experimental attention. Here we study spin-1 systems using the directed-loop quantum Monte Carlo technique. Depending on the configuration and parameters, even though the bulk system has a spin (Haldane) gap, the edge states can be gapless and described by an effective Luttinger liquid. We focus on the behavior of the edge states when the bulk undergoes a quantum phase transition from the AKLT to the Néel phase.

4:30PM X32.00011 Magnetic Properties of a Canted Antiferromagnet Mn(N₃)₂(4,4'-bpy), YOUCIF HAMIDA, DUSAN DANILOVIC, C.L. LIN, TAN YUEN, Dept. of Physics, Temple University, Philadelphia, PA, KUNHAO LI, JING LI, Dept. of Chemistry & Chemical Biology, Rutgers University, Piscataway, NJ — Results of magnetic susceptibility χ(T), isothermal magnetization M(H), and heat capacity C(T) measurements on a manganese complex with mixed ligands Mn(N₃)₂(4,4'-bpy) and Mn²⁺ moments, and a strong antiferromagnetic interaction of θ = 120 K. An antiferromagnetic transition with rather high transition temperature of 39 K was observed in the M(T)/H data of Mn(N₃)₂(4,4'-bpy), and large non-compensated component in χ(T) below T_N was seen. The result of M(H) measures showed that Mn(N₃)₂(4,4'-bpy) behaves like a ferrimagnet below T_N, with a small coercive field of H_c = 150 G at 1.8 K. A sizable anomaly was observed in C(T) data, and this confirms the long-range magnetic phase transition and the T_N. The magnetic behavior of this compound is discussed in terms of a strong Mn-Mn coupling through this unique network with end-to-end azido bridges, and compared with the magnetic behavior of its iron isostuctural analogue Fe(N₃)₂(4,4'-bpy).

4:42PM X32.00012 Magnetic switching and phase competition in the multi-ferroic antiferromagnet Mn₁₋ₓFeₓWO₄, FENG YE, Oak Ridge National Laboratory, Y. REN, Argonne National Laboratory, J.A. FERNANDEZ-BACA, H.A. MOOK, Oak Ridge National Laboratory, J.W. LYNN, NIST Center for Neutron Research, R.P. CHAUDHURY, Y.-Q. WANG, B. LORENZ, C.W. CHU, University of Houston — Elastic neutron scattering is used to study the spin correlations in the multiferroic Mn₁₋ₓFeₓWO₄ with x = 0.05, 0.05, and 0.10. The non-colinear incommensurate (ICM) magnetic structure associated with the ferroelectric (FE) phase in pure MnWO₄ is suppressed at x = 0.05 and completely absent at x = 0.10. The ICM spin order and FE phase can be restored by applying a magnetic field along the spin easy axis. The low-T° magnetic structure extends in both H/T with increasing Fe concentration. The systematic evolution of the magnetic and electric properties indicates that the noncollinear ICM spin order results from competing magnetic interactions and its stabilization can be tuned by the internal (x) or external magnetic-field perturbations.

4:54PM X32.00013 The ferromagnetic transition in LiHoF₄, ANDERS BILTMO, PATRIK HENELIUS, KTH, Stockholm — The rare-earth magnetic compound LiHoF₄ is considered to be one of the best realizations of a long-range dipolar Ising model. Several experimental studies have been carried out probing the magnetic properties of the material in the context of classical, as well as quantum, phase transitions. In this work we revisit the effective model for the non-dilute material using numerical simulations. We examine the accuracy of the model in relation to experiments and consider the logarithmic corrections derived in renormalization group theory.

5:06PM X32.00014 Examination of the magnetic structure of Cs₂CuCl₄ by first principles DFT calculations, CHANGHOON LEE, Department of Chemistry, NCSU, JINHEE KANG, Department of Chemistry, Wonkwang University, S. Korea, MIKE WHANGBO, Department of Chemistry, NCSU — The spin-1/2 Cu²⁺ ions of Cs₂CuCl₄ have a 3D arrangement, but the magnetic properties of Cs₂CuCl₄ are mainly described by a quasi-2D triangular antiferromagnetic layer model. To understand why the 3D arrangement of (CuCl₄)²⁻ ions leads to a 2D magnetic behavior, we evaluated the various spin exchange interactions between adjacent (CuCl₄)²⁻ ions by performing DFT calculations. Our results show that the 6p orbitals of Cs⁺ participate in the spin exchange interaction through the Cl⁻Cs⁻Cl bridges if the two (CuCl₄)²⁻ ions have a symmetric arrangement and if the Cl⁻Cs⁻Cl bridges are symmetric, and that the frustrated 2D triangular antiferromagnetism originates from this selective participation of the Cs 6p orbitals in the spin exchange interactions.

5:18PM X32.00015 Examination of the Coupled Magnetic-Structural Phase Transition in Gadolinium-Silicon-Germanium Magnetocaloric alloys at temperatures well above Tc. RAVI HADIMANI, EUGENE MELIKHOF, JOHN SNYDER, DAVID JILES, Wolfson Centre for Magnetics, Cardiff University, WOLFSON CENTRE FOR MAGNETICS TEAM — The first order phase transition in Gd5(Si2Ge1-x)14 from monoclinic phase to orthorhombic phase was investigated from 296-300 K at magnetic fields of up to 9 Tesla. The rate of change of transition temperature with magnetic field was found to be 4.9 K/Tesla in the field range up to 2.5 Tesla. This linear rate of change of transition temperature with field persisted even at higher magnetic fields of up to 9 Tesla. Measurements were made on single crystal Gd5Si2Ge1-x and Gd5Si2Ge2 using a high field VSM and a SQUID magnetometer. The single crystal samples were prepared by the Bridgman method at Ames Laboratory US DOE. The first order phase transition temperatures of single crystal samples at nearly zero field were determined to be 264 K and 267 K respectively. The magnetic field required to induce the first order phase transition at 289 K for the single crystal Gd5Si2Ge1-x was 4.8 Tesla and at 300 K it was 8 Tesla. For the single crystal Gd5Si2Ge2 sample, the magnetic field required to induce the first order transition at 289 K was 4.5 Tesla and at 300 K it was 8.4 Tesla. The magnetic field required to induce the first order phase transition increased linearly with the difference T-Tc.

Session X33 DCMP: MgB2 and Multigap Superconductivity 403

2:30PM X33.00001 Homogeneity and connectivity of doped MgB2 bulks and strands as probed by heat capacity and transport current1, MIKE SUMPTON, MIKE SUSNER, MSE, The Ohio State University, Columbus, OH USA, Z. SHI, Department of Physics, Southeast University, China, E. COLLINGS, MSE, The Ohio State University, Columbus, OH USA — Homogeneity and current percolation have been investigated for MgB2 bulks and strands. Sintered bulks were compared to dense bulks produced by HIPping, infiltration, and spark plasma synthesis in terms of their homogeneity as measured by heat capacity and resistivity. Various levels of carbon based dopants were introduced in each case, with control samples for comparison. The influence of higher temperature processing on inhomogeneity was investigated. These results are compared to those of MgB2 based strands made both with and without C-based doping. In addition, comparisons of transport and magnetization measurements at higher magnetic fields showed the onset of a regime where the anisotropy between Jc parallel to the strand and Jc perpendicular to the strand grows rapidly. This leads to large differences between transport and magnetically measured values of not only critical current, but also the irreversibility fields. Birr. Such effects can be described in terms of three different regimes, defining the dimensionality of the system. These regimes are distinct from the various states of vortex matter present in the magnetic phase diagram of MgB2, but in coexisting with them they influence our estimates of these boundaries.

2:42PM X33.00002 Upper critical field study of CH4 HPCVD carbon-doped MgB2, F. HUNTE, J. JAROSZYNSKI, A. GUREVICH, D.C. LARBALESTIER, NHMFL-Florida State University, Y. ZHU, P.M. VOYLES, University of Wisconsin, Madison, X.X. XI, K. CHEN, The Pennsylvania State University, S. BAILY, F. BALAKIREV, NHMFL-Los Alamos National Laboratory, C.G. ZHUANG, S. MENG, C.Y. ZHANG, Q.R. FENG, Z.Z. GAN, Peking University — The Hc2(T) of a set of four carbon-doped MgB2 films grown on both SiC and Al2O3 substrates by HPCVD from methane CH4 at flow rates from 7 to 10 sccm was measured in fields up to 65T. Compared to each metalorganic C sources which generated high Hc2(0), these films have much lower resistivities and higher connectivities. The curvature of Hc2(T) derived from low current four point magnetoresistance shows upturn at low temperatures, which is consistent with the dominance of π-band scattering in the theory of dirty two-gap superconductivity. Hc2(0) > 60 T is close to the paramagnetic limit of ~ 66 T for the 10 sccm film on SiC, though still a little lower than for the previously used metalorganic (Cu2H2)2Mg. Differences in the Hc2(T) behavior between films grown on the two substrates are attributed to variations in strain fields produced by the substrate coupled to the film at growth.

2:54PM X33.00003 Absolute Penetration Depth in MgB2, NICHOLAI SALOVICH, RUSSHEL GIANNETTA, Loomis Laboratory of Physics, Univ. of Illinois at Urbana-Champaign, Urbana IL 61801, MATT TILLMAN, PAUL CANFIELD, Ames Laboratory and Department of Physics and Astronomy, Iowa State University, Ames, Iowa 50011 — Absolute penetration depth measurements were carried out on single crystals of MgB2. λ(0) was determined by sputtering an Al film onto the sample crystal and measuring the change in Meissner screening as the Al film expels flux. The change in screening was measured with a tunnel diode oscillator [1]. Several samples were sputtered with films of different thicknesses and measured. Thickness dependent changes in Hc and Tc of the thin Al films provided a self-consistency check on properties of the films. Subsequent analysis using FIB/SEM and AFM independently measured the film thickness and roughness. Work at UIUC supported by NSF DMR-05-03982. Work at the Ames Laboratory was supported by the Department of Energy, Basic Energy Sciences under Contract No. DE-AC02-07CH11358. [1] R. Prozorov, et al, Appl. Phys. Lett. 77, 4202 (2000)

3:06PM X33.00004 High Upper Critical Field and Critical Current Density of Carbon-doped MgB2 Films by HPCVD Using TMB, WENQING DAI, KE CHEN, QI LI, Department of Physics, Pennsylvania State University, University Park, PA 16802, XIAOXING XI, Department of Physics, Department of Materials Science and Engineering, Pennsylvania State University, University Park, PA 16802 — Carbon-doping is effective to enhance upper critical field Hc2 and critical current density Jc of MgB2. Using Trimethylboron (TMB) as the doping source, we have successfully fabricated carbon-doped MgB2 thin films by the Hybrid Physical-Chemical Vapor Deposition (HPCVD) method. Large temperature derivative dHc2(0)/dT values near 4%, as high as 8.3 T/K, have been achieved for heavily doped samples. These values are much higher than what have been reported before. With Tc over 30 K, Hc2(0)/dT values over 100 T can be expected for these samples. For lightly doped films, Jc values, larger than 105 A/cm2 at 5 K under 9 T perpendicular field and 104 A/cm2 at 20 K under 5 T perpendicular field, were obtained. The results demonstrate that carbon-doped carbon-doped MgB2 films by HPCVD using TMB are promising for high field applications.

3:18PM X33.00005 Novel phase change in the mixed state of the multi-band MgB2 single crystal1, DAICHI KUBOTA, TAKEKAZU ISHIDA, Osaka Pref. Univ. (Sakai) — High-quality MgB2 single crystals of submillimeter size were synthesized successfully by the vapor transport method for carrying out magnetic torque measurements. The magnetic torque of MgB2 has been analyzed by a single-band model as well as a multi-band model for an anisotropic superconductor. The anisotropy in the coherence length 1/λ∥ and the anisotropy in the penetration depth 1/λ⊥ with the multi-band Kogan theory for the magnetic torque were simultaneously determined by means of the least-squares fittings. A systematic variation of two sorts of effective superconducting anisotropies, γ and λ, in the field-temperature plane was obtained as contours, and can be interpreted as a manifestation of the two-band nature of the MgB2 superconductivity. It is not a gradual crossover but a drastic change in the electronic state that an MgB2 superconductor transits from a π - σ multiband superconductor in lower fields to a σ single band superconductor in higher fields.

1This work was partly supported by a Grant-in-Aid for Scientific Research from the MEXT (Grant No. 19206104) and a special grant from Osaka Prefecture University.
Time Dependent Effects in Transport Measurements and Absence of Anisotropic Behavior in Polycrystalline MgB$_2$  

MURAT OLUTAS, ATILLA KILIC, KIVILCIM KILIC, ATILGAN ALTINKOK, HAKAN YETIS, KILIC TEAM — The flux dynamics in polycrystalline sample of MgB$_2$ have been studied by current-voltage (I-V) measurements for different sweep rates (dI/dt) of transport current at zero magnetic field (H=0) and H≠0, and also magnetovoltage measurements (V-H curves) for different sweep rates (dH/dt). It was observed that the time and hysteresis effects in I-V curves which appear upon cycling of transport current are not significant as compared to those of YBaCuO and BiSrCaCuO. The absence of hysteresis effects in I-V curves were attributed mainly to the absence of weak link structure in MgB$_2$. The hysteresis effects in V-H curves depend on field orientation of H with respect to I. Furthermore, it was observed that time dependent effects appear in V-H curves as the dH/dt varies and also the counterclockwise behavior which appears in forward region changes its character and becomes clockwise for reverse region. The magnetovoltage measurements were also carried out by varying the angle θ between H and I (V-θ curves). The V-θ curves show that there is no anisotropy in polycrystalline MgB$_2$. This behavior was discussed in terms of polycrystalline structure of MgB$_2$ and its band structure where the Fermi surface includes four sheets of one electron-like and three hole-like. The observations were interpreted mainly in terms of flux trapping in grains.

The conductivity percolation effects in CrO$_2$-MgB$_2$ nanocomposites  

XIANGDONG LIU, RAGHAVA PANGULURI, HUANG ZHI-FENG, BORIS NADGORYN, Department of Physics and Astronomy, Wayne State University, Detroit, MI 48201 — Cold-pressed half-metals/insulators are known to show an enhanced extrinsic powder magnetoresistance (MR) due to intergranular and intergrain spin-dependent tunneling. In this work we use a mixture of metal/superconductor (CrO$_2$)/(MgB$_2$)$_{1-x}$ nanocomposites to study conduction percolation effects. The samples were cold pressed in the form of pellets from the mixture of pure CrO$_2$ and MgB$_2$ powders. Transport and magneto-transport properties of various composition compacts measured as a function of temperature. Magneto-transport measurements performed over a temperature range of 2-100K show a hysteretic behavior with the peak values of MR coinciding with the CrO$_2$ coercive fields, with a maximum MR value for the composition near the percolation threshold of ∼ 42% at 2 K. The electrical resistivity displayed a sharp maximum near the percolation threshold, a feature that is likely to be unique for such systems of type. We will discuss the implications of our results for the analysis of conduction percolation within the framework of a simple percolation model and a possible connection to Andreev reflection effect in this system at low temperatures.

Flux penetration in mesoscale samples of multi-component unconventional superconductors  

DAVID GEORGE FERGUSON, PAUL GOLDBART, University of Illinois at Urbana-Champaign — Multi-component unconventional superconductors bring the possibility of unusual magnetic phenomena. Examples include spontaneous zero-field magnetization, and penetration by magnetic flux not only through one-dimensional vortices but also through two-dimensional domain walls in which superconductivity persists. How flux penetrates, both in and out of equilibrium, depends on the way in which the order parameter distorts—vortex versus domain wall—particularly in view of the fact that flux quantization is required for vortices but not for domain walls that traverse the sample. We study these issues in the setting of mesoscale samples, in which domain walls are more stable and any discreteness of flux penetration should be more readily observable, predicting an unusual variation of the magnetization with the applied magnetic field. The observation of such effects in Sr$_2$RuO$_4$, a proposed unconventional superconductor, via techniques such as cantilever torque magnetometry, should shed light on important issues such as the pairing symmetry and the prevalence of domain walls in bulk samples.
4:42PM X33.00012 Concomitant enhancement of spin susceptibility and pairing interaction in the reduced carrier-density regime of Li,ZrNCl superconductor . YUICHI KASAHARA, TSUKASA KISHIUME, TAKUMI TAKANO, KATSUKI KOBAYASHI, YOSHIHITO IWASA, IMR, Tohoku Univ., EIICHI MATSIUKA, HIDEYA ONODERA, Department of Physics, Tohoku Univ., YASUHIRO TAGUCHI, CMRG, ASI, RIKEN — Li-intercalated layered nitrides Li,ZrNCl are novel superconductors, in which superconductivity emerges at relatively high transition temperature \( T_c \sim 12 - 15 \) K with very low carrier density \( \sim 10^{21} \text{ cm}^{-3} \). The pristine \( \beta \) -ZrNCl is a simple band insulator, and electron doping is achieved by Li intercalation. Insulator-to-superconductor (IS) transition takes place at \( z \sim 0.05 \) with maximum \( T_c \) value of \( \sim 15 \) K and \( T_c \) decreases with further doping, which is opposite trend to the other superconductors in doped band insulators. Here we show the results of magnetic susceptibility measurements on Li\_2ZrNCl with systematically controlled \( z \). Estimated spin susceptibility \( \chi_s \) is almost temperature-independent without substantial anisotropy. With decreasing \( z \), \( \chi_s \) evolves strongly, same as \( T_c \). On the other hand, specific heat study revealed that the density of states is reduced but the pairing interaction is enhanced on the verge of IS transition. Therefore, our results may indicate that magnetic fluctuations are enhanced toward a band-insulator and that they are possibly responsible to superconductivity even in the present small carrier-density system.

4:54PM X33.00013 Absence of Superconductivity in the Hole Doped Li\(_{1+\delta}\)BC. ENGIN OZDAS, BORA KALKAN, EBRU GUNGOR, Advanced Materials Research Group, Physics Department, Hacettepe University, Beytepe, Ankara 06800, Turkey — The existence of several borocarbides with crystal structures highly related to MgB\(_2\), in which one of these, the layered LiBC has been predicted based on the electronic structure calculations that this compound should become superconducting on doping with holes. However, the superconducting features for Li off-stoichiometric borocarbid compounds have not been observed in any experimental studies, because of the difficulties in the sample preparation. In this work, the effects of synthesis conditions on the structure of Li\(_{1+\delta}\)BC samples with the different Li content and the phase stability were investigated. The structural studies showed that the intercalation process has a staging behavior as Li intercalated graphite and a novel Li vacancy ordered structure for off-stoichiometric stage-2 Li\(_{1+\delta}\)BC phase. The temperature dependence of the conductivity shows semiconducting behavior over the whole temperature range and the hopping type conduction improved by the hole doping.

Thursday, March 19, 2009 2:30PM - 5:30PM — Session X34 DCMP: Superconductivity: Magnetic Field Effects

4:24PM X34.00001 Ballistic acceleration phase of a supercurrent \(^1\) MILIND N. KUNCHUR, GABRIEL SARACLA \(^2\), University of South Carolina — One of the primitive but elusive current-voltage (I-V) responses of a superconductor is when its supercurrent grows steadily after a voltage is first applied, as per the first London equation. Because this phase lasts for a relatively short duration—until dissipative processes set in—it is difficult to conduct a correlated time-domain I-V measurement of it. The present work employed a measurement system that can simultaneously track and correlate I(t) and V(t) with sub-nanosecond timing accuracy, resulting in a clear time-domain measurement of this transient phase where the quantum system displays a Newtonian-like response. The highly controlled technique used here measures the near equilibrium response and should be distinguished from an impulse response measurement, which may probe non-equilibrium processes. The present technique should be valuable for the controlled investigation of other types of time-dependent and non-equilibrium phenomena.

4:24PM X34.00002 Spatial distribution of internal magnetic field in High T\(_c\) superconductors with pancake vortices. W.P. HALPERIN, S. MUKHOPADHYAY, A.M. MOUNCE, S. OH, Department of Physics and Astronomy, Northwestern University, IL, USA, A.P. REYES, P. KUHNS, National High Magnetic Field Laboratory, FL, USA, H. TAKAGI, Department of Physics, University of Tokyo, Tokyo, Japan, S. UCHIDA, Department of Advanced Materials Science, University of Tokyo, Chiba, Japan — We report here \(^{17}O\) \( T_1 \) measurements in single crystals of slightly overdoped \( (T_c = 82 \) K) Bi2212 at 5 K, in magnetic fields from 15 – 30 T. In previous work the internal magnetic field distribution in YBCO aligned powders at high magnetic fields has been probed by NMR imaging experiments [1]. Our results for single crystals of the highly anisotropic superconductor, BSCCO, are remarkably different, and is inconsistent with present theoretical predictions. At 5 K the system is in a 2-D vortex solid phase [2]. We conclude that the magnetic field distribution for 2-D vortices in the presence of interlayer magnetic and Josephson coupling is radically different from a London vortex lattice.

2:54PM X34.00003 Intermittent propagation of magnetic flux in superconductors. \(^\ast\) VITALY YURCHENKO, ATLE JORSTAD QIVILLER, Iouri GALPERINE, University of Oslo, JOERN BINDSLEV HANSEN, PETER MOZHAEV, Technical University of Denmark, TOM HENNING JOHANSEN, University of Oslo, UNIVERSITY OF OSLO TEAM, TECHNICAL UNIVERSITY OF DENMARK TEAM — Regular arrays of planar defects can be introduced in superconducting YBa2Cu3O7 thin films by depositing them on tilted substrates. This results in anisotropy of critical currents flowing in the plane of the film. At optimal tilt angles a substantial increase of the critical currents flowing in both directions, i.e. along and across the planar defects, has been observed. However, the artificially introduced defects also have a dramatic effect on dynamics of the flux propagation: it becomes intermittent. Previously we observed intermittent flux penetration in MgB2 thin films with thermo-magnetic instability, where such flux jumps trigger giant magnetic avalanches. In this report we present results of a real time magneto-optical visualization of the intermittent flux motion in YBCO and discuss possible consequences for its thermo-magnetic stability.

3:06PM X34.00004 Magnetic field-orientation independence of large basal-plane critical currents in RBCO films with correlated pinning nanostructure \(^1\) DAVID CHRISTEN, Y.L. ZUEV, Oak Ridge National Laboratory, S.H. WEE, University of Tennessee, A. GOYAL, C. CANTONI, Oak Ridge National Laboratory, C. TARANTINI, A. GUREVICH, D. LARBALESTIER, Florida State University — It has been widely confirmed that self-assembled columnar stacks of second-phase precipitates aligned near to the c-axis provide strong pinning force in RBCO epitaxial films. Such growth-controlled nanostructures can be produced by at least two different deposition techniques and for several species of oxide precipitates. For many of these systems, the usual dependence of in-plane critical current densities, \( J_c \), on field-orientation nearly vanishes at a specific temperature-dependent field, \( B^\ast(T)\). The phenomenon can be described by a competition between intrinsic electronic anisotropy and orientation-dependent pinning. A simple model parameterizes the effect through the dependencies \( H_{irr}(\theta) \) and the power-law decay exponent \( \alpha(\theta) \), where \( J_c \propto H^{-\alpha(\theta)} \) in the intermediate field regime. Limits to and fundamental aspects of the model with respect to these parameters will be discussed.

1Research sponsored by the U.S. Department of Energy - Office of Electricity Delivery and Energy Reliability and by the Office of Science, Division of Materials Sciences and Engineering.
3:18PM X34.00005 Angularly Dependent, Contact-free Current Density Measurements of YBCO Coated Conductor, J.W. SINCLAIR, J.R. THOMPSON, Dept Physics, Univ. Tennessee, Knoxville, TN, USA, D.K. CHRISTEN, Y. ZHANG, Oak Ridge Nati Lab, Oak Ridge, TN, USA — Studying the angular dependence of the current density J gives insight into vortex pinning. We investigated a coated conductor of YBa$_2$Cu$_3$O$_{7-x}$ containing c-axis correlated defects (stacks of BaZrO$_3$ particles), striated into six strips to give a high aspect ratio. The current density was determined inductively from the magnetic moment $m \sim J$, using a SQUID magnetometer. The sample was mounted on a horizontal rotating platform to vary the angle $\Theta$ of the sample with respect to the vertical applied magnetic field. The magnetometer allows us to measure both the longitudinal and transverse components of moment $m(\Theta)$, enabling calculation of the angular dependence of $J$. For a large range of applied magnetic fields at various temperatures, we found a pronounced peak in $J(\Theta)$ at an angular value $\Theta_{peak}$ near the c-axis. We observed that, for a large range of applied magnetic fields, $\Theta_{peak}$ linearly scales with $1/h$, where $h = (H/H_{c2})$ is the reduced field. Research sponsored by DOE, Division of Materials Sciences and Engineering, and Office of Electricity Delivery and Energy Reliability.

3:30PM X34.00006 Vortex States in Intrinsic Josephson Junctions of Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ in High Parallel Magnetic Fields, JOVAN MIRKOVIC, Faculty of Sciences, University of Montenegro, G. Washington Str., 81000 Podgorica, Montenegro, SAITO TAKASHI, Institute of Materials Science, University of Tsukuba, 305-8573 Tsukuba, Japan, YUIMARU KUBO, National Institute of Materials Science, 2-1-2 Sengen, Tsukuba 305-0047, Japan, ITSUHIRO KAKEYA, Electronic Science and Eng. Faculty, University of Kyoto, 615-8510 Kyoto, Japan, AHMED ORAL, Faculty of Engineering and Natural Sciences, Sabanci University, Tuzla, 34956 Istanbul, Turkey, TAKASHI YAMAMOTO, KAZUO KADOWAKI, Institute of Materials Science, University of Tsukuba, 305-8573 Tsukuba, Japan — The $I_c$-axis resistivity measurements were performed in the vicinity of the ab-plane in order to investigate the interaction between Josephson vortices (JVs) and pancake vortices (PVs) in Bi$_2$Sr$_2$CaCu$_2$O$_{8+\delta}$ mesoscopic single crystals. It was found that the vortex lock-in transition becomes considerably broad in high magnetic fields, while the angular dependence of resistance exhibits the sharp lock-in features in low magnetic field region. The magnetic field dependence of the resistance exhibits the non-monotonic behavior probing the different vortex phases in tilted magnetic fields. Sharp dips and steps in the $c$-axis resistance were observed accompanied by penetration of quantized pancake vortices by tilting external fields from the ab-plane.

3:42PM X34.00007 Hole doping-induced evolution of self-organized bulk vortex structure in the high temperature YBa$_2$Cu$_3$O$_{7-\delta}$ superconductor, AHMAD MANSOUR, RONGCHAO MA, MEHMET EGLIMEZ, MURAT OLUTAS, HAKAN YETIS, KILIC TEAM — Time and hysteresis effects have been studied by magneto-transport measurements for high temperature YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO) as a function of oxygen defect concentration $\delta$. These studies allowed us to map out the $(\mu,\delta)$ phase diagram of the vortex matter, where the exponent $\mu$ of the vortex structure was obtained using the scaling properties of the energy barrier against vortex motion. The reduction of the hole-doping level (an increase of $\delta$) of the material leads to a transformation of the vortex lattice into a glass and subsequently into a liquid phase. These vortex phases self-organize and produce relaxation plateaus in regions between step-like changes in the dependence of relaxation kinetics on hole doping, revealing the existence of a previously unknown correlation between the vortex structure and the hole-doping level in a cuprate superconductor, such as YBCO.

3:54PM X34.00008 Temperature Dependence of Flux Pinning Properties for Dilute Impurity Doped Y123 Single Crystals, YUI ISHI, Univ. Tokyo — Most of studies on pinning properties and relating vortex nature of the RE123 system were performed at high temperatures around 77 K, while extensive applications at low temperatures are also expected. However, both pinning properties and vortex states at low temperatures have not been well understood for RE123 crystals having intentionally introduced pinning sites. On the other hand, we have developed the chemical and versatile technique to introduce effective pinning site in the cuprates, that is dilute impurity doping for the target cation sites. In addition, compositional fluctuations of light rare earth (LRE) elements, which induce disorder transition of vortex system, are known to contribute enhanced pinning properties of LRE123. In this paper, we report that the changes of vortex state and $J_c$ characteristics of RE123 single crystals in $H//c$ at low temperatures by precise control of cation compositions. Our result suggested that dilute impurity doping to Cu (in CuO-chain) or Ba is more effective to enhance pinning strength of Y123 than introduction of compositional fluctuation for Gd123 single crystals at low temperatures below 70 K.

4:06PM X34.00009 Hysteresis Effects in Ag-Doped Superconducting Y-Ba-Cu-O, ATILGAN AL-TINKOK, KIVILCIM KILIC, ATILLA KILIC, MURAT OLUTAS, HAKAN YETIS, KILIC TEAM — Time and hysteresis effects have been studied by magnetovoltage $(V-H)$ curves measurements in Ag doped sample of YBa$_2$Cu$_3$O$_{7-\delta}$ (YBCO/Ag) as functions of transport current $(I)$, sweep rate of external magnetic field $(dH/dt)$ and temperature. Ag was added in the amount of 3% of nominal composition of Cu in YBCO. It was observed that the dissipation in V-H curves does not change as $dH/dt$ increases. This suggests that Ag doping destroys the weak-link structure along inter-grain boundaries and thus the vortices can find enough time to move in the sample irrespective of varying of external H. The hysteresis effects in V-H curves ride on a background voltage at the temperatures near the $T_c$. In one hand, the background voltage of V-H curves decreases by taking low values as the temperature decreases, in the other hand, the hysteresis effects become more significant. It was observed that the evolution of V-H curves depends also on the magnitude of transport current. The increase in $I$ causes a considerable enhancement in background voltage in V-H curves. Similar measurements were repeated for YBCO sample without Ag for a comparison. Experimental observations between YBCO/Ag and YBCO establish that adding of Ag into the superconducting matrix causes the formation of easy metallic flow paths for vortices and thus easy distribution of vortices along grain boundaries.

4:18PM X34.00010 Effect of pseudo-gap state to the vortices in the high-Tc cuprate superconductors, MASARU KATO, SATOSHI TOMITA, Osaka Prefecture University — The scanning tunneling spectroscopy (STS) experiments for high-Tc cuprate superconductor(SC) show the local density of states (LDOS) around a single vortex is different from that in a purely d-wave superconductor (dSC). Theoretically, in the dSC, there is a quasi-particle bound states peak around the vortex core, which is similar to that for an s-wave superconductor. This discrepancy means the superconductivity in high-Tc superconductors is simple dSC. In the high-Tc SC, dSC always coexists with unknown pseudo-gap state. Recent angle-resolved photoemission spectroscopy experiments show the energy gaps of pseudo-gap states and d-wave superconductivity are different. In this study, we show that the quasi-particle structure is reproducible theoretically, if we take into account the effect of the pseudo-gap state. We derived the Bogoliubov-de Gennes equation for the coexistence state with dSC and pseudo-gap (dSDW) state as the pseudo-gap state. We considered spin density wave (dSDW) state as the pseudo-gap state. We derived the Bogoliubov-de Gennes equation for the coexistence state with dSC and pseudo-gap state. We observed that, for a large range of applied magnetic fields, $\Theta_{peak}$ linearly scales with $1/h$, where $h = (H/H_{c2})$ is the reduced field. 2:30PM X35.00001 Electronic Structure of Fe-based Superconductors

DAVID J. SINGH, Oak Ridge National Laboratory — Understanding the electronic structure and electronic interactions in the layered Fe superconductors is prerequisite to understanding their superconductivity and other properties. The purpose of this talk is to overview results obtained within band structure approaches in relation to experiment. So far, many puzzles remain. The materials appear to be much more band-like and show much stronger signatures of metallic (Fermi surface related) physics than cuprates, with correspondingly weaker signatures of on-site Hubbard correlations. However, there remain substantial discrepancies between bare band structure calculations and experiment, and interestingly these discrepancies are in the opposite direction from those found in cuprates. These are discussed in the context of spin-fluctuations. This work was done in collaboration with I.I. Mazin, M.H. Du, Lijun Zhang, Alaska Subedi and Michelle Johannes.

3:06PM X35.00002 ABSTRACT WITHDRAWN —

3:18PM X35.00003 Theory for lattice collapse and frustrated magnetism in FeAs superconductors

RAFAEL FERNANDES, JOERG SCHMALIAN, Ames Laboratory and Department of Physics and Astronomy, Iowa State University — We present a theory for the pressure and temperature dependence of the magnetic and structural phase transitions in FeAs superconductors. Magnetic frustration in the FeAs planes leads to an enhanced coupling between lattice and magnetic degrees of freedom and is responsible for the strength of the first order transition from a paramagnetic tetragonal to an antiferromagnetic, orthorhombic phase. We analyze the phase diagram using a large N expansion for the magnetic degrees of freedom coupled to the lattice. Furthermore, we also address the importance of the lattice collapse in the CaFe2As2 compound and compare our predictions with experiments. Our results demonstrate that it is crucial to simultaneously include lattice and magnetic degrees of freedom for the FeAs systems.

3:30PM X35.00004 Formation and suppression of Fe magnetism in ferropnictides

IGOR MAZIN, MICHELLE JOHANNES, Naval Research Laboratory — First, I will address the issue of how the Fe magnetic moment in HTc pnictides is formed in the DFT calculation, why is it so large (up to 2 μB) and why the moments prefer to order in a stripe-like AFM manner. The role of the onsite Hund rule coupling in forming the moment and the role of one-electron (band) energy in selecting an AFM pattern will be explained and emphasized. The important distinction between AFM interactions local in real space (supercorrelation, e.g. in cuprates) and local in momentum space (SDW or AFM in ferropnictides, which is not an SDW in spin-Peierls sense). This part will be largely based upon our preceding talk. Next, I will present some speculations about possible solitonic fluctuations (dynamic AFM domain boundaries) in this system, and their relations to experiments. This pictures assumes that in the orthorhombic but nonmagnetic state the system consists of dynamic antiphase AFM domains, in the AFM state the domains are frozen (pinned), and in the nonmagnetic state dynamic twin domains dominate. This picture reconciles theory, thory and first principle calculations in surprisingly many aspects.

3:42PM X35.00005 First principles study of magnetic interactions and electronic structure in iron chalcogenide superconductors

MYUNG JOON HAN, SERGEY Y. SAVRASOV, University of California, Davis — By using first-principles density functional theory combined with linear response theory we investigate the magnetic interaction of the Fe chalcogenide high Tc superconductors, FeSe1-xTex. The exchange interaction terms are found to be different from those in pnictides, which suggests possibly different superconducting properties. The nearest neighbor antiferromagnetic coupling (J1a) is much stronger than the nearest neighbor ferromagnetic (J1b) and the next nearest neighbor coupling (J2). The J1a and J2 gradually decreases as x increases while J1b increases and becomes to be stronger than J2. Total energy calculation results and the electronic structure will be presented and compared to recent experiments.

3:54PM X35.00006 Microscopic origin of the structural and magnetic transitions in ferropnictide superconductor parent compounds

MICHELLE JOHANNES, IGOR MAZIN, DEVINA PILLAY, Naval Research Laboratory — The parent ferropnictide compounds exhibit two transitions: one is an orthorhombic distortion and the other is a magnetic transition. The transitions are simultaneous in the 122 structural type, but the structural transition precedes the magnetic one in the 1111 type. Although this temperature separation implies that the magnetism depends on the distortion, our computational results show that exactly the opposite is true. The structural distortion is fully dependent on the existence of magnetism and will not occur if a magnetic moment is not present. The particularities of the distortion, namely the expansion along the axis containing aligned spins, occurs as a result of minimizing the one-electron (band) energies. We show that the distortion depends not only on the existence of a magnetic moment, but on the particular ordering pattern chosen by the spins. Imposing a checkerboard ordering results in full x/y symmetry, while a so-called stripe ordering results in near perfect agreement with experimental neutron data below the transition temperature. Our results indicate that, even in the doped (superconducting) compounds, the underlying physics is magnetic.

4:06PM X35.00007 Magnetic Fluctuation and Anisotropy in High-Tc Iron Pnictides

QUAN YIN, MYUNG JOON HAN, WARREN E. PICKETT, SERGEY Y. SAVRASOV, University of California, Davis — Using first-principle density functional theory calculations combined with tight-binding method, dynamical mean field theory, and linear response theory, we extensively investigated the electronic structures and magnetic interactions of nine ferropnictides representing three different structural classes. The calculated magnetic interactions are found to be short-range, and the nearest (J1a) and next-nearest (J2) exchange constants follow the universal trend of J1a/2J2 → 1, despite their extreme sensitivity to the z-position of As. This suggests magnetic frustration as the key factor in stabilizing the superconducting ground state. The calculated spin wave dispersions show strong magnetic anisotropy in the Fe plane, in contrast to cuprates.

4:18PM X35.00008 Role of covalent Fe-As bonding in the magnetic moment formation and exchange mechanisms in iron-pnictide superconductors

KIRILL BELASHCHENKO, University of Nebraska-Lincoln, VLADIMIR ANTRPOV, Ames Laboratory — The electronic origin of the huge magnetoostructural effect in layered Fe-As compounds is elucidated using LiFeAs as a prototye. The crucial feature of these materials is the strong covalent bonding between Fe and As, which tends to suppress the exchange splitting. The bonding-antibonding splitting is very sensitive to the distance between Fe and As nuclei. We argue that the fragile interplay between bonding and magnetism is universal for this family of compounds. The exchange interaction is analyzed in real space, along with its correlation with covalency and doping. The range of interaction and itinerarity increase as the Fe-As distance is decreased. Supercorrelation makes a large antiferromagnetic contribution to the nearest-neighbor coupling, which develops large anisotropy when the local moment is not too small. This anisotropy is very sensitive to doping.
4:30PM X35.00009 The magnetic interactions in iron pnictides, JUJU PULIKKOTIL, VLADIMIR ANTROPOV, Ames Laboratory, Ames, I, USA, MARK VAN SCHILFGAARDE, Arizona State University, Tempe, AZ, USA — Using static linear response theory we studied the pair wise magnetic interaction parameters in many typical families of iron pnictides. Parameters have been obtained for a wide range of volumes and distance between Fe and As atoms. We demonstrate that two nearest neighbor couplings in plane dominate, with a third and fourth nearest neighbor coupling responsible for the appearance of non-collinear ordering when the magnetic moment is small. We found that the ratio between first and a second neighbor coupling is not universal and greatly varies as a function of pressure or Fe-As distance. A small interplane coupling is found, and it varies by a factor of 10-20 among pnictides. We analyze the Neel temperatures, adiabatic spin wave spectrum and a nature of magneto-structural transitions in different classes of pnictides.

4:42PM X35.00010 The magnetic phase diagram of iron pnictides, GERMAN SAMOLYUK, JUJU PULIKKOTIL, VLADIMIR ANTROPOV, Ames Laboratory, Ames, IA, 50011 — We study the stability of magnetic structures in iron pnictides as a function of doping, external pressure and the amount of defects. Several collinear and non-collinear magnetic structures are found to be stable in all classes of pnictides. This stability however is a result of a fragile competition between several nearest neighbor exchange couplings and depends greatly on doping. We determined that for a relatively small electron doping the non-magnetic instability is developed, while already for a small hole doping the stripe structure is instable in many pnictides and other magnetic structures are stabilized. For a larger hole doping the local magnetic moment phase with ferromagnetic long range order can be stabilized. A transition to non-collinear state at small moments is explained by a competition between the anisotropy of the nearest neighbors exchange couplings and third or forth neighbor couplings. Using very extensive calculations of magnetic stability parameter we build a generic pressure-concentration phase diagram of iron pnictides.

4:54PM X35.00011 Magnetic excitations in iron pnictides, VLADIMIR ANTROPOV, Ames Laboratory, Ames, IA, USA, LIQIN KE, TAKAO KOTANI, MARK VAN SCHILFGAARDE, Arizona State University, Tempe, AZ, USA — We analyze the dynamical spin susceptibility \( \chi(q, \omega) \) in the iron pnictides: FeSe, CaFe2As2 and SrFe2As2 and obtain the spectra of spin excitations. In the long wavelength limit we obtain parameters for the effective Heisenberg model and compare it with parameters generated by a static response method. Antiferromagnons are found for a small \( q \), while for the larger \( q \) strong Stoner excitations are developed. These results support the claim that iron pnictides are marginally itinerant systems. We also estimate zero-point fluctuations from \( \chi \) and find the following contributing mechanisms: adiabatic spin waves, hole-particle Stoner excitations and longitudinal fluctuations. Taking these effects into account improves the agreement between theory and experiment and indicate the importance of itinerant spin fluctuations.

5:06PM X35.00012 Collinear (Bi-collinear) antiferromagnetic order in iron-pnictides (chalcogenides)\(^1\), ZHONG-YI LU, Department of Physics, Renmin University of China, Beijing 100872, China, FENGJIE MA, Institute of Theoretical Physics, Chinese Academy of Sciences, Beijing 100190, China, TAO XUAN, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — By the first-principles electronic structure calculations, we find that the ground state of the tetragonal \( \alpha \)-FeTe is in a bi-collinear antiferromagnetic order, in which the Fe local moments (~ 2.5\( \mu_B \)) align ferromagnetically along a diagonal direction and antiferromagnetically along the other diagonal direction on the Fe–Fe square lattice. This novel bi-collinear order results from the interplay among the nearest, the next nearest, and the next next nearest neighbor superexchange interactions, mediated by Te 5p-band. In contrast, the ground state of the iron pnictides or chalcogenides is in a conventional collinear antiferromagnetic order, like LaFeAsO, resulting from the interplay between the nearest and the next-nearest neighbor superexchange antiferromagnetic interactions, bridged by As atoms. This finding sheds new light on the origin of magnetic ordering in Fe-based superconductors.

5:18PM X35.00013 Effective Hamiltonian for FeAs based superconductors\(^1\), EFRATIATOS MANOUSAKIS, Department of Physics and MARTECH, Florida State University, Tallahassee, Florida, 32306, USA and Department of Physics, University of Athens, Greece — The Fe-pnictide superconductors exhibit unusual properties attributed to electrons and holes occupying the Fe \( d \)-orbitals and the outermost occupied \( s \) and \( p \) pnictide orbitals. Starting from the atomic limit, we carry out a strong coupling expansion for the FeAs layer, where the on-site Coulomb repulsion parameters are assumed to be significantly larger than the hopping between Fe \( d \) orbitals and the hybridization parameters between the Fe \( d \) and As \( 1s \) or \( 1p \) orbitals; we derive an effective Hamiltonian that describes the low energy electron/hole behavior. If this condition for strong coupling expansion is not satisfied, still, we believe that our qualitative results capture important aspects of the physics in these materials. The hopping and the hybridization parameters are obtained by fitting the results of our calculations based on the local density approximation to a tight-binding model. The effective Hamiltonian, in the strong coupling limit, consists of three parts which operate on the three subspaces coupled through Hund’s rule and spanned by the following Fe orbitals: (a) the \( d_{x^2-y^2} \); (b) the degenerate orbitals \( d_{xz} \) and \( d_{yz} \); and (c) the \( d_{xy} \) and \( d_{z^2} \). Each of these parts is an extended \( t'-t'' \rightarrow J'-J'' \) model and is characterized by different coupling constants and filling factors. For the undoped material the second subspace alone prefers a ground state characterized by a spin-density-wave order similar to that observed in recent experimental studies, while the other two subspace prefer \( (\pi, \pi) \) antiferromagnetic order. The observed spin-density-wave order is imposed by the \( d_{z^2} \) subspace as the ground state of the total Hamiltonian of the undoped parent compounds. However, due to the above mentioned frustration the magnetic moment is small in agreement with observation. Our calculation illustrates in a simple manner the reason for the difference in the magnetic ordering between the Fe-pnictides and the cuprates. It also suggests a different evolution of the magnetic order upon electron versus hole doping.

Thursday, March 19, 2009 2:30PM - 5:06PM — Session X36 DCMP: Glassy, Amorphous, and Quasicrystalline Materials 408

2:30PM X36.00001 Using First-Principles Calculations to Describe Amorphous Metal Films for Hydrogen Purification, SHIQIANG HAO, MIKE WIDOM, DAVID SHOLL, GEORGIA INSTITUTE OF TECHNOLOGY TEAM, CARNEGIE MELLON UNIVERISTY TEAM — The increasing demand for clean and efficient energy has resulted in an increased global willingness to embrace the proposed hydrogen economy. The use of amorphous metal films as membranes to purify hydrogen has potential to overcome at least some of the disadvantages of existing crystalline metal membranes. We introduce a general strategy combining density functional theory and statistical mechanics to quantitatively predict solubility, diffusivity and permeability of interstitial \( H \) in amorphous metals. Our methods make it possible for the first time to quantitatively evaluate the performance of amorphous metal films as hydrogen purification membranes. These methods are introduced by examining amorphous Fe3B and a crystalline analogue with the same composition. A membrane made from the amorphous material is predicted to have a hydrogen permeability 1.5-2 orders of magnitude higher than a crystalline membrane. The methods we introduce here will be useful in accelerating the development of amorphous membranes for practical applications.
Can be improved by partially replacing elements such as boron and carbon that create ionic and covalent bonds with other elements such as phosphorous that do not contain phosphorus, and the Poisson’s ratios obtained are correspondingly high. The ductility of amorphous steels can be improved by chemically tuning the increased with the decrease in shear modulus. The shear moduli are appreciably lower than those reported for previous amorphous steel compositions that did not contain phosphorus, and the Poisson’s ratios obtained are correspondingly high. The ductility of amorphous steels can be improved by chemically tuning the elastic properties which are determined by the amorphous structure and chemical bonding. First-principles electronic structure calculations show that ductility can be improved by partially replacing elements such as boron and carbon that create ionic and covalent bonds with other elements such as phosphorous that favor metallic cohesion.

2:42PM X36.00002 Atomic structure of PdNiP bulk metallic glass from ab initio simulations. VIJAY KUMAR, Dr. Vijay Kumar Foundation, Gurgaon, India; T. FUJITA, M.W. CHEN, WPI-AIMR, Tohoku Univ. Sendai, Japan; A. INOUE, Tohoku Univ., Sendai, Japan; Y. KAWAZOE, IMR, Tohoku Univ. Sendai, Japan — The atomic structure of Pd40Ni40P20 bulk metallic glass (BMG) has been simulated using ab initio molecular dynamics plane wave method and PAW pseudopotentials. We use generalized gradient approximation to calculate the exchange-correlation energy and a cubic simulation box whose size and shape have been optimized after the BMG has been formed in simulations. The resulting radial distribution function and density agree remarkably well with the experimental data. The structure is analysed in terms of local clusters centered around Pd, Ni and P atoms and their electronic structures have been used to understand the bonding, stability, and the formation of the PdNiP BMG.

2:54PM X36.00003 Role of Electronic Structure on Ductility of Iron-Based Bulk Metallic Glasses1, N. KVALTINE, X.J. GU, S.J. POON, G.J. SHIFLET, University of Virginia, M. WIDOM, Carnegie Mellon University — Composition effects on the mechanical properties of iron-based amorphous steel alloys have been investigated, with attention to the metalloid content and the relative impact of boron, carbon and phosphorous. Phosphorous-containing amorphous steels exhibited enhanced plastic strains and fracture strengths. Moreover, the plastic strain increased with the decrease in shear modulus. The shear moduli are appreciably lower than those reported for previous amorphous steel compositions that did not contain phosphorus, and the Poisson’s ratios obtained are correspondingly high. The ductility of amorphous steels can be improved by chemically tuning the elastic properties which are determined by the amorphous structure and chemical bonding. First-principles electronic structure calculations show that ductility can be improved by partially replacing elements such as boron and carbon that create ionic and covalent bonds with other elements such as phosphorous that favor metallic cohesion.

1Supported by the DARPA Structural Amorphous Metals Program under ONR Grant No. N00014-06-1-0492

3:06PM X36.00004 Bond enthropy trends of high metalloid Fe-based bulk metallic glasses, M. WIDOM, B. SAUERWINE, Carnegie Mellon University, N. KVALTINE, X.J. GU, S.J. POON, G.J. SHIFLET, University of Virginia — Chemical bond types in metal-metalloid glass-forming compounds range from metallic to ioniic and covalent. Iron-rich alloys are dominated by metallic bonding, but charge transfer from iron atoms to highly electronegative metalloid elements such as boron, carbon and phosphorous creates ionicity, and the metalloid bonding is intrinsically covalent. For sufficiently large metalloid content their strong bonding character must increase the shear modulus, leading to an associated increase in brittleness of the material. However, for metalloid fractions below 30%, shear modulus is found to decrease with increasing metalloid content, leading to an associated increase in ductility of the material. We show this unexpected decrease in shear modulus is caused by depletion of the charge density around the iron atoms, weakening the iron-iron bonds. Our calculations are based on Crystal Orbital Hamilton Populations (COHPs) for crystalline structures that locally approximate the amorphous structure.

3:18PM X36.00005 Effect of excess electrons on hexagonal close-packed Mg and the model clusters for bulk metallic glasses, MASAE TAKAHASHI, MIKIO FUKUHARA, AKIHISA INOUE, YOSHIYUKI KAWAZOE, Tohoku University — Though empirical rules for a large glass forming ability (GFA) were proposed, the formation mechanism of the bulk metallic glasses (BMGs) and the main factors for the GFA have not been clearly elucidated. The advantages of Mg-based BMGs are the lightness and abundance of resources, and a wide supercooled liquid region with the very high thermal stability and extremely large GFA. In 1991, Inoue et al developed glassy Mg–Cu–Y alloys with a maximum diameter of 4.0mm. We report here the effect of excess electrons on hexagonal close-packed Mg and the model clusters explained by an inflation process using density functional theory-based calculations, in order to understand the role of conduction electron concentration (CEC) in Mg-based BMGs [M. Takahashi et al., J. Phys. D: Appl. Phys. 2008, 41, 155424]. The CEC of Mg increase in Mg-based BMGs. In our model calculations, the increased CEC is artificially realized by the injection of electrons into Mg clusters and hcp Mg. We find the volume expansion and distortion to a higher c/a ratio in the negative charge state. The increase in the values corresponding to the c/a ratio is also observed in the model clusters. In the density of states at the equilibrium cell parameters expanded by charging, the pseudogap near the Fermi level by α–π mixing becomes small and a spiky structure appears.

3:30PM X36.00006 Toward Understanding the Giant Frictional Anisotropy on AlNiCo. KEITH MCLAUGHLIN, HEATHER HARPER, DAVID RABSON, University of South Florida — In a 2005 article in Science [309, 1354], Park et al. measured in vacuum the friction between a coated atomic-force-microscope tip and the clean two-fold surface of an AlNiCo quasicrystal. Because the two-fold surface is periodic in one direction and aperiodic (with a quasiperiodicity related to the Fibonacci sequence) in the perpendicular direction, frictional anisotropy is not unexpected; however, the magnitude of that anisotropy in the Park experiment, a factor of 8, is unprecedented. By eliminating chemistry as a variable, the experiment also demonstrated that the low friction of quasicrystals must be tied in some way to their quasiperiodicity. Through molecular-dynamics simulations with pair potentials on quasiperiodic approximants, we investigate generic geometric mechanisms that might give rise to this anisotropy.

3:42PM X36.00007 Does the morphology of fracture surfaces reveal the structure of quasicrystals? LUC BARBIER, DANIEL BONAMY, CEA, Saclay, France; LAURENT PONSON, California Institute of Technology, Pasadena, USA — The roughness of surfaces obtained by cleavage of l-AlPdMn quasicrystals at room temperature are analyzed using tools of quantitative fractography. From the atomic scale up to 3 nm, they are shown to exhibit scale invariance properties hiding the cluster (0.45 nm) aperiodic structure. These properties are quantitatively similar to those observed on various disordered materials, albeit on other ranges of length scales. These properties are interpreted as the signature of damage mechanisms occurring within a 3 nm wide zone at the crack tip. The size of this process zone finds its origin in the local temperature elevation at the crack tip. This effect is not expected to be responsible for a transition from a perfectly brittle behavior to a nanoductile one. It explains also why the cluster structure of quasicrystals is not revealed on the fracture surfaces of l-AlPdMn broken at room temperature.

3:54PM X36.00008 Quasicrystal Growth and Thermal Expansion, SALLY JUNE TRACY, JASON COOLEY, HEATHER VOLTZ, JASON LASHLEY, Los Alamos National Laboratory — We have grown Au-Mn-Pd and RE-Mg-Zn quasicrystals (RE=Y, Er, Ho, Dy and Tb) from a high temperature metallic solution using a self-flux method with melt compositions presented in previous work by Canfield and Fisher1 The samples showed dodecahedral grains with pentagonal facets. The icosahedral structure was revealed with x-ray powder diffraction. We were able to index the diffraction patterns using Cahn’s two index scheme2 We have measured the thermal expansion of these samples and will present this data.

1High temperature solution growth of intermetallic single crystals and quasicrystals; Canfield, P.C.; Fisher, I.R., Journal of Crystal Growth (May 2001) Vol. 255, is 2-4, p. 155-161
2Indexing of icosahedral quasiperiodic crystals; Cahn, J.W.; Shechtman, D.; Gratias, D., Journal of Materials Research (Jan.-Feb.) vol. 1, no. 1, p. 13-26
A surprising result is confirmed by both DFT and Configuration Interaction. That both structures must be present in the cluster beam, even in cases where the higher energy isomer is up to 0.5 eV higher than the ground state. This is due to the fact that the photoelectron spectrum of small NbC<sub>n</sub> clusters is variable effects of doping on the electronic structure depending on the precise geometry and electron count. 

We calculate the photoelectron spectrum of small NbC<sub>n</sub> clusters using Dynamical X-ray scattering [1]. Under field, anisotropic translational dynamics and aging are observed. Moreover, a strong anisotropic cooperativity is reported, almost hundred times larger in the parallel direction. The results are discussed using a phenomenological picture. [1] E. Wandersman et al., J. Phys. Cond. Mat. 20 (2007) 155104

Gradient interactions and the low temperature universality in glasses, MOSHE SCHECHTER, PHILIP STAMP, University of British Columbia — Amorphous solids show striking universal characteristics at low temperatures, including unique temperature dependencies of the specific heat, thermal conductivity and internal friction, and a small and rather constant ratio between a phonon wavelength and its mean free path. These universal phenomena are observed in polymers and disordered lattices as well. The standard tunneling model proposed by Anderson, Halperin and Varma, and Philips, accounts well for much of the observed phenomena. However, questions regarding the nature of the two-level systems, the smallness of the above ratio, and the energy scale dictating the temperature range of the phenomena, remain unanswered. We propose a theory that suggests an answer to these questions, along with an explanation of the additional observed phenomena connected with the universal behavior. Our theory is rigorously derived for disordered lattices, and we argue for the plausibility of its applicability to amorphous solids.

Moment based approach to electronic structure calculations: applications to ordered and disordered systems, HIRO SHIMOYAMA, The University of Southern Mississippi, PARTHAPRATIM BISWAS, University of Southern Mississippi — We solve the classical moment problem via maximum entropy optimization to calculate the electronic density of states for ordered and disordered solids. The method employs the Shannon entropy functional and maximize it subject to the moment constraints to construct the spectral distribution of large Hamiltonian-matrices. We illustrate the efficiency and usefulness of the method by applying three candidate systems: a crystalline semiconductor, an amorphous material; and a completely disordered system via tight-binding Anderson model Hamiltonian. The band energy and Fermi level are computed from the reconstructed density of states with a high degree of precision. A possible extension of this method to calculate electronic forces is also discussed.

What is a dynamical glass transition?, CLAUDIO CHAMON, Boston University, CLAUDIO CASTELNOVO, DAVID SHERRINGTON, University of Oxford — Using the mapping between the Fokker-Planck description of classical stochastic dynamics into a quantum Hamiltonian, we argue that a dynamical glass transition must have a precise definition in terms of a quantum phase transition. At the static level, the transition affects the ground state wavefunction: while in some cases it could be picked up by the expectation value of a local operator, in others the order may be non-local, and impossible to be determined with any local probe. In general, even in the absence of a local order parameter, the transition can be detected via the quantum fidelity of the groundstate wavefunction, which we show translates directly into a singularity in the heat capacity of the classical system. We illustrate these ideas using exact diagonalizations of the mapped Hamiltonians for the p-spin models and the gonihedric model.

Session X37 DCP: Spectroscopy and Dynamics of Single Molecules and Nanoparticles

Reactivity of Aluminum and Doped Aluminum Clusters, ARTHUR REBER, SHIV KHANNA, Virginia Commonwealth University, PATRICK ROACH, WILLIAM WOODWARD, A. WELFORD CASTLEMAN JR., Penn State University — We examine the reactivity of aluminum cluster anions with water, and other nucleophiles. The clusters reveal size dependent reactivity which primarily results in either the chemisorption of one or more water molecules, or no observable reactivity. The reactivity of the clusters is found to be dependent on surface sites which facilitate the splitting of the water on the surface of the cluster. Clusters with two sets of active sites are found to selectively release molecular Hydrogen. We also investigated the reactivity of aluminum clusters doped with another metal and their reactivity with molecular Oxygen. As the reactivity of aluminum clusters with oxygen depends on the electronic shell closing, this serves as a probe of the effects of doping on the electronic shell structure. The results reveal variable effects of doping on the electronic structure depending on the precise geometry and electron count.

Multiple Isomers in the Photoelectron Spectra of NbC<sub>n</sub> clusters, IVAN IORDANOV, JORGE SOFO, Department of Physics, Penn State — We calculate the photoelectron spectrum of small NbC<sub>n</sub> clusters (2<n<7), to identify the atomic structure that best matches experimental photoelectron spectra. We use Density Functional Theory calculations to find all stable isomers. In order to obtain more accurate spectra, we use the Symmetry Adaptor Cluster Configuration Interaction method for the smaller clusters where the highly correlated niobium d-orbitals dominate the electronic structure. The most stable isomer configurations are linear and cyclic structures, with the cyclic being the ground state for all but NbC<sub>6</sub>. To fully explain all experimental observations we are required to use the combined spectra of both ring and linear structures. This means that both structures must be present in the cluster beam, even in cases where the higher energy isomer is up to 0.5 eV higher than the ground state. This surprising result is confirmed by both DFT and Configuration Interaction.

2:34PM X37.00003 Photoelectron Velocity Map Imaging and Density-Functional Investigation of Bismuth and Lead Anions Solvated in Ammonia. KRISTEN CASALENUVO, Department of Physics, Virginia Commonwealth University, Richmond VA, 23284, MOHAMED A. SOBH, Departments of Chemistry and Physics, The Pennsylvania State University, University Park, PA 16802, J. ULISES REVELES, Department of Physics, Virginia Commonwealth University, UJJWAL GUPTA, Departments of Chemistry and Physics, The Pennsylvania State University, SHIV N. KHANNA, Department of Physics, Virginia Commonwealth University, A.W. CASTLEMAN, JR., Departments of Chemistry and Physics, The Pennsylvania State University, SHIV KHANNA RESEARCH GROUP COLLABORATION, THE CASTLEMAN GROUP COLLABORATION — We present the results of photoelectron velocity map imaging experiments for the photodetachment of small negatively charged Bi, and Pb, \( n = 1-2 \) clusters solvated in ammonia using a Nd:YLF 527 nm laser. We report the vertical detachment energies of the observed multiple electronic bands and their respective anisotropy parameters derived from the photoelectron images. Density-functional theory calculations with generalized gradient approximation for the exchange-correlation potential were performed on these clusters to determine their molecular and electronic structures. Calculated ammonia binding energies and electronic charge transfers are used to rationalize the observed mass spectra distributions.

3:06PM X37.00004 Dielectric Phorephoresis and Dissociation of Micelles in AC-Electric Fields. VICTORIA FROUDE, YINGXI ELAINE ZHU, University of Notre Dame — Dielectrophoresis (DEP) of natural and synthetic colloids has been explored as a new route to rapidly manipulate and assemble colloidal particles in suspensions. Most work has been done with micron to submicron sized particles, yet AC-polarization and dielectric phorephoresis may provide facile methods to manipulate smaller particles. In this work we explore DEP and the dielectric phorephoresis of 10-100 nm polystyrene latex micelles. We find that the phorephoretic response of the micelles is modified by an AC field. This response can be tuned by the field strength and is sensitive to the micelle concentration, from which the DEP crossover frequency switching between the positive and negative DEP response is determined. Surprisingly, we also observe the AC-field induced dissociation of the micelle structure and the resultant release of fluorescent encapsulates at a characteristic low AC-field frequency of 1-10 kHz; the dissociation frequency can be tuned by encapsulated molecules with a strong dependence of their surface conductivity, which could have a potential application for controlled drug release by AC-electric fields.

3:18PM X37.00005 Raman Correlation Spectroscopy. MAKI NISHIDA, EDWARD VAN KEUREN, Georgetown University — We have developed a simple method for measurement of diffusion coefficients of specific components in complex mixtures of nanoparticles in a suspension. As a variation of Dynamic Light Scattering (DLS), this method analyzes temporal fluctuations of Raman scattered light from particles caused by Brownian motion. Due to the coherent nature of Raman scattering, the time autocorrelation functions of Raman emission lines will yield similar information as that obtained by DLS. Because each Raman emission line arises from a specific type of a molecular bond, only the diffusion coefficient of the particles containing that specific chemical species is measured. We demonstrate that this method can isolate diffusion coefficients from individual components in multicomponent nanoparticle dispersions.

3:30PM X37.00006 Nanosphere Templating Through Controlled Evaporation: A High Throughput Method For Building SERS Substrates. KRISTEN ALEXANDER, UNC Department of Chemistry, RENE LOPEZ, UNC Department of Physics, JOSEPH DESIMONE, UNC Department of Chemistry — When a pair of noble metal nanoparticles are brought close together, the plasmonic properties of the pair (known as a “dimer”) give rise to intense electric field enhancements in the interstitial gap. These fields present a simple yet exquisitely sensitive system for performing single molecule surface-enhanced Raman spectroscopy (SM-SERS). Problems associated with current fabrication methods of SERS-active substrates include reproducibility issues, high cost of production and low throughput. In this study, we present a novel method for the high throughput fabrication of high quality SERS substrates. Using a polymer templating technique followed by the placement of thiolated nanoparticles through meniscus force deposition, we are able to fabricate large arrays of identical, uniformly spaced dimers in a quick, reproducible manner. Subsequent theoretical and experimental studies have confirmed the strong dependence of the SERS enhancement on both substrate geometry (e.g. dimer size, shape and gap size) and the polarization of the excitation source.

3:42PM X37.00007 Resolving Single Molecule Dynamics with a Point-Functionalized Single-Walled Carbon Nanotube. DANNY W. WAN, ISSA S. MOODY, BRETT R. GOLDSMITH, JOHN G. CORONEUS, GREGORY A. WEISS, PHILIP G. COLLINS, Departments of Physics and Astronomy, Chemistry, Molecular Biology and Biochemistry, University of California, Irvine, CA 92697-4576 — We have achieved an unprecedented level of molecule-specific measurement of single molecule dynamics using a point-functionalized SWCNT electronic circuit [1]. Time-dependent components of the SWCNT conductance reveal real-time interactions between a covalently attached protein and the immediate electrodynamic environment. We will demonstrate electronic transduction of protein-substrate interactions with single molecule resolution. On-line analysis based on normalization of the power spectrum helps to enhance the resulting signals, even to the extent of providing the user with real time feedback regarding the experiment status. [1] B. Goldsmith et al, Science 315 77 (2007)

3:54PM X37.00008 Auger Rate Quenching in Nanocrystals. GEORGE E. CRAGG, Naval Research Laboratory, Washington, DC 20375, XIAOXI WANG, HUNG H. HU, Department of Chemistry, University of Rochester, Rochester, NY 14627, SARA MACCAGNANO-SCAGLIONE, ANDREW CHRISTIANSON, Oak Ridge National Laboratory, — We measured the far infrared vibrational properties of bulk and nanoscale MoS2 and MnO nanoparticles using the Photoelectron Velocity Map Imaging (P-VMI) technique. We find that the Auger rate suppression of the Auger rate has been suggested as the underlying mechanism for the non-blinking PL observed in soft-confinement, single CdZnSe/ZnSe NCs. To probe the interplay between the confinement geometry and the PL, we employ a coupled, two-band NC model which is analyzed with numerical routines based on the propagation matrix formalism. The results obtained will verify whether smooth confining potentials mitigate the Auger process, thereby eliminating blinking by allowing NCs to photoluminesce even in their charged state.
Ultrafast electronic energy redistribution in hollow gold nanoparticles. KENNETH KNAPPENBERGER, Florida State University, ADAM SCHWARTZBERG, LBNL — Nanostructured materials offer great potential for novel ways to generate, utilize, store and transport energy. These unique opportunities arise because nanoclusters often portray strikingly different chemical and physical properties than their bulk counterparts, and, perhaps more intriguingly, these vary widely with cluster size and shape. Here we report on the redistribution of electronic energy to thermal phonons in a series of hollow gold nanoparticles using femtosecond transient absorption. Qualitatively, the relaxation processes are similar to those of solid nanoparticles, however distinct differences are observed, likely owing to the unique properties of the hollow structures. In particular, a larger excitation power density is required to observe coherent vibrational oscillations in hollow gold nanoparticles than is needed for solid particles following electronic excitation. This effect is systematically studied over a range of hollow and solid particles, including multiple diameters and wall thicknesses. Models will be presented to account for the different relaxation mechanism observed for hollow and solid gold nanoparticles.

Optical spectra with spin-orbit effects on gold nanostructures. ALDO ROMERO, CINVESTAV, México, ALBERTO CASTRO, Institufur Theoretisch Physik, Freie Universitat Berlin, MIGUEL MARQUES, Université Lyon, France, MICAEL OLIVEIRA, University of Coimbra, Portugal, ANGEL RUBIO, ETSF, Universidad del País Vasco, Spain — The quest for more efficient optoelectronic devices requires a thorough understanding of the intrinsic properties of the metallic nanostructures such as the optical spectra. Many optoelectronic devices are based upon gold nanoparticles but even though, there is a large set of experimental studies, little is known theoretically. Between the concerns, it is important to identify where the spin-orbit effect has its optical spectra on the nanostructured materials. We report here the analysis of the effect of the spin-orbit interaction on the shape of the photoabsorption cross section of small gold clusters (Au$^+_n$, $n \leq 8$ and $n = 20$) and small nanowires ($n \leq 7$). As it is shown, the spin-orbit coupling has a strong effect on the absorption spectra mainly for nanowires and much less effect on static properties such as the dipole static polarizability. This has strong implications on transport calculations where no spin-orbit effects are considered.

First-principles studies of surface-enhanced Raman scattering: Benzene thiol on Au. ALEXEY ZAYAK, Department of Electrical Engineering and Computer Science, UC-Berkeley, CA, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory, Berkeley, CA — First-principles calculations based on density functional theory are used to investigate how chemisorption of organic molecules on metal surfaces affects their Raman spectra. Experiments have long reported Raman intensity enhancements of orders of magnitude for molecules on rough metal surfaces or near nanofabricated metallic tips. The goal of this work is to explore "chemical" effects that may contribute to this enhancement, specifically hybridization and charge transfer between the molecule and its metallic substrate. We consider benzene thiol chemisorbed on extended Au(111) surfaces and finite Au and Ag clusters. Using a finite-difference scheme, we compute the absorption site, molecular orientation, and coverage dependence of Raman-active phonon modes and their intensities. We also examine how the electronic structure of the molecule is modified in each case, and discuss implications for the strength of Raman processes.

Photoluminescence anti-blinking of single CdZnSe/ZnSe nanocrystals. XI-AOYONG WANG, Department of Chemistry, University of Rochester, XIAOFAN REN, KEITH KAHEN, Eastman Kodak Company, MEGAN HAHN, Department of Chemistry, University of Rochester, MANJU RAJESWARAN, Eastman Kodak Company, SARA MACCAGNANO-ZACHER, JOHN SILCOX, School of Applied and Engineering Physics, Cornell University, GEORGE CRAGG, ALEXANDER EFROS, Naval Research Laboratory, TODD KRAUSS, Department of Chemistry, University of Rochester, UNIVERSITY OF ROCHESTER TEAM, EASTMAN KODAK COMPANY COLLABORATION, CORNELL UNIVERSITY COLLABORATION, NAVAL RESEARCH LABORATORY COLLABORATION — We have synthesized soft-confinement nanocrystals (NCS) of CdZnSe/ZnSe that on the single particle level exhibit complete elimination of photoluminescence (PL) blinking. These continuously emitting NCS have a very short PL decay lifetime of 5 ns. Moreover, single CdZnSe/ZnSe PL spectra are highly unusual with three distinct peaks. These unique and remarkable optical properties are collectively explained by the radiative recombination of a trion due to suppressed Auger processes in a NC. Upon deformation of the soft-confinement potential, the PL intensity of a single CdZnSe/ZnSe NC switches between two bright states, but still never turns off. Possible mechanisms for this PL anti-blinking behavior will be discussed.

Single-Electron Spectroscopy of Quantum Dots using Vertically Self-aligned Electrode Structure. RAMKUMAR SUBRAMANIAN, PRADEEP BHADRACHALAM, VISHVA RAY, SEONG JIN KOH, The University of Texas at Arlington — We demonstrate single-electron tunneling spectroscopy of individual quantum dots using new vertical electrode structure, where the source and drain electrodes are vertically self-aligned and separated by a thin dielectric spacer. A quantum dot placed on the periphery between the source and the drain electrodes forms a double barrier tunnel junction, allowing for single-electron spectroscopy measurements. CMOS compatible fabrication allows many quantum dot units to be fabricated in parallel processing. This technique not only provides an accurate electronic structure of a single quantum dot, but such measurement can be made for many of individual quantum dot units fabricated in a single batch process. Thus, this simple procedure provides a powerful tool to study quantum dot properties, and allows for the measurement of both the single and collective properties of quantum dots.

Session X38 DCP: Focus Session: Ion Channel Physics and Chemical Physics II
We have measured the global radiation sensitivity of model protein crystals as a function of temperature in the range 300 K to 100 K. Our data show three regimes, each characterized by a different activation energy for radiation damage being diffusion limited. Below 160 K, the activation energy is very small, and the cluster structure and individual channels are imaged simultaneously in a total internal reflection microscope. While most Kv2.1 channels in the cell are labeled with green fluorescent proteins (GFP), only a few individual channels are tagged with red quantum dots. This approach allows us to track single molecules and probe their interaction with the cluster perimeter. Different models for the molecular mechanism that localizes Kv2.1 clusters on the cell surface and the implications of our data will be discussed.

From 225 to 160 K, the activation energy is consistent with radiation damage being diffusion limited. Below 160 K, the activation energy is very small, and the cluster structure and individual channels are imaged simultaneously in a total internal reflection microscope. Antifreeze proteins (AFP) and glycoproteins (AFGP) help fish, plants, insects and bacteria survive sub-freezing environments. It is well known that these proteins function via some surface interaction, but the exact mechanism has eluded scientists. Aside from mutagenesis experiments directed towards examining the functional importance of specific residues, conclusions about the mechanism have been drawn from indirect studies or more precisely from studies that describe the proteins effects on the ice interface. Our work is aimed at directly studying the protein kinetics at the ice/solution interface. Fluorescent microscopy is used to determine interaction planes, surface concentrations as well as adsorption characteristics and the segregation constants, while fourier transform infra-red attenuated total reectance (FTIR-ATR) is used to determine the protein structure vs. temperature in the liquid and solid states as well as the ice interface characteristics. All data show that AFGP do not function by the characteristic Gibbs-Thomson mechanism. While the surface coverage is similar for the AFPIII, segregation (amount in ice/amount in solution) is non-zero.

5:06PM X39.00010 ESR Spectroscopy Provides Direct Evidence of Cu$^{2+}$ Coordination by Three Histidine Residues in Aβ$_{1-10}$1. BYONG-KYU SHIN, SUNIL SAXENA, University of Pittsburgh — We provide direct evidence that all three histidine residues in amyloid-β$_{1-10}$ (Aβ$_{1-10}$) coordinate to Cu$^{2+}$. In our approach, we generate three Aβ$_{1-10}$ analogues, in each of which a selected histidine residue is isotopically enriched with $^{15}$N. Pulsed electron spin resonance (ESR) experiments such as electron spin echo envelope modulation (ESEEM) and hyperfine sublevel correlation (HYSCORE) clearly show that each of the three histidine imidazole rings at position 6, 13, and 14 in Aβ$_{1-10}$ binds to Cu$^{2+}$ as each of the three Cu$^{2+}$-$^{15}$N-labeled Aβ$_{1-10}$ complexes displays ESEEM and HYSCORE spectra which are distinctively different from those of the Cu$^{2+}$-nonlabeled Aβ$_{1-10}$ complex. The method employed here does not require either chemical side-chain modification or amino acid residue replacement, each of which is traditionally used to determine whether an amino acid residue in a protein binds to a metal ion. We also find that the histidine coordination in Aβ$_{1-10}$ is independent of the Cu$^{2+}$-to-peptide ratio, which is in contrast to the case of Aβ$_{1-40}$. The ESR results suggest tight binding between the histidine residues and the Cu$^{2+}$ ion, which is likely the reason of the high binding affinity of Aβ peptide to Cu$^{2+}$.

5:18PM X39.00011 Force Spectroscopy of Iron in Nitrosylated Hemes. J.T. SAGE, A. BARABANSCHIKOV, W. ZENG, Northeastern University, N.J. SILVERNAIL, W.R. SCHEIDT, Notre Dame University — Nitric oxide (NO) regulates important physiological processes by interacting with the Fe atom in heme proteins. We investigate the effect of NO binding on the local structure and dynamics of $^{57}$Fe by determining its vibrational density of states (VDOS), both experimentally, using nuclear resonance vibrational spectroscopy (NRVS) and computationally, using density functional theory (DFT). All Fe-ligand modes contribute to the VDOS, which provides uniquely quantitative information on the frequency, amplitude, and direction of the Fe motion. The VDOS also yields an experimental value for the stiffness, an effective force constant that probes nearest-neighbor interactions by measuring the force required to displace the Fe with the surrounding atoms fixed. Although vibrational mixing between Fe-NO stretching and FeNO bending character complicates structural interpretations of FeNO vibrations observed near 450 and 560 cm$^{-1}$, we find that the former mode contributes more strongly to the stiffness, indicating its sensitivity to the strength of the Fe-N bond. Comparison with DFT predictions identifies a feature observed near 130 cm$^{-1}$ in the VDOS of nitrosylated myoglobin as a vibration of the covalent link to the protein. We find that NO binding alters the interaction of the heme Fe with its local environment, and may facilitate NO recognition by heme proteins.

Thursday, March 19, 2009 2:30PM - 5:06PM — Session X40 DBP: Proteins in Membranes 412

2:30PM X40.00001 Copper coordination in the Glycine receptor by electron spin resonance. SHARON RUTHSTEIN, KATHERINE STONE, University of Pittsburgh, MICHAEL CASCIO, University of Pittsburgh School of Medicine, SUNIL SAXENA, University of Pittsburgh, SUNIL SAXENA’S GROUP TEAM, MICHAEL CASCIO’S GROUP TEAM — We describe the use of Electron Spin Resonance (ESR) to identify the coordination environment of copper in the extracellular domain of the protein, as well as the number of copper atoms that bind to Glycine receptor (GlyR). The GlyR channel mediates inhibitory neurotransmission in the central nervous system. It belongs to the superfamily of nicotinoid receptors. These receptors are formed by pentameric arrangement of subunits, each sharing a common topology having a large extracellular domain (ECD) and a transmembrane (TM) domain comprised of four membrane-spanning segments (TM1-TM4). For GlyR, four subunits (1-4) and one subunit have been identified to date, although the homomeric expression of just the α1 subunit of GlyR is sufficient to reconstitute native-like activity. The results are expected to shed light on the role of metals ion in modulating ion permeation in such receptor. In addition, an identification of copper binding sites will allow the measurement of large range distance constraints in the receptor by pulsed ESR. Such structural information on the GlyR in various allosteric states is essential in order to shed light on the gating mechanism of this protein membrane.

2:42PM X40.00002 Probing interaction of antimicrobial peptide duramycin with lipid monolayers. IZABELA I. RZEZNICKA, Riken, Advanced Science Institute, Wako-shi, Japan, MARIA SOVAGO, MISCHA BONN, Amolf, Institute for Atomic and Molecular Physics, Amsterdam, The Netherlands, TOSHIHIDE KOBAYASHI, TARO YAMADA, Riken, Advanced Science Institute, Wako-shi, Japan, MAKIKAWAI, Riken, Advanced Science Institute, Wako-shi, Japan. Department of Advanced Materials Science, The University of Tokyo, Japan — Antimicrobial peptides are group of peptides which disrupt the microbial cell membrane through hydrophobic insertion into the outer lipid layer. Duramycin is a small tetracyclic peptide antibiotic, which has recently been shown to bind specifically to phosphatidylethanolamine (PE) lipids. We report the interaction of duramycin with phospholipid monolayers at air-water interface, studied using vibrational sum-frequency generation spectroscopy (VSFG) and fluorescence microscopy (FM). For monolayers containing PE lipids, VSFG reveals binding of duramycin to the monolayer through the appearance of a vibrational peak at 3045 cm$^{-1}$, corresponding to the C-H stretching vibration of phenylalanine amino acid. In addition, the amide I vibrational region shows that peptide has a β sheet conformation. Similar experiments performed on phosphatidylcholine (PC) monolayers show the interaction is specific with PE.

2:54PM X40.00003 Alamethicin Structure in Lipid Bilayers1. STEPHANIE TRISTRAM-NAGLE, JIAN-JUN PAN, Biol. Phys. Group, Physics Dept., Carnegie Mellon University, Pittsburgh, PA, JOHN NAGLE, Dept. Biol. Sci. and Physics Dept., Carnegie Mellon University, Pittsburgh, PA — This investigation uses x-ray diffuse scattering and MD simulations to study alamethicin (Alm) in fully hydrated bilayers of DOPC and diC22:1PC. Comparison of the experimental and simulated form factors supports the standard conclusion that Alm helices are inserted transmembrane along the bilayer normal at high humidity and high concentrations. Little change in membrane thickness with inserted Alm helices occurs for DOPC up to 1/10 Alm/DOPC. By contrast, the x-ray data strongly indicate that the diC22:1PC membrane, which is thicker than DOPC by 7 Å, thins with added Alm. Fitting the data to models of the electron density gives a decrease in thickness of 4 Å at 1/10 Alm/diC22:1PC. Although Alm’s helical length is close to the hydrophobic thickness of DOPC (27 Å), it is mismatched with the thicker diC22:1PC. Alm decreases the bending modulus (K$_{B}$) by a factor of ~2 in DOPC and a factor ~4 in diC22:1PC membranes at P/L ~1/10. Determination of the B modulus reveals a large increase in Hamaker parameter when Alm is added to diC22:1PC, but not to DOPC.

1This research was supported by NIH Grant No. GM 44976 and NIH/NIGMS under NSF award DMR-0225180 to CHESS.
behavior induced by these different peptides we will discuss the importance of amino acid composition and placement on membrane rearrangement.

The relationship between membrane composition and peptide induced changes in membrane curvature and topology is examined. By comparing the membrane phase transitions, we observe that the protein preferentially adsorbs on smaller vesicles, of diameter similar to the size of the bacterial spore ($\sim 1 \mu m$). Using fluorescent GFP-tagged SpoV, we quantify the amount of adsorbed protein by confocal microscopy. Our results, when interpreted using existing protein adsorption models, suggest the existence of a cooperative adsorption mechanism for high enough membrane curvature, which involves the formation of small clusters of proteins. Membrane curvature could be a general cue for protein localization in bacteria.

We thank a UMass Biomedical Innovation Initiative Grant and the NSF IGERT Program in Nanotechnology Innovation at the University of Massachusetts Amherst for funding.

We have developed several models to enhance our understanding of the effect of proteins in cell membranes, on phase separation, budding, and coarsening. In this work we investigate the effect of membrane hydration and hydrophobic mismatch on the Alm channel superstructure in an oriented multilayer sample by x-ray scattering. Wide angle x-ray (WAXS) scattering near 14 nm$^{-1}$ indicates that the lipid chain region is not perturbed much by the incorporation of up to 10 mole percent Alm. Low angle x-ray scattering (LAXS) indicates that when the sample is very dry, which promotes interactions between neighboring bilayers, a body centered tetragonal crystal packing of Alm channels is formed. As the hydration level increases closer to biological conditions, the separation between bilayers increases, the interbilayer interactions weaken, and the crystalline order disappears while considerable diffuse scattering remains. The effect of hydrophobic mismatch is examined for two mono-unsaturated lipids, diC18:1PC and diC22:1PC, that differ in bilayer thickness by 0.7nm. There is also in-plane scattering at a medium q of 7nm$^{-1}$ that our analysis suggests may not be from the Alm channel structure.

We thank a UMass Biomedical Innovation Initiative Grant and the NSF IGERT Program in Nanotechnology Innovation at the University of Massachusetts Amherst for funding.

Effects of Proteins and Lipids on Each Other in a Simulated Non-equilibrium Biomembrane Model. ANDREW P. PARADIS, University of Maine Department of Physics & Astronomy, SUSAN R. MCKAY, University of Maine Department of Physics & Astronomy, SAMUEL T. HESS, University of Maine Department of Physics & Astronomy, Institute for Molecular Biophysics — Lateral organization in biomembranes plays a major role in membrane topology, and is thus implicated in many basic functions of biomembranes such as endocytosis and signal transduction. In this study, non-equilibrium Monte Carlo simulations are used to investigate two related scenarios: 1. the effect of a rigid distribution of proteins on the lateral organization of lipids in a biomembrane, and 2. the degree to which lipid interactions influence the lateral organization of membrane-associated proteins that are free to translate laterally. Our model includes generic saturated and unsaturated lipids, proteins, and cholesterol, and is driven out of equilibrium through simulated endo- and exo-cytosis events. By varying the temperature, the protein mole fraction, and the interaction strengths, we examine the conditions under which various types of lateral organization occur. Simulation results are analyzed with pair-correlation functions and the Ripley K-test. We compare results from simulations of the two scenarios above and from simulations of biomembranes lacking protein.

Interactions of Defensins with Model Cell Membranes. LORI K. SANDERS, Dept. of Materials Science and Engineering, UIUC, NATHAN W. SCHMIDT, Dept. of Physics, UIUC, LIHUA YANG, ABHIJIT MISHRA, Dept. of Materials Science and Engineering, UIUC, MICHAEL E. SELSTED, Dept. of Pathology and Laboratory Medicine, UCI, GERARD C. L. WONG, Dept. of Materials Science and Engineering, UIUC — Antimicrobial peptides (AMPs) comprise a key component of innate immunity for a wide range of multicellular organisms. For many AMPs, activity comes from their ability to selectively disrupt and lyse bacterial cell membranes. There are a number of proposed models for this action, but the detailed molecular mechanism of selective membrane permeation remains unclear. Theta defensins are circularized peptides with a high degree of selectivity. We investigate the interaction of model bacterial and eukaryotic cell membranes with theta defensins RTD-1, BTD-7, and compare them to propeptin PG-1, a prototypical AMP, using synchrotron small angle x-ray scattering (SAXS). The relationship between membrane composition and peptide induced changes in membrane curvature and topology is examined. By comparing the membrane phase behavior induced by these different peptides we will discuss the importance of amino acid composition and placement on membrane rearrangement.
4:18PM X40.00010 Membrane fluidity in the presence of membrane-binding peptides, BEATRIZ BURROLA GABILONDO, WOLFGANG LOSERT, University of Maryland, PAUL RANDAZZO, National Cancer Institute — Arf proteins are GTPases that participate in vesicle trafficking inside cells. They are able to interact with membranes through their N-terminus when they are bound to GTP, and they detach from the membrane when GTP is hydrolyzed. The N-terminus of Arf1 (amino acids 2-17) folds into an amphiphilic helix that can insert into lipid bilayers. Arf1 is also myristoylated; it has myristic acid, a 14-carbon fatty acid 'tail', attached to it. We set out to test the hypothesis that the binding of the myristoylated N-terminus of Arf1 to lipid membranes changes the mechanical properties of the membrane, in ways that myristic acid alone or amphotropic peptides alone do not. We use three reporter molecules embedded in vesicles, whose fluorescence emission spectrum depends on the properties of the environment in which they are found, to measure three distinct aspects of membrane fluidity: Bispynene is sensitive to lateral motion along the membrane, Prodan's emission gives a measure of the packing of the head groups, and DPH polarization reflects the packing of the hydrophobic tails. We will present effects found for four molecules (myristic acid, myristoylated and non-myristoylated N-terminus of Arf1, and the ALPS domain of KES) in a concentration-dependent manner, and discuss the importance of these results in the vesicle-trafficking picture.

4:30PM X40.00011 New insights into the bacterial cell wall peptidoglycan architecture, JOHN DUTCHER, AHMED TOUHAMI, University of Guelph, MANFRED JERICHO, Dalhousie University — The molecular architecture of the bacterial cell wall peptidoglycan (saccu) is among the most challenging, yet still unsoled, structural problems in biochemistry. Two models have been proposed: the planar model, in which the glycan strands lie in the plane of the cell surface, and the scaffold model, in which the glycan stands lie perpendicular to the cell surface. We have used atomic force microscopy (AFM) to investigate the molecular structure of this unique biopolymer in the rod-shaped bacterium Bacillus subtilis at high resolution. AFM images recorded in air on single saccu revealed a porous regular network with 25-50 nm-wide peptidoglycan fibers and a 5-25 nm pore size. Interestingly, the new bacterial pole showed a regular structure with the same fiber sizes but with the fibers running in a direction that is almost perpendicular to that observed away from the pole. This finding combined with our previous data on live hydrated bacteria (1) provides new insights into the three-dimensional architecture of the peptidoglycan of Gram-positive bacteria. 1- A. Touhami, M. H. Jericho, and T. J. Beveridge, J. Bacteriol., 2004 186: 3266-3295.

4:42PM X40.00012 An Analytic Study of Molecular Motion in Cell Membranes, ZIYA KALAY, Consortium of the Americas for Interdisciplinary Science and Dept. of Engineering and Mechanics, Univ. of New Mexico, Albuquerque, NM USA, LUCA GIUGGIOLI, Dept. of Engineering and Mechanics, Univ. of New Mexico, Albuquerque, NM USA, AMAL PARRIS, Missouri Univ. of Science and Technology, Rolla, MO, USA, VASUDEV KENKREV, Consortium of the Americas for Interdisciplinary Science and Dept. of Physics, Univ. of New Mexico, Albuquerque, NM USA — We present a theoretical calculation to describe the confined motion of transmembrane molecules in cell membranes. Understanding the motion of membrane-associated molecules, e.g. various types of receptors, has great modern relevance in cell biology. Our study is divided into two parts. In the first, we consider motion in an ordered system and in the second, we investigate the effects of disorder by employing an effective medium approximation. Both are based on Master equations for the probability of the molecules moving as random walkers, and leads to explicit usable solutions including expressions for the molecular mean square displacement and effective diffusion constants. As a result, the calculations make possible, in principle, the extraction of confinement parameters such as mean compartment sizes and mean intercompartmental transition rates from experimentally reported published observations.

4:54PM X40.00013 Detergent interaction with tethered bilayer lipid membranes for protein reconstitution, MATTEO BROCCIO, HAW ZAN GOH, MATHIAS LOESCHE, Carnegie Mellon University — Tethered bilayer lipid membranes (TBLMs) are self-assembled bimolecular layers in which the membrane is separated from a solid substrate by a nm-thick hydrated submembrane space. These model systems are being used in binding studies of peripheral proteins and exotoxins. Here we aim at their application for the reconstitution of water-insoluble integral membrane proteins. As an alternative to fusion of preformed protosomites we study the direct reconstitution of such proteins for applications in biophysics. In particular we show that TBLMs (DOPC – DOPG) were temporarily incubated with a detergent to screen for conditions that keep the detergent-saturated membrane stable and ready to incorporate detergent-solubilized proteins. We assess the electrical characteristics, i.e. specific resistance and capacitance, by means of electrochemical impedance spectroscopy (EIS) under timed incubation with deacylalyzed and deoxycholate detergents in a regime around their critical micelle concentration, 1.8 mM and 0.17 mM respectively and demonstrate the restoration of the TBLM upon detergent removal. Thereby a range of concentration and incubation times was identified, that represents optimal conditions for the subsequent membrane protein reconstitution.

Thursday, March 19, 2009 2:30PM - 4:42PM — Session X41 DMP DCMP: Strongly Correlated Electrons 413

2:30PM X41.00001 Breakdown of the BCS Ground State at a Quantum Phase Transition, RAFAEL JARAMILLO, The University of Chicago, YEJUN FENG, Advanced Photon Source, THOMAS ROSENBAUM, The University of Chicago, JONATHAN LANG, ZAHIR ISLAM, GEORGE SIMON ( IListed in alphabetical order), PETER LITTLEWOOD, Cambridge University — We use hydrostatic pressure to suppress the magnetism in elemental chromium, a simple cubic metal that demonstrates a subtle form of itinerant antiferromagnetism, formally equivalent to the BCS state in superconductors. By directly measuring the associated charge order with x-ray diffraction in a diamond anvil cell at low temperatures, we reveal a continuous magnetism in elemental chromium, a simple cubic metal that demonstrates a subtle form of itinerant antiferromagnetism, formally equivalent to the BCS state in superconductors. We use three reporter molecules embedded in vesicles, whose fluorescence emission spectrum depends on the properties of the environment in which they are found, to measure three distinct aspects of membrane fluidity: Bispynene is sensitive to lateral motion along the membrane, Prodan’s emission gives a measure of the packing of the head groups, and DPH polarization reflects the packing of the hydrophobic tails. We will present effects found for four molecules (myristic acid, myristoylated and non-myristoylated N-terminus of Arf1, and the ALPS domain of KES) in a concentration-dependent manner, and discuss the importance of these results in the vesicle-trafficking picture.

2:42PM X41.00002 Ultrafast photo-induced spin and charge dynamics in correlated electron system, SUMIO ISHIHARA, YU KANAMORI, Department of Physics, Tohoku University, HIROAKI MATSUEDA, Sendai National College of Technology — Photo-induced phenomena in correlated electron system are one of the attractive themes in recent solid state physics. One of the well known examples is magnetism with the perovskite crystal structure. The charge ordered insulating state associated with the antiferromagnetic (AFM) long-range order competes with the ferromagnetic metallic phase. After introduction of the pump photon into the charge-ordered insulating phase, dramatic changes in the optical reflectivity and in the optical Kerr rotation are observed. These results imply that the charge and magnetic structures are changed cooperatively by the photo-irradiation. We present a theoretical study of photo-induced dynamics in a correlated electron system where electronic charge couples with spin and lattice. The generalized double exchange model is analyzed by utilizing the two complementary methods, the exact diagonalization and inhomogeneous Hartree-Fock methods. Time evolutions of the optical absorption spectra, spin correlation, and charge correlation are calculated. There are two time scales in the photo-induced dynamics; the charge and AFM spin orders are collapsed within a short time scale corresponding to 10-100 fs, and the long-range FM spin correlation appears in a long time scale corresponding to a few ps.
3:06PM X41.00004 Probing orbitons in YTiO3 with Resonant Inelastic X-ray Scattering, LUCAS AMENT, Lorentz Institute, Leiden, GINIYAT KHALILULLIN, Max Planck Institute, Stuttgart, JEROEN VAN DEN BRINK, Lorentz Institute, Leiden — In YTiO₃, a strongly correlated electron system with degenerate orbitals, orbitons are predicted to exist [1]. The hallmark of collective excitations is dispersion. To observe the orbiton dispersion, the rapidly developing technique of Resonant Inelastic X-ray Scattering (RIXS) is especially well suited. We analyze recent experimental RIXS data on YTiO₃ in the Ultrashort Core hole Lifetime framework [2]. The Ti ions in this material have a 3d⁹ configuration, and the electron occupies one of the three degenerate t₂g orbitals. Many of this compound’s ground state properties are explained by assuming that the orbitals on these Ti ions talk to each other through a superexchange mechanism [1]. RIXS could couple to the orbital excitations (orbitons) in these kinds of materials in two ways: via modification of the superexchange interactions [3] and via a shakeup process. We compare our theoretical RIXS spectra to experimental ones, giving strong evidence for the existence of orbitons. // [1] G. Khalilullin and S. Okamoto, Phys. Rev. B 68, 205109 (2003) // [2] J. van den Brink and M. van Veenendaal, Europhys. Lett. 73, 121 (2006); L. J. P. Ament, F. Forte and J. van den Brink, Phys. Rev. B 75, 115118 (2007) // [3] compare F. Forte, L. J. P. Ament and J. van den Brink, PRL (2008)

3:18PM X41.00005 Polaronic hole-trapping in doped insulating oxide, CESARE FRANCHINI, GEORG KRESSE, RAIMUND PODLOUCKY, University of Vienna — In transition-metal oxides, local electronic correlation effects dominate the physics, and lattice degrees of freedom are often only treated as external perturbations. However, in systems dominated by s and p electrons, electronic correlation is expected to be less important, and in agreement with this conjecture, we show that lattice degrees of freedom are crucial to account for the hole doping driven insulator-to-metal/superconducting transition (IMT) in Ba₁₋ₓKₓBiO₃. Specifically, by using hybrid-DFT we show that Bi⁵⁺ sites trap two holes from the valence band accompanied by a large local lattice distortion, commonly referred to as bipolaronic state. We show that in pure Bi₃BiO₅ a single peak in the imaginary part of the dielectric function is visible which corresponds to the charge-ordered excitation between Bi⁵⁺ and Bi⁵⁺ sub-bands. Upon hole-doping a second peak emerges at x = 0.125 connected with the bipolaronic excitation. At x = 0.25 the bipolaronic peak increases in intensity and is shifted towards lower energy, thus indicating the incipient IMT observed at x ≈ 0.3. Our results describe all relevant experimental results.

3:30PM X41.00006 Systematic enhancement in magnetic susceptibilities and a study of Fermi Liquid behavior of Re₂Ta₁₀ where Re=Y and La, and T =Fe, Ru, and Os¹, KEESEONG PARK, YURI JANSEN, MOOSUNG KIM, Brookhaven National Laboratory, CARLOS MARQUES, Stony Brook University, MEIGAN ARONSON, Brookhaven National Laboratory — DC and AC magnetic susceptibilities, specific heat and resistivity are measured for YbFe₂Al₁₀-structure compounds, Re₂Ta₁₀ where Re=Y, and La, and T =Fe, Ru, and Os. The YT₂Al₁₀ show mean-field superconducting behavior in magnetic properties from Os to Ru and to Fe, and Fermi-liquid behaviour below around 100 K. With the linear term of the specific heat (γ₀) and the temperature independent susceptibility (χ₀) at low temperature, the Stoner enhancement parameter, Z, is utilized to find how close the compounds are to the ferromagnetic ordering, where Z = 1-(β₆/2γ₀²)穀γ₀/χ₀穀. Specifically, YFe₂Al₁₀ shows a larger Z (0.98) than that (0.83) of Pd, a well known example of nearly ferromagnetic materials. The implied proximity to the quantum criticality is tested by a power law analysis, where 1/(χ₀ − χ₀) =AT⁴ can describe well a wide range (2K to 100K) of AC magnetic susceptibility for YFe₂Al₁₀ with λ = 1.19, which is between the mean-field value (λ = 1) and that of the three-dimensional Ferromagnetic Heisenberg model (λ = 1.33).

3:42PM X41.00007 Soliton Wall Superlattice Charge-Density-Wave Phase in Quasi-One-Dimensional Conductor (Per)₂Pt(mnt)₂², SI WU, ANDREI LEBED, University of Arizona — We demonstrate that the Pauli’s spin splitting effects in a magnetic field improve nesting properties of a realistic quasi-one-dimensional electron spectrum. As a result, a high resistance Peierls charge-density-wave (CDW) phase is stabilized in high enough magnetic fields in (Per)₂Pt(mnt)₂ conductor. We show that, in low and very high magnetic field, the Pauli spin-splitting effects lead to a stabilization of a soliton wall superlattice (SWS) CDW phase, which is characterized by periodically arranged soliton and anti-soliton walls. We suggest experimental studies of the predicted first order phase transitions between the Peierls and SWS phases to discover a unique SWS phase. It is important that, in the absence of the magnetic field and in the limit of very high magnetic field, the suggested model is equivalent to the exactly soluble model of Brazovskii, Dzyaloshinskii, and Kirova.

3:54PM X41.00008 Non Fermi Liquid behavior and disorder in BaVS₃, ANA AKRAP, Brookhaven National Laboratory, Upton, New York, NEVEN BARISIC, Universitaet Stuttgart, Germany, FLORENCE RULLIER-ALBENQUE, SPEC, Orme des Merisiers, CEA, GIF sur Yvette, France, HELMUTH BERGER, LASZLO FORRO, Institut de Physique de la matiere complexe, EPFL, Lausanne, Switzerland — In strongly correlated BaVS₃, the interplay between a wide one-dimensional d² band and the localized ν₁ electrons leads to a wealth of electronic phases. In this work we investigate the high pressure non-Fermi liquid (NFL) phase of BaVS₃ by means of transport measurements, focusing on the influence of disorder, introduced by fast electron irradiation and sulfur deficiency. Our results are interpreted within a novel scenario in which quasi-one-dimensional 2kF-CDW fluctuations are responsible for the NFL behavior [3].

4:06PM X41.00009 The role of charge degrees of freedom in Mott insulators: coupling of dielectric and magnetic properties in Cr-trimer complexes, ROSS MCDONALD, OSCAR AYALA VALENZUELA, MARCELO JAIME, NHMFL-Los Alamos, JOHN MYDOSH, University of Koln — Materials that are insulating owing to strong electron correlations are pervasive in condensed matter physics—the parent phase of high-Tc cuprates, colossal magnetoresistive manganites and quantum magnets. All are characterized by a large onsite Coulomb repulsion relative to the dominant electron hopping. As such, at half-band filling the charge is localized. The independent properties of these materials are therefore controlled solely in terms of their spin degrees of freedom, with little attention given to any further role of the charge. Certain classes of Mott insulator are predicted to break this paradigm, providing a direct correlation between the magnetic spin texture and the dielectric properties of a material. We observe such a correlation in Cr-trimer systems, which combined with recent theoretical developments, indicates a purely electronic mechanism for multiferroic behavior. Magnetic field strengths of the order of the exchange interaction strongly perturb the spin texture, which is evident as steps and plateau in the magnetization. The corresponding shifts in dielectric properties reveal the role of the charge degrees of freedom. Electron Spin Resonance (ESR) results and the prospect of novel dipole-active ESR giving rise to the possibility of negative refractive indices will also be discussed.

4:18PM X41.00010 The Jahn-Teller effect in doped LiCuO₂, CHRIS MARIANETTI, Columbia University — LiCuO₂ displays one of the largest known Jahn-Teller distortions, where Cu⁺⁺ is in a low spin configuration. Previous density functional theory (DFT) calculations verified the fact that the high spin, non-Jahn-Teller distorted LiCuO₂ is a metastable phase. In this work, we use DFT calculations to demonstrate that doping this system with ions that are not Jahn-Teller active allows one to tune the energy difference between the high-spin, non-Jahn-Teller phase and the low-spin, Jahn-Teller phase. This occurs due to the elastic penalty of the non-Jahn-Teller ion in the Jahn-Teller phase. The effect of different non-Jahn-Teller dopants is presented, and the electronic nature of the two respective phases is detailed.
10:24AM Y1.00005 Thermally activated phase slips in superconducting nanowires. VINCENT DUBOST, University of Paris, CRISTIAN VAJU, Institut des Materiaux Jean Rouxel, TRISTAN CREU, University of Paris, BENNOU CORRAZI, Institut des Materiaux Jean Rouxel, FRANCOIS DEBONTRIDDER, University of Paris, ETIENNE JANOD, Institut des Materiaux Jean Rouxel, DIMITRI RODITCH, University of Paris, LAURENT CARIO, Institut des Materiaux Jean Rouxel, INSP DISPOSITIFS QUANTIQUES CONTROLES TEAM, IMN-PMN-MATERIAUX A PROPRIETES ELECTRONIQUE NON-CONVENTIONNELLES TEAM. We have recently discovered a bulk Electric Pulse Induced Insulator-Metal Transition and possible superconductivity in the cluster Mott Insulator GaTaeSe8. The transport measurements, conducted on single crystals, are consistent with a two-channel model, which suggests that the electric pulse generates electronic inhomogeneities in the bulk of the samples. Our Scanning Tunneling Microscopy (STM) experiments indeed confirmed the observed drop in the resistance which was interpreted as a superconducting transition driven by a Mott transition. The signature of the Mott transition is the appearance of quantum fluctuations which were detected by analyzing the tunneling current fluctuations. The tunneling current contains information on the electronic properties of the sample. The Mott transition is observed as a suppression of the tunneling current fluctuations which indicates that the sample becomes insulating. The suppression of the current fluctuations is observed for a wide range of temperatures and also for a wide range of voltages. The current fluctuations are associated with the interplay of the Mott transition and the superconducting transition. The interplay of the two transitions leads to a new universal behavior which is observed in the tunneling current fluctuations. The universal behavior is characterized by a new exponent which is different from the exponents observed in the classical Mott transition and the superconducting transition. The new exponent is related to the interplay of the two transitions. The new exponent is related to the nature of the Mott transition and the superconducting transition. The new exponent is related to the nature of the Mott transition and the superconducting transition. The new exponent is related to the nature of the Mott transition and the superconducting transition.

8:36AM Y2.00002 Differential Dynamic Microscopy: a simple means to measure dynamics with a microscope, ROBERTO CERBINO, Universita degli Studi di Milano — Optical microscopy is an excellent tool to investigate the structure and dynamics of soft and biological materials. In this contribution we present a novel scheme to measure the dynamics of a system using an ordinary microscope [1]. This scheme is based on the spatial Fourier analysis of a time series of microscopy images, which enables us to study the relaxation of the intensity Fourier components at different spatial frequencies. This quantifies the dynamic activity of the system at different wave-vectors, giving access to information similar to the one obtained in dynamic light scattering experiments. Our technique termed Differential Dynamic Microscopy (DDM) is capable of monitoring the dynamics of both objects that are larger and smaller than the wavelength of light. The remarkable simplicity of DDM makes it suitable for the use in any laboratory that is equipped with an ordinary microscope.

9:48AM Y2.00004 New techniques for fluorescence background rejection in microscopy and endoscopy, CATHIE VENTALON, Laboratory of Neurophysiology and New Microscopies, CNRS UMR 8154, INSERM S603, University Paris Descartes - 45 rue des Saints Pères - 75006 Paris — Confocal microscopy is a popular technique in the bioimaging community, mainly because it provides optical sectioning. However, its standard implementation requires 3-dimensional scanning of focused illumination throughout the sample. Efficient non-scanning alternatives have been implemented, among which the simple and well-established incoherent structured illumination microscopy (SIM) [1]. We recently proposed a similar technique, called Dynamic Speckle Illumination (DSI) microscopy, wherein the incoherent grid illumination pattern is replaced with a coherent speckle illumination pattern from a laser, taking advantage of the fact that speckle contrast is highly maintained in a scattering media, making the technique well adapted to tissue imaging [2]. DSI microscopy relies on the illumination of a sample with a sequence of dynamic speckle patterns and an image processing algorithm based only on an a priori knowledge of speckle statistics. The choice of this post-processing algorithm is crucial to obtain a good sectioning strength: in particular, we developed a novel post-processing algorithm based one wavelet pre-filtering of the raw images and obtained near-confocal fluorescence sectioning in a mouse brain labeled with GFP, with a good image quality maintained throughout a depth of ~100 μm [3]. In the purpose of imaging fluorescent tissue at higher depth, we recently applied structured illumination to endoscopy. We used a similar set-up wherein the illumination pattern (a one-dimensional grid) is transported to the sample with an imaging fiber bundle with miniaturized objective and the fluorescence image is collected through the same bundle. Using a post-processing algorithm similar to the one previously described [3], we obtained high-quality images of a fluorescein-labeled rat colonic mucosa [4], establishing the potential of our endomicroscope for bioimaging applications.

8:00AM Y3.00001 Phase Transitions of Dirac Electrons in Bismuth1, LU LI2, Physics Department, Princeton University, Princeton, NJ 08544 — The Fermi Surface (FS) in elemental bismuth consists of 3 electron ellipsoids and one hole ellipsoid [1]. The accidental coincidence of the hole and electron caliper areas when the field \( H \) is aligned with the trigonal axis \( Z \) has long stymied analyses of the quantum oscillations. Because of current strong interest in how electrons with Dirac dispersion behave in intense fields, we have renewed attack on this problem [2] using high-resolution torque magnetometry in fields up to 31 T and at temperatures \( T \) down to 300 mK. When \( H \) is tilted with respect to \( Z \) by a slight angle \( \theta \), the torque \( \tau \) on the sample derived from the 3 electron ellipsoids dominates the torque from the hole FS, allowing the Landau Level crossings of the Dirac electron to be resolved. By measuring the curves of \( \tau \) vs. \( H \) at 19 values of \( \theta \) straddling the trigonal axes, we completely resolve the Landau Levels of the Dirac electrons. A new result is the detection of jumps in the transverse magnetization when \( H \) exceeds the quantum limit of the electron pockets. By tracing the jumps in the plane of \( H \) vs. \( \theta \), we uncover a region in which the Dirac electrons enter a new ground state. Within this cone-shaped region, Landau Level anomalies are severely suppressed. We interpret the state as one in which the 3-fold valley degeneracy of the Dirac gas is lifted to form a many-body state. The unusual nature of the magnetization within this region will be described.

8:36AM Y3.00002 Hall Plateaus at magic angles in ultraquantum Bismuth. FAUQUE BENOIT, Laboratoire Photon et Matière — The behaviour of a three-dimensional electron gas in the presence of a magnetic field strong enough to put all carriers in the first Landau level (i.e. beyond the quantum limit) is a longstanding question of theoretical condensed matter physics [1]. This issue has been recently explored by two high-field experiments on elemental semi-metal Bismuth. In a first study of transport coefficients (which are dominated by hole-like carriers), the Nernst coefficient presented three unexpected maxima that are concomitant with quasi-plateaux in the Hall coefficient [2]. In a second series of experiments, torque magnetometry (which mainly probes the three Dirac valley electron pockets) detected a field-induced phase transition [3]. The full understanding of the electron and hole behaviours above the quantum limit of pure Bi is therefore still under debate. In this talk, we will present our measurement of the Hall resistivity and torque magnetometry with magnetic field up to 31 T and rotating in the trigonal-bisectrix plane [4]. The Hall response is dominated by the hole pockets according to its sign as well as the period and the angular dependence of its quantum oscillations. In the vicinity of the quantum limit, it presents additional anomalies which are the fingerprints of the electron pockets. We found that for particular orientations of the magnetic field (namely “magic angles”), the Hall response becomes field-independent within the experimental resolution around 20T. This drastic dependence of the plateaux on the field orientation provides strong constraints for theoretical scenarios.

9:12AM Y3.00003 Bismuth and graphite in the ultraquantum limit: signatures of fractional quantum Hall effect. YAKOV KOPELEVICH, Instituto de Física “Gleb Wataghin”, Universidade Estadual de Campinas, UNICAMP, Campinas, Brasil — Bismuth and graphite are semimetals that possess both conventional massive and Dirac-like quasiparticle spectra. High quality graphite is a multi-layer system with nearly decoupled two-dimensional (2D) graphene planes, in which the integer quantum Hall effect has already been found [1]. On the other hand, the fractional quantum Hall effect (FQHE) has been observed for 3D bismuth in the ultraquantum limit (UCL), i.e. above the field that pulls all carriers into the lowest Landau level [2]. Recent measurements performed on quasi-2D graphite in magnetic field up to B = 57 T revealed well defined plateaus in the Hall resistance for B > 10 T, suggesting also the FQHE occurrence in graphite in the UCL [3]. A striking similarity of the obtained results with the FQHE measured for 2D electron system in a GaAs/AlGaAs quantum well [4] is found. Our present results indicate the interplay between FQHE and charge density wave states in graphite. We discuss the FQHE occurrence in bismuth and graphite within the framework of available theoretical models.

9:48AM Y3.00004 AlAs 2D Electrons at High Magnetic Field: The Role of Spin and Valley Degree of Freedom. MANSOUR SHAYEGAN — Two-dimensional (2D) electrons in AlAs quantum wells occupy multiple conduction-band minima (or valleys) at the X point of the Brillouin zone. These valleys have large effective mass (m*e) and g-factor compared to the standard GaAs electrons, and are also highly anisotropic. The system is rather unique in that, with proper choice of well width and by applying in situ symmetry-breaking strain in the plane, one can control the occupation of different valleys, thus rendering a system with tuneable m*e, g-factor, Fermi contour anisotropy, and with single, double, or triple valley degeneracy. By adding a magnetic field, we obtain a system which allows us to explore very rich physics ensuing from the valley and spin degrees of freedom in a strongly interacting system. In this presentation, I will highlight some of our latest results on 2D electrons confined to wide AlAs quantum wells where the electrons reside in two in-plane valleys whose occupation can be controlled via the application of strain. I will present the results of our m*e measurements, via analyzing the temperature dependence of the Shubnikov-de Haas oscillations. The measured m*e shows a strong dependence on the occupation of valley and spin subbands, reflecting the electron-electron interaction in this system. Most remarkably, m*e is suppressed with respect the band value when the 2D electrons are fully spin- and valley-polarized. I will also discuss the relation of m*e suppression to the 2D metal-insulator transition problem. Our studies also include measurements of the valley susceptibility (dependence of valley population on applied strain) and the valley polarization of the fractional quantum Hall effect composite fermions. While part of our observations can be explained well by a simple Landau level fan diagram for composite fermions with a valley degree of freedom, there are some surprises.

10:24AM Y3.00005 High Mobility Sixfold Valley Degenerate Electrons on Silicon [111] Surfaces, ROBERT N. MCFARLAND, Laboratoy for Physical Sciences, University of Maryland, College Park — The 111 surface of silicon is predicted to retain the sixfold valley degeneracy of the ideal bulk crystal. We have developed a method for fabricating field effect transistors using vacuum as a dielectric in order to study electron transport on the bare hydrogen-terminated surface, free from the complications created by intrinsic disorder at Si-Si interfaces. The resulting devices display very high mobilities (up to 110,000 cm²/Vs at 70K, more than twice as large as the best silicon MOSFETs), enabling us to probe valley-dependent transport dynamics to a much greater degree than previously possible. Measurements made on a recent device over a density range of n,c = 0.7 – 7 x 10¹⁵/cm² reveal considerable information about the nature of this degeneracy and its role in 2D transport. In particular, we find (at n,c = 6.7) that 1) low field Shubnikov-de Haas oscillations reveal a clearly sixfold degenerate system and allow us to establish an upper bound on the valley splitting of 0.2K 2) longitudinal resistivity at B=0 displays a strong temperature dependence, consistent with predictions that large valley degeneracy should enhance screening[1] and 3) the Hall coefficient near B=0 is modified by the presence of multiple valleys, and we can use this correction to measure the intervalley Coulomb drag and its temperature dependence. 8:00AM Y4.00001 Neutron and X-Ray Scattering Studies of the Exchange Bias Problem. SUNIL K. SINHA, Department of Physics, University of California, San Diego — Exchange Bias, i.e. the shift of the hysteresis loop of a ferromagnet in juxtaposition to an antiferromagnet, is a phenomenon that has been known for fifty years, and has already been put to wide commercial use in devices such as magnetic read-heads and other devices. Nevertheless a detailed understanding of the effect has proved to be fairly controversial, notwithstanding much research on this problem over the years, and the development of several alternative theoretical models. This is partly due to the necessity of understanding the details of the interactions and the magnetic structure across and in the vicinity of the interface between the ferromagnet and the antiferromagnet. The details of how interface roughness and other defects affect exchange bias and the details of how magnetic domains are established on both sides of the interface are still not well understood. Non-destructive probing of such buried interfaces is conveniently accomplished with neutron scattering or synchrotron X-ray techniques such as X-Ray Magnetic Circular Dichroism, Photoemission imaging or Resonant Magnetic X-ray Scattering, and these types of experiments have been increasingly employed over the last decade. We shall attempt to discuss what has been learned from such experiments and what crucial issues remain unresolved, with particular emphasis on recent studies of the Co/Fe and Permalloy/CoO exchange bias bilayer systems.

8:36AM Y4.00002 Measuring interfacial magnetic configurations with Polarized Neutron Reflectometry. THOMAS HAUET, Hitachi GST — Polarized neutron reflectivity (PNR) is ideally suited for imaging both vertical structural and magnetic variations in the complex magnetic multilayers [1]. During the talk will be described particularly how this technique allows obtaining the magnetic depth-profile of exchange-coupled bilayer. For instance, Gd60Fe40/Tb12Fe88 is a model system to study exchange-bias phenomena origin in anti-ferromagnetically coupled AF/FM system, like FeF2/Fe. In these systems, unusual properties are observed such as a transition from positive to negative exchange bias field HE as the cooling field Hc is swept from small to large positive value [2]. Combining complementary techniques that are macroscopic magnetization measurements and PNR, we have demonstrated that the above properties, e.g. the cooling field dependence of HE, come from an interfacial domain wall (IDW) frozen in the TbFe as the sample is cooled down under a field [3, 4]. Moreover, PNR measurements have recently revealed that the frozen IDW is metastable and that the exchange bias training effect in TbFe/GdFe results from the thermally assisted relaxation of the IDW, with field cycling [4, 5]. Overall, PNR studies concerning the TbFe/GdFe have brought strong insights into the exchange bias mechanisms in exchange coupled hard/soft systems with in-plane anisotropy. However we have demonstrated as well that this powerful technique can be applied to systems with perpendicular magnetic anisotropy (PMA). Although, in that case, the perpendicular moments are parallel to the scattering vector and do not give rise to scattering via the neutron selection rules, we have used a unconventional geometry to obtain a depth-dependent magnetic profile of a PMA exchange-coupled system. Specifically, we have characterized antiferromagnetically-coupled, TbFeCo/[Co/Pd] multilayers [6].

9:12AM Y4.00003 Inelastic neutron scattering studies of exchange biased core-shell nanoparticles. MIKHAIL FEYGENSON, Brookhaven National Laboratory — Inelastic neutron scattering (INS) measurements of nanoparticle systems are very few, and we report here the first investigation of exchange biased core-shell nanoparticles. We present a study of spin dynamics in core-shell Co/CoO nanoparticles, which display an exchange bias field of 0.6T. We have used INS measurements to determine how the magnetic dynamics are affected, both by the onset of antiferromagnetic (AF) order at 250K and the subsequent onset of the exchange bias effect at 200K. At the highest temperatures, the scattering consists of two quasielastic peaks. The narrower peak is ascribed to superparamagnetic reorientations of the Co core. The broader peak originates with moments in the CoO shell. Surprisingly, their dynamics speed up with decreasing temperature, suggesting that the CoO shell absorbs some of the magnetic energy of the core as exchange blocking is approached. Below 200K, the scattering is dominated by an inelastic peak at ~3meV. The integrated spin wave intensity grows when the temperature is reduced below 200K, reaches a maximum near 150K, and nearly vanishes at the low temperatures. We attribute this peak to AF spin waves in the CoO shell, and their lack of dispersion and overall energy scale are consistent with predictions for low energy spin waves in bulk CoO [3,4]. It is remarkable that bulk-like spin wave behavior is observed in the CoO shell, which is only 4 nm thick.

9:48AM Y4.00004 Exchange bias in core/shell magnetic nanoparticles: experimental results and numerical simulations. XAVIER BATLLE, Dep. Fisica Fonamental and Institut de Nanociencia i Nanotecnologia IN2UB, Universitat de Barcelona, Catalonia, Spain — In this talk, we will review some of the main experimental observations related to the occurrence of exchange bias in magnetic systems, focusing the attention on the phenomenon appearing in nanoparticles with core/shell structure as compared to thin film bilayers [1]. The main open questions posed by the experimental observations will be discussed and contrasted to existing theories and models for exchange bias [1]. We will also present some recent numerical simulations [2-4] based on a simple model of a core/shell nanoparticle, showing evidence that the magnetic order of interfacial spins accounts for most of the experimental observations. Finally, we will discuss the occurrence of exchange bias on laser-ablated granular thin films composed of Co nanoparticles embedded in amorphous zirconia matrix [5]. The deposition method allows controlling the degree of oxidation of the Co particles by tuning the oxygen pressure at the vacuum chamber. The nature of the nanoparticles embedded in the magnetic multilayer may be monitored from metallic, ferromagnetic (FM) Co to antiferromagnetic (AFM) CoOx, with a FM/AFM intermediate regime for which the percentage of the AFM phase can be increased at the expense of the FM phase, leading to the occurrence of exchange bias in particles of about 2 nm in size. This is a model system to study some of the features of exchange bias in nanoparticles, such as particle size dependence, induced exchange anisotropy on the FM leading to high irreversible hysteresis loops, and blocking of the AFM clusters due to proximity to the FM phase.

10:24AM Y4.00005 Small-Angle Neutron Scattering Studies of Magnetic Correlation Lengths in Nanoparticle Assemblies, SARA MAJETICH, Carnegie Mellon University — Small-angle neutron scattering (SANS) measurements of ordered arrays of surfactant-coated magnetic nanoparticle reveal characteristic length scales associated with interparticle and intraparticle magnetic ordering. The high degree of uniformity in the monodisperse nanoparticle size and spacing leads to a pronounced diffraction peak and allows for a straightforward determination of these length scales [1]. There are notable differences in these length scales depending on the particle moment, which depends on the material (Fe, Co, Fe3O4) and diameter, and also on whether the metal particle core is surrounded by an oxide shell. For 8.5 nm particles containing an Fe core and thick Fe3O4 shell, evidence of a spin flop phase is seen in the magnetite shell when a field is applied, but not when the shell thickness is ~0.5 nm [2]. 8.0 nm particles with an e-Co core and 0.75 nm CoO shell show no exchange bias effects while similar particles with a 2 nm thick shell show significant training effects below 90 K. Polarized SANS studies of 7 nm Fe3O4 nanoparticle assemblies show the ability to resolve the magnetization components in 3D.

Session Y5 DBP: Self-Organization in Biological Cells and Tissues II 401/402

8:00AM Y5.00001 Cells anticipate periodic events, TOSHIYUKI NAKAGAKI, RIES, Hokkaido University — We show that an amoeboid organism can anticipate the timing of periodic events. The plasmodium of the true slime mold Physarum polycephalum moves rapidly under favourable conditions, but stops moving when transferred to less-favourable conditions. Plasmodia exposed to unfavourable conditions, presented in three consecutive pulses at constant intervals, reduced their locomotive speed in response to each episode. When subsequently subjected to favourable conditions, the plasmodia spontaneously reduced their speed at the time point when the next unfavourable episode would have occurred. This implied anticipation of impending environmental change. After this behaviour had been evoked several times, the locomotion of the plasmodia returned to normal; however, the anticipatory response could subsequently be induced by a single unfavourable pulse, implying recall of the memorized periodicity. We explored the mechanisms underlying these behaviours from a dynamical systems perspective. Our results hint at the cellular origins of primitive intelligence and imply that simple dynamics might be sufficient to explain its emergence.

8:36AM Y5.00002 The Physics of Cardiac Fibrillation: Strings that kill1, EBERHARD BODENSCHATZ, MPI for Dynamics and Self-Organization — Fibrillation is a state of spatio-temporal chaos in a 3d-biological excitable medium, namely the heart muscle. The building blocks are wave-emitting three-dimensional topological singularities in the electric excitation field of the tissue. These string like singularities send out rotating wave fields with very fast frequencies (up to 10 times normal heart rate) and thus dominate over the pacemaker. The incoherent electrical excitation of the spatio-temporal chaotic dynamics leads to an unsynchronized contraction of the cardiac muscle and to the loss of the pumping action, and if untreated to death. Due to the topological nature of the spatio-temporal chaotic state it is very difficult to control. Current defibrillation technologies use strong electric field pulses (1 kV, 30 A, 12 ms) to reset the whole muscle. Here we report that natural muscle heterogeneities act as wave emitting sites when a weak electric field pulse is applied across the tissue. We report theoretical predictions on the physics and support the findings by results from experiment. This work was conducted in collaboration with Stefan Luther (MPIDS), Falvio Fenton (Cornell), Amgad Squires (Cornell), Robert Gilmour (Cornell), Valentin Krinsky (MPIDS), Alain Pumir (Nice).

9:12AM Y5.00003 Spatiotemporal patterns of voltage and calcium signaling in heart cells and tissue, ALAIN KARMA, Department of Physics and CIRCS, Northeastern University, Boston, USA — This talk will describe recent progress made in understanding oscillatory patterns of voltage and calcium signals that precede the onset of electromechanical wave turbulence in the main chambers of the heart. Results will illustrate how both physiologically detailed and abstract models have proven useful to cope with the bewildering molecular complexity of cardiac biology and to bridge phenomena on cellular and tissue scales. A main conclusion is that those oscillatory patterns can be self-organized, resulting from symmetry-breaking linear instabilities, or/and a manifestation of underlying tissue heterogeneities. Thus studying the evolution of those patterns provides a valuable indirect probe of complex physiological processes that render the heart susceptible to the sudden onset of lethal heart rhythm disorders.

9:48AM Y5.00004 Synchronization of Eukaryotic Flagella and the Evolution of Multicellularity1, RAYMOND GOLDSTEIN, University of Cambridge — Flagella, among the most highly conserved structures in eukaryotes, are responsible for such tasks as fluid transport, motility and photoaxisis, establishment of embryonic left-right asymmetry, and intercellular communication, and are thought to have played a key role in the development of multicellularity. These tasks are usually performed by the coordinated action of groups of flagella (from pairs to thousands), which display various types of spatio-temporal organization. The origin and quantitative characterization of flagellar synchronization has remained an important open problem, involving interplay between intracellular biochemistry and interflagellar mechanical/hydrodynamic coupling. The Volvocine green algae serve as useful model organisms for the study of these phenomena, as they form a lineage spanning from unicellular Chlamydomonas to germ-soma differentiated Volvox, having as many as 50,000 biflagellated surface somatic cells. In this talk I will describe extensive studies [1], using micromanipulation and high-speed imaging, of the flagellar synchronization of two key species - Chlamydomonas reinhardtii and Volvox carteri - over tens of thousands of cycles. With Chlamydomonas we find that the flagellar dynamics moves back and forth between a stochastic synchronized state consistent with a simple model of hydrodynamically coupled noisy oscillators, and a deterministic one driven by a large interflagellar frequency difference. These results reconcile previously contradictory studies, based on short observations, showing only one or the other of these two states, and, more importantly, show that the flagellar beat frequencies themselves are regulated by the cell. Moreover, high-resolution three-dimensional tracking of swimming cells provides strong evidence that these dynamical states are related to reorientation events in the trajectories, yielding a eukaryotic equivalent of the “run and tumble” motion of peritrichously flagellated bacteria. The degree of synchronization is found to depend upon the presence of external fluid flow, an important aspect of the dynamics in the context of evolutionary transitions to multicellularity. Comparison is made with dynamics of somatic cells of Volvox, which we have found can display metachronal waves, not previously reported in this organism. Implications of these findings for phototactic steering are also discussed.

10:24AM Y5.00005 Novel orbital physics with fermions in optical lattices. 

KCONJUN WU, Department of Physics, University of California, San Diego — Orbitals, a degree of freedom characterized by orbital degeneracy and spatial anisotropy and independent of change and spin, play important roles in magnetism and superconductivity in transition metal oxides. In this talk, we will show that the rapid progress of cold atom physics has opened up an opportunity to study novel features of orbital physics, which do not appear usual solid state systems. In particular, the \( p_{\pm 3} \)-orbital system of the honeycomb lattice exhibits amazingly rich and fundamentally different behavior from that in the \( p_{\pm 3} \)-orbital system of graphene. Its flat band structure dramatically interacts with other bands and provides a natural way to study non-perturbative strong correlation phenomena such as Wigner crystallization, and ferromagnetism which is an important field in condensed matter physics but has not attracted much attention in the cold atom community. Furthermore, in the Mott-insulating states, the orbital degree of freedom enables superexchange interactions as spin does. We will show how spatial anisotropy generates frustration in such systems, which leads to a promising way to the exciting orbital liquid states. At last, we will present that a topological insulating phase occurs in the presence of the lattice rotation, as an orbital analog of the quantum anomalous Hall effect of electron systems.

Session Y6 DCMP DAMOP: Novel Orbital Quantum Phases in Cold Atom Optical Lattices

8:00AM Y6.00001 Dynamics of ultracold atoms in higher lattice orbitals. 

TORBEN MUELLER, Institute for Quantum Electronics, ETH Zurich, Switzerland — Ultracold quantum gases in far detuned optical lattices have enabled many intriguing experiments studying a new regime of strongly correlated quantum systems. So far, such experiments have mostly concentrated on atoms in the vibrational ground state of the lattice band structure. Here, we report on the realization of a multi-orbital system with ultracold atoms in the excited bands of a 3D optical lattice by selectively controlling the band population along a given lattice direction. The lifetime of the atoms in the excited band is found to be considerably longer (10-100 times) than the characteristic time scale for intersite tunneling, thus opening the path for orbital selective many-body physics with ultracold atoms in optical lattices. Upon exciting the atoms from the initial lowest band Mott-insulating state to higher lying bands, we observe the dynamical emergence of long-range coherence in 1D (and also 2D) at nonzero quasimomentum, providing a possible route for Bose-Einstein condensation to nonzero momentum.

8:36AM Y6.00002 Control of Bosons in a 2D optical lattice with checkerboard staggered field. 

TREY PORTO, NIST — I will describe experiments to control the vibrational and spin degrees of freedom of ultra-cold Rb atoms in a novel 2D optical lattice. This unit cell of the lattice can be dynamically transformed between a single-site and two-site configuration, allowing us to manipulate the vibrational degree of freedom of atoms in the unit cell, and merge separated atoms into the same site. In addition, the vector light shift of the optical lattice acts as a Zeeman field for the atoms on every other site of the lattice, providing a checkerboard staggered field. We use this field to control the spins on the two sub-lattices separately. I will also discuss the possibility of using this field to prepare low entropy anti-ferromagnetic states.

This work was partially supported by IARPA and ONR.

W. VINCENT LIU, University of Pittsburgh — Bose-Einstein condensation (BEC) is often associated with zero momentum to which a macroscopic fraction of bosons condense. Here we propose a new class of meta-stable quantum states where bosons condense at non-zero momenta, defying the paradigm. This becomes possible when bosonic atoms are confined in the \( p \)-orbital Bloch bands of an optical lattice rather than the usual \( s \)-orbital. A recent experiment at Mainz confirmed the discovery of such an exotic BEC with alkali-metal atoms in a 3D cubic lattice with anisotropic optical potentials. Non-zero momentum suggests crystalline order. Our theoretical studies further found that such non-zero momentum BECs are also naturally orbital ordered superfluids due to the fascinating, less studied center-of-mass \( p \)-wave symmetry (e.g., a vortex-like \( p_x + ip_y \) condensate). Varying with the geometry from standard optical lattices to double-well lattices, the interesting orderings include staggered orbital currents, stripes of angular momenta, and modulated super-current density wave. Different than a phase of coexisting orders such as supersolidity, this new class of states is characterized by a single order parameter. Work done in collaboration with J. Moore, S. Das Sarma, V. M. Stojanovic, C. Wu, and E. Zhao.

10:24AM Y6.00005 Realization of Extended Hubbard Models with Tailored Orbitals in Optical Lattices\textsuperscript{1}, VITO SCAROLA, UC Berkeley — Optical lattices containing cold atoms represent nearly ideal manifestations of Hubbard models free from disorder, defects, impurities and lattice phonons. Experiments with bosonic alkali atoms confined to the lowest optical lattice band demonstrate strongly correlated phases including the superfluid and Mott insulator that arise from a real space contact interaction between atoms. Can other quantum condensed phases of matter be observed in these systems? We show that promoting bosons to higher bands effectively extends the range of the contact interaction. Quasi-localized orbitals in higher bands overlap with nearest neighbors. They can be modeled with extended Bose-Hubbard models that harbor density wave and supersolid phases. Bosons promoted to higher bands can decay but the purity of optical lattice systems limits possible decay mechanisms (e.g. phonons). We propose that long-lived metastable states of bosons promoted to higher bands of optical lattices may therefore provide a route to a novel class of extended Hubbard models.

Session Y7 GSNP DCMP: The Statistical Properties of Forc...
10:24AM Y7.00005 Measuring the configurational temperature of granular media, MATTHIAS SCHRÖTER, Max Planck Institute for Dynamics and Self-Organization — Twenty years ago Edwards and Oakeshott suggested developing a statistical mechanics of static granular media based on the idea that the logarithm of the number of mechanically stable states of a specific sample constitutes the relevant entropy [1]. From this entropy then, a configurational temperature, named compactivity, could be derived. However, in the absence of an appropriate thermometer to measure compactivity, the question if it is indeed a relevant state variable remained untested. Only recently it was shown that the steady state volume fluctuations of a periodically driven sample can be used to measure the compactivity of a granular sample including its dependence on volume fraction and surface friction of the particles [2]. This opens up the possibility of studying questions like the existence of a zeroth law of granular thermodynamics or the relationship between compactivity and other forms of granular temperature.

Friday, March 20, 2009 8:00AM - 11:00AM – Session Y8 GIMS: Pushing the Limits of Mechanical Detection 414/415

8:00AM Y8.00001 Quantum Optical Control of Micromechanics, MARKUS ASPELMEYER, Institute for Quantum Optics and Quantum Information (IQOQI), Austrian Academy of Sciences, Vienna, Austria — Massive mechanical resonators are now approaching the quantum regime. This opens up not only a spectrum of new applications but also a previously inaccessible parameter range for macroscopic quantum experiments on optomechanical entanglement, which is at the heart of Schrödinger’s cat paradox.

8:36AM Y8.00002 Measurement of Dispersive Coupling Between a Nanoresonator and a Superconducting Qubit, MATTHEW LAHAYE, California Institute of Technology — Incorporating superconducting qubit technology into nano-electromechanical systems (NEMS) should enable the observation of quantum behavior in NEMS. Ultimately, it is expected that coupled qubit-NEMS systems could serve as a test bed for studying fundamental issues of quantum mechanics including the quantum limits of measurement and the quantum-classical divide. Proposals in the literature posit the qubits as verifiable toolboxes for preparing, manipulating and measuring quantum states of a nanomechanical resonator (or ‘nanoresonator’), and range from the nondestructive read-out of quantized-energy states (or ‘Fock states’) to the generation of Schrödinger-cat states. In an initial step toward implementing these advanced strategies, we have performed the first measurements of a nanoresonator coupled to a superconducting qubit, the Cooper-pair box (CPB). We find that the coupling produces a CPB-state-dependent shift in the frequency of the nanoresonator that is analogous to the single-atom phase shifts experienced by superconducting resonators in the dispersive limit of cavity quantum electrodynamics (CQED). In my talk, I will report on our latest measurements of the dispersive interaction between the CPB and nanoresonator, including how we utilize it to read-out quantum interference effects in the CPB. In the end, I will discuss how the interaction could soon be utilized for exploring the quantum limit of NEMS.

9:12AM Y8.00003 Nanoscale Magnetic Resonance Imaging Based on Ultrasensitive Force Detection1, H.J. MAMIN, IBM Research Division, Almaden Research Center — Magnetic Resonance Force Microscopy (MRFM) seeks to dramatically improve the sensitivity and resolution of magnetic resonance imaging (MRI), perhaps ultimately down to the molecular scale. It uses force detection to circumvent the sensitivity limits inherent in conventional inductively-detected MRI. By using an ultrasensitive, single crystal silicon cantilever cooled to 300 mK, we can detect forces smaller than 1 aN, allowing us to sense the magnetism from small ensembles of nuclear spins. We have used tobacco mosaic virus as a test object, detecting the hydrogen signal. Using three-dimensional scans and mathematical deconvolution algorithms, we have made 3D reconstructions of the viruses with resolution down to roughly 4 nm. This represents a 10^6 x improvement in minimum detectable volume compared to the best conventional MRI. Advancing the technique further will require reducing the force noise, increasing the achieved magnetic field gradients, and making use of the inherent chemical sensitivity of magnetic resonance.

1Work done in collaboration with Christian Degen, Martino Poggio, Charles Rettner, Tjerk Oosterkamp, Mark Sherwood and Dan Rugar

9:48AM Y8.00004 A Cantilever-based apparatus for detecting micron-scale deviations from Newtonian gravity1, AHARON KAPITULNIK, Stanford University — To test new theories of physics beyond the Standard Model, we have built a low temperature probe to measure forces as small as 10^{-18} N between masses separated by distances on the order of 20 microns. Our experiment is fundamentally a Cavendish-type experiment in the sense that its purpose is to directly measure the force between two masses [1]. A cryogenic helium gas bearing is used to rotate a disc containing a drive mass pattern of alternating density under a small test mass mounted on a micromachined cantilever. Any mass-dependent force between the two will produce a time-varying force on the test mass, and consequently a time-varying displacement of the cantilever. This displacement is read out with a laser interferometer, and the position of the drive mass is simultaneously recorded using an optical encoder. The displacement is then averaged over many cycles and converted to a force using measured properties of the cantilever. This AC “lock-in” type measurement enables significant noise rejection and allows us to operate on resonance to take advantage of the cantilever’s high quality factor. A novel feature of the apparatus is the utilization of feedback regulation of the response of the microcantilever using the radiation pressure of a laser. Our approach does not require a high-finesse cavity, and the feedback force is due solely to the momentum of the photons in the second laser.

10:24AM Y8.00005 The quantum limit and beyond in gravitational wave detection, NERGIS MAVALVALA, Massachusetts Institute of Technology — The sensitivity of current and next generation interferometric gravitational wave detectors is limited by quantum mechanics. We will explore this quantum limit, one aspect of which arises from the radiation pressure that laser light exerts on the movable mirrors of the interferometer. I will describe experiments in which the light force dominates the mechanical forces to such an extent that the mirror oscillators are optically trapped and cooled. Laser cooling of macroscopic mechanical oscillators has applications in high precision force and position measurements, gravitational wave detection, and exploration of the classical-quantum boundary. I will discuss the status of a variety of experimental efforts worldwide are working to approach the quantum regime, with the goal of observing non-classical effects such as quantum back-action, squeezing and entanglement of the light and mirror states, and conclude with an outlook on prospects for observation of quantum effects in macroscopic human-scale objects.

Friday, March 20, 2009 8:00AM - 10:48AM – Session Y9 GSNP: Stochastic Processes in Biological Systems II 303
8:00AM Y9.00001 A Stochastic Single-Molecule Event Triggers Phenotype Switching of a Bacterial Cell, SUNNEY XIE, PAUL CHOI, Harvard University, LONG CAI, Caltech — By monitoring fluorescently labeled lactose permease with single-molecule sensitivity, we investigated the molecular mechanism of how an Escherichia coli cell with the lac operon switches from one phenotype to another. At intermediate inducer concentrations, a population of genetically identical cells exhibits two phenotypes: induced cells with highly fluorescent membranes and uninduced cells with a small number of membrane-bound permeases. We found that this basal-level expression results from partial dissociation of the tetrmeric lactose repressor from one of its operators on looped DNA. In contrast, infrequent events of complete dissociation of the repressor from DNA result in large bursts of permease expression that trigger induction of the lac operon. Hence, a stochastic single-molecule event determines a cell’s phenotype.

1Current address

8:12AM Y9.00002 The role of time scales in extrinsic noise propagation, SRIVIDYA IYER-BISWAS, Dept. of Physics, The Ohio State University, JUAN MANUEL PEDRAZA, Dept. of Systems Biology, Harvard Medical School, C. JAYAPRAKASH, Dept. of Physics, The Ohio State University — Cell-to-cell variability in the number of proteins has been studied extensively experimentally. There are many sources of this stochastic variability or noise that can be classified as intrinsic, due to the stochasticity of chemical reactions and extrinsic, due to environmental differences. The different stages in the production of proteins in response to a stimulus, the signaling cascade before transcription, transcription, and translation are characterized by different time scales. We analyze how these time scales determine the effect of the reactions at each stage on different sources of noise. For example, even if intrinsic noise dominates the fluctuations in mRNA number, for typical degradation rates, extrinsic noise can dominate corresponding protein number fluctuations. Such results are important in determining the importance of intrinsic noise at earlier stages of a genetic network on the products of subsequent stages. We examine cases in which the dynamics of the extrinsic noise can lead to differences from cases in which extrinsic noise arises from static (in time) cell-to-cell variations. We will interpret the experiments of Pedraza et al. in the light of these results. *J. M. Pedraza et al, Science 25 March 2005: Vol. 307. no. 5717, pp. 1965 - 1969.

8:24AM Y9.00003 Determination of the equilibrium free energy for pulled single molecules from nonequilibrium work measurements1, LIAO CHEN, University of Texas at San Antonio — The Jarzynski equality (JE) is widely accepted for extracting equilibrium free energy from non-equilibrium work measured in single-molecule pulling experiments, even though questions remain on its validity and applicability. In this talk, I will show that the JE is actually inapplicable outside the near-equilibrium regime. We present a new fluctuation-dissipation theorem (FDT) that is derived within the context of Brownian dynamics. The new FDT agrees with the JE in the near equilibrium regime but it is valid in far nonequilibrium regime where the JE does not stand. In silico experiments of unfolding polypeptides show that the new FDT is indeed accurate for far non-equilibrium processes.

8:36AM Y9.00004 Efficient stochastic sampling of first passage times for multi-scale simulations, NAVODIT MISRA, RUSSELL SCHWARTZ, Carnegie Mellon University — Monte Carlo methods have become increasingly popular for simulating stochastic dynamics in biological systems. However, the standard Stochastic Simulation Algorithm (SSA) can become highly inefficient for multi-timescale problems, where important events occur in parallel and at a much slower rate than other relatively unimportant events. We present two new algorithms based on the spectral analysis of Continuous Time Markov Model (CTMM) graphs to achieve fast rare event sampling in SSA models. These methods are well suited for simulating a broad class of ‘stiff’ reaction networks such as models of bond networks and nucleation-limited self-assembly in biological systems.

8:48AM Y9.00005 Dynamics of segregation of polymers in a confined geometry, YA LIU, BULBUL CHAKRABORTY, Brandeis University — Chromosomes are enormous DNA molecules living in the crowded, confined environment of a cell. They carry important genetic information and are stably propagated to new generations through replication. During the replication, two identical DNA molecules are generated and segregate rapidly into opposite pole of the cell. We have used numerical simulation to investigate the effects of confinement on the segregation of two identical self-avoiding chains. Simulation shows the existence of a transition from a mixing state to a demixing state with changes in the confining geometry. Using the blob picture, we construct a free energy function that depends on the distance between the two chains. We describe the dynamics of segregation as a stochastic process driven by this energy function. We will present comparisons of our theoretical results with numerical simulations.

9:00AM Y9.00006 Modeling DNA unhooking from a single post as a translocation process, NABIL LAACHI, JAESOOL CHO, KEVIN DORFMAN, University of Minnesota-Twin Cities — We will present theoretical results on the stochastic unhooking of a long DNA chain from an isolated, stationary micropillar obtained by mapping the unhooking process to the translocation of a long chain through a nanopore. We show how stochastic methods, developed for DNA translocation, can thus be utilized to study chain-post unhooking. In particular, implementing such methods leads to the full probability distribution of the unhooking time and the ensuing moments in a fast and efficient manner for a wide range of chain and field parameters. The results thus obtained compare favorably to more realistic (and computationally intense) Brownian Dynamics simulation data, indicating that the finite size of the insulating micropillar and the elasticity of the DNA make at most a small contribution to the dynamics. We will also address the relevant electric fields and time scales for this process, making a connection between the theoretical data obtained here and experimental separations.

9:12AM Y9.00007 Evolutionary advantage of a mixed strategy for the competence phenotype in bacteria, CHRISTOPHER WYLIE, HERBERT LEVINE, UC San Diego, DAVID KESSLER, Bar Ilan University, CENTER FOR THEORETICAL BIOLOGICAL PHYSICS TEAM — Under certain stressful conditions, bacterial species such as B. subtilis undergo a differentiation process in which a finite subpopulation transiently and stochastically enters the “competent” state. This state is defined by the ability to import and homologously incorporate extracellular DNA fragments into the genome. This ability is accompanied by a growth rate that tends to slow adaptive evolution. On the other hand, the increased genetic diversity generated by recombination tends to speed evolution. Using stochastic simulation and analytic methods, we show that this tradeoff implies that a “mixed strategy” optimizes the rate at which populations acquire beneficial mutations.

9:24AM Y9.00008 Physical limits on computation by assemblies of allosteric proteins1, JOHN ROBINSON, University of Alabama at Birmingham — Assemblies of allosteric proteins are the principle information processing devices in biology. Using the Ca2+-sensitive cardiac regulatory assembly as a paradigm for Brownian computation, we examine how system complexity and system resetting impose physical limits on computation. Nearest-neighbor-limited interactions among assembly components constrains the topology of the system’s macrostate free energy landscape and produces degenerate transition probabilities. As a result, signaling fidelity and deactivation kinetics can not be simultaneously optimized. This imposes an upper limit on the rate of information processing by assemblies of allosteric proteins that couple to a single ligand type.

9:36AM Y9.00009 Calcium waves in the maturing oocyte
t. AMAN ULLAH, Ohio University, GHANIM ULLAH, The Pennsylvania State University, PETER JUNG, Ohio University, KHALED MACHACA, Weill Cornell Medical College, Qatar — Calcium waves in oocytes are sustained by release of Ca\textsuperscript{2+} from the endoplasmic reticulum (ER) through clustered release channels. As the oocytes mature, a) the calcium waves slow down by about a factor of two, b) the overall duration of Ca\textsuperscript{2+} elevation grows substantially, and c) the cell is more susceptible to wave initiation. At the same time, the kinetics of release of Ca\textsuperscript{2+} from a single cluster is changed only insignificantly. Based on a computational model that accurately reproduces elemental Ca\textsuperscript{2+} release kinetics from channel clusters, we propose that the changing spatial organization of signaling effectors is a common underlying cause for all the above described observations as the Ca\textsuperscript{2+} signaling machinery matures.
1This work was supported by NSF.

9:48AM Y9.00010 Calcium puffs: From microdomain to a channel. DIVYA SWAMINATHAN, PETER JUNG, Department of Physics and Astronomy, Ohio University — Calcium puffs describe the release of calcium (Ca\textsuperscript{2+}) ions from internal stores into the cytosol through clusters of up to tens of ion channels. It is believed that during the release process, when the channels open, steep Ca\textsuperscript{2+} concentration gradients are established around the cluster. These local large concentrations are consequential as they determine the opening and closing rates of the ion channel and therefore control receptor kinetics. We present a computational study, wherein we simulate the release and diffusion of Ca\textsuperscript{2+} ions and its interaction with buffers and indicator dyes around one channel cluster. Our goal is to relate local steep Ca\textsuperscript{2+} gradients with experimentally observable microdomain-averaged Ca\textsuperscript{2+} concentrations thereby putting the high concentration hypothesis to test.

10:00AM Y9.00011 Dynamical Phase Transitions In Periodically Driven Model Neurons R. ENGBRECHT\textsuperscript{1}, RENATO MIROLLO\textsuperscript{2}, Physics\textsuperscript{1} and Mathematics\textsuperscript{2} Departments, Boston College — Transitions between dynamical states in integrate-and-fire (IF) neuron models with periodic stimuli result from tangent or discontinuous bifurcations of a return map. We study their characteristic scaling laws and show that discontinuous bifurcations exhibit a new kind of phase transition intermediate between continuous and first order. We then consider a much more complicated Hodgkin-Huxley type of model and show that in the presence of periodic stimuli an attracting 2D invariant subspace develops in the 7D state space. A Poincare section on this subspace yields a 1D return map, remarkably similar to the IF case. This reduction to 1D map dynamics should extend to real neurons in a periodic current clamp setting.

10:12AM Y9.00012 Stochastic and Deterministic Flagellar Dynamics Provide a Mechanism for Eukaryotic Swimming Reorientation MARCO POLIN, IDAN TUVAL, KNUT DRESCHER, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — The biflagellated alga *Chlamydomonas reinhardtii* is a good model organism to study the origin of flagellar synchronization. Here we employ high-speed imaging to study the beating of the two flagella of *Chlamydomonas*, and show that a single cell can alternate between two distinct dynamical regimes: asynchronous and synchronous. The asynchronous state is characterized by a large interflagellar frequency difference. In the synchronous state, the flagella beat in phase for long periods, interrupted episodically by a large difference in frequency difference. The statistics of these events are consistent with a model of hydrodynamically coupled noisy oscillators. Previous observations have suggested that the two flagella have well separated intrinsic beat frequencies, and that they are synchronized by their mutual coupling. Our analysis shows instead that the synchronized state is consistent with coupling-induced synchronization of flagella with those intrinsic frequencies. This suggests that the beat frequencies themselves are under the control of the cell. Moreover, high-resolution three-dimensional tracking of swimming cells provides strong evidence that these dynamical states are related to non-phototactic reorientation events in the trajectories, yielding a eukaryotic equivalent of the "run and tumble" motion of peritrichously flagellated bacteria.

10:24AM Y9.00013 Active stochastic oscillations and amplification of mechanical stimuli in a hair cell model LIJUAN HAN, ALEXANDER NEIMAN, Ohio University — We study signal transduction in spontaneously oscillating hair bundles of an auditory hair cell using a computational model. The effects of intrinsic noise from the Brownian motion of hair bundles and from stochastic fluctuations of transduction ion channels as well as periodic fluctuations of the receptor potential are taken into account. The model shows the explosion of a canard trajectory near the Hopf bifurcation. We have found that the system's gain of weak mechanical stimuli can be greatly enhanced when the system operates slightly beyond the Hopf bifurcation, i.e. in the canard region. The gain can also be optimized by tuning the noise intensity.

10:36AM Y9.00014 The co-existence of spirals with multiple rates of rotation JOSEPH TRANQUILLO, Bucknell University — Two findings in homogeneous reaction-diffusion media are that a single spiral may break into multiple spirals and that rapidly rotating spirals push slowly rotating spirals to domain boundaries. These two findings together fail to explain how cardiac tissue can support multiple stable spirals with different periods of rotation. Numerical simulations are presented in which a thin inhomogeneous region forms a functionally protective barrier between spirals rotating at different rates. The only requirement of the insulating region is that it partially block alternating wavefronts from the fast spiral. Parameters of both reaction and diffusion can result in functional insulation and multiple insulating regions can result in the broad frequency spectrum characteristic of cardiac fibrillation. The results suggest that the healthy ventricle, although containing intrinsic inhomogeneities, is functionally connected, while disease may create functionally disconnected regions. This simple mechanism may shed light on why defibrillation and pacing are not always successful, and why some patients are more susceptible to a transition from tachycardia to fibrillation.

Session Y10 DMP: Focus Session: Optical Properties of Nanostructures VI: Artificially Structured Materials
8:00AM Y10.00001 Green’s Functions in Nanoscience1. MURILO L. TIAGO, Oak Ridge National Laboratory — Theoretical nanoscience is a fast growing area in physics. It gains momentum with the recent advances in related areas such as nanodevice design, synthesis and characterization of novel nanostructures, nanoscale imaging and spectroscopy. Several techniques common to quantum chemistry and condensed matter physics have been applied successfully to the modeling of nanoscale structures. In particular, methods based on many-body Green’s functions (MBGF) are becoming more and more popular. One of the reasons for this success is that these methods have predicted several phenomena at nanoscale, for example the peculiar dimensional confinement of excitons in nanostructures. Further advances in quantum transport and exciton dynamics can be foreseen. Moreover, algorithms tailored to confined systems have made calculations of Green’s functions in nanostructures much more manageable [1]. With those algorithms, we were able to investigate the properties of correlated excitations in clusters of semiconductors (CdSe and silicon)[1,2]. We were also able to explain the properties of electronic excitations in fullerene and other organic compounds [1,3]. This talk will present an overview of the current stage of MBGF techniques, discuss the various approximations that have been proposed, and review recent advances.

8:36AM Y10.00002 First Principles Absorption Spectra of Cu$_n$ ($n = 1$ − 10) Clusters, KOPINJOL BAISHYA, XIANG JUAN, C. IDROBO, SERDAR OGUT, Argonne National Laboratory — First principles optical absorption spectra, obtained within time-dependent density functional theory, for the ground state and low-energy isomers of Cu$_n$ ($n = 1$ − 10) are presented. Overall our theoretical results exhibit good agreement with available experimental data. We analyze the orbital character of the optical excitations as a function of size and energy. Compared to noble metal clusters of Ag and Au in the same size range, we find that Cu clusters have much higher d-electron contribution to low-energy optical excitations.

8:48AM Y10.00003 ABSTRACT HAS BEEN MOVED TO S1.00259 —

9:00AM Y10.00004 Calculations of second harmonic generation by periodically-structured surfaces, WILLIAM SCHAICH, Physics Department Indiana University — We have done finite-difference time-domain (fdtd) calculations of second harmonic generation (shg) from various surface structures. The periodic structures include pairs of metal strips, split-ring resonators, and fishnets. The nonlinear response is described by a set of parameters that multiply products of linear field components. These fields and the resultant second harmonic radiated fields are found in separate fdtd calculations. The shg spectra do not always correlate well with that seen in linear response.

9:12AM Y10.00005 Optical properties of the Folic Acid/APTMS/TiO$_2$ nanosystems, VOLODYMYR TURKOVSKYI, MICHAEL LEUENBERGER, TALAT RAHMAN, DUY LE, Dept. of Physics and NDSTC, Univ. of Central Florida, Orlando, FL 32816, SUDIPTA SEAL, AMPAC, Univ. of Central Florida, Orlando, FL 32816, SANKU MALLIK, Dept. of Pharmaceutical Sciences, North Dakota State Univ., Fargo, ND 58105, ANDRE GESQUIERE, NSTC, Univ. of Central Florida, Orlando, FL 32816 — Our photoluminescence experiments on folic acid (FA) conjugated nanoparticles of TiO$_2$, CeO$_2$ and SiO$_2$ show great promise for a variety of optoelectronic applications for these materials, in particular in the field of modern molecular photoelectronic devices, since they demonstrate a dramatic increase of the photoemission intensity at wavelengths between 500 to 700 nm when the nanoparticles are coated with the 3-aminopropyltrimethoxylane (APTMS) linker/spacer molecule. We report here results of accompanying time-dependent density-functional theory studies of the FA/APTMS/TiO$_2$ nanosystems by using the B3LYP exchange-correlation potential. We demonstrate that the large increase of the photoemission is due to enhanced optical transitions which involve the intermediate energy levels related to the APTMS states. We present details of the geometric and electronic structure and excited states of our nanosystems and their dependence on the characteristics of the nanoparticle. We discuss possible optoelectronic applications for this effect.

9:24AM Y10.00006 Optical Properties and Aging of Gasochromic WO$_3$, RUDRESH GHOSH, University of North Carolina at Chapel Hill, Dept of Physics and Astronomy, MATTHEW B. BAKER, RENE LOPEZ, University of North Carolina at Chapel Hill — WO$_3$ as a possible optical gas sensor has gained increasing importance with H$_2$ becoming a major fuel of the future. This has led to efforts to understand the theoretical and practical aspects of the gasochromic behavior of WO$_3$. WO$_3$ films were fabricated using pulsed laser deposition (PLD). Morphological and stoichiometric ratios of films obtained were observed as functions of deposition parameters. We present the optical constants induced by 2% H$_2$:Ar in WO$_3$ films. This allows us to obtain the limits of the gasochromatic change in comparison to ion injection. It was found using Langmuir’s adsorption equation that at low H$_2$ concentrations a high sensitivity is predicted but the coloration could saturate at 57.9 % of the material’s maximum ion adsorption. Poisoning of the films was also addressed by coating with a permeable polydimethylsiloxane layer. It is shown that gasochromic degradation is prevented thus eliminating common atmospheric gases as possible contaminants. Our studies suggest WO$_3$ thin films as highly sensitive and stable optical hydrogen sensors.

Supported in part by DOE-DE-FG02-07ER15842.

9:36AM Y10.00007 Ab initio Bethe-Salpeter Equation approach for aperiodic materials and core-excitations, H. M. LAWLER, J. VINSON, J.J. REHR, University of Washington, E.L. SHIRLEY, NIST — We have recently developed an interface dubbed AI2NBSE between the Bethe-Salpeter optical spectroscopy code NBSE developed at NIST and the $ab$ initio electronic structure code ABINIT [1]. This interface facilitates first-principles calculations of valence-band dielectric response including excitonic effects in insulating crystals. Here we report on the extension of this interface for calculations of 1) dielectric response in complex nano-scale, disordered, and molecular systems, and 2) core-level UV and x-ray response. For the treatment of complex systems, we discuss issues of cell selection, basis size, and the treatment of the screened electron- hole interaction. For the core level response, we address various strategies including explicit treatments of core and semi-core states with plane waves and the PAW representation.

Franz-Keldysh effect in the interband optical absorption of quantum wires

9:48AM Y10.00008 Franz-Keldysh effect in the interband optical absorption of quantum wires, HAROLD SPECTOR, Illinois Institute of Technology, CONGXIN XIA, Henan Normal University — We present a theoretical calculation of the effect of an electric field applied either parallel or perpendicular to the axis of a rectangular quantum wire on the interband optical absorption. We find that the application of the electric field decreases the optical absorption coefficient for both the parallel and perpendicular to the axis electric field configurations. The absorption is greater when the electric field is along the direction of carrier confinement than when it is along the axis of the wire. This difference is due to the effect of the field on the overlap of the electron and hole wave functions.

10:00AM Y10.00009 Surface Enhanced Raman Spectroscopy (SERS) of pyridine on Pt:1

QINGZHEN HAO, Physics Department, Penn State University, LASSE JENSEN, Chemistry Department, Penn State University, PETER EKLUND, Physics Department, Penn State University — SERS studies were carried out on vertically oriented Pt cylinders patterned on quartz substrates via e-beam lithography. Optical absorption indicates that Localized Surface Plasmon Resonance (LSPR) of the Pt cylinders in the UV region, around 300nm. Discrete Dipole Approximation (DDA) simulation was performed to confirm the position of the substrate’s LSFR and also to map the electric field distribution inside and at the surface of the Pt, which allows us to estimate the Electromagnetic enhancement factor (EF). Experimentally, we demonstrate that the total SERS EF is about 5×10^4 using 514.5nm excitation (far away from the LSFR resonance). Using time-dependent density functional theory we have calculated the off-resonance chemical SERS enhancements of pyridine interacting with small Pt clusters. Our results show that the enhancements are much larger than results obtained for small Ag clusters. We are currently exploring the enhancements for different Pt cluster sizes as well as the importance of charge-transfer excitations. These results will provide detailed insights into the mechanism responsible for the chemical enhancement in SERS.

10:12AM Y10.00010 The Effect of Roughened Metallic Films on Colloidal Quantum Dot Energy Transfer1

CHRISTOPHER FERRI, SOMNATH GHOSH, School of Natural Sciences, University of California, Merced, CA 95344, USA, BRENT RICH, MICHELLE KHINE, School of Engineering, University of California, Merced, CA 95344, USA, SAYANTANI GHOSH, School of Natural Sciences, University of California, Merced, CA 95344, USA — We investigate self-organized, roughened metallic surfaces as a platform for enhanced energy transfer between colloidal Cadmium Selenide (CdSe) quantum dots (QD). Pre-stressed thermoplastic substrates are sputter coated with gold palladium (AuPd) to create thin films. When heated, due to differing coefficients of thermal expansion of the plastic and metal, the AuPd film buckles to form micro- to nano-meter sized structures. QDs deposited on these self-organized metallic structures exhibit changes in their static and dynamic optical characteristics, which include spectral red-shift and multiple recombination decay rates. These observations can be attributed to a combination of enhanced electronic coupling between close-packed QDs and plasmonic coupling between the QD and metallic structures. We then leverage these properties to fabricate controlled, directional structures using this self-organized method which can be utilized as biochemical sensors.

Friday, March 20, 2009 8:00AM - 10:24AM — Session Y11 DCMP: Superlattices and Nanostructures - Electronic Properties 305

8:00AM Y11.00001 Finding structures with specific properties in complex configurational spaces using multi-target inverse band structure approach1

PAULO PIQUINI, Universidade Federal de Santa Maria, 97105-900, Santa Maria, RS, Brazil, ALEX ZUNGER, National Renewable Energy Lab., Golden, CO 80401 — The conventional strategy to look for materials with desired properties is to use physical intuition to select some candidates among an enormous number of possibilities. Apart the very special cases, the solutions to these search problems are far from obvious. The inverse band structure (IBS) approach, on the other hand, search for the desired electronic structures (instead of atomic configurations) from the beginning. Here we illustrate the power of this inverse approach by applying it to the simultaneous engineering of multi-target problems, which encompass huge configurational spaces: (i) the search of a specific band gap in the quaternary (In,Ga)(As,Sb) structures (instead of atomic configurations) from the beginning. Here we illustrate the power of this inverse approach by applying it to the simultaneous engineering of multi-target problems, which encompass huge configurational spaces: (i) the search of a specific band gap in the quaternary (In,Ga)(As,Sb) structures, (ii) the stacking sequence of (In,Ga)As/InP superlattices leading to band gaps and strains within the range suitable for thermophotovoltaic applications (b).

8:12AM Y11.00002 First-principles studies of structure and electronic level alignment at nanoscale CdSe/CdTe heterojunctions1

SHENYUAN YANG, DAVID PRENDERGAST, JEFFREY NEATON, Molecular Foundry, Lawrence Berkeley National Laboratory — Group II-VI semiconductor nanostructured heterojunctions with type-II interfacial band offsets have many potential applications in nanoscale optoelectronics and photovoltaics. A key open question is how the electronic level alignment at nanoscale heterojunctions differs from that at their bulk counterparts, and whether bulk intuition can be used to understand their electronic behavior. We use density functional theory and beyond to study the structure and electronic properties of CdSe/CdTe interfaces in bulk-planar and nanowire form. Both periodic “superlattice” geometries and slabs finite along the surface normal are compared. We compute interface atomic and electronic structure, and for small-diameter nanowires, we discuss the impact of quantum confinement, intrinsic strain, and organic ligand passivation on the electronic properties of the interface. Our results are discussed in the context of recent experiments.

1Prepared at LBNL under U.S. DOE contract DE-AC02-05CH11231.

8:24AM Y11.00003 P-type InSb and InxGa1-xAs quantum wells remotely doped with Be

CHOMANI GASPE, MADHAVIE EDIRISOORIYA, TETSUYA MISHIMA, MICHAEL SANTOS, University Of Oklahoma — CMOS circuits require p-type transistors with high hole mobility, in addition to n-type transistors with high electron mobility. We have observed room-temperature hole mobilities of 100 and 600 cm2/Vs in InxGa1-xAs and InSb quantum wells, respectively. The InxGa1-xAs as wells are remotely doped with Be in InxAl1-xSb barrier layers, and grown on InP substrates. The InSb wells are remotely doped with Be in AlxIn1-xSb barrier layers, and grown on GaAs substrates. We will discuss the effects of strain, structural parameters, and defect density on hole mobility in InSb and InxGa1-xAs quantum wells. In zinc-blend semiconductors, a narrower band gap leads to smaller effective masses for electrons and holes. Strain and confinement increase the energy splitting between holes with light in-plane mass and those with heavy in-plane mass. This work was supported by the NSF Grants DMR-0808086 and DMR-0520550.
8:36AM Y11.00004 Predicted Band Structures of Wurtzite III-V Semiconductors Based on Empirical Pseudopotentials , AMRIT DE, CRAIG PRYOR, Department of Physics and Astronomy,University of Iowa — The electronic properties of III-V semiconductor nanowhiskers present a problem since the nanowhiskers often crystallize in wurtzite (WZ) form while the corresponding bulk materials are zincblende. Using empirical pseudopotentials, including spin-orbit coupling, we have computed the bulk band structures for non-nitride III-V semiconductors grown in WZ form, which may be used for electronic structure calculations of nanowhiskers. The calculations make use of transferable model pseudopotentials fit to the zincblende form. We find that due to the stronger breaking of inversion symmetry in the WZ form, there are larger zero field spin splittings than in the corresponding zincblende materials, making WZ nanowhiskers good candidates for novel spin based devices.

8:48AM Y11.00005 Fundamental properties of TiO$_2$ nanostructures: the effects of the size confinement and the surface coverage , GIOVANNI CANTELE, CNR-INFM-Coherentia, Universita’ di Napoli Federico II., Naples, Italy, AMILCARE IACOMINO, Universita’ di Roma Tre and CNISM, U. di R. Napoli, Naples, Italy, FABIO TRANI, DOMENICO NINNO, Universita’ di Napoli Federico II, Naples, Italy, IVAN MARRI, STEFANO OSSICINI, CNR-INFM S-3, Universita’ di Modena Reggio Emilia, Modena, Italy — The titanium dioxide (TiO$_2$) complexes are widely investigated for their multipurpose capabilities. We discuss here a characterization of anatase TiO$_2$ nanocrystals grown by Buffer Layer Assister Growth (BLAG). Amorphous solid water (ASW) was adsorbed as a buffer layer onto SiO$_2$ perfect bipyramidal morphology and then used this NC as a chain repetition unit in the anatase NW. We studied the size confinement and analyzed the effect of surface coverage by functionalization with simple water-derived adsorbates. We found that the structural reconstruction fit the available experimental data, that the band gap shift depends on the crystallinity and that the hydration is important in stabilizing the nanostructures.

9:00AM Y11.00006 Ion scattering from Au nanoclusters formed by buffer layer assisted growth , SNJEZANA BALAZ, JORY YARMOFF, University of California-Riverside — Ion scattering is used to probe the atomic and electronic structure of Au nanoclusters grown by Buffer Layer Assister Growth (BLAG). Amorphous solid water (ASW) was adsorbed as a buffer layer onto SiO$_2$/Si(111) at liquid nitrogen temperature. Au was then evaporated onto the buffer layer to form nanoclusters. The samples were subsequently annealed to room temperature, causing the water to desorb and the clusters to deposit directly onto the substrate. Time-of-flight (TOF) spectroscopy was used to measure 2 keV $^3$Li$^+$ and $^{39}$K$^+$ ions scattered from Au atoms both at low temperature when the clusters reside atop the buffer layer, and after desorbing the water. Small Au depositions yielded a sharp single scattering peak that indicates single layer structures. Following larger depositions, multiple scattering features were present indicating the formation of multilayer nanoclusters. The neutral fraction of scattered $^3$K$^+$, which provides an indication of the filled quantum states, starts at ~50% for small Au coverages and decreases with further deposition, indicating changes in the quantum state occupancy with cluster size.

9:12AM Y11.00007 Cyclotron Resonance of Two-Dimensional Hole Systems in InSb Quantum Wells , JAMES COKER, R. DOEZEMAA, M. EDIRISORIYIA, T. MISHIMA, MIKE SANTOS, University of Oklahoma, X. PAN, G. SANDERS, C. STANTON, University of Florida, L. TUNG, Y.-J. WANG, NH, University of Florida — We report results on the cyclotron resonance of two-dimensional holes in InSb quantum wells. The samples were grown using molecular beam epitaxy. The two-dimensional holes were generated by doping the InSb with phosphorus. The measurements were made using a four-point probe Hall bar configuration. We observed cyclotron resonance features that were attributed to the two-dimensional holes. The energies of the features were determined using the cyclotron resonance expression. The widths of the channels were varied from a lithographic width of 500 nanometers to 2 micrometers, which suggests that high hole mobilities are possible. At higher fields, we observe separate features for different spin-conserving transitions between neighboring Landau levels. The energies of the features depend on the levels’ spin index and Landau level indices. The energies and intensities are explained by a modified Pidgeon-Brown model that explicitly incorporates pseudomorphic mechanical strain. This work was supported by the NSF under Grants DMR-0808086 and DMR-0520550.

9:24AM Y11.00008 Structural and electronic properties of crystals of thiolate-capped Au nanoparticles doped with donor and acceptor molecules: first-principles calculations1 , RONALDO BATISTA, Universidade Federal de Ouro Preto, JONATHAN MARTINS, HELIO CHACHAM, Universidade Federal de Minas Gerais — Structural and electronic properties of crystals of thiolate-capped Au nanoparticles doped with donor and acceptor molecules: first-principles calculations We perform first-principles calculations for crystals composed of periodic assemblies of Au$_{38}$ nanoparticles that are capped with methyliothiol molecules. We consider fcc structures, consistent with recent experimental results [1]. We also consider that the nanoparticle crystals can be doped with either donor (tetrabutylammonium) or acceptor (hexafluorophosphate) molecules, also consistent with recent experiments [2]. We find that the most stable positions of the dopant molecules are located near the nanoparticle surface and that the most interesting changes occur when the dopant molecules are in the center of the nanoparticle. When the concentration of dopants is increased, the stability of the crystal decreases, consistent with recent experiments [2]. Above that critical concentration, a new regime is observed due to a partial order in the dopant molecules. We also consider that the nanoparticle crystals can be doped with either donor (tetrabutylammonium) or acceptor (hexafluorophosphate) molecules, also consistent with recent experiments [2]. We find that the most stable positions of the dopant molecules are located near the nanoparticle surface and that the most interesting changes occur when the dopant molecules are in the center of the nanoparticle. When the concentration of dopants is increased, the stability of the crystal decreases, consistent with recent experiments [2]. Above that critical concentration, a new regime is observed due to a partial order in the dopant molecules. These features are reproduced by a simple capacitive model for the crystal. [1] Abecassis et al. Phys. Rev. Lett. 100, 115504 (2008) [2] Boettcher S. W. et al. Nature Mater. 6, 592-596 (2007).

9:36AM Y11.00009 Interaction effects in conductance of quasi-1D channels formed from Al-GaAs/GaAs 2DEG: Crossover from weakly-disordered Fermi liquid to Luttinger liquid1 , MATTHEW BELL, ANDREI SERGEEV, JONATHAN BIRD, VLADIMIR MITIN, ALEKSANDR VEREVKIN, University at Buffalo — We investigated the conductance of a long and narrow high-mobility channel and observed weakly-disordered multi-channel Fermi liquid [1] to Luttinger liquid with decreasing channel width to ~100nm. Quasi-one-dimensional channels were formed from an AlGaAs/GaAs heterostructure using the split-gate technique. The lengths of the channels were 100 μm. The width of the channels were varied from a lithographic width of 500 nm to ~50 nm by applying negative bias to the split-gate. The effective electron concentration and the channel widths were evaluated from magnetoresistance measurements. In the range of channel widths 500 - 100 nm, at temperatures 1-10 K we clearly observe the logarithmic temperature dependences of the conductance. These dependences are adequately explained by effects of electron-electron interaction in weakly-disordered quasi-one dimensional (with respect to the interaction) Fermi liquid [1]. When the width further decreases, the logarithmic dependences change to power-law dependences, which are typical for Luttinger liquid. This crossover takes place when the channel width corresponds to 2-3 one-dimensional subbands. [1] Sergeev et al., Phys. Rev. B. 69, 075310 (2004).

9:48AM Y11.00010 Giant Orbital Paramagnetism in Nanometer Scale 2DEG Strips , MICHAEL HARRISON, Michigan State University — An elementary calculation shows that Landau diamagnetism becomes significantly altered and very large paramagnetic effects emerge at low temperatures when the channels are penetrated by a perpendicular applied magnetic field and bounded by a parabolic potential, such as may arise from negative voltage applied to a split gate. These novel results are described by an expression which manifests the total system magnetization as a difference between evolved orbital paramagnetism and altered diamagnetism. These predicted effects correspond to drift motion of electrons parallel to the strip length arising from Landau eigenstates that are non-degenerate in the combined presence of a perpendicular applied magnetic field and electric fields associated with a confining parabolic potential. A new heterostructured magnetic material based on orbital electronic motion in 2DEG strips is proposed.
10:00AM Y11.00011 Excitonic condensation with different pairing symmetries in double quantum wells, CHRISTOPHER JAMEL, Indiana University-Purdue University Indianapolis — Double quantum wells with one containing electrons and the other containing holes as carriers are a promising candidate for condensation of dipolar excitons with lifetime much larger than lifetime of excitons in bulk quantum wells. When the inter-well distance is comparable to the interparticle distance within a single well, $d \leq r_{dip}$, inter-well coherence is expected to lead to an excited state condensation. We explore the ground state of a balanced system as a function of inter-well distance and order parameter dispersion with different pairing symmetries. We obtain the quasiparticle density of states in each case. These results lay the ground work for mean-field study of excitonic condensate states with spontaneously broken translational symmetry.

10:12AM Y11.00012 Coulomb Blockade in a Field Emitting Freely Suspended Island, CHULKI KIM, Physics, University of Wisconsin-Madison, HYUN S. KIM, Electrical & Computer Engineering, University of Wisconsin-Madison, HUA QIN, Suzhou Institute of Nano Tech and NanoBionics, ROBERT H. BLICK, Electrical & Computer Engineering, University of Wisconsin-Madison — We observe staircase current-voltage characteristics from an isolated nanomechanical island. The island is fixed by CF$_3$ connections, which makes the structure suspended 1m above SiO$_2$. The noteworthy difference to the “orthodox” single electron transistors is the fact that we observe Coulomb blockade in conjunction with field emission. We can trace and reproduce the transition from staircase to high bias regime. A theoretical model based on field emission current reproduces the experimental data. The full profile of the current-voltage measurement shows the transition from Coulomb staircase current to island field emission current.

WELLS, University of Aarhus, DK and University of Science and Technology, Trondheim, N, H. DIL, P. MEIER, University Zurich-Irchen and SLS, PSI, CH, J. LOBO-CHECA, University Zurich-Irchen and SLS, PSI and Basel University, CH, V.N. PETROV, St. Petersburg Technical University, RU, J. OSTERWALDER, University Zurich-Irchen, CH, M.M. UGEDA, Free University Berlin, D and University Autonoma de Madrid, ES, I. FERNANDEZ-TORRENTE, J.I. PASCUAL, Free University Berlin, D, E. Rienks, M.F. Jensen, University of Aarhus, DK — The (114) vicinal surface of the semimetal Bi is found to support a quasi one-dimensional, metallic surface state. As required by symmetry, the state is degenerate along the $\Gamma - X$ line of the surface Brillouin zone with a binding energy of $\sim$100 meV. In the $\Gamma - X$ direction the degeneracy is lifted by the strong spin-orbit interaction, as directly shown by spin-resolved photoemission. This results in a Fermi surface consisting of two closely separated, parallel lines of opposite spin direction. We discuss these findings in the light of the recently discovered topological stability of surface states on Bi$_2$S$_3$ topological insulators.

8:12AM Y12.00002 Plasmon Resonances in Ultrathin Magnesium Films, MUSTAFA M. OZER, ORNL Oak Ridge TN, EUN JU MOON, Univ Tennessee Knoxville TN, ADOLFO G. EGUILUZ, HANNO H. WEITERING, Univ Tennessee Knoxville TN & ORNL Oak Ridge TN — Low temperature growth of Mg on Si(111) results in the formation of atomically smooth thin films with precisely controlled film thickness. We employed x-ray photoelectron spectroscopy to monitor the evolution of a sharp shake-up satellite in the Mg 1s core level as a function of the film thickness. For films with thicknesses between five and five atomic layers the energy position of this peak is inversely proportional to the square of the film thickness. These results are consistent with the existence of quantized plasmons, which we interpret on the basis of theoretical (hydrodynamics and RPA) descriptions of the density-response function. We demonstrate that the observed loss feature corresponds to the $n = 1$ antisymmetric normal mode of the thin film, consistent with the fact that in the ultrathin film limit the symmetric plasmons have vanished spectral weight - a striking manifestation of the role of size quantization on plasmon resonances in precisely controlled nanostructures.

8:24AM Y12.00003 Structural analysis of the surface of bilayered ruthenate Sr$_3$Ru$_2$O$_7$, BIAO HU, University of Tennessee, Knoxville, TN, D. MANDRUS, A.P. LI, M.H. PAN, Oak Ridge National Laboratory, Oak Ridge, TN, SHUHENG PAN, University of Houston, Houston TX, V. Nascimento, E.W. PLUMMER, Louisiana State University, Baton Rouge, LA, R. JIN, Louisiana State University, Baton Rouge, LA and Oak Ridge National Laboratory, Oak Ridge, TN — The bilayered ruthenate Sr$_3$Ru$_2$O$_7$ exhibits interesting structural properties. For example, in the bulk the in-plane lattice parameter $a$ expands while the out-of-plane lattice parameter $c$ contracts as temperature decreases, accompanied by a rotation of RuO$_6$ octahedra. Remarkably, the broken translational symmetry at the surface causes a tilt of RuO$_6$ octahedra. The Low Energy Electron Diffraction (LEED) $I - V$ analysis shows that the tilt angle of RuO$_6$ is temperature dependent and hysteretic. The correlation between RuO$_6$ tilt at the surface, the surface thermal expansion, and the electrical properties were investigated using Scanning Tunneling Microscopy, (LEED)-$I - V$, and Scanning Electron Microscopy.

8:36AM Y12.00004 Interface-Induced Complex Electronic Interference Structures in Ag Films on Ge(111), TAI CHIANG, YANG LIU, NATHAN SPEER, University of Illinois, Urbana-Champaign, SHU TANG, National Tsing Hua University, TOM MILLER, University of Illinois, Urbana-Champaign, UNIVERSITY OF ILLINOIS, Urbana-Champaign TEAM — We have mapped the electronic structure of atomically-uniform films of Ag grown on Ge(111) by angle-resolved photoemission. Cuts in momentum space at constant energies near the Fermi surface reveal intricate patterns resembling interfering waves emanating from multiple centers. The measured dispersion relations exhibit zigzag patterns with multiple energy gaps. These features are attributed to the mixing of electronic standing waves by the Ag-Ge interface potential, as confirmed by the observed pattern symmetry and by an experimentally deduced interaction strength that scales as the inverse film thickness.

8:48AM Y12.00005 Influence of quantum well states on the formation of surface Au/Pb alloy in Pb/Si(111) quantum thin films, JUNGDAE KIM, SHENGYONG QIN, ALEXANDER KHAJETTOORIANS, University of Texas at Austin, WENGIANG ZHU, ZHENYU ZHANG, The University of Texas, Oak Ridge National Laboratory, CHIH-KANG SHIH, University of Texas at Austin — The thickness dependence of Au/Pb alloy formation on thin Pb quantum films is studied using in-situ low temperature STM/S. Sub-monolayer Au was deposited on thin Pb films on Si(111) substrates. When deposition is carried out at a substrate temperature close to room temperature, it is found that local Au/Pb surface alloys are formed in the form of nano-islands, with preferential formation probability at certain thicknesses. STS data shows this is directly related to quantum well states (QWS) of underlying Pb mesas. When the growth is carried out at low temperature (~80K), the alloy formation probability doesn't show strong thickness preference, but QWS has still strong influence on the nature of the Au/Pb alloy. Two types of Au/Pb alloy nano-islands are formed with quite different electronic properties.

1 NSF-FRG DMR-0606485
9:00AM Y12.00006 Coherent quantum-well electronic structure in bimetallic Pb/Ag films prepared on Si(111). MATTHEW BRINKLEY, Univ of Illinois at Urbana-Champaign, YANG LIU, NATHAN SPEER, THOMAS MILLER, TAI-CHANG CHIANG, UIUC — Angle-resolved photoemission is employed to investigate the electronic structure of Pb films of various thicknesses grown on atomically uniform Ag(111) films. The Ag films, which were deposited on Si(111) substrates, host fully confined electrons at energies within the absolute gap of Si and partially confined electrons outside. The question is: What is the electronic structure of the Pb films prepared over the Ag films? Our results reveal that the quantized electronic structure of the Ag films can be detected for Pb overlays with thicknesses much larger than the photoemission escape depth. Comprehensive simulations have been performed and are in agreement with the experimental results. This study reveals a strong coherent coupling of the Ag and Pb electronic structures despite the incommensurate Ag/Pb interface.

9:12AM Y12.00007 Pseudogap Mediated by Quantum-Size Effects in Lead Islands, KEDONG WANG, XIEQIU ZHANG, Chinese University of Hong Kong, M.M.T. LOY, Hong Kong University of Science and Technology, T.-C. CHIANG, University of Illinois at Urbana-Champaign, XUDONG XIAO, Chinese University of Hong Kong — Quantum confinement effects in both metallic and semiconducting materials are subjects of intense prevailing interest. For thin films and islands of Pb grown on semiconductor surface, quantum well states have been clearly identified and their consequences in growth, thermal stability, and superconductivity have been well studied. In this talk, we will present scanning tunneling spectroscopy measurement results of Pb islands on Si(111) at high energy resolution that reveal a novel pseudogap, or a pseudopeak in special cases, around the Fermi level in addition to the usual quantum well states. These gap or peak features persist to temperatures as high as ~80 K and are uniquely related to the quantum well nanostructure of the Pb islands. A systematic analysis indicates that electron-phonon scattering is responsible for the observed electronic structure. The behavior of the pseudogap has a strong resemblance to that of the pseudogap in high temperature superconductors and certain connections may be speculated.

9:24AM Y12.00008 Quantized Electronic Structure and Growth of Pb Films on Highly Oriented Pyrolytic Graphite, YANG LIU, UIUC, JENS PAGGEL, Continental Automotive GmbH, MARY UPTON, Argonne National Lab, TOM MILLER, TAI CHIANG, UIUC, UNIVERSITY OF ILLINOIS, URBANA-CHAMPAIGN TEAM — We have measured the electronic structure of thin Pb films grown on highly oriented pyrolytic graphite (HOPG) by angle-resolved photoemission spectroscopy. Quantum well states (QWS) corresponding to confined Pb valence electrons are observed. Although the films are rough, the thickness distribution is sufficiently narrow to allow a unique assignment for each QWS peak in terms of a quantum number and the exact film thickness in atomic layers. The even film thicknesses are found to be much more prevalent than the odd film thicknesses. These results are consistent with an available first-principles calculation of the surface energies of freestanding films; an implication is that the interaction between the Pb film and the HOPG substrate is weak. The effective masses of QWS at the surface zone center agree well with the results calculated from the bulk Pb band structure, in sharp contrast to the strongly enhanced or anomalous effective masses in Pb films grown on Si(111) as reported previously. This finding indicates that the anomalous effective masses in Pb/Si(111) are not caused by increased electron correlation effects in a confined geometry, but rather attributable to a strong interfacial interaction between the QWS and the substrate electronic structure.

9:36AM Y12.00009 Quantum stability and superconductive properties of atomically smooth ultrathin alloy films of thermodynamically immiscible metal elements1, EUN JU MOON, Univ Tennessee, Knoxville, MUSTAFA M. OZER, ORNL, JAMES R. THOMPSON, HANNO H. WEITERING, Univ Tennessee, Knoxville, and ORNL — Pb and Gd are immiscible in bulk form. However, atomically smooth ultrathin films of Pb1−xGdx (x=0.06) can be stabilized on a Si(111)7x7 substrate through the quantum size effect. The quantum stability and superconductive properties of these films were investigated using STM, XPS, and SQUID magnetometry measurements. Quantum stabilized growth defects, consisting of deep holes extending to the film-substrate interface, act as pinning centers for vortices in the superconducting state. The pinning centers support an extraordinarily robust critical state with critical current densities in excess of 3 MA/cm2 in 10 monolayer thick films. Anomalies in the dc magnetization and ac magnetic response below 2.5-3.5 K indicate a reduction of the flux pinning below these temperatures, which we attribute to the nature of the holes (deep holes as opposed to blind holes in pure Pb films). The present study highlights the possibility of growing new alloys beyond the solid solubility limit and controlling critical state properties in the quantum regime.

1Research at ORNL sponsored by DOE, Div of Mat Sci Eng.

9:48AM Y12.00010 First-principles study of SiOx/SiC(0001) surface insulating layer, YASUNOBU ANDO, University of Tokyo, KAZUTO AKAGI, WPI-AMR, Tohoku University, SHINJI TSUNEYUKI, University of Tokyo, TETSUROH SHIRASAWA, ISSP, University of Tokyo, HIROSHI TOCHIHARA, Kyushu University, MASAHIRO SATO, Kyushu University, HIROYUKI OHTOMO, Kyushu University, MASAHIRO SATO, Kyushu University, MASAHIRO SATO, Kyushu University, MASAHIRO SATO, Kyushu University — We have calculated by first-principles methods self-consistently the electronic structure of a SiC/SiO2/SiC heterostructure grown on SiC(0001) substrate. The SiO2 layer is terminated by a hydrogen atom, which acts as the source of the charge carriers. The charge carrier density and spatial distribution are not fully understood. In presentation, first-principles study for establishing the fundamental property of the charge carrier in the intrinsic n-type LaAlO3/SrTiO3 interface is introduced. To this end, large models systems including up to 20 layers of SrTiO3 and 1–10 layers of LaAlO3 are employed. The charge carrier is observed within the LaAlO3 layers, with a density as high as 10^18 cm^-3.

10:00AM Y12.00011 Electronic structures of intrinsic n-type SrTiO3−xLaAlO3 interface: density and spatial distribution of free carriers, WON-JOON SON, EUNAE CHOI, SEUNGWU HAN, Ewha Womans University — The seminal paper by Ohtomo and Hwang reporting the unexpected conductivity when two perovskite insulators, SrTiO3 and LaAlO3, formed an atomically abrupt interface along [001] direction, has aroused immense interest on the origin of the conductivity. While it is widely accepted that the intrinsic n-type interface is conducting, the carrier density and its spatial distribution are not fully understood. In presentation, first-principles study for establishing the fundamental property of the charge carrier in the intrinsic n-type LaAlO3/SrTiO3 interface is introduced. To this end, large models systems including up to 20 layers of SrTiO3 and 1–10 layers of LaAlO3 are employed. The charge carrier is observed when LaAlO3 is larger than 3 unit cells and confounded to 5 electrons per unit cell. It is also found that the charge carriers transferred from SrTiO3 surface are mostly localized within a few layers from the interface. Furthermore, the electronic states are quantized at the interface with different localization widths, which is similar to electrons in a wedge potential. The carrier density contributed by the interface-localized state shows a good agreement with the experiment.

10:12AM Y12.00012 ABSTRACT WITHDRAWN —
10:24AM Y12.00013 Positron states and annihilation characteristics at the reconstructed (100) and (111) surfaces of Si with adsorbed hydrogen and oxygen. N.G. FAZLEEV, W.B. MADDOX, A.H. WEISS, Department of Physics, University of Texas at Arlington — We present results of theoretical studies of positron surface states, work functions and annihilation characteristics at the reconstructed (100) and (111) surfaces of Si with adsorbed hydrogen and oxygen. Calculations are performed taking into account geometrically optimized surface structures using a modified superimposed-atom method, and employing the corrugated-mirror model in a full three-dimensional geometry. The effects of adsorption of hydrogen and oxygen on the positron binding energy at the reconstructed (100) and (111) surfaces of Si and the positron work function are explored. The positron surface-state annihilation characteristics are computed for different hydrogen and oxygen coverages of both reconstructed surfaces of Si. The obtained results predict attenuation of the Si positron-annihilation-induced Auger electron signal intensity with the increase of the hydrogen and oxygen coverage consistent with experimental data. These studies confirm that positron-annihilation-induced Auger electron spectroscopy can be used to study changes in the properties of semiconductor surfaces due to the presence of adsorbed hydrogen and oxygen.

10:36AM Y12.00014 Fabrication and transport measurement of periodic wavy structures of Si/SiGe nanomembranes, MINRUI YU, ROBERT BLICK, ARNOLD KIEFER, DON SAVAGE, MAX LAGALLY — We demonstrate fabrication of completely under-etched Hall-bars made from Si/SiGe nanomembranes with a highly doped SiGe layer. The sample material is epitaxially grown by chemical vapor deposition (CVD) on silicon-on-insulator (SOI) wafers. Hall-bars are defined by optical photolithography and etched by reactive ion etching (RIE). They are then completely released from the substrate through hydrogen fluoride (HF) vapor etching. The lattice mismatch between silicon (Si) and germanium (Ge) generates an initial strain inside the material, which tends to recover once the sacrificial oxide layer is removed. This combined with carefully designed geometric constraints causes the structures to buckle and generate periodic wavy patterns after releasing and rebonding to the wafer surface. We study the magneto-transport at both room and low temperatures, with and without light illumination. Our results show the effect of strain on band structure and electron mobility. This will further the understanding of mechanically modulated electron transport.

10:48AM Y12.00015 Electron accumulation on bare and hydrogenated indium nitride surfaces, BRIAN THOMS, RUDRA BHATTA, ANANTA ACHARYA, MUSTAFA ALEVLI, NIKOLAUS DIETZ, Georgia State University, DEPARTMENT OF PHYSICS & ASTRONOMY TEAM — Electron accumulation layers which affect device and contact properties have been reported on several semiconductor surfaces such as InAs, InN, and CdO. Adsorbates have been shown to affect the electron density on InAs surfaces, however, surface termination effects for InN have not been determined. In this work surface-sensitive electron spectroscopic techniques are used to study both the electron accumulation layer and the surface structure on N-polar InN. High resolution electron energy loss spectroscopy (HREELS) has been used to characterize the surface electron accumulation by observing changes in the energy of the conduction band plasmon loss with variations in incident electron energy. In addition, HREELS along with low energy electron diffraction and Auger electron spectroscopy allow characterization of the surface structure and bonding. By this method it is shown that both hydrogen-terminated and bare N-polar InN surfaces exhibit electron accumulation. These results indicate that surface electron accumulation on InN is not due to indium-indium bonding and is not substantially affected by the presence or absence of surface hydrogen, but may instead be intrinsic to the N-polar InN surface. The effects of other adsorbates will also be discussed.

Session Y13 DCOMP: General Theoretical and Computational Methods 309

8:00AM Y13.00001 A global EMC/FDTD simulation tool for modeling THz wave interaction with conductive media, K. J. WILLIS, S. C. HAGNESS, I. KNEZEVIC, University of Wisconsin - Madison — We present a computational tool for modeling the interaction between THz electromagnetic waves and conductive media. By coupling the ensemble Monte Carlo (EMC) simulator of carrier dynamics and the finite-difference time-domain (FDTD) solver of Maxwell's equations, we have developed a robust and versatile global simulator that can be applied to the fields of linear algebras, FFT, and others. We have experienced that one-dimensional CUFFT ver1.1 (GPU-FFT) is eight times faster than FFTW for single-precision case. We implement the GPU-FFT into our in-house first principles planewave code, in which the hot spot is the FFT routine. We will present the fields of linear algebras, FFT, and others. We have experienced that one-dimensional CUFFT ver1.1 (GPU-FFT) is eight times faster than FFTW for single-precision case. We implement the GPU-FFT into our in-house first principles planewave code, in which the hot spot is the FFT routine. We will present the performance of the implementation.

8:12AM Y13.00002 GPU Based Acceleration of First Principles Calculations, HIDEKAZU TOMONO, Meiji University, JAPAN, TOSHIKAI IITAKA, RIKEN, KAZUO TSUMURAYA, Meiji University, JAPAN — The saturation of the acceleration using the silicon devices has required the parallel computing using multiple CPU's (central processing units). The parallel computing has been widely used in the field of the high-performance computing. On the other hand, graphics processing units (GPU's) were designed to accelerate graphic applications in 1978. NVIDIA Co. began to provide CUDA for C-language users to manipulate the GPU's in 2007. They applied it to computational fluid dynamics, medical real time simulation and astronomical N-body problem among others. This is the GPGPU (general-purpose computation on GPU's), which is faster in operation than CPU in the fields of linear algebras, FFT, and others. We have experienced that one-dimensional CUFFT ver1.1 (GPU-FFT) is eight times faster than FFTW for single-precision case. We implement the GPU-FFT into our in-house first principles planewave code, in which the hot spot is the FFT routine. We will present the performance of the implementation.

8:24AM Y13.00003 Saturation effects in dispersion interactions, BO E. SERNELIUS, Linköping University — The interest in Casimir interactions has been very strong during the last decade. This increase in interest was spurred by the torsion pendulum experiment by Lamoreaux which produced results with good enough accuracy for the comparison between theory and experiment to be feasible. Theory and experiment agree quite well for low temperatures. However at room temperature, where most experiments are performed there are serious deviations. Each new experiment has lead to new puzzling discrepancies between theory and experiment. Theorists have been forced to resort to phenomenological approaches to the problems, with new prescriptions for each new experiment. Here we address three experiments: Casimir pressure between a gold sphere and a gold plate; Casimir force between a gold sphere and a laser excited silicon membrane; Casimir force between a Rub atom and a fused silica wall. In all these different experiments we show that inclusion of saturation effects makes the discrepancies go away.

8:36AM Y13.00004 Symmetries of non-relativistic quantum-mechanical Hamiltonian, BOJAN TUNGUZ, Wabash College — In non-relativistic quantum mechanics the most fundamental invariance group of the Hamiltonian is the Galilean group of transformations: the group spatial and temporal translations and rotations. The quantum-mechanical wave functions in that view belong to an infinite-dimensional representation of the Galilean group, and the generators are represented with first-order differential operators. In this work we look at all the higher order differential operators that commute with the Hamiltonian and construct the most general group that leaves the Hamiltonian invariant. We show how the Galilean group fits within this group, and we show how the interaction terms break the symmetry of the free-particle Hamiltonian. We argue that the interpretation of the Hamiltonian in terms of individual interacting particles is the consequence of this broken symmetry.
8:48AM Y13.00005 Planck’s High Temperature Catastrophe in Observational Astronomy:- (NASA proves Planck wrong) , CLARENCE A. GALL, Universidad del Zulia, Venezuela — Planck’s black body radiation law 

\[ I_B = \frac{2 \pi^2 \hbar^2 c^2}{\lambda^5 (e^{\lambda/\kappa} - 1)} \]

predicts that a hotter body (higher \( T \)) should always emit more intensely than a colder body (lower \( T \)) throughout the entire EMR spectrum. However, space age infrared astronomy contradicts this prediction! It is now known that as observation moves from the visible to the near-, mid- and far infrared; increasingly cold celestial objects come into view while hotter ones fade and disappear (http://coolcosmos.ipac.caltech.edu/cosmic_classroom/ir_tutorials.html). Were Planck’s law valid, the hottest stars would never disappear; and colder objects would not be detected. This can only be described as a high temperature catastrophe (APS, April Meeting 2008; H12.3, St Louis, MO) for Planck’s law! On the other hand, Gall’s black body radiation law

\[ I_B = \frac{\sigma T^4}{\lambda^5} \]

(http://sites.google.com/site/purefieldphysics) predicts that as wavelength increases, there is a crossover point above which a colder object will emit more intensely than a hotter one. Hence colder objects will appear and hotter ones will eventually disappear from view. The crossover point for black bodies at 6000K and 100K is 12.066 microns. These calculations with Gall’s law are in overall agreement with observational infrared astronomy.

9:00AM Y13.00006 Expressing n dimensions as n-1. JOHN LAUBENSTEIN, IWP Research Center — The IWP Scale Metrics team has explored a different conceptualization of multiple dimensions through a model expressing n dimensions as \( n-1 \). This is achieved by aligning time and a spatial dimension along the same orientation. We have shown that time and distance along the same axis in combination with a scalar is equivalent to two orthogonal dimensions. Scale Metrics is simply a different conceptualization of multi-dimension. However, it requires a change in the modeling of gravitation since time is no longer considered to be orthogonal to the three spatial dimensions. A model for Scale Metrics gravity has been developed and in the process a quantum theory of gravitation emerges. Why entertain IWP Scale Metrics? Because the Standard Model has not been successful in the unification of GR with QT. A new model of gravitation built on a foundation of quantum concepts (as opposed to a quantum fix to an inherently classical geometric theory) may be the key to understanding the universal stage for the unification of gravitation with quantum theory. Further, since Scale Metrics provides nothing more than a different way to conceptualize multiple dimensions in a manner that is equivalent to 4 vectors – it replaces nothing, but rather serves only to complement past and current achievements while providing a new view of quantum gravitation.

9:12AM Y13.00007 The mass, energy, space and time system theory-MEST- the theory of relativity and the quantum mechanics. DAYONG CAO, Beijing Natural Providence Science & Tech — Things have their own physical system of mass, energy, space and time of themselves. (The MEST for short thereafter) So we can use it to unite both the physical system of any thing. There are the transmutation between space-time and mass-energy. There are the conservation of space-time and mass-energy. The uf force like the gravitation is from space-time, the down force like repulsion is from mass-energy. So there are the positive and negative curvature. We need to develop the theory of relativity and get the new equation. By using the mass-energy wave equation, deduce the new uncertainty principle, uncertainty and probability can not be divided. New wave wave equation are being put forward. The quantum mechanics is the mass and energy theory of relativity; the theory of relativity is the space and time theory of relativity. MEST can unite both them.

9:24AM Y13.00008 Is Sound a Property of Space or Vacuum? , VENKATA CHAGANTI, Department of Physics, University of Texas, El Paso — Absolutist regards SPACE as an entity in its own right with properties of its own. Further more, relationists, scientists and laymen attribute many different sorts of properties to SPACE. In fact, we are able to distinguish every material from the other by its properties. We all know that SPACE is attributed by some of the properties listed below. 1. Electromagnetic Properties like permittivity and permeability. 2. Empty SPACE is a poor conductor. 3. Empty SPACE is transparent. 4. SPACE is penetrable by any particle / material. 5. SPACE is incapable of action. 6. SPACE is immovable. 7. SPACE is infinite. 8. SPACE is isotropic. 9. All bodies are place in SPACE. 10. SPACE is Isotropic. And many more properties can be made quite precise without any reference to an embedding space surrounding the SPACE of interest. SPACE as a physical object only makes sense if it can be detected, or if it can exert physical influences. Does the motion of an object through SPACE lead to detectable effects? Can SPACE act on a moving body in the way that the sea acts on a moving fish? In this paper an attempt is made to show that SPACE is indeed like any other medium / material and also SOUND is its property. Statistical Mechanics is used as a tool.

9:36AM Y13.00009 New Generally Covariant Generalization of the Dirac Equation Not Requiring Gauges , DAVID MAKER, mda — We introduce a new pde \( \left( \sum_{\mu} \sqrt{\gamma_{\mu} \gamma_5} \partial / \partial x_{\mu} \nu = 0 \right) \) with symmetrically diagonalized \( \kappa_\nu = 1 \rightarrow H \)

\[ \frac{1}{\kappa \nu} \] giving it common covariance. If \( \kappa_\nu = 2 \) this new pde reduces to the standard Dirac equation as \( \nu \rightarrow \infty \). Next we solve this equation directly using separation of variables (e.g., 2P, 25, 15 terms). Note metric time component \( \kappa_\nu = 0 \) at \( \nu \rightarrow H \) and so clocks slow down with baryon stability the result. Note also that near \( \nu \rightarrow H \) the 2P state for this new Dirac equation gives a circumtrifoulum, 3 lobe shape; so this ONE charge (so don’t need color to guarantee this) spends \( 1/3 \) of its time in each lobe (fractionally charged lobes), the lobe structure is locked into the center of mass (asymptotic freedom), there are six 2P states (corresponding to the 6 flavors); the P wave scattering gives the jets, all these properties together constituting the main properties of quarks! without invoking the many free parameters, gauge conditions of QCD. Also the 25L/1 \( \rightarrow \) the tauon and the 15L/1 \( \rightarrow \) the muon here. The 5S of this new pde gives the \( W \) and \( Z \) as resonances and does not require renormalization in free parameters. Thus we get nuclear, weak and E&M or phenomenology as one step solutions of this new pde, not requiring the standard method’s pathology of adhoc assumptions such as gauges and counterterms, 19 free parameters (you can vary any way you want) that have confused, blocked the progress of theoretical physics for the past 30 years.

9:48AM Y13.00010 The darkness of mere being: DM and DE explained , JAMES BEICHLER, Retired — In previous APS meetings, I have presented a geometrical explanation of Dark Matter and Dark Energy that makes testable predictions and is thus completely falsifiable. The theory is based on a macroscopically extended fourth dimension of space that yields a five-dimensional space-time structure. In this structure, the four-dimensional space-time of relativity is extrinsically curved in the higher spatial dimension. Dark Matter is curvature in the higher dimension that is not directly associated with local matter, but instead results from an interaction between local matter or curvature and the global curvature due to all matter in the universe. Criticisms that the theory was not mathematical have now been overcome and a simple algebraic formula that corresponds to the geometry of the four-dimensional structure of space has been derived. The algebraic formula appears to be Newtonian, but it implies a five-dimensional unified field structure such as that developed by Kaluza in 1921 and extended by Einstein and his colleagues in the late 1930s. The new equation also shows how gravity can be quantized on the basis of relativity without hypothesizing the discrete nature of matter, i.e., the existence of specific “particles” of gravity, inherent in quantum mechanics, the Standard Model and other quantum models.

10:00AM Y13.00011 Charged Particles are Preventing from Moving Faster than the Speed of Light by Light Itself , RANDY WAYNE, Department of Plant Biology, Cornell University, Ithaca, NY 14853 — Many problems in classical mechanics are solved by assuming that friction is negligible. At velocities close to the speed of light, however, friction is never negligible as a consequence of the dilatant optical molasses that results from the temperature-dependent blackbody distribution of photons. A body moving at relativistic velocities experiences the blackbody radiation as being Doppler shifted. This adds a nonlinear velocity-dependent component of friction. By accounting for this thermodynamic friction, I have obtained an equation of motion that is applicable for modeling the movement of particles at relativistic velocities. While the predictions of the opto-mechanical model are qualitatively consistent with the predictions of the Theory of Special Relativity in terms of the nonlinear relationship between force and acceleration, there are quantitative and testable differences.
10:12AM Y13.00012 Why So Many More Americans Die in Fires. LAWRENCE CRANBERG, Texas Fireframe Co. — “Why So Many More Americans Die in Fires” is the headline on Page 3 of The New York Times’ full-page story on December 22, 1991, by D. G. McNeil, Jr. — It is a partial report based on personal experience with domestic fire making for thermal comfort since 1975 (1) and a published claim (2) of unique safety benefits. The McNeil report attributes the problem to “A Case of Bad Attitude” and “A Reliance on Technology.” That implies a “bad attitude” on the part of technologists – a conclusion consistent with this technologist’s thirty-five years of experience with fellow technologists, who has found “buck-passing” the favorite recourse of technologists in the highest places in government even though, as McNeil has written, “Many children never wake up. Smoke or toxic gases overcome them as they sleep. When fire fighters lift them, their imprints remain.” Regrettably, in this author’s experience, the courts have also displayed a “bad attitude” where “life and death issues” have been pleaded. 1. L. Cranberg, Slot Flame Stability with Hohlraum Radiation Pattern, BAPS, Series II, Vol. 20, No. 9, Sept., 1978. 2. L. Cranberg, Fireplace Firesafety, Fire Journal, Letter, May/June, 1987.

10:24AM Y13.00013 A new Virtual Crystal Approximation approach, ROBERTA POLONI, ICMAB-CSIC, Campus UAB E-08193 Bellaterra, Barcelona (Spain) — It is well known that the virtual crystal approximation (VCA) provides an efficient method for studying disordered alloys and solid solutions by first-principles. Although several studies have reported VCA results regarding stability issues by using energetic considerations, here we propose a new approach based on alternative structural indicators. The reason for this is that it is still not clear whether energy comparisons for different virtual compositions are trustworthy. Our non-fully-predictive scheme makes use of some experimental information in order address structural problems like atomic ordering and/or partial occupation at some site. We look at different figures of merit (energy derivatives), depending on the amount of experimental information taken into account, and we minimize them with respect to different possible structural configurations. By applying our approach to a wide number of well known systems (oxinitrides, borocarides, perovskites, etc.) we have been able to reproduce the experimental structure in all cases.

Friday, March 20, 2009 8:00AM - 9:48AM — Session Y14 DFD: Nonequilibrium and Templated Assembly 315

8:00AM Y14.00001 Speeding up the understanding of Vertical Deposition of Diluted Colloids1, WENCESLAO GONZÁLEZ-VIÑAS, MAXIMILIANO GIULIANI2, MOORTHI PICHUMAN3, University of Navarra — We measured the speed of contact line in vertical deposition of diluted micron sized polymeric colloids. We correlated these results with the obtained morphologies for the deposits. We show that low velocities correspond to the formation of monolayer and high velocities to multilayer. These new results are explained in terms of the local concentration of particles in the suspension near the contact line and the porosity of the pre-deposited structure. The effect of an applied electric field to the system is also reported.

8:12AM Y14.00002 Kinetics of formation and disintegration of ionic and non-ionic spherical micelles1, GUNJAN MOHAN, PPG Industries, DMITRY KOPELEVICH, University of Florida — Dynamics of self-assembly and structural transitions in amphiphilic systems play an important role in various industrial and biological processes. Main challenge in computational modeling of these dynamics is a complex interplay between various length- and time-scales. In this talk, we discuss development of a multi-scale model for formation and disintegration of non-ionic and ionic spherical micelles. This study is performed under the assumption that the dominant mechanism of micelle formation (disintegration) is a stepwise addition (removal) of individual surfactant monomers to (from) a surfactant aggregate. A series of molecular dynamics simulations is used to develop reduced stochastic models for these elementary processes. It is demonstrated that these processes involve complex interactions of the translational degree of freedom (i.e., distance between centers of mass of the aggregate and the monomer) with degrees of freedom corresponding to the monomer orientation and the micellar shape and microstructure.

8:24AM Y14.00003 Using fluid flow to control the structure of soluble surfactants deposited through receding contact lines. BENJAMIN BEPPLER, KALYANI VARANASI, STEPHEN GAROFF, KRISTINA WOODS, Carnegie-Mellon University, GUENNADI EVMENENKO, Northwestern University — Moving contact lines are often used to deposit soluble organic molecules in applications such as spin coating and dip coating. In this study, we demonstrate that altering the flow field near such a contact line fundamentally changes the deposited surfactant structure. At slow contact line speeds, the substrate emerges dry. The rolling fluid motion near the contact line deposits a densely packed, tilted monolayer of surfactant along the emerging solid-vapor interface. Above a critical contact line speed, an evaporating thin film is entrained on the emerging substrate. Surfactant concentration constantly increases in this confined environment due to solvent evaporation. Monodisperse crystalline islands nucleate and grow on the substrate with sizes and shapes controlled by varying the deposition conditions. These results contrast with disordered deposits that result from evaporation at a pinned contact line. Our results suggest that dip-coating with control of dipping speed and evaporation rate produces unique assembled structures and may provide better control of deposition through moving contact lines.
8:36AM Y14.00004 Rapid Convective Deposition For Fabrication of Microlens Arrays
JAMES GILCHRIST, PISIST KUMNORKAEW, Department of Chemical Engineering, Lehigh University, NELSON TANSU, YIK-KHOON EE, Department of Electrical and Computer Engineering, Lehigh University — Micron-sized microspheres were deposited into thin films via rapid convective deposition, similar to the ‘coffee ring effect’ using a similar method to that studied by Prevo and Velev, Langmuir, 2003. By varying deposition rate and blade angle, the optimal operating ranges in which 2D close-packed arrays of microspheres existed were obtained. Previous models do not consider the effect of blade angle and blade surface energy on the deposition of the particles. Using a computer-aided scanning electron microscope, dynamic counts for particle engulfment and rejection by the dendrites during spin coating were revealed. The resulting microstructure controlled by varying the macro scale parameters and interaction between substrate and colloidal particles played an important role in formation of ordered crystalline arrays. These interactions were explored through a model comparing the residence time of a particle in the thin film and the characteristic time of capillary-driven crystallization to describe the morphology and microstructure of deposited particles. Fabricated microlens arrays assembled on LEDs using this process were demonstrated to enhance performance by 300%.

8:48AM Y14.00005 Permanent Flow-Induced Phase Transitions in Wormlike Surfactant Micelle Solutions
MUKUND VASUDEVAN, Cytec Industries Inc. Stamford, CT, ERIC BUSE, Washington University, Saint Louis, MO, AMY SHEN, University of Washington, Seattle, WA, BAMA KHOKAMI, University of Tennessee, Knoxville, TN, RAVINDKAR SURESHKUMAR, Washington University, Saint Louis, MO — It is well known that certain wormlike micelle solutions form flow-induced structures under shear flow. This structure transition is typically accompanied by an enhancement in the shear viscosity and the emergence of a new gel phase. However, such transitions are generally believed to be reversible, i.e., upon flow stoppage, the structure relaxes to equilibrium. In this work, we show that by subjecting translucent wormlike micelle solutions to high flow deformation over a rapid time scale, permanent flow-induced structures can be formed. We will discuss the phenomenology and plausible physical mechanisms underlying this discovery.

9:00AM Y14.00006 Understanding the structure of porous materials created by freeze casting
STEPHEN BARR, ERIK LULJET, University of Illinois at Urbana-Champaign — When a suspension of colloidal particles in water freezes, dendrites of ice with high aspect ratios are formed which can either engulf or reject the particles based on their size and the velocity of the advancing ice front. As the particles are pushed between the dendrites, concentrated regions of colloidal particles are formed. Recent experiments have shown that this can be exploited to create strong, lightweight, porous materials. We investigate this process using molecular dynamics simulations, focusing on the effect of the ice front velocity on the structure of the resulting material. We develop a simulation model which accounts for particle engulfment or rejection by the dendrites. We study both columnar and lamellar geometries. Our main finding is that variation of the front velocity not only affects the particle concentration in the interdendritic regions, but also the degree of order of the resulting solid.

9:12AM Y14.00007 End-Functionalized Triblock Copolymers as a Guide for Nanoparticle Ordering
RASTKO SKNEPNEK, JOSHUA ANDERSON, MONICA LAMM, JOERG SCHMALIAN, ALEX TRAVESSET, Iowa State University and Ames Laboratory — Using molecular dynamics simulations we show that triblock copolymers, designed to have specific affinity for nanoparticles at the chain ends, can successfully mediate assembly of nanoparticle/copolymer composites. In this talk, we will present a detailed investigation of the phase diagram of these nanocomposites as a function of both nanoparticle size and concentration. We find a rich phase diagram with two striking features. The first is the existence of an unconventional square columnar phase of two interpenetrating line-lattices of micellar cylinders and aligned nanoparticles, and the second is a drastically enhanced stability of the gyroid phase. We interpret the origin of the square columnar phase by making an analogy to the packing of binary mixtures of disks. Based on the analysis of stretching of copolymers we argue that nanoparticles help stabilize gyroid order and drastically widen the region of its stability. Our study suggests that combining nanoparticles with functionalized block copolymers can provide a simple and efficient tool for assembling novel materials with nanometer scale resolution.

9:24AM Y14.00008 Unexpectedly wide distributions in the stochastic synthesis of functionalized nanoparticles
JACK WADDELL, DOUGLAS MULLEN, BRADFORD ORR, MARK BANASZAK HOLL, LEONARD SANDER, University of Michigan — Functionalized nanoparticles are promising devices with a variety of applications, such as the targeted delivery of chemotherapy drugs to cancer cells. Their properties depend on the specifics of the distribution of functional groups on the nanoparticle. Stochastic ligand conjugation is an efficient strategy for synthesizing large quantities of functionalized nanoparticles. We developed a kinetic model for the study of ligand distribution on a generation 5 poly(amideamine) dendrimer, as measured by HPLC and SPR. We found a cooperative effect in single species ligandation, leading to a broader-than-Poisson distribution of ligands on nanoparticles, and suggesting a high spatial correlation of functional groups.

9:36AM Y14.00009 Self assembly of silica nanoparticles in a surfactant mesophase
K. SHARMA, Ph.D. student, K. GURUSWAMY, Scientist, O. MONDAIN-MONVAL, Professor, I. LY — We examine the organization of silica particles in a hexagonal mesophase of a non-ionic surfactant, C_{12}E_8 in water. The mesophase has a characteristic length scale (cylinder-center-to-center distance, \(a\sim 5.7\) nm). We vary the size of the silica particles from \(\sim 2\) nm \((<a)\) to \(\sim 500\) nm \((>a)\), to examine the effect of particle size, and use a combination of SAXS, freeze fracture TEM and optical microscopy to characterize our materials. We show that particles \(<a\) behave like a solvent and template the mesophase. Particles with a size \(a\) are partitioned into a dispersed phase and into strand-like aggregates. Particles \(>a\) separate from the mesophase and form strand-like aggregates that organize into a network. The formation of this network is reversible and heating into the high temperature isotropic phase leads to dispersion of the particles. Unusually an increase in hexagonal-isotropic transition temperature is seen for the mesophase-particle composites. We show that the network forms by expulsion of the particles from growing hexagonal phase domains — as these domains grow, the particles are concentrated in the isotropic regions until they jam to form the network. We show that we are able to tune the mesh size of the particulate networks by changing the cooling rate.

Friday, March 20, 2009 8:00AM - 11:00AM — Session Y15 DFD: Liquid Crystals III

8:00AM Y15.00001 Magnetic-field induced isotropic to nematic liquid crystal phase transition
J.T. GLEESON, T.B. OSTAPENKO, Kent State University, D. B. WIANT, Wake Forest University, S.N. SPRUNT, A. JAKLI, Kent State University — We report on measurements of magnetic field induced nematic order in the bent-core liquid crystal 4-chlororesorcinol bis[4-(4-n-dodecylxyloxybenzoxyl) benzolate]. Using the 31 Tesla solenoid at the National High Magnetic Field Laboratory, we have observed, at temperatures less than one degree above the clearing point, a first-order transition to the nematic phase. The critical magnetic field at which this occurs increases with temperature. We discuss these results within the context of both Mater-Saupe and Landau-Ginzburg mean field models for the nematic-isotropic transition. The implications of this transition for the mesophase stability of the liquid crystal were also discussed. To our knowledge, this is the first observation of such a magnetic field-induced transition in a thermotropic liquid crystal; the reasons for which this behavior is now attainable are discussed.
This work was supported by the NSF (DMR-0606160) and Kent State University. Work performed at NHMFL supported by NSF cooperative agreement DMR-0084173, the State of Florida and the DOE.
8:12AM Y15.00002 High Magnetic Field-Induced Birefringence in Lyotropic Chromonic Liquid Crystals, T. OSTOPENKO, Kent State University, YU. NASTISHIN, Inst. for Phys. Opt., Lviv, Ukr., J.T. GLEESON, S.N. SPRUNT, O.D. LAURENTOVICH, Kent State University, P.J. COLLINGS, Swarthmore College — We studied the effect of magnetic-field induced birefringence of a 14% solution of disodium cromoglycate (DSCG) in water at temperatures above the nematic-isotropic coexistence region. According to Landau-deGennes mean field theory, we expect to find a linear relationship between the inverse of the induced birefringence, $\Delta n$, and the quantity (T-$T^*$), where $T^*$ is the stability limit of the isotropic phase. Using the 31 T resistive magnet at the National High Magnetic Field Laboratory, we observed that, as we increase the temperature above the coexistence region, we deviate from this linear dependence. Our data shows that $\Delta n$ goes to zero, whereas Landau-deGennes predicts that $\Delta n$ should decrease asymptotically. This may be due to the lack of isodense aggregate formation at a finite temperature above the coexistence region. Supported by NSF (DMR-0710544 and DMR-0606160). Work performed at NHMFL, supported by NSF cooperative agreements DMR-0084173, the State of Florida and the DOE.

8:24AM Y15.00003 ABSTRACT WITHDRAWN

8:36AM Y15.00004 Chromonic liquid crystalline properties of dyes, XUXIA YAO, JUNG PARK, School of Polymer, Textile, and Fiber Engineering, Georgia Institute of Technology, MOHAN SRINIVASARAO, School of Polymer, Textile, and Fiber Engineering, School of Chemistry and Biochemistry, Georgia Institute of Technology — As a new class of lyotropic liquid crystals, chromonic liquid crystals (CLCs) can self-assemble into an ordered complex fluid, potentially useful for organic solar cells. Different from common amphiphilic lyotropic mesophases, CLCs have no optimum aggregation size, which implies the order parameter increases with concentration. We used capillary flow and magnetic field to induce alignment in chromonic dyes and studied the aggregation behavior by Vis-spectroscopy, the phase behavior by POM and DSC, and the order distribution by Raman Scattering. We also investigated how the molecular structures influence the structures of mesogens and the morphology in the dried film which will further influence the charge mobility in the solar cells.

8:48AM Y15.00005 Liquid Crystalline Phase Transition of Colloidal Platelets with Identical Thickness1, DAZHI SUN, ZHENDONG CHENG, HUNG-JUE SUE, Texas A&M University, PROF. SUE’S TEAM, PROF. CHENG’S COLLABORATION — The disorder – order transition in discotic colloids has been an active research area since the observation of the nematic phase in clay suspensions by I. Langmuir in 1938. In the past decade, synthetic platelets have been used extensively to investigate the discotic liquid crystal phase transitions. Here, we report the phase behavior of a new model platelet system – alpha-zirconium phosphate (ZrP). After exfoliation, the monolayer ZrP platelets possess uniform thickness, but have a high polydispersity in diameter. We observed an isotropic - nematic transition in our system upon increasing the platelet volume fraction, followed by the formation of the discotic smectic phase, an elusive phase that has been rarely seen in discotic liquid crystals. The discotic smectic phase (domain) is characterized by X-ray diffraction, high-resolution transmission electron microscopy, and optical microscopy. The equation of state (EOS) of our system is also discussed.

9:00AM Y15.00006 Study of the Isotropic-Nematic and the Nematic-Smectic-A Phase Transitions in Carbon Nanotubes and Liquid Crystal Composites, KRISHNA SIGDEL, GERMANO IANNACCCHIONE, Worcester Polytechnic Institute — A high-resolution ac-thermal study of the isotropic to nematic (I-N) and the nematic to smectic-A (N-SmA) phase transitions of carbon nanotubes (CNTs) and liquid crystal octyl-cyanobiphenyl (8CB) composites (8CB+c-CNTs) as a function of CNTs concentration is reported. Scans were performed on heating and cooling for all samples (0.5-6 wt% of CNTs) over a wide temperature range well above and below the two transitions in pure 8CB. Both the I-N and the N-SmA transitions evolve in character and have their transition temperatures shift lower as the wt% of CNTs increases. For intermediate wt% values, new transitions features are observed, which suggest new phase ordering of the CNTs within the liquid crystal host.

9:12AM Y15.00007 Recovery and stabilization of a reversed phase sequence in a ternary liquid crystal mixture, RONALD PINDAK, Brookhaven National Lab, SHUN WANG, LIDONG PAN, Univ. of Minnesota, B.K. MCCOY, Azusa Pacific Univ., SUNTAO WANG, Brookhaven National Lab, H.T. NGUYEN, Univ. Bordeaux, CHENG-CHER HUANG, Univ. of Minnesota — The nOHFBBB1M7 (n = 10) compound, 100HF, shows a reversed SmC*$_{F12}$ - SmC* phase sequence, unique among all known antiferroelectric liquid crystals. This reversed phase sequence is stabilized upon doping with 90TBBB1M7(C9) or 110TBBB1M7(C11). In contrast, doping with homologous compounds (n = 9, 11, or 12) eliminates the SmC*$_{F12}$ phase. One 100HF/110HF mixture without the SmC*$_{F12}$ phase was selected for further studies. Adding C9 into this mixture revives the reversed phase sequence. Unexpectedly, even though 110HF destabilizes the SmC*$_{F12}$ phase in binary mixtures with 100HF, it significantly increases the SmC*$_{F12}$ temperature range in 100HF/110HF/C9 ternary mixtures. The extended temperature range is important for device applications.

9:24AM Y15.00008 Room-Temperature Liquid Crystal Blue Phases, STEFANIE TAUSHANOFF, Kent State University, KHOA VAN LE, Tokyo Institute of Technology, ROBERT TWIENG, ANITAL JAKLI, Kent State University — The “blue phases” of a highly chiral liquid crystal are defect-studded structures of double-twist cylinders that are laced together. The three phases, BP1*, BP2* and BP3* differ in the packing of the double-twist cylinders. Until recently, blue phases were of limited practical use because they appeared for only a very narrow temperature range. Mixtures that show BP1* and BP2* phases for wide temperature ranges at or around room temperature are now available [1]. Relatively wide temperature BP3* (the blue fog) phase so far is available only at very high temperatures [2]. Here we present mixtures with room-temperature wide range BP2* phase and compare the ability of chiral dopants to form the different blue phases in a base nematic mixture. PDLC films cast with blue-phase material are also examined.

9:36AM Y15.00009 Hybrid shells of nematic liquid crystal, ALBERTO FERNANDEZ-NIEVES, TERESA LOPEZ-LEON, Georgia Tech — We investigate the consequences of changing the boundary conditions for the nematic director at the outer surface of a spherical shell from planar to homeotropic. We find there are different routes to the final equilibrium configuration, depending on the initial shell structure. For bipolar shells, which are shells having two pairs of $s=\pm 1/2$ boojums on either surface, a disclination ring forms, shrinks and disappears in a process that is highly reminiscent of that seen in bipolar drops. By contrast, shells with four $s=\pm 1/2$ defects develop open disclination lines in the inner surface; these lines form between the original $s=\pm 1/2$ defects and force their approach and coalescence. These results highlight the fascinating range of behaviors that are driven by the interplay between topological constraints and the nematic order of liquid crystals.

10:12AM Y15.00012 Second Harmonic Generation in a Bent-core Nematic Liquid Crystal.1
, SEUNG HO HONG, ANTAL JAKLI, JAMES GLEESON, SAMUEL SPRUNT, BRETTT ELLMAN, Kent State University — We studied second harmonic
generation (SHG) as a function of optical polarization in a magnetically-aligned bent-core nematic liquid crystal (BCN). At the isotropic to nematic transition
we detect the onset of a weak SH signal, which stays approximately constant through the nematic phase. Our results for polarization selectivity and for cells of
different thickness indicate that the signal from the BCN cannot be explained by quadrupoles, defects in director orientation, fluctuations or cell-surface
polarization. We discuss models for a noncentrosymmetric component of the BCN structure that can explain our data.

1Work supported by NSF DMR0606160.

10:24AM Y15.00013 Viscoelastic parameters and flexoelectric effect in a bent-core nematic liquid crystal studied by dynamic light scattering
. MADHABI MAJUMDAR, K. NEUPANE, JAMES T. GLEESON, ANTAL JAKLI, SAMUEL SPRUNT, Kent State University — Recent measurements of the flexure-induced
electric polarization in certain bent-core nematics (BCNs) have demonstrated a giant flexoelectric effect [1]. We present a study of nematic elasticities and viscosities in one of these compounds, together with an attempt to characterize the flexoelectricity by its effect on director fluctuations. Our results combined with a reanalysis of earlier data indicate that the flexoelectricity is a phenomenon distinct from the ordinary director modes; additionally we observe unusual, very slow fluctuations in polarized scattering which suggest the BCN has a heterogeneous, “glassy” character. Dilution in a miscible calamitic indicates a dramatic development of the slow dynamics between 30 wt % and 60 wt % BCN. We suggest a model to account for both our present results and the giant flexoelectricity discovered in [1]. Reference: [1] J. Harden et al., Phys. Rev. Lett., 97, 157802 (2006). Acknowledgement: NSF DMR-0606160.

10:36AM Y15.00014 Large Flow-Birefringence of Nematogenic Bent-Core Liquid Crystals
. CHRISTOPHER BAILEY, Kent State University, KATALIN FODOR-CSORBA, Research Institute for solid state physics and optics, Budapest, Hungary,
RAFAEL VERDUZCO, Oak Ridge National Laboratory, JAMES GLEESON, SAMUEL SPRUNT, ANTAL JAKLI, Kent State University — We have found that bent-core liquid crystalline materials show exceptionally large flow birefringence in their isotropic liquid phase. The flow birefringence is over two orders of magnitude larger than usual for low molecular weight liquid crystals. Comparing the flow birefringence per unit viscosity, the observed values are an order of magnitude larger than low molecular weight and side-chain polymeric calamatic liquid crystals. This large flow birefringence is attributed to the nanostructure of these materials that contain temporary smectic clusters of a few smectic layers, which exist even in their isotropic phase. These smectic clusters appear to shear align resulting in the observed flow birefringence behavior.

10:48AM Y15.00015 Activated Kinetics of Nematic and Smectic Phase Transitions in an
Aligned Matrix of Nano-colloidal Liquid Crystalline Gel
. DIPTI SHARMA, UML — This study investigates an interesting thermal behavior of an aligned aerosil nano-colloidal system in the aligned matrix of octyl-cyanobiphenyl liquid crystal. This system was prepared by solvent dispersion method (SDM) where different densities of aerosil nanoparticles were added into octyl-cyanobiphenyl liquid crystal. Then samples were cycled into magnetic field during SmA–I transition to get an aligned matrix of nanocolloids. Heating scans were performed at various heating rates from 20 to 1 K min−1 using DSC. Aligned samples follow Arrhenius behavior and showed a decrease in transitions temperature for SmA–N and N–I transitions when compared with the unaligned samples. The activation energy of the aligned system increases and its respective enthalpy decreases for the lowest density of aerosils 0.05 g cm−3, then for the further increase of aerosil density, the activation energy decreases and its respective enthalpy increases. The second order transition SmA–N shows a higher activated kinetics than the weak first order N–I transition. This can be explained in terms of molecular interaction between aerosil nanoparticles and aligned liquid crystal molecules, and developed strain in the matrix of the aligned system.

Friday, March 20, 2009 8:00AM - 11:00AM –
Session Y16 DPOLY: Elastomers and Gels II 317

8:00AM Y16.00001 Deuterium NMR studies of segment orientation in PDMS unimodal and
bimodal endlinked networks.1
, CLAUDE COHEN, GEOFFREY GENESKY, T. MICHAEL DUNCAN, Cornell University — Polymer segment orientation in elastomers is revealed by solid state deuterium NMR spectra: earlier work has focused on the frequency shift of the spectra from stretched elastomers rather than the details of the lineshape. The split has classically been interpreted as a measure of polymer segment order parameter S caused by excluded volume interactions between neighboring segments. We synthesized deuterated PDMS chains of about 5000 g/mol and 80,000 g/mol to probe the segmental orientation of each component separately in bimodal networks. Even in the unstretched state, the spectra for the labeled short chain networks show an evolving lineshape with varying short chain content. We compute the average absolute value of the frequency shift of the entire spectrum to better account for the highly aligned segments. This method allows us to probe the chain segment alignment with increasing strain in both unimodal and bimodal networks and confirms Monte Carlo simulation results.

1NSF Polymers Program DMR-0705665
8:12AM Y16.00002 Volume-phase Transitions and Confined Water in Surface-tethered Poly(N-isopropylacrylamide) Networks, AJAY VIDYASAGAR, RYAN TOOMEY, University of South Florida — We present a simple approach for studying volume-phase transitions in thin, mechanically anchored responsive polymer networks. The approach is based on the photo-cross-linking of copolymers synthesized from N-isopropylacrylamide NIPAAm) and methacryloyloxybenzophenone (MaBP). We monitored the swelling of poly(NIPAAm-co-MaBP) networks in contact with aqueous solution at a function of cross-link density with both neutron reflection and ATR-FTIR. Neutron reflection reveals that the volume-phase transition of tethered poly(NIPAAm) networks coincides with the miscibility gap of linear poly(NIPAAm) solutions. Whether or not the poly(NIPAAm) network undergoes a continuous or discontinuous collapse depends on its degree of cross-linking. At cross-link densities above 5 mole%, the network remains in the single-phase region of the linear solution phase diagram and shows only a continuous transition between the swollen and collapsed states. Moreover, in the collapsed state, 30-35% by volume of water remains in the network, which is independent of cross-link density. The relative position of the FTIR absorption peaks during the collapse follows very closely the amount of water in the layer and can be related to the local dielectric environment within the network.

8:24AM Y16.00003 Strain induced alignment of particles in an elastomer host, BEN SPOTT, JEREMY NEAL, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — The properties of composite materials consisting of anisometric nanoparticles depend on the orientation of the nanoparticles. It is interesting to ask how mechanical strain of the composite affects their orientation. We have carried out experiments stretching both two- and three-dimensional rubber samples containing rigid rod-like particles and measured their orientational order parameter as a function strain. We discuss these results, and make connections with theoretical models.

8:36AM Y16.00004 Dynamics of uniaxially oriented elastomers using dielectric spectroscopy, HYUNGKI LEE, DANIEL FRAGIADAKIS, Penn State University, DARREN MARTIN, University of Queensland, JAMES RUNT, Penn State University — We summarize our initial dielectric spectroscopy investigation of the dynamics of oriented segmented polyurethanes and crosslinked polyisoprene elastomers. A specially designed uniaxial stretching rig is used to control the draw ratio, and the electric field is applied normal to the draw direction. For the segmented PU s, we observe a dramatic reduction in relaxation strength of the soft phase segmental process with increasing extension ratio, accompanied by a modest decrease in relaxation frequency. Crosslinking of the polyisoprene was accomplished with dicumyl peroxide and the dynamics of uncrosslinked and crosslinked versions are investigated in the undrawn state and at different extension ratios. Complimentary analysis of the crosslinked PI is conducted with wide angle X-ray diffraction to examine possible strain-induced crystallization, DSC, and swelling experiments. Quantitative analysis of relaxation strengths and shapes as a function of draw ratio will be discussed.

3 Supported by the NSF Polymers Program, DMR-0605627.

8:48AM Y16.00005 Shape-Memory Polymers Based on Fatty Acid-Filled Elastomeric Ionomers, ELISE IZZO, ROBERT WEISS, University of Connecticut — Shape memory polymers (SMPs) have applications as medical devices, actuators, sensors, artificial muscles, switches, smart textiles, and self-deployable structures. All previous design of SMPs has involved synthesizing new polymers or modifying existing polymers. This paper describes a new type of SMP based on blends of an elastomeric ionomer and low molar mass fatty acids or their salts (FAS). Shape memory elastomers were prepared from mixtures of a sulfonated EPDM ionomer and various amounts of a FAS (e.g., zinc stearate, zinc oleate, and various aliphatic acids). Nanophase separation of the metal sulfonate groups provided the “permanent” crosslinks, while sub-microscopic crystals of the low molecular weight FAS provided a physical crosslink needed for the temporary shape. The material was deformed above the melting point of the FAS and the new shape was fixed by cooling the material while under stress to below the melting point of the FAS. Polar interactions between the ionomer and the FAS stabilized the dispersion of the FAS in the polymer and provided the continuity between the phases that allowed the crystals of the FAS to provide a second network of physical crosslinks. The temporary shape was erased and the material returned to the primary shape by heating above the melting point of the FAS.

9:00AM Y16.00006 Dynamics of Segmented Polyurethane Elastomers Using Dielectric Spectroscopy, JAMES RUNT, The Pennsylvania State University, DANIEL FRAGIADAKIS, ALICIA CASTAGNA, TAEYI CHOI — This investigation focuses on the molecular dynamics of segmented polyurethane copolymers with different hard segment contents (30 to 52 wt percent) and soft segment chemistries. Methylene bis(p-phenyl isocyanate) and 1,4-butanediol constitute the hard segments in all materials under investigation, while soft segments include poly(tetramethylene oxide) and a 80-20 mixture of poly(dimethylsiloxane) and poly(hexamethylene oxide). The dynamics of these materials were explored over a wide temperature and frequency range using dielectric spectroscopy. In addition to investigating the details of segmental and local processes, three dielectric relaxations above Tg were observed for the first time in segmented polyurethanes, and their origin discussed in the presentation. For example, the highest temperature process is assigned to Maxwell-Wagner-Sillars interfacial polarization. The strength of the MWS process is a sensitive indicator of the change in microphase-separated character. It disappears at a temperature similar to that at which the small-angle X-ray scattering maximum disappears, indicating the transformation to the single phase state.

9:12AM Y16.00007 Polydomain to monodomain transition in nematic liquid crystal elastomers, BADEL MBANGA, FANGFU YE, JONATHAN SELINGER, ROBIN SELINGER, Liquid Crystal Institute / Kent State University — Liquid crystal elastomers are crosslinked polymer networks covalently bonded with liquid crystal mesogens. In the nematic phase, due to strong coupling between mechanical strain and orientational order, these materials display strain-induced instabilities associated with formation and evolution of orientational domains. Deformation of an initially polydomain nematic elastomer film induces a transition to the monodomain configuration. We model this phenomenon using a recently developed finite element elastodynamics simulation method. We study the rate-dependent material response upon uniaxial extension and resolve the textures that form along with the associated stress-strain behavior. Our simulations yield qualitative agreement with experimental observations. This model allows us to explore the fundamental physics governing dynamic mechanical response of nematic elastomers and also provides a potentially useful computational tool for engineering device applications.

3 Supported by U.S. National Science Foundation DMR-0605889.
**9:24AM Y16.00008 Liquid crystal elastomers: Bent core flexoelectricity**¹, MARTIN CHAMBERS, Liquid Crystal Institute and Physics Department, Kent State University, Kent OH44240, USA, RAFAEL VERDUZZO, Center for Nanophase Materials Science, Oak Ridge National Laboratory, Oak Ridge TN37831, USA, SAMUEL SPRUNT, JAMES T. GLEESON, Physics Department, Kent State University, ANTAL JAKLI, Liquid Crystal Institute, Kent State University — We report on the swelling of calamatic liquid crystal elastomers (LCE) with bent-core mesogens (BCM); this swelling took place at a temperature where both materials were in their isotropic phase. The BCM used varied in the degree of saturation of their hydrocarbon tails, which affects both viscosity and phase behaviour. We determined both swelling magnitude and dynamics. The host LCE systems homogeneously imbibe BCM up to 30-40 mol. Based on differential scanning calorimetry, shape change anisotropy, and optical birefringence measurements, the swollen elastomers are all found to exhibit nematic phases, with some possessing a lower temperature smectic phase. Bent-core liquid crystal elastomers and swollen calamatic LCE in BCM were investigated for the flexoelectric properties by inducing a mechanical deformation. The value of the bend flexoelectric constant, e_{ij} of the swollen BCM containing LCE systems is comparable to that of the neat bent-core liquid crystal.

**9:36AM Y16.00009 Photoinduced distortions of polydomain liquid crystal elastomer samples**¹, WILDER IGLESIAS, PETER PALFFY-MUHORAY, Liquid Crystal Institute, Kent State University — We have studied the effects of illumination of a dye doped polydomain nematic elastomer. The sample was on a glass substrate, and its free surface was illuminated by polarized light from an Ar+ laser. The shape of the reflected light in the far field was studied to probe photoinduced deformations. Above a threshold intensity, a target pattern appeared in the far field, indicating sample deformation. We discuss the experimental observations, and relate these to the processes such as photoinduced surface relief. Experimental results are compared with the predictions of simple theory.

¹This work was supported by the NSF under grant DMR 0606357.

**9:48AM Y16.00010 Dynamic Aspect of Electro-Opto-Mechanical Effects in Swollen Nematic Elastomers**, KENJI URAYAMA, ATSUSHI FUKUNAGA, TOSHIKAZU TAKIGAWA, Dept. Mater. Chem., Kyoto Univ., ANTONIO DESIMONE, SISSA, LUCIANO TERESI, SMFM, Univ. Roma III, KYOTO UNIV. TEAM, SISSA COLLABORATION, UNIVERSI ROMA III COLLABORATION — The nematic elastomers swollen by low molecular mass liquid crystals exhibit a macroscopic deformation with a significant change in birefringence in fast response to electric fields. We experimentally characterize the dynamics of this "electro-opto-mechanical effect." The optical and mechanical rise times (in response to field-on) decrease in nearly proportion to the square of field strength, while the corresponding decay times (in response to field-off) are almost independent of field strength. The optical rise and decay times are about one order magnitude smaller than the mechanical ones. We also propose a minimal model to describe the main features of both static and dynamic characteristics of this phenomenon observed experimentally. 1) Urayama, K., Honda, S., Takigawa, T., Macromolecules, 2006, 39, 1943. 2) Fukunaga, A., Urayama, K., Takigawa, T., DeSimone, A., Teresi, L., Macromolecules, in press.

**10:00AM Y16.00011 Analysis of Diffusion through Dynamic Network Polymers using Multi-photon Fluorescence Recovery after Photobleaching**, JIAHUI LI, Department of Chemical Engineering, University of Rochester, KELLEY SULLIVAN, EDWARD BROWN, Department of Biomedical Engineering, University of Rochester, MITCHELL ANTHAMATTEN, Department of Chemical Engineering, University of Rochester — Multi-Photon Fluorescence Recovery after Photobleaching (FRAP) techniques are utilized to study small molecule transport through polymer networks containing multiple hydrogen-bonding functional groups. Experiments involve uniformly dispersing small dye molecules (fluorophores) into functionalized polymers and networks. Polymer samples are then locally bleached, and the recovery of fluorescence is studied using 2-photon fluorescence microscopy. By curve-fitting fluorescence recovery curves to a model, diffusion coefficients are obtained. We have investigated series of polymer networks containing H-bonding interactions with different compositions at different temperatures. The diffusion coefficient through these polymer networks shows an expected Arrhenius-like temperature dependence. The influence of hydrogen bonding and network architecture on transport activation energies will be discussed.

**10:12AM Y16.00012 Gelling Mechanism of Aluminum Di-Soaps in Oils**, XIAORONG WANG, Bridgestone Americas, Center for Research and Technology, 1200 Firestone Parkway, Akron, OH 44317, MINDAUGAS RACKAITIS — This work demonstrates that aluminum di-soaps form nano-sized spherical micelles in the oils and that the aggregation of these micelles forms a network that gives rise to a gel formation – thereby refuting a long-held belief that the gel formation was the result of linear polymeric chains of aluminum association. The discovery of such aluminum nano-particles could expand application of these materials to new technologies because these materials are chemically inert, odorless and nontoxic, and have been widely used in greases, paints, gels, cosmetics, drugs and foods.

**10:24AM Y16.00013 Surface Plasmon Resonance Effects in Responsive Polyelectrolyte/Gold Nanoparticles Hydrogel Thin Films**¹, IHOR TOKAREV, IRYNA TOKAREVA, VENKATESHWARLU GOPISHETTY, SERGIY MINKO, Clarkson University — In this study, we explored localized surface plasmon resonance excited in gold nanoparticles coupled with continuous and macroporous stimuli-responsive hydrogel thin films. The 100-nm-thick porous hydrogel film with vertically aligned cylindrical pores decorated with spherical Au nanoparticles (synthesized in the hydrogel) and placed on Au islands (prepared on a glass substrate) enabled the highly-sensitive optical detection of changes in the swelling degree of hydrogel induced by an external stimulus (pH). The strong optical response of our sensing platform is attributed to the electromagnetic coupling between the nanoparticles and islands that is highly sensitive to the inter-particle spacing. The transformation of a chemical signal into the optical effect can be used for analytical applications.

**10:36AM Y16.00014 Gelation, Dynamics and Mechanics of Associating Polymers: Exploring Parameter Space**, ROBERT S. HOY, GLENN H. FREDRICKSON, Materials Research Laboratory, University of California, Santa Barbara — We present simulation studies of associating polymer melts, where a fraction of the monomers are “sticky.” A coarse grained hybrid MD/MC model is used to accurately model polymer dynamics and qualitatively capture chemical kinetics. The effects of varying sticky bond strength, sticky monomer concentration and placement along chains, chain length N, temperature T, and chemical kinetics are examined. All have independent and interesting effects on the dynamics and mechanics. We focus on the “reversible” gel regime where almost all chains are instantaneously connected to the network, yet chains are delocalized and the system displays complex time and strain-dependent properties.
We present a theoretical analysis of a novel cavity electromechanical (or optomechanical) system where a mechanical resonator directly modulates the damping in obtaining information on the raw key in quantum key distribution. This construction essentially proves the intuition that separate measurements on the subsystems are sufficient to extract the maximal information about the separately prepared, we construct separate measurements on the subsystems from any given joint measurement such that the former always give at least as large information as the latter. This construction offers new insights into the understanding of measurements on this type of composite systems. Moreover, this effective model is derived, showing how coherent transfer between both two level systems can be achieved, and the possible advantages of the system as the standard quantum limit. Finally, we will outline several exciting applications of the novel magnetic sensors in areas ranging from bio- and materials science to electronic spin bath. As an outlook, we will discuss how engineering, controlling or harnessing the environment can lead to better sensitivity, even beyond the standard quantum limit. We also show that this system can be used to perform quantum-limited position measurements. The system described here could be implemented directly using setups similar to those used in recent experiments in cavity electromechanics.

10:48AM Y16.00015 Step Cycle Deformation Processing of Elastomers and Gels Based on Semicrystalline Polyolefin-based Block Copolymers, FANNY DEPLACE, ZHICANG WANG, NATHANIEL A. LYND, ATSUSHI HOTTITRA, GLENN H. FREDRICKSON, EDWARD J. KRAMER, UC BERKELEY - SCIENCE, Cornell University, HISAHI OHTAKI, K. HIROKANE, F. YAMADA, YONG-WOOL SHIN, FUMIHIKO SHIMIZU, Mitsubishi Chemical Group, Science and Technology Research Center — Recent catalysts have enabled the synthesis of block copolymers with semicrystalline syndiotactic and isotactic polypropylene endblocks and amorphous ethylene-propylene midblocks. In these copolymers, the crystals play the role of physical crosslinks which can deform plastically under stretching. Neat elastomers, gels in mineral oil and gels from which mineral oil has been extracted have been subjected to step cycle tensile tests. The incremental plastic deformation of the crystals has dramatic effects on the true stress versus extension ratio curves. Moreover, small and wide angle X-ray scattering experiments during step cyclic tests revealed the evolution of the microstructure of the crystalline blocks: crystal fibrils and crystals in the fibrils are oriented parallel to the tensile direction at large strains and once the stress has decreased to zero, the fibrils return to being randomly oriented again.

Friday, March 20, 2009 8:00AM - 11:00AM
Session Y17 GQI: Focus Session: Quantum Metrology and Nanomechanics 318

8:00AM Y17.00001 High-sensitivity diamond magnetometer with nanoscale resolution, PAOLA CAPPELLARO, ITAMP - Harvard Smithsonian CfA and Physics Department — We will discuss our recent work on using isolated electronic spins in the solid-state as sensitive magnetic sensors [1,2]. This novel approach to magnetometry is enabled by the good coherence properties of electronic qubits, such as the spins associated with Nitrogen-Vacancy (NV) centers in diamond, as well as by advanced techniques for their coherent control. The key feature of this solid-state magnetometer is the possibility to confine the sensing spins into a crystal of nanometer size that can be brought extremely close to the magnetic field source, thus achieving high spatial resolution. Our first experiments demonstrate that the resulting magnetic sensor provides an unprecedented combination of ultra-high sensitivity and spatial resolution. The ultimate sensitivity limit is set by the interaction of the spin sensor with its environment and in particular the nuclear and electronic spin bath. As an outlook, we will discuss how engineering, controlling or harnessing the environment can lead to better sensitivity, even beyond the standard quantum limit. Finally, we will outline several exciting applications of the novel magnetic sensors in areas ranging from bio- and materials science to fundamental physics and single electronic and nuclear spin detection.

8:36AM Y17.00002 Coupling Nitrogen Vacancy Centers in a Diamond Nanopillar to a Silica Microsphere, KHODADAD DINYARI, MATS LARSSON, HAILIN WANG, Department of Physics, Oregon Center for Optics, University of Oregon, Eugene, Oregon 97403 — Nitrogen vacancy (NV) centers in a diamond nanopillar have been coupled to the whispering gallery modes (WGMs) of a silica microsphere. The NV centers were coupled to the WGMs by positioning a nanopillar near the equator of the microsphere with nanometer precision. For cavity QED studies, WGMs with ℓ = m are of interest due to their small mode volumes. It was observed that when a 200 nm diameter nanopillar was optimally coupled to this particular mode in a 50 μm diameter microsphere, the quality factor (Q) was only reduced to 2x10^9 from an initial Q of 6x10^10. The nanopillars were fabricated from a bulk single crystal diamond by means of reactive ion etching, resulting in nanopillars with diameters as small as 200 nm with a height of approximately 1 μm. We estimate that a 140 nm pillar would allow a cavity linewidth of order 20 MHz, comparable to the zero phonon linewidth of a NV center. Producing a nanopillar with a 140 nm diameter is well within our fabrication technique making this composite system a suitable candidate for strong-coupling cavity QED. This nanopillar-microsphere system circumvents the poor controllability of nanocrystal based microresonator systems and utilizes the exceptional properties of both NV centers in bulk crystals and the ultra-high Q of silica microspheres.

8:48AM Y17.00003 An Ensemble of NV-centers in Diamond Coupled to a Flux Qubit, DAVID MARCOS, Consejo Superior de Investigaciones Científicas, MARTIJN WUBS, Niels Bohr Institute, R. AGUADO, Consejo Superior de Investigaciones Científicas, M.D. LUKN, ANDERS SORENSEN, Niels Bohr Institute — In the last years, the interface between quantum optics and solid state physics has been explored, and various models for hybrid qubits have been proposed. We consider a superconducting flux qubit coupled to an ensemble of NV-centers in diamond. An effective model is derived, showing how coherent transfer between both two level systems can be achieved, and the possible advantages of the system as the building block of a quantum computer.

9:00AM Y17.00004 Getting Information on Independently Prepared Quantum States — When are Individual Measurements as Powerful as Joint Measurements?, CHI-HANG FRED FUNG, H. F. CHAU, University of Hong Kong — Given a composite quantum system in which the states of the subsystems are independently (but not necessarily identically) prepared, we construct separate measurements on the subsystems from any given joint measurement such that the former always give at least as large information as the latter. This construction offers new insights into the understanding of measurements on this type of composite systems. Moreover, this construction essentially proves the intuition that separate measurements on the subsystems are sufficient to extract the maximal information about the separately prepared subsystems, thus making a joint measurement unnecessary. Furthermore, our result implies that individual attacks are as powerful as collective attacks in obtaining information on the raw key in quantum key distribution.

9:12AM Y17.00005 Quantum noise interference as a route to ground state cooling in cavity electromechanics, AASHISH CLERK, FLORIAN ELSTE, Dept. of Physics, McGill University, STEVE GIVIN, Dept. of Physics, Yale University — We present a theoretical analysis of a novel cavity electromechanical (or optomechanical) system where a mechanical resonator directly modulates the damping rate \( \kappa \) of a driven microwave (or optical) cavity. We show that due to a destructive interference of quantum noise, the driven cavity can effectively act like a zero-temperature bath irrespective of the ratio \( \kappa / \omega_m \), where \( \omega_m \) is the mechanical frequency. This scheme thus allows one to cool the mechanical resonator to its ground state without requiring the cavity to be in the so-called good cavity limit \( \kappa \ll \omega_m \). This behavior is in sharp contrast to the more common setup with a parametric coupling (where the mechanics modulates the frequency of the cavity): there, ground state cooling is only possible in the good cavity limit [1,2]. We also show that this system can be used to perform quantum-limited position measurements. The system described here could be implemented directly using setups similar to those used in recent experiments in cavity electromechanics [3].

9:24AM Y17.00006 Force sensitivity of a nanomechanical oscillator in a microwave cavity. JENNIFER HARLOW, JOHN TEUFEL, TOBIAS DONNER, KONRAD LEHNERT, JILA, University of Colorado and NIST — We describe our efforts to realize ultrasensitive force detection based on sensing the motion of nanomechanical oscillators embedded in superconducting resonant microwave cavities. Such a force sensor requires a readout mechanism quiet enough that the sensitivity is limited by thermal noise of the oscillator, as we recently demonstrated [1]. Force sensitivity is optimized by low mass, high-Q mechanical resonators with MHz resonance frequencies. We report measurements with sub-nN/√Hz force sensitivity and discuss prospects for further progress. [1] C. A. Regal, J. D. Teufel, and K. W. Lehnert, Nature Physics 4, 555 (2008).

9:36AM Y17.00007 Resolved-Sideband Cooling of Nanomechanical Motion within a Microwave Cavity. JOHN TEUFEL, JENNIFER HARLOW, TOBIAS DONNER, MICHAEL DEMORET, KONRAD LEHNERT, JILA, University of Colorado and NIST — We present recent experiments in which we couple the motion of a high-Q nanomechanical oscillator to the microwave fields in a superconducting resonant circuit [1]. This microwave optomechanical system is operated in the resolved-sideband regime in which the mechanical resonance frequency exceeds the cavity bandwidth. In this regime, the dynamic backaction of the microwave radiation further cools the mechanical motion from dilution refrigerator temperatures to even lower thermal occupancy. Recent improvements increase both the optomechanical coupling strength and the power handling capability of the cavity. We report progress toward cooling to the mechanical ground state with this system. [1] J. D. Teufel, J. W. Harlow, C. A. Regal and K. W. Lehnert, Phys. Rev. Lett., 101, 197203 (2008).

9:48AM Y17.00008 Photon-Mediated Magnetic Cooling of a Micromechanical Oscillator. JOONHO JANG, RAFFI BUDAKIAN, Physics Department, University of Illinois at Urbana-Champaign — In recent years, a number of techniques have been developed to cool a mode of a micromechanical oscillator to the ground state. In this talk, I will present a new scheme for cooling a micromechanical oscillator involving the interaction of a micron-size superconductor, attached to the cantilever, with an external magnetic field. When the cantilever is placed inside an optical cavity, the absorption of photons by the superconductor gives rise to a retarded force that modifies the damping of the oscillator. Initial measurements using NbSe₂ show approximately a factor of 25 reduction in the mode temperature from 5 K to 200 mK. By optimizing the cavity finesse, the magnetic field configuration, and the superconductor quasiparticle lifetime, a further reduction of 10⁴ in the cantilever mode temperature could be realized.

10:00AM Y17.00009 Parametric Amplification and Detection of Nanomechanical Motion. JARED HERTZBERG, Department of Physics, University of Maryland, TRISTAN ROCHELEAU, TCHEFOR NDUKUM, KEITH SCHWAB, Department of Physics, Cornell University — We have performed experiments with a 5.57 MHz nanomechanical resonator (NR) capacitively coupled to a 5 GHz superconducting microwave resonator and cooled to a temperature of 142mK. When driving with two microwave tones, a configuration appropriate for back-action evading measurements of a single motional quadrature, we find that a parametric instability appears at high drive powers. Due to the interference of the microwave tones, the capacitive frequency shift of the NR is periodically modulated at twice the mechanical frequency, resulting in a degenerate parametric amplification of the mechanical motion. In this regime, we demonstrate mechanical gains of up to 11.6dB and parametrically reduced linewidths of 2.1 Hz, resulting in a position resolution near the standard quantum limit. Although this effect is expected to limit the back-action evasion dynamics, it is useful for mechanical preamplification and noise squeezing, subjects of future work.

10:12AM Y17.00010 Back action evading quantum limited measurements of a nanomechanical resonator. TCHEFOR NDUKUM, TRISTAN ROCHELEAU, Department of Physics, Cornell University, JARED HERTZBERG, Department of Physics, University of Maryland, KEITH SCHWAB, Department of Physics, Cornell University — By driving a 5GHz superconducting, co-planar waveguide (CPW) resonator coupled to a radio-frequency nanomechanical resonator with both red- and blue-detuned, phase coherent microwave signals, we demonstrate amplifier noise back action evading (BAE) detection of one quadrature of nanomechanical motion. With this method we show precise measurements of a single motional quadrature with additive measurement noise of 4 times the zero point amplitude, and a reduction in sensitivity to injected measurement noise of a factor of 43 in comparison to a single tone, non-BAE measurement. We have also found a parametric instability which limits the coupling strength possible in our device, which will be described elsewhere. With straightforward improvements to the microwave resonator, we expect to be able to demonstrate sensitivity to one quadrature with additive measurement noise below the zero-point level, a necessary ingredient to produce and measure squeezed states of motion.

10:24AM Y17.00011 Sideband Resolved Cooling of a Nanomechanical Resonator Parametrically Coupled to a Microwave Resonator. TRISTAN ROCHELEAU, TCHEFOR NDUKUM, JARED HERTZBERG, KEITH SCHWAB, Department of Physics, Cornell University — We have fabricated a nanostructure formed by a radio-frequency nanomechanical (NEMS) resonator capacitively coupled to an aluminum 5 GHz superconducting, co-planar waveguide (CPW) resonator with 50 Ω characteristic impedance. By driving this coupled system at a frequency ω_pump = ω_CPW - ω_NEMS, we demonstrate back action cooling effects of a single NEMS mode achieving cooling from temperatures of 100mK to <10mK, with the lowest occupation factor of N<30. We have recently demonstrated a Nb, 130 Ω 5 GHz, Q=15,000 microwave resonator which we expect to be capable of cooling the NEMS close to ground state.

10:36AM Y17.00012 Ground state cooling of nanomechanical resonator via linear coupling in a superconducting circuit¹. LIN TIAN, School of Natural Sciences, University of California, Merced, CA 95344 — In recent experiments, it has been demonstrated that radiation pressure-like coupling between a nanomechanical resonator and a superconducting resonator can be explored for the cooling of the nanomechanical mode. In this work, we present a ground state cooling scheme for a nanomechanical resonator linearly coupled with a superconducting LC oscillator. The linear coupling, when periodically modulated at red detuning, up-converts the low-frequency nanomechanical mode to the high-frequency LC oscillator mode and generates backaction force that can cool the nanomechanical mode to its ground state in the resolved-sideband regime. Compared with schemes using radiation pressure-like coupling, the LC oscillator mode doesn’t need to be driven to high photon occupation number in our scheme. We calculate the cooling rate and the stationary occupation number of the nanomechanical mode and show that ground state can be reached with practical device parameters. A detailed study of our model shows that the quantum backaction noise that limits the cooling process is due to the counter rotating terms in the linear coupling. The scheme can be compared with laser cooling for the atomic systems as well.

¹The work is in part supported by the Karel Urbanek Fellowship at Stanford University.

10:48AM Y17.00013 Quantum Measurements of Coupled Systems. L. FEDICHKIN, M. SHAPIRO, M. I. DYKMAN, Michigan State University — Quantum measurements are often performed on coupled systems. Such measurements are of interest for various proposed applications of a quantum computer where the qubit-qubit coupling may not be completely turned off. Because of the coupling, the stationary state wave functions are not fully localized on individual qubits even where the energies of neighboring qubits are tuned away from each other. As a result, an instantaneous projective single-qubit measurement gives the state population with an error. We show that the error may be significantly reduced. This is accomplished by tuning the detector close to resonance with the measured qubit. The qubit- detector coupling should be small compared to the decay width γ of the excited level of the detector. For such tuning, there is a broad time interval where the probability of an error in detecting an excitation on the resonant qubit and distinguishing it from other excitations is smaller than that for a projective measurement by a factor ~ (γ/ΔE)², where ΔE is the difference in the qubit energies. The results bear on the scalability of quantum computers with permanently coupled qubits.
optoelectronics, and biotechnology, among other areas. The controlled, evaporative self-assembly of polymer or nanocrystal solutions yields a variety of complex, intriguing, and well-ordered structures over large confined in a simple geometry comprised of a curved surface placed upon a flat substrate. By changing the shape of the upper surface of the imposed geometry, microstructures possessing high regularity, dispensing with the need for lithographic techniques and externally applied fields. Polymer or nanocrystal solutions are sizes of high regularity and fidelity. Here, we report a facile, robust, and one-step evaporation method for producing in a precisely controllable manner versatile over the evaporation process of the drop, the challenge remains to use evaporative self-assembly to rationally “synthesize” “coffee rings” of different shapes and sizes of high regularity and fidelity. Here, we present experimentally-observed buckling morphologies resulting from a variety of surface geometries, as well as Finite Element Modeling results which provide insight into the specific evolution of stresses which led to the formation of these morphologies.

9:00AM Y18.00004 Mechanical instabilities in periodic porous elastomeric solids. We gratefully acknowledge support from NSF.

8:48AM Y18.00003 Lateral Instability of Nanoimprinted Polymer Patterns during Thermal Annealing, YIFU DING, University of Colorado, KYLIE ALVINE, Pacific Northwest National Laboratory, HYUNWOOK RO, MANISH KULKARNI, JACK DOUGLAS, CHRISTOPHER SOLES, NIST — Nanoimprint Lithography (NIL) is a promising candidate for next generation lithography. Dense polymer patterns with relatively high aspect ratios can be created using NIL. Upon thermal annealing, the as-imprinted polymer patterns will smooth out due to the surface energy and sometimes residual stress within the patterns. Both effects will predominately drive the pattern decay vertically. Here, we present that under certain patterning conditions, lateral instability of the surface patterns, driven by surface fluctuations, can also become an effective mechanism for reducing the total surface area. The characteristics of the lateral instability were successfully carried out by annealing the patterns under a temperature gradient. We demonstrate that the lateral instability can be controlled by the imprinting conditions, and can be greatly enhanced by the additions of surfactants.

8:36AM Y18.00002 Morphology of Osmotically-Driven Surface Buckles, DEREK BREID, ALFRED CROSBY, University of Massachusetts — The ordering of osmotically-driven surface buckles on an elastically-supported stiff plate depends strongly upon the dominant stresses acting on the surface during formation. For example, conditions which lead to buckle initiation at the center of the plate yield hexagonal dimple arrays characteristic of an isotropic surface stress, while buckles initiated at the edges align radially, indicating a theta-dominated state of compressive stress. Here, we work on PS-b-PEO and PS-b-PLLA shows, for the first time, the reduced tethering density value of the interacting regime transition regardless of molecular weight or solvent quality. Other factors that were not addressed include adsorption and chain stiffness effects. The work presented here will look at the role of chain adorption using miscible polymers, namely PMMA-b-PDLLA, and chain stiffness with PEO-b-PCL where PEO is the amorphous block. In addition to experimental results, Monte Carlo simulations were used to estimate the chain conformation of adsorbed PMMA.

8:12AM Y18.00005 Peculiarities in liquid phase of Styrene Butadiene rubber surface induced by Atomic Force Microscopy-assisted electrostatic nanolithography, MINDAUGAS RACKAITIS, Bridgestone Americas, SERGEI LYUKSYUTOV, The University of Akron, DMYTRO KASHYN, PAVELO PARAMONOVOV, ROBERT MALLIK — Nanoscale surface changes are reported for styrene butadiene rubber (SBR) films (100 nm) using protocol derived from Atomic Force Microscopy (AFM) electrostatic nanolithography. Under appropriate tip bias conditions, the electric field magnitude induced in SBR films is of the order of 10^8-10^9 V m^-1, which is sufficiently large to initiate cross-linking in the rubber. Peaklike surface features, surrounded by a circular trough and a raised ring, are observed after completing AFMEN-based protocol. The nanostructure dimensions vary from 0.5-20 nm high and 50-200 nm in diameter. The topology of the nanostructures is attributed to the interplay between film thickness (50 nm and thinner) and the radial component electrostatic pressure. Modeling of the electric field based on the numerical solution of Laplace equation for cylindrical geometry suggests that non-uniformity of electric field plays an important role in nanostructure formation. The stability of the features which remain stable for days suggests cross-linking between macromolecules at the nanoscale.

8:24AM Y18.00006 Diffusion-Controlled, Self-Organized Growth of Symmetric Wrinkling Patterns, CHRISTOPHER M. STAFFORD, JIN YOUNG CHUNG, ADAM J. NOLTE, Polymers Division, National Institute of Standards and Technology, POLYMERS DIVISION, NATIONAL INSTITUTE OF STANDARDS AND TECHNOLOGY TEAM — The formation of self-organized wrinkling patterns is a potential route for generating such tunable ordered patterns on surfaces across many length scales. Here, we demonstrate that surface wrinkling of ultraviolet/ozone (UVO) treated polymer films through osmotically driven swelling by solvent vapor sorption leads to unique and intriguing patterns, some of which have not been previously reported. The type of pattern and speed of its growth is coupled to the degree of UVO crosslinking and the rate of solvent diffusion into the film from the localized defect. This simple yet novel approach could serve as a test-bed for studying topography-driven phenomena such as wettability and adhesion and diffusion related processes, as well as facilitate a better understanding of dynamic self-assembly.

8:36AM Y18.00007 Transition from Non-interacting to Interacting Regime of Tethered Polymer Chains, RYAN VAN HORN, JOSEPH X. ZHENG, MING-SIAO HSIAO, BERNARD LOTZ, EDWIN L. THOMAS, JUTTA LUETTMER-STRATHMANN, STEPHEN Z.D. CHENG, University of Akron — Tethered polymer chains have become an important area of research over the last few decades. Their unique properties make them appealing for various applications. The tethering density of the chains determines the state of the chains as well as the resulting properties, as shown by various theoretical and experimental work. Our group uses single crystals of crystalline-amorphous diblock copolymers to study tethered polymer chains. This system provides better control of tethering density and molecular weight as compared to previous methods. Previous work on PS-b-PEO and PS-b-PDLLA shows, for the first time, the reduced tethering density value of the interacting regime transition regardless of molecular weight or solvent quality. Other factors that were not addressed include adsorption and chain stiffness effects. The work presented here will look at the role of chain adorption using miscible polymers, namely PMMA-b-PDLLA, and chain stiffness with PEO-b-PCL where PEO is the amorphous block. In addition to experimental results, Monte Carlo simulations were used to estimate the chain conformation of adsorbed PMMA.
Steric effects on the phase behavior of end-tethered temperature-responsive polymers, CHARLES HOGSHEAD, EVANGELOS MANIAS, Materials Sci & Eng; Penn State University — End-tethered polymers from a planar surface at high grafting density results in an apparent spatial confinement originating from interchain steric repulsion. This effective confinement can alter the phase behavior of temperature-responsive polymers in solution, relative to their bulk solution behavior. Here we report on experiments where we synthesized tethered polymer layers with a gradient in grafting density. The systems studied were temperature-responsive alternating copolymers in aqueous solutions. Under-water AFM was used to directly observe the tethered chain collapse upon heating through the bulk LCST, and the resulting reversible adhesion switch. The transition of the tethered layers occurs at temperatures that are similar to the binodal points of the respective solution, but over a much broader temperature range. This behavior is consistent with the collapse being a cooperative conformational transition, reflecting the effects of chain confinement, rather than a first-order thermodynamic LCST transition (as these same polymers exhibit in bulk aqueous solutions). The onset-temperature of the transition, of both the tethered layers and the LCST, was tailored by varying the copolymer composition, i.e., by tuning the hydrophilic/hydrophobic balance within the chain.

10:12 AM Y18.00010 Self-Assembling Pi-conjugated Monolayer on Silicon, J.-C. LIN, J. KELLAR, J.-H. KIM, S. NGUYEN, M. HERSAM, M. BEDZYK, Northwestern University, K. BEVAN, Purdue University — Pi-conjugated molecules play an important role in molecular electronic applications. For conductivity, the intrinsic ordering of the structure strongly influences its efficiency but is difficult to characterize by conventional scanning probe and IR spectroscopy techniques. In the present study, we combine a compliment of techniques, including XSW(X-ray standing waves), AFM, XPS, XRR(X-ray reflectivity), XRF(X-ray fluorescence), and DFT(Density functional theory) to determine the atomic scale molecular configurations and packing densities of two self-assembled aromatic monolayers (SAMs) grown on H-passivated silicon. P-4-bromophenyl-ethylphenyl-acrylene, which has two phenyl rings, is directly compared with p-4-bromophenyl-acetylene, which has only one phenyl ring. The results show a local dense packing in spite of the overall coverage being somewhat less than 0.5 monolayers. This packing of the p-4-bromophenyl-ethylphenyl-acrylene SAM suggests the average spacing between molecules is within the pi-pi interaction range, which will contribute to the charge transport. The detailed atomic structure of SAMs are also constructed using our characterization package. The result suggests the possibility of the application of self-assembling method on the growth of molecular electronics.

10:24 AM Y18.00011 The Dynamic Reinforcement of Polynvinyl Alcohol (PVA) as a Result of Non-equilibrium State of Polymer Supermolecular Structures and their Confinement in Nanofibers, EYAL ZUSSMAN, EMIL SHAKED, ARKADI ARINSTEIN, Technion — The results of mechanical testing of PVA-based electrospun nanofibers and bulk in static and dynamic modes are presented. An increase in the elastic moduli resulting from sample deformation was observed in both the bulk and as spun fibers. This increase occurs when the deformation rate exceeds a critical value and can be attributed to the non-equilibrium dynamics of the supermolecular structures of the polymer matrix. That is, the evolution of these supermolecular structures results in an observably extended relaxation time. It is noted that the rate of the modulus increase of the nanostructure is nearly double that of the bulk fibers' rate. This difference can be explained by confinement influence on the polymer matrix of the nanofibers. In addition, the tests revealed that the, Tg, of the nanofiber is noticeably higher than that of bulk specimen. Reinforcing the nanofibers by cellulose whiskers showing that the dependence of the effective modulus on the whisker concentration has an initial increase that changes to a decrease when the whisker concentration exceeds 2 %. Such behavior can be explained in the framework of an aggregation concept – when the cluster size reaches that of the fiber diameter (cluster confinement), the whisker distribution becomes inhomogeneous and results in a measurable weakening of the composite.

10:36 AM Y18.00012 Phenomenology of Polymer Thin Film Dewetting during Vapor Deposition Polymerization1, MITCHELL ANTHAMATTEN, XICHONG CHEN, University of Rochester, DEPARTMENT OF CHEMICAL ENGINEERING TEAM — Initiated chemical vapor deposition (iCVD) is a solventless technique to grow polymer thin films directly from gas phase feeds. The free radical technique involves the dissociation of gaseous initiator followed by adsorption onto a surface and subsequent polymerization with monomer to produce linear or crosslinked polymer films. We have designed and built an axisymmetric hot-zone iCVD vacuum reactor. Using this reactor, smooth poly (methyl methacrylate) polymer films are grown from methyl methacrylate and t-butyl peroxide gas feeds. When solvent vapors are added to the process, we observe dewetting of vapor deposited polymer films. The objective of the current study is to understand the phenomenology of the observed solvent-induced dewetting. White light interferometry was used to investigate the surface topography of dewetted structures. The observed length scale depends on several process parameters including the deposition rate, the type of solvent used, and the surface free energy. Higher deposition rates suppress dewetting, and higher solvent content leads to dewetted structures with larger length scales. A dynamic model is applied to explain how droplet size and droplet aerial density depend on time and process parameters.

8:00AM Y19.00001 Sequence-directed organization in self-assembled monolayers of betapeptides on solid surfaces: A Monte Carlo simulation study. JAGANNATH MONDAL, University of Wisconsin Madison, BONG JUN, SUNG, Solagun University, ARUN YETHIRAJ, University of Wisconsin Madison — The sequence-directed organization of self-assembled monolayers (SAM) of amphiphilic β-peptides adsorbed on gold surfaces is studied using Monte Carlo simulations. A phenomenological model is considered where each (helical) molecule is represented by a rigid nano-rod with the side groups at appropriate locations. This model effectively distinguishes between two, namely globally amphiphilic (GA) and non-globally amphiphilic (non-GA), sequence-isomers of an amphiphillic β peptide Y-(ACHC-ACHC-K)1. The simulations show that the GA isomers have a high degree of orientational order that is not exhibited by the non-GA isomers, consistent with experiment. The simulations quantify a subtle balance between electrostatic, hydrophilic, and hydrophobic interactions on the self-assembly of β-peptides on surfaces. 

8:12AM Y19.00002 Thermal Response of PNIPAM Brushes Studied by Numerical Self-Consistent Field Calculations. DONG MENG, QIANG WANG, Department of Chemical and Biological Engineering, Colorado State University — Unlike most polymers, poly(N-isopropyl acrylamide) (PNIPAM) exhibits a lower critical solution temperature in water, i.e., PNIPAM chains are soluble (expand) at low temperatures and insoluble (collapse) at high temperatures. This property has been used to “smart” surfaces of PNIPAM brushes that can switch wettability, porosity and cell-adhesion properties as temperature is changed. Such thermal response of PNIPAM brushes is strongly affected by both chain length and grafting density. In this study we use numerical self-consistent field calculations with a composition-dependent Flory-Huggins parameter obtained from experiments to study the thermal response of PNIPAM brushes. The effects of chain length and grafting density are systematically investigated to provide guidance to experimental design of PNIPAM brushes for targeted applications.

8:24AM Y19.00003 Time evolution of the structure of fluorinated alkanes near solid surfaces. MESFIN TSIGE, Southern Illinois University at Carbondale — The study of thin films of physisorbed molecules has attracted much experimental and theoretical interest in the past few decades. This is mainly due to numerous reports of anomalous behavior in the structural and dynamical properties of polymeric thin films at interfaces and the expected consequences in their wide range of practical applications. Although great advances have been made in our understanding of the physics and chemistry of polymer melt/solid and polymer melt/vapor interfaces, there remain a number of fundamental as well as practical issues that need to be addressed regarding the influence of interfaces on a polymer film. One of the issues, which I think no systematic study has been yet conducted on, is the stability or time-evolution of the molecular layering in a film next to a solid surface. The main focus of my presentation will be on our recent computer simulation study result that shows that the extent of layering in an alkane film next to a solid substrate may oscillate in time with an amplitude and period that strongly depends on temperature.

8:36AM Y19.00004 Activation of CO2 on transition metal surfaces and oxide supported metal thin films. SUJATA PAUL, MARCO BUONGIORNO NARDELLI, NC State Univ — Using first principles simulations based on Density Functional Theory, we have investigated the adsorption and activation properties of CO2 on a variety of transition metal surfaces and oxide supported metal thin films. We intend to focus on the chemical conversion of CO2 through heterogeneous catalysis using surfaces and interfaces where there is nanoscale control over charge density at the reactive sites. The activation of CO2 on clean metal surfaces is possible at very high temperatures and the situation changes drastically when reaction happens on oxide supported metal thin film. The chemical reactivity of the molecule on the surface depends on the charge rearrangement at the metal-alkaline earth oxide interface. We want to understand the possible catalytic systems and characterize the relevant geometrical and electronic parameters related to the reaction mechanisms, rates and yield.

8:48AM Y19.00005 Dynamics of an Adsorbed Polymer Chain. JOSHUA KALB, SANAT KUMAR, Columbia University — Because of the current precision in fluorescent labeling, it is possible to label single polymers such as DNA or PEG and track their dynamical and equilibrium properties in the bulk as well as near attractive surfaces [Maier et. al., Macro. 2000][Sukhishvili et. al., Macro. 2002]. Recent evidence from these experiments and related simulations has shown that the dynamics of a single polymer near an attractive surface appear diffusive, however further evidence coming from the ‘diffusion coefficient’ implies a different process other than diffusion is at work such as reptation, ‘hover crafting’, or ‘hopping’ [Sukhishvili et. al., Macro. 2002]. In general, these possible dynamical behaviors are determined by the length of the polymer itself as well as the microscopic details of the attractive surface which include the density, strength, and distribution of attractive surface sites[Desai et. al., PRL 2007][Qian et. al., PRL 2007]. In this presentation, we investigate the effects of microscopic surface sites on single polymer dynamics through DMD simulations and compare these results to the properties of the chain in the bulk and near a flat attractive surface.

9:00AM Y19.00006 Investigation of Carboxymethyl Cellulose Adsorption onto Regenerated Cellulose Surfaces via Quartz Crystal Microbalance with Dissipation Monitoring and Surface Plasmon Resonance Spectroscopy. ZELIN LIU, Department of Chemistry (0212), Virginia Tech, Blacksburg, VA 24061, PAUL GATENHOLM, Department of Materials Science and Engineering (0237), Virginia Tech, Blacksburg, VA 24061, ALAN ESKER, Department of Chemistry (0212), Virginia Tech, Blacksburg, VA 24061 — The adsorption of anionic polyelectrolytes, sodium salts of carboxymethyl celluloses (CMC), with different degrees of substitution (DS = 0.9 and 1.2) from aqueous electrolyte solutions onto regenerated cellulose surface was studied via quartz microbalance with dissipation monitoring (QCM-D) and surface plasmon resonance (SPR) spectroscopy. The adsorption of CMC (100 mg L−1) from 0.1 M sodium chloride (NaCl) was examined. Both QCM-D and SPR results indicate that CMC adsorption onto regenerated cellulose surfaces increases with increasing electrolyte concentration and CaCl2 (diluent) showed a significant effect on CMC adsorption compared to NaCl (monovalent cation) at the same ionic strength. Voigt-based viscoelastic modeling of the QCM-D data and analysis of the SPR data are consistent with the existence of a swollen CMC layer on the cellulose surface with a viscosity of ~1.310−3 kg m−1 s−1 and an elastic shear modulus of ~105 kg m−1 s−2.

9:12AM Y19.00007 Theory of Polymer Adsorption Onto Selected Chemically Patterned Substrates. ALEXANDER CHERVANYOV, GERT HENRICH, Leibniz Institute of Polymer Research Dresden — We theoretically studied the reversible adsorption of polymers onto selected rigid and soft chemically non-uniform substrates with an emphasis on the polymer adsorption onto the selective binary mixed brushes. In the course of our study, we developed two independent theoretical methods, the self-consistent perturbation expansion and the transfer operator formalism, which made it possible to thoroughly investigate the density structure of polymers adsorbed onto chemically non-uniform substrates. As successive stages of our research, we applied the above theoretical methods to the study of the polymer adsorption onto the selected substrates, as follows: (i) periodically patterned rigid surface; (ii) randomly patterned rigid surface; (iii) surface that bears an array of periodically distributed adsorption centers; (iv) ripple, random and dimple morphologies of the binary mixed brush. By comparing the results obtained for the above listed systems we derived the qualitative trends that are common for the polymer adsorption onto the investigated chemically non-uniform substrates. In this talk, we discuss what are the main factors that influence the polymer adsorption onto the patterned substrates and how to reduce/enhance the polymer adsorption by way of manipulating these competitive factors.
Tunable Sliding Angles from isotactic-Polypropylene / Polypropylene Chloride Blend

XIA DONG, CHARLES C. HAN, Institute of Chemistry, Chinese Academy of Sciences, SONG HONG, YONGHUA YAO — With proper selection of shear and thermal conditions, super-hydrophobic polymeric surfaces (Contact angle higher than 150°) with tunable sliding angles (From less than 1° to higher than 90°) can be prepared from isotactic polypropylene (iPP)/ polypropylene chloride (PPC) blend under ambient atmosphere. No further modification with low-surface-energy component is needed. The formed surfaces have good thermal property, chemical and moisture resistance and potentially low manufacturing cost.

8:00AM Y20.00001 Peptide Folding and Consequent Self-assembly for Shear Thinning Hydrogels with Immediate Recovery

DARRIN POCHEK, University of Delaware — The local nano- and overall network structure, and resultant viscoelastic properties, of hydrogels that are formed via beta-hairpin self-assembly will be presented. The 20 amino acid peptides have been shown to intramolecularly fold and intermolecularly self-assemble into a rigid hydrogel based on environmental cues such as pH, salt, and temperature including physico-chemical conditions. The hydrogel is composed of a network of fibrils that are 3 nm wide that physically crosslink (i.e. entangle and branch) with no covalent crosslinking required. Slight design variations of the peptide sequence allow for tunability of the self-assembly/hydrogelation kinetics. In turn, by controlling hydrogel self-assembly kinetics, one dictates the ultimate stiffness of the resultant network. This physical assembly process allows the encapsulation of desired payloads into the gel network such as large macromolecules or living cells. Importantly, once formed into a solid, the self-supporting gel network can be disrupted by the introduction of a shear stress. The system can shear thin but immediately heal to a stiff solid on the cessation of the shear stress. This shear thinning and recovery behavior makes them interesting candidates for injectable delivery in vivo.

In collaboration with Joel Schneider, University of Delaware.

8:36AM Y20.00002 Designing ‘smart’ hydrogels using peptide-responsive conjugates

ALBERTO SAIJANI, JEAN-BAPTISTE GUIBAUD, ALINE MILLER, The University of Manchester — Polymers displaying phase transitions in aqueous solution from a hydrophobic to hydrophobic state are of widespread interest as ‘smart’ biomedical materials. Hydrogels formed from self-assembling peptides have also attracted considerable attention in the past decade. These hydrogels are based on the self-assembly of short peptides into supra-molecular fibres that entangle or associate to form three dimensional networks and, ultimately, self-supporting hydrogels. In order to create a new generation of hydrogel based on self-assembling peptides but possessing an internal transition that can be used as a trigger to release a drug molecule or a specific biological signal we have synthesized a new family of peptide-polymers conjugates using free radical polymerization. We were able to create a new generation of ‘smart’ hydrogel in which gelation is driven by the peptide while the polymer phase transition can be used to release in a controlled fashion a specific signal or drug molecules. These materials are though to be of prime interest for tissue culture applications where they can be used to deliver specific signals stimulating a specific cell response.

In collaboration with Joel Schneider, University of Delaware.

8:48AM Y20.00003 “Backpack” Functionalized Living Immune Cells

ALBERT SWISTON, MIT Dept of Materials Science and Engr., SOONG HO UM, DARRELL IRVINE, MIT Dept of Biological Engr., ROBERT COHEN, MIT Dept of Chemical Engr., MICHAEL RUBNER, MIT Dept of Materials Science and Engr. — We demonstrate that functional polymeric “backpacks” built from polyelectrolyte multilayers (PEMs) can be attached to a fraction of the surface area of living, individual lymphocytes. Backpacks containing fluorescent polymers, superparamagnetic nanoparticles, and commercially available quantum dots have been attached to B and T-cells, which may be spatially manipulated using a magnetic field. Since the backpack does not occlude the entire cellular surface from the environment, this technique allows functional synthetic payloads to be attached to a cell that is free to perform its native functions, thereby synergistically utilizing both biological and synthetic functionalities. For instance, we have shown that backpack-modified T-cells are able to migrate on surfaces for several hours following backpack attachment. Possible payloads within the PEM backpack include drugs, vaccine antigens, therapeutically responsive polymers, nanoparticles, and imaging agents. We will discuss how this approach has broad potential for applications in bioimaging, single-cell functionalization, immune system and tissue engineering, and cell-based therapeutics where cell-environment interactions are critical.

This work was supported primarily by the MRSEC Program of the NSF under award number DMR-0819762, and is based upon work supported by a NSF Graduate Research Fellowship.

9:00AM Y20.00004 Reversible Structural Transition of a DNA Lipid Film

MATTHEW TIRRELL, SUREKHA GAJRIA, THORSTEN NEUMANN, LUC JAEGE, University of California, Santa Barbara, MATERIALS RESEARCH LABORATORY COLLABORATION — Polyanions such as nucleic acids (RNA and DNA) can self-assemble with cationic lipids via electrostatic complexation, driven thermodynamically by the release of counterions. The structures of these complexed films in water have been studied extensively and are recognized as potentially useful in the field of gene delivery. The structure of films in water is dominated by the nature of the lipid. Within these lamellar complexes in aqueous solution the lipid assumes a bilayer formation and the DNA is a double helix. It is possible to obtain dry nucleic acid lipid films when the dissolved cationic lipid complex of DDAB and nucleic acid is cast on a solid. These self-standing films have been characterized by tensile properties and nucleic acid intercalation experiments. The tensile properties of these films are adjustable by mixing different molecular weights. It was expected that these films would have the same characteristic structure as these complexes in water. However, our work shows that the film undergoes a transition from double stranded helical DNA complexed with a bilayer of DDAB in the wet state, while in the dry state we observed a repeat unit of single stranded DNA complexed with a monolayer of DDAB.

9:12AM Y20.00005 Gecko-Inspired Carbon Nanotube-Based Adhesives

LIEHUI GE, SUNNY SETHI, ANUBHA GOYAL, LIJIE CI, PULICKEL AJAYAN, ALI DHINOJWALA, THE UNIVERSITY OF AKRON COLLABORATION, RICE UNIVERSITY COLLABORATION — Nature has developed hierarchical hair structure on the wall-climbing gecko’s foot, consisting of microscopic hairs called setae, which further split into hundreds of smaller structures called spatulas. In the last five years, numerous attempts to mimic gecko foot hair using polymer soft molding and photolithography methods have been reported. However, most of these polymer-based synthetic gecko hairs fall short of the clinging ability of geckos. Vertically aligned carbon nanotubes (CNT) have shown strong adhesion at nanometer scale. Here, we present our work on developing CNT-based macroscopic flexible tape mimicking the hierarchical structure found on gecko’s foot. The synthetic gecko tape is made by transferring aligned CNT array onto flexible polymer tape. The unpatterned CNT-gecko tape can support a shear force stress similar to gecko foot (10 N/cm²). The supported shear stress increase by a factor of four, when we use micro-patterned CNT patches (50 to 500 μm). We find that both setae (replicated by CNT bundles) and spatulas (individual CNT) are necessary to achieve large macroscopic shear adhesion. The carbon nanotube-based tape offers an excellent synthetic option as a dry conductive reversible adhesive in microelectronics, robotics, and space applications.

Research Supported by National Science Foundation
the results of recent experiments to hyperpolarize the nuclear spins can be a significant limitation, whether the nuclear spins are used as qubits or act as an environment for the electronic spins. We report the

DNA:Ag visible excitation, suggesting energy transfer from the DNA bases to the Ag cluster. We make use of this UV excitation to image the emitters in unstained wavelengths for all DNA-bound Ag clusters. This UV peak corresponds to resonant absorbance by the DNA bases, and produces the same emission spectra as a ubiquitous feature of these emitters. Each emitter thus has two excitation peaks: a visible peak which is cluster-dependent, and a UV peak which has the same

KIM WEIRICH, DEBORAH FYGENSON, University of California Santa Barbara — Few-atom fluorescent Ag nanoclusters self-assemble on short, synthetic micropatterned surface layers of two different proteins: silk fibroin (for growth of gold and silver nanoparticles) and silaffin (for growth of titania nanoparticles). We demonstrate that all titania, gold, and silver nanoparticles can be grown with relatively monodisperse diameter within 4-6 nm surrounded by biological shells of 1-2 nm thick. As biological templates we utilized ultrathin, molecular uniform and inorganic nanoparticles at room temperature and ambient conditions. We will discuss possible preferential chain conformations that may provide the driving force for the superstructure.

9:48AM Y20.00008 The effects of supramolecular network topology on hapten-receptor avidity . JASON BENKOSKI, ANDREW MASON, JILL LA FAVORS, JOSHUA WOLFE, The Johns Hopkins University Applied Physics Laboratory — Antibodies produced in the early stages of the immune response have much lower affinities for a given antigen than those produced later on. Nature compensates for the initial weakness of these associative bonds by synthesizing multivalent antibodies. The total binding strength, represented by the avidity constant, is equal to the product of the affinity constants for the individual hapten/receptor sites. However, under realistic conditions the individual binding sites do not act independently. Factors such as steric hindrance, intramolecular stresses, and competitive binding can significantly alter the relationship between affinity and avidity. We investigate the influence of these factors on a model system consisting of synthetic multifunctional nanoparticles and polymers. Each polymer or nanoparticle is decorated with either multiple antigens (thromboxane B2) or multiple antibodies. We then measure the association and dissociation in real time using Surface Plasmon Resonance Spectroscopy (SPR). By using synthetic polymers and nanoparticles, we are able to systematically control the degree of functionality, flexibility, and distance between receptor and hapten sites.

10:00AM Y20.00009 Dynamic DNA Interactions with Functionalized Colloids , LU ZHANG, YINGXI ELAINE ZHU, Department of Chemical and Biomolecular Engineering, University of Notre Dame — Many biomedical processes, such as protein adsorption, DNA hybridization and enzyme reactivity, are intimately related to their interactions with surfaces and complex ionic environments, yet the details of biomacromolecular interaction remain insufficiently understood. In this work, we use confocal laser scanning microscopy to examine the interaction between DNA molecules and functionalized colloidal particles in aqueous suspension. We observe an intriguing attractive interaction between DNA molecules and carboxyl-functionalized silica particles of varied sizes from 50 nm to 3 um, resulting in complex DNA-colloid aggregation with a strong dependence on DNA/colloid size ration and ionic strength. As colloidal size becomes larger than DNA dimensions, colloidal doublets and triplets with adsorbed DNAs are observed at high DNA concentration and ionic strength. The intriguing DNA-colloid complex structures are further confirmed by SEM and appear stable for at least 2 weeks.

10:12AM Y20.00010 Growth of well-defined metal and oxide nanoparticles on biological surfaces . VLADIMIR TSUKRUK, Georgia Tech — We present a brief overview of our recent studies in the field of bio-enabled surface-mediated growth of inorganic nanoparticles at room temperature and ambient conditions. We demonstrate that all titania, gold, and silver nanoparticles can be grown with relatively monodisperse diameter within 4-6 nm surrounded by biological shells of 1-2 nm thick. As biological templates we utilized ultrathin, molecular uniform and micropatterned surface layers of two different proteins: silk fibroin (for growth of gold and silver nanoparticles) and silaffin (for growth of titania nanoparticles). To identify the grown nanophases and chemical composition/secondary structure of biological templates we applied combined AFM, SEM, TEM, XPS, SERS, UV-vis, and ATR-FTIR techniques.

10:24AM Y20.00011 Fluorescent DNA-bound Ag nanoclusters , PATRICK O’NEILL, LOURDES VELAZQUEZ, KIM WEIRICH, DEBORAH FYGENSON, University of California Santa Barbara — Few-atom fluorescent Ag nanoclusters self-assemble on short, synthetic DNA strands, and exhibit sequence and structure dependent fluorescence ranging from the blue to the near infrared. Here we report UV excitation as a ubiquitous feature of these emitters. Each emitter thus has two excitation peaks: a visible peak which is cluster-dependent, and a UV peak which has the same wavelength for all DNA-bound Ag clusters. This UV peak corresponds to resonant absorbance by the DNA bases, and produces the same emission spectra as a visible excitation, suggesting energy transfer from the DNA bases to the Ag cluster. We make use of this UV excitation to image the emitters in unstained polyacrylamide gels, and show that electrophoresis can be used to create a pure solution of green DNA:Ag11 clusters from an inhomogeneous red solution of DNA:Ag>12 clusters.

Session Y22 GMAG DMP FIAP: Focus Session: Spin Resonance in Semiconductors 324

8:00AM Y22.00001 Dynamic Nuclear Polarization in Silicon . CHANDRASEKHAR RAMANATHAN, Massachusetts Institute of Technology — Silicon is a promising material for spintronics and spin-based quantum information processing. However, the highly mixed state of the nuclear spins can be a significant limitation, whether the nuclear spins are used as qubits or act as an environment for the electronic spins. We report the results of recent experiments to hyperpolarize the 29Si spins in silicon. We used microwave-induced dynamic nuclear polarization to achieve 5% polarization of the 29Si in micro-crystalline silicon powder [1], and 5–8% polarization in antimony- and phosphorus-doped silicon wafers. Since silicon has long T1 relaxation times, polarized silicon micro- and nanoparticles could be of use in magnetic resonance imaging. In the powders the 29 Si nuclei in the amorphous region (containing unpaired electrons) are polarized by forced electron-nuclear spin flips driven by off-resonant microwave radiation while nuclei in the crystalline region are polarized by spin diffusion across crystalline boundaries. In the wafers the DNP is driven by an Overhauser mechanism within exchange-coupled clusters of donors.

AMRIT DE, CRAIG E. PRYOR, MICHAEL E. FLATTÉ, Department of Physics and Astronomy, University of Iowa — The orbital wave function of an electron

8:48AM Y22.00003 Electric-field control of a hydrogenic donor’s spin in a semiconductor1 .

AMRIT DE, CRAIG E. PRYOR, MICHAEL E. FLATTÉ, Department of Physics and Astronomy, University of Iowa — The orbital wave function of an electron

bound to a single donor in a semiconductor can be modulated by an applied AC electric field, which affects the electron spin dynamics via the spin-orbit

interaction. Numerical calculations of the spin dynamics of a single hydrogenic donor (Si) using a real-space multi-band $k$-$p$ formalism show that in addition to

breaking the high symmetry of the hydrogenic donor state, the $g$-tensor has a strong nonlinear dependence on the applied fields. By explicitly integrating the

time dependent Schrödinger equation it is seen that Rabi oscillations can be obtained for electric fields modulated at sub-harmonics of the Larmor frequency.

The Rabi frequencies obtained from sub-harmonic modulation depend on the magnitudes of the AC and DC components of the electric field. For a purely AC

field, the highest Rabi frequency is obtained when E is driven at the 2nd sub-harmonic of the Larmor frequency. Apart from suggesting ways to measure $g$-tensor

anisotropies and nonlinearities, these results also suggest the possibility of direct frequency domain measurements of Rabi frequencies.

8:00AM Y22.00004 Electronic spin polarization and spin-dependent band structure in GaAs

probed by optically-pumped NMR (OPNMR)1 . SOPHIA HAYES, KANANN RAMASWAMY, STACY MUI, Washington U., SCOTT CROOKER, NHMF, Los Alamos, XINGYUAN PAN, GARY SANDERS, CHRISTOPHER STANTON, Univ. of FL — Traditionally, magnetic fields have played an important role in determining the band structure of a material (de Haas-van Alphen techniques for metals and cyclotron resonance or magneto-

absorption for semiconductors). We report optically pumped NMR (OPNMR) spectra of 69Ga spins in bulk semi-insulating GaAs generated by a narrowband

laser. OPNMR involves optical orientation of electrons in a semiconductor with NMR detection of the polarized nuclear spins to which they are coupled. These

experiments resolve fine details of the spin-dependent electronic structure of the valence bands. By comparing the oscillations in the OPNMR signal intensity

with theoretical calculations, we have mapped out the conduction band electronic spin polarization. We show that OPNMR experiments in combination with

theoretical simulations have the potential to reveal information about spin polarization and electronic structure of bulk semiconductors with far greater sensitivity

than conventional techniques such as magneto-absorption.

1Supported by NSF through Grants: CHE- 0239560, DMR 0706313, and INT 0530220, and through I-CARES, Washington Univ.

9:12AM Y22.00005 Theory of the Spin-Splitting of the Valence Band Landau Levels in GaAs1

High Magnetic Field Laboratory — We present calculations of the spin-dependent band structure and magneto-optical absorption spectra in bulk GaAs.

Our calculations are based on the 8-band Pidgeon-Brown model. Optical properties are calculated within the golden rule approximation and compared with

experiments. Although GaAs has a small $g$-factor leading to nearly spin-degenerate conduction band Landau levels, the valence band Landau levels are spin-split

and the spin splitting can be observed in the circularly polarized magneto-absorption spectra. By carefully analyzing the energy band structure and the absorption

spectra together, we identify the origins of all the optical transitions. We also separate contributions to the absorption coefficient from spin-up electrons and

spin-down electrons to get the conduction band electron spin polarization. This information is used to compute the optically-pumped NMR (OPNMR) signal.

We demonstrate that OPNMR can provide unique insight into the spin-dependent valence band electronic states.

1Supported by NSF through Grants: CHE- 0239560, DMR 0706313, and INT 0530220, and through I-CARES, Washington Univ.

9:24AM Y22.00006 High bandwidth EDMR detection , H. HUEBL, L.H. WILLEMS VAN BEVEREN, R.P. STARRETT, D.R. MCCAMEY, A.J. FERGUSON, Centre for Quantum Computer Technology, University of New South Wales, Sydney — Several proposals discuss the realization of quantum computation with the help of the spin degree of freedom in semiconductors. Electrically detected magnetic resonance (EDMR) provides a well established tool to investigate spin states in semiconductors which was recently extended to investigate the spin dynamics of phosphorus donors in silicon.

Typically, the detection bandwidth of EDMR is limited by the characteristic RC time constant of the sample. In this contribution we show that by embedding

the sample in a LRC resonant circuit, a so-called tank circuit, it is possible to overcome this limitations. Here, we investigate a silicon MOSFET where the

microwave magnetic field to induce the spin transitions is generated on chip by a shorted coplanar stripline[1]. We monitor the MOSFET resistance with a current

preamplifier and in-situ by the response of the LRC resonant circuit and observe a spin resonance signature in both cases. Investigating the detection

bandwidth by using frequency modulation of the microwaves applied indicates that the spin signature observed with the tank circuit is limited at the high end

currently by the experimental setup. This shows that this method has the expected high bandwidth opening the view to faster phenomena in EDMR in a more

direct manner. [1] Willems van Beveren et al., APL 93, 072102 (2008)

9:36AM Y22.00007 Optically Detected Electron Spin Resonance of GaAs Spin-LEDs , JOHN COLTON, STEVE BROWN, BENJAMIN HEATON, DANIEL JENSON, MICHAEL JOHNSON, AARON JONES, Brigham Young University — GaAs “spin-

LED” samples give off circularly polarized light due to spin-polarized electrons being injected into a quantum well diode structure. The spin dynamics of these

electrons have been studied through electron spin resonance (ESR), with the resonance being optically detected by a change in the circular polarization of the

emitted light. Results of the ESR experiments will be presented.
9:48AM Y22.00008 Spin lifetime properties of a quantum well GaAs sample measured by optically detected magnetic resonance \(^1\), BENJAMIN HEATON, JOHN COLTON, STEVE BROWN, DANIEL JENSON, MICHAEL JOHNSON, AARON JONES, Brigham Young University — Optically detected Kerr rotation techniques were used to measure spin properties in GaAs. The samples studied were MBE-grown 14 nm n-type GaAs quantum wells. Magnetic resonance was observed with high sensitivity as the probe laser was tuned to the exciton resonance. The g-factor was measured to be \(|g|=0.35\). The \(T_1\) lifetime measured from the width of the ODMR peaks was 52 ns. Results from pulsed microwave Rabi oscillation and spin echo experiments (to measure the \(T_2\) spin coherence lifetime) are presented.

\(^1\)This work was supported by NSF grants 0419501, 0456074, and 0802831.

10:00AM Y22.00009 Ballistic Spin Resonance, SERGEY FROLOV, SILVIA LUESCHER, WING-WA YU, YUAN REN, JOSHUA FOLK, UBC, WERNER WEIGSCHIEBER, University of Regensburg — We demonstrate spin resonance driven by ballistic motion of electrons and mediated by spin-orbit interaction in a micron-scale channel of GaAs/AlGaAs two-dimensional electron gas. The resonance is observed when the frequency of electron bouncing trajectories in the channel matches the spin precession frequency set by a large in-plane magnetic field. The resonance is manifested as a suppression of pure spin currents that are generated in the channel by injection through quantum point contacts. The resonant frequency (10-50 GHz) can be tuned by varying electron density or channel width, as well as by bending the electron trajectories with a small out-of-plane magnetic field.

10:12AM Y22.00010 Scaling behavior of spin-dependent scattering off Neutral Donors in Silicon Field-Effect Transistors \(^1\), C. C. Lo, J. BOKOR, University of California, Berkeley, T. SCHENKEL, Lawrence Berkeley National Laboratory, J. HE, A. M. TYRYSHKIN, S.A. LYON, Princeton University — Spin-dependent scattering of conduction electrons by neutral impurities is a promising route towards donor nuclear spin-state readout for donor qubits in silicon. Using electron spin resonance techniques, the donor nuclear spin-state can be extracted from the position of the resonance signal. Contrary to readout schemes involving Coulomb/spin blockade or other single electron phenomenon, spin-dependent scattering can be observed and studied in the presence of an ensemble of donors. In our experiments we study neutral impurity scattering of two-dimensional conduction electrons by donor impurities in field-effect transistors [1]. In this talk, we will discuss the scaling behavior of donor resonance signals using electrically detected magnetic resonance techniques in devices with different sizes. [1] C. C. Lo et al, App. Phys. Lett., 91, 242106 (2007)

10:24AM Y22.00011 Electron Spin Resonance in Si/SiGe Heterostructures at 350 mK \(^1\), JIANHUA HE, A.M. TYRYSHKIN, S.A. LYON, Princeton University, D.E. SAVAGE, M.A. ERIKSSON, University of Wisconsin-Madison — Si/SiGe heterostructures are one of the promising matrices for electron spins as qubits in a silicon-based quantum computer. Many electron spin resonance (ESR) measurements have been done to characterize 2D electron spins embedded in such structures at temperatures above 2 K. Here we report the first CW and pulsed ESR experiments in Si/SiGe heterostructures in a \(^3\)He system at 350 mK. Electron beam lithography was used to pattern a large area (16 mm\(^2\)) of a CVD grown modulation doped Si/SiGe quantum well (QW) into an array of \(\sim 100 \) nm quantum dots (300 nm pitch) which has been wet etched about half-way through the doped layer. In the dark, only one signal is observed, which shows a Curie-like temperature dependence indicative of isolated spins. After brief illumination, two more signals appear: a line having g-factor \(g = 0.19\) and another line which disappears upon annealing to 20 K. The first of these lines \((g = 2.0003)\) shows a Pauli temperature dependence consistent with many-electron quantum dots, and a \(T_2\) relaxation time of about 150 ns at 350 mK. The origin of these ESR signals and their relaxation mechanisms will be discussed.

10:36AM Y22.00012 Electron spin resonance in silicon MOS structures down to 0.36 K \(^1\), S. SHANKAR, A. M. TYRYSHKIN, S. A. LYON, Princeton University — While transport of 2-dimensional (2D) electrons has been routinely measured down to few mK, performing electron spin resonance (ESR) at low temperatures is challenging. We report measurements of the paramagnetic susceptibility of 2D electrons in a silicon metal-oxide-semiconductor (MOS) structure using ESR at 0.34 T for temperature down to 0.36 K. When the MOS gate is biased below the threshold voltage, we measure electrons weakly confined below the conduction band edge and find that the susceptibility follows a simple Pauli temperature dependence, i.e., constant at low temperatures. Surprisingly, at an electron density of \(2.8 \times 10^{11} \text{ cm}^{-2}\) (Fermi temperature \(= 20 \text{ K}\), as the temperature is reduced from 4.2 K to 0.36 K, the susceptibility actually drops by a factor of 2. Furthermore, this effect becomes more pronounced at higher 2D electron densities. The drop in susceptibility for 2D conduction electrons at low temperature is unexpected and remains to be explained.

Friday, March 20, 2009 8:00AM - 10:48AM – Session Y24 DMP: Focus Session: Hydrogen Storage: Atomic and Molecular Motions 326

8:00AM Y24.00001 Atomic Motions in Ionic Hydrides: MgH\(_2\), NaMgH\(_3\), and LiBH\(_4\), MARK CONRADI, Washington University — In hydrogen storage, rapid hydrogen diffusion is a key component for rapid reaction rates of dehydriding and rehydriding. In metallic systems, the light interstitial H atoms typically do display rapid diffusion. However, recent interest has focused on ionic and complex hydrides of light metal-atoms because of their high weight fractions of reversible hydrogen. These ionic complex hydrides generally reveal slow hydrogen diffusion and resulting slow reaction kinetics. We report here studies of H diffusion using NMR in several such hydrides. In MgH\(_2\), the rate \(\omega_H\) of H hopping remains too slow to narrow the H NMR up to 400 °C. T\(_{1D}\) measurements, however, can detect the motion and find an activation energy of 1.72 eV, the first reported direct measurement of diffusion in MgH\(_2\). In ball-milled (bm) material with Nb\(_5\) catalyst additive, a fraction of the resonance intensity is narrowed starting at 50 °C, with the narrow fraction growing up to 30% by 400 °C. A model for continuous growth of the narrow line, based on a wide distribution of motion rates, is presented. Ball-milling also greatly increases the laboratory-frame relaxation rates, \(T_1^{-1}\), from paramagnetic defects created by the mechanical process. In bm NaMgH\(_3\), an even larger fraction of the resonance is motionally-narrowed, growing to nearly 100% by 300 °C. Clearly, ball-milling has a much more profound effect on ionic hydrides than the simple reduction of grain sizes and diffusion distances. In coarse-grain LiBH\(_4\) (with 13.8 weight%) reversible hydrogen), an orientationally disordered solid phase occurs above 110 °C. Above the transition, the rate of Li ion diffusion increases remarkably. H diffusion starts to narrow the H NMR line around 170 °C, continuing to narrow up to the melt near 280 °C. To distinguish diffusion of (already rapidly rotating) BH\(_4\) units from H exchange between neighboringBH\(_4\), the \(2^1\)B resonance was studied. The boron line central transition becomes much narrower (400 Hz) than the width (1500 Hz) expected from Van Vleck M\(_2\) for the case of static boron spins (with rapid Li and H diffusion). Thus, intact BH\(_4\) units are the diffusing species. Even in molten LiBH\(_4\), the BH\(_4\) lifetime is found to be at least 2 seconds from observations of the B-H J-coupling pattern, so it is probably much larger in the solid.
8:36AM Y24.00002 Understanding and Enhancing Hydrogen Diffusion in MgH2 and NaMgH3, DAVID SHOLL, SHIQIANG HAO, Georgia Tech — The transport properties of hydrogen in metal hydrides are crucial to the kinetics of H2 storage in these materials. We use first-principles calculations to identify the defects that are relevant for H transport in MgH2 and NaMgH3. In both materials, the physically relevant defects are charged and diffusion is dominated by mobility of negatively charged interstitial H. Interestingly, the diffusion of these species occurs via concerted mechanisms with low energy barriers. To improve the charged interstitial H diffusivity, a series of transition-metal additives are screened to lower the formation energy of mobile defects. Our results provide a practical way to examine and alter H diffusion in light metal hydrides.

8:48AM Y24.00003 Quasielastic Neutron Scattering of Hydrogen Adsorbed in KC24, JUSTIN PUREWAL, JAMES KEITH, CHANNING AHN, BRENT FULTZ, California Institute of Technology, CRAIG BROWN, NIST Center for Neutron Research — Quasielastic neutron scattering (QENS) and volumetric techniques were used to study the adsorption of H2 by the stage-2 potassium graphite intercalation compound KC24. A zero-coverge sorption enthalpy of 8.5 kJ/mol was measured from H2 isotherms recorded at 77 K and 87 K. The saturation H2 adsorption amount at 77 K was 1.2 mass%, corresponding to a stoichiometry of KC24/(H2)2/0. Quasielastic neutron scattering spectra for KC24/(H2)1/0 were collected at temperatures between 40 K and 80 K on a chopper spectrometer and a backscattering spectrometer. Two distinct H2 diffusion processes were identified with characteristic times of approximately τ = 10 ps and τ = 350 ps at 60 K, respectively. By operating the backscattering spectrometer in fixed window mode, the total elastic scattering of KC24/(H2)1/0 was measured as a function of temperature. A sharp decrease in elastic intensity was observed at 35 K due to the onset of quasielastic scattering. This was interpreted as a melting transition of the H2 adsorbate in KC24.1 This work was supported by the Office of Energy Efficiency and Renewable Energy through the Hydrogen Sorption Center of Excellence.

9:00AM Y24.00004 Novel geometry for simultaneous resistive, Hall and optical measurement of MgH2 thin films, D.W. KOON, C. C. W. GRIFFIN, St. Lawrence University, J.R. ARES, F. LEARDINI, C. SANCHEZ, Universidad Autónoma de Madrid — We describe a novel specmen geometry that we have used to simultaneously probe optical transmission, sheet resistance and sheet Hall resistance in 100 nm Mg films during hydrogen absorption. A Mg-film cloverleaf overlaps four rectangular Pd pads at the corners of a glass slide, a variation on a two-pad geometry used by Ingason and Olafsson for resistive studies of Pd-capped MgH2 films [J. Alloys and Compounds 404–406 (2005), 469–72]. Hydrogen diffuses laterally through the Pd pads before entering the magnesium layer from below. The sample holder also includes an LED-photodiode pair for measuring [monochromatic] optical transmission. We show that the simultaneous measurement of these three quantities during the metal-to-insulator transition in a hydriding MgH2 film allows for a more complete understanding of the hydriding process in these films.

9:12AM Y24.00005 Proton Tunneling: A Decay Channel of the O-H Stretch Mode in KTaO3, ERIK SPAHR, College of William and Mary, MICHAEL STAVOLA, Lehigh University, LANLIN WEN, Lehigh University, LYNN BOATNER, Oak Ridge National Lab, LEONARD FELDMAN, Vanderbilt, Rutgers, NORMAN TOLK, GUNTER LUPKE, College of William and Mary — Proton vibrational dynamics play a key role in the important processes of hydrogen diffusion and transport. In particular, perovskite structured proton conductors are an important class of hydrogen transport materials with a wide range of applications. We have measured for the first time the vibrational lifetimes of the O-H and O-D stretch modes in the perovskite oxide, KTaO3, by pump-probe infrared spectroscopy. Both stretch modes are exceptionally long lived and exhibit a large “reverse” isotope effect, due to a phonon-assisted proton tunneling process, which involves the O-Ta-O bending motion. The excited-state tunneling rate is found to be seven orders of magnitude larger than that in the ground state in the proton conducting oxide, BaCeO3 [1]. [1] I. Kuskovskiy et al., Phys. Rev. B 60, R3713 (1999).

9:24AM Y24.00006 Reversible Low Temperature Hydrogen Storage Using Ternary Borides, WEN LI, JOHN VAJO, ROBERT CUMBERLAND, PING LIU, HRL Laboratories, LLC, SÔN-JONG HWANG, CHUL KIM, California Institute of Technology, ROBERT BOWMAN, RCB Hydrides, LLC — Among many materials for hydrogen storage, complex borohydride of light metals with high hydrogen capacity, have been studied extensively. However, the thermodynamic and kinetic properties of borohydrides limit their ability to cycle hydrogen reversibly at low temperature. For example, although LiBH4 is thermodynamically quite stable, the formation of LiBH4 from LiH + B requires elevated temperatures and pressures of up to 600 C and 150 bar. Here, we report ternary borides with active boron species that can be hydrogenated forming [BH4]1− anions at temperatures as low as ~280 C. These ternary borohydrides were prepared through milling of precursors followed by thermal treatment under inert atmosphere. Samples were then milled with additional binary hydrides before hydrogenation. Analysis using FTIR and 11B MAS NMR indicated that the ternary borides were hydrogenated to [BH4]1− species with good kinetics. After hydrogenation, the mixture could be cycled with dehydrogenation occurring in two steps that begin at 280 C and 345 C, respectively. Characterization using FTIR, 11B MAS NMR, and XRD, indicates that the [BH4]1− anions are consumed in the first dehydrogenation step.

9:36AM Y24.00007 Thermodynamic and kinetic destabilization in LiBH4-based hydride systems, JOHN VAJO, WEN LI, PING LIU, HRL Laboratories, LLC — The LiBH4/MgH2 destabilized hydride system has attracted considerable attention recently because it is a reversible system, based on the [BH4]− anion, with a high hydrogen capacity (11.6 wt % gravimetric). However, hydrogen release during a temperature ramp occurs in two steps with dehydrogenation of MgH2 to Mg + H2 occurring first followed by reaction of Mg with LiBH4 to form LiH + MgB2 + H2. These two steps occur despite there being a direct reaction that is thermodynamically allowed at lower temperatures. In this talk we describe a LiBH4-based hydride system that is kinetically as well as thermodynamically destabilized. In this system, a direct (concerted) dehydrogenation reaction of LiBH4 occurs at temperatures lower than the dehydrogenation temperature of any of the components separately. In addition, the system is reversible with an equilibrium hydrogen pressure (based on preliminary measurements) that is ~20X higher than the pressure for the LiBH4/MgH2 system.

9:48AM Y24.00008 Structure and librational dynamics in borohydrides, MONIKA HARTL, Los Alamos National Laboratory, MICHAEL WOLVERTON, University of Arkansas - Little Rock, ALICE ACATRINEI, Los Alamos National Laboratory, ABHIJIT BHATTACHARYYA, University of Arkansas - Little Rock, LUKÉ DAEMEN, Los Alamos National Laboratory — Borohydrides are candidates for reversible hydrogen storage. The attention accorded to this class of materials is supported by extensive hydrogenation/dehydrogenation thermodynamic measurements. However, the understanding of the chemical reaction mechanisms remain uncertain. We used neutron diffraction and inelastic neutron scattering, together with a computational approach, to examine the connection between structure and dynamics in several borohydrides and the possible role played by dynamics in the approach to the underlying chemical reaction mechanisms. We used first-principles calculations to identify the defects that are relevant for H transport in MgH2 and NaMgH3. In both materials, the physically relevant defects are charged and diffusion is dominated by mobility of negatively charged interstitial H. Interestingly, the diffusion of these species occurs via concerted mechanisms with low energy barriers. To improve the charged interstitial H diffusivity, a series of transition-metal additives are screened to lower the formation energy of mobile defects. Our results provide a practical way to examine and alter H diffusion in light metal hydrides.

10:00AM Y24.00009 First-principles Study on the Vibrational Modes and Electronic Structure of Alkaline and Alkaline-earth Amides and Alanates, TAKAO TSUMURAYA, TATSUYA SHISHIDOU, TAMIO OGUCHI, Hiroshima University — Light alkaline and alkaline-earth metal hydrides such as amides M(NH2)2 and alanates M(AH)4, (M=K, Na, Li, Ca, and Mg) have attracted a growing interest as reversible hydrogen storage materials recently because of their innately high hydrogen contents. [1, 2] We study the electronic structure of the amides and alanates with different cations, focusing on the role of cation states from first-principles calculations based on the all-electron FLAPW method. Calculated breathing stretch vibration modes for these compounds are compared with measured infrared and Raman spectra. In the amides, we find a significant tendency such that the breathing stretch vibration frequencies and the structural parameters of NH22− may vary in accordance with the ionization energy of cation, which may be explained by the strength in hybridization between cation orbitals and molecular orbitals of (NH2)2−. We elucidate the microscopic mechanism of correlations between the breathing stretch vibration frequencies of N-H and structural parameters by analyzing the calculated electronic structure from a view point of the molecular-orbitals. A similar tendency in the alanates is also discussed. [1] P. Chen, Z. Xiong, J. Luo, J. Lin and K.L. Tan, Nature 420, 302 (2002). [2] B. Bogdanovi and M. Schwickardi, J. Alloys Compd. 253-254, 1 (1997).
10:12AM Y24.00010 Neutron spectroscopy of $\gamma$-AlH$_3$. ALEXANDER KOLESNIKOV, Oak Ridge National Laboratory, Oak Ridge, TN 37831, JASON GRAETZ, Brookhaven National Laboratory, Upton, NY 11973, CRAIG JENSEN, WALKER LANGLEY, University of Hawaii, Honolulu, HI 96822, VLADIMIR ANTONOV, Inst. Solid State Physics, RAS, Chernogolovka, Russia — The density of vibrational states, G(E), for $\gamma$-AlH$_3$ is measured by inelastic neutron scattering. The obtained spectrum noticeably differs from that of $\alpha$-AlH$_3$, because $\alpha$-AlH$_3$ has a structure built of corner-sharing AlH$_6$ octahedra, while the $\gamma$-AlH$_3$ is composed of both corner- and edge-sharing AlH$_6$ octahedra. The first acoustic phonon peak in the G(E) of $\gamma$-AlH$_3$ appears at a lower energy and the band of translational modes extends to higher energies (55 vs. 42 meV) than in the spectrum of $\alpha$-AlH$_3$. The bands of Al-H bending modes are observed at about the same energies of 60–140 meV in $\gamma$-AlH$_3$ and $\alpha$-AlH$_3$, only the structures of the bands are different. The Al-H stretching modes in the $\gamma$-phase show eight peaks in the range 145 to 265 meV, while in the $\alpha$-phase they exhibit only two peaks at 200 and 235 meV. The G(E) spectrum of $\gamma$-AlH$_3$ is in good agreement with recent simulations [Y. Wang et al., Phys. Rev. B 77 (2008) 014101], which took into account the existence of a unique double-bridge bond between certain Al and H atoms.

10:24AM Y24.00011 Cubic Metallic Phase of Aluminum Hydride Showing Improved Hydrogen Desorption. RALPH H. SCHEICHER, DUCK YOUNG KIM, Condensed Matter Theory Group, Department of Physics and Materials Science, Uppsala University, Uppsala, Sweden, RAJEEV AHUJA, CMT Group, Uppsala Univ.; Applied Materials Physics, Department of Materials and Engineering, Royal Institute of Technology (KTH), Stockholm, Sweden — AlH$_3$ is of great interest for hydrogen storage applications, with a particularly attractive feature being its large hydrogen capacity of 10 wt.%. Here we report the results of our density functional theory study of the dehydrogenation properties in a cubic phase of AlH$_3$. The metallic nature of the electronic structure entails a more favorable hydrogen removal energy which is lowered by 75% compared to the insulating hexagonal phase. This remarkable reduction in the Al-H bond strength might bear important consequences for feasible reductions of AlH$_3$ as an on-board hydrogen storage material for mobile applications. Suggestions are made how the cubic phase could be prepared and stabilized at ambient pressure by off-board quenching. See also: R. H. Scheicher, D. Y. Kim, S. Lebègue, B. Arnaud, M. Alouani, and R. Ahuja, Appl. Phys. Lett. 92, 201903 (2008) and D. Y. Kim, R. H. Scheicher, and R. Ahuja, Phys. Rev. B 78, 100102(R) (2008).

10:36AM Y24.00012 Regeneration of Aluminum Hydride studied with Raman Microscopy. DAVID LACINA, JASON GRAETZ, J.J. REILLY, Brookhaven National Laboratory — We are interested in developing new methods to form aluminum hydride directly from aluminum powder and hydrogen. Due to the low free energy of formation, aluminum and hydrogen require extremely high pressures to react and form the hydride. It is possible to form alone directly at low pressure when it is catalyzed with a small amount of titanium (2 mol %) and stabilized as an adduct. We have studied the formation of amine-alanes by direct hydrogenation of aluminum and have attempted to understand the mechanisms behind these reversible reactions and the role of the catalyst. We will present the results from our recent survey of possible reactions between aluminum, hydrogen and various amines. We will also present the results of a Raman spectroscopy study of the alane polymorphs at ambient and high pressure and alane amines.

Friday, March 20, 2009 8:00AM - 11:00AM – Session Y25 DMP: Focus Session: Graphene XVIII: Functionalization and Growth II 327

8:00AM Y25.00001 Edge states and nitrogen substitutional doping in carbon nanoribbons. JIE JIANG, NC State U., Raleigh, WENCHANG LU, JERRY BERNHOLC, NC State U., Raleigh; CSMD, ORNL; PIOTR BOGUSLAWSKI, NC State U., Raleigh; IPPAS, Poland — The edge states in carbon nanoribbons and the electronic and magnetic properties in N-doped carbon nanoribbons are investigated within density functional theory. While the ground state of zigzag nanoribbons is spin polarized, defects lead to the spin carrier to be delocalized into the armchair edge, which results in a non-magnetic ground state. Scanning tunneling microscopy will thus show different features depending on edge quality. Turning to substitutionally doped carbon nanoribbons, the impurity states are elongated along the ribbon width by edge and confinement effects, which also affect their ionization energies in armchair ribbons. Formation energy calculations reveal that N atoms preferentially occupy edge sites in carbon nanoribbons. The extra electron from the donor suppresses the spin-polarization and tailors the relative magnetization at the two edges in zigzag ribbons. The interplay of impurity and edge states in zigzag ribbons leads to rich electronic effects, resulting in semiconducting or metallic behavior depending on the dopant position.

8:12AM Y25.00002 Counting Graphene Layers on Glass by Optical Reflection Microscopy. HELGI SKULASON, PETER GASKELL, CHRIS RODENCUK, THOMAS SZKOPEK, McGill University — Using optical reflection microscopy we can locate and count graphene layers on a bulk glass substrate. This is a reliable and low cost technique for graphene flake metrology. Optical reflection measurements are in agreement with the universal optical conductance of graphene. We present measurements of the optical conductivity of graphitic flakes showing a transition from few layer graphene to bulk graphite.

8:24AM Y25.00003 Molecular Physisorption on Graphene. DAVID CAREY, THOMAS CONNOLLY, University of Surrey — Ab initio calculations using both LDA and GGA functionals have been used to examine the binding energy, optimum binding intermolecular separations, molecular orientation dependence for a range of graphene lattice sites with oxygen containing molecules such as CO and NO. For all sites investigated NO has a higher binding energy than CO. For example, we find that the most stable sites are for the intermolecular axis parallel to the plane of the graphene layer with a binding energy of 195 meV for NO and 131 meV for CO using LDA VWN functional. Using the GGA PW91 functional the corresponding binding energies are 45 meV and 28 meV. When the CO or NO molecular axis is perpendicular to the graphene layer, orientation with the O atom oriented away from the graphene layer has a higher binding energy than CO. For example, we find that the most stable sites are for the intermolecular axis parallel to the plane of the graphene layer with a binding energy of 195 meV for NO and 131 meV for CO using LDA VWN functional. Using the GGA PW91 functional the corresponding binding energies are 45 meV and 28 meV. When the CO or NO molecular axis is perpendicular to the graphene layer, orientation with the O atom oriented away from the graphene layer is favored to be favored than those with the O atom closer to the graphene layer. Molecular physisorption on graphene is discussed.

8:36AM Y25.00004 Interface structure for growth of epitaxial graphene on SiC(0001). S.H. RHIM, G. SUN, L. LI, M. WEINERT, U. Wisconsin-Milwaukee — In spite of the enormous effort devoted to the study of the epitaxial growth of graphene on SiC, there is not yet a consensus regarding the structure of the interface between graphene and the substrate. There have been a long standing discrepancy between low energy electron diffraction (LEED) and STM patterns regarding the periodicity of graphene on SiC(0001); the theoretical studies of the of $6\sqrt{3} \times 6\sqrt{3}$ or $\sqrt{3} \times \sqrt{3}$ periodicity, while describing some aspects, disagree in important details with scanning tunneling microscopy (STM) images. We present a combined theoretical and experimental study, employing density functional calculations and STM, to investigate this issue. We propose the formation of a defected graphene layer at the interface, and then subsequent growth of graphene. The calculated bias-dependent STM images are in good agreement with our STM images, and provide insight into the details of the interface structure.

1Supported by DOE (DE-FG02-05ER46228) and NSF (DMR-0706359)
8:48AM Y25.00005 In-situ IR studies of graphene oxide reduction.  
\footnote{Work supported by the Southwest Academy for Nanoelectronics funded by SRC-NRI.}

MUGE ACIK, LAURENCE GOUX, YVES CHABAL — Thermal reduction of graphene oxide \( (GO) \) synthesized by Hummer’s method is studied by in-situ infrared absorption spectroscopy in a vacuum reactor. Initially, water and hydroxyl groups are removed \( (100^\circ \text{C}) \), with release of \( \text{CO}_2 \). Upon reduction of epoxides and carbonyl groups, the appearance of sp2-bonded carbon \( (C=C) \) bonds is evident with detection of in-plane and out of plane vibrations. However, oxygen remains in the structure in the form of COC bonds even after \( 700^\circ \text{C} \) anneal. Around \( 290^\circ \text{C} \), a strong increase of the absorbance associated with structure changes of \( GO \) is observed. The increase of the refractive index is attributed to an increase of electrical conductivity after reduction of \( GO \).

9:00AM Y25.00006 AFM local oxidation nanolithography of graphene

LISHAN WENG, LIYUAN ZHANG, YONG P. CHEN, LEONID P. ROKHINSON, Purdue University — We demonstrate the local oxidation nanopatterning of graphene films by an atomic force microscope. The technique provides a method to form insulating trenches in graphene flakes and to fabricate nanodevices with sub-nanometer precision. By utilizing this technique, a nanowide nanoribbon and submicron size nanoring were fabricated from a graphene flake. In addition we found that either trenches or bumps can be written on the graphene surface depending on the lithography conditions. It is proposed that the trenches are created by defect-associated oxidation whereas the bumps are incorporation of oxygen into the graphene lattice. Some of the bumps disappear with time as quickly as in a few minutes or as slow as in a few days. We also further investigate the possibility to remove the bumps in a controllable manner by writing trenches on top, applying opposite voltage or change the environmental conditions.

9:12AM Y25.00007 Hydrogen Saturation of Graphene Nanoribbons: edge states suppression and gap behavior

THIAGO MARTINS, ANTONIO J. R. DA SILVA, ADALBERTO FAZZIO, Physics Institute - University of Sao Paulo — Di-hydrogenated zigzag edges Graphene Nanoribbons \( (2H-ZZ-GNR) \) are more stable than the usually studied mono-hydrogenated \([1]\) passivation \( (H-ZZ-GNR) \). Using density functional theory, we studied a variety of \( H-ZZ-GNR \) configurations. We investigated how the interaction between the \( CH_2 \) units depends on their separation at the same edge as well as on the width of the ribbon. We observe, in agreement with previous studies \([1]\), that the \( 2H-ZZ-GNR \) passivation suppresses the presence of edge states, thus eliminating the magnetic instability of \( H-ZZ-GNR \) that is responsible for the gap opening in the anti-ferromagnetic ground state configuration. Moreover, there is a reduction of coupling between edge and bulk carbon atoms, resulting in a band structure whose gap is dominated by bulk bands and confinement effects. We also studied the behavior of the gap as a function of the ribbon’s width, and we observed that it quickly closes as the width is increased.

9:24AM Y25.00008 Anomalous magnetic susceptibility and Hall effect from valley degrees of freedom

TIANYI CAI, WANG YAO, The university of Texas at Austin, JUNREN SHI, Chinese Academy of Science, QIAN NIU, The university of Texas at Austin — With a staggered sublattice potential, sizable gaps can occur in epitaxial graphenen films. Magnetic and transport properties of this system are studied. We predict large signal of magnetic susceptibility and relate it to the intrinsic large magnetic moments of electrons. There is also an anomalous contribution to the ordinary Hall effect, which is due to the valley dependent Berry phase.

9:36AM Y25.00009 ABSTRACT WITHDRAWN

9:48AM Y25.00010 Si diffusion on and between graphene sheets

LEDE XIAN, M.Y. CHOU, School of Physics, Georgia Tech — The growth of epitaxial graphene \( (EG) \) on the SiC substrate is accompanied by the evaporation of Si atoms during the growth process. The continuing loss of Si atoms takes place even after the surface graphene sheets have been formed. This atomic transport is believed to be a key element in establishing a growth mechanism to model and control the process. Using density functional theory \( (DFT) \) calculations, we have studied the diffision of Si atoms on a single layer of graphene and between graphene sheets. The potential energy surfaces are explored. For single-layer graphene, the diffusion barrier for Si is relatively low. While for multilayers, some buckling of graphene sheets will appear and the stacking pattern also plays a role. The connection with the growth process will be discussed.

10:00AM Y25.00011 Gauge field for the edge states in graphene

KEN-ICHI SASAKI, Department of Quantum Matter, AdSM, Hiroshima University, Japan, SHUICHI MURAKAMI, Department of Physics, Tokyo Institute of Technology and PRESTO, JST, Japan, RIICHIRO SAITO, Department of Physics, Tohoku University, Japan — By considering a continuous model for graphene, we study a special gauge field for the edge state. The gauge field explains the properties of the edge state such as the existence only on the zigzag edge, the partial appearance in the \( k \)-space, and the energy position around the Fermi energy. The gauge field polarizes the pseudospin. The applications of the gauge field to the ferromagnetism of edge states and the electron-photon interaction are reported on.

10:12AM Y25.00012 Collective properties of magnetobie excitons in quantum wells’ and graphene superlattices

OLEG BERMANN, ROMAN KEZERASHVILI, New York City College of Technology of CUNY, YURLII LOZOVIK, Institute of Spectroscopy — The Bose-Einstein condensation and superfluidity of quasi-two-dimensional spatially indirect magnetobie excitons in a slab of superlattice with alternating electron and hole layers consisting from the semiconducting quantum wells \( (QW) \) and graphene superlattice in high magnetic field are reported. The two different Hamiltonians of a dilute gas of magnetobie excitons with a dipole-dipole repulsion in superlattices consisting of both QWs and graphene layers \( (GL) \) in the limit of high magnetic field have been reduced to one effective Hamiltonian a dilute gas of two-dimensional excitons with the renormalized effective mass of the magnetobie exciton, which depends on the magnetic field. The instability of the ground state of the system of interacting two-dimensional indirect magnetobie excitons in a slab of superlattice with alternating electron and hole layers in high magnetic field is found. The stable system of indirect quasi-two-dimensional magnetobie excitons, consisting of pair of indirect excitons with opposite dipole moments is considered. The density of the superfuid component \( n_s(T) \) and the temperature of the Kosterlitz-Thouless phase transition to the superfluid state in the system of two- dimensional indirect magnetobie excitons, interacting as electrical quadrupoles, are obtained for both the QW and graphene realizations.

10:24AM Y25.00013 The Electronic Structure of Few-Layer Graphene: Probing the Evolution from a 2-Dimensional Sheet to a 3-Dimensional Solid by Optical Spectroscopy

KIN FAI MAK, MATTHEW SFEIR, JAMES MISIEWICH, TONY HEINZ, COLUMBIA UNIVERSITY, NEW YORK, NY 10027 COLLABORATION, BROOKHAVEN NATIONAL LABORATORY, UPTON, NY 11973 COLLABORATION — The evolution of the electronic structure of few-layer graphene, for \( n = 1, \ 2, \ 3, \ \ldots, \ 8 \) atomic layers, was characterized by optical absorption spectroscopy. Each thickness of few-layer graphene exhibited well defined and distinct infrared absorption peaks associated with interband transitions. The positions of the peaks were found to obey a simple scaling relation with layer thickness. The principal features of the experimental spectra for all samples could be described consistently in terms of the electronic states of the parent graphite material through application of a specific zone-folding construct obtained when only nearest-layer interactions are considered. Both the experiment and analysis permit one to follow the convergence of the multilayer graphene response to that of graphene with increasing sample thickness.
10:36 AM  Y25.00014  Edge effects in Bilayer Graphene Nanoribbons1, MATHEUS P. LIMA, ADALBERTO FAZZIO, ANTONIO J. R. DA SILVA, Physics Institute - University of Sao Paulo — We investigate the geometrical and electronic structure of zigzag bilayer graphene nanoribbons (B-ZGNR), with widths that range from \( w = 0.6 \) to \( w = 4.5 \) nm. The layers are in the Bernal stacking, which means that there are two types of C atoms, those that are positioned above the center of the hexagons of the other layer, defining a B-sublattice, and those right on top of the C atoms of the other layer, forming an A-sublattice. When we cut the layer along the zigzag edge, there are two possible alignments, \( \alpha \), where the outermost edge atoms belong to the A-sublattice, and \( \beta \), where the outermost edge atoms belong to the B-sublattice. Thus, only the inter-layer edge interaction differs. We found that the \( \alpha \) alignment is energetically favorable, with an inter-layer edges attraction, whereas for the \( \beta \) there is an inter-layer edges repulsion. These edge-related forces cause a deviation from the exact Bernal stacking, resulting in a non-monotonic behavior of the energy gap with the width \( w \) for the \( \beta \)-B-ZGNR, with a maximum value at \( w \approx 3.5 \) nm. This is a consequence of the competition between bulk and strongly attractive edge interactions. All results were obtained using density functional theory calculations with the inclusion of parameterized van der Waals interactions.

1We acknowledge financial support from FAPESP and CNPq.

10:48 AM Y25.00015  Measuring a Butterfly with Graphene, ANDRES CONCHA, Johns Hopkins University — The Hofstadter butterfly (HB) is a hierarchical structure that emerges as a consequence of the commensuration of two length scales, the magnetic length \( l \sim \frac{1}{\sqrt{B}} \) and the lattice spacing \( a \) between atomic sites. We argue that by using a set of scalar potentials and an external magnetic field it is possible to measure and manipulate the HB in graphene. Our claim is based in the fact that in graphene, close to the Dirac point the theory becomes critical and as such no length scale is present in the low energy description. Thus the only relevant length scales are dictated by the magnetic length and the distance between potential barriers. It is shown that the Hall conductance in the minigaps should be directly measurable with current available technology.

Friday, March 20, 2009 8:00AM - 11:00AM – Session Y26 DCMP: Glassy and Amorphous Systems 328

8:00AM Y26.00001  Long Term Aging of As<sub>x</sub>Se<sub>1-x</sub> glasses and the Intermediate Phase<sup>1</sup>, PING CHEN, JACOB WACHTMAN, P. BOOLCHAND, University of Cincinnati — The reversibility window in As<sub>x</sub>Se<sub>1-x</sub> glasses was reported<sup>2</sup> 8 years ago to reside in the 28% < \( x \) < 37% range. We have re-examined those samples in modulated DSC and Raman scattering. Both the 8 year old hermetically sealed samples in Al holders (set A) and samples from the same batch preparation but stored in plastic vials (set B) at laboratory ambient environment were studied. The reversibility window in samples of set A, after 8 years of aging, is found to be intact. In set B, analysis of the T<sub>g</sub> endotherm becomes difficult because of a precursor exotherm that appears in the 32% < \( x \) < 60% range, and steadily increases with \( x \). In addition, in both set of samples, one observes a sub T<sub>g</sub> endotherm upon aging in the 90 °C < T < 120 °C range. These m-DSC results supported by Raman scattering suggest that the exotherm is due to light induced nanocrystallization (nc) of As<sub>x</sub>Se<sub>y</sub> fragments (an extrinsic effect), while the sub-T<sub>g</sub> feature is due to nc fragments of trigonal Se formed upon long term aging (an intrinsic effect). These findings will be compared to a recent report<sup>3</sup>.

1Supported by NSF grant DMR 04-56472.

8:12AM Y26.00002  Molecular structure of virgin and T<sub>g</sub> cycled (Ag<sub>2</sub>Se)<sub>x</sub> (AsSe)<sub>1-x</sub> bulk glasses<sup>1</sup>, JACOB WACHTMAN, PING CHEN, P. BOOLCHAND, University of Cincinnati — AsSe, the base glass (x = 0) in the titled ternary, is an interesting example of a chalcogenide that is partially de-mixed into As<sub>2</sub>Se<sub>4</sub> molecules segregated from a connected AsSe network, with the latter determining glasses and the Intermediate Phase. Raman scattering reveals sharp modes of the Realgar molecules that are superimposed on broad modes coming from the backbone. Upon T<sub>g</sub> cycling virgin samples (as quenched melts), the concentration of de-mixed As<sub>2</sub>Se<sub>4</sub> molecules decreases, suggesting that thermally induced polymerization occurs; molecules break up to form part of the connective tissue. Modulated DSC experiments reveal a broad exotherm near 140 °C in virgin samples, which becomes nearly extinct in T<sub>g</sub> cycled samples. The exotherm may represent Realgar molecules nano-crystallizing as the temperature approaches T<sub>g</sub>. Compositional trends in thermal parameters such as T<sub>g</sub>, ∆C<sub>p</sub>(x), and the ∆H<sub>nr</sub>(x) as a function of Ag<sub>2</sub>Se content ‘x’ of the glasses will be reported.

1This work was supported by NSF Grant DMR 04-56472.

8:24AM Y26.00003  Atomic Picture of the Intermediate Phase in Ge<sub>x</sub>Sel-<x> glasses: A Joint Theoretical and Experimental Study<sup>1</sup>, FAKHAR UL INAM, GANG CHEN, Ohio University, DENYAGO TAFEN, West Virginia University, DAVID DRABOLD, Ohio University — Raman and calorimetric studies on GeSe1-x glasses have provided evidence for the existence of the intermediate phase (IP) in chalcogenide and other glasses. Here, Ab-initio molecular dynamics (MD) based models of these glasses are discussed, and an atomistic picture of the IP, based upon the models and available experiments, is presented. A thorough analysis of our models reveals that the IP in GeSe1-x glasses appears due to the competition between the percolating GeSe2 phase and the a-Se phase, which gives rise to the “flattening” of the observables in the IP window. We present X-Ray Absorption Near Edge Structure (XANES) measurements on germanium selenide glasses in the IP composition range, and detect an electronic signature of the IP in terms of the shift of the XANES white line (WL) and non-linear behavior of their intensities in the IP window. We show that these models appear to properly represent the XANES results.

1We wish to strongly acknowledge Prof. P. Boolchand for providing the samples we employed in the XANES work. Grants and Supports from NSF and U. S. Department of Energy is gratefully acknowledged.

8:36AM Y26.00004  Boson modes and Floppy modes in network glasses<sup>1</sup>, D. NOVITA, PING CHEN, P. BOOLCHAND, University of Cincinnati — Network glasses differ from their crystalline counterparts in a significant way— the presence of an excess of low-frequency vibrations. Here we show that in a covalent (As<sub>2</sub>S<sub>1-x</sub> and in a super-ion(1) (Ag<sub>x</sub>I<sub>1-x</sub>) glass system, Raman Bose peak scattering strength (I<sub>B</sub>) displays commonalities; in the flexible phase of these systems, I<sub>B</sub> is found to increase almost linearly as networks become more flexible or their connectivity decreases. Moreover, the rate at which dI<sub>B</sub>/dr changes is reminiscent of the variation dI<sub>f</sub>/dr of the floppy mode count (f) with r in rigidity theory. These results suggest that at least in the flexible phase, contributions to the boson peak must result in large part from floppy modes.

8:48AM Y26.00005 Characterization of dry B$_2$O$_3$ glass$^1$, K. VIGNAROOBAN, D. NOVITA, PING CHEN, P. BOOLC-HAND, University of Cincinnati — A sample of Puratronic B$_2$O$_3$ (Aesar) was vacuum (10$^{-6}$ Torr) melted in a Pt crucible at 520°C for 3 days and slow cooled to room temperature to obtain a glass. All sample manipulations were performed in a N$_2$ gas purged glove box. $T_g$ of the sample from inflexion point of the reversing heat flow in an m-DSC experiment, using a scan rate of 3°C/min, gave a value of $T_g$ (mDSC) = 308(1)°C. A traditional DSC experiment, using a scan rate of 10°C/min, gave a value of $T_g$ (DSC) = 309(2)°C. Our $T_g$ (DSC) value is 12°C to 20°C higher than previous reports$^2$ using the same scan rate. Vibrational features in IR reflectance in the 1200-1600 cm$^{-1}$ range (LO and TO modes), and in the 3200-3600 cm$^{-1}$ range (free and bonded water) evolve as transparent platelets are exposed to laboratory environment, providing evidence for water reactivity of dry samples. Raman scattering results complement IR reflectance ones. We confirm$^2$ density of dry samples (1.805(4)gms/cm$^3$) to be somewhat less than wet ones (1.815(4) gms/cm$^3$).$^2$ Ramos et al. JNCS 221, 170 (1997).$^1$ F. Galeener et al, PRB 22, 3983 (1980).

9:00AM Y26.00006 Silicon under mechanical shear: molecular dynamics study, ALI KERRACHE, NORMAND MOUSSEAU, LAURENT J. LEWIS, Univ. of Montreal — Relaxation processes and defect behavior in amorphous silicon (a-Si) under shear are investigated by molecular dynamics simulations using the empirical Environment Dependent Inter-Atomic Potential. Shear deformations allow us to reproduce a vast range of interesting dynamics in disordered materials. For example, it has been shown recently that high-energy ion irradiation deforms plastically a-Si samples, following a pattern similar to the application of a shear. While large shear reproduce high-irradiation effects, moderate one can accelerate defect diffusion. A controlled application of shear can therefore help us to understand better the nature of defect diffusion in a-Si, in addition to generating new defects that could be placed with the appropriate external field at critical positions or even lead, in some cases, to crystallization of the a-Si. The properties of a-Si under shear are analyzed as a function of imposed shear velocity and as a function of the distance from the wall.

9:12AM Y26.00007 Liquid-liquid transition in supercooled silicon determined by first-principles simulation, P. GANESH, Geophysical Laboratory, Carnegie Institution of Washington, M. WIDOM, Department of Physics, Carnegie Mellon University — First principles molecular dynamics simulations reveal a liquid-liquid phase transition in supercooled elemental silicon. Two phases coexist below T$_c$ $\approx$ 1232K. The low density phase is nearly tetra-coordinated, with a pseudogap at the Fermi surface, while the high density phase is more highly coordinated and metallic in nature. The transition is observed through the formation of van der Waals loops in pressure-volume isotherms below T$_c$.

9:24AM Y26.00008 High thermal conductivity of a hydrogenated amorphous silicon film, J.L. FELDMAN, George Mason University, XIAO LIU, Naval Research Laboratory, D.G. CAHILL, University of Illinois, R.S. CRANDALL, National Renewable Energy Laboratory, NOAM BERNSTEIN, D.M. PHOTIADIS, M.I. MEHL, Naval Research Laboratory, D.A. PAPACONSTANTOPOULOS, George Mason University, HO-SOON YANG, Pusan National University, Korea — We measured the thermal conductivity $\kappa$ of an 80 nm thick hydrogenated amorphous silicon (a-Si:H) film from 80K to room temperature with the 3$\mu$m method and at room temperature with the time-domain thermoreflectance (TDTR) method. The a-Si:H sample with 1 at.% hydrogen was prepared by hot-wire chemical-vapor deposition (HWCDV), a procedure which was found previously to produce superior material properties with a near absent atomic tunneling states that are ubiquitous in glasses. We find that $\kappa$ is higher than any of the previous temperature dependent measurements, and shows a strong phonon mean free path dependence. We also performed numerical calculations on three 1000 atom models using Kubo theory and a tight binding electronic structure method. Due to the restrictions of the TDTR results on low frequency extrapolations of calculated phonon diffusivities, the Kubo thermal conductivity is seen to be too small to explain our experiments. We conclude that the HWCDV a-Si:H sample has superior structural ordering relative to any amorphous silicon previously studied.

9:36AM Y26.00009 Specific heat of amorphous materials outside of the universal regime: a-Si and a-Si:H, DANIEL QUEEN, University of California, Berkeley, QI WANG, RICHARD CRANDALL, National Renewable Energy Lab, FRANCES HELLMAN, University of California, Berkeley — We present specific heat measurements for a-Si and a-Si:H films that are known to lack the broad distribution of tunneling level systems (TLS) as measured by internal friction. Below 1K the TLS model describes the universal behavior seen in specific heat, thermal conductivity, and other measurements. However, this model does not address the universal high temperature features, namely, the plateau in $\kappa$ and peak in $\frac{C}{T}$ that occur around 10K. Tetrahedrally bonded systems, such as a-Si and a-Ge, have long been thought to lack TLS due to the over constrained nature of their bonding. These materials prove difficult to quench from a bulk melt but are routinely grown by vapor deposition. We use our MEMS nanocalorimeter for heat capacity measurements between 2-300K on a range of a-Si and a-Ge films prepared by e-beam evaporation and Hot-wire CVD. Changes in the high temperature specific heat will be discussed for films that are known to have orders of magnitude lower densities of TLS as measured by internal friction.

9:48AM Y26.00010 Hydrogen microstructure and voids in amorphous silicon hydride: A first principles study, RAJENDRA TIMILSINA, PARTHAPRATIM BISWAS, University of Southern Mississippi — We study distribution of hydrogen in amorphous silicon hydride configurations in several models of a-Si:H using first-principles density functional calculations. Motivated by recent experimental results via small angle $x$-ray scattering, which reveals the presence of large voids (of linear dimension up to 4 nm) in a-Si:H, we develop models for a range of concentration, and study the effect of voids on hydrogen distribution. In particular, we investigate the presence of voids in two different concentration regime: high (14 at. % and above) and low (below 14 at. %) following a recent experimental observation from infrared absorption spectroscopy. The bonding environment of H atoms, and the local electronic structure near the voids are also presented.

10:00AM Y26.00011 Atomistic modeling of amorphous silicon carbide: A first-principles study, PARTHAPRATIM BISWAS, University of Southern Mississippi, RAYMOND ATTA-FYNN, University of Texas, Arlington — Localized basis ab initio molecular dynamics techniques within density functional theoretic framework have been used to model a realistic atomistic configuration of amorphous silicon carbide (a-Si$_{1-x}$C$_x$)$_{3}$ containing 1000 atoms. The structural, electronic and vibrational properties have been studied and compared to existing theoretical models and available experimental data. Our study clearly reveals that the short-range chemical order in this material is predominant due to presence of heteronuclear Si-C bonds with coordination defect concentration less than 5% and the chemical disorder parameter was $\chi = 0.083$. Our 1000-atom model shows the presence of a clean gap in the spectrum and we also study the nature of the localization of the electronic band tail states as well as the vibrational eigenmodes.

10:12AM Y26.00012 ABSTRACT WITHDRAWN —
10:24AM Y26.00013 Glass Formability of Aqueous Solutions, and the Critical Nucleation Radius of Cubic Ice, Ryan Dunn, Matthew Warkentin, Robert Thorne, Cornell University — We have determined critical cooling rates and critical warming rates for a range of concentrations of different solutes in aqueous solutions using high-speed video microscopy. Our results show that the glass formability of aqueous solutions is exponential in the concentration for all solutes tested, with a different characteristic concentration for each solute. The characteristic concentration correlates with molecular radius. A simple modification of critical droplet theory relates the characteristic concentration to the critical nucleation radius in pure water, and explains the relationship between molecular radius and the characteristic. This simple, general theory of glass formability in aqueous solutions is important at a fundamental level, and will also have broad consequences for the field of cryobiology.

10:36AM Y26.00014 Nanocalorimetry as a means to explore thin films of vapor-deposited organic glasses, Kenneth L. Kearns, Department of Chemistry, University of Wisconsin-Madison, Heiko Huth, Mathias Ahrenberg, Christoph Schick, Institute of Physics, University of Rostock, M. D. Ediger, Department of Chemistry, University of Wisconsin-Madison — Vapor deposition was used to prepare nanometer thick films of small molecule organic glasses. Films of indomethacin (IMC) and 1,3,5-tris(naphthyl)benzene (TNB) with a range of stabilities and thicknesses were created and characterized using differential nanocalorimetry. The heat capacity-like calorimetric signal was lower for the stable vapor-deposited glass films at temperatures below the glass transition $T_g$ than for an ordinary glass prepared by cooling the liquid. A gradual increase in the calorimetric signal was observed during the isothermal transformation above $T_g$ from stable to ordinary glass with the fastest transformation taking place in about 200 $\tau_m$. The time for this transformation was dependent on film thickness with 350 nm thick films transforming approximately 5 times faster than 40 $\mu$m thick films. Aging experiments on the ordinary glass also showed a thickness dependence with thinner films aging more rapidly. This thickness dependent behavior is consistent with a mechanism where the dynamics at the film interfaces are faster than those in the bulk.

10:48AM Y26.00015 Evidence for a new molecular packing at low temperatures in vapor-deposited indomethacin, Kevin Dawson, Ken Kearns, Werner Steffen, Lian Yu, Mark Ediger — Thin films of the low molecular weight organic glass former indomethacin were prepared at different substrate temperatures using physical vapor deposition. When analyzed by wide angle x-ray scattering, samples prepared at $T_D$-50 K showed a broad high intensity peak that is not present in samples prepared at $T_D$. When such samples were annealed at $T_g$-4 K the extra peak eventually vanished but only after 24,000 s (more than 500 $\tau_m$). At low deposition rates the WAXS signature of this new molecular packing is only observed for substrate temperatures below $T_g$-20 K. Based on WAXS data on supercooled indomethacin, the new WAXS peak is unexpected. These results suggest that ordinary indomethacin glasses aged to equilibrium 20 K below the conventional $T_g$ would undergo a first order transition to a new amorphous phase.

Friday, March 20, 2009 8:00AM - 10:36AM
Session Y27 DCMP: Mechanical Properties of Nanomaterials

8:00AM Y27.00001 Carbon nanotube dispersed liquid crystal: A nano electromechanical system, Rajratan Basu, Germano Iannacchione, Worcester Polytechnic Institute — Electric field induced director orientation of a nematic liquid crystal (LC) + carbon nanotube (CNT) system reveals insights on switching behavior for this anisotropic composite. Once the field goes off, the LC+CNT system relaxes back to the original orientation through a mechanical rotation, revealing the intrinsic dynamics. LC molecules and CNTs cooperatively form local pseudonematic systems in the isotropic phase due to strong LC-CNT interactions. These field-responsive anisotropic domains do not relax back to the original orientation on switching of the field off, which could find potential applications in memory devices.

8:12AM Y27.00002 Strong “position squared” optical readout of a micromechanical oscillator, Jack Sankey, Andrew Jayich, Benjamin Zwickl, Cheng Yang, Jack Harris, Yale University — Optomechanical devices with a flexible Si membrane inside an optical cavity allow for very high optical finesse and high mechanical quality factor in a single device. They also provide fundamentally new functionality: the cavity detuning can have a quadratic dependence on the membrane position. This enables a measurement of “position squared” ($x^2$) and in principle a QND phonon number readout of the membrane. However, the readout achieved using a single cavity mode is not sensitive enough to observe quantum jumps between phonon Fock states. Here we demonstrate an $x^2$-sensitivity that is orders of magnitude stronger using two nearly-degenerate transverse cavity modes, and that we can tune this sensitivity somewhat by tilting the membrane. We derive a perturbative treatment that describes the interactions between the transverse optical modes and achieve good agreement with observation using realistic parameters. We also show that the $x^2$-coupling should be easily tunable over a wide range via nm-scale membrane displacements along the cavity axis.

8:24AM Y27.00003 In-situ Transduction of the In-Plane and Out-of-Plane Modes of Nanowire-based Very-High Frequency Electromechanical Resonators, Wayne Fung, Wei Lu, University of Michigan — Recent advances in nano-electromechanical systems (NEMS) promise important applications such as mass and force sensing, rf signal generation and timing, and quantum measurement studies. Chemically synthesized nanowires appear especially attractive for NEMS because of their atomically smooth surfaces and large aspect ratios. Here we report the measurements of doubly-clamped beam mechanical resonators using SnO$_2$ nanowires with widths ranging from 30 to 80 nm. The devices are electrostatically actuated and detected on-chip using a dual-gate setup and an all-electronic transduction scheme. This setup also allows us to independently actuate and tune the resonant frequencies of both the in-plane and out-of-plane modes of vibration in situ, potentially leading to NEMS-based practical applications. Our devices exhibit resonant frequencies ranging from 30 to 100 MHz, quality factors up to 2000, force sensitivities down to $10^{-14}$ N/Hz$^{1/2}$, and mass sensitivities down to $5 \times 10^{-17}$ g. The frequency of the in-plane and out-of-plane modes can be tuned within $\pm 1$ MHz of their nominal values at gate voltages of $\pm 5$ V.

8:36AM Y27.00004 ABSTRACT WITHDRAWN

8:48AM Y27.00005 Mechanical properties of metal-repaired defective carbon nanotubes, Guang-Ping Zheng, Hong Kong Polytechnic University, Kowloon, Hong Kong — Carbon nanotubes (CNTs) are promising in the production of strong and light structural materials because of their unique mechanical properties such as ultrahigh mechanical strength and large ultimate tensile strain. However, CNTs are not totally defect-free. Instead, several types of intrinsic defects exist, hence the mechanical strength and ductility of CNT can be significantly lower than those of an ideal one. In this study, 3D transition-metal atoms (Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, Zn) or clusters are filled into the defective sites of single-walled (SW) CNT containing vacancy defects, resulting in stable repaired SWCN. The mechanical and electronic properties of the repaired SWCNs are investigated by spin-polarized density functional theory. The results indicate that the 3D transition-metal atoms acting as substitutional defects can substantially modify the electronic structure and magnetization of an un-deformed CNT. Compared with defective SWCN, the metal-repaired CNT shows significant enhancements in mechanical strength and ductility that are close to or even better than those of pristine CNTs. The underlying physics of these behaviors are analyzed by the structural transformation, electronic structures and spin and charge distributions during the tensile tests. Strong magneto-mechanical coupling effect is found to be responsible for the enhanced mechanical behaviors of metal-CNT hybrid structures.
Mechanics of Nanometric Water Wire

Manhee Lee, Baekman Sung, Bongsu Kim, Jongwoo Kim, Wonho Jhe, Seoul National University — Water has been one of the perfect Newtonian viscous liquids, which are exactly described by Navier-Stokes equation. However, it has been found that the effective shear viscosity of water confined between mica crystals at few nanometer thickness is very different from the one of 3-dimensional bulk water. While some researchers have measured very high viscoelasticity of the confined liquid [1], the other researchers reported the fluidic nature of water confined between mica surfaces at <3.5 nm interfacial separation like bulk-water viscosity [2]. These conflicting results concerning the mechanical properties of nanometric water have been continually reported for the past several years. None of them clearly clarified the mechanical properties of nanometric water, and the detailed behavior of the viscoelasticity within a tip-sample separation less than 1 nm has not been measured. Here, we investigate a nanometric water cluster formed between AFM tip and sample surface and present the nano-mechanical properties of it including viscoelasticity, dissipation energy, and phase transitions. [1] Y. Zhu and S. Granick, Phys. Rev. Lett. 87, 096104 (2001). [2] U. Raviv, P. Laurat, and J. Klein, Nature (London) 413, 51 (2001).

Torsional Stick-Slip Behavior in WS₂ Nanotubes

K.S. Nagapriya, Ohad Goldbart, Ifat Kaplan-Ashiri, Weizmann Institute of Science, Rehovot 76100, Israel, GOTTTHARD SEIFERT, Technische Universität Dresden, D-01062 Dresden, Germany, RESHEF TENNE, ERNESTO JOSÉVICH, Weizmann Institute of Science, Rehovot 76100, Israel — We experimentally observed atomic-scale torsional stick-slip behavior in individual nanotubes of tungsten disulfide (WS₂). When an external torque is applied to a WS₂ nanotube, all its walls initially stick and twist together, until a critical torsion angle, at which the outer wall slips and twists around the inner walls, further undergoes a series of stick-slip torque oscillations. This is contrary to what happens in a multi-wall carbon nanotube, where an external torque causes the outer wall to slip and twist smoothly around the inner walls. We present a theoretical model based on DFTB calculations, which explains the torsional stick-slip behavior of WS₂ nanotubes in terms of the competition between the effects of the in-plane shear stiffness of the WS₂ walls and the inter-wall friction arising from the atomic corrugation of the interaction between adjacent WS₂ walls. K. S. Nagapriya, Ohad Goldbart, Ifat Kaplan-Ashiri, Gotthard Seifert, Reshef Tenne, and Ernesto Joselevich, Phys. Rev. Lett. 101, 195501 (2008).

Optical Requirements for Quantum Mechanics with Micromechanical Systems

Dustin Kleckner, Brian Pepper, Physics Department, University of California, Santa Barbara, Evan Jeffrey, Petro Sonin, Huylens Laboratory, Universiteit Leiden, DIRK BOUWMEESTER, Physics Department, University of California, Santa Barbara and Huygens Laboratory, Universiteit Leiden — Interest in micro-optomechanical systems is motivated by the desire to test quantum mechanics on relatively massive scales. Proposals for realizing these effects have extremely challenging technical requirements, particularly with regards to optical quality. We present the results of simulations designed to determine the effects of imperfections in real systems on the maximum achievable optical finesse. Additionally, we will discuss recent progress in our efforts to fabricate novel devices with the required properties.

High-performance supercapacitors, actuators and elastomeric composites based on CNT assemblies

Mikhail Kozlov, Jiyoung Oh, Minkyoon Shin, Raquel Robles, Maricio Lima, Ray Baughman, University of Texas at Dallas — A number of materials ranging from carbon nanotube (CNT) yarns, sheets and CNT-based composites to shape memory alloys (SMA) have been explored for the application in the area of energy conversion and storage. Highly porous sheets comprised of Single Walled Carbon Nanotubes and doped poly-pyrrole (SWNT-PPy) were found to possess remarkably high specific capacitance of about 131 F/g. CNT-elastomeric polymer composites exhibited electrical conductivity of about 0.5 S/cm and can be stretched by 1400%. We found that if powered electrically, the isometric stress generation capability of commercial ferroelectrics and is significantly larger than that of natural muscles. We also report several types of artificial muscles that convert the chemical energy of high-energy-density fuels to mechanical energy. Because of more than 30 times higher energy density obtainable for fuels like methanol, compared to that for the most advanced batteries, the major expected benefits are dramatic increase in energy conversion efficiency, work capacity, power performance.

Determination of Intrinsic Damping in a MWNT using the Harmonic Detection of Resonance Method

Doyl DickeL, Gayatri Keskar, Malcolm Skove, Apparao Rao, Clemson University, Department of Physics and Astronomy, Clemson University, Clemson, SC 29634 COLLABORATION, CENTER FOR OPTICAL MATERIALS SCIENCE AND ENGINEERING TECHNOLOGIES, CLEMSON UNIVERSITY COLLABORATION — Harmonic Detection of Resonance (HDR) method has been shown to be an effective method of electrically determining the resonant frequency of cantilevered structures at both the micro- and nanometer scale. Previously, HDR has been used effectively to study nonlinear behavior in highly anharmonic systems, as a gas sensor, and to determine the resonant frequency of a Macro scale Carbon Nanotube (MWNT). In addition, the HDR method has been used for determining the material properties such as the Young’s Modulus. Here, we provide a simple model describing the theory underlying the HDR method and a demonstration of its use in determine the resonant behavior of a MWNT. Finally, we report the effects of varying pressures on both the resonant frequency and quality factor of the MWNT. We also estimate the intrinsic damping inherent in the MWNT from these effects and show its correlation with defect density. The MWNT examined was found to have a resonant frequency for its primary mode of oscillation of 2.79 MHz with a quality factor of 10.15 at a pressure less than 1 Pa.

Eigenmodes and Vibration Spectra of Ag₂Ga Nanoneedles Measured Using Laser Doppler Vibrometry

R. Reifenberger, L. Biedermann, T. Tung, A. Ramam, Birck Nanotechnology Center, Purdue University, M. Yanzdanpanah, ElectroOptics Research Institute and Nanotechnology Center, U. of Louisville and Naugatucelles LLC, R. Cohn, ElectroOptics Research Institute and Nanotechnology Center, U. of Louisville — Applications for selectively grown Ag₂Ga nanoneedles include high-aspect ratio conductive AFM tips, mass sensors, force sensors, and high resonant frequency nano-cantilevers. To help enable these applications, reliable estimates for the elastic modulus of these nanoneedles and the quality factors of their oscillations are of interest. We have used Laser Doppler Vibrometry (LDV) to measure the vibration spectra and eigenmodes of individual Ag₂Ga nanoneedles. An advantage of this technique is that the vibration spectra between 0 and 20 MHz can be measured with high frequency resolution, allowing the eigenfrequencies and quality factors of each resonance to be accurately determined. Using Euler-Bernoulli beam theory, the elastic modulus and spring constant can be calculated from the nanoneedles’ eigenfrequencies and the dimensions of the nanoneedles. The techniques developed can be used to measure the vibrational spectra of any suspended nanowire with high frequency resolution.
10:24AM Y27.00013 Digital Batteries1, ALFRED HUBLER, University of Illinois at Urbana-Champaign — The energy density in conventional capacitors is limited by sparking. We present nano-capacitor arrays, where - like in laser diodes and quantum wells [1] - quantization prevents dielectric breakdown. We show that the energy density and the power/weight ratio are very high, possibly larger than in hydrogen [2]. Digital batteries are a potential clean energy source for cars, laptops, and mobile devices. The technology is related to flash drives. However, because of the high energy density, safety is a concern. Digital batteries can be easily and safely charged and discharged. In the discharged state they pose no danger. Even if a charged digital battery were to explode, it would produce no radioactive waste, no long-term radiation, and probably could be designed to produce no noxious chemicals. We discuss methodologies to prevent shorts and other measures to make digital batteries safe. [1] H. Higurashki, A. Toriumi, F. Yamaguchi, K. Kawamura, A. Hubler, Correlation Tunnel Device, U. S. Patent No. 5,679,961 (1997) [2] Alfred Hubler, http://server10.how-why.com/blog/

Friday, March 20, 2009 8:00AM - 11:00AM – Session Y28 FIAP: Nanotechnology I 330

8:00AM Y28.00001 Nanoscale Assembly of Actuating Cilia-Mimetic1, LANCE BAIRD, JENNIFER BREIDENICH, BRUCE LAND, ALLEN HAYES, JASON BENKOSKI, Johns Hopkins University Applied Physics Laboratory, PEI KENG, JEFFREY PYLUN, University of Arizona — The cilium is among the smallest mechanical actuators found in nature. We have taken inspiration from this design to create magnetic nanochains, measuring approximately 1-5 µm long and 25 nm in diameter. Fabricated from the self-assembly of cobalt nanoparticles, these flexible filaments actuate in an oscillating magnetic field. The cobalt nanoparticles were functionalized with a polystyrene/benzaldehyde surface coating, thus allowing the particles to form imine bonds with one another in the presence of a diamine terminated polyethylene glycol. These imine bonds effectively cross-linked the particles and held the nanochains together in the absence of a magnetic field. Using design of experiments (DOE) to efficiently screen the effects of cobalt nanoparticle concentration, crosslinker concentration, and surface chemistry, we determined that the morphology of the final structures could be explained primarily by physical interactions (i.e. magnetic forces) rather than chemistry.

1 Johns Hopkins University Applied Physics Laboratory Internal Research and Development

8:12AM Y28.00002 Amplification by 1/f noise with stochastic resonance in silicon-based nanomechanical resonators. , DIEGO N. GUERRA, TYLER DUNN, PRITIRAJ MOHANTY, Department of Physics, Boston University, 590 Commonwealth Avenue, Boston, MA 02215 — We report signal amplification by 1/f noise with stochastic resonance in a nanomechanical two-state system of a nonlinear silicon resonator. The addition of 1/f noise to a sub-threshold modulation signal enhances the likelihood of an electrostatically driven resonator switching between its two states in the hysteretic region. Considering the prevalence of 1/f noise in integrated circuits, signal enhancement demonstrated here, using a fully on-chip electronic actuation/detection scheme, suggests potentially beneficial use of the otherwise detrimental noise.

8:24AM Y28.00003 High Frequency Antennas for Wireless Transmissions of Audio and Video Signals Using Threads Spun From Long Multi-Wall Carbon Nanotubes. , DAVID MAST, CHAMINDA JAYASINGHE, MARK SCHULZ, VESSELIN SHANOV, University of Cincinnati — We have used threads spun from long multiwall carbon nanotubes (MWCNT) to make antennas for audio and video broadcasts (transmission and reception) at GHz frequencies. The MWCNT used to make the threads have outer diameters from about 6 nm to 30 nm. These MWCNT’s have been grown in lengths up to 18 mm. The diameter of the CNT threads used to fabricate the high frequency antennas was 25 microns. Initial measurements consist of 1) transmission and reception of a CW signals at f = 694 MHz and 1386MHz , 2) the transmission and detection of a CW signal plus sidebands at ± 100kHz, 3) the broadcast and reception of an AM modulated audio signal, 4) the broadcast and reception of composite video images, 5) the simultaneous broadcast and reception of audio signals from a single CNT antenna, and 6) the simultaneous transmission and/or reception at multiple frequencies from a single CNT thread antenna. The results of using the CNT thread antenna for these transmissions will be discussed.

8:36AM Y28.00004 Noise color and asymmetry in stochastic resonance with silicon nanomechanical resonators. , TYLER DUNN, DIEGO N. GUERRA, PRITIRAJ MOHANTY, Boston University Physics — Stochastic resonance (SR) with white noise has been well established as a potential signal amplification mechanism in nanomechanical two-state systems. While white noise represents the archetypal stimulus for SR, typical operating environments for nanomechanical devices often contain different classes of noise, particularly colored noise with a 1/f spectrum. As a result, improved understanding of the effects of noise color is necessary in maximizing device performance. Here, we report measurements of SR in a silicon nanomechanical resonator using 1/f noise and exponentially correlated Ornstein-Uhlenbeck noise. Power spectral densities and residence time distributions provide insight into asymmetry of the bistable amplitude states, and evidence suggests that 1/fα spectra with increasing noise exponent α may lead to increasing asymmetry in the system, reducing the achievable signal-to-noise ratio. Furthermore, we explore the effects of correlation time τ on SR with the use of exponentially correlated noise. We find monotonic suppression of the spectral amplification as the correlation time increases.

8:48AM Y28.00005 Room-Temperature Single-Electron Transistors fabricated using CMOS-compatible processes , VISHVA RAY, RAMKUMAR SUBRAMANIAN, PRADEEP BHADRACHALAM, SEONG JIN KOH, The University of Texas at Arlington — A critical requirement for the fabrication of single-electron devices is that the device components (Coulomb island, source, drain, and gate electrodes) be arranged with nanometer scale precision. We present a new single-electron device structure which consists of vertically stacked source and drain electrodes separated by a thin dielectric film. Using this configuration, we were able to control the gap between the electrodes with nanometer scale precision over an entire wafer, thereby allowing the concurrent fabrication of many device units in parallel processing. Coulomb islands (10 nm Au nanoparticles) were positioned in the gap between the source and the drain electrodes. Individually addressable gate electrodes were then incorporated in these devices, also in complete parallel processing. These devices have yielded clear single-electron transport characteristics (Coulomb blockade/staircase and Coulomb oscillations) at room temperature as well as at low temperatures (~10 K). The experimental data is in excellent agreement with the orthodox theory of single-electron tunneling. This study suggests that the fabrication of chip-level integrated systems of single-electron devices may now be possible using current CMOS fabrication technology. (ONR (N00014-05-1-0030), NSF CAREER (ECS-0449958), and THECB ARP (003656-0014-2006)).

9:00AM Y28.00006 Electronic-structure modulation transistor: A new switch with few kT supply voltage, HASSAN RAZA, School of Electrical and Computer Engineering, Cornell University, Ithaca NY, 14853, TEHSEEN RAZA, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907, TUO-HUNG HOU, Department of Electrical Engineering, National Chiao Tung University, Hsinchu, Taiwan 300, ROC., EDWIN KAN, School of Electrical and Computer Engineering, Cornell University, Ithaca NY, 14853. — We present a novel electronic-structure modulation transistor (EMT) for post-CMOS logic applications. The device is based on the electronic structure modulation of the channel by an external gate voltage. Its functionality is theoretically analyzed using single-band tight-binding model and non-equilibrium Green’s function formalism. We report that the EMT is expected to have very large ON/OFF current ratio with reasonable self gain using a few kT Vdd. We provide an experimental proof-of-concept device of the proposed mechanism in a double gated structure using a 20 nm long and 10 um wide channel consisting of Au nanocrystals (NCs) and nitride. Putting negative charge on the NCs is results in wavefunction extension over larger distance due to lifting of the energy levels, resulting in reduction of the effective barrier. In transfer characteristics, we find a non-linear dependence of the drain current on gate voltage and charge stored in the channel, which we attribute to the wavefunction modulation of the Au NCs due to charging.

9:12AM Y28.00007 The electronic structure of diodes probed under bias, PER-ANDERS GLANS, JINGHUA GUO. Advanced Light Source, Lawrence Berkeley National Laboratory, JEONG PARK, SOMORJAI GABOR, Materials Sciences Division, Lawrence Berkeley National Laboratory. — Chemists have known for decades that when metal nano-particles are affixed to a catalytically inactive oxide surface, the catalytic turnover rate of the array is more than 10 times that of a metal surface alone. However, the mechanism behind the effect is not clear. To understand the catalytic activity of the interface between the metal nano-structures and the oxide substrate, we have investigated the electronic structure of Pt and Pd doped diodes on a TiO2 substrate. The devices were put under bias during the measurements in an attempt to reproduce the potential differences found over the diode when used as a catalyst. This is challenging for electron based measuring techniques, but using photon-in, photon-out techniques we have successfully probed the electronic structure of Pt and Pd doped diodes under bias. The results from soft x-ray absorption and emission will be presented.

9:24AM Y28.00008 Spatial Wavefunction Switched Field-Effect Transistors (SWS-FETs): A Novel Device with Multiple States and Functionality, FAQUIR JAIN, EVAN HELLER, University of Connecticut. — An asymmetric coupled quantum well transport channel FET is shown to confine carriers in either the lower of the two wells, both wells, or upper well (adjacent to the gate insulator) depending on the gate voltage. That is, as the gate voltage is increased above threshold in n-channel FET, the electron wavefunction is spatially switched, which in turn change the operating characteristics. A Spatial Wavefunction Switched (SWS) FET, having two coupled wells in the channel, provides four states 00, 01, 10, 11 corresponding to wavefunction location. No wavefunction being the OFF (00 state), electrons in well W2 (01 state), in well W1 (10 state), and both Wells W1-W2 (11 state). Simulation has verified the spatial switching in SiGe as well as InGaAs coupled well FET structures. The wavefunctions/carrier locations get more pronounced and result in additional states when the transport channel is configured as a quantum dot (QD) channel. Preliminary simulation of quantum dot gate 3-state structures, configured as SWS-QD channel FET, will also be presented.

9:36AM Y28.00009 Ultrathin germanium-on-insulator tunneling field effect transistors, D. KAZAZIS, P. JANNTAY, A. ZASLAVSKY. Brown University, Div. of Engineering, Providence, RI 02912, C. LE ROYER, C. TABONE, L. CLAVELIER, CEA-LETI, Grenoble, France. — As the CMOS downscaling is approaching its limits, there is greater need for alternative and unconventional devices to continue enhancing the performance of electronics. We report on the fabrication and electrical characterization of a CMOS-compatible germanium-on-insulator (GeOI) tunneling field effect transistor (TFET) device that can in principle switch more sharply than a standard FET. The source-drain current in the TFET is based on interband tunneling between an inversion channel and a counterdoped drain electrode. Taking advantage of the narrower bandgap of germanium, the devices are fabricated in ultra-thin GeOI and consist of a heavily p-type doped, epitaxially grown drain, an n-type ion-implanted source and a standard high-k dielectric gate stack with channel lengths down to 400 nm. The devices exhibit a reasonable on-off current ratio of more than 10² and improved on current compared to silicon-on-insulator TFETs. Current-voltage measurements at room and low temperatures will be presented to characterize the behavior of the fabricated transistors.

9:48AM Y28.00010 Full Recovery of PFET NBTI and NFET PBTI of high-k metal gate MOSFETs with high temperature bake, ANASTASIOS KATSETOS, JAMES STATHIS, FERNANDO GUARIN. — High-k metal gate MOSFETs exhibit Bias Temperature Instability (BTI) degradation mechanisms. The p-channel Field Effect Transistor (PFET) has NBTI which results in threshold voltage (Vt) decrease and drive current (Ion) decrease when the gate is biased negatively with respect to the channel. The n-channel Field Effect Transistor (NFET) has PBTI which results in threshold voltage (Vt) increase and drive current (Ion) decrease when the gate is biased positively with respect to the channel. The amount of NBTI and PBTI is process dependent and depends on temperature, gate voltage, time and gate oxide thickness. PBTI has stronger dependence on voltage than NBTI and NBTI has stronger temperature dependence than PBTI. However, with a high temperature (370°C) bake, full recovery of both NBTI and PBTI is achieved and the devices behave like unstressed devices on repeated BTI stress.

2IBM T.J. Watson Research Center Yorktown Heights, NY 10598.

10:00AM Y28.00011 Band Structure Engineering of PtSi, ALEX SLEPKO, ALEXANDER A. DEMKOV. The University of Texas — PtSi is being considered as a contact material in field effect transistors. It has an additional advantage of having a low Shottky barrier to p-type Si. The relatively low conductivity of PtSi compared for example to pure Pt can be traced to the low density of states at the Fermi level. In this theoretical study we discuss a method to increase the conductivity of PtSi by manipulating the density of states through alloying. The scheme is based on substituting Pt atoms by Ti atoms to shift the Fermi level to a higher density of states region. We find identify a compound with the carrier concentration 2.7 times larger than that of bulk PtSi. We estimate the formation energies of the compounds and determine the solubility limit of Ti in PtSi at room temperature. We analyze the effect of doping with Ti on the work function for the (121) surface (the lowest energy surface orientation of PtSi). Moreover, we study possible schemes to lower the formation energies of the alloys by further doping with boron, carbon, gallium and aluminum. We identify a stable alloy in the case of aluminum doping. All calculations are done within the framework of density functional theory.

10:12AM Y28.00012 Ideal SiC Schottky Barrier Diodes Fabricated Using Refractory Metal Borides\textsuperscript{1}. TOM ODER, RANI KUMMARI, Youngstown State University — We present results of n-type 4H-SiC Schottky barrier diodes fabricated using several refractory metal boride Schottky contacts deposited on SiC held at various temperatures. From the electrical properties determined by current-voltage measurements, diodes with contacts deposited on SiC substrates held at 600 °C had average ideality factors in the range 1.04 – 1.09 and Schottky barrier heights of 1.02 eV – 1.14 eV; and these values remained unchanged after the diodes were annealed at 600 °C for 20 min. Diodes with contacts deposited on substrates held at 20 °C had much higher ideality factors which decreased only slightly after the annealing. The Rutherford backscattering spectroscopy spectra of these contacts revealed a systematic decrease in oxygen with increase in the deposition temperature. The improved electrical properties and thermal stability are attributed to the removal of oxygen from the boride/SiC interface during high temperature deposition.

10:24AM Y28.00013 ABSTRACT WITHDRAWN

10:36AM Y28.00014 Low dimensional density of states in atomic layer deposited Al\textsubscript{2}O\textsubscript{3}on In\textsubscript{0.53}Ga\textsubscript{0.47}As. HAN-CHIN CHIU, L.T. TUNG, Y.H. CHANG, Y.J. LEE, C.C. CHANG, M. HONG, Department of Materials Science and Engineering, National Tsing Hua University, Hsinchu, Taiwan, J. KWÓ, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan — Atomic-layer-deposited (ALD) Al\textsubscript{2}O\textsubscript{3} dielectrics on In\textsubscript{0.53}Ga\textsubscript{0.47}As with short air exposure between oxide and semiconductor deposition has been demonstrated nearly ideal capacitance-voltage (C – V) characteristics with negligible frequency dispersion at flat-band and accumulation. A relationship of surface potential versus gate voltage derived by the excellent quasi-static C – V curve shows high efficiency of 63% for Fermi-level movement near the mid-gap. A low mean interfacial density of states (D\textsubscript{it}) \approx 2.5x10\textsuperscript{11} cm\textsuperscript{−2}eV\textsuperscript{−1} was determined using the charge pumping method, which was also employed to probe the depth profile of bulk trap density (N\textsubscript{bt}) and the energy dependence of D\textsubscript{it} measured at 50kHz: a low N\textsubscript{bt} \approx 7x10\textsuperscript{19} cm\textsuperscript{−2} and D\textsubscript{it} of 2-4x10\textsuperscript{11} cm\textsuperscript{−2}eV\textsuperscript{−1} in the lower half of the band-gap and a higher D\textsubscript{it} of \approx 10\textsuperscript{12} cm\textsuperscript{−2}eV\textsuperscript{−1} in the upper half of the band-gap. The employment of charge pumping method has given a more accurate determination of D\textsubscript{it}, which is usually overestimated using other commonly methods such as Terman, conductance, and high-low frequencies, due to the influence of weak inversion at room temperature.

10:48AM Y28.00015 Palladium and Palladium-Carbon Nanotube Composite Nanomechanical Resonator, SUNGWAN CHO, YOUNGDUCK KIM, JUNGHOO BAK, JUHYUNG LEE, SEUNGRAN LEE, KOOKRIN CHAR, SEUNGHUN HONG, YUN DANIEL PARK, School of Physics and Astronomy, Seoul National University — For its bio-compatibility, conductivity and optical reflectivity, metallic thin films are an attractive choice to realize multifunctional micromechanical resonators. However, moderate elastic properties of metallic thin films are ill suited for high frequency applications. Meanwhile, Carbon nanotubes have shown great potential with superior electrical and mechanical properties. Combined Metal-CNT nanolaminates have increased strengths and are less susceptible to onset of mechanical nonlinearity compared to equivalent metal beams without CNT. With palladium’s good affinity to CNT to further study the role of the metal-CNT interface, we realized doubly clamped beam and torsional resonators from Palladium and Palladium/CNT composite. Resonance frequencies were detected using optical modulation technique with different wavelength at room temperature.

Session Y29 GMAG: Focus Session: Spin Liquids 333

8:00AM Y29.00001 Topological pairing of skyrmions and symmetry breaking in low-dimensional SU(N) antiferromagnets\textsuperscript{1}. ALEXEI KOLEZHUK, RWTH Aachen University — I study what happens to a so-called SU(N) antiferromagnet when the high SU(N) symmetry gets explicitly broken. Physically, such SU(N) antiferromagnets can be realized in cold atom systems in optical lattices (partially, the N=3 case corresponds to spin-1 bosons), and similar models might be possibly relevant for some magnetic materials like NiGa\textsubscript{S}\textsubscript{1}. I consider two perturbations breaking the SU(N) symmetry down to O(N) and SU(N-1), respectively, and study the phase diagram of the system. Breaking symmetry has a twofold effect: except favoring a certain type of order (spin-nematic or antiferromagnetic), it also affects the topological (Berry) phases. It is shown that the physically interesting case N=3 is very special: the effect of “topological pairing” of skyrmions leads to a change in the degeneracy of the disordered phase in case of SU(N) to O(N) perturbation, and the SU(N) to SU(N-1) perturbation brings the system into a critical phase.

\textsuperscript{1}Supported by the Heisenberg Program of DFG.

8:12AM Y29.00002 Cascade of quantum phase transitions in the spin-1/2 triangular-lattice antiferromagnet Cs\textsubscript{2}CuBr\textsubscript{4}\textsuperscript{1}. NATHANAELE FORTUNE, ADRIENNE WILSON-MUENCHOW, Smith College, SCOTT HANNAHS, National High Magnetic Field Laboratory, YASU TAKANO, University of Florida, YASUO YOSHIDA, University of Hamburg, TODD SHERLINE, Oak Ridge National Laboratory, TOSHIO ONO, HIKEAKU TANAKA, Tokyo Institute of Technology — In classical magnetic spin systems, geometric frustration leads to a large number of states of identical energy. We report here calorimetric and magnetocaloric evidence that in Cs\textsubscript{2}CuBr\textsubscript{4} — a geometrically frustrated Heisenberg S=1/2 triangular antiferromagnet — quantum fluctuations stabilize a series of gapped collinear spin states bounded by first-order transitions at simple increasing fractions of the saturation magnetization for fields directed along the c axis. Only the first of these quantum phase transitions has been theoretically predicted. We discuss how the higher fraction quantum states might arise and propose model spin arrangements. The Dzyaloshinskii-Moriya interaction breaks the symmetry when the magnetic field is directed along the triangular layers, providing one possible explanation for the directional dependence and the 1st order nature of the transitions.

\textsuperscript{1}Supported by awards from the Research Corporation, JSPS, Monakash and the NHMFL, funded by NSF and the State of Florida.
8:24AM Y29.00003 Dzyaloshinskii-Moriya interactions and non-magnetic impurities in the s=1/2 kagome antiferromagnet\textsuperscript{1}, IOANNIS ROUSOCHATZAKIS, SALVATORE MANMANA, Ecole Polytechnique Federale de Lausanne, Switzerland, ANDREAS LAEUCHLI, Max Planck Institut für Physik Komplexer Systeme, Dresden, Germany, BRUCE NORMAND, FREDERIC MILA, Ecole Polytechnique Federale de Lausanne, Switzerland — Motivated by recent NMR experiments\textsuperscript{1} on ZnCu$_2$(OH)$_6$Cl$_2$, we present an exact diagonalization study of the combined effect of non-magnetic impurities and Dzyaloshinskii-Moriya (DM) interactions in the s=1/2 Kagomé antiferromagnet. The magnetization response and the correlation matrix data reveal that the dimer freezing which occurs around the vacancy for D = 0 \[2,3\] (D is the magnitude of the DM vectors) persists up to D/J ≃ 0.07, above which a phase transition to the Q = 0 semiclusal 120° state\textsuperscript{4} takes place. Surprisingly however, the dimers next to the vacancy remain strong up to D/J = 2 – 3, i.e. well above the critical point. Implications for ZnCu$_2$(OH)$_6$Cl$_2$ will be discussed. 1. A. Olariu, et al., Phys. Rev. Lett. 100, 067202 (2008). 2. S. Dommange, et al., Phys. Rev. B 68, 224416 (2003). 3. A. Läuchli, et al., Phys. Rev. B 76, 144113 (2007). 4. O. Cépas, et al., Phys. Rev. 8:36AM Y29.00004 Neel ordering and the stability of the spin 1/2 kagome lattice antiferromagnet in Zn-Paratacamite, MICHAEL J. LAWLER, Binghamton University, Cornell University, ERIK S. SORENSEN, McMaster University, YONG BAEK KIM, University of Toronto — Zn-Paratacamite is a rare spin 1/2 antiferromagnetic insulator with an ideal kagome lattice structure in part of its phase diagram. As a function of Zn doping, this material undergoes a structural distortion which relieves the frustration and introduces magnetic order in the ground state, though the precise nature of the order is not clear at this point. In this talk, I will present strong evidence for Neel ordering in the distorted phase of Zn-Paratacamite through the application of quantum Monte-carlo and exact diagonalization methods to the appropriate Heisenberg model. These numerical results strongly support a recent Schwinger-boson mean field theory of Zn-Paratacamite. Furthermore, our results indicate a large basin of stability of the ideal kagome lattice ground state in the presence of this type of distortion. This suggests that the ideal kagome ground state may be stable towards weak doping-induced distortion, though further studies of local effects may be necessary to make a firm conclusion.

8:48AM Y29.00005 Magnetization steps on the spin liquid ground state of the S = 1/2 kagome-like antiferromagnet Cu$_3$V$_2$O$_7$(OH)$_2$2H$_2$O, HIROYUKI YOSHIDA, YOSHIHIKO OKAMOTO, TAKASHI TAYAMA, TOSHIRO SAKAKIBARA, MASASHI TOKUNAGA, AKIRA MATSUO, YASUO NARUMI, KOICHI KINDO, MAKOTO YOSHIDA, MASASHI TAKIGAWA, ZENJI HIRAI, ISSP, Univ. of Tokyo, VOLTBOURTHITE COLLABORATION — The ground state of the S = 1/2 kagome antiferromagnet (KAFM) is expected to be a spin liquid with a finite spin gap $\Delta \sim J/2$. Here, we report the magnetic properties of S = 1/2 KAFM Cu$_3$V$_2$O$_7$(OH)$_2$2H$_2$O studied by magnetization, specific heat and V NMR measurements. Neither magnetic long-range order nor a spin gap has been detected down to 60 mK, in spite of a large antiferromagnetic interaction $J = 86$ K, suggesting a gapless spin liquid. Surprisingly, we observed three step-like increases in magnetization at $H_{S1} = 4.3$, $H_{S2} = 25.5$, and $H_{S3} = 46$ T, which implies that there exist at least four kinds of spin liquid or other quantum state under magnetic fields.

9:00AM Y29.00006 $^{69,71}$Ga NMR Probe of the Spin Dynamics in the Rare-Earth Kagomé Pr$_6$Ga$_5$SiO$_{14}$, LLOYD LUMATA, Department of Physics and National High Magnetic Field Laboratory, Florida State University, K.-Y. CHOI, Department of Physics, Chung-ang University, Seoul, South Korea, T. BESARA, M. R. HOCH, H. D. ZHOU, J. S. BROOKS, P. L. KUHNS, A. P. REYES, N. S. DALAL, C. R. WIEBE, NHMF/FSU — We report $^{69,71}$Ga nuclear magnetic resonance investigation of the spin dynamics in the rare-earth kagomé system Pr$_6$Ga$_5$SiO$_{14}$. We find that the spin-lattice relaxation rate $T_1^{-1}/T_2$ exhibits a peak around 30 K, below which the Pr$^{3+}$ spin correlation time $\tau$ shows novel field-dependent behavior consistent with a field-dependent gap in the excitation spectrum. The spin-spin relaxation rate $T_1^{-1}/T_2$ exhibits a maximum at a lower temperature (10 K) below which field-dependent power-law behavior close to $T^{2\alpha}$ is observed. These results point to the interplay of single-ion anisotropy and field-induced formation of nanoscale magnetic clusters consistent with recent neutron scattering measurements.

This work was supported in part by NSF DMR-0602859 and performed at the National High Magnetic Field Laboratory, which is supported by NSF Cooperative Agreement No. DMR-0084173, EIEG grant, by the State of Florida, and by the DOE.

9:12AM Y29.00007 Ba$_3$Cr$_2$O$_6$, a new non-Cu based quantum s=1/2 spin singlet system, MAIKO KOFU, Univ. of Virginia — Field-induced condensation of magnons has been experimentally observed in several weakly coupled quantum (s = 1/2) dimer systems that are based on Cu$^{2+}$ ions, such as TlCuCl$_2$ and BaCuSi$_2$O$_6$, and it has been adequately described by the Bose-Einstein condensation (BEC) theory. However, the robustness of such descriptions can only be truly evaluated with investigation into complementary materials, in particular materials that are based on non-Cu$^{2+}$ ions. Recently, a spin dimer system, BaCr$_2$O$_6$ has been found, where Cr$^{3+}$ (s = 1/2) ion with the unusual 5+ electronic valence forms quantum dimers along the c-axis and a frustrating triangular lattice in the ab-plane. Using elastic and inelastic neutron scattering measurements on single crystals and a powder sample, we have characterized the magnetic interactions to show that Ba$_3$Cr$_2$O$_6$ is indeed an excellent model system of weakly coupled quantum dimers\textsuperscript{[1]}. We have also investigate the field-induced condensation of magnons in this compound, using specific heat, bulk magnetization, and elastic neutron scattering measurements under an external magnetic field. The experimental results and comparison will be discussed.\textsuperscript{5}\textsuperscript{*}This work is in collaboration with J.-H. Kim, S. Ji, S.-H. Lee (University of Virginia), H. Ueda, Y. Ueda (ISSP, University of Tokyo), H. Nojiri (IMR, Tohoku University), B. Lake, K. Rule (Heinholz Centre Berlin).

9:48AM Y29.00008 BEC of triplon in the complex quantum spin liquid BaCuSi$_2$O$_6$, RAIVO STERN, NICPB, Tallinn, Estonia, STEFFEN KRAEMER, MLADEN HORTVATIC, GHMF, Grenoble, France, IVO HEINMÄA, ENNO JOON, NICPB, Tallinn, Estonia, CLAUDE BERTHIER, GHMF, Grenoble, France, TSUYOSHI KIMURA, Osaka University, Japan, JOEL MESOT, PSI, Switzerland — We present a $^{63,65}$Cu and $^{29}$Si NMR study of the quasi-2D coupled spin 1/2 compound BaCuSi$_2$O$_6$ in the magnetic field range 13-26 T and at temperatures as low as 50 mK. NMR data and neutron scattering experiments in the gapped phase reveal that below 90 K different in-dimer exchange couplings and different gaps ($\Delta_B/\Delta_A = 1.16$) exist in every second plane along the c-axis, in addition to a planar incommensurate (IC) modulation. $^{29}$Si spectra in the field induced magnetic ordered phase reveal that close to the quantum critical point at $H_{ic} = 23.35$ T the average boson density $\pi$ of the Bose-Einstein condensate (BEC) is strongly modulated along the c-axis with a density ratio for every second plane $\pi_A/\pi_B \approx 5$. An IC modulation of the local density is also present in each plane.

10:00AM Y29.00009 High-Frequency EPR Studies of the Antiferromagnet Spin Dimer Compound \( \text{Ba}_3\text{Mn}_2\text{O}_8 \). CHANGHYUN KOO, STEPHEN HILL, Department of Physics, University of Florida, Gainesville, FL 32611; NHMFL and Department of Physics, FSU, Tallahassee, FL 32310. ERIC C. SAMULON, IAN R. FISHER, Geballe Laboratory for Advanced Materials and Department of Applied Physics, Stanford University, Stanford, CA 94305 — \( \text{Ba}_3\text{Mn}_2\text{O}_8 \) is a triangular lattice antiferromagnetic spin-dimer system based on pairs of spin \( S = 1 \) Mn\(^{2+} \) ions. In zero-field, \( \text{Ba}_3\text{Mn}_2\text{O}_8 \) possesses a singlet ground state. Meanwhile, application of a large magnetic field induces several ordered phases associated with the closing of gaps to the excited triplet and quintet states. Field orientation dependent high frequency electron paramagnetic resonance (HEPFR) measurements for a single crystal of \( \text{Ba}_3\text{Mn}_2\text{O}_8 \) have been carried out in fields up to 45 T using the hybrid magnet at the National High Magnetic Field Laboratory. Broad low-frequency transitions are observed in the field ranges close to \(-9 \) T to \(-32 \) T, suggesting inter-spin multiplet excitations. Sharper resonances are observed at higher frequencies, which persist to 42 T. Meanwhile, low-field studies provide information on the magnetic anisotropy of the system, which is of the easy-plane type with \( D = -0.375 \) K. We attempt to account for the observed HEPFR spectra in the context of a model recently developed to explain the magnetic properties of this compound [E. C. Samulon et al., Phys. Rev. B 77, 214441 (2008)].

10:12AM Y29.00010 \(^{135,137}\) Ba NMR study of condensed phase and critical behavior in \( S=1 \) spin dimer system \( \text{Ba}_3\text{Mn}_2\text{O}_8 \). STEVE SUH, W.G. CLARK, S.E. BROWN, UCLA, E.C. SAMULON, I.R. FISHER, Stanford, C.D. BATISTA, LANI, A.P. REYES, P. KUHNS, L.L. LUMATA, J.S. BROOKS, NHMFL — \( \text{Ba}_3\text{Mn}_2\text{O}_8 \) is a trigonal \( S = 1 \) spin dimer system, in which we have used \(^{135,137}\) Ba NMR spectroscopy and relaxation to study the static and dynamic properties of the field-induced phases and phase transitions to temperatures as low as 20mK, and with emphasis on magnetic fields up to 12T. Specifically, we report on the nature and variation of the order parameter in the condensed phases as well as the form of the spin lattice relaxation in the condensed phases, and compare to behavior anticipated for BEC and 3DXY universality classes. The temperature dependence of magnetization and the relaxation rate at the quantum critical point at \( H \sim 9T \) is also reported. For the case of the magnetization, a 3D to 2D crossover is evident, and shown consistent with calculations based on the magnon dispersion relations (M.B. Stone et. al, PRL 100, 237201 (2008)).

10:24AM Y29.00011 ABSTRACT WITHDRAWN —

10:36AM Y29.00012 The symmetry of the spin Hamiltonian in herbertsmithite, a spin-1/2 kagomé lattice. OREN OFER, AMIT KEREN, Physics Department, Technion, Israel Institute of Technology, Haifa 32000, Israel — We present magnetization measurements on oriented powder of \( \text{ZnCu}_2(\text{OH})_6\text{Cl}_2 \) along and perpendicular to the orienting field. We find a dramatic difference in the magnetization between the two directions. It is biggest at low measurement fields \( H \) or high temperatures. We show that the difference at high temperatures must emerge from Ising-like exchange anisotropy. This allows us to explain muon spin rotation data at \( T \rightarrow 0 \) in terms of an exotic ferromagnetic ground state.

10:48AM Y29.00013 Magnetic Excitations in the Stacked Quantum Magnets \( \text{NaNiO}_2 \) and \( \text{LiNiO}_2 \). J.P. CLANCY, B.D. GAULIN, J.P.C. RUFF, K.A. ROSS, G.J. VAN GASTEL, McMaster University, D.L. ABERNATHY, M.B. STONE, Oak Ridge National Laboratory — \( \text{NaNiO}_2 \) and \( \text{LiNiO}_2 \) are isostructural stacked triangular lattice quantum magnets, in which magnetism is conventionally thought to arise due to spin 1/2 moments carried by \( \text{Ni}^{3+} \) ions. Surprisingly, while \( \text{NaNiO}_2 \) undergoes a cooperative Jahn-Teller transition at 480K and magnetically orders below \( T_N \sim 23K \), \( \text{LiNiO}_2 \) undergoes a glass transition at \( T_g \sim 9K \) and remains disordered down to the lowest measured temperatures. The absence of long-range magnetic order in \( \text{LiNiO}_2 \) has been attributed to either geometric frustration caused by mixing of the Li and Ni sublattices, or orbital degeneracy due to the absence of a coherent Jahn-Teller distortion. We have performed time of flight neutron scattering measurements on polycrystalline samples of \( \text{NaNiO}_2 \) and \( \text{LiNiO}_2 \) using the wide Angular-Range Chopper Spectrometer (ARCS) at the SNS. Our measurements reveal previously unobserved magnetic excitations at relatively high energy transfers, which we associate with ferromagnetic spin waves mediated by in-plane interactions. We also find evidence of critical scattering in \( \text{NaNiO}_2 \) near the magnetic phase transition at \( T_N \). These results will be compared with previous measurements collected using the DCS at NIST.

Friday, March 20, 2009 8:00AM - 11:00AM — Session Y30 GMAG DMP: Focus Session: LAO/STO Interfaces 334

8:00AM Y30.00001 Coulomb Catastrophe and the Origin of the Sheet Carrier Density at the n-type LaAlO\(_3\)/SrTiO\(_3\) Interface: What do band calculations tell us?\(^1\). ZORAN POPOVIC, Institute for Nuclear Sciences, Belgrade, SASHI SATPATHY, University of Missouri, Columbia, RICHARD MARTIN, University of Illinois, Urbana — Transport measurements of the two-dimensional electron gas (2DEG) at the intrinsic n-type LaAlO\(_3\)/SrTiO\(_3\) interface have found a density of carriers much lower than expected from the “Coulomb catastrophe” arguments. From a detail density-functional study, we suggest how this discrepancy may be reconciled. We find that electrons occupy multiple subbands at the interface leading to a rich array of transport properties. Some electrons are confined to a single interfacial layer and susceptible to localization, while others with small masses and extended over several layers are expected to contribute to transport.

8:12AM Y30.00002 Quantum nature of two-dimensional electron gas confinement at LaAlO\(_3\)/SrTiO\(_3\) interfaces. KAROLINA JANICKA, Department of Physics and Astronomy, University of Nebraska Lincoln, JULIAN VELEV, Department of Physics, Institute for Functional Nanomaterials, University of Puerto Rico, EVGENY TSYMBAL, Department of Physics and Astronomy, University of Nebraska Lincoln — Replace this text with your abstract body. The discovery of highly conducting interface between two insulating oxides LaAlO\(_3\) and SrTiO\(_3\) has attracted significant interest due to possible applications in all-oxide electronic devices. The two-dimensional electron gas (2DEG) formed at LaAlO\(_3\)/SrTiO\(_3\) interfaces exhibits extremely high mobility and high density of carriers. Stimulated by this discovery we perform density functional calculations to understand the mechanism controlling the confinement width of the two-dimensional electron gas (2DEG) at LaAlO\(_3\)/SrTiO\(_3\) interfaces. We find that the 2DEG confinement can be explained by the formation of metal induced gap states (MIGS) in the band gap of SrTiO\(_3\). These states are formed as the result of quantum-mechanical tunneling of the charge created at the interface due to electronic reconstruction. The penetration depth of the MIGS into the insulator is controlled by the lowest-decay-rate evanescent states of SrTiO\(_3\), as determined by its complex band structure. Our calculations predict that the 2DEG is confined in SrTiO\(_3\) within about 1 nm at the interface.

8:24AM Y30.00003 ABSTRACT WITHDRAWN —

Characterization tools that resolve spatially the physical properties and also detect spatial tiny changes of stoichiometry at the interface/surface of complex conductive-tip atomic force microscopy [1], electron energy loss spectroscopy [2] or low-temperature high-magnetic field measurements [3, 4], to characterize oxides. To characterize crucial aspects of these 2DEG such as the spatial extension as well as carrier density profiles, sophisticated techniques are required.

Contact to the 2DEG is relatively easy in this geometry since the current does not have to pass through the high band gap LAO layer. We have obtained a 2-D carrier density of 2x10^14 electrons/cm^2 at room temperature along with a mobility of 10 cm^2/Vs.

This work was supported by the DOE BES at the F. Seitz Materials Research Laboratory at the University of Illinois, Urbana.

9:00AM Y30.00006 Electrostatic doping in oxide heterostructures[1], ALEXANDER A. DEMKOV, JAEEKWANG LEE, NA SAI, The University of Texas — Recent experiments on perovskite heterostructures grown by methods ranging from molecular beam epitaxy to pulsed laser deposition suggest the existence of two dimensional electron gas of high mobility at the oxide/oxide interface, and even a possibility of a superconducting state. Both p-type and n-type interfaces have been reported. However, the origin of charge in these insulating materials is still under debate. We report a first-principles study of several heterostructures where we employ the internal filed in a polar oxide LaAlO$_3$ to demonstrate the possibility of the electrostatic doping, an effect similar to a well known polar catastrophe in e.g., III-V semiconductors. We use density functional theory at the LDA+U level. We mainly focus on the electronic structure of the oxide/oxide junctions. The results of our calculations suggest that once the critical thickness of the aluminate layer is reached the internal electric field is sufficient to produce the electrostatic doping. We will discuss simple estimates for the temperature of the superconducting transition and the role of oxygen-related defects such as vacancies in the electronic structure and thermodynamic stability of these fascinating oxide structures.

9:12AM Y30.00007 Nanoscale analysis of high-mobility electron gases at SrTiO$_3$ interfaces and surfaces, GERVASI HERRANZ, Institut de Ciencia de Materials de Barcelona, ICMAB-CSIC, Bellaterra, Spain — Electronic reconstructions or defects localized next to an interface between two oxides may lead to dramatic modifications of their physical properties. One intriguing example of such phenomena is the formation of high-mobility two-dimensional electron gases (2DEG) at the interface between LaAlO$_3$ and SrTiO$_3$ (STO), two insulating dielectric perovskite oxides. To characterize crucial aspects of these 2DEG such as the spatial extension as well as carrier density profiles, sophisticated techniques are required. Here I explain how we used the synergetic combination of different advanced characterization tools including depth-resolved positron annihilation spectroscopy, conductive-tip atomic force microscopy [1], electron energy loss spectroscopy [2] or low-temperature high-magnetic field measurements [3, 4], to characterize with nanometric space resolution high-mobility electron gases at STO interfaces and surfaces. Our results emphasize the relevance of using interface/surface characterization tools that resolve spatially the physical properties and also detect spatial tiny changes of stoichiometry at the interface/surface of complex oxide structures.

9:48AM Y30.00008 Band offsets between SrTiO$_3$ and LaAlO$_3$, KRISTOPHER E. ANDERSEN, Northern Arizona University, C. STEPHEN HELLBERG, Naval Research Laboratory — Although separately SrTiO$_3$ and LaAlO$_3$ are both band insulators, together a highly mobile, quasi-2D electron gas can form at their interface. Several mechanisms have been proposed to produce this electron gas, including the electrostatic divergence within LaAlO$_3$. A critical property in understanding this divergence is the valence band offset between SrTiO$_3$ and LaAlO$_3$. However, because the electrostatic potential can diverge, it is not clear where the valence band offset should be defined; an issue that may affect experimental band offset measurements. In this talk, the band offsets between SrTiO$_3$ and LaAlO$_3$ are presented within the framework of density functional theory. Both the layer projected density of states and macroscopically averaged potential are used to find the valence band offset for thin films and multilayers.

10:00AM Y30.00009 Transport and band profiles of MBE grown LaAlO$_3$/SrTiO$_3$, YARON SEGAL, J.H. NGAI, J.W. REINER, F.J. WALKER, C.H. AHN, Department of Applied Physics and Center for Research on Interface Structures and Phenomena, Yale University — Previously reported properties of the LaAlO$_3$/SrTiO$_3$ system showed strong dependence on growth parameters. This makes it difficult to identify the key physical quantities. To isolate the role of oxygen content, we grew LaAlO$_3$ films on SrTiO$_3$ using MBE. The thermal evaporation of MBE minimizes potential damage to the substrate and interface. The samples were then annealed at low temperature for a prolonged time, thus raising the oxygen content without damaging the structural integrity of the film. Transport and X-ray photoemission measurements were performed before and after annealing on films grown on both terminations of the substrate. Transport measurements show the in-plane conductivity decreases by several orders of magnitude upon annealing. A dependence on film thickness appears in certain oxygen content regimes, where it can be interpreted as being controlled by oxygen diffusion. Photoemission measurements reveal an intriguing band structure in the LaAlO$_3$ film. The termination of the SrTiO$_3$ determines the direction of apparent band bending, for which we discuss possible models. Our results imply that while transport behavior of this system is dominated by oxygen diffusion, the atomic details of the interface have a substantial impact on band structure.
10:12AM Y30.00010 Resonant Anomalous Synchrotron X-Ray Studies of LaAlO$_3$ Films on SrTiO$_3$(001)\(^\dagger\), DILLON FONG, TIM FISTER, MARIE-INGRID RICHARD, STEPHAN HRUSZKIEWYCZ, JEFFREY EASTMAN, PAUL FUOSS, Argonne National Laboratory, SUNG SEOK SEO, HO NYUNG LEE, Oak Ridge National Laboratory, ARGONNE NATIONAL LABORATORY TEAM — The high conductivity present at the interface between LaAlO$_3$ and TiO$_2$-terminated SrTiO$_3$(001) has been attributed to an electronic reconstruction [1] or atomic intermixing [2], both induced by the polar discontinuity. LaAlO$_3$ films with thicknesses equal to or thinner than a critical thickness (three unit cells [3]), however, can maintain the interface dipole, and no reconstruction (electronic or atomic) is expected. In this study, we employ resonant anomalous x-ray scattering at the Ti K-edge to investigate the structure and properties of the LaAlO$_3$ films both above and below the critical thickness. For films thicker than the critical thickness, an interfacial layer is observed to form. The structure and chemical properties of the interfacial layer as determined by both resonant scattering and x-ray spectroscopy will be discussed.

10:24AM Y30.00011 Oxygen vacancy, charge doping, and polarization screening in LaAlO$_3$/SrTiO$_3$ interface\(^\dagger\), YUN LI, JAEJUN YU, Seoul National University — A high mobility electron gas has been observed in the n-type (TiO$_2$)/(LaO) interface between two insulators: non-polar SrTiO$_3$ (STO) and polar LaAlO$_3$ (LAO) and the mechanism of conductivity and dimensionality of electron gas at the interface have been intensively investigated in various experiments. There are two mechanisms suggested for the observed conductivity at the interface: electronic reconstruction and oxygen vacancy. We carried out density-functional-theory calculations to investigate the distribution of electron carriers for the n-type LAO/STO interfaces with and without oxygen vacancy. When no oxygen vacancy is present, the critical thickness of LAO film for conducting interface was found to be consistent with experiments. The induced carrier density at the interface without oxygen vacancy turns out to be an order of magnitude smaller than the one expected from the electronic reconstruction. This implies that the lattice polarization takes a significant role in charge screening. On the other hand, when oxygen vacancies are present, the vacancy-induced states are found to affect the carrier doping as well as the screening of polar electric field of LAO film. From the results, we propose that the upper limit of carrier doping should be 0.375 electrons per unit cell.

10:36AM Y30.00012 The effect of strain on the SrTiO3/LaAlO3 heterointerface. C. TYLER DIGGANS, KRISTOPHER E. ANDERSEN, Northern Arizona University, C. STEPHEN HELLBERG, Naval Research Laboratory — Recent experiments have shown that it is possible to form a highly mobile, quasi-2D electron gas at the interface between SrTiO$_3$ and LaAlO$_3$. Although the origin of this effect is still debated, there is growing consensus that under certain growth conditions (e.g. high oxygen pressures) it is caused by the diverging electric potential within LaAlO$_3$ -the so-called polar catastrophe. One aspect of this system that has not been previously considered is the electric polarization of SrTiO$_3$, which can be effectively tuned by strain. This polarization can partially or fully compensate the diverging LaAlO$_3$ potential, and must be considered if SrTiO$_3$/LaAlO$_3$ is to be grown on a substrate such as Si. In this talk, an electrostatic model is presented to show how the polar catastrophe is modified by polarization within strained SrTiO$_3$. This model is supported by first-principles calculations on strained SrTiO$_3$/LaAlO$_3$ multilayers of varying thickness.

10:48AM Y30.00013 Polarization effects and the source of electrons in two-dimensional electron gas at insulating oxide heterointerfaces. H.W. JANG, D.A. FELKER, C.M. FOLKMAN, D.L. PROFITT, S.H. BAEK, M.S. RZCHOWSKI, C.B. EOM, University of Wisconsin-Madison, K. JANICKA, Y. WANG, M.K. NIRANJAN, E.Y. TSYM, University of Nebraska-Lincoln — The discovery of a two-dimensional electron gas (2DEG) at the heterointerface between insulating perovskite oxides LaAlO$_3$ and SrTiO$_3$ has stimulated intensive theoretical and experimental studies on the origin of the 2DEG. Empirically, the electron density has been found to be strongly dependent on the oxygen partial pressure during growth and the thickness of the polar LaAlO$_3$ layer. Understanding and controlling the source of the electrons in 2DEGs at oxide heterointerfaces is important for the optimization of their performance. In this talk, we will discuss electrical properties of heterointerfaces between various polar perovskites and SrTiO$_3$ fabricated by pulsed laser ablation. The importance of built-in electric fields due to polarization-induced charges, bandgap energy, and oxygen vacancies in the polar layers is highlighted using a simple analysis based on electrostatics. The experimental Hall data are then compared with the theoretical result from first-principles calculations.

Friday, March 20, 2009 8:00AM - 11:00AM —
Session Y31 GMG: Focus Session: Neutron Scattering

8:00AM Y31.00001 Anomalous spin-waves in triangular lattice antiferromagnets\(^\dagger\), MIKE ZHITOMIRSKY, CEA, Grenoble, SASHA CHERNYSHCHEV, UC Irvine — The distinct features of spin-wave excitations in the triangular-lattice antiferromagnet are (i) a finite lifetime at zero temperature due to spontaneous two-magnon decays, (ii) strong renormalization of magnon energies \(\epsilon_k\) with respect to the harmonic result, and (iii) logarithmic singularities in the decay rate \(\Gamma_k\). Detailed quantitative results are obtained for the magnon spectrum of the spin-1/2 model using both the on-shell and off-shell solutions of the Dyson’s equation. In the low-energy limit magnons remain well-defined excitations but with anomalous decay rates. At high energies, magnons are heavily damped by decay rates reaching \((2\Gamma_k/\epsilon_k) \sim 0.3\). The on-shell solution shows logarithmic singularities in \(\Gamma_k\) with the concomitant jump-like discontinuities in \(\epsilon_k\) along certain contours in the momentum space. Such singularities are even more prominent in the magnon spectral function \(\Lambda(k,\omega)\). Although the off-shell solution removes such log-singularities, the decay rates remain strongly enhanced. We also discuss the role of higher-order corrections and show that such singularities may lead to incomplete disappearance of the spectrum in the vicinity of certain k-points. We conclude that magnon decays and singularities must be prominent in a wide class of noncollinear antiferromagnets.

8:12AM Y31.00002 Two Dimensional Correlations and Field Induced Order in the Pyrochlore Ferromagnet Yb$_2$Ti$_2$O$_7$, KATE ROSS, J.P.C. RUFF, B.D. GAULIN, McMaster University, C.P. ADAMS, St Francis Xavier University, J.S. GARDNER, NCNR, H.A. DABKOWSKA, McMaster University, Y. QIU, UMD / NCNR, J.R.D. COPLEY, NCNR — The rare earth pyrochlore magnets are of intense current interest due to their often unconventional magnetic behaviour. The pyrochlore lattice, which is occupied by the magnetic ions in such materials, is the 3D archetype for geometric frustration. We have studied the frustrated pyrochlore magnet, Yb$_2$Ti$_2$O$_7$, in single crystal form using time-of-flight neutron scattering. Our study confirms the presence of diffuse rods of scattering, which indicate unexpected 2D magnetic correlations in this cubic system. The diffuse scattering is measured both above and below a previously reported first order transition at \(T_c \approx 240\text{K}\). Although rod-like scattering persists below \(T_c\), three dimensional correlations develop, indicating a build-up of interplane correlations. Yet Yb$_2$Ti$_2$O$_7$ continues to resist long range order down to \(\sim 50\text{K}\). We have discovered, however, that the application of a small magnetic field along the [110] direction readily induces a long range ordered magnetic state, as evidenced by well defined spin wave excitations. We will present a magnetic phase diagram for Yb$_2$Ti$_2$O$_7$ based on the results of this study.

\(^\dagger\)Work supported by NSERC
Excitations within the field-induced ordered phases in Ba$_3$Mn$_2$O$_7$ lead to a quasi-two-dimensional behavior. We also present magnetic field-dependent neutron scattering measurements examining long range order and excitations within the field-induced ordered phases in Ba$_3$Mn$_2$O$_7$.

This state consists of coexisting short and long range orders[3], and that both orders can be destroyed by the application of modest magnetic fields to be selected either by unusual anisotropic interactions, or via thermal and/or quantum fluctuations in an example of order-by-disorder [1,2]. Recently, we have shown that this state consists of coexisting short and long range orders[3], and that both orders can be destroyed by the application of modest magnetic fields[3]. This disordering of the magnetic system involves a seemingly continuous quantum critical point at $\mu_0H_c \sim 1.6$ Tesla [3]. The properties of the induced quantum paramagnetic state, and the dependence of these properties on the direction of applied field will be discussed. I will also make comparisons with a recent theoretical treatment of Er$_2$Ti$_2$O$_7$[2].

2McClarty et al. arXiv:0810.2483v2

Spin waves and quantum criticality in the frustrated XY pyrochlore antiferromagnet Er$_2$Ti$_2$O$_7$ - Jacob Ruff, McMaster University - Geometrically frustrated magnetism in the three dimensional pyrochlore lattice often gives rise to unconventional magnetic states at low temperatures. The effective elimination of leading energetic terms via geometric cancellation allows weak perturbations to ultimately determine the behaviour of a magnetic material. In this talk, I will describe the manifold of low energy states in the antiferromagnetic XY pyrochlore Er$_2$Ti$_2$O$_7$, as measured by the time-of-flight neutron scattering technique. In zero applied magnetic field, the ground state is purported to be selected either by unusual anisotropic interactions, or via thermal and/or quantum fluctuations in an example of order-by-disorder [1,2]. Recently, we have shown that this state consists of coexisting short and long range orders[3], and that both orders can be destroyed by the application of modest magnetic fields [3]. This disordering of the magnetic system involves a seemingly continuous quantum critical point at $\mu_0H_c \sim 1.6$ Tesla [3]. The properties of the induced quantum paramagnetic state, and the dependence of these properties on the direction of applied field will be discussed. 2McClarty et al. arXiv:0810.2483v2

Recent neutron scattering results from Gd-based pyrochlore oxides - Jason Gardiner, Indiana University - In my presentation I will present recent results that have determined the spin-spin correlations in the geometrically frustrated magnets Gd$_2$Sm$_2$O$_7$ and Gd$_2$Ti$_2$O$_7$. This will include polarised neutron diffraction, inelastic neutron scattering and neutron spin echo data. One sample of particular interest is Gd$_2$Sm$_2$O$_7$ which is believed to be a good approximation to a Heisenberg antiferromagnet on a pyrochlore lattice with exchange and dipole-dipole interactions. Theoretically such a system is expected to enter long range ordered ground state known as the “Palmer Chalker” state [1]. We show conclusively, through neutron scattering data, that the system indeed enters an ordered state with the Palmer-Chalker spin configuration below $T_c = 1$ K [2-3]. Within this state we have also observed long range collective spin dynamics, spin waves. This work has been performed in collaboration with many research groups including G. Ehlers (SNS), R. Stewart (ISIS).

Electric Control of Spin Chirality in Multiferroic Ni$_3$V$_2$O$_8$ - Ivelisse Cabrera, Johns Hopkins University, Michel Kenzelmann, University of Neutron Scattering, ETH Zurich and Paul Scherrer Institute, Gavín Lawes, Wayne State University, OKSana Zaharko, Laboratory for Neutron Scattering, ETH Zurich and Paul Scherrer Institute, Collins Broholm, Johns Hopkins University — We discuss electric control of spin chirality in the magnetically frustrated multiferroic Ni$_3$V$_2$O$_8$ through polarized magnetic neutron diffraction. Cooling to the cycloidal magneto-electrostatic phase in an electric field $E$ causes the incommensurate Bragg reflections to become neutron spin polarizing, the sense of neutron polarization reversing with $E$. Comprehensive polarized neutron diffraction measurements establish the chiral nature of the long range ordered spin configuration and its response to $E$. Concomitant evolution of chiral and ferroelectric domains is observed by comparing polarized neutron diffraction data to pyroelectric current measurements and hysteresis under different poling conditions [1].

8:36AM Y31.00004 Spin waves and quantum criticality in the frustrated XY pyrochlore antiferromagnet Er$_2$Ti$_2$O$_7$ - Jacob Ruff, McMaster University - Geometrically frustrated magnetism in the three dimensional pyrochlore lattice often gives rise to unconventional magnetic states at low temperatures. The effective elimination of leading energetic terms via geometric cancellation allows weak perturbations to ultimately determine the behaviour of a magnetic material. In this talk, I will describe the manifold of low energy states in the antiferromagnetic XY pyrochlore Er$_2$Ti$_2$O$_7$, as measured by the time-of-flight neutron scattering technique. In zero applied magnetic field, the ground state is purported to be selected either by unusual anisotropic interactions, or via thermal and/or quantum fluctuations in an example of order-by-disorder [1,2]. Recently, we have shown that this state consists of coexisting short and long range orders[3], and that both orders can be destroyed by the application of modest magnetic fields [3]. This disordering of the magnetic system involves a seemingly continuous quantum critical point at $\mu_0H_c \sim 1.6$ Tesla [3]. The properties of the induced quantum paramagnetic state, and the dependence of these properties on the direction of applied field will be discussed. I will also make comparisons with a recent theoretical treatment of Er$_2$Ti$_2$O$_7$ [2].

8:24AM Y31.00003 Beyond Simple Bilayers in the Triangular Lattice Dimer compound Ba$_3$Mn$_2$O$_7$ - Matthew Stone, Mark Lumsden, Oak Ridge National Laboratory, Sung Chang, NIST, Eric Samulon, Stanford University, Cristian Bátísta, Los Alamos National Laboratory, Kirrily Rule, Bensec, Eric Ressoüche, Beatrice Grenier, Ill, Jan Fisher, Stanford University — We present single crystal inelastic neutron scattering measurements of the $S = 1$ dimerized quasi-two-dimensional antiferromagnet Ba$_3$Mn$_2$O$_7$. The singlet-triplet dispersion reveals nearest-neighbor and nextnearest-neighbor ferromagnetic interactions between adjacent bilayers that compete against each other. Although the interbilayer exchange is comparable to the intrabilayer exchange, this additional frustration reduces the effective coupling along the $c$ axis and leads to a quasi-two-dimensional behavior. We also present magnetic field-dependent neutron scattering measurements examining long range order and excitations within the field-induced ordered phases in Ba$_3$Mn$_2$O$_7$.

9:36AM Y31.00007 CEF groundstate of the frustrated quantum magnets SrRE$_2$O$_4$ (RE = Dy, Ho), A. Desilets-Benoit, A. D. Bianchi, Dep. de physique, Universite de Montreal, Montreal, QC, Canada, V. Pomsakushin, B. R. Hansen, LNS, PSI, Villigen, Switzerland, M. Kenzelmann, LDM, PSI, Villigen, Switzerland, R. J. Cava, Dept. Chemistry, Princeton University, Princeton, NJ, USA — We have measured the crystalline electric field (CEF) niveaus of the magnetic ions in the frustrated quantum magnets SrRE$_2$O$_4$ with RE = Dy and Ho by inelastic neutron scattering. SrRE$_2$O$_4$ crystallizes in a $pmn$ structure, which as four in-equivalent rare earth sites, leading to a large degree of geometrical frustration. Fitting a CEF level scheme to the experimental data has allowed us to determine the CEF ground state of this system.

9:48AM Y31.00008 Dynamics of excitations in a one-dimensional Bose liquid, Maxim Khodas, Brookhaven National Laboratory — The dynamical structure factor $S(q, \omega)$ of interacting 1D liquid is studied. This quantity has become experimentally accessible in the recent experiments on cold atoms and neutron scattering off spin chains. We find power law non-analyticities $S(q, \omega) \propto (\omega - \epsilon_{1,2}(q))^{-\mu(q)}$ at the kinematical thresholds characterized by the momentum dependent exponents evaluated in a broad range of parameters.

10:24AM Y31.00009 Magnetic properties of LuFe$_2$O$_4+y$, Fan Wang, Jungho Kim, University of Toronto, G Xu, S.M. Shapiro, G.D. Gu, Brookhaven National Laboratory, Y. Lee, Yonsei University, Y.-J. Kim, University of Toronto — LuFe$_2$O$_4+y$ (LFO) has been drawing much attention as a potential multiferroic compound. We show that the oxygen stoichiometry plays an important role in determining the magnetic properties of LFO. The sample with excess oxygen shows two magnetic transitions at 236K and 228K. The transition at 236K is a paramagnetic to ferrimagnetic transition, and below 228 K the system enters a spin glass phase. The DC magnetization shows strong time and history dependence, while the AC susceptibility exhibits dynamic scaling behaviour similar to that of canonical spin glass systems. This spin glass behaviour seems to disappear in the more stoichiometric sample. In this second sample, long range ferrimagnetic ordering has been observed with neutron scattering experiments. Our X-ray scattering on single crystal and X-ray powder diffraction experiments both show there is a structural change around 170K, which seems to be responsible for an observed low field anomaly. When a small magnetic field is applied, magnetization is only turned on during heating the sample. With large applied field, a metamagnetic transition was observed.
10:36AM Y31.00010 Phonon renormalization of the Néel transition in KCuF$_3$. J.C.T. LEE, S. YUAN, University of Illinois, Urbana-Champaign, A. RUSYDI, National University of Singapore, S. SMADICI, L. COOPER, E. FRADKIN, P. ABBAMONTE, University of Illinois, Urbana-Champaign — Critical magnetic fluctuations in the one-dimensional antiferromagnet KCuF$_3$, in the form of diffuse scattering around the magnetic (001) Bragg peak, have been studied with resonant soft x-ray scattering. Using x-rays near the Cu $L_3$ edge to exploit the $2p \rightarrow 3d$ dipole transition, the (001) was directly observed at temperatures ranging from 23K to above the transition temperature ($T_N \approx 43$K). Notably, the phase transition exhibits hysteresis, with $T_N$ sensitive to whether the sample was cooled or heated prior to measurement. This suggests that the phase transition is weakly first order, as might be expected by a transition renormalized by phonons. The temperature dependence of the coherence length and the diffuse scattering, as well as the role played by Jahn-Teller phonons in the transition are discussed.

10:48AM Y31.00011 The influence of magnetic field on Cu(tn)Cl$_2$ - two-dimensional quantum magnet with Néel ground state. A. ORENDACOVA, M. ORENDAC, L. SEDLAKOVA, A. FEHER, Centre Low Temp. Phys., P. J. Safarik Univ. and SAS, Kosice, Slovakia, K. SIEMENSMEYER, A. BUCHSTEINER, Helmholtz Zentrum Berlin, Germany, J. S. XIA, L. YIN, M.W. MEISEL, NMHFL and Dept. Phys., Univ. Florida — AC susceptibility and neutron elastic scattering experiments were performed on Cu(tn)Cl$_2$ [1] to explore the origin of a field induced anomaly previously observed in specific heat below 1 K and in finite fields up to 7 T [2]. Isothermal AC susceptibility scans, made down to 40 mK and in fields up to 10 T, confirmed and extended the B vs. T phase diagram obtained from the specific heat data. Neutron spectra of a polycrystalline sample studied down to 0.5 K in B = 0 and 4 T did not reveal any magnetic peaks expected below 1 K and indicated a slight change of (200) nuclear peak intensity induced by the magnetic field. The possible reasons of the absence of a phase transition to ordered state will be discussed. [1] V. Zelenak et al., Inorg. Chem. 45 (2006) 1774. [2] A. Orendacova et al., in preparation.

Friday, March 20, 2009 8:00AM - 10:36AM — Session Y32 GMAG DMP FIAP: Focus Session: Current-Induced Magnetic Switching 336

8:00AM Y32.00001 Effect of spin diffusion in the polarizer on current-induced magnetic switching. SCOTT BUTTON, SERGEI URAZHDIN, West Virginia University — Current-induced magnetic switching of a nanomagnet occurs due to the spin transfer torque exerted by current spin-polarized by another ferromagnet. Efficient switching is generally achieved by enhancing the polarizing properties of the latter. However, calculations show that switching is affected not only by the polarizing properties of the polarizer, but also by the electron diffusion in this layer [1,2]. To test the effects of spin diffusion in the polarizer on current-induced switching, we performed measurements of magnetic multilayer nanopillars with three different structures of the polarizing magnetic layer: a thick Co layer, a thin Co layer, and a bilayer consisting of a thin Co layer and a strongly spin-flipping FeMn alloy. In the pillars with a thick Co polarizer, the switching currents dramatically increase below 130 K, while the magnetoresistance exhibits a nonmonotonic dependence on temperature with a peak at 130 K. In contrast, the samples with a thin Co polarizer exhibit weak monotonic dependencies of switching and magnetoresistance on temperature. We discuss the implications of our results for our understanding of spin-dependent diffusion in magnetic multilayers. [1] A.A. Kovalev, A. Brataas, and G.E.W. Bauer, Phys. Rev. B 66, 224424 (2002). 8:12AM Y32.00002 Spin transfer torque switching of Co nanoparticles. HAN ZOU, Department of Physics and Astronomy University of Delaware, XIAOJUN WANG, YI JI, Department of Physics and Astronomy University of Delaware — Spin transfer torque effect has potential application in Magnetic Random Access Memory (MRAM) devices as a way to address the memory elements. Most spin transfer studies are based on patterned multilayer thin films with 100 nm lateral dimension. In this work, we demonstrate the feasibility of the spin transfer switching of a few cobalt nanoparticles with a diameter of < 5 nm at 4.2 K. The motivation arises from the prospect of device miniaturization and the capability to manipulate an individual magnetic nanoparticle. We use a multilayer thin film Co/100nm/Co/10nm/Co/3nm/Co/0.5nm/Au/2nm. The 0.5 nm Co layer is not continuous, and it consists of isolated Co particles formed due to surface tension. A mechanical point contact is formed on the multilayer film at 4.2K. By varying the size of the contact, the number of nanoparticles underneath a point contact can be controlled between ~5 and ~50. Hysteric loops in $dV/dI$ measurements clearly indicates spin-transfer switching. The $dV/dI$ curves are qualitatively different between point contacts involving only few particles (5-10) and those involving many particles (40-50).

8:24AM Y32.00003 Stochastic Resonance Driven by Spin Torque. XIAO CHENG, CARL BOONE, JIAN ZHU, ILYA KRIVOROTOV, University of California Irvine, UNIVERSITY OF CALIFORNIA IRVINE TEAM — Application of a microwave ac current to a spin valve gives rise to a rectified voltage due to magnetization dynamics driven by ac spin torque. We study the effect of dc current bias on these dynamics in spin valves with superparamagnetic free layers. We observe large enhancement of the rectified voltage (up to two orders of magnitude) along a line in the dc current - magnetic field phase diagram of the system. This enhancement arises from large-amplitude nonlinear dynamics of magnetization of the free layer induced by the combined action of ac and dc spin torques. For small out-of-plane external magnetic field, the enhanced rectified signal is observed at low frequencies (~1GHz) of the ac drive. This signal enhancement arises from adiabatic stochastic resonance of magnetization of the free layer driven by ac spin torque. For large out-of-plane magnetic field, the rectified signal enhancement is found at the ac drive frequencies of several GHz. We interpret this new type of large-amplitude high-frequency dynamics as non-adiabatic stochastic resonance of magnetization. Temperature-dependent measurements of the rectified signal confirm the stochastic resonance nature of the observed phenomena.
8:36AM Y32.00004 Reduction of spin-torque switching currents by partially canceling the free layer demagnetization field. LUQIAO LIU, TAKAHIRO MORIYAMA, DAN RALPH, ROBERT BUHRMAN, CORNELL UNIVERSITY TEAM — A small switching or excitation current is crucial for the successful application of spin torque (ST) in magnetic memory and on-chip oscillator devices. The required ST current for an in-plane-polarized nanomagnet is proportional to its effective field, within which the out-of-plane component (H_z) dominates. This large H_z, however, does not contribute to the thermal stability of the free layer. So it will be of great advantage if we can reduce H_z. Co/Ni multilayer structures have been shown to exhibit perpendicular anisotropy and we have precisely controlled the thickness of these multilayer components so that this crystalline anisotropy can be used to cancel the demagnetization field, reducing H_z to a value comparable to the in-plane geometry-dependent coercive field. In comparison to a control sample with a relatively higher H_z and the same magnetic volume, we find that the low H_z sample has much smaller ST reversal currents in both the quasi-state thermally activated and short pulse reversal regimes. The fact that the free layer magnetization lies in plane and the fixed layer(s) can be conventional magnetic material(s) makes it more tractable to deal with the dipole coupling between the free and reference layers, and should also facilitate the incorporation of this approach in high performance ST devices that utilize magnetic tunnel junctions.

8:48AM Y32.00005 Effects of rf current on critical field for magnetization reversal in spin torque devices. WENYU CHEN, SYLVIA FLOREZ, JORDAN KATINE, MATTHEW CAREY, LIESL FOLKS, BRUCE TERRIS, Hitachi Global Storage Technologies — Current induced switching assisted by rf current has recently been observed in spin torque devices at low temperature [1, 2]. This effect allows control of spin transfer induced magnetization reversal through the frequency of an injected rf current. In this study, the effects of the rf current injection on critical field for magnetization reversal in spin valve junctions have been investigated. Measurements were conducted at room temperature, and the magnetic field was applied along the easy axis of the junction. An rf current was injected into the nanojunction at various frequencies ranging between 1 and 20 GHz. The dynamic resistance, dV/dI, was measured as a function of the rf frequency, power and the dc bias current while ramping the magnetic field. The rf current injection was observed to change the critical field for free layer magnetization reversal when the intrinsic spin-transfer-induced dynamics is frequency-locked with the injected rf. The results will be discussed in the context of macrospin models of spin transfer in metallic spin valve structures. [1] S. H. Florez et al. Phys. Rev. B 78, 184403 (2008) [2] Y.-T. Cui et al. Phys. Rev. B 77, 214440 (2008)

9:00AM Y32.00006 A Three Terminal Approach to Spin-Torque Written MRAM Cells, PATRICK BRAGANCA, Cornell University/Hitachi Global Storage Technologies — Magnetic random access memory (MRAM) is a potentially superior alternative to silicon-based memories due to a combination of properties including non-volatility, fast read/write times, and low power consumption. Future MRAM technologies have been considered which use the spin transfer effect as a mechanism for bit element writing. Here, a spin polarized current passing through a ferromagnetic element is used to reverse its moment via an exchange of angular momentum, as opposed to the magnetic fields from remote write lines used in more conventional toggle MRAM [1]. However, the large current densities required for spin transfer reversal create significant barrier wearout issues in the magnetic tunnel junctions (MTJs) used as bit elements. One possible solution is to develop a nanopillar structure where a third electrode can be made to any point within a thin-film multilayer stack, substantially enhancing the versatility of the device by providing the means of applying independent electrical biases to two separate parts of the device. Using experimental results and micromagnetic simulations, I will discuss a joint magnetic spin valve/tunnel junction structure sharing a common free layer nanomagnet contacted by this third electrode [2]. A spatially nonuniform spin-polarized current flowing into the free layer via the low-resistance spin valve path can reverse the magnetic orientation of the free layer as a consequence of the spin torque effect, by nucleating a reversal domain at the spin injection site that propagates across the free layer. The free layer magnetic state can then be read out separately via the higher-resistance magnetic tunnel junction. This three-terminal structure provides a strategy for developing high performance spin-torque MRAM cells which avoids the need to apply a large voltage across a MTJ during the writing step, thereby enhancing device reliability, while retaining the benefits of a high-impedance MTJ for read-out.

9:36AM Y32.00007 Invariant Form of the Spin-Transfer Switching Condition, INTI SODEMANN, YAROSLAV BAZALY, Department of Physics and Astronomy, University of South Carolina, USA — Conventional spin-transfer (ST) device with one fixed and one free layer is considered in the macrospin approximation for the case of constant driving current. The expression for the critical current capable of pushing the free layer magnetization out of the local energy minimum is obtained in an invariant form. It is found that the relevant quantity is the divergence of the spin-transfer torque, and not the strength of the torque itself. This shows that there is no essential difference between current induced switching in collinear and non-collinear geometries. The result further provides a qualitative picture of the influence of ST torque angular dependence on the switching current and allows to understand when the Slonczewski spin polarization coefficient g(θ) can, or cannot be approximated by a constant. We discuss the implications of the derived formulas for the engineering of low current devices.

9:48AM Y32.00008 Exchange assisted spin transfer torque switching, XI CHEN, Physics Department, University of Minnesota, RANDALL VICTORA, Electrical Engineering Department, University of Minnesota — The main challenge in the application of spin transfer torque switching is the high current required to reverse the magnetization. We propose a composite structure containing soft and hard magnetic layers that significantly lowered the switching current. The dynamic phase diagram of the structure is studied using a macrospin model, with Landau-Lifshitz-Gilbert equation including a spin-torque term. It is shown that the anisotropy of the hard layer, by using multiple soft layers with graded anisotropy, a further reduction can be achieved. We also show that the switching current grows linearly with the damping constant in the soft layer. This means that a low damping, soft material can facilitate the reversal of the hard layer and reduce the switching current by over an order of magnitude.

10:00AM Y32.00009 Structural Characterization of Spin-Torque Oscillators, SARAH C. PARKS, K. LI, A. HAUSER, J. E. THOMPSON, J. CIRALDO, J. EMERICK, J. LUCY, F. Y. YANG, E. JOHNSTON-HALPERIN, Department of Physics, The Ohio State University — The discovery of current-induced magnetodynamics in giant magnetoresistive (GMR) trilayers promises a novel platform for microwave electronics. A key factor in determining the potential of this platform remains the development of nanoscale fabrication techniques, typically resulting in either nanopillar or point-contact geometries. As a result, a considerable technical barrier to further progress is the fidelity of current nanoscale patterning techniques. In an effort to address this challenge, we present the results of development efforts aimed at fabricating prototype point-contact spin torque oscillator (PC-STO) structures with a focused ion beam (FIB). The flexibility of FIB-based nanofabrication allows in situ cross sectional imaging of contact structure, and these results are correlated with DC magnetotransport. This fabrication approach enables the rapid generation of structures in arbitrary geometries, and in conjunction with cross-sectional imaging promises increased control of device to device variation and the development of novel PC-STO structures.

10:24AM Y32.00011 All Spin Digital Circuits, BEHTASH BEHIN-AEIN, Purdue University / NSF Network for Computational Nanotechnology (NCN), DEEPANJAN DATTA, Purdue University, SAYEEF SALAHUDDIN, UC Berkeley, SUPRIYO DATTA, Purdue University — Switching of a magnetic free layer using spin polarized current has been demonstrated in Magnetic Tunnel Junction (MTJ) devices. Currently MTJ's are being studied for memory and microwave oscillator applications. The purpose of this talk is to explore a modified MTJ where a clock pulse via the fixed layer facilities the switching of the free layer in accordance with a weak field provided by an input magnet in the form of a spin current. Based on the Landau-Lifshitz-Gilbert equation (LLG) augmented with spin torque functions, we show the switching energy and the switching time of the free layer which indicates the possibility of very low power digital logic applications. Ordinary digital circuits store information in the form of capacitor charges that communicate through electrical interconnects. The purpose of this paper is to show that modified MTJ's can be the basis for all spin digital circuits. Our primary objective is to stimulate proof of concept experiments that could usher in a whole new set of devices suitable for spintronic circuits.

Session Y33 DCMP: Nanowires and Quantum Dots 403

8:00AM Y33.00001 Digital Wires, BENNY BROWN, UC Davis, ALFRED HUBLER, UIUC — We study hardware implementations of cellular automata as reliable, adjustable, and secure commination lines. We discuss energy efficient digital wires on a nano-scale, all-optical digital wires, and digital wires as power lines and present performance data of a prototype digital wire, a six cells wide and ten cells long Boolean network. We show that digital wires have the following advantages: (i) Fixed pulse shape (pulses have a rectangular shape with a constant height and a constant width and produce no echos); (ii) Robust against electric smog. Digital wires based on semiconductor technology are effectively inert against electro-magnetic radiation, except for low-frequency radiation (heat) and high frequency radiation (X-rays). Digital wires based on plasma technology have in addition a very high tolerance for heat and X-rays. In digital wire the pulse speed can be rapidly adjusted. Signals on digital wires can be encrypted. Some digital wires can be used as general purpose computers. The data and the code are the input of the wire. Then both travel along the wire and ‘collide’. The collision is the computation. The result travels to the end of the wire, for further processing, as parallel input by a CPU, an actuator, or another digital wire.

8:12AM Y33.00002 ABSTRACT WITHDRAWN

8:24AM Y33.00003 Renormalization of the dephasing by zero point fluctuations, SWARNAJ BAN-DOPADHYAY, Physics Department, Norwegian University of Science and Technology, NO-7491, Trondheim, Norway, DORON COHEN, Department of Physics, Ben-Gurion University, Beer-Sheva 84105, Israel — One of the most fundamental properties of an quantum particle is to maintain its phase-coherence. When an quantum particle is coupled to a fluctuating environment its wave-function gets phase-randomised. During the last decade a controversy has emerged in the mesoscopic literature regarding the role of zero-point-fluctuations (ZPF) in low temperature dephasing. We propose an exactly solvable model for dephasing due to short range scattering with environmental modes in dephasing at low temperature. Unlike the Caldeira-Leggett model where the interaction is with an homogeneous fluctuating field of force, here we consider the environment consisting of infinitely many localized fluctuating modes with (say) Ohmic spectral function and the interaction is local as in ‘s-scattering’. We find that in low temperature ZPF can enhance the inelastic cross-section. Our study shows [Phys. Rev. B 77, 155438 (2008)] we need finite temperature to see the effect. Thus indirectly ZPF might contribute to the dephasing at low temperature.

8:36AM Y33.00004 Helical [110] gold nanowires make longer linear atomic chains, EDGARD AMORIM, EDISON DA SILVA, Unicamp — Experiments performed on nanowires (NWs) synthesized by electron beam irradiation technique have shown that gold NWs formed along the [110] direction become helical when the NWs are sufficiently thin [1]. Moreover, helical and other non-crystalline structures have been theoretically predicted to other few metals [2]. Our study using tight-binding molecular dynamics show that gold NWs formed along the [110] direction reconstuct upon stress to form helical structures. We discuss this formation and our results seem to indicate that an intrinsic mechanism is responsible for the formation of the helical structure. These helical NWs evolve on stretching to form linear atomic chains (LACs) and because they do not form symmetrical tips, the NWs produce longer LACs than other NWs. We use ab initio calculations to study the NW obtained from the tight-binding simulations at stages close to rupture and compare LAC distances obtained with both methods. Furthermore, we investigate the electronic structure of the NW close to rupture [3].

8:48AM Y33.00005 Hall effect detection of time-reversal symmetry breaking under AC driving, ALEXEI CHEPELIANSKII, SOPHIE GUERON, Univ. Paris-Sud, CNRS, UMR 8502, F-91405, Orsay, France, FREDERIC PIERRE, ANTONELLA CAVANNA, BERNARD ETIENNE, Laboratoire de Photonique et de Nanostructures (LPN)-CNRS, ro ute de Nozay, 91460 Marcoussis, France, HELENE BOUCHAT, Laboratoire de Physique des Solides, Universite Paris Sud, Orsay France, GROUPE DE PHYSIQUE MESOSCOPIQUE TEAM, LABORATOIRE DE PHOTONIQUE ET DE NANOSTRUCTURES COLLABORATION — In a four terminal sample microscopic time-reversibility leads to symmetry relations between resistance measurements where the role of current and voltage leads are exchanged. These reciprocity relations are a manifestation of general Onsager-Casimir symmetries in equilibrium systems. We investigate experimentally the validity of time-reversal symmetry in a GaAs/Ga1-xAlxAs Hall bar irradiated by an external AC field at zero magnetic fields. For inhomogeneous AC fields we find strong deviations from reciprocity relations and show that their origin can be understood from the the billiard model of a Hall junction. Under homogeneous irradiation the symmetry is more robust indicating that time-reversal symmetry is preserved.

9:00AM Y33.00006 On time-dependent counting statistics of mesoscopic electron transport, WOLFGANG BELZIG, University of Konstanz — Full counting statistics (FCS) has emerged as a key concept to understand quantum transport in mesoscopic systems like heterostructures, quantum wires, and quantum dots. The knowledge of the FCS not only enables to predict all measurable zero-frequency quantities accessible via charge detection, but also allows to identify the elementary transport events and the correlations between them. We demonstrate this concept for a standard quantum point contact between normal and/or superconducting leads under dc- and ac-bias. [M. Vanevic, Yu. V. Nazarov, W. Belzig, Phys. Rev. Lett. 99, 076601 (2007)] Finally we address the question, how these concepts can be applied to time-resolved current measurements. [A. Bednorz and W. Belzig, Phys. Rev. Lett. 101, 206803 (2008)]
Friday, March 20, 2009 8:00AM - 11:00AM –
Session Y34 DCMP: Superconducting Devices and Applications 404

8:00AM Y34.00001 Designing electron refrigerators for improved cooling with an expanded thermal model. GALEN O’NEIL, ERIK LARSON, CU Boulder/NIST Boulder, JOEL ULLOM, NIST Boulder — Normal-metal/insulator/superconductor (NIS) tunnel junctions can act as refrigerators below 1K. Biasing the junction such that only thermally excited electrons have energy higher than the superconducting gap causes selective tunneling which cools the normal metal electrode. Because of their small size, low mass, and absence of moving parts, NIS refrigerators are an attractive cooling technology for space and industrial applications. We have demonstrated temperature reductions of 100mK from bath temperatures near 300mK. For example, we operated a superconducting x-ray detector at 160mK with a cryostat bath temperature of 260mK by using NIS junctions for the additional cooling. We will show a more complete thermal model of a large area NIS refrigerator accounting for quasiparticle injection, diffusion, and imperfect trapping. Using this model to guide NIS refrigerator design we expect to achieve our goal of cooling from 300mK to 100mK.

8:12AM Y34.00002 ABSTRACT WITHDRAWN –

8:24AM Y34.00003 Nanomechanical parametric amplification and oscillation via electrostatic coupling to Cooper-pair box. JUNHO SUH, MATT LAHAYE, Caltech, PIERRE ECHTERNACH, Jet Propulsion Laboratory, KEITH SCHWAB, Cornell University, MICHAEL ROUKES, Caltech — Nanomechanical resonator coupled to a Cooper-pair box exhibits frequency modulation as a function of the gate voltage when the qubit is adiabatically tuned. We utilize this effect to demonstrate mechanical degenerate parametric amplification and oscillation. Gain above 30dB and self-oscillation is observed. This technique could provide an efficient way to enhance the force sensitivity in the measurement of coupled dynamics of nanomechanical resonator modes and a solid state qubit.

8:36AM Y34.00004 Back-action and self-oscillation in the Double Pump Josephson Parametric Amplifier (DPA) , ARCHANA KAMAL, ADAM MARBLESTONE, MICHEL H. DEVORET, Yale University — Josephson Parametric amplifiers are the most promising candidates for reaching the quantum limit of amplification at RF frequencies. The DPA employs 2 pumps. The dual pumps ensure separation between the signal and the pump frequencies, which is necessary to observe delicate effects, such as self-oscillations. We present the model of the DPA. Our calculations are based on Input-Output Theory, and can easily be generalized to any coupled system involving parametric interactions. We analyze the operation of the device, taking into account the feedback introduced by the reaction of the signal amplification on the pump power and we compute various response functions - signal/idler gain, internal gain, and steady state signal response. To account for this back-action between signal and pump, we adopt a mean-field approach and self-consistently explore the boundary between amplification and self-oscillation. The potential of the DPA for quantum-limited measurements and as a squeezer is also discussed.

8:48AM Y34.00005 Detection and Reset Dynamics of Superconducting Nanowire Single Photon Detectors1, ANTHONY ANNUNZIATA, Yale University, ORLANDO QUARANTA, University of Salerno, DANIEL SANTAVICCA, JOEL CHUDOW, LUIGI FRUNZIO, Yale University, AVIAD FRYDMAN, Bar Ilan University, MICHAEL ROKOS, Yale University and IBM Research, DANIEL PROBER, Yale University — We investigate the single photon detection and reset mechanisms in superconducting nanowires, which have received recent, widespread attention for use in applications requiring fast optical and near infrared photon counting. These devices are fabricated from ultra-thin Nb and NbN films and read out by measuring short (~1 ns) transient voltage spikes that result from the localized suppression of superconductivity by an absorbed photon. We find that intrinsic electro-thermal instabilities necessitate a low impedance (<50 ohms) readout circuit for stable resetting to the superconducting state after detecting a photon. The actual impedance needed depends on the detailed physical properties of the device. We also investigate the detection mechanism and report the dependence of detection efficiency on the temperature and dc bias current as well as on film disorder, from which we present a model of the detection mechanism.

9:00AM Y34.00006 Measurements of a YBCO superconducting quantum interference filter with planar ion-damaged Josephson junctions1, STEVEN M. ANTON, SHANE A. CYBART, STEPHEN M. WU, JOHN CLARKE, R.C. DYNES, University of California, Berkeley — We have fabricated a two dimensional series-parallel array of 565 × 28 YBa2Cu3O7−δ thin film ion damage Josephson junctions. The loop areas were varied incommensurately from 28.5 to 90 µm2 so that the response of the current-biased array to an applied magnetic field is a prominent peak in voltage centered at zero field. We measured voltage versus applied magnetic field characteristics for several static bias currents at different temperatures. Additionally, we measured current-voltage (I-V) characteristics of the array with no applied magnetic field at several temperatures. To fit the I-V characteristics, we assumed that each parallel section of the array could be modeled as a single resistively shunted junction with critical currents following a normal distribution. Fitting the summed voltage contributions of the parallel sections to measurements of the array, we computed the resistance and critical current mean and spread. The standard deviation of these critical currents was 15 percent at 74 K.

9:12AM Y34.00007 Cryogenic Broadband Impedance-Matched Absorptive Microwave Filters . DANIEL SLICHTER, OFER NAAMAN, IRFAN SIDIQI, Quantum Nanoelectronics Lab, UC Berkeley — We report Johnson noise and S parameter measurements of a broadband impedance-matched low pass microwave filter consisting of a section of lossy stripline transmission line. The thermal noise power generated by the filter was measured in the frequency band of 1.2 GHz - 1.8 GHz at temperatures from 30 mK to 300 mK. The noise power was comparable to that of a 50Ω reference load held at the same temperature and measured with the same microwave measurement chain using a cryogenic mechanical switch. Transmission measurements on a filter with f_dB = 1.3 GHz show that the filter’s cutoff characteristics remain essentially unchanged between room temperature and 20 mK. The filters are robust to thermal cycling and are simple to manufacture. We have used these filters to obtain low Cooper pair temperatures in high-bandwidth microwave measurements on superconducting devices.
bilayers by treating the Al surface with an atomic nitrogen beam. Under optimum nitridation conditions the resultant analytical scanning transmission electron microscopy (STEM) with electron energy-loss spectroscopy (EELS) to investigate thin AlN layers formed on Nb/Al ultra-thin aluminum nitride (AlN) barrier layers can result in Josephson Junctions (JJ’s) with both very high critical current densities and low sub-gap leakage.

Josephson tunnel junctions have long been used as sensitive magnetic flux detectors. NanoSQUIDs, which use submicron weak link junctions for enhanced flux coupling, are attractive candidates for magnetic measurements of molecules. We present a novel method for nanoSQUID readout which involves embedding the SQUID in a superconducting transmission line cavity operating at microwave frequency. The magnetic flux dependence of the total SQUID inductance modulates the cavity resonant frequency; these frequency changes are determined using microwave reflectometry. This dispersive microwave measurement allows detection of changes in magnetic flux at submicrosecond timescales without creating dissipation in the vicinity of the molecule. Moreover, we can exploit the Josephson nonlinearity of the nanoSQUID for bifurcation amplification to enhance sensitivity. Optimization of the nanoSQUID design and cavity parameters for maximizing detector sensitivity and bandwidth is discussed. We also discuss the various sources of noise in this measurement scheme and how to minimize their impact. This work is supported by AFOSR and USDOE.

10:00AM Y34.00011 Single-artificial-atom lasing using a voltage-biased superconducting charge qubit, ROBERT JOHANSSON, RIKEN, SAHEL ASHHAB, RIKEN, University of Michigan, ALEXANDRE ZAGOSKIN, Loughborough University, FRANCO NORI, RIKEN, University of Michigan — We consider a system composed of a single artificial atom coupled to a cavity mode. The artificial atom is biased such that the most dominant relaxation process in the system takes the atom from its ground state to its excited state, thus ensuring population inversion. Even under this condition lasing cannot be suppressed if the relaxation rate is larger than a certain threshold value. Using simple transition-rate arguments and a semiclassical calculation, we derive analytic expressions for the lasing suppression condition and the state of the cavity in both the lasing and suppressed-lasing regimes. The results of numerical calculations agree very well with the analytically derived results. Our analysis and results are relevant to the recently realized superconducting artificial-atom laser. [arXiv:0803.1209]

10:12AM Y34.00012 A scanning SQUID microscope for imaging high-frequency magnetic fields, C. P. VLACHACOS, CNAM, Department of Electrical and Computer Engineering, University of Maryland College Park and the Laboratory of Physical Sciences, F. C. WELLSTOOD, Center for Nanophysics and Advanced Materials and Joint Quantum Institute, Physics Department, University of Maryland College Park, J. MATHIEWS, Physical Optics Corporation — We have developed a large-bandwidth scanning SQUID microscope in order to spatially image high frequency magnetic fields. By using a hysteric Nc-dc-SQUID and a pulsed sampling technique, rather than a non-hysteretic SQUID and a flux-locked loop, we have overcome the bandwidth limitations of existing scanning SQUID microscopes, which typically only image below about 1 MHz. The microscope allows for non-contact time-varying magnetic field images to be taken of room temperature samples with time steps down to 50 ps and spatial resolution ultimately limited by the size of the SQUID to about 10 μm. Towards this end, results will be presented on the design, development, and operation of a cryo-cooled 4.2 K scanning SQUID microscope with a bandwidth of dc to 3 GHz and a sensitivity of about 52.4 nT per sample.

10:24AM Y34.00013 The Josephson Microwave Photomultiplier1, BRENDAN OSBERG, JAY GAMBITTA, FRANK WILHELM, Institute for quantum computing — The current lack of single microwave photon counters as opposed to microwave amplifiers has become a problematic omission in the toolkit of available circuit QED devices. Hence, we propose a microwave photo-multiplier based on a modified phase qubit. Such a system, trapped in the metastable state, can be activated over its potential energy barrier by an incoming photon, creating an avalanche effect analogous to current photo-diodes. Linear coupling of the junction flux with the radiation field, in the weak damping regime, permits photodetection from an arbitrary quantum source in the GHz range. We model this device theoretically and investigate its sensitivity, bandwidth, efficiency, and dark-count rate using the Langevin stochastic differential equations and a path integral approach.

10:36AM Y34.00014 Transport Properties of a Hybrid SET-SQUID Device in Tunable Dissipative Environment, SHUCHAO MENG, JEFFREY QUILLIAM, CHAS MUGFORD, Department of Physics and Astronomy and Institute for Quantum Computing, University of Waterloo, Waterloo, ON, N2L 3G1, ANDY SACHRAJDA, Institute for Microstructural Sciences, NRC, 1200 Montreal Road, Ottawa, ON, K1A 0R6, JAN KYCIA, Department of Physics and Astronomy and Institute for Quantum Computing, University of Waterloo, Waterloo, ON, N2L 3G1 — We will present measurements of transport properties of a new type of superconducting device, designed to allow a fully adjustable Hamiltonian with charge term, Josephson coupling term, and dissipation term. This device consists of a superconducting Single Electron Transistor (SET) and two Superconducting Quantum Interference Devices (SQUIDs). A 2D electron gas embedded 90nm below the substrate surface provides a tunable dissipative environment. A small magnetic field can be applied to drive this hybrid device from the strong Josephson coupling regime to the SET regime. Dissipation and temperature dependence of the switching current out of the zero-voltage state show different characteristics for different settings of competition between Josephson coupling and charging energy.
and Vortex Dynamics 405

superconducting phase diagram (Tc, Hc2) on Ba(Fe1−xCox)2As2 single crystals. The upper critical field anisotropy diminishes with temperature and has an unusual temperature dependence, (ii) Hc2(T = 0) for this compound may easily approach fields of 75 tesla. 1

Session Y35 DMP: Focus Session: Iron Pnictides and Other Novel Superconductors XVI: Hc2 and Vortex Dynamics 405

8:00AM Y35.0001 Fluorine Doping Effect On Hc2 and Rh In LaFeAsO1−xFx . Y. KOHAMA, S. RIGGS, F. BALAKIREV, M. JAIME, Los Alamos National Laboratory, Y. KAMIHARA, T. ATAKE, M. HIRANO, H. HOSONO, Tokyo Institute of Technology — The iron arsenide superconductors discovered earlier this year have attracted much interest, and some families showing high-Tc have been identified. LaFeAsO (La: lanthanide) is the first copper-free family of compounds with Tc exceeding 50 K. Here, we present the first systematic study of Hc2 and Rh in the wide fluorine doping region (LaFeAsO1−xFx , x = 0, 0.25, 0.05, 0.07, 0.11 and 0.14). We found that Hc2 increases monotonically with decreasing x, while the superconducting phase diagram (Tc, x) displays the classic dome-shaped structure. Furthermore, the shape of Hc2(T) depends strongly on x. This, according to Gurevich’s model, suggests a multiband electronic structure. The Hall resistivity for non-superconducting samples x = 0, 0.025 show a non-linear magnetic field dependence, which also supports a multiband electronic structure interpretation. In addition, the estimated low-field limit of the Hc2 for x = 0, 0.025 detect a gap opening at the structural transition and magnetic transition. The evidence for multiband electronic structure links these materials to the famous multiband superconductor MgB2 rather than high-Tc cuprates.

8:12AM Y35.0002 Upper critical fields of NdFeAsO1.8F0.2 single crystal1. J. JAROSZYNSKI, F. HUNTE, L. BALICAS, YOUN-JUNG JO, IVANA RÀCEVIC, A. GUREVICH, D.C. LARBALESTIER, F.F. BALAKIREV, NHMFL, L. FANG, P. CHENG, Y. JIA, H.H. WEN, NLS CAS — We present measurements of the resistivity and the upper critical field Hc2 of NdFeAs O1.8F0.2 single crystals in strong DC and pulsed magnetic fields up to 45 T and 60 T, respectively. We found that the field scale of Hc2 is comparable to ~ 100 T of high Tc cuprates. Hc2(T) parallel to the c-axis exhibits a pronounced upward curvature similar to what was extracted from earlier measurements on polycrystalline samples. Thus this behavior is indeed an intrinsic feature of oxypnictides, rather than manifestation of vortex lattice melting or granularity. The orientational dependence of Hc2 shows deviations from the one-band Ginzburg-Landau scaling. The mass anisotropy decreases as T decreases, from 9.2 at 44 K to 5 at 34 K. We discuss to what extent different pairing scenarios can manifest themselves in the observed behavior of Hc2, using the two-band model of superconductivity. The results indicate the importance of paramagnetic effects on Hc2(T), which may significantly reduce Hc2(0) as compared to Hc2(0) ~ 200 – 300 T based on extrapolations of Hc2(T) near Tc down to low temperatures.

8:36AM Y35.0004 Thermodynamic estimation of the upper critical field slope of doped Sm-FeAsO from fluctuation conductivity in the critical regime . MARINA PUTTI, ILARIA PALLECCHI, CARLO FANCIULLI, MATTEO TROEPANO, MAURIZIO FERRETTI, ALBERTO MARTINELLI, ANDREA PALENZONA, CARLO VERDEGHINI, CNR-INFM-LAMIA and University of Genova, Via Dodecaneso 33, 16146 Genova, Italy — We measure magnetotransport in SmFeAs(O1−xFx)2 polycrystalline samples up to 28 T and we extract the upper critical fields, using different criteria. Due to fluctuation effects, not negligible magnetoresistance and resistivity not saturating to a residual value at Tc, Hc2 values turn out to be strongly criterion-dependent. In order to circumvent this problem, we propose a thermodynamic estimation of the upper critical field slope dHc2/dT based on the analysis of conductivity fluctuations in the critical regime at high fields. Indeed, in this regime we find evidence of a two-dimensional lowest Landau level (LLL) scaling for applied fields larger than μ0H baff ∼ 8T, which allows to extract a high field slope as large as -12T/K for the optimally doped sample SmFeAsO(O0.55K0.45)2. A comparison of the fluctuation behavior with that of high-Tc cuprates indicates that this Hc2,LLL value may be related to the Hc2 and κ values higher than those of cuprates.

8:48AM Y35.0005 Upper critical field in Ba(Fe1−xCo1−x)2As2 and FeSe1−yTe1−y compounds. CHIARA TARANTINI, JAN JAROSZYNSKI, JIANYI JIANG, ALEX GUREVICH, DAVID C. LARBALESTIER, National High Magnetic Field Laboratory, Florida State University, Tallahassee, FL 32310, USA, RONGYIN JIN, ATHENA S. SEFAT, MICHAEL A. MCGUIRE, BRIAN C. SALES, DAVID G. MANDRUS, Materials Science & Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — We report Hc2 measurements in high magnetic field up to 31 T on Ba(Fe1−xCo1−x)2As2 and FeSe1−yTe1−y pnictide compounds for different doping levels. Both materials exhibit a very high upper critical fields and unconventional temperature dependences of Hc2(T) with the extremely high slopes dHc2/dT from 10 to 30 T/K near Tc and a relatively low anisotropy: γ = Hc2(Tc) / Hc2(T) for the doped ternary compound and γ ≈ 1.1 ± 1.2 for the binary one. The observed temperature dependences of Hc2(T) and the high Hc2 values well above the BCS paramagnetic limit indicate the importance of the Zeeman pairbreaking effects in these compounds.
9:00AM Y35.00006 Thermodynamic Determination of the Upper Critical Field and Anisotropy of Ba$_{1.0}$K$_{0.4}$Fe$_2$As$_2$ Single Crystals

WAI-K. KWOK, ULRICH WELP, RUOBING XIE, ALEXEI KOSHELEV, JOHN SCHLUETER, JIONG HUA, Institute of Physics, Chinese Academy of Sciences, Beijing, China — We present anisotropic heat capacity measurements of the upper critical field of Ba$_{0.6}$K$_{0.4}$Fe$_2$As$_2$ single crystals in fields up to 8 Tesla. In zero-magnetic field a clear step in the heat capacity is observed at $T_c \sim 36K$. Using an entropy conserving construction we determined the transition temperatures in applied fields and the upper critical field slopes $dH_c^2(0)/dT = -6.5 \text{T/K}$ and $dH_c^2(4.5)/dT = -17.4 \text{T/K}$, the latter showing record high critical field slope near $T_c$.

9:12AM Y35.00007 Inter- and intra-granular current properties of iron pnictide superconductors

AKIYASU YAMAMOTO, ANATOLII POLYANSKII, JIANYI JIANG, FUMITAKE KAMETANI, MARINA PUTTI, CHIARA TANGANTINI, FRANK HUNTE, JAN JAROSZYNSKI, ERIC HELLSTROM, ALEX GUREVICH, DAVID LARBALESTIER, National High Magnetic Field Laboratory — The iron pnictide superconductors have very high upper critical field $B_c(0)$ of possibly over 100 T for 1111 and 50-70 T for 122. We have recently shown [1,2] that polycrystalline 1111 samples exhibit electromagnetic granular behavior, perhaps in an analogous way to that seen now to be intrinsic to the HTS cuprates. Detailed investigation is proceeding in parallel with serious efforts to make more single phase samples, since it appears that all present polycrystalline oxypnictides are multi-phase. In particular we are using magneto-optical imaging to study the local variation of current density and then performing detailed microstructural analysis by SEM, TEM and orientation analysis to understand intergranular current flow. At the present time we see that samples are multi-phase, often with a grain boundary wetting phase, but even so the global $J_c$ attains 1000-4000 A/cm$^2$, some 10-40 times that seen in single phase YBCO randomly polycrystalline Nb-Ti. On the other hand, very high intra-grain critical current owing to the strong pinning of Nb-Ti is observed in the Co doped Ba122 pnictide. We will report on our latest results on the inter- and intra-granular current properties in the high-$T_c$ pnictides. [1] A. Yamamoto et al., Appl. Phys. Lett. 92, 252501 (2008). [2] A. Yamamoto et al., Supercond. Sci. Technol. 21, 095008 (2008).

9:24AM Y35.00008 Magneto-optical imaging of flux distribution in single crystal Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ of various doping level $x$.

ERICK C. BLOMBERG, Ames laboratory and Department of Physics & Astronomy, Iowa State University, P. PROMMAPAN, M. A. TANATAR, V. C. KOGAN, N. NI, S. L. BUD’KO, P. C. CANFIELD, R. PROZOROV — Near optimal doping of Ba(Fe$_{0.93}$Co$_{0.07}$)$_2$As$_2$ crystals measured the uniform superconductivity and vortex properties similar to high-$T_c$ cuprates.[1] In this contribution, single crystals of Ba(Fe$_{1-x}$Co$_x$)$_2$As$_2$ with the measured doping level $x=3.8\%$, 4.7\%, 5.8\%, 7.4\%, 10\%, and 11.8\%, covering all regimes - from underdoped to overdoped were studied using real-time magneto-optical imaging. Inhomogeneity of the superconducting state as well as field and temperature dependencies of the magnetic induction distribution were analyzed. Superconductivity is homogeneous at all except for the highest doping level. The results are correlated with macroscopic transport and magnetic measurements.

9:36AM Y35.00009 ABSTRACT WITHDRAWN

9:48AM Y35.00010 Similarity Between Fe-based Pnictide Superconductors and High-$T_c$ Cuprates Revealed by the Irreversible Magnetic Behavior in the Vortex State

RUSLAN PROZOROV, M.A. TANATAR, C. MARTIN, R.T. GORDON, E.C. BLOMBERG, P. PROMMAPAN, V.G. KOGAN, N. NI, M.E. TILLMAN, S.L. BUD’KO, P.C. CANFIELD, Ames Laboratory and Department of Physics & Astronomy, Iowa State University — Static and dynamic measurements of DC magnetization and direct real-time magneto-optical imaging have revealed unconventional vortex behavior in NdFeAsO$_{x}$Fe$_2$O$_{1-x}$ and Ba(Fe$_{0.93}$Co$_{0.07}$)$_2$As$_2$ single crystals with superconducting transition temperature at 24 K. With detailed understanding of the flux pinning mechanism in the iron-based superconducting materials. Static and dynamic behavior of vortices are investigated by transport, bulk magnetization, and quantitative magneto-optical imaging techniques, while high resolution analytical TEM is used to investigate the structural inhomogeneity down to atomic level. Frequent flux jump, and enhanced flux pinning at elevated magnetic field, corresponding to the “fish tail” in magnetization hysteresis, are often observed. We will discuss the relationship between the flux pinning behavior and structural detailed properties in this and other related superconducting materials.

10:00AM Y35.00011 Flux Pinning and Structural Inhomogeneity in Superconducting BaFe$_{1.8}$Co$_{0.2}$As$_2$ Single Crystals

QIANG LI, JUAN ZHOU, Brookhaven National Lab, JIUFENG TU, City College of New York, YUHANG REN, Hunter College, CUNY, LINJUN LI, YONGKANG LUO, HANG CHEN, GUANZHANG CAO, ZHU’AN XU, Zhe Jiang University — We report coordinated studies of flux pinning behavior and structural inhomogeneity in BaFe$_{1.8}$Co$_{0.2}$As$_2$ single crystals with superconducting transition temperature at 24 K, in order to understand the flux pinning mechanism in the iron-based superconducting materials. Static and dynamic behavior of vortices are investigated by transport, bulk magnetization, and quantitative magneto-optical imaging techniques, while high resolution analytical TEM is used to investigate the structural inhomogeneity down to atomic level. Frequent flux jump, and enhanced flux pinning at elevated magnetic field, corresponding to the “fish tail” in magnetization hysteresis, are often observed. We will discuss the relationship between the flux pinning behavior and detailed structural properties in this and other related superconducting materials.

10:12AM Y35.00012 Thermally-activated and temperature-independent magnetic relaxation in aligned grains of NdFeAsO(F)

JAMES R. THOMPSON, Dept. of Physics, University of Tennessee and Oak Ridge National Laboratory, Y. L. ZUEV, D. K. CHRISTEN, E. D. SPECHT, R. JIN, B.C. SALES, M. A. MCGUIRE, A. SEFAT, D. G. MANDRUS, Oak Ridge National Laboratory — We have studied flux creep in a magnetically-aligned powder of NdFeAsOF and found it to be strikingly similar to the situation in cuprates. The magnetic relaxation rate $S = \ln M(t)/\ln t$ is linear in temperature at low temperatures. There is an extrapolated finite creep rate of about $S = 0.02$ at $T = 0$, indicative of a quantum tunneling of vortices under energy barriers. This quantum creep rate is field-independent. From the temperature-dependent creep data we have obtained activation energy as a function of persistent current density, $U(J)$. Comparison with existing creep theories will be made.

---

on-going torque magnetometry measurements are expected to check the validity of this interpretation. We developed and used a scheme that allows for the calculation of the essential transport parameters, such as the trap DOS, in an unambiguous controlled conditions. This was done by temperature-dependent gated four-terminal measurements on pentacene thin-film transistors prior to and after controlled oxygen exposure. We studied the influence of oxygen on the electronic trap states in a pentacene thin film kept under highly controlled conditions. These results demonstrate the possibility of dynamic field-guided patterning of molecule-on-metal systems. We also showed that applied electric fields can be employed to enhance or retard the diffusivity of FePc molecules which the arrangement of active molecules is fixed or can be controlled and the contact-molecule-contact system exhibits desirable electronic properties. Fe (II) logic and memory devices, sensors, fuel cells, and solar cells. The implementation of practical molecular electronic devices requires molecule-on-metal systems in which the arrangement of active molecules is fixed or can be controlled and the contact-molecule-contact system exhibits desirable electronic properties. We suggest that it is attributable to the distinctive electronic structure of the iron-arsenic compounds. Our measurements indicate that in contrast to the assumptions based on the cuprates, reduced dimensionality is not a prerequisite for “high-temperature” superconductivity.

Supported by DoE grant “Science in 100 T”.

8:12AM Y36.00002 Oxygen-related traps in pentacene thin films: Energetic position and implications for transistor performance, WOLFGANG KALB, Laboratory for Solid State Physics, ETH Zurich, Switzerland, KURT MATTENBERGER, BERTRAM BATLOGG — We studied the influence of oxygen on the electronic trap states in a pentacene thin film kept under highly controlled conditions. This was done by temperature-dependent gated four-terminal measurements on pentacene thin-film transistors prior to and after controlled oxygen exposure. We developed and used a scheme that allows for the calculation of the essential transport parameters, such as the trap DOS, in an unambiguous way. The results are free from parasitic contact artifacts. Oxidation of pentacene in light leads to a peak of trap states centered at 0.28 eV from the mobility edge, with trap densities of the order of $10^{18}$ cm$^{-3}$. The measurements reveal how these traps affect the key device parameters, i.e. subthreshold performance and field-effect mobility. The study supports the assumption of a mobility edge for charge transport, and contributes to a detailed understanding of an important degradation mechanism of organic field-effect transistors.

8:24AM Y36.00003 Grazing-incidence X-ray Diffraction of Tetracene Thin Films on Hydrogenated Si(001) Substrate, DE-TONG JIANG, ANDREW TERSIGNI, Dept. of Physics, University of Guelph, CHANG-YONG KIM, Canadian Light Source, JUN SHI, Dept. of Physics, University of Guelph, ROBERT GORDON, Physics Dept., Simon Fraser University, NING CHEN, Canadian Light Source, XIAORONG QIN, Dept. of Physics, University of Guelph — Ex situ grazing-incidence X-ray diffraction (GIXD) and wide angle Bragg diffraction have been performed on UHV epitaxially grown tetracene thin films on H/Si(001)-2×1 substrates. The in-plane lattice of the crystalline films were characterized by 2D reciprocal space imaging of the in-plane (11), (12) and (20) GIXD diffraction spots and the out-plane lattice of the crystalline films were characterized by the wide angle Bragg diffraction. The thickness of the tetracene films ranged from 1.2 monolayer (ML) to 15 ML. H/Si(001)-2×1 substrates with different surface roughness were used. The results indicate that the film structure characteristics are strongly influenced by the substrate conditions and under favorable conditions the homogeneous thin-film phase could dominate the growth up to about 8 ML. The implications of the results to the growth mechanisms and to thin film electronics applications will be discussed.
corresponding changes in the conductivity which occur when organic absorbates are present. By increasing the coverage from sub-monolayer to multilayer, it
is possible to see doping of the underlying Ag layer, as well as conductivity through the organic film. These measurements are supported by PES and NEXAFS
studies, and thus can be interpreted in terms of charge transfer and geometric structure.

8:48AM Y36.00005 Density Functional Theory of Transition Metal Phthalocyanines, NOA MAROM, LEEOR KRONIK, Weizmann Institute of Science, Israel. — Metal phthalocyanines (MPC’s) are a family of highly stable molecules that, as a molecular solid, form organic semiconductors. They have been used in a broad range of applications, e.g., light emitting diodes, solar cells, gas sensors, thin film transistors, and even as single molecule devices. Here, we present a systematic density functional theory (DFT) study of the electronic structure of selected transition metal PCs: CuPc, NiPc, CoPc, MnPc, and FePc. We critically assess the performance of several semi-local and hybrid exchange-correlation functionals for these systems, and compare the results to experimental photoemission data. For the low-spin systems CuPc, NiPc, and CoPc, we show that semi-local functionals fail qualitatively, primarily because of under- binding of localized orbitals due to self-interaction errors. For the intermediate-spin systems MnPc and FePc, we show that DFT calculations are extremely sensitive to the choice of functional and basis set with respect to the obtained electronic configuration and to symmetry breaking. However, interestingly, all simulated spectra are in good agreement with experiment despite the differences in the underlying electronic configurations.

9:00AM Y36.00006 Cascade and Accumulation of Spin at CuPc/GaAs (100) interface, HUANJUN DING, IRFAN IRFAN, YONGLI GAO, Department of Physics and Astronomy, University of Rochester, MIRKO CINCCHETTI, MARINA SANCHEZ-ALBANEDA, JAH-SUP HONG, IRFAN IRFAN, OLEKSII ANDREYEV, MICHAEL BAUER, MARTIN AESCHLIMANN, Department of Physics, University of Kaiserslautern. — We have investigated the spin dynamics in organic semiconductor, copper phthalocyanine (CuPc), with spin and time resolved two photon photoemission spectroscopy (STR-2PPE). Spin polarized electrons are generated optically from GaAs substrate, and injected into the unoccupied states of CuPc film. The apparent spin relaxation time is observed to have strong energy dependence. The spin polarization at high energy levels decreases much faster than that of the low energy levels. The experimental results are then explained by a cascade model. The calculation suggests that the spin information of the hot electrons can be well preserved during the energy relaxation process.

9:12AM Y36.00007 Electronic structure of MoO3 insertion layer at the interface between organic semiconductor and indium tin oxide (ITO), HUANJUN DING, IRFAN IRFAN, Department of Physics and Astronomy, University of Rochester, YONGLI GAO, university of rochester, FRANK SO, Department of Materials Science and Engineering, University of Florida. — We have investigated the electronic structure of the interfaces formed by inserting thin layer of MoO3 in between indium tin oxide (ITO) and different organic semiconductors, such as aluminium phthalocyanine chloride (AlPcCl) and copper phthalocyanine (CuPc), with photoemission and inverse photoemission spectroscopy (PES and IPES). The presents of MoO3 layer at the interface increases the workfunction dramatically. As a result, the organic HOMO is almost aligned with the Fermi level (EF) at the AlPcCl/MoO3 interface. For thicker AlPcCl layers, gradual band bending is observed. However, the recovery of the HOMO is incomplete for AlPcCl thickness of 200 Å, leading to a great reduction of the hole injection barrier compare to the case without MoO3. Similar situation is found in case of CuPc/MoO3, although the energy levels are almost fully recovered for CuPc film thicker than 200 Å. The energy level alignment of these interfaces will be discussed to explain the improved induced by MoO3 layer in device performance.

9:24AM Y36.00008 HPLC and Semi-Prep Scale Fractionations of Poly(3-alkyl thiophenes), SCOTT LEFEVRE, Rensselaer Polytechnic Institute, HEUNGYEOL CHOI, TAIHYUN CHANG, Pohang University of Science and Technology, CHANG RYU, Rensselaer Polytechnic Institute — Organic molecular nanofibers have been used in a broad range of applications, e.g., light emitting diodes, solar cells, gas sensors, thin film transistors, and even as single molecule devices. Here, we present a systematic density functional theory (DFT) study of the electronic structure of selected transition metal PCs: CuPc, NiPc, CoPc, MnPc, and FePc. We critically assess the performance of several semi-local and hybrid exchange-correlation functionals for these systems, and compare the results to experimental photoemission data. For the low-spin systems CuPc, NiPc, and CoPc, we show that semi-local functionals fail qualitatively, primarily because of under- binding of localized orbitals due to self-interaction errors. For the intermediate-spin systems MnPc and FePc, we show that DFT calculations are extremely sensitive to the choice of functional and basis set with respect to the obtained electronic configuration and to symmetry breaking. However, interestingly, all simulated spectra are in good agreement with experiment despite the differences in the underlying electronic configurations.

9:36AM Y36.00009 Tailored Assembly of Organic Molecular Nanofibers into Advanced Donor-Acceptor Architectures, VOLODIMYR DZUHKO, MICHAEL J. KELLEY, KENNETH D. SINGER, Case Western Reserve University. — Non-covalent self-assembly of organic molecules in organic solvents provides a multi-functional approach toward producing organic semiconducting nanostructures having versatile, well-ordered, architectures that are potentially integrable into useful electronic, optoelectronic and photonic device architectures. Aiming at molecular-scale tailoring of electron donor-acceptor blend architectures and rational engineering of their functionality for photovoltaic applications, we discuss our approach of solvent-based, electronic-field-activated integration of self-assembled donor (phthalocyanine) nanofibers into an acceptor (perylenediimide) matrix (or vice versa). We present results of our systematic spectroscopic, X-ray diffraction and scanning electron microscopy studies revealing the structure and morphology of neat fibers and fiber blends in various phases.

9:48AM Y36.00010 The substitution effect on the reorganization energy of metal free phthalocyanine, CHOONGKEUN LEE, KARL SOHLBERG, Department of Chemistry, Drexel University, Philadelphia, Pennsylvania 19104-2875. — Many discotic (disk-like) materials such as phthalocyanines are of interest for use in organic electronic devices because of their high charge mobility. The mobility of various discotic materials has been studied using the Marcus formalism. In the Marcus formalism, charge mobility is depends on two parameters, reorganization energy and coupling matrix constant.

9:48AM Y36.00010 The substitution effect on the reorganization energy of metal free phthalocyanine, CHOONGKEUN LEE, KARL SOHLBERG, Department of Chemistry, Drexel University, Philadelphia, Pennsylvania 19104-2875. — Many discotic (disk-like) materials such as phthalocyanines are of interest for use in organic electronic devices because of their high charge mobility. The mobility of various discotic materials has been studied using the Marcus formalism. In the Marcus formalism, charge mobility is depends on two parameters, reorganization energy and coupling matrix constant. Of these two parameters the reorganization energy has more influence on the charge hopping rate. A small change in reorganization energy leads to a large change of charge mobility. We have employed electronic structure methods to describe substitution effects on the reorganization energy of phthalocyanine. The substitutions on the external phenyl rings have almost no influence on reorganization energy, but the substitutions on the internal nitrogen in phthalocyanine have strong influence on reorganization energy. The detailed relation between reorganization energy and substitution will be presented.
Our recent experiments on single-molecule metal-to-ligand electron transfer (3) and single-molecule STM manipulation will also be discussed. Dynamic disorders in the dynamics. Furthermore, we have applied site-specific AFM-Raman spectroscopy on analyzing ET associated mode-specific vibrational to seconds. The fluctuation dynamics were found to be inhomogeneous from molecule to molecule and from time to time, showing significant static and at the surface of TiO$_2$.

Ensemble-averaged studies have indicated inhomogeneous and complex dynamics of interfacial ET reaction. To characterize the inhomogeniety and the complex Photochemical Sciences, Bowling Green, OH 43403 — Interfacial electron transfer dynamics is important for environmental and catalytic reactions. Extensive

The best to date discotics are built around the coronene unit and possess six fold symmetry. In the discotic phase six fold symmetric molecules stack with an average azimuthal twist of 30 deg, whereas the angle which would lead to the greatest electronic coupling and hence highest charge mobility is 60 deg. Here, a molecule with three fold symmetry and alternating hydrophilic/hydrophobic side chains is synthesized and X-ray scattering is used to prove the formation of the desired helical microstructure. Pulse radiolysis time resolved microwave conductivity measurements show that the material has indeed a very high mobility in the plastic crystalline phase, in the range of 0.1 – 0.2 cm$^2$/Vs. The physical structure of the assemblies of molecules are simulated using molecular dynamics. This, together with quantum chemical techniques, allows the computation of charge mobilities without fitting parameters. The calculations prove that mobility is still limited by structural defects and that a defect free assembly would lead to mobilities in excess of 10 cm$^2$/Vs.

10:12AM Y36.00012 Anisotropic phases in ferromagnetic ultrathin films from multipolar interactions1, DANIEL BARCI. University of the State of Rio de Janeiro, Brazil, DANIEL STARIOLO, Federal University of Rio Grande do Sul, Brazil — We present a model to describe complex phases observed at mesoscopic scales in ultrathin magnetic films with perpendicular anisotropy. The model is based on the interaction between magnetic dipolar as well as quadrupolar moments. This model has a very rich phase diagram. In the special case of films with strong perpendicular anisotropy, a nematic phase, characterized by orientational (stripe-like) but not translational order, is predicted. The isotropic-nematic transition belongs to the Kosterlitz-Thouless type in the thermodynamic limit. However, we find that in actual experimental scales the fluctuations of the nematic order parameter are regularized by the sample size, and real orientational order, as predicted by mean field, should be observable. The transition may be characterized experimentally from measurements of the magnetic structure factor, from which the nematic order parameter is derived.

8:00AM Y37.00001 Single-Molecule Interfacial Electron Transfer Dynamics at Dye-Sensitized TiO$_2$ Nanoparticles. H. PETER LU, YUANMIN WANG, YUFAN HE, Bowling Green State University, Department of Chemistry, Center for Photochemical Sciences, Bowling Green, OH 43403 — Interfacial electron transfer dynamics is important for environmental and catalytic reactions. Extensive ensemble-averaged studies have indicated inhomogeneous and complex dynamics of interfacial ET reaction. To characterize the inhomogeniety and the complex mechanism, we have applied single-molecule spectroscopy and correlated AFM/STM imaging to study the Interfacial ET dynamics of dye molecules adsorbed at the surface of TiO$_2$ nanoparticles. The interfacial ET activity of individual dye molecules showed fluctuations and intermittency at time scale of milliseconds to seconds. The fluctuation dynamics were found to be inhomogeneous from molecule to molecule and from time to time, showing significant static and dynamic disorders in the dynamics. Furthermore, we have applied site-specific AFM-Raman spectroscopy on analyzing ET associated mode-specific vibrational reorganization energy barriers. Our experiments revealed site-to-site variations in the vibrational reorganization energy barriers in the interfacial ET systems. Our recent experiments on single-molecule metal-to-ligand electron transfer (3) and single-molecule STM manipulation will also be discussed.

8:12AM Y37.00002 Phase Diagram of a Model of Nanoparticles in Electrolyte Solutions. XIAOFEI LI, STEVEN LETTIERI, NATHANIEL WENTZEL, JAMES GUNTON, Lehigh University — We obtain accurate fluid-fluid coexistence curves for a recent simple model of interacting nanoparticles that includes the effects of ion-dispersion forces. It has been proposed that these ion dispersion forces provide at least a partial explanation for the Hofmeister effect [Phys. Rev. Lett., 87:168103, 2001]. We study a model of aluminum oxide nanoparticle [Colloids and Surfaces A, 319:98-102, 2008] for three different electrolyte solutions with added salt type being sodium chloride, sodium iodide and a non-polarizable salt. We observe that the fluid-fluid coexistence curves depend substantially on the identity of added salt; this provides an efficient way of tuning the phase behavior of nanoparticles. The methods we employ include finite-size scaling (FSS), multicanonical histogram reweighting and Gibbs ensemble methods. We show that, as expected, all three cases belong to the universality class. The scaling fields and critical point parameters are obtained in the thermodynamic limit of infinite system size by extrapolation of our FSS results.

8:24AM Y37.00003 Prediction of Zeolite Framework Types by a Machine Learning Approach. SHUJIANG YANG, MOHAMMED LACH-HAB, IOSIF VAISMAN, ESTELA BLAISTEN-BAROJAS, Computational Materials Science Center, George Mason University, Fairfax, VA 22030 — Zeolites are microporous crystalline materials with highly regular framework structures consisting of molecular-sized pores and channels. Characteristic framework types of zeolites are traditionally determined by the combined information of coordination sequences and vertex symbols. Here we present a machine learning model for classifying zeolite crystals according to their framework types. An eighteen-dimensional feature vector is defined including topological descriptors and physical/chemical properties of zeolite crystals [Microporous and Mesoporous Materials 117, 339 (2009)]. Trained with crystallographic data of known zeolites, the new model can predict the framework types of unknown zeolite crystals with up to 98 % accuracy. Compared with conventional methods, the machine learning model is more robust handling crystal disorder and/or crystal defects in a more effective manner. This model can be adapted for classifying and clustering other crystalline species.

1Supported by NSF grant CHE-0626111
8:36AM Y37.00044 Site-specific polarizabilities as predictors of optimal binding sites of H₂O on Naₓ clusters. LI MA, KOBLAR JACKSON, Physics Dept., Central Michigan University, Mount Pleasant, MI 48859. JULIUS JELLINEK, Chemical Sciences and Engineering Division, Argonne National Laboratory, Argonne IL 60439 — We have used density functional theory (DFT), in the generalized gradient approximation to study the adsorption of water molecules on sodium clusters, Naₓ for n = 7, 12, 18, and 25. These clusters span a range of sizes and surface topographies. In each case, we conduct an extensive search to identify the optimal binding site of the ad-molecule on the cluster. We analyze the results within the framework of cluster polarizability, making use of a new methodology for partitioning the cluster polarizability into atomic components (Jackson et al., J. Chem. Phys. 129, 144309 (2008)). We show that the most favorable adsorption sites are at surface atoms that have the largest atomic polarizabilities. We will compare and contrast these results with corresponding findings for the adsorption of O₂ and NH₃ molecules on Naₓ clusters.

8:48AM Y37.00055 Effect of adsorbates on the isomer stability of Ir₄ clusters. VLADAN STEVANOVIC, ITP-EPFL and IRPMA, CH-1015 Lausanne, Switzerland, ZELIKO SLJIVANCANIN, IRPMA, CH-1015 Lausanne, Switzerland, ALFONSO BALDERESCHI, ITP-EPFL and IRPMA, CH-1015 Lausanne, Switzerland and Dipartimento di Fisica Teorica, Università di Trieste, I-34014 Trieste, Italy — The relative stability of Ir₄ isomers, both in the gas phase and on MgO(100) substrate, is studied using density functional theory. The square Ir₄ is the most stable in both cases. The metastable tetrahedral isomer, which experimental data suggest as the most stable form of Ir₄ on MgO(100), is highly distorted by the strong Ir–Ir interactions. The relative stability of Ir₄ isomers is strongly altered by adsorption of a single C atom since the binding energy of the C adatom to tetrahedral and butterfly Ir₄ is much larger (~1.7 eV) than that to the square one, both in the gas-phase and on MgO(100). After carbon adsorption, the most stable structure of Ir₄ is the butterfly geometry for free clusters and the “tetrahedral” one for Ir₄/MgO(100). The C adatom binds in a bridge configuration in all cases and reduces the distortions produced by the MgO substrate. Energetics and equilibrium atomic geometries will also be discussed for the adsorption (i) one H or O atom and (ii) one CO molecule.

9:00AM Y37.00066 Control and manipulation of Au nanocatalysis: effects of metal oxide support thickness and composition. BOKWON YOON, School of Physics, Georgia Institute of Technology, CHRIS HARDING, VAHIDEH HABIBPOUR, SEBASTIAN KUNZ, ADRIAN NAM-SU FARNBACHER, UELI HEIZ, Lehrstuhl fur Physikalische Chemie, Technische Universität München, Germany, UZI LANDMAN, School of Physics, Georgia Institute of Technology — Control and tunability of the catalytic oxidation of CO by gold clusters deposited on MgO surfaces grown on molybdenum, Mo(100), to various thicknesses, are explored through temperature programmed reaction measurements on mass selected 20-atom gold clusters and via first-principles density-functional theory calculations. Dependencies of the catalytic activities and microscopic reaction mechanisms on the thickness and stoichiometry of the MgO films, and on the dimensionalities and structures of the adsorbed gold clusters are demonstrated and elucidated. Langmuir-Hinshelwood mechanisms and reaction barriers corresponding to observed low and high temperature CO oxidation reactions are calculated and analyzed. Along with the oxidation reactions on stoichiometric ultra thin MgO films we also study reactions catalyzed by Au₅₉ nanoclusters adsorbed on relatively thick defect-poor MgO films supported on Mo, and on defect-rich thick MgO surfaces containing oxygen vacancy defects.

9:12AM Y37.00077 Role of anharmonic contributions for the elasticity of ice. MIRA TODOROVA, LARS ISMER, JÖRG NEUGEBAUER, Max-Planck-Institut fuer Eisenforschung GmbH, Duesseldorf — Water, one of the simplest molecules in chemistry, forms a liquid and solid phase with features essential to live and environment. Many of these can be attributed to hydrogen bonding, but that does not mean that they are fully understood. For water, there should be an easier material to understand, because its properties are somewhat understandable. Yet even the determination of basic properties as the bulk modulus and the elastic constants proves to be a challenge. Using first principles calculations we investigate the bulk properties of hexagonal ice. Our initial density-functional theory calculations (GGA-PBE level) yield values, which are much too high when compared to experiment. Even though the consideration of thermal effects within the quasi-harmonic approximation leads to a qualitative agreement between measured and calculated quantities, such as the linear expansion coefficient, ice remains much too hard. The large overestimation of the ice’s softness demonstrates the importance of anharmonic contributions, which will be shown to be crucial and lead to a dramatic reduction of the bulk modulus and the elastic constants.

9:24AM Y37.00087 An Assessment of Hubbard U Corrections on Manganese Oxide Clusters. ELISE Y. LI, Chemistry, Massachusetts Institute of Technology. DAVIDE CERESOLI, NICOLA MARZARI, DMSE, Massachusetts Institute of Technology — Conventional density-functional approaches often fall in offering an accurate description of the spin-reversed energetics in transition metal complexes, due to spurious self-interaction errors (SIE). Previous studies have shown that a self-consistent DFT + U approach [1] can accurately correct SIE in TM complexes, providing excellent agreement with high-level quantum chemistry calculations. In this work we report a systematic evaluation of DFT + U in a series of small manganese oxide clusters (MnOₓ, x=1-4) and via first-principles density-functional theory calculations. Dependencies of the catalytic activities and microscopic reaction mechanisms on the thickness and stoichiometry of the MgO films, and on the dimensionalities and structures of the adsorbed gold clusters are demonstrated and elucidated. Langmuir-Hinshelwood mechanisms and reaction barriers corresponding to observed low and high temperature CO oxidation reactions are calculated and analyzed. Along with the oxidation reactions on stoichiometric ultra thin MgO films we also study reactions catalyzed by Au₅₉ nanoclusters adsorbed on relatively thick defect-poor MgO films supported on Mo, and on defect-rich thick MgO surfaces containing oxygen vacancy defects.

9:36AM Y37.00097 ABSTRACT WITHDRAWN — 8:48AM Y37.00010 Advances in a Joint Density-Functional Theory for Electronic Systems in Contact with Liquid Water: A New Form of Density Functional for Water. JOHANNES LISCHNER, TOMAS ARIAS, Cornell University — We present a framework for studying complex electronic systems, such as biological molecules or electrochemical interfaces, that are dissolved in liquid water. The key ingredient, that renders calculations possible, is the usage of an approximate, yet accurate “classical” density-functional theory of water, while the electronic system is described by traditional Kohn-Sham theory. The electronic system (e.g. biosolite) is then coupled to the aqueous environment via molecular pseudopotentials. Here, we present a new form of “classical” density functional for water which is the first to properly account for the structure of the molecule in an exact way. We accomplish this by writing the free energy in terms of three effective potentials, one for the oxygen and one for each hydrogen atom, in which fictitious non-interacting water molecules move. In this talk, we will show that the resulting functional correctly reproduces the following properties of water: the linear and nonlinear dielectric response, the site-site correlation functions, the surface tension, the bulk modulus of the liquid and its variation with pressure, the density of the liquid and the vapor phases, and their coexistence.

10:00AM Y37.00011 The AM05 density functional applied to the water molecule, dimer, and bulk liquid. ANN E. MATTSOHN, THOMAS R. MATTSOHN, Sandia National Labs — We show that the AM05 exchange-correlation density functional (Armiento and Mattsson, Phys. Rev. B 72, 085108 (2005)) yields a H₂O dimer binding energy of 4.9 kcal/mol. The result is thus within 0.15 kcal/mol of CCSD(T) level theory (5.02 ± 0.05 kcal/mol). We compare the AM05 results with those of five other functionals: LDA, PBE, PBEsol, RPBE, and BLYP. For liquid water, AM05 yields an O–O pair correlation function that is more structured than the ones of PBE and BLYP, which, in turn, are more structured than the one of RPBE. However, LDA and PBEsol yields more structured water than AM05. We confirm that accuracy in the water dimer binding energy is not a strong indicator for the fidelity of the resulting structure of liquid water. We will also report on the performance of AM05 for other systems and discuss the sub-system functional scheme used in the construction of AM05. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.
10:12AM Y37.00012 Heat capacities of aluminum clusters . ANNE STARACE, BAOPENG CAO, OSCAR JUDD, MARTIN JARROLD, Indiana University–Bloomington — Clusters of certain elements are known to undergo phase transitions from solid-like to liquid-like states. Aluminum clusters have emerged as a model system for metal cluster phase transitions [1]. We report here the measurement of heat capacities of cationic clusters containing 84 to 127 Al atoms using a multi-collision induced dissociation mass spectrometry method [2]. We find two major changes in the heat capacities with increasing cluster size: (1) the fluctuations in the temperature of the phase transition vary more smoothly and (2) the peaks in heat capacity become sharper. Furthermore, we have found a range of cluster sizes (115-117 atoms) that contain two distinct peaks, separated by baseline, in their heat capacities. The origin of the extra peaks in the heat capacity, which is suspected to be due either to a pre-melt transition or to a solid-to-solid transition prior to the melting transition, will be further investigated by means of annealing experiments. The current work extends prior work on singly charged Al cluster cations having 16-83 atoms [2, 3]. [1] Breux, G. A.; Neal, C. M.; Cao, B.; Jarrold, M. F. Physical Review Letters 2005, 94. [2] Neal, C. M.; Starace, A. K.; Jarrold, M. F. Journal of the American Society for Mass Spectrometry 2007, 18, 74-81. [3] Neal, C. M.; Starace, A. K.; Jarrold, M. F. Physical Review B 2007, 76. [4] This work is supported by NSF.

10:24AM Y37.00013 From Atomic Clusters towards Nano-Materials with Controlled properties1 . S.N. KHANNA, M.C. QIAN, A.C. REBER, J.U. REVELES, R. ROBLES, P.A. CLAYBORNE, S.V. ONG, K. CASALENUOVO, Virginia Commonwealth University, A.W. CASTLEMAN JR., A. SEN, P.W. WEISS, H. SAAVEDRA, A. UGRINOV, N. CHAKI, Pennsylvania State University — One pathway towards the synthesis of nanomaterials with controllable properties is to assemble solids using chosen clusters as the building blocks. The talk will outline a new protocol that enables synthesis of nanomaterials from clusters and highlight how the character of the cluster emerges in the assembled material. Through studies on assemblies involving polyvalent anions As7–, As5–, and alkali based cations, we will show how the studies can provide novel ways of controlling the bandgap through energy level of the countercation and the degree of charge transfer. The theoretical predictions will be compared with experimental findings.

The authors are grateful to the Army Research Office for supporting this work through a MURI grant (Grant # W911NF-06-1-0280).

Friday, March 20, 2009 8:00AM - 11:00AM –
Session Y38 DCP: Surfaces, Interfaces, and Colloids I 410

8:00AM Y38.00001 Aqueous Solutions on Silica Surfaces: Structure and Dynamics from Simulations1 . ALBERTO STRIOLO, DIMITRIOS ARGYRIS, NAGA RAJESH TUMMALA, University of Oklahoma, MOLECULAR SCIENCE AND ENGINEERING AT OU TEAM — Our group is interested in understanding the properties of aqueous electrolyte solutions at interfaces. The fundamental questions we seek to answer include: (A) how does a solid structure perturb interfacial water? (B) How far from the solid does this perturbation persist? (C) What is the rate of water reorientation and exchange in the perturbed layer? (D) What happens in the presence of simple electrolytes? To address such topics we implemented atomistic molecular dynamics simulations. Recent results for water and simple electrolytes near silicon dioxide surfaces of various degrees of hydroxylation will be presented. The data suggest the formation of a layered aqueous structure near the interface. The density profile of interfacial water seems to dictate the density profiles of aqueous solutions containing NaCl, CaCl2, CsCl, and SrCl2 near the solid surfaces. These results suggest that ion-ion and ion-water correlations are extremely important factors that should be considered when it is desired to predict the distribution of electrolytes near a charged surface. Our results will benefit a number of practical applications including water desalination, exploitation of the oil shale in the Green River Basin, nuclear waste sites remediation, and design of nanofluidic devices.

8:12AM Y38.00002 Formation of Organic Peroxides and Ethers at Post-Discharge Plasma Plume-Liquid Interfaces . MILAN BEGLJARBEKOV, STEVEN KOTOWICH, VLADIMIR TARNOVSKY, Stevens Institute of Technology — A direct current (DC) micro-hollow cathode plasma source operating in a mixed glow-streamer regime was used to generate an atmospheric pressure N2 plasma. The post-discharge plume / afterglow was interfaced with a target liquid-phase solution, and caused a change in the chemistry of the target solution. In the present work we study the interaction of an N2 plume with a mixture of 2-methyl-1-propanol and hexane, which results in the formation of organic peroxides and ethers at the plume-liquid interface. The presence of the peroxide and ether functional groups is established by 1H-NMR, FTIR, and Raman spectra of the reaction products. Fast Atom Bombardment (FAB) mass spectrometry is also used to further characterize the reaction products.

8:24AM Y38.00003 Deducing 2D Crystal Structure at the Solid/Liquid Interface with Atomic Resolution by Combined STM and SFG Study . ARTHUR MCCLELLAND, University of Michigan, Applied Physics Program, SEOKHOON AHN, ADAM J. MATZGER, ZHAN CHEN, University of Michigan, Chemistry Department — Supplemented by computed models, Scanning Tunneling Microscopy (STM) can provide detailed structural information of 2D crystals formed at the liquid/solid interface with atomic resolution. However, some structural information such as functional group orientations in such 2D crystals needs to be tested experimentally to ensure the accuracy of the deduced structures. Due to the limited sensitivity, many other experimental techniques such as Raman and infrared spectroscopy have not been allowed to provide such structural information of 2D crystals. Here we showed that Sum Frequency Generation Vibrational Spectroscopy (SFG) can measure average orientation of functional groups in such 2D crystals, or physisorbed monolayers, providing key experimental data to aid in the modeling and interpretation of the STM images. The usefulness of combining these two techniques is demonstrated with a phthalate diesters monolayer formed at the 1-phenyloctane/ highly oriented pyrolytic graphite (HOPG) interface. The spatial orientation of the ester C=O of the monolayer was successfully determined using SFG.

8:36AM Y38.00004 Curved space crystallography at an oil-water interface . WILLIAM IRVINE, STEFANO SACANNA, YAEL ROICHMAN, ANDREW HOLLINGSWORTH, MARK ELSESSER, Center for Soft Matter Research, New York University, MARK BOWICK, Physics Department, Syracuse University, DAVID GRIER, PAUL CHAIKIN, Center for Soft Matter Research, New York University — We study two-dimensional crystallography on a curved oil-water interface. Charged hydrophobic (PMMA) colloids in an oil phase (cyclohexyl bromide) are attracted, without wetting, by image charge effects to an oil-water interface. The micron size spheres form a monolayer on the interface and interact via screened coulomb interactions to form a crystalline lattice. We create a curved oil-water interface by controlling wetting conditions between a water droplet and a substrate or support, to produce interfaces of both constant and varying gaussian curvature with boundary. We simultaneously image and manipulate the full crystal on the curved surface using a setup capable of simultaneous holographic optical tweezing and confocal imaging. We study the resulting dynamics of topological defects.
8:48AM Y38.00005 On the nanometer Gold projectile - surface interaction in SIMS experiments. FRANCISCO A. FERNANDEZ-LIMA, VERONICA PINNICK, MICHAEL ELLER, STANISLAV VERKHOTUROV, EMILLE SCHWEIKERT, Texas A&M University — In an effort to increase the secondary molecular ion signal under ion bombardment, a series of cluster sources have been developed with sputtering yields that deviate from the linear cascade prediction due to the collective cluster beam - surface interaction. In the present talk, the variation of the massive gold \( \text{Au}_{n}^{+} \) projectile size (n=1-400) and velocity on the interaction volume and number of desorbed/sputtered particles per impact will be discussed for alkali halide targets. As the projectile size increases, a larger number of cluster ions is observed, where the secondary ion yield can be describe as a decreasing exponential function of the cluster size. Theoretical ab initio calculations show that the relative MS abundances are related to the cluster structure stabilities, defined by a “fine” ratio of short and long range interactions between the cluster counterparts. Angular distribution measurements of the secondary ions suggest that under keV bombardment emission normal to the target surface is favored, independent of the cluster ion size. Applications of the massive gold \( \text{Au}_{n}^{+} \) projectiles as nanometric imaging probes (< 10^4 nm²) will be presented.

9:00AM Y38.00006 Binding energy of adsorbates on a noble-metal surface: Exchange and correlation effects. MICHAEL ROHLFING, University of Osnabrueck, THOMAS BREDOW, University of Bonn — We discuss the physisorption of atoms (xenon) and molecules (PTCDA) to a noble-metal surface (silver) within a first-principles approach, focusing on the adsorption energy as a function of distance. Instead of density-functional theory (which fails to describe physisorption) we employ a combination of exact exchange and correlation energies, which we evaluate within the adiabatic-connection fluctuation-dissipation theorem. Correlation accounts for non-local dispersion energy, which is crucial in the present cases. At large distance Z from the surface the correlation causes van der Waals attraction with a characteristic \(-C_{6}/(Z-Z_{0})^{6}\) asymptotic form. At closer distance the attraction deviates from the asymptotic form and, in combination with the retractive exchange-correlation energy, yields an equilibrium bond for xenon on and of PTCDA on the Ag(111) surface in close agreement with experiment.

9:12AM Y38.00007 Bonding of adenine on Cu(110). GEOFFREY STENUIT, CNR-INFM DEMOCRITOS Theory@Elettra Group, Sincrotrone Trieste, in Area Science Park, I-34012 Basovizza (Trieste), Italy, OKSANA PLEKAN, VITALY FYEYER, KEVIN PRINCE, Sincrotrone Trieste, in Area Science Park, I-34012 Basovizza (Trieste), Italy, PAOLO UMARI, CIN-IRN-M DEMOCRITOS Theory@Elettra Group, Sincrotrone Trieste, in Area Science Park, I-34012 Basovizza (Trieste), Italy — We present a density functional study of the adsorption of adenine molecules on the Cu(110) surface. In agreement with experimental core level photoemission and x-ray absorption data, our calculations predict the existence of two phases: a parallel one at low coverage and a perpendicular one at high coverage. These findings resolve contradictions between calculated geometries and published vibrational spectra, and illustrate the complexity of the interaction between a relatively simple bio-molecule and a metal.

9:24AM Y38.00008 ABSTRACT WITHDRAWN —

9:36AM Y38.00009 Two-photon photoemission spectroscopy of thiophene/Au(111).1, JING ZHOU, Chemistry Department, Stony Brook University, Stony Brook, NY 11794, NICHOLAS CAMILLONE, Chemistry Department, Brookhaven National Laboratory, Upton, NY 11973, MICHAEL WHITE, Chemistry Department, Stony Brook University & Chemistry Department, Brookhaven National Laboratory — The electronic structure of thiophene adsorbed on Au(111) is investigated by two-photon photoemission (2PPE) spectroscopy and density functional theory (DFT) calculation. The adsorption of thiophene lowers the work function from 5.50 eV for clean Au(111) to 4.62 eV for Au(111) exposed to 4.0 L thiophene, due to the electron donation from the thiophene to the substrate. With thiophene adsorbed on Au(111), a localized \( \sigma^* \) state forms with increasing thiophene exposure on Au(111). This \( \sigma^* \) state is attributed to the \( \pi^* \) antibonding orbital of a Au-S bond and is evidence of an orientational phase transition of thiophene adsorbed. Preliminary 2PPE results will also be presented for aromatic molecules bound to the Au surface via sulfur or other functional goups (e.g., isocyanide).

1 This work is supported by the US Department of Energy, Office of Basic Energy Science, Division of chemical sciences under contract DE-AC02-98CH10886.

9:48AM Y38.00010 Interfacial Structure imaging of Pentacene/Si(111) by model- independent method. SONGTAO WO, HUA ZHOU, RANDALL HEADRICK, University of Vermont, ALEXANDER KAZIMIROV, Cornell High Energy Synchrotron Source, CORNHILL HIGH ENERGY SYNCHROTRON SOURCE TEAM — Synchrontron x-ray reflectivity is utilized to study the Pentacene/Si(111) interfacial structure in the direction normal to the surface. Model-independent algorithm is used to analyze the reflectivity data to extract the electron density profile. It indicates two partially ordered layers along the interfacial normal with thickness ~0.6 nm and an interfacial water layer ~0.9 nm as we reported in our previous work. A pentacene monolayer ~1.6 nm can also be revealed.

10:00AM Y38.00011 Optical Trapping of Colloidal Nanoparticles by a Weakly Focused Laser Beam. CHUN-YU LIN, HSIA-YU LIN, Lehigh University, SHEAN-JEN CHEN, STEVEN M.T. WEI, H.D. OU-YANG, Lehigh University — We present an analysis of the behavior of an ensemble of colloidal nanoparticles in the focal region of a weakly focused laser beam. Using a mechanical balance of the laser radiation pressure that causes particle migration into the light field and the osmotic pressure of these particles opposing migration, we propose a new method for quantifying the optical trapping potential of individual particles by measuring the increase of the particle concentration as a function of the laser intensity. We find comparable results for the optical trapping potential from this method with values obtained by single particle trapping methods, indicating that radiation-induced particle convection from a weakly focused laser beam does not affect the steady state distribution of the particles in the light field.

10:12AM Y38.00012 Colloidal Crosstalk: Brownian Diffusion of Hydrodynamically Coupled Colloids. STEPHEN ANTHONY, University of Illinois, MINSU KIM, UC San Diego, STEVE GRANICK, University of Illinois — Except at dilute concentrations, the Stokes-Einstein Equation inadequately describes the thermal motion of colloids, due to hydrodynamic interactions between nearby particles. Using single-particle tracking, the rotational and translational motion of hydrodynamically interacting colloids is observed, and deviations from the Stokes-Einstein Equation are readily apparent. The thermal motion of nearby colloids is found to couple in a non-additive fashion, with increasing degrees of non-linearity as particle separation decreases. Similar coupling is observed for colloids near surfaces.

10:24AM Y38.00013 Depletion-Driven Selective Optical Trapping in Nanoparticle Suspensions. YI HU, JOSEPH JUNIO, H.D. OU-YANG, Lehigh University — We report results of an optical trapping study that demonstrates the effects of size-asymmetric particles in suspension have on optical trapping efficiency. Using a model colloid system with selective fluorescent dying and particle sizing, we show that the trapping efficiency of nanoparticles can be effectively tuned by adding different sized particles, promoting the use of optical trapping for particle sorting. A variable power IR laser coupled into a high NA objective was used for trapping. For particle detection, we used a 532nm excitation laser aligned to be parfocal with the IR trapping beam through the same objective lens. Fluorescent signals emanating from the focal region common to both beams was band-passed to a pinhole set to be conjugate to the focal region for confocal detection. In a system composed of 160nm and 63nm particles we demonstrated the synergistic effect of size mixing. Experimental results are also shown for fluorescent particles being driven out of the region by size selective trapping of undesired 160nm particles.
10:48AM Y38.00015 Determination of Charge Interactions of Nanoparticles by Optical Trapping, JOSEPH JUNIO, H.D. OU-YANG, Lehigh University — We report an experimental study of interactions in colloidal nanoparticles through optical trapping. Using an optical trap with a size much larger than the trapped particles, we were able to create an optical bottle to confine and concentrate the nanoparticles. We measured the highly focused light-induced particle density fluctuation with confocal fluorescent detection. A theory based on a balance between the optical trapping radiation pressure and the osmotic pressure has been developed to calculate the isothermal osmotic compressibility from the forced density fluctuation. The measured osmotic compressibilities of colloidal crystals are then used to determine the surface charge density of the colloidal particle(1). Comparison of the experimentally determined charge density is compared to that determined by zeta potential measurements. (1)S. Alexander, P. M. Chaikin, P. Grant, G. J. Morales, and P. Pincus, D. Hone, Charge renormalization, osmotic pressure, and bulk modulus of colloidal crystals: Theory, J. Chem. Phys. 80, 5776 (1984).

Friday, March 20, 2009 8:00AM - 11:00AM
Session Y39 DPB: Techniques in Biophysics 411

8:00AM Y39.00001 The Molecular Splash Test: when applied physics help stroke patients, CEDRIC HURTH, LENA VAN NIMWEGEN, DEEPTHI JAMPALA, Applied Nanobioscience, Biodesign Institute, KRIS VIJAY, Scottsdale Clinical Research Institute, FREDERICK ZEHNHAUSERN, Applied Nanobioscience, Biodesign Institute — The Molecular Splash Test (MST) stems from recent observations of a solid sphere producing a splash when impacting a liquid (Bocquet et al. 2007, Nature Physics, 3, 180). We have developed the experimental setup incorporating a high-speed camera operated at 8,000 frames/s to perform biologically-relevant experiments, e.g. rheology studies from the impact of a native glass bead and molecular recognition tests when the impacting bead is functionalized with biomarkers. We present preliminary results with millimeter-sized glass beads impacting water mixtures of increasing glycerol content, i.e. increasing viscosities, as well as biotin-modified glass beads impacting avidin solutions (0.1 – 1 mg/mL). The viscosity increase of a human blood sample containing hirudin, once hirudinase II is added to re-induce coagulation, is monitored over time to assess the ability of MST to function on samples of medical interest. The beads can then be derivatized with an antibody for detection of C-reactive protein in blood serum.

8:12AM Y39.00002 Surfaced-Enhanced Raman Scattering of λ-DNA1, DIANE ALVAREZ, JIANDI ZHANG, Louisiana State University, Baton Rouge, LA 70803, HONG WEI, HONGXING XU, Institute of Physics, CAS, Beijing, 100080, China — The ability to engineer metal particles at the nanoscale in which plasmons can be excited, directed, and manipulated has led to the rapid development of the field of “plasmonics”. Here we demonstrate that the Raman scattering of λ-DNA molecules with colloidal silver nanoparticles is drastically enhanced by surface plasmon excitations. Colloidal silver nanoparticles (~90 nm size) were assembled onto DNA molecules using the molecular combing method. Surface-enhanced Raman scattering (SERS) spectra were obtained and compared for different solution concentrations of the DNA/Ag system. It is evident that the SERS peaks were shifted to a lower or higher wavenumber, depending on the concentration of the solution. These different shifts of Raman frequencies may indicate that the different stretching states of DNA molecules in different concentrations probably influence the Raman frequencies. It is speculated that the coiling states of DNA molecules might be different in different concentrations, thus making it a promising method for the study of DNA functionalities and DNA-nanoparticle interactions.

1Supported by China NSF 10625418 & 90406024, MOST Grant No. 2006DFB02020, and US NSF CIEH-0415421.

8:24AM Y39.00003 Sub-cellular structure studied by combined atomic force-fluorescence microscopy1, ANDREEA TRACHE, Texas A&M Health Science Center — A novel experimental technique that integrates atomic force microscopy (AFM) with fluorescence imaging was used to study the role of extracellular matrix proteins in cellular organization. To understand the mechanism by which living cells sense mechanical forces, and how they respond and adapt to their environment, we developed a new technology able to investigate cellular behavior at sub-cellular level that integrates an AFM with total internal reflection fluorescence (TIRF) microscopy and fast-spinning disk (FSD) confocal microscopy. Live smooth muscle cells exhibited differences in focal adhesions and actin pattern depending on the extracellular matrix used for substrate coating. Data obtained by using the AFM-optical imaging integrated technique offer novel quantitative information that allows understanding the fundamental processes of cellular reorganization in response to extracellular matrix modulation. The integrated microscope presented here is broadly applicable across a wide range of molecular dynamics studies in any adherent live cells.

8:36AM Y39.00004 Expanding the applicability of multi-photon fluorescence recovery after photobleaching in vivo by incorporating convective flow into the recovery model1, KELLEY SULLIVAN, University of Rochester Department of Physics and Astronomy, WILLIAM SIPPRELL, University of Rochester Department of Biomedical Engineering, EDWARD BROWN, JR., Manhattan College Department of Physics, EDWARD BROWN, III, University of Rochester Department of Biomedical Engineering — Multi-photon fluorescence recovery after photobleaching is a well-established microscopy technique used to study diffusion, with expanding applications in vivo. We present a new model of fluorescence recovery that explicitly includes the effect of convective flows within a system, thereby improving the efficacy of the technique in vivo, where convective flows are omnipresent. We test this “flow” model through both simulations and in vitro experimentation, and demonstrate the effectiveness of the new model in vivo. Our results show that the flow model significantly improves the capabilities of multi-photon fluorescence recovery after photobleaching in vivo, by enabling an accurate determination of the diffusion coefficient, even when significant flows are present.

8:48 AM Y39.00005 Electrophoretic Migration of Branched DNA in Polymer Solutions. HENRY LAU, LYNDEEN ARCHER, School of Chemical and Biomolecular Engineering, Cornell University — The electrophoretic migration of large, star-branched DNA molecules has previously been studied in both neutral polymer solutions and gels, and the results have provided insight into the local interactions between the analytes and the sieving matrix during electrophoresis (Electrophoresis, 2006, 27, 3128). This talk focuses on using rigid-rod DNA molecules of complex shapes as model analytes in studying the effects of analyte architecture on mobility in polymer solutions. Electrophoresis of a series of Y-shaped DNA molecules that mimic the shapes of antibodies, was performed in polymer solutions above the overlap concentration and at electric fields up to 300V/cm. The location of the branch point as well as the arm sizes are varied in order to examine their influence on mobility. Our results point to novel, topology-based fractionation strategies for separating biological molecules using capillary electrophoresis with polymer sieving media.

9:00 AM Y39.00006 Time-resolved dielectric spectroscopy of protein aggregation performed on model system of hen lysozyme and beta-lactoglobulin. BRIAN MAZZEO, Brigham Young University, ANDREW FLEWITT, University of Cambridge — Time-resolved dielectric spectroscopy measurements of solutions containing hen lysozyme and beta-lactoglobulin reveal changes in electrical configuration and hydrodynamic parameters during their interaction. These measurements were performed in a temperature-controlled dielectric cell connected to an HP4194A impedance analyzer. The protein titrations were performed by sequential additions of reacting proteins. Differential spectra reveal the electrical contributions by each species. The computer-controlled measurements and relevant post-processing of the obtained spectra allow quantitative extraction of reaction parameters. This is demonstrated for a model system of proteins consisting of hen lysozyme and beta-lactoglobulin. Reorientation time constants, dielectric increments, and relaxation spread parameters are plotted against time and indicate binding processes. The technique is demonstrated to be a useful analytical tool for monitoring reactions in biological and colloidal systems.

9:12 AM Y39.00007 “Shooting Bead” Method with Filament Energy Loss Consideration for Finding the Flexural Rigidity of the Rodelike Biological Filaments. ABDORREZA SAMARBKHSH, JACK TUSZYNSKI1. Department of Physics, University of Alberta, Edmonton, Canada — Flexural rigidity is one of the important characteristics of flexible polymers including biological filaments. For elastic deformation it is analogous to the spring constant in the Hook’s law for bending. In this work we propose a new method for experimentally evaluating the cantilever stiffness and flexural rigidity of semiflexible rodlike biological filaments based on the measurement of just two distances. The method is based on applying a force normal to the filament with a microsphere bead trapped in the laser tweezer followed by its sudden release. Through two simple measurements of the initial and final position of the bead, the cantilever stiffness and flexural rigidity of the filament can be found from the formula that has been provided. In the second part, the effect of filament radius has been taken into account and a new formula with filament energy loss consideration, for flexural rigidity and the cantilever stiffness has been found.

9:24 AM Y39.00008 Electrostatic Force Microscopy Identification of Different Peptide Structures, CASPER HYTTTEL CLAUSEN, DTU Nanotech — In this work electrostatic force microscopy (EFM) was used to distinguish between different dipeptides tubes, silver filled peptides, spheres and silver wires, all the samples were placed on pre fabricated SiO2 surfaces with a backgate under ambient conditions. The EFM method used for the experiments was force gradient signal, which uses a dual scan approach in order to minimize the atomic force interactions. The investigation shows that it is possible to distinguish between the three types of structures. Further an agreement between the detected signal and the structure of the hollow peptide was demonstrated. These measurements only show qualitative agreement with the mathematical expressing for the peptide tubes. Further during EFM mapping of the silver filled peptide structures showed a changing effect between the tip and the sample. Investigations of this effect were carried out in order to get a better understanding of the physical properties of the peptide structures.

9:36 AM Y39.00009 Specific Detection of Vascular Endothelial Growth Factor Using Microcantilever Resonators. JASON FRANCIS, Dept. of Physics, West Virginia University, STEPHANIE ARCHER, LISA HOLLAND, Dept. of Chemistry, West Virginia University, DAVID LEDERMAN, Dept. of Physics, West Virginia University — We demonstrate the specific detection of vascular endothelial growth factor, a protein indicated in tumor angiogenesis, using resonant frequency shifts in microcantilevers due to mass loading, avoiding the need to use tagged antibodies and multiple reagents as is needed with enzyme linked immunosorbent assays (ELISA). Cantilever surfaces were functionalized using F(ab')2 fragments linked to gold surfaces via their native thiol groups, eliminating the need for complex linking processes. The cantilever surfaces were then passivated with bovine serum albumin to minimize shifts due to nonspecific binding. This technique allows the detection of pg/ml-level concentrations of analyte.

9:48 AM Y39.00010 Positioning and guidance of neurons on Au by directed assembly of proteins using Atomic Force Microscopy. CRISTIAN STAII, Department of Physics, University of Wisconsin, Madison. CHRISS VIESSELMANN, JASON BALLWEG, Department of Anatomy, UW-Madison, JUSTIN WILLIAMS, Department of Biomedical Engineering, UW-Madison, ERIK DENT, Department of Anatomy, UW-Madison, SUSAN COPPERSMITH, MARK ERIKSSON, Department of Physics, UW-Madison — The specific interactions between neurons and guidance factors as well as the mechanism of axonal navigation toward a target in the developing brain are not well understood. To address this problem we present a new approach for controlling the adhesion, growth and interconnectivity of cortical neurons on Au surfaces. Specifically, we use AFM nanolithography to immobilize extracellular matrix proteins at well-defined locations on Au surfaces, and show that these protein patterns can confine neuronal cells and control their growth and interconnectivity. We will compare this method with other nanofabrication techniques and discuss its main advantages: 1) the procedure is carried out in aqueous solutions, so that the proteins retain their bioactivity, 2) a high degree of control over location and shape of the protein patterns can be achieved, and 3) the minimum protein feature size can be as small as 50nm.

10:00 AM Y39.00011 Determination of Frank-Oseen parameters in collagen using polarization modulated second harmonic signal. CLAYTON BRATTON, University of California, Davis - Physics, KAREN REISER, University of California, Davis - Neurosurgery, ANDRE KNOESEN, DIEGO YANKELEVICH, MINGSHI WANG, University of California, Davis - Electrical and Computer Engineering, ISRAEL ROCHA - MENDOZA, Cardiff University, Cardiff, Wales - Cardiff School of Biosciences — A method is presented for determining the Frank-Oseen parameters for the elastic modulus of collagen based on analysis of polarization-modulated second harmonic signal (PM-SHG). The liquid crystal structure of collagen and its associated order parameter, the director field, were characterized in samples of tendon and annulus fibrosus. Deformation of the director field caused by controlled stress loading or heating was assessed. Three distinct curvature strains—splay, twist, and bend—were determined, using the PM-SHG data. This optical technique permits highly localized determination of the three major elastic deformations.
10:12AM Y39.00012 Direct measurement of the non-conservative force field generated by optical tweezers, PINYU WU, RONGXIN HUANG, University of Texas - Austin, Austin, TX USA, CHRISTIAN TISCHER, ALEXANDR JONAS, ERNST-LUDWIG FLORIN, University of Texas - Austin, Austin, TX USA — Optical tweezers have been widely used in soft condensed matter physics and biophysics to measure forces in molecular processes on the single molecule level. The usual assumption is that the force applied to a particle confined with the tweezers is directly proportional to the displacement of the particle from the trapping center, which would imply that the force field of the tweezers is conservative. However, the Gaussian beam model indicates that this force field is actually non-conservative, yet no experiments have measured this effect. We developed a new experimental method that can directly measure the force field with femtonewton precision without assuming its conservative character. We successfully obtained the 3-D force field for an optically trapped Rayleigh particle with 10 nm resolution by analyzing its Brownian motion. We found a non-conservative contribution that increases as the trapped particle moves away from the optical axis. In the light of this finding, optical trapping experiments that assumed a conservative force field may need careful reevaluation.

10:24AM Y39.00013 SERS-Active Nanoinjector for Intracellular Spectroscopy, ELINA VITOL, Drexel University, ZULFIYA ORYNBAYEVA, MICHAEL BOUCHARD, JANE AZIZKHAN-CLIFFORD, GARY FRIEDMAN, YURY GOGOTSI, KECK INSTITUTE FOR ATTOFLUIDIC NANOTUBE-BASED PROBES TEAM — We developed a multifunctional nanopipette which allows simultaneous cell injection and intracellular surface-enhanced Raman spectroscopy (SERS) analysis. SERS spectra contain the characteristic frequencies of molecular bond vibrations. This is a unique method for studying cell biochemistry and physiology on a single organelle level. Unlike the fluorescence spectroscopy, it does not require any specific staining. The principle of SERS is based on very large electromagnetic field enhancement localized around a nano-rough metallic surface. Gold colloids are widely used SERS substrates. Previously, the colloidal nanoparticles were introduced into a cell by the mechanism of endocytosis. The disadvantage of this method is the uncontrollable aggregation and distribution of gold nanoparticles inside a cell which causes a significant uncertainty in the origin of the acquired data. At the same time, the nanopipette uptake is irreversible. We present a SERS-active nanoinjector, coated with gold nanoparticles, which enables selective signal acquisition from any point-of-interest inside a cell. The nanoinjector provides a highly localized SERS signal with sub-nanometer resolution in real time.

10:36AM Y39.00014 Evaluating Epithelial Mechanics with Laser Hole-drilling1, M. SHANE HUTSON, DAVID N. MASHBURN, XIAOYAN MA, HOLLEY E. LYNCH, Dept of Physics & Astronomy, Vanderbilt University — During the development of an organism, sheets of epithelial cells expand, contract and bend due to intra- and intercellular forces. We have previously developed laser hole-drilling as a technique to probe such epithelial mechanics — with a focus on the ms-to-s dynamic recoll of single, directly adjacent cell edges. Here we extend the analysis to consider ablation-induced deformations for the entire field of surrounding cells. We treat each epithelium as a homogeneous, linearly elastic, thin sheet. This simplification provides analytical solutions for the expected strain relaxation after hole-drilling (under either plane stress or plane strain). We have developed routines that use these analytic mappings (plus potential rigid body motions) to warp and match pre- and post-drilling images. These mappings account for the majority of the observed deformations and allow one to estimate the epithelium’s Poisson ratio and pre-drilling average strain tensor (which yields the anisotropy and direction of principle stress/strain). The unaccounted, residual displacements provide clues to how each epithelium deviates from a homogeneous sheet.

10:48AM Y39.00015 Top-Down Fabricated Silicon Nanochannel Field-Effect Transistors for Biosensing Applications, YU CHEN, XIHUA WANG, SHYAMSUNDER ERRAMILLI, PRITIRAJ MOHANTY, Physics department of Boston University, NANO LAB OF BU TEAM — Silicon nanochannel field-effect transistors have great promise for biomolecular sensing. The sensitivity is enhanced at the nanoscale due to the large surface-to-volume ratio. Specificity is achieved by functionalizing the devices with selected antibodies or complimentary target molecules. These devices are important as building blocks for high density bioanoelectronics. Top-down fabrication of these devices is compatible with advanced microfabrication processes. We show top-down fabricated silicon nanochannel devices with 3-dimensional relief can serve as a platform for biosensing applications. Three sides of the silicon nanowire are covered with a thin Al2O3 layer using Atomic Layer Deposition to form an insulating layer. When the surface is modified for binding to specific biomarkers, the device conductance change can be used to detect binding events through a field effect. Applications include building immunosensors to detect the breast cancer antigen 15-3 and other protein biomarkers, and constructing enzyme-based sensors to detect metabolites like glucose and urea.

8:00AM Y40.00001 Biophysical investigation of the apoptotic force1, YUSUKE TOYAMA, XOMALIN PERALTA, Duke University, Physics Department, ADRIENNE WELLS, DANIEL KIEHART, Duke University, Department of Biology, GLENN EDWARDS, Duke University, Physics Department — Understanding tissue dynamics during development requires knowledge of how cells produce and respond to forces. We have experimentally shown that apoptosis (programmed cell death, which remodels tissue by eliminating cells) also contributes a significant tissue force that promotes cell sheet fusion during dorsal closure in Drosophila development [Science, 321, 1683 (2008)]. By genetically suppressing (enhancing) apoptosis, we slow (increase) the rate of dorsal closure. These changes correlate with the forces produced by the amniotosa tissue and the rate of seam formation (zipping) for two advancing sheets of lateral epidermis. This apoptotic force is used to drive cell sheet movements during development, a role not classically attributed to apoptosis.1 This research has been supported by the NIH (GM33830).

8:12AM Y40.00002 Reorganization of neuronal circuits in growing visual cortex, WOLFGANG KEIL, MPIDS Goettingen, SIGRID LOEWEL, University Jena, FRED WOLF, MPIDS Goettingen, MATTHIAS KASCHUBE, Princeton University — The dynamics of reorganization of large cortical circuits is rooted in plasticity of individual synapses, but the rules governing the collective behavior of large networks of neurons are only poorly understood. The postnatal brain growth partly evoked by extensive formation of new synaptic connections may expose cortical areas to a ‘natural perturbation’ sufficiently strong to observe signatures of large scale reorganization. Quantifying large sets of imaging data from juvenile cat visual cortex, we observed a novel mode of reorganization of domains that prefer inputs from one eye or the other. Our theoretical analysis shows that this mode can be explained quantitatively by the so called Zigzag instability, a dynamical reorganization, well-known in the field of pattern formation in physics, by which 2D isotropic sheets of lateral epidermis. This apoptotic force is used to drive cell sheet movements during development, a role not classically attributed to apoptosis.

This research has been supported by the NIH (GM33830).
8:24 AM Y40.00003 Epithelial oscillations enhance signal detection in a peripheral sensory system. ALEXANDER NEUMAN, Ohio University, TATIANA ENGEL, Yale University School of Medicine, DAVID RUSSELL, BRIAN HELBIG, Ohio University, LUTZ SCHIMANSKY-GEIER, Humboldt University at Berlin — Rhythmic spontaneous activity was observed in various peripheral sensory systems. Many sensory receptors have a specific structure where detector cells in a sensory epithelium excite primary afferent neurons. We explore how stochastic oscillations of epithelial cells affect the ability of peripheral receptors to detect weak stimuli. We use a simple analytically tractable model to contrast signal detection in two situations: (i) when epithelial oscillations are coherent, and (ii) when the coherence of epithelial oscillations is destroyed. We show that coherent epithelial oscillations decrease the variability of neuronal firing, and thus to enhance discriminability of weak signals. Model predictions are supported by the analysis of experimental data from the electoreceptors of paddlefish.

8:36 AM Y40.00004 Sound Localization in Lizards: Functioning of a Pressure-Gradient Receiver. J. LEO VAN HEMMEN, Physik Department, TU Muenchen — Because of their small interaural distance, lizards as well as some other animals have developed a special hearing mechanism, the “pressure-gradient receiver.” The lizard peripheral auditory system differs from the mammalian one by a coupling of the two eardrums through the internal mouth cavity. We present a three-dimensional analytical model of the pressure-gradient receiver. The central aspect of the coupling of the membranes through the mouth cavity is realized by means of the boundary conditions. Moreover, the lizard’s middle ear, a simple lever construction called columna, is asymmetrically attached to the tympanic membrane. This has motivated us to solve the problem of how the middle ear influences the spatial-ambient profile and the frequency distribution of the tympanic membrane vibration. Finally, we show results from numerical simulations of the eigenfunctions and eigenfrequencies in a lizard’s internal mouth cavity bounded by the eardrums. To this end, we have constructed the complex geometry of the coupled model.

8:48 AM Y40.00005 Direct Neural Imaging using Ultra-Low Field Magnetic Resonance. KARLENE MASKALY, MICHELLE ESPY, MARK FLYNN, JOHN GOMEZ, ROBERT KRAUS, ANDREI MATLASHOV, Los Alamos National Laboratory, JOHN MOSHER, Cleveland Clinic, SHAUN NEWMAN, TUBA OWENS, MARK PETERS, J. SANDIN, LARRY SCHULTZ, ALGIS URBAITIS, PETR VOLEGOV, VAIMO ZOTEV, Los Alamos National Laboratory — An enduring challenge in neuroscience is the accurate in vivo mapping of neural activity with high spatial and temporal resolution. A method being developed by our group tries to meet this challenge by using Ultra-Low Field (ULF) MRI. Other groups have attempted direct neural imaging (DNI) using high field MRI. However, the use of ULF presents two advantages. First, the susceptibility artifact at high fields, which masks the DNI signal, is negligible at low fields. Second, the reduced Larmor frequency at ULF may overlap with the frequency spectrum of the neural magnetic field, resonantly enhancing the MRI signal. In this presentation, we will first show our custom-built ULF MRI setups that have successfully produced ULF anatomical images. I will then highlight the numerous studies we have done to investigate the feasibility of DNI with these systems, including both experimental and theoretical studies.

9:00 AM Y40.00006 Synaptic vesicle dynamics in Hippocampal Slices. KRASTAN BLAGOEV, National Science Foundation, DENIS BRAGIN, WOLFGANG MUELLER, University of New Mexico — Synaptic vesicle pool dynamics in hippocampal slices have been observed using FM-dye as an activity-dependent contrast agent with two-photon microscopy. Separate vesicle pools for spontaneous and stimulated vesicle release and vesicle dynamics, and vesicle exchange dynamics between the pools was inferred from the signal with and without stimulation. To interpret the experimental results we developed a multi-compartmental kinetic model of the FM-dye dynamics during loading and unloading of vesicles. Using this mathematical model we estimated the exchange rates between the synaptic vesicle pools and the resulting vesicle release dynamics. We will discuss important differences between the vesicle pool dynamics in ex vivo brain slices and in dissociated neuronal cultures.

9:12 AM Y40.00007 The surface properties of a lung mucus model system. MARKUS WEYGAND, BEAUTIA DEW, STEPHEN GAROFF, MATHIAS LÖSCHKE, TODD PRZBYCICHEN, ROBERT TILTON, Carnegie Mellon University — Adding surfactants to aerosol drug therapies may improve drug delivery by inducing surface tension gradient driven flows along the lung airway surfaces. Understanding the surface structure and properties of the mucus that lines the lung airways is crucial to the proper design of such formulations. In our studies, we use mucin solutions made from porcine gastric mucus as a model system. Surface tension measurements revealed a time and humidity dependence, which led us to investigate the structure of the air/solution interface using X-ray and neutron reflectivity. These studies reveal a compact adsorption layer at the air/liquid interface whose density distribution decays with a long tail extension into the bulk liquid. This structure showed only a minor dependence on the humidity above the mucus surface. To examine possible interaction between lipids present in the lung with the mucus, we deposited DPPC and DMPC onto the mucin solution surface and observed that the lipid layer remained on the solution surface for times long compared to the lifetime of mucus in the lung. The analysis of the reflectivity data impart a microscopic picture of the mucin solution surface and its alteration by lipid deposition.

9:24 AM Y40.00008 Structural Measurements from Images of Noble Gas Diffusion. ROBERT V. CADMAN, STEPHEN J. KADLECEK, KIARASH EMAMI, JOHN MACDUFFIE WOODBURN, VAHID VAHDAT, Department of Radiology, University of Pennsylvania, MASARU ISHII, Department of Otolaryngology, Johns Hopkins University, RAHIM R. RIZI, Department of Radiology, University of Pennsylvania — Magnetic resonance imaging of externally polarized noble gases such as He has been used for pulmonary imaging for more than a decade. Because gas diffusion is impeded by the alveoli, the diffusion coefficient of gas in the lung, measured on a time scale of milliseconds, is reduced compared to that of the same gas mixture in the absence of restrictions. When the alveolar walls decay, as in emphysema, diffusivity in the lung increases. In this paper, the relationship between diffusion measurements and the size of the restricting structures will be discussed. The simple case of diffusion in an impermeable cylinder, a structure similar to the upper respiratory airways in mammals, has been studied. A procedure will be presented by which airways of order 2 mm in diameter may be accurately measured; demonstration experiments with plastic tubes will also be presented. The additional developments needed before this technique becomes practical will be briefly discussed.

9:36 AM Y40.00009 Clusters of decelerations of heart rate appear to be a Hopf bifurcation, and provide early warning of illness in premature infants. ABIGAIL FLOWER, Biophysics, University of Virginia, RANDALL MOORMAN, DOUGLAS LAKE, Internal Medicine, U. Virginia, JOHN DELOS, Physics, William and Mary — The pacemaking system of the heart is complex; a healthy heart constantly integrates and responds to extracardiac signals, resulting in highly complex heart rate patterns with a great deal of variability. In the laboratory and in some pathological or age-related states, however, dynamics can show reduced complexity that is more readily described and modeled. Reduced heart rate complexity has both clinical and dynamical significance — it may provide warning of impending illness or clues about the dynamics of the heart’s pacemaking system. Here we describe uniquely simple and interesting heart rate dynamics observed in premature human infants — reversible transitions to large-amplitude periodic oscillations. We propose a mathematical interpretation based on Hopf bifurcation theory. (Supported by NIH/NIGMS, by the National Heart, Lung, and Blood Institute, and by NSF, with computing support provided by William and Mary.)

9:48AM Y40.00010 New Outlet Conditions for Three-Dimensional Computational Fluid Dynamic Simulations of Blood Flow in Arteries1, DAVID JOHNSON, Graduate Student, Dept. of Chemical Engr., ULHAS NAIK, Professor, Dept. of Chemical Engr.. In three-dimensional (3D) simulation of a component of the arterial network, we have the problem of properly specifying outlet conditions due to coupling with the rest of the arterial network. In this work we propose to use an approximate solution, based on a one-dimensional (in space) but time periodic approximation of the flow, in order to obtain these outlet conditions. These are used in fully 3D and time periodic computational fluid dynamic (CFD) simulations of a coronary arterial junction, using the commercial software Fluent. A consistent implementation requires an iterative procedure that has been developed based on a lubrication approximation. The application of these boundary conditions has been applied to both a normal/healthy coronary artery junction and a diseased case, where an occlusion has developed causing impairment of flow. Results will be shown that demonstrate significant changes to the solution.

1 NSF - IGERT Program and NASA DE Space Grant Consortium

10:00AM Y40.00011 Millimeter Wave Spectroscopy for Breast Cancer Diagnostics and Detection, KONSTANTIN KOROLEV, SHU CHEN, MOHAMMED AESAR, Tufts University, Medford, MA 02155, STEPHEN NABER, Tufts Medical Center, Boston, MA 02111 — Broad-band millimeter wave transmittance measurements of normal and tumorous (cancerous) human breast tissue samples have been acquired in–vitro by employing a free-space, quasi-optical spectrometer. Freshly excised breast tissues were prepared and preserved in 10% neutral-buffered formalin solution before testing. Significant differences in the transmittance profiles have been found between the normal and tumorous tissues. It has been found that despite the inhomogeneity and variable structure and composition of each single tissue, the tumorous specimens consistently manifest much higher absorption level of millimeter wave radiation than the normal ones. It has been shown that free space, quasi-optical spectrometer is capable of contributing valuable insights into the dielectric properties of normal and tumorous human breast tissues and aiding in further developments of millimeter wave spectroscopy and mammography for the breast cancer diagnostics and detection.

10:12AM Y40.00012 Diffusion dependence of proton NMR relaxation rates in the presence of ferritin, MICHAEL BOSS, P. CHRIS HAMMEL, The Ohio State University, Department of Physics — Ferritin is the predominant iron-storage protein in living organisms. It may serve as an indicator of neurodegenerative diseases such as Alzheimer’s. Measuring brain ferritin concentration non-invasively via MRI could enable better diagnoses and treatments of such diseases. Quantitative MRI determination of the ferritin concentration requires an understanding of the NMR relaxation mechanisms of hydrogen protons in the presence of ferritin. In aqueous solutions, ferritin enhances the transverse relaxation rate (R_2) of the protons. This is thought to occur due to a diffusive mechanism, where protons diffusing near ferritin pass through a region of elevated magnetic field, and a chemical exchange mechanism, where protons bind to the protein for a period of time, experiencing an even higher magnetic field. These two mechanisms exhibit different dependencies on the self-diffusion coefficient of the protons. By adding glycerol to aqueous solutions, we control the self-diffusion of protons. We measure the R_2 of protons in ferritin-containing binary mixtures of water and glycerol using CPMG sequences, and compare the experimental results to theoretical predictions of diffusion dependence in order to distinguish the relative importance of the mechanisms.

10:24AM Y40.00013 Application of Histogram Analysis in Radiation Therapy (HART) in Intensity Modulation Radiation Therapy (IMRT) Treatments, ANIL PYAKURYAL, Northwestern Memorial Hospital, Chicago, IL — A carcinoma is a malignant cancer that emerges from epithelial cells in structures throughout the body. It invades the critical organs, could metastasize or spread to lymph nodes. IMRT is an advanced mode of radiation therapy treatment for cancer. It delivers more conformal doses to malignant tumors sparing the critical organs by modulating the intensity of radiation beam. An automated software, HART (S. Jang et al., 2008, Med Phys 35, p. 2812) was used for efficient analysis of dose volume histograms (DVH) for multiple targets and critical organs in four IMRT treatment plans for each patient. IMRT data for ten head and neck cancer patients were exported as AAPM/RTG format files from a commercial treatment planning system at Northwestern Memorial Hospital (NMH). HART extracted DVH statistics were used to evaluate plan indices and to analyze dose tolerance of critical structures at prescription dose (PD) for each patient. Mean plan indices (n=10) were found to be in good agreement with published results for Linac based plans. The least irradiated volume at tolerance dose (TD50) was observed for brainstem and the highest volume for larynx in SIB treatment techniques. Thus HART, an open source platform, has extensive clinical implications in IMRT treatments.

10:36AM Y40.00014 Role of Physique on Probability of Injury to the Low Back, SAAMI J. SHAIBANI, Independent Modeling, Algorithms & Analytical Studies (IMMAS) — In a related study of the response of the upper and lower cervical spine[1], there was some correlation between a change in physique and the potential for injury to the neck during automotive events. A similar undertaking in this research on the lumbar spine and sacral spine revealed a much more marked effect, namely an increase in injury potential to the low back when weight is increased. Although there were some exceptions to this, the overall trend was distinct. This is perhaps to be expected when one considers that most additional weight at the same height tends to be located in the center or lower torso. However, it is first time in any comparable analysis of injury causation that there has been a more noticeable correlation between a change in physique and the potential for injury to the neck during automotive events. 11:15AM Z1.00001 Status of Experiments on the 5/2 Quantized Hall State: A Theorist’s View1, BERTRAND I. HALPERIN, Physics Department, Harvard University — A number of experiments have been proposed, which, at least in principle, should clarify the nature of the fractional quantized Hall state at filling fraction 5/2. For example, experiments might measure the spin polarization of the ground state and the charge of the elementary quasiparticles, and could test whether the quasiparticles indeed obey non-Abelian statistics, as predicted by the Moore-Read model. These experiments are difficult, however, and their interpretation may be complicated by non-uniformities in the electron density and other problems, which also pose difficulties at simpler filling fractions. We shall discuss the current experimental situation, with these issues in mind.

11:51AM Z1.00002 Fractionally charged quasiparticles at filling fraction 5/2, MOTY HEIUBLM, Weizmann Institute of Science — No abstract available.
12:27PM Z1.00003 Quasiparticle Tunneling in the Fractional Quantum Hall effect at filling fraction \( \nu = 5/2 \), IULIANA P. RADU, MIT — In a two-dimensional electron gas (2DEG), in the fractional quantum Hall regime, the quasiparticles are predicted to have fractional charge and statistics, as well as modified Coulomb interactions. The state at filling fraction \( \nu = 5/2 \) is predicted by some theories to have non-Abelian statistics, a property that might be exploited for topological quantum computation. Interferometric devices may be employed to manipulate and measure quantum Hall edge excitations. Here we use a small area edge state interferometer designed to observe quasiparticle interference effects. Oscillations in transmission consistent in detail with the Aharonov-Bohm effect are observed for integer and fractional quantum Hall states (filling factors 2, 5/3 and 7/3) with periods corresponding to their respective charges and magnetic field positions. With these charge calibrations, at filling factor 5/2 and at lowest temperatures periodic transmission through the device consistent with quasiparticle charge e/4 is observed. The principal finding of this work is that in addition to these e/4 oscillations, periodic structures corresponding to e/2 are also observed at filling factor 5/2 and at lowest temperatures. Properties of the e/4 and e/2 oscillations at 5/2 are examined with the device sensitivity sufficient to observe the relative prevalence of e/4 and e/2 oscillations, transitions between the periods, and temperature evolution of the 5/2 quasiparticle interference. Among possible etiologies, this presence of an effective e/2 period may empirically reflect an e/2 quasiparticle charge, or may reflect multiple passes of the e/4 quasiparticle around the interferometer. These results are discussed within a potential picture of e/4 quasiparticle excitations possessing non-Abelian statistics. Some critical consistencies are met between the experimental results and properties of non-Abelian e/4 quasiparticles. These studies demonstrate the capacity to perform interferometry on 5/2 excitations and reveal properties important for understanding this state and its excitations.

1:03PM Z1.00004 Measurement of filling factor 5/2 quasiparticle interference\(^1\), ROBERT WILLETT, Bell Laboratories, Alcatel-Lucent — A standing problem in low dimensional electron systems is the nature of the 5/2 fractional quantum Hall state: its elementary excitations are a focus for both elucidating the state’s properties and as candidates in methods to perform topological quantum computation. Interferometric devices may be employed to manipulate and measure quantum Hall edge excitations. Here we use a small area edge state interferometer designed to observe quasiparticle interference effects. Oscillations in transmission consistent in detail with the Aharonov-Bohm effect are observed for integer and fractional quantum Hall states (filling factors 2, 5/3 and 7/3) with periods corresponding to their respective charges and magnetic field positions. With these charge calibrations, at filling factor 5/2 and at lowest temperatures periodic transmission through the device consistent with quasiparticle charge e/4 is observed. The principal finding of this work is that in addition to these e/4 oscillations, periodic structures corresponding to e/2 are also observed at filling factor 5/2 and at lowest temperatures. Properties of the e/4 and e/2 oscillations at 5/2 are examined with the device sensitivity sufficient to observe the relative prevalence of e/4 and e/2 oscillations, transitions between the periods, and temperature evolution of the 5/2 quasiparticle interference. Among possible etiologies, this presence of an effective e/2 period may empirically reflect an e/2 quasiparticle charge, or may reflect multiple passes of the e/4 quasiparticle around the interferometer. These results are discussed within a potential picture of e/4 quasiparticle excitations possessing non-Abelian statistics. Some critical consistencies are met between the experimental results and properties of non-Abelian e/4 quasiparticles. These studies demonstrate the capacity to perform interferometry on 5/2 excitations and reveal properties important for understanding this state and its excitations.

Friday, March 20, 2009 11:15AM - 2:15PM — Session Z2 DCMP: Detection of Non-Gaussian Noise in Mesoscopic Systems

11:15AM Z2.00001 Detection of the third moment of shot noise by a Josephson junction, JUKKA PEKOLA, Temperature Laboratory, Helsinki University of Technology — We use a hysteretic Josephson junction as an on-chip detector of shot noise of a tunnel junction. The detectable bandwidth is determined by the plasma frequency of the detector, which is about 50 GHz in the experiments that we report. The second moment of shot noise manifests itself as increased effective temperature of junction switching. The third moment results in a measurable change of the switching rate when reversing polarity of the current through the noise source. We have successfully analyzed the observed asymmetry using a phenomenological model. We compare our results to the more quantitative theories as well. Experiments on quantum point contacts and further work on tunnel junctions are in progress.

11:51AM Z2.00002 Asymmetric noise probed with a Josephson junction\(^1\), HUGUES POTHIER, Quantronics, CEA-Saclay — Using a Josephson junction, we have measured the fluctuations of the current through a tunnel junction. The current noise adds to the bias current of the Josephson junction and affects its switching out of the supercurrent branch. The experiment is carried out in a regime where switching is determined by thermal activation. The variance of the noise results in an elevated effective temperature, whereas the third moment, related to its asymmetric character, leads to a difference in the switching rates observed for opposite signs of the current through the tunnel junction. Measurements are compared quantitatively with recent theoretical predictions.

12:27PM Z2.00003 Fluctuation-induced switching and the switching path distribution, MARK DYKMAN, Michigan State University — Fluctuation-induced switching is at the root of diverse phenomena currently studied in Josephson junctions, nano-electromechanical systems, nano-magnets, and optically trapped atoms. In a fluctuation leading to switching the system must overcome an effective barrier, making switching events rare, for low fluctuation intensity. We will provide an overview of the methods of finding the switching barrier for systems away from thermal equilibrium. Generic features of the barrier, such as scaling with the system parameters, will be discussed. We will also discuss the motion of the system in switching and the ways of controlling it. Two major classes of systems will be considered: dynamical systems, where fluctuations are induced by noise, and birth-death systems. Even though the motion during switching is random, the paths followed in switching form a narrow tube in phase space of the system centered at the most probable path. The paths distribution is generally Gaussian and has specific features, which have been seen in the experiment [1]. Finding the most probable path itself can be reduced to solving a problem of Hamiltonian dynamics of an auxiliary noise-free system. The solution also gives the switching barrier. The barrier can be found exactly close to parameter values where the number of stable states of the system changes and the dynamics is controlled by a slow variable. The scaling of the barrier height depends on the type of the corresponding bifurcation. We show that, both for birth-death and for Gaussian noise driven systems, the presence of even weak non-Gaussian noise can strongly modify the switching rate. The effect is described in a simple explicit form [2,3]. Weak deviations of the noise statistics from Gaussian can be sensitively detected using balanced dynamical bridge, where this deviation makes the populations of coexisting stable states different from each other; a realization of such a bridge will be discussed. We will also discuss the sharp anisotropy of fluctuations induced by Poisson noise in overdamped systems and how it is changed with decreasing damping.

delivery by rapid injection of a large volume of DNA solution into a blood vessel, commonly called hydrodynamic gene delivery, has become a common method for gene delivery in humans. Our study employed swine as an animal model and the procedure developed includes image-guided insertion of a balloon catheter for gene therapy studies in rodents. In this presentation, I will focus on our recent work aiming at establishment of an image-guided hydrodynamic procedure. This requires solving the Kramer's problem of noise-activated escape from a metastable state beyond the Gaussian noise approximation and investigating how the measurement circuit affects threshold detection.

1:39PM Z2.00005 Theory of Josephson junction detectors of higher order noise cumulants\textsuperscript{1}. HERMANN GRABERT, Freiburg Institute for Advanced Studies — A promising strategy pursued at various laboratories to measure higher order cumulants of the electrical current of nanoscopic devices employs on-chip Josephson junction detectors. The non-Gaussian nature of the noise generated by electronic nanostructures modifies the switching rate of the Josephson junction output from the zero voltage state, and the noise cumulants can be extracted from this modification. When the decay of the metastable zero voltage state occurs by noise activation to the top of the barrier of the Josephson potential, the third noise cumulant gives rise to an asymmetry of the rate when the bias current is inverted. In the range of decay by macroscopic quantum tunneling (MQT) through the barrier potential, the forth noise cumulant leads to an enhancement of the MQT rate. The theoretical methods to describe a Josephson junction noise detector in these parameter regimes are outlined and associated experimental strategies are discussed.

11:15AM Z3.00001 Small Bioactive Lipoplex (SBL) Nanoparticles Self-Assembled at Elevated Temperature and Pressure\textsuperscript{1}. LEAF HUANG, University of North Carolina at Chapel Hill — Conventional lipoplex (cationic liposome/DNA complex) serves well for gene transfer in cultured cells. However, their in vivo gene delivery activity is limited due to its relatively large size (~100 nm). This is due to incomplete charge neutralization as a result of the steric hindrance during the complexation between DNA and liposomes. Behr et al hypothesized that monomolecular DNA condensate can be prepared if the DNA sees the cationic lipid as monomers. Indeed, small nanoparticles (~30 nm) were prepared by using a single-chain cationic amphiphile which has a high solubility at the physiological condition. To stabilize the monomolecular condensate, Behr has included a SH group in the cationic amphiphile which could be oxidized to form a dimer. Unfortunately, the stabilized nanoparticles showed no transfection activity when delivered into cells. We hypothesized that similar small lipoplex can be prepared by using a double-chain cationic amphiphile if both DNA and the amphiphile can be soluble in the same solvent. A hydrofluorocarbon HFC-152a is an excellent solvent for the cationic lipid DOTAP at an elevated temperature (~35 °C) and pressure (~300 atm). Since the solvent can accommodate small amounts of water, DNA or siRNA could be introduced into the system to allow lipoplex formation. The resulting Small Bioactive Lipoplex (SBL) is 30-50 nm in diameter and can transfect cultured cells. Freeze-fracture electron microscopy showed that SBL are solid nanoparticles without any lipid bilayer structure. Since plasmid DNA is fragile at elevated temperature and pressure, we have concentrated our effort in siRNA which is stable under the same conditions. The new formulation shows great promise as an in vivo delivery vector when small particles are required for efficient penetration into the tissues.

11:51AM Z3.00002 New Developments in Non Viral Gene Delivery. RAM MAHATO, University of Tennessee Health Science Center — No abstract available.

12:27PM Z3.00003 Image-Guided Hydrodynamic Gene Delivery, DEXI LIU, University of Pittsburgh — Gene delivery by rapid injection of a large volume of DNA solution into a blood vessel, commonly called hydrodynamic gene delivery, has become a common method for gene therapy studies in rodents. In this presentation, I will focus on our recent work aiming at establishment of an image-guided hydrodynamic procedure for gene delivery in humans. Our study employed swine as an animal model and the procedure developed includes image-guided insertion of a balloon catheter into the selected blood vessel of the targeted organ from the jugular vein and hydrodynamic injection of plasmid DNA in saline. The talk will cover the rationale of our approach, the effectiveness of procedure for gene delivery to liver and muscle, and the impact of the procedure on physiological functions and serum chemistry of the animals. The results will be discussed with respect to potential applications of the hydrodynamic gene delivery to human gene therapy.

1:03PM Z3.00004 Revisit an old problem — Complexation between DNA and PEI. CHI WU, Department of Chemistry, The Chinese University of Hong Kong — After revisiting the captioned problem by using a combination of chemical synthesis and physical methods, we studied the dynamics of the complexation between branched polyethyleneimine (iPEI) and plasmid DNA (pDNA) and characterized the structure, size and surface charge of the resultant DNA/PEI complexes (polyplexes). As expected, in order to reach a high efficiency in gene transfection into cells it is necessary to use a higher N:P ratio and make the polyplexes positively charged. Our results reveal that it is those uncomplexed iPEI chains free in the solution mixture that plays a vitally important role in enhancing the transfection efficiency, inspiring new thinking of how to correlate in vitro and in vivo studies so that we can improve the in vivo transfection efficiency. Increasing the N:P ratio normally results in a higher cytotoxicity, which is a catch-22 problem. Recently, we found that a proper modification of iPEI can greatly reduce its cytotoxicity without any suffering in the transfection efficiency. In this lecture, we will show that our properly modified iPEI is even much more effective and less cytotoxic in the gene transfection than those commercially available lipoplexes. Our recent breakthrough leads to a complete new direction in the development of non-viral vectors for molecular medicines, including gene transfection.

Friday, March 20, 2009 11:15AM - 2:15PM – Session Z4 DPOLY DBP: Biological Polyelectrolytes 306/307
Electrostatic Rigidity of Biological Polyelectrolytes. ANDREY DOBRYNIN, University of Connecticut — Electrostatic persistence length is one of the most controversial subjects in polymer physics. In this talk I will present an overview of the history of the problem and a new results showing that the bending rigidity of the biological polyelectrolytes ( semiflexible charged polymers) is a multiscale process. The existence of the different length scales in the bending process is manifested in change of the form of the correlation function, describing bond-bond orientational correlations, with salt concentration. At high salt concentrations when the electrostatic interactions are significantly screened these correlations may be approximated by a single exponential function indicating the existence of a dominant length scale. However, when the Debye screening length exceeds a critical value the orientational correlations between chain’s bond vectors undergo a qualitative change resulting in appearance of two different bending rigidities ( persistence lengths). One increases quadratically and the other changes logarithmically with the Debye screening length. This transition occurs when the chain’s bare persistence length becomes on the order of so-called OSF electrostatic persistence length. Simulation results and theoretical model demonstrate good qualitative agreement.

12:27PM Z4.00003 Deafness and espin-actin self-organization in stereocilia, GERARD C.L. WONG, University of Illinois at Urbana-Champaign — Espins are F-actin-bundling proteins associated with large parallel actin bundles found in hair cell stereocilia in the ear, as well as brush border microvilli and Sertoli cell junctions. We examine actin bundle structures formed by different wild-type espin isoforms, fragments, and naturally-occurring human espin mutants linked to deafness and/or vestibular dysfunction. The espin-actin bundle structure consisted of a hexagonal arrangement of parallel actin filaments in a non-native twist state. We delineate the structural consequences caused by mutations in espin’s actin-bundling module. For espin mutation with a severely damaged actin-bundling module, which are implicated in deafness in mice and humans, oriented nematic-like actin filament structures, which strongly impinges on bundle mechanical stiffness. Finally, we examine what makes espin different, via a comparative study of bundles formed by espin and those formed by fascin, a prototypical bundling protein found in functionally different regions of the cell, such as filopodia.

1:03PM Z4.00004 Mesoscale Modeling of Chromatin Folding, TAMAR SCHLICK, New York University — Eukaryotic chromatin is the fundamental protein/nucleic acid unit that stores the genetic material. Understanding how chromatin fibers fold and unfold in physiological conditions is important for interpreting fundamental biological processes like DNA replication and transcription regulation. Using a mesoscale model of oligonucleosome chains and tailored sampling protocols, we elucidate the energetics of oligonucleosome folding/unfolding and the role of each histone tail, linker histones, and divalent ions in regulating chromatin structure. The resulting compact topologies reconcile features of the zigzag model with straight linker DNAs with the solenoid model with bent linker DNAs for optimal fiber organization and reveal dynamic and energetic aspects involved.

In collaboration with Gaurav Arya, S. Grigoryev, S. Correll, and C. Woodcock.

1:39PM Z4.00005 Complexation of oppositely charged polyelectrolytes in gene delivery and biology, BORIS SHKLOVSKII, University of Minnesota — Charge inversion of a DNA double helix by a positively charged flexible polymer (polyelectrolyte) is widely used to facilitate DNA contact with negative cell membranes for gene delivery. Motivated by this application in the first part of the talk I study the phase diagram a solution of long polyanions (PA) with a shorter polycations (PC) as a function the ratio of total charges of PC and PA in the solution, x, and the concentration of monovalent salt. Each PA attracts many PCs to form a complex. When x = 1, the complexes are neutral and condense in a macroscopic drop. When x is far from one, complexes are strongly charged and stable. PA are overcharged by PC at x > 1 and undercharged by PC at x < 1. As x approaches 1, PCs attached to PA disproportionate between complexes. Some complexes become neutral and condensed in a macroscopic drop while others become even stronger charged and stay free. The second part of the talk deals with biological example of PA - PC complexes namely self-assembly of vegetable viruses from long ss-RNA molecule paying role of scaffold and identical capsid proteins with long positive tails. I show that optimization Coulomb energy of the virus leads to the charge of virus twice larger than the charge of the capsid, in agreement with the experimental data. Then I discuss kinetics of the Coulomb complexation driven virus self-assembly. Capsid proteins stick to un assembled chain of ss RNA (which we call “antenna”) and slide on it towards the assembly site. I show that at excess of capsid proteins such one-dimensional diffusion accelerates self-assembly more than ten times. On the other hand at excess of ss-RNA, antenna slows self-assembly down. Several experiments are proposed to verify the role of ss-RNA antenna in self-assembly.
suggesting intriguing possibilities for genetic analysis.

The basic principle behind this is that when DNA is electrophoretically driven through a nanopore, it blocks a measurable fraction of the current. Our work also focuses on solid-state nanopores, single-nanometer-scale devices that can not only manipulate single molecules, but also can manipulate long DNA molecules by a variety of nanoscale phenomena, including electrokinetics, hydrodynamics, Coulomb interactions, and the statistical mechanics of polymers.

As we shrink fluidic devices down to the nanoscale to probe samples as minute as a single molecule, what physical phenomena grew increasingly important. One of the most dramatic manifestations of the quantum nature of light in the past half-century has been the Casimir force: a force between neutral objects at close separations caused by quantum vacuum fluctuations in the electromagnetic fields. In classical photonics, wavelength-scale structures can be designed to dramatically alter the behavior of light, so it is natural to consider whether analogous geometry-based effects occur for Casimir forces. However, this problem turns out to be surprisingly difficult for all but the simplest planar geometries. (The deceptively simple case of an infinite plate and infinite cylinder, for perfect metals, was first solved in 2006.) Many formulations of the Casimir force, indeed, correspond to impossibly hard numerical problems. We will discuss how the availability of large-scale computing resources in NSF's TeraGrid, combined with reformulations of the Casimir-force problem oriented towards numerical computation, are enabling the exploration of Casimir forces in new regimes of geometry and materials.

MICHAEL ROUKES, California Institute of Technology — Mass spectrometry (MS) has become a preeminent methodology of proteomics since it provides rapid and quantitative identification of protein species with relatively low sample consumption. Yet with the trend toward biological analysis at increasingly smaller scales, ultimately down to the volume of an individual cell, MS with few-to-single molecule resolution will be required. We report the first realization of MS based on single-molecule mass spectrometry providing proof-of-principle for this new technique. Nanoparticles and protein species are introduced by electrospray injection from the fluid phase into ambient conditions into vacuum and subsequently delivered to the NEMS detector by hexapole ion optics. Mass measurements are then recorded in real-time as analytes adsorb, one-by-one, onto a phase-locked, ultrahigh frequency (UHF) NEMS resonator. These first NEMS-MS spectra, obtained with modest resolution from only several hundred mass adsorption events, presage the future capabilities of this methodology. We outline the substantial improvements feasible in near term, through recent advances and technological avenues that are unique to NEMS-MS.

1:03PM Z7.00004 Using Photoactivation Light Microscopy (PALM) to construct comprehensive, nanometer precision atlases of signaling complexes

JAN LIPHARDT, University of California, Berkeley — The E. coli chemotaxis network is a model system for biological signal processing. In E. coli, transmembrane receptors responsible for signal transduction assemble into large clusters containing several thousand proteins. These sensory clusters have been observed at cell poles and future division sites. Despite extensive study, it remains unclear how chemotaxis clusters form, what controls cluster size and density, and how the cellular location of clusters is robustly maintained in growing and dividing cells. Here we use photoactivated localization microscopy (PALM) to map the cellular locations of three proteins central to bacterial chemotaxis (the Tar receptor, CheY, and CheW) with a precision of 15 nanometers. We find that cluster sizes are approximately exponentially distributed, with no characteristic cluster size. One third of Tar receptors are part of smaller lateral clusters and not the large polar clusters. Analysis of the relative cellular locations of 3.1 million individual proteins (from 326 cells) suggests that clusters form via stochastic self-assembly. The super-resolution PALM maps of E. coli receptors support the notion that stochastic self-assembly can create and maintain approximately periodic structures in biological membranes, without direct cytoskeletal involvement or active transport.

1:39PM Z7.00005 Single-molecule dynamics in nanofabricated traps

ADAM COHEN, Harvard University — The Anti-Brownian Electokinetic trap (ABEL trap) provides a means to immobilize a single fluorescent molecule in solution, without surface attachment chemistry. The ABEL trap works by tracking the Brownian motion of a single molecule, and applying feedback electric fields to induce an electokinetic motion that approximately cancels the Brownian motion. We present a new design for the ABEL trap that allows smaller molecules to be trapped and more information to be extracted from the dynamics of a single molecule than was previously possible. In particular, we present strategies for extracting dynamically fluctuating mobilities and diffusion coefficients, as a means to probe dynamic changes in molecular charge and shape. If one trapped molecule is good, many trapped molecules are better. An array of single molecules in solution, each immobilized without surface attachment chemistry, provides an ideal test-bed for single-molecule analyses of intramolecular dynamics and intermolecular interactions. We present a technology for creating such an array, using a fused silica plate with nanofabricated dimples that have removable cover for sealing single molecules within the dimples. With this device one can watch the shape fluctuations of single molecules of DNA or study cooperative interactions in weakly associating protein complexes.

Session Z8 DBP: Statistical Physics in Biology 414/415

11:15AM Z8.00001 Allometric Scaling in Biology

JAYANTH BANAVAR, Penn State — The unity of life is expressed not only in the universal basis of inheritance and energetics at the molecular level, but also in the pervasive scaling of traits with body size at the whole-organism level. More than 75 years ago, Kleiber and Brody and Proctor independently showed that the metabolic rates, B, of mammals and birds scale as the three-quarter power of their mass, M. Subsequent studies showed that most biological rates and times scale as $M^{-1/4}$ and $M^{1/4}$, respectively, and that these so-called quarter-power scaling relations hold for a variety of organisms, from unicellular prokaryotes and eukaryotes to trees and mammals. The wide applicability of Kleiber’s law, across the 22 orders of magnitude of body mass from minute bacteria to giant whales and sequoias, raises the hope that there is a relationship between metabolic rate, B, and body mass, M. We show how the pervasive quarter-power biological scaling relations arise naturally from optimal directed resource supply systems. This framework robustly predicts that: 1) whole organism power and resource supply rate, B, scale as $M^{5/4}$; 2) most other rates, such as heart rate and maximal population growth rate scale as $M^{-1/4}$; 3) most biological times, such as blood circulation time and lifespan, scale as $M^{1/4}$; and 4) the average velocity of flow through the network, $\bar{v}$, such as the speed of blood and oxygen delivery, scales as $M^{1/12}$. Our framework is valid even when there is no underlying network. Our theory is applicable to unicellular organisms as well as to large animals and plants. This work was carried out in collaboration with Amos Maritan along with Jim Brown, John Damuth, Melanie Moses, Andrea Rinaldo, and Geoff West.

11:51AM Z8.00002 From gene expressions to genetic networks

MAREK CIEPLAK, Institute of Physics, Polish Academy of Sciences — A method based on the principle of entropy maximization is used to identify the gene interaction network with the highest probability of giving rise to experimentally observed transcript profiles [1]. In its simplest form, the method yields the pairwise gene interaction network, but it can also be extended to deduce higher order correlations. Analysis of microarray data from genes in Saccharomyces cerevisiae chemostat cultures exhibiting energy metabolic oscillations identifies a gene interaction network that reflects the intracellular communication pathways. These pathways adjust cellular metabolic activity and cell division to the limiting nutrient conditions that trigger metabolic oscillations. The success of the present approach in extracting meaningful genetic connections suggests that the maximum entropy principle is a useful concept for understanding living systems, as it is for other complex, nonequilibrium systems. The time-dependent behavior of the genetic network is found to involve only a few fundamental modes [2,3].

12:27PM Z8.00003 Non-equilibrium thermodynamic effects during cell division, JORGE JOSE, SUNY at Buffalo — A mitotic spindle is a regular structure within a cell consisting of oriented microtubule fibers. It plays a fundamental role in chromosome separation during cell division. Forming a spindle pattern is a major structural step towards mitosis. We have developed biophysical non-equilibrium thermodynamic models to describe in vitro chromosome driven spindle formation experiments in Xenopus extracts. Our first 2D model calculations [1] successfully described the order of events seen in some of the Xenopus extracts experiments, where the chromosomes are replaced by chromatin-covered micrometer magnetic beads. I will describe more realistic 3D improvements in our modeling analysis, which include microtubule contact forces and excluded volume [2, 3]. There are, however, a number of challenges that must be addressed for spindle modeling to continue to be a useful tool for understanding this fundamental biological process, in particular the biophysical simulation times. In this talk I will describe some important problems needing better biological data and hypothesis. I will also discuss our most recent numerical algorithmic improvements that are expected to greatly increase the simulations speed and thus allowing a more realistic representation of the experimental situation in Xenopus extracts. 1:03PM Z8.00004 New Proposed Mechanism for Actin-Polymerization-Driven Motility1, ANDREA LIU, University of Pennsylvania — When a cells crawls, its shape re-organizes via polymerization and depolymerization of a network of actin filaments. The growing ends of the filaments are localized near the leading edge of the crawling cell, and their polymerization, regulated by a host of proteins, pushes the cell membrane forwards in a biological model known as the dendritic nucleation model. We have performed Brownian dynamics simulations to see how the dendritic nucleation model leads to motion. Our results are not consistent with previous models of motility, and suggest a new picture for the physical mechanism underlying this form of motility.

Friday, March 20, 2009 11:15AM - 2:15PM –
Session Z9 GSNP: Nonlinear Dynamics and Chaotic Systems 303

11:15AM Z9.00001 Rotating Space Elevator: Classical and Statistical Mechanics of cosmic scale spinning strings1, STEVEN KNUDSEN, LEONARDO GOLUBOVIC, West Virginia University — We introduce a novel and unique nonlinear dynamical system, the Rotating Space Elevator (RSE). The RSE is a multiply rotating system of cables (strings) reaching beyond the Earth geo-synchronous satellite orbit. Strikingly, objects sliding along the RSE cable do not require internal engines or propulsion to be transported far away from the Earth’s surface. The RSE actio employs, in a very fundamental way, basic natural phenomena – gravitation and inertial forces. The RSE exhibits interesting nonlinear dynamics and statistical physics phenomena. Its kinetic phase diagram involves both chaotic and quasi-periodic states of motion separated by a morphological phase transition that occurs with changing the RSE angular frequency.

11:27AM Z9.00002 Numerical investigation on the chaos assisted tunneling for a coupled microwave cavity1, HOSHIK LEE, Temple University, LOUIS PECORA, DONG HO WU, Naval Research Laboratory — It is known that chaos-assisted dynamical tunneling may occur in nonintegrable (chaotic) systems. Recently we investigate wave chaotic systems to see if the system may promote the chaos-assisted spatial tunneling in addition to the dynamic tunneling. Our previous experiments suggest some enhancement of the spatial tunneling rate in a coupled, wave-chaotic 2D microwave double cavity, indicating that the presence of chaotic modes changes not only the dynamical tunneling rate but also the spatial tunneling rate. To understand the underlying physics we carry out numerical simulations on nonintegrable 2D cavities as well as on integrable 2D cavities. We will present details about the experiments and numerical simulation results.

11:39AM Z9.00003 Scaling properties of delay times in one-dimensional random media1, JOSHUA BODYFELT, Department of Physics, Wesleyan University, Middletown, Connecticut, ANTONIO MENDEZ-BERMUDEZ, Instituto de Fisica, Universidad Autonoma de Puebla, Puebla, Mexico, ANDREY CHABANOV, Department of Physics and Astronomy, The University of Texas at San Antonio, Texas, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, Middletown, Connecticut — The scaling properties of the inverse moments of Wigner delay times are investigated in finite one-dimensional (1D) random media with one channel attached to the boundary of the sample. We find that they follow a simple scaling law which is independent of the microscopic details of the random potential. Our theoretical considerations are confirmed numerically for systems as diverse as 1D disordered wires and optical lattices to microwave waveguides with correlated scatterers.

11:51AM Z9.00004 Lyapunov exponent calculation via reconstruction of the invariant density function from iterative Chebyshev maximum entropy approach1, NAGENDRA DHAKAL, HIRO SHIMOYAMA, PARTHAPRATIM BISWAS, The University of Southern Mississippi — We apply a maximum entropy approach (MaxEnt) to compute invariant density functions to obtain the Lyapunov exponents. The method gives the solution by iteratively calculating the Lagrange multipliers within the maximum entropy method from moment constraints. We illustrate our method by reproducing known invariant densities for several cases of discrete maps (in both chaotic and non-chaotic regimes). The global convergence of invariant density function is studied with particular emphasis on Lyapunov exponent of the map by varying number of moments. We demonstrate that Lyapunov exponent of a chaotic map can be computed with a high degree of precision from this approach.

1University of Southern Mississippi, Grant No. DE00945
12:03PM Z9.00005 Time-Shifted Synchronization of Chaotic Oscillator Chains without Explicit Coupling Delays

Jonathan Blakey, Mark Stahl, Ned Corron, US Army RDECOM — It has recently been reported that time-shifted synchronization (i.e., lag or anticipation) of chaotic oscillators can result from forms of coupling that do not contain explicit delay terms. Identical time-shifted synchronization is not a solution in these systems so the dynamics are a form of generalized synchronization where trajectories are similar but not exactly identical. Here we examine chains of unidirectionally coupled oscillators in which time-shifted synchronization occurs without delays in the coupling. We observe the distortion of the waveforms of the response oscillators located far from the drive oscillator. Under weak coupling, we see much less distortion occurs over chains with significant total time shift than predicted by a recently introduced theoretical estimate. Under stronger coupling, we find better agreement with the theoretical prediction and, despite sometimes severe attenuation, propagation structure is maintained even over long chain lengths. We report results from numerical models as well as from an experimental system of electronic circuits. Such oscillator chains may prove useful in applications requiring a variable delay such as chaotic radar or beam forming.

12:15PM Z9.00006 Combining Wave Chaos and the Loschmidt Echo to Extend the Concept of Fidelity to Classical Waves

Dmitry V. Dynlov, Jason W. Fleischer, Princeton University, Princeton, NJ 08544, USA — We experimentally and theoretically consider a double-bump-on-tail instability of a classical laser system by applying the wave mechanical concept of fidelity loss to classical waves. The sensor makes explicit use of time-reversal invariance and spatial reciprocity in a wave chaotic system to sensitively and remotely measure the presence of small perturbations to the system. The loss of fidelity is measured through a classical wave-analog of the Loschmidt echo by employing a single-channel time-reversal mirror to rebroadcast a probe signal into the perturbed system. We also introduce the use of exponential amplification of the probe signal to partially overcome the effects of propagation losses. It is demonstrated that exponential amplification can be used to vary the spatial range of sensitivity to perturbations, thereby actively modifying the range of operation of the sensor. Experimental results are presented for both electromagnetic and acoustic versions of the Loschmidt echo based sensor.

12:27PM Z9.00007 Synchronization and Competition in a Double-Bump-on-Tail Instability

DMITRY V. DYLOV, JASON W. FLEISCHER, Princeton University, Princeton, NJ 08544, USA — We experimentally and theoretically consider a double-bump-on-tail instability by mapping the general wave-kinetic problem to a multiple beam propagation problem using statistical light. More specifically, we consider the nonlinear interaction of three spatially-incoherent beams in a self-focusing photoconstructive crystal. For weak nonlinearity, we observe instability competition and sequential flattening of the bumps in momentum space, with no observable variations in position-space intensity. This joint dynamics resembles the phase synchronization of a “classical” laser system (relaxation to a lower-energy state) with the corresponding intensity modulations appearing from the optical equivalent of inverse Landau damping. For strong nonlinearity, intensity modulations appear and the triple-hump spectrum merges into a single-peaked profile with an algebraic $k^{-2}$ inertial range. This spectrum, with its associated modulations, is a definitive observation of soliton, or Langmuir, turbulence.

12:39PM Z9.00008 Stratospheric Ozone and Dynamical Systems

FRANCISCO J. URIBE, ROSA MARIA VELASCO, ERNESTO PEREZ-CHAVELA, Universidad Autonoma Metropolitana — We consider the Chapman mechanism for stratospheric ozone dynamics. The resulting nonlinear differential equations are studied from the point of view of the theory of dynamical systems. In particular we calculate and analyze the nature of the critical points and show that the region in which the concentrations are non-negative is a positively invariant set, meaning that initial conditions with non-negative concentrations always give non-negative concentrations. Poincaré compactification is used to elucidate the global flow. Comments about the inclusion of nitrogen oxides are also given.

1:03PM Z9.00010 Scattering a pulse from a chaotic cavity: Transitioning from algebraic to exponential decay

James Hart, Thomas Antonsen, Edward Ott, University of Maryland — The ensemble averaged power scattered in and out of lossless chaotic cavities (such as microwave resonators, acoustic cavities and quantum dots) decays as a power law in time for large times. In the case of a pulse with a finite duration, the power scattered from a single realization of a cavity closely tracks the power law ensemble decay initially, but eventually transitions to an exponential decay. In this presentation, we explore the nature of this transition in the case of coupling to a single port. We find that for a given pulse shape, the properties of the transition are universal if time is properly normalized. We define the crossover time to be the time at which the deviations from the mean of the reflected power in individual realizations become comparable to the mean reflected power. We demonstrate numerically that, for randomly chosen cavity realizations and given pulse shapes, the probability distribution function of reflected power depends only on time, normalized to this crossover time. Paper: http://arxiv.org/abs/0810.1664

1:15PM Z9.00011 Stability of large complex systems

Harold Hastings, Hofstra University — We use a random matrix model to study the stability of large, complex systems. Our approach was motivated by a long-standing dilemma concerning stability of large systems. MacArthur (1955) and Hutchinson (1959) argued that more “complex” natural systems tended to be more stable than less complex systems based upon energy flow. May (1972) argued the opposite, using random matrix models. In prior work we showed that in some sense both are right: under reasonable scaling assumptions on interaction strength, Lyapunov stability increases but structural stability decreases as complexity is increased (c.f. Harrison, 1979; Hastings, 1984). We now apply these methods to a variety of complex systems.

1:27PM Z9.00012 Synchronization Delays and Fidelity of State Change in Chaotic Systems

Dmitry V. Dynlov, Jason W. Fleischer, Princeton University, Princeton, NJ 08544, USA — Time-reversal mirrors have been successfully used to demonstrate time-reversal invariance in a number of different situations. By employing a two-channel time-reversal mirror scheme, we have experimentally demonstrated that the Loschmidt echo is a universal phenomenon for chaotic systems. In this presentation, we investigate the effect of time delays on the Loschmidt echo. We show that, for randomly chosen cavity realizations and given pulse shapes, the probability distribution function of reflected power depends only on time, normalized to this crossover time. Paper: http://arxiv.org/abs/0810.1664

1:39PM Z9.00013 Stability of large complex systems

Harold Hastings, Hofstra University — We use a random matrix model to study the stability of large, complex systems. Our approach was motivated by a long-standing dilemma concerning stability of large systems. MacArthur (1955) and Hutchinson (1959) argued that more “complex” natural systems tended to be more stable than less complex systems based upon energy flow. May (1972) argued the opposite, using random matrix models. In prior work we showed that in some sense both are right: under reasonable scaling assumptions on interaction strength, Lyapunov stability increases but structural stability decreases as complexity is increased (c.f. Harrison, 1979; Hastings, 1984). We now apply these methods to a variety of complex systems.

1.27PM Z9.00012 The Initiation of Optical Breakdown in Simple Liquids, KEVIN CISSNER, Air Force Research Laboratories — The probability of breakdown in 40 simple HPLC hydrocarbons and water from a Q-switched laser at 1064 (6ns) and 532 nm (5 ns) was measured using a variety of lenses and cell path length. In each instance a plot of the cumulative distribution function vs. the input laser fluence fits an error-function well, except at low probabilities. Care was taken to measure the light distribution in situ across the entire focal plane. The transmission within the HOMO-LUMO gap was also measured using the long-path-length cells. Trends in the breakdown data with the optical/electronic properties of the target liquids are confounded by spherical aberration. However, the data suggest a connection to the chemical group of the liquid and especially to the C-X bond. In all cases the threshold at 1064 nm is actually less than that at 532 nm. No evidence was found for a mechanism involving dissolved air. A comparison is made to the behavior for static breakdown in gases.

1.39PM Z9.00013 Analysis of Laser Breakdown Data, ROGER BECKER, Air Force Research Labs — Experiments on laser breakdown for ns pulses of 532 nm or 1064 nm light in water and dozens of simple hydrocarbon liquids are analyzed and compared to widely-used models and other laser breakdown experiments reported in the literature. Particular attention is given to the curve for the probability of breakdown as a function of the laser fluence at the beam focus. Criticism is made of the naive forms of both “avalanche” breakdown and multi-photon breakdown. It appears that the process is complex and is intimately tied to the chemical group of the material. Difficulties with developing an accurate model of laser breakdown in liquids are outlined.

1.51PM Z9.00014 Fidelity Gap in Dynamical Systems with Critical Chaos, CARL T. WEST, Department of Physics, Wesleyan University, Middletown, Connecticut 06459, USA and MPI for Dynamics and Self-Organization, 37073 Goettingen, Germany — We analyze the fidelity decay for a class of dynamical systems showing critical chaos, using a Kicked Rotor with singular kicking potential as a prototype model. We found that the classical fidelity shows a gap $F_0$ (initial drop of fidelity) which scales as $F_0(\alpha, \epsilon, \eta) = \chi(\epsilon \equiv \frac{2\pi}{\alpha\eta})$ where $\alpha$ is the order of singularity of the non-analytical potential, $\eta$ is the characteristic spread of the initial phase space density and $\epsilon$ is the perturbation strength. Instead, the corresponding quantum fidelity gap is insensitive to $\alpha$ due to strong diffraction effects that dominate the quantum dynamics.

2.03PM Z9.00015 Irreversibility, Poincare Recurrence and Stochasticity in Statistical Mechanics, PURU GUJRATI, The University of Akron — We will show that deterministic dynamics always leads to the conservation of entropy and Poincare recurrence. Thus, recurrence is incompatible with entropy change. The law of increase of entropy can only occur for systems with stochastic dynamics, and the irreversibility emerges out of their indeterminate evolution as we will discuss. This stochasticity requires some weak but uncontrollable interaction of the system outside or the walls of the container. Boltzmann incurs this stochasticity in his deterministic approach by invoking the assumption of molecular chaos. The molecular chaos cannot emerge out of deterministic dynamics, as shown elsewhere in this meeting.

3Pradeep Fernando and P.D. Gujrati (poster)

11:15AM Z10.00001 Dielectric properties of cluster-deposited TiO$_2$ nanocomposites, B. BALAMURUGAN, University of Nebraska, KRISTIN KRAEMER, University of Nebraska, X. WEI, University of Nebraska, STEPHEN DUCHARME, University of Nebraska, D.J. SELLMYER, University of Nebraska — TiO$_2$-polymer nanocomposites are expected to have a high dielectric permittivity of TiO$_2$ and large breakdown strength of the polymer, resulting in high energy density suitable for energy storage devices. Since chemically prepared nanocomposites tend to have poor film quality and inhomogeneities due to agglomeration, cluster deposition technique was used to prepare monodispersed TiO$_2$-paraffin nanocomposite films. TiO$_2$ clusters were coated in-flight with paraffin wax having comparatively better dielectric strength (7.9 – 11.8 MV/m) using a thermal evaporation source in prior to deposition. Bare TiO$_2$ clusters with average particle size ranging from 8 to 12 nm having a maximum dielectric permittivity of 54 were obtained. The structural and dielectric properties of these nanocomposites with varying volume fractions will be discussed. This research is supported by ONR and NCMN.

11:27AM Z10.00002 Lattice Dielectric and Thermodynamic Properties of Yttria Stabilized Zirconia (YSZ) Solids, KAH CHUN LAU, Department of Chemistry, George Washington University, Washington D.C. 20052, BRETT I. DUNLAP, Code 6189, Naval Research Laboratory, Washington D.C. 20375 — A study of lattice dielectric and thermodynamic properties of Yttria Stabilized Zirconia (YSZ) solids as a function of yttria concentration is reported. Within the local density approximation (LDA) and the harmonic approximation, we find excellent agreement between calculated and experimental specific heat and dielectric constants. From the variation of the specific heat of YSZ with yttria composition, we propose a simple additive rule that estimates the dependence of the specific heat of YSZ on yttria concentration. Whereas for the dielectric constants of YSZ, the values are bounded by the dielectric constants of the cubic and amorphous zirconia.

11:39AM Z10.00003 Space-Charge-Limited Conduction Under Trap Density Gradient Exhibiting Bulk-Limited Diode, YUKIO WATANABE, Kyushu Univ. — Space-charge-limited (SCL) conduction in the presence of a trap density gradient is studied theoretically, which is compared with experiments in detail. Under this condition, the current ($J$) – voltage ($V$) characteristics at low voltage are ohmic and symmetric with respect to the bias polarity. At high voltage, $JV$ characteristics follow the $J \propto V^m \left(1 \leq m \leq 2\right)$ law at both polarities and are asymmetric with respect to the bias polarity. These characteristics have not been reported in the previous studies and agree well with experiments. These agreements verify that a bulk-limited conduction can exhibit rectifying, i.e., diode-like $JV$ characteristics without relying on Schottky barriers and diffusion currents. The theory is presented in easily tractable algebraic recurrence formulae and reproduces experimental $JV$ characteristics excellently using three free parameters, only one more than that used in standard SCL theory.

11:51AM Z10.00004 Optical second-harmonic generation measurements of porous low-k dielectric materials

JOANNA ATKIN, Columbia University, THOMAS SHAW, IBM Yorktown, ROBERT LAIBOWITZ, TONY HEINZ, Columbia University — Low-k dielectric materials based on porous carbon-doped oxides, with relative dielectric constants as low as 2.1, are widely used as thin insulating films in the microelectronics industry. Knowledge of these materials’ basic electronic properties, such as energy gaps, barrier heights, and trap states, is essential for modeling their electrical leakage and stability characteristics. We use femtosecond laser pulses to probe the dynamics of charge-carrier transfer processes across Si/LKD interfacial barriers by optical second harmonic generation (SHG). Larger electric fields from multiphoton injection can be developed in Si/LKD systems compared to Si/SiO2, indicating a significantly higher density of traps in the LKD. This is consistent with previously reported measurements of trap density by photoinjection techniques alike. We will also discuss results on the dynamics of discharging and on the dependence of charging phenomena on layer thickness. * J. M. Atkin, D. Song, T. M. Shaw, E. Cartier, R. B. Laibowitz, and T. F. Heinz, J. Appl. Phys. 103, 094104 (2008).

12:03PM Z10.00005 Energy-band parameters of atomic-layer-deposited Al2O3 and HfO2 on InxGa1-xAs

M.L. HUANG, Y.C. CHANG, Y.H. CHANG, T.D. LIN, M. HONG, J. KWO, National Tsing Hua University, DEPARTMENT OF MATERIALS SCIENCE AND ENGINEERING TEAM, DEPARTMENT OF PHYSICS TEAM — X-ray photoelectron spectroscopy (XPS) combined with reflection electron energy loss spectroscopy (REELS) were used to determine the energy-band parameters, valence-band offsets ΔEv, conduction-band offsets ΔEc, and energy-band gap Es, of the atomic layer deposited (ALD) high k dielectrics of Al2O3 and HfO2 on InxGa1-xAs (x=0, 0.15, 0.25, and 0.53). Using REELS, Eg values of the ALD-Al2O3 and -HfO2 were estimated to be 6.77 and 5.56 ±0.05 eV, respectively. The ΔEv’s and ΔEc’s are larger than 1.5 and 2.5 eV, respectively, for all the ALD-oxide/InGa1-xAs samples. The ΔEc values obtained from the HR-XPS and REELS analyses are in good agreement with those estimated from the electrical measurement according to Fowler-Nordheim tunneling. The results are valuable to the understanding and modeling of the III-V high k MOS devices.

12:15PM Z10.00006 Resonant photo-ionization of charged oxygen vacancy defects in Si/SiO2/HfO2 film stacks observed by second-harmonic generation.

J. PRICE, M. C. DOWNER, University of Texas, Austin — The semiconductor industry recently achieved a historic milestone with the introduction of high-k gate dielectrics. However, much effort continues to focus on characterizing defects in these materials that promote charge trapping. Using internal multi-photon photoemission (IMPE) and time-dependent electrostatic field-induced second harmonic (TD-EFISH) generation, we probe the charge trapping kinetics in Si/SiO2/HfO2 gate stacks. During IMPE charging, the TD-EFISH response of the HfO2 film uniquely increases and then decreases when irradiated at the characteristic three-photon energy of 4.71 eV. The decrease in TD-EFISH is explained by resonant three-photon excitation of HfO2-induced negatively charged oxygen vacancy defects in the SiO2 interfacial layer, and subsequent removal of its negative charge by tunneling to the Si substrate. This interpretation is supported by spectroscopic ellipsometry and electron spin resonance measurements, and ab initio calculations, which identify the 4.71 eV transition with this defect. Photo-ionization of this defect also explains hysteresis in the TD-EFISH response when charges trapped at the surface are quenched between successive IMPE charging cycles. The results demonstrate that second harmonic generation can potentially be used as an in situ, real time monitor of charge trapping kinetics prior to device fabrication.

12:27PM Z10.00007 Combined theoretical and experimental study of thin hafnia films

XUHUI LUO, ALEXANDER A. DEMKOV, The University of Texas, DINA TRIYSO, PETER FEJES, RICH GREGORY, STEFAN ZOLLNER, Freescale Semiconductor, Inc. — Hafnia-based dielectric films have replaced silica as a gate dielectric in field effect transistors. We present a joint experimental and theoretical study of ultra thin hafnia films grown on Si (001) by atomic layer deposition. Using density functional theory we investigate the surface energy of monoclinic and tetragonal hafnia films in search for thermodynamic means of controlling the film microstructure. Our calculations of the surface phase diagram reveal that in the absence of hydrogen (111), and (111) are the lowest energy surface terminations of monoclinic hafnia under a wide range of chemical environment. On the other hand, the structural analysis, indicates films with thickness of 4 nm or less to be polycrystalline, predominantly monoclinic with the texture axis being normal to the (211), (112). Our calculations suggest that under oxygen rich conditions the (112) termination can be stabilized. Furthermore, we discuss the effects of the hydroxylation on the thermodynamics of the hafnia film grown by ALD and provide a new perspective into the dynamics of the film growth.

12:39PM Z10.00008 Resonant Localized Nanoplasma in Oblique Far Infrared Reflectivity of Transition Metal Granular Films

N.E. MASSA, LANAINA EFO-CEQINOR, ULP, CC 962, 1900 La Plata, Argentina, J.C. DENARDIN, Dpto de Física, USACh, Santiago, Chile, L.M. SOCOLOVSKY, ITCI ,UBA, Buenos Aires, Argentina, M. KNOBEL, Inst. de Física, UNICAMP, Campinas, Brazil, X.X. ZHANG, INST- HKUST, Hong Kong, China — We report on near normal and angle dependent specular infrared reflectivity of transition metal and SiO2 cosputtered nanogranular ~550 nm thick films in the insulating regime. Their reflectivity is characterized by well defined vibrational bands, an overdamped Drude contribution, due to carriers denoting the existence of conducting critical paths not yet truncated, and a distinctive band at ~1450 cm⁻¹ originating in electron promotion, localization, and polaron formation. (TM) P-polarized oblique reflectivity, as from globally isolating Co3(38)SiO2(30.62)Fe3(34)SiO2(30.66) or Ni(28)SiO2(70.2), reveals a remarkable resonance at the ~1450 cm⁻¹ band threshold. Its maximum intensity is reached at the radiation tangential component null condition allowing for a collective electronic excitation induced as localized plasma. It is attributed to carriers that are not able to overcome the metal-dielectric rough interface. As the angle of incidence increases the longitudinal highest frequency vibrational band merges with the P-polarized resonance inducing broadening and softening reminiscent to lattice modes undergoing strong electron-photon interactions.

12:51PM Z10.00009 Phase Equilibrium of Size-Dispersed Colloid Systems with soft pair interactions: A Monte Carlo Study

JOANNIS BITSANIS, FORTH-IESL, Heraklion, Greece, IOANNIS ECONOMOY, MARIANNA YIANNOUKAKOU, NRCPs “Demokritos”, Ag. Paraskevi, Greece — We have studied the solid-fluid coexistence for systems of polydisperse soft spheres that interact via power-law potentials. We employed isobaric semi-grand ensemble simulations. Gibbs-Duhem integration traced the coexistence pressure as a function of the breadth of particle variance of the imposed activity distribution. Fluid-solid coexistence densities were determined to be monotonically increasing functions of the breadth of particle size dispersion, and ab initio calculations, which identify the 4.71 eV transition with this defect. Photo-ionization of this defect also explains hysteresis in the TD-EFISH response when charges trapped at the surface are quenched between successive IMPE charging cycles. The results demonstrate that second harmonic generation can potentially be used as an in situ, real time monitor of charge trapping kinetics prior to device fabrication.
**1:03PM Z10.00010 First-principles simulations of extended phosphorus oxynitride structures in LiPON glasses**¹, YAOJUN DU, N. A. W. HOLZWARTH, Wake Forest University — The thin film electrolyte LiPON, having the composition of Li$_{1.2}$PO$_{1.5}$F$_x$N$_{1-x}$ with $x = 3z - 2y$, was developed at Oak Ridge National Lab in the 1990’s for use in solid state batteries and related applications. In an effort to understand and to optimize properties of this electrolyte material, we expanded previous studies of isolated defects in crystalline Li$_{1.2}$PO$_{1.5}$F$_x$N$_{1-x}$ to focus on more complicated phosphate structures based on combinations of tetrahedral P–O bonds and bridging P=O–P bonds. For example, crystalline Li$_{1.2}$PO$_{1.5}$F$_x$N$_{1-x}$ and P$_2$O$_5$ are composed of phosphate structures with linear and branched chains, respectively. Both these and related structures derived from substituting O with N and adjusting mobile Li ion concentrations approximate components found in LiPON films. In the simulated structures, we find that N is energetically more stable at bridging bond sites than at tetrahedral sites by 2-3 eV and that the Li ion migration energies are 0.5–0.6 eV, similar to values measured in LiPON films.

¹Supported by NSF Grants DMR-0405456, 0427055, and 0705239.

**1:39PM Z10.00013 Low temperature C/T$^3$ peak in dipole disordered Bi$_{2}$Ti$_{2}$O$_{7}$** GAVIN LAWES, RON TACKETT, AMBESH DIXIT, Wayne State University, ART RAMIREZ, LGS Innovations, JIM O’BRIAN, Quantum Design, BRENT MELOT, RAM SESHAIDI, UC Santa Barbara — The presence of a low temperature peak in C/T$^3$ vs T, indicating excess entropy above the Debye contribution, is practically ubiquitous among both crystalline and amorphous materials. We present specific heat measurements on Bi$_{2}$Ti$_{2}$O$_{7}$, which is known to have incoherent ionic displacements leading to dipole disorder, and other related crystalline materials, including Bi$_{2}$NbInO$_{7}$, Bi$_{2}$Ti$_{2}$O$_{7}$, Y$_2$Ti$_2$O$_7$, and PbTiO$_3$, all of which exhibit excess low temperature entropy. We find that the C/T$^3$ peak for these samples agree roughly with a proposed scaling relation, with the peak temperature for Bi$_{2}$Ti$_{2}$O$_{7}$ among the lowest reported for any crystalline material. We discuss our results in the context of understanding the evolution of crystalline degrees of freedom to glassy degrees of freedom through our investigations of more complicated phosphate structures based on combinations of tetrahedral P–O bonds and bridging P=O–P bonds. For example, crystalline Li$_{1.2}$PO$_{1.5}$F$_x$N$_{1-x}$ and P$_2$O$_5$ are composed of phosphate structures with linear and branched chains, respectively. Both these and related structures derived from substituting O with N and adjusting mobile Li ion concentrations approximate components found in LiPON films. In the simulated structures, we find that N is energetically more stable at bridging bond sites than at tetrahedral sites by 2-3 eV and that the Li ion migration energies are 0.5–0.6 eV, similar to values measured in LiPON films.

**2:03PM Z10.00015 Using High-Voltage Direct Current in Removing Coke from a Zeolite Catalyst Grain**¹, ABDULAZIZ ALJALAL, King Fahd University of Petroleum and Minerals — Zeolite catalysts are commonly used in petroleum refining processes. Over a period of time, these catalysts lose their activity due to gradual deposition of carbonaceous materials, called coke. The coke catalysts are usually reactivated by combusting the coke at elevated temperatures in presence of an oxygen-enriched gas. But the elevated temperatures cause damages to the structure of the catalyst which result in reduced activity. Normally, the catalyst is reactivated 3 or 4 times before it must be returned to the manufacturer for reclamation of the valuable platinum and/or rhodium content. This study is an attempt to come up with a new procedure to remove coke from a zeolite catalyst grain using high-voltage direct current. It is found that the process is self-terminated due to the loss of electrical conductivity of the grain. In addition, it is found that there an optimum current range for which up to 90% of the coke can be removed. Higher or lower currents result in much smaller removal of the coke.

¹The support of KFUPM is acknowledged.

Session Z12 DCMP DMP: Phase Transitions at Surfaces 308
11:15 AM Z12.00001 A martensitic-like transition in a normal alkane, JEFFREY HUTTER, SHAILESH NENE, ERIC KARHU, ROBERTA FLEMMING, The University of Western Ontario — The normal alkanes, \( \text{C}_n \text{H}_{2n+2} \), with a structure consisting of a single chain, are the simplest hydrocarbons. These are an interesting class of material, both in terms of their intrinsic properties and the fact that many biological molecules contain hydrocarbon domains. Normal alkanes exhibit an unusual phase diagram with several solid phases, some of which—the “rotator phases”—are characterized by positional order without long-range orientational order. We have found a striking pattern of twinned, striped domains that occurs in thin layers the monolonic rotator RV phase of tricosane (\( \text{C}_{23}\text{H}_{48} \)). We have studied this structure, and its transitions to other phases, by X-ray diffraction, as well as by optical and atomic-force microscopy. Intriguingly, transitions between the RV phase and the RI orthorhombic phase lying at higher temperatures appear to be diffusionless, and preserve molecular-scale features even after multiple transitions between the phases. These properties are reminiscent of martensitic transformations, which are better-known in metal alloys, but occur here at convenient temperatures and with slow kinetics.

11:27 AM Z12.00002 Monolayer solids of short (perfluoro)alkanes on graphite, L.W. BRUCH, University of Wisconsin-Madison — Calculations are reported for the relative stability of monolayer solid lattices on graphite for \( \text{C}_n\text{H}_6, \text{C}_n\text{F}_8, \text{C}_n\text{F}_6, \) and \( \text{C}_n\text{F}_x \). Triangular, centered rectangular and two-sublattice herringbone lattices are treated. The calculations use all-atom (AA) models and are based on non-bonding interactions formulated for three dimensional dense phases of alkanes and perfluoroalkanes.

11:39 AM Z12.00003 Simulation of methane on Al(111), MAJID KARIMI, CARL LEBLOND, IUP, WAHYU SETYAWAN, STEFANO CURTAROLO, Duke University, RENEE DIEHL, Penn State University, DUKE UNIVERSITY COLLABORATION, PENN STATE UNIVERSITY COLLABORATION, IUP COLLABORATION — Classical many-body interatomic potentials for methane molecules interacting with Al(111) are developed using the embedded-atom method (EAM). The optimized EAM parameters for methane-Al(111) are obtained by fitting to the data generated from the first principles calculations. Adsorption of methane on the Al(111) substrate is studied using the Grand Canonical Monte-Carlo method. Adsorption isotherms are calculated at several temperatures near the triple point temperature of methane \( T_t = 90K \), and structural parameters obtained from the adsorbed density profiles. The structures and the thermodynamics of film growth are compared to methane adsorption on other metal surfaces, graphite and the d-Al-Co-Ni quasicrystal. This research is supported by NSF and ACS-PRF.

11:51 AM Z12.00004 Conformation-controlled networking of H-bonded assemblies on surfaces, M. ENACHE, M. MATENA, M. STOEHR, University of Basel, Switzerland, T.A. JUNG, Paul-Scherer-Institute, Switzerland, A. LLANES-PALLAS, D. BONIFAZI, Universita di Trieste, Italy — In order to prepare networks that could undergo phase transitions through a thermally-induced inversion of the molecular conformation leading to a variation of the intermolecular interactions, directional intermolecular forces can be regarded as promising candidates. In particular, H-bonding interactions will be exploited since their intermolecular interaction strength and geometry can be controlled by the number and arrangement of available H-bonding donor or acceptor moieties. We studied the 2D self-organization of a conjugated molecule bearing terminal 2,6-di(acylamino)pyridine moieties [1], which are well-known to form H-bonds, on a Ag(111) surface by STM. The hexagonal porous network, which is formed for room temperature deposition, is transformed into a close-packed rhombic pattern by a thermally induced trans-cis inversion of the terminal groups. This transformation can be explained by the fact that the system wants to minimize its energy: at the same time the free surface energy is minimized while the number of H-bonds per terminal group is doubled from two to four. [1] A. Llanes-Pallas et al., Angew. Chem. Int. Ed. 2008, 47, 7726

12:03 PM Z12.00005 IR enhancement and the surface potential of n-alkanethiol SAMs on GaAs(001), GREGORY M. MARSHALL, Department of Electrical and Computer Engineering, Université de Sherbrooke, Sherbrooke, CAN, GREGORY P. LOPINSKI, Steacie Institute for Molecular Sciences, National Research Council of Canada, Ottawa, CAN, FARID BENSAEBA, Institute for Chemical Process and Environmental Technology, National Research Council of Canada, Ottawa, CAN, JAN J. DUBOWSKI, Department of Electrical and Computer Engineering, Université de Sherbrooke, Sherbrooke, CAN — n-Alkanethiol self-assembled monolayers (SAMs) were prepared on the GaAs(001) surface according to [1]. FTIR modal analysis of the CH\(_2\) stretching mode region (2800-3000 cm\(^{-1}\)) verified SAM structural coherence, revealed evidence of an assembly threshold and allowed the absorption coefficient of the SAM phase to be directly measured. A 6x enhancement factor was observed relative to coefficients derived from the ion and polycrystalline phases. This effect is reviewed in terms of the molecular order and is largely attributed to the chemical properties of the surface [2]. Confirmation is provided by Kelvin Probe measurement of the sheet dipole potential, interpreted in terms of the Cooperative Molecular Field Effect [3]. [1] McGuiness et al., J. Am. Chem. Soc. 128, 5231 (2006). [2] Marshall et al., submitted. [3] Cahen et al., Adv. Funct. Mater. 15, 1571 (2005).

12:15 PM Z12.00006 Faceting of Ru(1120) Surface: A Model System for Catalysis, QUANTONG SHEN, WENHUA CHEN, HAO WANG, ROBERT BARTYNSKI, Rutgers University, PROFESSOR ROBERT A. BARTYNSKI TEAM — We have studied NO\(_2\)-induced faceting of a Ru(1120) surface by means of low energy electron diffraction (LEED), scanning tunneling microscopy (STM), and Auger electron spectroscopy (AES). By annealing the sample at \( > 600 \) K in NO\(_2\) \(-10^{-8}\) Torr, the surface becomes fully faceted as revealed by LEED although it is rather smooth, with only two layers exposed. The faceted surface remains the same at NO\(_2\) exposure ranging from 20 L to 12000 L and is stable for substrate temperature \( T < 850 \) K. The STM results confirmed the LEED observations and showed that the faceted surface consists of sawtooth ridges along the [001] direction with typical dimensions of \( \sim 5 \) nm in width and \( > 100 \) nm in length. We have found that the faceted O/Ru surface is very active for NH\(_3\) decomposition to produce H\(_2\) with high selectivity to N\(_2\) at room temperature.

12:27 PM Z12.00007 Oxygen-induced nano-faceting of the Pd(112) surface, ALINA VLAD, ANDREAS STIERLE, Max Planck Institute for Metals Research, 70569 Stuttgart, Germany, RASMUS WESTERSTROEM, EDVIN LUNGDREN, Department of Synchrotron Radiation Research, Institute of Physics, University of Lund, SE-221 00 Lund, Sweden, HELMUT DOSCH, Max Planck Institute for Metals Research — Extensive efforts are currently made to understand the elementary steps in heterogeneous catalytic reactions, with the ultimate goal of designing more efficient catalysts. The structure of the catalytically active particles, as well as the temperature and the gas phase pressure, play a decisive role in the behavior of these systems. We studied the interaction of oxygen with the Pd(112) surface from ultrahigh vacuum to atmospheric oxygen pressures by means of in-situ surface x-ray diffraction, high resolution core level spectroscopy and scanning tunneling microscopy. The rearrangement of the stepped (112) surface into different type of facets was observed and is strongly dependent on the oxygen pressure. The transition from different adsorbed-oxygen phases to the bulk oxide was also followed as a function of the oxygen pressure.
12:39PM Z12.00008 ABSTRACT WITHDRAWN

12:51PM Z12.00009 Phase-field theory for phase transition dynamics of reconstructed semiconductor surfaces, BANG-GUI LIU, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — We propose a natural two-speed model for the phase dynamics of Si(111) 7×7 phase transition to unreconstructed phase. Our simulated results show that a 7×7 island decays with its shape kept unchanged, and its area decay rate is a constant increasing with its initial area. LEEM experiments concerned are explained, which confirms that the dimer chains and corner holes are broken first, and then the stacking fault is remedied slowly. We also propose a phase-field-crystal model for the (2×1)-(1×1) phase transitions of Si(001) and Ge(001) surfaces. Simulated periodic arrays of dimerization is consistent with STM images. Calculated temperature dependence of the dimerization indicates that normal dimers and broken ones coexist between T_N and T_F, and a first-order phase transition takes place in between. This phase-field method is a reliable approach to phase dynamics of surface phase transitions. Phys. Rev. Lett. 100, 056103 (2008).

1:03PM Z12.00010 Investigation of Structural Phase Transitions on Wurtzite Gallium Nitride Surfaces, TIANJIAO CHEN, ABHIJIT CHINCHORE, YINGHAO LIU, KANGKANG WANG, WENZHI LIN, ARTHUR SMITH, Nanoscale and Quantum Phenomena Institute, Department of Physics and Astronomy, Ohio University, Athens, OH 45701 — Surface structures of wurtzite gallium nitride (w-GaN) have been investigated previously,[1][2] and it is well known that above 300K there exist order-disorder phase transitions. For N-polar w-GaN (000-1) at 300K, a family of surface reconstructions occurs, including 1×1, 3×3, 6×6, and c(6×12). Not much is known, however, about what happens to these structures as they are cooled below 300K. We have recently developed a new epitaxy/analysis system, including a sample stage which can be both heated and cooled. The N-polar w-GaN surfaces are prepared using rf N-plasma-assisted molecular beam epitaxy, and monitored in-situ using reflection high energy electron diffraction (RHEED). The approach is to monitor the [11-20] and [10-10] RHEED diffractions during cryogenic cooling, starting with the 1×1 or 3×3 structures. A critical issue to explore is the interrelationship between surface gallium concentration and structural deformation. This study may provide the missing link to new reconstructions of w-GaN recently observed using LT scanning tunneling microscopy.[3] This work is supported by NSF (Grant No. 0730257). [1] A. R. Smith et al., Phys. Rev. Lett. 79, 3934 (1997). [2] A. R. Smith et al., Surface Science 423, 70 (1999). [3] D. Acharya, S.-W. Hla et al., unpubished.

1:15PM Z12.00011 Magnetism of bulk CrO_2 and its (0001) surface: An ab initio study, SIQI SHI, Department of Physics, Center for Optoelectronics Materials and Devices, Zhejiang Sci-Tech University, ALEKSANDER WYSOCKI, KIRILL BELASHCHENKO, Department of Physics and Astronomy, University of Nebraska Lincoln — Magnetic properties of bulk CrO_2 and its (0001) surface are surface studied using the LSDA+U method. Magnetic energies are well fitted by the Heisenberg model and the Neel temperature is calculated using the quantum pair-cluster approximation. Very good agreement with experiment is found for the equilibrium volume, spectral density, local magnetic moment, band gap, and the Neel temperature. The stable (0001) surface is known to be terminated by a Cr semilayer [1], but its detailed structure is unknown. We identify two competing surface sites. The configurational surface Hamiltonian is constructed from supercells and the structural thermodynamics is studied. We find that in a wide range of temperatures about 1/3 of Cr atoms are below the oxygen layer and that there is a ordering phase transition from \sqrt{3} \times \sqrt{3} to 1 \times 1. Further, we find that (0001) surface has a unique feature of having an uncompensated magnetic moment that is not destroyed by surface roughness. This phenomenon makes CrO_2 a promising exchange bias application. [1] M. Bender, et. al. J. Phys. Condens. Matter 7, 5289 (1995).

1:27PM Z12.00012 Fingerprint of surface magnetism in CrO_3 based exchange bias heterostructures, XI HE, YI WANG, CH. BINEK, University of Nebraska-Lincoln — Magnetolectric (ME) compounds have a recent revival as promising components of novel spintronic devices [1, 2, 3]. Since the magnetoelastic (ME) effect is relativistically small in traditional antiferromagnetic (AF) compounds like CrO_2 (max. αzz ≈ 4ps/m) and also cross-coupling between ferroic order parameters is typically small in the modern multiferroics, it is a challenge to electrically induce sufficient magnetization required for the envisioned device applications. In exchange bias systems the bias field depends critically on the AF interface magnetization. Hence, a strong relation between the latter and the surface magnetization of the free CrO_2 layer can be expected. Our recent research indicates that there are two magnetic phase transitions in free CrO_2 films accompanying surface structural phase transitions. Well defined AF interface magnetization is initialized through ME annealing to T=20K. Subsequently, the interface magnetization is thermally driven through phase transitions at T=120 and 210K. Their effects on the exchange bias are studied in CrO_2 (111)/CoPt films with the help of polar Kerr and SQUID magnetometry. [1] P. Borisov et al. Phys. Rev. Lett. 94, 117203 (2005). [2] Ch. Binek, B.Doudin, J. Phys. Condens. Matter 17, L39 (2005). [3] R. Ramesh et al. 2007 Nature Materials 6 21. Financial support by NSF through Career DMR-0547887, MRSEC DMR-0820521 and the NRI.

1:39PM Z12.00013 Magnetic Susceptibility χ of O_2 in Confined Geometries, TIMOTHY PRISK, PAUL SOKOL, Indiana University Cyclotron Facility — Bulk solid oxygen exhibits three distinct crystallographic and paramagnetic phases, α, β, γ (in order of ascending temperature). The thermodynamic behavior of some systems, including their possible phases and phase transition temperatures, are known to change in interesting and nontrivial ways as these systems are subjected to confined geometries. Recent work by Kilburn and Sokol on the phonon density of states for confined solid oxygen indicates that the first of these crystallographic phases, α, is completely suppressed. The magnetic susceptibility χ of solid oxygen confined within various porous materials will be presented. The effect of confinement on the magnitude of the susceptibility χ and the transition temperatures will be discussed.

This work was supported by the U.S. Department of Commerce, under Grant 70NANB5H1163.

1:51PM Z12.00014 Size dependent transport of amorphous Indium Oxide films, SWATI SOMAN, DAN SHAHAR, Weizmann Institute of Science, Israel. — Superconductivity in presence of disorder is a topic of interest among experimentalists as well as theoreticians for past several decades. Experiments performed on disordered films of various materials, elemental as well as mixture, have demonstrated Superconductor to Insulator transition (SIT) with increase in disorder or externally applied magnetic field. Disorder is difficult to quantify. However, in an experiment it is controlled by tuning film thickness and/or composition. We present experimental evidence of SIT, in disordered, amorphous Indium Oxide (aInO_x) films, which is tuned by films’ lateral dimensions. By fabricating films of same thickness and composition in Hall bar geometry and changing only the sizes of Hall bars, we observe that the sheet resistance per square, R changes with the size of the square, contrary to its definition. The systematic dependence of R on square size is observed to occur only for a critical disorder, similar to percolation model. The observations suggest an inhomogeneous nature of transport near SIT in our samples which are found to be structurally homogeneous. We postulate that such size dependent transport properties are possible to observe in disordered films of other materials that exhibit SIT.
2:03PM Z12.00015 Impact of Boron Additions on the A1 to L1₀ Phase Transformation in FePt Alloy Films. B. WANG, K. BARMAK, Department of Materials Science and Engineering, Carnegie Mellon University, Pittsburgh, PA 15213 — The combination of high magnetocrystalline anisotropy energy density and good corrosion resistance has resulted in significant interest in L1₀ ordered alloys such as FePt for ultrahigh density, heat assisted magnetic recording (HAMR) media, with areal storage densities of ≥1Tb/in². When deposited at room temperature, these FePt forms in the chemically-disordered A1 state, requiring a post-deposition anneal to form the ordered L1₀ phase. Previous work has shown that the composition of FePt films has a significant impact on the kinetics and thermodynamics of the A1 to L1₀ phase transformation. In this paper, we report on the impact of ternary additions of B to FePt on the thermodynamic and kinetic parameters of the transformation. We also compare and contrast the impact of B additions with those of ternary additions of Cu and Ni. It is shown that the introduction of B into Pt-rich FePt films lowers the activation energy and the kinetic ordering temperature for the A1 to L1₀ phase transformation. However, this impact becomes negligible when B is introduced into Fe-rich FePt films.

Session Z14 DFD: Equilibrium Self-Assembly

11:15AM Z14.00001 Para-, ferro- and antiferro-magnetic order in beta-sheet tapes of oligopeptides. SARA JABBARI-FAROUJII, PAUL VAN DER SCHOOT, Eindhoven University of Technology — Beta-sheet-forming peptides give rise to self-assembled hierarchical structures such as tapes, ribbons and fibrils, which at sufficiently high concentrations form nematic liquid crystalline solutions and gels. Applications of these novel materials are found in nanotechnology, medicine and personal care products. Such aggregates not only appear in the context of desirable biomaterials but also in pathological self-assembly of mis-folded proteins, forming aggregates such as “amyloids”. Recently a theoretical model was developed to understand the properties of these self-assembling structures [1]. The question which arises is what happens if we mix different peptide species varying e.g. in length or interaction energy. Do they mix in self-assembled structures or form separate ones? This is of crucial importance as most of industrially produced materials are not monodisperse. To model the simplest polydisperse system, we apply two-component self-assembled Ising model, in which three energy contributions play a role, depending on the relative values of these energy scales and concentrations of the two components, different morphologies of tapes consisting of both components are formed exhibiting paramagnetic, ferromagnetic or antiferromagnetic order. [1] A. Aggeli, et al; PNAS 2001, 98, 11857

11:27AM Z14.00002 Self-assembly induced protein crystallization. HONGJUN LIU, SANAT KUMAR, Columbia University, JACK DOUGLAS, NIST — The strongly anisotropic nature of inter-protein interactions naturally leads them to self-assemble into structures mirroring the symmetry of the inter-protein potential. Self-assembly is a thermodynamically distinct phenomenon from phase separation, and we consider whether it can play a direct role in nucleating protein crystals. Previous simulations and measurements have established that protein clusters formed below the critical point for liquid-liquid phase separation (Tc) can facilitate crystal nucleation. However, recent experiments have indicated the existence of clustering-induced protein nucleation even for T > Tc, where phase separation does not exist. Here we simulate a minimal model of patchy particles and indeed find that transient clusters formed through self-assembly (even above Tc) can nucleate crystal growth. Importantly, the self-assembled clusters help to select the symmetry of the resulting crystal growth. In contrast, protein crystallization for T < Tc does not have this directing influence, and polycrystalline growth forms, such as spherulites, are then prevalent. Our simulations suggest that self-assembly directed crystallization might be common in protein solutions and that this process is relevant for understanding protein crystallization polymorphism.

11:39AM Z14.00003 Mechanisms for semi-flexible filament self-assembly: an experimental and simulation study. LAM NGUYEN, Center for Materials Research and Technology (MARTECH), Department of Physics, Florida State University, WEI YANG, STEVE ACQUAH, HAROLD KROTO, Department of Chemistry & Biochemistry, Florida State University, LINDA HIRST, School of Natural Sciences, University of California, Merced — The self-assembly of semi-flexible filaments, such as F-actin, in the presence of cross-linkers has been studied experimentally and via molecular dynamics simulation. Several imaging techniques including fluorescence and electron microscopy have been used to elucidate the structural properties of formed bundles and networks of filaments. With the help of simulation we are able to observe the dynamical process of the self-assembly and study the driving forces behind filament aggregation. The roles of different parameters such as cross-linker density and filament length have been investigated, determining the assembled system properties. We find both of these parameters to play a key role in the final structure formation. Understanding the mechanism for the self-assembly of these semi-flexible filaments will be very useful in the application of developing a new class of biological materials.

1This research is supported by MARTECH at Florida State University and by the National Science Foundation Biomaterials Program (DMR-0745786).

12:03PM Z14.00005 Reversible pH-Induced Structural Transition in a Polyelectrolyte-Surfactant System: from Semi-flexible Rod to String of Spheres. VIET LAM, LYNN WALKER, Carnegie Mellon University — We have characterized a polyelectrolyte-surfactant system that forms stable rod-like aggregates in aqueous solution. While this structure is stable to most changes in solution condition, we have observed a reversible change in behavior with pH. This is due to a pH-induced structural transition from the original semi-flexible rod at neutral pH to a more flexible object at acidic conditions. A simple model of polyelectrolyte chain crossing multiple surfactant spherical micelles, or a string of spheres, has been proposed as the structure of the aggregates at low pH. This represents a novel rod-like nanoscale system that goes through a reversible gelation with pH, with possible use in oil drilling (matrix acidification aid), liquid flow control, or transport of hydrophobic materials. Here, we will present a simple model of the structural change and experimental justification.
12:15PM Z14.00006 Self-Assembly of Highly Segregating Diblock Copolymer in Solution, DILRU RATNAWEERA, Clemson University, STEPHEN CLARSON, University of Cincinnati, DVORA PERAHIA, Clemson University — Solvent affinity drives the association of diblock co-polymers in selective solvents. The shape of the micelles is affected by the size of the blocks and their interaction with the solvent. Most experimental and theoretical studies have investigated solutions of diblocks with a relatively low incompatibility, requiring relatively large blocks to associate. The current work introduces a small angle neutron scattering study of a highly segregated diblock-copolymer, a trifluoro propylmethyl siloxane - polystyrene (PTFPMS-PS) in toluene, a good solvent for the polystyrene. Studies were carried out over volume fractions of 0.1 to 0.5 of the fluorinated siloxane segment. The high degree of segregation results in association into star-like micelles with the fluorinated siloxane in the core and a swollen corona even at very low volume fractions of the fluorinated segments. The micelles exhibit unique temperature stability in comparison with aggregates formed by diblock-copolymers in a lower segregation regime. The detailed structure of these aggregates as a function of volume fraction and temperature will be discussed.

12:27PM Z14.00007 Mesophases of soft-sphere aggregates, HOMIN SHIN, GREGORY GRASON, CHRISTIAN SANTANGELO, University of Massachusetts, Amherst — Soft spheres interacting via a hard core and purely repulsive shoulder self-assemble into clusters forming a variety of mesophases. We combine a mean field theory developed from a lattice model with a level surface analysis of the periodic structures of soft-sphere aggregates to study stable morphologies for a class of interaction potentials. The mean-field solution shows that the site occupation densities and interparticle potential are self-consistently related to an “effective field” acting on each particle. In the strong segregation limit, the space group symmetry of possible aggregate structures associated with the spatially modulated field, together with a half-filling condition at the interface of morphology, allows us to produce a phase diagram including Lamella, Hexagonal-columnar, and BCC phases, and their inverse phases in the parameter space of chemical potential and interparticle potential. Finally, we discuss the finite-temperature corrections to strong segregation theory in terms of Sommerfeld-like expansion and how these corrections affect the thermodynamic stability of bicontinuous mesophase structures, such as gyroid.

12:39PM Z14.00008 Breaking it up: Simulations of micelle fission in explicit solvent, MIKKO KARTTUNEN, The University of Western Ontario, MARIA SAMMALKORPI, MIKKO HAATAJA, Princeton University — We study self-assembly in micellar systems consisting of sodium dodecyl sulfate (SDS) using detailed 200-400 ns atomic scale molecular dynamics simulations. The simulations were done with explicit solvent, counterions and salt. We focus on the role of molecular level interactions driving self-assembly [1] and, in particular, show how micelle fission can be controlled using electrostatics. As our main result, we demonstrate the existence of a new fission pathway in charged micelles [2] and provide a physical explanation for it.

12:51PM Z14.00009 Neutron Scattering Analysis of the Dynamics and Structure of Semi-flexible, Self-Assembled Peptide Chain Networks and WormLike Micelles, N. WAGNER, M. BRANCO, D.POCHAN, J. SCHNEIDER, University of Delaware — Self-assembled peptide hydrogels are formed from synthetic β-hairpin peptides that undergo triggered self-assembly to form a physically crosslinked network of entangled fibrils. Upon salt addition at pH 7.4, these peptides fold into a β-hairpin self-assembly to form a rigid hydrogel stabilized by non-covalent crosslinks. A single amino acid substitution is performed to charge the peptide and greatly alter the rate of assembly. As a result, faster folding and self assembly kinetics are observed leading to more rigid gels. Transmission electron microscopy (TEM) and rheology demonstrate that the resultant, rigid networks of the semiflexible fibrils are composed of a bilayer of hairpins with a cross-sectional diameter of 3 nm, corresponding to the width of a folded peptide. Neutron spin echo (NSE) measurements show that the peptides can be modeled as semiflexible chains on length scales shorter than the characteristic chain size. The chain diffusivity is reduced by the peptide substitution and this can be attributed to alteration of the electrostatic interactions between peptides in the fibril. Small angle neutron scattering (SANS) measurements show a transition from a cylindrical rod-like geometry to a more branched, fractal-like network topology upon amino acid substitution. These measurements explain the large increase in gel modulus observed upon amino acid substitution. These results facilitate the rational design of self-assembling peptide materials for biomaterial applications. NSE results for semiflexible wormlike micelles will also be discussed.

1:03PM Z14.00010 Chiral Self-Assembly of Rodlike Viruses, EDWARD BARRY, ZVONIMIR DOGIC, ROBERT MEYER, Brandeis University, ROBERT PELCOVITS, Brown University, RUDOLF OLDENBOURG, Marine Biological Laboratory — The self-assembly of two dimensional achiral membranes which occurs in entropic mixtures of monodisperse colloidal rods and non-adsorbing polymers will be described. The colloidal nature of the rod/polymer model system enables us to simultaneously examine the behavior of self-assembled membranes at both the molecular and continuum lengthscales. Combining observations made at the very different lengthscales, we investigate how chirality frustrates assembly of achiral 2D membranes altogether, and instead drives the formation of very complex and highly regular chiral structures. Representative structures obtained through chiral self-assembly include: twisted ribbons, double helices, two dimensional analogs of a TGB phase, and regular arrays of pores embedded within a 2D membrane.

Friday, March 20, 2009 11:15AM - 2:15PM –
Session Z16 DAMOP: Bosons in Optical Lattices II

11:15AM Z16.00001 Optical lattice-based addressing and control of long-lived neutral-atom qubits, NATHAN LUNDBLAD, TREY PORTO, IAN SPIELMAN, RADU CHICIREANU, WILLIAM PHILLIPS, QJI/NIST/UMD — Many proposed quantum computational platforms are driven by competing needs: isolating the quantum system from the environment to prevent decoherence, and easily and accurately controlling the system with external fields. For example, neutral-atom optical-lattice architectures provide environmental isolation through the use of states that are robust against fluctuating external fields, yet external fields are inherently useful for qubit addressing. Here we demonstrate a technique to address qubits formed from a pair of field-insensitive states by transferring the qubit into a different pair of field-insensitive states. A spatially inhomogeneous external field allows the addressing of particular “marked” elements of a qubit register, leaving unmarked qubits unaffected, despite the presence of crosstalk or leakage of the addressing field. We demonstrate this technique in an ensemble of $^{87}$Rb atoms and show that we can robustly perform single-qubit rotations on qubits located at addressed lattice sites. This precise coherent control is an important step forward for lattice-based neutral-atom quantum computation, and is applicable to state transfer and qubit isolation in other architectures using field-insensitive qubits.

11:27AM Z16.00002 ABSTRACT WITHDRAWN –
11:39AM Z16.00003 Vortices near the Mott phase of a trapped Bose-Einstein condensate\textsuperscript{1}, DANIEL GOLDBAUM, ERICH MUELLER, Cornell University — We present a theoretical study of vortices within a harmonically trapped Bose-Einstein condensate in a rotating optical lattice. We find that proximity to the Mott insulating state dramatically affects the vortex structures. To illustrate we give examples in which the vortices: (i) all sit at a fixed distance from the center of the trap, forming a ring, or (ii) coalesce at the center of the trap, forming a giant vortex. We model the imaging of these structures by calculating time-of-flight column densities. As in the absence of the optical lattice, the vortices are much more easily observed in a time-of-flight image than in-situ.

\textsuperscript{1}This material is based on work supported by the National Science Foundation through grant No. PHY-0758104

11:51AM Z16.00004 Boson Hubbard model with weakly coupled fermions\textsuperscript{1}, SUMANTA TEWARI, Department of Physics, Clemson University, Clemson, SC, ROMAN LUTCHYN, Condensed Matter Theory Center (CMTC) and Joint Quantum Institute (JQI), Department of Physics, University of Maryland, College Park, MD, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD — Using an imaginary-time path integral approach, we develop the perturbation theory suited to the boson Hubbard model, and apply it to calculate the effects of a dilute gas of spin-polarized fermions weakly interacting with the bosons. The full theory captures both the static and the dynamic effects of the fermions on the generic superfluid-insulator phase diagram. We find that, in a homogenous system described by a single-band boson Hubbard Hamiltonian, the intrinsic perturbative effect of the fermions is to suppress the Mott insulating lobes and enhance the superfluid phase.

\textsuperscript{1}Work supported by ARO-DARPA

12:03PM Z16.00005 Boson Hubbard model with weakly coupled fermions: Effects of higher bands and shrinking of the superfluid phase\textsuperscript{1}, SANKAR DAS SARMA, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, MD, ROMAN LUTCHYN, Condensed Matter Theory Center (CMTC) and Joint Quantum Institute (JQI), University of Maryland, College Park, MD, SUMANTA TEWARI, Department of Physics, Clemson University, Clemson, SC — We study Boson Hubbard model with weakly coupled fermions and take into account the effects of the higher boson Bloch bands. For attractive couplings between the bosons and the fermions, mixing of the higher bands results in an effective enhancement of the boson on-site repulsion. The overall shift of the boson Hubbard phase diagram due to the presence of the fermions is thus determined by two competing effects: an effective fermion-mediated interaction between the constituent bosons (which favors the superfluid phase), and the renormalization of the boson-boson interaction due to the virtual boson transitions to the higher Bloch bands (which favors the Mott insulating phase). We find that the latter is typically dominant for the cold-atom experiments, which is consistent with the observed loss of the superfluid coherence in recent experiments.

\textsuperscript{1}Work supported by ARO-DARPA

12:15PM Z16.00006 Scattering Properties of Bose-Hubbard Hamiltonians with Two and Three Sites, MORITZ HILLER, STEFAN HU NN, Department of Physics, Albert Ludwigs University of Freiburg, Germany, TSAMPIKOS KOTTOS, Department of Physics, Wesleyan University, Middletown CT-USA and MPI for Dynamics and Self-Organization, Göttingen-Germany, DORON COHEN, Department of Physics, Ben-Gurion University, Beer-Sheva, Israel, ANDREAS BUCHLEITNER, Department of Physics, Albert Ludwigs University of Freiburg, Germany — We consider a probe particle in a tight binding with two leads and a central site that is coupled to a Bose-Hubbard system consisting of two or three wells (dimer/trimer). In the case of the dimer we find that the resonance widths undergo a sequence of bifurcations resulting from the complexity of the underlying classical phase space structure. For the trimer we show that the statistical properties of the scattering matrix are well described by the random matrix theory predictions for chaotic scattering. The origin of this agreement is due to the fact that inelastic scattering from a chaotic system (trimer) is formally equivalent to elastic scattering in a waveguide that has a chaotic mode space.

12:27PM Z16.00007 Quantum fluctuations and self-organization of a BEC in a multimode optical cavity, SARANG GOPALAKRISHNAN, BENJAMIN LEV, PAUL GOLDBART, University of Illinois at Urbana-Champaign — An ultracold bosonic gas, trapped in an optical cavity, crystallizes at either the even or the odd antinodes of the cavity mode, if the cavity is pumped transversely with a strong laser beam. Spontaneous symmetry breaking between even and odd antinodes is favored because atoms spaced one wavelength apart coherently emit light absorbed from the laser, populate the cavity with photons, and thus trap themselves in attractive optical potential wells. For a single-mode cavity, the transition to a crystalline state has been observed \cite{1} and is well described by mean-field theory \cite{2}. However, in multimode cavities, either confocal or concentric, fluctuations are enhanced and change the character of the transition, resulting in a quantal version of the Brazovskii transition in layering systems. We derive a field-theoretic description of the atom-cavity system near the transition, and describe how fluctuations and defects imprint themselves on the correlations of the light leaking out of the cavity. \cite{1} A.T. Black et al, Phys. Rev. Lett. 91, 203001 (2003). \cite{2} J.K. Asboth et al, Phys. Rev. A 72, 053417 (2005).

12:39PM Z16.00008 Role of Spatial Inhomogeneity in the Experimental Determination of the Two Dimensional Bose-Hubbard Model Critical Point, KHAN W. MAHMUD, University of California, Davis, VALERY G. ROUSSEAU, Institut-Lorentz, LIÓN, Universiteit Leiden, Postbus 9504, 2300 RA Leiden, The Netherlands, MARCOS RIGOL, Georgetown University, GEORGE G. BATROUNI, University of Nice, RICHARD T. SCALETTER, University of California, Davis — Recent experiments at NIST on confined Rb atoms in two dimensions, combined with high precision Quantum Monte Carlo (QMC) values for the homogeneous Bose-Hubbard model critical point, represented important progress toward testing the concept of optical lattice emulator. The experimentally determined critical coupling for the superfluid-Mott transition is in quite good agreement with the QMC results \(U/J_0 = 16.74\) for the homogeneous case. We present an analysis of these results which takes into account the spatial inhomogeneity arising from the confining potential. We perform a detailed QMC calculation of the density profile, local density fluctuations, and condensate fraction along the trajectory followed experimentally. We demonstrate how the number of atoms, optical lattice depth, curvature of the confining potential, and temperature in the NIST experiment, the critical value for the formation of Mott domains is rather close to that of the homogeneous system.

12:51PM Z16.00009 Superfluid to Mott-insulator transition of hardcore bosons in a superlattice, ITAY HEN, MARCOS RIGOL, Georgetown University — We present results of analytical and numerical studies of the superfluid to Mott-insulator transition of hardcore bosons in a superlattice potential in arbitrary dimensions. In this study, we use mean-field plus spin-wave corrections and the stochastic series expansion (SSE) algorithm to compute various properties of the system, such as the ground-state energy, the condensate fraction, the superfluid density, and the compressibility. We will show that in some cases the spin-wave approximation is in remarkable agreement with the exact numerical results.
1:03PM Z16.00010 The single-atom box: bosonic staircase and effects of parity, CHRISTOPH BRUDER, Department of Physics, University of Basel, 4056 Basel, Switzerland, D.V. AVERIN, T. BERGEMAN, Department of Physics and Astronomy, SUNY, Stony Brook, NY 11794-3800 University of Stony Brook, P.R. HOSUR, Department of Physics, Indian Institute of Technology Bombay, Mumbai 400076, India — We have developed [1] a theory of a Josephson junction formed by two tunnel-coupled Bose-Einstein condensates in a double-well potential in the regime of strong atom-atom interaction for an arbitrary total number \( N \) of bosons in the condensates. The tunnel resonances in the junction are shown to be periodically spaced by the interaction energy, forming a single-atom staircase sensitive to the parity of \( N \) even for large \( N \). One of the manifestations of the staircase structure is the periodic modulation with the bias energy of the visibility of the interference pattern in lattices of junctions. A different, e.g. fermionic, additional particle in the junction leads to non-trivial modifications of the staircase, that can be experimentally observed in the visibility of the interference pattern. [1] D.V. Averin, T. Bergeman, P.R. Hosur, and C. Bruder, Phys. Rev. A 78, 031601(R) (2008).

1:15PM Z16.00011 Spin field effect transistors with ultracold atoms\(^1\) , G. JUZELIUNAS, J. RUSECKAS, Institute of Theoretical Physics and Astronomy of Vilnius University, CHARLES W. CLARK, J.Y. VAISHNAV, Joint Quantum Institute, National Institute of Standards and Technology — We propose a method of constructing cold atom analogs of the spintronic device known as the Datta-Das transistor (DDT), which despite its seminal conceptual role in spintronics, has never been successfully realized with electrons. We propose two alternative schemes for an atomic DDT, both of which are based on the experimental setup for tripod stimulated Raman adiabatic passage. Both setups involve atomic beams incident on a series of laser fields mimicking the relativistic spin orbit coupling for electrons that is the operating mechanism of the DDT.

1:27PM Z16.00012 Vortex quantum dynamics of two dimensional lattice bosons, NETANEL LINDNER, ASSA AUERBACH, Physics Department, Technion, Israel, DANIEL P. AROVAS, University of California at San Diego — We study hard core lattice bosons in a magnetic field near half filling\(^2\). The strong periodic potential scatters the vortices by units of reciprocal lattice momenta, enhancing their mobility and modifying their effective Magnus field. The bare vortex hopping rate on the dual lattice is extracted by exact diagonalizations of square clusters. We deduce quantum melting of the vortex lattice above vortex density of \( 6.5 \times 10^{-3} \) per lattice site. The Hall conductivity, which reflects the vortex Magnus dynamics, reverses sign abruptly at half filling. The characteristic temperature scale of the Hall conductivity vanishes at the transition point. We prove that at half filling, each vortex carries a spin half quantum number ('v-spin'). Experimental implications of these results are relevant for diverse systems of current interest, e.g. cold atoms on rotating optical lattices, arrays of Josephson junctions and underdoped cuprate superconductors.

1:39PM Z16.00013 Mapping out the finite temperature phase diagram of the Bose-Hubbard model\(^3\), QI ZHOU, Department of Physics, The Ohio State University, YASUYUKI KATO, NAOKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo, QI ZHOU, Department of Physics, The Ohio State University, NAOKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo — We propose a method to experimentally map out the phase diagram of Bose-Hubbard Model at finite temperatures solely based on the density distribution of trapped bosonic atoms in optical lattices. Based on Quantum Monte Carlo simulations in a trap with 10\(^5\) bosons, we show that the phase boundary between the superfluid and normal state is directly located from kinks in the compressibility, which are extracted from the density profile itself. The temperature of bosons in the lattice is obtained from the density profile at the edge. Our method uses general aspects of critical fluctuations at a phase transition and can be extended to other systems, even when exact numerical simulations are not available.

1:51PM Z16.00014 Distributions of entropy and superfluid density of trapped bosons in optical lattices\(^4\), NANDINI TRIVEDI, Department of Physics, The Ohio State University, YASUYUKI KATO, Institute for Solid State Physics, University of Tokyo, QI ZHOU, Department of Physics, The Ohio State University, NAOKI KAWASHIMA, Institute for Solid State Physics, University of Tokyo — Based on a large scale quantum Monte Carlo simulations of the Bose Hubbard model using the worm algorithm\(^1\), we calculate the inhomogeneous distribution of entropy and superfluid density of trapped bosons in optical lattices. We show that most of the entropy is concentrated in the conducting shells. As the lattice is ramped up under adiabatic conditions, we show that the temperature increases and the superfluid regions in the trap can vanish. However, by opening up the trap at fixed lattice height, the system effectively cools, the entropy gets redistributed in the trap and superfluid regions reemerge. [1] Sharp Peaks in the Momentum Distribution of Bosons in Optical Lattices in Normal State Yasuyuki Kato, Qi Zhou, Naoki Kawashima and Randini Trivedi Nature Physics, 4, 617 (2008)

2:03PM Z16.00015 Observing the Quantum Spin Hall Effect with Ultracold Atoms, J.Y. VAISHNAV, Joint Quantum Institute, National Institute of Standards and Technology, Gaithersburg MD 20899, TUDOR D. STANESCU, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, CHARLES W. CLARK, Joint Quantum Institute, National Institute of Standards and Technology, Gaithersburg MD 20899, VICTOR GALITSKI, Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742 — The quantum spin Hall (QSH) state is a topologically nontrivial state of matter proposed to exist in certain 2-D systems with spin-orbit coupling. While the electronic states of a QSH insulator are gapped in the bulk, a QSH insulator is characterized by gapless edge states of different spins which counterpropagate at a given edge; the spin is correlated with the direction of propagation. Recent proposals\(^5\) suggest that synthetic spin-orbit couplings can be created for cold atoms moving in spatially varying light fields. Here, we identify an optical lattice setup which generates an effective QSH effect for cold, multilevel atoms. We also discuss methods for experimental detection of the atomic QSH effect.

11:39AM Z17.00003 Soft-pulse refocusing in the presence of Markovian dephasing. GREGORY D. QUIROZ, USC, LEONID P. PRYADKO, UCR — We consider the effect of Markovian decoherence on the performance of refocusing sequences. This is relevant if dynamical coupling is to be concatenated with quantum error correcting codes as the first stage of decoherence protection. The basic effect is that an asymmetric decoherence can cause a change in the direction of polarization of a quantum system. For example, dephasing of a single qubit reduces transverse components of the spin polarization vector, thus shifting it towards the z axis. In this work we construct perturbation expansions of effective decoherence operators for generic shaped pulses, and for several sequences of π and π/2-pulses. While in general the performance of soft pulses is worse that that of the ideal δ-pulses, the detrimental effect of dephasing can be reduced by pulse shaping.

11:51AM Z17.00004 Fock-Space Coherence in Quantum Dots. EDUARDO VAZ, JORDAN KYRIAKIDIS, Dalhousie University — We investigate the non-Markovian time evolution of the Fock-space coherence between states with different particle numbers in a multilevel quantum dot. By analyzing the off diagonal density matrix elements for a model for which the dominant relaxation mechanism is through sequential tunneling transport, we observe a decoupling between the evolution of the Fock-space coherence and that of the population probabilities for the dot states. When tunneling rates to distinct orbitals differ — a common occurrence — the decoherence time of the Fock-space elements of the density matrix can be dramatically increased even when the Hilbert-space coherence between states with particle number decreases. This is an example of how a many-body coherence can remain robust even in the presence of rather large single-particle noise.

12:03PM Z17.00005 Randomized Benchmarking of Superconducting Qubits. JERRY M. CHOW, Yale University, JAY GAMBITTA, University of Waterloo, LARS TORNBERG, Chalmers University, JENS KOCH, LEV BISHOP, ANDREW HOUCIK, STEVEN GIVIN, Yale University, ROBERT SCHÖLEKOPF, YALE CIRCUIT QED TEAM — We present measurements of average gate errors for a superconducting qubit using randomized benchmarking [1]. The results are compared with gate errors obtained from a double π pulse experiment and quantum process tomography. Randomized benchmarking reveals a minimum average gate error of 1.1 ± 0.3% and a simple exponential dependence of fidelity on the number of applied gates. It shows that the limits on gate fidelity are primarily imposed by qubit decoherence and finite gate lengths (constrained by qubit anharmonicity), in agreement with theory.

12:15PM Z17.00006 Simulating quantum spin systems with superconducting electrical circuits. EMILY PRITCHETT, MICHAEL GELLER, University of Georgia — There is currently great interest in the simulation of quantum spin and lattice models using cold atoms. Motivated by experimental progress in the fabrication and control of superconducting electrical circuits and their use in quantum information processing, we investigate their use as simulators of quantum spin systems, and consider a wide family of spin models that can be simulated with existing Josephson junction devices.

12:27PM Z17.00007 Electromagnetic radiation emanating from the molecular nanomagnet Fe₈. AMIT KEREN, Department of Physics, Technion - Israel Institute of Technology, Haifa 32000, Israel, OREN SHAFIR, Physics Department, Technion-Israel Institute of Technology, Haifa 32000, Israel. — Photons emitted by transition between the discrete levels of single molecular magnets have an interesting property: their wave length can be similar to that of the sample size. This is the elementary condition for Dicke's super-radiance. In this radiative process a short intense pulse of light from a molecular system appears as a result of enhanced spontaneous emission rate due to interactions via the electromagnetic field. Conversely, several investigators have been looking for this type of radiation in the molecular magnet Mn₁₂, where energy bursts were reported after magnetic avalanches. We investigate the same phenomenon in the Fe₈ molecule. Unlike in Mn₁₂, we found energy bursts each time there is a jump in the magnetization, confirming their quantum nature. A series of tests indicated that photons carry out the energy. These photons obey the elementary conditions for super-radiance.

12:39PM Z17.00008 Asymmetries in electron spin resonance signal of magnetized spin chains and quantum wires due to spin-orbital interactions. SUHAS GANGADHARAAIHAV, University of California, Irvine, OLEG STARYKH, University of Utah, Salt Lake City — We discuss consequences of the symmetry breaking Zeeman and uniform Dzyaloshinskii-Moriya (DM) terms for the electron-spin-resonance (ESR) measurements in a spin-1/2 Heisenberg anti-ferromagnetic spin chain. At the non-interacting level, a non-orthogonal orientation of the magnetic field and DM vector leads to a sharp delta-function ESR signal for the right and left moving excitations. The peak positions and their intensities generally differ, and can serve as a possible chiral probe for the two excitations. Similar results hold for a magnetized quantum wire with spin-orbit terms. Including a momentum dependent fluctuations in the spin-orbit coupling smears the delta-function and instead results in an asymmetric square root singularity. We discuss the role of temperature and interactions in the further modification of the ESR signal.

Friday, March 20, 2009 11:15AM - 2:15PM — Session Z18 DPOLY: Surfaces and Adsorption II 319

11:15AM Z18.00001 Dynamics of six-member molecular rings adsorbed onto graphite and MgO(100). JOHN Z. LARESE, Oak Ridge National Laboratory and University of Tennessee, PETER YARON, University of Tennessee — Molecular dynamic studies of adsorption of six-member molecular rings (cyclohexane and benzene) onto various substrates (like MgO(100) and graphite) have been undertaken using a commercial modeling package (Materials Studio by Accelrys Software Inc.) that employs central force field potentials. These studies indicate that both systems exhibit rotational translational coupling and strong signs that the translational diffusion is lattice-like on graphite. The cyclohexane rotational motion has a distinct out of plane component coupled to the translational diffusion much like the rolling motion of a wobbly wheel with three hydrogen atoms in “contact” with the substrate plane, while the benzene is more planar. These studies will be compared to results of neutron scattering investigations of the temperature dependence of the dynamics.

1 Supported by the U.S. Department of Energy, Materials Science Division under contract No. DE-AC05-00OR22725 with Oak Ridge National Laboratory and operated by UT-Battelle, LLC, and the National Science Foundation under grant DMR-0412231.
The scaling parameter has no universal value but depends on the molecular length. C12, C24) of different lengths (7-30 ˚A) are scaled down by the use of the “scaling factor” (SF). Typically, this SF is assumed to be universal (and ∼ 0.5). In this talk, we study this universality hypothesis by comparing computational and experimental melting temperatures of alkane monolayers adsorbed on a solid graphite surface. In particular, melting of the bilayer is preceded by compression of the first layer, which has not been observed before. The results are compared with simulations of two similar systems: (i) three nitrogen layers confined in slit graphite pore, and (ii) an adsorbed incommensurate structure that mimics low temperature alpha phase of bulk nitrogen.

Surface Hopping and Sliding of Single DNA Chains under Electric Field, BENXIN JING, JIANG ZHAO, Institute of Chemistry, Chinese Academy of Sciences, Beijing, China — The motion of non-adsorbing DNA chains under electric field at solid-liquid interfaces was investigated by single molecule fluorescence microscopy at the total internal reflection geometry (TIRF). In-situ observation discovered that the motion of single non-adsorbing lambda-DNA chains was hopping-and-sliding-like along the surface. By varying the surface chemistry of the solid substrates, from the negative-charged hydroxyl group-rich surface to positive-charged amino group-rich surface, as well as hydrophobic surfaces, the dependence of DNA mobility on the surface-DNA interaction was studied. The results show that a well-defined dependence of the mobility of DNA on the surface polarity with respect to DNA itself. The study on different surfaces such as hydroxyl, amide, amino, and methyl-group rich surface show a sequence of DNA mobility of hydroxyl > amide> amino. The mobility of DNA on methyl terminated surface was found to be similar to that in amino surface.

First Principles study of the formation of molecular junctions: benzenethiolate on Au (111), YONGDUO LIU, VIDVUDS OZOLINS — We perform density functional calculations to study the formation mechanism of benzenethiolate molecular junctions on the Au (111) surface. Specifically, we investigate the geometry change and the mechanical properties of the molecular contact when it is under stretching. It is found that by pulling up the thiolate molecule from Au (111), one Au surface atom can be converted to an adatom. Moreover, if the stretching is continued, another Au atom would successively be pulled up to form a two-atom bridge between the Au (111) and the sulfur end group. Based on these findings, we propose a mechanism to the formation of pyramidal molecular junctions: benzenethiolate on Au (111).

Molecular Dynamics Simulation of friction in contact-mode Atomic Force Microscopy of alkane films and nanoparticles, F.Y. HANSEN, Tech. U. of Denmark, P. SOZA, P.U. Catolica Chile, H. TAUB, U. Mo-Columbia, U. VOLKMAN, P.U. Catolica Chile — In addition to sample topography, contact-mode Atomic Force Microscopy (AFM) can yield the lateral frictional force experienced by the AFM tip as it moves across a surface. This frictional force is measured by the torsional angle of the microscope’s cantilever arm, which, in the case of a surface composed of highly anisotropic alkane molecules, can depend on the molecular orientation. We have conducted molecular dynamics simulations of an AFM tip moving over films and nanoparticles of C14H30 (C24) in the contact mode. For films in which the long axis of the C24 molecules is oriented parallel to the surface, we find a smaller frictional force in a scan direction perpendicular to the long axis than parallel to it. On surfaces where the alkane molecules are oriented perpendicular to the interface, we find that in all scan directions the frictional force is less than when the long molecular axis is parallel to the interface. All of these findings are consistent with experimental observations.

The Measurement of Surface Rheological and Surface Adhesive Properties of a PDMS Rubber using Micro- and Nano-Particle Embedment, STEPHEN HUTCHESON, GREGORY MCKENNA, Texas Tech University — In previous work, we used particle embedment data to determine the rheological response of the surfaces of a polystyrene film, a phase separated copolymer and a commercially available polydimethylsiloxane (PDMS) rubber through the application of a viscoelastic contact mechanics model. The goal of the current research is to build off this analysis and use micro- and nano-sphere embedment experiments to probe the surface rheological behavior of PDMS in the rubbery state. The work includes measurements made with different particle diameters and chemistries. An atomic force microscope (AFM) is used to measure the embedment depth as nanoparticles are pulled into the surface by the thermodynamic work of adhesion. Present results show that silica probes of different sizes (500 nm and 300 nm) give different results for the surface adhesion properties and the surface rheological properties determined from the particle embedment data and at scales much larger than the nanometer size scale where one might expect such deviations. Possible water entrapment and effects of particle surface composition on the results will be discussed.

Test of the universality of the scaling energy in alkanes based on the melting transition of monolayers adsorbed on graphite, L. FIRLEJ, Université Montpellier 2, B. KUCHTA, Université de Provence, M. ROTH, University of Northern Iowa, C. WEXLER, University of Missouri — The quality of the results of computational treatment of complex systems depends crucially on the quality of the interaction potentials used. When modeling non-rigid molecules an essential difficulty resides in the correct accounting for all energies related to internal degrees of freedom. Of particular importance is to avoid over- or under-counting non-bonded intramolecular van der Waals and electrostatic interactions between close neighbors that are chemically bonded. In many force fields (e.g. CHARMM) 1-4 non-bonded interactions are scaled down by the use of the “scaling factor” (SF). Typically, this SF is assumed to be universal (and ∼ 0.5). In this talk, we study this universality hypothesis by comparing computational and experimental melting temperatures of alkane monolayers adsorbed on a solid graphite surface. Three alkanes (C6, C12, C24) of different lengths (7-30 Å) have been analyzed using an all-atom representation, standard CHARMM parameters, and various SF’s. We show that the scaling parameter has no universal value but depends on the molecular length.

12:39PM Z18.00008 The role of local domain formation in the melting of hexane adlayers on graphite\textsuperscript{1}, M.W. ROTH, Univ. of Northern Iowa, L. FIRLEJ, B. KUCHTA, C. WEXLER, Univ. of Missouri — Hexane is the shortest alkane [CH$_3$-(CH$_2$)$_n$-CH$_3$] whose flexibility has any considerable impact on its dynamics. When adsorbed on graphite, a monolayer of hexane melts at a temperature of approximately 175 K. To understand the mechanisms of this transition we have performed large scale molecular dynamics simulations (several runs over 100 ns, total computation time ~ 10 cpu-years), using the most realistic model of the system (a fully atomistic representation of hexane, explicit site-by-site interaction with graphite carbons and CHARMM force field with carefully chosen adjustable parameters of interactions). We show that the melting of the low temperature herringbone solid phase starts with the formation of gauche defects at the ends of neighboring molecules, followed by molecular reorientation within a lamella, without perturbing the overall structure of the adsorbed film. The melted phase has a domain-type structure with domains’ orientation that reflects the 6-fold symmetry of graphite. The size of domains decreases progressively when the temperature increases and the deformation of molecules to quasi globular shape is driven by progressive formation of gauche defects.

12:51PM Z18.00009 Chain-length dependence in surface stresses of alkanethiolate-covered Au(111)\textsuperscript{1}, V. SRINIVASAN, Berkeley Nanoscience and Nanoengineering Institute, UC Berkeley, CA 94720, G. CICERO, Materials Science and Chemical Engineering Department, Politecnico di Torino, C.so Duca degli abruzzi 24, 10129, Torino, Italy, J. C. GROSSMAN, Berkeley Nanoscience and Nanoengineering Institute, UC Berkeley, CA 94720 — We have recently shown\textsuperscript{[1]} that adsorption-induced stresses in alkanethiolate-covered Au(111) contribute significantly to the stress-response in nano-mechanical cantilever sensors. In particular, we proposed a local stress relief (LSR) mechanism whereby charge removal by the Au-S bond from the Au surface promotes a stress reducing rearrangement of surface Au atoms. Since LSR depends on the nature of the Au-S bond it was unclear how the contribution to the stress- response would depend on the alkanethiolate structure. We present a first-principles study of the chain-length dependence in surface stresses of alkanethiolate-covered Au(111). We find that the surface stress upon adsorption is anisotropic and tensile, increasing in magnitude with the chain-length. We analyze this trend in the context of the LSR mechanism and inter-adsorbate interactions.

\textsuperscript{1}Supported by LDRD/Lawrence Livermore National Laboratory and UC Berkeley/NSF Grant No. 0425914

1:03PM Z18.00010 All-atom Molecular Dynamics simulations of partial pentane and hexane films on graphite\textsuperscript{1}, J. KASPAR, M.W. ROTH, University of Northern Iowa, CARLOS WEXLER, University of Missouri, L. FIRLEJ, Université Montpellier, B. KUCHTA, Université de Provence — We compare the self-assembly patterns of pentane (C$_{5}$H$_{12}$) and hexane (C$_{6}$H$_{14}$) adlayers physisorbed onto graphite at various coverages using the results of molecular dynamics simulations. Near monolayer coverage, the solid low temperature structure of the pentane film is nematic-like, and that of hexane-herringbone-like. At submonolayer coverages both systems exhibit three distinct topological regimes: vacancy patches in surface stresses of alkanethiolate-covered Au(111). We find that the surface stress upon adsorption is anisotropic and tensile, increasing in magnitude with the chain-length. We analyze this trend in the context of the LSR mechanism and inter-adsorbate interactions.

\textsuperscript{1}Work supported by the U.S. Department of Energy (DE-FG02-07ER46411) and the American Chemical Society Petroleum Research Fund (PRF43277-B5). Computational resources were provided by the University of Missouri Bioinformatics Consortium.

1:15PM Z18.00011 Temperature Dependent Adsorption Dynamics of Binary Mixtures of Halomethanes on Graphite and α-quartz Surfaces\textsuperscript{1}, JONATHAN NEHRING, North Park University, G. LEUTY, MESFIN TSIGE, Southern Illinois University at Carbondale — Using atomistic molecular dynamics simulations, we have investigated the structure and dynamics of binary mixtures of halomethanes (CF$_{3}$, CF$_{2}$Cl, and CF$_{2}$Br) as a function of temperature on two structurally and chemically different surfaces. The initial distribution of the binary mixture is either they are uniformly mixed or a layer or layers of one component is placed on top of a layer or layers of the other component. As a function of temperature (below and above the melting temperature of CF$_{3}$) and the two surface types, we observed a marked change on the concentration, dynamics, orientation, and structure of each of the components in the first layer of the binary mixtures next to the surfaces.

1:27PM Z18.00012 Liquid Chromatography at Critical Conditions: Balancing size exclusion and adsorption in nanopores\textsuperscript{1}, ASEM ABDULAHAD, JEFFREY AMOS, CHANG RYU, Rensselaer Polytechnic Institute — Liquid chromatography at critical condition (LCCC) is a measure to identify thermodynamic conditions, in which polymers elute independently of molar mass during high performance liquid chromatography. Under these critical conditions the entropic exclusions that dominate size exclusion chromatography (SEC) and the enthalpic adsorption that governs adsorption-based interaction chromatography (IC) are said to negate one another resulting in simultaneous elution of the polymer of different molecular weights. Using multiple C18-bonded silica columns with different average nanopore sizes (from 5 nm to 30 nm), we will study the LCCC conditions of PS in methylene chloride/acetone solvent mixture at different temperature. In addition, we will show that the separation of polystyrene can be fine tuned using a refined temperature gradient interaction chromatography (TGIC) that employs multiple columns of varying pore size in sequence.

\textsuperscript{1}This work is supported by the Nano / Bio Interface Center at the University of Pennsylvania and the U.S. National Science Foundation under grant number DMR-0425780.

1:39PM Z18.00013 Using Amphiphilic Copolymers and Nanoparticles to Organize Charged Biopolymers\textsuperscript{1}, JUNG HYUN PARK, MARLA MCCONNELL, YUJIE SUN, YALE GOLDMAN, RUSSELL COMPOSTO, University of Pennsylvania — Nanoparticles (NPs) on amphiphilic random copolymers control filamentous actin (F-actin) attachment. 3-aminopropyltriethoxysilane (APTES) coated silica NPs are selectively bonded to acrylic acid groups on the surface of a polystyrene-r-acrylic acid (PS-r-PAA) film. By changing the concentration of NPs in the medium, the surface density of positively charged anchors is tuned. Using total internal reflection fluorescence (TIRF) microscopy, immobilization of F-actin is observed via electrostatic interaction with NPs at high NP coverages. Below a critical coverage, F-actin is weakly attached and undergoes thermal fluctuations near the surface. Another method to tune F-actin attachment is to use APTES to cross-link and create positive charge in PAA films. Here, the surface coverage of F-actin decreases as APTES concentration increases. This observation is attributed to an increase in surface roughness and hydrophobicity that reduces the effective surface sites that attract F-actin. In addition, in-situ G-actin polymerization to F-actin is observed on both the NP and cross-linked PAA templates.

\textsuperscript{1}This work is supported by the Nano / Bio Interface Center at the University of Pennsylvania and the U.S. National Science Foundation under grant number DMR-0425780.
SCOTT MILNER, Penn State University — The conformation of polymer chains emerging from the face of a crystalline lamella has long been a matter of dispute. Long ago, arguments pitted “adjacent reentry” versus the “switchboard model” as extreme limits of possible behavior. Later, two theoretical approaches were attempted, but one (the Gambler’s Ruin model) did not properly account for the constraint of melt density, and the other (heuristic configuration counting of Flory et al.) did not account for chain connectivity. These shortcomings are resolved by a new “pseudobrush” theory of the amorphous interphase, which represents the reentrant chains as a polydisperse brush of loops in a self-consistent hydrostatic pressure field. This theory predicts the fraction of adjacent reentry, shows how the anisotropy of the interphase dies away with distance, and how the Gambler’s Ruin model is recovered far from the interface. Extension to the case of a finite slab between two crystal-melt interfaces predicts the frequency of tie chains, a key parameter for nonlinear deformation and ductile failure of semicrystalline polymers.

BERNARD LOTZ, Institut Charles Sadron, Strasbourg, INSTITUT CHARLES SADRON TEAM — The major structure and morphology features of polymer lamellae (and single crystals) are usually defined by the characteristics of the crystal lattice (cell geometry and symmetry, stem length). However, the fold surfaces that sandwich the crystalline core may have an impact on that crystalline core. In isotactic polyolefins, restrictions on the relative (up/down) orientation of stems linked by a fold may result in lowered unit-cell symmetry. Also, surface stresses linked with the presence of folds determine to a large extent the non-planar shape of polymer crystals. In bulk crystallization, they may induce twisted and/or scrolled lamellae. However, this impact can be inferred only for specific polymers and/or crystal structures and/or unit-cell symmetries. (Work performed with Dr. A. Thierry and J. Ruan.)

11:39AM Z19.00003 Unexpected Observation of 2.5 Dimensional Growth of Polymer Spherulite.  
DUJIN WANG, Dr., Prof., CHANGMING WANG, YING ZHAO, JINLIANG SONG, BUXING HAN — Preparation of integrated polymer spherulite from both solution and melt has been a challenging subject. In this letter, micro-sized spherulites of ultrahigh molecular weight polyethylene (UHMWPE) have been successfully prepared from supercritical ethanol. The spherulite grows to 2.5 but not 3 dimensions with only one nucleation site on the surface. The 2.5 dimensional growth makes it possible to observe both the nucleation site and sheaf-like structure on the surface of a spherulite and to obtain one global final spherulite as a single particle. A possible mechanism for the particular morphology of spherulites is proposed based on the contributions of surface nucleation on polymer droplet, high molecular weight of UHMWPE as well as the soft confinement of supercritical fluid.

11:51AM Z19.00004 Structural evolution under uniaxial drawing of Poly(D, L-lactide) Films.  
GREGORY STOCLET, JEAN-MARC LEBREVRE, ROLAND SEGUELA, Laboratoire de Structure et Proprietes de l Etat Solide — Aliphatic polyesters are an important class of biodegradable polymers. They have drawn particular attention in the last few years as food packaging materials because they can be derived from renewable resources. Among this family, polylactide (PLA) is considered as one of the most promising “green” polymer for use as a substitute to petroleum-based polymers. In the present work, we investigate the mechanical behaviour of amorphous poly(D, L-lactide) films in relation to the structural evolution upon stretching at various draw temperatures (Td) above the glass transition temperature. Examination of the drawing behaviour shows that PLA initially behaves like a rubbery material until a true strain of the order of 1. Strain hardening occurs beyond this strain level, up to film fracture. Such strain hardening is generally ascribed to a strain induced crystallization phenomenon. In the present case, it is clearly more pronounced for Td = 90 °C than for Td = 70 °C. The corresponding structural evolutions are investigated by means of WAXS. The diffraction patterns reveal the marked influence of draw temperature. Indeed for Td = 70 °C a mesophase is induced whereas strain-induced crystallisation takes place at Td = 90 °C. Further work is in progress, in order to elucidate mesophase development and mechanical response.
12:03PM Z19.00005 Vitrification and Devitrification of Rigid Amorphous Fraction of PET during Quasi-isothermal Cooling and Heating\textsuperscript{1}, PEGGY CEBE, HUIPENG CHEN, Tufts University — Poly(ethylene terephthalate), PET, was studied by quasi-isothermal (QI) Temperature Modulated Differential Scanning Calorimetry (TM-DSC). For the first time, both the temperature dependent crystallization fraction and rigid amorphous fraction (RAF) were quantitatively analyzed during QI cooling and reheating. Specific reversing heat capacity measurements show that most RAF vitrifies step by step during QI cooling after completion of crystallization. Upon subsequent QI reheating, the RAF devitrifies also step by step and only a small RAF of 0.04 remains at 470K, while melting starts above 473K. To obtain the exact temperature of the start of melting, heat capacity measurements were made using subsequent standard DSC heating, after QI cooling. By combining this method with the QI results, the temperature dependent phase fractions were obtained during standard DSC heating. We conclude that RAF completely devitrifies before the temperature reaches the crystal melting endotherm under the conditions used in this work.

12:15PM Z19.00006 Crystallization of Model Long Chain Branched Polyethylenes with Different Branching Architectures, M. VADLAMUDI, R. G. ALAMO, FAMU-FSU College of Engineering — While the impact of long chain branching (LCB) of different architectures (stars, α − ω H type, pom-pom, combs) on rheology has been studied extensively, the effect on crystallization is less known. This work analyses the influence of LCB architecture on crystallization from quiescent melts using models based on hydrogenated polybutadienes, all with a constant 2.1 mol% of ethyl branches (LCB PEs). Crystallization rates measured by DCS, the phase structure, and morphology of the LCB PEs are studied in reference to the linear chain. At a fixed undercooling the crystallization rates of all LCB PEs are 30 to 40% lower than the rate of the linear as expected from transport limitations to the nucleation rate of the LCB systems. Smaller differences in the rate are found within the various LCB architectures. The components of the phase structure are controlled by the content of short chain branching with a negligible effect from the LCB architectures. For all LCB PEs the crystalline component is ∼30% and the interphase region ∼15% as determined by WAXD, RAMAN and DSC. A major impact of LCB is found in the supermolecular morphology. Restrictions from the LCB melt topology to propagate long organized arrays bring about a change from spherulites (linear) to poorly organized crystallites (LCB PEs). Long range dynamics (NMR T\textsubscript{2}) and lamellar structures (AFM) are presently investigated.

12:27PM Z19.00007 An anomaly in the crystallisation rate of bimodal poly(ethylene oxide) weight distributions, JESSICA L. CARVALHO, SARA L. CORMIER, KARI DALNOKI-VERESS, Department of Physics & Astronomy and the Brockhouse Institute for Materials Research, McMaster University, Hamilton, ON, Canada, L8S 4M1 — We present results on the crystallisation of blends of poly(ethylene oxide) (PEO) of differing molecular weight, $M_w$. Previous studies probing PEO blends have mainly focused on blends of low $M_w$, for which integral chain folding is important, with very high $M_w$. The PEO samples used in this study consist of a blend with both $M_w$'s well above the integral chain folding limit. In general, one would expect that such blends should show a monotonic decrease in spherulite growth rate, $G$, as the blend contains more high-$M_w$ component. Our results however show a clear non-monotonic $G$, with a minimum in a plot of $G$ as a function of the volume fraction. In short, blending a small amount of the low-$M_w$ into the high-$M_w$ PEO slows the growth kinetics. These results along with a possible mechanism will be discussed.

12:39PM Z19.00008 Effect of ppm Levels of Long Chain Branching on the Crystallization of Isotactic Poly(propylences) from the Melt and from Solution, RUFINA G. ALAMO, JUAN P. FERNANDEZ-BLAZQUEZ, SYED A. ABDULLAH, MADHAVI VADLAMUDI, FAMU-FSU College of Engineering — Small concentrations of long chain branching (LCB) added via copolymerization with a diene to a linear poly(propylene) chain have a dramatic effect on crystallization. LCB iPPs with diene levels between 100 and 400 ppm show greatly enhanced nucleation density, increasing with diene content. The increased nucleation observed in optical micrographs, is also evident in the crystallization half-time observed by DSC in isothermal crystallization as a function of crystallization temperature. Isotermal crystallization studies from dilute solution measured by light scattering gave the same trend with diene content and rule out any effect of gel structures affecting the nucleation rate. The linear growth rates are unchanged. The increase in nucleation rate is not linear with the increase of diene as revealed from studies of blends of LCBiPPs with the linear matrix, suggesting that length of molecules and connectivity of the LCB type, pom-pom, combs) on rheology has been studied extensively, the effect on crystallization is less known. This work analyses the influence of LCB architecture on crystallization from quiescent melts using models based on hydrogenated polybutadienes, all with a constant 2.1 mol% of ethyl branches (LCB PEs). Crystallization rates measured by DCS, the phase structure, and morphology of the LCB PEs are studied in reference to the linear chain. At a fixed undercooling the crystallization rates of all LCB PEs are 30 to 40% lower than the rate of the linear as expected from transport limitations to the nucleation rate of the LCB systems. Smaller differences in the rate are found within the various LCB architectures. The components of the phase structure are controlled by the content of short chain branching with a negligible effect from the LCB architectures. For all LCB PEs the crystalline component is ∼30% and the interphase region ∼15% as determined by WAXD, RAMAN and DSC. A major impact of LCB is found in the supermolecular morphology. Restrictions from the LCB melt topology to propagate long organized arrays bring about a change from spherulites (linear) to poorly organized crystallites (LCB PEs). Long range dynamics (NMR T\textsubscript{2}) and lamellar structures (AFM) are presently investigated.

12:51PM Z19.00009 Melting, Recrystallization and Superheating of Polymer Crystals Studied by Fast Calorimetry (1 MK/s)\textsuperscript{1}, CHRISTOPH SCHICK, ALEXANDER MINAKOV, ANDREAS WURM, EVGENY ZHURAVLEV, University of Rostock — For polymers the origin of the multiple melting peaks observed in DSC curves is still controversially discussed. This is due to the difficulty to investigate the melting of the originally formed crystals exclusively. Recrystallization is a fast process and most experimental techniques applied so far do not allow fast heating in order to prevent recrystallization totally. We developed a thin-film (chip) calorimeter allowing scanning rates as high as one million Kelvin per second. The calorimeter was used to study the melting of isothermally crystallized polymers like isotactic poly(ethyl methylenesulfone) (IPS), isotactic poly(propylene) (iPP), poly(ethylene terephthalate) (PET) and others. Our results on melting at rates as high as 1,000,000 K/s support the validity of a melting-recrystallization-melting process at low scanning rates (DSC) for all studied polymers. At isothermal conditions they form crystals, which all melt within a few dozens of K slightly above the isothermal crystallization temperature. There is no evidence for the formation of different populations of crystals with significantly different stability (melting temperatures) under isothermal conditions.

1:03PM Z19.00010 Nano-Scale Confinement Effects on Poly(ε-caprolactone) Crystallization at the Air/Water Interface, QIONGDAN XIE, BINGBING LI, TOMONORI SAITO, WEN YIN, TIMOTHY LONG, RICHARD GANDOUR, ALAN ESKER, Department of Chemistry (0212), Virginia Tech, Blacksburg, VA 24061 — Poly(ε-caprolactone) (PCL) with different mole mass were synthesized by using tri-ester primary amine as an initiator, tin(II) 2-ethylhexanoate as the catalyst, anhydrous tetrahydrofuran as a solvent at 80 °C. The three triester ε-caprolactones (PCL) with different mole mass were synthesized by using tri-ester primary amine as an initiator, tin(II) 2-ethylhexanoate as the catalyst, anhydrous tetrahydrofuran as a solvent at 80 °C. The three triester groups were further hydrolyzed to render PCL linear polymers with triacid end groups (PCL Triacid). The as-synthesized PCL triacids were attached to 9 nm magnetic nanoparticles (MNP) by ligand exchange with oleic acid in refluxing chloroform for 24 h. The crystallization behavior of PCL trihead and PCL MNPs at the air/water interface were compared with reported linear PCL crystallization. Regular crystalline morphologies observed for linear PCL are not observed for PCL-trihead and PCL-MNPs.
1:15PM Z19.00011 Microphase Separation Controlled Beta Sheet Crystallization Kinetics in Silk Fibroin Protein. XIAO HU, QIANG LU, DAVID KAPLAN, PEGGY CEBE, Tufts University — We investigate the mechanism of isothermal crystallization kinetics of beta-sheet crystals in silk multiblock fibrous proteins. The Avrami analysis kinetic theory, for studies of synthetic polymer crystal growth, is for the first time extended to investigate protein self-assembly in beta-sheet rich Bombyx mori crystallization kinetics of beta-sheet crystals in silk multiblock fibrous proteins. Observations by scanning electron microscopy support the view that the protein structures vary during the different stages of crystal growth, and show a microphase separation pattern after chymotrypsin enzyme biodegradation. We present a model to explain the crystallization of the multiblock silk fibroin protein, by analogy to synthetic block copolymers. This model could be widely applicable in other proteins with multiblock (i.e., crystallizable and non-crystallizable) domains.

1:27PM Z19.00012 Correlation between Structure and Vapor Sorption in Semi-crystalline Polymers: One Dimensional Nano-Swelling Measured using iVSANS. MAN-HO KIM, MATERIALS SCIENCE AND ENGINEERING, Northwestern University — Microemulsions and lamellar phases have been observed in previous experiments wherein block copolymers are added to blends of immiscible homopolymers. To our knowledge, all of the previous studies are restricted to homopolymers of nearly identical chain lengths with critical volume fractions in the vicinity of 0.5 (symmetric systems). The present study concerns the formation of microemulsions and lamellar phases in blends of immiscible polymers with substantial differences in chain lengths and critical volume fractions far removed from 0.5 (asymmetric systems). The characteristics of the block copolymers that enable the creation of these phases will be discussed in the presentation.

Friday, March 20, 2009 11:15AM - 2:03PM —
Session Z20 DPOLY: Polymer Blends

11:15AM Z20.00001 Microemulsions in Asymmetric Polymer Blends. ALISYN NEDOMA, Univ. of California, Berkeley, MEGAN ROBERTSON, Univ. of Minnesota, NITASH BALSARA, Univ. of California, Berkeley — Microemulsions and lamellar phases have been observed in previous experiments wherein block copolymers are added to blends of immiscible homopolymers. To our knowledge, all of the previous studies are restricted to homopolymers of nearly identical chain lengths with critical volume fractions in the vicinity of 0.5 (symmetric systems). The present study concerns the formation of microemulsions and lamellar phases in blends of immiscible polymers with substantial differences in chain lengths and critical volume fractions far removed from 0.5 (asymmetric systems). The characteristics of the block copolymers that enable the creation of these phases will be discussed in the presentation.

11:27AM Z20.00002 Nanostructured polymer blends by addition of gradient copolymer during melt mixing: Effects of copolymer sequence distribution on morphology and crystallization behavior. ROBERT SANDOVAL, JUNGKI KIM, JOHN TORKELSON, Northwestern University — Nanostructured blends of polystyrene and poly(ethylene oxide) (PEO) are produced via the addition of styrene/methyl methacrylate (S/MMA) gradient copolymer during conventional melt mixing, introducing dipole-dipole interactions between PEO and MMA repeat units. Upon addition of S/MMA gradient copolymer, stable PEO domains with diameters of ~100 nm are formed in optimized cases. This results in PEO domains homogenously crystallizing at ~20 °C, well below the crystallization temperature of bulk PEO (~50 °C). Additionally, nanostructured blends annealed at room temperature for 40 days resulted in no melting behavior upon heating, showing that the nanoconfined PEO domains remain in a rubbery state at room temperature, while bulk PEO typically remains in a crystalline state. This demonstrates that the blend properties can be easily tuned by adjusting the copolymer characteristics. This study is the first to lead to nanostructured polymer blends from non-reactive, simple melt mixing of two homopolymers and a compatibilizer.

11:39AM Z20.00003 A Morphological Study of Poly(Butylene Succinate)/Poly(Butylene Adipate) Blends with Different Blend Ratios and Crystallization Processes. JEROLD SCHULTZ, University of Delaware, HAIJUN WANG, ZHIGUA GAN, SHOUKE YAN, Chinese Academy of Sciences — Morphologies of blends of poly(butylene succinate) (PBS, m.p. 114 °C) with poly(butylene adipate) (PBA, m.p. 60 °C) varying in blend ratio and in crystallization temperature of the PBS component were studied using optical and atomic force microscopies. When PBS is crystallized at 75 °C, subsequent PBA crystallization occurs only within PBS spherulites. When PBS is crystallized at 100 °C, a portion of the PBA is rejected from the growing PBS. The morphological difference is also reflected in the time-dependence of the crystallization kinetics. The difference in behavior at these two temperatures reflects a large change in the diffusion length. Further, the location of PBA crystals within PBS spherulites depends on PBA concentration and on PBS crystallization temperature. Lower PBA concentrations lead to interlamellar segregation, while when PBA is the majority phase, interfibrillar crystallization crystallization dominates. Replace this text with your abstract body.

11:51AM Z20.00004 Phase equilibria and crystallization in mixtures of azobenzene chromophore and triacrylate. GARRETT O’MALLEY, Bucknell University, KENNETH MILAM, NAMIL KIM, THEIN KYU, University of Akron — A temperature versus composition phase diagram of azobenzene chromophore/triacrylate system was established by means of differential scanning calorimetry (DSC). The isotropic liquid (I) and crystal solid + liquid (Cr1 + I) coexistence regions bound by liquidus and solidus lines were tested with the theoretical curves obtained by self consistently solving the combined free energies of Flory-Huggins (FH) theory for isotropic mixing and phase field (PF) theory for crystal solidification pertaining to the compositional order parameter (ψ1, ψ2) and the crystal order parameter (ψ3), respectively. With the aid of phase diagram, various phase morphologies were mapped through thermal quenching into various coexistence gaps. Azobenzene in the blend produced multiple crystal structures, including gigantic single crystals. Real time images demonstrating the nucleation and growth of the crystallization process were captured using polarized optical microscopy. The spatiotemporal growth of such single crystal has been elucidated theoretically using the time-dependent Ginzburg Landau (TDGL) dynamics.

12:03PM Z20.00005 Miscibility Studies on Polymer Blends Modified with Phytochemicals

NEELAKANDAN CHANDRASEKARAN, THEIN KYU, The University of Akron — The miscibility studies related to an amorphous poly(amide)/poly(vinyl pyrrolidone) [PA/PVP] blend with a crystalline phytochemical called “Mangiferin” is presented. Phytochemicals are plant derived chemicals which intrinsically possess multiple salubrious properties that are associated with prevention of diseases such as cancer, diabetes, cardiovascular disease, and hypertension. Incorporation of phytochemicals into polymers has shown to have very promising applications in wound healing, drug delivery, etc. The morphology of these materials is crucial to applications like hemodialysis, which is governed by thermodynamics and kinetics of the phase separation process. Hence, miscibility studies of PA/PVP blends with and without mangiferin have been carried out using dimethyl sulfoxide as a common solvent. Differential scanning calorimetry studies revealed that the binary PA/PVP blends were completely miscible at all compositions. However, the addition of mangiferin has led to liquid-liquid phase separation and solid-liquid phase transition in a composition dependent manner. Fourier transformed infrared spectroscopy was undertaken to determine specific interaction between the polymer constituents and the role of possible hydrogen bonding among three constituents will be discussed.

12:15PM Z20.00006 Phase Separation Mechanism of Polybutadiene/Polyisoprene Blends Under Oscillatory Shear Flow

CHARLES C. HAN, Dr., Prof., RUOYU ZHANG, HE CHENG, XIA DONG, Dr., Prof. — Viscoelastic polymer blends of polybutadiene (PB)/low vinyl content polyisoprene (LPI), with a lower critical solution temperature (LCST) has been studied under oscillatory flow conditions. The phase separation mechanism has been investigated with the consideration of the nucleation mechanism, spinodal fluctuations, and also the shear induced mixing. Frequency and temperature ramping rate dependence of the apparent binodal and spinodal points will be discussed.

12:27PM Z20.00007 Impact of Deuterium Substitution on the Physical Properties of Polymer Melts and Blends

RONALD WHITE, JANE LIPOSON, Dartmouth College — We examine the effects on blend properties when one of the polymeric components is deuterated. Here we use SANS-fitted model calculations to explore the underlying physical behavior, and relate our findings to subtle effects in molecular size and energetics. A special emphasis is given to the prediction and analysis of phase behavior for polymeric mixtures (e.g. liquid-liquid partial miscibility), including a comparison of phase diagrams for several related systems. We discuss effects such as pressure and molecular weight dependence and also include an analysis of calculations in which we probe the influence of key model parameters on blend miscibility. As with our earlier studies, the results featured here involve the application of a microscopically parameterized equation of state derived from an integral equation theory for lattice-based chain molecule fluids.

12:39PM Z20.00008 Mapping Mechanical Properties and Glass Transition Temperature in Polymer Materials with sub-100 nm Resolution

MAXIM NIKIFOROV, Oak Ridge National Laboratory, STEPHEN JESSE, SANGEH GAM, RUSSELL COMPOSTO, LOUIS GERMINARIO, SERGEI KALININ, OAK RIDGE NATIONAL LABORATORY TEAM, UNIVERSITY OF PENNSYLVANIA TEAM, EASTMAN CHEMICAL CO. TEAM — Thermomechanical properties at the nanoscale are extremely important for understanding fundamental as well as technological problems. To date, Local Thermal Analysis (LTA) provides information about glass transition and melting temperature with about 1-2 µm spatial resolution. We developed LTA technique based on Scanning Probe Microscopy that allows probing not only melting and glass transition temperatures, but also elastic and loss moduli on a 100 nanometer length scale. This universal method for quantitative thermomechanical analysis was used to study the kinetics of phase separation in PMMA/SAN system. The maps of mechanical properties as function of temperature were obtained with sub-100 nm resolution. The difference of mechanical properties for two materials was determined.

1This Research at Oak Ridge National Laboratory’s Center for Nanophase Materials Sciences was sponsored by the Scientific User Facilities Division, Office of Basic Energy Sciences, U.S. Department of Energy.

12:51PM Z20.00009 Understanding Dynamics of Multicomponent Polymer Systems Using Homopolymer/Copolymer Blends

CALEB DYER, Department of Chemistry, Univ. of TN, DIAS LINTON, Dept. of Chemistry, Univ. of TN, MARK DAMMUN, Oak Ridge National Lab, Oak Ridge TN and Dept. of Chemistry, Univ. of TN — Blending two polymers is a cost-effective method to produce new materials with tailored properties, although the effect of the presence of one component on the dynamics of the second component is not well understood. Recent studies on miscible polymer blends show that the local environment in a polymer blend has a critical impact on the dynamics of each component in the blend. To this end we have utilized neutron reflectivity (NR), quasi-elastic neutron scattering (QENS), and rheology to study the dynamics of a polystyrene-ran-poly(methyl methacrylate) (PS-ran-PMA) copolymer in a PMMA matrix. The system consists of a miscible blend that is 90% PMMA/10% random copolymer. The copolymer composition varies from 60% to 90% MMA in the blend, effectively tuning the thermodynamic interactions in the system. We will present these results to provide insight into the role of thermodynamic interactions on the dynamics of this miscible polymer blend.

1:03PM Z20.00010 Influence of polymer chain connectivity on local composition distribution in miscible polymer blends

DMITRY BEDROV, University of Utah, WENJUAN LIU, RALPH COLBY, Pennsylvania State University — Molecular dynamics simulations using bead-necklace model have been utilized to investigate concentration distribution of local environments in model polymer blends. Distribution of effective composition around polymer segments has been investigated for different blend scenarios and bulk concentrations. Inter- and intramolecular contributions to the effective composition have been analyzed. Our analysis indicates that chains connectivity has a significant and nontrivial effect on distribution of effective composition around polymer segment. The results of this work are compared with assumptions of several theoretical models that commonly used to describe structural and dynamical correlations in miscible polymer blends.

1:15PM Z20.00011 Origins of Deviations from the RPA in Polymer Blends: Simulations and Theory

JUN KYUNG CHUNG, School of Physics and Astronomy, University of Minnesota, DAVID MORSE, Department of Chemical Engineering and Materials Science, University of Minnesota — We performed continuum Monte Carlo simulations of symmetric binary polymer blends to precisely quantify deviations from RPA predictions for composition fluctuations, including critical phenomena. This comparison is made possible by an unambiguous procedure for determining the self-consistent field (SCF) χ parameter by extrapolating thermodynamic perturbation theory to the limit of infinite chain length L. Corrections to the RPA are shown to be proportional to L−1/2, and to be accurately predicted outside of the critical region by a renormalized one-loop theory. The difference between the apparent (i.e., measured) interaction parameter and the SCF value is positive (destabilizing) far from the spinodal (χN ≲ 1) as the result of an N-dependence of the depth of the correlation hole in a melt. Near the critical point, this effect is almost exactly cancelled by the stabilizing effect of long-wavelength composition fluctuations, yielding a critical value of χN quite close to the RPA prediction of (χN) ≈ 2.
1:27PM Z20.00012 Two DSC Glass Transitions in Miscible Blends of Polyisoprene / Poly(4-tert-butyl styrene), JUNSHU ZHAO, YE SUN, LIAN YU, MARK EDIGER, University of Wisconsin-Madison — Conventional and temperature modulated differential scanning calorimetry experiments have been carried out on miscible blends of polyisoprene (PI) and poly(4-tert-butyl styrene) (P4tBS) over a broad composition range. This system is characterized by an extraordinarily large component T_g difference (∼215 K) between the two homopolymers. Two distinct calorimetric T_g's were observed in blends with an intermediate composition range (25%-50% PI) by both conventional and temperature modulated DSC. Good agreement was found between the T_g values measured by the two methods. Fitting of the measured T_g's to the Lodge-McLeish model gives a φ_{eff} of 0.62~0.64 for PI in this blend and 0.02~0.05 for P4tBS. The extracted φ_{eff} for PIs comparable to reported values for PEO in blends with PMMA and is significantly larger than those reported for other PI blends with smaller component T_g differences. This observation suggests the presence of a confinement effect in PI/P4tBS blends, which results in enhanced fast component dynamics below the effective T_g of the slow component.

1:39PM Z20.00013 Segmental dynamics in polymer blends: adapting the Long-Dequeux model, GARETH ROYSTON, PAUL SOTTA, DIDIER LONG, Laboratoire Polymères et Matériaux Avancés (FRE2911) — In recent years several models have been proposed which attempt to describe the distribution of relaxation times in glass forming systems as they approach vitrification. We have adapted the Long-Dequeux model, initially proposed for van der Waals liquids, for application to polymer blends. Considering thermally induced density fluctuations, the glass transition is shown to be established by percolation of small domains of slow dynamics. Here we present a comparison of the model with experimental data including recently acquired data on miscible blends of poly(alpha-methylstyrene) and poly(cyclohexyl methacrylate). The model is shown to provide a good fit to the data over a range of conditions.

1:51PM Z20.00014 The Viscoelastic Behavior of Polymer/Oligomer Blends, WEI ZHENG, GREGORY MCKENNA, SINDEE SIMON, Texas Tech University — The dynamics in athermal blends of poly(α-methyl styrene) (PaMS) and its short chain oligomer are investigated using rheometry and differential scanning calorimetry (DSC). Master curves for the dynamic shear responses, G' and G'', are successfully constructed for both the pure materials and the blends, indicating the validity of the time-temperature superposition principle. The temperature dependence of the shift factor follows the WLF (Williams-landel-Ferry) behavior over the temperature range studied, and for the blends, the dependence is dominated by the high mobility oligomer. The discrete relaxation spectra of the materials are calculated and are found to be broader for the blends than for the pure materials. A similar domination of the dynamics by the oligomer is observed in DSC enthalpy recovery studies and in the broadened glass transition from DSC. The ability to predict the dynamic responses of the blends from the responses of the neat materials is examined, and whether this prediction needs to incorporate the self-concentration idea as described in Colmenero’s model will be discussed.

Friday, March 20, 2009 11:15AM - 1:51PM
Session Z22 GMG DMP FIAP: Focus Session: Quantum Spin Hall Effect 324

11:15AM Z22.00001 Optical Control of Topological Quantum Transport in Semiconductors, WANG YAO, The University of Hong Kong — Spin-orbit coupling enables electrical manipulations of spins, e.g. through the spin Hall effect, but it also causes spin relaxation and thus a rapid loss of information stored in spins. We propose a solution to this dilemma by exploiting light-matter interactions in the reactive regime: light is used as a control knob to switch on/off spin-orbit coupling readily without exciting real carriers. In electron-doped semiconductors, when an off-resonant optical field virtually excites interband transitions, the large spin-orbit coupling in the valence bands can be partially transferred to the photon-dressed conduction band. The adiabatic electronic ground state can thus be reactively controlled by optical pulses, exhibiting anomalous Hall conductivity. By the control of linearly polarized light, a pure spin Hall current of electrons can be driven by an in-plane DC electric field, which results in net spin accumulations at the edges of the optical excitation area. Effectively, one has created a spin battery powered by optical pulses together with DC electric field, which allows the spatial and temporal control of spin generations. The resultant electron spin accumulations can have long lifetime when spin-orbit coupling vanishes with the adiabatic switch off of the control light. Circularly polarized light breaks the time reversal symmetry and can result in spin polarized charge Hall conductance.

11:51AM Z22.00002 Spin resonance and spin-orbit coupling effects in quantum Hall edge channels1, A.V. STIER, C.J. MEINING, V.R. WHITESIDE, B.D. MCCOMBE, University at Buffalo, E.I. RASHBA, Harvard University, P. GRABS, L.W. MOLENKAMP, Universitaet Wuerzburg — We report studies of far-infrared (FIR) photo-response (E_{FIR}=3.15meV) of a 2D electron gas in an asymmetric 15nm InAs quantum well in a field/frequency regime where electron spin resonance is expected. Photo-induced changes in the longitudinal resistance were measured in a Hall-bar geometry in a tilted magnetic field (B) whose angle θ was varied. For θ ≈ 40˚ and Landau Level (LL) filling factor ν ≈ 7, we observe several sharp minima with a dominant central feature. This feature vanishes for θ < 38.4˚ and splits into two sharper lines at larger angles. The center of gravity of this pair tracks approximately the center of the ν = 7 Quantum Hall (QH) plateau. The appearance of the central feature coincides with the condition of complete filling of the ν = 7 LL at an applied B where the Zeeman spin splitting equals the energy of the FIR laser line. We attribute the sharp multiple line structure to EDSR transitions in pairs of QH edge channels whose resonance conditions are modified by Rashba effective fields. A detailed model that describes qualitatively the experimental findings will be discussed.

12:03PM Z22.00003 Tunneling between edge states in a quantum spin Hall system1, ANDERS STRÖM, HENRIK JOHANNESSON, Department of Physics, University of Gothenburg, Sweden — We analyze a quantum spin Hall (QSH) device with a point contact connecting two of its edges. The contact supports a net spin tunneling current that can be probed experimentally via a two-terminal resistance measurement. We find that the low-bias tunneling current and the differential conductance exhibit scaling with voltage and temperature that depend nonlinearly on the strength of the electron-electron interaction.

1Supported by the Swedish Research Council under Grant No. VR-2005-3942

12:15PM Z22.00004 Kondo effect in the helical edge liquid of the quantum spin Hall state, JOSEPH MACIEJKO, Stanford University, CHAOXING LIU, Center for Advanced Study, Tsinghua University / Stanford University, YUVAL OREG, Weizmann Institute of Science, XIAO-LIANG QI, Stanford University, CONGJUN WU, University of California, San Diego, SHOU-CHENG ZHANG, Stanford University — Following the recent observation of the quantum spin Hall (QSH) effect in HgTe/CdTe quantum wells, an important question is to understand the effect of impurities on transport in the QSH regime. Using linear response and renormalization group methods, we calculate the edge conductance of a QSH insulator in the presence of a single magnetic impurity. At high temperatures, due to Kondo scattering we find a logarithmic temperature dependence consistent with current experiments. At low temperatures, for weak Coulomb interactions in the edge liquid the conductance is restored to unitarity with unusual power-laws due to the formation of the Kondo singlet, while for strong interactions transport proceeds by weak tunneling through the impurity where only half an electron charge is transferred in each tunneling event. We propose scanning gate and shot noise experiments to search for these effects.
12:27PM Z22.00005 Corner Junction as a Probe of Helical Edge States. CHANG-YU HOU, Department of Physics, Boston University, EUN-AH KIM, Department of Physics, Cornell University, CLAUDIO CHAMÓN, Department of Physics, Princeton University — We propose and analyze inter-edge tunneling in a quantum spin Hall corner junction as a mean to probe the helical nature of the edge states. We show that electron-electron interactions in the one-dimensional helical edge states result in Luttinger parameters for spin and charge that are intertwined, and thus rather different from those for a quantum wire with spin rotation invariance. Consequently, we find that the four-terminal conductance in a corner junction has a distinctive form that could be used as evidence for the helical nature of the edge states.

12:39PM Z22.00006 A topological Dirac insulator in a quantum spin Hall phase. DAVID HSIEH, DONG QIAN, LEWIS WRAY, YUQI XIA, Department of Physics, Princeton University, YEW SAN HOR, ROBERT CAVA, Department of Chemistry, Princeton University, ZAHID HASAN, Department of Physics, Princeton University — When electrons are subject to a large external magnetic field, the conventional charge quantum Hall effect dictates that an electronic excitation gap is generated in the sample bulk, but metallic conduction is permitted at the boundary. Recent theoretical models suggest that certain bulk insulators with large spin orbit interactions may also naturally support conducting topological boundary states in the quantum limit, which opens up the possibility for studying unusual quantum Hall-like phenomena in zero external magnetic fields. Bulk Bi$_1-x$Sb$_x$ single crystals are predicted to be prime candidates for one such unusual Hall phase of matter known as the topological insulator. The hallmark of a topological insulator is the existence of metallic surface states that are higher-dimensional analogues of the edge states that characterize a quantum spin Hall insulator. Here, using incident-photon-energy-modulated angle-resolved photoemission spectroscopy, we report the direct observation of massive Dirac particles in the bulk of Bi$_0.9$Sb$_0.1$, and provide a comprehensive mapping of the Dirac insulators gapless surface electron bands. These findings taken together suggest that the observed surface state on the boundary of the bulk insulator is a realization of the topological metal.

12:51PM Z22.00007 Non-magnetic disorder effects on 3-dimensional $Z_2$ quantum spin Hall systems. RYUICHI SHINDOU, RIKEN (the Institute of Physical and Chemical Research), SHUICHI MURAKAMI, Tokyo Institute of Technology — Motivated by the recent discovery of the $Z_2$ quantum spin Hall insulator (QSHI) in the antimony doped bismuth, we have studied the non-magnetic disorder effects onto the quantum critical point (QCP) which always exists between an ordinary insulator and the $Z_2$ QSHI. Namely, intervening the topologically distinct states of matter, such QCP should be generally stable against any perturbations (i.e. disorders), as far as the time-reversal symmetry is preserved. In this talk, I will present a possible microscopic mechanism of this stability, based on simple weak-localization calculations. Specifically, at the QCP between the topological insulator and an ordinary insulator, so-called the particle degree of freedom also becomes the conserved quantity, in addition to the usual charge. As a result of this, the diffusion near the QCP consists of the two quasi-degenerate dominant contributions having the diffusion poles; one contributes to the usual charge diffusion, while the other is ascribed to the particle diffusion. In terms of these two quasi-degenerate low-energy modes, I will construct a possible microscopic picture for the stability of the QCP against non-magnetic disorders.

1:03PM Z22.00008 Magnetic impurities on the surface of a topological insulator. QIN LIU, CHAO-XING LIU, CENKE XU, XIAO-LIANG QI, SHOU-CHENG ZHANG — The surface states of a topological insulator are described by an emergent relativistic massless Dirac equation in 2+1 dimensions. In contrast to graphene, there is an odd number of Dirac points, and the electron spin is directly coupled to the momentum. We show that a magnetic impurity opens up a local gap and suppresses the local density of states. Furthermore, the Dirac electronic states mediate an RKKY interaction among the magnetic impurities which is always ferromagnetic, whenever the chemical potential lies near the Dirac point. These effects can be directly measured in STM experiments. We also study the case of quenched disorder through a renormalization group analysis.

1:15PM Z22.00009 Seeing the magnetic monopole through the mirror of topological surface states. XIAO-LIANG QI, RUN-DONG LI, Stanford University, JIADONG ZANG, Fudan University, SHOU-CHENG ZHANG, Stanford University — Existence of the magnetic monopole is compatible with the fundamental laws of nature, however, this illusive particle has yet to be detected experimentally. In this work, we show that an electric charge near the topological surface state induces an image magnetic monopole charge due to the topological magneto-electric effect. The magnetic field generated by the image magnetic monopole can be experimentally measured, and the inverse square law of the field dependence can be determined quantitatively. We propose that this effect can be used to experimentally realize a gas of quantum particles carrying fractional statistics, consisting of the bound states of the electric charge and the image magnetic monopole charge.

1:27PM Z22.00010 Theoretical study on quantum spin Hall phases in bismuth ultrathin films. SHUICHI MURAKAMI, Tokyo Institute of Technology and PRESTO, JST, MASAKI WADA, Tokyo Institute of Technology, FRANK FREIMUTH, GUSTAV BHIJMAYER, Forschungszentrum Juelich — It has been proposed that the (111) 1-bilayer bismuth is in the quantum spin Hall phase [1]. This argument is based on a simple tight-binding model for the 3D bismuth, and it is desirable to examine this result by more realistic methods. In this presentation, we investigate possibilities of the quantum spin Hall phases in two of the bismuth ultrathin films by first-principle calculations and confirmed the result in Ref.[1]. Bulk bismuth is a semimetal, while some of the bismuth ultrathin films have a gap. As proposed by first-principle calculations, among various phases seen in experiments, only two cases are gapped: (i) (111) 1-bilayer film and (ii) (012) 2-monolayer film. These two structures are almost degenerate in energy. We calculate the $Z_2$ topological numbers for the two structures, both from the bulk Bloch wavefunctions and from band structure calculations in the geometry with edges. In the calculations we use the maximally localized Wannier orbitals constructed from first-principle calculations. We found that (i) is the quantum spin Hall phase while (ii) is an ordinary insulator. Their difference can be observed in STM/STS and other possible experiments to verify our results are discussed.

1:39PM Z22.00011 Probing Surface States of the Topological Insulator Bi$_{1-x}$Sb$_x$ with Scanning Tunneling Microscopy and Spectroscopy. PEDRAM ROUSHAN, ANTHONY RICHARDELLA, COLIN PARKER, KENJIRO GOMES, ABHAY PASUPATHY, AAKASH PUSHP, YEW SAN HOR, ROBERT CAVA, ALI YAZDANI, Princeton University — There is a considerable interest in surface properties of Bi$_1-x$Sb$_x$ alloys, for which there is growing evidence that they host novel surface states [1]. We have used a cryogenic scanning tunneling microscope (STM) to probe the surface of Bi$_{1-x}$Sb$_x$ directly, and confirming the presence of surface states within the bulk band gap. Energy resolved conductance mapping of these surface states reveal strong spatial modulations, similar to those observed with the STM for noble metal surface states [2]. Fourier analysis of these maps shows that the spatial modulation of the surface states can be understood within a model for scattering between various k-states of the band structure of the surface. We will present these results in connection with the angle-resolved photoemission measurements of the contours of constant energy. [1] D. Hsieh et al., Nature 452, 970 (2008) [2] M. F. Crommie et al., Nature 363, 524 (1993)
11:15AM Z24.00001 Effect of Ti Dopant on Surface Diffusion of Isolated Alane Species: A Comparison between Al (111) and Al (100) surfaces1, ALTAF KARIM, JAMES MUCKERMAN, Brookhaven National Lab — Our density functional theory-based kinetic Monte Carlo simulations show that an embedded Ti atom creates a well in the potential energy surfaces of Al(111) and Al(100) as probed by hydrogen and other isolated alanine species. Hydrogen adatoms become trapped around Ti atoms on an Al(111) surface, whereas Al adatoms do not exhibit any significant effect of the potential energy well created by the Ti atoms. In contrast to the case of Al(111), Al adatoms on an Al(100) surface also become trapped around the Ti atoms for a longer period of time compared to the hydrogen adatoms on this surface. Therefore, Ti sites on Al(100) become poisoned by the presence of Al adatoms around them for long periods of time, thereby blocking further dissociative adsorption of hydrogen. The overall diffusion of Al adatoms on an Al(100) surface is significantly lower compared to the Al(111) surface. This fact suggests that the Ti-doped Al(111) surface is perhaps more conducive to the production of alanine species than the Ti-doped Al(100) surface despite its higher activation barrier for the dissociation of molecular hydrogen.

11:27AM Z24.00002 Hydrogen adsorption on Al (100) facilitated by surface alloying with Sc. FENG ZHANG, YAN WANG, M. Y. CHOU — We report first-principles investigations of hydrogen adsorption on the Al (100) surface modified by alloying with Sc, as the first step to understand the catalytic role of scandium in the hydrogenation process in Sc-doped NaAlH4. Sc prefers to stay at subsurface sites with or without adsorbed hydrogen. The adsorption energy on the Sc-modified surface is 0.5 eV/H2 lower than that on the pure Al surface, while the dissociation barrier of H2 is similar for the two systems. The structure with two H atoms adsorbed on two nearest-neighbor bridge sites is at least 0.3 eV more stable than other structures, but no additional activation energy is required for H to diffuse among these structures. Electronic structures are also examined to explain these alloying-induced effects.

11:39AM Z24.00003 Hydrogen-related defects and the role of metal additives in complex hydrides1, KHANG HOANG, CHRIS G. VAN DE WALLE, Materials Department, University of California, Santa Barbara, CA 93106-5050 — Complex hydrides such as NaAlH4 and LiBH4 have attractive properties as hydrogen storage materials. The mechanism of the enhancement in (de)hydrogenation rates caused by these metals is, however, not well understood. We have carried out first-principles studies based on density functional theory of hydrogen vacancies and interstitials, which play an important role in the (de)hydrogenation processes. We find that these defects are always charged, their formation energy therefore depends on the Fermi level. The metallic impurities can also exist in different charged states and, therefore, modify the Fermi level, thus changing the defect concentrations. Our first-principles results shed light on the role of transition-metal impurities in hydrides and lead to the design of storage materials with improved characteristics.

11:51AM Z24.00004 First-principles and Tight-binding Calculations in the Pd-H System, A. SHABADEV, D.A. PAPCONSTANTOPOULOS, Department of Computational and Data Sciences, George Mason University, Fairfax, VA 22030, USA — Using the linearized augmented plane wave(LAPW) method we have generated a large database of electronic structure results that include fcc, bcc, NaCl, CsCl, CuAu. Fluorite crystal structures as well as supercell configurations with various hydrogen occupations for the Pd-H system. The formation energies and energy bands from this database were used to construct a tight-binding model that reproduces well the above LAPW results and, in addition, is transferable to other crystal lattices including random occupation of crystal sites as well as treating vacancies. We calculate the phonon frequencies, elastic constants, the density of states, coefficient of thermal expansion, mean-squared displacement and the energy of vacancies formation in Pd. The objective of this work is to be able to perform electronic structure calculations for systems containing up to a few thousand atoms where first-principles calculations are computationally intractable. This approach is used in both static and dynamic calculations and enables us to vary the amount of hydrogen entering into the Pd matrix.

12:03PM Z24.00005 Nitrogen and Hydrogen on a Palladium-covered proton conductor: a first principle study of Ammonia catalysis, LORENZO PAULATTO, STEFANO DE GIRONCOLI, SISSA, I-34014 Trieste and DEMOCRITOS I-34014 Trieste — Being liquid at ambient conditions Ammonia would be an ideal Hydrogen vector. However, the industrial Haber process for Ammonia synthesis involves high pressures (≥ 100 bar) and temperatures (450 – 500 °C), making the process very expensive. Recently, ambient pressure Ammonia production, in the 570 – 750 °C temperature range, has been reported at the Palladium cathode of a proton conducting cell-reactor [1]. The rate limiting step in the Haber process is N2 dissociation, while the observed limiting factor in Ref. [1] appears to be the proton transfer through the conductor and it has been proposed that Nitrogen hydrogenation may in this case precede dissociation. We use first-principles techniques to study Nitrogen, Hydrogen and Ammonia interaction with flat and stepped Pd surfaces, in presence of external electric fields. Our aim is to study the effect of electrochemically provided protons on the catalysis of the reaction. [1] G. Marnellos and M. Stoukides, Science 282, 98 (1998); G. Marnellos, S. Zisekas, and M. Stoukides, J. of Catalysis 193, 8087 (2000)

12:15PM Z24.00006 Synthesis and Characterization of Au and Pd Decorated ZnO Powders1, PAIGE LANDRY, University of Tennessee, HANGNING CHEN, Lanzhou University, University of Tennessee, ANDI BARBOUR, MICHAEL FELTY, University of Tennessee. — We report our synthesis and characterization of ZnO nanopowders decorated with Pd and Au clusters. Ultrapure ZnO powders are readily produced. Pd and Au nanoclusters are deposited from solution and reduced using hydrogen gas. Characterization of these materials using high resolution adsorption isothersms and inelastic neutron scattering have been performed. Particular attention has been paid to the adsorption of hydrogen and deuterium on these pure and decorated materials. Preliminary results indicate that hydrogen preferentially adsorbs on Pd and Au nanoclusters. Ultrapure ZnO powders are readily produced. Pd and Au nanoclusters are deposited from solution and reduced using hydrogen gas.

11:15AM Z25.00001 Chiral structure and mixed parity anomalies in graphene-related systems, AKIHIRO TANAKA, Natl. Inst. for Materials Sci. — We reanalyze the chiral symmetry structure of graphene and its variants (boron-nitride sheets, bond alternated graphene, etc) using a representation of Dirac fermions previously employed by the author in a search for topological effects in the pi- flux state of a square lattice electron system (PRL 95 036402 (2005)). We find that the electromagnetic responses of nontopological insulators to curvature-induced gauge fields mimics in an interesting way the responses of topological insulators of the Haldane/Kane-Mele category to conventional (Maxwellian) gauge fields.
Our energetics calculations show that the OH group tends to aggregate to the neighboring carbon sites of an epoxy group, resulting in the formation of several effects of the oxidation functional groups (epoxy and hydroxyl) on the structural, energetics, and electronic properties of graphene by first-principles calculations.

JIA-AN YAN, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology, Atlanta, GA 30332 — Opening a band gap in monolayer graphene is of and thus generate a big perturbation on graphene Dirac point energy level. Here we show that physical adsorption of suitable aromatic molecules onto graphene can generate a moderate band gap of approximately 0.125 eV, with an gap opening near the Fermi level. The oxidation concentration dependence of the energy gap is investigated.

WANLIN GUO, Institute of Nanoscience, Nanjing University of Aeronautics and Astronautics, Nanjing, 210016, China, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA — We explore the response of epitaxial bilayer graphene on SiC and Ru to electric field and mechanical tuning using first-principles calculations. Our calculations reveal that, in contrast to prevailing view, the buffer layer plays an active role in the distribution of charge transfer within the epitaxial graphene layers and with the substrate. The charge distribution and electronic structure are also sensitive to the type of substrate. These results provide new insights for fundamental understanding and practical application of these fascinating materials.

ANTONIO J. R. DA SILVA, Physics Institute, University of São Paulo, São Paulo, Brazil — Single layer graphene has been recently isolated and can pave the way to a number of nanoscale technologies. One interesting possibility is to use the spin of the electron - instead of its charge - as information carrier in carbon-based systems where the spin coherence length can reach hundreds of nanometers. Up until now, spintronics devices have been assembled using magnetic electrodes as a source of spin polarized electrons. In this work we use a combination of density functional theory and nonequilibrium Green’s functions techniques to study the electronic transport properties of graphene nanoribbons (GNRB) up to 500 nm long containing substitutional Boron atoms. We demonstrate that in realistic systems where the B atoms are randomly distributed along the GNRB, the polarization of the current can reach up to 100% and is independent of impurity concentration. These effects can be explained in terms of different scattering probabilities for majority and minority spins from a single B atom. This consequently leads to different Anderson localization lengths for each spin population.

MICHELE LAZZERI, IMPMC, Paris, France, CLAUDIO ATTACALITE, ETSF, Universidad del Pais Vasco, Spain, LUDGER WIRTZ, IEMN, ISEN, Villeneuve d’Asq, France, ANGEL RUBIO, ETSF, Universidad del Pais Vasco, Spain, FRANCESCO MAURI, IMPMC, Paris, France — GW is nowadays the most accurate ab-initio method to determine electronic bands. So far GW has never been used to determine neither the electron-phonon coupling (EPC) nor phonon dispersions. We show that GW approach [1] can be used to compute the EPC and the phonon dispersion. In particular, in graphene and graphite, standard DFT (LDA and GGA) underestimates, by a factor of 2, the slope of the highest optical branch at the zone boundary (K) and the square of its EPC by almost 80%. On the contrary, GW reproduces the experimental phonon dispersion near K, the value of the EPC, and the electronic band dispersion, in agreement with phonon dispersions from inelastic x-ray scattering and Raman spectroscopy. Comparing these results with other computational methods, the B3LYP hybrid functional gives phonons close to GW but overestimates the EPC at K by about 30%. Within Hartree-Fock, the graphene structure displays an instability under a distortion following the A'1 phonon at K. [1] M. Lazzzieri et al., Phys. Rev. B 78, 081406(R) (2008).

11:27PM Z25.00002 Many-electron Effects on the Electronic Structure and Optical Spectrum of Few-layer Graphene, LI YANG, JACK DESLIPPE, CHEOL-HWAN PARK, MARVIN COHEN, STEVEN LOUIE, The department of Physics, University of California at Berkeley and Materials Sciences Division, Lawrence Berkeley National Laboratory — We present a first-principles calculation of the optical properties of single- and few-layer graphene with many-electron effects included, employing the GW-Bethe Salpeter equation (GW- BSE) approach. We have found enhanced excitonic effects that result in significant changes in the optical absorption of few- layer graphene as compared to the independent-particle picture. Our calculated absorption spectrum is in good agreement with recent experiments. This study is of importance for understanding excitonic effects in two-dimensional semimetal systems and expected to be useful for possible optoelectronics applications of graphene.

11:39AM Z25.00003 Geometrical constraint on alkali and halogen adsorption on graphene, CHENGING CHIA, Department of Physics, Penn State University — A seamless sp2 graphene sheet prevents the penetration of atoms through the sheet, yet allows the penetration of electrons. Thus, a suspended single sheet graphene forms a geometrical constrained background by separating the surrounding vacuum into upper half and lower half spaces. Alkali and halogen atoms, each constrained to one of the spaces, are forced to interact electrostatically via charge transfer through the sheet. A new type of chemical interaction is formed under this constraint, which we call topologically frustration bonding. We have calculated the interaction of a K atom on the upper surface with a halogen atom on the lower surface of a pure-carbon graphene sheet using density functional theory. The system becomes ferroelectric under this new geometrical constraint.

11:51AM Z25.00004 Pivotal role of buffer layer in tuning electronic properties of epitaxial graphene, YUFENG GUO, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA, WANLIN GUO, Institute of Nanoscience, Nanjing University of Aeronautics and Astronautics, Nanjing, 210016, China, CHANGFENG CHEN, Department of Physics and High Pressure Science and Engineering Center, University of Nevada, Las Vegas, Nevada 89154, USA — We explore the response of epitaxial bilayer graphene on SiC and Ru to electric field and mechanical tuning using first-principles calculations. Our calculations reveal that, in contrast to prevailing view, the buffer layer plays an active role in the distribution of charge transfer within the epitaxial graphene layers and with the substrate. The charge distribution and electronic structure are also sensitive to the type of substrate. These results provide new insights for fundamental understanding and practical application of these fascinating materials.

12:03PM Z25.00005 Graphene on Silicon Dioxide: Band gap modulation via substrate surface chemistry, PHILIP SHEMELELLA, SAROJ K. NAYAK, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, Troy, NY — We have studied the electronic structure of graphene deposited on a SiO2 surface using density functional methods. The band structure of the graphene monolayer strongly depends on surface characteristics of the underlying SiO2 surface: for an oxygen-terminated surface, the monolayer exhibits a finite energy band gap while the band gap is closed when the oxygen atoms on the substrate are passivated with hydrogen atoms. We find that at least a graphene bilayer is required for a near zero energy gap when deposited on a substrate without H-passivation. Our results are discussed in the light of recent experiments.

12:15PM Z25.00006 Current polarization in B-doped graphene nanoribbons: ab initio simulations, ALEXANDRE ROCHA, Centro de Ciências Naturais e Humanas, UFABC, Santo André, Brazil, THIAGO MARTINS, ADALBERTO FAZZIO, ANTONIO J. R. DA SILVA, Physics Institute, University of São Paulo, São Paulo, Brazil — Single layer graphene has been recently isolated and can pave the way to a number of nanoscale technologies. One interesting possibility is to use the spin of the electron - instead of its charge - as information carrier in carbon-based systems where the spin coherence length can reach hundreds of nanometers. Up until now, spintronics devices have been assembled using magnetic electrodes as a source of spin polarized electrons. In this work we use a combination of density functional theory and nonequilibrium Green’s functions techniques to study the electronic transport properties of graphene nanoribbons (GNRB) up to 500 nm long containing substitutional Boron atoms. We demonstrate that in realistic systems where the B atoms are randomly distributed along the GNRB, the polarization of the current can reach up to 100% and is independent of impurity concentration. These effects can be explained in terms of different scattering probabilities for majority and minority spins from a single B atom. This consequently leads to different Anderson localization lengths for each spin population.

12:27PM Z25.00007 Impact of the electron-electron correlation on phonon dispersion: Failure of LDA and GGA DFT functionals in graphene and graphite, MICHELE LAZZERI, IMPMC, Paris, France, CLAUDIO ATTACALITE, ETSF, Universidad del Pais Vasco, Spain, LUDGER WIRTZ, IEMN, ISEN, Villeneuve d’Asq, France, ANGEL RUBIO, ETSF, Universidad del Pais Vasco, Spain, FRANCESCO MAURI, IMPMC, Paris, France — GW is nowadays the most accurate ab-initio method to determine electronic bands. So far GW has never been used to determine neither the electron-phonon coupling (EPC) nor phonon dispersions. We show that GW approach [1] can be used to compute the EPC and the phonon dispersion. In particular, in graphene and graphite, standard DFT (LDA and GGA) underestimates, by a factor of 2, the slope of the highest optical branch at the zone boundary (K) and the square of its EPC by almost 80%. On the contrary, GW reproduces the experimental phonon dispersion near K, the value of the EPC, and the electronic band dispersion, in agreement with phonon dispersions from inelastic x-ray scattering and Raman spectroscopy. Comparing these results with other computational methods, the B3LYP hybrid functional gives phonons close to GW but overestimates the EPC at K by about 30%. Within Hartree-Fock, the graphene structure displays an instability under a distortion following the A1 phonon at K. [1] M. Lazzzieri et al., Phys. Rev. B 78, 081406(R) (2008).

12:39PM Z25.00008 First-Principles Studies of Oxidation Functional Groups on Graphene, JIA-AN YAN, MEI-YIN CHOU, School of Physics, Georgia Institute of Technology, Atlanta, GA 30332 — Opening a band gap in monolayer graphene is of special interest for the graphene-based electronic applications. Inspired by the potential applications of graphene oxide, we have systematically investigated the effects of the oxidation functional groups (epoxy and hydroxy) on the structural, energetic, and electronic properties of graphene by first-principles calculations. Our energetic calculations show that the OH group tends to aggregate to the neighboring carbon sites of an epoxy group, resulting in the formation of several possible building units. We find that the epoxy group strongly hybridizes with the extended π (nπ) bands, giving rise to a shift of the Dirac point in the momentum space and a decrease in the Fermi velocity. In contrast, the adsorption of a single hydroxyl group leads to the formation of a localized state and a gap opening near the Fermi level. The oxidation concentration dependence of the energy gap is investigated.

12:51PM Z25.00009 Physical adsorption induced band gap opening in graphene, YOUJIAN TANG, Penn State, VINCENT CRESPI, VINCENT CRESPI GROUP TEAM — Gapping graphene is crucial for enabling its use in next-generation electronic devices. Here we show that physical adsorption of suitable aromatic molecules onto graphene can generate a moderate band gap of approximately 0.125 eV, with an adsorption energy 0.67 eV. The reason for such a band gap is that the Lowest unoccupied molecular orbit of adsorbate is right across the Fermi level of graphene and thus generates a big perturbation on graphene Dirac point energy level.
1:03PM Z25.00010 First-Principles Studies of Covalent Functionalization of Graphene by Carboxyl Groups1, NABIL AL-AQTASH, IGOR VASILIEV, Department of Physics, New Mexico State University, Las Cruces, New Mexico — We study the mechanism of covalent functionalization of graphene by the carboxyl (COOH) group in the framework of density functional theory combined with the generalized gradient approximation. The structures and binding energies of the COOH group attached to the surface of graphene are examined in cases of graphene containing no defects, containing a Stone-Wales defect, and containing a vacancy. Our calculations confirm that the binding of the COOH group with graphene is significantly stronger in the presence of surface defects. We also observe substantial changes in the structure of defective graphene after the attachment of the COOH group. These results suggest that surface defects play an important role in the carboxylation of graphene.  

1Supported by DOE DE-FG36-08GO80008 and ACS PRF-48556-AC10.

1:15PM Z25.00011 First-principles calculations of electronic transport through graphene with realistic metallic leads, SALVADOR BARRAZA-LOPEZ, M. Y. CHOU, School of Physics, Georgia Institute of Technology — We present transmission characteristics for electrons through graphene with realistic metallic contacts. The methodology relies on an in-house version of the electronic transport SMEAGOL code [1], in which the memory required to allocate for the matrices of contact leads and the graphene sheet in the Green’s function solver is distributed into more than one processor, for a given electron energy. We are able to accommodate for commensurate graphene-metal supercells which have the correct atomic structure (namely, stress caused by contracting/ extending the metal contacts to match the periodicity of graphene is avoided). In addition, and despite of the large size of the leads, the electronic properties and transport are computed at the density-functional theory level [2] within a double-zeta plus polarization basis[3], ensuring the accuracy of the atomic forces in the system, as well as on the final transmission characteristics. [1] A. R. Rocha et al, PRB. 73, 085414 (2006); [2] J. M. Soler et al, J. Phys.: Condens. Matter 14, 2745-2779 (2002); [3] J. Junquera et al, PRB 64, 235111 (2001).

1:27PM Z25.00012 Exfoliation of graphene flake from SiC substrate using hydrogen injection; a first-principle study, BORA LEE, SEUNGWU HAN, Ewha Womans University, YONG-SUNG KIM, Korea Research Institute of Standards and Science — Recently there is an immense interest in studying graphene for investigating its unique electronic properties as well as practical applications to nanoscale devices. Up to now there are two methods to obtain graphene layers. The first one is a mechanical method in which the single graphene sheet is split off the bulk graphite crystals using adhesives. The other method is graphitization of SiC surfaces by annealing at elevated temperatures. Even though the latter approach can provide a graphene layer in a more controlled way, the exfoliation of the graphene layer still poses a big challenge. In this presentation, based on the first-principles results, we propose a novel exfoliation method using hydrogen. As a model system, the 6H-SiC(0001) 4×4 cell is used, which corresponds to the 3×3 graphene cell. We calculate the binding energy of single hydrogen atom in various places; above and below graphene surface and inside the first SiC layer. The binding energies of hydrogen are calculated for different coverages. It is found that at high coverages, the hydrogen atoms prefer to bind below the graphene surface, cutting the graphene-SiC bonds. This means that the graphene can be exfoliated in the hydrogen-rich environment. The detailed analysis including the electronic structures will be presented.

1:39PM Z25.00013 Electronic Properties of Graphene Oxide1, GEUNSIK LEE, KEEONGJAE CHO, Department of Physics, UT Dallas, TX 75080 — Graphene has shown promising electronic properties as future device applications beyond the current CMOS (complimentary metal-oxide-semiconductor) technology based on silicon microelectronics. As a critical insulating component in all-carbon nanoelectronic devices, graphene oxides (GOs) are shown to have insulating behavior, but their electronic and atomic structures are poorly understood. We investigated electrical property of GO using density functional theory (DFT) and non-equilibrium Green’s function (NEGF) method with tight binding (TB) scheme. We model the basal plane oxidation with top (OH) and bridge (epoxide) chemisorptions. By varying the chemisorption ratio of the hydroxyls and epoxides as well as their coverage, the conductance of GO is calculated and quantitatively compared with experimental reports. We have investigated the electronic structure of graphene and GO multilayers for pseudospin device application.

1:51PM Z25.00014 Lattice Monte Carlo studies of quantum critical phenomena in graphene, TIMO LAHDE, University of Washington, JOAQUIN DRUT, The Ohio State University — The Lattice Monte Carlo approach is well suited to the study of strongly interacting fermionic systems, such as the quasi-relativistic charge carriers in graphene, as it is non-perturbative and takes full account of quantum fluctuations. Recent simulational results on the semimetal-insulator critical point in graphene are presented, with emphasis on the question whether the transition to an insulating phase is of second order or of first order. This critical point is likely to be relevant for the physics of suspended graphene, as its location determined in arXiv:0807.0834 (see abstract by J. E. Drut) suggests that suspended graphene should be an insulator rather than a semimetal. An observable of particular interest is the DC conductivity of graphene, as most analytical studies underestimate this by a factor ~3. It has been pointed out that a complete description of the DC conductivity of graphene should account for non-perturbative effects due to the long-range Coulomb interaction between the fermionic quasiparticles. A possible method for determining the DC conductivity of graphene using the Lattice Monte Carlo technique is presented.

Friday, March 20, 2009 11:15AM - 2:15PM – Session Z26 DCMP: Composite and Porous Media 328

11:15AM Z26.00001 Flexibility of zeolite frameworks, VITALIY KAPKO, MICHAEL TREACY, MICHAEL THORPE, Department of Physics Arizona State University — Zeolites are an important class of industrial catalysts because of their large internal surfaces and molecular-sieving properties. Recent geometric simulations [1] show that almost all of the known zeolites can exist without distortion of their tetrahedra within some range of densities, which we call the flexibility window. Within this window, the framework accommodates density changes by rotations about the shared Si-O-Si bonds. We are able to accommodate for commensurate graphene-metal supercells which have the correct atomic structure (namely, stress caused by contracting/ extending the metal contacts to match the periodicity of graphene is avoided). In addition, and despite of the large size of the leads, the electronic properties and transport are computed at the density-functional theory level [2] within a double-zeta plus polarization basis[3], ensuring the accuracy of the atomic forces in the system, as well as on the final transmission characteristics. [1] A. R. Rocha et al, PRB. 73, 085414 (2006); [2] J. M. Soler et al, J. Phys.: Condens. Matter 14, 2745-2779 (2002); [3] J. Junquera et al, PRB 64, 235111 (2001).

11:27AM Z26.00002 Electronic and ionic conduction in oxo-vanadium arsenates, VICTORIA SOGHOMONIAN, Vincenzo Tech, Department of Physics — Oxides conducting microporous zeolite-like or zeolite frameworks are widely studied as electronic materials, but may offer new avenues in catalysis and in electrical energy storage applications. Zeolites and zeotypes are characterized by the presence of nano channels and cavities delineated by their crystalline framework, and occur naturally or can be synthesized by inorganic methods. The material under discussion here, an oxo-vanadium arsenate system, combines the properties of the well known but electrically insulating microporous zeolites, with an electronically active framework. We present the structure and the experimentally measured electronic and ionic conductivities of the materials system, the temperature dependences of the conductivities, and discuss possible electronic and ionic conduction mechanisms at play in empty frameworks and ion-exchanged frameworks. We also discuss how microporous electrically conducting frameworks can find use in electrical energy storage, and compare the zeolite frameworks in such applications to other materials systems such as mesoporous carbon.
11:39AM Z26.00003 Synthesis of hybrid zeolite materials with TiO2 nanocrystals using solid-solid method1, CORINA ORHA, CARMEN LAZAU, CORNELIA RATIU, PAULA SFIRLOAGA, PAULINA VLAZAN, ALEXANDRA IOITESCU, National Institute for Research and Development in Electrochemistry and Condensed Matter, Timisoara, Romania — Zeolite seems to be a promising support for TiO2 photocatalyst because of its regular pores and good adsorption ability. TiO2 supported on zeolite integrates the photocatalytic activity of TiO2 with the adsorption properties of zeolites. The aim of this paper was the syntheses and characterizations of functionalized zeolite materials with undoped, Fe-doped and N-doped TiO2 nanocrystals. The zeolite hybrid materials impregnation with titanium dioxide was achieved through solid-solid method. TiO2 doped with metallic (Fe) and non-metallic (N) ions was obtained directly from precursors by sol-gel and hydrothermal methods. The hybrid materials were characterized by XRD, SEM with EDAX, IR and AFM.

11:51AM Z26.00004 Carbon dioxide and methane transport in DDR zeolite: insights from molecular simulations into carbon dioxide separations in small pore zeolites, SANG EUN JEE, DAVID SHOLL, Georgia Institute of Technology, EXXON MOBIL CORPORATION COLLABORATION — Zeolites are good candidates as a membranes for chemical separations because of their excellent chemical and thermal stability. Cage type zeolites are promising materials for gas separation since their narrow windows are expected to control molecular transport. DDR is one of the strongest candidates for light gas separations because of its narrow 8MR window. In our study, we examined the separation selectivity of DDR for CO2/CH4 separation using atomistic simulation methods. We introduced new force fields which can reproduce experimental single component adsorption and diffusion data for this material for the first time. Previously interatomic potentials that have been applied to DDR overestimate experimental diffusivities at least one order of magnitude. We characterized single-component and binary adsorption using Grand Canonical Monte Carlo, and single-component diffusion using a combination of Molecular Dynamics and Transition State Theory. The most important observation from our calculation is that CO2/CH4 diffusion in DDR is very different from the usual situation in nanoporous materials, where the presence of a slowly diffusing species retards transport rates of a more rapidly diffusing species. In DDR, we show that CO2 diffusion rates are only weakly affected by the presence of CH4, despite the very slow diffusion of the latter species. The physical origins of this unusual behavior are explained by analyzing the adsorption sites and diffusion mechanism for each species.

12:03PM Z26.00005 Effects of inhomogeneous partial absorption and the orientation of the boundary on the population evolution of molecules diffusing in general porouos media, SEUNGHO RYU, DAVID L. JOHNSON, Schlumberger Doll Research — We consider the diffusion-relaxation dynamics in porous media with partially absorbing boundary conditions. Spectral analysis of Helmholtz equation for the uniform boundary condition has been widely used as a probe of geometry of the medium. The NMR relaxation of the fluid magnetization, for example, is used for a variety of media such as rocks, cement, bones, and cheese. While direct relationship between their geometry and the spectrum forms the basis for such applications, little attention has been paid to the spatial variation of the boundary condition. We report on the way the geometry and such inhomogeneity become intertwined and affect the spectrum. It is often impossible to gauge how severe such interference is in the biological or geophysical experiments. We develop a perturbative theory and numerical techniques and test for cases for which exact solution is obtained.

12:15PM Z26.00006 Decomposing First Passage Random Walks, LAWRENCE SCHWARTZ, DAVID JOHNSON, Schlumberger, SIDNEY REDNER, Boston University — We develop a simulation method to model the time dependence of diffusion in composite materials with a wide range of pore sizes. Here, first passage techniques are useful because they allow a walker to move efficiently through the large open regions of the pore space. However, because one does not keep track of each intermediate position, these techniques are not well suited to calculating the effective diffusion coefficient, D(t). To address this problem we show that first passage propagation can be decomposed in terms of a sequence of intermediate probability distributions. For example, given a first passage walk from the origin to the surface of a sphere of radius R in a time t, we can evaluate the probability distributions for the particle's location at any earlier time t'. We will illustrate the behavior of these intermediate distributions with a series of examples in one and three dimensions.

12:27PM Z26.00007 Thermally Stable Mesoporous Silica Spheres synthesized under Mild Conditions1, CHRISTOPHER ZIEGLER, EUNYOUNG YOU, JAMES WATKINS, University of Massachusetts Amherst — Thermally stable, mesoporous silica spheres were synthesized using a one-pot technique under mild conditions. As-calced silica spheres were shown to be highly porous with surface areas greater than 1000 m2/g and pore volumes on the order of 1 cc/g. Pore walls were found to be highly resistant to collapse as a consequence of thermal treatment at temperatures exceeding 750 °C or hydrothermal treatment in boiling water at temperatures exceeding 100 °C for over 100 hours. 29Si-1H cross polarization NMR data indicate that the silica is highly condensed at the surface providing rationale for the exceptional pore wall stability observed. The mesoporous silica spheres were synthesized from tetraethyl orthosilicate (TEOS) at room temperature and near-neutral pH using cysteamine and cetyltrimethylammonium bromide (CTAB) in a mixed water and ethanol system. Sphere diameters ranging from 30 nm to 560 nm were observed. The preparation method and characterization of functionalized zeolite materials with

12:39PM Z26.00008 Ordered and disordered pores in porous anodic alumina: Partial equilibrium results from hexagonal lattice1, ARIEF BUDIMAN, DANIEL LO, University of Calgary — Cluster variation method is employed to find equilibrium states of pore arrangement in porous anodic alumina. Our work is motivated by a need to predict the extent of pore ordering in the anodic alumina. The pores are assumed to occupy a hexagonal two-dimensional lattice and interact with each other through their elastic deformations. Alumina-electrolyte interface energy and metal-oxide interface stress are included in the analysis. Equilibrium ordered and disordered states are obtained. Spatial pore arrangements of these states will be presented. Incorporation of ionic transports in the electrolyte and aluminum-to-alumina reactions to the model will be discussed.

12:51PM Z26.00009 Nanoporous Substrate with Mixed Nanoclusters for Surface Enhanced Raman Scattering. SEHOOON CHANG, Georgia Institute of Technology, HYUNHYUB KO, UC Berkeley, SRIKANTH SINGAMANENI, RAY GUNAWIDJAJA, VLADIMIR TSUKRUK, Georgia Institute of Technology — Rapid detection of plastic and liquid explosives is an urgent need due to various societal and technological reasons. We employed a novel design of surface enhanced Raman scattering (SERS)-active substrate based on porous aluminia membranes decorated with mixed nanoclusters of gold nanorods and nanoparticles. We demonstrated trace level detection of several important explosives such as dinitrotoluene (DNT), trinitrotoluene (TNT), and hexamethylenetriperoxidediamine (HMTD) by fast, sensitive, reliable Raman spectroscopic method. We achieved near molecular-level detection (about 15 ~ 30 molecules) of DNT and TNT utilizing the SERS substrate. However, trace level detection is challenging due to the lack of common optical signatures (fluorescence, absorption in UV-vis range) or chemical functionality of peroxide-based explosives such as HMTD. To overcome this, we employed photochemical decomposition approach and analyzed chemical fragments using SERS. We suggest that tailored polymer coating, mixed nanoclusters, and laser-induced photocatalytic decomposition are all critical for achieving this unprecedented sensitivity level.

1:03PM Z26.00010 Sorption Isotherms in Networked Nanoporous Media: Do the Parts Equal the Whole?1. CASEY E. CHIANG, FELIX CASANOVA, ANNE M. RUMINSKI, MICHAEL J. SAILOR, IVAN K. SCHULLER, University of California-San Diego — Sorption isotherms are a very important tool in the characterization of nanoporous materials. However, there is still controversy as to how capillary condensation and evaporation transitions along the isotherm correlate with the pore morphology (shape) and topology (within a network). We combined narrow (<10 nm) and wide (>30 nm) pores in nanoporous silicon to tailor the simplest networks: narrow above wide (ink-bottle) and vice versa (funnel). In addition, we compared these against their single-layered constituents. From sorption isotherms measured by optical interferometry, we observe that capillary condensation occurs identically in all pores with direct access to the gas reservoir and delayed (pore-blocking) when access is blocked, while capillary evaporation occurs identically in all pores with direct access to the gas reservoir and is delayed (pore-blocking) until direct access is allowed otherwise. These experimental results allow us to understand the global capillary behavior in nanoporous silicon.

1:15PM Z26.00011 Mechanical stability of Metal Organic Framework-5. WEI LIU, JU LI, University of Pennsylvania — Metal organic frameworks (MOFs) are crystalline structures of metal ions bridged by organic linkers. They have been proved to be highly useful in gas storage, separation, purification and catalysis. Mechanical stability is very important for their applications in industry. We studied the stress-strain relations of MOF-5 (the prototypical MOF) under different temperatures via Molecular Dynamics method (MD). It has been found that under normal stress MOF-5 is relatively strong; while under shear stress it is easy to collapse. Furthermore, under both normal and shear stress condition, its stability becomes weaker as temperature increases.

1:27PM Z26.00012 Smart nanoporous preconcentrator of explosives based on MOF51, KHORGOLKHHUU ODBADRAKH2, JAMES LEWIS, WVU — We present investigations of interactions of explosive molecules RDX and TATP with metal organic framework MOF-5, using DFTY based ab-initio simulation method FIREBALL. Energetics studies in bulk shows that only one of the binding sites of RDX in MOF-5 suggested by quantum chemistry calculations confirm. The absorption site is on a linker of the framework through 2-(OH) bond. However, surface interactions are stronger, with significantly higher binding barriers. We confirmed two adsorption sites on the surface: one with the linker and the other on a connector of the framework through 3-(OH) bonds. The stronger interactions on the surface suggest importance of size, and surfaces of MOF nanoparticles in preconcentrating the explosive molecules in the framework. Ab-initio Molecular Dynamics simulations show that the absorption of the RDX in MOF-5 is highly sensitive to temperatures, suggesting high diffusion rates for the explosive molecules at room temperature.

1:39PM Z26.00013 Optical birefringence in Compressed Aerogels1, P. BHUPATHI, J. HWANG, R. M. MARTIN, L. JAWORSKI, D. B. TANNER, Y. LEE, Department of Physics, University of Florida, Gainesville, FL 32611, J. BLANKSTEIN, Alexander W. Dreyfoos School of the Arts, West Palm Beach, FL 33401, N. MULDERS, Department of Physics and Astronomy, University of Delaware, Newark, DE 19716 — We performed optical birefringence measurements on 98% porosity silica aerogel samples subjected to various degrees of uniaxial compression up to 15% strain over a wide range of wavelength, 200 to 800 nm. Silica aerogels are composed of an entangled network of 3 - 5 nm diameter SiO2 strands and can be synthesized in a wide range of porosity, especially in the high porosity limit close to 99.9%, yet maintaining good mechanical stability. Uncompressed aerogels exhibit no or minimal degree of birefringence, indicating the isotropic nature of the material. Uniaxial compression of aerogel introduces global anisotropy, which produces optical activity in the material. We observed a quasi-linear strain dependence in |Δn| = |n_e - n_o| in compressed aerogels, where n_e(o) is the index of refraction for the extraordinary (ordinary) ray which has its polarization parallel to the compression axis. This effect has potential applications for aerogels as tunable waveplates operating in a broad spectral range.

1:51PM Z26.00014 Microwave Absorption in Percolating Metal-insulator Composites1, DARIN ZIMMERMAN, JEREMY CARDELLINO, KYLE CRAVENER, KELLY FEATHER, NICHOLAS MISKOVSKY, GARY WEISEL, The Pennsylvania State University, Altoona — We measure several electromagnetic properties of tungsten-Teflon composites as a function of metal volume concentration. The electric (E) and magnetic (H) loss tangents at 2.45 GHz and the dc conductivity each exhibit a percolation transition at a different critical value of the metal volume fraction, p. Moreover, the transition behavior depends on the average particle size and size distribution of the metal component. We explain the variation in each case by a schematic model derived from established percolation theory and the distinct response of conducting particles to microwave electric and magnetic fields.

2:03PM Z26.00015 Anisotropy of induced polarization in the context of the generalized effective-medium theory.1, VLADIMIR BURMAN, Physics and Geophysics department, University of Utah, MICHAEL S. ZHDANOV2, Geophysics department, University of Utah, ALEXANDER GRIEBENKO, Geophysics Department, University of Utah — The rock samples are examples of heterogeneous complex structure material. Modeling of electromagnetic response of this medium makes it possible to study the anisotropy of induced polarization (IP) effect. The IP effect is studied in the context of the developed generalized effective-medium theory of induced polarization (GEMTIP). The effective-medium conductivity defined by the GEMTIP model, in a general case, is represented by a tensor function. This tensorial property of the effective-medium conductivity provides a new insight in the anisotropy phenomenon in the IP effect. As an example, we consider a multiphase composite polarized model of a rock formation with ellipsoidal inclusions. We demonstrate that the effective conductivity of this formation may be anisotropic, even if the host rock and all the grains are electrically isotropic.

11:15AM Z27.00001 ABSTRACT WITHDRAWN —

11:27AM Z27.00002 Surface Coatings for Gas Detection via Porous Silicon, SERDAR OZDEMIR, School of Physics, Georgia Institute of Technology, JI-GUANG LI, Nano Ceramics Center, National Institute for Materials Science, Japan, JAMES GOLE, School of Physics, Georgia Institute of Technology — Nanopore covered microporous silicon interfaces have been formed via an electrochemical etch for gas sensor applications. Rapid reversible and sensitive gas sensors have been fabricated. The fabricated porous silicon (PS) gas sensors display the advantages of operation at room temperature as well as at a single, readily accessible temperature with an insensitivity to temperature drift; operation in a heat-sunk configuration, ease of coating with gas-selective materials, low cost of fabrication and operation, and the ability to rapidly assess false positives by operating the sensor in a pulsed mode. The PS surface has been modified with unique coatings on the basis of a general theory in order to achieve maximum sensitivity and selectivity. Sensing of NH3, NO2, and PH3 at or below the ppm level have been observed. A typical PS nanostructure coated microstructured hybrid configuration when coated with tin oxide (NOx, CO) and gold nanostructures (NH3) provides a greatly increased sensitivity to the indicated gases. Al2O3 coating of the porous silicon using atomic layer deposition and its effect on PH3 sensing has been investigated. 20-100 nm TiO2 nanoparticles have been produced using sol-gel methods to coat PS surfaces and the effects on the selectivity and the sensitivity have been studied.

11:39AM Z27.00003 Directed-Assembly of Carbon Nanotubes on Soft Substrates for Flexible Biosensor Array1, HYOYUNG WOO LEE, JUNTAE KOH, BYUNG YANG LEE, TAE HYUN KIM, JOOYUNG LEE, SEUNGHI HONG, Department of Physics and Astronomy, Seoul National University, MIHYE YI, Korea Research Institute of Chemical Technology, YOUNG MIN JHON, Korea Institute of Science and Technology — We developed a method to selectively assemble and align carbon nanotubes (CNTs) on soft substrates for flexible biosensors. In this strategy, thin oxide layer was deposited on soft substrates via low temperature plasma enhanced chemical vapor deposition, and linker-free assembly process was applied onto the oxide surface where the assembly of carbon nanotubes was guided by methyl-terminated molecular patterns on the oxide surface. The electrical characterization of the fabricated CNT devices exhibited typical p-type gating effect and 1/f noise behavior. The bare oxide regions near CNTs were functionalized with glutamate oxidase to fabricate selective biosensors to detect two forms of glutamate substances existing in different situations: L-glutamic acid, a neuro-transmitting material, and monosodium glutamate, a food additive.

11:51AM Z27.00004 Mid-infrared Verdet coefficient studies in GaAs, BaF2, and LaSrGaO3, and ZnSe, MYOUNG-HWAN KIM, Physics Dept., University at Buffalo, SUNY, VOLKER KURZ, Physics Dept., Universitaet Wuerzburg, GHEORGHE ACBAS, CHASE ELLIS, JOHN CERNE, Physics Dept., University at Buffalo, SUNY — We measure the mid-infrared (wavelength \( \lambda = 11 - 0.8 \mu m \); 0.1 - 1.5 eV) Faraday rotation and ellipticity in GaAs, BaF2, LaSrGaO3, and ZnSe. Since these materials are commonly used as substrates and windows in the mid-infrared, it is important to measure the Faraday signals for background subtraction and to test the accuracy of our measurement techniques. The light sources are lasers and a new custom-modified double-pass prism monochromator with a Xe lamp, which allowed continuous broadband measurements in the 0.31-1.5 eV energy range. Surprisingly, we find reproducible ellipticity signals, even though the radiation is well below the absorption edge of these materials and therefore no circular dichroism is expected. We suggest that the Faraday ellipticity is produced by the static retardance \( R_s \) of the ZnSe photoelastic modulator (PEM), which converts rotation signals into ellipticity. We determine \( R_s \) experimentally from the Faraday rotation and ellipticity ratio, produced by either applying a magnetic field or rotating the polarization of light incident on the PEM. Work supported by the Research Corp. Cottrell Scholar Award, NSF-CAREER-DMR0449899, and an instrumentation award from the CAS.

12:03PM Z27.00005 Diffraction by a Metallic Edge Near Plasma Frequency, MIGUEL A. ALVAREZ-CABANILLAS, National Polytechnic Institute, CITEDI — The behaviors of the fields diffracted by a metallic half-plane near plasma frequency are obtained. Incident plane wave with transverse magnetic polarization TM is diffracted by a gold sheet. The size of the atoms and the interatomic distance in the metallic sheet are assumed to be smaller than the wavelength. The electromagnetic field cannot detect the inner structure of the system and thus observes a medium conductivity defined by the GEMTIP model, in a general case, is represented by a tensor function. This tensorial property of the effective-medium conductivity provides a new insight in the anisotropy phenomenon in the IP effect. As an example, we consider a multiphase composite polarized model of a rock formation with ellipsoidal inclusions. We demonstrate that the effective conductivity of this formation may be anisotropic, even if the host rock and all the grains are electrically isotropic.

12:15PM Z27.00006 ABSTRACT WITHDRAWN —
These measurements show that the probe tips do not move with changing temperature and magnetic fields. To prevent materials from moving due to external vibrations, variable temperature magnetotransport measurements were performed. However, until this time a major inconvenience was caused by the thermal expansion of the probe tips and probe station as the temperature changed. To prevent movement, materials important for characterization and understanding of materials and devices are in use. Electrical and magnetic property measurements of nanoscale materials are important for characterizing and understanding of materials and devices. Equally important is to measure these properties at various temperatures.

In view of this, an optical system was constructed that closely simulates the Martian solar spectral irradiation, including seasonal variations due to the planet's orbit and attenuation by atmospheric dust. Upon exposure to this simulated environment, the OSL dating behavior of a suite of Martian sediment analogue materials were catalogued. Results suggest that the presence of the additional ionizing UV radiation on the surface of Mars will not compromise optical dating measurements of K- and Ca-feldspars, anhydrite, or hydrous Ca and Mg sulfates. However, Na-feldspar does appear to retain a trapped charge population, which could hinder optical dating of sediments containing more than trace amounts of sodic feldspars.

This work is supported by NSF-DMR-0602846.

12:39PM Z27.00008 The OSL dating behavior of Martian sediment analogue materials exposed to a simulated Martian solar spectrum. MARISSA DETSCH, Dept. of Physics, North Dakota State Univ., KEN LEPPER, Dept. of Geosciences, North Dakota State Univ. — Optically stimulated luminescence dating (OSL) is a terrestrial geochronometric technique being developed for in-situ dating of the geomorphic features on the surface of Mars. The solar spectral irradiance reaching the surface of Mars includes ionizing ultraviolet (UV) radiation that does not reach the surface of the Earth. In view of this, an optical system was constructed that closely simulates the Martian solar spectral irradiance, including seasonal variations due to the planet’s orbit and attenuation by atmospheric dust. Upon exposure to this simulated environment, the OSL dating behavior of a suite of Martian sediment analogue materials were catalogued. Results suggest that the presence of the additional ionizing UV radiation on the surface of Mars will not compromise optical dating measurements of K- and Ca-feldspars, anhydrite, or hydrous Ca and Mg sulfates. However, Na-feldspar does appear to retain a trapped charge population, which could hinder optical dating of sediments containing more than trace amounts of sodic feldspars.

1:03PM Z27.00010 Variable temperature measurements in cryogenic probe stations; Measurements with Magnetic Fields. JEFFREY LINDEMUTH, Lake Shore Cryotronics — Electrical and magnetic property measurements of nanoscale materials are important for characterizing and understanding of materials and devices. Equally important is to measure these properties at various temperatures. These measurements are facilitated with cryogenic probe stations that provide a variable temperature environment over a wide range of temperatures. However, until this time a major inconvenience was caused by the thermal expansion of the probe tips and probe station as the temperature changed. To prevent movement from damaging the sample, the normal procedure is to lift the probe tips as the temperature changes. This prevents the implementation of totally automated variable temperature measurements. We present results using a new probe design that allows the probe tips to remain in contact to sample during temperature changes. With this new design we demonstrate, with optical microscopy, the total tip movement of less than 2 microns when the temperature of the sample changes from 4.2K to 300K. The same probes that eliminate the movement from thermal expansion also improve the isolation of the measurements to external vibrations. To show the performance of this probe design, variable temperature magnetotransport measurements were performed. These measurements show that the probe tips do not move with changing temperature and magnetic fields.

1:15PM Z27.00011 GHz-Bandwidth Signal Processing for Time-Resolved Faraday/Kerr Rotation Experiments1, YANJUN MA, PATRICK IRVIN, JEREMY LEVY — Faraday/Kerr rotation is a sensitive measurement of the electron spin and its dynamics in semiconductor nanoscale devices such as GaAs quantum dots. The Kerr rotation angle from a single spin, however, can be as small as 10^-6 rad, which requires massive averaging of the Kerr signal in order to maximize the signal-to-noise ratio. By replacing the mechanical delay line typically found in time resolved Kerr rotation (TRKR) measurements with a continuous wave probe and high-speed electronics, the signal and noise can be sampled more often which results in a higher SNR. However, real-time methods for data collection are typically limited by available memory, resulting in unavoidable dead time for which data cannot be collected and averaged. The approach we have developed integrates a field-programmable gate array (FPGA) with a high-speed digitizer, thus allowing high-speed on-board averaging to overcome these technical limitations. We will demonstrate the performance of this instrument by comparing the results of this study with traditional pump-probe (sampling) techniques and discuss its applicability for a variety of dynamical spin-sensitive experiments in the solid state.

11:15AM Z28.00001 Fundamental Etching and Roughening Mechanisms of Photoresist Polymers during Plasma Processing, DUSTIN NEST, TING-YING CHUNG, DAVID GRAVES, UC-Berkeley Dept. of Chemical Eng., FLORIAN WEILNOECKER, ROBERT BRUCE, TSUNG CHENG LIN, RAY PHANEUF, GOTTFRIED OEHRLEIN, University of Maryland, College Park, ERIC HUDSON, Lam Research Corp., DEYAN WANG, CECILY ANDES, Rohm and Haas Electronic Materials — Reducing the etching and roughening of photoresist polymers during plasma processing is required as optical lithography for integrated circuit manufacture is extended to patterning features with critical dimension control on the order of nanometers. We use a vacuum beam system to simulate plasma exposure but under well-defined conditions. Samples are exposed to well-characterized beams of ions, vacuum ultraviolet (VUV) radiation, and electrons under high vacuum conditions. Post-exposure analysis includes atomic force and scanning electron microscopy and FTIR spectroscopy. We show that VUV radiation, ion bombardment, the ion / photon flux ratio and heating all play a role in the roughening of current-generation PMMA-based 193 nm photoresists. VUV radiation breaks carbon-oxygen bonds to a depth of approximately 100 nm whereas ion bombardment forms a dehydrogenated surface layer. Qualitatively similar roughening was observed in plasmas with the same ion bombardment energy and ion and VUV fluence.

11:27AM Z28.00002 Understanding the Differences between Electron and Ion Guiding, SUSANTA DAS, BUDDHIKA S. DASSANAYAKE, JOHN A. TANIS, Western Michigan University, NIKOLAUS STOLTERFOHT, Helmholtz-Zentrum Berlin, ATOMIC PHYSICS GROUP TEAM — Significant differences in the transmission and guiding of slow positive ions and fast electrons through insulating PET nanocapillary foils have been observed.1,2 While ions are transmitted without energy loss or change in charge state even when the foil is tilted with respect to the incoming ion beam, electrons undergo inelastic as well as elastic scattering leading to considerable reduction in the transmitted intensities. The underlying reasons for the differences between ions and electrons will be discussed and quantitative comparisons made. Qualitatively, slow positive ions are fully neutralized when striking a surface and consequently deposit all of their charge, whereas electrons can be elastically or inelastically scattered.3 Additionally, secondary electron emission by incident ions increases the deposited charge, while this same emission decreases the deposited charge for electrons. *Supported by Research Corporation 1N. Stolterfoht et al., Phys. Rev. A 77, 032905 (2008). 2S. Das et al., Phys. Rev. A 76, 042716 (2007). 3B. Stix et al., XXV ICPEAC, Freiburg, Germany, July 2007, Abstracts, MO 128.
11:39 AM Z28.00003 Laser Manipulation of Nanostructures, DINKO CHAKAROV, Chalmers University of Technology — This work describes a new method for controlling the pattern into which nanoparticles in a disordered metal-nanoparticle layer organize themselves by a single light pulse. The phenomena behind formation of one- and two-dimensional grating patterns are attributed to interference effects between the incident light and waveguided modes. Such self-patterning behavior could be useful for the fabrication of complex nanostructures and advanced phononic devices.

1This work was partly supported through Swedish Foundation for Strategic Research program PHOTO/NANO.

11:51 AM Z28.00004 A new method of nano-manipulation with AFM derived from nanotribology, SUENNE KIM, Department of Physics, University of Texas at Austin, DANIEL RATCHFORD, XIAOQIN LI — Based on principles of nanotribology, a new approach is explored for manipulating nanoparticles (ranging from 5nm to 60nm in diameter) with an Atomic Force Microscope (AFM). In this new approach, one first kicks a nanoparticle. Immediately following the kicking event, static friction is greatly reduced. One can then dribble the nanoparticle to the desired position in the tapping (imaging) mode of the AFM. The major advantage of this scheme lies in the active manipulation with simultaneous visual feedback. Our study revealed the mechanism for the nano-displacement is primarily governed by the “stick” events of the stick-slip process. We also found that the manipulation can be effectively controlled by adjusting the scanning speed, and the critical speed depends on the local roughness of the surface.

1This research is supported by NSF DMR-0747822, NSF-IGERT, Welch Foundation grant F-1662 and ONR grant N00014-08-1-0745.

12:03 PM Z28.00005 Single-Particle Placement on a large scale, PRADEEP BHADRACHALAM, HONG-WEN HUANG, VISHVA RAY, SEONG JIN KOH, University of Texas at Arlington — The capability of positioning single nanoparticles onto exact substrate locations holds prime technological and scientific importance. We present a novel technique to precisely place exactly one single nanoparticle onto a targeted substrate location on a large scale. This was done by defining an electrostatic guiding structure using CMOS compatible fabrication technology, which guides exactly one single 20nm gold nanoparticle onto a desired substrate location with a success rate over 90%. The measured precision of this single-particle placement (SPP) was 12.1nm. This technique has an inherent capability of limiting one single nanoparticle for each target location. Theoretical calculations has revealed that this self-limiting capability originates from an increased free energy barrier after a nanoparticle is placed on the target location, effectively blocking the approach of other nanoparticles. We also demonstrate size-selective placement of single nanoparticles, where individual nanoparticles of different sizes are guided to different target locations on the same substrate.

1(Supported by: NSF-CAREER(ECS-0449958), ONR(N00014-05-1-0050), THECB(003656-0014-2006))

12:15 PM Z28.00006 Magnetically Driven Swimming of Nanoscale Colloidal Assemblies, JENNIFER BREIDENICH, JASON BENKOSKI, LANCE BAIRD, RYAN DEACON, H. BRUCE LAND, ALLEN HAYES, Milton S. Eisenhower Research Center, The Johns Hopkins University Applied Physics Laboratory, Laurel MD 20723, PEI KENG, JEFFREY PYUN, Department of Chemistry, University of Arizona, Tucson AZ 85721 — At microscopic length scales, locomotion can only be generated through asymmetric conformation changes, such as the undulating flagellum employed by protozoa. This simple yet elegant design is optimized according to the dueling needs of miniaturization and the fluid dynamics of the low Reynolds number environment. In this study, we fabricate nanoscale colloidal assemblies that mimic the head + tail structure of flagellates. The assemblies consist of two types of magnetic colloids: 25 nm polystyrene-coated Co nanoparticles, and 250 nm polyethylene glycol coated magnetite nanoparticles. When mixed together in N-dimethylformamide, the Co nanoparticles assemble into flexible, segmented chains ranging in length from 1 - 5 µm. These chains then attach at one end to the larger magnetic beads due to magnetic attraction. This head + tail structure aligns with an external uniform magnetic field and is actuated by an oscillating transverse field. We examine the effects of Co nanoparticle concentration, magnetite bead concentration, magnetic field strength, and oscillation frequency on the formation of swimmers and the speed of locomotion.

12:27 PM Z28.00007 Observation of Fano Interference and Field Dependence by Raman Spectroscopy of Molecularly Doped Silicon, BRIAN BURKE, KEITH WILLIAMS, JACK CHAN, University of Virginia — We have investigated various doping techniques on silicon to form thin, highly p-doped layers near the surface (approximately 10 nm). We are able to observe through Raman spectroscopy the signature Fano lineshape present in the zone-centre optical phonon. We have defined high resolution channels by electron beam lithography and subsequently annealed adsorbed dopant molecules into the silicon lattice by RTA. We have performed sheet resistance measurements as well as Raman mapping to characterize the doping profile. The Raman laser line of 325 nm provides a penetration depth of roughly 8 nm, ideal for studying the surface of silicon. After studying the highly doped channel, electrodes were deposited and field dependence measurements were made. Additionally, IETS and transport measurements have been conducted for various geometries to compare with Raman data.

12:39 PM Z28.00008 Profiling surfaces with a carbon nanotube oscillator, ADRIAN POPESCU, LILIA WOODS, University of South Florida, IGOR BONDAREV, North Carolina Central University — A practical device for profiling surfaces is proposed, as an alternative to an Atomic Force Microscopy (AFM) tip. The device consists of a finite length double wall carbon nanotube oscillator with the outer tube being stationary and oriented perpendicular to the surface plane. By investigating the changes in the oscillatory behavior of the inner tube due to the proximity of the surface, the roughness of the surface can be determined. The role of the length and the initial extrusion of the moving tube, and the friction losses in the motion process are also explored. We suggest that such a device can be virtually a non-fatigue, non-wear system, and that it is possible to obtain a higher in-plane resolution as compared to the “traditional” AFM tip.

12:51 PM Z28.00009 An Electrodynamics Ratchet Motor, JIUFU LIM, University of Melbourne, School of Chemistry, JOHN SADER, University of Melbourne, Department of Mathematics and Statistics, PAUL MULVANEY, University of Melbourne, School of Chemistry — Brownian ratchets are often used to generate translational motion for biological separation processes and colloidal transport. This talk will propose a Brownian ratchet motor that enables the transduction of electrical energy into rotary micro-mechanical work. This is achieved through torque generation provided by boundary shaping of equipotential surfaces. Stochastic simulations elucidate the performance characteristics of this device as a function of its geometry. Miniaturization to nanoscale dimensions yields rotational speeds in excess of 1kHz, which is comparable to biomolecular motors of similar size.

< 0.20 heat-treated to increase the magnetostriction that is otherwise absent. This diffuse scattering exhibits asymmetric peaks at the (100) and (300) reciprocal lattice positions that are consistent with the coexistence of short-range ordered, coherent nanoprecipitates embedded in a long-range ordered, body-centered cubic matrix. A large peak splitting is observed at (300) for x=0.19, which suggests that the nanoprecipitates are not cubic but have a lower symmetry and a large elastic strain. The strongest diffuse scattering occurs for x=0.19 where the maximum magnetostriction is found. This suggests a structural origin for the enhanced magnetostriction in these materials.

11:39AM Z28.00010 When a magnetized quantum wire can act as an “active” laser medium

, MANVIR KUSHWAHA, University of Puebla, Mexico — We report on the theoretical investigation of magnetoplasmon excitations in a quantum wire characterized by a confining harmonic potential and in the presence of a perpendicular magnetic field. The problem involves two length scales: l_0 = \sqrt{\hbar/\mu_0 \omega_0} and l_\perp = \sqrt{\hbar/m^* \omega_\perp}, which characterize the relative strengths in the interplay of confinement and the magnetic field. We embark on the charge-density excitations within a two-subband model in the framework of Bohm-Pines’ random-phase approximation. The main focus of our study is the (intersubband) magnetoroton excitation which changes the sign of its group velocity twice before merging with the respective single-particle continuum. We analyze the terms and conditions within which the magnetoroton excitation persists in the quantum wires. It is suggested that the electronic device based on such magnetoroton modes can act as an active laser medium.

11:39AM Z28.00011 Suppression of electric field domains in semiconductor superlattices with side shunting layer

1. HUIDONG XU, Duke University, ANDREAS AMANN, Tyndall National Institute, Ireland, ECKEHARD SCHÖLL, Technical University of Berlin, Germany, STEPHEN TEITSWORTH, Duke University — We have numerically studied the electronic transport properties of a weakly-coupled semiconductor superlattice that possesses a conductive side shunting layer, using a model that includes lateral dynamics in each quantum well of the superlattice [1]. Depending on the lateral size of the superlattice quantum wells and the quality of the connection between the shunt layer and the superlattice, the shunt may inhibit the formation of electric field domains in the superlattice under conditions of negative differential resistance (NDR). We determine conditions to achieve a stable spatially-uniform electric field distribution, an important condition for practical NDR devices such as superlattice THz oscillators. For a superlattice with small lateral extent, a high quality shunt stabilizes the uniform field configuration in the entire structure, whereas a lower quality shunt leads to current oscillations and/or static field domains. We characterize the bifurcations associated with the transitions between these different behaviors. [1] A. Amann and E. Schöll, Phys. Rev. B 72, 165319 (2005).

11:15AM Z29.00001 Non-cubic, coherent nanoprecipitates observed by neutron diffuse scattering in highly magnetostrictive Galfenol (Fe1−xGax) alloys.

1. PETER GEHRING, National Institute of Standards and Technology, HU CÃO, CHRIS DEVREUGD, Virginia Tech, JOSE ABELARDO RODRIGUEZ, University of Maryland, JIE FANG LI, DWIGHT VIEHLAND, Virginia Tech — We report neutron diffuse scattering measurements on highly magnetostrictive Fe1−xGax alloys with different thermal treatments. Diffuse scattering is seen for compositions 0.14<x<0.20 heat-treated to increase the magnetostriction that is otherwise absent. This diffuse scattering exhibits asymmetric peaks at the (100) and (300) reciprocal lattice positions that are consistent with the coexistence of short-range ordered, coherent nanoprecipitates embedded in a long-range ordered, body-centered cubic matrix. A large peak splitting is observed at (300) for x=0.19, which suggests that the nanoprecipitates are not cubic but have a lower symmetry and a large elastic strain. The strongest diffuse scattering occurs for x=0.19 where the maximum magnetostriction is found. This suggests a structural origin for the enhanced magnetostriction in these materials.

1Supported in part by NSF grant DMR-0804232.

11:27AM Z29.00002 Magnetic and magnetoelastic properties of Ge/Co co-substituted cobalt ferrite

1. NARESH RANVAH, EUGENE MELIKHOV, JOHN SNYDER, DAVID JILES, Wolfson Centre for Magnetics, Cardiff University, WOLFSON CENTRE FOR MAGNETICS TEAM — The highly magnetostrictive material cobalt ferrite and its derivatives based on substitution of cations have been shown to have extreme sensitivity of their magnetization to stress. In order to control their properties (e.g. magnetostriction, magnetic anisotropy, strain derivative, and hysteresis) substitution of specific cations are needed. We have shown Ge1/4/Co3/4 co-substituted cobalt ferrites (Co1.25+Ge0.25Fe0.75O4) to have very interesting combinations of magneto-elastic properties. In the present study the variation of magnetic anisotropy with composition and temperature was investigated, for the new germanium/cobalt co-substituted cobalt ferrite Co1+x,GexFe2−x,O4. Hysteresis loops were measured in the range T = 10 - 400 K, with μHmax = 0 - 5 T. The high field regions of these loops were then fitted to the Law of Approach to Saturation (LA) for cubic materials as given by M = M_s[1-(8/105)(K1/\mu_0 M_s H)^2], plus a linear forced magnetisation term. Values for first order cubic anisotropy constant K1 were calculated and it was found that anisotropy increased as temperature decreases for all compositions. At most temperatures anisotropy decreased with increase in x.

11:39AM Z29.00003 Magnetostriction of Fe-based alloy

1. YANNING ZHANG, JUEXIAN CAO, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, California, 92697 USA — High magnetostrictive materials are important for sensor and actuator applications. Although the rare earth-3d metal compound, such like TbFe2, have large positive magnetostriction of ~2600ppm, their practical application was hindered due to larger activation external magnetic field and their high material costs. Large-scale industrial applications require soft magnetic materials with high magnetostrictive materials with low material costs. Nanocrystalline Fe-based alloys without rareearths are very interesting candidates due to the fact doping some nonmagnetic element, such as Ga, Al, Zn and Be, strongly alters the anisotropy energy and enhances the magnetostriction, which indicated substituting Fe by nonmagnetic elements might be a new method to develop cheap and soft magnetic material with high magnetostriction. With First-principle calculations, we have investigated the Young’s modulus, shear modulus, anisotropy energy and magnetostriction of Ga, Al, Zn, Ge and Be doped in bulk Fe. The magneto-crystalline anisotropy energy E_{JC,4} and the magnetostrictive coefficients (λ_{M4}) strongly depend on the compositions and atomic arrangement. A rigid band picture is proposed to estimate the trend of magnetostrictive coefficients of Fe, Ga and Zn compounds.

1Work is supported by US DOE (Grant No. DEFG02-05ER46237).
11:51AM Z29.00004 The Magnetocaloric Effect in Single Crystal and Processed Polycrystalline MnP\footnote{Work supported by DOE grant #DE-FG02-08ER46481.}, RYAN A. BOOTH, SARA A. MAJETHI, Carnegie Mellon University — Manganese Phosphide (MnP) is a promising magnetocaloric effect (MCE) material for use in room temperature-magnetic refrigeration because it exhibits a first-order ferromagnetic to paramagnetic phase transition at a Curie temperature of 290 K, possesses no measurable magnetic hysteresis, and has a saturation field of lower than 7.5 kOe along the c-axis. The magnetic entropy change ($\Delta S$) was measured in single crystals along the c-axis to be 2.2, 3.3, and 6.0 J / kg K in applied fields of 10 kOe, 20 kOe, and 50 kOe respectively. Cold-rolling followed by a short annealing of polycrystalline MnP was shown to create preferential crystallographic alignment that mimics the favorable properties of single crystals without the expenses associated with their growth. A comparison of the magnetocaloric effect between single crystals and rolled polycrystalline MnP is presented.

12:03PM Z29.00005 Magnetic anisotropy dependency on structural properties in strained MnAs thin films, MAGNUS WIKBERG, Dep. Eng. Sciences, Uppsala University, MIKAEL OTTOSON, Dep. Materials Chemistry, Uppsala University, JANUSZ SADOWSKI, MAX-Lab, Lund University, RONNY KNUST, OLOF KARIS, Dep. Physics and Materials Science, Uppsala University, PETER SVELLINDH, Dep. Eng. Sciences, Uppsala University — High quality thin films of MnAs (between 30 and 200 Å) have been grown with molecular beam epitaxy (MBE) on GaAs(111)B and (001) substrates and under different growth conditions. The magnetic anisotropy of the MnAs layers has been investigated with SQUID magnetometry and magnetic force microscopy (MFM). A clear correlation between choice of substrate, growth temperature and film thickness can be seen in the magnetic anisotropy and $T_c$ measurements with a rapid transition towards bulk like anisotropy constants as the film thickness is increased. From X-ray diffraction, a relationship between $T_c$ and lattice strain has been established, where the film with increasing film thickness rapidly exhibits a transition from a highly strained to a fully relaxed film. A complex dependence on the structural transition from the ferromagnetic to the paramagnetic phase is also seen in X-ray magnetic circular dichroism (XMCD) measurements, where the orbital moment does not strictly follow the spin moment near the ferromagnetic-paramagnetic phase transition.

12:15PM Z29.00006 Coercivity of Melt-Spun Gd$_{100-x}$Fe$_x$\footnote{Funded by NSF Grants Nos. DMR-0504177 and DMR-0504706}, PAUL SHAND, ANDREW MEYER, University of Northern Iowa, DAVID SCHMITTER, Providence College, GEOFFREY ROJAS, JEFFREY SHIELD, JARED GOERTZEN, University of Nebraska-Lincoln, DANIAL HASKEL, Argonne National Laboratory, DIANDRA LESLIE-PELECKY, University of Texas at Dallas — We have measured the coercivity of melt-spun Gd$_{100-x}$Fe$_x$ (0 \leq x \leq 50) alloys over the temperature range 2 K \leq T \leq 340 K. Previously performed structural measurements revealed that the system consists of crystalline hcp-Gd grains surrounded by a non-crystalline Gd or Gd-Fe phase composed of $\text{Gd}_{25-y} \cdot \text{Fe}_y$, where $x > y$ is the iron concentration in the amorphous region. The two-phase structure is responsible for an unusual dependence of the coercivity on temperature in which non-zero coercivity is observed above the hcp-Gd $T_c$ with a peak near 320 K. The coercivity decreases as the hcp-Gd grains order, then increases with decreasing temperature. This behavior is explained by the presence of Fe-rich magnetically correlated regions.

12:27PM Z29.00007 ABSTRACT WITHDRAWN —

12:39PM Z29.00008 Epitaxial growth and spin dependent states of Co$_2$Mn$_x$Si$_{1-x}$ (111) thin films\footnote{The work is supported by DOE BES DE-FG02-05ER46216 and NSF DMR-0441218.}, LIANG HE, BRIAN COLLINS, FRANK TSUI, University of North Carolina at Chapel Hill, YONG CHU, APS, Argonne National Laboratory — Epitaxial growth of Co$_2$Mn$_x$Si$_{1-x}$ on Ge (111) substrates has been studied using combinatorial MBE techniques, including that of the Heusler alloy Co$_2$MnSi. For Si concentration of 25 at. \%, in-situ RHEED and ex-situ X-ray diffraction experiments indicate that the epitaxial growth is coherent for atomic ratio Co:Mn between 1 and 9, while the film is microcrystalline for Co:Mn < 1 and it is rough and of poor crystalline quality for Co:Mn > 9. The crystalline quality is the highest around Co:Mn = 4, whereas it exhibits a plateau around a ratio of 2, i.e. the Heusler alloy, Co$_2$MnSi. Within the region of coherent growth, at coverages below 100 Å, the growth front is smooth and 2D-like. As thickness increases, the surface morphology systematically changes from quasi-2D into 3D. The morphology transition also depends sensitively on composition, i.e. Co:Mn ratio, and temperature. Spin-dependent states as a function of composition at low coverages have been examined by tunneling spectroscopy using Al$_2$O$_3$ as the tunneling barrier and Fe and Nb as the detector layers.

12:51PM Z29.00009 Self-energy of half-metallic ferromagnet Mn$_x$Si$_{3-x}$ calculated from infrared spectroscopy data, S.V. DORDEVIC, The University of Akron, N. STOJILOVIC, John Carroll University, L.W. KOHLMAN, The University of Akron, C. PETROVIC, Brookhaven National Laboratory — We will report the results of our infrared and optical spectroscopy study of a half-metallic ferromagnet Mn$_x$Si$_{3-x}$. This compound is currently being investigated as potential injector of spin polarized currents into germanium. Infrared measurements have been performed over a broad frequency (30 - 50000 cm$^{-1}$) and temperature (10 - 300 K) range. From the complex optical conductivity $\sigma(\omega)$ we extract the electron self-energy $\Sigma(\omega)$. The calculation of $\Sigma(\omega)$ is based on novel numerical technique which uses Lvenberg–Marquardt algorithm for solution of systems of non-linear equations. Obtained self-energy provides a new insight into electron correlations in Mn$_x$Si$_{3-x}$.

1:03PM Z29.00010 Electronic and Magnetic properties of Transition Metal Borides, ADITI HERWADKAR, National Renewable Energy Laboratory, YUFENG ZHAO — Boron has three valence electron and a small covalent radius undergoing sp$_2$ hybridization in many boron clusters. It is also known to form large variety of crystal structures both planar and 3D caged molecules. Our current work is to study transition metal boride clusters. This would be useful towards designing metal boride nanoclusters with tunable optical, magnetic and electron transport properties. Different stoichiometries are studied. The metal to Boron ratio varies from 0.3 to 0.75. For each of these compositions the lowest energy geometries were determined by optimizing the bond length for several initial symmetric geometries. The lowest energy structure is then chosen as the equilibrium structure. Most strikingly, all these transition-metal boride clusters are cage-like although both boron and transition metal usually favor high coordination number. We also find that some of the clusters have an extremely high magnetic moment per unit mass. This renders metal boride nanoparticles as potentially promising light-weighted magnetic materials. All the calculations are done using the spin-polarized density functional theory method implemented in the Vienna ab initio simulation package. A plane wave basis set with (400 eV cutoff) was used in combination with an all electron like projector augmented wave potential and PBE exchange correlation functional with in the generalized gradient approximation.
1:15PM Z29.00011 Revisiting Classical Diamagnetism: A Surprise of Physics, NARENDR A KUMAR, Raman Research Institute, VIJAY KUMAR KRISHNAMURTHY, Indian Institute of Science — The Classic Bohr-van Leeuwen (BvL) theorem states that the orbital diamagnetism of a classical system of charged particles in thermal equilibrium is identically zero. This theorem is universally accepted and has entered textbooks. Physically, the theorem derives from the exact cancellation of the orbital diamagnetic moment associated with the completed cyclotron orbits of the charged particles by the paramagnetic moment subtended by the incomplete orbits skipping the boundary cuspidally in the opposite sense. In this work we have revisited the problem of this crucial but subtle role of the boundary by considering the case of a finite but unbounded system, namely that of a charged particle moving on a sphere in the presence of an externally applied magnetic field. The orbital moment calculated on the basis of the classical Langevin equation in the infinite time limit now indeed turns out to be non-zero, and has the diamagnetic sign. This violates the BvL theorem as stated in the literature. To the best of our knowledge, this is the first report of non-zero classical diamagnetism. It is explicitly owing to the above avoided cancellation. We also present possible experimental realization of the predicted classical diamagnetism.

11:15AM Z30.00001 Multiferroic states in perovskite type orthoferrites, YUSUKE TOKUNAGA, ERATO-JST, SATOSHI IGUCHI, The Univ. of Tokyo, YASUJIRO TAGUCHI, CMRGC, RIKEN, TAHAKISA ARIMA, Tohoku Univ., YOSHINORI TOKURA, ERATO-JST, The Univ. of Tokyo, CMRGC, RIKEN — Versatile and gigantic magneto-electric (ME) phenomena have been found for a single crystal of perovskite-type orthoferrite DyFeO$_3$. Below the antiferromagnetic ordering temperature of Dy moments, a linear ME tensor component as large as $a_{xx} \sim 2.4 \times 10^{-2}$ in dimensionless CGS unit is observed. In addition, it is revealed that the application of magnetic field along the c axis induced a ferroelectric order whose large polarization ($\geq 0.2 \mu$C/cm$^2$ along the c-axis) can be directly reversed by either of magnetic field or electric field. It is noteworthy that this magnetically driven ferroelectric state is even weakly ferromagnetic, i.e., truly multiferroic, in nature. We propose here that the exchange striction working between adjacent Fe$^{3+}$ and Dy$^{3+}$ layer with the respective layered antiferromagnetic components can be the origin of the ferroelectricity with such a large polarization value. It is further argued that the reversal process of electric polarization by magnetic (electric) field is inherently related to the change of the relative phase of antiferromagnetic spin (moment) arrangement of Fe (Dy) [1].

11:27AM Z30.00002 Composite Domain Walls in Multiferroic Orthoferrites RFeO$_3$, NOBUO FURUKAWA, Dept. of Physics, Aoyama Gakuin Univ. and ERATO-Multiferroics, JST, HOSHO KATSURA, CMRGC, RIKEN — In order to analyze novel magneto-electric effects such as electric-field controlled magnetization-flips in multiferroic orthoferrites RFeO$_3$, we study an effective model which includes d-spins on Fe sites and f-spins on R sites. Order parameters for d and f spins are coupled through Peierls distortions. Ginzburg-Landau theory is applied to investigate domain wall structures of the model. As a result, we find various types of solitons corresponding to ferromagnetic, ferroelectric and composite ferromagnetic-ferroelectric domain walls. Dynamics of the domain walls under external fields will also be presented.

11:39AM Z30.00003 Multiferroic BiFeO$_3$, SANG-WOOK CHEONG — BiFeO$_3$ (BFO) is a unique multiferroic in the sense that the magnitude of ferroelectric polarization is large (about 90 microC/cm$^2$) - similar with that of standard ferroelectrics such as BaTiO$_3$ and PbTiO$_3$. In addition, both magnetic and ferroelectric temperatures are much high than room temperature. BFO has been extensively studied, but mostly in the form of films. In order to explore the intrinsic properties of BFO and also properties that cannot be measured in film forms, we have investigated comprehensive physical properties of bulk BFO single crystals using a number of techniques such as neutron scattering, piezoelectric force microscopy and transport property measurement.

11:51AM Z30.00004 Polarized Neutron Investigations of BiFeO$_3$, WILLIAM RATCLIFF, NIST, SEONGSU LEE, TAEKJIB CHOI, Department of Physics, Rutgers University, ROSS ERWIN, NIST, SANG WOOK CHEONG, VALERY KIRYUKHIN, Department of Physics, Rutgers University — BiFeO$_3$ is a multiferroic material at room temperature. Until recently, the only studies on this material were performed on either thin films or powders. We report on the results of neutron diffraction studies performed on single crystals of BiFeO$_3$. Polarized neutron diffraction results unambiguously reveal that the magnetic structure of this material is chiral. Furthermore, neutron diffraction experiments have shown that it is possible to control magnetic domain populations through the application of an external electric field. These results may suggest directions for future research performed in thin films.

12:03PM Z30.00005 Weak ferromagnetism in a high-pressure phase of FeTiO$_3$ with polar lattice distortion, TAMAS VARGA, JOHN MITCHELL, Argonne National Laboratory, CRAIG FENNIE, Cornell University, STEPHEN STREIFFER, SEUNGBUM HONG, MOONKYU PARK, Argonne National Laboratory, VENKATRAMAN GOPALAN, AMIT KUMAR, EFTHTIA VLHOS, Pennsylvania State University, TAKESHI SANEHIRA, YANBIN WANG, University of Chicago — Today’s challenge in multiferroics is to identify materials in which polarization and magnetization – normally considered contraindicated properties - are strongly coupled. Recent density functional theory calculations have predicted that the family of compounds MFeO$_3$ ($M = Mn$, Fe, Ni) are promising candidates where a polar lattice distortion can induce weak ferromagnetism. The crucial insight is that while the equilibrium one-atmosphere structure of these is ilmenite, they must be transformed to a closely related LiNbO$_3$-type structure. We have corresponded the FeTiO$_3$ phase at 18 GPa and 1200 °C. It shows a sharp antiferromagnetic (AF) transition at 111.5 K. FeTiO$_3$ also displays ferroelectric domains, and weak ferromagnetism coincident with the AF transition. Possible coupling between its polarization and weak ferromagnetism is discussed based on results of piezoelectric force microscopy (PFM), second harmonic generation (SHG), dielectric, and polarization measurements.

3 The work at Argonne National Laboratory, including the use of the Advanced Photon Source, was supported by the U.S. DOE Office of Science, Basic Energy Sciences, under Contract No. DE-AC02-06CH11357.

12:15PM Z30.00006 EXAFS Studies of Multiferroic Pb(Ti,Fe)O$_3$, YING ZOU, SOMADITYA SEN, SHISHIR RAY, MARK WILLIAMSEN, University of Wisconsin-Milwaukee, USA, TOMOHIRO SHIBATA, SOMA CHATTOPADHYAY, Illinois Institute of Technology, USA, MALI BALASUBRAMANIAN, APS-Argonne National Laboratory, USA, PRASENJIT GUPTASARMA, University of Wisconsin-Milwaukee, USA — Recent suggestions [1] of multiferroic behavior in Pb(Ti,Fe)O$_3$ has revived an interest in this text-book ABO$_3$ type ferroelectric material. Here, we study the effect of Fe-substitution on the local structural and chemical environment of the parent PbTiO$_3$ phase. We have carried out extended x-ray absorption fine structure (EXAFS) measurements at the Fe-K, Ti-K and Pb-LIII edge at the Advanced Photon Source, on a series of single phase samples of PbTi$_{1-x}$Fe$_x$O$_3$ ($0 < x < 0.5$) synthesized using a sol-gel technique. The near edge fine structure (XANES) reveals that Fe cations are trivalent. A fascinating new result is the observation of charge disproportionation of Pb into Pb2+ and Pb4+, likely a result of charge redistribution arising from Fe3+ substitution. Radial distribution function (RDF) study of EXAFS spectra from the Ti-K edge and the Fe-K edge confirms that Fe substitutes Ti up to x=0.5. 1. Palmer et al, Appl. Phys. Lett. 90(2007)172901.

12:27PM Z30.00007 Phase formation, Crystal Lattice and Microstructure Studies of sol-gel derived Pb(Ti,Fe)O$_3$. SOMADITYA SEN, DAVID GELTING, SHISHIR RAY, YING ZOU, DONALD ROBERTSON, MARIJA GAJDARDZIKA-JOSIFOVSKA, LARRY BUROKER, MARK WILLIAMSEN, PRASENJIT GUPTASARMA$^2$. Physics Dept., Univ. of Wisconsin, Milwaukee, 1900 E Kenwood Blvd, Milwaukee, WI 53211, USA — It has recently been suggested$^1$ that Fe-substituted PbTiO$_3$ can exhibit magnetoelectric multiferroic behavior. With an intent to examine whether Fe can fully substitute the lattice in Pb(Ti,Fe)O$_3$ and to study its effect on crystal structure, we have synthesized highly phase pure nanopowders from citric acid metal ion chelate complexes stabilized by glycercoll in a sol gel. Using variety of probes, we demonstrate that Fe can substitute Ti up to at least 0.5 atoms per formula unit of Pb(Ti,Fe)O$_3$. Rietveld refinement of XRD data, from both laboratory and synchrotron sources, demonstrates that crystal structure of Fe substituted phases can be derived from the parent orthorhombic PbTiO$_3$ phase. Increasing concentration of Fe up to $x=0.3$ results in drastic change in lattice parameters and decrease in orthorhombic distortion. These results are supported by detailed studies of XRD, TEM and XAFS.

12:39PM Z30.00008 Electric polarization and magneto-dielectric effect in charge ordered system with frustrated geometry. TSUTOMU WATANABE, IMRAM, Tohoku University, SUMIO ISHIHARA COLLABORATION — Recently discovered multiferroic materials, where electric polarization and non-collinear spin structure coexist, are recognized as ferroelectric materials driven by spin ordering. There is another class of ferroelectricity where the electric polarization is attributed to the electronic charge ordering. Layered iron oxide LuFe$_2$O$_4$ belongs to this class of material. Ferroelectric transition occurs at almost the same temperature with the charge ordering one where Fe$^{1+}$ and Fe$^{3+}$ are aligned in the paired triangular lattices. Therefore, it is expected that the frustration plays important roles on breaking of the space inversion symmetry. We study theoretically a possibility of the charge-driven ferroelectric transition, and, in particularly, focus on the electron quantum transfer effects. We analyzed the V-t model, where t and V are the transfer integral and the Coulomb repulsion between nearest-neighbor sites, respectively, by using the variational Monte Carlo method. We found that the quantum fluctuation and frustration tend to enhance the stabilization of a three-fold charge ordered state and electric polarization although the polarization is small. In addition, we studied the effect of the spin ordering. It is found that, in some spin ordered structures, the electric polarization is stabilized accompanying the three-fold charge orderd state.

12:51PM Z30.00009 Charge order, dynamics, and magneto-structural transition in multiferroic LuFe$_2$O$_4$. XIAOSHAN XU, University of Tennessee, Knoxville, MANUEL ANGST, Oak Ridge National Laboratory, TATIANA BRINZARI, University of Tennessee, Knoxville, RAPHAEL HERMANN, Institut für Festkörperforschung, Forschungszentrum Jülich GmbH, Université de Liège, JANICE MUSFELDT, University of Tennessee, Knoxville, ANDY CHRISTIANSON, Oak Ridge National Laboratory, DAVID MANDRUS, Oak Ridge National Laboratory, University of Tennessee, BRIAN SALES, Oak Ridge National Laboratory, STEVE MCGILL, National High Magnetic Field Laboratory, JONG-WOO KIM, Ames Laboratory, ZAHIRUL ISLAM, Argonne National laboratory — We investigated the series of temperature and field-driven transitions in LuFe$_2$O$_4$. Magnetization and x-ray scattering in order to understand the interplay between charge, structure, and magnetism in this multiferroic material. We demonstrate that charge fluctuation has an onset well below the charge ordering transition, supporting the “order by fluctuation” mechanism for the development of charge order superstructure. Bragg splitting and large magneto optical contrast suggest a low temperature monoclinic distortion that can be driven by both temperature and magnetic field.

1:03PM Z30.00010 Electronic approaches on orbital anisotropy and spin configuration in Multiferroic LuFe$_2$O$_4$. K.-T. KO, POSTECH, H.-J. NOH, Chonnam National University, B.-G. PARK, POSTECH, J.-Y. KIM, PAL, J.-H. PARK, POSTECH, A. TANAKA, Hiroshima University, SUNG-BAEK KIM, POSTECH, S.-W. CHEONG, Rutgers University — The orbital anisotropy and spin configuration of the multiferroic LuFe$_2$O$_4$ are investigated by the x-ray absorption spectroscopy (XAS) at Fe $L_3$- and O $K$-edges, and the theoretical cluster model calculations including the configuration interactions and full multiplets. The x-ray magnetic circular dichroism (XMCD) results show that the system has a surprisingly large orbital moment as large as $m_O \sim 0.8 \mu_B/f.u.$, which also agrees with the theoretical calculation result. This result also well explains the observed total magnetic moment of 2.9 $\mu_B/f.u.$ The polarization dependent XAS enables us to identify the orbital level and occupation, which turns out to be rather different from the band structure prediction. We also found that the charge order plays an essential role for the 0.7 eV charge gap. Finally, we discuss the local electronic structure, orbital anisotropy, and the spin configuration of LuFe$_2$O$_4$.

1:15PM Z30.00011 Multiple magnetic transitions and glass dynamics in LuFe$_2$O$_4$. HARI SRIKANTH, MANH-HUONG PHAN, NATALIE FREY, University of South Florida, MANUEL ANGST, BRIAN SALES, DAVID MANDRUS, Oak Ridge National Laboratory — LuFe$_2$O$_4$ is a complex oxide of topical interest as ferroelectricity in this material arises from charge ordering and it also exhibits multiferroic behavior. A good understanding of the magnetic phase diagram has remained elusive due to the complexity of the system as well as the sensitivity to sample quality. In this study, we report on the magnetic properties of high quality LuFe$_2$O$_4$ single crystals grown by the floating zone method. Temperature dependent DC, AC susceptibility and isothermal magnetization reveal a rich and complex phase diagram. Magnetic transitions at 240K and 175K are accompanied by strong frequency dependence of the real ($\chi'$) and imaginary ($\chi''$) parts of the AC susceptibility indicative of glassy behavior. Quantitative fits to the glass model confirm cluster glass dynamics and this is consistent with the presence of ferrimagnetic domains within the Fe-O planes. Magnetocaloric effect (MCE) in these materials will also be presented. We will place our results in the context of work by other groups on this system and clarify the nature of the magnetic phase diagram that emerges from our studies.

1:27PM Z30.00012 Stacking the Collinear Magnetic Phases of the Geometrically-Frustrated Antiferromagnet CuFeO$_2$. RANDY FISHERMAN, FENG YE, JAIME FERNANDEZ-BACA, Oak Ridge National Laboratory — The correct stacking of hexagonal layers is used to obtain accurate estimates for the exchange and anisotropy parameters of the geometrically-frustrated antiferromagnet CuFeO$_2$. Those parameters are highly constrained by the stability of a collinear metamagnetic phase between fields of 13.5 and 20 T. Constrained fits of the spin-wave frequencies of the “up up down down” phase below 7 T are used to identify the magnetic unit cell of the metamagnetic “up up down down” phase, which contains two hexagonal layers and 10 Fe$^{3+}$ spins. The resulting exchange parameters are much smaller than those obtained from an unconstrained fit of the zero-field spin-wave data and successfully describe not only the main branch of spin-wave excitations but also the spin-wave excitations of the two twins in the $\{H,K,0\}$ plane $^1$. Research sponsored by the Division of Materials Sciences and Engineering, U.S. Department of Energy under contract with UT-Battelle, LLC. $^1$ R.S. Fishman, F. Ye, J.A. Fernandez-Baca, J.T. Haraldsen, and T. Kimura, Phys. Rev. B 78, 140407 (2008).
Site occupancy and magnetic properties of aluminum substituted barium hexaferrite, AMITAVA MOITRA, SUNGHO KIM, SEONG-GON KIM, Mississippi State University, YANG-KI HONG, University of Alabama, STEVEN C. ERWIN, Naval Research Laboratory — Aluminum substituted barium hexaferrite has been studied using density functional theory (DFT). The substitution has been carried out for BaFe_{12-χ}Al_{χ}O_{19} from χ = 1 to χ = 3 in steps of 0.5. With the aid of accurate DFT study, our result show that the Al^{3+} ions preferentially occupy the 2a and 12k site, unlike the previously reported 4f2, 2a, 4f1, and 12k sites. Our result confirms the experimental fact that with increasing of Al substitution the total magnetic moment monotonically decreases. We also present a possible reason of the site preference of 2a and 12k site, unlike the previously reported 4f2, 2a, 4f1, and 12k sites.

Magnetoelectric Coupling and Relaxation in Yttrium Iron Garnet, YUCHI YAMASAKI, YUKI KOHARA, University of Tokyo, YOSHINORI TOKURA, University of Tokyo, ERATO-JST, and RIKEN — We report the results of the magnetic and dielectric relaxation measurement on yttrium iron garnet Y_{2}Fe_{3}O_{12} which shows the 2nd order magnetoelectric (ME) effect under an applied electric field [1] and the 1st order ME effect by an electric field cooling procedure [2]. We found that the temperature dependence of the dielectric relaxation dynamics coincides with that of magnetic one. This suggests a strong magneto-electric coupling between dielectric and magnetic relaxation dynamics. Indeed the dielectric relaxation strengths are enhanced by an applied magnetic field; namely the amplitude of electric dipole moment can be tuned by magnetic field. This effect accounts for the magnetic field induced change of the static dielectric permittivity and thereby the gigantic 2nd order ME effect as observed. [1] T.H. O’Dell, Phil. Mag. 16, 487 (1967), [2] H. Ogawa et al., JPSJ 56, 452 (1987).

Dielectric and magnetic properties of the Non-centrosymmetric Fe-Lagarosite, NARA LEE, YOUNG JAI CHO, SANG-WOOK CHEONG, Rutgers University — The non-centrosymmetric compound Ba_{2}NbFe_{5}S_{12}O_{19} known as the Fe-lagarsite forms in a unique magnetic triangular lattice of Fe^{3+} spins. The interesting magnetic and dielectric properties may arise from the spin frustration of the triangular magnetic lattice as well as the broken inversion symmetry of the crystallographic structure. In order to understand the complex structure and magnetic spin ordering, we have performed comprehensive experiments on single crystals grown by a floating zone method, including x-ray diffraction analysis and measurements of magnetic susceptibility, dielectric constant and heat capacity under variation of temperature and magnetic field.

Crystal Structure and Magnetic properties of Fe-substituted nanoscale Hydroxypatite, ANDREAS KYRIACOU, RICCARDO VENTURELLI, KOREY SORGE, THEODORA LEVENTOURI, Department of Physics and Center for Biological and Materials Physics, Florida Atlantic University, Boca Raton FL 33431, USA — Magnetic nanoscale hydroxyapatite (HAp) of chemical formula Ca_{1-x-y}Fe_{x}(PO_{4})_{3}OH has been prepared by a chemical precipitation method where x varies from 0 to 1.26. Single phase HAp is identified in XRD patterns of samples with x ≤ 0.30 while maghemite (Fe_{2}O_{3}) is formed as a secondary phase for x ≥ 0.60. The average crystal size as calculated by the Scherrer equation varies from 16 nm to 28 nm. Rietveld refinement reveals a decrease of the unit cell for x ≤ 0.15. Magnetic moment measurements as a function of temperature at applied field μ_{A}H = 1.5 T shows a two component system: a temperature-dependent paramagnet (PM) or superparamagnet (SPM) and a roughly temperature-independent ferromagnetic (FM) component. No FM activity is shown for low x, followed by increased activity for higher x. Increasing SPM activity is observed for x ≥ 0.60. Hysteresis measurements show irreversible loops for x ≥ 0.22.

Structure determination of CoPt nanoparticles: Chemical ordering and its effect on magnetic properties, NILS BLANC, LAUREN BARDOTTI, MATTHIAS HILLENKAMP, ALEXANDRE TAMION, FLORIAN TOURNUS, JULIETTE TUAILLON-COMBES, VERONIQUE DUPUIS, LPMCN, EDGAR BONET, HELIO TOLENTINO, ALINE RAMOS, MAURIZIO DE SANTIS, Institut Neel, PHILIPPE OHRESSER, Synchrotron SOLEIL, THIERRY EPIERCIER, Laboratoire MATEIS — Due to the huge magnetocrystalline anisotropy of bulk CoPt crystallized in the L1_{0} phase, CoPt nanoparticles have been widely studied during the last decade. In order to determine the intrinsic magnetic properties of CoPt clusters, we synthesize benchmark samples: 3 nm diameter CoPt clusters, pre-formed in the gas phase, are embedded in an amorphous carbon matrix under UVH conditions. The transition from the chemically disordered A1 to the ordered L1_{0} phase is then obtained by annealing. Chemical ordering has clearly been evidenced by different techniques (HRTEM, GIXRD). In the case of nanoparticles, this phase transition goes with a magnetic anisotropy increase much lower than for the bulk. Besides, XMCD measurements have revealed a μ_{A}L/μ_{A}S increase for Co and Pt atoms and a strong μ_{A}S enhancement for Co upon L1_{0} ordering. F. Tournus et al. Phys. Rev. B 77, 144411 (2008) Thanks are due to the CLYM (Centre Lyonnais de Microscope) for the access to the transmission electron microscope.

Origin of magnetic anomalies and relaxation mechanisms in ferrofluids, M. B. MORALES, M. H. PHAN, N. A. FREY, S. PAL, H. SRIKANTH, Dept. of Physics, University of South Florida — From a fundamental physics perspective, it is proposed that blocking of magnetic nanoparticles and a carrier of freezing would affect the magnetization and relaxation processes in ferrofluids. To verify this hypothesis, we have conducted systematic DC magnetization and AC susceptibility studies in different ferrofluids composed of Fe_{3}O_{4} and CoFe_{2}O_{4} nanoparticles suspended in hexane and dodecan, which respectively have freezing temperatures below (178K) and above (264K) the blocking temperature of magnetic nanoparticles (~200K). Experimental results reveal that the particle blocking and carrier fluid freezing effects play key roles in the formation of glass-like relaxation peaks in ferrofluids, which remained largely unexplained in previous studies. It is also shown that the nature of these peaks is strongly affected by varying particle size and carrier fluid medium. Quantitative fits of the frequency dependent AC susceptibility to the Vogel-Fulcher model, f = f_{0}exp[E_{a}/(k(T-T_{f})], clearly indicate that the blocking of magnetic nanoparticles in the frozen state significantly affects the interparticle dipole-dipole interaction, causing characteristic spin-glass-like dynamics. A clear correlation between the blocking and freezing temperatures emerges from our studies for the first time.

Competing effect of blocking and spin frustration in nanostructured gadolinium iron garnets, M.H. PHAN, M.B. MORALES, H. SRIKANTH, University of South Florida, C.N. CHINNASAMY, V.G. HARIS, Northeastern University — The ground state magnetic properties and relaxation mechanism in magnetically frustrated system of Gd_{3}Fe_{5}O_{12} is of topical interest due to its complex magnetic structure. As a consequence of geometric and magnetic frustrations, the Gd_{3}Fe_{5}O_{12} system is expected to show glassy magnetic behavior. Through a comprehensive study of DC magnetization, AC susceptibility, transverse susceptibility, and magetocaloric effect in Gd_{3}Fe_{5}O_{12} bulk and nanostructured materials, we provide physical insights into the glassy nature and magnetic relaxation mechanisms in the gadolinium iron garnet system. It is shown that bulk Gd_{3}Fe_{5}O_{12} undergoes two different glassy states at temperatures below its compensation temperature with the low temperature glassy state strongly influenced by Gd ordering. However, the glassy nature is largely suppressed in Gd_{3}Fe_{5}O_{12} nanoparticles in which the blocking phenomenon competes with the spin frustration effect. As particle size is decreased, the blocking effect is dominant over the spin frustration effect. As a result, the nanostructured system shows magnetic relaxation features arising mainly from superparamagnetism.
12:03PM Z31.00005 Thermoinduced Magnetization in NiO Nanoparticles, GREGORY BROWN, Oak Ridge National Laboratory — The low-temperature magnetic susceptibility for model NiO nanoparticles is calculated using the Monte Carlo method, and three different behaviors are seen. With uncompensated spins present, the susceptibility diverges as $T^{-\alpha} \rightarrow 0$. For cube-shaped nanoparticles, a temperature-dependent thermoinduced magnetization is observed. For spherical and octahedral nanoparticles, a temperature-independent susceptibility associated with the spin-flop configuration is observed. Calculations for arbitrary values of the uniaxial anisotropy indicate that thermoinduced magnetization can be observed for all geometries in materials with strong enough anisotropy. This work was supported by the LDRD program of ORNL, by the DOE-OS through the Offices of BES, Division of MSE and ASCR, MICS Division. The V–Mag tool set was developed as part of a BES sponsored Computational Material Science Network project. ORNL is managed by UT-Battelle, LLC under Contract No. DE-AC05-00OR22725.

12:15PM Z31.00006 Magnetic and EPR Characterization of Ni(core)/NiO(shell) Nanoparticles, SARITHA NELLUTLA, ALEX SMIRNOV, JUNWEI WANG, JOSEPH B. TRACY, North Carolina State University — Core/shell nanoparticles have interesting applications in various fields [1-4]. Among these systems, ferromagnet(core)/antiferromagnet(shell) are of particular importance because of their potential use as MRI contrasting agents, high density magnetic recording devices, etc. [3, 4]. Here, Ni(core)/NiO(shell) nanoparticles of different core sizes ranging from 8 nm to 22 nm have been synthesized and characterized by TEM, magnetic susceptibility and electron paramagnetic resonance (EPR) spectroscopy, as "free" (non-agglomerated) particles and agglomerated clusters. Using EPR at 9.1 GHz it is shown that the temperature dependence of the g-value and the EPR linewidth are similar for both the free particles and the agglomerated clusters. This suggests that at this magnetic field (~0.3 T) the EPR signal arises mostly from the saturated magnetic moment. EPR measurements at multiple fields/frequencies provide further insight on the microscopic magnetic structure in the free particles and the agglomeration effects. [1]. M. A. Hines, P. Guyot-Sionnest, J. Phys. Chem., 100, 468 (1996). [2]. Z.C. Xu, Y.L. Hou, S.H. Sun, J. Am. Chem. Soc., 129, 8698 (2007). [3]. V. Skumryev, S. Stoyanov, Z. Zhang, G. Hadjipanayis, D. Givord, J. Nougues, Nature 423, 850 (2003). [4]. A. Hütten, D. Sudfeld, T. Ennen, G. Reiss, W. Hachmann, U. Heinemann, K. Wojczykowski, P. Justzi, W. Saikaly, G. Thomas J. Biotechnology 112, 47-63 (2004).

12:27PM Z31.00007 Development of Novel Biopolymer/Synthetic-Polymer/Iron Oxide Nanocomposites, MARLETH MENA MONTOYA, SUGEHEIDY CARRANZA, MOISÉS HINOJOSA, VIRGILIO GONZÁLEZ, FIME-UANL — In this work we report the successful development of a family of magnetic nanocomposites based on chitosan/or/polyamide 6 matrix with dispersed iron oxide nanoparticles synthesized by chemical co-precipitation. The iron oxide contents varied from 5 up to 23 wt%, the nanocomposites were studied by FTIR, UV-vis, TGA, XRD, TEM and magnetometry. The FTIR analysis demonstrates an interaction between the amide group of the polyamide 6 and the ceramic material. In formic acid, the nanocomposites absorb in the UV-Vis range, and the magnitude of the band gap (optical), calculated using the band of higher wavelength, is between 2.16 and 2.19 eV. In nanocomposites with chitosan/polyamide 6 matrix the developed morphologies are spherulites of polyamide 6 surrounded by chitosan, with the iron oxide particles presumably in the form of ferrititide. The measured magnetic properties revealed a superparamagnetic character on the studied specimens.

12:39PM Z31.00008 Characterization of ultrasonically prepared γ-Fe$_2$O$_3$/Al$_2$O$_3$ shell-core nanocomposites, MATTHEW VANNETTE, JOSHUA HUGEN, DANIEL STOECKLEIN, BRETT MCCARTY, RUSLAN PROZOROV, Ames Lab/Dept. of Physics and Astronomy, Iowa State University — High intensity ultrasonic irradiation (sonication) of slurries of Al$_2$O$_3$ nanopowder in an Fe(CO)$_5$/decane mixture produce superparamagnetic γ-Fe$_2$O$_3$ shells on non-magnetic cores. In this contribution we discuss the effect of the various adjustable parameters (sonication time and intensity, powder loading, and Fe(CO)$_5$/decane ratio) on the dc and ac magnetic properties of these composite materials. Effects of post production modification such as heat treating powders and cold pressing pellets is also presented for a subset of samples.

12:51PM Z31.00009 Phase Transformation in Silica-Coated FePt Nanoparticles, LEVENT COLAK, GEORGE HADJIPANAYIS, University of Delaware — The A1 to L1$_0$ phase transformation has been examined in silica-coated FePt particles. The nanoparticles were synthesized by reduction of platinum acetylacetonate (Pt(acac)$_2$) followed by thermal decomposition of iron pentacarbonyl (Fe(CO)$_5$) in the presence of oleic acid (OA) and oleyl amine (OY) as surfactants at low temperature [1]. The monodispersed FePt nanoparticles, with a size of 5.8 nm were then coated with silica (SiO$_2$) shells [2]. The thickness of the silica shell could be controlled between 7.5-25 nm. The coated particles were subjected to thermal processing at 900 °C for various amounts of times. No significant sintering was observed up to 2 hours of annealing for the shell thickness of 15.0 nm. In some silica-coated samples an increase in the particle size was observed after annealing. Selected Area Diffraction analysis and magnetic measurements showed the development of ordered L1$_0$ structure. Coercivity values up to 15 kOe at 7K are obtained. The phase transformation is currently being examined in other samples annealed at different times and temperatures and the results will be reported.1. Levent Colak and George C. Hadjipanayis, Nanotechnology 19 (2008) 235703.2.M. Aslam, L. Fu, S. Li, Vinayak P. Dravid, Journal of Colloid and Interface Science 290 (2005) 444-449.

1:03PM Z31.00010 Crystallization thermodynamics and kinetics of SmCo$_5$/Fe system, CHUAN-BONG RONG, J. PING LIU, Department of Physics, University of Texas at Arlington, Arlington, TX 76019 — High energy ball milling is an effective and economic way to produce the hard/soft nanocomposite permanent magnetic materials which have immense potential to exhibit much higher energy products than the conventional single phase hard magnets. Intermetallic materials undertaken high energy ball milling are usually of amorphous structures. It is therefore necessary to study the grain nucleation and growth behavior of the ball-milled amorphous powders. There has not been a systematical study of thermal dynamic and kinetic behavior of the mechanically milled nanocomposite powders. In this work, powder mixtures of SmCo$_5$ + α-Fe (α=0-30 wt%) were mechanically milled for 2 - 10 hours. The thermal dynamic and kinetic behavior of the powders was studied by measuring the differential scanning calorimetry (DSC) curves with different heating rate and isothermal methods. It was observed that the crystallization process of the SmCo$_5$ phase shifted to higher temperature while that of Fe phase shifted to low temperature with increasing milling time. Kissinger analysis shows that the activation energy of SmCo$_5$ phase significantly decreased with increasing milling time and increasing Fe content. Isothermal analysis showed that the nucleation of SmCo$_5$ phase started around 300-350 °C which is 100-150 °C lower than the crystallization temperature (460 °C).

1:15PM Z31.00011 Magneto-structural study of phase pure α and β type MnAs nanoparticles, P. KHAREL, KEERTHI SENEVIRATHNE, RON TACKETT, STEPHANIE BROCK, G. LAVES, Wayne State University — There is extensive interest in understanding the properties of nanoscale materials that exhibit magneto-structural phase transitions because of their possible use in magnetocaloric applications. Bulk MnAs exhibits a ferromagnetic transition in the range 313-317 K, together with a structural transition from a hexagonal (α-MnAs) to an orthorhombic (β-MnAs) lattice. We have studied the structural and magnetic properties of α-MnAs and β-MnAs nanoparticles synthesized using solution-phase arrested precipitation method. XRD and TEM studies show that both the α and β phase nanoparticles are crystalline, phase pure, and stable for weeks at room temperature. Magnetic measurements show that both the α-MnAs and β-MnAs phase nanoparticles undergo ferromagnetic phase transitions near 315K, but we find no evidence for the associated α to β structural transition seen in bulk MnAs. We will present an experimental investigation on the connection between structural and magnetic properties in α and β type MnAs nanoparticles, and discuss relevance to studies on other nanostructured systems.
1:27PM Z31.00012 Magnetic Force Microscopy of Ferromagnetic MnAs Nanoparticles in GaAs.

BEN CHAPRUT, RADIHKAR BARUA, LAURA LEWIS, DON HEIMAN, Northeastern University — The switching behavior and anisotropy of ferromagnetic MnAs nanoparticles in GaAs was investigated with variable-temperature magnetic force microscopy. Nanoparticles of MnAs were synthesized by annealing thin layers of GaMnAs, with Mn/Ga=0.1. Annealing at 640°C resulted in thin disc-shaped MnAs particles with diameters ~100 nm embedded in GaAs. Magnetization measurements at room temperature show that the samples are ferromagnetic and exhibit hysteresis with a coercive field ~0.1 T. In MFM images at room temperature, the majority of the nanoparticles have a single-domain magnetic dipole moment which can be oriented in one direction after applying a magnetic field ~0.1 T. The dipole orientation can be reversed after applying a field in the opposite direction. After raising the temperature above the Curie point, Tc=337 K, the sample becomes demagnetized at room temperature, with equal numbers of particles aligned in opposite directions. A sharp phase transition, from the ferromagnetic hexagonal phase to the paramagnetic orthorhombic phase, was found at 340°C, nearly coincident with the Curie temperature. This transition occurs ~30°C higher than in thin MnAs films and is attributed to tensile strain on the nanoparticles from the surrounding GaAs.

1:39PM Z31.00013 Nanoparticulate Alnico Thin Films with High Coercivity1.

OZAN AKDOGAN, GEORGE C. HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, Newark, DE, U.S.A. — Alnico V (Fe-8% Al-14% Ni-24% Co-3% Cu) nanoparticulate thin films have been produced by dc magnetron sputtering. The films were sputtered on Si substrates for magnetic measurements and carbon-coated copper grids for TEM measurements. The as-deposited films have a fine-grained microstructure with the bcc crystal structure. The as-made films were subjected to a full heat treatment which consists of heating the sample to 900°C, then cooling it to 600°C and finally annealing it at 600°C for several hours. After the heat treatment, the thin films broke up into large nanoparticles (20-60 nm) surrounded by small nanoparticles (2 nm). Electron diffraction data showed that the annealed samples had an fcc structure. The maximum room temperature coercivity was found to be 2 kOe after 6h of annealing at 600°C. The high coercivity could be due to strain that was induced during precipitation. The evolution of crystal structure and microstructure with annealing will be monitored and related to the observed magnetic properties.

1:51PM Z31.00014 Magnetic Properties of As-Prepared and Annealed Nanocrystalline Fe Particles.

KARL UNRUH, THOMAS EKIERT, University of Delaware — Air stable Fe-core/oxide-shell particles with diameters between about 100 and 200 nm have been synthesized by the reduction of a ferrous Fe salt in the presence of citrate ions. Structural, chemical, and magnetic measurements indicate that the oxide shell is 2-3 nm thick and that the core consists of essentially oxide free, α-Fe nanocrystals (about 5 nm in diameter) in addition to regions of non-crystalline, disordered Fe. The as-prepared particles evolve into a continuous porous solid structured at about the 100 nm scale after annealing in forming gas at temperatures near 750°C followed by a progressive elimination of the porosity at higher annealing temperatures. Prior to the formation of the porous solid the saturation magnetization, coercivity, and remanence ratio all increase slightly with annealing temperature due to an increase in the size of the core Fe crystallites at the expense of the disordered Fe component. The structural transformation to a porous solid, however, results in an abrupt increase in both the coercivity (by about 50% at 300 K and 100% at 5 K) and remanence ratio (about 100% at 300 K and 150% at 5 K).

2:03PM Z31.00015 Anisotropic Sm-Co(Fe) Nanoparticles Produced by Surfactant-Assisted Ball Milling1.

NILAY GUNDUZ-ASKDOGAN, GEORGE C. HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, Newark, DE, U.S.A., DAVID J. SELLMYER, Department of Physics and Astronomy, University of Nebraska, Lincoln, NE 68588 USA. — Magnetic hard SmCo and Sm2(Co8-δFe2δ)-17 nanoparticles have been produced by using surfactant assisted low- and high-energy ball milling. Surfactants prevent the re-welding of the crashed nanoparticles during the milling process and thus limit the particle growth. Oleic acid was used as the surfactant and the heptane as the milling medium. High energy ball milling experiments took place in a milling vial with carbon steel balls by using a Spex 8000M high energy ball milling machine. The coercivity was found to increase with milling time with a value of 2.9 kOe for Sm2(Co8.5Fe2.5)17 and 19.5 kOe for SmCo5 after 12 hrs of milling. TEM data showed that the milled powders have a narrow size distribution. The TEM grid-deposited samples showed self-assembled nanoparticles in the Sm2(Co8-δFe2δ)17 alloy after 4 hours of milling, which could be further aligned when subjected to a magnetic field. The evolution of structural and microstructural properties of the particles will be monitored and compared with their magnetic properties.

Session Z32 GMAG DMP FIAP: Focus Session: Magnetoresistance and Spin-dependent Transport

11:15AM Z32.00001 Nitrogen doping in single-crystal MgO magnetic tunnel junctions.

JUSTIN BROCKMAN, CHENG-HAN YANG, IBM / Stanford, MAHESH SAMANT, KEVIN ROCHE, STUART PANKIN, IBM — Recent experiments have shown evidence for induced ferromagnetism in thin films of carbon and nitrogen-doped zinc oxide. We have discovered similar behavior in nitrogen-doped MgO films grown by plasma-assisted thermal evaporation. Here, we incorporate these films as tunneling barriers into single-crystal multilayer magnetic tunnel junctions and present experimental results showing the magnetoresistance and current-voltage characteristics for these structures.

11:27AM Z32.00002 Bias dependence of Fe-MgO-Fe magnetic tunnel junction devices within a single-band tight-binding model.

TEHSEEN RAZA, School of Electrical and Computer Engineering, Purdue University, West Lafayette, IN 47907, HASSAN RAZA, School of Electrical and Computer Engineering, Cornell University, Ithaca NY. 14853 — We have developed a transferable single-band tight-binding model benchmarked with the ab initio methods for Fe-MgO-Fe magnetic tunnel junction (MTJ) devices [1]. The computational complexity of our model is on the order of an effective mass one, but additionally it includes the bandstructure physics over the two-dimensional transverse Brillouin zone in an average manner. We study the bias dependence of the tunnel magnetoresistance (TMR) ratio in MTJ devices. At low bias, for both the 4-layer and 12-layer MgO barrier, the TMR is bias-independent. It is higher for the 12-layer device due to relatively a larger decrease in the AP current density. At high bias, our model predicts a sharp roll-off in TMR ratio, which is attributed to a rapid increase in the Delta1 band current density in the anti parallel (AP) configuration due to the bandedge states entering the conduction window. The TMR ultimately becomes negative when the AP current becomes higher than the P current due to the different k-states tunneling through the same barrier. [1] T. Z. Raza and H. Raza, arXiv:0804.2957
11:39 AM Z32.00003 Magnetoresistance in Double Spin Filter Tunnel Junctions with Nonmagnetic Electrodes and Its Unconventional Bias Dependence1, GUO-XING MIAO, MARTINA MULLER, JAGADEESH MOODERA, MIT — We demonstrate a large tunnel magnetoresistance (TMR) originating purely from the tuning of tunnel barrier heights in double barrier junctions with nonmagnetic electrodes. This is achieved by the spin filtering that occurs due to the selective tunneling probabilities for spin-up and -down electrons through a magnetic semiconductor barrier resulting in highly spin polarized tunnel currents. Combining two such barriers in a tunnel junction thus leads to a TMR without the necessity of magnetic electrodes. This is significantly different from traditional approaches for generating TMR involving two ferromagnetic electrodes and for example, using Al2O3 or MgO barriers. We demonstrate the first realization of such unconventional tunnel junctions and TMR using EuS / EuO based spin filter barriers with nonmagnetic Al electrodes. The novel non-monotonic and asymmetric bias behavior in magnetoresistance can be qualitatively modeled in the framework of WKB approximations.

1Work supported by NSF, ONR and KIST-MIT project funds.

11:51 AM Z32.00004 The critical role of the barrier thickness in spin filter tunneling1, CASEY MILLER, University of South Florida, Department of Physics — Spin filter tunneling is considered in the low bias limit as functions of the temperature dependent barrier parameters. We demonstrate the generation of spin polarized tunneling currents in relation to the magnetic order parameter, and discuss how an interfacially suppressed order parameter leads to a temperature dependent tunneling current asymmetry. Analyzing the full parameter space reveals that the often overlooked barrier thickness plays a critical role in spin filter tunneling. With all else fixed, thicker barriers yield higher spin polarization, and allow a given polarization to be achieved at higher temperatures.

12:03PM Z32.00005 Spin-Dependent Electronic Transport in Fe/MnAs/Fe Structures, KYUNG-YEON KIM, HYOUNG JOON CHOI, Department of Physics and IPAP, Yonsei University — We have performed first-principles calculations of electronic structures and tunnel magnetoresistances of Fe/MnAs/Fe structures, which are junctions of two semi-infinite metals and a half-metal placed between them. The electronic structures are described by the Kohn-Sham density functional theory, with local spin density approximation, norm-conserving semicore pseudopotentials, and pseudo-atomic orbital basis set. The tunnel magnetoresistance is obtained by using a scattering- state method, considering different configurations of the magnetization. This work was supported by the KRF (KRF-2007-314-C00075) and by the KOSEF Grant No. R01-2007-000-20922-0. Computational resources have been provided by KISTI Supercomputing Center (KSC-2008-S02-0004).

12:15PM Z32.00006 Spin dependent transport in FeCo|MgBO|FeCo magnetic tunnel junctions: Can boron in the oxide region be a good thing?, DEREK STEWART, Cornell Nanoscale Facility, Cornell University — Recent experimental studies on FeCoB/MgO/FeCoB tunnel junctions have shown that boron can diffuse into the oxide region during rf-sputtering and result in the formation of crystalline MgBO regions[1,2]. These tunnel junctions still provide high tunneling magnetoresistance values as well as very low RA products[3]. Using a plane wave-pseudopotential density functional approach, I have examined potential Mg(B) oxides such as MgB2O4 as well as kotoite (Mg2B2O5). Total energy calculations indicate that these oxides should be more stable than the formation of separate regions of MgO and B2O3. Kotoite (Mg2B2O5) also has a boron concentration close to that found in the experimentally grown MgBO regions. In addition, kotoite provides a good lattice match with MgO and could act to template neighboring FeCo into crystalline bcc layers during annealing. This evidence suggests that kotoite is formed during the deposition process. I will also discuss the complex band structure of kotoite (Mg2B2O5) and examine how this will also affect spin dependent transport from the FeCo leads. [1] J. Y. Bae et al., J. Appl. Phys. 99 08T316 (2006) [2] J. C. Read et al., Appl. Phys. Lett. 90 132503 (2007) [3] J. C. Read personal communication

12:27PM Z32.00007 Effect of thermal spin disorder on transport through magnetic tunnel junctions, ALEKSANDER WYSOCKI, KIRILL BELASCHENKO, Department of Physics and Astronomy, University of Nebraska Lincoln — We study the transport properties of Fe1−xMgOFe1−xMgO tunnel junctions in the presence of spin disorder using the noncollinear density functional theory. For a given temperature the spin disorder in ferromagnetic leads is introduced by randomizing the directions of spin densities in atomic spheres according to the mean-field angular distribution function. For pure FeMgOFe we found that even small spin disorder has a dramatic effect on transmission as compared to the zero temperature case due to the presence of interface states in the minority spin channel that are strongly affected by spin disorder. This results in a complicated temperature dependence of the tunneling magnetoresistance (TMR). On the other hand, in the case of Fe1−xMgOFe1−xMgO the interface states are less important and the main effect of the spin disorder is to decrease the spin polarization diminishing TMR. The temperature dependence of TMR is in agreement with Julliere model prediction with the spin polarization being proportional to magnetization.

12:39PM Z32.00008 Evolution of low-frequency resistance noise during annealing in CoFeB/MgO/CoFeB tunnel junctions1, RYAN STEARRETT, WEIGANG WANG, LUBNA SHAH, EDMUND NOWAK, JOHN XIAO, University of Delaware — We have studied the evolution of tunneling magnetoresistance (TMR) and resistance noise in magnetic tunnel junctions (MTJs) as a function of annealing time at 425°C. Previously, we showed that short annealing times do lead to significant improvement in the MgO crystal structure and crystallization of the CoFeB electrodes, resulting in large TMR values up to 200%. We also observe that the low-frequency resistance noise decreases significantly after annealing for only a few minutes. The resistance noise has a 1/f spectrum and is quantified by a Hooge-like parameter, α, given in units of μm². In unannealed samples α is of order 10⁻⁹ μm² and decreases with increasing voltage bias. Upon annealing, α drops to 10⁻¹⁰ μm² and is less dependent on bias, particularly in the parallel configuration. We attribute the decrease in α and its bias dependence, α(V), to a reduction of defects in and around the barrier due to annealing. The implications for optimizing the signal to noise ratio of MgO-based MTJ sensors will also be discussed.

1:03PM Z32.00010 Current-Perpendicular-to-Plane Magnetoresistance of CoFe-based Exchange-Biased Spin-Valves1. CHIYUI AHN, KYUNG-HO SHIN, Korea Institute of Science and Technology, REZA LOLLOEE, JACK BASS, WILLIAM PRATT, Michigan State University — Concentrated Co(50)/Fe(50) and Co(70)/Fe(30) alloys are of interest for spintronics applications. We have constrained the spin-transport properties of these alloys by measuring at 4.2 K the specific resistance (CPP area times resistance) and magnetoresistance of exchange-biased spin-valves (EBSVs) of the form (FeMn/CoFe/Cu/CoFe)—here CoFe indicates one of the two alloys of interest—where the magnetization of one CoFe layer is exchange bias pinned by the adjacent antiferromagnetic FeMn layer, and the magnetization of the other CoFe layer is free to switch from parallel (P) to anti-parallel (AP) to that of the pinned layer in a modest magnetic field. For each CoFe alloy, we have measured EBSVs where the thicknesses of both the fixed and free layers were held equal and varied together, and EBSVs where the thickness of the pinned CoFe layer was held fixed and that of the free layer was varied. From such measurements we have estimated two parameters: the bulk scattering asymmetry and the spin-diffusion length, for each of the two CoFe alloys. We will present both our data and the derived parameters.

1:27PM Z32.00012 Enhancement of Biquadratic Coupling in Co/Fe/MgO/Fe(001). JARED WONG, YUEH-FENG CHIANG, ANDREW HOFF, XIAOJING TAN, YAN LI, KEYU PI, WEI HAU WANG, HARRY TOM, ROLAND KAWAKAMI, University of California, Riverside — One interesting aspect of the interlayer exchange coupling (IEC) across MgO is that in addition to the bilinear coupling, a biquadratic coupling favoring 90° magnetization alignment has been observed [1, 2, 3]. We investigate IEC in Co/Fe/MgO/Fe(001) and the affects of non-ideal aspects of the MgO-heterostructure, such as interface oxidation and impurities in the MgO, via molecular beam epitaxy (MBE) synthesis and magneto-optic Kerr effect (MOKE) measurements across aged samples. By independently varying the oxygen content of the MgO film and the Fe/MgO interface, we find that the biquadratic coupling is correlated to the interfacial oxidation. Furthermore, the temperature dependence of the biquadratic coupling exhibits a strong increase at low temperatures. Our findings strongly support the loose spin mechanism as the origin of the biquadratic coupling across MgO[4]. 1. J. Jaure-Vincent, C. Tiusan, C. Bellouard, et al., Phys. Rev. 1:39PM Z32.00013 Magnetic tunnel junctions with a ferroelectric barrier using epitaxial La$_{0.7}$Ca$_{0.3}$MnO$_3$/(Ba, Sr)TiO$_3$/La$_{0.7}$Ca$_{0.3}$MnO$_3$ trilayers1. SHENMING GUO, KE CHEN, XIAOXING XI, QI LI, Pennsylvania State University, YONGGANG ZHAO, Tsinghua University — We have fabricated multiferroic tunnel junctions using ferromagnetic La$_{0.7}$Ca$_{0.3}$MnO$_3$ as electrodes and ferroelectric (Ba, Sr)TiO$_3$ as the barrier. We have observed tunneling magnetoresistance as in a typical magnetic tunnel junction (MTJ). Since the ferroelectric barrier can be charge polarized in two opposite directions which alters tunneling conductance, we have observed large tunnelling resistances (~50%) when the charge polarization is switched. This is consistent with the results of both magnetic parallel and antiparallel states. As a result, this type of junctions has four resistance states instead of two for a normal MTJ, corresponding to positive- and negative-polarized parallel and antiparallel states. The four states can be manipulated by the magnetic and electric fields. The dependence of the magnetoresistance and electroresistance as functions of magnetic field, electric field, and bias voltage will be presented.

Friday, March 20, 2009 11:15AM - 2:03PM — Session Z33 DCMP: Fluctuation Phenomena 403

11:15AM Z33.00001 Fluctuations of the superconducting order parameter as an origin of the Nernst effect. KAREN MICHAELI, Department of Condensed Matter Physics, The Weizmann Institute of Science, Rehovot 76100, Israel, ALEXANDER FINKELSTEIN, The Weizmann Institute of Science, Israel and Department of Physics, Texas A&M University, College Station, TX 77843-4242, USA — We show that the strong Nernst signal observed recently in amorphous superconducting films far above the critical temperature is caused by the fluctuations of the superconducting order parameter. We demonstrate a striking agreement between our theoretical calculations and the experimental data at various temperatures and magnetic fields. Besides, the Nernst effect is interesting not only in the context of superconductivity. We discuss some subtle issues in the theoretical study of thermal phenomena that we have encountered while calculating the Nernst coefficient. In particular, we explain how the Nernst theorem (the third law of thermodynamics) imposes a strict constrain on the magnitude of the Nernst effect.

11:27AM Z33.00002 Interstate switching induced by non-Gaussian noise1. LORA BILLINGS, Montclair State University, MARK DYKMAN, Michigan State University, IRA SCHWARTZ, US Naval Research Laboratory — We consider the rate of switching between stable states of a dynamical system driven by a non-Gaussian noise. The problem of the switching barrier is reduced to a variational problem of finding a mechanical action for an auxiliary noise-free system. The emphasis of our analysis is placed on the generic system-independent features of fluctuations induced by Poisson noise. If the system is overdamped, Poisson noise leads to switching only for a certain polarity of pulses. This is qualitatively different from the noise effect on underdamped systems. We study the transition between these types of behavior with varying damping. For systems close to a bifurcation point, the barrier height displays a scaling dependence on the control parameter and on the noise parameters. We study parametric dependence for generic types of bifurcations, such as saddle-node and pitchfork bifurcations. Analytical results are compared with the results of detailed numerical simulations.

Josephson current noise above $T_c$ in superconducting tunnel junctions

Josephson current noise above $T_c$ in superconducting tunnel junctions

Benjamin Phillabaum, Purdue University, and Yen Lee Lo, Ohio State University

We propose that hysteretic effects in superconducting tunnel junctions may be used as a probe of electronic nematic order in cuprate superconductors. Stripes, a unidirectional, nanoscale modulation of electronic charge, are strongly affected by quenched disorder in two-dimensional and quasi-two-dimensional systems. While stripe orientations tend to lock to ma jor lattice directions, dopant disorder locally breaks rotational symmetry. In a host crystal with otherwise C4 rotational symmetry, stripe orientations in the presence of quenched disorder map to the random field Ising model. We use simulations of the random field Ising model to generate ensembles of local stripe orientations, and then further simulate the effects of such a pattern on the superfluid density within the XY model. We find clear hysteretic effects in the superfluid density anisotropy as a function of applied orienting field.

Current-driven quantum switch

M.V. Milosevic, Departement Fysica, Universiteit Antwerpen, Belgium, A. Kanda, S. Hatsumi Hatsumi, Institute of Physics and TIMS, University of Tsukuba, Japan, and F.M. Peeters, Departement Fysica, Universiteit Antwerpen, Belgium, Y. Ootuka, Institute of Physics and TIMS, University of Tsukuba, Japan

We investigate the effect of static anti-phase stripe order on the weak-field Hall effect in superconducting $T_c$ in bi- and trilayers. These interfaces are partially oriented within the crystallographic ab-plane are achieved by tilted epitaxial growth on SrTiO$_3$ (305) substrates. Sharp magnetization switching behavior is observed in the (305) oriented structures, due to the uniaxial magnetic anisotropy. At temperatures close to $T_c$, resistance jumps are induced by magnetization switching. Our results indicate that the switching behavior arises from magnetic stray fields from the ferromagnetic layers that penetrate into the superconductor, rather than spin-switch or spin-accumulation effects.

Theory of Low-Temperature Hall Effect in Stripe-Ordered Cuprates

Jie Lin, Andrew Millis, Department of Physics, and Philip Phillips, University of Illinois at Urbana-Champaign

We investigate the effect of static anti-phase stripe order on the weak-field Hall effect of electrons with dispersion appropriate to the high $T_c$ cuprates. We first consider the cases where the magnitudes of the spin and charge stripe potentials are smaller than or of the same order as the bandwidth of electrons. In a model with only spin stripe potential, and at carrier concentrations appropriate to hole-doped cuprates, the calculated $R_H$ shows sign change as increasing the stripe potential, in semi-quantitative agreement with data. In a charge-stripe-potential-only model, $R_H$ increases as the charge stripe potential increases, with no sign change occurring. In a model with both stripe potentials, $R_H$ may be enhanced or may change sign. We also consider the case in which the magnitudes of the stripe potentials are much larger than the bandwidth, where analytical results can be obtained.

Emergence of Particle-Hole Symmetry near Optimal Doping in High-Temperature Copper Oxide Superconductors

Shiladitya Chakraborty, University of Illinois at Urbana-Champaign

High-temperature copper oxide superconductors (cuprates) display unconventional physics when they are lightly doped whereas the standard theory of metals prevails in the opposite regime. For example, the thermoelectric power changes sign abruptly near optimal doping in a wide class of cuprates, a stark departure from the standard theory of metals in which the thermopower vanishes only when one electron exists per site. We show that this effect arises from proximity to a state in which particle-hole symmetry is dynamically generated. The operative mechanism is dynamical spectral weight transfer from states that lie at least 2eV away from the chemical potential. The emergence of this symmetry close to optimal doping points to pairing in the cuprates being driven by high-energy electronic states.

Exact two-band model of Cu-O planes with charge stripes and plaquettes

Stellan Ostlund, Mats Granath, Gothenburg University

A standard model of the Cu-O planes of high $T_c$ superconductors suggests the relevance of a three-band model of electrons with strong Coulomb repulsion. Particularly dominant is the copper site interaction and charge fluctuations are most strongly suppressed on these sites. We simplify this model further by completely suppressing the charge fluctuations on the copper sites and replacing the copper spins by a spin texture that couples to the local hopping. The resulting generic two-band model of electrons in is then studied for various spin textures on the copper atoms. For general values of the effective hopping parameters, the low energy eigenstates strongly favor charge stripe and plaquette ordering, with a complex multiply connected Fermi surface with the possibility of both pockets and open orbits coexisting. Particularly striking is the emergence of multiparticle ground states that are both delocalized and still effectively minimize nearest neighbor density correlations.

Two-order-parameter theory of magnetism and superconductivity

Victor Galitski, Tudor Stanescu, University of Maryland

Starting with a microscopic interacting electron Hamiltonian, we derive a self-consistent two-order-parameter theory to describe a general case of competing or co-existing magnetic and superconducting instabilities. This is achieved by splitting the initial interaction in two different channels and weighting each channel with an auxiliary field with a non-linear constraint. The double Hubbard-Stratonovich transform leads to a model similar to that in gauge theories. We analyze the resulting theory and argue that generally the magnetic and superconducting fluctuations are equally important and should be treated on equal footing. We discuss the general criteria of the two transitions occurring at similar energy scales and discuss the relevance of these results to superconductivity in the heavy fermion compounds and possibly the cuprates.
11:15AM Z35.00011 Two band model for the cuprates. SHU LIU, STEVEN WHITE, UC, Irvine — We use a numerical canonical transformation approach to derive an effective two-band model for the hole-doped cuprates, which keeps both oxygen and copper orbitals but removes double occupancy from each. A similar model was considered previously by Frenkel, Gooding, Shraiman, and Siggia (PRB 41, number 1, page 350). We compare the numerically derived model with previously obtained analytical results. In addition to the usual hopping terms between oxygens $t_{pp}$ and Cu-Cu exchange terms $J_{cu}$, the model also includes a strong copper-oxygen exchange interaction $J_{po}$ and a Kondo-like spin-flip oxygen-oxygen hopping term $K_{po}$. We use the density matrix renormalization group to study the charge, spin, and pairing properties of the derived model on ladder systems.

11:27PM Z33.00012 Classification of topological insulators and superconductors in three spatial dimensions. SHINSEI RYU, Department of Physics, University of California, Berkeley, ANDREAS SCHNYDER, Kavli Institute for Theoretical Physics, University of California, Santa Barbara, AKIRA FURUSAKI, RIKEN, ANDREAS LUDWIG, Department of Physics, University of California, Santa Barbara — We systematically study topological phases of insulators and superconductors (or superfluids) in 3D. We find that there exist 3D topologically non-trivial insulators or superconductors in five out of ten symmetry classes introduced in seminal work by Altland and Zirnbauer within the context of random matrix theory, more than a decade ago. One of these is the recently introduced $Z_2$ topological insulator in the symplectic (or spin-orbit) symmetry class. We show there exist precisely four more topological insulators. For these systems, all of which are time-reversal invariant in 3D, the space of insulating ground states satisfying certain discrete symmetry properties is partitioned into topological sectors that are separated by quantum phase transitions. Three of the above five topologically non-trivial phases can be realized as time-reversal invariant superconductors, and in these the different topological sectors are characterized by an integer winding number defined in momentum space. When such 3D topological insulators are terminated by a 2D surface, they support stable surface Dirac (Majorana) fermion modes.

11:39PM Z33.00013 Spin-Orbit Scattering and Quantum Metallicity in Ultra-Thin Be Films. PHILIP ADAMS, YIMIN XIONG, AMAR KARKI, DAVID YOUNG, Louisiana State University — We compare and contrast the low temperature magnetotransport properties of ultra-thin, insulating, Be films with and without spin-orbit scattering (SOS). Beryllium films have very little intrinsic SOS, but by “dusting” them with sub-monolayer coverages of Au, one can introduce a well controlled SOS rate. Pure Be films with sheet resistance $R > R_Q$ exhibit a low-temperature negative magnetoresistance (MR) that saturates to the quantum resistance $R_Q = h/e^2$. This high-field quantum metal phase is believed to represent a new ground state of the system. In contrast, the corresponding negative MR in Be/Au films is greatly diminished, suggesting that, in the presence of strong SOS, the quantum metal phase can only be reached at field scales well beyond those typically available in a low temperature laboratory.

11:51PM Z33.00014 Quantum critical point and van Hove singularity in La$_{2-x-y}$Sr$_x$Nd$_y$CuO$_4$. BEN MALLETT, Victoria University, JEFFERY TALLON, Industrial Research Ltd — By means of Zn substitution, thermopower and magnetic measurements we locate, distinguish and track the evolution of the pseudogap critical point and the van Hove singularity as a function of Nd content and relate these to pressure dependent effects in the Nd-free compound. The results have generic implications for all HTS cuprates.

11:15AM Z35.00001 Properties of iron selenide single crystals. CEDOMIR PETROVIC, Brookhaven National Laboratory, RONGWEI HU, Brookhaven National Laboratory and Brown University, BROOKHAVEN NATIONAL LABORATORY TEAM — Single crystals of FeSe$_x$ were grown by molten metallic flux technique. Synchrotron powder X-ray diffraction confirms phase purity. Thermodynamic, magnetic and electrical transport properties will be presented.

Supported by the Office of Basic Energy Sciences US Department of Energy

11:27AM Z35.00002 Single crystal growth and anisotropy of magnetic and transport properties of FeTe and FeTe$_{1-x}$Sn$_x$ superconductors. RONGWEI HU, Physics Department, Brown University, CEDOMIR PETROVIC, Condensed Matter Physics and Materials Science Department, Brookhaven National Laboratory — Single crystals of FeTe and FeTe$_{1-x}$Sn$_x$ were grown by molten metallic flux technique. Synchrotron powder X-ray diffraction confirms phase purity. We will present anisotropy of magnetic and electrical transport properties in normal and superconducting state of these compounds.

11:39AM Z33.00003 New Fe-based superconductor $S$ doped FeTe using nontoxic elements. YOSHIHIKO TAKANO, YOSHIKAZU MIZUGUCHI, National Institute for Materials Science (NIMS) — Discovery of Fe-based new superconductor was received with considerable surprise. The Fe based-superconductor is expected to be a new series of high-Tc superconductors such as cuprate High-Tcs. However, one of the demerits of Fe based-superconductor is that it contains toxic element of As or Se. So, new Fe based- superconductors composed of nontoxic elements were required. Recently, we have discovered $S$ doped FeTe as a new superconductor using nontoxic elements. Its superconducting transition temperature is around 10K and the upper critical fields is 70T. This material has merit for superconducting applications.

11:51AM Z35.00004 Superconducting and magnetic properties of Fe-Se-Te compounds. C.V. TOMY, G. BALAKRISHNAN, M.R. LEES, Department of Physics, University of Warwick, Coventry CV4 7AL, UK — The discovery of a new Fe based superconductor $a$Fe$_x$Se$_y$ with a $T_c$ of 8 K, hot on the heels of the discovery of superconductivity in LaOFeP/As compounds, has triggered a fresh interest in the study of Fe based superconductors. $S$ can be replaced with Te in FeSe$_{1-x}$Te$_x$, and this results in an increase in $T_c$ from 8 K for $x = 0$ to 15 K for $x = 0.5$ while compounds for $x > 0.8$ are no longer superconducting. We report the synthesis and characterization of the compounds FeSe$_{1-x}$Te$_x$ covering the entire solid solution range. The superconducting transition in resistivity measurements does not show any broadening in magnetic fields up to 9 T, but shifts to lower temperatures linearly with a value $\sim -0.22$ K/T. This results in extremely high upper critical fields ($H_{c2}$) of the order of 70-80 T in these compounds. The superconducting properties are also sensitive to applied pressure and exhibit a positive $dT_c/dP$ of around 0.41 K/kbar for the $x = 0.5$ composition. We observe a jump in specific heat at $T_c$ corresponding to a superconducting gap of 1.8 meV, indicating the bulk nature of superconductivity. Detailed investigations through magnetization, transport and specific heat measurements are presented. A study of the magnetic properties of the non superconducting end compound, FeTe is also presented to gain insight into the onset of superconductivity in the doped systems.

This work supported by DOE under grant Grant DE-FG02-07ER46420.
12:03PM Z35.00005 High Pressure Structure and Transport Properties of the FeSe_{0.88} Superconductor, T. WU, Z. CHEN, T.A. TYSON, Z. QIN, T. ZHOU, Physics Department, New Jersey Institute of Technology, C. ZHANG, S.-W. CHEONG, Department of Physics and Astronomy, Rutgers University — The structure of FeSe_{0.88} was measured for pressures up to 7 GPa using diamond anvil cells in order to probe the changes in the lattice which coincide with change in the transport properties. These measurements are being complemented by high pressure transport measurement over the same pressure range. The trends in structure and transport with pressure will be presented in order to understand the origin of the strong pressure dependence of the superconducting transition temperature.

12:15PM Z35.00006 Superconductivity and antiferromagnetism in Fe(Se_{1-x}Te_{x})_{0.82}, E.K. VEHESTEDT, M.H. FANG, B. QIAN, T.J. LIU, Tulane University, L. SPINU, H.M. PHAM, University of New Orleans, W. BAO, M.R. FITZSIMMONS, M. ZHERNENKOY, Los Alamos, Y. QIU, Q. HUANG, M.A. GREEN, P. ZAJDEL, NIST, J. YANG, Zhejiang University, Y. LIU, Pennsylvania State University, Z.Q. MAO, Tulane University — The search for unconventional superconductors has been reenergized by the discovery of Tc up to 56 K in FeAs type materials [1]. Revelation of the binary superconductor FeSe, Tc = 8 K [2], prompted our investigation of the phase diagram and the evolution of superconductivity and magnetism in the ternary Fe(Se_{1-x}Te_{x})_{0.82} (0 < x < 1.0) system. We discovered a new superconducting phase with Tc,max = 14 K for 0.3 < x < 1.0. End member FeTe_{0.82} is non-superconducting and exhibits incommensurate antiferromagnetic (AFM) order. The AFM order contains both linear and spiral components, propagating diagonally in the Fe tetragonal lattice, in contrast with the commensurate AFM order in FeAs-based superconductors. Superconductivity occurs when the long-range AFM order evolves into short-range correlations with the isovalent substitution of Se for Te. These findings strongly suggest that superconductivity in this system is associated with magnetic correlations, and thus may be unconventional in nature.

12:27PM Z35.00007 ABSTRACT WITHDRAWN

12:39PM Z35.00008 Growth and superconductivity of FeSe_{x} crystals, ZHI LI XIAO*, UMESH PATEL*, SUHONG YU*, HELMUT CLAUS, VITALI VLASTKO-VLASOV, SEVDA AVCI*, JOHN SCHLIEUTER, ULRICH WELP, WAI-KWONG KWOK, Argonne National Laboratory, *Northern Illinois University — Stimulated by the recent discovery of high temperature superconductivity in ferrous pnictides, other iron-based planar compounds have been revisited to search for superconductivity. The most promising outcome of this effort is the discovery of superconductivity in alpha - FeSe which is less toxic but has a FeSe_{x} tetrahedral planar crystal sublattice similar to that consisting FeAs_{x} in the oxypnictides. Investigations on the superconducting in FeSe_{x} can shed light on the superconducting mechanism in oxypnictides. We report the growth of FeSe_{x} crystals through a vapor self-transport approach. Both tetragonal and hexagonal shaped FeSe_{x} crystals with a lateral dimension of up to a few millimeters were obtained and their superconductivity was investigated with both magnetization and resistive measurements. We systematically explored the effect of synthesis parameters such as Fe/Se ratio, sintering temperature and cooling rate on the quality of the crystals.

1 This work is supported by DOE, under contract DE-AC02-06CH11357, Award DE-FG02-06ER46334, and by NSF Grant No. DMR-0605748.

12:51PM Z35.00009 Superconductivity and Antiferromagnetism In Fe(Se_{1-x}S_{x}) System, T.J. LIU, Tulane University, M.H. FANG, B. QIAN, E.K. VEHESTEDT, Tulane University, J.H. YANG, Zhejiang University, H.M. PHAM, L. SPINU, University of New Orleans, Z.Q. MAO, Tulane University — The surprising discovery of superconductivity up to 56 K [1] in FeAs based compounds has reinvigorated the search for unusual superconductors. The recently revealed FeSe superconductor [2] has inspired the community to take a second look at other previously studied materials, such as FeTe. We have investigated properties of Fe(Se_{1-x}S_{x}). Our results show that the solid solution of S in this system is limited, < 30%. We observed superconductivity at 9 K in both polycrystalline samples Fe(Se_{1-x}S_{x}) with 0 < x < 0.3 and 0.86 ≤ y ≤ 1.1, and single crystals with the composition Fe(Se_{0.9}S_{0.1})_91. In addition, our results suggest that this superconducting phase coexists with antiferromagnetism and that the superconducting volume fraction depends on excess Fe at interstitial sites, and excess Fe suppresses superconductivity. This allows us a unique view into the important role of magnetic correlations in mediating superconducting pairing.

1:03PM Z35.00010 Superconductivity of Iron Selenide Thin Films, YUEFENG NIE, ERIND BRAHIMI, JOSEPH BUDNICK, WILLIAM HINES, MENKA JAIN, BARRETT WELLS, University of Connecticut — Near stoichiometry FeSe films were successfully grown on MgO, SrTiO_{3}, and LaAlO_{3} single crystal substrates using pulsed laser deposition (PLD). X-ray diffraction analysis showed that the FeSe films have a tetragonal structure on SrTiO_{3} and LaAlO_{3} substrates. A mixture of tetragonal and hexagonal structures was observed on MgO substrates due to the larger lattice constant mismatch. The superconductivity of films exhibited a strong dependence on epitaxial strain and thickness. Thicker films (∼ 200 nm) are strained. Films on nearly lattice-matched LaAlO_{3} are superconducting, while films under tension on SrTiO_{3} or MgO are metallic but not superconducting down to 5K. The onset temperature for superconductivity have a near linear magnetic field dependence with dH/dT = -2.8 T/K for fields up to 9T.

1 The work is supported by the US-DOE through contract # DE-FG02-00ER45801.

1:15PM Z35.00011 Crystal growth and superconductivity of new Fe–Te base materials, GENDA GUN, CMP&MS, Brookhaven National Laboratory, NY 11973, USA, JINSHENG WEN, ZHIJUN XU, Z.W. LIN, QIAN Li, J.M. TRANQUADA, CMP&MS, BNL, CMP&MS, BNL TEAM — A number of Fe-base superconducting materials with critical superconducting temperature up to 56K have been discovered recently. Because As and its oxide of the Fe–As base superconducting materials is poison, it is a serious safety issue for researchers to make the bulk materials. The new Fe–Te base superconducting materials with Se doping are less toxic and safe to handle. We have grown a number of the FeTe_{1-x}Se_{x} single crystals (x = 0–0.5) by using a modified floating-zone growth technique. The effects of the growth condition and the composition of a feed rod on the critical superconducting temperature of FeTe_{1-x}Se_{x} have been studied by using a floating zone machine. The single crystals of the PbO-type tetragonal structure FeTe_{1-y}Fe_{y} (y = 0.04 to 0.08) are not superconducting. When Se substitutes for Te in FeTe_{1-x}Se_{x} single crystals, the superconducting transition temperature increases with increasing Se content.

1 This work is supported by DOE under contract No. DE-AC02-98CH10886.
which indicates that this cluster's stability could be accounted for by the Jellium model. The Al$_3$Bi cluster has a large ionization potential of 7.1 eV, a low electron affinity of 1.4 eV and a HOMO-LUMO gap of 1.7 eV. The molecular orbitals of Al$_3$Bi are two very compact structure of Al$_3$Bi, which consist of alternated Fe-X and electron-doping Tl layers, very similar to ternary BaFe$_2$As$_2$ system. As in all the Fe-based superconductors, the electronic structure near the Fermi level is dominated by Fe 3d states, with a pseudogap. Tl occurs with valence Tl$^+_{1}$, and thus provides heavy electron-doping with 0.5 additional carrier per Fe relative to Fe-X layers. This pushes the Fermi level to the upper edge of the pseudogap and results in disappearance of hole cylinders of Fermi surface at zone center. As expected, the spin density wave instability is completely suppressed and the checkerboard antiferromagnetism becomes the favored magnetic order. This over-doped system may be helpful in elucidating the magnetic, superconducting mechanism, and spin pseudogap behavior in Fe-based materials. Ti deficiency is predicted to reinstate the part of hole Fermi surface and again induce spin fluctuations corresponding to the spin density wave, which are essential for pairing states in Fe-based superconductors.

We gratefully acknowledge support from the U. S. Department of the Army through a MURI grant W911NF-06-1-0280.
11:51 AM Z37.00004 Copper nanocluster growth at experimental conditions using temperature accelerated dynamics, C. S. DIAS, GCEP-Centro de Física da Universidade do Minho, Braga, Portugal. T-1 Group, MS B268, Los Alamos National Laboratory, Los Alamos, USA. — We study the dynamics of vapor phase cluster growth near experimental conditions of pressure at temperatures below 200K. To this end, we carried out temperature accelerated dynamics (TAD) simulations at different vapor pressures to characterize the morphology of the resulting nanoparticles, which leads to a range of values of the flux of impinging atoms at fixed vapor temperature. At typical experimental pressures of $10^{-3}$ – $10^{-4}$ bar TAD provides substantial boost over regular Molecular Dynamics (MD). TAD is also advantageous over MD, regarding the sampling of the network of visited states, which provides a deeper understanding of the evolution of the system. We characterize the growth of such clusters at different vapor pressures.

12:03PM Z37.00005 Photoabsorption by Volume Plasmons in Metal Clusters1, CHUNRONG YIN, CHUNLEI XIA, Vitaly Kresin. University of Southern California. Metal clusters exhibit strong photoabsorption resonances in the visible part of the spectrum. These are collective "surface plasmon" excitations which have been extensively investigated. However, the UV part of the spectrum has remained rather unexplored. Some theoretical calculations have predicted that a measurable portion of the delocalized valence electrons' dipole oscillator strength should be located in this region. This predicted absorption feature has been ascribed to a volume-plasmon type of excitation, which in small particles can couple to light, in contradistinction to the situation in bulk metals. We have carried out a photodepletion cross section measurement on a pair of prototypical simple-metal nanoclusters, Na$_{20}$ and Na$_{55}$, finding that these systems indeed possess a broad volume-plasmon absorption peak centered at $\approx 4$ eV and having an oscillator strength contents of $\approx$15-20% of the total, in good agreement with theoretical calculations. These spectra provide the first experimental confirmation of the existence of optically active volume-type collective electronic excitations in metal nanocluster particles.

12:15PM Z37.00006 Atomic Dipole Moments and Polarizabilities of Na$_N$ Clusters, N= 2-30, 38, and 55, 1, KOBLAR JACKSON, LI MA, Central Michigan University, Mount Pleasant, MI 48859, MINGLI YANG, Institute for Nanobiomedical Technology and Membrane Biology, West-China Medical School/West-China Hospital, Sichuan University, Chengdu, China, JULIUS JELLINEK, Chemical Sciences and Engineering Division, Argonne National Laboratory, Argonne IL 60439, USA. — The response of Na$_N$ clusters, N = 2 - 30, 38, and 55 to a static external electric field is studied using a new method that decomposes the total cluster dipole moment and polarizability into contributions from non-overlapping atomic volumes (Jackson et al., J. Chem. Phys. 129, 144309 (2008)). The atomic dipole moments and polarizabilities are in turn partitioned into local dipole and charge-transfer components, corresponding to dielectric and metallic responses, respectively. Analysis of the atomic polarizabilities indicates a strong dependence on the location of the atoms within the clusters and shows directly the effect of electrostatic screening in the clusters. We show that the relative importance of the charge-transfer component of the cluster polarizability increases with cluster size and approaches the bulk-limit on a per-atom basis for clusters as small as 20 atoms. The charge-transfer component is shown to be responsible for the structure/shape driven variations, and for shape-related anisotropies, in the cluster polarizabilities.

12:27PM Z37.00007 Magnetic Properties of Arsenic Cluster Assemblies1, MEICHUN QIAN, A. C. REBER, S. N. KHANNA, Dept. of Physics, Virginia Commonwealth University, A. SEN, S. MANDAL, N. K. CHAKI, Depts. of Chemistry and Physics, Penn. State University. — Clusters have the potential to serve as building blocks of materials, enabling the tailoring of materials with novel properties. Recently, we synthesized a magnetic cluster assembled material using the As$_7$ cluster and cryptated K, which are the elements from main group. X-ray studies show that the As$_7$ cluster is distorted to accompany two cryptated K. We have investigated the magnetic properties of As cluster assembly using density functional theory. We found the As$_7$ cluster has the (-2) valence state and possess one unpaired electron. The magnetic state is stabilized in the crystal and has a lower energy of 90 meV than the nonmagnetic state. The magnetic moments are located on the As$_7$ cluster and display antiferromagnetic order in the crystal. We also study the magnetic properties of the As cluster assemblies with transition metal as a linker, and these findings are possible to provide a new kind of magnetic materials.

12:39PM Z37.00008 Interpreting the magnetic and electric deflections of free metal clusters in molecular beams, ANTHONY LIANG, JOHN BOWLAN, WALTER DE HEER. — A short review of the analysis of magnetic and electric deflection data will be presented. Electric and magnetic beam deflection of several metal clusters, including Au$_N$, Al$_N$, Nb$_N$O, Na$_N$, Ho$_N$, Co$_N$, Rh$_N$ at various temperatures (20K-300K) and field strengths will be presented. The relation between the broadening of the deflected beam and the polarization distribution of the ensemble assuming a classical polar spherical rigid rotor model is demonstrated. Complicating factors including asymmetry effects and residual temperature effects will be discussed.

12:51PM Z37.00009 Comparative study of metal clusters by Quantum Monte Carlo method1, YUNING WU, HAI-PING CHENG, Quantum Theory Project, Department of Physics, University of Florida, PAUL KENT, CNMS, Oak Ridge National Lab — Lithium and sodium clusters have been studied by fixed-node diffusion quantum Monte Carlo method. This stochastic wave-function-based approach can provide more accurate results and serve as benchmarks against which other techniques may be compared. We studied the binding energies and investigate different geometries to decide the ground state. Our results are compared with those derived from other method such as DFT and CI methods. Our objective is to validate current quantum Monte Carlo methods for small metal clusters that undergo size dependent geometrical transitions.

modeled using Lennard-Jones potentials. Our results show that the cantilever deflection depend on the combination of the Lennard-Jones parameters as well as surface tension and strain energy. In this work, we use a molecular approach to describe the entire system. In particular, the solid beam is modeled as a collection of biosensors utilizing nano or micro-sized cantilevers. Through chemical coating of probe molecules that exhibit strong affinity to the target molecules, the calculated HOMO-LUMO gap of 1.89 eV, and can be viewed as a gas phase Zintl analogue of Sn.

CASTLEMAN GROUP COLLABORATION — Here we present evidence that the gap between the highest occupied and lowest unoccupied molecular orbitals (XANES), will also be presented to demonstrate the evolution of O vacancies and possible N impurities due to thermal annealing in the IBAD deposited films. Of structural stability, the short-range-order local structural information obtained from EXAFS measurements is of central importance. Powder samples with (EXAFS) technique. These materials have shown cubic long-range-order structure and high hardness without chemical stabilizers. To understand the origin of structural stability, the short-range-order local structural information obtained from EXAFS measurements is of central importance. Powder samples with different nanoparticle sizes prepared by different sol-gel processes were analyzed. Zr k-edge EXAFS, as well as N k-edge x-ray absorption near-edge structures (XANES), will also be presented to demonstrate the evolution of O vacancies and possible N impurities due to thermal annealing in the IBAD deposited films.

TPD over laboratory time scales. Although the simulated TPD spectra agree with experiment, a detailed analysis reveals underlying kinetic phenomena that contrast the standard experimental interpretation and opens new possibilities for understanding molecular kinetics at solid surfaces.

In this work, we use accelerated molecular-dynamics to simulate TPD of pentane from the basal plane of graphite, in the first atomistic simulations to probe TPD over laboratory time scales. Although the simulated TPD spectra agree with experiment, a detailed analysis reveals underlying kinetic phenomena that contrast the standard experimental interpretation and opens new possibilities for understanding molecular kinetics at solid surfaces.

1:03PM Z37.00010 Electronic Structure of Bi₃Ga₃−y Semiconductor Clusters and the Special Stability of Bi₃Ga₃ - A Gas Phase Zintl Analogue; JOSE ULISES REVELES, Department of Physics, Virginia Commonwealth University, Richmond VA, 23284, UJJWAL GUPTA, JOSHUA J. MELKO, Departments of Chemistry and Physics, The Pennsylvania State University, University Park, PA 16802, SHIV N. KHANNA, Department of Physics, Virginia Commonwealth University, Richmond VA, 23284, A. W. CASTLEMAN, JR., Departments of Chemistry and Physics, The Pennsylvania State University, University Park, PA 16802, SHIV KHANNA RESEARCH GROUP COLLABORATION, THE CASTLEMAN GROUP COLLABORATION — Here we present evidence that the gap between the highest occupied and lowest unoccupied molecular orbitals (HOMO-LUMO gap) can be tuned (1.12eV-1.89eV) by changing the Ga composition of Bi₃Ga₃ neutral and anionic clusters, some of which display special stability. Collaboratively, mass spectrometry, photoelectron spectroscopy and computational results show that Bi₃Ga₃ is a very stable cluster with a large calculated HOMO-LUMO gap of 1.89 eV, and can be viewed as a gas phase Zintl analogue of Sn⁺², already synthesized in the solution phase. The stability of Bi₃Ga₃ is further attributed to the fact that it has 12 valence electrons and possesses a closo structure in agreement with Wade’s rules.

1:15PM Z37.00011 Simulation of the Adsorption on Nano/Micro-Cantilever Sensors; PADET KHOSATHIT, PHILLIP CHOI, P.-Y. BEN JAR, University of Alberta — Recent advances in nano/micro fabrication techniques have led to the development of biosensors utilizing nano or micro-sized cantilevers. Through chemical coating of probe molecules that exhibit strong affinity to the target molecules, the cantilever would deflect when the target molecules bind with the probe molecules. Previous simulation studies on these systems often involved the use of a multi-scale approach in which molecular models are used for the probe and target molecules while the cantilever is modeled as a continuum solid beam using surface tension and strain energy. In this work, we use a molecular approach to describe the entire system. In particular, the solid beam is modeled as a collection of molecules connected by lattice springs. The intermolecular interactions between the three types of molecules (i.e., probe, target and cantilever molecules) are modeled using Lennard-Jones potentials. Our results show that the cantilever deflection depend on the combination of the Lennard-Jones parameters as well as the number and positions of the probe and target molecules. Details of their effects will be presented in the paper.

1:27PM Z37.00012 Origin of Structural Stability in Cubic ZrO2 Nanocrystals Studied by EXAFS; Y.-L. SOO, S.L. CHANG, National Tsing Hua University, Taiwan, C.L. CHEUNG, R. SABIRIANOV, F. NAMARAV, W.N. MEI, University of Nebraska, P. CHU, National Central University, Taiwan, J.F. LEE, NSRRC, Taiwan — Local environments surrounding Zr nanocrystalline powders and thin films of cubic zirconia prepared by sol-gel and ion beam assisted deposition (IBAD) methods were investigated by using extended x-ray absorption fine structure (EXAFS) technique. These materials have shown cubic long-range-order structure and high hardness without chemical stabilizers. To understand the origin of structural stability, the short-range-order local structural information obtained from EXAFS measurements is of central importance. Powder samples with different nanoparticle sizes prepared by different sol-gel processes were analyzed. Zr k-edge EXAFS, as well as N k-edge x-ray absorption near-edge structures (XANES), will also be presented to demonstrate the evolution of O vacancies and possible N impurities due to thermal annealing in the IBAD deposited films.

11:15AM Z38.00001 Understanding surface energies of transition metals with density-functional theory; ALOYSIUS SOON, MARTIN FUCHS, MATTHIAS SCHEFFLER, Fritz-Haber-Institut der MPG — Determining index-specific surface energies of metals is, to date, still a non-trivial task, both experimentally and theoretically. Density-functional theory (DFT) calculations within the local-density approximation (LDA) for exchange-correlation (XC) have provided understanding of qualitative trends. Yet, absolute surface energies, in particular of d/metals still exhibit significant uncertainties related to the description of XC: gradient-corrected functionals (GGA) which improve over the LDA for other properties often predict less accurate surface energies. This calls for a careful analysis of XC effects on surface energies, including non-local exchange and/or correlation. Here we analyze the surface energies of 4d/metals with modern GGA functionals (PBEsol, AM05, developed to better describe bulk solids and (jellium) surfaces than the LDA and previous GGAs), using the all-electron FHI-aims code [1]. Relating the bulk cohesive energy and surface energy via a bond-cutting model we find modern GGA can indeed correct the poorer results of the usual PBE-GGA but worsen the bulk cohesive energies of 4d/metals. In addition, we consider hybrid XC functionals, using a cluster correction scheme [2], and discuss the effects of including exact exchange on the calculated surface energies.

11:27AM Z38.00002 The initial stages of NaCl dissolution: Ion or ion pair solvation?; JIRI KLIMES, ANGELOS MICHAELIDES, London Centre for Nanotechnology and Department of Chemistry, University College London — The interaction of water with rock salt (NaCl) is important in a wide variety of natural processes and human activities. A lot is known about NaCl dissolution at the macroscopic level but we do not yet have a detailed atomic scale picture of how salt crystals dissolve. Here we report an extensive series of density functional theory, forcefield and molecular dynamics studies of water clusters at flat and defective NaCl surfaces and NaCl clusters. The focus is on answering seemingly elementary questions such as how many water molecules are needed before it becomes favorable to extract an ion or a pair of ions from the crystal or the cluster. It turns out, however, that the answers to these questions are not so straightforward: below a certain number of water molecules (~12) solvation of individual ions is less costly and above this number solvation of ion pairs is favored. These results reveal a hitherto unknown complexity in the NaCl dissolution process born out of a subtle interplay between water-water and water-ion interactions.

11:39AM Z38.00003 Accelerated Molecular Dynamics of Temperature-Programmed Desorption; KRISTEN FICHTHORN, KELLY BECKER, MARIA MIGNOGNA, Penn State University — The most widely used experimental method for quantifying thermal desorption is temperature-programmed desorption (TPD). Despite its extensive use, interpretation of this experiment can still be controversial. A significant difficulty with interpreting TPD is that this macroscopic experiment offers a limited picture of the underlying microscopic kinetic events. In this work, we use accelerated molecular-dynamics to simulate TPD of n-pentane from the basal plane of graphite, in the first atomistic simulations to probe TPD over laboratory time scales. Although the simulated TPD spectra agree with experiment, a detailed analysis reveals underlying kinetic phenomena that contrast the standard experimental interpretation and opens new possibilities for understanding molecular kinetics at solid surfaces.

### 12:03PM Z38.00005 Probing colloidal physics on the nanometer length scale

**SUNIL SAINIS, Post Doc. Fellow, FRANK VOLLMER, Rowland Junior Fellow** — The sharp spectral features associated with ultra-high Q microresonator modes are sensitive to changes in the local environment and surface of the resonator [1]. Microresonator cavities have been used to detect the binding of single molecules [2] and viruses in an aqueous medium. We report on recent experiments that use microresonators to access colloidal physics on the nanometer length scale. We examine shifts in the resonator as a function of bulk ionic strengths and surface adsorption in a colloid.

### 12:15PM Z38.00006 Effect of boundary condition on the viscosity of olefins: A molecular dynamics study

**LING TI KONG, COLIN DENNISTON, MARTIN MUSER, University of Western Ontario, YUE QI, General Motor** — The viscosity of hexene was examined by means of non-equilibrium molecular dynamics simulations under different wall-liquid boundary conditions, namely over-smooth wall, more or less realistic wall, and over-adhesive wall. It is found that the wall-liquid interaction plays an important role in the ordering/layering of liquid, and consequently affects the behavior of olefins upon different normal pressures. With the same moving speeds of walls, the shear-rate (the slope of velocity profile) in the liquid is found to decrease with the increasing of normal pressure under over-smooth wall condition, while it is found to increase under the over-adhesive wall condition. The viscosity, in turn, shows a linear dependence on the normal pressure under over-smooth condition while exhibits an exponential dependence under the over-adhesive wall condition. The underlying mechanism of these observations will be presented and discussed in this talk.

### 12:27PM Z38.00007 Suppressing and Amplifying Depletion Attractions between Surfaces Roughened by Asperities

**KUN ZHAO, THOMAS MASON, UCLA** — Motivated by recent experiments on roughness-controlled depletion attractions, we study the effect of roughness on depletion attractions between flat surfaces decorated using hemispherical and hemispherial asperities. Our calculations show that the depletion attraction between rough surfaces can be either dramatically reduced or amplified depending on the details of the surface morphologies. This model also explains the observed self-assembly of rough Janus platelets into dimers and provides quantitative predictions of roughness-controlled depletion attractions for conditions that have not yet been explored experimentally.

### 12:39PM Z38.00008 The Dynamics of Charging of Muscovite Mica: Measurement and Modeling

**PAUL J. SIDES, Professor, Carnegie Mellon Univ, DANISH FARUQUI, PhD Student, Carnegie Mellon University, ANDREW J. GELLMAN, Professor, Carnegie Mellon Univ** — The advent of a new method for measuring the zeta potential of planar surfaces, the rotating disk, allowed the investigation of the charging process of mica after immersion in water. The zeta potential of freshly-cleaved muscovite mica was recorded within seconds of immersion of the sample and in fractions of a second thereafter. The zeta potential of mica in water at pH = 5.6 with no added potassium changed by 40 – 50 mV over the charging process of mica after immersion in water. The charging of mica in alkaline KCl solutions of arbitrary concentration, however, was too fast for observation. The charging of mica in alkaline KCl solutions of arbitrary concentration, however, was too fast for observation. The equilibrium zeta potential depended on the logarithm of salt concentration, in agreement with a model based on ion exchange reactions. The average values of the potassium adsorption, proton desorption, potassium adsorption, and potassium desorption rate coefficients were 45 liter/s ± 0.0014/s ± 0.0006, 58 liter/s ± 5, and 0.14/s ± 0.03, respectively. ### 12:51PM Z38.00009 Effects of Embedded Dipoles on the Electrical Response of Self Assembled Monolayers

**P.P. ZHANG, O.M. CABARCOS, T.A. DANIEL, P.S. WEISS, D.L. ALLARA, The Pennsylvania State University** — There has been recent interest in the use of polar molecules assembled at electrodes for tuning work functions and engineering charge injection barriers in organic electronic devices. With this in mind we have been investigating the electrostatic properties of simple model systems prepared from self-assembled alkanethiolate monolayers on Au(111) with the incorporation of an embedded ester moiety [-(CO$_2$)$_{n}$ = $E$] in the adsorbate molecules. The intrinsic static dipole moment of the ester moiety of ~1 Debye magnitude leads to the formation of a strong, highly organized, planar electric dipole layer in the SAM. From our previous X-ray photoelectron spectroscopy data we observe a consistent shift of the C 1s photoelectron kinetic energies between the top and bottom alkyl segments, defined as -(CH$_2$)$_m$ –E-(CH$_2$)$_n$, regardless of the relative lengths $m$ and $n$. This shift correlates well with the value of the electrostatic potential across the E layer. Our recent surface potential AFM measurements, however, reveal an apparently anomalous strong dependence of surface potential on the sizes and ratios of $m$ and $n$, in contrast to the constant electrostatic potential observed in XPS measurements. Mechanisms underlying these effects will be discussed, with possible implications for the electrostatic behavior of more complicated organic and biological systems.

### 1:03PM Z38.00010 Interfacial Composition of the Ionic Aqueous Solution Studied by the Adsorption of the Cationic Molecules

**JINSUK SONG, MAHN KIM, Physics Department, KAIST** — Knowing the interfacial composition of the ionic aqueous solution is important not only for understanding many atmospheric and environmental chemistry processes 1 but also for understanding many biological processes because the interaction between biomaterials happens often at the interfacial region such as water-vesicle interface in ionic aqueous solution. In this study, the surface anion density is estimated by measuring the surface density and adsorption angle of the cationic molecule, Malachite Green(MG) adsorbed at the air-ionic aqueous solution interface using the second harmonic generation technique. The anion number density at the interface increases with the increasing concentration of the ions and with the increasing size of the anions for spherical ions. It is consistent with other experimental measurements and simulation results2,3. However, it seems that the anion density depends not only on the anion but also on the cation and shape and chemical composition of the ions. 1 E. Knipping et al., Science 288, 301 (2000) 2 S. Ghosal et al., Science 307, 563 (2005) 3 P. Jungwirth et al., J. Phys. Chem. B 105, 10468 (2001)
Coverage Dependent X-ray Photoemission on Halogenated Benzene on Graphite

We studied the adsorption of isomers of halogenated benzene on graphite. We found difference in the behavior of three different symmetry types, (1,2), (1,3), and (1,4), of diiodobenzene (C_6H_4I_2) and 1,4-bromiodobenzene (C_6H_4IBr) adsorbed on graphite surface at 95K by X-ray photoemission spectroscopy. Although the molecules are expected to be similar in their electronic structure, the sticking coefficients and the strength of screening effects are considerably different for the different isomers. We find evidence for different intermolecular interactions both in the initial state and in the final state as well. Symmetry, not simply the chemical constituents, play a role in adsorbate chemistry.

Retardation of ice crystallization by short peptides

The effect of short peptides on the growth of ice crystals is studied using molecular dynamics simulations. The simulations focus on two sequences (Gly-Pro-Ala-Gly and Gly-Gly-Ala-Gly) that are found in collagen hydrolysate, a substance that is known to retard crystal growth. In the absence of peptides, the growth of ice crystal in the solution with the ice/water interface is observed at a rate comparable to the experimental data. When peptides are present in the liquid phase, the crystal growth is retarded to a significant extent compared to the pure water. It is found that Gly-Pro-Ala-Gly is more effective (crystallization is up to 5 times slower than in its absence) than Gly-Gly-Ala-Gly (up to 3 times slower) implying that the role of the proline residue is important. The mechanism can be understood in the nature of binding of the peptides to the growing crystal.

AC Electrowetting of Polymer Aqueous Drops on Parallel Electrodes

We have recently observed the strong field dependence of AC-electrowetting of simple electrolyte aqueous drops on parallel gold electrodes, yet the detailed dynamic process of AC-field induced surface wetting remains unclear. In this work, we use fluorescence labeled DNA aqueous solution as a model system to directly visualize the wetting process of aqueous drops under varied AC electric fields by using combined fluorescence microscopy and contact angle goniometer. The electrowetting behavior of DNA aqueous drops is observed at AC-field frequency greater than the reciprocal of the RC time scale for electrode screening. And the onset of AC electrowetting is accompanied by the observed oscillation in drop contour shape and contact line. In addition, the ejection of nanodrops from the parent aqueous drop is observed when the threshold AC-field amplitude is exceeded. A scaling theory based on electrode interfacial screening is developed to quantify the AC-electrowetting behavior with the dependence of AC-field frequency, strength and medium conductivity.

The research is supported by the Petroleum Research Fund, American Chemical Society.
